with a copy of the donor's data. When the remote cloning operation is complete and the joining member has restarted, state transfer from a donor's binary log is carried out to get the transactions that the group applied while the remote cloning operation was in progress. If there is not a large transaction gap, or if the clone plugin is not installed, Group Replication proceeds directly to state transfer from a donor's binary log.

For state transfer from a donor's binary log, a connection is established between the joining member and the donor and state transfer begins. This interaction with the donor continues until the server joining the group's applier thread processes the view change log event that corresponds to the view change triggered when the server joining the group came into the group. In other words, the server joining the group replicates from the donor, until it gets to the marker with the view identifier which matches the view marker it is already in.

Figure 18.10 State Transfer: Catching Up

As view identifiers are transmitted to all members in the group at the same logical time, the server joining the group knows at which view identifier it should stop replicating. This avoids complex GTID set calculations because the view identifier clearly marks which data belongs to each group view.

While the server joining the group is replicating from the donor, it is also caching incoming transactions from the group. Eventually, it stops replicating from the donor and switches to applying those that are cached.

Figure 18.11 Queued Transactions

Key

- Transactions ■
- VCN-View Change Entry ■

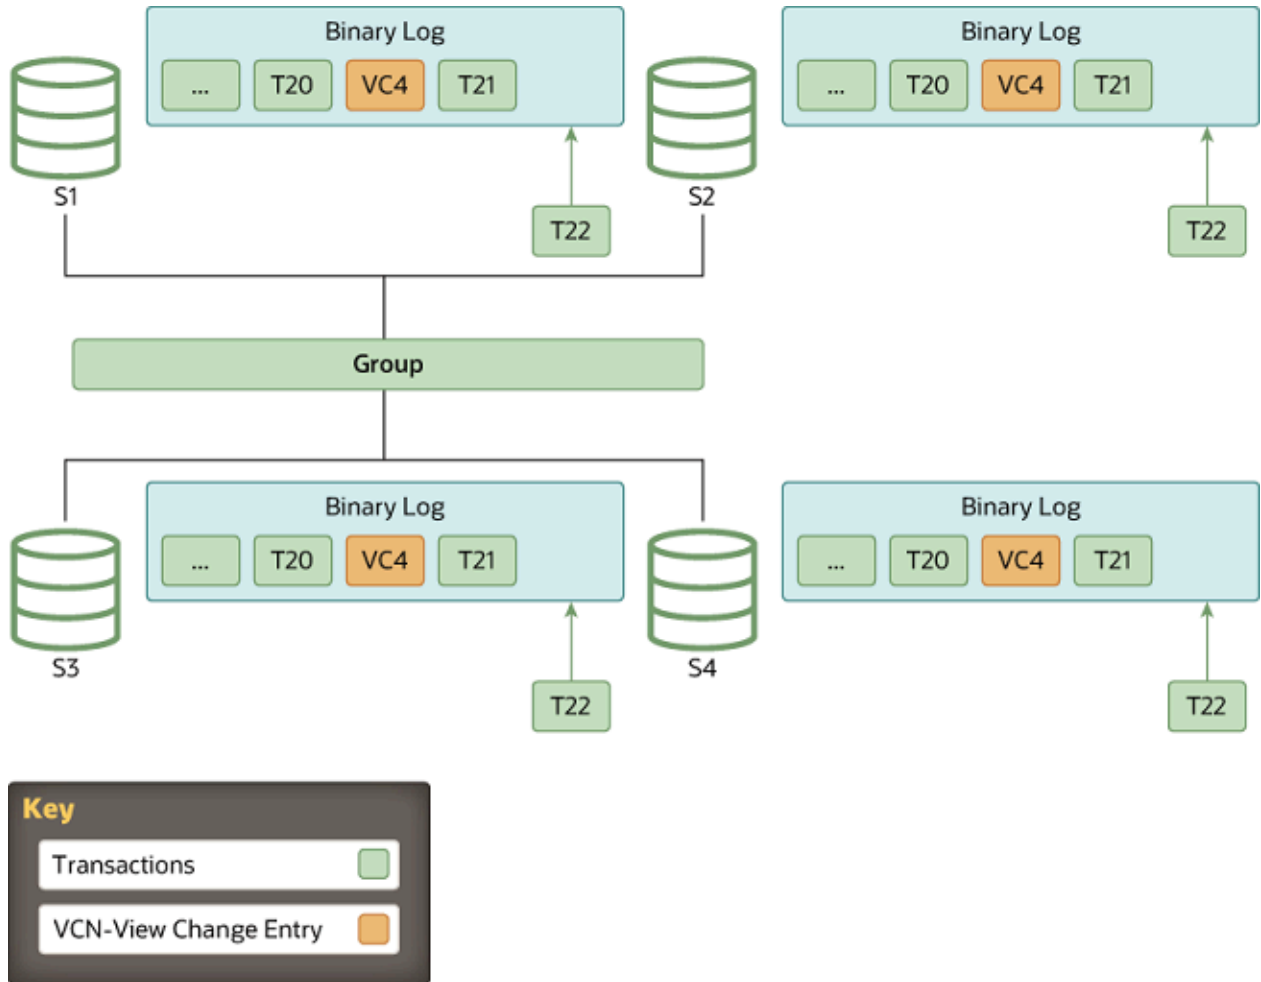

Finish: Caught Up

When the server joining the group recognizes a view change log event with the expected view identifier, the connection to the donor is terminated and it starts applying the cached transactions. Although it acts as a marker in the binary log, delimiting view changes, the view change log event also plays another role. It conveys the certification information as perceived by all servers when the server joining the group entered the group, in other words the last view change. Without it, the server joining the group would not have the necessary information to be able to certify (detect conflicts) subsequent transactions.

The duration of the catch up is not deterministic, because it depends on the workload and the rate of incoming transactions to the group. This process is completely online and the server joining the group does not block any other server in the group while it is catching up. Therefore the number of transactions the server joining the group is behind when it moves to this stage can, for this reason, vary and thus increase or decrease according to the workload.

When the server joining the group reaches zero queued transactions and its stored data is equal to the other members, its public state changes to online.

Figure 18.12 Instance Online

18.5.4 Network Partitioning

The group needs to achieve consensus whenever a change that needs to be replicated happens. This is the case for regular transactions but is also required for group membership changes and some internal messaging that keeps the group consistent. Consensus requires a majority of group members to agree on a given decision. When a majority of group members is lost, the group is unable to progress and blocks because it cannot secure majority or quorum.

Quorum may be lost when there are multiple involuntary failures, causing a majority of servers to be removed abruptly from the group. For example, in a group of 5 servers, if 3 of them become silent at once, the majority is compromised and thus no quorum can be achieved. In fact, the remaining two are not able

to tell if the other 3 servers have crashed or whether a network partition has isolated these 2 alone and therefore the group cannot be reconfigured automatically.

On the other hand, if servers exit the group voluntarily, they instruct the group that it should reconfigure itself. In practice, this means that a server that is leaving tells others that it is going away. This means that other members can reconfigure the group properly, the consistency of the membership is maintained and the majority is recalculated. For example, in the above scenario of 5 servers where 3 leave at once, if the 3 leaving servers warn the group that they are leaving, one by one, then the membership is able to adjust itself from 5 to 2, and at the same time, securing quorum while that happens.

Note

Loss of quorum is by itself a side-effect of bad planning. Plan the group size for the number of expected failures (regardless whether they are consecutive, happen all at once or are sporadic).

The following sections explain what to do if the system partitions in such a way that no quorum is automatically achieved by the servers in the group.

Tip

A primary that has been excluded from a group after a majority loss followed by a reconfiguration can contain extra transactions that are not included in the new group. If this happens, the attempt to add back the excluded member from the group results in an error with the message `This member has more executed transactions than those present in the group.`

Detecting Partitions

The `replication_group_members` performance schema table presents the status of each server in the current view from the perspective of this server. The majority of the time the system does not run into partitioning, and therefore the table shows information that is consistent across all servers in the group. In other words, the status of each server on this table is agreed by all in the current view. However, if there is network partitioning, and quorum is lost, then the table shows the status `UNREACHABLE` for those servers that it cannot contact. This information is exported by the local failure detector built into Group Replication.

Figure 18.13 Losing Quorum

To understand this type of network partition the following section describes a scenario where there are initially 5 servers working together correctly, and the changes that then happen to the group once only 2 servers are online. The scenario is depicted in the figure.

As such, let's assume that there is a group with these 5 servers in it:

- Server s1 with member identifier `199b2df7-4aaf-11e6-bb16-28b2bd168d07`
- Server s2 with member identifier `199bb88e-4aaf-11e6-babe-28b2bd168d07`
- Server s3 with member identifier `1999b9fb-4aaf-11e6-bb54-28b2bd168d07`
- Server s4 with member identifier `19ab72fc-4aaf-11e6-bb51-28b2bd168d07`

- Server s5 with member identifier `19b33846-4aaf-11e6-ba81-28b2bd168d07`

Initially the group is running fine and the servers are happily communicating with each other. You can verify this by logging into s1 and looking at its `replication_group_members` performance schema table. For example:

```
mysql> SELECT MEMBER_ID, MEMBER_STATE, MEMBER_ROLE FROM performance_schema.replication_group_members;
```

| MEMBER_ID | MEMBER_STATE | MEMBER_ROLE |
|--------------------------------------|--------------|-------------|
| 1999b9fb-4aaf-11e6-bb54-28b2bd168d07 | ONLINE | SECONDARY |
| 199b2df7-4aaf-11e6-bb16-28b2bd168d07 | ONLINE | PRIMARY |
| 199bb88e-4aaf-11e6-babe-28b2bd168d07 | ONLINE | SECONDARY |
| 19ab72fc-4aaf-11e6-bb51-28b2bd168d07 | ONLINE | SECONDARY |
| 19b33846-4aaf-11e6-ba81-28b2bd168d07 | ONLINE | SECONDARY |

However, moments later there is a catastrophic failure and servers s3, s4 and s5 stop unexpectedly. A few seconds after this, looking again at the `replication_group_members` table on s1 shows that it is still online, but several others members are not. In fact, as seen below they are marked as `UNREACHABLE`. Moreover, the system could not reconfigure itself to change the membership, because the majority has been lost.

```
mysql> SELECT MEMBER_ID, MEMBER_STATE FROM performance_schema.replication_group_members;
```

| MEMBER_ID | MEMBER_STATE |
|--------------------------------------|--------------|
| 1999b9fb-4aaf-11e6-bb54-28b2bd168d07 | UNREACHABLE |
| 199b2df7-4aaf-11e6-bb16-28b2bd168d07 | ONLINE |
| 199bb88e-4aaf-11e6-babe-28b2bd168d07 | ONLINE |
| 19ab72fc-4aaf-11e6-bb51-28b2bd168d07 | UNREACHABLE |
| 19b33846-4aaf-11e6-ba81-28b2bd168d07 | UNREACHABLE |

The table shows that s1 is now in a group that has no means of progressing without external intervention, because a majority of the servers are unreachable. In this particular case, the group membership list needs to be reset to allow the system to proceed, which is explained in this section. Alternatively, you could also choose to stop Group Replication on s1 and s2 (or stop completely s1 and s2), figure out what happened with s3, s4 and s5 and then restart Group Replication (or the servers).

Unblocking a Partition

Group replication enables you to reset the group membership list by forcing a specific configuration. For instance in the case above, where s1 and s2 are the only servers online, you could choose to force a membership configuration consisting of only s1 and s2. This requires checking some information about s1 and s2 and then using the `group_replication_force_members` variable.

Figure 18.14 Forcing a New Membership

Suppose that you are back in the situation where s1 and s2 are the only servers left in the group. Servers s3, s4 and s5 have left the group unexpectedly. To make servers s1 and s2 continue, you want to force a membership configuration that contains only s1 and s2.

**Warning**

This procedure uses `group_replication_force_members` and should be considered a last resort remedy. It *must* be used with extreme care and only for overriding loss of quorum. If misused, it could create an artificial split-brain scenario or block the entire system altogether.

Recall that the system is blocked and the current configuration is the following (as perceived by the local failure detector on s1):

```
mysql> SELECT MEMBER_ID, MEMBER_STATE FROM performance_schema.replication_group_members;
+-----+-----+
| MEMBER_ID          | MEMBER_STATE |
+-----+-----+
| 1999b9fb-4aaf-11e6-bb54-28b2bd168d07 | UNREACHABLE  |
| 199b2df7-4aaf-11e6-bb16-28b2bd168d07 | ONLINE       |
| 199bb88e-4aaf-11e6-babe-28b2bd168d07 | ONLINE       |
| 19ab72fc-4aaf-11e6-bb51-28b2bd168d07 | UNREACHABLE  |
| 19b33846-4aaf-11e6-ba81-28b2bd168d07 | UNREACHABLE  |
+-----+-----+
```

The first thing to do is to check what is the local address (group communication identifier) for s1 and s2. Log in to s1 and s2 and get that information as follows.

```
mysql> SELECT @@group_replication_local_address;
```

Once you know the group communication addresses of s1 (127.0.0.1:10000) and s2 (127.0.0.1:10001), you can use that on one of the two servers to inject a new membership configuration, thus overriding the existing one that has lost quorum. To do that on s1:

```
mysql> SET GLOBAL group_replication_force_members="127.0.0.1:10000,127.0.0.1:10001";
```

This unblocks the group by forcing a different configuration. Check `replication_group_members` on both s1 and s2 to verify the group membership after this change. First on s1.

```
mysql> SELECT MEMBER_ID, MEMBER_STATE FROM performance_schema.replication_group_members;
+-----+-----+
| MEMBER_ID          | MEMBER_STATE |
+-----+-----+
| b5ffe505-4ab6-11e6-b04b-28b2bd168d07 | ONLINE       |
| b60907e7-4ab6-11e6-afb7-28b2bd168d07 | ONLINE       |
+-----+-----+
```

And then on s2.

```
mysql> SELECT * FROM performance_schema.replication_group_members;
+-----+-----+
| MEMBER_ID          | MEMBER_STATE |
+-----+-----+
| b5ffe505-4ab6-11e6-b04b-28b2bd168d07 | ONLINE       |
| b60907e7-4ab6-11e6-afb7-28b2bd168d07 | ONLINE       |
+-----+-----+
```

When forcing a new membership configuration, make sure that any servers are going to be forced out of the group are indeed stopped. In the scenario depicted above, if s3, s4 and s5 are not really unreachable but instead are online, they may have formed their own functional partition (they are 3 out of 5, hence they have the majority). In that case, forcing a group membership list with s1 and s2 could create an artificial split-brain situation. Therefore it is important before forcing a new membership configuration to ensure that the servers to be excluded are indeed shut down and if they are not, shut them down before proceeding.

After you have used the `group_replication_force_members` system variable to successfully force a new group membership and unblock the group, ensure that you clear the system variable. `group_replication_force_members` must be empty in order to issue a `START GROUP_REPLICATION` statement.

18.5.5 Support For IPv6 And For Mixed IPv6 And IPv4 Groups

From MySQL 8.0.14, Group Replication group members can use IPv6 addresses as an alternative to IPv4 addresses for communications within the group. To use IPv6 addresses, the operating system on the server host and the MySQL Server instance must both be configured to support IPv6. For instructions to set up IPv6 support for a server instance, see [Section 5.1.13, “IPv6 Support”](#).

IPv6 addresses, or host names that resolve to them, can be specified as the network address that the member provides in the `group_replication_local_address` option for connections from other members. When specified with a port number, an IPv6 address must be specified in square brackets, for example:

```
group_replication_local_address= "[2001:db8:85a3:8d3:1319:8a2e:370:7348]:33061"
```

The network address or host name specified in `group_replication_local_address` is used by Group Replication as the unique identifier for a group member within the replication group. If a host name specified as the Group Replication local address for a server instance resolves to both an IPv4 and an IPv6 address, the IPv4 address is always used for Group Replication connections. The address or host name specified as the Group Replication local address is not the same as the MySQL server SQL protocol host and port, and is not specified in the `bind_address` system variable for the server instance. For the purpose of IP address permissions for Group Replication (see [Section 18.6.1, “Group Replication IP Address Permissions”](#)), the address that you specify for each group member in `group_replication_local_address` must be added to the list for the `group_replication_ip_allowlist` (from MySQL 8.0.22) or `group_replication_ip_whitelist` system variable on the other servers in the replication group.

A replication group can contain a combination of members that present an IPv6 address as their Group Replication local address, and members that present an IPv4 address. When a server joins such a mixed group, it must make the initial contact with the seed member using the protocol that the seed member advertises in the `group_replication_group_seeds` option, whether that is IPv4 or IPv6. If any of the seed members for the group are listed in the `group_replication_group_seeds` option with an IPv6 address when a joining member has an IPv4 Group Replication local address, or the reverse, you must also set up and permit an alternative address for the joining member for the required protocol (or a host name that resolves to an address for that protocol). If a joining member does not have a permitted address for the appropriate protocol, its connection attempt is refused. The alternative address or host name only needs to be added to the `group_replication_ip_allowlist` (from MySQL 8.0.22) or `group_replication_ip_whitelist` system variable on the other servers in the replication group, not to the `group_replication_local_address` value for the joining member (which can only contain a single address).

For example, server A is a seed member for a group, and has the following configuration settings for Group Replication, so that it is advertising an IPv6 address in the `group_replication_group_seeds` option:

```
group_replication_bootstrap_group=on
group_replication_local_address= "[2001:db8:85a3:8d3:1319:8a2e:370:7348]:33061"
group_replication_group_seeds= "[2001:db8:85a3:8d3:1319:8a2e:370:7348]:33061"
```

Server B is a joining member for the group, and has the following configuration settings for Group Replication, so that it has an IPv4 Group Replication local address:

```
group_replication_bootstrap_group=off
group_replication_local_address= "203.0.113.21:33061"
group_replication_group_seeds= "[2001:db8:85a3:8d3:1319:8a2e:370:7348]:33061"
```

Server B also has an alternative IPv6 address `2001:db8:8b0:40:3d9c:cc43:e006:19e8`. For Server B to join the group successfully, both its IPv4 Group Replication local address, and its alternative IPv6 address, must be listed in Server A's allowlist, as in the following example:

```
group_replication_ip_allowlist=
"203.0.113.0/24,2001:db8:85a3:8d3:1319:8a2e:370:7348,
2001:db8:8b0:40:3d9c:cc43:e006:19e8"
```

As a best practice for Group Replication IP address permissions, Server B (and all other group members) should have the same allowlist as Server A, unless security requirements demand otherwise.

If any or all members of a replication group are using an older MySQL Server version that does not support the use of IPv6 addresses for Group Replication, a member cannot participate in the group using an IPv6 address (or a host name that resolves to one) as its Group Replication local address. This applies both in the case where at least one existing member uses an IPv6 address and a new member that does not support this attempts to join, and in the case where a new member attempts to join using an IPv6 address but the group includes at least one member that does not support this. In each situation, the new member cannot join. To make a joining member present an IPv4 address for group communications, you can either change the value of `group_replication_local_address` to an IPv4 address, or configure your DNS to resolve the joining member's existing host name to an IPv4 address. After you have upgraded every group member to a MySQL Server version that supports IPv6 for Group Replication, you can change the `group_replication_local_address` value for each member to an IPv6 address, or configure your DNS to present an IPv6 address. Changing the value of `group_replication_local_address` takes effect only when you stop and restart Group Replication.

IPv6 addresses can also be used as distributed recovery endpoints, which can be specified from MySQL 8.0.21 using the `group_replication_advertise_recovery_endpoints` system variable. The same rules apply to addresses used in this list. See [Section 18.5.3.1, "Connections for Distributed Recovery"](#).

18.5.6 Using MySQL Enterprise Backup with Group Replication

[MySQL Enterprise Backup](#) is a commercially-licensed backup utility for MySQL Server, available with [MySQL Enterprise Edition](#). This section explains how to back up and subsequently restore a Group Replication member using MySQL Enterprise Backup. The same technique can be used to quickly add a new member to a group.

Backing up a Group Replication Member Using MySQL Enterprise Backup

Backing up a Group Replication member is similar to backing up a stand-alone MySQL instance. The following instructions assume that you are already familiar with how to use MySQL Enterprise Backup to perform a backup; if that is not the case, please review the [MySQL Enterprise Backup 8.0 User's Guide](#), especially [Backing Up a Database Server](#). Also note the requirements described in [Grant MySQL Privileges to Backup Administrator](#) and [Using MySQL Enterprise Backup with Group Replication](#).

Consider the following group with three members, `s1`, `s2`, and `s3`, running on hosts with the same names:

```
mysql> SELECT member_host, member_port, member_state FROM performance_schema.replication_group_members;
+-----+-----+-----+
| member_host | member_port | member_state |
+-----+-----+-----+
| s1          | 3306        | ONLINE       |
| s2          | 3306        | ONLINE       |
| s3          | 3306        | ONLINE       |
+-----+-----+-----+
```

Using MySQL Enterprise Backup, create a backup of `s2` by issuing on its host, for example, the following command:

```
s2> mysqlbackup --defaults-file=/etc/my.cnf --backup-image=/backups/my.mbi_`date +%d%m_%H%M` \
--backup-dir=/backups/backup_`date +%d%m_%H%M` --user=root -p \
--host=127.0.0.1 backup-to-image
```

Notes

- *For MySQL Enterprise Backup 8.0.18 and earlier*, If the system variable `sql_require_primary_key` is set to `ON` for the group, MySQL Enterprise Backup is not able to log the backup progress on the servers. This is because the `backup_progress` table on the server is a CSV table, for which primary keys are not supported. In that case, `mysqlbackup` issues the following warnings during the backup operation:

```
181011 11:17:06 MAIN WARNING: MySQL query 'CREATE TABLE IF NOT EXISTS
mysql.backup_progress( `backup_id` BIGINT NOT NULL, `tool_name` VARCHAR(4096)
NOT NULL, `error_code` INT NOT NULL, `error_message` VARCHAR(4096) NOT NULL,
`current_time` TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON
UPDATE CURRENT_TIMESTAMP, `current_state` VARCHAR(200) NOT NULL ) ENGINE=CSV
DEFAULT CHARSET=utf8 COLLATE=utf8_bin': 3750, Unable to create a table
without PK, when system variable 'sql_require_primary_key' is set. Add a PK
to the table or unset this variable to avoid this message. Note that tables
without PK can cause performance problems in row-based replication, so please
consult your DBA before changing this setting.
181011 11:17:06 MAIN WARNING: This backup operation's progress info cannot be
logged.
```

This does not prevent `mysqlbackup` from finishing the backup though.

- *For MySQL Enterprise Backup 8.0.20 and earlier*, when backing up a secondary member, as MySQL Enterprise Backup cannot write backup status and metadata to a read-only server instance, it might issue warnings similar to the following one during the backup operation:

```
181113 21:31:08 MAIN WARNING: This backup operation cannot write to backup
progress. The MySQL server is running with the --super-read-only option.
```

You can avoid the warning by using the `--no-history-logging` option with your backup command. This is not an issue for MySQL Enterprise Backup 8.0.21 and higher—see [Using MySQL Enterprise Backup with Group Replication](#) for details.

Restoring a Failed Member

Assume one of the members (`s3` in the following example) is irreconcilably corrupted. The most recent backup of group member `s2` can be used to restore `s3`. Here are the steps for performing the restore:

1. *Copy the backup of s2 onto the host for s3.* The exact way to copy the backup depends on the operating system and tools available to you. In this example, we assume the hosts are both Linux servers and use SCP to copy the files between them:

```
s2/backups> scp my.mbi_2206_1429 s3:/backups
```

2. *Restore the backup.* Connect to the target host (the host for `s3` in this case), and restore the backup using MySQL Enterprise Backup. Here are the steps:

- a. Stop the corrupted server, if it is still running. For example, on Linux distributions that use `systemd`:

```
s3> systemctl stop mysqld
```

- b. Preserve the two configuration files in the corrupted server's data directory, `auto.cnf` and `mysqld-auto.cnf` (if it exists), by copying them to a safe location outside of the data directory. This is for preserving the [server's UUID](#) and [Section 5.1.9.3, "Persisted System Variables"](#) (if used), which are needed in the steps below.

- c. Delete all contents in the data directory of `s3`. For example:

```
s3> rm -rf /var/lib/mysql/*
```

If the system variables `innodb_data_home_dir`, `innodb_log_group_home_dir`, and `innodb_undo_directory` point to any directories other than the data directory, they should also be made empty; otherwise, the restore operation fails.

- d. Restore backup of `s2` onto the host for `s3`:

```
s3> mysqlbackup --defaults-file=/etc/my.cnf \
--datadir=/var/lib/mysql \
--backup-image=/backups/my.mbi_2206_1429 \
--backup-dir=/tmp/restore_`date +%d%m_%H%M` copy-back-and-apply-log
```

Note

The command above assumes that the binary logs and relay logs on `s2` and `s3` have the same base name and are at the same location on the two servers. If these conditions are not met, you should use the `--log-bin` and `--relay-log` options to restore the binary log and relay log to their original file paths on `s3`. For example, if you know that on `s3` the binary log's base name is `s3-bin` and the relay-log's base name is `s3-relay-bin`, your restore command should look like:

```
mysqlbackup --defaults-file=/etc/my.cnf \
--datadir=/var/lib/mysql \
--backup-image=/backups/my.mbi_2206_1429 \
--log-bin=s3-bin --relay-log=s3-relay-bin \
--backup-dir=/tmp/restore_`date +%d%m_%H%M` copy-back-and-apply-log
```

Being able to restore the binary log and relay log to the right file paths makes the restore process easier; if that is impossible for some reason, see [Rebuild the Failed Member to Rejoin as a New Member](#).

3. Restore the `auto.cnf` file for `s3`. To rejoin the replication group, the restored member *must* have the same `server_uuid` it used to join the group before. Supply the old server UUID by copying the `auto.cnf` file preserved in step 2 above into the data directory of the restored member.

Note

If you cannot supply the failed member's original `server_uuid` to the restored member by restoring its old `auto.cnf` file, you must let the restored member join the group as a new member; see instructions in [Rebuild the Failed Member to Rejoin as a New Member](#) below on how to do that.

4. Restore the `mysqld-auto.cnf` file for `s3` (only required if `s3` used persistent system variables). The settings for the [Section 5.1.9.3, "Persisted System Variables"](#) that were used to configure the failed member must be provided to the restored member. These settings are to be found in the `mysqld-auto.cnf` file of the failed server, which you should have preserved in step 2 above. Restore the file to the data directory of the restored server. See [Restoring Persisted System Variables](#) on what to do if you do not have a copy of the file.

5. *Start the restored server.* For example, on Linux distributions that use systemd:

```
systemctl start mysqld
```

Note

If the server you are restoring is a primary member, perform the steps described in [Restoring a Primary Member](#) before starting the restored server.

6. *Restart Group Replication.* Connect to the restarted `s3` using, for example, a `mysql` client, and issue the following command:

```
mysql> START GROUP_REPLICATION;
```

Before the restored instance can become an online member of the group, it needs to apply any transactions that have happened to the group after the backup was taken; this is achieved using Group Replication's [distributed recovery](#) mechanism, and the process starts after the `START GROUP_REPLICATION` statement has been issued. To check the member status of the restored instance, issue:

```
mysql> SELECT member_host, member_port, member_state FROM performance_schema.replication_group_members;
+-----+-----+-----+
| member_host | member_port | member_state |
+-----+-----+-----+
| s1          |          3306 | ONLINE       |
| s2          |          3306 | ONLINE       |
| s3          |          3306 | RECOVERING   |
+-----+-----+-----+
```

This shows that `s3` is applying transactions to catch up with the group. Once it has caught up with the rest of the group, its `member_state` changes to `ONLINE`:

```
mysql> SELECT member_host, member_port, member_state FROM performance_schema.replication_group_members;
+-----+-----+-----+
| member_host | member_port | member_state |
+-----+-----+-----+
| s1          |          3306 | ONLINE       |
| s2          |          3306 | ONLINE       |
| s3          |          3306 | ONLINE       |
+-----+-----+-----+
```

Note

If the server you are restoring is a primary member, once it has gained synchrony with the group and become `ONLINE`, perform the steps described at the end of [Restoring a Primary Member](#) to revert the configuration changes you had made to the server before you started it.

The member has now been fully restored from the backup and functions as a regular member of the group.

Rebuild the Failed Member to Rejoin as a New Member

Sometimes, the steps outlined above in [Restoring a Failed Member](#) cannot be carried out because, for example, the binary log or relay log is corrupted, or it is just missing from the backup. In such a situation, use the backup to rebuild the member, and then add it to the group as a new member. In the steps below, we assume the rebuilt member is named `s3`, like the failed member, and that it runs on the same host as `s3`:

1. *Copy the backup of s2 onto the host for s3*. The exact way to copy the backup depends on the operating system and tools available to you. In this example we assume the hosts are both Linux servers and use SCP to copy the files between them:

```
s2/backups> scp my.mbi_2206_1429 s3:/backups
```

2. *Restore the backup*. Connect to the target host (the host for s3 in this case), and restore the backup using MySQL Enterprise Backup. Here are the steps:

- a. Stop the corrupted server, if it is still running. For example, on Linux distributions that use systemd:

```
s3> systemctl stop mysqld
```

- b. Preserve the configuration file `mysqld-auto.cnf`, if it is found in the corrupted server's data directory, by copying it to a safe location outside of the data directory. This is for preserving the server's [Section 5.1.9.3, "Persisted System Variables"](#), which are needed later.

- c. Delete all contents in the data directory of s3. For example:

```
s3> rm -rf /var/lib/mysql/*
```

If the system variables `innodb_data_home_dir`, `innodb_log_group_home_dir`, and `innodb_undo_directory` point to any directories other than the data directory, they should also be made empty; otherwise, the restore operation fails.

- d. Restore the backup of s2 onto the host of s3. With this approach, we are rebuilding s3 as a new member, for which we do not need or do not want to use the old binary and relay logs in the backup; therefore, if these logs have been included in your backup, exclude them using the `--skip-binlog` and `--skip-relaylog` options:

```
s3> mysqlbackup --defaults-file=/etc/my.cnf \
--datadir=/var/lib/mysql \
--backup-image=backups/my.mbi_2206_1429 \
--backup-dir=/tmp/restore_`date +%d%m_%H%M` \
--skip-binlog --skip-relaylog \
copy-back-and-apply-log
```

Note

If you have healthy binary log and relay logs in the backup that you can transfer onto the target host with no issues, you are recommended to follow the easier procedure as described in [Restoring a Failed Member](#) above.

3. *Restore the `mysqld-auto.cnf` file for s3 (only required if s3 used persistent system variables)*. The settings for the [Section 5.1.9.3, "Persisted System Variables"](#) that were used to configure the failed member must be provided to the restored server. These settings are to be found in the `mysqld-auto.cnf` file of the failed server, which you should have preserved in step 2 above. Restore the file to the data directory of the restored server. See [Restoring Persisted System Variables](#) on what to do if you do not have a copy of the file.

Note

Do NOT restore the corrupted server's `auto.cnf` file to the data directory of the new member—when the rebuilt s3 joins the group as a new member, it is going to be assigned a new server UUID.

4. *Start the restored server*. For example, on Linux distributions that use systemd:

```
systemctl start mysqld
```

**Note**

If the server you are restoring is a primary member, perform the steps described in [Restoring a Primary Member](#) before starting the restored server.

5. *Reconfigure the restored member to join Group Replication.* Connect to the restored server with a `mysql` client and reset the source and replica information with the following commands:

```
mysql> RESET MASTER;
```

```
mysql> RESET SLAVE ALL;
Or from MySQL 8.0.22:
mysql> RESET REPLICA ALL;
```

For the restored server to be able to recover automatically using Group Replication's built-in mechanism for [distributed recovery](#), configure the server's `gtid_executed` variable. To do this, use the `backup_gtid_executed.sql` file included in the backup of `s2`, which is usually restored under the restored member's data directory. Disable binary logging, use the `backup_gtid_executed.sql` file to configure `gtid_executed`, and then re-enable binary logging by issuing the following statements with your `mysql` client:

```
mysql> SET SQL_LOG_BIN=OFF;
mysql> SOURCE datadir/backup_gtid_executed.sql
mysql> SET SQL_LOG_BIN=ON;
```

Then, configure the [Group Replication user credentials](#) on the member:

```
mysql> CHANGE MASTER TO MASTER_USER='rpl_user', MASTER_PASSWORD='password' /
FOR CHANNEL 'group_replication_recovery';

Or from MySQL 8.0.23:
mysql> CHANGE REPLICATION SOURCE TO SOURCE_USER='rpl_user', SOURCE_PASSWORD='password' /
FOR CHANNEL 'group_replication_recovery';
```

6. *Restart Group Replication.* Issue the following command to the restored server with your `mysql` client:

```
mysql> START GROUP_REPLICATION;
```

Before the restored instance can become an online member of the group, it needs to apply any transactions that have happened to the group after the backup was taken; this is achieved using Group Replication's [distributed recovery](#) mechanism, and the process starts after the `START GROUP_REPLICATION` statement has been issued. To check the member status of the restored instance, issue:

```
mysql> SELECT member_host, member_port, member_state FROM performance_schema.replication_group_members;
+-----+-----+-----+
| member_host | member_port | member_state |
+-----+-----+-----+
| s3          |          3306 | RECOVERING   |
| s2          |          3306 | ONLINE       |
| s1          |          3306 | ONLINE       |
+-----+-----+-----+
```

This shows that `s3` is applying transactions to catch up with the group. Once it has caught up with the rest of the group, its `member_state` changes to `ONLINE`:

```
mysql> SELECT member_host, member_port, member_state FROM performance_schema.replication_group_members;
+-----+-----+-----+
| member_host | member_port | member_state |
+-----+-----+-----+
| s3          |          3306 | ONLINE       |
+-----+-----+-----+
```

| | | |
|----|------|--------|
| s2 | 3306 | ONLINE |
| s1 | 3306 | ONLINE |

**Note**

If the server you are restoring is a primary member, once it has gained synchrony with the group and become `ONLINE`, perform the steps described at the end of [Restoring a Primary Member](#) to revert the configuration changes you had made to the server before you started it.

The member has now been restored to the group as a new member.

Restoring Persisted System Variables. `mysqlbackup` does not provide support for backing up or preserving [Section 5.1.9.3, “Persisted System Variables”](#)—the file `mysqld-auto.cnf` is not included in a backup. To start the restored member with its persisted variable settings, you need to do one of the following:

- Preserve a copy of the `mysqld-auto.cnf` file from the corrupted server, and copy it to the restored server's data directory.
- Copy the `mysqld-auto.cnf` file from another member of the group into the restored server's data directory, if that member has the same persisted system variable settings as the corrupted member.
- After the restored server is started and before you restart Group Replication, set all the system variables manually to their persisted values through a `mysql` client.

Restoring a Primary Member. If the restored member is a primary in the group, care must be taken to prevent writes to the restored database during the Group Replication distributed recovery process. Depending on how the group is accessed by clients, there is a possibility of DML statements being executed on the restored member once it becomes accessible on the network, prior to the member finishing its catch-up on the activities it has missed while off the group. To avoid this, *before starting the restored server*, configure the following system variables in the server option file:

```
group_replication_start_on_boot=OFF
super_read_only=ON
event_scheduler=OFF
```

These settings ensure that the member becomes read-only at startup and that the event scheduler is turned off while the member is catching up with the group during the distributed recovery process. Adequate error handling must also be configured on the clients, as they are prevented temporarily from performing DML operations during this period on the restored member. Once the restore process is fully completed and the restored member is in-sync with the rest of the group, revert those changes; restart the event scheduler:

```
mysql> SET global event_scheduler=ON;
```

Edit the following system variables in the member's option file, so things are correctly configured for the next startup:

```
group_replication_start_on_boot=ON
super_read_only=OFF
event_scheduler=ON
```

18.6 Group Replication Security

This section explains how to secure a group, securing the connections between members of a group, or by establishing a security perimeter using an IP address allowlist.

18.6.1 Group Replication IP Address Permissions

The Group Replication plugin lets you specify an allowlist of hosts from which an incoming Group Communication System connection can be accepted. If you specify an allowlist on a server `s1`, then when server `s2` is establishing a connection to `s1` for the purpose of engaging group communication, `s1` first checks the allowlist before accepting the connection from `s2`. If `s2` is in the allowlist, then `s1` accepts the connection, otherwise `s1` rejects the connection attempt by `s2`. From MySQL 8.0.22, the system variable `group_replication_ip_allowlist` is used to specify the allowlist, and for releases before MySQL 8.0.22, the system variable `group_replication_ip_whitelist` is used. The new system variable works in the same way as the old system variable, only the terminology has changed.

If you do not specify an allowlist explicitly, the group communication engine (XCom) automatically scans active interfaces on the host, and identifies those with addresses on private subnetworks, together with the subnet mask that is configured for each interface. These addresses, and the `localhost` IP address for IPv4 and (from MySQL 8.0.14) IPv6 are used to create an automatic Group Replication allowlist. The automatic allowlist therefore includes any IP addresses that are found for the host in the following ranges after the appropriate subnet mask has been applied:

```
IPv4 (as defined in RFC 1918)
10/8 prefix      (10.0.0.0 - 10.255.255.255) - Class A
172.16/12 prefix (172.16.0.0 - 172.31.255.255) - Class B
192.168/16 prefix (192.168.0.0 - 192.168.255.255) - Class C

IPv6 (as defined in RFC 4193 and RFC 5156)
fc00:/7 prefix   - unique-local addresses
fe80::/10 prefix - link-local unicast addresses

127.0.0.1 - localhost for IPv4
::1       - localhost for IPv6
```

An entry is added to the error log stating the addresses that have been allowed automatically for the host.

The automatic allowlist of private addresses cannot be used for connections from servers outside the private network, so a server, even if it has interfaces on public IPs, does not by default allow Group Replication connections from external hosts. For Group Replication connections between server instances that are on different machines, you must provide public IP addresses and specify these as an explicit allowlist. If you specify any entries for the allowlist, the private and `localhost` addresses are not added automatically, so if you use any of these, you must specify them explicitly.

To specify an allowlist manually, use the `group_replication_ip_allowlist` (from MySQL 8.0.22) or `group_replication_ip_whitelist` system variable. Before MySQL 8.0.24, you cannot change the allowlist on a server while it is an active member of a replication group. If the member is active, you must execute `STOP GROUP_REPLICATION` before changing the allowlist, and `START GROUP_REPLICATION` afterwards. From MySQL 8.0.24, you can change the allowlist while Group Replication is running.

The allowlist must contain the IP address or host name that is specified in each member's `group_replication_local_address` system variable. This address is not the same as the MySQL server SQL protocol host and port, and is not specified in the `bind_address` system variable for the server instance. If a host name used as the Group Replication local address for a server instance resolves to both an IPv4 and an IPv6 address, the IPv4 address is preferred for Group Replication connections.

IP addresses specified as distributed recovery endpoints, and the IP address for the member's standard SQL client connection if that is used for distributed recovery (which is the default), do not need to be added to the allowlist. The allowlist is only for the address specified by `group_replication_local_address` for each member. A joining member must have its initial connection to the group permitted by the allowlist in order to retrieve the address or addresses for distributed recovery.

In the allowlist, you can specify any combination of the following:

- IPv4 addresses (for example, [198.51.100.44](#))
- IPv4 addresses with CIDR notation (for example, [192.0.2.21/24](#))
- IPv6 addresses, from MySQL 8.0.14 (for example, [2001:db8:85a3:8d3:1319:8a2e:370:7348](#))
- IPv6 addresses with CIDR notation, from MySQL 8.0.14 (for example, [2001:db8:85a3:8d3::/64](#))
- Host names (for example, [example.org](#))
- Host names with CIDR notation (for example, [www.example.com/24](#))

Before MySQL 8.0.14, host names could only resolve to IPv4 addresses. From MySQL 8.0.14, host names can resolve to IPv4 addresses, IPv6 addresses, or both. If a host name resolves to both an IPv4 and an IPv6 address, the IPv4 address is always used for Group Replication connections. You can use CIDR notation in combination with host names or IP addresses to permit a block of IP addresses with a particular network prefix, but do ensure that all the IP addresses in the specified subnet are under your control.

Note

When a connection attempt from an IP address is refused because the address is not in the allowlist, the refusal message always prints the IP address in IPv6 format. IPv4 addresses are preceded by `::ffff:` in this format (an IPv4-mapped IPv6 address). You do not need to use this format to specify IPv4 addresses in the allowlist; use the standard IPv4 format for them.

You must stop and restart Group Replication on a member in order to change its allowlist. A comma must separate each entry in the allowlist. For example:

```
mysql> STOP GROUP_REPLICATION;
mysql> SET GLOBAL group_replication_ip_allowlist="192.0.2.21/24,198.51.100.44,203.0.113.0/24,2001:db8:85a3:8d3:1319:8a2e:370:7348/64";
mysql> START GROUP_REPLICATION;
```

To join a replication group, a server needs to be permitted on the seed member to which it makes the request to join the group. Typically, this would be the bootstrap member for the replication group, but it can be any of the servers listed by the `group_replication_group_seeds` option in the configuration for the server joining the group. If any of the seed members for the group are listed in the `group_replication_group_seeds` option with an IPv6 address when a joining member has an IPv4 `group_replication_local_address`, or the reverse, you must also set up and permit an alternative address for the joining member for the protocol offered by the seed member (or a host name that resolves to an address for that protocol). This is because when a server joins a replication group, it must make the initial contact with the seed member using the protocol that the seed member advertises in the `group_replication_group_seeds` option, whether that is IPv4 or IPv6. If a joining member does not have a permitted address for the appropriate protocol, its connection attempt is refused. For more information on managing mixed IPv4 and IPv6 replication groups, see [Section 18.5.5, “Support For IPv6 And For Mixed IPv6 And IPv4 Groups”](#).

When a replication group is reconfigured (for example, when a new primary is elected or a member joins or leaves), the group members re-establish connections between themselves. If a group member is only permitted by servers that are no longer part of the replication group after the reconfiguration, it is unable to reconnect to the remaining servers in the replication group that do not permit it. To avoid this scenario entirely, specify the same allowlist for all servers that are members of the replication group.

Note

It is possible to configure different allowlists on different group members according to your security requirements, for example, in order to keep different subnets

separate. If you need to configure different allowlists to meet your security requirements, ensure that there is sufficient overlap between the allowlists in the replication group to maximize the possibility of servers being able to reconnect in the absence of their original seed member.

For host names, name resolution takes place only when a connection request is made by another server. A host name that cannot be resolved is not considered for allowlist validation, and a warning message is written to the error log. Forward-confirmed reverse DNS (FCrDNS) verification is carried out for resolved host names.

Warning

Host names are inherently less secure than IP addresses in an allowlist. FCrDNS verification provides a good level of protection, but can be compromised by certain types of attack. Specify host names in your allowlist only when strictly necessary, and ensure that all components used for name resolution, such as DNS servers, are maintained under your control. You can also implement name resolution locally using the hosts file, to avoid the use of external components.

18.6.2 Securing Group Communication Connections with Secure Socket Layer (SSL)

Secure sockets can be used for group communication connections between members of a group. The Group Replication system variable `group_replication_ssl_mode` is used to activate the use of SSL for group communication connections and specify the security mode for the connections. The default setting means that SSL is not used. The option has the following possible values:

Table 18.1 `group_replication_ssl_mode` configuration values

| Value | Description |
|-----------------|---|
| DISABLED | Establish an unencrypted connection (the default). |
| REQUIRED | Establish a secure connection if the server supports secure connections. |
| VERIFY_CA | Like REQUIRED, but additionally verify the server TLS certificate against the configured Certificate Authority (CA) certificates. |
| VERIFY_IDENTITY | Like VERIFY_CA, but additionally verify that the server certificate matches the host to which the connection is attempted. |

The remainder of the configuration for Group Replication's group communication connections is taken from the server's SSL configuration. For more information on the options for configuring the server SSL, see [Command Options for Encrypted Connections](#). The server SSL options that are applied to Group Replication's group communication connections are as follows:

Table 18.2 SSL Options

| Server Configuration | Description |
|----------------------|--|
| <code>ssl_key</code> | The path name of the SSL private key file in PEM format. On the client side, this is the client private key. On the server side, this is the server private key. |

| Server Configuration | Description |
|-------------------------------|---|
| <code>ssl_cert</code> | The path name of the SSL public key certificate file in PEM format. On the client side, this is the client public key certificate. On the server side, this is the server public key certificate. |
| <code>ssl_ca</code> | The path name of the Certificate Authority (CA) certificate file in PEM format. |
| <code>ssl_capath</code> | The path name of the directory that contains trusted SSL certificate authority (CA) certificate files in PEM format. |
| <code>ssl_crl</code> | The path name of the file containing certificate revocation lists in PEM format. |
| <code>ssl_crlpath</code> | The path name of the directory that contains certificate revocation list files in PEM format. |
| <code>ssl_cipher</code> | A list of permissible ciphers for encrypted connections. |
| <code>tls_version</code> | A list of the TLS protocols the server permits for encrypted connections. |
| <code>tls_ciphersuites</code> | Which TLSv1.3 ciphersuites the server permits for encrypted connections. |

Important

- Support for the TLSv1.3 protocol is available in MySQL Server as of MySQL 8.0.16, provided that MySQL was compiled using OpenSSL 1.1.1 or higher. Group Replication supports TLSv1.3 from MySQL 8.0.18. In MySQL 8.0.16 and MySQL 8.0.17, if the server supports TLSv1.3, the protocol is not supported in the group communication engine and cannot be used by Group Replication.
- In the list of TLS protocols specified in the `tls_version` system variable, ensure the specified versions are contiguous (for example, `TLSv1, TLSv1.1, TLSv1.2`). If there are any gaps in the list of protocols (for example, if you specified `TLSv1, TLSv1.2`, omitting TLS 1.1) Group Replication might be unable to make group communication connections.
- In MySQL 8.0.18, TLSv1.3 can be used in Group Replication for the distributed recovery connection, but the `group_replication_recovery_tls_version` and `group_replication_recovery_tls_ciphersuites` system variables are not available. The donor servers must therefore permit the use of at least one TLSv1.3 ciphersuite that is enabled by default, as listed in [Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#). From MySQL 8.0.19, you can use the options to configure client support for any selection of ciphersuites, including only non-default ciphersuites if you want.

In a replication group, OpenSSL negotiates the use of the highest TLS protocol that is supported by all members. A joining member that is configured to use only TLSv1.3 (`tls_version=TLSv1.3`) cannot join a replication group where any existing member does not support TLSv1.3, because the group members in that case are using a lower TLS protocol version. To join the member to the group, you must configure the joining member to also permit the use of lower TLS protocol versions supported by the existing group members. Conversely, if a joining member does not support TLSv1.3, but the existing group members all do and are using that version for connections to each other, the member can join if the existing group

members already permit the use of a suitable lower TLS protocol version, or if you configure them to do so. In that situation, OpenSSL uses a lower TLS protocol version for the connections from each member to the joining member. Each member's connections to other existing members continue to use the highest available protocol that both members support.

From MySQL 8.0.16, you can change the `tls_version` system variable at runtime to alter the list of permitted TLS protocol versions for the server. Note that for Group Replication, the `ALTER INSTANCE RELOAD TLS` statement, which reconfigures the server's TLS context from the current values of the system variables that define the context, does not change the TLS context for Group Replication's group communication connection while Group Replication is running. To apply the reconfiguration to these connections, you must execute `STOP GROUP_REPLICATION` followed by `START GROUP_REPLICATION` to restart Group Replication on the member or members where you changed the `tls_version` system variable. Similarly, if you want to make all members of a group change to using a higher or lower TLS protocol version, you must carry out a rolling restart of Group Replication on the members after changing the list of permitted TLS protocol versions, so that OpenSSL negotiates the use of the higher TLS protocol version when the rolling restart is completed. For instructions to change the list of permitted TLS protocol versions at runtime, see [Section 6.3.2, "Encrypted Connection TLS Protocols and Ciphers"](#) and [Server-Side Runtime Configuration and Monitoring for Encrypted Connections](#).

The following example shows a section from a `my.cnf` file that configures SSL on a server, and activates SSL for Group Replication group communication connections:

```
[mysqld]
ssl_ca = "cacert.pem"
ssl_capath = "../ca_directory"
ssl_cert = "server-cert.pem"
ssl_cipher = "DHE-RSA-AES256-SHA"
ssl_crl = "crl-server-revoked.crl"
ssl_crlpath = "../crl_directory"
ssl_key = "server-key.pem"
group_replication_ssl_mode= REQUIRED
```

Important

The `ALTER INSTANCE RELOAD TLS` statement, which reconfigures the server's TLS context from the current values of the system variables that define the context, does not change the TLS context for Group Replication's group communication connections while Group Replication is running. To apply the reconfiguration to these connections, you must execute `STOP GROUP_REPLICATION` followed by `START GROUP_REPLICATION` to restart Group Replication.

Connections made between a joining member and an existing member for distributed recovery are not covered by the options described above. These connections use Group Replication's dedicated distributed recovery SSL options, which are described in [Section 18.6.3.2, "Secure Socket Layer \(SSL\) Connections for Distributed Recovery"](#).

18.6.3 Securing Distributed Recovery Connections

When a member joins the group, distributed recovery is carried out using a combination of a remote cloning operation, if available and appropriate, and an asynchronous replication connection. For a full description of distributed recovery, see [Section 18.5.3, "Distributed Recovery"](#).

The connection that an existing member offers to a joining member for distributed recovery is not the same connection that is used by Group Replication for communication between online members of the group. Up to MySQL 8.0.20, group members offer their standard SQL client connection to joining members for distributed recovery, as specified by MySQL Server's `hostname` and `port` system variables. From

MySQL 8.0.21, group members may advertise an alternative list of distributed recovery endpoints as dedicated client connections for joining members. For more details, see [Section 18.5.3.1, “Connections for Distributed Recovery”](#).

To secure distributed recovery connections in the group, ensure that user credentials for the replication user are properly secured, and use SSL for distributed recovery connections if possible.

18.6.3.1 Secure User Credentials for Distributed Recovery

State transfer from the binary log requires a replication user with the correct permissions so that Group Replication can establish direct member-to-member replication channels. The same replication user is used for distributed recovery on all the group members. If group members have been set up to support the use of a remote cloning operation as part of distributed recovery, which is available from MySQL 8.0.17, this replication user is also used as the clone user on the donor, and requires the correct permissions for this role too. For detailed instructions to set up this user, see [Section 18.2.1.3, “User Credentials For Distributed Recovery”](#).

To secure the user credentials, you can require SSL for connections with the user account, and (from MySQL 8.0.21) you can provide the user credentials when Group Replication is started, rather than storing them in the replica status tables. Also, if you are using caching SHA-2 authentication, you must set up RSA key-pairs on the group members.

Replication User With The Caching SHA-2 Authentication Plugin

By default, users created in MySQL 8 use [Section 6.4.1.2, “Caching SHA-2 Pluggable Authentication”](#). If the replication user you configure for distributed recovery uses the caching SHA-2 authentication plugin, and you are *not* using SSL for distributed recovery connections, RSA key-pairs are used for password exchange. For more information on RSA key-pairs, see [Section 6.3.3, “Creating SSL and RSA Certificates and Keys”](#).

In this situation, you can either copy the public key of the `rpl_user` to the joining member, or configure the donors to provide the public key when requested. The more secure approach is to copy the public key of the replication user account to the joining member. Then you need to configure the `group_replication_recovery_public_key_path` system variable on the joining member with the path to the public key for the replication user account.

The less secure approach is to set `group_replication_recovery_get_public_key=ON` on donors so that they provide the public key of the replication user account to joining members. There is no way to verify the identity of a server, therefore only set `group_replication_recovery_get_public_key=ON` when you are sure there is no risk of server identity being compromised, for example by a man-in-the-middle attack.

Replication User With SSL

A replication user that requires an SSL connection must be created *before* the server joining the group (the joining member) connects to the donor. Typically, this is set up at the time you are provisioning a server to join the group. To create a replication user for distributed recovery that requires an SSL connection, issue these statements on all servers that are going to participate in the group:

```
mysql> SET SQL_LOG_BIN=0;
mysql> CREATE USER 'rec_ssl_user'@'%' IDENTIFIED BY 'password' REQUIRE SSL;
mysql> GRANT replication slave ON *.* TO 'rec_ssl_user'@'%';
mysql> GRANT BACKUP_ADMIN ON *.* TO 'rec_ssl_user'@'%';
mysql> FLUSH PRIVILEGES;
mysql> SET SQL_LOG_BIN=1;
```

Providing Replication User Credentials Securely

To supply the user credentials for the replication user, you can set them permanently as the credentials for the `group_replication_recovery` channel, using a `CHANGE REPLICATION SOURCE TO | CHANGE MASTER TO` statement. Alternatively, from MySQL 8.0.21, you can specify them on the `START GROUP_REPLICATION` statement each time Group Replication is started. User credentials specified on `START GROUP_REPLICATION` take precedence over any user credentials that have been set using a `CHANGE REPLICATION SOURCE TO | CHANGE MASTER TO` statement.

User credentials set using `CHANGE REPLICATION SOURCE TO | CHANGE MASTER TO` are stored in plain text in the replication metadata repositories on the server, but user credentials specified on `START GROUP_REPLICATION` are saved in memory only, and are removed by a `STOP GROUP_REPLICATION` statement or server shutdown. Using `START GROUP_REPLICATION` to specify the user credentials therefore helps to secure the Group Replication servers against unauthorized access. However, this method is not compatible with starting Group Replication automatically, as specified by the `group_replication_start_on_boot` system variable.

If you want to set the user credentials permanently using a `CHANGE REPLICATION SOURCE TO | CHANGE MASTER TO` statement, issue this statement on the member that is going to join the group:

```
mysql> CHANGE MASTER TO MASTER_USER='rec_ssl_user', MASTER_PASSWORD='password'
      FOR CHANNEL 'group_replication_recovery';
```

Or from MySQL 8.0.23:

```
mysql> CHANGE REPLICATION SOURCE TO SOURCE_USER='rec_ssl_user', SOURCE_PASSWORD='password'
      FOR CHANNEL 'group_replication_recovery';
```

To supply the user credentials on `START GROUP_REPLICATION`, issue this statement when starting Group Replication for the first time, or after a server restart:

```
mysql> START GROUP_REPLICATION USER='rec_ssl_user', PASSWORD='password';
```

Important

If you switch to using `START GROUP_REPLICATION` to specify user credentials on a server that previously supplied the credentials using `CHANGE REPLICATION SOURCE TO | CHANGE MASTER TO`, you must complete the following steps to get the security benefits of this change.

1. Stop Group Replication on the group member using a `STOP GROUP_REPLICATION` statement. Although it is possible to take the following two steps while Group Replication is running, you need to restart Group Replication to implement the changes.
2. Set the value of the `group_replication_start_on_boot` system variable to `OFF` (the default is `ON`).
3. Remove the distributed recovery credentials from the replica status tables by issuing this statement:

```
mysql> CHANGE MASTER TO MASTER_USER='', MASTER_PASSWORD=''
      FOR CHANNEL 'group_replication_recovery';
```

Or from MySQL 8.0.23:

```
mysql> CHANGE REPLICATION SOURCE TO SOURCE_USER='', SOURCE_PASSWORD=''
      FOR CHANNEL 'group_replication_recovery';
```

4. Restart Group Replication on the group member using a `START GROUP_REPLICATION` statement that specifies the distributed recovery user credentials.

Without these steps, the credentials remain stored in the replica status tables, and can also be transferred to other group members during remote cloning operations for distributed recovery. The

`group_replication_recovery` channel could then be inadvertently started with the stored credentials, on either the original member or members that were cloned from it. An automatic start of Group Replication on server boot (including after a remote cloning operation) would use the stored user credentials, and they would also be used if an operator did not specify the distributed recovery credentials on a `START GROUP_REPLICATION` command.

18.6.3.2 Secure Socket Layer (SSL) Connections for Distributed Recovery

Whether the distributed recovery connection is made using the standard SQL client connection or a distributed recovery endpoint, to configure the connection securely, you can use Group Replication's dedicated distributed recovery SSL options. These options correspond to the server SSL options that are used for group communication connections, but they are only applied for distributed recovery connections. By default, distributed recovery connections do not use SSL, even if you activated SSL for group communication connections, and the server SSL options are not applied for distributed recovery connections. You must configure these connections separately.

If a remote cloning operation is used as part of distributed recovery, Group Replication automatically configures the clone plugin's SSL options to match your settings for the distributed recovery SSL options. (For details of how the clone plugin uses SSL, see [Configuring an Encrypted Connection for Cloning](#).)

The distributed recovery SSL options are as follows:

- `group_replication_recovery_use_ssl`: Set to `ON` to make Group Replication use SSL for distributed recovery connections, including remote cloning operations and state transfer from a donor's binary log. You can just set this option and none of the other distributed recovery SSL options, in which case the server automatically generates certificates to use for the connection, and uses the default cipher suites. If you want to configure the certificates and cipher suites for the connection, use the other distributed recovery SSL options to do this.
- `group_replication_recovery_ssl_ca`: The path name of the Certificate Authority (CA) file to use for distributed recovery connections. Group Replication automatically configures the clone SSL option `clone_ssl_ca` to match this.

`group_replication_recovery_ssl_capath`: The path name of a directory that contains trusted SSL certificate authority (CA) certificate files.
- `group_replication_recovery_ssl_cert`: The path name of the SSL public key certificate file to use for distributed recovery connections. Group Replication automatically configures the clone SSL option `clone_ssl_cert` to match this.
- `group_replication_recovery_ssl_key`: The path name of the SSL private key file to use for distributed recovery connections. Group Replication automatically configures the clone SSL option `clone_ssl_cert` to match this.
- `group_replication_recovery_ssl_verify_server_cert`: Makes the distributed recovery connection check the server's Common Name value in the donor sent certificate. Setting this option to `ON` is the equivalent for distributed recovery connections of setting `VERIFY_IDENTITY` for the `group_replication_ssl_mode` option for group communication connections.
- `group_replication_recovery_ssl_crl`: The path name of a file containing certificate revocation lists.
- `group_replication_recovery_ssl_crlpath`: The path name of a directory containing certificate revocation lists.
- `group_replication_recovery_ssl_cipher`: A list of permissible ciphers for connection encryption for the distributed recovery connection. Specify a list of one or more cipher names, separated by

colons. For information about which encryption ciphers MySQL supports, see [Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).

- `group_replication_recovery_tls_version`: A comma-separated list of one or more permitted TLS protocols for connection encryption when this server instance is the client in the distributed recovery connection, that is, the joining member. Ensure the specified versions are contiguous (for example, “`TLSv1,TLSv1.1,TLSv1.2`”). If this system variable is not set, the default “`TLSv1,TLSv1.1,TLSv1.2,TLSv1.3`” is used. The group members involved in each distributed recovery connection as the client (joining member) and server (donor) negotiate the highest protocol version that they are both set up to support. This system variable is available from MySQL 8.0.19.
- `group_replication_recovery_tls_ciphersuites`: A colon-separated list of one or more permitted ciphersuites when TLSv1.3 is used for connection encryption for the distributed recovery connection, and this server instance is the client in the distributed recovery connection, that is, the joining member. If this system variable is set to `NULL` when TLSv1.3 is used (which is the default if you do not set the system variable), the ciphersuites that are enabled by default are allowed, as listed in [Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#). If this system variable is set to the empty string, no cipher suites are allowed, and TLSv1.3 are therefore not used. This system variable is available beginning with MySQL 8.0.19.

18.7 Group Replication Performance

This section explains how to use the available configuration options to gain the best performance from your replication group.

18.7.1 Fine Tuning the Group Communication Thread

The group communication thread (GCT) runs in a loop while the Group Replication plugin is loaded. The GCT receives messages from the group and from the plugin, handles quorum and failure detection related tasks, sends out some keep alive messages and also handles the incoming and outgoing transactions from/to the server/group. The GCT waits for incoming messages in a queue. When there are no messages, the GCT waits. By configuring this wait to be a little longer (doing an active wait) before actually going to sleep can prove to be beneficial in some cases. This is because the alternative is for the operating system to switch out the GCT from the processor and do a context switch.

To force the GCT to do an active wait, use the `group_replication_poll_spin_loops` option, which makes the GCT loop, doing nothing relevant for the configured number of loops, before actually polling the queue for the next message.

For example:

```
mysql> SET GLOBAL group_replication_poll_spin_loops= 10000;
```

18.7.2 Flow Control

Group Replication ensures that a transaction only commits after a majority of the members in a group have received it and agreed on the relative order between all transactions that were sent concurrently. This approach works well if the total number of writes to the group does not exceed the write capacity of any member in the group. If it does and some of the members have less write throughput than others, particularly less than the writer members, those members can start lagging behind of the writers.

Having some members lagging behind the group brings some problematic consequences, particularly, the reads on such members may externalize very old data. Depending on why the member is lagging behind, other members in the group may have to save more or less replication context to be able to fulfil potential data transfer requests from the slow member.

There is however a mechanism in the replication protocol to avoid having too much distance, in terms of transactions applied, between fast and slow members. This is known as the flow control mechanism. It tries to address several goals:

1. to keep the members close enough to make buffering and de-synchronization between members a small problem;
2. to adapt quickly to changing conditions like different workloads or more writers in the group;
3. to give each member a fair share of the available write capacity;
4. to not reduce throughput more than strictly necessary to avoid wasting resources.

Given the design of Group Replication, the decision whether to throttle or not may be decided taking into account two work queues: (i) the *certification* queue; (ii) and on the binary log *applier* queue. Whenever the size of one of these queues exceeds the user-defined threshold, the throttling mechanism is triggered. Only configure: (i) whether to do flow control at the certifier or at the applier level, or both; and (ii) what is the threshold for each queue.

The flow control depends on two basic mechanisms:

1. the monitoring of members to collect some statistics on throughput and queue sizes of all group members to make educated guesses on what is the maximum write pressure each member should be subjected to;
2. the throttling of members that are trying to write beyond their fair-share of the available capacity at each moment in time.

18.7.2.1 Probes and Statistics

The monitoring mechanism works by having each member deploying a set of probes to collect information about its work queues and throughput. It then propagates that information to the group periodically to share that data with the other members.

Such probes are scattered throughout the plugin stack and allow one to establish metrics, such as:

- the certifier queue size;
- the replication applier queue size;
- the total number of transactions certified;
- the total number of remote transactions applied in the member;
- the total number of local transactions.

Once a member receives a message with statistics from another member, it calculates additional metrics regarding how many transactions were certified, applied and locally executed in the last monitoring period.

Monitoring data is shared with others in the group periodically. The monitoring period must be high enough to allow the other members to decide on the current write requests, but low enough that it has minimal impact on group bandwidth. The information is shared every second, and this period is sufficient to address both concerns.

18.7.2.2 Group Replication Throttling

Based on the metrics gathered across all servers in the group, a throttling mechanism kicks in and decides whether to limit the rate a member is able to execute/commit new transactions.

Therefore, metrics acquired from all members are the basis for calculating the capacity of each member: if a member has a large queue (for certification or the applier thread), then the capacity to execute new transactions should be close to ones certified or applied in the last period.

The lowest capacity of all the members in the group determines the real capacity of the group, while the number of local transactions determines how many members are writing to it, and, consequently, how many members should that available capacity be shared with.

This means that every member has an established write quota based on the available capacity, in other words a number of transactions it can safely issue for the next period. The writer-quota is enforced by the throttling mechanism if the queue size of the certifier or the binary log applier exceeds a user-defined threshold.

The quota is reduced by the number of transactions that were delayed in the last period, and then also further reduced by 10% to allow the queue that triggered the problem to reduce its size. In order to avoid large jumps in throughput once the queue size goes beyond the threshold, the throughput is only allowed to grow by the same 10% per period after that.

The current throttling mechanism does not penalize transactions below quota, but delays finishing those transactions that exceed it until the end of the monitoring period. As a consequence, if the quota is very small for the write requests issued some transactions may have latencies close to the monitoring period.

18.7.3 Message Compression

For messages sent between online group members, Group Replication enables message compression by default. Whether a specific message is compressed depends on the threshold that you configure using the `group_replication_compression_threshold` system variable. Messages that have a payload larger than the specified number of bytes are compressed.

The default compression threshold is 1000000 bytes. You could use the following statements to increase the compression threshold to 2MB, for example:

```
STOP GROUP_REPLICATION;
SET GLOBAL group_replication_compression_threshold = 2097152;
START GROUP_REPLICATION;
```

If you set `group_replication_compression_threshold` to zero, message compression is disabled.

Group Replication uses the LZ4 compression algorithm to compress messages sent in the group. Note that the maximum supported input size for the LZ4 compression algorithm is 2113929216 bytes. This limit is lower than the maximum possible value for the `group_replication_compression_threshold` system variable, which is matched to the maximum message size accepted by XCom. The LZ4 maximum input size is therefore a practical limit for message compression, and transactions above this size cannot be committed when message compression is enabled. With the LZ4 compression algorithm, do not set a value greater than 2113929216 bytes for `group_replication_compression_threshold`.

The value of `group_replication_compression_threshold` is not required by Group Replication to be the same on all group members. However, it is advisable to set the same value on all group members in order to avoid unnecessary rollback of transactions, failure of message delivery, or failure of message recovery.

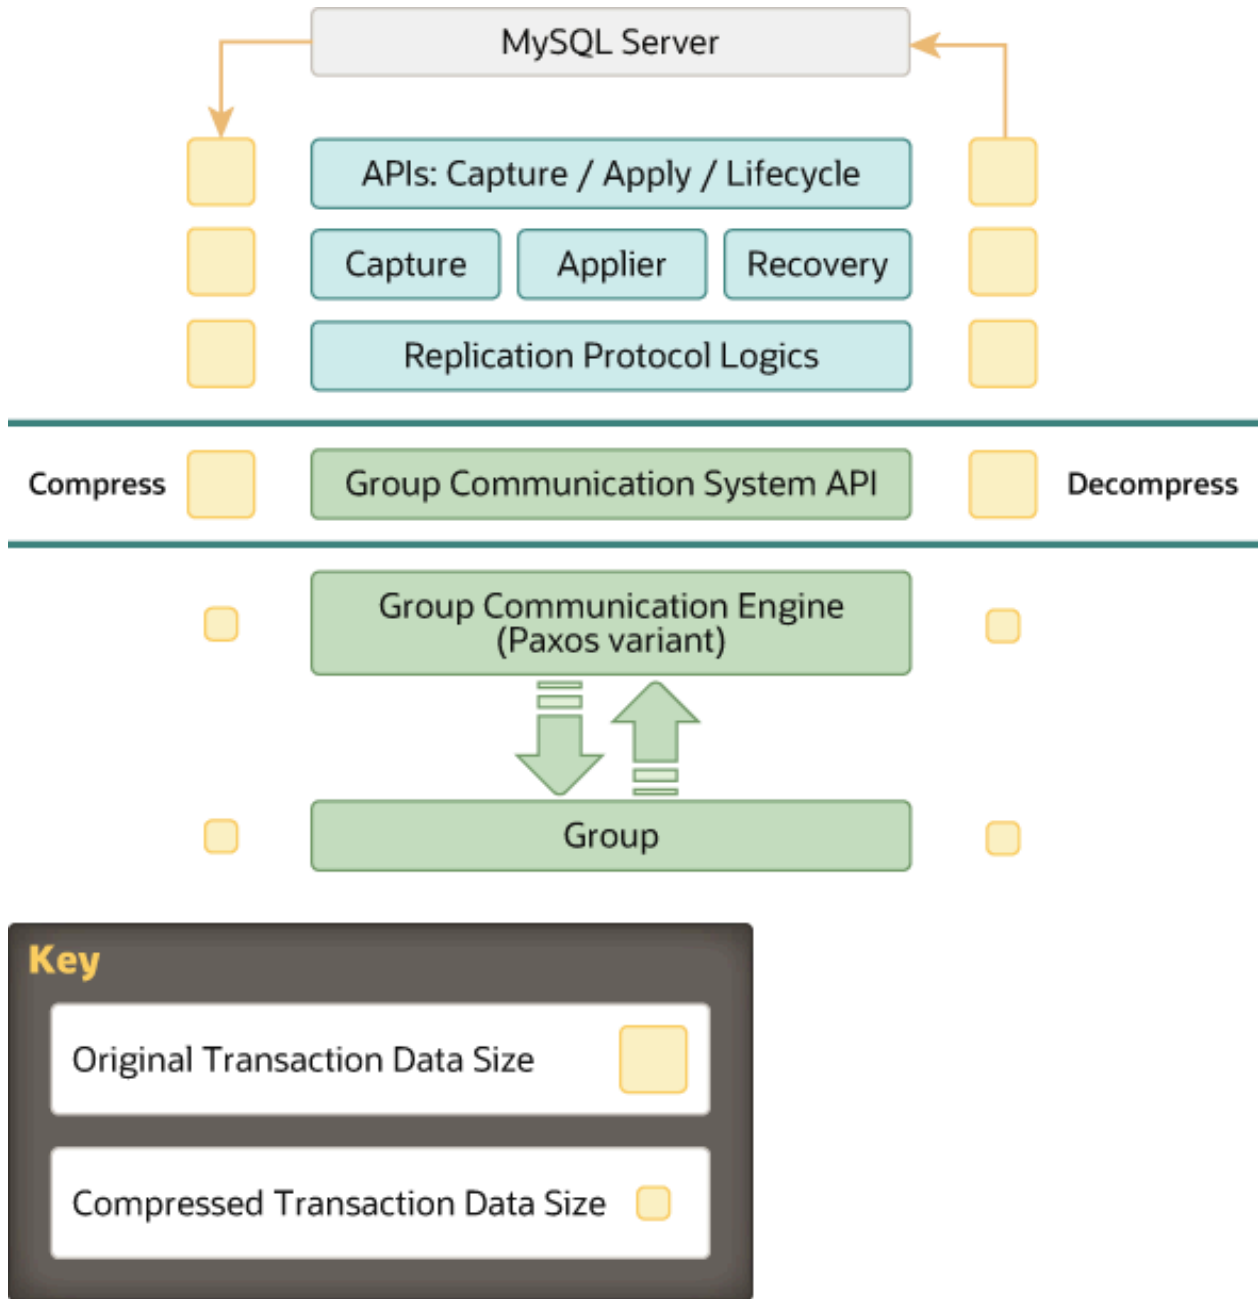

From MySQL 8.0.18, you can also configure compression for messages sent for distributed recovery by the method of state transfer from a donor's binary log. Compression for these messages, which are sent from a donor already in the group to a joining member, is controlled separately using the `group_replication_recovery_compression_algorithms` and

`group_replication_recovery_zstd_compression_level` system variables. For more information, see [Section 4.2.8, “Connection Compression Control”](#).

Binary log transaction compression (available as of MySQL 8.0.20), which is activated by the `binlog_transaction_compression` system variable, can also be used to save bandwidth. The transaction payloads remain compressed when they are transferred between group members. If you use binary log transaction compression in combination with Group Replication's message compression, message compression has less opportunity to act on the data, but can still compress headers and those events and transaction payloads that are uncompressed. For more information on binary log transaction compression, see [Section 5.4.4.5, “Binary Log Transaction Compression”](#).

Compression for messages sent in the group happens at the group communication engine level, before the data is handed over to the group communication thread, so it takes place within the context of the `mysql` user session thread. If the message payload size exceeds the threshold set by `group_replication_compression_threshold`, the transaction payload is compressed before being sent out to the group, and decompressed when it is received. Upon receiving a message, the member checks the message envelope to verify whether it is compressed or not. If needed, then the member decompresses the transaction, before delivering it to the upper layer. This process is shown in the following figure.

Figure 18.15 Compression Support

When network bandwidth is a bottleneck, message compression can provide up to 30-40% throughput improvement at the group communication level. This is especially important within the context of large groups of servers under load. The TCP peer-to-peer nature of the interconnections between N participants in the group makes the sender send the same amount of data N times. Furthermore, binary logs are likely to exhibit a high compression ratio. This makes compression a compelling feature for Group Replication workloads that contain large transactions.

18.7.4 Message Fragmentation

When an abnormally large message is sent between Group Replication group members, it can result in some group members being reported as failed and expelled from the group. This is because the single

thread used by Group Replication's group communication engine (XCom, a Paxos variant) is occupied processing the message for too long, so some of the group members might report the receiver as failed. From MySQL 8.0.16, by default, large messages are automatically split into fragments that are sent separately and reassembled by the recipients.

The system variable `group_replication_communication_max_message_size` specifies a maximum message size for Group Replication communications, above which messages are fragmented. The default maximum message size is 10485760 bytes (10 MiB). The greatest permitted value is the same as the maximum value of the `replica_max_allowed_packet` and `slave_max_allowed_packet` system variables, which is 1073741824 bytes (1 GB). The setting for `group_replication_communication_max_message_size` must be less than the `replica_max_allowed_packet` or `slave_max_allowed_packet` setting, because the applier thread cannot handle message fragments larger than the maximum permitted packet size. To switch off fragmentation, specify a zero value for `group_replication_communication_max_message_size`.

As with most other Group Replication system variables, you must restart the Group Replication plugin for the change to take effect. For example:

```
STOP GROUP_REPLICATION;  
SET GLOBAL group_replication_communication_max_message_size= 5242880;  
START GROUP_REPLICATION;
```

Message delivery for a fragmented message is considered complete when all the fragments of the message have been received and reassembled by all the group members. Fragmented messages include information in their headers that enables a member joining during message transmission to recover the earlier fragments that were sent before it joined. If the joining member fails to recover the fragments, it expels itself from the group.

In order for a replication group to use fragmentation, all group members must be at MySQL 8.0.16 or above, and the Group Replication communication protocol version in use by the group must allow fragmentation. You can inspect the communication protocol in use by a group by using the `group_replication_get_communication_protocol()` function, which returns the oldest MySQL Server version that the group supports. Versions from MySQL 5.7.14 allow compression of messages, and versions from MySQL 8.0.16 also allow fragmentation of messages. If all group members are at MySQL 8.0.16 or above and there is no requirement to allow members at earlier releases to join, you can use the `group_replication_set_communication_protocol()` function to set the communication protocol version to MySQL 8.0.16 or above in order to allow fragmentation. For more information, see [Section 18.5.1.4, "Setting a Group's Communication Protocol Version"](#).

If a replication group cannot use fragmentation because some members do not support it, the system variable `group_replication_transaction_size_limit` can be used to limit the maximum size of transactions the group accepts. In MySQL 8.0, the default setting is approximately 143 MB. Transactions above this size are rolled back. You can also use the system variable `group_replication_member_expel_timeout` to allow additional time (up to an hour) before a member under suspicion of having failed is expelled from the group.

18.7.5 XCom Cache Management

The group communication engine for Group Replication (XCom, a Paxos variant) includes a cache for messages (and their metadata) exchanged between the group members as a part of the consensus protocol. Among other functions, the message cache is used for recovery of missed messages by members that reconnect with the group after a period where they were unable to communicate with the other group members.

From MySQL 8.0.16, a cache size limit can be set for XCom's message cache using the `group_replication_message_cache_size` system variable. If the cache size limit is reached, XCom

removes the oldest entries that have been decided and delivered. The same cache size limit should be set on all group members, because an unreachable member that is attempting to reconnect selects any other member at random for recovery of missed messages. The same messages should therefore be available in each member's cache.

Before MySQL 8.0.16, the cache size was 1 GB, and the default setting for the cache size from MySQL 8.0.16 is the same. Ensure that sufficient memory is available on your system for your chosen cache size limit, considering the size of MySQL Server's other caches and object pools. Note that the limit set using [group_replication_message_cache_size](#) applies only to the data stored in the cache, and the cache structures require an additional 50 MB of memory.

When selecting a [group_replication_message_cache_size](#) setting, do so with reference to the expected volume of messages in the time period before a member is expelled. The length of this time period is controlled by the [group_replication_member_expel_timeout](#) system variable, which determines the waiting period (up to an hour) that is allowed in addition to the initial 5-second detection period for members to return to the group rather than being expelled. Note that before MySQL 8.0.21, this time period defaulted to 5 seconds from the member becoming unavailable, which is just the detection period before a suspicion is created, because the additional expel timeout set by the [group_replication_member_expel_timeout](#) system variable defaulted to zero. From 8.0.21 the expel timeout defaults to 5 seconds, so by default a member is not expelled until it has been absent for at least 10 seconds.

18.7.5.1 Increasing the cache size

If a member is absent for a period that is not long enough for it to be expelled from the group, it can reconnect and start participating in the group again by retrieving missed transactions from another member's XCom message cache. However, if the transactions that happened during the member's absence have been deleted from the other members' XCom message caches because their maximum size limit was reached, the member cannot reconnect in this way.

Group Replication's Group Communication System (GCS) alerts you, by a warning message, when a message that is likely to be needed for recovery by a member that is currently unreachable is removed from the message cache. This warning message is logged on all the active group members (only once for each unreachable member). Although the group members cannot know for sure what message was the last message seen by the unreachable member, the warning message indicates that the cache size might not be sufficient to support your chosen waiting period before a member is expelled.

In this situation, consider increasing the [group_replication_message_cache_size](#) limit with reference to the expected volume of messages in the time period specified by the [group_replication_member_expel_timeout](#) system variable plus the 5-second detection period, so that the cache contains all the missed messages required for members to return successfully. You can also consider increasing the cache size limit temporarily if you expect a member to become unreachable for an unusual period of time.

18.7.5.2 Reducing the cache size

The minimum setting for the XCom message cache size is 1 GB up to MySQL 8.0.20. From MySQL 8.0.21, the minimum setting is 134217728 bytes (128 MB), which enables deployment on a host that has a restricted amount of available memory. Having a very low [group_replication_message_cache_size](#) setting is not recommended if the host is on an unstable network, because a smaller message cache makes it harder for group members to reconnect after a transient loss of connectivity.

If a reconnecting member cannot retrieve all the messages it needs from the XCom message cache, the member must leave the group and rejoin it, in order to retrieve the missing transactions from another member's binary log using distributed recovery. From MySQL 8.0.21, a member that has left a group

makes three auto-rejoin attempts by default, so the process of rejoining the group can still take place without operator intervention. However, rejoining using distributed recovery is a significantly longer and more complex process than retrieving messages from an XCom message cache, so the member takes longer to become available and the performance of the group can be impacted. On a stable network, which minimizes the frequency and duration of transient losses of connectivity for members, the frequency of this occurrence should also be minimized, so the group might be able to tolerate a smaller XCom message cache size without a significant impact on its performance.

If you are considering reducing the cache size limit, you can query the Performance Schema table `memory_summary_global_by_event_name` using the following statement:

```
SELECT * FROM performance_schema.memory_summary_global_by_event_name
WHERE EVENT_NAME LIKE 'memory/group_rpl/GCS_XCom:xcom_cache';
```

This returns memory usage statistics for the message cache, including the current number of cached entries and current size of the cache. If you reduce the cache size limit, XCom removes the oldest entries that have been decided and delivered until the current size is below the limit. XCom might temporarily exceed the cache size limit while this removal process is ongoing.

18.7.6 Responses to Failure Detection and Network Partitioning

Group Replication's failure detection mechanism is designed to identify group members that are no longer communicating with the group, and expel them as and when it seems likely that they have failed. Having a failure detection mechanism increases the chance that the group contains a majority of correctly working members, and that requests from clients are therefore processed correctly.

Normally, all group members regularly exchange messages with all other group members. If a group member does not receive any messages from a particular fellow member for 5 seconds, when this detection period ends, it creates a suspicion of the fellow member. When a suspicion times out, the suspected member is assumed to have failed, and is expelled from the group. An expelled member is removed from the membership list seen by the other members, but it does not know that it has been expelled from the group, so it sees itself as online and the other members as unreachable. If the member has not in fact failed (for example, because it was just disconnected due to a temporary network issue) and it is able to resume communication with the other members, it receives a view containing the information that it has been expelled from the group.

The responses of group members, including the failed member itself, to these situations can be configured at a number of points in the process. By default, the following behaviors happen if a member is suspected of having failed:

1. Up to MySQL 8.0.20, when a suspicion is created, it times out immediately. The suspected member is liable for expulsion as soon as the expired suspicion is identified by the group. The member could potentially survive for a further few seconds after the timeout because the check for expired suspicions is carried out periodically. From MySQL 8.0.21, a waiting period of 5 seconds is added before the suspicion times out and the suspected member is liable for expulsion.
2. If an expelled member resumes communication and realises that it was expelled, up to MySQL 8.0.20, it does not try to rejoin the group. From MySQL 8.0.21, it makes three automatic attempts to rejoin the group (with 5 minutes between each attempt), and if this auto-rejoin procedure does not work, it then stops trying to rejoin the group.
3. When an expelled member is not trying to rejoin the group, it switches to super read only mode and awaits operator attention. (The exception is in releases from MySQL 8.0.12 to 8.0.15, where the default was for the member to shut itself down. From MySQL 8.0.16, the behavior was changed to match the behavior in MySQL 5.7.)

You can use the Group Replication configuration options described in this section to change these behaviors either permanently or temporarily, to suit your system's requirements and your priorities. If you are experiencing unnecessary expulsions caused by slower networks or machines, networks with a high rate of unexpected transient outages, or planned network outages, consider increasing the expel timeout and auto-rejoin attempts. From MySQL 8.0.21, the default settings have been changed in this direction to reduce the frequency of the need for operator intervention to reinstate expelled members in these situations. Note that while a member is undergoing any of the default behaviors described above, although it does not accept writes, reads can still be made if the member is still communicating with clients, with an increasing likelihood of stale reads over time. If avoiding stale reads is a higher priority for you than avoiding operator intervention, consider reducing the expel timeout and auto-rejoin attempts or setting them to zero.

Members that have not failed might lose contact with part, but not all, of the replication group due to a network partition. For example, in a group of 5 servers (S1,S2,S3,S4,S5), if there is a disconnection between (S1,S2) and (S3,S4,S5) there is a network partition. The first group (S1,S2) is now in a minority because it cannot contact more than half of the group. Any transactions that are processed by the members in the minority group are blocked, because the majority of the group is unreachable, therefore the group cannot achieve quorum. For a detailed description of this scenario, see [Section 18.5.4, "Network Partitioning"](#). In this situation, the default behavior is for the members in both the minority and the majority to remain in the group, continue to accept transactions (although they are blocked on the members in the minority), and wait for operator intervention. This behavior is also configurable.

Note that where group members are at an older MySQL Server release that does not support a relevant setting, or at a release with a different default, they act towards themselves and other group members according to the default behaviors stated above. For example, a member that does not support the `group_replication_member_expel_timeout` system variable expels other members as soon as an expired suspicion is detected, and this expulsion is accepted by other members even if they support the system variable and have a longer timeout set.

18.7.6.1 Expel Timeout

You can use the `group_replication_member_expel_timeout` system variable, which is available from MySQL 8.0.13, to allow additional time between the creation of a suspicion and the expulsion of the suspect member. A suspicion is created when one server does not receive messages from another server, as explained in [Section 18.1.4.2, "Failure Detection"](#).

There is an initial 5-second detection period before a Group Replication group member creates a suspicion of another member (or of itself). A group member is then expelled when another member's suspicion of it (or its own suspicion of itself) times out. A further short period of time might elapse after that before the expelling mechanism detects and implements the expulsion. `group_replication_member_expel_timeout` specifies the period of time in seconds, called the expel timeout, that a group member waits between creating a suspicion, and expelling the suspected member. Suspect members are listed as `UNREACHABLE` during this waiting period, but are not removed from the group's membership list.

- If a suspect member becomes active again before the suspicion times out at the end of the waiting period, the member applies all the messages that were buffered by the remaining group members in XCom's message cache and enters `ONLINE` state, without operator intervention. In this situation, the member is considered by the group as the same incarnation.
- If a suspect member becomes active only after the suspicion times out and is able to resume communications, it receives a view where it is expelled and at that point realises it was expelled. You can use the `group_replication_autorejoin_tries` system variable, which is available from MySQL 8.0.16, to make the member automatically try to rejoin the group at this point. From MySQL 8.0.21, this feature is activated by default and the member makes three auto-rejoin attempts. If the auto-

rejoin procedure does not succeed or is not attempted, the expelled member then follows the exit action specified by `group_replication_exit_state_action`.

The waiting period before expelling a member only applies to members that have previously been active in the group. Non-members that were never active in the group do not get this waiting period and are removed after the initial detection period because they took too long to join.

If `group_replication_member_expel_timeout` is set to 0, there is no waiting period, and a suspected member is liable for expulsion immediately after the 5-second detection period ends. This setting is the default up to and including MySQL 8.0.20. This is also the behavior of a group member which is at a MySQL Server version that does not support the `group_replication_member_expel_timeout` system variable. From MySQL 8.0.21, the value defaults to 5, meaning that a suspected member is liable for expulsion 5 seconds after the 5-second detection period. It is not mandatory for all members of a group to have the same setting for `group_replication_member_expel_timeout`, but it is recommended in order to avoid unexpected expulsions. Any member can create a suspicion of any other member, including itself, so the effective expel timeout is that of the member with the lowest setting.

Consider increasing the value of `group_replication_member_expel_timeout` from the default in the following scenarios:

- The network is slow and the default 5 or 10 seconds before expulsion is not long enough for group members to always exchange at least one message.
- The network sometimes has transient outages and you want to avoid unnecessary expulsions and primary member changes at these times.
- The network is not under your direct control and you want to minimize the need for operator intervention.
- A temporary network outage is expected and you do not want some or all of the members to be expelled due to this.
- An individual machine is experiencing a slowdown and you do not want it to be expelled from the group.

You can specify an expel timeout up to a maximum of 3600 seconds (1 hour). It is important to ensure that XCom's message cache is sufficiently large to contain the expected volume of messages in your specified time period, plus the initial 5-second detection period, otherwise members cannot reconnect. You can adjust the cache size limit using the `group_replication_message_cache_size` system variable. For more information, see [Section 18.7.5, "XCom Cache Management"](#).

If any members in a group are currently under suspicion, the group membership cannot be reconfigured (by adding or removing members or electing a new leader). If group membership changes need to be implemented while one or more members are under suspicion, and you want the suspect members to remain in the group, take any actions required to make the members active again, if that is possible. If you cannot make the members active again and you want them to be expelled from the group, you can force the suspicions to time out immediately. Do this by changing the value of `group_replication_member_expel_timeout` on any active members to a value lower than the time that has already elapsed since the suspicions were created. The suspect members then become liable for expulsion immediately.

If a replication group member stops unexpectedly and is immediately restarted (for example, because it was started with `mysqld_safe`), it automatically attempts to rejoin the group if `group_replication_start_on_boot=on` is set. In this situation, it is possible for the restart and rejoin attempt to take place before the member's previous incarnation has been expelled from the group, in which case the member cannot rejoin. From MySQL 8.0.19, Group Replication automatically uses a Group Communication System (GCS) feature to retry the rejoin attempt for the member 10 times, with a 5-second interval between each retry. This should cover most cases and allow enough time

for the previous incarnation to be expelled from the group, letting the member rejoin. Note that if the `group_replication_member_expel_timeout` system variable is set to specify a longer waiting period before the member is expelled, the automatic rejoin attempts might still not succeed.

For alternative mitigation strategies to avoid unnecessary expulsions where the `group_replication_member_expel_timeout` system variable is not available, see [Section 18.3.2, “Group Replication Limitations”](#).

18.7.6.2 Unreachable Majority Timeout

By default, members that find themselves in a minority due to a network partition do not automatically leave the group. You can use the system variable `group_replication_unreachable_majority_timeout` to set a number of seconds for a member to wait after losing contact with the majority of group members, and then exit the group. Setting a timeout means you do not need to pro-actively monitor for servers that are in a minority group after a network partition, and you can avoid the possibility of creating a split-brain situation (with two versions of the group membership) due to inappropriate intervention.

When the timeout specified by `group_replication_unreachable_majority_timeout` elapses, all pending transactions that have been processed by the member and the others in the minority group are rolled back, and the servers in that group move to the `ERROR` state. You can use the `group_replication_autorejoin_tries` system variable, which is available from MySQL 8.0.16, to make the member automatically try to rejoin the group at this point. From MySQL 8.0.21, this feature is activated by default and the member makes three auto-rejoin attempts. If the auto-rejoin procedure does not succeed or is not attempted, the minority member then follows the exit action specified by `group_replication_exit_state_action`.

Consider the following points when deciding whether or not to set an unreachable majority timeout:

- In a symmetric group, for example a group with two or four servers, if both partitions contain an equal number of servers, both groups consider themselves to be in a minority and enter the `ERROR` state. In this situation, the group has no functional partition.
- While a minority group exists, any transactions processed by the minority group are accepted, but blocked because the minority servers cannot reach quorum, until either `STOP GROUP_REPLICATION` is issued on those servers or the unreachable majority timeout is reached.
- If you do not set an unreachable majority timeout, the servers in the minority group never enter the `ERROR` state automatically, and you must stop them manually.
- Setting an unreachable majority timeout has no effect if it is set on the servers in the minority group after the loss of majority has been detected.

If you do not use the `group_replication_unreachable_majority_timeout` system variable, the process for operator invention in the event of a network partition is described in [Section 18.5.4, “Network Partitioning”](#). The process involves checking which servers are functioning and forcing a new group membership if necessary.

18.7.6.3 Auto-Rejoin

The `group_replication_autorejoin_tries` system variable, which is available from MySQL 8.0.16, makes a member that has been expelled or reached its unreachable majority timeout try to rejoin the group automatically. Up to MySQL 8.0.20, the value of the system variable defaults to 0, so auto-rejoin is not activated by default. From MySQL 8.0.21, the value of the system variable defaults to 3, meaning that the member automatically makes 3 attempts to rejoin the group, with 5 minutes between each.

When auto-rejoin is not activated, a member accepts its expulsion as soon as it resumes communication, and proceeds to the action specified by the `group_replication_exit_state_action` system

variable. After this, manual intervention is needed to bring the member back into the group. Using the auto-rejoin feature is appropriate if you can tolerate the possibility of stale reads and want to minimize the need for manual intervention, especially where transient network issues fairly often result in the expulsion of members.

With auto-rejoin, when the member's expulsion or unreachable majority timeout is reached, it makes an attempt to rejoin (using the current plugin option values), then continues to make further auto-rejoin attempts up to the specified number of tries. After an unsuccessful auto-rejoin attempt, the member waits 5 minutes before the next try. The auto-rejoin attempts and the time between them are called the auto-rejoin procedure. If the specified number of tries is exhausted without the member rejoining or being stopped, the member proceeds to the action specified by the `group_replication_exit_state_action` system variable.

During and between auto-rejoin attempts, a member remains in super read only mode and displays an `ERROR` state on its view of the replication group. During this time, the member does not accept writes. However, reads can still be made on the member, with an increasing likelihood of stale reads over time. If you do want to intervene to take the member offline during the auto-rejoin procedure, the member can be stopped manually at any time by using a `STOP GROUP_REPLICATION` statement or shutting down the server. If you cannot tolerate the possibility of stale reads for any period of time, set the `group_replication_autorejoin_tries` system variable to 0.

You can monitor the auto-rejoin procedure using the Performance Schema. While an auto-rejoin procedure is taking place, the Performance Schema table `events_stages_current` shows the event "Undergoing auto-rejoin procedure", with the number of retries that have been attempted so far during this instance of the procedure (in the `WORK_COMPLETED` field). The `events_stages_summary_global_by_event_name` table shows the number of times the server instance has initiated the auto-rejoin procedure (in the `COUNT_STAR` field). The `events_stages_history_long` table shows the time each of these auto-rejoin procedures was completed (in the `TIMER_END` field).

18.7.6.4 Exit Action

The `group_replication_exit_state_action` system variable, which is available from MySQL 8.0.12 and MySQL 5.7.24, specifies what Group Replication does when the member leaves the group unintentionally due to an error or problem, and either fails to auto-rejoin or does not try. Note that in the case of an expelled member, the member does not know that it was expelled until it reconnects to the group, so the specified action is only taken if the member manages to reconnect, or if the member raises a suspicion on itself and expels itself.

In order of impact, the exit actions are as follows:

1. If `READ_ONLY` is the exit action, the instance switches MySQL to super read only mode by setting the system variable `super_read_only` to `ON`. When the member is in super read only mode, clients cannot make any updates, even if they have the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege). However, clients can still read data, and because updates are no longer being made, there is a probability of stale reads which increases over time. With this setting, you therefore need to pro-actively monitor the servers for failures. This exit action is the default from MySQL 8.0.15. After this exit action is taken, the member's status is displayed as `ERROR` in the view of the group.
2. If `OFFLINE_MODE` is the exit action, the instance switches MySQL to offline mode by setting the system variable `offline_mode` to `ON`. When the member is in offline mode, connected client users are disconnected on their next request and connections are no longer accepted, with the exception of client users that have the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege). Group Replication also sets the system variable `super_read_only` to `ON`, so clients cannot make any updates, even if they have connected with the `CONNECTION_ADMIN` or `SUPER` privilege. This exit action prevents both updates and stale reads (with the exception of reads by client users with

the stated privileges), and enables proxy tools such as MySQL Router to recognize that the server is unavailable and redirect client connections. It also leaves the instance running so that an administrator can attempt to resolve the issue without shutting down MySQL. This exit action is available from MySQL 8.0.18. After this exit action is taken, the member's status is displayed as `ERROR` in the view of the group (not `OFFLINE`, which means a member has Group Replication functionality available but does not currently belong to a group).

3. If `ABORT_SERVER` is the exit action, the instance shuts down MySQL. Instructing the member to shut itself down prevents all stale reads and client updates, but it means that the MySQL Server instance is unavailable and must be restarted, even if the issue could have been resolved without that step. This exit action was the default from MySQL 8.0.12, when the system variable was added, to MySQL 8.0.15 inclusive. After this exit action is taken, the member is removed from the listing of servers in the view of the group.

Bear in mind that operator intervention is required whatever exit action is set, as an ex-member that has exhausted its auto-rejoin attempts (or never had any) and has been expelled from the group is not allowed to rejoin without a restart of Group Replication. The exit action only influences whether or not clients can still read data on the server that was unable to rejoin the group, and whether or not the server stays running.

Important

If a failure occurs before the member has successfully joined the group, the exit action specified by `group_replication_exit_state_action` is *not taken*. This is the case if there is a failure during the local configuration check, or a mismatch between the configuration of the joining member and the configuration of the group. In these situations, the `super_read_only` system variable is left with its original value, and the server does not shut down MySQL. To ensure that the server cannot accept updates when Group Replication did not start, we therefore recommend that `super_read_only=ON` is set in the server's configuration file at startup, which Group Replication changes to `OFF` on primary members after it has been started successfully. This safeguard is particularly important when the server is configured to start Group Replication on server boot (`group_replication_start_on_boot=ON`), but it is also useful when Group Replication is started manually using a `START GROUP_REPLICATION` command.

If a failure occurs after the member has successfully joined the group, the specified exit action is taken. This is the case in the following situations:

1. *Applier error* - There is an error in the replication applier. This issue is not recoverable.
2. *Distributed recovery not possible* - There is an issue that means Group Replication's distributed recovery process (which uses remote cloning operations and state transfer from the binary log) cannot be completed. Group Replication retries distributed recovery automatically where this makes sense, but stops if there are no more options to complete the process. For details, see [Section 18.5.3.4, "Fault Tolerance for Distributed Recovery"](#).
3. *Group configuration change error* - An error occurred during a group-wide configuration change carried out using a function, as described in [Section 18.5.1, "Configuring an Online Group"](#).
4. *Primary election error* - An error occurred during election of a new primary member for a group in single-primary mode, as described in [Section 18.1.3.1, "Single-Primary Mode"](#).
5. *Unreachable majority timeout* - The member has lost contact with a majority of the group members so is in a minority, and a timeout that was set by the `group_replication_unreachable_majority_timeout` system variable has expired.

6. *Member expelled from group* - A suspicion has been raised on the member, and any timeout set by the `group_replication_member_expel_timeout` system variable has expired, and the member has resumed communication with the group and found that it has been expelled.
7. *Out of auto-rejoin attempts* - The `group_replication_autorejoin_tries` system variable was set to specify a number of auto-rejoin attempts after a loss of majority or expulsion, and the member completed this number of attempts without success.

The following table summarizes the failure scenarios and actions in each case:

Table 18.3 Exit actions in Group Replication failure situations

| Failure situation | Group Replication started with <code>START GROUP_REPLICATION</code> | Group Replication started with <code>group_replication_start_on_boot=ON</code> |
|---|--|--|
| Member fails local configuration check | <code>super_read_only</code> and <code>offline_mode</code> unchanged | <code>super_read_only</code> and <code>offline_mode</code> unchanged |
| Mismatch between joining member and group configuration | MySQL continues running Set <code>super_read_only=ON</code> at startup to prevent updates | MySQL continues running Set <code>super_read_only=ON</code> at startup to prevent updates (Important) |
| Applier error on member | <code>super_read_only</code> set to <code>ON</code> | <code>super_read_only</code> set to <code>ON</code> |
| Distributed recovery not possible | OR | OR |
| Group configuration change error | <code>offline_mode</code> and <code>super_read_only</code> set to <code>ON</code> | <code>offline_mode</code> and <code>super_read_only</code> set to <code>ON</code> |
| Primary election error | OR | OR |
| Unreachable majority timeout | MySQL shuts down | MySQL shuts down |
| Member expelled from group | | |
| Out of auto-rejoin attempts | | |

18.8 Upgrading Group Replication

This section explains how to upgrade a Group Replication setup. The basic process of upgrading members of a group is the same as upgrading stand-alone instances, see [Section 2.11, “Upgrading MySQL”](#) for the actual process of doing upgrade and types available. Choosing between an in-place or logical upgrade depends on the amount of data stored in the group. Usually an in-place upgrade is faster, and therefore is recommended. You should also consult [Section 17.5.3, “Upgrading a Replication Setup”](#).

While you are in the process of upgrading an online group, in order to maximize availability, you might need to have members with different MySQL Server versions running at the same time. Group Replication includes compatibility policies that enable you to safely combine members running different versions of MySQL in the same group during the upgrade procedure. Depending on your group, the effects of these policies might affect the order in which you should upgrade group members. For details, see [Section 18.8.1, “Combining Different Member Versions in a Group”](#).

If your group can be taken fully offline see [Section 18.8.2, “Group Replication Offline Upgrade”](#). If your group needs to remain online, as is common with production deployments, see [Section 18.8.3, “Group Replication Online Upgrade”](#) for the different approaches available for upgrading a group with minimal downtime.

18.8.1 Combining Different Member Versions in a Group

Group Replication is versioned according to the MySQL Server version that the Group Replication plugin was bundled with. For example, if a member is running MySQL 5.7.26 then that is the version of the Group Replication plugin. To check the version of MySQL Server on a group member issue:

```
SELECT MEMBER_HOST, MEMBER_PORT, MEMBER_VERSION FROM performance_schema.replication_group_members;
```

| member_host | member_port | member_version |
|-------------|-------------|----------------|
| example.com | 3306 | 8.0.13 |

For guidance on understanding the MySQL Server version and selecting a version, see [Section 2.1.2, “Which MySQL Version and Distribution to Install”](#).

For optimal compatibility and performance, all members of a group should run the same version of MySQL Server and therefore of Group Replication. However, while you are in the process of upgrading an online group, in order to maximize availability, you might need to have members with different MySQL Server versions running at the same time. Depending on the changes made between the versions of MySQL, you could encounter incompatibilities in this situation. For example, if a feature has been deprecated between major versions, then combining the versions in a group might cause members that rely on the deprecated feature to fail. Conversely, writing to a member running a newer MySQL version while there are read-write members in the group running an older MySQL version might cause issues on members that lack functions introduced in the newer release.

To prevent these issues, Group Replication includes compatibility policies that enable you to safely combine members running different versions of MySQL in the same group. A member applies these policies to decide whether to join the group normally, or join in read-only mode, or not join the group, depending on which choice results in the safe operation of the joining member and of the existing members of the group. In an upgrade scenario, each server must leave the group, be upgraded, and rejoin the group with its new server version. At this point the member applies the policies for its new server version, which might have changed from the policies it applied when it originally joined the group.

As the administrator, you can instruct any server to attempt to join any group by configuring the server appropriately and issuing a `START GROUP_REPLICATION` statement. A decision to join or not join the group, or to join the group in read-only mode, is made and implemented by the joining member itself after you attempt to add it to the group. The joining member receives information on the MySQL Server versions of the current group members, assesses its own compatibility with those members, and applies the policies used in its own MySQL Server version (*not* the policies used by the existing members) to decide whether it is compatible.

The compatibility policies that a joining member applies when attempting to join a group are as follows:

- A member does not join a group if it is running a lower MySQL Server version than the lowest version that the existing group members are running.
- A member joins a group normally if it is running the same MySQL Server version as the lowest version that the existing group members are running.
- A member joins a group but remains in read-only mode if it is running a higher MySQL Server version than the lowest version that the existing group members are running. This behavior only makes a difference when the group is running in multi-primary mode, because in a group that is running in single-primary mode, newly added members default to being read-only in any case.

Members running MySQL 8.0.17 or higher take into account the patch version of the release when checking their compatibility. Members running MySQL 8.0.16 or lower, or MySQL 5.7, only take into

account the major version. For example, if you have a group with members all running MySQL version 8.0.13:

- A member that is running MySQL version 5.7 does not join.
- A member running MySQL 8.0.16 joins normally (because it considers the major version).
- A member running MySQL 8.0.17 joins but remains in read-only mode (because it considers the patch version).

Note that joining members running releases before MySQL 5.7.27 check against all group members to find whether their own MySQL Server major version is lower. They therefore fail this check for a group where any members are running MySQL 8.0 releases, and cannot join the group even if it already has other members running MySQL 5.7. From MySQL 5.7.27, joining members only check against the group members that are running the lowest major version, so they can join a mixed version group where other MySQL 5.7 servers are present.

In a multi-primary mode group with members that use different MySQL Server versions, Group Replication automatically manages the read-write and read-only status of members running MySQL 8.0.17 or higher. If a member leaves the group, the members running the version that is now the lowest are automatically set to read-write mode. When you change a group that was running in single-primary mode to run in multi-primary mode, using the `group_replication_switch_to_multi_primary_mode()` function, Group Replication automatically sets members to the correct mode. Members are automatically placed in read-only mode if they are running a higher MySQL server version than the lowest version present in the group, and members running the lowest version are placed in read-write mode.

18.8.1.1 Member Versions During Upgrades

During an online upgrade procedure, if the group is in single-primary mode, all the servers that are not currently offline for upgrading function as they did before. The group elects a new primary whenever necessary, following the election policies described in [Section 18.1.3.1, “Single-Primary Mode”](#). Note that if you require the primary to remain the same throughout (except when it is being upgraded itself), you must first upgrade all of the secondaries to a version higher than or equal to the target primary member version, then upgrade the primary last. The primary cannot remain as the primary unless it is running the lowest MySQL Server version in the group. After the primary has been upgraded, you can use the `group_replication_set_as_primary()` function to reappoint it as the primary.

If the group is in multi-primary mode, fewer online members are available to perform writes during the upgrade procedure, because upgraded members join in read-only mode after their upgrade. From MySQL 8.0.17, this applies to upgrades between patch versions, and for lower releases, this only applies to upgrades between major versions. When all members have been upgraded to the same release, from MySQL 8.0.17, they all change back to read-write mode automatically. For earlier releases, you must set `super_read_only` to `OFF` manually on each member that should function as a primary following the upgrade.

To deal with a problem situation, for example if you have to roll back an upgrade or add extra capacity to a group in an emergency, it is possible to allow a member to join an online group although it is running a lower MySQL Server version than the lowest version in use by other group members. The Group Replication system variable `group_replication_allow_local_lower_version_join` can be used in such situations to override the normal compatibility policies. It is important to note that setting the option to `ON` does not make the new member compatible with the group, and allows it to join the group without any safeguards against incompatible behaviors by the existing members. The option must therefore only be used carefully in specific situations, and you must take additional precautions to avoid the new member failing due to normal group activity. For details of these precautions, see the description for `group_replication_allow_local_lower_version_join`.

18.8.1.2 Group Replication Communication Protocol Version

A replication group uses a Group Replication communication protocol version that can differ from the MySQL Server version of the members. To check the group's communication protocol version, issue the following statement on any member:

```
SELECT group_replication_get_communication_protocol();
```

The return value shows the oldest MySQL Server version that can join this group and use the group's communication protocol. Versions from MySQL 5.7.14 allow compression of messages, and versions from MySQL 8.0.16 also allow fragmentation of messages. Note that the `group_replication_get_communication_protocol()` function returns the minimum MySQL version that the group supports, which might differ from the version number that was passed to the `group_replication_set_communication_protocol()` function, and from the MySQL Server version that is installed on the member where you use the function.

When you upgrade all the members of a replication group to a new MySQL Server release, the Group Replication communication protocol version is not automatically upgraded, in case there is still a requirement to allow members at earlier releases to join. If you do not need to support older members and want to allow the upgraded members to use any added communication capabilities, after the upgrade use the `group_replication_set_communication_protocol()` function to upgrade the communication protocol, specifying the new MySQL Server version to which you have upgraded the members. For more information, see [Section 18.5.1.4, “Setting a Group's Communication Protocol Version”](#).

18.8.2 Group Replication Offline Upgrade

To perform an offline upgrade of a Group Replication group, you remove each member from the group, perform an upgrade of the member and then restart the group as usual. In a multi-primary group you can shutdown the members in any order. In a single-primary group, shutdown each secondary first and then finally the primary. See [Section 18.8.3.2, “Upgrading a Group Replication Member”](#) for how to remove members from a group and shutdown MySQL.

Once the group is offline, upgrade all of the members. See [Section 2.11, “Upgrading MySQL”](#) for how to perform an upgrade. When all members have been upgraded, restart the members.

If you upgrade all the members of a replication group when they are offline and then restart the group, the members join using the new release's Group Replication communication protocol version, so that becomes the group's communication protocol version. If you have a requirement to allow members at earlier releases to join, you can use the `group_replication_set_communication_protocol()` function to downgrade the communication protocol version, specifying the MySQL Server version of the prospective group member that has the oldest installed server version.

18.8.3 Group Replication Online Upgrade

When you have a group running which you want to upgrade but you need to keep the group online to serve your application, you need to consider your approach to the upgrade. This section describes the different elements involved in an online upgrade, and various methods of how to upgrade your group.

18.8.3.1 Online Upgrade Considerations

When upgrading an online group you should consider the following points:

- Regardless of the way which you upgrade your group, it is important to disable any writes to group members until they are ready to rejoin the group.
- When a member is stopped, the `super_read_only` variable is set to on automatically, but this change is not persisted.

- When MySQL 5.7.22 or MySQL 8.0.11 tries to join a group running MySQL 5.7.21 or lower it fails to join the group because MySQL 5.7.21 does not send its value of `lower_case_table_names`.

18.8.3.2 Upgrading a Group Replication Member

This section explains the steps required for upgrading a member of a group. This procedure is part of the methods described at [Section 18.8.3.3, “Group Replication Online Upgrade Methods”](#). The process of upgrading a member of a group is common to all methods and is explained first. The way which you join upgraded members can depend on which method you are following, and other factors such as whether the group is operating in single-primary or multi-primary mode. How you upgrade the server instance, using either the in-place or provision approach, does not impact on the methods described here.

The process of upgrading a member consists of removing it from the group, following your chosen method of upgrading the member, and then rejoining the upgraded member to a group. The recommended order of upgrading members in a single-primary group is to upgrade all secondaries, and then upgrade the primary last. If the primary is upgraded before a secondary, a new primary using the older MySQL version is chosen, but there is no need for this step.

To upgrade a member of a group:

- Connect a client to the group member and issue `STOP GROUP_REPLICATION`. Before proceeding, ensure that the member's status is `OFFLINE` by monitoring the `replication_group_members` table.
- Disable Group Replication from starting up automatically so that you can safely connect to the member after upgrading and configure it without it rejoining the group by setting `group_replication_start_on_boot=0`.

Important

If an upgraded member has `group_replication_start_on_boot=1` then it could rejoin the group before you can perform the MySQL upgrade procedure and could result in issues. For example, if the upgrade fails and the server restarts again, then a possibly broken server could try to join the group.

- Stop the member, for example using `mysqladmin shutdown` or the `SHUTDOWN` statement. Any other members in the group continue running.
- Upgrade the member, using the in-place or provisioning approach. See [Section 2.11, “Upgrading MySQL”](#) for details. When restarting the upgraded member, because `group_replication_start_on_boot` is set to 0, Group Replication does not start on the instance, and therefore it does not rejoin the group.
- Once the MySQL upgrade procedure has been performed on the member, `group_replication_start_on_boot` must be set to 1 to ensure Group Replication starts correctly after restart. Restart the member.
- Connect to the upgraded member and issue `START GROUP_REPLICATION`. This rejoins the member to the group. The Group Replication metadata is in place on the upgraded server, therefore there is usually no need to reconfigure Group Replication. The server has to catch up with any transactions processed by the group while the server was offline. Once it has caught up with the group, it becomes an online member of the group.

Note

The longer it takes to upgrade a server, the more time that member is offline and therefore the more time it takes for the server to catch up when added back to the group.

When an upgraded member joins a group which has any member running an earlier MySQL Server version, the upgraded member joins with `super_read_only=on`. This ensures that no writes are made to upgraded members until all members are running the newer version. In a multi-primary mode group, when the upgrade has been completed successfully and the group is ready to process transactions, members that are intended as writeable primaries must be set to read-write mode. From MySQL 8.0.17, when all members of a group have been upgraded to the same release, they all change back to read-write mode automatically. For earlier releases you must set each member manually to read-write mode. Connect to each member and issue:

```
SET GLOBAL super_read_only=OFF;
```

18.8.3.3 Group Replication Online Upgrade Methods

Choose one of the following methods of upgrading a Group Replication group:

Rolling In-Group Upgrade

This method is supported provided that servers running a newer version are not generating workload to the group while there are still servers with an older version in it. In other words servers with a newer version can join the group only as secondaries. In this method there is only ever one group, and each server instance is removed from the group, upgraded and then rejoined to the group.

This method is well suited to single-primary groups. When the group is operating in single-primary mode, if you require the primary to remain the same throughout (except when it is being upgraded itself), it should be the last member to be upgraded. The primary cannot remain as the primary unless it is running the lowest MySQL Server version in the group. After the primary has been upgraded, you can use the `group_replication_set_as_primary()` function to reappoint it as the primary. If you do not mind which member is the primary, the members can be upgraded in any order. The group elects a new primary whenever necessary from among the members running the lowest MySQL Server version, following the election policies described in [Section 18.1.3.1, “Single-Primary Mode”](#).

For groups operating in multi-primary mode, during a rolling in-group upgrade the number of primaries is decreased, causing a reduction in write availability. This is because if a member joins a group when it is running a higher MySQL Server version than the lowest version that the existing group members are running, it automatically remains in read-only mode (`super_read_only=ON`). Note that members running MySQL 8.0.17 or higher take into account the patch version of the release when checking this, but members running MySQL 8.0.16 or lower, or MySQL 5.7, only take into account the major version. When all members have been upgraded to the same release, from MySQL 8.0.17, they all change back to read-write mode automatically. For earlier releases, you must set `super_read_only=OFF` manually on each member that should function as a primary following the upgrade.

For full information on version compatibility in a group and how this influences the behavior of a group during an upgrade process, see [Section 18.8.1, “Combining Different Member Versions in a Group”](#).

Rolling Migration Upgrade

In this method you remove members from the group, upgrade them and then create a second group using the upgraded members. For groups operating in multi-primary mode, during this process the number of primaries is decreased, causing a reduction in write availability. This does not impact groups operating in single-primary mode.

Because the group running the older version is online while you are upgrading the members, you need the group running the newer version to catch up with any transactions executed while the members were being upgraded. Therefore one of the servers in the new group is configured as a replica of a primary from the older group. This ensures that the new group catches up with the older group. Because this method

relies on an asynchronous replication channel which is used to replicate data from one group to another, it is supported under the same assumptions and requirements of asynchronous source-replica replication, see [Chapter 17, *Replication*](#). For groups operating in single-primary mode, the asynchronous replication connection to the old group must send data to the primary in the new group, for a multi-primary group the asynchronous replication channel can connect to any primary.

The process is to:

- remove members from the original group running the older server version one by one, see [Section 18.8.3.2, “Upgrading a Group Replication Member”](#)
- upgrade the server version running on the member, see [Section 2.11, “Upgrading MySQL”](#). You can either follow an in-place or provision approach to upgrading.
- create a new group with the upgraded members, see [Chapter 18, *Group Replication*](#). In this case you need to configure a new group name on each member (because the old group is still running and using the old name), bootstrap an initial upgraded member, and then add the remaining upgraded members.
- set up an asynchronous replication channel between the old group and the new group, see [Section 17.1.3.4, “Setting Up Replication Using GTIDs”](#). Configure the older primary to function as the asynchronous replication source server and the new group member as a GTID-based replica.

Before you can redirect your application to the new group, you must ensure that the new group has a suitable number of members, for example so that the group can handle the failure of a member. Issue `SELECT * FROM performance_schema.replication_group_members` and compare the initial group size and the new group size. Wait until all data from the old group is propagated to the new group and then drop the asynchronous replication connection and upgrade any missing members.

Rolling Duplication Upgrade

In this method you create a second group consisting of members which are running the newer version, and the data missing from the older group is replicated to the newer group. This assumes that you have enough servers to run both groups simultaneously. Due to the fact that during this process the number of primaries is *not* decreased, for groups operating in multi-primary mode there is no reduction in write availability. This makes rolling duplication upgrade well suited to groups operating in multi-primary mode. This does not impact groups operating in single-primary mode.

Because the group running the older version is online while you are provisioning the members in the new group, you need the group running the newer version to catch up with any transactions executed while the members were being provisioned. Therefore one of the servers in the new group is configured as a replica of a primary from the older group. This ensures that the new group catches up with the older group. Because this method relies on an asynchronous replication channel which is used to replicate data from one group to another, it is supported under the same assumptions and requirements of asynchronous source-replica replication, see [Chapter 17, *Replication*](#). For groups operating in single-primary mode, the asynchronous replication connection to the old group must send data to the primary in the new group, for a multi-primary group the asynchronous replication channel can connect to any primary.

The process is to:

- deploy a suitable number of members so that the group running the newer version can handle failure of a member
- take a backup of the existing data from a member of the group
- use the backup from the older member to provision the members of the new group, see [Section 18.8.3.4, “Group Replication Upgrade with `mysqlbackup`”](#) for one method.

**Note**

You must restore the backup to the same version of MySQL which the backup was taken from, and then perform an in-place upgrade. For instructions, see [Section 2.11, “Upgrading MySQL”](#).

- create a new group with the upgraded members, see [Chapter 18, Group Replication](#). In this case you need to configure a new group name on each member (because the old group is still running and using the old name), bootstrap an initial upgraded member, and then add the remaining upgraded members.
- set up an asynchronous replication channel between the old group and the new group, see [Section 17.1.3.4, “Setting Up Replication Using GTIDs”](#). Configure the older primary to function as the asynchronous replication source server and the new group member as a GTID-based replica.

Once the ongoing data missing from the newer group is small enough to be quickly transferred, you must redirect write operations to the new group. Wait until all data from the old group is propagated to the new group and then drop the asynchronous replication connection.

18.8.3.4 Group Replication Upgrade with `mysqlbackup`

As part of a provisioning approach you can use MySQL Enterprise Backup to copy and restore the data from a group member to new members. However you cannot use this technique to directly restore a backup taken from a member running an older version of MySQL to a member running a newer version of MySQL. The solution is to restore the backup to a new server instance which is running the same version of MySQL as the member which the backup was taken from, and then upgrade the instance. This process consists of:

- Take a backup from a member of the older group using `mysqlbackup`. See [Section 18.5.6, “Using MySQL Enterprise Backup with Group Replication”](#).
- Deploy a new server instance, which must be running the same version of MySQL as the older member where the backup was taken.
- Restore the backup from the older member to the new instance using `mysqlbackup`.
- Upgrade MySQL on the new instance, see [Section 2.11, “Upgrading MySQL”](#).

Repeat this process to create a suitable number of new instances, for example to be able to handle a failover. Then join the instances to a group based on the [Section 18.8.3.3, “Group Replication Online Upgrade Methods”](#).

18.9 Group Replication System Variables

This section lists the system variables that are specific to the Group Replication plugin. Every configuration option is prefixed with `"group_replication"`.

Some system variables on a Group Replication group member, including some Group Replication-specific system variables and some general system variables, are group-wide configuration settings. These system variables must have the same value on all group members, cannot be changed while Group Replication is running, and require a full reboot of the group (a bootstrap by a server with `group_replication_bootstrap_group=ON`) in order for the value change to take effect. If the group has a value set for one of the system variables, and a joining member has a different value set for that system variable, the joining member cannot join the group until the value is changed to match. If the group has a value set for one of the system variables, and the joining member does not support the system variable, it cannot join the group. These conditions apply to the following system variables:

- `group_replication_single_primary_mode`

- `group_replication_enforce_update_everywhere_checks`
- `group_replication_gtid_assignment_block_size`
- `group_replication_view_change_uuid`
- `default_table_encryption`
- `lower_case_table_names`
- `transaction_write_set_extraction` (deprecated from MySQL 8.0.26)

From MySQL 8.0.16, you can use the `group_replication_switch_to_single_primary_mode()` and `group_replication_switch_to_multi_primary_mode()` functions to change the values of `group_replication_single_primary_mode` and `group_replication_enforce_update_everywhere_checks` while the group is still running. For more information, see [Section 18.5.1.2, “Changing a Group’s Mode”](#).

Most system variables for Group Replication can have different values on different group members. For the following system variables, it is advisable to set the same value on all members of a group in order to avoid unnecessary rollback of transactions, failure of message delivery, or failure of message recovery:

- `group_replication_auto_increment_increment`
- `group_replication_communication_max_message_size`
- `group_replication_compression_threshold`
- `group_replication_message_cache_size`
- `group_replication_transaction_size_limit`

Most system variables for Group Replication are described as dynamic, and their values can be changed while the server is running. However, in most cases, the change only takes effect after you stop and restart Group Replication on the group member using a `STOP GROUP_REPLICATION` statement followed by a `START GROUP_REPLICATION` statement. Changes to the following system variables take effect without stopping and restarting Group Replication:

- `group_replication_advertise_recovery_endpoints`
- `group_replication_autorejoin_tries`
- `group_replication_consistency`
- `group_replication_exit_state_action`
- `group_replication_flow_control_applier_threshold`
- `group_replication_flow_control_certifier_threshold`
- `group_replication_flow_control_hold_percent`
- `group_replication_flow_control_max_commit_quota`
- `group_replication_flow_control_member_quota_percent`
- `group_replication_flow_control_min_quota`
- `group_replication_flow_control_min_recovery_quota`
- `group_replication_flow_control_mode`

- `group_replication_flow_control_period`
- `group_replication_flow_control_release_percent`
- `group_replication_force_members`
- `group_replication_ip_allowlist`
- `group_replication_ip_whitelist`
- `group_replication_member_expel_timeout`
- `group_replication_member_weight`
- `group_replication_transaction_size_limit`
- `group_replication_unreachable_majority_timeout`

Important

- A number of system variables for Group Replication are not completely validated during server startup if they are passed as command line arguments to the server. These system variables include `group_replication_group_name`, `group_replication_single_primary_mode`, `group_replication_force_members`, the SSL variables, and the flow control system variables. They are only fully validated after the server has started.
- System variables for Group Replication that specify IP addresses or host names for group members are not validated until a `START GROUP_REPLICATION` statement is issued. Group Replication's Group Communication System (GCS) is not available to validate the values until that point.

The system variables that are specific to the Group Replication plugin are as follows:

- `group_replication_advertise_recovery_endpoints`

| | |
|-----------------------------------|---|
| Command-Line Format | <code>--group-replication-advertise-recovery-endpoints=value</code> |
| Introduced | 8.0.21 |
| System Variable | <code>group_replication_advertise_recovery_endpoints</code> |
| Scope | Global |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | String |
| Default Value | <code>DEFAULT</code> |

The value of this system variable can be changed while Group Replication is running. The change takes effect immediately on the member. However, a joining member that already received the previous value of the system variable continues to use that value. Only members that join after the value change receive the new value.

`group_replication_advertise_recovery_endpoints` specifies how a joining member can establish a connection to an existing member for state transfer for distributed recovery. The connection is used for both remote cloning operations and state transfer from the donor's binary log.

A value of `DEFAULT`, which is the default setting, means joining members use the existing member's standard SQL client connection, as specified by MySQL Server's `hostname` and `port` system variables. If an alternative port number is specified by the `report_port` system variable, that one is used instead. The Performance Schema table `replication_group_members` shows this connection's address and port number in the `MEMBER_HOST` and `MEMBER_PORT` fields. This is the behavior of group members at releases up to and including MySQL 8.0.20.

Instead of `DEFAULT`, you can specify one or more distributed recovery endpoints, which the existing member advertises to joining members for them to use. Offering distributed recovery endpoints lets administrators control distributed recovery traffic separately from regular MySQL client connections to the group members. Joining members try each of the endpoints in turn in the order they are specified on the list.

Specify the distributed recovery endpoints as a comma-separated list of IP addresses and port numbers, for example:

```
group_replication_advertise_recovery_endpoints= "127.0.0.1:3306,127.0.0.1:4567,[::1]:3306,localhost:3306"
```

IPv4 and IPv6 addresses and host names can be used in any combination. IPv6 addresses must be specified in square brackets. Host names must resolve to a local IP address. Wildcard address formats cannot be used, and you cannot specify an empty list. Note that the standard SQL client connection is not automatically included on a list of distributed recovery endpoints. If you want to use it as an endpoint, you must include it explicitly on the list.

For details of how to select IP addresses and ports as distributed recovery endpoints, and how joining members use them, see [Selecting addresses for distributed recovery endpoints](#). A summary of the requirements is as follows:

- The IP addresses do not have to be configured for MySQL Server, but they do have to be assigned to the server.
- The ports do have to be configured for MySQL Server using the `port`, `report_port`, or `admin_port` system variable.
- Appropriate permissions are required for the replication user for distributed recovery if the `admin_port` is used.
- The IP addresses do not need to be added to the Group Replication allowlist specified by the `group_replication_ip_allowlist` or `group_replication_ip_whitelist` system variable.
- The SSL requirements for the connection are as specified by the `group_replication_recovery_ssl_*` options.
- `group_replication_allow_local_lower_version_join`

| | |
|-----------------------------------|--|
| Command-Line Format | <code>--group-replication-allow-local-lower-version-join[={OFF ON}]</code> |
| System Variable | <code>group_replication_allow_local_lower_version_</code> |
| Scope | Global |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Boolean |

| | |
|---------------|-----|
| Default Value | OFF |
|---------------|-----|

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_allow_local_lower_version_join` allows the current server to join the group even if it is running a lower MySQL Server version than the group. With the default setting `OFF`, servers are not permitted to join a replication group if they are running a lower version than the existing group members. This standard policy ensures that all members of a group are able to exchange messages and apply transactions. Note that members running MySQL 8.0.17 or higher take into account the patch version of the release when checking their compatibility. Members running MySQL 8.0.16 or lower, or MySQL 5.7, only take into account the major version.

Set `group_replication_allow_local_lower_version_join` to `ON` only in the following scenarios:

- A server must be added to the group in an emergency in order to improve the group's fault tolerance, and only older versions are available.
- You want to roll back an upgrade for one or more replication group members without shutting down the whole group and bootstrapping it again.

Warning

Setting this option to `ON` does not make the new member compatible with the group, and allows it to join the group without any safeguards against incompatible behaviors by the existing members. To ensure the new member's correct operation, take *both* of the following precautions:

1. Before the server running the lower version joins the group, stop all writes on that server.
2. From the point where the server running the lower version joins the group, stop all writes on the other servers in the group.

Without these precautions, the server running the lower version is likely to experience difficulties and terminate with an error.

- `group_replication_auto_increment_increment`

| | |
|-----------------------------------|---|
| Command-Line Format | <code>--group-replication-auto-increment-increment=#</code> |
| System Variable | <code>group_replication_auto_increment_increment</code> |
| Scope | Global |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Integer |
| Default Value | 7 |
| Minimum Value | 1 |

| | |
|---------------|-------|
| Maximum Value | 65535 |
|---------------|-------|

This system variable should have the same value on all group members. You cannot change the value of this system variable while Group Replication is running. You must stop Group Replication, change the value of the system variable, then restart Group Replication, on each of the group members. During this process, the value of the system variable is permitted to differ between group members, but some transactions on group members might be rolled back.

`group_replication_auto_increment_increment` determines the interval between successive values for auto-incremented columns for transactions that execute on this server instance. Adding an interval avoids the selection of duplicate auto-increment values for writes on group members, which causes rollback of transactions. The default value of 7 represents a balance between the number of usable values and the permitted maximum size of a replication group (9 members). If your group has more or fewer members, you can set this system variable to match the expected number of group members before Group Replication is started.

When Group Replication is started on a server instance, the value of the server system variable `auto_increment_increment` is changed to this value, and the value of the server system variable `auto_increment_offset` is changed to the server ID. The changes are reverted when Group Replication is stopped. These changes are only made and reverted if `auto_increment_increment` and `auto_increment_offset` each have their default value of 1. If their values have already been modified from the default, Group Replication does not alter them. From MySQL 8.0, the system variables are also not modified when Group Replication is in single-primary mode, where only one server writes.

- `group_replication_autorejoin_tries`

| | |
|--------------------------|---|
| Command-Line Format | <code>--group-replication-autorejoin-tries=#</code> |
| Introduced | 8.0.16 |
| System Variable | <code>group_replication_autorejoin_tries</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value (≥ 8.0.21) | 3 |
| Default Value (≤ 8.0.20) | 0 |
| Minimum Value | 0 |
| Maximum Value | 2016 |

The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately. The system variable's current value is read when an issue occurs that means the behavior is needed.

`group_replication_autorejoin_tries` specifies the number of tries that a member makes to automatically rejoin the group if it is expelled, or if it is unable to contact a majority of the group before the `group_replication_unreachable_majority_timeout` setting is reached. When the member's expulsion or unreachable majority timeout is reached, it makes an attempt to rejoin (using the current plugin option values), then continues to make further auto-rejoin attempts up to the specified number of tries. After an unsuccessful auto-rejoin attempt, the member waits 5 minutes before the next try. If the specified number of tries is exhausted without the member rejoining or being stopped, the

member proceeds to the action specified by the `group_replication_exit_state_action` system variable.

Up to MySQL 8.0.20, the default setting is 0, meaning that the member does not try to rejoin automatically. From MySQL 8.0.21, the default setting is 3, meaning that the member automatically makes 3 attempts to rejoin the group, with 5 minutes between each. You can specify a maximum of 2016 tries.

During and between auto-rejoin attempts, a member remains in super read only mode and does not accept writes, but reads can still be made on the member, with an increasing likelihood of stale reads over time. If you cannot tolerate the possibility of stale reads for any period of time, set `group_replication_autorejoin_tries` to 0. For more information on the auto-rejoin feature, and considerations when choosing a value for this option, see [Section 18.7.6.3, “Auto-Rejoin”](#).

- `group_replication_bootstrap_group`

| | |
|----------------------|---|
| Command-Line Format | <code>--group-replication-bootstrap-group[={OFF ON}]</code> |
| System Variable | <code>group_replication_bootstrap_group</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Boolean |
| Default Value | OFF |

`group_replication_bootstrap_group` configures this server to bootstrap the group. This system variable must *only* be set on one server, and *only* when starting the group for the first time or restarting the entire group. After the group has been bootstrapped, set this option to `OFF`. It should be set to `OFF` both dynamically and in the configuration files. Starting two servers or restarting one server with this option set while the group is running may lead to an artificial split brain situation, where two independent groups with the same name are bootstrapped.

- `group_replication_clone_threshold`

| | |
|----------------------|--|
| Command-Line Format | <code>--group-replication-clone-threshold=#</code> |
| Introduced | 8.0.17 |
| System Variable | <code>group_replication_clone_threshold</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value | 9223372036854775807 |
| Minimum Value | 1 |
| Maximum Value | 9223372036854775807 |

| | |
|------|--------------|
| Unit | transactions |
|------|--------------|

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_clone_threshold` specifies the transaction gap, as a number of transactions, between the existing member (donor) and the joining member (recipient) that triggers the use of a remote cloning operation for state transfer to the joining member during the distributed recovery process. If the transaction gap between the joining member and a suitable donor exceeds the threshold, Group Replication begins distributed recovery with a remote cloning operation. If the transaction gap is below the threshold, or if the remote cloning operation is not technically possible, Group Replication proceeds directly to state transfer from a donor's binary log.

Warning

Do not use a low setting for `group_replication_clone_threshold` in an active group. If a number of transactions above the threshold takes place in the group while the remote cloning operation is in progress, the joining member triggers a remote cloning operation again after restarting, and could continue this indefinitely. To avoid this situation, ensure that you set the threshold to a number higher than the number of transactions that you would expect to occur in the group during the time taken for the remote cloning operation.

To use this function, both the donor and the joining member must be set up beforehand to support cloning. For instructions, see [Section 18.5.3.2, “Cloning for Distributed Recovery”](#). When a remote cloning operation is carried out, Group Replication manages it for you, including the required server restart, provided that `group_replication_start_on_boot=ON` is set. If not, you must restart the server manually. The remote cloning operation replaces the existing data dictionary on the joining member, but Group Replication checks and does not proceed if the joining member has additional transactions that are not present on the other group members, because these transactions would be erased by the cloning operation.

The default setting (which is the maximum permitted sequence number for a transaction in a GTID) means that state transfer from a donor's binary log is virtually always attempted rather than cloning. However, note that Group Replication always attempts to execute a cloning operation, regardless of your threshold, if state transfer from a donor's binary log is impossible, for example because the transactions needed by the joining member are not available in the binary logs on any existing group member. If you do not want to use cloning at all in your replication group, do not install the clone plugin on the members.

- [group_replication_communication_debug_options](#)

| | |
|----------------------|--|
| Command-Line Format | <code>--group-replication-communication-debug-options=value</code> |
| System Variable | group_replication_communication_debug_options |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | String |
| Default Value | <code>GCS_DEBUG_NONE</code> |
| Valid Values | <code>GCS_DEBUG_NONE</code> <code>GCS_DEBUG_BASIC</code> |

| | |
|--|------------------|
| | GCS_DEBUG_TRACE |
| | XCOM_DEBUG_BASIC |
| | XCOM_DEBUG_TRACE |
| | GCS_DEBUG_ALL |

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_communication_debug_options` configures the level of debugging messages to provide for the different Group Replication components, such as the Group Communication System (GCS) and the group communication engine (XCom, a Paxos variant). The debug information is stored in the `GCS_DEBUG_TRACE` file in the data directory.

The set of available options, specified as strings, can be combined. The following options are available:

- `GCS_DEBUG_NONE` disables all debugging levels for both GCS and XCom.
- `GCS_DEBUG_BASIC` enables basic debugging information in GCS.
- `GCS_DEBUG_TRACE` enables trace information in GCS.
- `XCOM_DEBUG_BASIC` enables basic debugging information in XCom.
- `XCOM_DEBUG_TRACE` enables trace information in XCom.
- `GCS_DEBUG_ALL` enables all debugging levels for both GCS and XCom.

Setting the debug level to `GCS_DEBUG_NONE` only has an effect when provided without any other option. Setting the debug level to `GCS_DEBUG_ALL` overrides all other options.

- `group_replication_communication_max_message_size`

| | |
|----------------------|---|
| Command-Line Format | <code>--group-replication-communication-max-message-size=#</code> |
| Introduced | 8.0.16 |
| System Variable | <code>group_replication_communication_max_message_size</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value | 10485760 |
| Minimum Value | 0 |
| Maximum Value | 1073741824 |
| Unit | bytes |

This system variable should have the same value on all group members. You cannot change the value of this system variable while Group Replication is running. You must stop Group Replication, change the value of the system variable, then restart Group Replication, on each of the group members. During

this process, the value of the system variable is permitted to differ between group members, but some transactions on group members might be rolled back.

`group_replication_communication_max_message_size` specifies a maximum message size for Group Replication communications. Messages greater than this size are automatically split into fragments that are sent separately and reassembled by the recipients. For more information, see [Section 18.7.4, “Message Fragmentation”](#).

A maximum message size of 10485760 bytes (10 MiB) is set by default, which means that fragmentation is used by default in releases from MySQL 8.0.16. The greatest permitted value is the same as the maximum value of the `replica_max_allowed_packet` and `slave_max_allowed_packet` system variables, which is 1073741824 bytes (1 GB). The setting for `group_replication_communication_max_message_size` must be less than the `replica_max_allowed_packet` or `slave_max_allowed_packet` setting, because the applier thread cannot handle message fragments larger than the maximum permitted packet size. To switch off fragmentation, specify a zero value for `group_replication_communication_max_message_size`.

In order for members of a replication group to use fragmentation, the group's communication protocol version must be MySQL 8.0.16 or above. Use the `group_replication_get_communication_protocol()` function to view the group's communication protocol version. If a lower version is in use, group members do not fragment messages. You can use the `group_replication_set_communication_protocol()` function to set the group's communication protocol to a higher version if all group members support it. For more information, see [Section 18.5.1.4, “Setting a Group's Communication Protocol Version”](#).

- `group_replication_components_stop_timeout`

| | |
|--------------------------|--|
| Command-Line Format | <code>--group-replication-components-stop-timeout=#</code> |
| System Variable | <code>group_replication_components_stop_timeout</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value (≥ 8.0.27) | 300 |
| Default Value (≤ 8.0.26) | 31536000 |
| Minimum Value | 2 |
| Maximum Value | 31536000 |
| Unit | seconds |

The value of this system variable can be changed while Group Replication is running, but the change takes effect only after you stop and restart Group Replication on the group member.

`group_replication_components_stop_timeout` specifies the time, in seconds, for which Group Replication waits for each of its modules to complete ongoing processes while shutting down. The component timeout applies after a `STOP GROUP_REPLICATION` statement is issued, which happens automatically during server restart or auto-rejoin.

The timeout is used to resolve situations in which Group Replication components cannot be stopped normally, which might happen if a member is expelled from the group while it is in an error state, or while a process such as MySQL Enterprise Backup is holding a global lock on tables on the member.

In such situations, the member cannot stop the applier thread or complete the distributed recovery process to rejoin. `STOP GROUP_REPLICATION` does not complete until either the situation is resolved (for example, by the lock being released), or the component timeout expires and the modules are shut down regardless of their status.

Before MySQL 8.0.27, the default component timeout is 31536000 seconds, or 365 days. With this setting, the component timeout does not help in situations such as those described, so a lower setting is recommended. Beginning with MySQL 8.0.27, the default value is 300 seconds, so that Group Replication components are stopped after 5 minutes if the situation is not resolved before that time, allowing the member to be restarted and to rejoin.

- `group_replication_compression_threshold`

| | |
|----------------------|--|
| Command-Line Format | <code>--group-replication-compression-threshold=#</code> |
| System Variable | <code>group_replication_compression_threshold</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value | 1000000 |
| Minimum Value | 0 |
| Maximum Value | 4294967295 |
| Unit | bytes |

This system variable should have the same value on all group members. The value of this system variable can be changed while Group Replication is running. The change takes effect on each group member after you stop and restart Group Replication on the member. During this process, the value of the system variable is permitted to differ between group members, but message delivery does not have the same efficiency on all members.

`group_replication_compression_threshold` specifies the threshold value in bytes above which compression is applied to messages sent between group members. If this system variable is set to zero, compression is disabled.

Group Replication uses the LZ4 compression algorithm to compress messages sent in the group. Note that the maximum supported input size for the LZ4 compression algorithm is 2113929216 bytes. This limit is lower than the maximum possible value for the `group_replication_compression_threshold` system variable, which is matched to the maximum message size accepted by XCom. With the LZ4 compression algorithm, do not set a value greater than 2113929216 bytes for `group_replication_compression_threshold`, because transactions above this size cannot be committed when message compression is enabled.

For more information, see [Section 18.7.3, “Message Compression”](#).

- `group_replication_consistency`

| | |
|---------------------|--|
| Command-Line Format | <code>--group-replication-consistency=value</code> |
| Introduced | 8.0.14 |
| System Variable | <code>group_replication_consistency</code> |

| | |
|----------------------|---|
| Scope | Global, Session |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Enumeration |
| Default Value | EVENTUAL |
| Valid Values | EVENTUAL BEFORE_ON_PRIMARY_FAILOVER BEFORE AFTER BEFORE_AND_AFTER |

The value of this system variable can be changed while Group Replication is running. `group_replication_consistency` is a server system variable rather than a Group Replication plugin-specific variable, so a restart of Group Replication is not required for the change to take effect. Changing the session value of the system variable takes effect immediately, and changing the global value takes effect for new sessions that start after the change. The `GROUP_REPLICATION_ADMIN` privilege is required to change the global setting for this system variable.

`group_replication_consistency` controls the transaction consistency guarantee which a group provides. You can configure the consistency globally or per transaction. `group_replication_consistency` also configures the fencing mechanism used by newly elected primaries in single primary groups. The effect of the variable must be considered for both read only (RO) and read write (RW) transactions. The following list shows the possible values of this variable, in order of increasing transaction consistency guarantee:

- `EVENTUAL`

Both RO and RW transactions do not wait for preceding transactions to be applied before executing. This was the behavior of Group Replication before this variable was added. A RW transaction does not wait for other members to apply a transaction. This means that a transaction could be externalized on one member before the others. This also means that in the event of a primary failover, the new primary can accept new RO and RW transactions before the previous primary transactions are all applied. RO transactions could result in outdated values, RW transactions could result in a rollback due to conflicts.

- `BEFORE_ON_PRIMARY_FAILOVER`

New RO or RW transactions with a newly elected primary that is applying backlog from the old primary are held (not applied) until any backlog has been applied. This ensures that when a primary failover happens, intentionally or not, clients always see the latest value on the primary. This guarantees consistency, but means that clients must be able to handle the delay in the event that a backlog is being applied. Usually this delay should be minimal, but does depend on the size of the backlog.

- `BEFORE`

A RW transaction waits for all preceding transactions to complete before being applied. A RO transaction waits for all preceding transactions to complete before being executed. This ensures that this transaction reads the latest value by only affecting the latency of the transaction. This reduces the overhead of synchronization on every RW transaction, by ensuring synchronization is used only

on RO transactions. This consistency level also includes the consistency guarantees provided by [BEFORE_ON_PRIMARY_FAILOVER](#).

- [AFTER](#)

A RW transaction waits until its changes have been applied to all of the other members. This value has no effect on RO transactions. This mode ensures that when a transaction is committed on the local member, any subsequent transaction reads the written value or a more recent value on any group member. Use this mode with a group that is used for predominantly RO operations to ensure that applied RW transactions are applied everywhere once they commit. This could be used by your application to ensure that subsequent reads fetch the latest data which includes the latest writes. This reduces the overhead of synchronization on every RO transaction, by ensuring synchronization is used only on RW transactions. This consistency level also includes the consistency guarantees provided by [BEFORE_ON_PRIMARY_FAILOVER](#).

- [BEFORE_AND_AFTER](#)

A RW transaction waits for 1) all preceding transactions to complete before being applied and 2) until its changes have been applied on other members. A RO transaction waits for all preceding transactions to complete before execution takes place. This consistency level also includes the consistency guarantees provided by [BEFORE_ON_PRIMARY_FAILOVER](#).

For more information, see [Section 18.5.2, “Transaction Consistency Guarantees”](#).

- [group_replication_enforce_update_everywhere_checks](#)

| | |
|--------------------------------------|--|
| Command-Line Format | <code>--group-replication-enforce-update-everywhere-checks[={OFF ON}]</code> |
| System Variable | <code>group_replication_enforce_update_everywhere_checks</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Boolean |
| Default Value | <code>OFF</code> |

This system variable is a group-wide configuration setting. It must have the same value on all group members, cannot be changed while Group Replication is running, and requires a full reboot of the group (a bootstrap by a server with `group_replication_bootstrap_group=ON`) in order for the value change to take effect. If the group has a value set for this system variable, and a joining member has a different value set for the system variable, the joining member cannot join the group until the value is changed to match. If the group members have a value set for this system variable, and the joining member does not support the system variable, it cannot join the group.

From MySQL 8.0.16, you can use the `group_replication_switch_to_single_primary_mode()` and `group_replication_switch_to_multi_primary_mode()` functions to change the value of this system variable while the group is still running. For more information, see [Section 18.5.1.2, “Changing a Group's Mode”](#).

`group_replication_enforce_update_everywhere_checks` enables or disables strict consistency checks for multi-primary update everywhere. The default is that checks are disabled. In single-primary mode, this option must be disabled on all group members. In multi-primary mode, when

this option is enabled, statements are checked as follows to ensure they are compatible with multi-primary mode:

- If a transaction is executed under the `SERIALIZABLE` isolation level, then its commit fails when synchronizing itself with the group.
- If a transaction executes against a table that has foreign keys with cascading constraints, then the transaction fails to commit when synchronizing itself with the group.
- `group_replication_exit_state_action`

| | |
|------------------------------------|--|
| Command-Line Format | <code>--group-replication-exit-state-action=value</code> |
| Introduced | 8.0.12 |
| System Variable | <code>group_replication_exit_state_action</code> |
| Scope | Global |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Enumeration |
| Default Value (≥ 8.0.16) | <code>READ_ONLY</code> |
| Default Value (≥ 8.0.12, ≤ 8.0.15) | <code>ABORT_SERVER</code> |
| Valid Values (≥ 8.0.18) | <code>ABORT_SERVER</code> <code>OFFLINE_MODE</code> <code>READ_ONLY</code> |
| Valid Values (≥ 8.0.12, ≤ 8.0.17) | <code>ABORT_SERVER</code> <code>READ_ONLY</code> |

The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately. The system variable's current value is read when an issue occurs that means the behavior is needed.

`group_replication_exit_state_action` configures how Group Replication behaves when this server instance leaves the group unintentionally, for example after encountering an applier error, or in the case of a loss of majority, or when another member of the group expels it due to a suspicion timing out. The timeout period for a member to leave the group in the case of a loss of majority is set by the `group_replication_unreachable_majority_timeout` system variable, and the timeout period for suspicions is set by the `group_replication_member_expel_timeout` system variable. Note that an expelled group member does not know that it was expelled until it reconnects to the group, so the specified action is only taken if the member manages to reconnect, or if the member raises a suspicion on itself and expels itself.

When a group member is expelled due to a suspicion timing out or a loss of majority, if the member has the `group_replication_autorejoin_tries` system variable set to specify a number of auto-rejoin attempts, it first makes the specified number of attempts while in super read only mode, and then follows

the action specified by `group_replication_exit_state_action`. Auto-rejoin attempts are not made in case of an applier error, because these are not recoverable.

When `group_replication_exit_state_action` is set to `READ_ONLY`, if the member exits the group unintentionally or exhausts its auto-rejoin attempts, the instance switches MySQL to super read only mode (by setting the system variable `super_read_only` to `ON`). The `READ_ONLY` exit action was the behavior for MySQL 8.0 releases before the system variable was introduced, and became the default again from MySQL 8.0.16.

When `group_replication_exit_state_action` is set to `OFFLINE_MODE`, if the member exits the group unintentionally or exhausts its auto-rejoin attempts, the instance switches MySQL to offline mode (by setting the system variable `offline_mode` to `ON`). In this mode, connected client users are disconnected on their next request and connections are no longer accepted, with the exception of client users that have the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege). Group Replication also sets the system variable `super_read_only` to `ON`, so clients cannot make any updates, even if they have connected with the `CONNECTION_ADMIN` or `SUPER` privilege. The `OFFLINE_MODE` exit action is available from MySQL 8.0.18.

When `group_replication_exit_state_action` is set to `ABORT_SERVER`, if the member exits the group unintentionally or exhausts its auto-rejoin attempts, the instance shuts down MySQL. This setting was the default from MySQL 8.0.12, when the system variable was added, to MySQL 8.0.15 inclusive.

Important

If a failure occurs before the member has successfully joined the group, the specified exit action *is not taken*. This is the case if there is a failure during the local configuration check, or a mismatch between the configuration of the joining member and the configuration of the group. In these situations, the `super_read_only` system variable is left with its original value, connections continue to be accepted, and the server does not shut down MySQL. To ensure that the server cannot accept updates when Group Replication did not start, we therefore recommend that `super_read_only=ON` is set in the server's configuration file at startup, which Group Replication changes to `OFF` on primary members after it has been started successfully. This safeguard is particularly important when the server is configured to start Group Replication on server boot (`group_replication_start_on_boot=ON`), but it is also useful when Group Replication is started manually using a `START GROUP_REPLICATION` command.

For more information on using this option, and the full list of situations in which the exit action is taken, see [Section 18.7.6.4, “Exit Action”](#).

- `group_replication_flow_control_applier_threshold`

| | |
|----------------------|---|
| Command-Line Format | <code>--group-replication-flow-control-applier-threshold=#</code> |
| System Variable | <code>group_replication_flow_control_applier_threshold</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value | 25000 |
| Minimum Value | 0 |

| | |
|---------------|--------------|
| Maximum Value | 2147483647 |
| Unit | transactions |

The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately.

`group_replication_flow_control_applier_threshold` specifies the number of waiting transactions in the applier queue that trigger flow control.

- `group_replication_flow_control_certifier_threshold`

| | |
|----------------------|---|
| Command-Line Format | <code>--group-replication-flow-control-certifier-threshold=#</code> |
| System Variable | <code>group_replication_flow_control_certifier_thr</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value | 25000 |
| Minimum Value | 0 |
| Maximum Value | 2147483647 |
| Unit | transactions |

The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately.

`group_replication_flow_control_certifier_threshold` specifies the number of waiting transactions in the certifier queue that trigger flow control.

- `group_replication_flow_control_hold_percent`

| | |
|----------------------|--|
| Command-Line Format | <code>--group-replication-flow-control-hold-percent=#</code> |
| System Variable | <code>group_replication_flow_control_hold_percent</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value | 10 |
| Minimum Value | 0 |
| Maximum Value | 100 |

| | |
|------|------------|
| Unit | percentage |
|------|------------|

The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately.

`group_replication_flow_control_hold_percent` defines what percentage of the group quota remains unused to allow a cluster under flow control to catch up on backlog. A value of 0 implies that no part of the quota is reserved for catching up on the work backlog.

- `group_replication_flow_control_max_commit_quota`

| | |
|----------------------|--|
| Command-Line Format | <code>--group-replication-flow-control-max-commit-quota=#</code> |
| System Variable | <code>group_replication_flow_control_max_commit_quota</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value | 0 |
| Minimum Value | 0 |
| Maximum Value | 2147483647 |

The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately.

`group_replication_flow_control_max_commit_quota` defines the maximum flow control quota of the group, or the maximum available quota for any period while flow control is enabled. A value of 0 implies that there is no maximum quota set. The value of this system variable cannot be smaller than `group_replication_flow_control_min_quota` and `group_replication_flow_control_min_recovery_quota`.

- `group_replication_flow_control_member_quota_percent`

| | |
|----------------------|--|
| Command-Line Format | <code>--group-replication-flow-control-member-quota-percent=#</code> |
| System Variable | <code>group_replication_flow_control_member_quota_per</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value | 0 |
| Minimum Value | 0 |
| Maximum Value | 100 |

| | |
|------|------------|
| Unit | percentage |
|------|------------|

The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately.

`group_replication_flow_control_member_quota_percent` defines the percentage of the quota that a member should assume is available for itself when calculating the quotas. A value of 0 implies that the quota should be split equally between members that were writers in the last period.

- `group_replication_flow_control_min_quota`

| | |
|----------------------|---|
| Command-Line Format | <code>--group-replication-flow-control-min-quota=#</code> |
| System Variable | <code>group_replication_flow_control_min_quota</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value | 0 |
| Minimum Value | 0 |
| Maximum Value | 2147483647 |

The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately.

`group_replication_flow_control_min_quota` controls the lowest flow control quota that can be assigned to a member, independently of the calculated minimum quota executed in the last period. A value of 0 implies that there is no minimum quota. The value of this system variable cannot be larger than `group_replication_flow_control_max_commit_quota`.

- `group_replication_flow_control_min_recovery_quota`

| | |
|----------------------|--|
| Command-Line Format | <code>--group-replication-flow-control-min-recovery-quota=#</code> |
| System Variable | <code>group_replication_flow_control_min_recovery_quota</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value | 0 |
| Minimum Value | 0 |
| Maximum Value | 2147483647 |

The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately.

`group_replication_flow_control_min_recovery_quota` controls the lowest quota that can be assigned to a member because of another recovering member in the group,

independently of the calculated minimum quota executed in the last period. A value of 0 implies that there is no minimum quota. The value of this system variable cannot be larger than `group_replication_flow_control_max_commit_quota`.

- `group_replication_flow_control_mode`

| | |
|----------------------|--|
| Command-Line Format | <code>--group-replication-flow-control-mode=value</code> |
| System Variable | <code>group_replication_flow_control_mode</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Enumeration |
| Default Value | QUOTA |
| Valid Values | DISABLED QUOTA |

The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately.

`group_replication_flow_control_mode` specifies the mode used for flow control.

- `group_replication_flow_control_period`

| | |
|----------------------|--|
| Command-Line Format | <code>--group-replication-flow-control-period=#</code> |
| System Variable | <code>group_replication_flow_control_period</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value | 1 |
| Minimum Value | 1 |
| Maximum Value | 60 |
| Unit | seconds |

The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately.

`group_replication_flow_control_period` defines how many seconds to wait between flow control iterations, in which flow control messages are sent and flow control management tasks are run.

- `group_replication_flow_control_release_percent`

| | |
|---------------------|---|
| Command-Line Format | <code>--group-replication-flow-control-release-percent=#</code> |
| System Variable | <code>group_replication_flow_control_release_percent</code> |

| | |
|--------------------------------------|------------|
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value | 50 |
| Minimum Value | 0 |
| Maximum Value | 1000 |
| Unit | percentage |

The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately.

[group_replication_flow_control_release_percent](#) defines how the group quota should be released when flow control no longer needs to throttle the writer members, with this percentage being the quota increase per flow control period. A value of 0 implies that once the flow control thresholds are within limits the quota is released in a single flow control iteration. The range allows the quota to be released at up to 10 times current quota, as that allows a greater degree of adaptation, mainly when the flow control period is large and the quotas are very small.

- [group_replication_force_members](#)

| | |
|--------------------------------------|--|
| Command-Line Format | <code>--group-replication-force-members=value</code> |
| System Variable | <code>group_replication_force_members</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | String |

This system variable is used to force a new group membership. The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately. You only need to set the value of the system variable on one of the group members that is to remain in the group. For details of the situation in which you might need to force a new group membership, and a procedure to follow when using this system variable, see [Section 18.5.4, “Network Partitioning”](#).

[group_replication_force_members](#) specifies a list of peer addresses as a comma separated list, such as `host1:port1,host2:port2`. Any existing members that are not included in the list do not receive a new view of the group and are blocked. For each existing member that is to continue as a member, you must include the IP address or host name and the port, as they are given in the [group_replication_local_address](#) system variable for each member. An IPv6 address must be specified in square brackets. For example:

```
"198.51.100.44:33061,[2001:db8:85a3:8d3:1319:8a2e:370:7348]:33061,example.org:33061"
```

The group communication engine for Group Replication (XCom) checks that the supplied IP addresses are in a valid format, and checks that you have not included any group members that are currently unreachable. Otherwise, the new configuration is not validated, so you must be careful to include only

online servers that are reachable members of the group. Any incorrect values or invalid host names in the list could cause the group to be blocked with an invalid configuration.

It is important before forcing a new membership configuration to ensure that the servers to be excluded have been shut down. If they are not, shut them down before proceeding. Group members that are still online can automatically form new configurations, and if this has already taken place, forcing a further new configuration could create an artificial split-brain situation for the group.

After you have used the `group_replication_force_members` system variable to successfully force a new group membership and unblock the group, ensure that you clear the system variable. `group_replication_force_members` must be empty in order to issue a `START GROUP_REPLICATION` statement.

- `group_replication_group_name`

| | |
|-----------------------------------|---|
| Command-Line Format | <code>--group-replication-group-name=value</code> |
| System Variable | <code>group_replication_group_name</code> |
| Scope | Global |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | String |

The value of this system variable cannot be changed while Group Replication is running.

`group_replication_group_name` specifies the name of the group which this server instance belongs to, which must be a valid UUID. This UUID forms part of the GTIDs that are used when transactions received by group members from clients, and view change events that are generated internally by the group members, are written to the binary log.

Important

A unique UUID must be used.

- `group_replication_group_seeds`

| | |
|-----------------------------------|--|
| Command-Line Format | <code>--group-replication-group-seeds=value</code> |
| System Variable | <code>group_replication_group_seeds</code> |
| Scope | Global |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | String |

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_group_seeds` is a list of group members to which a joining member can connect to obtain details of all the current group members. The joining member uses these details to select and connect to a group member to obtain the data needed for synchrony with the group. The list consists of a single internal network address or host name for each included seed member, as configured in the seed member's `group_replication_local_address` system variable (not the seed member's SQL client connection, as specified by MySQL Server's `hostname` and `port` system

variables). The addresses of the seed members are specified as a comma separated list, such as `host1:port1,host2:port2`. An IPv6 address must be specified in square brackets. For example:

```
group_replication_group_seeds= "198.51.100.44:33061,[2001:db8:85a3:8d3:1319:8a2e:370:7348]:33061, example1
```

Note that the value you specify for this variable is not validated until a `START GROUP_REPLICATION` statement is issued and the Group Communication System (GCS) is available.

Usually this list consists of all members of the group, but you can choose a subset of the group members to be seeds. The list must contain at least one valid member address. Each address is validated when starting Group Replication. If the list does not contain any valid member addresses, issuing `START GROUP_REPLICATION` fails.

When a server is joining a replication group, it attempts to connect to the first seed member listed in its `group_replication_group_seeds` system variable. If the connection is refused, the joining member tries to connect to each of the other seed members in the list in order. If the joining member connects to a seed member but does not get added to the replication group as a result (for example, because the seed member does not have the joining member's address in its allowlist and closes the connection), the joining member continues to try the remaining seed members in the list in order.

A joining member must communicate with the seed member using the same protocol (IPv4 or IPv6) that the seed member advertises in the `group_replication_group_seeds` option. For the purpose of IP address permissions for Group Replication, the allowlist on the seed member must include an IP address for the joining member for the protocol offered by the seed member, or a host name that resolves to an address for that protocol. This address or host name must be set up and permitted in addition to the joining member's `group_replication_local_address` if the protocol for that address does not match the seed member's advertised protocol. If a joining member does not have a permitted address for the appropriate protocol, its connection attempt is refused. For more information, see [Section 18.6.1, "Group Replication IP Address Permissions"](#).

- `group_replication_gtid_assignment_block_size`

| | |
|-----------------------------------|---|
| Command-Line Format | <code>--group-replication-gtid-assignment-block-size=#</code> |
| System Variable | <code>group_replication_gtid_assignment_block_size</code> |
| Scope | Global |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Integer |
| Default Value | 1000000 |
| Minimum Value | 1 |
| Maximum Value (64-bit platforms) | 9223372036854775807 |
| Maximum Value (32-bit platforms) | 4294967295 |

This system variable is a group-wide configuration setting. It must have the same value on all group members, cannot be changed while Group Replication is running, and requires a full reboot of the group (a bootstrap by a server with `group_replication_bootstrap_group=ON`) in order for the value change to take effect. If the group has a value set for this system variable, and a joining member has a different value set for the system variable, the joining member cannot join the group until the value

is changed to match. If the group members have a value set for this system variable, and the joining member does not support the system variable, it cannot join the group.

`group_replication_gtid_assignment_block_size` specifies the number of consecutive GTIDs that are reserved for each group member. Each member consumes its own blocks and reserves more when needed.

- `group_replication_ip_allowlist`

| | |
|-----------------------------------|---|
| Command-Line Format | <code>--group-replication-ip-allowlist=value</code> |
| Introduced | 8.0.22 |
| System Variable | <code>group_replication_ip_allowlist</code> |
| Scope | Global |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | String |
| Default Value | <code>AUTOMATIC</code> |

`group_replication_ip_allowlist` is available from MySQL 8.0.22 to replace `group_replication_ip_whitelist`. From MySQL 8.0.24, the value of this system variable can be changed while Group Replication is running, and the change takes effect immediately on the member.

`group_replication_ip_allowlist` specifies which hosts are permitted to connect to the group. The address that you specify for each group member in `group_replication_local_address` must be permitted on the other servers in the replication group. Note that the value you specify for this variable is not validated until a `START GROUP_REPLICATION` statement is issued and the Group Communication System (GCS) is available.

By default, this system variable is set to `AUTOMATIC`, which permits connections from private subnetworks active on the host. The group communication engine for Group Replication (XCom) automatically scans active interfaces on the host, and identifies those with addresses on private subnetworks. These addresses and the `localhost` IP address for IPv4 and (from MySQL 8.0.14) IPv6 are used to create the Group Replication allowlist. For a list of the ranges from which addresses are automatically permitted, see [Section 18.6.1, “Group Replication IP Address Permissions”](#).

The automatic allowlist of private addresses cannot be used for connections from servers outside the private network. For Group Replication connections between server instances that are on different machines, you must provide public IP addresses and specify these as an explicit allowlist. If you specify any entries for the allowlist, the private addresses are not added automatically, so if you use any of these, you must specify them explicitly. The `localhost` IP addresses are added automatically.

As the value of the `group_replication_ip_allowlist` option, you can specify any combination of the following:

- IPv4 addresses (for example, `198.51.100.44`)
- IPv4 addresses with CIDR notation (for example, `192.0.2.21/24`)
- IPv6 addresses, from MySQL 8.0.14 (for example, `2001:db8:85a3:8d3:1319:8a2e:370:7348`)
- IPv6 addresses with CIDR notation, from MySQL 8.0.14 (for example, `2001:db8:85a3:8d3::/64`)

- Host names (for example, [example.org](#))
- Host names with CIDR notation (for example, [www.example.com/24](#))

Before MySQL 8.0.14, host names could only resolve to IPv4 addresses. From MySQL 8.0.14, host names can resolve to IPv4 addresses, IPv6 addresses, or both. If a host name resolves to both an IPv4 and an IPv6 address, the IPv4 address is always used for Group Replication connections. You can use CIDR notation in combination with host names or IP addresses to permit a block of IP addresses with a particular network prefix, but do ensure that all the IP addresses in the specified subnet are under your control.

A comma must separate each entry in the allowlist. For example:

```
"192.0.2.21/24,198.51.100.44,203.0.113.0/24,2001:db8:85a3:8d3:1319:8a2e:370:7348,example.org,www.example.com"
```

If any of the seed members for the group are listed in the `group_replication_group_seeds` option with an IPv6 address when a joining member has an IPv4 `group_replication_local_address`, or the reverse, you must also set up and permit an alternative address for the joining member for the protocol offered by the seed member (or a host name that resolves to an address for that protocol). For more information, see [Section 18.6.1, “Group Replication IP Address Permissions”](#).

It is possible to configure different allowlists on different group members according to your security requirements, for example, in order to keep different subnets separate. However, this can cause issues when a group is reconfigured. If you do not have a specific security requirement to do otherwise, use the same allowlist on all members of a group. For more details, see [Section 18.6.1, “Group Replication IP Address Permissions”](#).

For host names, name resolution takes place only when a connection request is made by another server. A host name that cannot be resolved is not considered for allowlist validation, and a warning message is written to the error log. Forward-confirmed reverse DNS (FCrDNS) verification is carried out for resolved host names.

Warning

Host names are inherently less secure than IP addresses in an allowlist. FCrDNS verification provides a good level of protection, but can be compromised by certain types of attack. Specify host names in your allowlist only when strictly necessary, and ensure that all components used for name resolution, such as DNS servers, are maintained under your control. You can also implement name resolution locally using the hosts file, to avoid the use of external components.

- `group_replication_ip_whitelist`

| | |
|-----------------------------------|---|
| Command-Line Format | <code>--group-replication-ip-whitelist=value</code> |
| Deprecated | 8.0.22 |
| System Variable | <code>group_replication_ip_whitelist</code> |
| Scope | Global |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | String |

| | |
|---------------|------------------------|
| Default Value | <code>AUTOMATIC</code> |
|---------------|------------------------|

From MySQL 8.0.22, `group_replication_ip_whitelist` is deprecated, and `group_replication_ip_allowlist` is available to replace it. For both system variables, the default value is `AUTOMATIC`.

At Group Replication startup, if either one of the system variables has been set to a user-defined value and the other has not, the changed value is used. If both of the system variables have been set to a user-defined value, the value of `group_replication_ip_allowlist` is used.

If you change the value of `group_replication_ip_whitelist` or `group_replication_ip_allowlist` while Group Replication is running, which is possible from MySQL 8.0.24, neither variable has precedence over the other.

The new system variable works in the same way as the old system variable, only the terminology has changed. The behavior description given for `group_replication_ip_allowlist` applies to both the old and new system variables.

- `group_replication_local_address`

| | |
|-----------------------------------|--|
| Command-Line Format | <code>--group-replication-local-address=value</code> |
| System Variable | <code>group_replication_local_address</code> |
| Scope | Global |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | String |

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_local_address` sets the network address which the member provides for connections from other members, specified as a `host:port` formatted string. This address must be reachable by all members of the group because it is used by the group communication engine for Group Replication (XCom, a Paxos variant) for TCP communication between remote XCom instances. Communication with the local instance is over an input channel using shared memory.

Warning

Do not use this address for communication with the member. This is not the MySQL server SQL protocol host and port.

The address or host name that you specify in `group_replication_local_address` is used by Group Replication as the unique identifier for a group member within the replication group. You can use the same port for all members of a replication group as long as the host names or IP addresses are all different, and you can use the same host name or IP address for all members as long as the ports are all different. The recommended port for `group_replication_local_address` is 33061. Note that the value you specify for this variable is not validated until the `START GROUP_REPLICATION` statement is issued and the Group Communication System (GCS) is available.

The network address configured by `group_replication_local_address` must be resolvable by all group members. For example, if each server instance is on a different machine with a fixed network address, you could use the IP address of the machine, such as 10.0.0.1. If you use a host name, you

must use a fully qualified name, and ensure it is resolvable through DNS, correctly configured `/etc/hosts` files, or other name resolution processes. From MySQL 8.0.14, IPv6 addresses (or host names that resolve to them) can be used as well as IPv4 addresses. An IPv6 address must be specified in square brackets in order to distinguish the port number, for example:

```
group_replication_local_address= "[2001:db8:85a3:8d3:1319:8a2e:370:7348]:33061"
```

If a host name specified as the Group Replication local address for a server instance resolves to both an IPv4 and an IPv6 address, the IPv4 address is always used for Group Replication connections. For more information on Group Replication support for IPv6 networks and on replication groups with a mix of members using IPv4 and members using IPv6, see [Section 18.5.5, “Support For IPv6 And For Mixed IPv6 And IPv4 Groups”](#).

For the purpose of IP address permissions for Group Replication, the address that you specify for each group member in `group_replication_local_address` must be added to the list for the `group_replication_ip_allowlist` (from MySQL 8.0.22) or `group_replication_ip_whitelist` system variable on the other servers in the replication group. If any of the seed members for the group are listed in the `group_replication_group_seeds` option with an IPv6 address when this member has an IPv4 `group_replication_local_address`, or the reverse, you must also set up and permit an alternative address for this member for the required protocol (or a host name that resolves to an address for that protocol). For more information, see [Section 18.6.1, “Group Replication IP Address Permissions”](#).

- `group_replication_member_expel_timeout`

| | |
|-----------------------------------|---|
| Command-Line Format | <code>--group-replication-member-expel-timeout=#</code> |
| Introduced | 8.0.13 |
| System Variable | <code>group_replication_member_expel_timeout</code> |
| Scope | Global |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Integer |
| Default Value (≥ 8.0.21) | 5 |
| Default Value (≤ 8.0.20) | 0 |
| Minimum Value | 0 |
| Maximum Value (≥ 8.0.14) | 3600 |
| Maximum Value (≤ 8.0.13) | 31536000 |
| Unit | <code>seconds</code> |

The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately. The current value of the system variable is read whenever Group Replication checks the timeout. It is not mandatory for all members of a group to have the same setting, but it is recommended in order to avoid unexpected expulsions.

`group_replication_member_expel_timeout` specifies the period of time in seconds that a Group Replication group member waits after creating a suspicion, before expelling from the group the member suspected of having failed. The initial 5-second detection period before a suspicion is created does not count as part of this time. Up to and including MySQL 8.0.20, the value of `group_replication_member_expel_timeout` defaults to 0, meaning that there is no waiting period

and a suspected member is liable for expulsion immediately after the 5-second detection period ends. From MySQL 8.0.21, the value defaults to 5, meaning that a suspected member is liable for expulsion 5 seconds after the 5-second detection period.

Changing the value of `group_replication_member_expel_timeout` on a group member takes effect immediately for existing as well as future suspicions on that group member. You can therefore use this as a method to force a suspicion to time out and expel a suspected member, allowing changes to the group configuration. For more information, see [Section 18.7.6.1, “Expel Timeout”](#).

Increasing the value of `group_replication_member_expel_timeout` can help to avoid unnecessary expulsions on slower or less stable networks, or in the case of expected transient network outages or machine slowdowns. If a suspect member becomes active again before the suspicion times out, it applies all the messages that were buffered by the remaining group members and enters `ONLINE` state, without operator intervention. You can specify a timeout value up to a maximum of 3600 seconds (1 hour). It is important to ensure that XCom's message cache is sufficiently large to contain the expected volume of messages in your specified time period, plus the initial 5-second detection period, otherwise members are unable to reconnect. You can adjust the cache size limit using the `group_replication_message_cache_size` system variable. For more information, see [Section 18.7.5, “XCom Cache Management”](#).

If the timeout is exceeded, the suspect member is liable for expulsion immediately after the suspicion times out. If the member is able to resume communications and receives a view where it is expelled, and the member has the `group_replication_autorejoin_tries` system variable set to specify a number of auto-rejoin attempts, it proceeds to make the specified number of attempts to rejoin the group while in super read only mode. If the member does not have any auto-rejoin attempts specified, or if it has exhausted the specified number of attempts, it follows the action specified by the system variable `group_replication_exit_state_action`.

For more information on using the `group_replication_member_expel_timeout` setting, see [Section 18.7.6.1, “Expel Timeout”](#). For alternative mitigation strategies to avoid unnecessary expulsions where this system variable is not available, see [Section 18.3.2, “Group Replication Limitations”](#).

- `group_replication_member_weight`

| | |
|-----------------------------------|--|
| Command-Line Format | <code>--group-replication-member-weight=#</code> |
| System Variable | <code>group_replication_member_weight</code> |
| Scope | Global |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Integer |
| Default Value | 50 |
| Minimum Value | 0 |
| Maximum Value | 100 |
| Unit | percentage |

The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately. The system variable's current value is read when a failover situation occurs.

`group_replication_member_weight` specifies a percentage weight that can be assigned to members to influence the chance of the member being elected as primary in the event of failover, for example when the existing primary leaves a single-primary group. Assign numeric weights to members

to ensure that specific members are elected, for example during scheduled maintenance of the primary or to ensure certain hardware is prioritized in the event of failover.

For a group with members configured as follows:

- `member-1`: `group_replication_member_weight=30`, `server_uuid=aaaa`
- `member-2`: `group_replication_member_weight=40`, `server_uuid=bbbb`
- `member-3`: `group_replication_member_weight=40`, `server_uuid=cccc`
- `member-4`: `group_replication_member_weight=40`, `server_uuid=dddd`

during election of a new primary the members above would be sorted as `member-2`, `member-3`, `member-4`, and `member-1`. This results in `member-2` being chosen as the new primary in the event of failover. For more information, see [Section 18.1.3.1, “Single-Primary Mode”](#).

- `group_replication_message_cache_size`

| | |
|--|---|
| Command-Line Format | <code>--group-replication-message-cache-size=#</code> |
| Introduced | 8.0.16 |
| System Variable | <code>group_replication_message_cache_size</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value | <code>1073741824</code> (1 GB) |
| Minimum Value (64-bit platforms, ≥ 8.0.21) | <code>134217728</code> (128 MB) |
| Minimum Value (64-bit platforms, ≤ 8.0.20) | <code>1073741824</code> (1 GB) |
| Minimum Value (32-bit platforms, ≥ 8.0.21) | <code>134217728</code> (128 MB) |
| Minimum Value (32-bit platforms, ≤ 8.0.20) | <code>1073741824</code> (1 GB) |
| Maximum Value (64-bit platforms) | <code>18446744073709551615</code> (16 EiB) |
| Maximum Value (32-bit platforms) | <code>315360004294967295</code> (4 GB) |
| Unit | bytes |

This system variable should have the same value on all group members. The value of this system variable can be changed while Group Replication is running. The change takes effect on each group member after you stop and restart Group Replication on the member. During this process, the value of the system variable is permitted to differ between group members, but members might be unable to reconnect in the event of a disconnection.

`group_replication_message_cache_size` sets the maximum amount of memory that is available for the message cache in the group communication engine for Group Replication (XCom). The XCom message cache holds messages (and their metadata) that are exchanged between the group members as a part of the consensus protocol. Among other functions, the message cache is used for recovery of

missed messages by members that reconnect with the group after a period where they were unable to communicate with the other group members.

The `group_replication_member_expel_timeout` system variable determines the waiting period (up to an hour) that is allowed in addition to the initial 5-second detection period for members to return to the group rather than being expelled. The size of the XCom message cache should be set with reference to the expected volume of messages in this time period, so that it contains all the missed messages required for members to return successfully. Up to MySQL 8.0.20, the default is only the 5-second detection period, but from MySQL 8.0.21, the default is a 5-second waiting period after the 5-second detection period, for a total time period of 10 seconds.

Ensure that sufficient memory is available on your system for your chosen cache size limit, considering the size of MySQL Server's other caches and object pools. The default setting is 1073741824 bytes (1 GB). The minimum setting is also 1 GB up to MySQL 8.0.20. From MySQL 8.0.21, the minimum setting is 134217728 bytes (128 MB), which enables deployment on a host that has a restricted amount of available memory, and good network connectivity to minimize the frequency and duration of transient losses of connectivity for group members. Note that the limit set using `group_replication_message_cache_size` applies only to the data stored in the cache, and the cache structures require an additional 50 MB of memory.

The cache size limit can be increased or reduced dynamically at runtime. If you reduce the cache size limit, XCom removes the oldest entries that have been decided and delivered until the current size is below the limit. Group Replication's Group Communication System (GCS) alerts you, by a warning message, when a message that is likely to be needed for recovery by a member that is currently unreachable is removed from the message cache. For more information on tuning the message cache size, see [Section 18.7.5, "XCom Cache Management"](#).

- `group_replication_poll_spin_loops`

| | |
|----------------------------------|--|
| Command-Line Format | <code>--group-replication-poll-spin-loops=#</code> |
| System Variable | <code>group_replication_poll_spin_loops</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value | 0 |
| Minimum Value | 0 |
| Maximum Value (64-bit platforms) | 18446744073709551615 |
| Maximum Value (32-bit platforms) | 4294967295 |

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_poll_spin_loops` specifies the number of times the group communication thread waits for the communication engine mutex to be released before the thread waits for more incoming network messages.

- `group_replication_recovery_complete_at`

| | |
|---------------------|---|
| Command-Line Format | <code>--group-replication-recovery-complete-at=value</code> |
|---------------------|---|

| | |
|----------------------|--|
| System Variable | <code>group_replication_recovery_complete_at</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Enumeration |
| Default Value | <code>TRANSACTIONS_APPLIED</code> |
| Valid Values | <code>TRANSACTIONS_CERTIFIED</code> <code>TRANSACTIONS_APPLIED</code> |

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_recovery_complete_at` specifies the policy applied during the distributed recovery process when handling cached transactions after state transfer from an existing member. You can choose whether a member is marked online after it has received and certified all transactions that it missed before it joined the group (`TRANSACTIONS_CERTIFIED`), or only after it has received, certified, and applied them (`TRANSACTIONS_APPLIED`).

- `group_replication_recovery_compression_algorithms`

| | |
|----------------------|--|
| Command-Line Format | <code>--group-replication-recovery-compression-algorithms=value</code> |
| Introduced | 8.0.18 |
| System Variable | <code>group_replication_recovery_compression_algorithms</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Set |
| Default Value | <code>uncompressed</code> |
| Valid Values | <code>zlib</code> <code>zstd</code> <code>uncompressed</code> |

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_recovery_compression_algorithms` specifies the compression algorithms permitted for Group Replication distributed recovery connections for state transfer from a donor's binary log. The available algorithms are the same as for the `protocol_compression_algorithms` system variable. For more information, see [Section 4.2.8, "Connection Compression Control"](#).

This setting does not apply if the server has been set up to support cloning (see [Section 18.5.3.2, "Cloning for Distributed Recovery"](#)) and a remote cloning operation is used during distributed recovery. For this method of state transfer, the clone plugin's `clone_enable_compression` setting applies.

- `group_replication_recovery_get_public_key`

| | |
|----------------------|---|
| Command-Line Format | <code>--group-replication-recovery-get-public-key[={OFF ON}]</code> |
| System Variable | <code>group_replication_recovery_get_public_key</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Boolean |
| Default Value | OFF |

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_recovery_get_public_key` specifies whether to request from the source the public key required for RSA key pair-based password exchange. If `group_replication_recovery_public_key_path` is set to a valid public key file, it takes precedence over `group_replication_recovery_get_public_key`. This variable applies if you are not using SSL for distributed recovery over the `group_replication_recovery` channel (`group_replication_recovery_use_ssl=ON`), and the replication user account for Group Replication authenticates with the `caching_sha2_password` plugin (which is the default in MySQL 8.0). For more details, see [Replication User With The Caching SHA-2 Authentication Plugin](#).

- `group_replication_recovery_public_key_path`

| | |
|----------------------|---|
| Command-Line Format | <code>--group-replication-recovery-public-key-path=file_name</code> |
| System Variable | <code>group_replication_recovery_public_key_path</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | File name |
| Default Value | NULL |

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_recovery_public_key_path` specifies the path name to a file containing a replica-side copy of the public key required by the source for RSA key pair-based password exchange. The file must be in PEM format. If `group_replication_recovery_public_key_path` is set to a valid public key file, it takes precedence over `group_replication_recovery_get_public_key`. This variable applies if you are not using SSL for distributed recovery over the `group_replication_recovery` channel (so `group_replication_recovery_use_ssl` is set to OFF), and the replication user account for Group Replication authenticates with the `caching_sha2_password` plugin (which is the default in MySQL 8.0) or the `sha256_password` plugin. (For `sha256_password`, setting `group_replication_recovery_public_key_path` applies only if MySQL was built using OpenSSL.) For more details, see [Replication User With The Caching SHA-2 Authentication Plugin](#).

- `group_replication_recovery_reconnect_interval`

| | |
|----------------------|--|
| Command-Line Format | <code>--group-replication-recovery-reconnect-interval=#</code> |
| System Variable | <code>group_replication_recovery_reconnect_interval</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value | 60 |
| Minimum Value | 0 |
| Maximum Value | 31536000 |
| Unit | seconds |

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_recovery_reconnect_interval` specifies the sleep time, in seconds, between reconnection attempts when no suitable donor was found in the group for distributed recovery.

- `group_replication_recovery_retry_count`

| | |
|----------------------|---|
| Command-Line Format | <code>--group-replication-recovery-retry-count=#</code> |
| System Variable | <code>group_replication_recovery_retry_count</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value | 10 |
| Minimum Value | 0 |
| Maximum Value | 31536000 |

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_recovery_retry_count` specifies the number of times that the member that is joining tries to connect to the available donors for distributed recovery before giving up.

- `group_replication_recovery_ssl_ca`

| | |
|---------------------|--|
| Command-Line Format | <code>--group-replication-recovery-ssl-ca=value</code> |
| System Variable | <code>group_replication_recovery_ssl_ca</code> |
| Scope | Global |
| Dynamic | Yes |

| | |
|-----------------------------------|--------|
| <code>SET_VAR</code> Hint Applies | No |
| Type | String |

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_recovery_ssl_ca` specifies the path to a file that contains a list of trusted SSL certificate authorities for distributed recovery connections. See [Section 18.6.2, “Securing Group Communication Connections with Secure Socket Layer \(SSL\)”](#) for information on configuring SSL for distributed recovery.

If this server has been set up to support cloning (see [Section 18.5.3.2, “Cloning for Distributed Recovery”](#)), and you have set `group_replication_recovery_use_ssl` to `ON`, Group Replication automatically configures the setting for the clone SSL option `clone_ssl_ca` to match your setting for `group_replication_recovery_ssl_ca`.

- `group_replication_recovery_ssl_capath`

| | |
|-----------------------------------|--|
| Command-Line Format | <code>--group-replication-recovery-ssl-capath=value</code> |
| System Variable | <code>group_replication_recovery_ssl_capath</code> |
| Scope | Global |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | String |

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_recovery_ssl_capath` specifies the path to a directory that contains trusted SSL certificate authority certificates for distributed recovery connections. See [Section 18.6.2, “Securing Group Communication Connections with Secure Socket Layer \(SSL\)”](#) for information on configuring SSL for distributed recovery.

- `group_replication_recovery_ssl_cert`

| | |
|-----------------------------------|--|
| Command-Line Format | <code>--group-replication-recovery-ssl-cert=value</code> |
| System Variable | <code>group_replication_recovery_ssl_cert</code> |
| Scope | Global |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | String |

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_recovery_ssl_cert` specifies the name of the SSL certificate file to use for establishing a secure connection for distributed recovery. See [Section 18.6.2, “Securing Group](#)

[Communication Connections with Secure Socket Layer \(SSL\)](#)” for information on configuring SSL for distributed recovery.

If this server has been set up to support cloning (see [Section 18.5.3.2, “Cloning for Distributed Recovery”](#)), and you have set `group_replication_recovery_use_ssl` to ON, Group Replication automatically configures the setting for the clone SSL option `clone_ssl_cert` to match your setting for `group_replication_recovery_ssl_cert`.

- `group_replication_recovery_ssl_cipher`

| | |
|----------------------|--|
| Command-Line Format | <code>--group-replication-recovery-ssl-cipher=value</code> |
| System Variable | <code>group_replication_recovery_ssl_cipher</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | String |

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_recovery_ssl_cipher` specifies the list of permissible ciphers for SSL encryption. See [Section 18.6.2, “Securing Group Communication Connections with Secure Socket Layer \(SSL\)”](#) for information on configuring SSL for distributed recovery.

- `group_replication_recovery_ssl_crl`

| | |
|----------------------|---|
| Command-Line Format | <code>--group-replication-recovery-ssl-crl=value</code> |
| System Variable | <code>group_replication_recovery_ssl_crl</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | File name |

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_recovery_ssl_crl` specifies the path to a directory that contains files containing certificate revocation lists. See [Section 18.6.2, “Securing Group Communication Connections with Secure Socket Layer \(SSL\)”](#) for information on configuring SSL for distributed recovery.

- `group_replication_recovery_ssl_crlpath`

| | |
|---------------------|---|
| Command-Line Format | <code>--group-replication-recovery-ssl-crlpath=value</code> |
| System Variable | <code>group_replication_recovery_ssl_crlpath</code> |
| Scope | Global |
| Dynamic | Yes |

| | |
|-----------------------------------|----------------|
| <code>SET_VAR</code> Hint Applies | No |
| Type | Directory name |

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_recovery_ssl_crlpath` specifies the path to a directory that contains files containing certificate revocation lists. See [Section 18.6.2, “Securing Group Communication Connections with Secure Socket Layer \(SSL\)”](#) for information on configuring SSL for distributed recovery.

- `group_replication_recovery_ssl_key`

| | |
|-----------------------------------|---|
| Command-Line Format | <code>--group-replication-recovery-ssl-key=value</code> |
| System Variable | <code>group_replication_recovery_ssl_key</code> |
| Scope | Global |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | String |

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_recovery_ssl_key` specifies the name of the SSL key file to use for establishing a secure connection. See [Section 18.6.2, “Securing Group Communication Connections with Secure Socket Layer \(SSL\)”](#) for information on configuring SSL for distributed recovery.

If this server has been set up to support cloning (see [Section 18.5.3.2, “Cloning for Distributed Recovery”](#)), and you have set `group_replication_recovery_use_ssl` to `ON`, Group Replication automatically configures the setting for the clone SSL option `clone_ssl_key` to match your setting for `group_replication_recovery_ssl_key`.

- `group_replication_recovery_ssl_verify_server_cert`

| | |
|-----------------------------------|---|
| Command-Line Format | <code>--group-replication-recovery-ssl-verify-server-cert[={OFF ON}]</code> |
| System Variable | <code>group_replication_recovery_ssl_verify_server_cert</code> |
| Scope | Global |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Boolean |
| Default Value | <code>OFF</code> |

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_recovery_ssl_verify_server_cert` specifies whether the distributed recovery connection should check the server's Common Name value in the certificate sent by the donor. See [Section 18.6.2, “Securing Group Communication Connections with Secure Socket Layer \(SSL\)”](#) for information on configuring SSL for distributed recovery.

- `group_replication_recovery_tls_ciphersuites`

| | |
|----------------------|--|
| Command-Line Format | <code>--group-replication-recovery-tls-ciphersuites=value</code> |
| Introduced | 8.0.19 |
| System Variable | <code>group_replication_recovery_tls_ciphersuites</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | String |
| Default Value | NULL |

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_recovery_tls_ciphersuites` specifies a colon-separated list of one or more permitted ciphersuites when TLSv1.3 is used for connection encryption for the distributed recovery connection, and this server instance is the client in the distributed recovery connection, that is, the joining member. If this system variable is set to `NULL` when TLSv1.3 is used (which is the default if you do not set the system variable), the ciphersuites that are enabled by default are allowed, as listed in [Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#). If this system variable is set to the empty string, no cipher suites are allowed, and TLSv1.3 is therefore not used. This system variable is available beginning with MySQL 8.0.19. See [Section 18.6.2, “Securing Group Communication Connections with Secure Socket Layer \(SSL\)”](#), for information on configuring SSL for distributed recovery.

- `group_replication_recovery_tls_version`

| | |
|----------------------|---|
| Command-Line Format | <code>--group-replication-recovery-tls-version=value</code> |
| Introduced | 8.0.19 |
| System Variable | <code>group_replication_recovery_tls_version</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | String |
| Default Value | <code>TLSv1, TLSv1.1, TLSv1.2, TLSv1.3</code> (OpenSSL 1.1.1 or higher) <code>TLSv1, TLSv1.1, TLSv1.2</code> (otherwise) |

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_recovery_tls_version` specifies a comma-separated list of one or more permitted TLS protocols for connection encryption when this server instance is the client in the distributed recovery connection, that is, the joining member. Ensure the specified versions are contiguous (for example, `TLSv1, TLSv1.1, TLSv1.2`). If this system variable is not set, the default `TLSv1, TLSv1.1, TLSv1.2, TLSv1.3` is used. The group members involved in each distributed

recovery connection as the client (joining member) and server (donor) negotiate the highest protocol version that they are both set up to support. This system variable is available from MySQL 8.0.19. See [Section 18.6.2, “Securing Group Communication Connections with Secure Socket Layer \(SSL\)”](#) for information on configuring SSL for distributed recovery.

- `group_replication_recovery_use_ssl`

| | |
|----------------------|--|
| Command-Line Format | <code>--group-replication-recovery-use-ssl[={OFF ON}]</code> |
| System Variable | <code>group_replication_recovery_use_ssl</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Boolean |
| Default Value | OFF |

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_recovery_use_ssl` specifies whether Group Replication distributed recovery connections between group members should use SSL or not. See [Section 18.6.2, “Securing Group Communication Connections with Secure Socket Layer \(SSL\)”](#) for information on configuring SSL for distributed recovery.

If this server has been set up to support cloning (see [Section 18.5.3.2, “Cloning for Distributed Recovery”](#)), and you set this option to `ON`, Group Replication uses SSL for remote cloning operations as well as for state transfer from a donor's binary log. If you set this option to `OFF`, Group Replication does not use SSL for remote cloning operations.

- `group_replication_recovery_zstd_compression_level`

| | |
|----------------------|--|
| Command-Line Format | <code>--group-replication-recovery-zstd-compression-level=#</code> |
| Introduced | 8.0.18 |
| System Variable | <code>group_replication_recovery_zstd_compression_level</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value | 3 |
| Minimum Value | 1 |
| Maximum Value | 22 |

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_recovery_zstd_compression_level` specifies the compression level to use for Group Replication distributed recovery connections that use the `zstd` compression algorithm. The permitted levels are from 1 to 22, with larger values indicating increasing levels of compression.

The default `zstd` compression level is 3. For distributed recovery connections that do not use `zstd` compression, this variable has no effect.

For more information, see [Section 4.2.8, “Connection Compression Control”](#).

- `group_replication_single_primary_mode`

| | |
|-----------------------------------|---|
| Command-Line Format | <code>--group-replication-single-primary-mode[={OFF ON}]</code> |
| System Variable | <code>group_replication_single_primary_mode</code> |
| Scope | Global |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Boolean |
| Default Value | <code>ON</code> |

This system variable is a group-wide configuration setting. It must have the same value on all group members, cannot be changed while Group Replication is running, and requires a full reboot of the group (a bootstrap by a server with `group_replication_bootstrap_group=ON`) in order for the value change to take effect. If the group has a value set for this system variable, and a joining member has a different value set for the system variable, the joining member cannot join the group until the value is changed to match. If the group members have a value set for this system variable, and the joining member does not support the system variable, it cannot join the group.

From MySQL 8.0.16, you can use the `group_replication_switch_to_single_primary_mode()` and `group_replication_switch_to_multi_primary_mode()` functions to change the value of this system variable while the group is still running. For more information, see [Section 18.5.1.2, “Changing a Group’s Mode”](#).

`group_replication_single_primary_mode` instructs the group to automatically pick a single server to be the one that handles read/write workload. This server is the PRIMARY and all others are SECONDARIES.

- `group_replication_ssl_mode`

| | |
|-----------------------------------|--|
| Command-Line Format | <code>--group-replication-ssl-mode=value</code> |
| System Variable | <code>group_replication_ssl_mode</code> |
| Scope | Global |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Enumeration |
| Default Value | <code>DISABLED</code> |
| Valid Values | <code>DISABLED</code> <code>REQUIRED</code> <code>VERIFY_CA</code> |

| | |
|--|------------------------------|
| | <code>VERIFY_IDENTITY</code> |
|--|------------------------------|

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_ssl_mode` sets the security state of group communication connections between Group Replication members. The possible values are as follows:

| | |
|-----------------|---|
| DISABLED | Establish an unencrypted connection (the default). |
| REQUIRED | Establish a secure connection if the server supports secure connections. |
| VERIFY_CA | Like <code>REQUIRED</code> , but additionally verify the server TLS certificate against the configured Certificate Authority (CA) certificates. |
| VERIFY_IDENTITY | Like <code>VERIFY_CA</code> , but additionally verify that the server certificate matches the host to which the connection is attempted. |

See [Section 18.6.2, “Securing Group Communication Connections with Secure Socket Layer \(SSL\)”](#) for information on configuring SSL for group communication.

- `group_replication_start_on_boot`

| | |
|-----------------------------------|---|
| Command-Line Format | <code>--group-replication-start-on-boot[={OFF ON}]</code> |
| System Variable | <code>group_replication_start_on_boot</code> |
| Scope | Global |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Boolean |
| Default Value | <code>ON</code> |

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

`group_replication_start_on_boot` specifies whether the server should start Group Replication automatically (`ON`) or not (`OFF`) during server start. When you set this option to `ON`, Group Replication restarts automatically after a remote cloning operation is used for distributed recovery.

To start Group Replication automatically during server start, the user credentials for distributed recovery must be stored in the replication metadata repositories on the server using the `CHANGE REPLICATION SOURCE TO | CHANGE MASTER TO` statement. If you prefer to specify the user credentials on the `START GROUP_REPLICATION` statement, which stores the user credentials only in memory, ensure that `group_replication_start_on_boot` is set to `OFF`.

- `group_replication_tls_source`

| | |
|---------------------|---|
| Command-Line Format | <code>--group-replication-tls-source=value</code> |
| Introduced | 8.0.21 |
| System Variable | <code>group_replication_tls_source</code> |

| | |
|--------------------------------------|---|
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Enumeration |
| Default Value | <code>mysql_main</code> |
| Valid Values | <code>mysql_main</code> <code>mysql_admin</code> |

The value of this system variable can be changed while Group Replication is running, but the change only takes effect after you stop and restart Group Replication on the group member.

[group_replication_tls_source](#) specifies the source of TLS material for Group Replication.

- [group_replication_transaction_size_limit](#)

| | |
|--------------------------------------|---|
| Command-Line Format | <code>--group-replication-transaction-size-limit=#</code> |
| System Variable | group_replication_transaction_size_limit |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value | <code>150000000</code> |
| Minimum Value | <code>0</code> |
| Maximum Value | <code>2147483647</code> |
| Unit | <code>bytes</code> |

This system variable should have the same value on all group members. The value of this system variable can be changed while Group Replication is running. The change takes effect immediately on the group member, and applies from the next transaction started on that member. During this process, the value of the system variable is permitted to differ between group members, but some transactions might be rejected.

[group_replication_transaction_size_limit](#) configures the maximum transaction size in bytes which the replication group accepts. Transactions larger than this size are rolled back by the receiving member and are not broadcast to the group. Large transactions can cause problems for a replication group in terms of memory allocation, which can cause the system to slow down, or in terms of network bandwidth consumption, which can cause a member to be suspected of having failed because it is busy processing the large transaction.

When this system variable is set to 0 there is no limit to the size of transactions the group accepts. From MySQL 8.0, the default setting for this system variable is 150000000 bytes (approximately 143 MB). Adjust the value of this system variable depending on the maximum message size that you need the group to tolerate, bearing in mind that the time taken to process a transaction is proportional to its size. The value of [group_replication_transaction_size_limit](#) should be the same on all group members. For further mitigation strategies for large transactions, see [Section 18.3.2, “Group Replication Limitations”](#).

- `group_replication_unreachable_majority_timeout`

| | |
|-----------------------------------|---|
| Command-Line Format | <code>--group-replication-unreachable-majority-timeout=#</code> |
| System Variable | <code>group_replication_unreachable_majority_timeout</code> |
| Scope | Global |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Integer |
| Default Value | 0 |
| Minimum Value | 0 |
| Maximum Value | 31536000 |
| Unit | seconds |

The value of this system variable can be changed while Group Replication is running, and the change takes effect immediately. The current value of the system variable is read when an issue occurs that means the behavior is needed.

`group_replication_unreachable_majority_timeout` specifies a number of seconds for which members that suffer a network partition and cannot connect to the majority wait before leaving the group. In a group of 5 servers (S1,S2,S3,S4,S5), if there is a disconnection between (S1,S2) and (S3,S4,S5) there is a network partition. The first group (S1,S2) is now in a minority because it cannot contact more than half of the group. While the majority group (S3,S4,S5) remains running, the minority group waits for the specified time for a network reconnection. For a detailed description of this scenario, see [Section 18.5.4, “Network Partitioning”](#).

By default, `group_replication_unreachable_majority_timeout` is set to 0, which means that members that find themselves in a minority due to a network partition wait forever to leave the group. If you set a timeout, when the specified time elapses, all pending transactions processed by the minority are rolled back, and the servers in the minority partition move to the `ERROR` state. If a member has the `group_replication_autorejoin_tries` system variable set to specify a number of auto-rejoin attempts, it proceeds to make the specified number of attempts to rejoin the group while in super read only mode. If the member does not have any auto-rejoin attempts specified, or if it has exhausted the specified number of attempts, it follows the action specified by the system variable `group_replication_exit_state_action`.

Warning

When you have a symmetric group, with just two members for example (S0,S2), if there is a network partition and there is no majority, after the configured timeout all members enter the `ERROR` state.

For more information on using this option, see [Section 18.7.6.2, “Unreachable Majority Timeout”](#).

- `group_replication_view_change_uuid`

| | |
|---------------------|---|
| Command-Line Format | <code>--group-replication-view-change-uuid=value</code> |
| Introduced | 8.0.26 |
| System Variable | <code>group_replication_view_change_uuid</code> |

| | |
|--------------------------------------|---------------------------|
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | String |
| Default Value | AUTOMATIC |

This system variable is a group-wide configuration setting. It must have the same value on all group members, cannot be changed while Group Replication is running, and requires a full reboot of the group (a bootstrap by a server with [group_replication_bootstrap_group=ON](#)) in order for the value change to take effect. If the group has a value set for this system variable, and a joining member has a different value set for the system variable, the joining member cannot join the group until the value is changed to match. If the group members have a value set for this system variable, and the joining member does not support the system variable, it cannot join the group.

[group_replication_view_change_uuid](#) specifies an alternative UUID to use as the UUID part of the identifier in the GTIDs for view change events generated by the group. The alternative UUID makes these internally generated transactions easy to distinguish from transactions received by the group from clients. This can be useful if your setup allows for failover between groups, and you need to identify and discard transactions that were specific to the backup group. The default value for this system variable is [AUTOMATIC](#), meaning that the GTIDs for view change events use the group name specified by the [group_replication_group_name](#) system variable, as transactions from clients do. Group members at a release that does not have this system variable are treated as having the value [AUTOMATIC](#).

The alternative UUID must be different from the group name specified by the [group_replication_group_name](#) system variable, and it must be different from the server UUID of any group member. It must also be different from any UUIDs used in the GTIDs that are applied to anonymous transactions on replication channels anywhere in this topology, using the [ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS](#) option of the [CHANGE REPLICATION SOURCE TO](#) statement.

Group Replication Status Variable

This section describes the status variable which provides information about Group Replication. The variable has the following meaning:

- [group_replication_primary_member](#)

Shows the primary member's UUID when the group is operating in single-primary mode. If the group is operating in multi-primary mode, shows an empty string.

Warning

The [group_replication_primary_member](#) status variable has been deprecated and is scheduled to be removed in a future version.

See [Finding the Primary](#).

18.10 Frequently Asked Questions

This section provides answers to frequently asked questions.

What is the maximum number of MySQL servers in a group?

A group can consist of maximum 9 servers. Attempting to add another server to a group with 9 members causes the request to join to be refused. This limit has been identified from testing and benchmarking as a safe boundary where the group performs reliably on a stable local area network.

How are servers in a group connected?

Servers in a group connect to the other servers in the group by opening a peer-to-peer TCP connection. These connections are only used for internal communication and message passing between servers in the group. This address is configured by the `group_replication_local_address` variable.

What is the `group_replication_bootstrap_group` option used for?

The bootstrap flag instructs a member to *create* a group and act as the initial seed server. The second member joining the group needs to ask the member that bootstrapped the group to dynamically change the configuration in order for it to be added to the group.

A member needs to bootstrap the group in two scenarios. When the group is originally created, or when shutting down and restarting the entire group.

How do I set credentials for the distributed recovery process?

You can set the user credentials permanently as the credentials for the `group_replication_recovery` channel, using a `CHANGE REPLICATION SOURCE TO` statement (from MySQL 8.0.23) or `CHANGE MASTER TO` statement (before MySQL 8.0.23). Alternatively, from MySQL 8.0.21, you can specify them on the `START GROUP_REPLICATION` statement each time Group Replication is started.

User credentials set using `CHANGE REPLICATION SOURCE TO` | `CHANGE MASTER TO` are stored in plain text in the replication metadata repositories on the server, but user credentials specified on `START GROUP_REPLICATION` are saved in memory only, and are removed by a `STOP GROUP_REPLICATION` statement or server shutdown. Using `START GROUP_REPLICATION` to specify the user credentials therefore helps to secure the Group Replication servers against unauthorized access. However, this method is not compatible with starting Group Replication automatically, as specified by the `group_replication_start_on_boot` system variable. For more information, see [Section 18.6.3.1, “Secure User Credentials for Distributed Recovery”](#).

Can I scale-out my write-load using Group Replication?

Not directly, but MySQL Group replication is a shared nothing full replication solution, where all servers in the group replicate the same amount of data. Therefore if one member in the group writes N bytes to storage as the result of a transaction commit operation, then roughly N bytes are written to storage on other members as well, because the transaction is replicated everywhere.

However, given that other members do not have to do the same amount of processing that the original member had to do when it originally executed the transaction, they apply the changes faster. Transactions are replicated in a format that is used to apply row transformations only, without having to re-execute transactions again (row-based format).

Furthermore, given that changes are propagated and applied in row-based format, this means that they are received in an optimized and compact format, and likely reducing the number of IO operations required when compared to the originating member.

To summarize, you can scale-out processing, by spreading conflict free transactions throughout different members in the group. And you can likely scale-out a small fraction of your IO operations, since remote servers receive only the necessary changes to read-modify-write changes to stable storage.

Does Group Replication require more network bandwidth and CPU, when compared to simple replication and under the same workload?

Does Group Replication require more network bandwidth and CPU, when compared to simple replication and under the same workload?

Some additional load is expected because servers need to be constantly interacting with each other for synchronization purposes. It is difficult to quantify how much more data. It also depends on the size of the group (three servers puts less stress on the bandwidth requirements than nine servers in the group).

Also the memory and CPU footprint are larger, because more complex work is done for the server synchronization part and for the group messaging.

Can I deploy Group Replication across wide-area networks?

Yes, but the network connection between each member *must* be reliable and have suitable performance. Low latency, high bandwidth network connections are a requirement for optimal performance.

If network bandwidth alone is an issue, then [Section 18.7.3, “Message Compression”](#) can be used to lower the bandwidth required. However, if the network drops packets, leading to re-transmissions and higher end-to-end latency, throughput and latency are both negatively affected.

Warning

When the network round-trip time (RTT) between any group members is 5 seconds or more you could encounter problems as the built-in failure detection mechanism could be incorrectly triggered.

Do members automatically rejoin a group in case of temporary connectivity problems?

This depends on the reason for the connectivity problem. If the connectivity problem is transient and the reconnection is quick enough that the failure detector is not aware of it, then the server may not be removed from the group. If it is a "long" connectivity problem, then the failure detector eventually suspects a problem and the server is removed from the group.

From MySQL 8.0, two settings are available to increase the chances of a member remaining in or rejoining a group:

- `group_replication_member_expel_timeout` increases the time between the creation of a suspicion (which happens after an initial 5-second detection period) and the expulsion of the member. You can set a waiting period of up to 1 hour. From MySQL 8.0.21, a waiting period of 5 seconds is set by default.
- `group_replication_autorejoin_tries` makes a member try to rejoin the group after an expulsion or unreachable majority timeout. The member makes the specified number of auto-rejoin attempts five minutes apart. From MySQL 8.0.21, this feature is activated by default and the member makes three auto-rejoin attempts.

If a server is expelled from the group and any auto-rejoin attempts do not succeed, you need to join it back again. In other words, after a server is removed explicitly from the group you need to rejoin it manually (or have a script doing it automatically).

When is a member excluded from a group?

If the member becomes silent, the other members remove it from the group configuration. In practice this may happen when the member has crashed or there is a network disconnection.

The failure is detected after a given timeout elapses for a given member and a new configuration without the silent member in it is created.

What happens when one node is significantly lagging behind?

There is no method for defining policies for when to expel members automatically from the group. You need to find out why a member is lagging behind and fix that or remove the member from the group. Otherwise, if the server is so slow that it triggers the flow control, then the entire group slows down as well. The flow control can be configured according to the your needs.

Upon suspicion of a problem in the group, is there a special member responsible for triggering a reconfiguration?

No, there is no special member in the group in charge of triggering a reconfiguration.

Any member can suspect that there is a problem. All members need to (automatically) agree that a given member has failed. One member is in charge of expelling it from the group, by triggering a reconfiguration. Which member is responsible for expelling the member is not something you can control or set.

Can I use Group Replication for sharding?

Group Replication is designed to provide highly available replica sets; data and writes are duplicated on each member in the group. For scaling beyond what a single system can provide, you need an orchestration and sharding framework built around a number of Group Replication sets, where each replica set maintains and manages a given shard or partition of your total dataset. This type of setup, often called a “sharded cluster”, allows you to scale reads and writes linearly and without limit.

How do I use Group Replication with SELinux?

If SELinux is enabled, which you can verify using `sestatus -v`, then you need to enable the use of the Group Replication communication port. See [Setting the TCP Port Context for Group Replication](#).

How do I use Group Replication with iptables?

If `iptables` is enabled, then you need to open up the Group Replication port for communication between the machines. To see the current rules in place on each machine, issue `iptables -L`. Assuming the port configured is 33061, enable communication over the necessary port by issuing `iptables -A INPUT -p tcp --dport 33061 -j ACCEPT`.

How do I recover the relay log for a replication channel used by a group member?

The replication channels used by Group Replication behave in the same way as replication channels used in asynchronous source to replica replication, and as such rely on the relay log. In the event of a change of the `relay_log` variable, or when the option is not set and the host name changes, there is a chance of errors. See [Section 17.2.4.1, “The Relay Log”](#) for a recovery procedure in this situation. Alternatively, another way of fixing the issue specifically in Group Replication is to issue a `STOP GROUP_REPLICATION` statement and then a `START GROUP_REPLICATION` statement to restart the instance. The Group Replication plugin creates the `group_replication_applier` channel again.

Why does Group Replication use two bind addresses?

Group Replication uses two bind addresses in order to split network traffic between the SQL address, used by clients to communicate with the member, and the `group_replication_local_address`,

used internally by the group members to communicate. For example, assume a server with two network interfaces assigned to the network addresses `203.0.113.1` and `198.51.100.179`. In such a situation you could use `203.0.113.1:33061` for the internal group network address by setting `group_replication_local_address=203.0.113.1:33061`. Then you could use `198.51.100.179` for `hostname` and `3306` for the `port`. Client SQL applications would then connect to the member at `198.51.100.179:3306`. This enables you to configure different rules on the different networks. Similarly, the internal group communication can be separated from the network connection used for client applications, for increased security.

How does Group Replication use network addresses and hostnames?

Group Replication uses network connections between members and therefore its functionality is directly impacted by how you configure hostnames and ports. For example, Group Replication's distributed recovery process creates a connection to an existing group member using the server's hostname and port. When a member joins a group it receives the group membership information, using the network address information that is listed at `performance_schema.replication_group_members`. One of the members listed in that table is selected as the donor of the missing data from the group to the joining member.

This means that any value you configure using a hostname, such as the SQL network address or the group seeds address, must be a fully qualified name and resolvable by each member of the group. You can ensure this for example through DNS, or correctly configured `/etc/hosts` files, or other local processes. If you want to configure the `MEMBER_HOST` value on a server, specify it using the `--report-host` option on the server before joining it to the group.

Important

The assigned value is used directly and is not affected by the `skip_name_resolve` system variable.

To configure `MEMBER_PORT` on a server, specify it using the `report_port` system variable.

Why did the auto increment setting on the server change?

When Group Replication is started on a server, the value of `auto_increment_increment` is changed to the value of `group_replication_auto_increment_increment`, which defaults to 7, and the value of `auto_increment_offset` is changed to the server ID. The changes are reverted when Group Replication is stopped. These settings avoid the selection of duplicate auto-increment values for writes on group members, which causes rollback of transactions. The default auto increment value of 7 for Group Replication represents a balance between the number of usable values and the permitted maximum size of a replication group (9 members).

The changes are only made and reverted if `auto_increment_increment` and `auto_increment_offset` each have their default value of 1. If their values have already been modified from the default, Group Replication does not alter them. From MySQL 8.0, the system variables are also not modified when Group Replication is in single-primary mode, where only one server writes.

How do I find the primary?

If the group is operating in single-primary mode, it can be useful to find out which member is the primary. See [Finding the Primary](#)

Chapter 19 MySQL Shell

MySQL Shell is an advanced client and code editor for MySQL Server. In addition to the provided SQL functionality, similar to `mysql`, MySQL Shell provides scripting capabilities for JavaScript and Python and includes APIs for working with MySQL. MySQL Shell is a component that you can install separately.

The following discussion briefly describes MySQL Shell's capabilities. For more information, see the MySQL Shell manual, available at <https://dev.mysql.com/doc/mysql-shell/en/>.

MySQL Shell includes the following APIs implemented in JavaScript and Python which you can use to develop code that interacts with MySQL.

- The X DevAPI enables developers to work with both relational and document data when MySQL Shell is connected to a MySQL server using the X Protocol. This enables you to use MySQL as a Document Store, sometimes referred to as “using NoSQL”. For more information, see [Chapter 20, Using MySQL as a Document Store](#). For documentation on the concepts and usage of X DevAPI, which is implemented in MySQL Shell, see [X DevAPI User Guide](#).
- The AdminAPI enables database administrators to work with InnoDB Cluster, which provides an integrated solution for high availability and scalability using InnoDB based MySQL databases, without requiring advanced MySQL expertise. The AdminAPI also includes support for InnoDB ReplicaSet, which enables you to administer a set of MySQL instances running asynchronous GTID-based replication in a similar way to InnoDB Cluster. Additionally, the AdminAPI makes administration of MySQL Router easier, including integration with both InnoDB Cluster and InnoDB ReplicaSet. See [MySQL AdminAPI](#).

MySQL Shell is available in two editions, the Community Edition and the Commercial Edition. The Community Edition is available free of charge. The Commercial Edition provides additional Enterprise features at low cost.

This chapter introduces an alternative way of working with MySQL as a document store, sometimes referred to as “using NoSQL”. If your intention is to use MySQL in a traditional (SQL) way, this chapter is probably not relevant to you.

Traditionally, relational databases such as MySQL have usually required a schema to be defined before documents can be stored. The features described in this section enable you to use MySQL as a document store, which is a schema-less, and therefore schema-flexible, storage system for documents. For example, when you create documents describing products, you do not need to know and define all possible attributes of any products before storing and operating with the documents. This differs from working with a relational database and storing products in a table, when all columns of the table must be known and defined before adding any products to the database. The features described in this chapter enable you to choose how you configure MySQL, using only the document store model, or combining the flexibility of the document store model with the power of the relational model.

To use MySQL as a document store, you use the following server features:

- X Plugin enables MySQL Server to communicate with clients using X Protocol, which is a prerequisite for using MySQL as a document store. X Plugin is enabled by default in MySQL Server as of MySQL 8.0. For instructions to verify X Plugin installation and to configure and monitor X Plugin, see [Section 20.5, “X Plugin”](#).
- X Protocol supports both CRUD and SQL operations, authentication via SASL, allows streaming (pipelining) of commands and is extensible on the protocol and the message layer. Clients compatible with X Protocol include MySQL Shell and MySQL 8.0 Connectors.

- Clients that communicate with a MySQL Server using X Protocol can use X DevAPI to develop applications. X DevAPI offers a modern programming interface with a simple yet powerful design which provides support for established industry standard concepts. This chapter explains how to get started using either the JavaScript or Python implementation of X DevAPI in MySQL Shell as a client. See [X DevAPI User Guide](#) for in-depth tutorials on using X DevAPI.

20.1 Interfaces to a MySQL Document Store

To work with MySQL as a document store, you use dedicated components and a choice of clients that support communicating with the MySQL server to develop document based applications.

- The following MySQL products support X Protocol and enable you to use X DevAPI in your chosen language to develop applications that communicate with a MySQL Server functioning as a document store:
 - MySQL Shell (which provides implementations of X DevAPI in JavaScript and Python)
 - Connector/C++
 - Connector/J
 - Connector/Node.js
 - Connector/NET
 - Connector/Python
- MySQL Shell is an interactive interface to MySQL supporting JavaScript, Python, or SQL modes. You can use MySQL Shell to prototype applications, execute queries and update data. [Installing MySQL Shell](#) has instructions to download and install MySQL Shell.
- The quick-start guides (tutorials) in this chapter help you to get started using MySQL Shell with MySQL as a document store.

The quick-start guide for JavaScript is here: [Section 20.3, “JavaScript Quick-Start Guide: MySQL Shell for Document Store”](#).

The quick-start guide for Python is here: [Section 20.4, “Python Quick-Start Guide: MySQL Shell for Document Store”](#).

- The *MySQL Shell User Guide* at [MySQL Shell 8.0](#) provides detailed information about configuring and using MySQL Shell.

20.2 Document Store Concepts

This section explains the concepts introduced as part of using MySQL as a document store.

- [JSON Document](#)
- [Collection](#)
- [CRUD Operations](#)

JSON Document

A JSON document is a data structure composed of key-value pairs and is the fundamental structure for using MySQL as document store. For example, the `world_x` schema (installed later in this chapter) contains this document:

```
{
  "GNP": 4834,
  "_id": "00005de917d8000000000000000023",
  "Code": "BWA",
  "Name": "Botswana",
  "IndepYear": 1966,
  "geography": {
    "Region": "Southern Africa",
    "Continent": "Africa",
    "SurfaceArea": 581730
  },
  "government": {
    "HeadOfState": "Festus G. Mogae",
    "GovernmentForm": "Republic"
  },
  "demographics": {
    "Population": 1622000,
    "LifeExpectancy": 39.29999923706055
  }
}
```

This document shows that the values of keys can be simple data types, such as integers or strings, but can also contain other documents, arrays, and lists of documents. For example, the `geography` key's value consists of multiple key-value pairs. A JSON document is represented internally using the MySQL binary JSON object, through the `JSON` MySQL datatype.

The most important differences between a document and the tables known from traditional relational databases are that the structure of a document does not have to be defined in advance, and a collection can contain multiple documents with different structures. Relational tables on the other hand require that their structure be defined, and all rows in the table must contain the same columns.

Collection

A collection is a container that is used to store JSON documents in a MySQL database. Applications usually run operations against a collection of documents, for example to find a specific document.

CRUD Operations

The four basic operations that can be issued against a collection are Create, Read, Update and Delete (CRUD). In terms of MySQL this means:

- Create a new document (insertion or addition)
- Read one or more documents (queries)
- Update one or more documents
- Delete one or more documents

20.3 JavaScript Quick-Start Guide: MySQL Shell for Document Store

This quick-start guide provides instructions to begin prototyping document store applications interactively with MySQL Shell. The guide includes the following topics:

- Introduction to MySQL functionality, MySQL Shell, and the `world_x` example schema.
- Operations to manage collections and documents.
- Operations to manage relational tables.

- Operations that apply to documents within tables.

To follow this quick-start guide you need a MySQL server with X Plugin installed, the default in 8.0, and MySQL Shell to use as the client. [MySQL Shell 8.0](#) provides more in-depth information about MySQL Shell. The Document Store is accessed using X DevAPI, and MySQL Shell provides this API in both JavaScript and Python.

Related Information

- [MySQL Shell 8.0](#) provides more in-depth information about MySQL Shell.
- See [Installing MySQL Shell](#) and [Section 20.5, “X Plugin”](#) for more information about the tools used in this quick-start guide.
- [X DevAPI User Guide](#) provides more examples of using X DevAPI to develop applications which use Document Store.
- A [Python](#) quick-start guide is also available.

20.3.1 MySQL Shell

This quick-start guide assumes a certain level of familiarity with MySQL Shell. The following section is a high level overview, see the MySQL Shell documentation for more information. MySQL Shell is a unified scripting interface to MySQL Server. It supports scripting in JavaScript and Python. JavaScript is the default processing mode.

Start MySQL Shell

After you have installed and started MySQL server, connect MySQL Shell to the server instance. You need to know the address of the MySQL server instance you plan to connect to. To be able to use the instance as a Document Store, the server instance must have X Plugin installed and you should connect to the server using X Protocol. For example to connect to the instance `ds1.example.com` on the default X Protocol port of 33060 use the network string `user@ds1.example.com:33060`.

Tip

If you connect to the instance using classic MySQL protocol, for example by using the default `port` of 3306 instead of the `mysqlx_port`, you *cannot* use the Document Store functionality shown in this tutorial. For example the `db` global object is not populated. To use the Document Store, always connect using X Protocol.

If MySQL Shell is not already running, open a terminal window and issue:

```
mysqlsh user@ds1.example.com:33060/world_x
```

Alternatively, if MySQL Shell is already running use the `\connect` command by issuing:

```
\connect user@ds1.example.com:33060/world_x
```

You need to specify the address of the MySQL server instance which you want to connect MySQL Shell to. For example in the previous example:

- `user` represents the user name of your MySQL account.
- `ds1.example.com` is the hostname of the server instance running MySQL. Replace this with the hostname of the MySQL server instance you are using as a Document Store.

- The default schema for this session is `world_x`. For instructions on setting up the `world_x` schema, see [Section 20.3.2, “Download and Import world_x Database”](#).

For more information, see [Section 4.2.5, “Connecting to the Server Using URI-Like Strings or Key-Value Pairs”](#).

Once MySQL Shell opens, the `mysql-js>` prompt indicates that the active language for this session is JavaScript.

```
mysql-js>
```

MySQL Shell supports input-line editing as follows:

- **left-arrow** and **right-arrow** keys move horizontally within the current input line.
- **up-arrow** and **down-arrow** keys move up and down through the set of previously entered lines.
- **Backspace** deletes the character before the cursor and typing new characters enters them at the cursor position.
- **Enter** sends the current input line to the server.

Get Help for MySQL Shell

Type `mysqlsh --help` at the prompt of your command interpreter for a list of command-line options.

```
mysqlsh --help
```

Type `\help` at the MySQL Shell prompt for a list of available commands and their descriptions.

```
mysql-js> \help
```

Type `\help` followed by a command name for detailed help about an individual MySQL Shell command. For example, to view help on the `\connect` command, issue:

```
mysql-js> \help \connect
```

Quit MySQL Shell

To quit MySQL Shell, issue the following command:

```
mysql-js> \quit
```

Related Information

- See [Interactive Code Execution](#) for an explanation of how interactive code execution works in MySQL Shell.
- See [Getting Started with MySQL Shell](#) to learn about session and connection alternatives.

20.3.2 Download and Import world_x Database

As part of this quick-start guide, an example schema is provided which is referred to as the `world_x` schema. Many of the examples demonstrate Document Store functionality using this schema. Start your MySQL server so that you can load the `world_x` schema, then follow these steps:

1. Download [world_x-db.zip](#).
2. Extract the installation archive to a temporary location such as `/tmp/`. Unpacking the archive results in a single file named `world_x.sql`.

3. Import the `world_x.sql` file to your server. You can either:

- Start MySQL Shell in SQL mode and import the file by issuing:

```
mysqlsh -u root --sql --file /tmp/world_x-db/world_x.sql
Enter password: ****
```

- Set MySQL Shell to SQL mode while it is running and source the schema file by issuing:

```
\sql
Switching to SQL mode... Commands end with ;
\source /tmp/world_x-db/world_x.sql
```

Replace `/tmp/` with the path to the `world_x.sql` file on your system. Enter your password if prompted. A non-root account can be used as long as the account has privileges to create new schemas.

The world_x Schema

The `world_x` example schema contains the following JSON collection and relational tables:

- Collection
 - `countryinfo`: Information about countries in the world.
- Tables
 - `country`: Minimal information about countries of the world.
 - `city`: Information about some of the cities in those countries.
 - `countrylanguage`: Languages spoken in each country.

Related Information

- [MySQL Shell Sessions](#) explains session types.

20.3.3 Documents and Collections

When you are using MySQL as a Document Store, collections are containers within a schema that you can create, list, and drop. Collections contain JSON documents that you can add, find, update, and remove.

The examples in this section use the `countryinfo` collection in the `world_x` schema. For instructions on setting up the `world_x` schema, see [Section 20.3.2, “Download and Import world_x Database”](#).

Documents

In MySQL, documents are represented as JSON objects. Internally, they are stored in an efficient binary format that enables fast lookups and updates.

- Simple document format for JavaScript:

```
{field1: "value", field2 : 10, "field 3": null}
```

An array of documents consists of a set of documents separated by commas and enclosed within `[` and `]` characters.

- Simple array of documents for JavaScript:

```
[{"Name": "Aruba", "Code": "ABW"}, {"Name": "Angola", "Code": "AGO"}]
```

MySQL supports the following JavaScript value types in JSON documents:

- numbers (integer and floating point)
- strings
- boolean (False and True)
- null
- arrays of more JSON values
- nested (or embedded) objects of more JSON values

Collections

Collections are containers for documents that share a purpose and possibly share one or more indexes. Each collection has a unique name and exists within a single schema.

The term schema is equivalent to a database, which means a group of database objects as opposed to a relational schema, used to enforce structure and constraints over data. A schema does not enforce conformity on the documents in a collection.

In this quick-start guide:

- Basic objects include:

| Object form | Description |
|----------------------------------|---|
| <code>db</code> | <code>db</code> is a global variable assigned to the current active schema. When you want to run operations against the schema, for example to retrieve a collection, you use methods available for the <code>db</code> variable. |
| <code>db.getCollections()</code> | <code>db.getCollections()</code> returns a list of collections in the schema. Use the list to get references to collection objects, iterate over them, and so on. |

- Basic operations scoped by collections include:

| Operation form | Description |
|-------------------------------|---|
| <code>db.name.add()</code> | The <code>add()</code> method inserts one document or a list of documents into the named collection. |
| <code>db.name.find()</code> | The <code>find()</code> method returns some or all documents in the named collection. |
| <code>db.name.modify()</code> | The <code>modify()</code> method updates documents in the named collection. |
| <code>db.name.remove()</code> | The <code>remove()</code> method deletes one document or a list of documents from the named collection. |

Related Information

- See [Working with Collections](#) for a general overview.

- [CRUD EBNF Definitions](#) provides a complete list of operations.

20.3.3.1 Create, List, and Drop Collections

In MySQL Shell, you can create new collections, get a list of the existing collections in a schema, and remove an existing collection from a schema. Collection names are case-sensitive and each collection name must be unique.

Confirm the Schema

To show the value that is assigned to the schema variable, issue:

```
mysql-js> db
```

If the schema value is not `Schema:world_x`, then set the `db` variable by issuing:

```
mysql-js> \use world_x
```

Create a Collection

To create a new collection in an existing schema, use the `db` object's `createCollection()` method. The following example creates a collection called `flags` in the `world_x` schema.

```
mysql-js> db.createCollection("flags")
```

The method returns a collection object.

```
<Collection:flags>
```

List Collections

To display all collections in the `world_x` schema, use the `db` object's `getCollections()` method. Collections returned by the server you are currently connected to appear between brackets.

```
mysql-js> db.getCollections()
[
  <Collection:countryinfo>,
  <Collection:flags>
]
```

Drop a Collection

To drop an existing collection from a schema, use the `db` object's `dropCollection()` method. For example, to drop the `flags` collection from the current schema, issue:

```
mysql-js> db.dropCollection("flags")
```

The `dropCollection()` method is also used in MySQL Shell to drop a relational table from a schema.

Related Information

- See [Collection Objects](#) for more examples.

20.3.3.2 Working with Collections

To work with the collections in a schema, use the `db` global object to access the current schema. In this example we are using the `world_x` schema imported previously, and the `countryinfo` collection.

Therefore, the format of the operations you issue is `db.collection_name.operation`, where `collection_name` is the name of the collection which the operation is executed against. In the following examples, the operations are executed against the `countryinfo` collection.

Add a Document

Use the `add()` method to insert one document or a list of documents into an existing collection. Insert the following document into the `countryinfo` collection. As this is multi-line content, press **Enter** twice to insert the document.

```
mysql-js> db.countryinfo.add(
  {
    GNP: .6,
    IndepYear: 1967,
    Name: "Sealand",
    Code: "SEA",
    demographics: {
      LifeExpectancy: 79,
      Population: 27
    },
    geography: {
      Continent: "Europe",
      Region: "British Islands",
      SurfaceArea: 193
    },
    government: {
      GovernmentForm: "Monarchy",
      HeadOfState: "Michael Bates"
    }
  }
)
```

The method returns the status of the operation. You can verify the operation by searching for the document. For example:

```
mysql-js> db.countryinfo.find("Name = 'Sealand'")
{
  "GNP": 0.6,
  "_id": "00005e2ff4af00000000000000f4",
  "Name": "Sealand",
  "Code": "SEA",
  "IndepYear": 1967,
  "geography": {
    "Region": "British Islands",
    "Continent": "Europe",
    "SurfaceArea": 193
  },
  "government": {
    "HeadOfState": "Michael Bates",
    "GovernmentForm": "Monarchy"
  },
  "demographics": {
    "Population": 27,
    "LifeExpectancy": 79
  }
}
```

Note that in addition to the fields specified when the document was added, there is one more field, the `_id`. Each document requires an identifier field called `_id`. The value of the `_id` field must be unique among all documents in the same collection. In MySQL 8.0.11 and higher, document IDs are generated by the server, not the client, so MySQL Shell does not automatically set an `_id` value. A MySQL server at 8.0.11 or higher sets an `_id` value if the document does not contain the `_id` field. A MySQL server at an earlier 8.0 release or at 5.7 does not set an `_id` value in this situation, so you must specify it explicitly. If

you do not, MySQL Shell returns error 5115 `Document is missing a required field`. For more information see [Understanding Document IDs](#).

Related Information

- See [CollectionAddFunction](#) for the full syntax definition.
- See [Understanding Document IDs](#).

20.3.3.3 Find Documents

You can use the `find()` method to query for and return documents from a collection in a schema. MySQL Shell provides additional methods to use with the `find()` method to filter and sort the returned documents.

MySQL provides the following operators to specify search conditions: `OR (| |)`, `AND (&&)`, `XOR`, `IS`, `NOT`, `BETWEEN`, `IN`, `LIKE`, `!=`, `<>`, `>`, `>=`, `<`, `<=`, `&`, `|`, `<<`, `>>`, `+`, `-`, `*`, `/`, `~`, and `%`.

Find All Documents in a Collection

To return all documents in a collection, use the `find()` method without specifying search conditions. For example, the following operation returns all documents in the `countryinfo` collection.

```
mysql-js> db.countryinfo.find()
[
  {
    "GNP": 828,
    "Code": "ABW",
    "Name": "Aruba",
    "IndepYear": null,
    "geography": {
      "Continent": "North America",
      "Region": "Caribbean",
      "SurfaceArea": 193
    },
    "government": {
      "GovernmentForm": "Nonmetropolitan Territory of The Netherlands",
      "HeadOfState": "Beatrix"
    },
    "demographics": {
      "LifeExpectancy": 78.4000015258789,
      "Population": 103000
    },
    ...
  }
]
240 documents in set (0.00 sec)
```

The method produces results that contain operational information in addition to all documents in the collection.

An empty set (no matching documents) returns the following information:

```
Empty set (0.00 sec)
```

Filter Searches

You can include search conditions with the `find()` method. The syntax for expressions that form a search condition is the same as that of traditional MySQL [Chapter 12, Functions and Operators](#). You must enclose all expressions in quotes. For the sake of brevity, some of the examples do not display output.

A simple search condition could consist of the `Name` field and a value we know is in a document. The following example returns a single document:

```
mysql-js> db.countryinfo.find("Name = 'Australia'")
[
  {
    "GNP": 351182,
    "Code": "AUS",
    "Name": "Australia",
    "IndepYear": 1901,
    "geography": {
      "Continent": "Oceania",
      "Region": "Australia and New Zealand",
      "SurfaceArea": 7741220
    },
    "government": {
      "GovernmentForm": "Constitutional Monarchy, Federation",
      "HeadOfState": "Elisabeth II"
    },
    "demographics": {
      "LifeExpectancy": 79.80000305175781,
      "Population": 18886000
    }
  }
]
```

The following example searches for all countries that have a GNP higher than \$500 billion. The `countryinfo` collection measures GNP in units of million.

```
mysql-js> db.countryinfo.find("GNP > 500000")
...[output removed]
10 documents in set (0.00 sec)
```

The `Population` field in the following query is embedded within the `demographics` object. To access the embedded field, use a period between `demographics` and `Population` to identify the relationship. Document and field names are case-sensitive.

```
mysql-js> db.countryinfo.find("GNP > 500000 and demographics.Population < 10000000")
...[output removed]
6 documents in set (0.00 sec)
```

Arithmetic operators in the following expression are used to query for countries with a GNP per capita higher than \$30000. Search conditions can include arithmetic operators and most MySQL functions.

Note

Seven documents in the `countryinfo` collection have a population value of zero. Therefore warning messages appear at the end of the output.

```
mysql-js> db.countryinfo.find("GNP*1000000/demographics.Population > 30000")
...[output removed]
9 documents in set, 7 warnings (0.00 sec)
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
```

You can separate a value from the search condition by using the `bind()` method. For example, instead of specifying a hard-coded country name as the condition, substitute a named placeholder consisting of a colon followed by a name that begins with a letter, such as `country`. Then use the `bind(placeholder, value)` method as follows:

```
mysql-js> db.countryinfo.find("Name = :country").bind("country", "Italy")
{
  "GNP": 1161755,
  "_id": "00005de917d800000000000000006a",
  "Code": "ITA",
  "Name": "Italy",
  "Airports": [],
  "IndepYear": 1861,
  "geography": {
    "Region": "Southern Europe",
    "Continent": "Europe",
    "SurfaceArea": 301316
  },
  "government": {
    "HeadOfState": "Carlo Azeglio Ciampi",
    "GovernmentForm": "Republic"
  },
  "demographics": {
    "Population": 57680000,
    "LifeExpectancy": 79
  }
}
1 document in set (0.01 sec)
```

Tip

Within a program, binding enables you to specify placeholders in your expressions, which are filled in with values before execution and can benefit from automatic escaping, as appropriate.

Always use binding to sanitize input. Avoid introducing values in queries using string concatenation, which can produce invalid input and, in some cases, can cause security issues.

You can use placeholders and the `bind()` method to create saved searches which you can then call with different values. For example to create a saved search for a country:

```
mysql-js> var myFind = db.countryinfo.find("Name = :country")
mysql-js> myFind.bind('country', 'France')
{
  "GNP": 1424285,
  "_id": "00005de917d8000000000000000048",
  "Code": "FRA",
  "Name": "France",
  "IndepYear": 843,
  "geography": {
    "Region": "Western Europe",
    "Continent": "Europe",
    "SurfaceArea": 551500
  },
  "government": {
    "HeadOfState": "Jacques Chirac",
    "GovernmentForm": "Republic"
  },
  "demographics": {
    "Population": 59225700,
    "LifeExpectancy": 78.80000305175781
  }
}
1 document in set (0.0028 sec)

mysql-js> myFind.bind('country', 'Germany')
{
  "GNP": 2133367,
  "_id": "00005de917d8000000000000000038",
```

```

    "Code": "DEU",
    "Name": "Germany",
    "IndepYear": 1955,
    "geography": {
      "Region": "Western Europe",
      "Continent": "Europe",
      "SurfaceArea": 357022
    },
    "government": {
      "HeadOfState": "Johannes Rau",
      "GovernmentForm": "Federal Republic"
    },
    "demographics": {
      "Population": 82164700,
      "LifeExpectancy": 77.4000015258789
    }
  }
}
1 document in set (0.0026 sec)

```

Project Results

You can return specific fields of a document, instead of returning all the fields. The following example returns the GNP and Name fields of all documents in the `countryinfo` collection matching the search conditions.

Use the `fields()` method to pass the list of fields to return.

```

mysql-js> db.countryinfo.find("GNP > 5000000").fields(["GNP", "Name"])
[
  {
    "GNP": 8510700,
    "Name": "United States"
  }
]
1 document in set (0.00 sec)

```

In addition, you can alter the returned documents—adding, renaming, nesting and even computing new field values—with an expression that describes the document to return. For example, alter the names of the fields with the following expression to return only two documents.

```

mysql-js> db.countryinfo.find().fields(
mysqlx.expr('{ "Name": upper(Name), "GNPPerCapita": GNP*1000000/demographics.Population}')).limit(2)
{
  "Name": "ARUBA",
  "GNPPerCapita": 8038.834951456311
}
{
  "Name": "AFGHANISTAN",
  "GNPPerCapita": 263.0281690140845
}

```

Limit, Sort, and Skip Results

You can apply the `limit()`, `sort()`, and `skip()` methods to manage the number and order of documents returned by the `find()` method.

To specify the number of documents included in a result set, append the `limit()` method with a value to the `find()` method. The following query returns the first five documents in the `countryinfo` collection.

```

mysql-js> db.countryinfo.find().limit(5)
... [output removed]
5 documents in set (0.00 sec)

```

To specify an order for the results, append the `sort()` method to the `find()` method. Pass to the `sort()` method a list of one or more fields to sort by and, optionally, the descending (`desc`) or ascending (`asc`) attribute as appropriate. Ascending order is the default order type.

For example, the following query sorts all documents by the `IndepYear` field and then returns the first eight documents in descending order.

```
mysql-js> db.countryinfo.find().sort(["IndepYear desc"]).limit(8)
... [output removed]
8 documents in set (0.00 sec)
```

By default, the `limit()` method starts from the first document in the collection. You can use the `skip()` method to change the starting document. For example, to ignore the first document and return the next eight documents matching the condition, pass to the `skip()` method a value of 1.

```
mysql-js> db.countryinfo.find().sort(["IndepYear desc"]).limit(8).skip(1)
... [output removed]
8 documents in set (0.00 sec)
```

Related Information

- The [MySQL Reference Manual](#) provides detailed documentation on functions and operators.
- See [CollectionFindFunction](#) for the full syntax definition.

20.3.3.4 Modify Documents

You can use the `modify()` method to update one or more documents in a collection. The X DevAPI provides additional methods for use with the `modify()` method to:

- Set and unset fields within documents.
- Append, insert, and delete arrays.
- Bind, limit, and sort the documents to be modified.

Set and Unset Document Fields

The `modify()` method works by filtering a collection to include only the documents to be modified and then applying the operations that you specify to those documents.

In the following example, the `modify()` method uses the search condition to identify the document to change and then the `set()` method replaces two values within the nested `demographics` object.

```
mysql-js> db.countryinfo.modify("Code = 'SEA']").set(
"demographics", {"LifeExpectancy": 78, "Population": 28})
```

After you modify a document, use the `find()` method to verify the change.

To remove content from a document, use the `modify()` and `unset()` methods. For example, the following query removes the `GNP` from a document that matches the search condition.

```
mysql-js> db.countryinfo.modify("Name = 'Sealand']").unset("GNP")
```

Use the `find()` method to verify the change.

```
mysql-js> db.countryinfo.find("Name = 'Sealand'")
{
  "_id": "00005e2ff4af00000000000000f4",
  "Name": "Sealand",
```

```

"Code": "SEA",
"IndepYear": 1967,
"geography": {
  "Region": "British Islands",
  "Continent": "Europe",
  "SurfaceArea": 193
},
"government": {
  "HeadOfState": "Michael Bates",
  "GovernmentForm": "Monarchy"
},
"demographics": {
  "Population": 27,
  "LifeExpectancy": 79
}
}

```

Append, Insert, and Delete Arrays

To append an element to an array field, or insert, or delete elements in an array, use the `arrayAppend()`, `arrayInsert()`, or `arrayDelete()` methods. The following examples modify the `countryinfo` collection to enable tracking of international airports.

The first example uses the `modify()` and `set()` methods to create a new `Airports` field in all documents.

Caution

Use care when you modify documents without specifying a search condition; doing so modifies all documents in the collection.

```
mysql-js> db.countryinfo.modify("true").set("Airports", [])
```

With the `Airports` field added, the next example uses the `arrayAppend()` method to add a new airport to one of the documents. `$.Airports` in the following example represents the `Airports` field of the current document.

```
mysql-js> db.countryinfo.modify("Name = 'France'").arrayAppend("$.Airports", "ORY")
```

Use `find()` to see the change.

```

mysql-js> db.countryinfo.find("Name = 'France'")
{
  "GNP": 1424285,
  "_id": "00005de917d80000000000000048",
  "Code": "FRA",
  "Name": "France",
  "Airports": [
    "ORY"
  ],
  "IndepYear": 843,
  "geography": {
    "Region": "Western Europe",
    "Continent": "Europe",
    "SurfaceArea": 551500
  },
  "government": {
    "HeadOfState": "Jacques Chirac",
    "GovernmentForm": "Republic"
  },
  "demographics": {
    "Population": 59225700,
    "LifeExpectancy": 78.80000305175781
  }
}

```

To insert an element at a different position in the array, use the `arrayInsert()` method to specify which index to insert in the path expression. In this case, the index is 0, or the first element in the array.

```
mysql-js> db.countryinfo.modify("Name = 'France'").arrayInsert("$.Airports[0]", "CDG")
```

To delete an element from the array, you must pass to the `arrayDelete()` method the index of the element to be deleted.

```
mysql-js> db.countryinfo.modify("Name = 'France'").arrayDelete("$.Airports[1]")
```

Related Information

- The [MySQL Reference Manual](#) provides instructions to help you search for and modify JSON values.
- See [CollectionModifyFunction](#) for the full syntax definition.

20.3.3.5 Remove Documents

You can use the `remove()` method to delete some or all documents from a collection in a schema. The X DevAPI provides additional methods for use with the `remove()` method to filter and sort the documents to be removed.

Remove Documents Using Conditions

The following example passes a search condition to the `remove()` method. All documents matching the condition are removed from the `countryinfo` collection. In this example, one document matches the condition.

```
mysql-js> db.countryinfo.remove("Code = 'SEA'")
```

Remove the First Document

To remove the first document in the `countryinfo` collection, use the `limit()` method with a value of 1.

```
mysql-js> db.countryinfo.remove("true").limit(1)
```

Remove the Last Document in an Order

The following example removes the last document in the `countryinfo` collection by country name.

```
mysql-js> db.countryinfo.remove("true").sort(["Name desc"]).limit(1)
```

Remove All Documents in a Collection

You can remove all documents in a collection. To do so, use the `remove("true")` method without specifying a search condition.

Caution

Use care when you remove documents without specifying a search condition. This action deletes all documents from the collection.

Alternatively, use the `db.drop_collection('countryinfo')` operation to delete the `countryinfo` collection.

Related Information

- See [CollectionRemoveFunction](#) for the full syntax definition.

- See [Section 20.3.2, “Download and Import world_x Database”](#) for instructions to recreate the `world_x` schema.

20.3.3.6 Create and Drop Indexes

Indexes are used to find documents with specific field values quickly. Without an index, MySQL must begin with the first document and then read through the entire collection to find the relevant fields. The larger the collection, the more this costs. If a collection is large and queries on a specific field are common, then consider creating an index on a specific field inside a document.

For example, the following query performs better with an index on the Population field:

```
mysql-js> db.countryinfo.find("demographics.Population < 100")
...[output removed]
8 documents in set (0.00 sec)
```

The `createIndex()` method creates an index that you can define with a JSON document that specifies which fields to use. This section is a high level overview of indexing. For more information see [Indexing Collections](#).

Add a Nonunique Index

To create a nonunique index, pass an index name and the index information to the `createIndex()` method. Duplicate index names are prohibited.

The following example specifies an index named `popul`, defined against the `Population` field from the `demographics` object, indexed as an `Integer` numeric value. The final parameter indicates whether the field should require the `NOT NULL` constraint. If the value is `false`, the field can contain `NULL` values. The index information is a JSON document with details of one or more fields to include in the index. Each field definition must include the full document path to the field, and specify the type of the field.

```
mysql-js> db.countryinfo.createIndex("popul", {fields:
[{"field": '$.demographics.Population', type: 'INTEGER'}]})
```

Here, the index is created using an integer numeric value. Further options are available, including options for use with GeoJSON data. You can also specify the type of index, which has been omitted here because the default type “index” is appropriate.

Add a Unique Index

To create a unique index, pass an index name, the index definition, and the index type “unique” to the `createIndex()` method. This example shows a unique index created on the country name (`"Name"`), which is another common field in the `countryinfo` collection to index. In the index field description, `"TEXT(40)"` represents the number of characters to index, and `"required": True` specifies that the field is required to exist in the document.

```
mysql-js> db.countryinfo.createIndex("name",
{"fields": [{"field": "$.Name", "type": "TEXT(40)", "required": true}], "unique": true})
```

Drop an Index

To drop an index, pass the name of the index to drop to the `dropIndex()` method. For example, you can drop the “popul” index as follows:

```
mysql-js> db.countryinfo.dropIndex("popul")
```

Related Information

- See [Indexing Collections](#) for more information.

- See [Defining an Index](#) for more information on the JSON document that defines an index.
- See [Collection Index Management Functions](#) for the full syntax definition.

20.3.4 Relational Tables

You can also use X DevAPI to work with relational tables. In MySQL, each relational table is associated with a particular storage engine. The examples in this section use [InnoDB](#) tables in the `world_x` schema.

Confirm the Schema

To show the schema that is assigned to the `db` global variable, issue `db`.

```
mysql-js> db
<Schema:world_x>
```

If the returned value is not `Schema:world_x`, set the `db` variable as follows:

```
mysql-js> \use world_x
Schema `world_x` accessible through db.
```

Show All Tables

To display all relational tables in the `world_x` schema, use the `getTables()` method on the `db` object.

```
mysql-js> db.getTables()
{
  "city": <Table:city>,
  "country": <Table:country>,
  "countrylanguage": <Table:countrylanguage>
}
```

Basic Table Operations

Basic operations scoped by tables include:

| Operation form | Description |
|-------------------------------|--|
| <code>db.name.insert()</code> | The <code>insert()</code> method inserts one or more records into the named table. |
| <code>db.name.select()</code> | The <code>select()</code> method returns some or all records in the named table. |
| <code>db.name.update()</code> | The <code>update()</code> method updates records in the named table. |
| <code>db.name.delete()</code> | The <code>delete()</code> method deletes one or more records from the named table. |

Related Information

- See [Working with Relational Tables](#) for more information.
- [CRUD EBNF Definitions](#) provides a complete list of operations.
- See [Section 20.3.2, "Download and Import world_x Database"](#) for instructions on setting up the `world_x` schema sample.

20.3.4.1 Insert Records into Tables

You can use the `insert()` method with the `values()` method to insert records into an existing relational table. The `insert()` method accepts individual columns or all columns in the table. Use one or more `values()` methods to specify the values to be inserted.

Insert a Complete Record

To insert a complete record, pass to the `insert()` method all columns in the table. Then pass to the `values()` method one value for each column in the table. For example, to add a new record to the city table in the `world_x` schema, insert the following record and press **Enter** twice.

```
mysql-js> db.city.insert("ID", "Name", "CountryCode", "District", "Info").values(
None, "Olympia", "USA", "Washington", '{"Population": 5000}')
```

The city table has five columns: ID, Name, CountryCode, District, and Info. Each value must match the data type of the column it represents.

Insert a Partial Record

The following example inserts values into the ID, Name, and CountryCode columns of the city table.

```
mysql-js> db.city.insert("ID", "Name", "CountryCode").values(
None, "Little Falls", "USA").values(None, "Happy Valley", "USA")
```

When you specify columns using the `insert()` method, the number of values must match the number of columns. In the previous example, you must supply three values to match the three columns specified.

Related Information

- See [TableInsertFunction](#) for the full syntax definition.

20.3.4.2 Select Tables

You can use the `select()` method to query for and return records from a table in a database. The X DevAPI provides additional methods to use with the `select()` method to filter and sort the returned records.

MySQL provides the following operators to specify search conditions: `OR (| |)`, `AND (&&)`, `XOR`, `IS`, `NOT`, `BETWEEN`, `IN`, `LIKE`, `!=`, `<>`, `>`, `>=`, `<`, `<=`, `&`, `|`, `<<`, `>>`, `+`, `-`, `*`, `/`, `~`, and `%`.

Select All Records

To issue a query that returns all records from an existing table, use the `select()` method without specifying search conditions. The following example selects all records from the city table in the `world_x` database.

Note

Limit the use of the empty `select()` method to interactive statements. Always use explicit column-name selections in your application code.

```
mysql-js> db.city.select()
+-----+-----+-----+-----+-----+
| ID | Name      | CountryCode | District | Info                                     |
+-----+-----+-----+-----+-----+
| 1 | Kabul    | AFG         | Kabul    | {"Population": 1780000}                 |
| 2 | Qandahar | AFG         | Qandahar | {"Population": 237500}                  |
| 3 | Herat    | AFG         | Herat    | {"Population": 186800}                  |
...  ...    ...         ...      ...
```

```
| 4079 | Rafah      | PSE      | Rafah      | {"Population": 92020} |
+-----+-----+-----+-----+-----+
4082 rows in set (0.01 sec)
```

An empty set (no matching records) returns the following information:

```
Empty set (0.00 sec)
```

Filter Searches

To issue a query that returns a set of table columns, use the `select()` method and specify the columns to return between square brackets. This query returns the Name and CountryCode columns from the city table.

```
mysql-js> db.city.select(["Name", "CountryCode"])
+-----+-----+
| Name          | CountryCode |
+-----+-----+
| Kabul         | AFG         |
| Qandahar      | AFG         |
| Herat         | AFG         |
| Mazar-e-Sharif | AFG         |
| Amsterdam     | NLD         |
| ...          | ...         |
| Rafah        | PSE         |
| Olympia       | USA         |
| Little Falls  | USA         |
| Happy Valley  | USA         |
+-----+-----+
4082 rows in set (0.00 sec)
```

To issue a query that returns rows matching specific search conditions, use the `where()` method to include those conditions. For example, the following example returns the names and country codes of the cities that start with the letter Z.

```
mysql-js> db.city.select(["Name", "CountryCode"]).where("Name like 'Z%'")
+-----+-----+
| Name          | CountryCode |
+-----+-----+
| Zaanstad      | NLD         |
| Zoetermeer    | NLD         |
| Zwolle        | NLD         |
| Zenica        | BIH         |
| Zagazig       | EGY         |
| Zaragoza      | ESP         |
| Zamboanga     | PHL         |
| Zahedan       | IRN         |
| Zanzan        | IRN         |
| Zabol         | IRN         |
| Zama          | JPN         |
| Zhezqazghan   | KAZ         |
| Zhengzhou     | CHN         |
| ...          | ...         |
| Zeleznogorsk  | RUS         |
+-----+-----+
59 rows in set (0.00 sec)
```

You can separate a value from the search condition by using the `bind()` method. For example, instead of using `"Name = 'Z%' "` as the condition, substitute a named placeholder consisting of a colon followed by a name that begins with a letter, such as `name`. Then include the placeholder and value in the `bind()` method as follows:

```
mysql-js> db.city.select(["Name", "CountryCode"]).
  where("Name like :name").bind("name", "Z%")
```

Tip

Within a program, binding enables you to specify placeholders in your expressions, which are filled in with values before execution and can benefit from automatic escaping, as appropriate.

Always use binding to sanitize input. Avoid introducing values in queries using string concatenation, which can produce invalid input and, in some cases, can cause security issues.

Project Results

To issue a query using the `AND` operator, add the operator between search conditions in the `where()` method.

```
mysql-js> db.city.select(["Name", "CountryCode"]).where(
  "Name like 'Z%' and CountryCode = 'CHN'")
+-----+-----+
| Name          | CountryCode |
+-----+-----+
| Zhengzhou    | CHN         |
| Zibo          | CHN         |
| Zhangjiakou  | CHN         |
| Zhuzhou      | CHN         |
| Zhangjiang   | CHN         |
| Zigong       | CHN         |
| Zaozhuang    | CHN         |
| ...          | ...         |
| Zhangjiagang | CHN         |
+-----+-----+
22 rows in set (0.01 sec)
```

To specify multiple conditional operators, you can enclose the search conditions in parenthesis to change the operator precedence. The following example demonstrates the placement of `AND` and `OR` operators.

```
mysql-js> db.city.select(["Name", "CountryCode"]).
  where("Name like 'Z%' and (CountryCode = 'CHN' or CountryCode = 'RUS')")
+-----+-----+
| Name          | CountryCode |
+-----+-----+
| Zhengzhou    | CHN         |
| Zibo          | CHN         |
| Zhangjiakou  | CHN         |
| Zhuzhou      | CHN         |
| ...          | ...         |
| Zeleznogorsk | RUS         |
+-----+-----+
29 rows in set (0.01 sec)
```

Limit, Order, and Offset Results

You can apply the `limit()`, `orderBy()`, and `offset()` methods to manage the number and order of records returned by the `select()` method.

To specify the number of records included in a result set, append the `limit()` method with a value to the `select()` method. For example, the following query returns the first five records in the country table.

```
mysql-js> db.country.select(["Code", "Name"]).limit(5)
+-----+-----+
| Code | Name          |
+-----+-----+
| ABW  | Aruba         |
| AFG  | Afghanistan   |
```

```
| AGO | Angola |
| AIA | Anguilla |
| ALB | Albania |
+-----+-----+
5 rows in set (0.00 sec)
```

To specify an order for the results, append the `orderBy()` method to the `select()` method. Pass to the `orderBy()` method a list of one or more columns to sort by and, optionally, the descending (`desc`) or ascending (`asc`) attribute as appropriate. Ascending order is the default order type.

For example, the following query sorts all records by the Name column and then returns the first three records in descending order .

```
mysql-js> db.country.select(["Code", "Name"]).orderBy(["Name desc"]).limit(3)
+-----+-----+
| Code | Name |
+-----+-----+
| ZWE | Zimbabwe |
| ZMB | Zambia |
| YUG | Yugoslavia |
+-----+-----+
3 rows in set (0.00 sec)
```

By default, the `limit()` method starts from the first record in the table. You can use the `offset()` method to change the starting record. For example, to ignore the first record and return the next three records matching the condition, pass to the `offset()` method a value of 1.

```
mysql-js> db.country.select(["Code", "Name"]).orderBy(["Name desc"]).limit(3).offset(1)
+-----+-----+
| Code | Name |
+-----+-----+
| ZMB | Zambia |
| YUG | Yugoslavia |
| YEM | Yemen |
+-----+-----+
3 rows in set (0.00 sec)
```

Related Information

- The [MySQL Reference Manual](#) provides detailed documentation on functions and operators.
- See [TableSelectFunction](#) for the full syntax definition.

20.3.4.3 Update Tables

You can use the `update()` method to modify one or more records in a table. The `update()` method works by filtering a query to include only the records to be updated and then applying the operations you specify to those records.

To replace a city name in the city table, pass to the `set()` method the new city name. Then, pass to the `where()` method the city name to locate and replace. The following example replaces the city Peking with Beijing.

```
mysql-js> db.city.update().set("Name", "Beijing").where("Name = 'Peking'")
```

Use the `select()` method to verify the change.

```
mysql-js> db.city.select(["ID", "Name", "CountryCode", "District", "Info"]).where("Name = 'Beijing'")
+-----+-----+-----+-----+-----+
| ID | Name | CountryCode | District | Info |
+-----+-----+-----+-----+-----+
| 1891 | Beijing | CHN | Peking | {"Population": 7472000} |
```

```
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

Related Information

- See [TableUpdateFunction](#) for the full syntax definition.

20.3.4.4 Delete Tables

You can use the `delete()` method to remove some or all records from a table in a database. The X DevAPI provides additional methods to use with the `delete()` method to filter and order the records to be deleted.

Delete Records Using Conditions

The following example passes search conditions to the `delete()` method. All records matching the condition are deleted from the city table. In this example, one record matches the condition.

```
mysql-js> db.city.delete().where("Name = 'Olympia'")
```

Delete the First Record

To delete the first record in the city table, use the `limit()` method with a value of 1.

```
mysql-js> db.city.delete().limit(1)
```

Delete All Records in a Table

You can delete all records in a table. To do so, use the `delete()` method without specifying a search condition.

Caution

Use care when you delete records without specifying a search condition; doing so deletes all records from the table.

Drop a Table

The `dropCollection()` method is also used in MySQL Shell to drop a relational table from a database. For example, to drop the `citytest` table from the `world_x` database, issue:

```
mysql-js> session.dropCollection("world_x", "citytest")
```

Related Information

- See [TableDeleteFunction](#) for the full syntax definition.
- See [Section 20.3.2, “Download and Import world_x Database”](#) for instructions to recreate the `world_x` database.

20.3.5 Documents in Tables

In MySQL, a table may contain traditional relational data, JSON values, or both. You can combine traditional data with JSON documents by storing the documents in columns having a native `JSON` data type.

Examples in this section use the city table in the `world_x` schema.

city Table Description

The city table has five columns (or fields).

| Field | Type | Null | Key | Default | Extra |
|-------------|----------|------|-----|---------|----------------|
| ID | int(11) | NO | PRI | null | auto_increment |
| Name | char(35) | NO | | | |
| CountryCode | char(3) | NO | | | |
| District | char(20) | NO | | | |
| Info | json | YES | | null | |

Insert a Record

To insert a document into the column of a table, pass to the `values()` method a well-formed JSON document in the correct order. In the following example, a document is passed as the final value to be inserted into the Info column.

```
mysql-js> db.city.insert().values(
None, "San Francisco", "USA", "California", '{"Population":830000}')
```

Select a Record

You can issue a query with a search condition that evaluates document values in the expression.

```
mysql-js> db.city.select(["ID", "Name", "CountryCode", "District", "Info"]).where(
"CountryCode = :country and Info->'$.Population' > 1000000").bind(
'country', 'USA')
```

| ID | Name | CountryCode | District | Info |
|------|--------------|-------------|--------------|-------------------------|
| 3793 | New York | USA | New York | {"Population": 8008278} |
| 3794 | Los Angeles | USA | California | {"Population": 3694820} |
| 3795 | Chicago | USA | Illinois | {"Population": 2896016} |
| 3796 | Houston | USA | Texas | {"Population": 1953631} |
| 3797 | Philadelphia | USA | Pennsylvania | {"Population": 1517550} |
| 3798 | Phoenix | USA | Arizona | {"Population": 1321045} |
| 3799 | San Diego | USA | California | {"Population": 1223400} |
| 3800 | Dallas | USA | Texas | {"Population": 1188580} |
| 3801 | San Antonio | USA | Texas | {"Population": 1144646} |

9 rows in set (0.01 sec)

Related Information

- See [Working with Relational Tables and Documents](#) for more information.
- See [Section 11.5, "The JSON Data Type"](#) for a detailed description of the data type.

20.4 Python Quick-Start Guide: MySQL Shell for Document Store

This quick-start guide provides instructions to begin prototyping document store applications interactively with MySQL Shell. The guide includes the following topics:

- Introduction to MySQL functionality, MySQL Shell, and the `world_x` example schema.
- Operations to manage collections and documents.
- Operations to manage relational tables.

- Operations that apply to documents within tables.

To follow this quick-start guide you need a MySQL server with X Plugin installed, the default in 8.0, and MySQL Shell to use as the client. MySQL Shell includes X DevAPI, implemented in both JavaScript and Python, which enables you to connect to the MySQL server instance using X Protocol and use the server as a Document Store.

Related Information

- [MySQL Shell 8.0](#) provides more in-depth information about MySQL Shell.
- See [Installing MySQL Shell](#) and [Section 20.5, “X Plugin”](#) for more information about the tools used in this quick-start guide.
- See [Supported Languages](#) for more information about the languages MySQL Shell supports.
- [X DevAPI User Guide](#) provides more examples of using X DevAPI to develop applications which use MySQL as a Document Store.
- A [JavaScript](#) quick-start guide is also available.

20.4.1 MySQL Shell

This quick-start guide assumes a certain level of familiarity with MySQL Shell. The following section is a high level overview, see the MySQL Shell documentation for more information. MySQL Shell is a unified scripting interface to MySQL Server. It supports scripting in JavaScript and Python. JavaScript is the default processing mode.

Start MySQL Shell

After you have installed and started MySQL server, connect MySQL Shell to the server instance. You need to know the address of the MySQL server instance you plan to connect to. To be able to use the instance as a Document Store, the server instance must have X Plugin installed and you should connect to the server using X Protocol. For example to connect to the instance `ds1.example.com` on the default X Protocol port of 33060 use the network string `user@ds1.example.com:33060`.

Tip

If you connect to the instance using classic MySQL protocol, for example by using the default `port` of 3306 instead of the `mysqlx_port`, you *cannot* use the Document Store functionality shown in this tutorial. For example the `db` global object is not populated. To use the Document Store, always connect using X Protocol.

If MySQL Shell is not already running, open a terminal window and issue:

```
mysqlsh user@ds1.example.com:33060/world_x
```

Alternatively, if MySQL Shell is already running use the `\connect` command by issuing:

```
\connect user@ds1.example.com:33060/world_x
```

You need to specify the address of the MySQL server instance which you want to connect MySQL Shell to. For example in the previous example:

- `user` represents the user name of your MySQL account.

- `ds1.example.com` is the hostname of the server instance running MySQL. Replace this with the hostname of the MySQL server instance you are using as a Document Store.
- The default schema for this session is `world_x`. For instructions on setting up the `world_x` schema, see [Section 20.4.2, “Download and Import world_x Database”](#).

For more information, see [Section 4.2.5, “Connecting to the Server Using URI-Like Strings or Key-Value Pairs”](#).

Once MySQL Shell opens, the `mysql-js>` prompt indicates that the active language for this session is JavaScript. To switch MySQL Shell to Python mode, use the `\py` command.

```
mysql-js> \py
Switching to Python mode...
mysql-py>
```

MySQL Shell supports input-line editing as follows:

- **left-arrow** and **right-arrow** keys move horizontally within the current input line.
- **up-arrow** and **down-arrow** keys move up and down through the set of previously entered lines.
- **Backspace** deletes the character before the cursor and typing new characters enters them at the cursor position.
- **Enter** sends the current input line to the server.

Get Help for MySQL Shell

Type `mysqlsh --help` at the prompt of your command interpreter for a list of command-line options.

```
mysqlsh --help
```

Type `\help` at the MySQL Shell prompt for a list of available commands and their descriptions.

```
mysql-py> \help
```

Type `\help` followed by a command name for detailed help about an individual MySQL Shell command. For example, to view help on the `\connect` command, issue:

```
mysql-py> \help \connect
```

Quit MySQL Shell

To quit MySQL Shell, issue the following command:

```
mysql-py> \quit
```

Related Information

- See [Interactive Code Execution](#) for an explanation of how interactive code execution works in MySQL Shell.
- See [Getting Started with MySQL Shell](#) to learn about session and connection alternatives.

20.4.2 Download and Import world_x Database

As part of this quick-start guide, an example schema is provided which is referred to as the `world_x` schema. Many of the examples demonstrate Document Store functionality using this schema. Start your MySQL server so that you can load the `world_x` schema, then follow these steps:

1. Download [world_x-db.zip](#).
2. Extract the installation archive to a temporary location such as `/tmp/`. Unpacking the archive results in a single file named `world_x.sql`.
3. Import the `world_x.sql` file to your server. You can either:
 - Start MySQL Shell in SQL mode and import the file by issuing:

```
mysqlsh -u root --sql --file /tmp/world_x-db/world_x.sql
Enter password: ****
```

- Set MySQL Shell to SQL mode while it is running and source the schema file by issuing:

```
\sql
Switching to SQL mode... Commands end with ;
\source /tmp/world_x-db/world_x.sql
```

Replace `/tmp/` with the path to the `world_x.sql` file on your system. Enter your password if prompted. A non-root account can be used as long as the account has privileges to create new schemas.

The world_x Schema

The `world_x` example schema contains the following JSON collection and relational tables:

- Collection
 - `countryinfo`: Information about countries in the world.
- Tables
 - `country`: Minimal information about countries of the world.
 - `city`: Information about some of the cities in those countries.
 - `countrylanguage`: Languages spoken in each country.

Related Information

- [MySQL Shell Sessions](#) explains session types.

20.4.3 Documents and Collections

When you are using MySQL as a Document Store, collections are containers within a schema that you can create, list, and drop. Collections contain JSON documents that you can add, find, update, and remove.

The examples in this section use the `countryinfo` collection in the `world_x` schema. For instructions on setting up the `world_x` schema, see [Section 20.4.2, “Download and Import world_x Database”](#).

Documents

In MySQL, documents are represented as JSON objects. Internally, they are stored in an efficient binary format that enables fast lookups and updates.

- Simple document format for Python:

```
{"field1": "value", "field2" : 10, "field 3": null}
```

An array of documents consists of a set of documents separated by commas and enclosed within [and] characters.

- Simple array of documents for Python:

```
[{"Name": "Aruba", "Code": "ABW"}, {"Name": "Angola", "Code": "AGO"}]
```

MySQL supports the following Python value types in JSON documents:

- numbers (integer and floating point)
- strings
- boolean (False and True)
- None
- arrays of more JSON values
- nested (or embedded) objects of more JSON values

Collections

Collections are containers for documents that share a purpose and possibly share one or more indexes. Each collection has a unique name and exists within a single schema.

The term schema is equivalent to a database, which means a group of database objects as opposed to a relational schema, used to enforce structure and constraints over data. A schema does not enforce conformity on the documents in a collection.

In this quick-start guide:

- Basic objects include:

| Object form | Description |
|-----------------------------------|---|
| <code>db</code> | <code>db</code> is a global variable assigned to the current active schema. When you want to run operations against the schema, for example to retrieve a collection, you use methods available for the <code>db</code> variable. |
| <code>db.get_collections()</code> | <code>db.get_collections()</code> returns a list of collections in the schema. Use the list to get references to collection objects, iterate over them, and so on. |

- Basic operations scoped by collections include:

| Operation form | Description |
|-------------------------------|---|
| <code>db.name.add()</code> | The <code>add()</code> method inserts one document or a list of documents into the named collection. |
| <code>db.name.find()</code> | The <code>find()</code> method returns some or all documents in the named collection. |
| <code>db.name.modify()</code> | The <code>modify()</code> method updates documents in the named collection. |
| <code>db.name.remove()</code> | The <code>remove()</code> method deletes one document or a list of documents from the named collection. |

Related Information

- See [Working with Collections](#) for a general overview.
- [CRUD EBNF Definitions](#) provides a complete list of operations.

20.4.3.1 Create, List, and Drop Collections

In MySQL Shell, you can create new collections, get a list of the existing collections in a schema, and remove an existing collection from a schema. Collection names are case-sensitive and each collection name must be unique.

Confirm the Schema

To show the value that is assigned to the schema variable, issue:

```
mysql-py> db
```

If the schema value is not `Schema:world_x`, then set the `db` variable by issuing:

```
mysql-py> \use world_x
```

Create a Collection

To create a new collection in an existing schema, use the `db` object's `createCollection()` method. The following example creates a collection called `flags` in the `world_x` schema.

```
mysql-py> db.create_collection("flags")
```

The method returns a collection object.

```
<Collection:flags>
```

List Collections

To display all collections in the `world_x` schema, use the `db` object's `get_collections()` method. Collections returned by the server you are currently connected to appear between brackets.

```
mysql-py> db.get_collections()
[
  <Collection:countryinfo>,
  <Collection:flags>
]
```

Drop a Collection

To drop an existing collection from a schema, use the `db` object's `drop_collection()` method. For example, to drop the `flags` collection from the current schema, issue:

```
mysql-py> db.drop_collection("flags")
```

The `drop_collection()` method is also used in MySQL Shell to drop a relational table from a schema.

Related Information

- See [Collection Objects](#) for more examples.

20.4.3.2 Working with Collections

To work with the collections in a schema, use the `db` global object to access the current schema. In this example we are using the `world_x` schema imported previously, and the `countryinfo` collection. Therefore, the format of the operations you issue is `db.collection_name.operation`, where `collection_name` is the name of the collection which the operation is executed against. In the following examples, the operations are executed against the `countryinfo` collection.

Add a Document

Use the `add()` method to insert one document or a list of documents into an existing collection. Insert the following document into the `countryinfo` collection. As this is multi-line content, press **Enter** twice to insert the document.

```
mysql-py> db.countryinfo.add(
{
  "GNP": .6,
  "IndepYear": 1967,
  "Name": "Sealand",
  "Code": "SEA",
  "demographics": {
    "LifeExpectancy": 79,
    "Population": 27
  },
  "geography": {
    "Continent": "Europe",
    "Region": "British Islands",
    "SurfaceArea": 193
  },
  "government": {
    "GovernmentForm": "Monarchy",
    "HeadOfState": "Michael Bates"
  }
}
)
```

The method returns the status of the operation. You can verify the operation by searching for the document. For example:

```
mysql-py> db.countryinfo.find("Name = 'Sealand'")
{
  "GNP": 0.6,
  "_id": "00005e2ff4af00000000000000f4",
  "Name": "Sealand",
  "Code": "SEA",
  "IndepYear": 1967,
  "geography": {
    "Region": "British Islands",
    "Continent": "Europe",
    "SurfaceArea": 193
  },
  "government": {
    "HeadOfState": "Michael Bates",
    "GovernmentForm": "Monarchy"
  },
  "demographics": {
    "Population": 27,
    "LifeExpectancy": 79
  }
}
```

Note that in addition to the fields specified when the document was added, there is one more field, the `_id`. Each document requires an identifier field called `_id`. The value of the `_id` field must be unique among all documents in the same collection. In MySQL 8.0.11 and higher, document IDs are generated by the server, not the client, so MySQL Shell does not automatically set an `_id` value. A MySQL server at

8.0.11 or higher sets an `_id` value if the document does not contain the `_id` field. A MySQL server at an earlier 8.0 release or at 5.7 does not set an `_id` value in this situation, so you must specify it explicitly. If you do not, MySQL Shell returns error 5115 `Document is missing a required field`. For more information see [Understanding Document IDs](#).

Related Information

- See [CollectionAddFunction](#) for the full syntax definition.
- See [Understanding Document IDs](#).

20.4.3.3 Find Documents

You can use the `find()` method to query for and return documents from a collection in a schema. MySQL Shell provides additional methods to use with the `find()` method to filter and sort the returned documents.

MySQL provides the following operators to specify search conditions: `OR (| |)`, `AND (&&)`, `XOR`, `IS`, `NOT`, `BETWEEN`, `IN`, `LIKE`, `!=`, `<>`, `>`, `>=`, `<`, `<=`, `&`, `|`, `<<`, `>>`, `+`, `-`, `*`, `/`, `~`, and `%`.

Find All Documents in a Collection

To return all documents in a collection, use the `find()` method without specifying search conditions. For example, the following operation returns all documents in the `countryinfo` collection.

```
mysql-py> db.countryinfo.find()
[
  {
    "GNP": 828,
    "Code": "ABW",
    "Name": "Aruba",
    "IndepYear": null,
    "geography": {
      "Continent": "North America",
      "Region": "Caribbean",
      "SurfaceArea": 193
    },
    "government": {
      "GovernmentForm": "Nonmetropolitan Territory of The Netherlands",
      "HeadOfState": "Beatrix"
    },
    "demographics": {
      "LifeExpectancy": 78.4000015258789,
      "Population": 103000
    },
    ...
  }
]
240 documents in set (0.00 sec)
```

The method produces results that contain operational information in addition to all documents in the collection.

An empty set (no matching documents) returns the following information:

```
Empty set (0.00 sec)
```

Filter Searches

You can include search conditions with the `find()` method. The syntax for expressions that form a search condition is the same as that of traditional MySQL [Chapter 12, Functions and Operators](#). You must enclose all expressions in quotes. For the sake of brevity, some of the examples do not display output.

A simple search condition could consist of the `Name` field and a value we know is in a document. The following example returns a single document:

```
mysql-py> db.countryinfo.find("Name = 'Australia'")
[
  {
    "GNP": 351182,
    "Code": "AUS",
    "Name": "Australia",
    "IndepYear": 1901,
    "geography": {
      "Continent": "Oceania",
      "Region": "Australia and New Zealand",
      "SurfaceArea": 7741220
    },
    "government": {
      "GovernmentForm": "Constitutional Monarchy, Federation",
      "HeadOfState": "Elisabeth II"
    },
    "demographics": {
      "LifeExpectancy": 79.80000305175781,
      "Population": 18886000
    }
  }
]
```

The following example searches for all countries that have a GNP higher than \$500 billion. The `countryinfo` collection measures GNP in units of million.

```
mysql-py> db.countryinfo.find("GNP > 500000")
...[output removed]
10 documents in set (0.00 sec)
```

The `Population` field in the following query is embedded within the `demographics` object. To access the embedded field, use a period between `demographics` and `Population` to identify the relationship. Document and field names are case-sensitive.

```
mysql-py> db.countryinfo.find("GNP > 500000 and demographics.Population < 10000000")
...[output removed]
6 documents in set (0.00 sec)
```

Arithmetic operators in the following expression are used to query for countries with a GNP per capita higher than \$30000. Search conditions can include arithmetic operators and most MySQL functions.

Note

Seven documents in the `countryinfo` collection have a population value of zero. Therefore warning messages appear at the end of the output.

```
mysql-py> db.countryinfo.find("GNP*1000000/demographics.Population > 30000")
...[output removed]
9 documents in set, 7 warnings (0.00 sec)
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
```

You can separate a value from the search condition by using the `bind()` method. For example, instead of specifying a hard-coded country name as the condition, substitute a named placeholder consisting of a colon followed by a name that begins with a letter, such as `country`. Then use the `bind(placeholder, value)` method as follows:

```
mysql-py> db.countryinfo.find("Name = :country").bind("country", "Italy")
{
  "GNP": 1161755,
  "_id": "00005de917d80000000000000006a",
  "Code": "ITA",
  "Name": "Italy",
  "Airports": [],
  "IndepYear": 1861,
  "geography": {
    "Region": "Southern Europe",
    "Continent": "Europe",
    "SurfaceArea": 301316
  },
  "government": {
    "HeadOfState": "Carlo Azeglio Ciampi",
    "GovernmentForm": "Republic"
  },
  "demographics": {
    "Population": 57680000,
    "LifeExpectancy": 79
  }
}
1 document in set (0.01 sec)
```

Tip

Within a program, binding enables you to specify placeholders in your expressions, which are filled in with values before execution and can benefit from automatic escaping, as appropriate.

Always use binding to sanitize input. Avoid introducing values in queries using string concatenation, which can produce invalid input and, in some cases, can cause security issues.

You can use placeholders and the `bind()` method to create saved searches which you can then call with different values. For example to create a saved search for a country:

```
mysql-py> myFind = db.countryinfo.find("Name = :country")
mysql-py> myFind.bind('country', 'France')
{
  "GNP": 1424285,
  "_id": "00005de917d800000000000000048",
  "Code": "FRA",
  "Name": "France",
  "IndepYear": 843,
  "geography": {
    "Region": "Western Europe",
    "Continent": "Europe",
    "SurfaceArea": 551500
  },
  "government": {
    "HeadOfState": "Jacques Chirac",
    "GovernmentForm": "Republic"
  },
  "demographics": {
    "Population": 59225700,
    "LifeExpectancy": 78.80000305175781
  }
}
1 document in set (0.0028 sec)

mysql-py> myFind.bind('country', 'Germany')
{
  "GNP": 2133367,
  "_id": "00005de917d800000000000000038",
```

```

"Code": "DEU",
"Name": "Germany",
"IndepYear": 1955,
"geography": {
  "Region": "Western Europe",
  "Continent": "Europe",
  "SurfaceArea": 357022
},
"government": {
  "HeadOfState": "Johannes Rau",
  "GovernmentForm": "Federal Republic"
},
"demographics": {
  "Population": 82164700,
  "LifeExpectancy": 77.4000015258789
}
}
1 document in set (0.0026 sec)

```

Project Results

You can return specific fields of a document, instead of returning all the fields. The following example returns the GNP and Name fields of all documents in the `countryinfo` collection matching the search conditions.

Use the `fields()` method to pass the list of fields to return.

```

mysql-py> db.countryinfo.find("GNP > 5000000").fields(["GNP", "Name"])
[
  {
    "GNP": 8510700,
    "Name": "United States"
  }
]
1 document in set (0.00 sec)

```

In addition, you can alter the returned documents—adding, renaming, nesting and even computing new field values—with an expression that describes the document to return. For example, alter the names of the fields with the following expression to return only two documents.

```

mysql-py> db.countryinfo.find().fields(
mysqlx.expr('{ "Name": upper(Name), "GNPPerCapita": GNP*1000000/demographics.Population}')).limit(2)
{
  "Name": "ARUBA",
  "GNPPerCapita": 8038.834951456311
}
{
  "Name": "AFGHANISTAN",
  "GNPPerCapita": 263.0281690140845
}

```

Limit, Sort, and Skip Results

You can apply the `limit()`, `sort()`, and `skip()` methods to manage the number and order of documents returned by the `find()` method.

To specify the number of documents included in a result set, append the `limit()` method with a value to the `find()` method. The following query returns the first five documents in the `countryinfo` collection.

```

mysql-py> db.countryinfo.find().limit(5)
... [output removed]
5 documents in set (0.00 sec)

```

To specify an order for the results, append the `sort()` method to the `find()` method. Pass to the `sort()` method a list of one or more fields to sort by and, optionally, the descending (`desc`) or ascending (`asc`) attribute as appropriate. Ascending order is the default order type.

For example, the following query sorts all documents by the `IndepYear` field and then returns the first eight documents in descending order.

```
mysql-py> db.countryinfo.find().sort(["IndepYear desc"]).limit(8)
... [output removed]
8 documents in set (0.00 sec)
```

By default, the `limit()` method starts from the first document in the collection. You can use the `skip()` method to change the starting document. For example, to ignore the first document and return the next eight documents matching the condition, pass to the `skip()` method a value of 1.

```
mysql-py> db.countryinfo.find().sort(["IndepYear desc"]).limit(8).skip(1)
... [output removed]
8 documents in set (0.00 sec)
```

Related Information

- The [MySQL Reference Manual](#) provides detailed documentation on functions and operators.
- See [CollectionFindFunction](#) for the full syntax definition.

20.4.3.4 Modify Documents

You can use the `modify()` method to update one or more documents in a collection. The X DevAPI provides additional methods for use with the `modify()` method to:

- Set and unset fields within documents.
- Append, insert, and delete arrays.
- Bind, limit, and sort the documents to be modified.

Set and Unset Document Fields

The `modify()` method works by filtering a collection to include only the documents to be modified and then applying the operations that you specify to those documents.

In the following example, the `modify()` method uses the search condition to identify the document to change and then the `set()` method replaces two values within the nested demographics object.

```
mysql-py> db.countryinfo.modify("Code = 'SEA']").set(
"demographics", {"LifeExpectancy": 78, "Population": 28})
```

After you modify a document, use the `find()` method to verify the change.

To remove content from a document, use the `modify()` and `unset()` methods. For example, the following query removes the GNP from a document that matches the search condition.

```
mysql-py> db.countryinfo.modify("Name = 'Sealand']").unset("GNP")
```

Use the `find()` method to verify the change.

```
mysql-py> db.countryinfo.find("Name = 'Sealand'")
{
  "_id": "00005e2ff4af00000000000000f4",
  "Name": "Sealand",
```

```

"Code": "SEA",
"IndepYear": 1967,
"geography": {
  "Region": "British Islands",
  "Continent": "Europe",
  "SurfaceArea": 193
},
"government": {
  "HeadOfState": "Michael Bates",
  "GovernmentForm": "Monarchy"
},
"demographics": {
  "Population": 27,
  "LifeExpectancy": 79
}
}

```

Append, Insert, and Delete Arrays

To append an element to an array field, or insert, or delete elements in an array, use the `array_append()`, `array_insert()`, or `array_delete()` methods. The following examples modify the `countryinfo` collection to enable tracking of international airports.

The first example uses the `modify()` and `set()` methods to create a new `Airports` field in all documents.

Caution

Use care when you modify documents without specifying a search condition; doing so modifies all documents in the collection.

```
mysql-py> db.countryinfo.modify("true").set("Airports", [])
```

With the `Airports` field added, the next example uses the `array_append()` method to add a new airport to one of the documents. `$.Airports` in the following example represents the `Airports` field of the current document.

```
mysql-py> db.countryinfo.modify("Name = 'France'").array_append("$.Airports", "ORY")
```

Use `find()` to see the change.

```

mysql-py> db.countryinfo.find("Name = 'France'")
{
  "GNP": 1424285,
  "_id": "00005de917d800000000000000048",
  "Code": "FRA",
  "Name": "France",
  "Airports": [
    "ORY"
  ],
  "IndepYear": 843,
  "geography": {
    "Region": "Western Europe",
    "Continent": "Europe",
    "SurfaceArea": 551500
  },
  "government": {
    "HeadOfState": "Jacques Chirac",
    "GovernmentForm": "Republic"
  },
  "demographics": {
    "Population": 59225700,
    "LifeExpectancy": 78.80000305175781
  }
}

```

To insert an element at a different position in the array, use the `array_insert()` method to specify which index to insert in the path expression. In this case, the index is 0, or the first element in the array.

```
mysql-py> db.countryinfo.modify("Name = 'France'").array_insert("$.Airports[0]", "CDG")
```

To delete an element from the array, you must pass to the `array_delete()` method the index of the element to be deleted.

```
mysql-py> db.countryinfo.modify("Name = 'France'").array_delete("$.Airports[1]")
```

Related Information

- The [MySQL Reference Manual](#) provides instructions to help you search for and modify JSON values.
- See [CollectionModifyFunction](#) for the full syntax definition.

20.4.3.5 Remove Documents

You can use the `remove()` method to delete some or all documents from a collection in a schema. The X DevAPI provides additional methods for use with the `remove()` method to filter and sort the documents to be removed.

Remove Documents Using Conditions

The following example passes a search condition to the `remove()` method. All documents matching the condition are removed from the `countryinfo` collection. In this example, one document matches the condition.

```
mysql-py> db.countryinfo.remove("Code = 'SEA'")
```

Remove the First Document

To remove the first document in the `countryinfo` collection, use the `limit()` method with a value of 1.

```
mysql-py> db.countryinfo.remove("true").limit(1)
```

Remove the Last Document in an Order

The following example removes the last document in the `countryinfo` collection by country name.

```
mysql-py> db.countryinfo.remove("true").sort(["Name desc"]).limit(1)
```

Remove All Documents in a Collection

You can remove all documents in a collection. To do so, use the `remove("true")` method without specifying a search condition.

Caution

Use care when you remove documents without specifying a search condition. This action deletes all documents from the collection.

Alternatively, use the `db.drop_collection('countryinfo')` operation to delete the `countryinfo` collection.

Related Information

- See [CollectionRemoveFunction](#) for the full syntax definition.

- See [Section 20.4.2, “Download and Import world_x Database”](#) for instructions to recreate the `world_x` schema.

20.4.3.6 Create and Drop Indexes

Indexes are used to find documents with specific field values quickly. Without an index, MySQL must begin with the first document and then read through the entire collection to find the relevant fields. The larger the collection, the more this costs. If a collection is large and queries on a specific field are common, then consider creating an index on a specific field inside a document.

For example, the following query performs better with an index on the Population field:

```
mysql-py> db.countryinfo.find("demographics.Population < 100")
...[output removed]
8 documents in set (0.00 sec)
```

The `create_index()` method creates an index that you can define with a JSON document that specifies which fields to use. This section is a high level overview of indexing. For more information see [Indexing Collections](#).

Add a Nonunique Index

To create a nonunique index, pass an index name and the index information to the `create_index()` method. Duplicate index names are prohibited.

The following example specifies an index named `popul`, defined against the `Population` field from the `demographics` object, indexed as an `Integer` numeric value. The final parameter indicates whether the field should require the `NOT NULL` constraint. If the value is `false`, the field can contain `NULL` values. The index information is a JSON document with details of one or more fields to include in the index. Each field definition must include the full document path to the field, and specify the type of the field.

```
mysql-py> db.countryinfo.createIndex("popul", {fields:
[{"field": '$.demographics.Population', type: 'INTEGER'}]})
```

Here, the index is created using an integer numeric value. Further options are available, including options for use with GeoJSON data. You can also specify the type of index, which has been omitted here because the default type “index” is appropriate.

Add a Unique Index

To create a unique index, pass an index name, the index definition, and the index type “unique” to the `create_index()` method. This example shows a unique index created on the country name (`"Name"`), which is another common field in the `countryinfo` collection to index. In the index field description, `"TEXT(40)"` represents the number of characters to index, and `"required": True` specifies that the field is required to exist in the document.

```
mysql-py> db.countryinfo.create_index("name",
{"fields": [{"field": "$.Name", "type": "TEXT(40)", "required": True}], "unique": True})
```

Drop an Index

To drop an index, pass the name of the index to drop to the `drop_index()` method. For example, you can drop the “popul” index as follows:

```
mysql-py> db.countryinfo.drop_index("popul")
```

Related Information

- See [Indexing Collections](#) for more information.

- See [Defining an Index](#) for more information on the JSON document that defines an index.
- See [Collection Index Management Functions](#) for the full syntax definition.

20.4.4 Relational Tables

You can also use X DevAPI to work with relational tables. In MySQL, each relational table is associated with a particular storage engine. The examples in this section use [InnoDB](#) tables in the `world_x` schema.

Confirm the Schema

To show the schema that is assigned to the `db` global variable, issue `db`.

```
mysql-py> db
<Schema:world_x>
```

If the returned value is not `Schema:world_x`, set the `db` variable as follows:

```
mysql-py> \use world_x
Schema `world_x` accessible through db.
```

Show All Tables

To display all relational tables in the `world_x` schema, use the `get_tables()` method on the `db` object.

```
mysql-py> db.get_tables()
[
  <Table:city>,
  <Table:country>,
  <Table:countrylanguage>
]
```

Basic Table Operations

Basic operations scoped by tables include:

| Operation form | Description |
|-------------------------------|--|
| <code>db.name.insert()</code> | The <code>insert()</code> method inserts one or more records into the named table. |
| <code>db.name.select()</code> | The <code>select()</code> method returns some or all records in the named table. |
| <code>db.name.update()</code> | The <code>update()</code> method updates records in the named table. |
| <code>db.name.delete()</code> | The <code>delete()</code> method deletes one or more records from the named table. |

Related Information

- See [Working with Relational Tables](#) for more information.
- [CRUD EBNF Definitions](#) provides a complete list of operations.
- See [Section 20.4.2, “Download and Import world_x Database”](#) for instructions on setting up the `world_x` schema sample.

20.4.4.1 Insert Records into Tables

You can use the `insert()` method with the `values()` method to insert records into an existing relational table. The `insert()` method accepts individual columns or all columns in the table. Use one or more `values()` methods to specify the values to be inserted.

Insert a Complete Record

To insert a complete record, pass to the `insert()` method all columns in the table. Then pass to the `values()` method one value for each column. For example, to add a new record to the city table in the `world_x` database, insert the following record and press **Enter** twice.

```
mysql-py> db.city.insert("ID", "Name", "CountryCode", "District", "Info").values(
None, "Olympia", "USA", "Washington", '{"Population": 5000}')
```

The city table has five columns: ID, Name, CountryCode, District, and Info. Each value must match the data type of the column it represents.

Insert a Partial Record

The following example inserts values into the ID, Name, and CountryCode columns of the city table.

```
mysql-py> db.city.insert("ID", "Name", "CountryCode").values(
None, "Little Falls", "USA").values(None, "Happy Valley", "USA")
```

When you specify columns using the `insert()` method, the number of values must match the number of columns. In the previous example, you must supply three values to match the three columns specified.

Related Information

- See [TableInsertFunction](#) for the full syntax definition.

20.4.4.2 Select Tables

You can use the `select()` method to query for and return records from a table in a database. The X DevAPI provides additional methods to use with the `select()` method to filter and sort the returned records.

MySQL provides the following operators to specify search conditions: `OR (| |)`, `AND (&&)`, `XOR`, `IS`, `NOT`, `BETWEEN`, `IN`, `LIKE`, `!=`, `<>`, `>`, `>=`, `<`, `<=`, `&`, `|`, `<<`, `>>`, `+`, `-`, `*`, `/`, `~`, and `%`.

Select All Records

To issue a query that returns all records from an existing table, use the `select()` method without specifying search conditions. The following example selects all records from the city table in the `world_x` database.

Note

Limit the use of the empty `select()` method to interactive statements. Always use explicit column-name selections in your application code.

```
mysql-py> db.city.select()
+-----+-----+-----+-----+-----+
| ID | Name | CountryCode | District | Info |
+-----+-----+-----+-----+-----+
| 1 | Kabul | AFG | Kabul | {"Population": 1780000} |
| 2 | Qandahar | AFG | Qandahar | {"Population": 237500} |
| 3 | Herat | AFG | Herat | {"Population": 186800} |
... ..
```

```
| 4079 | Rafah      | PSE      | Rafah      | {"Population": 92020} |
+-----+-----+-----+-----+-----+
4082 rows in set (0.01 sec)
```

An empty set (no matching records) returns the following information:

```
Empty set (0.00 sec)
```

Filter Searches

To issue a query that returns a set of table columns, use the `select()` method and specify the columns to return between square brackets. This query returns the Name and CountryCode columns from the city table.

```
mysql-py> db.city.select(["Name", "CountryCode"])
+-----+-----+
| Name          | CountryCode |
+-----+-----+
| Kabul         | AFG         |
| Qandahar      | AFG         |
| Herat         | AFG         |
| Mazar-e-Sharif | AFG         |
| Amsterdam     | NLD         |
| ...           | ...         |
| Rafah         | PSE         |
| Olympia       | USA         |
| Little Falls  | USA         |
| Happy Valley  | USA         |
+-----+-----+
4082 rows in set (0.00 sec)
```

To issue a query that returns rows matching specific search conditions, use the `where()` method to include those conditions. For example, the following example returns the names and country codes of the cities that start with the letter Z.

```
mysql-py> db.city.select(["Name", "CountryCode"]).where("Name like 'Z%'")
+-----+-----+
| Name          | CountryCode |
+-----+-----+
| Zaanstad      | NLD         |
| Zoetermeer    | NLD         |
| Zwolle        | NLD         |
| Zenica        | BIH         |
| Zagazig       | EGY         |
| Zaragoza      | ESP         |
| Zamboanga     | PHL         |
| Zahedan       | IRN         |
| Zanzan        | IRN         |
| Zabol         | IRN         |
| Zama          | JPN         |
| Zhezqazghan   | KAZ         |
| Zhengzhou     | CHN         |
| ...           | ...         |
| Zeleznogorsk  | RUS         |
+-----+-----+
59 rows in set (0.00 sec)
```

You can separate a value from the search condition by using the `bind()` method. For example, instead of using `"Name = 'Z%'"` as the condition, substitute a named placeholder consisting of a colon followed by a name that begins with a letter, such as `name`. Then include the placeholder and value in the `bind()` method as follows:

```
mysql-py> db.city.select(["Name", "CountryCode"]).where(
    "Name like :name").bind("name", "Z%")
```

**Tip**

Within a program, binding enables you to specify placeholders in your expressions, which are filled in with values before execution and can benefit from automatic escaping, as appropriate.

Always use binding to sanitize input. Avoid introducing values in queries using string concatenation, which can produce invalid input and, in some cases, can cause security issues.

Project Results

To issue a query using the `AND` operator, add the operator between search conditions in the `where()` method.

```
mysql-py> db.city.select(["Name", "CountryCode"]).where(
    "Name like 'Z%' and CountryCode = 'CHN'")
+-----+-----+
| Name          | CountryCode |
+-----+-----+
| Zhengzhou    | CHN         |
| Zibo         | CHN         |
| Zhangjiakou  | CHN         |
| Zhuzhou      | CHN         |
| Zhangjiang   | CHN         |
| Zigong       | CHN         |
| Zaozhuang    | CHN         |
| ...          | ...         |
| Zhangjiagang | CHN         |
+-----+-----+
22 rows in set (0.01 sec)
```

To specify multiple conditional operators, you can enclose the search conditions in parenthesis to change the operator precedence. The following example demonstrates the placement of `AND` and `OR` operators.

```
mysql-py> db.city.select(["Name", "CountryCode"]).where(
    "Name like 'Z%' and (CountryCode = 'CHN' or CountryCode = 'RUS'")
+-----+-----+
| Name          | CountryCode |
+-----+-----+
| Zhengzhou    | CHN         |
| Zibo         | CHN         |
| Zhangjiakou  | CHN         |
| Zhuzhou      | CHN         |
| ...          | ...         |
| Zeleznogorsk | RUS         |
+-----+-----+
29 rows in set (0.01 sec)
```

Limit, Order, and Offset Results

You can apply the `limit()`, `order_by()`, and `offset()` methods to manage the number and order of records returned by the `select()` method.

To specify the number of records included in a result set, append the `limit()` method with a value to the `select()` method. For example, the following query returns the first five records in the country table.

```
mysql-py> db.country.select(["Code", "Name"]).limit(5)
+-----+-----+
| Code | Name          |
+-----+-----+
| ABW  | Aruba         |
| AFG  | Afghanistan   |
```

```

| AGO | Angola      |
| AIA | Anguilla    |
| ALB | Albania     |
+-----+-----+
5 rows in set (0.00 sec)
    
```

To specify an order for the results, append the `order_by()` method to the `select()` method. Pass to the `order_by()` method a list of one or more columns to sort by and, optionally, the descending (`desc`) or ascending (`asc`) attribute as appropriate. Ascending order is the default order type.

For example, the following query sorts all records by the Name column and then returns the first three records in descending order .

```

mysql-py> db.country.select(["Code", "Name"]).order_by(["Name desc"]).limit(3)
+-----+-----+
| Code | Name      |
+-----+-----+
| ZWE  | Zimbabwe  |
| ZMB  | Zambia    |
| YUG  | Yugoslavia |
+-----+-----+
3 rows in set (0.00 sec)
    
```

By default, the `limit()` method starts from the first record in the table. You can use the `offset()` method to change the starting record. For example, to ignore the first record and return the next three records matching the condition, pass to the `offset()` method a value of 1.

```

mysql-py> db.country.select(["Code", "Name"]).order_by(["Name desc"]).limit(3).offset(1)
+-----+-----+
| Code | Name      |
+-----+-----+
| ZMB  | Zambia    |
| YUG  | Yugoslavia |
| YEM  | Yemen     |
+-----+-----+
3 rows in set (0.00 sec)
    
```

Related Information

- The [MySQL Reference Manual](#) provides detailed documentation on functions and operators.
- See [TableSelectFunction](#) for the full syntax definition.

20.4.4.3 Update Tables

You can use the `update()` method to modify one or more records in a table. The `update()` method works by filtering a query to include only the records to be updated and then applying the operations you specify to those records.

To replace a city name in the city table, pass to the `set()` method the new city name. Then, pass to the `where()` method the city name to locate and replace. The following example replaces the city Peking with Beijing.

```

mysql-py> db.city.update().set("Name", "Beijing").where("Name = 'Peking'")
    
```

Use the `select()` method to verify the change.

```

mysql-py> db.city.select(["ID", "Name", "CountryCode", "District", "Info"]).where("Name = 'Beijing'")
+-----+-----+-----+-----+-----+
| ID   | Name      | CountryCode | District | Info                                     |
+-----+-----+-----+-----+-----+
| 1891 | Beijing   | CHN         | Peking   | {"Population": 7472000}                 |
    
```

```
+-----+-----+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

Related Information

- See [TableUpdateFunction](#) for the full syntax definition.

20.4.4.4 Delete Tables

You can use the `delete()` method to remove some or all records from a table in a database. The X DevAPI provides additional methods to use with the `delete()` method to filter and order the records to be deleted.

Delete Records Using Conditions

The example that follows passes search conditions to the `delete()` method. All records matching the condition are deleted from the `city` table. In this example, one record matches the condition.

```
mysql-py> db.city.delete().where("Name = 'Olympia'")
```

Delete the First Record

To delete the first record in the `city` table, use the `limit()` method with a value of 1.

```
mysql-py> db.city.delete().limit(1)
```

Delete All Records in a Table

You can delete all records in a table. To do so, use the `delete()` method without specifying a search condition.

Caution

Use care when you delete records without specifying a search condition; doing so deletes all records from the table.

Drop a Table

The `drop_collection()` method is also used in MySQL Shell to drop a relational table from a database. For example, to drop the `citytest` table from the `world_x` database, issue:

```
mysql-py> db.drop_collection("citytest")
```

Related Information

- See [TableDeleteFunction](#) for the full syntax definition.
- See [Section 20.4.2, “Download and Import world_x Database”](#) for instructions to recreate the `world_x` database.

20.4.5 Documents in Tables

In MySQL, a table may contain traditional relational data, JSON values, or both. You can combine traditional data with JSON documents by storing the documents in columns having a native `JSON` data type.

Examples in this section use the `city` table in the `world_x` schema.

city Table Description

The city table has five columns (or fields).

| Field | Type | Null | Key | Default | Extra |
|-------------|----------|------|-----|---------|----------------|
| ID | int(11) | NO | PRI | null | auto_increment |
| Name | char(35) | NO | | | |
| CountryCode | char(3) | NO | | | |
| District | char(20) | NO | | | |
| Info | json | YES | | null | |

Insert a Record

To insert a document into the column of a table, pass to the `values()` method a well-formed JSON document in the correct order. In the following example, a document is passed as the final value to be inserted into the Info column.

```
mysql-py> db.city.insert().values(
None, "San Francisco", "USA", "California", '{"Population":830000}')
```

Select a Record

You can issue a query with a search condition that evaluates document values in the expression.

```
mysql-py> db.city.select(["ID", "Name", "CountryCode", "District", "Info"]).where(
"CountryCode = :country and Info->'$.Population' > 100000").bind(
'country', 'USA')
```

| ID | Name | CountryCode | District | Info |
|------|--------------|-------------|--------------|-------------------------|
| 3793 | New York | USA | New York | {"Population": 8008278} |
| 3794 | Los Angeles | USA | California | {"Population": 3694820} |
| 3795 | Chicago | USA | Illinois | {"Population": 2896016} |
| 3796 | Houston | USA | Texas | {"Population": 1953631} |
| 3797 | Philadelphia | USA | Pennsylvania | {"Population": 1517550} |
| 3798 | Phoenix | USA | Arizona | {"Population": 1321045} |
| 3799 | San Diego | USA | California | {"Population": 1223400} |
| 3800 | Dallas | USA | Texas | {"Population": 1188580} |
| 3801 | San Antonio | USA | Texas | {"Population": 1144646} |

9 rows in set (0.01 sec)

Related Information

- See [Working with Relational Tables and Documents](#) for more information.
- See [Section 11.5, “The JSON Data Type”](#) for a detailed description of the data type.

20.5 X Plugin

This section explains how to use, configure and monitor X Plugin.

20.5.1 Checking X Plugin Installation

X Plugin is enabled by default in MySQL 8, therefore installing or upgrading to MySQL 8 makes the plugin available. You can verify X Plugin is installed on an instance of MySQL server by using the `SHOW plugins` statement to view the plugins list.

To use MySQL Shell to verify X Plugin is installed, issue:

```
shell> mysqlsh -u user --sqlc -P 3306 -e "SHOW plugins"
```

To use MySQL Client to verify X Plugin is installed, issue:

```
shell> mysql -u user -p -e "SHOW plugins"
```

An example result if X Plugin is installed is highlighted here:

```
+-----+-----+-----+-----+-----+
| Name           | Status  | Type           | Library | License |
+-----+-----+-----+-----+-----+
...
| mysqlx         | ACTIVE  | DAEMON        | NULL   | GPL     |
...
+-----+-----+-----+-----+-----+
```

20.5.2 Disabling X Plugin

The X Plugin can be disabled at startup by either setting `mysqlx=0` in your MySQL configuration file, or by passing in either `--mysqlx=0` or `--skip-mysqlx` when starting the MySQL server.

Alternatively, use the `-DWITH_MYSQLX=OFF` CMake option to compile MySQL Server without X Plugin.

20.5.3 Using Encrypted Connections with X Plugin

This section explains how to configure X Plugin to use encrypted connections. For more background information, see [Section 6.3, “Using Encrypted Connections”](#).

To enable configuring support for encrypted connections, X Plugin has `mysqlx_ssl_xxx` system variables, which can have different values from the `ssl_xxx` system variables used with MySQL Server. For example, X Plugin can have SSL key, certificate, and certificate authority files that differ from those used for MySQL Server. These variables are described at [Section 20.5.6.2, “X Plugin Options and System Variables”](#). Similarly, X Plugin has its own `mysqlx_ssl_xxx` status variables that correspond to the MySQL Server encrypted-connection `ssl_xxx` status variables. See [Section 20.5.6.3, “X Plugin Status Variables”](#).

At initialization, X Plugin determines its TLS context for encrypted connections as follows:

- If all `mysqlx_ssl_xxx` system variables have their default values, X Plugin uses the same TLS context as the MySQL Server main connection interface, which is determined by the values of the `ssl_xxx` system variables.
- If any `mysqlx_ssl_xxx` variable has a nondefault value, X Plugin uses the TLS context defined by the values of its own system variables. (This is the case if any `mysqlx_ssl_xxx` system variable is set to a value different from its default.)

This means that, on a server with X Plugin enabled, you can choose to have MySQL Protocol and X Protocol connections share the same encryption configuration by setting only the `ssl_xxx` variables, or have separate encryption configurations for MySQL Protocol and X Protocol connections by configuring the `ssl_xxx` and `mysqlx_ssl_xxx` variables separately.

To have MySQL Protocol and X Protocol connections use the same encryption configuration, set only the `ssl_xxx` system variables in `my.cnf`:

```
[mysqld]
ssl_ca=ca.pem
ssl_cert=server-cert.pem
ssl_key=server-key.pem
```

To configure encryption separately for MySQL Protocol and X Protocol connections, set both the `ssl_XXX` and `mysqlx_ssl_XXX` system variables in `my.cnf`:

```
[mysqld]
ssl_ca=ca1.pem
ssl_cert=server-cert1.pem
ssl_key=server-key1.pem

mysqlx_ssl_ca=ca2.pem
mysqlx_ssl_cert=server-cert2.pem
mysqlx_ssl_key=server-key2.pem
```

For general information about configuring connection-encryption support, see [Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”](#). That discussion is written for MySQL Server, but the parameter names are similar for X Plugin. (The X Plugin `mysqlx_ssl_XXX` system variable names correspond to the MySQL Server `ssl_XXX` system variable names.)

The `tls_version` system variable that determines the permitted TLS versions for MySQL Protocol connections also applies to X Protocol connections. The permitted TLS versions for both types of connections are therefore the same.

Encryption per connection is optional, but a specific user can be required to use encryption for X Protocol and MySQL Protocol connections by including an appropriate `REQUIRE` clause in the `CREATE USER` statement that creates the user. For details, see [Section 13.7.1.3, “CREATE USER Statement”](#). Alternatively, to require all users to use encryption for X Protocol and MySQL Protocol connections, enable the `require_secure_transport` system variable. For additional information, see [Configuring Encrypted Connections as Mandatory](#).

20.5.4 Using X Plugin with the Caching SHA-2 Authentication Plugin

X Plugin supports MySQL user accounts created with the `caching_sha2_password` authentication plugin. For more information on this plugin, see [Section 6.4.1.2, “Caching SHA-2 Pluggable Authentication”](#). You can use X Plugin to authenticate against such accounts using non-SSL connections with `SHA256_MEMORY` authentication and SSL connections with `PLAIN` authentication.

Although the `caching_sha2_password` authentication plugin holds an authentication cache, this cache is not shared with X Plugin, so X Plugin uses its own authentication cache for `SHA256_MEMORY` authentication. The X Plugin authentication cache stores hashes of user account passwords, and cannot be accessed using SQL. If a user account is modified or removed, the relevant entries are removed from the cache. The X Plugin authentication cache is maintained by the `mysqlx_cache_cleaner` plugin, which is enabled by default, and has no related system variables or status variables.

Before you can use non-SSL X Protocol connections to authenticate an account that uses the `caching_sha2_password` authentication plugin, the account must have authenticated at least once over an X Protocol connection with SSL, to supply the password to the X Plugin authentication cache. Once this initial authentication over SSL has succeeded, non-SSL X Protocol connections can be used.

It is possible to disable the `mysqlx_cache_cleaner` plugin by starting the MySQL server with the option `--mysqlx_cache_cleaner=0`. If you do this, the X Plugin authentication cache is disabled, and therefore SSL must always be used for X Protocol connections when authenticating with `SHA256_MEMORY` authentication.

20.5.5 Connection Compression with X Plugin

From MySQL 8.0.19, X Plugin supports compression of messages sent over X Protocol connections. Connections can be compressed if the server and the client agree on a mutually supported compression algorithm. Enabling compression reduces the number of bytes sent over the network, but adds to the server and client an additional CPU cost for compression and decompression operations. The benefits of compression therefore occur primarily when there is low network bandwidth, network transfer time dominates the cost of compression and decompression operations, and result sets are large.

Note

Different MySQL clients implement support for connection compression differently; consult your client documentation for details. For example, for classic MySQL protocol connections, see [Section 4.2.8, “Connection Compression Control”](#).

- [Configuring Connection Compression for X Plugin](#)
- [Compressed Connection Characteristics for X Plugin](#)
- [Monitoring Connection Compression for X Plugin](#)

Configuring Connection Compression for X Plugin

By default, X Plugin supports the zstd, LZ4, and Deflate compression algorithms. Compression with the Deflate algorithm is carried out using the zlib software library, so the `deflate_stream` compression algorithm setting for X Protocol connections is equivalent to the `zlib` setting for classic MySQL protocol connections.

On the server side, you can disallow any of the compression algorithms by setting the `mysqlx_compression_algorithms` system variable to include only those permitted. The algorithm names `zstd_stream`, `lz4_message`, and `deflate_stream` can be specified in any combination, and the order and lettercase are not important. If the system variable value is the empty string, no compression algorithms are permitted and connections are uncompressed.

The following table compares the characteristics of the different compression algorithms and shows their assigned priorities. By default, the server chooses the highest-priority algorithm permitted in common by the server and the client; clients may change the priorities as described later. The short form alias for the algorithms can be used by clients when specifying them.

Table 20.1 X Protocol Compression Algorithm Characteristics

| Algorithm | Alias | Compression Ratio | Throughput | CPU Cost | Default Priority |
|-----------------------------|----------------------|-------------------|------------|----------|------------------|
| <code>zsth_stream</code> | <code>zstd</code> | High | High | Medium | First |
| <code>lz4_message</code> | <code>lz4</code> | Low | High | Lowest | Second |
| <code>deflate_stream</code> | <code>deflate</code> | High | Low | Highest | Third |

The X Protocol set of permitted compression algorithms (whether user-specified or default) is independent of the set of compression algorithms permitted by MySQL Server for classic MySQL protocol connections, which is specified by the `protocol_compression_algorithms` server system variable. If you do not specify the `mysqlx_compression_algorithms` system variable, X Plugin does not fall back to using compression settings for classic MySQL protocol connections. Instead, its default is to permit all algorithms shown in [Table 20.1, “X Protocol Compression Algorithm Characteristics”](#). This is unlike the situation for the TLS context, where MySQL Server settings are used if the X Plugin system variables are not set, as described in [Section 20.5.3, “Using Encrypted Connections with X Plugin”](#). For information about compression for classic MySQL protocol connections, see [Section 4.2.8, “Connection Compression Control”](#).

On the client side, an X Protocol connection request can specify several parameters for compression control:

- The compression mode.
- The compression level (from MySQL 8.0.20).
- The list of permitted compression algorithms in priority order (from MySQL 8.0.22).

Note

Some clients or Connectors might not support a given compression-control feature. For example, specifying compression level for X Protocol connections is supported only by MySQL Shell, not by other MySQL clients or Connectors. See the documentation for specific products for details about supported features and how to use them.

The connection mode has these permitted values:

- `disabled`: The connection is uncompressed.
- `preferred`: The server and client negotiate to find a compression algorithm they both permit. If no common algorithm is available, the connection is uncompressed. This is the default mode if not specified explicitly.
- `required`: Compression algorithm negotiation occurs as for `preferred` mode, but if no common algorithm is available, the connection request terminates with an error.

In addition to agreeing on a compression algorithm for each connection, the server and client can agree on a compression level from the numeric range that applies to the agreed algorithm. As the compression level for an algorithm increases, the data compression ratio increases, which reduces the network bandwidth and transfer time needed to send the message to the client. However, the effort required for data compression also increases, taking up time and CPU and memory resources on the server. Increases in the compression effort do not have a linear relationship to increases in the compression ratio.

In MySQL 8.0.19, X Plugin always uses the library default compression level for each algorithm (3 for `zstd`, 0 for `LZ4`, and 6 for `Deflate`), and the client cannot negotiate this. From MySQL 8.0.20, the client can request a specific compression level during capability negotiations with the server for an X Protocol connection.

The default compression levels used by X Plugin from MySQL 8.0.20 have been selected through performance testing as being a good trade-off between compression time and network transit time. These defaults are not necessarily the same as the library default for each algorithm. They apply if the client does not request a compression level for the algorithm. The default compression levels are initially set to 3 for `zstd`, 2 for `LZ4`, and 3 for `Deflate`. You can adjust these settings using the `mysqlx_zstd_default_compression_level`, `mysqlx_lz4_default_compression_level`, and `mysqlx_deflate_default_compression_level` system variables.

To prevent excessive resource consumption on the server, X Plugin sets a maximum compression level that the server permits for each algorithm. If a client requests a compression level that exceeds this setting, the server uses its maximum permitted compression level (compression level requests by a client are supported only by MySQL Shell). The maximum compression levels are initially set to 11 for `zstd`, 8 for `LZ4`, and 5 for `Deflate`. You can adjust these settings using the `mysqlx_zstd_max_client_compression_level`, `mysqlx_lz4_max_client_compression_level`, and `mysqlx_deflate_max_client_compression_level` system variables.

If the server and client permit more than one algorithm in common, the default priority order for choosing an algorithm during negotiation is shown in [Table 20.1, “X Protocol Compression Algorithm Characteristics”](#). From MySQL 8.0.22, for clients that support specifying compression algorithms, the connection request can include a list of algorithms permitted by the client, specified using the algorithm name or its alias. The order of these algorithms in the list is taken as a priority order by the server. The algorithm used in this case is the first of those in the client list that is also permitted on the server side. However, the option for compression algorithms is subject to the compression mode:

- If the compression mode is `disabled`, the compression algorithms option is ignored.
- If the compression mode is `preferred` but no algorithm permitted on the client side is permitted on the server side, the connection is uncompressed.
- If the compression mode is `required` but no algorithm permitted on the client side is permitted on the server side, an error occurs.

To monitor the effects of message compression, use the X Plugin status variables described in [Monitoring Connection Compression for X Plugin](#). You can use these status variables to calculate the benefit of message compression with your current settings, and use that information to tune your settings.

Compressed Connection Characteristics for X Plugin

X Protocol connection compression operates with the following behaviors and boundaries:

- The `_stream` and `_message` suffixes in algorithm names refer to two different operational modes: In stream mode, all X Protocol messages in a single connection are compressed into a continuous stream and must be decompressed in the same manner—following the order they were compressed and without skipping any messages. In message mode, each message is compressed individually and independently, and need not be decompressed in the order in which they were compressed. Also, message mode does not require all compressed messages to be decompressed.
- Compression is not applied to any messages that are sent before authentication succeeds.
- Compression is not applied to control flow messages such as `Mysqlx.Ok`, `Mysqlx.Error`, and `Mysqlx.Sql.StmtExecuteOk` messages.
- All other X Protocol messages can be compressed if the server and client agree on a mutually permitted compression algorithm during capability negotiation. If the client does not request compression at that stage, neither the client nor the server applies compression to messages.
- When messages sent over X Protocol connections are compressed, the limit specified by the `mysqlx_max_allowed_packet` system variable still applies. The network packet must be smaller than this limit after the message payload has been decompressed. If the limit is exceeded, X Plugin returns a decompression error and closes the connection.
- The following points pertain to compression level requests by clients, which is supported only by MySQL Shell:
 - Compression levels must be specified by the client as an integer. If any other type of value is supplied, the connection closes with an error.
 - If a client specifies an algorithm but not a compression level, the server uses its default compression level for the algorithm.
 - If a client requests an algorithm compression level that exceeds the server maximum permitted level, the server uses the maximum permitted level.

- If a client requests an algorithm compression level that is less than the server minimum permitted level, the server uses the minimum permitted level.

Monitoring Connection Compression for X Plugin

You can monitor the effects of message compression using the X Plugin status variables. When message compression is in use, the session `Mysqlx_compression_algorithm` status variable shows which compression algorithm is in use for the current X Protocol connection, and `Mysqlx_compression_level` shows the compression level that was selected. These session status variables are available from MySQL 8.0.20.

From MySQL 8.0.19, X Plugin status variables can be used to calculate the efficiency of the compression algorithms that are selected (the data compression ratio), and the overall effect of using message compression. Use the session value of the status variables in the following calculations to see what the benefit of message compression was for a specific session with a known compression algorithm. Or use the global value of the status variables to check the overall benefit of message compression for your server across all sessions using X Protocol connections, including all the compression algorithms that have been used for those sessions, and all sessions that did not use message compression. You can then tune message compression by adjusting the permitted compression algorithms, maximum compression level, and default compression level, as described in [Configuring Connection Compression for X Plugin](#).

When message compression is in use, the `Mysqlx_bytes_sent` status variable shows the total number of bytes sent out from the server, including compressed message payloads measured after compression, any items in compressed messages that were not compressed such as X Protocol headers, and any uncompressed messages. The `Mysqlx_bytes_sent_compressed_payload` status variable shows the total number of bytes sent as compressed message payloads, measured after compression, and the `Mysqlx_bytes_sent_uncompressed_frame` status variable shows the total number of bytes for those same message payloads but measured before compression. The compression ratio, which shows the efficiency of the compression algorithm, can therefore be calculated using the following expression:

```
mysqlx_bytes_sent_uncompressed_frame / mysqlx_bytes_sent_compressed_payload
```

The effectiveness of compression for X Protocol messages sent by the server can be calculated using the following expression:

```
(mysqlx_bytes_sent - mysqlx_bytes_sent_compressed_payload + mysqlx_bytes_sent_uncompressed_frame) / mysqlx.
```

For messages received by the server from clients, the `Mysqlx_bytes_received_compressed_payload` status variable shows the total number of bytes received as compressed message payloads, measured before decompression, and the `Mysqlx_bytes_received_uncompressed_frame` status variable shows the total number of bytes for those same message payloads but measured after decompression. The `Mysqlx_bytes_received` status variable includes compressed message payloads measured before decompression, any uncompressed items in compressed messages, and any uncompressed messages.

20.5.6 X Plugin Options and Variables

This section describes the command options and system variables that configure X Plugin, as well as the status variables available for monitoring purposes. If configuration values specified at startup time are incorrect, X Plugin could fail to initialize properly and the server does not load it. In this case, the server could also produce error messages for other X Plugin settings because it cannot recognize them.

20.5.6.1 X Plugin Option and Variable Reference

This table provides an overview of the command options, system variables, and status variables provided by X Plugin.

Table 20.2 X Plugin Option and Variable Reference

| Name | Cmd-Line | Option File | System Var | Status Var | Var Scope | Dynamic |
|--|----------|-------------|------------|------------|-----------|---------|
| mysqlx | Yes | Yes | | | | |
| Mysqlx_aborted_clients | | | | Yes | Global | No |
| Mysqlx_address | | | | Yes | Global | No |
| mysqlx_bind_address | Yes | Yes | Yes | | Global | No |
| Mysqlx_bytes_received | | | | Yes | Both | No |
| Mysqlx_bytes_received_compressed_payload | | | | Yes | Both | No |
| Mysqlx_bytes_received_uncompressed_frame | | | | Yes | Both | No |
| Mysqlx_bytes_sent | | | | Yes | Both | No |
| Mysqlx_bytes_sent_compressed_payload | | | | Yes | Both | No |
| Mysqlx_bytes_sent_uncompressed_frame | | | | Yes | Both | No |
| Mysqlx_compression_algorithm | | | | Yes | Session | No |
| mysqlx_compression_algorithm | Yes | Yes | Yes | | Global | Yes |
| Mysqlx_compression_level | | | | Yes | Session | No |
| mysqlx_connect_timeout | Yes | Yes | Yes | | Global | Yes |
| Mysqlx_connection_accept_errors | | | | Yes | Both | No |
| Mysqlx_connection_errors | | | | Yes | Both | No |
| Mysqlx_connections_accepted | | | | Yes | Global | No |
| Mysqlx_connections_closed | | | | Yes | Global | No |
| Mysqlx_connections_rejected | | | | Yes | Global | No |
| Mysqlx_crud_create_view | | | | Yes | Both | No |
| Mysqlx_crud_delete | | | | Yes | Both | No |
| Mysqlx_crud_drop_view | | | | Yes | Both | No |
| Mysqlx_crud_find | | | | Yes | Both | No |
| Mysqlx_crud_insert | | | | Yes | Both | No |
| Mysqlx_crud_modify_view | | | | Yes | Both | No |
| Mysqlx_crud_update | | | | Yes | Both | No |
| mysqlx_deflate_default_compression_level | Yes | Yes | Yes | | Global | Yes |

20.5.6.2 X Plugin Options and System Variables

To control activation of X Plugin, use this option:

- `--mysqlx[=value]`

| | |
|---------------------|-------------------------------|
| Command-Line Format | <code>--mysqlx[=value]</code> |
| Type | Enumeration |
| Default Value | ON |
| Valid Values | ON OFF |

| |
|----------------------|
| FORCE |
| FORCE_PLUS_PERMANENT |

This option controls how the server loads X Plugin at startup. In MySQL 8.0, X Plugin is enabled by default, but this option may be used to control its activation state.

The option value should be one of those available for plugin-loading options, as described in [Section 5.6.1, “Installing and Uninstalling Plugins”](#).

If X Plugin is enabled, it exposes several system variables that permit control over its operation:

- `mysqlx_bind_address`

| | |
|----------------------|---|
| Command-Line Format | <code>--mysqlx-bind-address=addr</code> |
| System Variable | <code>mysqlx_bind_address</code> |
| Scope | Global |
| Dynamic | No |
| SET_VAR Hint Applies | No |
| Type | String |
| Default Value | * |

The network address on which X Plugin listens for TCP/IP connections. This variable is not dynamic and can be configured only at startup. This is the X Plugin equivalent of the `bind_address` system variable; see that variable description for more information.

By default, X Plugin accepts TCP/IP connections on all server host IPv4 interfaces, and, if the server host supports IPv6, on all IPv6 interfaces. If `mysqlx_bind_address` is specified, its value must satisfy these requirements:

- Prior to MySQL 8.0.21, `mysqlx_bind_address` accepts a single address value, which may specify a single non-wildcard IP address (either IPv4 or IPv6), or a host name, or one of the wildcard address formats that permit listening on multiple network interfaces (`*`, `0.0.0.0`, or `::`).
- As of MySQL 8.0.21, `mysqlx_bind_address` accepts either a single value as just described, or a list of comma-separated values. When the variable names a list of multiple values, each value must specify a single non-wildcard IP address (either IPv4 or IPv6) or a host name. Wildcard address formats (`*`, `0.0.0.0`, or `::`) are not allowed in a list of values.
- As of MySQL 8.0.22, the value may include a network namespace specifier.

IP addresses can be specified as IPv4 or IPv6 addresses. For any value that is a host name, X Plugin resolves the name to an IP address and binds to that address. If a host name resolves to multiple IP addresses, X Plugin uses the first IPv4 address if there are any, or the first IPv6 address otherwise.

X Plugin treats different types of addresses as follows:

- If the address is `*`, X Plugin accepts TCP/IP connections on all server host IPv4 interfaces, and, if the server host supports IPv6, on all IPv6 interfaces. Use this address to permit both IPv4 and IPv6 connections for X Plugin. This value is the default. If the variable specifies a list of multiple values, this value is not permitted.

- If the address is `0.0.0.0`, X Plugin accepts TCP/IP connections on all server host IPv4 interfaces. If the variable specifies a list of multiple values, this value is not permitted.
- If the address is `:::`, X Plugin accepts TCP/IP connections on all server host IPv4 and IPv6 interfaces. If the variable specifies a list of multiple values, this value is not permitted.
- If the address is an IPv4-mapped address, X Plugin accepts TCP/IP connections for that address, in either IPv4 or IPv6 format. For example, if X Plugin is bound to `::ffff:127.0.0.1`, a client such as MySQL Shell can connect using `--host=127.0.0.1` or `--host>::ffff:127.0.0.1`.
- If the address is a “regular” IPv4 or IPv6 address (such as `127.0.0.1` or `:::1`), X Plugin accepts TCP/IP connections only for that IPv4 or IPv6 address.

These rules apply to specifying a network namespace for an address:

- A network namespace can be specified for an IP address or a host name.
- A network namespace cannot be specified for a wildcard IP address.
- For a given address, the network namespace is optional. If given, it must be specified as a `/ns` suffix immediately following the address.
- An address with no `/ns` suffix uses the host system global namespace. The global namespace is therefore the default.
- An address with a `/ns` suffix uses the namespace named `ns`.
- The host system must support network namespaces and each named namespace must previously have been set up. Naming a nonexistent namespace produces an error.
- If the variable value specifies multiple addresses, it can include addresses in the global namespace, in named namespaces, or a mix.

For additional information about network namespaces, see [Section 5.1.14, “Network Namespace Support”](#).

Important

Because X Plugin is not a mandatory plugin, it does not prevent server startup if there is an error in the specified address or list of addresses (as MySQL Server does for `bind_address` errors). With X Plugin, if one of the listed addresses cannot be parsed or if X Plugin cannot bind to it, the address is skipped, an error message is logged, and X Plugin attempts to bind to each of the remaining addresses. X Plugin's `Mysqlx_address` status variable displays only those addresses from the list for which the bind succeeded. If none of the listed addresses results in a successful bind, or if a single specified address fails, X Plugin logs the error message `ER_XPLUGIN_FAILED_TO_PREPARE_IO_INTERFACES` stating that X Protocol cannot be used. `mysqlx_bind_address` is not dynamic, so to fix any issues you must stop the server, correct the system variable value, and restart the server.

- `mysqlx_compression_algorithms`

| | |
|---------------------|--|
| Command-Line Format | <code>--mysqlx-compression-algorithms=value</code> |
|---------------------|--|

| | |
|--------------------------------------|--|
| Introduced | 8.0.19 |
| System Variable | mysqlx_compression_algorithms |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Set |
| Default Value | deflate_stream , lz4_message , zstd_stream |
| Valid Values | deflate_stream lz4_message zstd_stream |

The compression algorithms that are permitted for use on X Protocol connections. By default, the Deflate, LZ4, and zstd algorithms are all permitted. To disallow any of the algorithms, set [mysqlx_compression_algorithms](#) to include only the ones you permit. The algorithm names [deflate_stream](#), [lz4_message](#), and [zstd_stream](#) can be specified in any combination, and the order and case are not important. If you set the system variable to the empty string, no compression algorithms are permitted and only uncompressed connections are used. Use the algorithm-specific system variables to adjust the default and maximum compression level for each permitted algorithm. For more details, and information on how connection compression for X Protocol relates to the equivalent settings for MySQL Server, see [Section 20.5.5, “Connection Compression with X Plugin”](#).

- [mysqlx_connect_timeout](#)

| | |
|--------------------------------------|---|
| Command-Line Format | <code>--mysqlx-connect-timeout=#</code> |
| System Variable | mysqlx_connect_timeout |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value | 30 |
| Minimum Value | 1 |
| Maximum Value | 1000000000 |

The number of seconds X Plugin waits for the first packet to be received from newly connected clients. This is the X Plugin equivalent of [connect_timeout](#); see that variable description for more information.

- [mysqlx_deflate_default_compression_level](#)

| | |
|--------------------------------------|--|
| Command-Line Format | <code>-- mysqlx_deflate_default_compression_level=#</code> |
| Introduced | 8.0.20 |
| System Variable | mysqlx_deflate_default_compression_level |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |

| | |
|---------------|---------|
| Type | Integer |
| Default Value | 3 |
| Minimum Value | 1 |
| Maximum Value | 9 |

The default compression level that the server uses for the Deflate algorithm on X Protocol connections. Specify the level as an integer from 1 (the lowest compression effort) to 9 (the highest effort). This level is used if the client does not request a compression level during capability negotiation. If you do not specify this system variable, the server uses level 3 as the default. For more information, see [Section 20.5.5, “Connection Compression with X Plugin”](#).

- `mysqlx_deflate_max_client_compression_level`

| | |
|-----------------------------------|--|
| Command-Line Format | -- <code>mysqlx_deflate_max_client_compression_level=#</code> |
| Introduced | 8.0.20 |
| System Variable | <code>mysqlx_deflate_max_client_compression_level</code> |
| Scope | Global |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Integer |
| Default Value | 5 |
| Minimum Value | 1 |
| Maximum Value | 9 |

The maximum compression level that the server permits for the Deflate algorithm on X Protocol connections. The range is the same as for the default compression level for this algorithm. If the client requests a higher compression level than this, the server uses the level you set here. If you do not specify this system variable, the server sets a maximum compression level of 5.

- `mysqlx_document_id_unique_prefix`

| | |
|-----------------------------------|--|
| Command-Line Format | -- <code>mysqlx-document-id-unique-prefix=#</code> |
| System Variable | <code>mysqlx_document_id_unique_prefix</code> |
| Scope | Global |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Integer |
| Default Value | 0 |
| Minimum Value | 0 |
| Maximum Value | 65535 |

Sets the first 4 bytes of document IDs generated by the server when documents are added to a collection. By setting this variable to a unique value per instance, you can ensure document IDs are unique across instances. See [Understanding Document IDs](#).

- `mysqlx_enable_hello_notice`

| | |
|-----------------------------------|--|
| Command-Line Format | <code>--mysqlx-enable-hello-notice[={OFF ON}]</code> |
| System Variable | <code>mysqlx_enable_hello_notice</code> |
| Scope | Global |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Boolean |
| Default Value | ON |

Controls messages sent to classic MySQL protocol clients that try to connect over X Protocol. When enabled, clients which do not support X Protocol that attempt to connect to the server X Protocol port receive an error explaining they are using the wrong protocol.

- `mysqlx_idle_worker_thread_timeout`

| | |
|-----------------------------------|--|
| Command-Line Format | <code>--mysqlx-idle-worker-thread-timeout=#</code> |
| System Variable | <code>mysqlx_idle_worker_thread_timeout</code> |
| Scope | Global |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Integer |
| Default Value | 60 |
| Minimum Value | 0 |
| Maximum Value | 3600 |

The number of seconds after which idle worker threads are terminated.

- `mysqlx_interactive_timeout`

| | |
|-----------------------------------|---|
| Command-Line Format | <code>--mysqlx-interactive-timeout=#</code> |
| System Variable | <code>mysqlx_interactive_timeout</code> |
| Scope | Global |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Integer |
| Default Value | 28800 |
| Minimum Value | 1 |
| Maximum Value | 2147483 |

The default value of the `mysqlx_wait_timeout` session variable for interactive clients. (The number of seconds to wait for interactive clients to timeout.)

- `mysqlx_lz4_default_compression_level`

| | |
|-----------------------------------|---|
| Command-Line Format | -- <code>mysqlx_lz4_default_compression_level=#</code> |
| Introduced | 8.0.20 |
| System Variable | <code>mysqlx_lz4_default_compression_level</code> |
| Scope | Global |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Integer |
| Default Value | 2 |
| Minimum Value | 0 |
| Maximum Value | 16 |

The default compression level that the server uses for the LZ4 algorithm on X Protocol connections. Specify the level as an integer from 0 (the lowest compression effort) to 16 (the highest effort). This level is used if the client does not request a compression level during capability negotiation. If you do not specify this system variable, the server uses level 2 as the default. For more information, see [Section 20.5.5, “Connection Compression with X Plugin”](#).

- `mysqlx_lz4_max_client_compression_level`

| | |
|-----------------------------------|--|
| Command-Line Format | -- <code>mysqlx_lz4_max_client_compression_level=#</code> |
| Introduced | 8.0.20 |
| System Variable | <code>mysqlx_lz4_max_client_compression_level</code> |
| Scope | Global |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Integer |
| Default Value | 8 |
| Minimum Value | 0 |
| Maximum Value | 16 |

The maximum compression level that the server permits for the LZ4 algorithm on X Protocol connections. The range is the same as for the default compression level for this algorithm. If the client requests a higher compression level than this, the server uses the level you set here. If you do not specify this system variable, the server sets a maximum compression level of 8.

- `mysqlx_max_allowed_packet`

| | |
|-----------------------------------|---|
| Command-Line Format | -- <code>mysqlx-max-allowed-packet=#</code> |
| System Variable | <code>mysqlx_max_allowed_packet</code> |
| Scope | Global |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |

| | |
|---------------|------------|
| Type | Integer |
| Default Value | 67108864 |
| Minimum Value | 512 |
| Maximum Value | 1073741824 |

The maximum size of network packets that can be received by X Plugin. This limit also applies when compression is used for the connection, so the network packet must be smaller than this size after the message has been decompressed. This is the X Plugin equivalent of `max_allowed_packet`; see that variable description for more information.

- `mysqlx_max_connections`

| | |
|-----------------------------------|---|
| Command-Line Format | <code>--mysqlx-max-connections=#</code> |
| System Variable | <code>mysqlx_max_connections</code> |
| Scope | Global |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Integer |
| Default Value | 100 |
| Minimum Value | 1 |
| Maximum Value | 65535 |

The maximum number of concurrent client connections X Plugin can accept. This is the X Plugin equivalent of `max_connections`; see that variable description for more information.

For modifications to this variable, if the new value is smaller than the current number of connections, the new limit is taken into account only for new connections.

- `mysqlx_min_worker_threads`

| | |
|-----------------------------------|--|
| Command-Line Format | <code>--mysqlx-min-worker-threads=#</code> |
| System Variable | <code>mysqlx_min_worker_threads</code> |
| Scope | Global |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Integer |
| Default Value | 2 |
| Minimum Value | 1 |
| Maximum Value | 100 |

The minimum number of worker threads used by X Plugin for handling client requests.

- `mysqlx_port`

| | |
|---------------------|-------------------------------------|
| Command-Line Format | <code>--mysqlx-port=port_num</code> |
| System Variable | <code>mysqlx_port</code> |

| | |
|--------------------------------------|---------|
| Scope | Global |
| Dynamic | No |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value | 33060 |
| Minimum Value | 1 |
| Maximum Value | 65535 |

The network port on which X Plugin listens for TCP/IP connections. This is the X Plugin equivalent of [port](#); see that variable description for more information.

- [mysqlx_port_open_timeout](#)

| | |
|--------------------------------------|---|
| Command-Line Format | <code>--mysqlx-port-open-timeout=#</code> |
| System Variable | mysqlx_port_open_timeout |
| Scope | Global |
| Dynamic | No |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value | 0 |
| Minimum Value | 0 |
| Maximum Value | 120 |

The number of seconds X Plugin waits for a TCP/IP port to become free.

- [mysqlx_read_timeout](#)

| | |
|--------------------------------------|--------------------------------------|
| Command-Line Format | <code>--mysqlx-read-timeout=#</code> |
| System Variable | mysqlx_read_timeout |
| Scope | Session |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value | 28800 |
| Minimum Value | 30 |
| Maximum Value | 2147483 |

The number of seconds that X Plugin waits for blocking read operations to complete. After this time, if the read operation is not successful, X Plugin closes the connection and returns a warning notice with the error code [ER_IO_READ_ERROR](#) to the client application.

- [mysqlx_socket](#)

| | |
|---------------------|--|
| Command-Line Format | <code>--mysqlx-socket=file_name</code> |
| System Variable | mysqlx_socket |

| | |
|----------------------|-------------------------------|
| Scope | Global |
| Dynamic | No |
| SET_VAR Hint Applies | No |
| Type | String |
| Default Value | <code>/tmp/mysqlx.sock</code> |

The path to a Unix socket file which X Plugin uses for connections. This setting is only used by MySQL Server when running on Unix operating systems. Clients can use this socket to connect to MySQL Server using X Plugin.

The default `mysqlx_socket` path and file name is based on the default path and file name for the main socket file for MySQL Server, with the addition of an `x` appended to the file name. The default path and file name for the main socket file is `/tmp/mysql.sock`, therefore the default path and file name for the X Plugin socket file is `/tmp/mysqlx.sock`.

If you specify an alternative path and file name for the main socket file at server startup using the `socket` system variable, this does not affect the default for the X Plugin socket file. In this situation, if you want to store both sockets at a single path, you must set the `mysqlx_socket` system variable as well. For example in a configuration file:

```
socket=/home/sockets/mysql/mysql.sock
mysqlx_socket=/home/sockets/xplugin/xplugin.sock
```

If you change the default path and file name for the main socket file at compile time using the `MYSQL_UNIX_ADDR` compile option, this does affect the default for the X Plugin socket file, which is formed by appending an `x` to the `MYSQL_UNIX_ADDR` file name. If you want to set a different default for the X Plugin socket file at compile time, use the `MYSQLX_UNIX_ADDR` compile option.

The `MYSQLX_UNIX_PORT` environment variable can also be used to set a default for the X Plugin socket file at server startup (see [Section 4.9, "Environment Variables"](#)). If you set this environment variable, it overrides the compiled `MYSQLX_UNIX_ADDR` value, but is overridden by the `mysqlx_socket` value.

- `mysqlx_ssl_ca`

| | |
|----------------------|--|
| Command-Line Format | <code>--mysqlx-ssl-ca=file_name</code> |
| System Variable | <code>mysqlx_ssl_ca</code> |
| Scope | Global |
| Dynamic | No |
| SET_VAR Hint Applies | No |
| Type | File name |
| Default Value | <code>NULL</code> |

The `mysqlx_ssl_ca` system variable is like `ssl_ca`, except that it applies to X Plugin rather than the MySQL Server main connection interface. For information about configuring encryption support for X Plugin, see [Section 20.5.3, "Using Encrypted Connections with X Plugin"](#).

- `mysqlx_ssl_capath`

| | |
|---------------------|---|
| Command-Line Format | <code>--mysqlx-ssl-capath=dir_name</code> |
| System Variable | <code>mysqlx_ssl_capath</code> |

| | |
|--------------------------------------|----------------------|
| Scope | Global |
| Dynamic | No |
| SET_VAR Hint Applies | No |
| Type | Directory name |
| Default Value | NULL |

The `mysqlx_ssl_cacpath` system variable is like `ssl_cacpath`, except that it applies to X Plugin rather than the MySQL Server main connection interface. For information about configuring encryption support for X Plugin, see [Section 20.5.3, “Using Encrypted Connections with X Plugin”](#).

- `mysqlx_ssl_cert`

| | |
|--------------------------------------|--|
| Command-Line Format | <code>--mysqlx-ssl-cert=file_name</code> |
| System Variable | <code>mysqlx_ssl_cert</code> |
| Scope | Global |
| Dynamic | No |
| SET_VAR Hint Applies | No |
| Type | File name |
| Default Value | NULL |

The `mysqlx_ssl_cert` system variable is like `ssl_cert`, except that it applies to X Plugin rather than the MySQL Server main connection interface. For information about configuring encryption support for X Plugin, see [Section 20.5.3, “Using Encrypted Connections with X Plugin”](#).

- `mysqlx_ssl_cipher`

| | |
|--------------------------------------|---------------------------------------|
| Command-Line Format | <code>--mysqlx-ssl-cipher=name</code> |
| System Variable | <code>mysqlx_ssl_cipher</code> |
| Scope | Global |
| Dynamic | No |
| SET_VAR Hint Applies | No |
| Type | String |
| Default Value | NULL |

The `mysqlx_ssl_cipher` system variable is like `ssl_cipher`, except that it applies to X Plugin rather than the MySQL Server main connection interface. For information about configuring encryption support for X Plugin, see [Section 20.5.3, “Using Encrypted Connections with X Plugin”](#).

- `mysqlx_ssl_crl`

| | |
|--------------------------------------|---|
| Command-Line Format | <code>--mysqlx-ssl-crl=file_name</code> |
| System Variable | <code>mysqlx_ssl_crl</code> |
| Scope | Global |
| Dynamic | No |
| SET_VAR Hint Applies | No |
| Type | File name |

| | |
|---------------|------|
| Default Value | NULL |
|---------------|------|

The `mysqlx_ssl_crl` system variable is like `ssl_crl`, except that it applies to X Plugin rather than the MySQL Server main connection interface. For information about configuring encryption support for X Plugin, see [Section 20.5.3, “Using Encrypted Connections with X Plugin”](#).

- `mysqlx_ssl_crlpath`

| | |
|----------------------|--|
| Command-Line Format | <code>--mysqlx-ssl-crlpath=dir_name</code> |
| System Variable | <code>mysqlx_ssl_crlpath</code> |
| Scope | Global |
| Dynamic | No |
| SET_VAR Hint Applies | No |
| Type | Directory name |
| Default Value | NULL |

The `mysqlx_ssl_crlpath` system variable is like `ssl_crlpath`, except that it applies to X Plugin rather than the MySQL Server main connection interface. For information about configuring encryption support for X Plugin, see [Section 20.5.3, “Using Encrypted Connections with X Plugin”](#).

- `mysqlx_ssl_key`

| | |
|----------------------|---|
| Command-Line Format | <code>--mysqlx-ssl-key=file_name</code> |
| System Variable | <code>mysqlx_ssl_key</code> |
| Scope | Global |
| Dynamic | No |
| SET_VAR Hint Applies | No |
| Type | File name |
| Default Value | NULL |

The `mysqlx_ssl_key` system variable is like `ssl_key`, except that it applies to X Plugin rather than the MySQL Server main connection interface. For information about configuring encryption support for X Plugin, see [Section 20.5.3, “Using Encrypted Connections with X Plugin”](#).

- `mysqlx_wait_timeout`

| | |
|----------------------|--------------------------------------|
| Command-Line Format | <code>--mysqlx-wait-timeout=#</code> |
| System Variable | <code>mysqlx_wait_timeout</code> |
| Scope | Session |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value | 28800 |
| Minimum Value | 1 |

| | |
|---------------|---------|
| Maximum Value | 2147483 |
|---------------|---------|

The number of seconds that X Plugin waits for activity on a connection. After this time, if the read operation is not successful, X Plugin closes the connection. If the client is noninteractive, the initial value of the session variable is copied from the global `mysqlx_wait_timeout` variable. For interactive clients, the initial value is copied from the session `mysqlx_interactive_timeout`.

- `mysqlx_write_timeout`

| | |
|-----------------------------------|---------------------------------------|
| Command-Line Format | <code>--mysqlx-write-timeout=#</code> |
| System Variable | <code>mysqlx_write_timeout</code> |
| Scope | Session |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Integer |
| Default Value | 60 |
| Minimum Value | 1 |
| Maximum Value | 2147483 |

The number of seconds that X Plugin waits for blocking write operations to complete. After this time, if the write operation is not successful, X Plugin closes the connection.

- `mysqlx_zstd_default_compression_level`

| | |
|-----------------------------------|--|
| Command-Line Format | <code>--mysqlx_zstd_default_compression_level=#</code> |
| Introduced | 8.0.20 |
| System Variable | <code>mysqlx_zstd_default_compression_level</code> |
| Scope | Global |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Integer |
| Default Value | 3 |
| Minimum Value | -131072 |
| Maximum Value | 22 |

The default compression level that the server uses for the zstd algorithm on X Protocol connections. For versions of the zstd library from 1.4.0, you can set positive values from 1 to 22 (the highest compression effort), or negative values which represent progressively lower effort. A value of 0 is converted to a value of 1. For earlier versions of the zstd library, you can only specify the value 3. This level is used if the client does not request a compression level during capability negotiation. If you do not specify this system variable, the server uses level 3 as the default. For more information, see [Section 20.5.5, “Connection Compression with X Plugin”](#).

- `mysqlx_zstd_max_client_compression_level`

| | |
|---------------------|---|
| Command-Line Format | <code>--mysqlx_zstd_max_client_compression_level=#</code> |
|---------------------|---|

| | |
|--------------------------------------|--|
| Introduced | 8.0.20 |
| System Variable | mysqlx_zstd_max_client_compression_level |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value | 11 |
| Minimum Value | -131072 |
| Maximum Value | 22 |

The maximum compression level that the server permits for the zstd algorithm on X Protocol connections. The range is the same as for the default compression level for this algorithm. If the client requests a higher compression level than this, the server uses the level you set here. If you do not specify this system variable, the server sets a maximum compression level of 11.

20.5.6.3 X Plugin Status Variables

The X Plugin status variables have the following meanings.

- [Mysqlx_aborted_clients](#)

The number of clients that were disconnected because of an input or output error.

- [Mysqlx_address](#)

The network address or addresses for which X Plugin accepts TCP/IP connections. If multiple addresses were specified using the [mysqlx_bind_address](#) system variable, [Mysqlx_address](#) displays only those addresses for which the bind succeeded. If the bind has failed for every network address specified by [mysqlx_bind_address](#), or if the [skip_networking](#) option has been used, the value of [Mysqlx_address](#) is `UNDEFINED`. If X Plugin startup is not yet complete, the value of [Mysqlx_address](#) is empty.

- [Mysqlx_bytes_received](#)

The total number of bytes received through the network. If compression is used for the connection, this figure comprises compressed message payloads measured before decompression ([Mysqlx_bytes_received_compressed_payload](#)), any items in compressed messages that were not compressed such as X Protocol headers, and any uncompressed messages.

- [Mysqlx_bytes_received_compressed_payload](#)

The number of bytes received as compressed message payloads, measured before decompression.

- [Mysqlx_bytes_received_uncompressed_frame](#)

The number of bytes received as compressed message payloads, measured after decompression.

- [Mysqlx_bytes_sent](#)

The total number of bytes sent through the network. If compression is used for the connection, this figure comprises compressed message payloads measured after compression ([Mysqlx_bytes_sent_compressed_payload](#)), any items in compressed messages that were not compressed such as X Protocol headers, and any uncompressed messages.

- `Mysqlx_bytes_sent_compressed_payload`
The number of bytes sent as compressed message payloads, measured after compression.
- `Mysqlx_bytes_sent_uncompressed_frame`
The number of bytes sent as compressed message payloads, measured before compression.
- `Mysqlx_compression_algorithm`
(Session scope) The compression algorithm in use for the X Protocol connection for this session. The permitted compression algorithms are listed by the `mysqlx_compression_algorithms` system variable.
- `Mysqlx_compression_level`
(Session scope) The compression level in use for the X Protocol connection for this session.
- `Mysqlx_connection_accept_errors`
The number of connections which have caused accept errors.
- `Mysqlx_connection_errors`
The number of connections which have caused errors.
- `Mysqlx_connections_accepted`
The number of connections which have been accepted.
- `Mysqlx_connections_closed`
The number of connections which have been closed.
- `Mysqlx_connections_rejected`
The number of connections which have been rejected.
- `Mysqlx_crud_create_view`
The number of create view requests received.
- `Mysqlx_crud_delete`
The number of delete requests received.
- `Mysqlx_crud_drop_view`
The number of drop view requests received.
- `Mysqlx_crud_find`
The number of find requests received.
- `Mysqlx_crud_insert`
The number of insert requests received.
- `Mysqlx_crud_modify_view`
The number of modify view requests received.

- `Mysqlx_crud_update`
The number of update requests received.
- `Mysqlx_cursor_close`
The number of cursor-close messages received
- `Mysqlx_cursor_fetch`
The number of cursor-fetch messages received
- `Mysqlx_cursor_open`
The number of cursor-open messages received
- `Mysqlx_errors_sent`
The number of errors sent to clients.
- `Mysqlx_errors_unknown_message_type`
The number of unknown message types that have been received.
- `Mysqlx_expect_close`
The number of expectation blocks closed.
- `Mysqlx_expect_open`
The number of expectation blocks opened.
- `Mysqlx_init_error`
The number of errors during initialisation.
- `Mysqlx_messages_sent`
The total number of messages of all types sent to clients.
- `Mysqlx_notice_global_sent`
The number of global notifications sent to clients.
- `Mysqlx_notice_other_sent`
The number of other types of notices sent back to clients.
- `Mysqlx_notice_warning_sent`
The number of warning notices sent back to clients.
- `Mysqlx_notified_by_group_replication`
Number of Group Replication notifications sent to clients.
- `Mysqlx_port`
The TCP port which X Plugin is listening to. If a network bind has failed, or if the `skip_networking` system variable is enabled, the value shows `UNDEFINED`.

- `Mysqlx_prep_deallocate`
The number of prepared-statement-deallocate messages received
- `Mysqlx_prep_execute`
The number of prepared-statement-execute messages received
- `Mysqlx_prep_prepare`
The number of prepared-statement messages received
- `Mysqlx_rows_sent`
The number of rows sent back to clients.
- `Mysqlx_sessions`
The number of sessions that have been opened.
- `Mysqlx_sessions_accepted`
The number of session attempts which have been accepted.
- `Mysqlx_sessions_closed`
The number of sessions that have been closed.
- `Mysqlx_sessions_fatal_error`
The number of sessions that have closed with a fatal error.
- `Mysqlx_sessions_killed`
The number of sessions which have been killed.
- `Mysqlx_sessions_rejected`
The number of session attempts which have been rejected.
- `Mysqlx_socket`
The Unix socket which X Plugin is listening to.
- `Mysqlx_ssl_accept_renegotiates`
The number of negotiations needed to establish the connection.
- `Mysqlx_ssl_accepts`
The number of accepted SSL connections.
- `Mysqlx_ssl_active`
If SSL is active.
- `Mysqlx_ssl_cipher`
The current SSL cipher (empty for non-SSL connections).

- `Mysqlx_ssl_cipher_list`
A list of possible SSL ciphers (empty for non-SSL connections).
- `Mysqlx_ssl_ctx_verify_depth`
The certificate verification depth limit currently set in ctx.
- `Mysqlx_ssl_ctx_verify_mode`
The certificate verification mode currently set in ctx.
- `Mysqlx_ssl_finished_accepts`
The number of successful SSL connections to the server.
- `Mysqlx_ssl_server_not_after`
The last date for which the SSL certificate is valid.
- `Mysqlx_ssl_server_not_before`
The first date for which the SSL certificate is valid.
- `Mysqlx_ssl_verify_depth`
The certificate verification depth for SSL connections.
- `Mysqlx_ssl_verify_mode`
The certificate verification mode for SSL connections.
- `Mysqlx_ssl_version`
The name of the protocol used for SSL connections.
- `Mysqlx_stmt_create_collection`
The number of create collection statements received.
- `Mysqlx_stmt_create_collection_index`
The number of create collection index statements received.
- `Mysqlx_stmt_disable_notices`
The number of disable notice statements received.
- `Mysqlx_stmt_drop_collection`
The number of drop collection statements received.
- `Mysqlx_stmt_drop_collection_index`
The number of drop collection index statements received.
- `Mysqlx_stmt_enable_notices`
The number of enable notice statements received.

- `Mysqlx_stmt_ensure_collection`
The number of ensure collection statements received.
- `Mysqlx_stmt_execute_mysqlx`
The number of StmtExecute messages received with namespace set to `mysqlx`.
- `Mysqlx_stmt_execute_sql`
The number of StmtExecute requests received for the SQL namespace.
- `Mysqlx_stmt_execute_xplugin`
The number of StmtExecute requests received for the `xplugin` namespace. From MySQL 8.0.19, the `xplugin` namespace has been removed so this status variable is no longer used.
- `Mysqlx_stmt_get_collection_options`
The number of get collection object statements received.
- `Mysqlx_stmt_kill_client`
The number of kill client statements received.
- `Mysqlx_stmt_list_clients`
The number of list client statements received.
- `Mysqlx_stmt_list_notices`
The number of list notice statements received.
- `Mysqlx_stmt_list_objects`
The number of list object statements received.
- `Mysqlx_stmt_modify_collection_options`
The number of modify collection options statements received.
- `Mysqlx_stmt_ping`
The number of ping statements received.
- `Mysqlx_worker_threads`
The number of worker threads available.
- `Mysqlx_worker_threads_active`
The number of worker threads currently used.

20.5.7 Monitoring X Plugin

For general X Plugin monitoring, use the status variables that it exposes. See [Section 20.5.6.3, “X Plugin Status Variables”](#). For information specifically about monitoring the effects of message compression, see [Monitoring Connection Compression for X Plugin](#).

Monitoring SQL Generated by X Plugin

This section describes how to monitor the SQL statements which X Plugin generates when you run X DevAPI operations. When you execute a CRUD statement, it is translated into SQL and executed against the server. To be able to monitor the generated SQL, the Performance Schema tables must be enabled. The SQL is registered under the `performance_schema.events_statements_current`, `performance_schema.events_statements_history`, and `performance_schema.events_statements_history_long` tables. The following example uses the `world_x` schema, imported as part of the quickstart tutorials in this section. We use MySQL Shell in Python mode, and the `\sql` command which enables you to issue SQL statements without changing to SQL mode. This is important, because if you instead try to switch to SQL mode, the procedure shows the result of this operation rather than the X DevAPI operation. The `\sql` command is used in the same way if you are using MySQL Shell in JavaScript mode.

1. Check if the `events_statements_history` consumer is enabled. Issue:

```
mysql-py> \sql SELECT enabled FROM performance_schema.setup_consumers WHERE NAME = 'events_statements_h
+-----+
| enabled |
+-----+
| YES     |
+-----+
```

2. Check if all instruments report data to the consumer. Issue:

```
mysql-py> \sql SELECT NAME, ENABLED, TIMED FROM performance_schema.setup_instruments WHERE NAME LIKE 's
```

If this statement reports at least one row, you need to enable the instruments. See [Section 27.4, “Performance Schema Runtime Configuration”](#).

3. Get the thread ID of the current connection. Issue:

```
mysql-py> \sql SELECT thread_id INTO @id FROM performance_schema.threads WHERE processlist_id=connectio
```

4. Execute the X DevAPI CRUD operation for which you want to see the generated SQL. For example, issue:

```
mysql-py> db.CountryInfo.find("Name = :country").bind("country", "Italy")
```

You must not issue any further operations for the next step to show the correct result.

5. Show the last SQL query made by this thread ID. Issue:

```
mysql-py> \sql SELECT THREAD_ID, MYSQL_ERRNO,SQL_TEXT FROM performance_schema.events_statements_history
+-----+-----+-----+
| THREAD_ID | MYSQL_ERRNO | SQL_TEXT
+-----+-----+-----+
|          29 |           0 | SELECT doc FROM `world_x`.`CountryInfo` WHERE (JSON_EXTRACT(doc,'$.Name') =
```

The result shows the SQL generated by X Plugin based on the most recent statement, in this case the X DevAPI CRUD operation from the previous step.

Chapter 21 InnoDB Cluster

This chapter introduces MySQL InnoDB Cluster, which combines MySQL technologies to enable you to deploy and administer a complete integrated high availability solution for MySQL. This content is a high-level overview of InnoDB Cluster, for full documentation, see [MySQL InnoDB Cluster](#).

Important

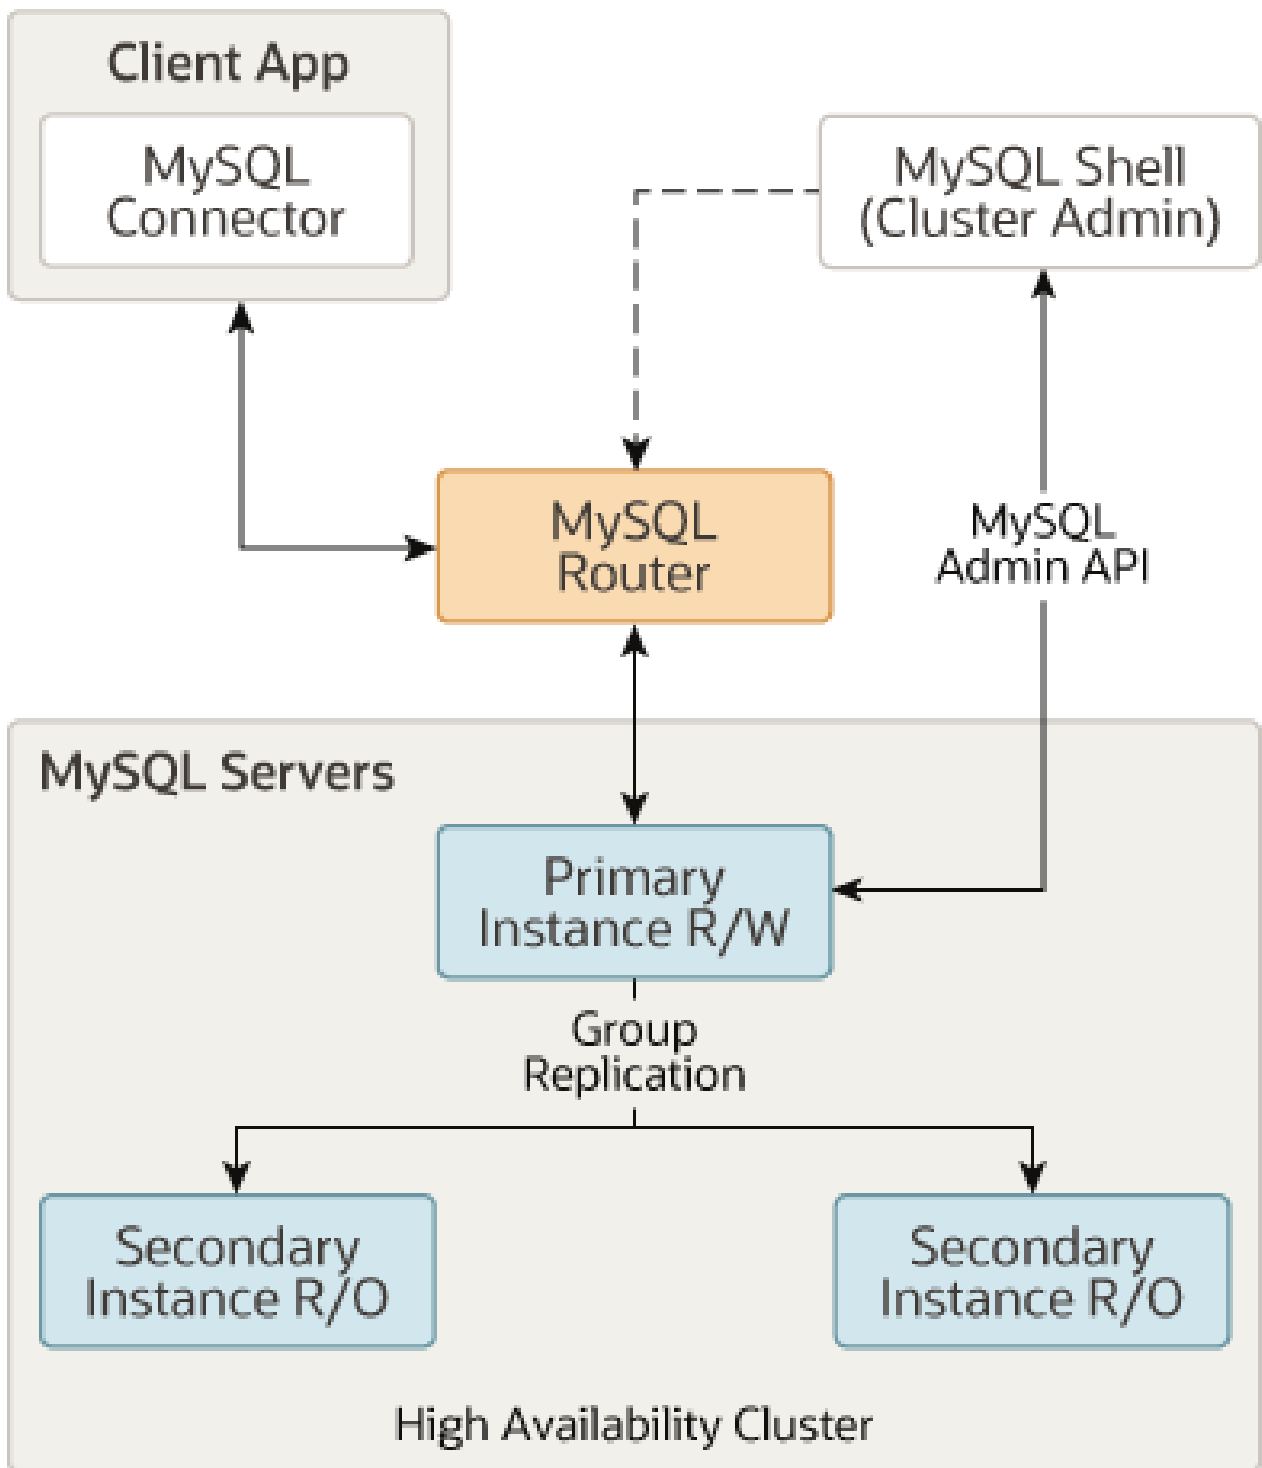

InnoDB Cluster does not provide support for MySQL NDB Cluster. For more information about MySQL NDB Cluster, see [Chapter 23, MySQL NDB Cluster 8.0](#) and [Section 23.2.6, “MySQL Server Using InnoDB Compared with NDB Cluster”](#).

An InnoDB Cluster consists of at least three MySQL Server instances, and it provides high-availability and scaling features. InnoDB Cluster uses the following MySQL technologies:

- [MySQL Shell](#), which is an advanced client and code editor for MySQL.
- MySQL Server, and [Group Replication](#), which enables a set of MySQL instances to provide high-availability. InnoDB Cluster provides an alternative, easy to use programmatic way to work with Group Replication.
- [MySQL Router](#), a lightweight middleware that provides transparent routing between your application and InnoDB Cluster.

The following diagram shows an overview of how these technologies work together:

Figure 21.1 InnoDB Cluster overview

Being built on MySQL [Group Replication](#), provides features such as automatic membership management, fault tolerance, automatic failover, and so on. An InnoDB Cluster usually runs in a single-primary mode, with one primary instance (read-write) and multiple secondary instances (read-only). Advanced users can also take advantage of a [multi-primary](#) mode, where all instances are primaries. You can even change the topology of the cluster while InnoDB Cluster is online, to ensure the highest possible availability.

You work with InnoDB Cluster using the [AdminAPI](#), provided as part of MySQL Shell. AdminAPI is available in JavaScript and Python, and is well suited to scripting and automation of deployments of MySQL to achieve high-availability and scalability. By using MySQL Shell's AdminAPI, you can avoid the need to configure many instances manually. Instead, AdminAPI provides an effective modern interface to sets of MySQL instances and enables you to provision, administer, and monitor your deployment from one central tool.

To get started with InnoDB Cluster you need to [download](#) and [install](#) MySQL Shell. You need some hosts with MySQL Server instances [installed](#), and you can also [install](#) MySQL Router.

InnoDB Cluster supports [MySQL Clone](#), which enables you to provision instances simply. In the past, to provision a new instance before it joins a set of MySQL instances you would need to somehow manually transfer the transactions to the joining instance. This could involve making file copies, manually copying them, and so on. Using InnoDB Cluster, you can simply [add an instance](#) to the cluster and it is automatically provisioned.

Similarly, InnoDB Cluster is tightly integrated with [MySQL Router](#), and you can use AdminAPI to [work with](#) them together. MySQL Router can automatically configure itself based on an InnoDB Cluster, in a process called [bootstrapping](#), which removes the need for you to configure routing manually. MySQL Router then transparently connects client applications to the InnoDB Cluster, providing routing and load-balancing for client connections. This integration also enables you to administer some aspects of a MySQL Router bootstrapped against an InnoDB Cluster using AdminAPI. InnoDB Cluster status information includes details about MySQL Routers bootstrapped against the cluster. Operations enable you to [create MySQL Router users](#) at the cluster level, to work with the MySQL Routers bootstrapped against the cluster, and so on.

For more information on these technologies, see the user documentation linked in the descriptions. In addition to this user documentation, there is developer documentation for all AdminAPI methods in the MySQL Shell JavaScript API Reference or MySQL Shell Python API Reference, available from [Connectors and APIs](#).

Chapter 22 InnoDB ReplicaSet

This chapter introduces MySQL InnoDB ReplicaSet, which combines MySQL technologies to enable you to deploy and administer [Chapter 17, Replication](#). This content is a high-level overview of InnoDB ReplicaSet, for full documentation, see [MySQL InnoDB ReplicaSet](#).

An InnoDB ReplicaSet consists of at least two MySQL Server instances, and it provides all of the MySQL Replication features you are familiar with, such as read scale-out and data security. InnoDB ReplicaSet uses the following MySQL technologies:

- [MySQL Shell](#), which is an advanced client and code editor for MySQL.
- MySQL Server, and [Chapter 17, Replication](#), which enables a set of MySQL instances to provide availability and asynchronous read scale-out. InnoDB ReplicaSet provides an alternative, easy to use programmatic way to work with Replication.
- [MySQL Router](#), a lightweight middleware that provides transparent routing between your application and InnoDB ReplicaSet.

The interface to an InnoDB ReplicaSet is similar to [MySQL InnoDB Cluster](#), you use MySQL Shell to work with MySQL Server instances as a ReplicaSet, and MySQL Router is also tightly integrated in the same way as InnoDB Cluster.

Being based on MySQL Replication, an InnoDB ReplicaSet has a single primary, which replicates to one or more secondary instances. An InnoDB ReplicaSet does not provide all of the features which InnoDB Cluster provides, such as automatic failover, or multi-primary mode. But, it does support features such as configuring, adding, and removing instances in a similar way. You can manually switch over or fail over to a secondary instance, for example in the event of a failure. You can even adopt an existing Replication deployment and then administer it as an InnoDB ReplicaSet.

You work with InnoDB ReplicaSet using the [AdminAPI](#), provided as part of MySQL Shell. AdminAPI is available in JavaScript and Python, and is well suited to scripting and automation of deployments of MySQL to achieve high-availability and scalability. By using MySQL Shell's AdminAPI, you can avoid the need to configure many instances manually. Instead, AdminAPI provides an effective modern interface to sets of MySQL instances and enables you to provision, administer, and monitor your deployment from one central tool.

To get started with InnoDB ReplicaSet you need to [download](#) and [install](#) MySQL Shell. You need some hosts with MySQL Server instances [installed](#), and you can also [install](#) MySQL Router.

InnoDB ReplicaSet supports [MySQL Clone](#), which enables you to provision instances simply. In the past, to provision a new instance before it joined a MySQL Replication deployment, you would need to somehow manually transfer the transactions to the joining instance. This could involve making file copies, manually copying them, and so on. You can simply [add an instance](#) to the replica set and it is automatically provisioned.

Similarly, InnoDB ReplicaSet is tightly integrated with [MySQL Router](#), and you can use AdminAPI to [work with](#) them together. MySQL Router can automatically configure itself based on an InnoDB ReplicaSet, in a process called [bootstrapping](#), which removes the need for you to configure routing manually. MySQL Router then transparently connects client applications to the InnoDB ReplicaSet, providing routing and load-balancing for client connections. This integration also enables you to administer some aspects of a MySQL Router bootstrapped against an InnoDB ReplicaSet using AdminAPI. InnoDB ReplicaSet status information includes details about MySQL Routers bootstrapped against the ReplicaSet. Operations enable you to [create MySQL Router users](#) at the ReplicaSet level, to work with the MySQL Routers bootstrapped against the ReplicaSet, and so on.

For more information on these technologies, see the user documentation linked in the descriptions. In addition to this user documentation, there is developer documentation for all AdminAPI methods in the [MySQL Shell JavaScript API Reference](#) or [MySQL Shell Python API Reference](#), available from [Connectors and APIs](#).

Chapter 23 MySQL NDB Cluster 8.0

Table of Contents

| | | |
|---------|---|------|
| 23.1 | General Information | 4001 |
| 23.2 | NDB Cluster Overview | 4003 |
| 23.2.1 | NDB Cluster Core Concepts | 4005 |
| 23.2.2 | NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions | 4007 |
| 23.2.3 | NDB Cluster Hardware, Software, and Networking Requirements | 4011 |
| 23.2.4 | What is New in NDB Cluster | 4012 |
| 23.2.5 | Options, Variables, and Parameters Added, Deprecated or Removed in NDB 8.0 | 4036 |
| 23.2.6 | MySQL Server Using InnoDB Compared with NDB Cluster | 4041 |
| 23.2.7 | Known Limitations of NDB Cluster | 4044 |
| 23.3 | NDB Cluster Installation | 4056 |
| 23.3.1 | Installation of NDB Cluster on Linux | 4058 |
| 23.3.2 | Installing NDB Cluster on Windows | 4067 |
| 23.3.3 | Initial Configuration of NDB Cluster | 4076 |
| 23.3.4 | Initial Startup of NDB Cluster | 4078 |
| 23.3.5 | NDB Cluster Example with Tables and Data | 4079 |
| 23.3.6 | Safe Shutdown and Restart of NDB Cluster | 4082 |
| 23.3.7 | Upgrading and Downgrading NDB Cluster | 4083 |
| 23.3.8 | The NDB Cluster Auto-Installer (No longer supported) | 4086 |
| 23.4 | Configuration of NDB Cluster | 4108 |
| 23.4.1 | Quick Test Setup of NDB Cluster | 4109 |
| 23.4.2 | Overview of NDB Cluster Configuration Parameters, Options, and Variables | 4111 |
| 23.4.3 | NDB Cluster Configuration Files | 4132 |
| 23.4.4 | Using High-Speed Interconnects with NDB Cluster | 4317 |
| 23.5 | NDB Cluster Programs | 4318 |
| 23.5.1 | ndbd — The NDB Cluster Data Node Daemon | 4318 |
| 23.5.2 | ndbinfo_select_all — Select From ndbinfo Tables | 4329 |
| 23.5.3 | ndbmtd — The NDB Cluster Data Node Daemon (Multi-Threaded) | 4335 |
| 23.5.4 | ndb_mgmd — The NDB Cluster Management Server Daemon | 4336 |
| 23.5.5 | ndb_mgm — The NDB Cluster Management Client | 4349 |
| 23.5.6 | ndb_blob_tool — Check and Repair BLOB and TEXT columns of NDB Cluster Tables | 4354 |
| 23.5.7 | ndb_config — Extract NDB Cluster Configuration Information | 4361 |
| 23.5.8 | ndb_delete_all — Delete All Rows from an NDB Table | 4373 |
| 23.5.9 | ndb_desc — Describe NDB Tables | 4378 |
| 23.5.10 | ndb_drop_index — Drop Index from an NDB Table | 4388 |
| 23.5.11 | ndb_drop_table — Drop an NDB Table | 4393 |
| 23.5.12 | ndb_error_reporter — NDB Error-Reporting Utility | 4398 |
| 23.5.13 | ndb_import — Import CSV Data Into NDB | 4399 |
| 23.5.14 | ndb_index_stat — NDB Index Statistics Utility | 4416 |
| 23.5.15 | ndb_move_data — NDB Data Copy Utility | 4426 |
| 23.5.16 | ndb_perror — Obtain NDB Error Message Information | 4432 |
| 23.5.17 | ndb_print_backup_file — Print NDB Backup File Contents | 4435 |
| 23.5.18 | ndb_print_file — Print NDB Disk Data File Contents | 4440 |
| 23.5.19 | ndb_print_frag_file — Print NDB Fragment List File Contents | 4441 |
| 23.5.20 | ndb_print_schema_file — Print NDB Schema File Contents | 4442 |
| 23.5.21 | ndb_print_sys_file — Print NDB System File Contents | 4442 |
| 23.5.22 | ndb_redo_log_reader — Check and Print Content of Cluster Redo Log | 4442 |
| 23.5.23 | ndb_restore — Restore an NDB Cluster Backup | 4445 |
| 23.5.24 | ndb_select_all — Print Rows from an NDB Table | 4479 |

| | | |
|---------|--|------|
| 23.5.25 | <code>ndb_select_count</code> — Print Row Counts for NDB Tables | 4486 |
| 23.5.26 | <code>ndb_setup.py</code> — Start browser-based Auto-Installer for NDB Cluster (DEPRECATED) .. | 4490 |
| 23.5.27 | <code>ndb_show_tables</code> — Display List of NDB Tables | 4494 |
| 23.5.28 | <code>ndb_size.pl</code> — NDBCLUSTER Size Requirement Estimator | 4499 |
| 23.5.29 | <code>ndb_top</code> — View CPU usage information for NDB threads | 4502 |
| 23.5.30 | <code>ndb_waiter</code> — Wait for NDB Cluster to Reach a Given Status | 4508 |
| 23.5.31 | <code>ndbxfrm</code> — Compress, Decompress, Encrypt, and Decrypt Files Created by NDB Cluster | 4515 |
| 23.6 | Management of NDB Cluster | 4518 |
| 23.6.1 | Commands in the NDB Cluster Management Client | 4519 |
| 23.6.2 | NDB Cluster Log Messages | 4525 |
| 23.6.3 | Event Reports Generated in NDB Cluster | 4544 |
| 23.6.4 | Summary of NDB Cluster Start Phases | 4556 |
| 23.6.5 | Performing a Rolling Restart of an NDB Cluster | 4558 |
| 23.6.6 | NDB Cluster Single User Mode | 4560 |
| 23.6.7 | Adding NDB Cluster Data Nodes Online | 4561 |
| 23.6.8 | Online Backup of NDB Cluster | 4572 |
| 23.6.9 | MySQL Server Usage for NDB Cluster | 4578 |
| 23.6.10 | NDB Cluster Disk Data Tables | 4580 |
| 23.6.11 | Online Operations with ALTER TABLE in NDB Cluster | 4586 |
| 23.6.12 | Distributed MySQL Privileges with NDB_STORED_USER | 4589 |
| 23.6.13 | NDB API Statistics Counters and Variables | 4591 |
| 23.6.14 | <code>ndbinfo</code> : The NDB Cluster Information Database | 4602 |
| 23.6.15 | INFORMATION_SCHEMA Tables for NDB Cluster | 4676 |
| 23.6.16 | Quick Reference: NDB Cluster SQL Statements | 4676 |
| 23.6.17 | NDB Cluster Security Issues | 4683 |

| 23.7.11 | NDB Cluster Replication Conflict Resolution | 4725 |
| 23.8 | NDB Cluster Release Notes | 4737 |

This chapter provides information about MySQL *NDB Cluster*, a high-availability, high-redundancy version of MySQL adapted for the distributed computing environment. The most recent NDB Cluster release series uses version 8 of the [NDB](#) storage engine (also known as [NDBCLUSTER](#)) to enable running several computers with MySQL servers and other software in a cluster. NDB Cluster 8.0, now available as a General Availability (GA) release (beginning with version 8.0.19), incorporates version 8.0 of the [NDB](#) storage engine. NDB Cluster 7.6 and NDB Cluster 7.5, still available as GA releases, use versions 7.6 and 7.5 of [NDB](#), respectively. Previous GA releases still available for use in production, NDB Cluster 7.4 and NDB Cluster 7.3, incorporate [NDB](#) versions 7.4 and 7.3, respectively. *NDB 7.2 and older release series are no longer supported or maintained.*

This chapter contains information about NDB Cluster 8.0 releases through 8.0.27. NDB Cluster 8.0 is now available (beginning with NDB 8.0.19) as a General Availability release, and recommended for new deployments; the latest available release is NDB 8.0.26. NDB Cluster 7.6 and 7.5 are previous GA

releases still supported in production; for information about NDB Cluster 7.6, see [What is New in NDB Cluster 7.6](#). For similar information about NDB Cluster 7.5, see [What is New in NDB Cluster 7.5](#). NDB Cluster 7.4 and 7.3 are previous GA releases still supported in production, although we recommend that new deployments for production use NDB Cluster 8.0; see [MySQL NDB Cluster 7.3 and NDB Cluster 7.4](#).

23.1 General Information

MySQL NDB Cluster uses the MySQL server with the [NDB](#) storage engine. Support for the [NDB](#) storage engine is not included in standard MySQL Server 8.0 binaries built by Oracle. Instead, users of NDB Cluster binaries from Oracle should upgrade to the most recent binary release of NDB Cluster for supported platforms—these include RPMs that should work with most Linux distributions. NDB Cluster 8.0 users who build from source should use the sources provided for MySQL 8.0 and build with the options required to provide NDB support. (Locations where the sources can be obtained are listed later in this section.)

Important

MySQL NDB Cluster does not support InnoDB Cluster, which must be deployed using MySQL Server 8.0 with the [InnoDB](#) storage engine as well as additional applications that are not included in the NDB Cluster distribution. MySQL Server 8.0 binaries cannot be used with MySQL NDB Cluster. For more information about deploying and using InnoDB Cluster, see [MySQL AdminAPI, Section 23.2.6, “MySQL Server Using InnoDB Compared with NDB Cluster”](#), discusses differences between the [NDB](#) and [InnoDB](#) storage engines.

Supported Platforms. NDB Cluster is currently available and supported on a number of platforms. For exact levels of support available for on specific combinations of operating system versions, operating system distributions, and hardware platforms, please refer to <https://www.mysql.com/support/supportedplatforms/cluster.html>.

Availability. NDB Cluster binary and source packages are available for supported platforms from <https://dev.mysql.com/downloads/cluster/>.

NDB Cluster release numbers. NDB 8.0 follows the same release pattern as the MySQL Server 8.0 series of releases, beginning with MySQL 8.0.13 and MySQL NDB Cluster 8.0.13. In this *Manual* and other MySQL documentation, we identify these and later NDB Cluster releases employing a version number that begins with “NDB”. This version number is that of the [NDBCLUSTER](#) storage engine used in the NDB 8.0 release, and is the same as the MySQL 8.0 server version on which the NDB Cluster 8.0 release is based.

Version strings used in NDB Cluster software. The version string displayed by the `mysql` client supplied with the MySQL NDB Cluster distribution uses this format:

```
mysql-mysql_server_version-cluster
```

`mysql_server_version` represents the version of the MySQL Server on which the NDB Cluster release is based. For all NDB Cluster 8.0 releases, this is `8.0.n`, where `n` is the release number. Building from source using `-DWITH_NDBCLUSTER` or the equivalent adds the `-cluster` suffix to the version string. (See [Section 23.3.1.4, “Building NDB Cluster from Source on Linux”](#), and [Section 23.3.2.2, “Compiling and Installing NDB Cluster from Source on Windows”](#).) You can see this format used in the `mysql` client, as shown here:

```
shell> mysql
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 2
Server version: 8.0.27-cluster Source distribution
```

```
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SELECT VERSION()\G
***** 1. row *****
VERSION(): 8.0.27-cluster
1 row in set (0.00 sec)
```

The first General Availability release of NDB Cluster using MySQL 8.0 is NDB 8.0.19, using MySQL 8.0.19.

The version string displayed by other NDB Cluster programs not normally included with the MySQL 8.0 distribution uses this format:

```
mysql-mysql_server_version ndb-ndb_engine_version
```

`mysql_server_version` represents the version of the MySQL Server on which the NDB Cluster release is based. For all NDB Cluster 8.0 releases, this is `8.0.n`, where `n` is the release number. `ndb_engine_version` is the version of the NDB storage engine used by this release of the NDB Cluster software. For all NDB 8.0 releases, this number is the same as the MySQL Server version. You can see this format used in the output of the `SHOW` command in the `ndb_mgm` client, like this:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
-----
[ndbd(NDB)] 2 node(s)
id=1 @10.0.10.6 (mysql-8.0.26 ndb-8.0.27, Nodegroup: 0, *)
id=2 @10.0.10.8 (mysql-8.0.26 ndb-8.0.27, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=3 @10.0.10.2 (mysql-8.0.26 ndb-8.0.27)

[mysqld(API)] 2 node(s)
id=4 @10.0.10.10 (mysql-8.0.26 ndb-8.0.27)
id=5 (not connected, accepting connect from any host)
```

Compatibility with standard MySQL 8.0 releases. While many standard MySQL schemas and applications can work using NDB Cluster, it is also true that unmodified applications and database schemas may be slightly incompatible or have suboptimal performance when run using NDB Cluster (see [Section 23.2.7, “Known Limitations of NDB Cluster”](#)). Most of these issues can be overcome, but this also means that you are very unlikely to be able to switch an existing application datastore—that currently uses, for example, `MyISAM` or `InnoDB`—to use the NDB storage engine without allowing for the possibility of changes in schemas, queries, and applications. A `mysqld` compiled without NDB support (that is, built without `-DWITH_NDBCLUSTER_STORAGE_ENGINE` or its alias `-DWITH_NDBCLUSTER`) cannot function as a drop-in replacement for a `mysqld` that is built with it.

NDB Cluster development source trees. NDB Cluster development trees can also be accessed from <https://github.com/mysql/mysql-server>.

The NDB Cluster development sources maintained at <https://github.com/mysql/mysql-server> are licensed under the GPL. For information about obtaining MySQL sources using Git and building them yourself, see [Section 2.9.5, “Installing MySQL Using a Development Source Tree”](#).

Note

As with MySQL Server 8.0, NDB Cluster 8.0 releases are built using `CMake`.

NDB Cluster 8.0 is available beginning with NDB 8.0.19 as a General Availability release, and is recommended for new deployments. NDB Cluster 7.6 and 7.5 are previous GA releases still supported

in production; for information about NDB Cluster 7.6, see [What is New in NDB Cluster 7.6](#). For similar information about NDB Cluster 7.5, see [What is New in NDB Cluster 7.5](#). NDB Cluster 7.4 and 7.3 are previous GA releases still supported in production, although we recommend that new deployments for production use NDB Cluster 8.0; see [MySQL NDB Cluster 7.3 and NDB Cluster 7.4](#).

The contents of this chapter are subject to revision as NDB Cluster continues to evolve. Additional information regarding NDB Cluster can be found on the MySQL website at <http://www.mysql.com/products/cluster/>.

Additional Resources. More information about NDB Cluster can be found in the following places:

- For answers to some commonly asked questions about NDB Cluster, see [Section A.10, “MySQL 8.0 FAQ: NDB Cluster”](#).
- The NDB Cluster Forum: <https://forums.mysql.com/list.php?25>.
- Many NDB Cluster users and developers blog about their experiences with NDB Cluster, and make feeds of these available through [PlanetMySQL](#).

23.2 NDB Cluster Overview

NDB Cluster is a technology that enables clustering of in-memory databases in a shared-nothing system. The shared-nothing architecture enables the system to work with very inexpensive hardware, and with a minimum of specific requirements for hardware or software.

NDB Cluster is designed not to have any single point of failure. In a shared-nothing system, each component is expected to have its own memory and disk, and the use of shared storage mechanisms such as network shares, network file systems, and SANs is not recommended or supported.

NDB Cluster integrates the standard MySQL server with an in-memory clustered storage engine called **NDB** (which stands for “*Network DataBase*”). In our documentation, the term **NDB** refers to the part of the setup that is specific to the storage engine, whereas “MySQL NDB Cluster” refers to the combination of one or more MySQL servers with the **NDB** storage engine.

An NDB Cluster consists of a set of computers, known as *hosts*, each running one or more processes. These processes, known as *nodes*, may include MySQL servers (for access to NDB data), data nodes (for storage of the data), one or more management servers, and possibly other specialized data access programs. The relationship of these components in an NDB Cluster is shown here:

Figure 23.1 NDB Cluster Components

All these programs work together to form an NDB Cluster (see [Section 23.5, “NDB Cluster Programs”](#)). When data is stored by the `NDB` storage engine, the tables (and table data) are stored in the data nodes. Such tables are directly accessible from all other `MySQL` servers (SQL nodes) in the cluster. Thus, in a payroll application storing data in a cluster, if one application updates the salary of an employee, all other `MySQL` servers that query this data can see this change immediately.

Although an NDB Cluster SQL node uses the `mysqld` server daemon, it differs in a number of critical respects from the `mysqld` binary supplied with the `MySQL 8.0` distributions, and the two versions of `mysqld` are not interchangeable.

In addition, a `MySQL` server that is not connected to an NDB Cluster cannot use the `NDB` storage engine and cannot access any NDB Cluster data.

The data stored in the data nodes for NDB Cluster can be mirrored; the cluster can handle failures of individual data nodes with no other impact than that a small number of transactions are aborted due to losing the transaction state. Because transactional applications are expected to handle transaction failure, this should not be a source of problems.

Individual nodes can be stopped and restarted, and can then rejoin the system (cluster). Rolling restarts (in which all nodes are restarted in turn) are used in making configuration changes and software upgrades (see [Section 23.6.5, “Performing a Rolling Restart of an NDB Cluster”](#)). Rolling restarts are also used as part of the process of adding new data nodes online (see [Section 23.6.7, “Adding NDB Cluster Data Nodes Online”](#)). For more information about data nodes, how they are organized in an NDB Cluster, and how they handle and store NDB Cluster data, see [Section 23.2.2, “NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions”](#).

Backing up and restoring NDB Cluster databases can be done using the NDB-native functionality found in the NDB Cluster management client and the `ndb_restore` program included in the NDB Cluster distribution. For more information, see [Section 23.6.8, “Online Backup of NDB Cluster”](#), and [Section 23.5.23, “ndb_restore — Restore an NDB Cluster Backup”](#). You can also use the standard MySQL functionality provided for this purpose in `mysqldump` and the MySQL server. See [Section 4.5.4, “mysqldump — A Database Backup Program”](#), for more information.

NDB Cluster nodes can employ different transport mechanisms for inter-node communications; TCP/IP over standard 100 Mbps or faster Ethernet hardware is used in most real-world deployments.

23.2.1 NDB Cluster Core Concepts

NDBCLUSTER (also known as **NDB**) is an in-memory storage engine offering high-availability and data-persistence features.

The **NDBCLUSTER** storage engine can be configured with a range of failover and load-balancing options, but it is easiest to start with the storage engine at the cluster level. NDB Cluster's **NDB** storage engine contains a complete set of data, dependent only on other data within the cluster itself.

The “Cluster” portion of NDB Cluster is configured independently of the MySQL servers. In an NDB Cluster, each part of the cluster is considered to be a *node*.

Note

In many contexts, the term “node” is used to indicate a computer, but when discussing NDB Cluster it means a *process*. It is possible to run multiple nodes on a single computer; for a computer on which one or more cluster nodes are being run we use the term *cluster host*.

There are three types of cluster nodes, and in a minimal NDB Cluster configuration, there are at least three nodes, one of each of these types:

- **Management node:** The role of this type of node is to manage the other nodes within the NDB Cluster, performing such functions as providing configuration data, starting and stopping nodes, and running backups. Because this node type manages the configuration of the other nodes, a node of this type should be started first, before any other node. A management node is started with the command `ndb_mgmd`.
- **Data node:** This type of node stores cluster data. There are as many data nodes as there are fragment replicas, times the number of fragments (see [Section 23.2.2, “NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions”](#)). For example, with two fragment replicas, each having two fragments, you need four data nodes. One fragment replica is sufficient for data storage, but provides no redundancy; therefore, it is recommended to have two (or more) fragment replicas to provide redundancy, and thus high availability. A data node is started with the command `ndbd` (see [Section 23.5.1, “ndbd — The NDB Cluster Data Node Daemon”](#)) or `ndbmt d` (see [Section 23.5.3, “ndbmt d — The NDB Cluster Data Node Daemon \(Multi-Threaded\)”](#)).

NDB Cluster tables are normally stored completely in memory rather than on disk (this is why we refer to NDB Cluster as an *in-memory* database). However, some NDB Cluster data can be stored on disk; see [Section 23.6.10, “NDB Cluster Disk Data Tables”](#), for more information.

- **SQL node:** This is a node that accesses the cluster data. In the case of NDB Cluster, an SQL node is a traditional MySQL server that uses the **NDBCLUSTER** storage engine. An SQL node is a `mysqld` process started with the `--ndbcluster` and `--ndb-connectstring` options, which are explained elsewhere in this chapter, possibly with additional MySQL server options as well.

An SQL node is actually just a specialized type of *API node*, which designates any application which accesses NDB Cluster data. Another example of an API node is the `ndb_restore` utility that is used to restore a cluster backup. It is possible to write such applications using the NDB API. For basic information about the NDB API, see [Getting Started with the NDB API](#).

Important

It is not realistic to expect to employ a three-node setup in a production environment. Such a configuration provides no redundancy; to benefit from NDB Cluster's high-availability features, you must use multiple data and SQL nodes. The use of multiple management nodes is also highly recommended.

For a brief introduction to the relationships between nodes, node groups, fragment replicas, and partitions in NDB Cluster, see [Section 23.2.2, “NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions”](#).

Configuration of a cluster involves configuring each individual node in the cluster and setting up individual communication links between nodes. NDB Cluster is currently designed with the intention that data nodes are homogeneous in terms of processor power, memory space, and bandwidth. In addition, to provide a single point of configuration, all configuration data for the cluster as a whole is located in one configuration file.

The management server manages the cluster configuration file and the cluster log. Each node in the cluster retrieves the configuration data from the management server, and so requires a way to determine where the management server resides. When interesting events occur in the data nodes, the nodes transfer information about these events to the management server, which then writes the information to the cluster log.

In addition, there can be any number of cluster client processes or applications. These include standard MySQL clients, NDB-specific API programs, and management clients. These are described in the next few paragraphs.

Standard MySQL clients. NDB Cluster can be used with existing MySQL applications written in PHP, Perl, C, C++, Java, Python, Ruby, and so on. Such client applications send SQL statements to and receive responses from MySQL servers acting as NDB Cluster SQL nodes in much the same way that they interact with standalone MySQL servers.

MySQL clients using an NDB Cluster as a data source can be modified to take advantage of the ability to connect with multiple MySQL servers to achieve load balancing and failover. For example, Java clients using Connector/J 5.0.6 and later can use `jdbc:mysql:loadbalance://` URLs (improved in Connector/J 5.1.7) to achieve load balancing transparently; for more information about using Connector/J with NDB Cluster, see [Using Connector/J with NDB Cluster](#).

NDB client programs. Client programs can be written that access NDB Cluster data directly from the `NDBCLUSTER` storage engine, bypassing any MySQL Servers that may be connected to the cluster, using the *NDB API*, a high-level C++ API. Such applications may be useful for specialized purposes where an SQL interface to the data is not needed. For more information, see [The NDB API](#).

NDB-specific Java applications can also be written for NDB Cluster using the *NDB Cluster Connector for Java*. This NDB Cluster Connector includes *ClusterJ*, a high-level database API similar to object-relational mapping persistence frameworks such as Hibernate and JPA that connect directly to `NDBCLUSTER`, and so does not require access to a MySQL Server. See [Java and NDB Cluster](#), and [The ClusterJ API and Data Object Model](#), for more information.

NDB Cluster also supports applications written in JavaScript using Node.js. The MySQL Connector for JavaScript includes adapters for direct access to the `NDB` storage engine and as well as for the MySQL

Server. Applications using this Connector are typically event-driven and use a domain object model similar in many ways to that employed by ClusterJ. For more information, see [MySQL NoSQL Connector for JavaScript](#).

Management clients. These clients connect to the management server and provide commands for starting and stopping nodes gracefully, starting and stopping message tracing (debug versions only), showing node versions and status, starting and stopping backups, and so on. An example of this type of program is the `ndb_mgm` management client supplied with NDB Cluster (see [Section 23.5.5, “ndb_mgm — The NDB Cluster Management Client”](#)). Such applications can be written using the *MGM API*, a C-language API that communicates directly with one or more NDB Cluster management servers. For more information, see [The MGM API](#).

Oracle also makes available MySQL Cluster Manager, which provides an advanced command-line interface simplifying many complex NDB Cluster management tasks, such as restarting an NDB Cluster with a large number of nodes. The MySQL Cluster Manager client also supports commands for getting and setting the values of most node configuration parameters as well as `mysqld` server options and variables relating to NDB Cluster. MySQL Cluster Manager 1.4.8 provides experimental support for NDB 8.0. See [MySQL Cluster Manager 1.4.8 User Manual](#), for more information.

Event logs. NDB Cluster logs events by category (startup, shutdown, errors, checkpoints, and so on), priority, and severity. A complete listing of all reportable events may be found in [Section 23.6.3, “Event Reports Generated in NDB Cluster”](#). Event logs are of the two types listed here:

- *Cluster log*: Keeps a record of all desired reportable events for the cluster as a whole.
- *Node log*: A separate log which is also kept for each individual node.

Note

Under normal circumstances, it is necessary and sufficient to keep and examine only the cluster log. The node logs need be consulted only for application development and debugging purposes.

Checkpoint. Generally speaking, when data is saved to disk, it is said that a *checkpoint* has been reached. More specific to NDB Cluster, a checkpoint is a point in time where all committed transactions are stored on disk. With regard to the NDB storage engine, there are two types of checkpoints which work together to ensure that a consistent view of the cluster's data is maintained. These are shown in the following list:

- *Local Checkpoint (LCP)*: This is a checkpoint that is specific to a single node; however, LCPs take place for all nodes in the cluster more or less concurrently. An LCP usually occurs every few minutes; the precise interval varies, and depends upon the amount of data stored by the node, the level of cluster activity, and other factors.

NDB 8.0 supports partial LCPs, which can significantly improve performance under some conditions. See the descriptions of the `EnablePartialLcp` and `RecoveryWork` configuration parameters which enable partial LCPs and control the amount of storage they use.

- *Global Checkpoint (GCP)*: A GCP occurs every few seconds, when transactions for all nodes are synchronized and the redo-log is flushed to disk.

For more information about the files and directories created by local checkpoints and global checkpoints, see [NDB Cluster Data Node File System Directory](#).

23.2.2 NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions

This section discusses the manner in which NDB Cluster divides and duplicates data for storage.

A number of concepts central to an understanding of this topic are discussed in the next few paragraphs.

Data node. An `ndbd` or `ndbmtid` process, which stores one or more *fragment replicas*—that is, copies of the *partitions* (discussed later in this section) assigned to the node group of which the node is a member.

Each data node should be located on a separate computer. While it is also possible to host multiple data node processes on a single computer, such a configuration is not usually recommended.

It is common for the terms “node” and “data node” to be used interchangeably when referring to an `ndbd` or `ndbmtid` process; where mentioned, management nodes (`ndb_mgmd` processes) and SQL nodes (`mysqld` processes) are specified as such in this discussion.

Node group. A node group consists of one or more nodes, and stores partitions, or sets of *fragment replicas* (see next item).

The number of node groups in an NDB Cluster is not directly configurable; it is a function of the number of data nodes and of the number of fragment replicas (`NoOfReplicas` configuration parameter), as shown here:

```
[# of node groups] = [# of data nodes] / NoOfReplicas
```

Thus, an NDB Cluster with 4 data nodes has 4 node groups if `NoOfReplicas` is set to 1 in the `config.ini` file, 2 node groups if `NoOfReplicas` is set to 2, and 1 node group if `NoOfReplicas` is set to 4. Fragment replicas are discussed later in this section; for more information about `NoOfReplicas`, see [Section 23.4.3.6, “Defining NDB Cluster Data Nodes”](#).

Note

All node groups in an NDB Cluster must have the same number of data nodes.

You can add new node groups (and thus new data nodes) online, to a running NDB Cluster; see [Section 23.6.7, “Adding NDB Cluster Data Nodes Online”](#), for more information.

Partition. This is a portion of the data stored by the cluster. Each node is responsible for keeping at least one copy of any partitions assigned to it (that is, at least one fragment replica) available to the cluster.

The number of partitions used by default by NDB Cluster depends on the number of data nodes and the number of LDM threads in use by the data nodes, as shown here:

```
[# of partitions] = [# of data nodes] * [# of LDM threads]
```

When using data nodes running `ndbmtid`, the number of LDM threads is controlled by the setting for `MaxNoOfExecutionThreads`. When using `ndbd` there is a single LDM thread, which means that there are as many cluster partitions as nodes participating in the cluster. This is also the case when using `ndbmtid` with `MaxNoOfExecutionThreads` set to 3 or less. (You should be aware that the number of LDM threads increases with the value of this parameter, but not in a strictly linear fashion, and that there are additional constraints on setting it; see the description of `MaxNoOfExecutionThreads` for more information.)

NDB and user-defined partitioning. NDB Cluster normally partitions `NDBCLUSTER` tables automatically. However, it is also possible to employ user-defined partitioning with `NDBCLUSTER` tables. This is subject to the following limitations:

1. Only the `KEY` and `LINEAR KEY` partitioning schemes are supported in production with `NDB` tables.
2. The maximum number of partitions that may be defined explicitly for any `NDB` table is $8 * [\textit{number of LDM threads}] * [\textit{number of node groups}]$, the number of node groups in an NDB Cluster being determined as discussed previously in this section. When running `ndbd` for data node processes,

setting the number of LDM threads has no effect (since `ThreadConfig` applies only to `ndbmttd`); in such cases, this value can be treated as though it were equal to 1 for purposes of performing this calculation.

See [Section 23.5.3, “ndbmttd — The NDB Cluster Data Node Daemon \(Multi-Threaded\)”](#), for more information.

For more information relating to NDB Cluster and user-defined partitioning, see [Section 23.2.7, “Known Limitations of NDB Cluster”](#), and [Section 24.6.2, “Partitioning Limitations Relating to Storage Engines”](#).

Fragment replica. This is a copy of a cluster partition. Each node in a node group stores a fragment replica. Also sometimes known as a *partition replica*. The number of fragment replicas is equal to the number of nodes per node group.

A fragment replica belongs entirely to a single node; a node can (and usually does) store several fragment replicas.

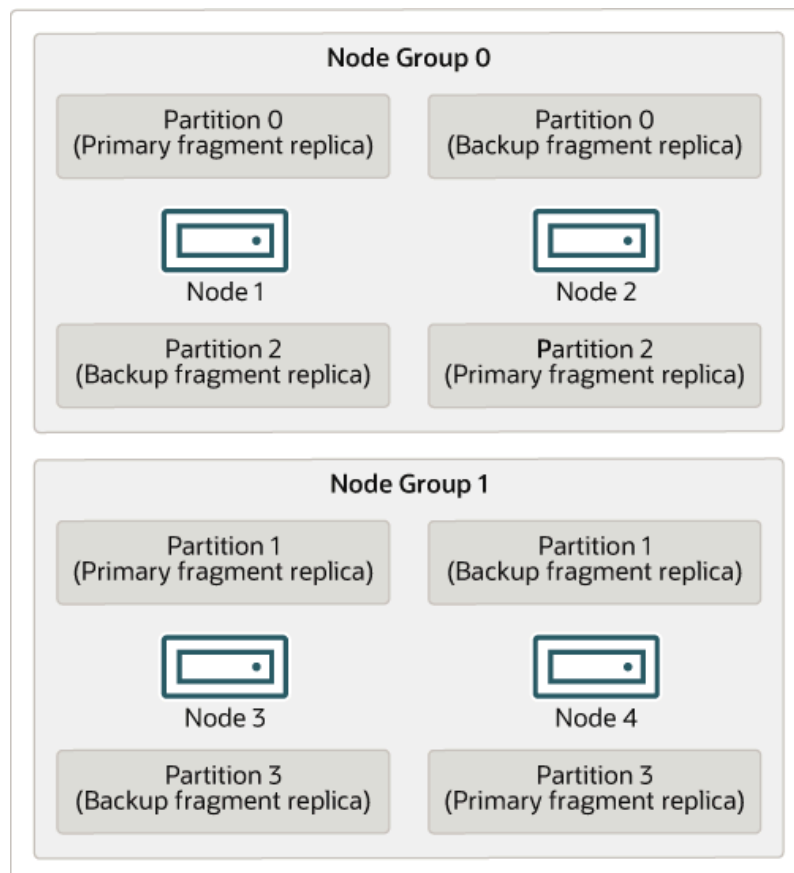

The following diagram illustrates an NDB Cluster with four data nodes running `ndbd`, arranged in two node groups of two nodes each; nodes 1 and 2 belong to node group 0, and nodes 3 and 4 belong to node group 1.

Note

Only data nodes are shown here; although a working NDB Cluster requires an `ndb_mgmd` process for cluster management and at least one SQL node to access the data stored by the cluster, these have been omitted from the figure for clarity.

Figure 23.2 NDB Cluster with Two Node Groups

The data stored by the cluster is divided into four partitions, numbered 0, 1, 2, and 3. Each partition is stored—in multiple copies—on the same node group. Partitions are stored on alternate node groups as follows:

- Partition 0 is stored on node group 0; a *primary fragment replica* (primary copy) is stored on node 1, and a *backup fragment replica* (backup copy of the partition) is stored on node 2.
- Partition 1 is stored on the other node group (node group 1); this partition's primary fragment replica is on node 3, and its backup fragment replica is on node 4.
- Partition 2 is stored on node group 0. However, the placing of its two fragment replicas is reversed from that of Partition 0; for Partition 2, the primary fragment replica is stored on node 2, and the backup on node 1.
- Partition 3 is stored on node group 1, and the placement of its two fragment replicas are reversed from those of partition 1. That is, its primary fragment replica is located on node 4, with the backup on node 3.

What this means regarding the continued operation of an NDB Cluster is this: so long as each node group participating in the cluster has at least one node operating, the cluster has a complete copy of all data and remains viable. This is illustrated in the next diagram.

Figure 23.3 Nodes Required for a 2x2 NDB Cluster

In this example, the cluster consists of two node groups each consisting of two data nodes. Each data node is running an instance of `ndbd`. Any combination of at least one node from node group 0 and at least one node from node group 1 is sufficient to keep the cluster “alive”. However, if both nodes from a single node group fail, the combination consisting of the remaining two nodes in the other node group is not sufficient. In this situation, the cluster has lost an entire partition and so can no longer provide access to a complete set of all NDB Cluster data.

The maximum number of node groups supported for a single NDB Cluster instance is 48.

23.2.3 NDB Cluster Hardware, Software, and Networking Requirements

One of the strengths of NDB Cluster is that it can be run on commodity hardware and has no unusual requirements in this regard, other than for large amounts of RAM, due to the fact that all live data storage is done in memory. (It is possible to reduce this requirement using Disk Data tables—see [Section 23.6.10, “NDB Cluster Disk Data Tables”](#), for more information about these.) Naturally, multiple and faster CPUs can enhance performance. Memory requirements for other NDB Cluster processes are relatively small.

The software requirements for NDB Cluster are also modest. Host operating systems do not require any unusual modules, services, applications, or configuration to support NDB Cluster. For supported operating systems, a standard installation should be sufficient. The MySQL software requirements are simple: all that is needed is a production release of NDB Cluster. It is not strictly necessary to compile MySQL yourself merely to be able to use NDB Cluster. We assume that you are using the binaries appropriate to your platform, available from the NDB Cluster software downloads page at <https://dev.mysql.com/downloads/cluster/>.

For communication between nodes, NDB Cluster supports TCP/IP networking in any standard topology, and the minimum expected for each host is a standard 100 Mbps Ethernet card, plus a switch, hub, or router to provide network connectivity for the cluster as a whole. We strongly recommend that an NDB Cluster be run on its own subnet which is not shared with machines not forming part of the cluster for the following reasons:

- **Security.** Communications between NDB Cluster nodes are not encrypted or shielded in any way. The only means of protecting transmissions within an NDB Cluster is to run your NDB Cluster on a protected network. If you intend to use NDB Cluster for Web applications, the cluster should definitely reside behind your firewall and not in your network's De-Militarized Zone (DMZ) or elsewhere.

See [Section 23.6.17.1, “NDB Cluster Security and Networking Issues”](#), for more information.

- **Efficiency.** Setting up an NDB Cluster on a private or protected network enables the cluster to make exclusive use of bandwidth between cluster hosts. Using a separate switch for your NDB Cluster not only helps protect against unauthorized access to NDB Cluster data, it also ensures that NDB Cluster nodes are shielded from interference caused by transmissions between other computers on the network. For enhanced reliability, you can use dual switches and dual cards to remove the network as a single point of failure; many device drivers support failover for such communication links.

Network communication and latency. NDB Cluster requires communication between data nodes and API nodes (including SQL nodes), as well as between data nodes and other data nodes, to execute queries and updates. Communication latency between these processes can directly affect the observed performance and latency of user queries. In addition, to maintain consistency and service despite the silent failure of nodes, NDB Cluster uses heartbeating and timeout mechanisms which treat an extended loss of communication from a node as node failure. This can lead to reduced redundancy. Recall that, to maintain data consistency, an NDB Cluster shuts down when the last node in a node group fails. Thus, to avoid increasing the risk of a forced shutdown, breaks in communication between nodes should be avoided wherever possible.

The failure of a data or API node results in the abort of all uncommitted transactions involving the failed node. Data node recovery requires synchronization of the failed node's data from a surviving data node, and re-establishment of disk-based redo and checkpoint logs, before the data node returns to service. This recovery can take some time, during which the Cluster operates with reduced redundancy.

Heartbeating relies on timely generation of heartbeat signals by all nodes. This may not be possible if the node is overloaded, has insufficient machine CPU due to sharing with other programs, or is experiencing delays due to swapping. If heartbeat generation is sufficiently delayed, other nodes treat the node that is slow to respond as failed.

This treatment of a slow node as a failed one may or may not be desirable in some circumstances, depending on the impact of the node's slowed operation on the rest of the cluster. When setting timeout values such as `HeartbeatIntervalDbDb` and `HeartbeatIntervalDbApi` for NDB Cluster, care must be taken to achieve quick detection, failover, and return to service, while avoiding potentially expensive false positives.

Where communication latencies between data nodes are expected to be higher than would be expected in a LAN environment (on the order of 100 μ s), timeout parameters must be increased to ensure that any allowed periods of latency periods are well within configured timeouts. Increasing timeouts in this way has a corresponding effect on the worst-case time to detect failure and therefore time to service recovery.

LAN environments can typically be configured with stable low latency, and such that they can provide redundancy with fast failover. Individual link failures can be recovered from with minimal and controlled latency visible at the TCP level (where NDB Cluster normally operates). WAN environments may offer a range of latencies, as well as redundancy with slower failover times. Individual link failures may require route changes to propagate before end-to-end connectivity is restored. At the TCP level this can appear as large latencies on individual channels. The worst-case observed TCP latency in these scenarios is related to the worst-case time for the IP layer to reroute around the failures.

23.2.4 What is New in NDB Cluster

The following sections describe changes in the implementation of NDB Cluster in MySQL NDB Cluster 8.0 through 8.0.27, as compared to earlier release series. NDB Cluster 8.0 is available as a General Availability (GA) release, beginning with NDB 8.0.19. NDB Cluster 7.6 and 7.5 are previous GA releases still supported in production; for information about NDB Cluster 7.6, see [What is New in NDB Cluster 7.6](#). For similar information about NDB Cluster 7.5, see [What is New in NDB Cluster 7.5](#). NDB Cluster 7.4 and 7.3 are previous GA releases still supported in production, although we recommend that new deployments for production use NDB Cluster 8.0; see [MySQL NDB Cluster 7.3 and NDB Cluster 7.4](#).

What is New in NDB Cluster 8.0

Major changes and new features in NDB Cluster 8.0 which are likely to be of interest are shown in the following list:

- **Compatibility enhancements.** The following changes reduce longstanding nonessential differences in [NDB](#) behavior as compared to that of other MySQL storage engines:
- **Development in parallel with MySQL server.** Beginning with this release, MySQL NDB Cluster is being developed in parallel with the standard MySQL 8.0 server under a new unified release model with the following features:
 - NDB 8.0 is developed in, built from, and released with the MySQL 8.0 source code tree.
 - The numbering scheme for NDB Cluster 8.0 releases follows the scheme for MySQL 8.0.
 - Building the source with [NDB](#) support appends `-cluster` to the version string returned by `mysql -V`, as shown here:

```
shell>> mysql -V
mysql Ver 8.0.27-cluster for Linux on x86_64 (Source distribution)
```

[NDB](#) binaries continue to display both the MySQL Server version and the [NDB](#) engine version, like this:

```
shell> ndb_mgm -V
MySQL distrib mysql-8.0.27 ndb-8.0.27, for Linux (x86_64)
```

In MySQL Cluster NDB 8.0, these two version numbers are always the same.

To build the MySQL 8.0 source with NDB Cluster support, use the CMake option `-DWITH_NDBCLUSTER`.

- **Platform support notes.** NDB 8.0 makes the following changes in platform support:
 - `NDBCLUSTER` no longer supports 32-bit platforms. Beginning with NDB 8.0.21, the NDB build process checks the system architecture and aborts if it is not a 64-bit platform.
 - It is now possible to build NDB from source for 64-bit ARM CPUs. Currently, this support is source-only, and we do not provide any precompiled binaries for this platform.
- **Database and table names.** NDB 8.0 removes the previous 63-byte limit on identifiers for databases and tables. These identifiers can now use up to 64 bytes, as for such objects using other MySQL storage engines. See [Section 23.2.7.11, “Previous NDB Cluster Issues Resolved in NDB Cluster 8.0”](#).
- **Generated names for foreign keys.** NDB now uses the pattern `tbl_name_fk_N` for naming internally generated foreign keys. This is similar to the pattern used by InnoDB.
- **Schema and metadata distribution and synchronization.** NDB 8.0 makes use of the MySQL data dictionary to distribute schema information to SQL nodes joining a cluster and to synchronize new schema changes between existing SQL nodes. The following list describes individual enhancements relating to this integration work:
 - **Schema distribution enhancements.** The NDB schema distribution coordinator, which handles schema operations and tracks their progress, has been extended in NDB 8.0 to ensure that resources used during a schema operation are released at its conclusion. Previously, some of this work was done by the schema distribution client; this has been changed due to the fact that the client did not always have all needed state information, which could lead to resource leaks when the client decided to abandon the schema operation prior to completion and without informing the coordinator.

To help fix this issue, schema operation timeout detection has been moved from the schema distribution client to the coordinator, providing the coordinator with an opportunity to clean up any resources used during the schema operation. The coordinator now checks ongoing schema operations for timeout at regular intervals, and marks participants that have not yet completed a given schema operation as failed when detecting timeout. It also provides suitable warnings whenever a schema operation timeout occurs. (It should be noted that, after such a timeout is detected, the schema operation itself continues.) Additional reporting is done by printing a list of active schema operations at regular intervals whenever one or more of these operations is ongoing.

As an additional part of this work, a new `mysqld` option `--ndb-schema-dist-timeout` makes it possible to set the length of time to wait until a schema operation is marked as having timed out.

- **Disk data file distribution.** NDB Cluster 8.0.14, uses the MySQL data dictionary to make sure that disk data files and related constructs such as tablespaces and log file groups are correctly distributed between all connected SQL nodes.
- **Schema synchronization of tablespace objects.** When a MySQL Server connects as an SQL node to an NDB cluster, it checks its data dictionary against the information found in the NDB dictionary.

Previously, the only NDB objects synchronized on connection of a new SQL node were databases and tables; MySQL NDB Cluster 8.0 also implements schema synchronization of disk data objects

including tablespaces and log file groups. Among other benefits, this eliminates the possibility of a mismatch between the MySQL data dictionary and the NDB dictionary following a native backup and restore, in which tablespaces and log file groups were restored to the NDB dictionary, but not to the MySQL Server's data dictionary.

It is also no longer possible to issue a `CREATE TABLE` statement that refers to a nonexistent tablespace. Such a statement now fails with an error.

- **Database DDL synchronization enhancements.** Work done for NDB 8.0 insures that synchronization of databases by newly joined (or rejoined) SQL nodes with those on existing SQL nodes now makes proper use of the data dictionary so that any database-level operations (`CREATE DATABASE`, `ALTER DATABASE`, or `DROP DATABASE`) that may have been missed by this SQL node are now correctly duplicated on it when it connects (or reconnects) to the cluster.

As part of the schema synchronization procedure performed when starting, an SQL node now compares all databases on the cluster's data nodes with those in its own data dictionary, and if any of these is found to be missing from the SQL node's data dictionary, the SQL Node installs it locally by executing a `CREATE DATABASE` statement. A database thus created uses the default MySQL Server database properties (such as those as determined by `character_set_database` and `collation_database`) that are in effect on this SQL node at the time the statement is executed.

- **NDB metadata change detection and synchronization.** NDB 8.0 implements a new mechanism for detection of updates to metadata for data objects such as tables, tablespaces, and log file groups with the MySQL data dictionary. This is done using a thread, the NDB metadata change monitor thread, which runs in the background and checks periodically for inconsistencies between the NDB dictionary and the MySQL data dictionary.

The monitor performs metadata checks every 60 seconds by default. The polling interval can be adjusted by setting the value of the `ndb_metadata_check_interval` system variable; polling can be disabled altogether by setting the `ndb_metadata_check` system variable to `OFF`. The status variable `Ndb_metadata_detected_count` shows the number of times since `mysqld` was last started that inconsistencies have been detected.

NDB ensures that NDB database, table, log file group, and tablespace objects submitted by the metadata change monitor thread during operations following startup are automatically checked for mismatches and synchronized by the NDB binlog thread.

NDB 8.0 adds two status variables relating to automatic synchronization:

`Ndb_metadata_synced_count` shows the number of objects synchronized automatically; `Ndb_metadata_excluded_count` indicates the number of objects for which synchronization has failed (prior to NDB 8.0.22, this variable was named `Ndb_metadata_blacklist_size`). In addition, you can see which objects have been synchronized by inspecting the cluster log.

Setting the `ndb_metadata_sync` system variable to `true` overrides any settings that have been made for `ndb_metadata_check_interval` and `ndb_metadata_check`, causing the change monitor thread to begin continuous metadata change detection.

In NDB 8.0.22 and later, setting `ndb_metadata_sync` to `true` clears the list of objects for which synchronization has failed previously, which means it is no longer necessary to discover individual

tables or to re-trigger synchronization by reconnecting the SQL node to the cluster. In addition, setting this variable to `false` clears the list of objects waiting to be retried.

Beginning with NDB 8.0.21, more detailed information about the current state of automatic synchronization than can be obtained from log messages or status variables is provided by two new tables added to the MySQL Performance Schema. The tables are listed here:

- `ndb_sync_pending_objects`: Contains information about database objects for which mismatches have been detected between the NDB dictionary and the MySQL data dictionary (and which have not been excluded from automatic synchronization).
- `ndb_sync_excluded_objects`: Contains information about NDB database objects which have been excluded because they cannot be synchronized between the NDB dictionary and the MySQL data dictionary, and thus require manual intervention.

A row in one of these tables provides the database object's parent schema, name, and type. Types of objects include schemas, tablespaces, log file groups, and tables. (If the object is a log file group or tablespace, the parent schema is `NULL`.) In addition, the `ndb_sync_excluded_objects` table shows the reason for which the object has been excluded.

These tables are present only if `NDBCLUSTER` storage engine support is enabled. For more information about these tables, see [Section 27.12.12, “Performance Schema NDB Cluster Tables”](#).

- **Changes in NDB table extra metadata.** The extra metadata property of an NDB table is used for storing serialized metadata from the MySQL data dictionary, rather than storing the binary representation of the table as in previous versions. (This was a `.frm` file, no longer used by the MySQL Server—see [Chapter 14, *MySQL Data Dictionary*](#).) As part of the work to support this change, the available size of the table's extra metadata has been increased. This means that NDB tables created in NDB Cluster 8.0 are not compatible with previous NDB Cluster releases. Tables created in previous releases can be used with NDB 8.0, but cannot be opened afterwards by an earlier version.

This metadata is accessible using the NDB API methods `getExtraMetadata()` and `setExtraMetadata()`.

For more information, see [Section 23.3.7, “Upgrading and Downgrading NDB Cluster”](#).

- **On-the-fly upgrades of tables using `.frm` files.** A table created in NDB 7.6 and earlier contains metadata in the form of a compressed `.frm` file, which is no longer supported in MySQL 8.0. To facilitate online upgrades to NDB 8.0, NDB performs on-the-fly translation of this metadata and writes it into the MySQL Server's data dictionary, which enables the `mysqld` in NDB Cluster 8.0 to work with the table without preventing subsequent use of the table by a previous version of the NDB software.

Important

Once a table's structure has been modified in NDB 8.0, its metadata is stored using the data dictionary, and it can no longer be accessed by NDB 7.6 and earlier.

This enhancement also makes it possible to restore an NDB backup made using an earlier version to a cluster running NDB 8.0 (or later).

- **Metadata consistency check error logging.** As part of work previously done in NDB 8.0, the metadata check performed as part of auto-synchronization between the representation of an NDB table in the NDB dictionary and its counterpart in the MySQL data dictionary includes the table's

name, storage engine, and internal ID. Beginning with NDB 8.0.23, the range of properties checked is expanded to include properties of the following data objects:

- Columns
- Indexes
- Foreign keys

In addition, details of any mismatches in metadata properties are now written to the MySQL server error log. The formats used for the error log messages differ slightly depending on whether the discrepancy is found on the table level or on the level of a column, index, or foreign key. The format for a log error resulting from a table-level property mismatch is shown here, where *property* is the property name, *ndb_value* is the property value as stored in the NDB dictionary, and *mysql_d_value* is the value of the property as stored in the MySQL data dictionary:

```
Diff in 'property' detected, 'ndb_value' != 'mysql_d_value'
```

For mismatches in properties of columns, indexes, and foreign keys, the format is as follows, where *obj_type* is one of *column*, *index*, or *foreign key*, and *obj_name* is the name of the object:

```
Diff in obj_type 'obj_name.property' detected, 'ndb_value' != 'mysql_d_value'
```

Metadata checks are performed during automatic synchronization of NDB tables when they are installed in the data dictionary of any *mysqld* acting as an SQL node in an NDB Cluster. If the *mysqld* is debug-compiled, checks are also made whenever a `CREATE TABLE` statement is executed, and whenever an NDB table is opened.

- **Synchronization of user privileges with NDB_STORED_USER.** A new mechanism for sharing and synchronizing users, roles, and privileges between SQL nodes is available in NDB 8.0, using the `NDB_STORED_USER` privilege. Distributed privileges as implemented in NDB 7.6 and earlier (see [Distributed Privileges Using Shared Grant Tables](#)) are no longer supported.

Once a user account is created on an SQL node, the user and its privileges can be stored in NDB and thus shared between all SQL nodes in the cluster by issuing a `GRANT` statement such as this one:

```
GRANT NDB_STORED_USER ON *.* TO 'jon'@'localhost';
```

`NDB_STORED_USER` always has global scope and must be granted using `ON *.*`. System reserved accounts such as `mysql.session@localhost` or `mysql.infoschema@localhost` cannot be assigned this privilege.

Roles can also be shared between SQL nodes by issuing the appropriate `GRANT NDB_STORED_USER` statement. Assigning such a role to a user does not cause the user to be shared; the `NDB_STORED_USER` privilege must be granted to each user explicitly.

A user or role having `NDB_STORED_USER`, along with its privileges, is shared with all SQL nodes as soon as they join a given NDB Cluster. It is possible to make such changes from any connected SQL node, but recommended practice is to do so from a designated SQL node only, since the order of execution of statements affecting privileges from different SQL nodes cannot be guaranteed to be the same on all SQL nodes.

Prior to NDB 8.0.27, changes to the privileges of a user or role were synchronized immediately with all connected SQL nodes. Beginning with MySQL 8.0.27, an SQL node takes a global read lock when

updating privileges, which keeps concurrent changes executed by multiple SQL nodes from causing a deadlock.

Implications for upgrades. Due to changes in the MySQL server's privilege system (see [Section 6.2.3, “Grant Tables”](#)), privilege tables using the `NDB` storage engine do not function correctly in NDB 8.0. It is safe but not necessary to retain such privilege tables created in NDB 7.6 or earlier, but they are no longer used for access control. In NDB 8.0, a `mysqld` acting as an SQL node and detecting such tables in `NDB` writes a warning to the MySQL server log, and creates `InnoDB` shadow tables local to itself; such shadow tables are created on each MySQL server connected to the cluster. When performing an upgrade from NDB 7.6 or earlier, the privilege tables using `NDB` can be removed safely using `ndb_drop_table` once all MySQL servers acting as SQL nodes have been upgraded (see [Section 23.3.7, “Upgrading and Downgrading NDB Cluster”](#)).

The `ndb_restore` utility's `--restore-privilege-tables` option is deprecated but continues to be honored in NDB 8.0, and can still be used to restore distributed privilege tables present in a backup taken from a previous release of NDB Cluster to a cluster running NDB 8.0. These tables are handled as described in the preceding paragraph.

Shared users and grants are stored in the `ndb_sql_metadata` table, which `ndb_restore` by default does not restore in NDB 8.0; you can specify the `--include-stored-grants` option to cause it to do so.

See [Section 23.6.12, “Distributed MySQL Privileges with NDB_STORED_USER”](#), for more information.

- **INFORMATION_SCHEMA changes.** The following changes are made in the display of information regarding Disk Data files in the `INFORMATION_SCHEMA.FILES` table:
 - Tablespaces and log file groups are no longer represented in the `FILES` table. (These constructs are not actually files.)
 - Each data file is now represented by a single row in the `FILES` table. Each undo log file is also now represented in this table by one row only. (Previously, a row was displayed for each copy of each of these files on each data node.)

In addition, `INFORMATION_SCHEMA` tables are now populated with tablespace statistics for MySQL Cluster tables. (Bug #27167728)

- **Error information with `ndb_perror`.** The deprecated `--ndb` option for `perror` has been removed. Instead, use `ndb_perror` to obtain error message information from `NDB` error codes. (Bug #81704, Bug #81705, Bug #23523926, Bug #23523957)
- **Condition pushdown enhancements.** Previously, condition pushdown was limited to predicate terms referring to column values from the same table to which the condition was being pushed. In NDB 8.0, this restriction is removed such that column values from tables earlier in the query plan can also be referred to from pushed conditions. NDB 8.0 supports joins comparing column expressions, as well as comparisons between columns in the same table. Columns and column expressions to be compared must be of exactly the same type; this means they must also be of the same signedness, length, character set, precision, and scale, whenever these attributes apply.

Pushing down larger parts of a condition allows more rows to be filtered out by the data nodes, thereby reducing the number of rows which `mysqld` must handle during join processing. Another benefit of these enhancements is that filtering can be performed in parallel in the LDM threads, rather than in a single `mysqld` process on an SQL node; this has the potential to improve query performance significantly.

Existing rules for type compatibility between column values being compared continue to apply (see [Section 8.2.1.5, “Engine Condition Pushdown Optimization”](#)).

These additional improvements are made in NDB 8.0.21:

- Antijoins produced by the MySQL Optimizer through the transformation of `NOT EXISTS` and `NOT IN` queries (see [Section 8.2.2.1, “Optimizing IN and EXISTS Subquery Predicates with Semijoin Transformations”](#)) can be pushed down to the data nodes by `NDB`.

This can be done when there is no unpushed condition on the table, and the query fulfills any other conditions which must be met for an outer join to be pushed down.

- `NDB` attempts to identify and evaluate a non-dependent scalar subquery before trying to retrieve any rows from the table to which it is attached. When it can do so, the value obtained is used as part of a pushed condition, instead of using the subquery which provided the value.

Beginning with NDB 8.0.27, conditions pushed as part of a pushed query can now refer to columns from ancestor tables within the same pushed query, subject to the following conditions:

- Pushed conditions may include any of the comparison operators `<`, `<=`, `>`, `>=`, `=`, and `<>`.
- Values being compared must be of the same type, including length, precision, and scale.
- `NULL` handling is performed according to the comparison semantics specified by the ISO SQL standard; any comparison with `NULL` returns `NULL`.

Consider the table created using the statement shown here:

```
CREATE TABLE t (  
  x INT PRIMARY KEY,  
  y INT  
) ENGINE=NDB;
```

A query such as `SELECT * FROM t AS a LEFT JOIN t AS b ON a.x=0 AND b.y>5` can now use the engine condition pushdown optimization to push down the condition column `y`.

See [Section 8.2.1.5, “Engine Condition Pushdown Optimization”](#), for more information.

The `NDB` API methods `branch_col_eq_param()`, `branch_col_ne_param()`, `branch_col_lt_param()`, `branch_col_le_param()`, `branch_col_gt_param()`, and `branch_col_ge_param()` were added in NDB 8.0.27 as part of this work. These `NdbInterpretedCode` can be used to compare column values with values of parameters.

In addition, `NdbScanFilter::cmp_param()`, also added in NDB 8.0.27, makes it possible to define comparisons between column values and parameter values for use in performing scans.

- **Increase in maximum row size.** NDB 8.0 increases the maximum number of bytes that can be stored in an `NDBCLUSTER` table from 14000 to 30000 bytes.

A `BLOB` or `TEXT` column continues to use 264 bytes of this total, as before.

The maximum offset for a fixed-width column of an `NDB` table is 8188 bytes; this is also unchanged from previous releases.

See [Section 23.2.7.5, “Limits Associated with Database Objects in NDB Cluster”](#), for more information.

- **ndb_mgm SHOW command and single user mode.** In NDB 8.0, when the cluster is in single user mode, the output of the management client `SHOW` command indicates which API or SQL node has exclusive access while this mode is in effect.

- **Online column renames.** Columns of [NDB](#) tables can now be renamed online, using `ALGORITHM=INPLACE`. See [Section 23.6.11, “Online Operations with ALTER TABLE in NDB Cluster”](#), for more information.
- **Improved `ndb_mgmd` startup times.** Start times for management nodes daemon have been significantly improved in NDB 8.0, in the following ways:
 - Due to replacing the list data structure formerly used by `ndb_mgmd` for handling node properties from configuration data with a hash table, overall startup times for the management server have been decreased by a factor of 6 or more.
 - In addition, in cases where data and SQL node host names not present in the management server's `hosts` file are used in the cluster configuration file, `ndb_mgmd` start times can be up to 20 times shorter than was previously the case.
- **NDB API enhancements.** `NdbScanFilter::cmp()` and several comparison methods of `NdbInterpretedCode` can now be used to compare table column values with each other. The affected `NdbInterpretedCode` methods are listed here:
 - `branch_col_eq()`
 - `branch_col_ge()`
 - `branch_col_gt()`
 - `branch_col_le()`
 - `branch_col_lt()`
 - `branch_col_ne()`

For all of the methods just listed, table column values to be compared must be of exactly matching types, including with respect to length, precision, signedness, scale, character set, and collation, as applicable.

See the descriptions of the individual API methods for more information.

- **Offline multithreaded index builds.** It is now possible to specify a set of cores to be used for I/O threads performing offline multithreaded builds of ordered indexes, as opposed to normal I/O duties such as file I/O, compression, or decompression. “Offline” in this context refers to building of ordered indexes performed when the parent table is not being written to; such building takes place when an [NDB](#) cluster performs a node or system restart, or as part of restoring a cluster from backup using `ndb_restore --rebuild-indexes`.

In addition, the default behavior for offline index build work is modified to use all cores available to `ndbmtcd`, rather limiting itself to the core reserved for the I/O thread. Doing so can improve restart and restore times and performance, availability, and the user experience.

This enhancement is implemented as follows:

1. The default value for `BuildIndexThreads` is changed from 0 to 128. This means that offline ordered index builds are now multithreaded by default.
2. The default value for `TwoPassInitialNodeRestartCopy` is changed from `false` to `true`. This means that an initial node restart first copies all data from a “live” node to one that is starting—without creating any indexes—builds ordered indexes offline, and then again synchronizes its data with the live node, that is, synchronizing twice and building indexes offline between the two

synchronizations. This causes an initial node restart to behave more like the normal restart of a node, and reduces the time required for building indexes.

3. A new thread type (`idxbld`) is defined for the `ThreadConfig` configuration parameter, to allow locking of offline index build threads to specific CPUs.

In addition, NDB now distinguishes the thread types that are accessible to `ThreadConfig` by these two criteria:

1. Whether the thread is an execution thread. Threads of types `main`, `ldm`, `recv`, `rep`, `tc`, and `send` are execution threads; thread types `io`, `watchdog`, and `idxbld` are not.
2. Whether the allocation of the thread to a given task is permanent or temporary. Currently all thread types except `idxbld` are permanent.

For additional information, see the descriptions of the indicated parameters in the Manual. (Bug #25835748, Bug #26928111)

- **logbuffers table backup process information.** When performing an NDB backup, the `ndbinfo.logbuffers` table now displays information regarding buffer usage by the backup process on each data node. This is implemented as rows reflecting two new log types in addition to `REDO` and `DD-UNDO`. One of these rows has the log type `BACKUP-DATA`, which shows the amount of data buffer used during backup to copy fragments to backup files. The other row has the log type `BACKUP-LOG`, which displays the amount of log buffer used during the backup to record changes made after the backup has started. One each of these `log_type` rows is shown in the `logbuffers` table for each data node in the cluster. Rows having these two log types are present in the table only while an NDB backup is currently in progress. (Bug #25822988)
- **ndbinfo.processes table on Windows.** The process ID of the monitor process used on Windows platforms by `RESTART` to spawn and restart a `mysqld` is now shown in the `processes` table as an `angel_pid`.
- **String hashing improvements.** Prior to NDB 8.0, all string hashing was based on first transforming the string into a normalized form, then MD5-hashing the resulting binary image. This could give rise to some performance problems, for the following reasons:
 - The normalized string is always space padded to its full length. For a `VARCHAR`, this often involved adding more spaces than there were characters in the original string.
 - The string libraries were not optimized for this space padding, which added considerable overhead in some use cases.
 - The padding semantics varied between character sets, some of which were not padded to their full length.
 - The transformed string could become quite large, even without space padding; some Unicode 9.0 collations can transform a single code point into 100 bytes or more of character data.
 - Subsequent MD5 hashing consisted mainly of padding with spaces, and was not particularly efficient, possibly causing additional performance penalties by flushing significant portions of the L1 cache.

A collation provides its own hash function, which hashes the string directly without first creating a normalized string. In addition, for a Unicode 9.0 collation, the hash is computed without padding. NDB

now takes advantage of this built-in function whenever hashing a string identified as using a Unicode 9.0 collation.

Since, for other collations, there are existing databases which are hash partitioned on the transformed string, NDB continues to employ the previous method for hashing strings that use these, to maintain compatibility. (Bug #89590, Bug #89604, Bug #89609, Bug #27515000, Bug #27523758, Bug #27522732)

- **RESET MASTER changes.** Because the MySQL Server now executes `RESET MASTER` with a global read lock, the behavior of this statement when used with NDB Cluster has changed in the following two respects:
 - It is no longer guaranteed to be synchronous; that is, it is now possible that a read coming immediately before `RESET MASTER` is issued may not be logged until after the binary log has been rotated.
 - It now behaves in exactly the same fashion, whether the statement is issued on the same SQL node that is writing the binary log, or on a different SQL node in the same cluster.

Note

`SHOW BINLOG EVENTS`, `FLUSH LOGS`, and most data definition statements continue, as they did in previous NDB versions, to operate in a synchronous fashion.

- **ndb_restore option usage.** The `--nodeid` and `--backupid` options are now both required when invoking `ndb_restore`.
- **ndb_log_bin default.** NDB 8.0 changes the default value of the `ndb_log_bin` system variable from `TRUE` to `FALSE`.
- **Dynamic transactional resource allocation.** Allocation of resources in the transaction coordinator (see [The DBTC Block](#)) is now performed using dynamic memory pools. This means that resource allocation determined by data node configuration parameters such as `MaxDMLOperationsPerTransaction`, `MaxNoOfConcurrentIndexOperations`, `MaxNoOfConcurrentOperations`, `MaxNoOfConcurrentScans`, `MaxNoOfConcurrentTransactions`, `MaxNoOfFiredTriggers`, `MaxNoOfLocalScans`, and `TransactionBufferMemory` is now done in such a way that, if the load represented by each of these parameters is within the target load for all such resources, others of these resources can be limited so as not to exceed the total resources available.

As part of this work, several new data node parameters controlling transactional resources in [DBTC](#), listed here, have been added:

- `ReservedConcurrentIndexOperations`
- `ReservedConcurrentOperations`
- `ReservedConcurrentScans`
- `ReservedConcurrentTransactions`
- `ReservedFiredTriggers`
- `ReservedLocalScans`

- [ReservedTransactionBufferMemory](#).

See the descriptions of the parameters just listed for further information.

- **Backups using multiple LDMs per data node.** NDB backups can now be performed in a parallel fashion on individual data nodes using multiple local data managers (LDMs). (Previously, backups were done in parallel across data nodes, but were always serial within data node processes.) No special syntax is required for the `START BACKUP` command in the `ndb_mgm` client to enable this feature, but all data nodes must be using multiple LDMs. This means that data nodes must be running `ndbmysqld` (`ndbmysqld` is single-threaded and thus always has only one LDM) and they must be configured to use multiple LDMs before taking the backup; you can do this by choosing an appropriate setting for one of the multi-threaded data node configuration parameters `MaxNoOfExecutionThreads` or `ThreadConfig`.

Backups using multiple LDMs create subdirectories, one per LDM, under the `BACKUP/BACKUP-backup_id/` directory. `ndb_restore` now detects these subdirectories automatically, and if they exist, attempts to restore the backup in parallel; see [Section 23.5.23.3, "Restoring from a backup taken in parallel"](#), for details. (Single-threaded backups are restored as in previous versions of NDB.) It is also possible to restore backups taken in parallel using an `ndb_restore` binary from a previous version of NDB Cluster by modifying the usual restore procedure; [Restoring a parallel backup serially](#), provides information on how to do this.

You can force the creation of single-threaded backups by setting the `EnableMultithreadedBackup` data node parameter to 0 for all data nodes in the `[ndbmysqld default]` section of the cluster's global configuration file (`config.ini`).

- **Binary configuration file enhancements.** NDB 8.0 uses a new format for the management server's binary configuration file. Previously, a maximum of 16381 sections could appear in the cluster configuration file; now the maximum number of sections is 4G. This is intended to support larger numbers of nodes in a cluster than was possible before this change.

Upgrades to the new format are relatively seamless, and should seldom if ever require manual intervention, as the management server continues to be able to read the old format without issue. A downgrade from NDB 8.0 to an older version of the NDB Cluster software requires manual removal of any binary configuration files or, alternatively, starting the older management server binary with the `--initial` option.

For more information, see [Section 23.3.7, "Upgrading and Downgrading NDB Cluster"](#).

- **Increased number of data nodes.** NDB 8.0 increases the maximum number of data nodes supported per cluster to 144 (previously, this was 48). Data nodes can now use node IDs in the range 1 to 144, inclusive.

Previously, the recommended node IDs for management nodes were 49 and 50. These are still supported for management nodes, but using them as such limits the maximum number of data nodes to 142; for this reason, it is now recommended that node IDs 145 and 146 are used for management nodes.

As part of this work, the format used for the data node `sysfile` has been updated to version 2. This file records information such as the last global checkpoint index, restart status, and node group membership of each node (see [NDB Cluster Data Node File System Directory](#)).

- **RedoOverCommitCounter and RedoOverCommitLimit changes.** Due to ambiguities in the semantics for setting them to 0, the minimum value for each of the data node configuration parameters `RedoOverCommitCounter` and `RedoOverCommitLimit` has been increased to 1.

- **ndb_autoincrement_prefetch_sz changes.** The default value of the `ndb_autoincrement_prefetch_sz` server system variable is increased to 512.
- **Changes in parameter maximums and defaults.** NDB 8.0 makes the following changes in configuration parameter maximum and default values:
 - The maximum for `DataMemory` is increased to 16 terabytes.
 - The maximum for `DiskPageBufferMemory` is also increased to 16 terabytes.
 - The default value for `StringMemory` is increased to 25%.
 - The default for `LcpScanProgressTimeout` is increased to 180 seconds.
- **Disk Data checkpointing improvements.** NDB Cluster 8.0 provides a number of new enhancements which help to reduce the latency of checkpoints of Disk Data tables and tablespaces when using non-volatile memory devices such as solid-state drives and the NVMe specification for such devices. These improvements include those in the following list:
 - Avoiding bursts of checkpoint disk writes
 - Speeding up checkpoints for disk data tablespaces when the redo log or the undo log becomes full
 - Balancing checkpoints to disk and in-memory checkpoints against one other, when necessary
 - Protecting disk devices from overload to help ensure low latency under high loads

As part of this work, two data node configuration parameters have been added. `MaxDiskDataLatency` places a ceiling on the degree of latency permitted for disk access and causes transactions taking longer than this length of time to be aborted. `DiskDataUsingSameDisk` makes it possible to take advantage of housing Disk Data tablespaces on separate disks by increasing the rate at which checkpoints of such tablespaces can be performed.

In addition, three new tables in the `ndbinfo` database provide information about Disk Data performance:

- The `diskstat` table reports on writes to Disk Data tablespaces during the past second
 - The `diskstats_1sec` table reports on writes to Disk Data tablespaces for each of the last 20 seconds
 - The `pgman_time_track_stats` table reports on the latency of disk operations relating to Disk Data tablespaces
- **Memory allocation and TransactionMemory.** A new `TransactionMemory` parameter simplifies allocation of data node memory for transactions as part of the work done to pool transactional and Local

Data Manager (LDM) memory. This parameter is intended to replace several older transactional memory parameters which have been deprecated.

Transaction memory can now be set in any of the three ways listed here:

- Several configuration parameters are incompatible with `TransactionMemory`. If any of these are set, `TransactionMemory` cannot be set (see [Parameters incompatible with TransactionMemory](#)), and the data node's transaction memory is determined as it was previous to NDB 8.0.

Note

Attempting to set `TransactionMemory` and any of these parameters concurrently in the `config.ini` file prevents the management server from starting.

- If `TransactionMemory` is set, this value is used for determining transaction memory. `TransactionMemory` cannot be set if any of the incompatible parameters mentioned in the previous item have also been set.
- If none of the incompatible parameters are set and `TransactionMemory` is also not set, transaction memory is set by `NDB`.

For more information, see the description of `TransactionMemory`, as well as [Section 23.4.3.13, “Data Node Memory Management”](#).

- **Support for additional fragment replicas.** NDB 8.0 increases the maximum number of fragment replicas supported in production from two to four. (Previously, it was possible to set `NoOfReplicas` to 3 or 4, but this was not officially supported or verified in testing.)
- **Restoring by slices.** Beginning with NDB 8.0.20, it is possible to divide a backup into roughly equal portions (slices) and to restore these slices in parallel using two new options implemented for `ndb_restore`:
 - `--num-slices` determines the number of slices into which the backup should be divided.
 - `--slice-id` provides the ID of the slice to be restored by the current instance of `ndb_restore`.

This makes it possible to employ multiple instances of `ndb_restore` to restore subsets of the backup in parallel, potentially reducing the amount of time required to perform the restore operation.

For more information, see the description of the `ndb_restore --num-slices` option.

- **Read from any fragment replica enabled.** Read from any fragment replica is enabled by default for all `NDB` tables. This means that the default value for the `ndb_read_backup` system variable is now `ON`, and that the value of the `NDB_TABLE` comment option `READ_BACKUP` is 1 when creating a new `NDB` table. Enabling read from any fragment replica significantly improves performance for reads from `NDB` tables, with minimal impact on writes.

For more information, see the description of the `ndb_read_backup` system variable, and [Section 13.1.20.11, “Setting NDB_TABLE Options”](#).

- **ndb_blob_tool enhancements.** Beginning with NDB 8.0.20, the `ndb_blob_tool` utility can detect missing blob parts for which inline parts exist and replace these with placeholder blob parts (consisting of space characters) of the correct length. To check whether there are missing blob parts, use the `--`

`check-missing` option with this program. To replace any missing blob parts with placeholders, use the `--add-missing` option.

For more information, see [Section 23.5.6, “ndb_blob_tool — Check and Repair BLOB and TEXT columns of NDB Cluster Tables”](#).

- **ndbinfo versioning.** NDB 8.0.20 and later supports versioning for `ndbinfo` tables, and maintains the current definitions for its tables internally. At startup, NDB compares its supported `ndbinfo` version with the version stored in the data dictionary. If the versions differ, NDB drops any old `ndbinfo` tables and recreates them using the current definitions.
- **Support for Fedora Linux.** Beginning with NDB 8.0.20, Fedora Linux is a supported platform for NDB Cluster Community releases and can be installed using the RPMs supplied for this purpose by Oracle. These can be obtained from the [NDB Cluster downloads page](#).
- **NDB programs—NDBT dependency removal.** The dependency of a number of NDB utility programs on the `NDBT` library has been removed. This library is used internally for development, and is not required for normal use; its inclusion in these programs could lead to unwanted issues when testing.

Affected programs are listed here, along with the NDB versions in which the dependency was removed:

- `ndb_restore`
- `ndb_delete_all`
- `ndb_show_tables` (NDB 8.0.20)
- `ndb_waiter` (NDB 8.0.20)

The principal effect of this change for users is that these programs no longer print `NDBT_ProgramExit - status` following completion of a run. Applications that depend upon such behavior should be updated to reflect the change when upgrading to the indicated versions.

- **Pushdown of outer joins and semijoins.** Work done in NDB 8.0.20 allows many outer joins and semijoins, and not only those using a primary key or unique key lookup, to be pushed down to the data nodes (see [Section 8.2.1.5, “Engine Condition Pushdown Optimization”](#)).

Outer joins using scans which can now be pushed include those which meet the following conditions:

- There are no unpushed conditions on the table
- There are no unpushed conditions on other tables in the same join nest, or in upper join nests on which it depends
- All other tables in the same join nest, or in upper join nests on which it depends, are also pushed

A semijoin that uses an index scan can now be pushed if it meets the the conditions just noted for a pushed outer join, and it uses the `firstMatch` strategy (see [Section 8.2.2.1, “Optimizing IN and EXISTS Subquery Predicates with Semijoin Transformations”](#)).

When a join cannot be pushed, `EXPLAIN` should provide the reason or reasons.

- **Foreign keys and lettercasing.** NDB stores the names of foreign keys using the case with which they were defined. Formerly, when the value of the `lower_case_table_names` system variable was set to 0, it performed case-sensitive comparisons of foreign key names as used in `SELECT` and other SQL statements with the names as stored. Beginning with NDB 8.0.20, such comparisons are now always performed in a case-insensitive fashion, regardless of the value of `lower_case_table_names`.

- **Multiple transporters.** NDB 8.0.20 introduces support for multiple transporters to handle node-to-node communication between pairs of data nodes. This facilitates higher rates of update operations for each node group in the cluster, and helps avoid constraints imposed by system or other limitations on inter-node communications using a single socket.

By default, NDB now uses a number of transporters based on the number of local data management (LDM) threads or the number of transaction coordinator (TC) threads, whichever is greater. By default, the number of transporters is equal to half of this number. While the default should perform well for most workloads, it is possible to adjust the number of transporters employed by each node group by setting the `NodeGroupTransporters` data node configuration parameter (also introduced in NDB 8.0.20), up a maximum of the greater of the number of LDM threads or the number of TC threads. Setting it to 0 causes the number of transporters to be the same as the number of LDM threads.

- **ndb_restore: primary key schema changes.** NDB 8.0.21 (and later) supports different primary key definitions for source and target tables when restoring an NDB native backup with `ndb_restore` when it is run with the `--allow-pk-changes` option. Both increasing and decreasing the number of columns making up the original primary key are supported.

When the primary key is extended with an additional column or columns, any columns added must be defined as `NOT NULL`, and no values in any such columns may be changed during the time that the backup is being taken. Because some applications set all column values in a row when updating it, whether or not all values are actually changed, this can cause a restore operation to fail even if no values in the column to be added to the primary key have changed. You can override this behavior using the `--ignore-extended-pk-updates` option also added in NDB 8.0.21; in this case, you must ensure that no such values are changed.

A column can be removed from the table's primary key whether or not this column remains part of the table.

For more information, see the description of the `--allow-pk-changes` option for `ndb_restore`.

- **Merging backups with ndb_restore.** In some cases, it may be desirable to consolidate data originally stored in different instances of NDB Cluster (all using the same schema) into a single target NDB Cluster. This is now supported when using backups created in the `ndb_mgm` client (see [Section 23.6.8.2, "Using The NDB Cluster Management Client to Create a Backup"](#)) and restoring them with `ndb_restore`, using the `--remap-column` option added in NDB 8.0.21 along with `--restore-data` (and possibly additional compatible options as needed or desired). `--remap-column` can be employed to handle cases in which primary and unique key values are overlapping between source clusters, and it is necessary that they do not overlap in the target cluster, as well as to preserve other relationships between tables such as foreign keys.

`--remap-column` takes as its argument a string having the format `db.tbl.col:fn:args`, where `db`, `tbl`, and `col` are, respectively, the names of the database, table, and column, `fn` is the name of a remapping function, and `args` is one or more arguments to `fn`. There is no default value. Only `offset` is supported as the function name, with `args` as the integer offset to be applied to the value of the column when inserting it into the target table from the backup. This column must be one of `INT` or

`BIGINT`; the allowed range of the offset value is the same as the signed version of that type (this allows the offset to be negative if desired).

The new option can be used multiple times in the same invocation of `ndb_restore`, so that you can remap to new values multiple columns of the same table, different tables, or both. The offset value does not have to be the same for all instances of the option.

In addition, two new options are provided for `ndb_desc`, also beginning in NDB 8.0.21:

- `--auto-inc` (short form `-a`): Includes the the next auto-increment value in the output, if the table has an `AUTO_INCREMENT` column.
- `--context` (short form `-x`): Provides extra information about the table, including the schema, database name, table name, and internal ID.

For more information and examples, see the description of the `--remap-column` option.

- **Send thread improvements.** As of NDB 8.0.20, each send thread now handles sends to a subset of transporters, and each block thread now assists only one send thread, resulting in more send threads, and thus better performance and data node scalability.
- **Adaptive spin control using `SpinMethod`.** A simple interface for setting up adaptive CPU spin on platforms supporting it, using the `SpinMethod` data node parameter. This parameter (added in NDB 8.0.20, functional beginning with NDB 8.0.24) has four settings, one each for static spinning, cost-based adaptive spinning, latency-optimized adaptive spinning, and adaptive spinning optimized for database machines on which each thread has its own CPU. Each of these settings causes the data node to use a set of predetermined values for one or more spin parameters which enable adaptive spinning, set spin timing, and set spin overhead, as appropriate to a given scenario, thus obviating the need to set these directly for common use cases.

For fine-tuning spin behavior, it is also possible to set these and additional spin parameters directly, using the existing `SchedulerSpinTimer` data node configuration parameter as well as the following `DUMP` commands in the `ndb_mgm` client:

- `DUMP 104000 (SetSchedulerSpinTimerAll)`: Sets spin time for all threads
- `DUMP 104001 (SetSchedulerSpinTimerThread)`: Sets spin time for a specified thread
- `DUMP 104002 (SetAllowedSpinOverhead)`: Sets spin overhead as the number of units of CPU time allowed to gain 1 unit of latency
- `DUMP 104003 (SetSpintimePerCall)`: Sets the time for a call to spin
- `DUMP 104004 (EnableAdaptiveSpinning)`: Enables or disables adpative spinning

NDB 8.0.20 also adds a new TCP configuration parameter `TcpSpinTime` which sets the time to spin for a given TCP connection.

The `ndb_top` tool is also enhanced to provide spin time information per thread.

For additional information, see the description of the `SpinMethod` parameter, the listed `DUMP` commands, and [Section 23.5.29, “ndb_top — View CPU usage information for NDB threads”](#).

- **Disk Data and cluster restarts.** Beginning with NDB 8.0.21, an initial restart of the cluster forces the removal of all Disk Data objects such as tablespaces and log file groups, including any data files and undo log files associated with these objects.

See [Section 23.6.10, “NDB Cluster Disk Data Tables”](#), for more information.

- **Disk Data extent allocation.** Beginning with NDB 8.0.20, allocation of extents in data files is done in a round-robin fashion among all data files used by a given tablespace. This is expected to improve distribution of data in cases where multiple storage devices are used for Disk Data storage.

For more information, see [Section 23.6.10.1, “NDB Cluster Disk Data Objects”](#).

- **--ndb-log-fail-terminate option.** Beginning with NDB 8.0.21, you can cause the SQL node to terminate whenever it is unable to log all row events fully. This can be done by starting `mysqld` with the `--ndb-log-fail-terminate` option.
- **AllowUnresolvedHostNames parameter.** By default, a management node refuses to start when it cannot resolve a host name present in the global configuration file, which can be problematic in some environments such as Kubernetes. Beginning with NDB 8.0.22, it is possible to override this behavior by setting `AllowUnresolvedHostNames` to `true` in the `[tcp default]` section of the cluster global configuration file (`config.ini` file). Doing so causes such errors to be treated as warnings instead, and to permit `ndb_mgmd` to continue starting
- **Blob write performance enhancements.** NDB 8.0.22 implements a number of improvements which allow more efficient batching when modifying multiple blob columns in the same row, or when modifying multiple rows containing blob columns in the same statement, by reducing the number of round trips required between an SQL or other API node and the data nodes when applying these modifications. The performance of many `INSERT`, `UPDATE`, and `DELETE` statements can thus be improved. Examples of such statements are listed here, where `table` is an NDB table containing one or more Blob columns:

- `INSERT INTO table VALUES ROW(1, blob_value1, blob_value2, ...)`, that is, insertion of a row containing one or more Blob columns
- `INSERT INTO table VALUES ROW(1, blob_value1), ROW(2, blob_value2), ROW(3, blob_value3), ...`, that is, insertion of multiple rows containing one or more Blob columns
- `UPDATE table SET blob_column1 = blob_value1, blob_column2 = blob_value2, ...`
- `UPDATE table SET blob_column = blob_value WHERE primary_key_column in (value_list)`, where the primary key column is not a Blob type
- `DELETE FROM table WHERE primary_key_column = value`, where the primary key column is not a Blob type
- `DELETE FROM table WHERE primary_key_column IN (value_list)`, where the primary key column is not a Blob type

Other SQL statements may benefit from these improvements as well. These include `LOAD DATA INFILE` and `CREATE TABLE ... SELECT ...`. In addition, `ALTER TABLE table ENGINE = NDB`, where `table` uses a storage engine other than NDB prior to execution of the statement, may also execute more efficiently.

This enhancement applies to statements affecting columns of MySQL type `BLOB`, `MEDIUMBLOB`, `LONGBLOB`, `TEXT`, `MEDIUMTEXT`, and `LONGTEXT`. Statements which update `TINYBLOB` or `TINYTEXT` columns (or both types) only are not affected by this work, and no changes in their performance should be expected.

The performance of some SQL statements is not noticeably improved by this enhancement, due to the fact that they require scans of table Blob columns, which breaks up batching. Such statements include those of the types listed here:

- `SELECT FROM table [WHERE key_column IN (blob_value_list)]`, where rows are selected by matching on a primary key or unique key column which uses a Blob type
- `UPDATE table SET blob_column = blob_value WHERE condition`, using a *condition* which does not depend on a unique value
- `DELETE FROM table WHERE condition` to delete rows containing one or more Blob columns, using a *condition* which does not depend on a unique value
- A copying `ALTER TABLE` statement on a table which already used the NDB storage engine prior to executing the statement, and whose rows contain one or more Blob columns before or after the statement is executed (or both)

To take advantage of this improvement to its fullest extent, you may wish to increase the values used for the `--ndb-batch-size` and `--ndb-blob-write-batch-bytes` options for `mysqld`, to minimize the number of round trips required to modify Blobs. For replication, it is also recommended that you enable the `slave_allow_batching` system variable, which minimizes the number of round trips required by the replica cluster to apply epoch transactions.

- **Node.js update.** Beginning with NDB 8.0.22, the NDB adapter for Node.js is built using version 12.18.3, and only that version (or a later version of Node.js) is now supported.
- **Encrypted backups.** NDB 8.0.22 adds support for backup files encrypted using AES-256-CBC; this is intended to protect against recovery of data from backups that have been accessed by unauthorized parties. When encrypted, backup data is protected by a user-supplied password. The password can be any string consisting of up to 256 characters from the range of printable ASCII characters other than `!`, `'`, `"`, `$`, `%`, `\`, and `^`. Retention of the password used to encrypt any given NDB Cluster backup must be performed by the user or application; NDB does not save the password. The password can be empty, although this is not recommended.

When taking an NDB Cluster backup, you can encrypt it by using `ENCRYPT PASSWORD=password` with the management client `START BACKUP` command. Users of the MGM API can also initiate an encrypted backup by calling `ndb_mgm_start_backup4()`.

You can encrypt existing backup files using the `ndbxfrm` utility which is added to the NDB Cluster distribution in the 8.0.22 release; this program can also be employed for decrypting encrypted backup files. In addition, `ndbxfrm` can compress backup files and decompress compressed backup files using the same method that is employed by NDB Cluster for creating backups when the `CompressedBackup` configuration parameter is set to 1.

To restore from an encrypted backup, use `ndb_restore` with the options `--decrypt` and `--backup-password`. Both options are required, along with any others that would be needed to restore the same

backup if it were not encrypted. `ndb_print_backup_file` and `ndbxfrm` can also read encrypted files using, respectively, `-P password` and `--decrypt-password=password`.

In all cases in which a password is supplied together with an option for encryption or decryption, the password must be quoted; you can use either single or double quotation marks to delimit the password.

Beginning with NDB 8.0.24, several NDB programs, listed here, also support input of the password from standard input, similarly to how this is done when logging in interactively with the `mysql` client using the `--password` option (without including the password on the command line):

- For `ndb_restore` and `ndb_print_backup_file`, the `--backup-password-from-stdin` option enables input of the password in a secure fashion, similar to how it is done by the `mysql` client's `--password` option. For `ndb_restore`, use the option together with the `--decrypt` option; for `ndb_print_backup_file`, use the option in place of the `-P` option.
- For `ndb_mgm` the option `--backup-password-from-stdin`, is supported together with `execute "START BACKUP [options]"` for starting a cluster backup from the system shell.
- Two `ndbxfrm` options, `--encrypt-password-from-stdin` and `--decrypt-password-from-stdin`, cause similar behavior when using that program to encrypt or to decrypt a backup file.

See the descriptions of the programs just listed for more information.

It is also possible, beginning with NDB 8.0.22, to enforce encryption of backups by setting `RequireEncryptedBackup=1` in the `[ndbd default]` section of the cluster global configuration file. When this is done, the `ndb_mgm` client rejects any attempt to perform a backup that is not encrypted.

Beginning with NDB 8.0.24, you can cause `ndb_mgm` to use encryption whenever it creates a backup by starting it with `--encrypt-backup`. In this case, the user is prompted for a password when invoking `START BACKUP` if none is supplied.

- **IPv6 support.** Beginning with NDB 8.0.22, IPv6 addressing is supported for connections to management and data nodes; this includes connections between management and data nodes with SQL nodes. When configuring a cluster, you can use numeric IPv6 addresses, host names which resolve to IPv6 addresses or both.

For IPv6 addressing to work, the operating platform and network on which the cluster is deployed must support IPv6. As when using IPv4 addressing, hostname resolution to IPv6 addresses must be provided by the operating platform.

IPv4 addressing continues to be supported by NDB. Using IPv4 and IPv6 addresses concurrently is not recommended, but can be made to work in the following cases:

- When the management node is configured with IPv6 and data nodes are configured with IPv4 addresses in the `config.ini` file: This works if `--bind-address` is not used with `mgmd`, and data nodes are started with `--ndb-connectstring` set to the IPv4 address of the management nodes.
- When the management node is configured with IPv4 and data nodes are configured with IPv6 addresses in `config.ini`: Similarly to the other case, this works if `--bind-address` is not passed to `mgmd` and data nodes are started with `--ndb-connectstring` set to the IPv6 address of the management node.

These cases work because `ndb_mgmd` does not bind to any IP address by default.

To perform an upgrade from a version of NDB that does not support IPv6 addressing to one that does, provided that the network supports IPv4 and IPv6, first perform the software upgrade; after this has been

done, you can update IPv4 addresses used in the `config.ini` file with IPv6 addresses. After this, to cause the configuration changes to take effect and to make the cluster start using the IPv6 addresses, it is necessary to perform a system restart of the cluster.

- **Auto-Installer deprecation and removal.** The MySQL NDB Cluster Auto-Installer web-based installation tool (`ndb_setup.py`) is deprecated in NDB 8.0.22, and is removed in NDB 8.0.23 and later. It is no longer supported.
- **ndbmemcache deprecation and removal.** `ndbmemcache` is no longer supported. `ndbmemcache` was deprecated in NDB 8.0.22, and removed in NDB 8.0.23.
- **ndbinfo backup_id table.** NDB 8.0.24 adds a `backup_id` table to the `ndbinfo` information database. This is intended to serve as a replacement for obtaining this information by using `ndb_select_all` to dump the contents of the internal `SYSTAB_0` ttable, which is error-prone and takes an excessively long time to perform.

This table has a single column and row containing the ID of the most recent backup of the cluster taken using the `START BACKUP` management client command. In the event that no backup of this cluster can be found, the table contains a single row whose column value is `0`.

- **Table partitioning enhancements.** NDB 8.0.23 introduces a new method for handling table partitions and fragments, which can determine the number of local data managers (LDMs) for a given data node independently of the number of redo log parts. This means that the number of LDMs can now be highly variable. NDB can employ this method when the `ClassicFragmentation` data node configuration parameter, also implemented in NDB 8.0.23, is set to `false`; when this is the case, the number of LDMs is no longer used to determine how many partitions to create for a table per data node, and the value of the `PartitionsPerNode` parameter (also introduced in NDB 8.0.23) determines this number instead, which is also used for calculating the number of fragments used for a table.

When `ClassicFragmentation` has its default value `true`, then the traditional method of using the number of LDMs is used to determine the number of fragments that a table should have.

For more information, see the descriptions of the new parameters referenced previously, in [Multi-Threading Configuration Parameters \(ndbmt\)](#).

- **Terminology updates.** To align with work begun in MySQL 8.0.21 and NDB 8.0.21, NDB 8.0.23 implements a number of changes in terminology, listed here:
 - The system variable `ndb_slave_conflict_role` is now deprecated. It is replaced by `ndb_conflict_role`.
 - Many NDB status variables are deprecated. These variables, and their replacements, are shown in the following table:

Table 23.1 Deprecated NDB status variables and their replacements

| Deprecated variable | Replacement |
|---|---|
| <code>Ndb_api_adaptive_send_deferred_count_slave</code> | <code>Ndb_api_adaptive_send_deferred_count_replica</code> |
| <code>Ndb_api_adaptive_send_forced_count_slave</code> | <code>Ndb_api_adaptive_send_forced_count_replica</code> |
| <code>Ndb_api_adaptive_send_unforced_count_slave</code> | <code>Ndb_api_adaptive_send_unforced_count_replica</code> |
| <code>Ndb_api_bytes_received_count_slave</code> | <code>Ndb_api_bytes_received_count_replica</code> |
| <code>Ndb_api_bytes_sent_count_slave</code> | <code>Ndb_api_bytes_sent_count_replica</code> |
| <code>Ndb_api_pk_op_count_slave</code> | <code>Ndb_api_pk_op_count_replica</code> |
| <code>Ndb_api_pruned_scan_count_slave</code> | <code>Ndb_api_pruned_scan_count_replica</code> |

| Deprecated variable | Replacement |
|---|---|
| <code>Ndb_api_range_scan_count_slave</code> | <code>Ndb_api_range_scan_count_replica</code> |
| <code>Ndb_api_read_row_count_slave</code> | <code>Ndb_api_read_row_count_replica</code> |
| <code>Ndb_api_scan_batch_count_slave</code> | <code>Ndb_api_scan_batch_count_replica</code> |
| <code>Ndb_api_table_scan_count_slave</code> | <code>Ndb_api_table_scan_count_replica</code> |
| <code>Ndb_api_trans_abort_count_slave</code> | <code>Ndb_api_trans_abort_count_replica</code> |
| <code>Ndb_api_trans_close_count_slave</code> | <code>Ndb_api_trans_close_count_replica</code> |
| <code>Ndb_api_trans_commit_count_slave</code> | <code>Ndb_api_trans_commit_count_replica</code> |
| <code>Ndb_api_trans_local_read_row_count_slave</code> | <code>Ndb_api_trans_local_read_row_count_replica</code> |
| <code>Ndb_api_trans_start_count_slave</code> | <code>Ndb_api_trans_start_count_replica</code> |
| <code>Ndb_api_uk_op_count_slave</code> | <code>Ndb_api_uk_op_count_replica</code> |
| <code>Ndb_api_wait_exec_complete_count_slave</code> | <code>Ndb_api_wait_exec_complete_count_replica</code> |
| <code>Ndb_api_wait_meta_request_count_slave</code> | <code>Ndb_api_wait_meta_request_count_replica</code> |
| <code>Ndb_api_wait_nanos_count_slave</code> | <code>Ndb_api_wait_nanos_count_replica</code> |
| <code>Ndb_api_wait_scan_result_count_slave</code> | <code>Ndb_api_wait_scan_result_count_replica</code> |
| <code>Ndb_slave_max_replicated_epoch</code> | <code>Ndb_replica_max_replicated_epoch</code> |

The deprecated status variables continue to be shown in the output of `SHOW STATUS`, but applications should be updated as soon as possible not to rely upon them any longer, since their availability in future release series is not guaranteed.

- The values `ADD_TABLE_MASTER` and `ADD_TABLE_SLAVE` previously shown in the `tab_copy_status` column of the `ndbinfo.ndbinfo.table_distribution_status` table are deprecated. These are replaced by, respectively, the values `ADD_TABLE_COORDINATOR` and `ADD_TABLE_PARTICIPANT`.
- The `--help` output of some NDB client and utility programs such as `ndb_restore` has been modified.
- **ThreadConfig enhancements.** As of NDB 8.0.23, the configurability of the `ThreadConfig` parameter has been extended with two new thread types, listed here:
 - `query`: A query thread works (only) on `READ COMMITTED` queries. A query thread also acts as a recovery thread. The number of query threads must be 0, 1, 2, or 3 times the number of LDM threads. 0 (the default, unless using `ThreadConfig`, or `AutomaticThreadConfig` is enabled) causes LDMs to behave as they did prior to NDB 8.0.23.

- `recover`: A recovery thread retrieves data from a local checkpoint. A recovery thread specified as such never acts as a query thread.

It is also possible to combine the existing `main` and `rep` threads in either of two ways:

- Into a single thread by setting either one of these arguments to 0. When this is done, the resulting combined thread is shown with the name `main_rep` in the `ndbinfo.threads` table.
- Together with the `recv` thread by setting both `ldm` and `tc` to 0, and setting `recv` to 1. In this case, the combined thread is named `main_rep_recv`.

In addition, the maximum numbers of a number of existing thread types have been increased. The new maximums, including those for query threads and recovery threads, are listed here:

- LDM: 332
- Query: 332
- Recovery: 332
- TC: 128
- Receive: 64
- Send: 64
- Main: 2

Maximums for other thread types remain unchanged.

For more information, see the descriptions of the `ThreadConfig` parameter and the `ndbinfo.threads` table.

Also, as the result of work done relating to this task, `NDB` now employs mutexes to protect job buffers when using more than 32 block threads. While this can cause a slight decrease in performance (1 to 2 percent in most cases), it also significantly reduces the amount of memory required by very large configurations. For example, a setup with 64 threads which used 2 GB of job buffer memory prior to `NDB 8.0.23` should require only about 1 GB instead in `NDB 8.0.23` and later. In our testing this has resulted in an overall improvement on the order of 5 percent in the execution of very complex queries.

- **ndbmtd Thread Auto-Configuration.** Beginning with `NDB 8.0.23`, it is possible to employ automatic configuration of threads for multi-threaded data nodes using the `ndbmtd` configuration parameter `AutomaticThreadConfig`. When this parameter is set to 1, `NDB` sets up thread assignments automatically, based on the number of processors available to applications, for all thread supported thread types, including the new `query` and `recover` thread types described in the previous item. If

the system does not limit the number of processors, you can do so if desired by setting `NumCPUs` (also added in NDB 8.0.23). Otherwise, automatic thread configuration accommodates up to 1024 CPUs.

Automatic thread configuration occurs regardless of any values set for `ThreadConfig` or `MaxNoOfExecutionThreads` in `config.ini`; this means that it is not necessary to set either of these parameters.

In addition, NDB 8.0.23 implements a number of new `ndbinfo` information database tables providing information about hardware and CPU availability, as well as CPU usage by NDB data nodes. These tables are listed here:

- `cpudata`
- `cpudata_1sec`
- `cpudata_20sec`
- `cpudata_50ms`
- `cpuinfo`
- `hwinfo`

Some of these tables are not available on every platform supported by NDB Cluster; see the individual descriptions of them for more information.

- **Hierarchical views of NDB database objects.** The `dict_obj_tree` table, added to the `ndbinfo` information database in NDB 8.0.24, can provide hierarchical and tree-like views of many NDB database objects, including the following:
 - Tables and associated indexes
 - Tablespaces and associated data files
 - Logfile groups and associated undo log files

For more information and examples, see [Section 23.6.14.22, “The `ndbinfo dict_obj_tree` Table”](#).

- **Index statistics enhancements.** NDB 8.0.24 implements the following improvements in calculation of index statistics:
 - Index statistics were previously collected from one fragment only; this is changed such that this extrapolation is extended to additional fragments.
 - The algorithm used for very small tables, such as those having very few rows where results are discarded, has been improved, so that estimates for such tables should be more accurate than previously.

As of NDB 8.0.27, the index statistics tables are created and updated automatically by default, `IndexStatAutoCreate` and `IndexStatAutoUpdate` both default to `1` (enabled) rather than `0` (disabled), and it is no longer necessary to run `ANALYZE TABLE` to update the statistics.

For additional information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- **Conversion between NULL and NOT NULL during restore operations.** Beginning with NDB 8.0.26, `ndb_restore` can support restoring of `NULL` columns as `NOT NULL` and the reverse, using the options listed here:

- To restore a `NULL` column as `NOT NULL`, use the `--lossy-conversions` option.

The column originally declared as `NULL` must not contain any `NULL` rows; if it does, `ndb_restore` exits with an error.

- To restore a `NOT NULL` column as `NULL`, use the `--promote-attributes` option.

For more information, see the descriptions of the indicated `ndb_restore` options.

- **SQL-compliant NULL comparison mode for NdbScanFilter.** Traditionally, when making comparisons involving `NULL`, `NdbScanFilter` treats `NULL` as equal to `NULL` (and thus considers `NULL == NULL` to be `TRUE`). This is not the same as specified by the SQL Standard, which requires that any comparison with `NULL` return `NULL`, including `NULL == NULL`.

Previously, it was not possible for an NDB API application to override this behavior; beginning with NDB 8.0.26, you can do so by calling `NdbScanFilter::setSqlCmpSemantics()` prior to creating a scan filter. (Thus, this method is always invoked as a class method and not as an instance method.) Doing so causes the next `NdbScanFilter` object to be created to employ SQL-compliant `NULL` comparison for all comparison operations performed over the lifetime of the instance. You must invoke the method for each `NdbScanFilter` object that should use SQL-compliant comparisons.

For more information, see `NdbScanFilter::setSqlCmpSemantics()`.

- **Deprecation of NDB API .FRM file methods.** MySQL 8.0 and NDB 8.0 no longer use `.FRM` files for storing table metadata. For this reason, the NDB API methods `getFrmData()`, `getFrmLength()`, and `setFrm()` are deprecated as of NDB 8.0.27, and subject to removal in a future release. For reading and writing table metadata, use `getExtraMetadata()` and `setExtraMetadata()` instead.
- **Preference for IPv4 or IPv6 Addressing.** NDB 8.0.26 adds the `PreferIPVersion` configuration parameter, which controls the addressing preference for DNS resolution. IPv4 (`PreferIPVersion=4`) is the default. Because configuration retrieval in NDB requires that this preference be the same for all TCP connections, you should set it only in the `[tcp default]` section of the cluster global configuration (`config.ini`) file.

See [Section 23.4.3.10, “NDB Cluster TCP/IP Connections”](#), for more information.

- **Logging enhancements.** Previously, analysis of NDB Cluster data node and management node logs could be hampered by the fact that different log messages used different formats, and that not all log messages included timestamps. Such issues were due in part to the fact that logging was performed by a number of different mechanisms, such as the functions `printf`, `fprintf`, `ndbout`, and `ndbout_c`, overloading of the `<<` operator, and so on.

We fix these problems by standardizing on the `EventLogger` mechanism, which is already present in NDB, and which begins each log message with a timestamp in `YYYY-MM-DD HH:MM:SS` format.

See [Section 23.6.3, “Event Reports Generated in NDB Cluster”](#), for more information about NDB Cluster event logs and the `EventLogger` log message format.

- **Copying ALTER TABLE Improvements.** Beginning with NDB 8.0.27, a copying `ALTER TABLE` on an NDB table compares the fragment commit counts for the source table before and after performing

the copy. This allows the SQL node executing this statement to determine whether there has been any concurrent write activity to the table being altered; if so, the SQL node can then terminate the operation.

When concurrent writes are detected being made to the table being altered, the `ALTER TABLE` statement is rejected with the error `Detected change to data in source table during copying ALTER TABLE. Alter aborted to avoid inconsistency (ER_TABLE_DEF_CHANGED)`. Stopping the alter operation, rather than allowing it to proceed with concurrent writes taking place, can help prevent silent data loss or corruption.

MySQL Cluster Manager 1.4.8 also provides experimental support for NDB Cluster 8.0. MySQL Cluster Manager has an advanced command-line interface that can simplify many complex NDB Cluster management tasks. See [MySQL Cluster Manager 1.4.8 User Manual](#), for more information.

23.2.5 Options, Variables, and Parameters Added, Deprecated or Removed in NDB 8.0

- [Parameters Introduced in NDB 8.0](#)
- [Parameters Deprecated in NDB 8.0](#)
- [Parameters Removed in NDB 8.0](#)
- [Options and Variables Introduced in NDB 8.0](#)
- [Options and Variables Deprecated in NDB 8.0](#)
- [Options and Variables Removed in NDB 8.0](#)

The next few sections contain information about `NDB` node configuration parameters and NDB-specific `mysqld` options and variables that have been added to, deprecated in, or removed from NDB 8.0.

Parameters Introduced in NDB 8.0

The following node configuration parameters have been added in NDB 8.0.

- `AllowUnresolvedHostNames`: When false (default), failure by management node to resolve host name results in fatal error; when true, unresolved host names are reported as warnings only. Added in NDB 8.0.22.
- `AutomaticThreadConfig`: Use automatic thread configuration; overrides any settings for `ThreadConfig` and `MaxNoOfExecutionThreads`. Added in NDB 8.0.23.
- `ClassicFragmentation`: When true, use traditional table fragmentation; set false to enable flexible distribution of table fragments among LDMs. Added in NDB 8.0.23.
- `DiskDataUsingSameDisk`: Set to false if Disk Data tablespaces are located on separate physical disks. Added in NDB 8.0.19.
- `EnableMultithreadedBackup`: Enable multi-threaded backup. Added in NDB 8.0.16.
- `KeepAliveSendInterval`: Time between keep-alive signals on links between data nodes, in milliseconds. Set to 0 to disable. Added in NDB 8.0.27.
- `MaxDiskDataLatency`: Maximum allowed mean latency of disk access (ms) before starting to abort transactions. Added in NDB 8.0.19.
- `NodeGroupTransporters`: Number of transporters to use between nodes in same node group. Added in NDB 8.0.20.

- [NumCPUs](#): Specify number of CPUs to use with AutomaticThreadConfig. Added in NDB 8.0.23.
- [PartitionsPerNode](#): Determines the number of table partitions created on each data node; not used if ClassicFragmentation is enabled. Added in NDB 8.0.23.
- [PreferIPVersion](#): Indicate DNS resolver preference for IP version 4 or 6. Added in NDB 8.0.26.
- [RequireEncryptedBackup](#): Whether backups must be encrypted (1 = encryption required, otherwise 0). Added in NDB 8.0.22.
- [ReservedConcurrentIndexOperations](#): Number of simultaneous index operations having dedicated resources on one data node. Added in NDB 8.0.16.
- [ReservedConcurrentOperations](#): Number of simultaneous operations having dedicated resources in transaction coordinators on one data node. Added in NDB 8.0.16.
- [ReservedConcurrentScans](#): Number of simultaneous scans having dedicated resources on one data node. Added in NDB 8.0.16.
- [ReservedConcurrentTransactions](#): Number of simultaneous transactions having dedicated resources on one data node. Added in NDB 8.0.16.
- [ReservedFiredTriggers](#): Number of triggers having dedicated resources on one data node. Added in NDB 8.0.16.
- [ReservedLocalScans](#): Number of simultaneous fragment scans having dedicated resources on one data node. Added in NDB 8.0.16.
- [ReservedTransactionBufferMemory](#): Dynamic buffer space (in bytes) for key and attribute data allocated to each data node. Added in NDB 8.0.16.
- [SpinMethod](#): Determines spin method used by data node; see documentation for details. Added in NDB 8.0.20.
- [TcpSpinTime](#): Time to spin before going to sleep when receiving. Added in NDB 8.0.20.
- [TransactionMemory](#): Memory allocated for transactions on each data node. Added in NDB 8.0.19.

Parameters Deprecated in NDB 8.0

The following node configuration parameters have been deprecated in NDB 8.0.

- [BatchSizePerLocalScan](#): Used to calculate number of lock records for scan with hold lock. Deprecated in NDB 8.0.19.
- [MaxAllocate](#): No longer used; has no effect. Deprecated in NDB 8.0.27.
- [MaxNoOfConcurrentIndexOperations](#): Total number of index operations that can execute simultaneously on one data node. Deprecated in NDB 8.0.19.
- [MaxNoOfConcurrentTransactions](#): Maximum number of transactions executing concurrently on this data node, total number of transactions that can be executed concurrently is this value times number of data nodes in cluster. Deprecated in NDB 8.0.19.
- [MaxNoOfFiredTriggers](#): Total number of triggers that can fire simultaneously on one data node. Deprecated in NDB 8.0.19.
- [MaxNoOfLocalOperations](#): Maximum number of operation records defined on this data node. Deprecated in NDB 8.0.19.

- [MaxNoOfLocalScans](#): Maximum number of fragment scans in parallel on this data node. Deprecated in NDB 8.0.19.
- [ReservedTransactionBufferMemory](#): Dynamic buffer space (in bytes) for key and attribute data allocated to each data node. Deprecated in NDB 8.0.19.
- [UndoDataBuffer](#): Unused; has no effect. Deprecated in NDB 8.0.27.
- [UndoIndexBuffer](#): Unused; has no effect. Deprecated in NDB 8.0.27.

Parameters Removed in NDB 8.0

No node configuration parameters have been removed in NDB 8.0.

Options and Variables Introduced in NDB 8.0

The following system variables, status variables, and server options have been added in NDB 8.0.

- [Ndb_api_adaptive_send_deferred_count_replica](#): Number of adaptive send calls not actually sent by this replica. Added in NDB 8.0.23.
- [Ndb_api_adaptive_send_forced_count_replica](#): Number of adaptive sends with forced-send set sent by this replica. Added in NDB 8.0.23.
- [Ndb_api_adaptive_send_unforced_count_replica](#): Number of adaptive sends without forced-send sent by this replica. Added in NDB 8.0.23.
- [Ndb_api_bytes_received_count_replica](#): Quantity of data (in bytes) received from data nodes by this replica. Added in NDB 8.0.23.
- [Ndb_api_bytes_sent_count_replica](#): Quantity of data (in bytes) sent to data nodes by this replica. Added in NDB 8.0.23.
- [Ndb_api_pk_op_count_replica](#): Number of operations based on or using primary keys by this replica. Added in NDB 8.0.23.
- [Ndb_api_pruned_scan_count_replica](#): Number of scans that have been pruned to one partition by this replica. Added in NDB 8.0.23.
- [Ndb_api_range_scan_count_replica](#): Number of range scans that have been started by this replica. Added in NDB 8.0.23.
- [Ndb_api_read_row_count_replica](#): Total number of rows that have been read by this replica. Added in NDB 8.0.23.
- [Ndb_api_scan_batch_count_replica](#): Number of batches of rows received by this replica. Added in NDB 8.0.23.
- [Ndb_api_table_scan_count_replica](#): Number of table scans that have been started, including scans of internal tables, by this replica. Added in NDB 8.0.23.
- [Ndb_api_trans_abort_count_replica](#): Number of transactions aborted by this replica. Added in NDB 8.0.23.
- [Ndb_api_trans_close_count_replica](#): Number of transactions aborted (may be greater than sum of TransCommitCount and TransAbortCount) by this replica. Added in NDB 8.0.23.
- [Ndb_api_trans_commit_count_replica](#): Number of transactions committed by this replica. Added in NDB 8.0.23.

- [Ndb_api_trans_local_read_row_count_replica](#): Total number of rows that have been read by this replica. Added in NDB 8.0.23.
- [Ndb_api_trans_start_count_replica](#): Number of transactions started by this replica. Added in NDB 8.0.23.
- [Ndb_api_uk_op_count_replica](#): Number of operations based on or using unique keys by this replica. Added in NDB 8.0.23.
- [Ndb_api_wait_exec_complete_count_replica](#): Number of times thread has been blocked while waiting for operation execution to complete by this replica. Added in NDB 8.0.23.
- [Ndb_api_wait_meta_request_count_replica](#): Number of times thread has been blocked waiting for metadata-based signal by this replica. Added in NDB 8.0.23.
- [Ndb_api_wait_nanos_count_replica](#): Total time (in nanoseconds) spent waiting for some type of signal from data nodes by this replica. Added in NDB 8.0.23.
- [Ndb_api_wait_scan_result_count_replica](#): Number of times thread has been blocked while waiting for scan-based signal by this replica. Added in NDB 8.0.23.
- [Ndb_config_generation](#): Generation number of the current configuration of the cluster. Added in NDB 8.0.24.
- [Ndb_metadata_blacklist_size](#): Number of NDB metadata objects that NDB binlog thread has failed to synchronize; renamed in NDB 8.0.22 as [Ndb_metadata_excluded_count](#). Added in NDB 8.0.18.
- [Ndb_metadata_detected_count](#): Number of times NDB metadata change monitor thread has detected changes. Added in NDB 8.0.16.
- [Ndb_metadata_excluded_count](#): Number of NDB metadata objects that NDB binlog thread has failed to synchronize. Added in NDB 8.0.22.
- [Ndb_metadata_synced_count](#): Number of NDB metadata objects which have been synchronized. Added in NDB 8.0.18.
- [Ndb_trans_hint_count_session](#): Number of transactions using hints that have been started in this session. Added in NDB 8.0.17.
- [ndb-log-fail-terminate](#): Terminate mysqld process if complete logging of all found row events is not possible. Added in NDB 8.0.21.
- [ndb-schema-dist-timeout](#): How long to wait before detecting timeout during schema distribution. Added in NDB 8.0.17.
- [ndb_conflict_role](#): Role for replica to play in conflict detection and resolution. Value is one of PRIMARY, SECONDARY, PASS, or NONE (default). Can be changed only when replication SQL thread is stopped. See documentation for further information. Added in NDB 8.0.23.
- [ndb_dbg_check_shares](#): Check for any lingering shares (debug builds only). Added in NDB 8.0.13.
- [ndb_metadata_check](#): Enable auto-detection of NDB metadata changes with respect to MySQL data dictionary; enabled by default. Added in NDB 8.0.16.
- [ndb_metadata_check_interval](#): Interval in seconds to perform check for NDB metadata changes with respect to MySQL data dictionary. Added in NDB 8.0.16.
- [ndb_metadata_sync](#): Triggers immediate synchronization of all changes between NDB dictionary and MySQL data dictionary; causes [ndb_metadata_check](#) and [ndb_metadata_check_interval](#) values to be ignored. Resets to false when synchronization is complete. Added in NDB 8.0.19.

- [ndb_schema_dist_lock_wait_timeout](#): Time during schema distribution to wait for lock before returning error. Added in NDB 8.0.18.
- [ndb_schema_dist_timeout](#): Time to wait before detecting timeout during schema distribution. Added in NDB 8.0.16.
- [ndb_schema_dist_upgrade_allowed](#): Allow schema distribution table upgrade when connecting to NDB. Added in NDB 8.0.17.
- [ndbinfo](#): Enable ndbinfo plugin, if supported. Added in NDB 8.0.13.
- [replica_allow_batching](#): Turns update batching on and off for replica. Added in NDB 8.0.26.

Options and Variables Deprecated in NDB 8.0

The following system variables, status variables, and options have been deprecated in NDB 8.0.

- [Ndb_api_adaptive_send_deferred_count_slave](#): Number of adaptive send calls not actually sent by this replica. Deprecated in NDB 8.0.23.
- [Ndb_api_adaptive_send_forced_count_slave](#): Number of adaptive sends with forced-send set sent by this replica. Deprecated in NDB 8.0.23.
- [Ndb_api_adaptive_send_unforced_count_slave](#): Number of adaptive sends without forced-send sent by this replica. Deprecated in NDB 8.0.23.
- [Ndb_api_bytes_received_count_slave](#): Quantity of data (in bytes) received from data nodes by this replica. Deprecated in NDB 8.0.23.
- [Ndb_api_bytes_sent_count_slave](#): Quantity of data (in bytes) sent to data nodes by this replica. Deprecated in NDB 8.0.23.
- [Ndb_api_pk_op_count_slave](#): Number of operations based on or using primary keys by this replica. Deprecated in NDB 8.0.23.
- [Ndb_api_pruned_scan_count_slave](#): Number of scans that have been pruned to one partition by this replica. Deprecated in NDB 8.0.23.
- [Ndb_api_range_scan_count_slave](#): Number of range scans that have been started by this replica. Deprecated in NDB 8.0.23.
- [Ndb_api_read_row_count_slave](#): Total number of rows that have been read by this replica. Deprecated in NDB 8.0.23.
- [Ndb_api_scan_batch_count_slave](#): Number of batches of rows received by this replica. Deprecated in NDB 8.0.23.
- [Ndb_api_table_scan_count_slave](#): Number of table scans that have been started, including scans of internal tables, by this replica. Deprecated in NDB 8.0.23.
- [Ndb_api_trans_abort_count_slave](#): Number of transactions aborted by this replica. Deprecated in NDB 8.0.23.
- [Ndb_api_trans_close_count_slave](#): Number of transactions aborted (may be greater than sum of TransCommitCount and TransAbortCount) by this replica. Deprecated in NDB 8.0.23.
- [Ndb_api_trans_commit_count_slave](#): Number of transactions committed by this replica. Deprecated in NDB 8.0.23.

- [Ndb_api_trans_local_read_row_count_slave](#): Total number of rows that have been read by this replica. Deprecated in NDB 8.0.23.
- [Ndb_api_trans_start_count_slave](#): Number of transactions started by this replica. Deprecated in NDB 8.0.23.
- [Ndb_api_uk_op_count_slave](#): Number of operations based on or using unique keys by this replica. Deprecated in NDB 8.0.23.
- [Ndb_api_wait_exec_complete_count_slave](#): Number of times thread has been blocked while waiting for operation execution to complete by this replica. Deprecated in NDB 8.0.23.
- [Ndb_api_wait_meta_request_count_slave](#): Number of times thread has been blocked waiting for metadata-based signal by this replica. Deprecated in NDB 8.0.23.
- [Ndb_api_wait_nanos_count_slave](#): Total time (in nanoseconds) spent waiting for some type of signal from data nodes by this replica. Deprecated in NDB 8.0.23.
- [Ndb_api_wait_scan_result_count_slave](#): Number of times thread has been blocked while waiting for scan-based signal by this replica. Deprecated in NDB 8.0.23.
- [Ndb_metadata_blacklist_size](#): Number of NDB metadata objects that NDB binlog thread has failed to synchronize; renamed in NDB 8.0.22 as [Ndb_metadata_excluded_count](#). Deprecated in NDB 8.0.21.
- [Ndb_replica_max_replicated_epoch](#): Most recently committed NDB epoch on this replica. When this value is greater than or equal to [Ndb_conflict_last_conflict_epoch](#), no conflicts have yet been detected. Deprecated in NDB 8.0.23.
- [ndb_slave_conflict_role](#): Role for replica to play in conflict detection and resolution. Value is one of PRIMARY, SECONDARY, PASS, or NONE (default). Can be changed only when replication SQL thread is stopped. See documentation for further information. Deprecated in NDB 8.0.23.
- [slave_allow_batching](#): Turns update batching on and off for replica. Deprecated in NDB 8.0.26.

Options and Variables Removed in NDB 8.0

The following system variables, status variables, and options have been removed in NDB 8.0.

- [Ndb_metadata_blacklist_size](#): Number of NDB metadata objects that NDB binlog thread has failed to synchronize; renamed in NDB 8.0.22 as [Ndb_metadata_excluded_count](#). Removed in NDB 8.0.22.

23.2.6 MySQL Server Using InnoDB Compared with NDB Cluster

MySQL Server offers a number of choices in storage engines. Since both [NDB](#) and [InnoDB](#) can serve as transactional MySQL storage engines, users of MySQL Server sometimes become interested in NDB Cluster. They see [NDB](#) as a possible alternative or upgrade to the default [InnoDB](#) storage engine in MySQL 8.0. While [NDB](#) and [InnoDB](#) share common characteristics, there are differences in architecture and implementation, so that some existing MySQL Server applications and usage scenarios can be a good fit for NDB Cluster, but not all of them.

In this section, we discuss and compare some characteristics of the [NDB](#) storage engine used by NDB 8.0 with [InnoDB](#) used in MySQL 8.0. The next few sections provide a technical comparison. In many instances, decisions about when and where to use NDB Cluster must be made on a case-by-case basis, taking all factors into consideration. While it is beyond the scope of this documentation to provide specifics for every conceivable usage scenario, we also attempt to offer some very general guidance on the relative suitability of some common types of applications for [NDB](#) as opposed to [InnoDB](#) back ends.

NDB Cluster 8.0 uses a `mysqld` based on MySQL 8.0, including support for [InnoDB 1.1](#). While it is possible to use [InnoDB](#) tables with NDB Cluster, such tables are not clustered. It is also not possible to use programs or libraries from an NDB Cluster 8.0 distribution with MySQL Server 8.0, or the reverse.

While it is also true that some types of common business applications can be run either on NDB Cluster or on MySQL Server (most likely using the [InnoDB](#) storage engine), there are some important architectural and implementation differences. [Section 23.2.6.1, “Differences Between the NDB and InnoDB Storage Engines”](#), provides a summary of these differences. Due to the differences, some usage scenarios are clearly more suitable for one engine or the other; see [Section 23.2.6.2, “NDB and InnoDB Workloads”](#). This in turn has an impact on the types of applications that better suited for use with [NDB](#) or [InnoDB](#). See [Section 23.2.6.3, “NDB and InnoDB Feature Usage Summary”](#), for a comparison of the relative suitability of each for use in common types of database applications.

For information about the relative characteristics of the [NDB](#) and [MEMORY](#) storage engines, see [When to Use MEMORY or NDB Cluster](#).

See [Chapter 16, Alternative Storage Engines](#), for additional information about MySQL storage engines.

23.2.6.1 Differences Between the NDB and InnoDB Storage Engines

The [NDB](#) storage engine is implemented using a distributed, shared-nothing architecture, which causes it to behave differently from [InnoDB](#) in a number of ways. For those unaccustomed to working with [NDB](#), unexpected behaviors can arise due to its distributed nature with regard to transactions, foreign keys, table limits, and other characteristics. These are shown in the following table:

Table 23.2 Differences between InnoDB and NDB storage engines

| Feature | InnoDB (MySQL 8.0) | NDB 8.0 |
|------------------------------|---|--|
| MySQL Server Version | 8.0 | 8.0 |
| InnoDB Version | InnoDB 8.0.26 | InnoDB 8.0.26 |
| NDB Cluster Version | N/A | NDB 8.0.27/8.0.27 |
| Storage Limits | 64TB | 128TB |
| Foreign Keys | Yes | Yes |
| Transactions | All standard types | READ COMMITTED |
| MVCC | Yes | No |
| Data Compression | Yes | No (NDB checkpoint and backup files can be compressed) |
| Large Row Support (> 14K) | Supported for VARBINARY , VARCHAR , BLOB , and TEXT columns | Supported for BLOB and TEXT columns only (Using these types to store very large amounts of data can lower NDB performance) |
| Replication Support | Asynchronous and semisynchronous replication using MySQL Replication; MySQL Group Replication | Automatic synchronous replication within an NDB Cluster; asynchronous replication between NDB Clusters, using MySQL Replication (Semisynchronous replication is not supported) |
| Scaleout for Read Operations | Yes (MySQL Replication) | Yes (Automatic partitioning in NDB Cluster; NDB Cluster Replication) |

| Feature | InnoDB (MySQL 8.0) | NDB 8.0 |
|--|--|--|
| Scaleout for Write Operations | Requires application-level partitioning (sharding) | Yes (Automatic partitioning in NDB Cluster is transparent to applications) |
| High Availability (HA) | Built-in, from InnoDB cluster | Yes (Designed for 99.999% uptime) |
| Node Failure Recovery and Failover | From MySQL Group Replication | Automatic (Key element in NDB architecture) |
| Time for Node Failure Recovery | 30 seconds or longer | Typically < 1 second |
| Real-Time Performance | No | Yes |
| In-Memory Tables | No | Yes (Some data can optionally be stored on disk; both in-memory and disk data storage are durable) |
| NoSQL Access to Storage Engine | Yes | Yes (Multiple APIs, including Memcached, Node.js/JavaScript, Java, JPA, C++, and HTTP/REST) |
| Concurrent and Parallel Writes | Yes | Up to 48 writers, optimized for concurrent writes |
| Conflict Detection and Resolution (Multiple Sources) | Yes (MySQL Group Replication) | Yes |
| Hash Indexes | No | Yes |
| Online Addition of Nodes | Read/write replicas using MySQL Group Replication | Yes (all node types) |
| Online Upgrades | Yes (using replication) | Yes |
| Online Schema Modifications | Yes, as part of MySQL 8.0 | Yes |

23.2.6.2 NDB and InnoDB Workloads

NDB Cluster has a range of unique attributes that make it ideal to serve applications requiring high availability, fast failover, high throughput, and low latency. Due to its distributed architecture and multi-node implementation, NDB Cluster also has specific constraints that may keep some workloads from performing well. A number of major differences in behavior between the NDB and InnoDB storage engines with regard to some common types of database-driven application workloads are shown in the following table::

Table 23.3 Differences between InnoDB and NDB storage engines, common types of data-driven application workloads.

| Workload | InnoDB | NDB Cluster (NDB) |
|--|--------|--|
| High-Volume OLTP Applications | Yes | Yes |
| DSS Applications (data marts, analytics) | Yes | Limited (Join operations across OLTP datasets not exceeding 3TB in size) |
| Custom Applications | Yes | Yes |
| Packaged Applications | Yes | Limited (should be mostly primary key access); NDB Cluster 8.0 supports foreign keys |
| In-Network Telecoms Applications (HLR, HSS, SDP) | No | Yes |

| Workload | InnoDB | NDB Cluster (NDB) |
|---------------------------------------|--------|-------------------|
| Session Management and Caching | Yes | Yes |
| E-Commerce Applications | Yes | Yes |
| User Profile Management, AAA Protocol | Yes | Yes |

23.2.6.3 NDB and InnoDB Feature Usage Summary

When comparing application feature requirements to the capabilities of InnoDB with NDB, some are clearly more compatible with one storage engine than the other.

The following table lists supported application features according to the storage engine to which each feature is typically better suited.

Table 23.4 Supported application features according to the storage engine to which each feature is typically better suited

| Preferred application requirements for InnoDB | Preferred application requirements for NDB |
|---|---|
| <ul style="list-style-type: none"> Foreign keys <div style="display: flex; align-items: center; margin-top: 10px;">  <div style="border-left: 2px solid black; padding-left: 10px;"> <p>Note</p> <p>NDB Cluster 8.0 supports foreign keys</p> </div> </div> <ul style="list-style-type: none"> Full table scans Very large databases, rows, or transactions Transactions other than <code>READ COMMITTED</code> | <ul style="list-style-type: none"> Write scaling 99.999% uptime Online addition of nodes and online schema operations Multiple SQL and NoSQL APIs (see NDB Cluster APIs: Overview and Concepts) Real-time performance Limited use of <code>BLOB</code> columns Foreign keys are supported, although their use may have an impact on performance at high throughput |

23.2.7 Known Limitations of NDB Cluster

In the sections that follow, we discuss known limitations in current releases of NDB Cluster as compared with the features available when using the MyISAM and InnoDB storage engines. If you check the “Cluster” category in the MySQL bugs database at <http://bugs.mysql.com>, you can find known bugs in the following categories under “MySQL Server:” in the MySQL bugs database at <http://bugs.mysql.com>, which we intend to correct in upcoming releases of NDB Cluster:

- NDB Cluster
- Cluster Direct API (NDBAPI)
- Cluster Disk Data
- Cluster Replication
- ClusterJ

This information is intended to be complete with respect to the conditions just set forth. You can report any discrepancies that you encounter to the MySQL bugs database using the instructions given in [Section 1.6, “How to Report Bugs or Problems”](#). Any problem which we do not plan to fix in NDB Cluster 8.0, is added to the list.

See [Section 23.2.7.11, “Previous NDB Cluster Issues Resolved in NDB Cluster 8.0”](#) for a list of issues in earlier releases that have been resolved in NDB Cluster 8.0.

**Note**

Limitations and other issues specific to NDB Cluster Replication are described in [Section 23.7.3, “Known Issues in NDB Cluster Replication”](#).

23.2.7.1 Noncompliance with SQL Syntax in NDB Cluster

Some SQL statements relating to certain MySQL features produce errors when used with NDB tables, as described in the following list:

- **Temporary tables.** Temporary tables are not supported. Trying either to create a temporary table that uses the NDB storage engine or to alter an existing temporary table to use NDB fails with the error `Table storage engine 'ndbcluster' does not support the create option 'TEMPORARY'`.
- **Indexes and keys in NDB tables.** Keys and indexes on NDB Cluster tables are subject to the following limitations:
 - **Column width.** Attempting to create an index on an NDB table column whose width is greater than 3072 bytes succeeds, but only the first 3072 bytes are actually used for the index. In such cases, a warning `Specified key was too long; max key length is 3072 bytes` is issued, and a `SHOW CREATE TABLE` statement shows the length of the index as 3072.
 - **TEXT and BLOB columns.** You cannot create indexes on NDB table columns that use any of the `TEXT` or `BLOB` data types.
 - **FULLTEXT indexes.** The NDB storage engine does not support `FULLTEXT` indexes, which are possible for `MyISAM` and `InnoDB` tables only.

However, you can create indexes on `VARCHAR` columns of NDB tables.

- **USING HASH keys and NULL.** Using nullable columns in unique keys and primary keys means that queries using these columns are handled as full table scans. To work around this issue, make the column `NOT NULL`, or re-create the index without the `USING HASH` option.
- **Prefixes.** There are no prefix indexes; only entire columns can be indexed. (The size of an NDB column index is always the same as the width of the column in bytes, up to and including 3072 bytes, as described earlier in this section. Also see [Section 23.2.7.6, “Unsupported or Missing Features in NDB Cluster”](#), for additional information.)
- **BIT columns.** A `BIT` column cannot be a primary key, unique key, or index, nor can it be part of a composite primary key, unique key, or index.
- **AUTO_INCREMENT columns.** Like other MySQL storage engines, the NDB storage engine can handle a maximum of one `AUTO_INCREMENT` column per table. However, in the case of an NDB table with no explicit primary key, an `AUTO_INCREMENT` column is automatically defined and used as a “hidden” primary key. For this reason, you cannot define a table that has an explicit `AUTO_INCREMENT` column unless that column is also declared using the `PRIMARY KEY` option. Attempting to create a table with an `AUTO_INCREMENT` column that is not the table's primary key, and using the NDB storage engine, fails with an error.

- **Restrictions on foreign keys.** Support for foreign key constraints in NDB 8.0 is comparable to that provided by [InnoDB](#), subject to the following restrictions:
 - Every column referenced as a foreign key requires an explicit unique key, if it is not the table's primary key.
 - `ON UPDATE CASCADE` is not supported when the reference is to the parent table's primary key.

This is because an update of a primary key is implemented as a delete of the old row (containing the old primary key) plus an insert of the new row (with a new primary key). This is not visible to the [NDB](#) kernel, which views these two rows as being the same, and thus has no way of knowing that this update should be cascaded.
 - `ON DELETE CASCADE` is also not supported where the child table contains one or more columns of any of the `TEXT` or `BLOB` types. (Bug #89511, Bug #27484882)
 - `SET DEFAULT` is not supported. (Also not supported by [InnoDB](#).)
 - The `NO ACTION` keyword is accepted but treated as `RESTRICT`. `NO ACTION`, which is a standard SQL keyword, is the default in MySQL 8.0. (Also the same as with [InnoDB](#).)
 - In earlier versions of NDB Cluster, when creating a table with foreign key referencing an index in another table, it sometimes appeared possible to create the foreign key even if the order of the columns in the indexes did not match, due to the fact that an appropriate error was not always returned internally. A partial fix for this issue improved the error used internally to work in most cases; however, it remains possible for this situation to occur in the event that the parent index is a unique index. (Bug #18094360)

For more information, see [Section 13.1.20.5, “FOREIGN KEY Constraints”](#), and [Section 1.7.3.2, “FOREIGN KEY Constraints”](#).

- **NDB Cluster and geometry data types.** Geometry data types (`WKT` and `WKB`) are supported for [NDB](#) tables. However, spatial indexes are not supported.
- **Character sets and binary log files.** Currently, the `ndb_apply_status` and `ndb_binlog_index` tables are created using the `latin1` (ASCII) character set. Because names of binary logs are recorded in this table, binary log files named using non-Latin characters are not referenced correctly in these tables. This is a known issue, which we are working to fix. (Bug #50226)

To work around this problem, use only Latin-1 characters when naming binary log files or setting any the `--basedir`, `--log-bin`, or `--log-bin-index` options.

- **Creating NDB tables with user-defined partitioning.** Support for user-defined partitioning in NDB Cluster is restricted to `[LINEAR] KEY` partitioning. Using any other partitioning type with `ENGINE=NDB` or `ENGINE=NDBCLUSTER` in a `CREATE TABLE` statement results in an error.

It is possible to override this restriction, but doing so is not supported for use in production settings. For details, see [User-defined partitioning and the NDB storage engine \(NDB Cluster\)](#).

Default partitioning scheme. All NDB Cluster tables are by default partitioned by `KEY` using the table's primary key as the partitioning key. If no primary key is explicitly set for the table, the “hidden” primary key automatically created by the [NDB](#) storage engine is used instead. For additional discussion of these and related issues, see [Section 24.2.5, “KEY Partitioning”](#).

`CREATE TABLE` and `ALTER TABLE` statements that would cause a user-partitioned `NDBCLUSTER` table not to meet either or both of the following two requirements are not permitted, and fail with an error:

1. The table must have an explicit primary key.
2. All columns listed in the table's partitioning expression must be part of the primary key.

Exception. If a user-partitioned `NDBCLUSTER` table is created using an empty column-list (that is, using `PARTITION BY [LINEAR] KEY()`), then no explicit primary key is required.

Maximum number of partitions for NDBCLUSTER tables. The maximum number of partitions that can be defined for a `NDBCLUSTER` table when employing user-defined partitioning is 8 per node group. (See [Section 23.2.2, “NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions”](#), for more information about NDB Cluster node groups.

DROP PARTITION not supported. It is not possible to drop partitions from `NDB` tables using `ALTER TABLE ... DROP PARTITION`. The other partitioning extensions to `ALTER TABLE`—`ADD PARTITION`, `REORGANIZE PARTITION`, and `COALESCE PARTITION`—are supported for `NDB` tables, but use copying and so are not optimized. See [Section 24.3.1, “Management of RANGE and LIST Partitions”](#) and [Section 13.1.9, “ALTER TABLE Statement”](#).

- **JSON data type.** The MySQL `JSON` data type is supported for `NDB` tables in the `mysqld` supplied with `NDB 8.0`.

An `NDB` table can have a maximum of 3 `JSON` columns.

The `NDB` API has no special provision for working with `JSON` data, which it views simply as `BLOB` data. Handling data as `JSON` must be performed by the application.

23.2.7.2 Limits and Differences of NDB Cluster from Standard MySQL Limits

In this section, we list limits found in `NDB` Cluster that either differ from limits found in, or that are not found in, standard MySQL.

Memory usage and recovery. Memory consumed when data is inserted into an `NDB` table is not automatically recovered when deleted, as it is with other storage engines. Instead, the following rules hold true:

- A `DELETE` statement on an `NDB` table makes the memory formerly used by the deleted rows available for re-use by inserts on the same table only. However, this memory can be made available for general re-use by performing `OPTIMIZE TABLE`.

A rolling restart of the cluster also frees any memory used by deleted rows. See [Section 23.6.5, “Performing a Rolling Restart of an NDB Cluster”](#).

- A `DROP TABLE` or `TRUNCATE TABLE` operation on an `NDB` table frees the memory that was used by this table for re-use by any `NDB` table, either by the same table or by another `NDB` table.

Note

Recall that `TRUNCATE TABLE` drops and re-creates the table. See [Section 13.1.37, “TRUNCATE TABLE Statement”](#).

- **Limits imposed by the cluster's configuration.** A number of hard limits exist which are configurable, but available main memory in the cluster sets limits. See the complete list of configuration parameters in [Section 23.4.3, “NDB Cluster Configuration Files”](#). Most configuration parameters can be upgraded online. These hard limits include:

- Database memory size and index memory size (`DataMemory` and `IndexMemory`, respectively).

`DataMemory` is allocated as 32KB pages. As each `DataMemory` page is used, it is assigned to a specific table; once allocated, this memory cannot be freed except by dropping the table.

See [Section 23.4.3.6, “Defining NDB Cluster Data Nodes”](#), for more information.

- The maximum number of operations that can be performed per transaction is set using the configuration parameters `MaxNoOfConcurrentOperations` and `MaxNoOfLocalOperations`.

Note

Bulk loading, `TRUNCATE TABLE`, and `ALTER TABLE` are handled as special cases by running multiple transactions, and so are not subject to this limitation.

- Different limits related to tables and indexes. For example, the maximum number of ordered indexes in the cluster is determined by `MaxNoOfOrderedIndexes`, and the maximum number of ordered indexes per table is 16.
- **Node and data object maximums.** The following limits apply to numbers of cluster nodes and metadata objects:

- The maximum number of data nodes is 145. (In NDB 7.6 and earlier, this was 48.)

A data node must have a node ID in the range of 1 to 144, inclusive.

Management and API nodes may use node IDs in the range 1 to 255, inclusive.

- The total maximum number of nodes in an NDB Cluster is 255. This number includes all SQL nodes (MySQL Servers), API nodes (applications accessing the cluster other than MySQL servers), data nodes, and management servers.
- The maximum number of metadata objects in current versions of NDB Cluster is 20320. This limit is hard-coded.

See [Section 23.2.7.11, “Previous NDB Cluster Issues Resolved in NDB Cluster 8.0”](#), for more information.

23.2.7.3 Limits Relating to Transaction Handling in NDB Cluster

A number of limitations exist in NDB Cluster with regard to the handling of transactions. These include the following:

- **Transaction isolation level.** The `NDBCLUSTER` storage engine supports only the `READ COMMITTED` transaction isolation level. (`InnoDB`, for example, supports `READ COMMITTED`, `READ UNCOMMITTED`, `REPEATABLE READ`, and `SERIALIZABLE`.) You should keep in mind that `NDB` implements `READ COMMITTED` on a per-row basis; when a read request arrives at the data node storing the row, what is returned is the last committed version of the row at that time.

Uncommitted data is never returned, but when a transaction modifying a number of rows commits concurrently with a transaction reading the same rows, the transaction performing the read can observe “before” values, “after” values, or both, for different rows among these, due to the fact that a given row read request can be processed either before or after the commit of the other transaction.

To ensure that a given transaction reads only before or after values, you can impose row locks using `SELECT ... LOCK IN SHARE MODE`. In such cases, the lock is held until the owning transaction is committed. Using row locks can also cause the following issues:

- Increased frequency of lock wait timeout errors, and reduced concurrency
- Increased transaction processing overhead due to reads requiring a commit phase
- Possibility of exhausting the available number of concurrent locks, which is limited by `MaxNoOfConcurrentOperations`

NDB uses `READ COMMITTED` for all reads unless a modifier such as `LOCK IN SHARE MODE` or `FOR UPDATE` is used. `LOCK IN SHARE MODE` causes shared row locks to be used; `FOR UPDATE` causes exclusive row locks to be used. Unique key reads have their locks upgraded automatically by NDB to ensure a self-consistent read; `BLOB` reads also employ extra locking for consistency.

See [Section 23.6.8.4, “NDB Cluster Backup Troubleshooting”](#), for information on how NDB Cluster's implementation of transaction isolation level can affect backup and restoration of NDB databases.

- **Transactions and BLOB or TEXT columns.** `NDBCLUSTER` stores only part of a column value that uses any of MySQL's `BLOB` or `TEXT` data types in the table visible to MySQL; the remainder of the `BLOB` or `TEXT` is stored in a separate internal table that is not accessible to MySQL. This gives rise to two related issues of which you should be aware whenever executing `SELECT` statements on tables that contain columns of these types:
 1. For any `SELECT` from an NDB Cluster table: If the `SELECT` includes a `BLOB` or `TEXT` column, the `READ COMMITTED` transaction isolation level is converted to a read with read lock. This is done to guarantee consistency.
 2. For any `SELECT` which uses a unique key lookup to retrieve any columns that use any of the `BLOB` or `TEXT` data types and that is executed within a transaction, a shared read lock is held on the table for the duration of the transaction—that is, until the transaction is either committed or aborted.

This issue does not occur for queries that use index or table scans, even against NDB tables having `BLOB` or `TEXT` columns.

For example, consider the table `t` defined by the following `CREATE TABLE` statement:

```
CREATE TABLE t (
  a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  b INT NOT NULL,
  c INT NOT NULL,
  d TEXT,
  INDEX i(b),
  UNIQUE KEY u(c)
) ENGINE = NDB,
```

The following query on `t` causes a shared read lock, because it uses a unique key lookup:

```
SELECT * FROM t WHERE c = 1;
```

However, none of the four queries shown here causes a shared read lock:

```
SELECT * FROM t WHERE b = 1;

SELECT * FROM t WHERE d = '1';

SELECT * FROM t;
```

```
SELECT b,c WHERE a = 1;
```

This is because, of these four queries, the first uses an index scan, the second and third use table scans, and the fourth, while using a primary key lookup, does not retrieve the value of any `BLOB` or `TEXT` columns.

You can help minimize issues with shared read locks by avoiding queries that use unique key lookups that retrieve `BLOB` or `TEXT` columns, or, in cases where such queries are not avoidable, by committing transactions as soon as possible afterward.

- **Unique key lookups and transaction isolation.** Unique indexes are implemented in `NDB` using a hidden index table which is maintained internally. When a user-created `NDB` table is accessed using a unique index, the hidden index table is first read to find the primary key that is then used to read the user-created table. To avoid modification of the index during this double-read operation, the row found in the hidden index table is locked. When a row referenced by a unique index in the user-created `NDB` table is updated, the hidden index table is subject to an exclusive lock by the transaction in which the update is performed. This means that any read operation on the same (user-created) `NDB` table must wait for the update to complete. This is true even when the transaction level of the read operation is `READ COMMITTED`.

One workaround which can be used to bypass potentially blocking reads is to force the SQL node to ignore the unique index when performing the read. This can be done by using the `IGNORE INDEX` index hint as part of the `SELECT` statement reading the table (see [Section 8.9.4, “Index Hints”](#)). Because the MySQL server creates a shadowing ordered index for every unique index created in `NDB`, this lets the ordered index be read instead, and avoids unique index access locking. The resulting read is as consistent as a committed read by primary key, returning the last committed value at the time the row is read.

Reading via an ordered index makes less efficient use of resources in the cluster, and may have higher latency.

It is also possible to avoid using the unique index for access by querying for ranges rather than for unique values.

- **Rollbacks.** There are no partial transactions, and no partial rollbacks of transactions. A duplicate key or similar error causes the entire transaction to be rolled back.

This behavior differs from that of other transactional storage engines such as `InnoDB` that may roll back individual statements.

- **Transactions and memory usage.**

As noted elsewhere in this chapter, `NDB Cluster` does not handle large transactions well; it is better to perform a number of small transactions with a few operations each than to attempt a single large transaction containing a great many operations. Among other considerations, large transactions require very large amounts of memory. Because of this, the transactional behavior of a number of MySQL statements is affected as described in the following list:

- `TRUNCATE TABLE` is not transactional when used on `NDB` tables. If a `TRUNCATE TABLE` fails to empty the table, then it must be re-run until it is successful.
- `DELETE FROM` (even with no `WHERE` clause) is transactional. For tables containing a great many rows, you may find that performance is improved by using several `DELETE FROM ... LIMIT ...`

statements to “chunk” the delete operation. If your objective is to empty the table, then you may wish to use `TRUNCATE TABLE` instead.

- **LOAD DATA statements.** `LOAD DATA` is not transactional when used on `NDB` tables.

Important

When executing a `LOAD DATA` statement, the `NDB` engine performs commits at irregular intervals that enable better utilization of the communication network. It is not possible to know ahead of time when such commits take place.

- **ALTER TABLE and transactions.** When copying an `NDB` table as part of an `ALTER TABLE`, the creation of the copy is nontransactional. (In any case, this operation is rolled back when the copy is deleted.)
- **Transactions and the COUNT() function.** When using `NDB` Cluster Replication, it is not possible to guarantee the transactional consistency of the `COUNT()` function on the replica. In other words, when performing on the source a series of statements (`INSERT`, `DELETE`, or both) that changes the number of rows in a table within a single transaction, executing `SELECT COUNT(*) FROM table` queries on the replica may yield intermediate results. This is due to the fact that `SELECT COUNT(...)` may perform dirty reads, and is not a bug in the `NDB` storage engine. (See Bug #31321 for more information.)

23.2.7.4 NDB Cluster Error Handling

Starting, stopping, or restarting a node may give rise to temporary errors causing some transactions to fail. These include the following cases:

- **Temporary errors.** When first starting a node, it is possible that you may see Error 1204 `Temporary failure, distribution changed` and similar temporary errors.
- **Errors due to node failure.** The stopping or failure of any data node can result in a number of different node failure errors. (However, there should be no aborted transactions when performing a planned shutdown of the cluster.)

In either of these cases, any errors that are generated must be handled within the application. This should be done by retrying the transaction.

See also [Section 23.2.7.2, “Limits and Differences of NDB Cluster from Standard MySQL Limits”](#).

23.2.7.5 Limits Associated with Database Objects in NDB Cluster

Some database objects such as tables and indexes have different limitations when using the `NDBCLUSTER` storage engine:

- **Number of database objects.** The maximum number of *all* `NDB` database objects in a single `NDB` Cluster—including databases, tables, and indexes—is limited to 20320.
- **Attributes per table.** The maximum number of attributes (that is, columns and indexes) that can belong to a given table is 512.
- **Attributes per key.** The maximum number of attributes per key is 32.
- **Row size.** In `NDB` 8.0, the maximum permitted size of any one row is 30000 bytes (increased from 14000 bytes in previous releases).

Each `BLOB` or `TEXT` column contributes $256 + 8 = 264$ bytes to this total; this includes `JSON` columns. See [String Type Storage Requirements](#), as well as [JSON Storage Requirements](#), for more information relating to these types.

In addition, the maximum offset for a fixed-width column of an NDB table is 8188 bytes; attempting to create a table that violates this limitation fails with NDB error 851 `Maximum offset for fixed-size columns exceeded`. For memory-based columns, you can work around this limitation by using a variable-width column type such as `VARCHAR` or defining the column as `COLUMN_FORMAT=DYNAMIC`; this does not work with columns stored on disk. For disk-based columns, you may be able to do so by reordering one or more of the table's disk-based columns such that the combined width of all but the disk-based column defined last in the `CREATE TABLE` statement used to create the table does not exceed 8188 bytes, less any possible rounding performed for some data types such as `CHAR` or `VARCHAR`; otherwise it is necessary to use memory-based storage for one or more of the offending column or columns instead.

- **BIT column storage per table.** The maximum combined width for all `BIT` columns used in a given NDB table is 4096.
- **FIXED column storage.** NDB Cluster 8.0 supports a maximum of 128 TB per fragment of data in `FIXED` columns.

23.2.7.6 Unsupported or Missing Features in NDB Cluster

A number of features supported by other storage engines are not supported for NDB tables. Trying to use any of these features in NDB Cluster does not cause errors in or of itself; however, errors may occur in applications that expects the features to be supported or enforced. Statements referencing such features, even if effectively ignored by NDB, must be syntactically and otherwise valid.

- **Index prefixes.** Prefixes on indexes are not supported for NDB tables. If a prefix is used as part of an index specification in a statement such as `CREATE TABLE`, `ALTER TABLE`, or `CREATE INDEX`, the prefix is not created by NDB.

A statement containing an index prefix, and creating or modifying an NDB table, must still be syntactically valid. For example, the following statement always fails with Error 1089 `Incorrect prefix key; the used key part isn't a string, the used length is longer than the key part, or the storage engine doesn't support unique prefix keys`, regardless of storage engine:

```
CREATE TABLE t1 (
  c1 INT NOT NULL,
  c2 VARCHAR(100),
  INDEX i1 (c2(500))
);
```

This happens on account of the SQL syntax rule that no index may have a prefix larger than itself.

- **Savepoints and rollbacks.** Savepoints and rollbacks to savepoints are ignored as in `MyISAM`.
- **Durability of commits.** There are no durable commits on disk. Commits are replicated, but there is no guarantee that logs are flushed to disk on commit.
- **Replication.** Statement-based replication is not supported. Use `--binlog-format=ROW` (or `--binlog-format=MIXED`) when setting up cluster replication. See [Section 23.7, “NDB Cluster Replication”](#), for more information.

Replication using global transaction identifiers (GTIDs) is not compatible with NDB Cluster, and is not supported in NDB Cluster 8.0. Do not enable GTIDs when using the NDB storage engine, as this is very likely to cause problems up to and including failure of NDB Cluster Replication.

Semisynchronous replication is not supported in NDB Cluster.

- **Generated columns.** The [NDB](#) storage engine does not support indexes on virtual generated columns.

As with other storage engines, you can create an index on a stored generated column, but you should bear in mind that [NDB](#) uses [DataMemory](#) for storage of the generated column as well as [IndexMemory](#) for the index. See [JSON columns and indirect indexing in NDB Cluster](#), for an example.

[NDB Cluster](#) writes changes in stored generated columns to the binary log, but does not log those made to virtual columns. This should not effect [NDB Cluster Replication](#) or replication between [NDB](#) and other MySQL storage engines.

Note

See [Section 23.2.7.3, “Limits Relating to Transaction Handling in NDB Cluster”](#), for more information relating to limitations on transaction handling in [NDB](#).

23.2.7.7 Limitations Relating to Performance in NDB Cluster

The following performance issues are specific to or especially pronounced in [NDB Cluster](#):

- **Range scans.** There are query performance issues due to sequential access to the [NDB](#) storage engine; it is also relatively more expensive to do many range scans than it is with either [MyISAM](#) or [InnoDB](#).
- **Reliability of Records in range.** The [Records in range](#) statistic is available but is not completely tested or officially supported. This may result in nonoptimal query plans in some cases. If necessary, you can employ [USE INDEX](#) or [FORCE INDEX](#) to alter the execution plan. See [Section 8.9.4, “Index Hints”](#), for more information on how to do this.
- **Unique hash indexes.** Unique hash indexes created with [USING HASH](#) cannot be used for accessing a table if [NULL](#) is given as part of the key.

23.2.7.8 Issues Exclusive to NDB Cluster

The following are limitations specific to the [NDB](#) storage engine:

- **Machine architecture.** All machines used in the cluster must have the same architecture. That is, all machines hosting nodes must be either big-endian or little-endian, and you cannot use a mixture of both. For example, you cannot have a management node running on a PowerPC which directs a data node that is running on an x86 machine. This restriction does not apply to machines simply running [mysql](#) or other clients that may be accessing the cluster's SQL nodes.
- **Binary logging.** [NDB Cluster](#) has the following limitations or restrictions with regard to binary logging:
 - [sql_log_bin](#) has no effect on data operations; however, it is supported for schema operations.
 - [NDB Cluster](#) cannot produce a binary log for tables having [BLOB](#) columns but no primary key.
 - Only the following schema operations are logged in a cluster binary log which is *not* on the [mysqld](#) executing the statement:
 - [CREATE TABLE](#)
 - [ALTER TABLE](#)
 - [DROP TABLE](#)

- `CREATE DATABASE / CREATE SCHEMA`
 - `DROP DATABASE / DROP SCHEMA`
 - `CREATE TABLESPACE`
 - `ALTER TABLESPACE`
 - `DROP TABLESPACE`
 - `CREATE LOGFILE GROUP`
 - `ALTER LOGFILE GROUP`
 - `DROP LOGFILE GROUP`
- **Schema operations.** Schema operations (DDL statements) are rejected while any data node restarts. Schema operations are also not supported while performing an online upgrade or downgrade.
 - **Number of fragment replicas.** The number of fragment replicas, as determined by the `NoOfReplicas` data node configuration parameter, is the number of copies of all data stored by NDB Cluster. Setting this parameter to 1 means there is only a single copy; in this case, no redundancy is provided, and the loss of a data node entails loss of data. To guarantee redundancy, and thus preservation of data even if a data node fails, set this parameter to 2, which is the default and recommended value in production.

Setting `NoOfReplicas` to a value greater than 2 is supported (to a maximum of 4) but unnecessary to guard against loss of data.

See also [Section 23.2.7.10, "Limitations Relating to Multiple NDB Cluster Nodes"](#).

23.2.7.9 Limitations Relating to NDB Cluster Disk Data Storage

Disk Data object maximums and minimums. Disk data objects are subject to the following maximums and minimums:

- Maximum number of tablespaces: 2^{32} (4294967296)
- Maximum number of data files per tablespace: 2^{16} (65536)
- The minimum and maximum possible sizes of extents for tablespace data files are 32K and 2G, respectively. See [Section 13.1.21, "CREATE TABLESPACE Statement"](#), for more information.

In addition, when working with NDB Disk Data tables, you should be aware of the following issues regarding data files and extents:

- Data files use `DataMemory`. Usage is the same as for in-memory data.
- Data files use file descriptors. It is important to keep in mind that data files are always open, which means the file descriptors are always in use and cannot be re-used for other system tasks.
- Extents require sufficient `DiskPageBufferMemory`; you must reserve enough for this parameter to account for all memory used by all extents (number of extents times size of extents).

Disk Data tables and diskless mode. Use of Disk Data tables is not supported when running the cluster in diskless mode.

23.2.7.10 Limitations Relating to Multiple NDB Cluster Nodes

Multiple SQL nodes.

The following are issues relating to the use of multiple MySQL servers as NDB Cluster SQL nodes, and are specific to the `NDBCLUSTER` storage engine:

- **Stored programs not distributed.** Stored procedures, stored functions, triggers, and scheduled events are all supported by tables using the `NDB` storage engine, but these do *not* propagate automatically between MySQL Servers acting as Cluster SQL nodes, and must be re-created separately on each SQL node. See [Stored routines and triggers in NDB Cluster](#).
- **No distributed table locks.** A `LOCK TABLES` works only for the SQL node on which the lock is issued; no other SQL node in the cluster “sees” this lock. This is also true for a lock issued by any statement that locks tables as part of its operations. (See next item for an example.)
- **ALTER TABLE operations.** `ALTER TABLE` is not fully locking when running multiple MySQL servers (SQL nodes). (As discussed in the previous item, NDB Cluster does not support distributed table locks.)

Multiple management nodes.

When using multiple management servers:

- If any of the management servers are running on the same host, you must give nodes explicit IDs in connection strings because automatic allocation of node IDs does not work across multiple management servers on the same host. This is not required if every management server resides on a different host.
- When a management server starts, it first checks for any other management server in the same NDB Cluster, and upon successful connection to the other management server uses its configuration data. This means that the management server `--reload` and `--initial` startup options are ignored unless the management server is the only one running. It also means that, when performing a rolling restart of an NDB Cluster with multiple management nodes, the management server reads its own configuration file if (and only if) it is the only management server running in this NDB Cluster. See [Section 23.6.5, “Performing a Rolling Restart of an NDB Cluster”](#), for more information.

Multiple network addresses. Multiple network addresses per data node are not supported. Use of these is liable to cause problems: In the event of a data node failure, an SQL node waits for confirmation that the data node went down but never receives it because another route to that data node remains open. This can effectively make the cluster inoperable.

Note

It is possible to use multiple network hardware *interfaces* (such as Ethernet cards) for a single data node, but these must be bound to the same address. This also means that it not possible to use more than one `[tcp]` section per connection in the `config.ini` file. See [Section 23.4.3.10, “NDB Cluster TCP/IP Connections”](#), for more information.

23.2.7.11 Previous NDB Cluster Issues Resolved in NDB Cluster 8.0

A number of limitations and related issues that existed in earlier versions of NDB Cluster have been resolved in NDB 8.0. These are described briefly in the following list:

- **Database and table names.** In NDB 7.6 and earlier, when using the `NDB` storage engine, the maximum allowed length both for database names and for table names was 63 characters, and a statement using a database name or table name longer than this limit failed with an appropriate error. In NDB 8.0, this restriction is lifted; identifiers for `NDB` databases and tables may now use up to 64 bytes, as with other MySQL database and table names.

- **IPv6 support.** Prior to NDB 8.0.22, it was necessary for all network addresses used for connections between nodes within an NDB Cluster to use or to be resolvable to IPv4 addresses. Beginning with NDB 8.0.22, NDB supports IPv6 addresses for all types of cluster nodes, as well as for applications that use the NDB API or MGM API.

23.3 NDB Cluster Installation

This section describes the basics for planning, installing, configuring, and running an NDB Cluster. Whereas the examples in [Section 23.4, “Configuration of NDB Cluster”](#) provide more in-depth information on a variety of clustering options and configuration, the result of following the guidelines and procedures outlined here should be a usable NDB Cluster which meets the *minimum* requirements for availability and safeguarding of data.

For information about upgrading or downgrading an NDB Cluster between release versions, see [Section 23.3.7, “Upgrading and Downgrading NDB Cluster”](#).

This section covers hardware and software requirements; networking issues; installation of NDB Cluster; basic configuration issues; starting, stopping, and restarting the cluster; loading of a sample database; and performing queries.

Assumptions. The following sections make a number of assumptions regarding the cluster's physical and network configuration. These assumptions are discussed in the next few paragraphs.

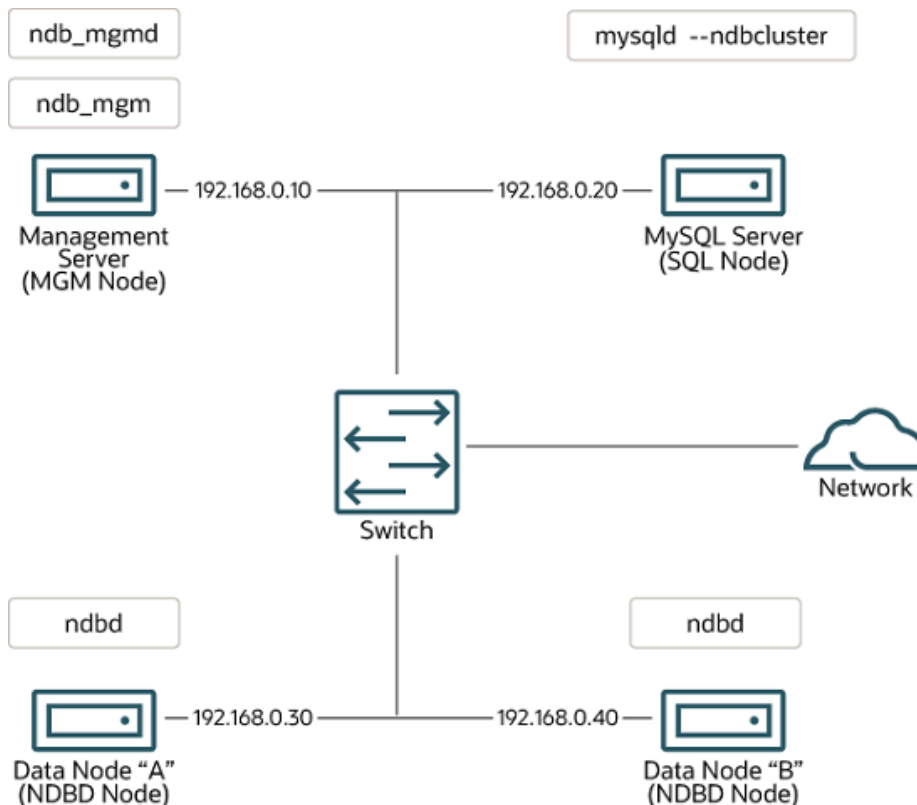

Cluster nodes and host computers. The cluster consists of four nodes, each on a separate host computer, and each with a fixed network address on a typical Ethernet network as shown here:

Table 23.5 Network addresses of nodes in example cluster

| Node | IP Address |
|---------------------------------------|---------------|
| Management node (<code>mgmd</code>) | 198.51.100.10 |
| SQL node (<code>mysqld</code>) | 198.51.100.20 |
| Data node "A" (<code>ndbd</code>) | 198.51.100.30 |
| Data node "B" (<code>ndbd</code>) | 198.51.100.40 |

This setup is also shown in the following diagram:

Figure 23.4 NDB Cluster Multi-Computer Setup

Network addressing. In the interest of simplicity (and reliability), this *How-To* uses only numeric IP addresses. However, if DNS resolution is available on your network, it is possible to use host names in lieu of IP addresses in configuring Cluster. Alternatively, you can use the `hosts` file (typically `/etc/hosts` for Linux and other Unix-like operating systems, `C:\WINDOWS\system32\drivers\etc\hosts` on Windows, or your operating system's equivalent) for providing a means to do host lookup if such is available.

Prior to NDB 8.0.22, all network addresses used for connections to or from data and management nodes must use or be resolvable using IPv4. This includes addresses used by SQL nodes to contact the other nodes. Beginning with NDB 8.0.22, NDB Cluster supports IPv6 for connections between any and all cluster nodes.

Potential hosts file issues. A common problem when trying to use host names for Cluster nodes arises because of the way in which some operating systems (including some Linux distributions) set up the system's own host name in the `/etc/hosts` during installation. Consider two machines with the host names `ndb1` and `ndb2`, both in the `cluster` network domain. Red Hat Linux (including some derivatives such as CentOS and Fedora) places the following entries in these machines' `/etc/hosts` files:

```
# ndb1 /etc/hosts:
127.0.0.1    ndb1.cluster ndb1 localhost.localdomain localhost

# ndb2 /etc/hosts:
127.0.0.1    ndb2.cluster ndb2 localhost.localdomain localhost
```

SUSE Linux (including OpenSUSE) places these entries in the machines' `/etc/hosts` files:

```
# ndb1 /etc/hosts:
127.0.0.1    localhost
127.0.0.2    ndb1.cluster ndb1
```

```
# ndb2 /etc/hosts:
127.0.0.1      localhost
127.0.0.2      ndb2.cluster ndb2
```

In both instances, `ndb1` routes `ndb1.cluster` to a loopback IP address, but gets a public IP address from DNS for `ndb2.cluster`, while `ndb2` routes `ndb2.cluster` to a loopback address and obtains a public address for `ndb1.cluster`. The result is that each data node connects to the management server, but cannot tell when any other data nodes have connected, and so the data nodes appear to hang while starting.

Caution

You cannot mix `localhost` and other host names or IP addresses in `config.ini`. For these reasons, the solution in such cases (other than to use IP addresses for *all* `config.ini` `HostName` entries) is to remove the fully qualified host names from `/etc/hosts` and use these in `config.ini` for all cluster hosts.

Host computer type. Each host computer in our installation scenario is an Intel-based desktop PC running a supported operating system installed to disk in a standard configuration, and running no unnecessary services. The core operating system with standard TCP/IP networking capabilities should be sufficient. Also for the sake of simplicity, we also assume that the file systems on all hosts are set up identically. In the event that they are not, you should adapt these instructions accordingly.

Network hardware. Standard 100 Mbps or 1 gigabit Ethernet cards are installed on each machine, along with the proper drivers for the cards, and that all four hosts are connected through a standard-issue Ethernet networking appliance such as a switch. (All machines should use network cards with the same throughput. That is, all four machines in the cluster should have 100 Mbps cards *or* all four machines should have 1 Gbps cards.) NDB Cluster works in a 100 Mbps network; however, gigabit Ethernet provides better performance.

Important

NDB Cluster is *not* intended for use in a network for which throughput is less than 100 Mbps or which experiences a high degree of latency. For this reason (among others), attempting to run an NDB Cluster over a wide area network such as the Internet is not likely to be successful, and is not supported in production.

Sample data. We use the `world` database which is available for download from the MySQL website (see <https://dev.mysql.com/doc/index-other.html>). We assume that each machine has sufficient memory for running the operating system, required NDB Cluster processes, and (on the data nodes) storing the database.

For general information about installing MySQL, see [Chapter 2, *Installing and Upgrading MySQL*](#). For information about installation of NDB Cluster on Linux and other Unix-like operating systems, see [Section 23.3.1, “Installation of NDB Cluster on Linux”](#). For information about installation of NDB Cluster on Windows operating systems, see [Section 23.3.2, “Installing NDB Cluster on Windows”](#).

For general information about NDB Cluster hardware, software, and networking requirements, see [Section 23.2.3, “NDB Cluster Hardware, Software, and Networking Requirements”](#).

23.3.1 Installation of NDB Cluster on Linux

This section covers installation methods for NDB Cluster on Linux and other Unix-like operating systems. While the next few sections refer to a Linux operating system, the instructions and procedures given there should be easily adaptable to other supported Unix-like platforms. For manual installation and setup instructions specific to Windows systems, see [Section 23.3.2, “Installing NDB Cluster on Windows”](#).

Each NDB Cluster host computer must have the correct executable programs installed. A host running an SQL node must have installed on it a MySQL Server binary (`mysqld`). Management nodes require the management server daemon (`ndb_mgmd`); data nodes require the data node daemon (`ndbd` or `ndbmtbd`). It is not necessary to install the MySQL Server binary on management node hosts and data node hosts. It is recommended that you also install the management client (`ndb_mgm`) on the management server host.

Installation of NDB Cluster on Linux can be done using precompiled binaries from Oracle (downloaded as a `.tar.gz` archive), with RPM packages (also available from Oracle), or from source code. All three of these installation methods are described in the section that follow.

Regardless of the method used, it is still necessary following installation of the NDB Cluster binaries to create configuration files for all cluster nodes, before you can start the cluster. See [Section 23.3.3, “Initial Configuration of NDB Cluster”](#).

23.3.1.1 Installing an NDB Cluster Binary Release on Linux

This section covers the steps necessary to install the correct executables for each type of Cluster node from precompiled binaries supplied by Oracle.

For setting up a cluster using precompiled binaries, the first step in the installation process for each cluster host is to download the binary archive from the [NDB Cluster downloads page](#). (For the most recent 64-bit NDB 8.0 release, this is `mysql-cluster-gpl-8.0.26-linux-glibc2.12-x86_64.tar.gz`.) We assume that you have placed this file in each machine's `/var/tmp` directory.

If you require a custom binary, see [Section 2.9.5, “Installing MySQL Using a Development Source Tree”](#).

Note

After completing the installation, do not yet start any of the binaries. We show you how to do so following the configuration of the nodes (see [Section 23.3.3, “Initial Configuration of NDB Cluster”](#)).

SQL nodes. On each of the machines designated to host SQL nodes, perform the following steps as the system `root` user:

1. Check your `/etc/passwd` and `/etc/group` files (or use whatever tools are provided by your operating system for managing users and groups) to see whether there is already a `mysql` group and `mysql` user on the system. Some OS distributions create these as part of the operating system installation process. If they are not already present, create a new `mysql` user group, and then add a `mysql` user to this group:

```
shell> groupadd mysql
shell> useradd -g mysql -s /bin/false mysql
```

The syntax for `useradd` and `groupadd` may differ slightly on different versions of Unix, or they may have different names such as `adduser` and `addgroup`.

2. Change location to the directory containing the downloaded file, unpack the archive, and create a symbolic link named `mysql` to the `mysql` directory.

Note

The actual file and directory names vary according to the NDB Cluster version number.

```
shell> cd /var/tmp
shell> tar -C /usr/local -xzf mysql-cluster-gpl-8.0.26-linux-glibc2.12-x86_64.tar.gz
shell> ln -s /usr/local/mysql-cluster-gpl-8.0.26-linux-glibc2.12-x86_64 /usr/local/mysql
```

3. Change location to the `mysql` directory and set up the system databases using `mysqld --initialize` as shown here:

```
shell> cd mysql
shell> mysqld --initialize
```

This generates a random password for the MySQL `root` account. If you do *not* want the random password to be generated, you can substitute the `--initialize-insecure` option for `--initialize`. In either case, you should review [Section 2.10.1, “Initializing the Data Directory”](#), for additional information before performing this step. See also [Section 4.4.2, “mysql_secure_installation — Improve MySQL Installation Security”](#).

4. Set the necessary permissions for the MySQL server and data directories:

```
shell> chown -R root .
shell> chown -R mysql data
shell> chgrp -R mysql .
```

5. Copy the MySQL startup script to the appropriate directory, make it executable, and set it to start when the operating system is booted up:

```
shell> cp support-files/mysql.server /etc/rc.d/init.d/
shell> chmod +x /etc/rc.d/init.d/mysql.server
shell> chkconfig --add mysql.server
```

(The startup scripts directory may vary depending on your operating system and version—for example, in some Linux distributions, it is `/etc/init.d`.)

Here we use Red Hat's `chkconfig` for creating links to the startup scripts; use whatever means is appropriate for this purpose on your platform, such as `update-rc.d` on Debian.

Remember that the preceding steps must be repeated on each machine where an SQL node is to reside.

Data nodes. Installation of the data nodes does not require the `mysqld` binary. Only the NDB Cluster data node executable `ndbd` (single-threaded) or `ndbmtbd` (multithreaded) is required. These binaries can also be found in the `.tar.gz` archive. Again, we assume that you have placed this archive in `/var/tmp`.

As system `root` (that is, after using `sudo`, `su root`, or your system's equivalent for temporarily assuming the system administrator account's privileges), perform the following steps to install the data node binaries on the data node hosts:

1. Change location to the `/var/tmp` directory, and extract the `ndbd` and `ndbmtbd` binaries from the archive into a suitable directory such as `/usr/local/bin`:

```
shell> cd /var/tmp
shell> tar -zxvf mysql-cluster-gpl-8.0.26-linux-glibc2.12-x86_64.tar.gz
shell> cd mysql-cluster-gpl-8.0.26-linux-glibc2.12-x86_64
shell> cp bin/ndbd /usr/local/bin/ndbd
shell> cp bin/ndbmtbd /usr/local/bin/ndbmtbd
```

(You can safely delete the directory created by unpacking the downloaded archive, and the files it contains, from `/var/tmp` once `ndb_mgm` and `ndb_mgmd` have been copied to the executables directory.)

2. Change location to the directory into which you copied the files, and then make both of them executable:

```
shell> cd /usr/local/bin
shell> chmod +x ndb*
```

The preceding steps should be repeated on each data node host.

Although only one of the data node executables is required to run an NDB Cluster data node, we have shown you how to install both `ndbd` and `ndbmtbd` in the preceding instructions. We recommend that you do this when installing or upgrading NDB Cluster, even if you plan to use only one of them, since this saves time and trouble in the event that you later decide to change from one to the other.

Note

The data directory on each machine hosting a data node is `/usr/local/mysql/data`. This piece of information is essential when configuring the management node. (See [Section 23.3.3, “Initial Configuration of NDB Cluster”](#).)

Management nodes. Installation of the management node does not require the `mysqld` binary. Only the NDB Cluster management server (`ndb_mgmd`) is required; you most likely want to install the management client (`ndb_mgm`) as well. Both of these binaries also be found in the `.tar.gz` archive. Again, we assume that you have placed this archive in `/var/tmp`.

As system `root`, perform the following steps to install `ndb_mgmd` and `ndb_mgm` on the management node host:

1. Change location to the `/var/tmp` directory, and extract the `ndb_mgm` and `ndb_mgmd` from the archive into a suitable directory such as `/usr/local/bin`:

```
shell> cd /var/tmp
shell> tar -zxvf mysql-cluster-gpl-8.0.26-linux-glibc2.12-x86_64.tar.gz
shell> cd mysql-cluster-gpl-8.0.26-linux-glibc2.12-x86_64
shell> cp bin/ndb_mgm* /usr/local/bin
```

(You can safely delete the directory created by unpacking the downloaded archive, and the files it contains, from `/var/tmp` once `ndb_mgm` and `ndb_mgmd` have been copied to the executables directory.)

2. Change location to the directory into which you copied the files, and then make both of them executable:

```
shell> cd /usr/local/bin
shell> chmod +x ndb_mgm*
```

In [Section 23.3.3, “Initial Configuration of NDB Cluster”](#), we create configuration files for all of the nodes in our example NDB Cluster.

23.3.1.2 Installing NDB Cluster from RPM

This section covers the steps necessary to install the correct executables for each type of NDB Cluster 8.0 node using RPM packages supplied by Oracle.

As an alternative to the method described in this section, Oracle provides MySQL Repositories for NDB Cluster that are compatible with many common Linux distributions. Two repositories, listed here, are available for RPM-based distributions:

- For distributions using `yum` or `dnf`, you can use the MySQL Yum Repository for NDB Cluster. See [Installing MySQL NDB Cluster Using the Yum Repository](#), for instructions and additional information.
- For SLES, you can use the MySQL SLES Repository for NDB Cluster. See [Installing MySQL NDB Cluster Using the SLES Repository](#), for instructions and additional information.

RPMs are available for both 32-bit and 64-bit Linux platforms. The filenames for these RPMs use the following pattern:

```
mysql-cluster-community-data-node-8.0.26-1.el7.x86_64.rpm
```

```
mysql-cluster-license-component-ver-rev.distro.arch.rpm

license:= {commercial | community}

component: {management-server | data-node | server | client | other-see text}

ver: major.minor.release

rev: major[.minor]

distro: {el6 | el7 | sles12}

arch: {i686 | x86_64}
```

license indicates whether the RPM is part of a Commercial or Community release of NDB Cluster. In the remainder of this section, we assume for the examples that you are installing a Community release.

Possible values for *component*, with descriptions, can be found in the following table:

Table 23.6 Components of the NDB Cluster RPM distribution

| Component | Description |
|--|--|
| <code>auto-installer</code> (DEPRECATED) | NDB Cluster Auto Installer program; see Section 23.3.8, “The NDB Cluster Auto-Installer (No longer supported)” , for usage |
| <code>client</code> | MySQL and NDB client programs; includes <code>mysql</code> client, <code>ndb_mgm</code> client, and other client tools |
| <code>common</code> | Character set and error message information needed by the MySQL server |
| <code>data-node</code> | <code>ndbd</code> and <code>ndbmt</code> data node binaries |
| <code>devel</code> | Headers and library files needed for MySQL client development |
| <code>embedded</code> | Embedded MySQL server |
| <code>embedded-compat</code> | Backwards-compatible embedded MySQL server |
| <code>embedded-devel</code> | Header and library files for developing applications for embedded MySQL |
| <code>java</code> | JAR files needed for support of ClusterJ applications |
| <code>libs</code> | MySQL client libraries |
| <code>libs-compat</code> | Backwards-compatible MySQL client libraries |
| <code>management-server</code> | The NDB Cluster management server (<code>ndb_mgmd</code>) |
| <code>memcached</code> | Files needed to support <code>ndbmemcache</code> |
| <code>minimal-debuginfo</code> | Debug information for package server-minimal; useful when developing applications that use this package or when debugging this package |
| <code>ndbclient</code> | NDB client library for running NDB API and MGM API applications (<code>libndbclient</code>) |
| <code>ndbclient-devel</code> | Header and other files needed for developing NDB API and MGM API applications |
| <code>nodejs</code> | Files needed to set up Node.JS support for NDB Cluster |

| Component | Description |
|-----------------------------|---|
| <code>server</code> | The MySQL server (<code>mysqld</code>) with NDB storage engine support included, and associated MySQL server programs |
| <code>server-minimal</code> | Minimal installation of the MySQL server for NDB and related tools |
| <code>test</code> | <code>mysqltest</code> , other MySQL test programs, and support files |

A single bundle (`.tar` file) of all NDB Cluster RPMs for a given platform and architecture is also available. The name of this file follows the pattern shown here:

```
mysql-cluster-license-ver-rev.distro.arch.rpm-bundle.tar
```

You can extract the individual RPM files from this file using `tar` or your preferred tool for extracting archives.

The components required to install the three major types of NDB Cluster nodes are given in the following list:

- *Management node*: `management-server`
- *Data node*: `data-node`
- *SQL node*: `server` and `common`

In addition, the `client` RPM should be installed to provide the `ndb_mgm` management client on at least one management node. You may also wish to install it on SQL nodes, to have `mysql` and other MySQL client programs available on these. We discuss installation of nodes by type later in this section.

`ver` represents the three-part NDB storage engine version number in 8.0.x format, shown as `8.0.26` in the examples. `rev` provides the RPM revision number in `major.minor` format. In the examples shown in this section, we use `1.1` for this value.

The `distro` (Linux distribution) is one of `rhel5` (Oracle Linux 5, Red Hat Enterprise Linux 4 and 5), `e16` (Oracle Linux 6, Red Hat Enterprise Linux 6), `e17` (Oracle Linux 7, Red Hat Enterprise Linux 7), or `sles12` (SUSE Enterprise Linux 12). For the examples in this section, we assume that the host runs Oracle Linux 7, Red Hat Enterprise Linux 7, or the equivalent (`e17`).

`arch` is `i686` for 32-bit RPMs and `x86_64` for 64-bit versions. In the examples shown here, we assume a 64-bit platform.

The NDB Cluster version number in the RPM file names (shown here as `8.0.26`) can vary according to the version which you are actually using. *It is very important that all of the Cluster RPMs to be installed have the same version number.* The architecture should also be appropriate to the machine on which the RPM is to be installed; in particular, you should keep in mind that 64-bit RPMs (`x86_64`) cannot be used with 32-bit operating systems (use `i686` for the latter).

Data nodes. On a computer that is to host an NDB Cluster data node it is necessary to install only the `data-node` RPM. To do so, copy this RPM to the data node host, and run the following command as the system root user, replacing the name shown for the RPM as necessary to match that of the RPM downloaded from the MySQL website:

```
shell> rpm -Uhv mysql-cluster-community-data-node-8.0.26-1.e17.x86_64.rpm
```

This installs the `ndbd` and `ndbmtbd` data node binaries in `/usr/sbin`. Either of these can be used to run a data node process on this host.

SQL nodes. Copy the `server` and `common` RPMs to each machine to be used for hosting an NDB Cluster SQL node (`server` requires `common`). Install the `server` RPM by executing the following command as the system root user, replacing the name shown for the RPM as necessary to match the name of the RPM downloaded from the MySQL website:

```
shell> rpm -Uhv mysql-cluster-community-server-8.0.26-1.el7.x86_64.rpm
```

This installs the MySQL server binary (`mysqld`), with NDB storage engine support, in the `/usr/sbin` directory. It also installs all needed MySQL Server support files and useful MySQL server programs, including the `mysql.server` and `mysqld_safe` startup scripts (in `/usr/share/mysql` and `/usr/bin`, respectively). The RPM installer should take care of general configuration issues (such as creating the `mysql` user and group, if needed) automatically.

Important

You must use the versions of these RPMs released for NDB Cluster ; those released for the standard MySQL server do not provide support for the NDB storage engine.

To administer the SQL node (MySQL server), you should also install the `client` RPM, as shown here:

```
shell> rpm -Uhv mysql-cluster-community-client-8.0.26-1.el7.x86_64.rpm
```

This installs the `mysql` client and other MySQL client programs, such as `mysqladmin` and `mysqldump`, to `/usr/bin`.

Management nodes. To install the NDB Cluster management server, it is necessary only to use the `management-server` RPM. Copy this RPM to the computer intended to host the management node, and then install it by running the following command as the system root user (replace the name shown for the RPM as necessary to match that of the `management-server` RPM downloaded from the MySQL website):

```
shell> rpm -Uhv mysql-cluster-community-management-server-8.0.26-1.el7.x86_64.rpm
```

This RPM installs the management server binary `ndb_mgmd` in the `/usr/sbin` directory. While this is the only program actually required for running a management node, it is also a good idea to have the `ndb_mgm` NDB Cluster management client available as well. You can obtain this program, as well as other NDB client programs such as `ndb_desc` and `ndb_config`, by installing the `client` RPM as described previously.

See [Section 2.5.4, “Installing MySQL on Linux Using RPM Packages from Oracle”](#), for general information about installing MySQL using RPMs supplied by Oracle.

After installing from RPM, you still need to configure the cluster; see [Section 23.3.3, “Initial Configuration of NDB Cluster”](#), for the relevant information.

It is very important that all of the Cluster RPMs to be installed have the same version number. The `architecture` designation should also be appropriate to the machine on which the RPM is to be installed; in particular, you should keep in mind that 64-bit RPMs cannot be used with 32-bit operating systems.

Data nodes. On a computer that is to host a cluster data node it is necessary to install only the `server` RPM. To do so, copy this RPM to the data node host, and run the following command as the system root user, replacing the name shown for the RPM as necessary to match that of the RPM downloaded from the MySQL website:

```
shell> rpm -Uvh MySQL-Cluster-server-gpl-8.0.26-1.sles11.i386.rpm
```

Although this installs all NDB Cluster binaries, only the program `ndbd` or `ndbmtdd` (both in `/usr/sbin`) is actually needed to run an NDB Cluster data node.

SQL nodes. On each machine to be used for hosting a cluster SQL node, install the `server` RPM by executing the following command as the system root user, replacing the name shown for the RPM as necessary to match the name of the RPM downloaded from the MySQL website:

```
shell> rpm -Uvh MySQL-Cluster-server-gpl-8.0.26-1.sles11.i386.rpm
```

This installs the MySQL server binary (`mysqld`) with NDB storage engine support in the `/usr/sbin` directory, as well as all needed MySQL Server support files. It also installs the `mysql.server` and `mysqld_safe` startup scripts (in `/usr/share/mysql` and `/usr/bin`, respectively). The RPM installer should take care of general configuration issues (such as creating the `mysql` user and group, if needed) automatically.

To administer the SQL node (MySQL server), you should also install the `client` RPM, as shown here:

```
shell> rpm -Uvh MySQL-Cluster-client-gpl-8.0.26-1.sles11.i386.rpm
```

This installs the `mysql` client program.

Management nodes. To install the NDB Cluster management server, it is necessary only to use the `server` RPM. Copy this RPM to the computer intended to host the management node, and then install it by running the following command as the system root user (replace the name shown for the RPM as necessary to match that of the `server` RPM downloaded from the MySQL website):

```
shell> rpm -Uvh MySQL-Cluster-server-gpl-8.0.26-1.sles11.i386.rpm
```

Although this RPM installs many other files, only the management server binary `ndb_mgmd` (in the `/usr/sbin` directory) is actually required for running a management node. The `server` RPM also installs `ndb_mgm`, the NDB management client.

See [Section 2.5.4, “Installing MySQL on Linux Using RPM Packages from Oracle”](#), for general information about installing MySQL using RPMs supplied by Oracle. See [Section 23.3.3, “Initial Configuration of NDB Cluster”](#), for information about required post-installation configuration.

23.3.1.3 Installing NDB Cluster Using .deb Files

The section provides information about installing NDB Cluster on Debian and related Linux distributions such as Ubuntu using the `.deb` files supplied by Oracle for this purpose.

Oracle also provides an NDB Cluster APT repository for Debian and other distributions. See [Installing MySQL NDB Cluster Using the APT Repository](#), for instructions and additional information.

Oracle provides `.deb` installer files for NDB Cluster for 32-bit and 64-bit platforms. For a Debian-based system, only a single installer file is necessary. This file is named using the pattern shown here, according to the applicable NDB Cluster version, Debian version, and architecture:

```
mysql-cluster-gpl-ndbver-debiandebianver-arch.deb
```

Here, `ndbver` is the 3-part NDB engine version number, `debianver` is the major version of Debian (8 or 9), and `arch` is one of `i686` or `x86_64`. In the examples that follow, we assume you wish to install NDB 8.0.26 on a 64-bit Debian 9 system; in this case, the installer file is named `mysql-cluster-gpl-8.0.26-debian9-x86_64.deb-bundle.tar`.

Once you have downloaded the appropriate `.deb` file, you can untar it, and then install it from the command line using `dpkg`, like this:

```
shell> dpkg -i mysql-cluster-gpl-8.0.26-debian9-i686.deb
```

You can also remove it using `dpkg` as shown here:

```
shell> dpkg -r mysql
```

The installer file should also be compatible with most graphical package managers that work with `.deb` files, such as `GDebi` for the GNOME desktop.

The `.deb` file installs NDB Cluster under `/opt/mysql/server-version/`, where `version` is the 2-part release series version for the included MySQL server. For NDB 8.0, this is always `5.7`. The directory layout is the same as that for the generic Linux binary distribution (see [Table 2.3, “MySQL Installation Layout for Generic Unix/Linux Binary Package”](#)), with the exception that startup scripts and configuration files are found in `support-files` instead of `share`. All NDB Cluster executables, such as `ndb_mgm`, `ndbd`, and `ndb_mgmd`, are placed in the `bin` directory.

23.3.1.4 Building NDB Cluster from Source on Linux

This section provides information about compiling NDB Cluster on Linux and other Unix-like platforms. Building NDB Cluster from source is similar to building the standard MySQL Server, although it differs in a few key respects discussed here. For general information about building MySQL from source, see [Section 2.9, “Installing MySQL from Source”](#). For information about compiling NDB Cluster on Windows platforms, see [Section 23.3.2.2, “Compiling and Installing NDB Cluster from Source on Windows”](#).

Building MySQL NDB Cluster 8.0 requires using the MySQL Server 8.0 sources. These are available from the MySQL downloads page at <https://dev.mysql.com/downloads/>. The archived source file should have a name similar to `mysql-8.0.26.tar.gz`. You can also obtain the sources from GitHub at <https://github.com/mysql/mysql-server>.

Note

In previous versions, building of NDB Cluster from standard MySQL Server sources was not supported. In MySQL 8.0 and NDB Cluster 8.0, this is no longer the case —both products are now built from the same sources.

The `WITH_NDBCLUSTER` option for `CMake` causes the binaries for the management nodes, data nodes, and other NDB Cluster programs to be built; it also causes `mysqld` to be compiled with NDB storage engine support. This option (or one of its aliases `WITH_NDBCLUSTER_STORAGE_ENGINE` and `WITH_PLUGIN_NDBCLUSTER`) is required when building NDB Cluster.

Important

The `WITH_NDB_JAVA` option is enabled by default. This means that, by default, if `CMake` cannot find the location of Java on your system, the configuration process fails; if you do not wish to enable Java and ClusterJ support, you must indicate this explicitly by configuring the build using `-DWITH_NDB_JAVA=OFF`. Use `WITH_CLASSPATH` to provide the Java classpath if needed.

For more information about `CMake` options specific to building NDB Cluster, see [Options for Compiling NDB Cluster](#).

After you have run `make && make install` (or your system's equivalent), the result is similar to what is obtained by unpacking a precompiled binary to the same location.

Management nodes. When building from source and running the default `make install`, the management server and management client binaries (`ndb_mgmd` and `ndb_mgm`) can be found in `/usr/`

`local/mysql/bin`. Only `ndb_mgmd` is required to be present on a management node host; however, it is also a good idea to have `ndb_mgm` present on the same host machine. Neither of these executables requires a specific location on the host machine's file system.

Data nodes. The only executable required on a data node host is the data node binary `ndbd` or `ndbmtd`. (`mysqld`, for example, does not have to be present on the host machine.) By default, when building from source, this file is placed in the directory `/usr/local/mysql/bin`. For installing on multiple data node hosts, only `ndbd` or `ndbmtd` need be copied to the other host machine or machines. (This assumes that all data node hosts use the same architecture and operating system; otherwise you may need to compile separately for each different platform.) The data node binary need not be in any particular location on the host's file system, as long as the location is known.

When compiling NDB Cluster from source, no special options are required for building multithreaded data node binaries. Configuring the build with NDB storage engine support causes `ndbmtd` to be built automatically; `make install` places the `ndbmtd` binary in the installation `bin` directory along with `mysqld`, `ndbd`, and `ndb_mgm`.

SQL nodes. If you compile MySQL with clustering support, and perform the default installation (using `make install` as the system `root` user), `mysqld` is placed in `/usr/local/mysql/bin`. Follow the steps given in [Section 2.9, “Installing MySQL from Source”](#) to make `mysqld` ready for use. If you want to run multiple SQL nodes, you can use a copy of the same `mysqld` executable and its associated support files on several machines. The easiest way to do this is to copy the entire `/usr/local/mysql` directory and all directories and files contained within it to the other SQL node host or hosts, then repeat the steps from [Section 2.9, “Installing MySQL from Source”](#) on each machine. If you configure the build with a nondefault `PREFIX` option, you must adjust the directory accordingly.

In [Section 23.3.3, “Initial Configuration of NDB Cluster”](#), we create configuration files for all of the nodes in our example NDB Cluster.

23.3.2 Installing NDB Cluster on Windows

This section describes installation procedures for NDB Cluster on Windows hosts. NDB Cluster 8.0 binaries for Windows can be obtained from <https://dev.mysql.com/downloads/cluster/>. For information about installing NDB Cluster on Windows from a binary release provided by Oracle, see [Section 23.3.2.1, “Installing NDB Cluster on Windows from a Binary Release”](#).

It is also possible to compile and install NDB Cluster from source on Windows using Microsoft Visual Studio. For more information, see [Section 23.3.2.2, “Compiling and Installing NDB Cluster from Source on Windows”](#).

23.3.2.1 Installing NDB Cluster on Windows from a Binary Release

This section describes a basic installation of NDB Cluster on Windows using a binary “no-install” NDB Cluster release provided by Oracle, using the same 4-node setup outlined in the beginning of this section (see [Section 23.3, “NDB Cluster Installation”](#)), as shown in the following table:

Table 23.7 Network addresses of nodes in example cluster

| Node | IP Address |
|---------------------------------------|---------------|
| Management node (<code>mgmd</code>) | 198.51.100.10 |
| SQL node (<code>mysqld</code>) | 198.51.100.20 |
| Data node "A" (<code>ndbd</code>) | 198.51.100.30 |
| Data node "B" (<code>ndbd</code>) | 198.51.100.40 |

As on other platforms, the NDB Cluster host computer running an SQL node must have installed on it a MySQL Server binary (`mysqld.exe`). You should also have the MySQL client (`mysql.exe`) on this host. For management nodes and data nodes, it is not necessary to install the MySQL Server binary; however, each management node requires the management server daemon (`ndb_mgmd.exe`); each data node requires the data node daemon (`ndbd.exe` or `ndbmttd.exe`). For this example, we refer to `ndbd.exe` as the data node executable, but you can install `ndbmttd.exe`, the multithreaded version of this program, instead, in exactly the same way. You should also install the management client (`ndb_mgm.exe`) on the management server host. This section covers the steps necessary to install the correct Windows binaries for each type of NDB Cluster node.

**Note**

As with other Windows programs, NDB Cluster executables are named with the `.exe` file extension. However, it is not necessary to include the `.exe` extension when invoking these programs from the command line. Therefore, we often simply refer to these programs in this documentation as `mysqld`, `mysql`, `ndb_mgmd`, and so on. You should understand that, whether we refer (for example) to `mysqld` or `mysqld.exe`, either name means the same thing (the MySQL Server program).

For setting up an NDB Cluster using Oracle's `no-install` binaries, the first step in the installation process is to download the latest NDB Cluster Windows ZIP binary archive from <https://dev.mysql.com/downloads/cluster/>. This archive has a filename of the `mysql-cluster-gpl-ver-winarch.zip`, where `ver` is the NDB storage engine version (such as `8.0.26`), and `arch` is the architecture (`32` for 32-bit binaries, and `64` for 64-bit binaries). For example, the NDB Cluster 8.0.26 archive for 64-bit Windows systems is named `mysql-cluster-gpl-8.0.26-win64.zip`.

You can run 32-bit NDB Cluster binaries on both 32-bit and 64-bit versions of Windows; however, 64-bit NDB Cluster binaries can be used only on 64-bit versions of Windows. If you are using a 32-bit version of Windows on a computer that has a 64-bit CPU, then you must use the 32-bit NDB Cluster binaries.

To minimize the number of files that need to be downloaded from the Internet or copied between machines, we start with the computer where you intend to run the SQL node.

SQL node. We assume that you have placed a copy of the archive in the directory `C:\Documents and Settings\username\My Documents\Downloads` on the computer having the IP address `198.51.100.20`, where `username` is the name of the current user. (You can obtain this name using `ECHO %USERNAME%` on the command line.) To install and run NDB Cluster executables as Windows services, this user should be a member of the `Administrators` group.

Extract all the files from the archive. The Extraction Wizard integrated with Windows Explorer is adequate for this task. (If you use a different archive program, be sure that it extracts all files and directories from the archive, and that it preserves the archive's directory structure.) When you are asked for a destination directory, enter `C:\`, which causes the Extraction Wizard to extract the archive to the directory `C:\mysql-cluster-gpl-ver-winarch`. Rename this directory to `C:\mysql`.

It is possible to install the NDB Cluster binaries to directories other than `C:\mysql\bin`; however, if you do so, you must modify the paths shown in this procedure accordingly. In particular, if the MySQL Server (SQL node) binary is installed to a location other than `C:\mysql` or `C:\Program Files\MySQL\MySQL Server 8.0`, or if the SQL node's data directory is in a location other than `C:\mysql\data` or `C:\Program Files\MySQL\MySQL Server 8.0\data`, extra configuration options must be used on the command line or added to the `my.ini` or `my.cnf` file when starting the SQL node. For more information about configuring a MySQL Server to run in a nonstandard location, see [Section 2.3.4, "Installing MySQL on Microsoft Windows Using a noinstall ZIP Archive"](#).

For a MySQL Server with NDB Cluster support to run as part of an NDB Cluster, it must be started with the options `--ndbcluster` and `--ndb-connectstring`. While you can specify these options on the

command line, it is usually more convenient to place them in an option file. To do this, create a new text file in Notepad or another text editor. Enter the following configuration information into this file:

```
[mysqld]
# Options for mysqld process:
ndbcluster                # run NDB storage engine
ndb-connectstring=198.51.100.10 # location of management server
```

You can add other options used by this MySQL Server if desired (see [Section 2.3.4.2, “Creating an Option File”](#)), but the file must contain the options shown, at a minimum. Save this file as `C:\mysql\my.ini`. This completes the installation and setup for the SQL node.

Data nodes. An NDB Cluster data node on a Windows host requires only a single executable, one of either `ndbd.exe` or `ndbmtd.exe`. For this example, we assume that you are using `ndbd.exe`, but the same instructions apply when using `ndbmtd.exe`. On each computer where you wish to run a data node (the computers having the IP addresses 198.51.100.30 and 198.51.100.40), create the directories `C:\mysql`, `C:\mysql\bin`, and `C:\mysql\cluster-data`; then, on the computer where you downloaded and extracted the `no-install` archive, locate `ndbd.exe` in the `C:\mysql\bin` directory. Copy this file to the `C:\mysql\bin` directory on each of the two data node hosts.

To function as part of an NDB Cluster, each data node must be given the address or hostname of the management server. You can supply this information on the command line using the `--ndb-connectstring` or `-c` option when starting each data node process. However, it is usually preferable to put this information in an option file. To do this, create a new text file in Notepad or another text editor and enter the following text:

```
[mysql_cluster]
# Options for data node process:
ndb-connectstring=198.51.100.10 # location of management server
```

Save this file as `C:\mysql\my.ini` on the data node host. Create another text file containing the same information and save it on as `C:\mysql\my.ini` on the other data node host, or copy the `my.ini` file from the first data node host to the second one, making sure to place the copy in the second data node's `C:\mysql` directory. Both data node hosts are now ready to be used in the NDB Cluster, which leaves only the management node to be installed and configured.

Management node. The only executable program required on a computer used for hosting an NDB Cluster management node is the management server program `ndb_mgmd.exe`. However, in order to administer the NDB Cluster once it has been started, you should also install the NDB Cluster management client program `ndb_mgm.exe` on the same machine as the management server. Locate these two programs on the machine where you downloaded and extracted the `no-install` archive; this should be the directory `C:\mysql\bin` on the SQL node host. Create the directory `C:\mysql\bin` on the computer having the IP address 198.51.100.10, then copy both programs to this directory.

You should now create two configuration files for use by `ndb_mgmd.exe`:

1. A local configuration file to supply configuration data specific to the management node itself. Typically, this file needs only to supply the location of the NDB Cluster global configuration file (see item 2).

To create this file, start a new text file in Notepad or another text editor, and enter the following information:

```
[mysql_cluster]
# Options for management node process
config-file=C:/mysql/bin/config.ini
```

Save this file as the text file `C:\mysql\bin\my.ini`.

2. A global configuration file from which the management node can obtain configuration information governing the NDB Cluster as a whole. At a minimum, this file must contain a section for each node in the NDB Cluster, and the IP addresses or hostnames for the management node and all data nodes (`HostName` configuration parameter). It is also advisable to include the following additional information:

- The IP address or hostname of any SQL nodes
- The data memory and index memory allocated to each data node (`DataMemory` and `IndexMemory` configuration parameters)
- The number of fragment replicas, using the `NoOfReplicas` configuration parameter (see [Section 23.2.2, "NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions"](#))
- The directory where each data node stores its data and log file, and the directory where the management node keeps its log files (in both cases, the `DataDir` configuration parameter)

Create a new text file using a text editor such as Notepad, and input the following information:

```
[ndbd default]
# Options affecting ndbd processes on all data nodes:
NoOfReplicas=2          # Number of fragment replicas
DataDir=C:/mysql/cluster-data  # Directory for each data node's data files
                          # Forward slashes used in directory path,
                          # rather than backslashes. This is correct;
                          # see Important note in text

DataMemory=80M         # Memory allocated to data storage
IndexMemory=18M        # Memory allocated to index storage
                          # For DataMemory and IndexMemory, we have used the
                          # default values. Since the "world" database takes up
                          # only about 500KB, this should be more than enough for
                          # this example Cluster setup.

[ndb_mgmd]
# Management process options:
HostName=198.51.100.10  # Hostname or IP address of management node
DataDir=C:/mysql/bin/cluster-logs  # Directory for management node log files

[ndbd]
# Options for data node "A":
                          # (one [ndbd] section per data node)
HostName=198.51.100.30  # Hostname or IP address

[ndbd]
# Options for data node "B":
HostName=198.51.100.40  # Hostname or IP address

[mysqld]
# SQL node options:
HostName=198.51.100.20  # Hostname or IP address
```

Save this file as the text file `C:\mysql\bin\config.ini`.

Important

A single backslash character (\) cannot be used when specifying directory paths in program options or configuration files used by NDB Cluster on Windows. Instead, you must either escape each backslash character with a second backslash (\\), or replace the backslash with a forward slash character (/). For example, the following line from the `[ndb_mgmd]` section of an NDB Cluster `config.ini` file does not work:

```
DataDir=C:\mysql\bin\cluster-logs
```

Instead, you may use either of the following:

```
DataDir=C:\\mysql\\bin\\cluster-logs # Escaped backslashes
```

```
DataDir=C:/mysql/bin/cluster-logs # Forward slashes
```

For reasons of brevity and legibility, we recommend that you use forward slashes in directory paths used in NDB Cluster program options and configuration files on Windows.

23.3.2.2 Compiling and Installing NDB Cluster from Source on Windows

Oracle provides precompiled NDB Cluster binaries for Windows which should be adequate for most users. However, if you wish, it is also possible to compile NDB Cluster for Windows from source code. The procedure for doing this is almost identical to the procedure used to compile the standard MySQL Server binaries for Windows, and uses the same tools. However, there are two major differences:

- Building MySQL NDB Cluster 8.0 requires using the MySQL Server 8.0 sources. These are available from the MySQL downloads page at <https://dev.mysql.com/downloads/>. The archived source file should have a name similar to `mysql-8.0.26.tar.gz`. You can also obtain the sources from GitHub at <https://github.com/mysql/mysql-server>.
- You must configure the build using the `WITH_NDBCLUSTER` option in addition to any other build options you wish to use with `CMake`. `WITH_NDBCLUSTER_STORAGE_ENGINE` and `WITH_PLUGIN_NDBCLUSTER` are supported as aliases for `WITH_NDBCLUSTER`, and work in exactly the same way.

Important

The `WITH_NDB_JAVA` option is enabled by default. This means that, by default, if `CMake` cannot find the location of Java on your system, the configuration process fails; if you do not wish to enable Java and ClusterJ support, you must indicate this explicitly by configuring the build using `-DWITH_NDB_JAVA=OFF`. (Bug #12379735) Use `WITH_CLASSPATH` to provide the Java classpath if needed.

For more information about `CMake` options specific to building NDB Cluster, see [Options for Compiling NDB Cluster](#).

Once the build process is complete, you can create a Zip archive containing the compiled binaries; [Section 2.9.4, “Installing MySQL Using a Standard Source Distribution”](#) provides the commands needed to perform this task on Windows systems. The NDB Cluster binaries can be found in the `bin` directory of the resulting archive, which is equivalent to the `no-install` archive, and which can be installed and configured in the same manner. For more information, see [Section 23.3.2.1, “Installing NDB Cluster on Windows from a Binary Release”](#).

23.3.2.3 Initial Startup of NDB Cluster on Windows

Once the NDB Cluster executables and needed configuration files are in place, performing an initial start of the cluster is simply a matter of starting the NDB Cluster executables for all nodes in the cluster. Each cluster node process must be started separately, and on the host computer where it resides. The management node should be started first, followed by the data nodes, and then finally by any SQL nodes.

1. On the management node host, issue the following command from the command line to start the management node process. The output should appear similar to what is shown here:

```
C:\mysql\bin> ndb_mgmd
2010-06-23 07:53:34 [MgmtSrvr] INFO -- NDB Cluster Management Server. mysql-8.0.27-ndb-8.0.27
```

```
2010-06-23 07:53:34 [MgmtSrvr] INFO -- Reading cluster configuration from 'config.ini'
```

The management node process continues to print logging output to the console. This is normal, because the management node is not running as a Windows service. (If you have used NDB Cluster on a Unix-like platform such as Linux, you may notice that the management node's default behavior in this regard on Windows is effectively the opposite of its behavior on Unix systems, where it runs by default as a Unix daemon process. This behavior is also true of NDB Cluster data node processes running on Windows.) For this reason, do not close the window in which `ndb_mgmd.exe` is running; doing so kills the management node process. (See [Section 23.3.2.4, "Installing NDB Cluster Processes as Windows Services"](#), where we show how to install and run NDB Cluster processes as Windows services.)

The required `-f` option tells the management node where to find the global configuration file (`config.ini`). The long form of this option is `--config-file`.

Important

An NDB Cluster management node caches the configuration data that it reads from `config.ini`; once it has created a configuration cache, it ignores the `config.ini` file on subsequent starts unless forced to do otherwise. This means that, if the management node fails to start due to an error in this file, you must make the management node re-read `config.ini` after you have corrected any errors in it. You can do this by starting `ndb_mgmd.exe` with the `--reload` or `--initial` option on the command line. Either of these options works to refresh the configuration cache.

It is not necessary or advisable to use either of these options in the management node's `my.ini` file.

2. On each of the data node hosts, run the command shown here to start the data node processes:

```
C:\mysql\bin> ndbd
2010-06-23 07:53:46 [ndbd] INFO -- Configuration fetched from 'localhost:1186', generation: 1
```

In each case, the first line of output from the data node process should resemble what is shown in the preceding example, and is followed by additional lines of logging output. As with the management node process, this is normal, because the data node is not running as a Windows service. For this reason, do not close the console window in which the data node process is running; doing so kills `ndbd.exe`. (For more information, see [Section 23.3.2.4, "Installing NDB Cluster Processes as Windows Services"](#).)

3. Do not start the SQL node yet; it cannot connect to the cluster until the data nodes have finished starting, which may take some time. Instead, in a new console window on the management node host, start the NDB Cluster management client `ndb_mgm.exe`, which should be in `C:\mysql\bin` on the management node host. (Do not try to re-use the console window where `ndb_mgmd.exe` is running by typing **CTRL+C**, as this kills the management node.) The resulting output should look like this:

```
C:\mysql\bin> ndb_mgm
-- NDB Cluster -- Management Client --
ndb_mgm>
```

When the prompt `ndb_mgm>` appears, this indicates that the management client is ready to receive NDB Cluster management commands. You can observe the status of the data nodes as they start by entering `ALL STATUS` at the management client prompt. This command causes a running report of the data nodes's startup sequence, which should look something like this:

```
ndb_mgm> ALL STATUS
Connected to Management Server at: localhost:1186
Node 2: starting (Last completed phase 3) (mysql-8.0.27-ndb-8.0.27)
Node 3: starting (Last completed phase 3) (mysql-8.0.27-ndb-8.0.27)
```

```
Node 2: starting (Last completed phase 4) (mysql-8.0.27-ndb-8.0.27)
Node 3: starting (Last completed phase 4) (mysql-8.0.27-ndb-8.0.27)

Node 2: Started (version 8.0.27)
Node 3: Started (version 8.0.27)

ndb_mgm>
```

**Note**

Commands issued in the management client are not case-sensitive; we use uppercase as the canonical form of these commands, but you are not required to observe this convention when inputting them into the `ndb_mgm` client. For more information, see [Section 23.6.1, “Commands in the NDB Cluster Management Client”](#).

The output produced by `ALL STATUS` is likely to vary from what is shown here, according to the speed at which the data nodes are able to start, the release version number of the NDB Cluster software you are using, and other factors. What is significant is that, when you see that both data nodes have started, you are ready to start the SQL node.

You can leave `ndb_mgm.exe` running; it has no negative impact on the performance of the NDB Cluster, and we use it in the next step to verify that the SQL node is connected to the cluster after you have started it.

4. On the computer designated as the SQL node host, open a console window and navigate to the directory where you unpacked the NDB Cluster binaries (if you are following our example, this is `C:\mysql\bin`).

Start the SQL node by invoking `mysqld.exe` from the command line, as shown here:

```
C:\mysql\bin> mysqld --console
```

The `--console` option causes logging information to be written to the console, which can be helpful in the event of problems. (Once you are satisfied that the SQL node is running in a satisfactory manner, you can stop it and restart it out without the `--console` option, so that logging is performed normally.)

In the console window where the management client (`ndb_mgm.exe`) is running on the management node host, enter the `SHOW` command, which should produce output similar to what is shown here:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
-----
[ndbd(NDB)]      2 node(s)
id=2      @198.51.100.30 (Version: 8.0.27-ndb-8.0.27, Nodegroup: 0, *)
id=3      @198.51.100.40 (Version: 8.0.27-ndb-8.0.27, Nodegroup: 0)

[ndb_mgmd(MGM)]  1 node(s)
id=1      @198.51.100.10 (Version: 8.0.27-ndb-8.0.27)

[mysqld(API)]   1 node(s)
id=4      @198.51.100.20 (Version: 8.0.27-ndb-8.0.27)
```

You can also verify that the SQL node is connected to the NDB Cluster in the `mysql` client (`mysql.exe`) using the `SHOW ENGINE NDB STATUS` statement.

You should now be ready to work with database objects and data using NDB Cluster's `NDBCLUSTER` storage engine. See [Section 23.3.5, "NDB Cluster Example with Tables and Data"](#), for more information and examples.

You can also install `ndb_mgmd.exe`, `ndbd.exe`, and `ndbmttd.exe` as Windows services. For information on how to do this, see [Section 23.3.2.4, "Installing NDB Cluster Processes as Windows Services"](#).

23.3.2.4 Installing NDB Cluster Processes as Windows Services

Once you are satisfied that NDB Cluster is running as desired, you can install the management nodes and data nodes as Windows services, so that these processes are started and stopped automatically whenever Windows is started or stopped. This also makes it possible to control these processes from the command line with the appropriate `SC START` and `SC STOP` commands, or using the Windows graphical `Services` utility. `NET START` and `NET STOP` commands can also be used.

Installing programs as Windows services usually must be done using an account that has Administrator rights on the system.

To install the management node as a service on Windows, invoke `ndb_mgmd.exe` from the command line on the machine hosting the management node, using the `--install` option, as shown here:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --install
Installing service 'NDB Cluster Management Server'
as 'C:\mysql\bin\ndbd.exe' "--service=ndb_mgmd"
Service successfully installed.
```

Important

When installing an NDB Cluster program as a Windows service, you should always specify the complete path; otherwise the service installation may fail with the error `The system cannot find the file specified`.

The `--install` option must be used first, ahead of any other options that might be specified for `ndb_mgmd.exe`. However, it is preferable to specify such options in an options file instead. If your options file is not in one of the default locations as shown in the output of `ndb_mgmd.exe --help`, you can specify the location using the `--config-file` option.

Now you should be able to start and stop the management server like this:

```
C:\> SC START ndb_mgmd
C:\> SC STOP ndb_mgmd
```

Note

If using `NET` commands, you can also start or stop the management server as a Windows service using the descriptive name, as shown here:

```
C:\> NET START 'NDB Cluster Management Server'
The NDB Cluster Management Server service is starting.
The NDB Cluster Management Server service was started successfully.

C:\> NET STOP 'NDB Cluster Management Server'
The NDB Cluster Management Server service is stopping..
The NDB Cluster Management Server service was stopped successfully.
```

It is usually simpler to specify a short service name or to permit the default service name to be used when installing the service, and then reference that name when starting or stopping the service. To specify a service name other than `ndb_mgmd`, append it to the `--install` option, as shown in this example:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --install=mgmdl
Installing service 'NDB Cluster Management Server'
  as 'C:\mysql\bin\ndb_mgmd.exe" "--service=mgmdl"'
Service successfully installed.
```

Now you should be able to start or stop the service using the name you have specified, like this:

```
C:\> SC START mgmdl

C:\> SC STOP mgmdl
```

To remove the management node service, use `SC DELETE service_name`:

```
C:\> SC DELETE mgmdl
```

Alternatively, invoke `ndb_mgmd.exe` with the `--remove` option, as shown here:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --remove
Removing service 'NDB Cluster Management Server'
Service successfully removed.
```

If you installed the service using a service name other than the default, pass the service name as the value of the `ndb_mgmd.exe --remove` option, like this:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --remove=mgmdl
Removing service 'mgmdl'
Service successfully removed.
```

Installation of an NDB Cluster data node process as a Windows service can be done in a similar fashion, using the `--install` option for `ndbd.exe` (or `ndbmtd.exe`), as shown here:

```
C:\> C:\mysql\bin\ndbd.exe --install
Installing service 'NDB Cluster Data Node Daemon' as 'C:\mysql\bin\ndbd.exe" "--service=ndbd"'
Service successfully installed.
```

Now you can start or stop the data node as shown in the following example:

```
C:\> SC START ndbd

C:\> SC STOP ndbd
```

To remove the data node service, use `SC DELETE service_name`:

```
C:\> SC DELETE ndbd
```

Alternatively, invoke `ndbd.exe` with the `--remove` option, as shown here:

```
C:\> C:\mysql\bin\ndbd.exe --remove
Removing service 'NDB Cluster Data Node Daemon'
Service successfully removed.
```

As with `ndb_mgmd.exe` (and `mysqld.exe`), when installing `ndbd.exe` as a Windows service, you can also specify a name for the service as the value of `--install`, and then use it when starting or stopping the service, like this:

```
C:\> C:\mysql\bin\ndbd.exe --install=dnodel
Installing service 'dnodel' as 'C:\mysql\bin\ndbd.exe" "--service=dnodel"'
Service successfully installed.

C:\> SC START dnodel
```

```
C:\> SC STOP dnode1
```

If you specified a service name when installing the data node service, you can use this name when removing it as well, as shown here:

```
C:\> SC DELETE dnode1
```

Alternatively, you can pass the service name as the value of the `ndbd.exe --remove` option, as shown here:

```
C:\> C:\mysql\bin\ndbd.exe --remove=dnode1
Removing service 'dnode1'
Service successfully removed.
```

Installation of the SQL node as a Windows service, starting the service, stopping the service, and removing the service are done in a similar fashion, using `mysqld --install`, `SC START`, `SC STOP`, and `SC DELETE` (or `mysqld --remove`). `NET` commands can also be used to start or stop a service. For additional information, see [Section 2.3.4.8, “Starting MySQL as a Windows Service”](#).

23.3.3 Initial Configuration of NDB Cluster

In this section, we discuss manual configuration of an installed NDB Cluster by creating and editing configuration files.

For our four-node, four-host NDB Cluster (see [Cluster nodes and host computers](#)), it is necessary to write four configuration files, one per node host.

- Each data node or SQL node requires a `my.cnf` file that provides two pieces of information: a *connection string* that tells the node where to find the management node, and a line telling the MySQL server on this host (the machine hosting the data node) to enable the `NDBCLUSTER` storage engine.

For more information on connection strings, see [Section 23.4.3.3, “NDB Cluster Connection Strings”](#).

- The management node needs a `config.ini` file telling it how many fragment replicas to maintain, how much memory to allocate for data and indexes on each data node, where to find the data nodes, where to save data to disk on each data node, and where to find any SQL nodes.

Configuring the data nodes and SQL nodes. The `my.cnf` file needed for the data nodes is fairly simple. The configuration file should be located in the `/etc` directory and can be edited using any text editor. (Create the file if it does not exist.) For example:

```
shell> vi /etc/my.cnf
```

Note

We show `vi` being used here to create the file, but any text editor should work just as well.

For each data node and SQL node in our example setup, `my.cnf` should look like this:

```
[mysqld]
# Options for mysqld process:
ndbcluster                # run NDB storage engine

[mysql_cluster]
# Options for NDB Cluster processes:
ndb-connectstring=198.51.100.10 # location of management server
```

After entering the preceding information, save this file and exit the text editor. Do this for the machines hosting data node “A”, data node “B”, and the SQL node.

Important

Once you have started a `mysqld` process with the `ndbcluster` and `ndb-connectstring` parameters in the `[mysqld]` and `[mysql_cluster]` sections of the `my.cnf` file as shown previously, you cannot execute any `CREATE TABLE` or `ALTER TABLE` statements without having actually started the cluster. Otherwise, these statements fail with an error. This is by design.

Configuring the management node. The first step in configuring the management node is to create the directory in which the configuration file can be found and then to create the file itself. For example (running as `root`):

```
shell> mkdir /var/lib/mysql-cluster
shell> cd /var/lib/mysql-cluster
shell> vi config.ini
```

For our representative setup, the `config.ini` file should read as follows:

```
[ndbd default]
# Options affecting ndbd processes on all data nodes:
NoOfReplicas=2    # Number of fragment replicas
DataMemory=98M   # How much memory to allocate for data storage

[ndb_mgmd]
# Management process options:
HostName=198.51.100.10    # Hostname or IP address of management node
DataDir=/var/lib/mysql-cluster # Directory for management node log files

[ndbd]
# Options for data node "A":
# (one [ndbd] section per data node)
HostName=198.51.100.30    # Hostname or IP address
NodeId=2                  # Node ID for this data node
DataDir=/usr/local/mysql/data # Directory for this data node's data files

[ndbd]
# Options for data node "B":
HostName=198.51.100.40    # Hostname or IP address
NodeId=3                  # Node ID for this data node
DataDir=/usr/local/mysql/data # Directory for this data node's data files

[mysqld]
# SQL node options:
HostName=198.51.100.20    # Hostname or IP address
# (additional mysqld connections can be
# specified for this node for various
# purposes such as running ndb_restore)
```

Note

The `world` database can be downloaded from <https://dev.mysql.com/doc/index-other.html>.

After all the configuration files have been created and these minimal options have been specified, you are ready to proceed with starting the cluster and verifying that all processes are running. We discuss how this is done in [Section 23.3.4, “Initial Startup of NDB Cluster”](#).

For more detailed information about the available NDB Cluster configuration parameters and their uses, see [Section 23.4.3, “NDB Cluster Configuration Files”](#), and [Section 23.4, “Configuration of NDB Cluster”](#).

For configuration of NDB Cluster as relates to making backups, see [Section 23.6.8.3, “Configuration for NDB Cluster Backups”](#).

Note

The default port for Cluster management nodes is 1186; the default port for data nodes is 2202. However, the cluster can automatically allocate ports for data nodes from those that are already free.

23.3.4 Initial Startup of NDB Cluster

Starting the cluster is not very difficult after it has been configured. Each cluster node process must be started separately, and on the host where it resides. The management node should be started first, followed by the data nodes, and then finally by any SQL nodes:

1. On the management host, issue the following command from the system shell to start the management node process:

```
shell> ndb_mgmd --initial -f /var/lib/mysql-cluster/config.ini
```

The first time that it is started, `ndb_mgmd` must be told where to find its configuration file, using the `-f` or `--config-file` option. This option requires that `--initial` or `--reload` also be specified; see [Section 23.5.4, “ndb_mgmd — The NDB Cluster Management Server Daemon”](#), for details.

2. On each of the data node hosts, run this command to start the `ndbd` process:

```
shell> ndbd
```

3. If you used RPM files to install MySQL on the cluster host where the SQL node is to reside, you can (and should) use the supplied startup script to start the MySQL server process on the SQL node.

If all has gone well, and the cluster has been set up correctly, the cluster should now be operational. You can test this by invoking the `ndb_mgm` management node client. The output should look like that shown here, although you might see some slight differences in the output depending upon the exact version of MySQL that you are using:

```
shell> ndb_mgm
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
-----
[ndbd(NDB)]      2 node(s)
id=2      @198.51.100.30 (Version: 8.0.27-ndb-8.0.27, Nodegroup: 0, *)
id=3      @198.51.100.40 (Version: 8.0.27-ndb-8.0.27, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=1      @198.51.100.10 (Version: 8.0.27-ndb-8.0.27)

[mysqld(API)]   1 node(s)
id=4      @198.51.100.20 (Version: 8.0.27-ndb-8.0.27)
```

The SQL node is referenced here as `[mysqld(API)]`, which reflects the fact that the `mysqld` process is acting as an NDB Cluster API node.

Note

The IP address shown for a given NDB Cluster SQL or other API node in the output of `SHOW` is the address used by the SQL or API node to connect to the cluster data nodes, and not to any management node.

You should now be ready to work with databases, tables, and data in NDB Cluster. See [Section 23.3.5, “NDB Cluster Example with Tables and Data”](#), for a brief discussion.

23.3.5 NDB Cluster Example with Tables and Data

Note

The information in this section applies to NDB Cluster running on both Unix and Windows platforms.

Working with database tables and data in NDB Cluster is not much different from doing so in standard MySQL. There are two key points to keep in mind:

- For a table to be replicated in the cluster, it must use the `NDBCLUSTER` storage engine. To specify this, use the `ENGINE=NDBCLUSTER` or `ENGINE=NDB` option when creating the table:

```
CREATE TABLE tbl_name (col_name column_definitions) ENGINE=NDBCLUSTER;
```

Alternatively, for an existing table that uses a different storage engine, use `ALTER TABLE` to change the table to use `NDBCLUSTER`:

```
ALTER TABLE tbl_name ENGINE=NDBCLUSTER;
```

- Every `NDBCLUSTER` table has a primary key. If no primary key is defined by the user when a table is created, the `NDBCLUSTER` storage engine automatically generates a hidden one. Such a key takes up space just as does any other table index. (It is not uncommon to encounter problems due to insufficient memory for accommodating these automatically created indexes.)

If you are importing tables from an existing database using the output of `mysqldump`, you can open the SQL script in a text editor and add the `ENGINE` option to any table creation statements, or replace any existing `ENGINE` options. Suppose that you have the `world` sample database on another MySQL server that does not support NDB Cluster, and you want to export the `City` table:

```
shell> mysqldump --add-drop-table world City > city_table.sql
```

The resulting `city_table.sql` file contains this table creation statement (and the `INSERT` statements necessary to import the table data):

```
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (
  `ID` int(11) NOT NULL auto_increment,
  `Name` char(35) NOT NULL default '',
  `CountryCode` char(3) NOT NULL default '',
  `District` char(20) NOT NULL default '',
  `Population` int(11) NOT NULL default '0',
  PRIMARY KEY (`ID`)
) ENGINE=MyISAM DEFAULT CHARSET=latin1;

INSERT INTO `City` VALUES (1,'Kabul','AFG','Kabol',1780000);
INSERT INTO `City` VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO `City` VALUES (3,'Herat','AFG','Herat',186800);
(remaining INSERT statements omitted)
```

You need to make sure that MySQL uses the `NDBCLUSTER` storage engine for this table. There are two ways that this can be accomplished. One of these is to modify the table definition *before* importing it into the Cluster database. Using the `City` table as an example, modify the `ENGINE` option of the definition as follows:

```
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (
```

```

`ID` int(11) NOT NULL auto_increment,
`Name` char(35) NOT NULL default '',
`CountryCode` char(3) NOT NULL default '',
`District` char(20) NOT NULL default '',
`Population` int(11) NOT NULL default '0',
PRIMARY KEY (`ID`)
) ENGINE=NDBCLUSTER DEFAULT CHARSET=latin1;

INSERT INTO `City` VALUES (1,'Kabul','AFG','Kabol',1780000);
INSERT INTO `City` VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO `City` VALUES (3,'Herat','AFG','Herat',186800);
(remaining INSERT statements omitted)

```

This must be done for the definition of each table that is to be part of the clustered database. The easiest way to accomplish this is to do a search-and-replace on the file that contains the definitions and replace all instances of `TYPE=engine_name` or `ENGINE=engine_name` with `ENGINE=NDBCLUSTER`. If you do not want to modify the file, you can use the unmodified file to create the tables, and then use `ALTER TABLE` to change their storage engine. The particulars are given later in this section.

Assuming that you have already created a database named `world` on the SQL node of the cluster, you can then use the `mysql` command-line client to read `city_table.sql`, and create and populate the corresponding table in the usual manner:

```
shell> mysql world < city_table.sql
```

It is very important to keep in mind that the preceding command must be executed on the host where the SQL node is running (in this case, on the machine with the IP address `198.51.100.20`).

To create a copy of the entire `world` database on the SQL node, use `mysqldump` on the noncluster server to export the database to a file named `world.sql` (for example, in the `/tmp` directory). Then modify the table definitions as just described and import the file into the SQL node of the cluster like this:

```
shell> mysql world < /tmp/world.sql
```

If you save the file to a different location, adjust the preceding instructions accordingly.

Running `SELECT` queries on the SQL node is no different from running them on any other instance of a MySQL server. To run queries from the command line, you first need to log in to the MySQL Monitor in the usual way (specify the `root` password at the `Enter password:` prompt):

```

shell> mysql -u root -p
Enter password:
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 8.0.27-ndb-8.0.27

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>

```

We simply use the MySQL server's `root` account and assume that you have followed the standard security precautions for installing a MySQL server, including setting a strong `root` password. For more information, see [Section 2.10.4, “Securing the Initial MySQL Account”](#).

It is worth taking into account that NDB Cluster nodes do *not* make use of the MySQL privilege system when accessing one another. Setting or changing MySQL user accounts (including the `root` account) effects only applications that access the SQL node, not interaction between nodes. See [Section 23.6.17.2, “NDB Cluster and MySQL Privileges”](#), for more information.

If you did not modify the `ENGINE` clauses in the table definitions prior to importing the SQL script, you should run the following statements at this point:

```
mysql> USE world;
mysql> ALTER TABLE City ENGINE=NDBCLUSTER;
mysql> ALTER TABLE Country ENGINE=NDBCLUSTER;
mysql> ALTER TABLE CountryLanguage ENGINE=NDBCLUSTER;
```

Selecting a database and running a `SELECT` query against a table in that database is also accomplished in the usual manner, as is exiting the MySQL Monitor:

```
mysql> USE world;
mysql> SELECT Name, Population FROM City ORDER BY Population DESC LIMIT 5;
+-----+-----+
| Name      | Population |
+-----+-----+
| Bombay    | 10500000  |
| Seoul     | 9981619   |
| São Paulo | 9968485   |
| Shanghai  | 9696300   |
| Jakarta   | 9604900   |
+-----+-----+
5 rows in set (0.34 sec)

mysql> \q
Bye

shell>
```

Applications that use MySQL can employ standard APIs to access `NDB` tables. It is important to remember that your application must access the SQL node, and not the management or data nodes. This brief example shows how we might execute the `SELECT` statement just shown by using the PHP 5.X `mysqli` extension running on a Web server elsewhere on the network:

```
<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01 Transitional//EN"
"http://www.w3.org/TR/html4/loose.dtd">
<html>
<head>
  <meta http-equiv="Content-Type"
        content="text/html; charset=iso-8859-1">
  <title>SIMPLE mysqli SELECT</title>
</head>
<body>
<?php
  # connect to SQL node:
  $link = new mysqli('198.51.100.20', 'root', 'root_password', 'world');
  # parameters for mysqli constructor are:
  #   host, user, password, database

  if( mysqli_connect_errno() )
    die("Connect failed: " . mysqli_connect_error());

  $query = "SELECT Name, Population
           FROM City
           ORDER BY Population DESC
           LIMIT 5";

  # if no errors...
  if( $result = $link->query($query) )
  {
?>
<table border="1" width="40%" cellpadding="4" cellspacing="1">
  <tbody>
    <tr>
      <th width="10%">City</th>
      <th>Population</th>
    </tr>
  </tbody>
</table>
<?
  # then display the results...
```

```

while($row = $result->fetch_object())
    printf("<tr>\n  <td align=\"center\">%s</td><td>%d</td>\n</tr>\n",
        $row->Name, $row->Population);
?>
</tbody>
</table>
<?
# ...and verify the number of rows that were retrieved
printf("<p>Affected rows: %d</p>\n", $link->affected_rows);
}
else
    # otherwise, tell us what went wrong
    echo mysqli_error();

# free the result set and the mysqli connection object
$result->close();
$link->close();
?>
</body>
</html>

```

We assume that the process running on the Web server can reach the IP address of the SQL node.

In a similar fashion, you can use the MySQL C API, Perl-DBI, Python-mysql, or MySQL Connectors to perform the tasks of data definition and manipulation just as you would normally with MySQL.

23.3.6 Safe Shutdown and Restart of NDB Cluster

To shut down the cluster, enter the following command in a shell on the machine hosting the management node:

```
shell> ndb_mgm -e shutdown
```

The `-e` option here is used to pass a command to the `ndb_mgm` client from the shell. The command causes the `ndb_mgm`, `ndb_mgmd`, and any `ndbd` or `ndbmtbd` processes to terminate gracefully. Any SQL nodes can be terminated using `mysqladmin shutdown` and other means. On Windows platforms, assuming that you have installed the SQL node as a Windows service, you can use `SC STOP service_name` or `NET STOP service_name`.

To restart the cluster on Unix platforms, run these commands:

- On the management host (198.51.100.10 in our example setup):

```
shell> ndb_mgmd -f /var/lib/mysql-cluster/config.ini
```

- On each of the data node hosts (198.51.100.30 and 198.51.100.40):

```
shell> ndbd
```

- Use the `ndb_mgm` client to verify that both data nodes have started successfully.
- On the SQL host (198.51.100.20):

```
shell> mysqld_safe &
```

On Windows platforms, assuming that you have installed all NDB Cluster processes as Windows services using the default service names (see [Section 23.3.2.4, "Installing NDB Cluster Processes as Windows Services"](#)), you can restart the cluster as follows:

- On the management host (198.51.100.10 in our example setup), execute the following command:

```
C:\> SC START ndb_mgmd
```

- On each of the data node hosts (198.51.100.30 and 198.51.100.40), execute the following command:

```
C:\> SC START ndbd
```

- On the management node host, use the `ndb_mgm` client to verify that the management node and both data nodes have started successfully (see [Section 23.3.2.3, “Initial Startup of NDB Cluster on Windows”](#)).
- On the SQL node host (198.51.100.20), execute the following command:

```
C:\> SC START mysql
```

In a production setting, it is usually not desirable to shut down the cluster completely. In many cases, even when making configuration changes, or performing upgrades to the cluster hardware or software (or both), which require shutting down individual host machines, it is possible to do so without shutting down the cluster as a whole by performing a *rolling restart* of the cluster. For more information about doing this, see [Section 23.6.5, “Performing a Rolling Restart of an NDB Cluster”](#).

23.3.7 Upgrading and Downgrading NDB Cluster

This section provides information about NDB Cluster software and table file compatibility between different NDB Cluster 8.0 releases with regard to performing upgrades and downgrades as well as compatibility matrices and notes. You should already be familiar with installing and configuring NDB Cluster prior to attempting an upgrade or downgrade. See [Section 23.4, “Configuration of NDB Cluster”](#).

Schema operations, including SQL DDL statements, cannot be performed while any data nodes are restarting, and thus during an online upgrade or downgrade of the cluster. For other information regarding the rolling restart procedure used to perform an online upgrade, see [Section 23.6.5, “Performing a Rolling Restart of an NDB Cluster”](#).

Important

Only compatibility between MySQL versions with regard to `NDBCLUSTER` is taken into account in this section, and there are likely other issues to be considered. *As with any other MySQL software upgrade or downgrade, you are strongly encouraged to review the relevant portions of the MySQL Manual for the MySQL versions from which and to which you intend to migrate, before attempting an upgrade or downgrade of the NDB Cluster software.* See [Section 2.11, “Upgrading MySQL”](#).

The table shown here provides information on NDB Cluster upgrade and downgrade compatibility among different releases of NDB 8.0. Additional notes about upgrades and downgrades to, from, or within the NDB Cluster 8.0 release series can be found following the table.

Upgrades and Downgrades, NDB Cluster 8.0

Figure 23.5 NDB Cluster Upgrade and Downgrade Compatibility, MySQL NDB Cluster 8.0

Version support. The following versions of NDB Cluster are supported for upgrades to GA releases of NDB Cluster 8.0 (8.0.19 and later):

- NDB Cluster 7.6: NDB 7.6.4 and later
- NDB Cluster 7.5: NDB 7.5.4 and later
- NDB Cluster 7.4: NDB 7.4.6 and later

To upgrade from a release series previous to NDB 7.4, you must upgrade in stages, first to one of the versions just listed, and then from that version to the latest NDB 8.0 release. In such cases, upgrading to the latest NDB 7.6 release is recommended as the first step.

Known Issues. The following issues are known to occur when upgrading to or between NDB 8.0 releases:

- Online downgrades from NDB 8.0 to previous releases are not supported. Tables created in NDB 8.0 are not backwards compatible with previous releases. This is due to a change in usage of the extra metadata property implemented by NDB tables to provide full support for the MySQL data dictionary.

For more information, see [Changes in NDB table extra metadata](#). See also [Chapter 14, MySQL Data Dictionary](#).

- In NDB 8.0, the default values changed for `log_bin` (from 0 to 1) and `ndb_log_bin` (from 1 to 0). This means that you must now explicitly set `ndb_log_bin` to 1 to enable binary logging.
- Distributed privileges shared between MySQL servers as implemented in prior release series (see [Distributed Privileges Using Shared Grant Tables](#)) are not supported in NDB Cluster 8.0. When started, the `mysqld` supplied with NDB 8.0 and later checks for the existence of any grant tables which use

the [NDB](#) storage engine; if it finds any, it creates local copies (“shadow tables”) of these using [InnoDB](#). This is true for each MySQL server connected to NDB Cluster. After this has been performed on all MySQL servers acting as NDB Cluster SQL nodes, the [NDB](#) grant tables may be safely removed using the [ndb_drop_table](#) utility supplied with the NDB Cluster distribution, like this:

```
ndb_drop_table -d mysql user db columns_priv tables_priv proxies_priv procs_priv
```

It is safe to retain the [NDB](#) grant tables, but they are not used for access control and are effectively ignored.

For more information about the MySQL privileges system used in NDB 8.0, see [Section 23.6.12, “Distributed MySQL Privileges with NDB_STORED_USER”](#), as well as [Section 6.2.3, “Grant Tables”](#).

- In NDB 8.0, the binary configuration file format has been enhanced to provide support for greater numbers of nodes than in previous versions. The new format is not accessible to nodes running older versions of [NDB](#), although newer management servers can detect older nodes and communicate with them using the appropriate format.

Upgrades to NDB 8.0 should not be problematic in this regard. When downgrading from NDB 8.0 to previous versions, because older management servers cannot read the newer binary configuration file format, some manual intervention is required. When performing such a downgrade, it is necessary to remove any cached binary configuration files prior to starting the management using the older [NDB](#) software version, and to have the plaintext configuration file available for the management server to read. Alternatively, you can start the older management server using the `--initial` option (again, it is necessary to have the `config.ini` available). If the cluster uses multiple management servers, one of these two things must be done for each management server binary.

Also in connection with support for increased numbers of nodes, due to incompatible changes implemented in NDB 8.0 in the data node LCP `Sysfile`, it is necessary, when performing an online downgrade from NDB 8.0 to a prior NDB Cluster release, to restart all data nodes using the `--initial` option.

Restarting the data nodes with `--initial` is also required when upgrading any release prior to NDB 7.6.4 to any NDB 8.0 release.

- Direct downgrades of clusters running more than 48 data nodes, or with data nodes using node IDs greater than 48, to earlier NDB Cluster releases from NDB 8.0 are not supported. It is necessary in such cases to reduce the number of data nodes, change the configurations for all data nodes such that they use node IDs less than or equal to 48, or both, as required not to exceed the old maximums.
- If you are downgrading from NDB 8.0 to NDB 7.5 or NDB 7.4, you must set an explicit value for `IndexMemory` in the cluster configuration file if none is already present. This is because NDB 8.0 does not use this parameter (which was removed in NDB 7.6) and sets it to 0 by default, whereas it is required in NDB 7.5 and NDB 7.4, in both of which the cluster refuses to start with `Invalid configuration received from Management Server...` if `IndexMemory` is not set to a nonzero value.

Setting `IndexMemory` is *not* required for downgrades from NDB 8.0 to NDB 7.6.

- NDB 8.0.22 adds support for IPv6 addressing for management nodes and data nodes in the `config.ini` file. To begin using IPv6 addresses as part of an upgrade, perform the following steps:
 1. Perform an upgrade of the cluster to version 8.0.22 or a later version of the NDB Cluster software in the usual manner.
 2. Change the addresses used in the `config.ini` file to IPv6 addresses.
 3. Perform a system restart of the cluster.

- Due to changes in the internal `mysql.ndb_schema` table, if you upgrade to an NDB 8.0 release prior to 8.0.24, then you are advised to use `ndb_schema_dist_upgrade_allowed = 0` to avoid unexpected outages (Bug #30876990, Bug #31016905).

23.3.8 The NDB Cluster Auto-Installer (No longer supported)

Note

This feature has been removed from NDB Cluster, and is no longer supported. See [Section 23.2.4, “What is New in NDB Cluster”](#), for more information.

This section describes the web-based graphical configuration installer included as part of the NDB Cluster distribution. Topics discussed include an overview of the installer and its parts, software and other requirements for running the installer, navigating the GUI, and using the installer to set up and start or stop an NDB Cluster on one or more host computers.

The NDB Cluster Auto-Installer is made up of two components. The front end is a GUI client implemented as a Web page that loads and runs in a standard Web browser such as Firefox or Microsoft Internet Explorer. The back end is a server process (`ndb_setup.py`) that runs on the local machine or on another host to which you have access.

These two components (client and server) communicate with each other using standard HTTP requests and responses. The back end can manage NDB Cluster software programs on any host where the back end user has granted access. If the NDB Cluster software is on a different host, the back end relies on SSH for access.

23.3.8.1 NDB Cluster Auto-Installer Requirements

This section provides information on supported operating platforms and software, required software, and other prerequisites for running the NDB Cluster Auto-Installer.

Supported platforms. The NDB Cluster Auto-Installer is available with NDB 8.0 distributions for recent versions of Linux, Windows, Solaris, and macOS. For more detailed information about platform support for NDB Cluster and the NDB Cluster Auto-Installer, see <https://www.mysql.com/support/supportedplatforms/cluster.html>.

Supported web browsers. The web-based installer is supported with recent versions of Firefox and Microsoft Internet Explorer. It should also work with recent versions of Opera, Safari, and Chrome, although we have not thoroughly tested for compability with these browsers.

Required software—setup host. The following software must be installed on the host where the Auto-Installer is run:

- **Python 2.6 or higher.** The Auto-Installer requires the Python interpreter and standard libraries. If these are not already installed on the system, you may be able to add them using the system's package manager. Otherwise, you can download them from <http://python.org/download/>.
- **Paramiko 2 or higher.** You can download this from <http://www.lag.net/paramiko/> if it is not available from your system's package manager.
- **Pycrypto version 1.9 or higher.** This cryptography module is required by Paramiko, and can be iunstalled using `pip install cryptography`. If `pip` is not installed, and the module is not available using your system's package manage, you can download it from <https://www.dlitz.net/software/pycrypto/>.

All of the software in the preceding list is included in the Windows version of the configuration tool, and does not need to be installed separately.

Required software—remote hosts. The only software required for remote hosts where you wish to deploy NDB Cluster nodes is the SSH server, which is usually installed by default on Linux and Solaris systems. Several alternatives are available for Windows; for an overview of these, see http://en.wikipedia.org/wiki/Comparison_of_SSH_servers.

An additional requirement when using multiple hosts is that it is possible to authenticate to any of the remote hosts using SSH and the proper keys or user credentials, as discussed in the next few paragraphs:

Authentication and security. Three basic security or authentication mechanisms for remote access are available to the Auto-Installer, which we list and describe here:

- **SSH.** A secure shell connection is used to enable the back end to perform actions on remote hosts. For this reason, an SSH server must be running on the remote host. In addition, the operating system user running the installer must have access to the remote server, either with a user name and password, or by using public and private keys.

Important

You should never use the system `root` account for remote access, as this is extremely insecure. In addition, `mysqld` cannot normally be started by system `root`. For these and other reasons, you should provide SSH credentials for a regular user account on the target system, and not for system `root`. For more information about this issue, see [Section 6.1.5, “How to Run MySQL as a Normal User”](#).

- **HTTPS.** Remote communication between the Web browser front end and the back end is not encrypted by default, which means that information such as the user's SSH password is transmitted as cleartext that is readable to anyone. For communication from a remote client to be encrypted, the back end must have a certificate, and the front end must communicate with the back end using HTTPS rather than HTTP. Enabling HTTPS is accomplished most easily through issuing a self-signed certificate. Once the certificate is issued, you must make sure that it is used. You can do this by starting `ndb_setup.py` from the command line with the `--use-https (-S)` and `--cert-file (-c)` options.

A sample certificate file `cfg.pem` is included and is used by default. This file is located in the `mcc` directory under the installation share directory; on Linux, the full path to the file is normally `/usr/share/mysql/mcc/cfg.pem`. On Windows systems, this is usually `C:\Program Files\MySQL\MySQL Server 8.0\share\mcc\cfg.pem`. Letting the default be used means that, for testing purposes, you can simply start the installer with the `-S` option to use an HTTPS connection between the browser and the back end.

The Auto-Installer saves the configuration file for a given cluster `mycluster01` as `mycluster01.mcc` in the home directory of the user invoking the `ndb_setup.py` executable. This file is encrypted with a passphrase supplied by the user (using [Fernet](#)); because HTTP transmits the passphrase in the clear, *it is strongly recommended that you always use an HTTPS connection to access the Auto-Installer on a remote host.*

- **Certificate-based authentication.** The back end `ndb_setup.py` process can execute commands on the local host as well as remote hosts. This means that anyone connecting to the back end can take charge of how commands are executed. To reject unwanted connections to the back end, a certificate may be required for authentication of the client. In this case, a certificate must be issued by the user, installed in the browser, and made available to the back end for authentication purposes. You can enact this requirement (together with or in place of password or key authentication) by starting `ndb_setup.py` with the `--ca-certs-file (-a)` option.

There is no need or requirement for secure authentication when the client browser is running on the same host as the Auto-Installer back end.

See also [Section 23.6.17, “NDB Cluster Security Issues”](#), which discusses security considerations to take into account when deploying NDB Cluster, as well as [Chapter 6, Security](#), for more general MySQL security information.

23.3.8.2 Using the NDB Cluster Auto-Installer

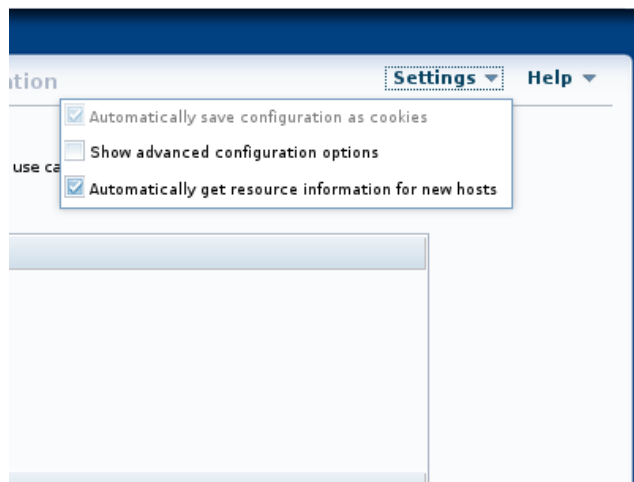

The NDB Cluster Auto-Installer interface is made up of several pages, each corresponding to a step in the process used to configure and deploy an NDB Cluster. These pages are listed here, in order:

- **Welcome:** Begin using the Auto-Installer by choosing either to configure a new NDB Cluster, or to continue configuring an existing one.
- **Define Cluster:** Set basic information about the cluster as a whole, such as name, hosts, and load type. Here you can also set the SSH authentication type for accessing remote hosts, if needed.
- **Define Hosts:** Identify the hosts where you intend to run NDB Cluster processes.
- **Define Processes:** Assign one or more processes of a given type or types to each cluster host.
- **Define Parameters:** Set configuration attributes for processes or types of processes.
- **Deploy Configuration:** Deploy the cluster with the configuration set previously; start and stop the deployed cluster.

NDB Cluster Installer Settings and Help Menus

These menus are shown on all screens except for the **Welcome** screen. They provide access to installer settings and information. The **Settings** menu is shown here in more detail:

Figure 23.6 NDB Cluster Auto-Installer Settings menu

The **Settings** menu has the following entries:

- **Automatically save configuration as cookies:** Save your configuration information—such as host names, process data, and parameter values—as a cookie in the browser. When this option is chosen, all information except any SSH password is saved. This means that you can quit and restart the browser, and continue working on the same configuration from where you left off at the end of the previous session. This option is enabled by default.

The SSH password is never saved; if you use one, you must supply it at the beginning of each new session.

- **Show advanced configuration options:** Shows by default advanced configuration parameters where available.

Once set, the advanced parameters continue to be used in the configuration file until they are explicitly changed or reset. This is regardless of whether the advanced parameters are currently visible in the installer; in other words, disabling the menu item does not reset the values of any of these parameters.

You can also toggle the display of advanced parameters for individual processes on the [Define Parameters](#) screen.

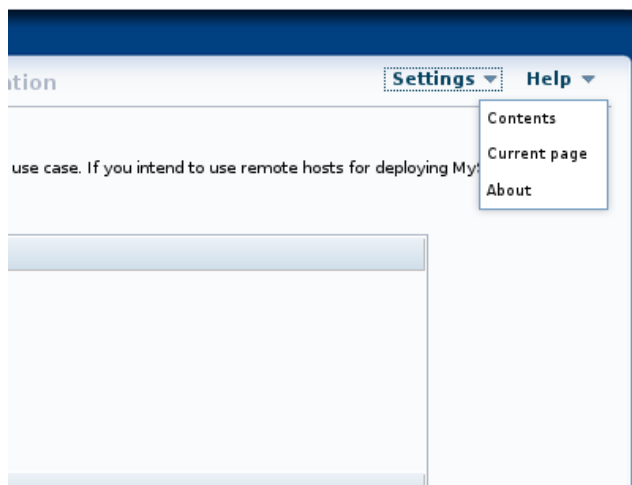

This option is disabled by default.

- **Automatically get resource information for new hosts:** Query new hosts automatically for hardware resource information to pre-populate a number of configuration options and values. In this case, the suggested values are not mandatory, but they are used unless explicitly changed using the appropriate editing options in the installer.

This option is enabled by default.

The installer **Help** menu is shown here:

Figure 23.7 NDB Cluster Auto-Installer Help menu

The **Help** menu provides several options, described in the following list:

- **Contents:** Show the built-in user guide. This is opened in a separate browser window, so that it can be used simultaneously with the installer without interrupting workflow.
- **Current page:** Open the built-in user guide to the section describing the page currently displayed in the installer.
- **About:** open a dialog displaying the installer name and the version number of the NDB Cluster distribution with which it was supplied.

The Auto-Installer also provides context-sensitive help in the form of tooltips for most input widgets.

In addition, the names of most NDB configuration parameters are linked to their descriptions in the online documentation. The documentation is displayed in a separate browser window.

The next section discusses starting the Auto-Installer. The sections immediately following it describe in greater detail the purpose and function of each of these pages in the order listed previously.

Starting the NDB Cluster Auto-Installer

The Auto-Installer is provided together with the NDB Cluster software. Separate RPM and `.deb` packages containing only the Auto-Installer are also available for many Linux distributions. (See [Section 23.3, “NDB Cluster Installation”](#).)

The present section explains how to start the installer. You can do by invoking the `ndb_setup.py` executable.

User and privileges

You should run the `ndb_setup.py` as a normal user; no special privileges are needed to do so. You should *not* run this program as the `mysql` user, or using the system `root` or Administrator account; doing so may cause the installation to fail.

`ndb_setup.py` is found in the `bin` within the NDB Cluster installation directory; a typical location might be `/usr/local/mysql/bin` on a Linux system or `C:\Program Files\MySQL\MySQL Server 8.0\bin` on a Windows system. This can vary according to where the NDB Cluster software is installed on your system, and the installation method.

On Windows, you can also start the installer by running `setup.bat` in the NDB Cluster installation directory. When invoked from the command line, this batch file accepts the same options as `ndb_setup.py`.

`ndb_setup.py` can be started with any of several options that affect its operation, but it is usually sufficient to allow the default settings be used, in which case you can start `ndb_setup.py` by either of the following two methods:

1. Navigate to the NDB Cluster `bin` directory in a terminal and invoke it from the command line, without any additional arguments or options, like this:

```
shell> ndb_setup.py
Running out of install dir: /usr/local/mysql/bin
Starting web server on port 8081
URL is https://localhost:8081/welcome.html
deathkey=627876
Press CTRL+C to stop web server.
The application should now be running in your browser.
(Alternatively you can navigate to https://localhost:8081/welcome.html to start it)
```

This works regardless of operating platform.

2. Navigate to the NDB Cluster `bin` directory in a file browser (such as Windows Explorer on Windows, or Konqueror, Dolphin, or Nautilus on Linux) and activate (usually by double-clicking) the `ndb_setup.py` file icon. This works on Windows, and should work with most common Linux desktops as well.

On Windows, you can also navigate to the NDB Cluster installation directory and activate the `setup.bat` file icon.

In either case, once `ndb_setup.py` is invoked, the Auto-Installer's [Welcome screen](#) should open in the system's default web browser. If not, you should be able to open the page <http://localhost:8081/welcome.html> or <https://localhost:8081/welcome.html> manually in the browser.

In some cases, you may wish to use non-default settings for the installer, such as specifying HTTPS for connections, or a different port for the Auto-Installer's included web server to run on, in which case you must invoke `ndb_setup.py` with one or more startup options with values overriding the necessary defaults. The same startup options can be used on Windows systems with the `setup.bat` file supplied for

such platforms in the NDB Cluster software distribution. This can be done using the command line, but if you want or need to start the installer from a desktop or file browser while employing one or more of these options, it is also possible to create a script or batch file containing the proper invocation, then to double-click its file icon in the file browser to start the installer. (On Linux systems, you might also need to make the script file executable first.) If you plan to use the Auto-Installer from a remote host, you should start using the `-s` option. For information about this and other advanced startup options for the NDB Cluster Auto-Installer, see [Section 23.5.26, “ndb_setup.py — Start browser-based Auto-Installer for NDB Cluster \(DEPRECATED\)”](#).

NDB Cluster Auto-Installer Welcome Screen

The **Welcome** screen is loaded in the default browser when `ndb_setup.py` is invoked. The first time the Auto-Installer is run (or if for some other reason there are no existing configurations), this screen appears as shown here:

Figure 23.8 The NDB Cluster Auto-Installer Welcome screen, first run

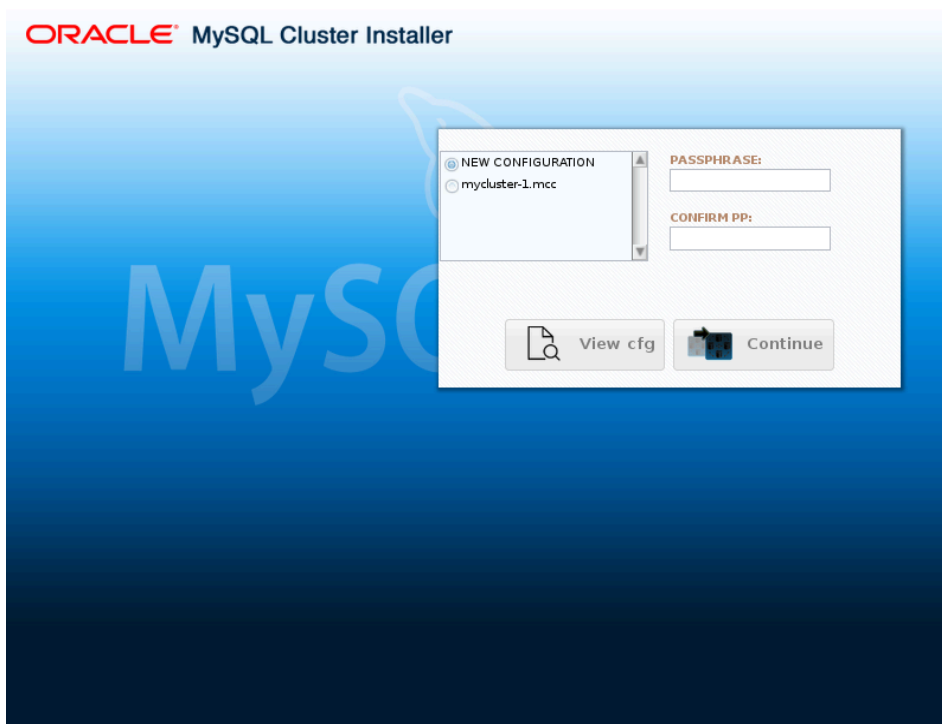

In this case, the only choice of cluster listed is for configuration of a new cluster, and both the **View Cfg** and **Continue** buttons are inactive.

To create a new configuration, enter and confirm a passphrase in the text boxes provided. When this has been done, you can click **Continue** to proceed to the **Define Cluster** screen where you can assign a name to the new cluster.

If you have previously created one or more clusters with the Auto-Installer, they are listed by name. This example shows an existing cluster named `mycluster-1`:

Figure 23.9 The NDB Cluster Auto-Installer Welcome screen, with previously created cluster mycluster-1

To view the configuration for and work with a given cluster, select the radiobutton next to its name in the list, then enter and confirm the passphrase that was used to create it. When you have done this correctly, you can click **View Cfg** to view and edit this cluster's configuration.

NDB Cluster Auto-Installer Define Cluster Screen

The **Define Cluster** screen is appears following the [Welcome screen](#), and is used for setting general properties of the cluster. The layout of the **Define Cluster** screen is shown here:

Figure 23.10 The NDB Cluster Auto-Installer Define Cluster screen

ORACLE MySQL Cluster Installer

Define cluster > Define hosts > Define processes > Define parameters > Deploy configuration

Cluster Type and SSH Credentials
 MySQL Cluster is able to operate in various configurations. Please specify the settings below to define the right cluster type that fits your use case. If you intend to use remote hosts for deploying MySQL Cluster, SSH must be enabled. Unless key based SSH is possible, you must submit your user name and password below.

| Cluster property | Value |
|----------------------|----------------|
| Cluster name [?] | mycluster-1 |
| Host list [?] | |
| Application area [?] | simple testing |
| Write load [?] | medium |

| SSH property (Cluster-wide) | Value |
|-----------------------------|--------------------------|
| Key based SSH [?] | <input type="checkbox"/> |
| Key user: [?] | |
| User name [?] | |
| Key passphrase: [?] | |
| Password [?] | |
| Key file: [?] | |

| Install properties (Cluster-wide) | Value |

| | |

Previous Save&Next Finish

This screen and subsequent screens also include **Settings** and **Help** menus which are described later in this section; see [NDB Cluster Installer Settings and Help Menus](#).

The **Define Cluster** screen allows you to set three sorts of properties for the cluster: cluster properties, SSH properties, and installation properties.

Cluster properties that can be set on this screen are listed here:

- **Cluster name:** A name that identifies the cluster; in this example, this is `mycluster-1`. The name is set on the previous screen and cannot be changed here.
- **Host list:** A comma-delimited list of one or more hosts where cluster processes should run. By default, this is `127.0.0.1`. If you add remote hosts to the list, you must be able to connect to them using the credentials supplied as SSH properties.
- **Application type:** Choose one of the following:
 1. **Simple testing:** Minimal resource usage for small-scale testing. This the default. *Not intended for production environments.*
 2. **Web:** Maximize performance for the given hardware.
 3. **Real-time:** Maximize performance while maximizing sensitivity to timeouts in order to minimize the time needed to detect failed cluster processes.
- **Write load:** Choose a level for the anticipated number of writes for the cluster as a whole. You can choose any one of the following levels:
 1. **Low:** The expected load includes fewer than 100 write transactions for second.
 2. **Medium:** The expected load includes 100 to 1000 write transactions per second; this is the default.

3. **High:** The expected load includes more than 1000 write transactions per second.

SSH properties are described in the following list:

- **Key-Based SSH:** Check this box to use key-enabled login to the remote host. If checked, the key user and passphrase must also be supplied; otherwise, a user and password for a remote login account are needed.
- **User:** Name of user with remote login access.
- **Password:** Password for remote user.
- **Key user:** Name of the user for whom the key is valid, if not the same as the operating system user.
- **Key passphrase:** Passphrase for the key, if required.
- **Key file:** Path to the key file. The default is `~/.ssh/id_rsa`.

The SSH properties set on this page apply to all hosts in the cluster. They can be overridden for a given host by editing that host's properties on the **Define Hosts** screen.

Two installation properties can also be set on this screen:

- **Install MySQL Cluster:** This setting determines the source from which the Auto-Installer installs NDB Cluster software, if any, on the cluster hosts. Possible values and their effects are listed here:
 1. **DOCKER:** Try to install the MySQL Cluster Docker image from <https://hub.docker.com/r/mysql/mysql-cluster/> on each host
 2. **REPO:** Try to install the NDB Cluster software from the [MySQL Repositories](#) on each host
 3. **BOTH:** Try to install either the Docker image or the software from the repository on each host, giving preference to the repository
 4. **NONE:** Do not install the NDB Cluster software on the hosts; this is the default
- **Open FW Ports:** Check this check box to have the installer attempt to open ports required by NDB Cluster processes on all hosts.

The next figure shows the **Define Cluster** page with settings for a small test cluster with all nodes running on `localhost`:

Figure 23.11 The NDB Cluster Auto-Installer Define Cluster screen, with settings for a test cluster

ORACLE MySQL Cluster Installer

◀ Previous Save & Next Finish ▶

After making the desired settings, you can save them to the configuration file and proceed to the **Define Hosts** screen by clicking the **Save & Next** button.

If you exit the installer without saving, no changes are made to the configuration file.

NDB Cluster Auto-Installer Define Hosts Screen

The **Define Hosts** screen, shown here, provides a means of viewing and specifying several key properties of each cluster host:

Figure 23.12 NDB Cluster Define Hosts screen, start

Properties shown include the following:

- **Host:** Name or IP address of this host
- **Res.info:** Shows *OK* if the installer was able to retrieve requested resource information from this host
- **Platform:** Operating system or platform
- **Memory (MB):** Amount of RAM on this host
- **Cores:** Number of CPU cores available on this host
- **MySQL Cluster install directory:** Path to directory where the NDB Cluster software is installed on this host; defaults to `/usr/local/bin`
- **MySQL Cluster data directory:** Path to directory used for data by NDB Cluster processes on this host; defaults to `/var/lib/mysql-cluster`.
- **DiskFree:** Free disk space in bytes

For hosts with multiple disks, only the space available on the disk used for the data directory is shown.

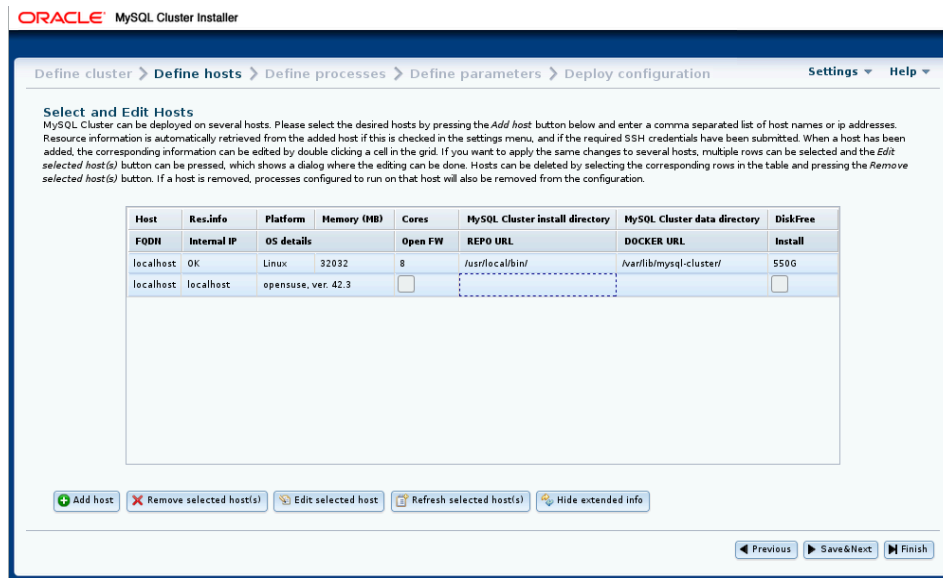

This screen also provides an extended view for each host that includes the following properties:

- **FDQN:** This host's fully qualified domain name, used by the installer to connect with it, distribute configuration information to it, and start and stop cluster processes on it.
- **Internal IP:** The IP address used for communication with cluster processes running on this host by processes running elsewhere.
- **OS Details:** Detailed operating system name and version information.
- **Open FW:** If this check box is enabled, the installer attempts to open ports in the host's firewall needed by cluster processes.
- **REPO URL:** URL for MySQL NDB Cluster repository

- **DOCKER URL:** URL for MySQL NDB CLuster Docker images; for NDB 8.0, this is `mysql/mysql-cluster:8.0`.
- **Install:** If this check box is enabled, the Auto-Installer attempts to install the NDB Cluster software on this host

The extended view is shown here:

Figure 23.13 NDB Cluster Define Hosts screen, extended host info view

All cells in the display are editable, with the exceptions of those in the **Host**, **Res.info**, and **FQDN** columns.

Be aware that it may take some time for information to be retrieved from remote hosts. Fields for which no value could be retrieved are indicated with an ellipsis (...). You can retry the fetching of resource information from one or more hosts by selecting the hosts in the list and then clicking the **Refresh selected host(s)** button.

Adding and Removing Hosts

You can add one or more hosts by clicking the **Add Host** button and entering the required properties where indicated in the **Add new host** dialog, shown here:

Figure 23.14 NDB Cluster Add Host dialog

The dialog box is titled "Add new host" and contains the following fields and controls:

- Host name: [?]**: A text input field with a red border and a red exclamation mark icon on the right, indicating an error.
- Host internal IP (VPN): [?]**: A text input field.
- Key-based auth: [?]**: A checkbox.
- User [?]**: A text input field.
- Passphrase [?]**: A text input field.
- Key file [?]**: A text input field.
- Ordinary login:**
 - User [?]**: A text input field.
 - Password [?]**: A text input field.
- Open FW ports [?]**: A checkbox.
- Configure installation [?]**: A checkbox.
- Cancel** and **Add** buttons at the bottom.

This dialog includes the following fields:

- **Host name:** A comma-separated list of one or more host names, IP addresses, or both. These must be accessible from the host where the Auto-Installer is running.
- **Host internal IP (VPN):** If you are setting up the cluster to run on a VPN or other internal network, enter the IP address or addresses used for contact by cluster nodes on other hosts.
- **Key-based auth:** If checked, enables key-based authentication. You can enter any additional needed information in the **User**, **Passphrase**, and **Key file** fields.
- **Ordinary login:** If accessing this host using a password-based login, enter the appropriate information in the **User** and **Password** fields.
- **Open FW ports:** Selecting this check box allows the installer try opening any ports needed by cluster processes in this host's firewall.
- **Configure installation:** Checking this allows the Auto-Install to attempt to set up the NDB Cluster software on this host.

To save the new host and its properties, click **Add**. If you wish to cancel without saving any changes, click **Cancel** instead.

Similarly, you can remove one or more hosts using the button labelled **Remove selected host(s)**. *When you remove a host, any process which was configured for that host is also removed.*

Warning

Remove selected host(s) acts immediately. There is no confirmation dialog. If you remove a host in error, you must re-enter its name and properties manually using **Add host**.

If the SSH user credentials on the [Define Cluster screen](#) are changed, the Auto-Installer attempts to refresh the resource information from any hosts for which information is missing.

You can edit the host's platform name, hardware resource information, installation directory, and data directory by clicking the corresponding cell in the grid, by selecting one or more hosts and clicking the button labelled **Edit selected host(s)**. This causes a dialog box to appear, in which these fields can be edited, as shown here:

Figure 23.15 NDB Cluster Auto-Installer Edit Hosts dialog

Edit selected host(s)

Please edit the fields you want to change. The changes will be applied to all selected hosts. Fields that are not edited in the form below will be left unchanged.

| Platform [?] | Memory (MB) [?] | CPU cores [?] | MySQL Cluster install directory [?] | MySQL Cluster data directory [?] | DiskFree [?] |
|--------------|-----------------|---------------|-------------------------------------|----------------------------------|--------------|
| Linux | 32,032 | 8 | | | 550G |

Host external IP: [?]
localhost

Host internal IP (VPN): [?]
localhost

Key-based auth: [?]

User [?] Passphrase [?]
[] []

Key file [?]
[]

Ordinary login:
User [?] Password [?]
[] []

Open FW ports [?] Configure installation [?]

Cancel Save

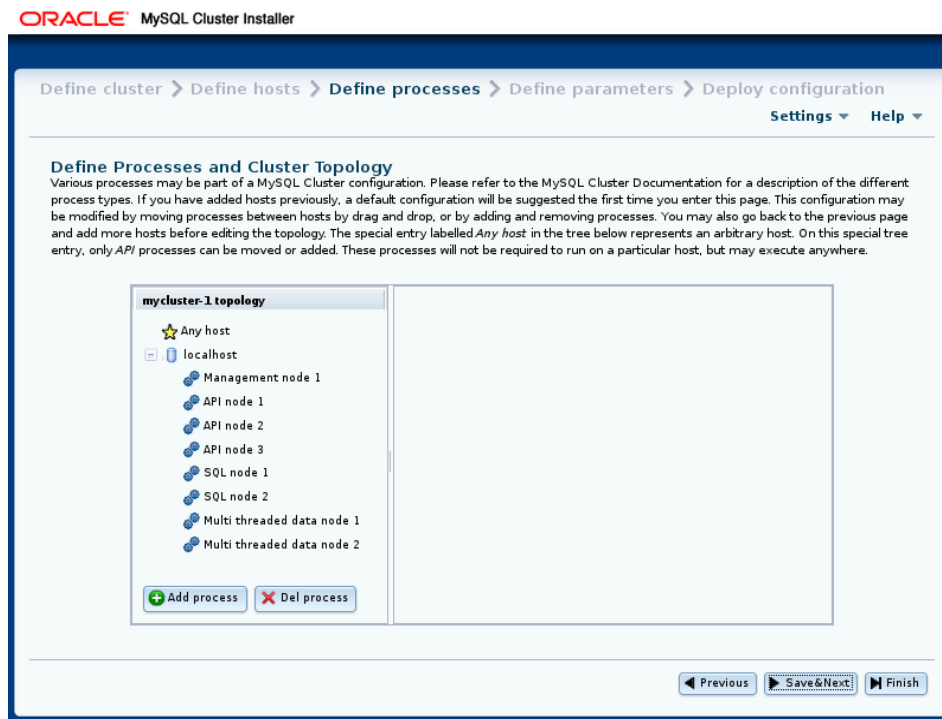

When more than one host is selected, any edited values are applied to all selected hosts.

Once you have entered all desired host information, you can use the **Save & Next** button to save the information to the cluster's configuration file and proceed to the **Define Processes screen**, where you can set up NDB Cluster processes on one or more hosts.

NDB Cluster Auto-Installer Define Processes Screen

The **Define Processes** screen, shown here, provides a way to assign NDB Cluster processes (nodes) to cluster hosts:

Figure 23.16 NDB Cluster Auto-Installer Define Processes dialog

This screen contains a process tree showing cluster hosts and processes set up to run on each one, as well as a panel which displays information about the item currently selected in the tree.

When this screen is accessed for the first time for a given cluster, a default set of processes is defined for you, based on the number of hosts. If you later return to the [Define Hosts screen](#), remove all hosts, and add new hosts, this also causes a new default set of processes to be defined.

NDB Cluster processes are of the types described in this list:

- **Management node.** Performs administrative tasks such as stopping individual data nodes, querying node and cluster status, and making backups. Executable: `ndb_mgmd`.
- **Single-threaded data node.** Stores data and executes queries. Executable: `ndbd`.
- **Multi threaded data node.** Stores data and executes queries with multiple worker threads executing in parallel. Executable: `ndbmtdd`.
- **SQL node.** MySQL server for executing SQL queries against NDB. Executable: `mysqld`.
- **API node.** A client accessing data in NDB by means of the NDB API or other low-level client API, rather than by using SQL. See [MySQL NDB Cluster API Developer Guide](#), for more information.

For more information about process (node) types, see [Section 23.2.1, “NDB Cluster Core Concepts”](#).

Processes shown in the tree are numbered sequentially by type, for each host—for example, `SQL node 1`, `SQL node 2`, and so on—to simplify identification.

Each management node, data node, or SQL process must be assigned to a specific host, and is not allowed to run on any other host. An API node *may* be assigned to a single host, but this is not required. Instead, you can assign it to the special **Any host** entry which the tree also contains in addition to any

other hosts, and which acts as a placeholder for processes that are allowed to run on any host. *Only API processes may use this **Any host** entry.*

Adding processes. To add a new process to a given host, either right-click that host's entry in the tree, then select the **Add process** popup when it appears, or select a host in the process tree, and press the **Add process** button below the process tree. Performing either of these actions opens the add process dialog, as shown here:

Figure 23.17 NDB Cluster Auto-Installer Add Process Dialog

Here you can select from among the available process types described earlier this section; you can also enter an arbitrary process name to take the place of the suggested value, if desired.

Removing processes. To delete a process, select that process in the tree and use the **Del process** button.

When you select a process in the process tree, information about that process is displayed in the information panel, where you can change the process name and possibly its type. You can change a multi-threaded data node (`ndbmtd`) to a single-threaded data node (`ndbd`), or the reverse, only; no other process type changes are allowed. *If you want to make a change between any other process types, you must delete the original process first, then add a new process of the desired type.*

NDB Cluster Auto-Installer Define Parameters Screen

Like the [Define Processes screen](#), this screen includes a process tree; the **Define Parameters** process tree is organized by process or node type, in groups labelled **Management Layer**, **Data Layer**, **SQL Layer**, and **API Layer**. An information panel displays information regarding the item currently selected. The **Define Attributes** screen is shown here:

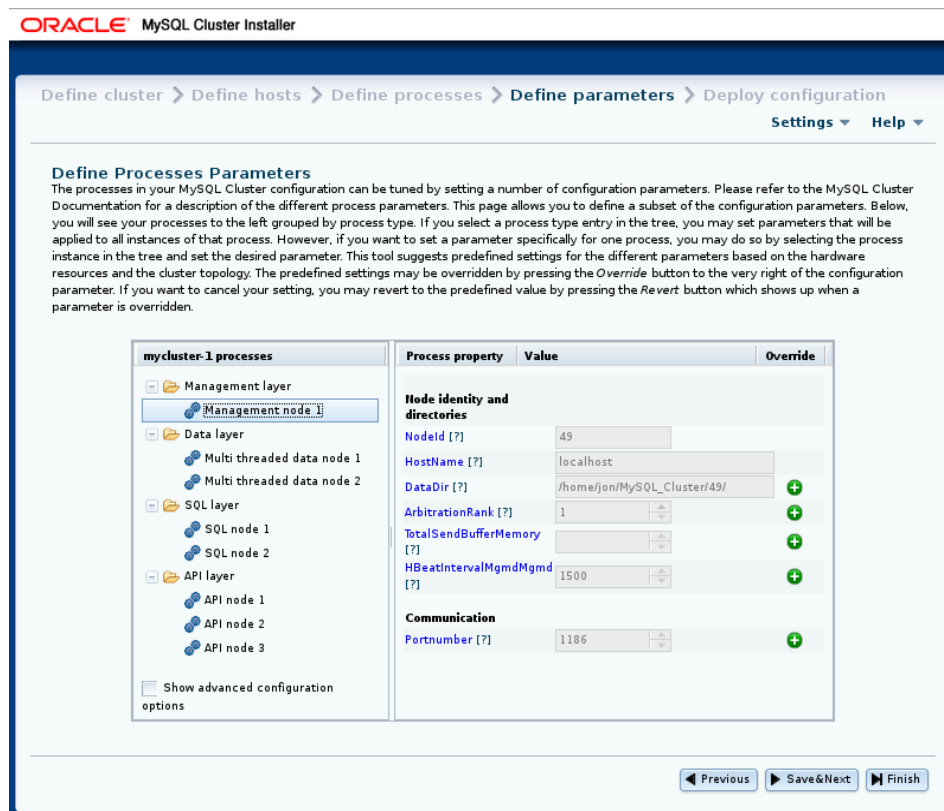

Figure 23.18 NDB Cluster Auto-Installer Define Parameters screen

The check box labelled **Show advanced configuration**, when checked, makes advanced options for data node and SQL node processes visible in the information pane. These options are set and used whether or not they are visible. You can also enable this behavior globally by checking **Show advanced configuration options** under **Settings** (see [NDB Cluster Installer Settings and Help Menus](#)).

You can edit attributes for a single process by selecting that process from the tree, or for all processes of the same type in the cluster by selecting one of the **Layer** folders. A per-process value set for a given attribute overrides any per-group setting for that attribute that would otherwise apply to the process in question. An example of such an information panel (for an SQL process) is shown here:

Figure 23.19 Define Parameters—Process Attributes

Attributes whose values can be overridden are shown in the information panel with a button bearing a plus sign. This + button activates an input widget for the attribute, enabling you to change its value. When the value has been overridden, this button changes into a button showing an X. The X button undoes any changes made to a given attribute, which immediately reverts to the predefined value.

All configuration attributes have predefined values calculated by the installer, based such factors as host name, node ID, node type, and so on. In most cases, these values may be left as they are. If you are not familiar with it already, it is highly recommended that you read the applicable documentation before making changes to any of the attribute values. To make finding this information easier, each attribute name shown in the information panel is linked to its description in the online NDB Cluster documentation.

NDB Cluster Auto-Installer Deploy Configuration Screen

This screen allows you to perform the following tasks:

- Review process startup commands and configuration files to be applied
- Distribute configuration files by creating any necessary files and directories on all cluster hosts—that is, *deploy* the cluster as presently configured
- Start and stop the cluster

The **Deploy Configuration** screen is shown here:

Figure 23.20 NDB Cluster Auto-Installer Deploy Configuration screen

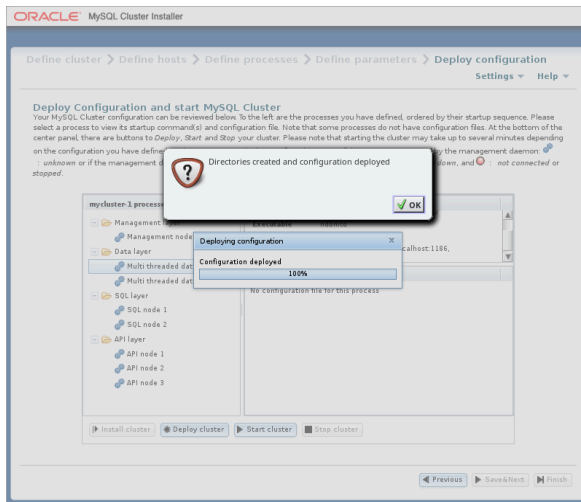

Like the [Define Parameters screen](#), this screen features a process tree which is organized by process type. Next to each process in the tree is a status icon indicating the current status of the process: connected (`CONNECTED`), starting (`STARTING`), running (`STARTED`), stopping (`STOPPING`), or disconnected (`NO_CONTACT`). The icon shows green if the process is connected or running; yellow if it is starting or stopping; red if the process is stopped or cannot be contacted by the management server.

This screen also contains two information panels, one showing the startup command or commands needed to start the selected process. (For some processes, more than one command may be required—for example, if initialization is necessary.) The other panel shows the contents of the configuration file, if any, for the given process.

This screen also contains four buttons, labelled as and performing the functions described in the following list:

- **Install cluster:** Nonfunctional in this release; implementation intended for a future release.
- **Deploy cluster:** Verify that the configuration is valid. Create any directories required on the cluster hosts, and distribute the configuration files onto the hosts. A progress bar shows how far the deployment has proceeded, as shown here, and a dialog is displayed when the deployment has completed, as shown here:

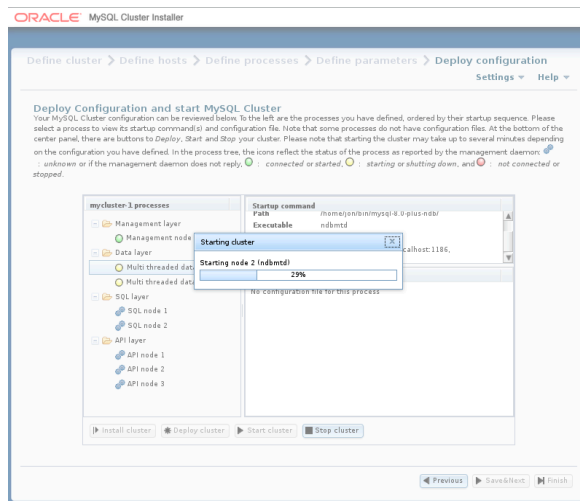

Figure 23.21 Cluster Deployment Process

- **Start cluster:** The cluster is deployed as with **Deploy cluster**, after which all cluster processes are started in the correct order.

Starting these processes may take some time. If the estimated time to completion is too large, the installer provides an opportunity to cancel or to continue of the startup procedure. A progress bar indicates the current status of the startup procedure, as shown here:

Figure 23.22 Cluster Startup Process with Progress Bar

The process status icons next to the items shown in the process tree also update with the status of each process.

A confirmation dialog is shown when the startup process has completed, as shown here:

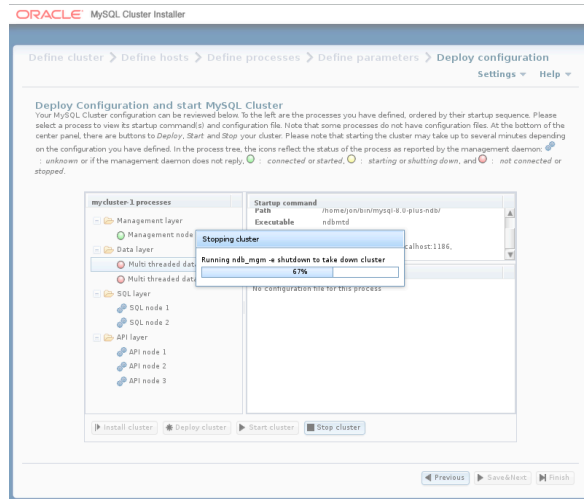

Figure 23.23 Cluster Startup, Process Completed Dialog

- **Stop cluster:** After the cluster has been started, you can stop it using this. As with starting the cluster, cluster shutdown is not instantaneous, and may require some time complete. A progress bar, similar

to that displayed during cluster startup, shows the approximate current status of the cluster shutdown procedure, as do the process status icons adjoining the process tree. The progress bar is shown here:

Figure 23.24 Cluster Shutdown Process, with Progress Bar

A confirmation dialog indicates when the shutdown process is complete:

Figure 23.25 Cluster Shutdown, Process Completed Dialog

The Auto-Installer generates a `config.ini` file containing NDB node parameters for each management node, as well as a `my.cnf` file containing the appropriate options for each `mysqld` process in the cluster. No configuration files are created for data nodes or API nodes.

23.4 Configuration of NDB Cluster

A MySQL server that is part of an NDB Cluster differs in one chief respect from a normal (nonclustered) MySQL server, in that it employs the **NDB** storage engine. This engine is also referred to sometimes as **NDBCLUSTER**, although **NDB** is preferred.

To avoid unnecessary allocation of resources, the server is configured by default with the **NDB** storage engine disabled. To enable **NDB**, you must modify the server's `my.cnf` configuration file, or start the server with the `--ndbcluster` option.

This MySQL server is a part of the cluster, so it also must know how to access a management node to obtain the cluster configuration data. The default behavior is to look for the management node on `localhost`. However, should you need to specify that its location is elsewhere, this can be done in `my.cnf`, or with the `mysql` client. Before the NDB storage engine can be used, at least one management node must be operational, as well as any desired data nodes.

For more information about `--ndbcluster` and other `mysqld` options specific to NDB Cluster, see [MySQL Server Options for NDB Cluster](#).

For general information about installing NDB Cluster, see [Section 23.3, "NDB Cluster Installation"](#).

23.4.1 Quick Test Setup of NDB Cluster

To familiarize you with the basics, we describe the simplest possible configuration for a functional NDB Cluster. After this, you should be able to design your desired setup from the information provided in the other relevant sections of this chapter.

First, you need to create a configuration directory such as `/var/lib/mysql-cluster`, by executing the following command as the system `root` user:

```
shell> mkdir /var/lib/mysql-cluster
```

In this directory, create a file named `config.ini` that contains the following information. Substitute appropriate values for `HostName` and `DataDir` as necessary for your system.

```
# file "config.ini" - showing minimal setup consisting of 1 data node,
# 1 management server, and 3 MySQL servers.
# The empty default sections are not required, and are shown only for
# the sake of completeness.
# Data nodes must provide a hostname but MySQL Servers are not required
# to do so.
# If you don't know the hostname for your machine, use localhost.
# The DataDir parameter also has a default value, but it is recommended to
# set it explicitly.
# Note: [db], [api], and [mgm] are aliases for [ndbd], [mysqld], and [ndb_mgmd],
# respectively. [db] is deprecated and should not be used in new installations.

[ndbd default]
NoOfReplicas= 1

[mysqld default]
[ndb_mgmd default]
[tcp default]

[ndb_mgmd]
HostName= myhost.example.com

[ndbd]
HostName= myhost.example.com
DataDir= /var/lib/mysql-cluster

[mysqld]
[mysqld]
[mysqld]
```

You can now start the `ndb_mgmd` management server. By default, it attempts to read the `config.ini` file in its current working directory, so change location into the directory where the file is located and then invoke `ndb_mgmd`:

```
shell> cd /var/lib/mysql-cluster
shell> ndb_mgmd
```

Then start a single data node by running `ndbd`:

```
shell> ndbd
```

By default, `ndbd` looks for the management server at `localhost` on port 1186.

Note

If you have installed MySQL from a binary tarball, you must to specify the path of the `ndb_mgmd` and `ndbd` servers explicitly. (Normally, these can be found in `/usr/local/mysql/bin.`)

Finally, change location to the MySQL data directory (usually `/var/lib/mysql` or `/usr/local/mysql/data`), and make sure that the `my.cnf` file contains the option necessary to enable the NDB storage engine:

```
[mysqld]
ndbcluster
```

You can now start the MySQL server as usual:

```
shell> mysqld_safe --user=mysql &
```

Wait a moment to make sure the MySQL server is running properly. If you see the notice `mysql ended`, check the server's `.err` file to find out what went wrong.

If all has gone well so far, you now can start using the cluster. Connect to the server and verify that the `NDBCLUSTER` storage engine is enabled:

```
shell> mysql
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 8.0.26

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SHOW ENGINES\G
...
***** 12. row *****
Engine: NDBCLUSTER
Support: YES
Comment: Clustered, fault-tolerant, memory-based tables
***** 13. row *****
Engine: NDB
Support: YES
Comment: Alias for NDBCLUSTER
...
```

The row numbers shown in the preceding example output may be different from those shown on your system, depending upon how your server is configured.

Try to create an `NDBCLUSTER` table:

```
shell> mysql
mysql> USE test;
Database changed

mysql> CREATE TABLE ctest (i INT) ENGINE=NDBCLUSTER;
Query OK, 0 rows affected (0.09 sec)

mysql> SHOW CREATE TABLE ctest \G
***** 1. row *****
      Table: ctest
Create Table: CREATE TABLE `ctest` (
  `i` int(11) default NULL
) ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

To check that your nodes were set up properly, start the management client:

```
shell> ndb_mgm
```

Use the `SHOW` command from within the management client to obtain a report on the cluster's status:

```
ndb_mgm> SHOW
Cluster Configuration
-----
[ndbd(NDB)]      1 node(s)
id=2      @127.0.0.1 (Version: 8.0.27-ndb-8.0.27, Nodegroup: 0, *)

[ndb_mgmd(MGM)] 1 node(s)
id=1      @127.0.0.1 (Version: 8.0.27-ndb-8.0.27)

[mysqld(API)]   3 node(s)
id=3      @127.0.0.1 (Version: 8.0.27-ndb-8.0.27)
id=4 (not connected, accepting connect from any host)
id=5 (not connected, accepting connect from any host)
```

At this point, you have successfully set up a working NDB Cluster. You can now store data in the cluster by using any table created with `ENGINE=NDBCLUSTER` or its alias `ENGINE=NDB`.

23.4.2 Overview of NDB Cluster Configuration Parameters, Options, and Variables

The next several sections provide summary tables of NDB Cluster node configuration parameters used in the `config.ini` file to govern various aspects of node behavior, as well as of options and variables read by `mysqld` from a `my.cnf` file or from the command line when run as an NDB Cluster process. Each of the node parameter tables lists the parameters for a given type (`ndbd`, `ndb_mgmd`, `mysqld`, `computer`, `tcp`, or `shm`). All tables include the data type for the parameter, option, or variable, as well as its default, minimum, and maximum values as applicable.

Considerations when restarting nodes. For node parameters, these tables also indicate what type of restart is required (node restart or system restart)—and whether the restart must be done with `--initial`—to change the value of a given configuration parameter. When performing a node restart or an initial node restart, all of the cluster's data nodes must be restarted in turn (also referred to as a *rolling restart*). It is possible to update cluster configuration parameters marked as `node` online—that is, without shutting down the cluster—in this fashion. An initial node restart requires restarting each `ndbd` process with the `--initial` option.

A system restart requires a complete shutdown and restart of the entire cluster. An initial system restart requires taking a backup of the cluster, wiping the cluster file system after shutdown, and then restoring from the backup following the restart.

In any cluster restart, all of the cluster's management servers must be restarted for them to read the updated configuration parameter values.

Important

Values for numeric cluster parameters can generally be increased without any problems, although it is advisable to do so progressively, making such adjustments in relatively small increments. Many of these can be increased online, using a rolling restart.

However, decreasing the values of such parameters—whether this is done using a node restart, node initial restart, or even a complete system restart of the cluster—is not to be undertaken lightly; it is recommended that you do so only

after careful planning and testing. This is especially true with regard to those parameters that relate to memory usage and disk space, such as `MaxNoOfTables`, `MaxNoOfOrderedIndexes`, and `MaxNoOfUniqueHashIndexes`. In addition, it is generally the case that configuration parameters relating to memory and disk usage can be raised using a simple node restart, but they require an initial node restart to be lowered.

Because some of these parameters can be used for configuring more than one type of cluster node, they may appear in more than one of the tables.

Note

`4294967039` often appears as a maximum value in these tables. This value is defined in the `NDBCLUSTER` sources as `MAX_INT_RNIL` and is equal to `0xFFFFFFFF`, or $2^{32} - 2^8 - 1$.

23.4.2.1 NDB Cluster Data Node Configuration Parameters

The listings in this section provide information about parameters used in the `[ndbd]` or `[ndbd default]` sections of a `config.ini` file for configuring NDB Cluster data nodes. For detailed descriptions and other additional information about each of these parameters, see [Section 23.4.3.6, “Defining NDB Cluster Data Nodes”](#).

These parameters also apply to `ndbmtd`, the multithreaded version of `ndbd`. A separate listing of parameters specific to `ndbmtd` follows.

- `Arbitration`: How arbitration should be performed to avoid split-brain issues in event of node failure.
- `ArbitrationTimeout`: Maximum time (milliseconds) database partition waits for arbitration signal.
- `BackupDataBufferSize`: Default size of databuffer for backup (in bytes).
- `BackupDataDir`: Path to where to store backups. Note that string `'/BACKUP'` is always appended to this setting, so that *effective* default is `FileSystemPath/BACKUP`.
- `BackupDiskWriteSpeedPct`: Sets percentage of data node's allocated maximum write speed (`MaxDiskWriteSpeed`) to reserve for LCPs when starting backup.
- `BackupLogBufferSize`: Default size of log buffer for backup (in bytes).
- `BackupMaxWriteSize`: Maximum size of file system writes made by backup (in bytes).
- `BackupMemory`: Total memory allocated for backups per node (in bytes).
- `BackupReportFrequency`: Frequency of backup status reports during backup in seconds.
- `BackupWriteSize`: Default size of file system writes made by backup (in bytes).
- `BatchSizePerLocalScan`: Used to calculate number of lock records for scan with hold lock.
- `BuildIndexThreads`: Number of threads to use for building ordered indexes during system or node restart. Also applies when running `ndb_restore --rebuild-indexes`. Setting this parameter to 0 disables multithreaded building of ordered indexes.
- `CompressedBackup`: Use `zlib` to compress backups as they are written.
- `CompressedLCP`: Write compressed LCPs using `zlib`.
- `ConnectCheckIntervalDelay`: Time between data node connectivity check stages. Data node is considered suspect after 1 interval and dead after 2 intervals with no response.

- `CrashOnCorruptedTuple`: When enabled, forces node to shut down whenever it detects corrupted tuple.
- `DataDir`: Data directory for this node.
- `DataMemory`: Number of bytes on each data node allocated for storing data; subject to available system RAM and size of `IndexMemory`.
- `DefaultHashMapSize`: Set size (in buckets) to use for table hash maps. Three values are supported: 0, 240, and 3840.
- `DictTrace`: Enable DBDICT debugging; for NDB development.
- `DiskDataUsingSameDisk`: Set to false if Disk Data tablespaces are located on separate physical disks.
- `DiskIOThreadPool`: Number of unbound threads for file access, applies to disk data only.
- `Diskless`: Run without using disk.
- `DiskPageBufferEntries`: Memory to allocate in `DiskPageBufferMemory`; very large disk transactions may require increasing this value.
- `DiskPageBufferMemory`: Number of bytes on each data node allocated for disk page buffer cache.
- `DiskSyncSize`: Amount of data written to file before synch is forced.
- `EnablePartialLcp`: Enable partial LCP (true); if this is disabled (false), all LCPs write full checkpoints.
- `EnableRedoControl`: Enable adaptive checkpointing speed for controlling redo log usage.
- `EventLogBufferSize`: Size of circular buffer for NDB log events within data nodes.
- `ExecuteOnComputer`: String referencing earlier defined COMPUTER.
- `ExtraSendBufferMemory`: Memory to use for send buffers in addition to any allocated by `TotalSendBufferMemory` or `SendBufferMemory`. Default (0) allows up to 16MB.
- `FileSystemPath`: Path to directory where data node stores its data (directory must exist).
- `FileSystemPathDataFiles`: Path to directory where data node stores its Disk Data files. Default value is `FileSystemPathDD`, if set; otherwise, `FileSystemPath` is used if it is set; otherwise, value of `DataDir` is used.
- `FileSystemPathDD`: Path to directory where data node stores its Disk Data and undo files. Default value is `FileSystemPath`, if set; otherwise, value of `DataDir` is used.
- `FileSystemPathUndoFiles`: Path to directory where data node stores its undo files for Disk Data. Default value is `FileSystemPathDD`, if set; otherwise, `FileSystemPath` is used if it is set; otherwise, value of `DataDir` is used.
- `FragmentLogFileSize`: Size of each redo log file.
- `HeartbeatIntervalDbApi`: Time between API node-data node heartbeats. (API connection closed after 3 missed heartbeats).
- `HeartbeatIntervalDbDb`: Time between data node-to-data node heartbeats; data node considered dead after 3 missed heartbeats.

- **HeartbeatOrder**: Sets order in which data nodes check each others' heartbeats for determining whether given node is still active and connected to cluster. Must be zero for all data nodes or distinct nonzero values for all data nodes; see documentation for further guidance.
- **HostName**: Host name or IP address for this data node.
- **IndexMemory**: Number of bytes on each data node allocated for storing indexes; subject to available system RAM and size of DataMemory.
- **IndexStatAutoCreate**: Enable/disable automatic statistics collection when indexes are created.
- **IndexStatAutoUpdate**: Monitor indexes for changes and trigger automatic statistics updates.
- **IndexStatSaveScale**: Scaling factor used in determining size of stored index statistics.
- **IndexStatSaveSize**: Maximum size in bytes for saved statistics per index.
- **IndexStatTriggerPct**: Threshold percent change in DML operations for index statistics updates. Value is scaled down by IndexStatTriggerScale.
- **IndexStatTriggerScale**: Scale down IndexStatTriggerPct by this amount, multiplied by base 2 logarithm of index size, for large index. Set to 0 to disable scaling.
- **IndexStatUpdateDelay**: Minimum delay between automatic index statistics updates for given index. 0 means no delay.
- **InitFragmentLogFiles**: Initialize fragment logfiles (sparse/full).
- **InitialLogFileGroup**: Describes log file group that is created during initial start. See documentation for format.
- **InitialNoOfOpenFiles**: Initial number of files open per data node. (One thread is created per file).
- **InitialTablespace**: Describes tablespace that is created during initial start. See documentation for format.
- **InsertRecoveryWork**: Percentage of RecoveryWork used for inserted rows; has no effect unless partial local checkpoints are in use.
- **LateAlloc**: Allocate memory after connection to management server has been established.
- **LcpScanProgressTimeout**: Maximum time that local checkpoint fragment scan can be stalled before node is shut down to ensure systemwide LCP progress. Use 0 to disable.
- **LockExecuteThreadToCPU**: Comma-delimited list of CPU IDs.
- **LockMaintThreadsToCPU**: CPU ID indicating which CPU runs maintenance threads.
- **LockPagesInMainMemory**: 0=disable locking, 1=lock after memory allocation, 2=lock before memory allocation.
- **LogLevelCheckpoint**: Log level of local and global checkpoint information printed to stdout.
- **LogLevelCongestion**: Level of congestion information printed to stdout.
- **LogLevelConnection**: Level of node connect/disconnect information printed to stdout.
- **LogLevelError**: Transporter, heartbeat errors printed to stdout.
- **LogLevelInfo**: Heartbeat and log information printed to stdout.

- [LogLevelNodeRestart](#): Level of node restart and node failure information printed to stdout.
- [LogLevelShutdown](#): Level of node shutdown information printed to stdout.
- [LogLevelStartup](#): Level of node startup information printed to stdout.
- [LogLevelStatistic](#): Level of transaction, operation, and transporter information printed to stdout.
- [LongMessageBuffer](#): Number of bytes allocated on each data node for internal long messages.
- [MaxAllocate](#): No longer used; has no effect.
- [MaxBufferedEpochs](#): Allowed number of epochs that subscribing node can lag behind (unprocessed epochs). Exceeding causes lagging subscribers to be disconnected.
- [MaxBufferedEpochBytes](#): Total number of bytes allocated for buffering epochs.
- [MaxDiskDataLatency](#): Maximum allowed mean latency of disk access (ms) before starting to abort transactions.
- [MaxDiskWriteSpeed](#): Maximum number of bytes per second that can be written by LCP and backup when no restarts are ongoing.
- [MaxDiskWriteSpeedOtherNodeRestart](#): Maximum number of bytes per second that can be written by LCP and backup when another node is restarting.
- [MaxDiskWriteSpeedOwnRestart](#): Maximum number of bytes per second that can be written by LCP and backup when this node is restarting.
- [MaxFKBuildBatchSize](#): Maximum scan batch size to use for building foreign keys. Increasing this value may speed up builds of foreign keys but impacts ongoing traffic as well.
- [MaxDMLOperationsPerTransaction](#): Limit size of transaction; aborts transaction if it requires more than this many DML operations. Set to 0 to disable.
- [MaxLCPStartDelay](#): Time in seconds that LCP polls for checkpoint mutex (to allow other data nodes to complete metadata synchronization), before putting itself in lock queue for parallel recovery of table data.
- [MaxNoOfAttributes](#): Suggests total number of attributes stored in database (sum over all tables).
- [MaxNoOfConcurrentIndexOperations](#): Total number of index operations that can execute simultaneously on one data node.
- [MaxNoOfConcurrentOperations](#): Maximum number of operation records in transaction coordinator.
- [MaxNoOfConcurrentScans](#): Maximum number of scans executing concurrently on data node.
- [MaxNoOfConcurrentSubOperations](#): Maximum number of concurrent subscriber operations.
- [MaxNoOfConcurrentTransactions](#): Maximum number of transactions executing concurrently on this data node, total number of transactions that can be executed concurrently is this value times number of data nodes in cluster.
- [MaxNoOfFiredTriggers](#): Total number of triggers that can fire simultaneously on one data node.
- [MaxNoOfLocalOperations](#): Maximum number of operation records defined on this data node.
- [MaxNoOfLocalScans](#): Maximum number of fragment scans in parallel on this data node.
- [MaxNoOfOpenFiles](#): Maximum number of files open per data node.(One thread is created per file).

- **MaxNoOfOrderedIndexes**: Total number of ordered indexes that can be defined in system.
- **MaxNoOfSavedMessages**: Maximum number of error messages to write in error log and maximum number of trace files to retain.
- **MaxNoOfSubscribers**: Maximum number of subscribers.
- **MaxNoOfSubscriptions**: Maximum number of subscriptions (default 0 = MaxNoOfTables).
- **MaxNoOfTables**: Suggests total number of NDB tables stored in database.
- **MaxNoOfTriggers**: Total number of triggers that can be defined in system.
- **MaxNoOfUniqueHashIndexes**: Total number of unique hash indexes that can be defined in system.
- **MaxParallelCopyInstances**: Number of parallel copies during node restarts. Default is 0, which uses number of LDMs on both nodes, to maximum of 16.
- **MaxParallelScansPerFragment**: Maximum number of parallel scans per fragment. Once this limit is reached, scans are serialized.
- **MaxReorgBuildBatchSize**: Maximum scan batch size to use for reorganization of table partitions. Increasing this value may speed up table partition reorganization but impacts ongoing traffic as well.
- **MaxStartFailRetries**: Maximum retries when data node fails on startup, requires StopOnError = 0. Setting to 0 causes start attempts to continue indefinitely.
- **MaxUIBuildBatchSize**: Maximum scan batch size to use for building unique keys. Increasing this value may speed up builds of unique keys but impacts ongoing traffic as well.
- **MemReportFrequency**: Frequency of memory reports in seconds; 0 = report only when exceeding percentage limits.
- **MinDiskWriteSpeed**: Minimum number of bytes per second that can be written by LCP and backup.
- **MinFreePct**: Percentage of memory resources to keep in reserve for restarts.
- **NodeGroup**: Node group to which data node belongs; used only during initial start of cluster.
- **NodeGroupTransporters**: Number of transporters to use between nodes in same node group.
- **NodeId**: Number uniquely identifying data node among all nodes in cluster.
- **NoOfFragmentLogFiles**: Number of 16 MB redo log files in each of 4 file sets belonging to data node.
- **NoOfReplicas**: Number of copies of all data in database.
- **Numa**: (Linux only; requires libnuma) Controls NUMA support. Setting to 0 permits system to determine use of interleaving by data node process; 1 means that it is determined by data node.
- **ODirect**: Use O_DIRECT file reads and writes when possible.
- **ODirectSyncFlag**: O_DIRECT writes are treated as synchronized writes; ignored when ODirect is not enabled, InitFragmentLogFiles is set to SPARSE, or both.
- **RealtimeScheduler**: When true, data node threads are scheduled as real-time threads. Default is false.
- **RecoveryWork**: Percentage of storage overhead for LCP files: greater value means less work in normal operations, more work during recovery.
- **RedoBuffer**: Number of bytes on each data node allocated for writing redo logs.

- [RedoOverCommitCounter](#): When RedoOverCommitLimit has been exceeded this many times, transactions are aborted, and operations are handled as specified by DefaultOperationRedoProblemAction.
- [RedoOverCommitLimit](#): Each time that flushing current redo buffer takes longer than this many seconds, number of times that this has happened is compared to RedoOverCommitCounter.
- [ReservedConcurrentIndexOperations](#): Number of simultaneous index operations having dedicated resources on one data node.
- [ReservedConcurrentOperations](#): Number of simultaneous operations having dedicated resources in transaction coordinators on one data node.
- [ReservedConcurrentScans](#): Number of simultaneous scans having dedicated resources on one data node.
- [ReservedConcurrentTransactions](#): Number of simultaneous transactions having dedicated resources on one data node.
- [ReservedFiredTriggers](#): Number of triggers having dedicated resources on one data node.
- [ReservedLocalScans](#): Number of simultaneous fragment scans having dedicated resources on one data node.
- [ReservedTransactionBufferMemory](#): Dynamic buffer space (in bytes) for key and attribute data allocated to each data node.
- [RestartOnErrorInsert](#): Control type of restart caused by inserting error (when StopOnError is enabled).
- [SchedulerExecutionTimer](#): Number of microseconds to execute in scheduler before sending.
- [SchedulerResponsiveness](#): Set NDB scheduler response optimization 0-10; higher values provide better response time but lower throughput.
- [SchedulerSpinTimer](#): Number of microseconds to execute in scheduler before sleeping.
- [ServerPort](#): Port used to set up transporter for incoming connections from API nodes.
- [SharedGlobalMemory](#): Total number of bytes on each data node allocated for any use.
- [SpinMethod](#): Determines spin method used by data node; see documentation for details.
- [StartFailRetryDelay](#): Delay in seconds after start failure prior to retry; requires StopOnError = 0.
- [StartFailureTimeout](#): Milliseconds to wait before terminating. (0=Wait forever).
- [StartNoNodeGroupTimeout](#): Time to wait for nodes without nodegroup before trying to start (0=forever).
- [StartPartialTimeout](#): Milliseconds to wait before trying to start without all nodes. (0=Wait forever).
- [StartPartitionedTimeout](#): Milliseconds to wait before trying to start partitioned. (0=Wait forever).
- [StartupStatusReportFrequency](#): Frequency of status reports during startup.
- [StopOnError](#): When set to 0, data node automatically restarts and recovers following node failures.
- [StringMemory](#): Default size of string memory (0 to 100 = % of maximum, 101+ = actual bytes).
- [TcpBind_INADDR_ANY](#): Bind IP_ADDR_ANY so that connections can be made from anywhere (for autogenerated connections).

- [TimeBetweenEpochs](#): Time between epochs (synchronization used for replication).
- [TimeBetweenEpochsTimeout](#): Timeout for time between epochs. Exceeding causes node shutdown.
- [TimeBetweenGlobalCheckpoints](#): Time between group commits of transactions to disk.
- [TimeBetweenGlobalCheckpointsTimeout](#): Minimum timeout for group commit of transactions to disk.
- [TimeBetweenInactiveTransactionAbortCheck](#): Time between checks for inactive transactions.
- [TimeBetweenLocalCheckpoints](#): Time between taking snapshots of database (expressed in base-2 logarithm of bytes).
- [TimeBetweenWatchDogCheck](#): Time between execution checks inside data node.
- [TimeBetweenWatchDogCheckInitial](#): Time between execution checks inside data node (early start phases when memory is allocated).
- [TotalSendBufferMemory](#): Total memory to use for all transporter send buffers..
- [TransactionBufferMemory](#): Dynamic buffer space (in bytes) for key and attribute data allocated for each data node.
- [TransactionDeadlockDetectionTimeout](#): Time transaction can spend executing within data node. This is time that transaction coordinator waits for each data node participating in transaction to execute request. If data node takes more than this amount of time, transaction is aborted.
- [TransactionInactiveTimeout](#): Milliseconds that application waits before executing another part of transaction. This is time transaction coordinator waits for application to execute or send another part (query, statement) of transaction. If application takes too much time, then transaction is aborted. Timeout = 0 means that application never times out.
- [TransactionMemory](#): Memory allocated for transactions on each data node.
- [TwoPassInitialNodeRestartCopy](#): Copy data in 2 passes during initial node restart, which enables multithreaded building of ordered indexes for such restarts.
- [UndoDataBuffer](#): Unused; has no effect.
- [UndoIndexBuffer](#): Unused; has no effect.
- [UseShm](#): Use shared memory connections between this data node and API node also running on this host.

The following parameters are specific to `ndbmt`:

- [AutomaticThreadConfig](#): Use automatic thread configuration; overrides any settings for `ThreadConfig` and `MaxNoOfExecutionThreads`.
- [ClassicFragmentation](#): When true, use traditional table fragmentation; set false to enable flexible distribution of table fragments among LDMs.
- [EnableMultithreadedBackup](#): Enable multi-threaded backup.
- [MaxNoOfExecutionThreads](#): For `ndbmt` only, specify maximum number of execution threads.
- [NoOfFragmentLogParts](#): Number of redo log file groups belonging to this data node.
- [NumCPUs](#): Specify number of CPUs to use with `AutomaticThreadConfig`.

- [PartitionsPerNode](#): Determines the number of table partitions created on each data node; not used if `ClassicFragmentation` is enabled.
- [ThreadConfig](#): Used for configuration of multithreaded data nodes (`ndbmysd`). Default is empty string; see documentation for syntax and other information.

23.4.2.2 NDB Cluster Management Node Configuration Parameters

The listing in this section provides information about parameters used in the `[ndb_mgmd]` or `[mgm]` section of a `config.ini` file for configuring NDB Cluster management nodes. For detailed descriptions and other additional information about each of these parameters, see [Section 23.4.3.5, “Defining an NDB Cluster Management Server”](#).

- [ArbitrationDelay](#): When asked to arbitrate, arbitrator waits this long before voting (milliseconds).
- [ArbitrationRank](#): If 0, then management node is not arbitrator. Kernel selects arbitrators in order 1, 2.
- [DataDir](#): Data directory for this node.
- [ExecuteOnComputer](#): String referencing earlier defined `COMPUTER`.
- [ExtraSendBufferMemory](#): Memory to use for send buffers in addition to any allocated by `TotalSendBufferMemory` or `SendBufferMemory`. Default (0) allows up to 16MB.
- [HeartbeatIntervalMgmdMgmd](#): Time between management-node-to-management-node heartbeats; connection between management nodes is considered lost after 3 missed heartbeats.
- [HeartbeatThreadPriority](#): Set heartbeat thread policy and priority for management nodes; see manual for allowed values.
- [HostName](#): Host name or IP address for this management node.
- [Id](#): Number identifying management node. Now deprecated; use `NodeId` instead.
- [LogDestination](#): Where to send log messages: console, system log, or specified log file.
- [NodeId](#): Number uniquely identifying management node among all nodes in cluster.
- [PortNumber](#): Port number to send commands to and fetch configuration from management server.
- [PortNumberStats](#): Port number used to get statistical information from management server.
- [TotalSendBufferMemory](#): Total memory to use for all transporter send buffers.
- [wan](#): Use WAN TCP setting as default.

Note

After making changes in a management node's configuration, it is necessary to perform a rolling restart of the cluster for the new configuration to take effect. See [Section 23.4.3.5, “Defining an NDB Cluster Management Server”](#), for more information.

To add new management servers to a running NDB Cluster, it is also necessary perform a rolling restart of all cluster nodes after modifying any existing `config.ini` files. For more information about issues arising when using multiple management nodes, see [Section 23.2.7.10, “Limitations Relating to Multiple NDB Cluster Nodes”](#).

23.4.2.3 NDB Cluster SQL Node and API Node Configuration Parameters

The listing in this section provides information about parameters used in the `[mysqld]` and `[api]` sections of a `config.ini` file for configuring NDB Cluster SQL nodes and API nodes. For detailed descriptions and other additional information about each of these parameters, see [Section 23.4.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”](#).

- `ApiVerbose`: Enable NDB API debugging; for NDB development.
- `ArbitrationDelay`: When asked to arbitrate, arbitrator waits this many milliseconds before voting.
- `ArbitrationRank`: If 0, then API node is not arbitrator. Kernel selects arbitrators in order 1, 2.
- `AutoReconnect`: Specifies whether an API node should reconnect fully when disconnected from cluster.
- `BatchByteSize`: Default batch size in bytes.
- `BatchSize`: Default batch size in number of records.
- `ConnectBackoffMaxTime`: Specifies longest time in milliseconds (~100ms resolution) to allow between connection attempts to any given data node by this API node. Excludes time elapsed while connection attempts are ongoing, which in worst case can take several seconds. Disable by setting to 0. If no data nodes are currently connected to this API node, `StartConnectBackoffMaxTime` is used instead.
- `ConnectionMap`: Specifies which data nodes to connect.
- `DefaultHashMapSize`: Set size (in buckets) to use for table hash maps. Three values are supported: 0, 240, and 3840.
- `DefaultOperationRedoProblemAction`: How operations are handled in event that `RedoOverCommitCounter` is exceeded.
- `ExecuteOnComputer`: String referencing earlier defined `COMPUTER`.
- `ExtraSendBufferMemory`: Memory to use for send buffers in addition to any allocated by `TotalSendBufferMemory` or `SendBufferMemory`. Default (0) allows up to 16MB.
- `HeartbeatThreadPriority`: Set heartbeat thread policy and priority for API nodes; see manual for allowed values.
- `HostName`: Host name or IP address for this SQL or API node.
- `Id`: Number identifying MySQL server or API node (Id). Now deprecated; use `NodeId` instead.
- `MaxScanBatchSize`: Maximum collective batch size for one scan.
- `NodeId`: Number uniquely identifying SQL node or API node among all nodes in cluster.
- `StartConnectBackoffMaxTime`: Same as `ConnectBackoffMaxTime` except that this parameter is used in its place if no data nodes are connected to this API node.
- `TotalSendBufferMemory`: Total memory to use for all transporter send buffers.
- `wan`: Use WAN TCP setting as default.

For a discussion of MySQL server options for NDB Cluster, see [MySQL Server Options for NDB Cluster](#). For information about MySQL server system variables relating to NDB Cluster, see [NDB Cluster System Variables](#).

**Note**

To add new SQL or API nodes to the configuration of a running NDB Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new `[mysqld]` or `[api]` sections to the `config.ini` file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.

It is *not* necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.

23.4.2.4 Other NDB Cluster Configuration Parameters

The listings in this section provide information about parameters used in the `[computer]`, `[tcp]`, and `[shm]` sections of a `config.ini` file for configuring NDB Cluster. For detailed descriptions and additional information about individual parameters, see [Section 23.4.3.10, “NDB Cluster TCP/IP Connections”](#), or [Section 23.4.3.12, “NDB Cluster Shared-Memory Connections”](#), as appropriate.

The following parameters apply to the `config.ini` file's `[computer]` section:

- `HostName`: Host name or IP address of this computer.
- `Id`: Unique identifier for this computer.

The following parameters apply to the `config.ini` file's `[tcp]` section:

- `AllowUnresolvedHostNames`: When false (default), failure by management node to resolve host name results in fatal error; when true, unresolved host names are reported as warnings only.
- `Checksum`: If checksum is enabled, all signals between nodes are checked for errors.
- `Group`: Used for group proximity; smaller value is interpreted as being closer.
- `HostName1`: Name or IP address of first of two computers joined by TCP connection.
- `HostName2`: Name or IP address of second of two computers joined by TCP connection.
- `NodeId1`: ID of node (data node, API node, or management node) on one side of connection.
- `NodeId2`: ID of node (data node, API node, or management node) on one side of connection.
- `NodeIdServer`: Set server side of TCP connection.
- `OverloadLimit`: When more than this many unsent bytes are in send buffer, connection is considered overloaded.
- `PreferIPVersion`: Indicate DNS resolver preference for IP version 4 or 6.
- `PreSendChecksum`: If this parameter and `Checksum` are both enabled, perform pre-send checksum checks, and check all TCP signals between nodes for errors.
- `Proxy`:
- `ReceiveBufferMemory`: Bytes of buffer for signals received by this node.
- `SendBufferMemory`: Bytes of TCP buffer for signals sent from this node.
- `SendSignalId`: Sends ID in each signal. Used in trace files. Defaults to true in debug builds.

- [TCP_MAXSEG_SIZE](#): Value used for TCP_MAXSEG.
- [TCP_RCV_BUF_SIZE](#): Value used for SO_RCVBUF.
- [TCP_SND_BUF_SIZE](#): Value used for SO_SNDBUF.
- [TcpBind_INADDR_ANY](#): Bind InAddrAny instead of host name for server part of connection.

The following parameters apply to the `config.ini` file's `[shm]` section:

- [Checksum](#): If checksum is enabled, all signals between nodes are checked for errors.
- [Group](#): Used for group proximity; smaller value is interpreted as being closer.
- [HostName1](#): Name or IP address of first of two computers joined by SHM connection.
- [HostName2](#): Name or IP address of second of two computers joined by SHM connection.
- [NodeId1](#): ID of node (data node, API node, or management node) on one side of connection.
- [NodeId2](#): ID of node (data node, API node, or management node) on one side of connection.
- [NodeIdServer](#): Set server side of SHM connection.
- [OverloadLimit](#): When more than this many unsend bytes are in send buffer, connection is considered overloaded.
- [PreSendChecksum](#): If this parameter and Checksum are both enabled, perform pre-send checksum checks, and check all SHM signals between nodes for errors.
- [SendBufferMemory](#): Bytes in shared memory buffer for signals sent from this node.
- [SendSignalId](#): Sends ID in each signal. Used in trace files.
- [ShmKey](#): Shared memory key; when set to 1, this is calculated by NDB.
- [ShmSpinTime](#): When receiving, number of microseconds to spin before sleeping.
- [ShmSize](#): Size of shared memory segment.
- [Signum](#): Signal number to be used for signalling.

23.4.2.5 NDB Cluster `mysqld` Option and Variable Reference

The following table provides a list of the command-line options, server and status variables applicable within `mysqld` when it is running as an SQL node in an NDB Cluster. For a table showing *all* command-line options, server and status variables available for use with `mysqld`, see [Section 5.1.4, “Server Option, System Variable, and Status Variable Reference”](#).

- [Com_show_ndb_status](#): Count of SHOW NDB STATUS statements.
- [Handler_discover](#): Number of times that tables have been discovered.
- [ndb-batch-size](#): Size (in bytes) to use for NDB transaction batches.
- [ndb-blob-read-batch-bytes](#): Specifies size in bytes that large BLOB reads should be batched into. 0 = no limit.
- [ndb-blob-write-batch-bytes](#): Specifies size in bytes that large BLOB writes should be batched into. 0 = no limit.
- [ndb-cluster-connection-pool](#): Number of connections to cluster used by MySQL.

- `ndb-cluster-connection-pool-nodeids`: Comma-separated list of node IDs for connections to cluster used by MySQL; number of nodes in list must match value set for `--ndb-cluster-connection-pool`.
- `ndb-connectstring`: Address of NDB management server distributing configuration information for this cluster.
- `ndb-default-column-format`: Use this value (FIXED or DYNAMIC) by default for COLUMN_FORMAT and ROW_FORMAT options when creating or adding table columns.
- `ndb-deferred-constraints`: Specifies that constraint checks on unique indexes (where these are supported) should be deferred until commit time. Not normally needed or used; for testing purposes only.
- `ndb-distribution`: Default distribution for new tables in NDBCLUSTER (KEYHASH or LINHASH, default is KEYHASH).
- `ndb-log-apply-status`: Cause MySQL server acting as replica to log `mysql.ndb_apply_status` updates received from its immediate source in its own binary log, using its own server ID. Effective only if server is started with `--ndbcluster` option.
- `ndb-log-empty-epochs`: When enabled, causes epochs in which there were no changes to be written to `ndb_apply_status` and `ndb_binlog_index` tables, even when `--log-slave-updates` is enabled.
- `ndb-log-empty-update`: When enabled, causes updates that produced no changes to be written to `ndb_apply_status` and `ndb_binlog_index` tables, even when `--log-slave-updates` is enabled.
- `ndb-log-exclusive-reads`: Log primary key reads with exclusive locks; allow conflict resolution based on read conflicts.
- `ndb-log-fail-terminate`: Terminate `mysqld` process if complete logging of all found row events is not possible.
- `ndb-log-orig`: Log originating server id and epoch in `mysql.ndb_binlog_index` table.
- `ndb-log-transaction-id`: Write NDB transaction IDs in binary log. Requires `--log-bin-v1-events=OFF`.
- `ndb-log-update-as-write`: Toggles logging of updates on source between updates (OFF) and writes (ON).
- `ndb-mgmd-host`: Set host (and port, if desired) for connecting to management server.
- `ndb-nodeid`: NDB Cluster node ID for this MySQL server.
- `ndb-optimized-node-selection`: Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.
- `ndb-transid-mysql-connection-map`: Enable or disable `ndb_transid_mysql_connection_map` plugin; that is, enable or disable INFORMATION_SCHEMA table having that name.
- `ndb-wait-connected`: Time (in seconds) for MySQL server to wait for connection to cluster management and data nodes before accepting MySQL client connections.
- `ndb-wait-setup`: Time (in seconds) for MySQL server to wait for NDB engine setup to complete.
- `ndb-allow-copying-alter-table`: Set to OFF to keep ALTER TABLE from using copying operations on NDB tables.
- `Ndb_api_adaptive_send_deferred_count`: Number of adaptive send calls not actually sent by this MySQL Server (SQL node).

- `Ndb_api_adaptive_send_deferred_count_session`: Number of adaptive send calls not actually sent in this client session.
- `Ndb_api_adaptive_send_deferred_count_replica`: Number of adaptive send calls not actually sent by this replica.
- `Ndb_api_adaptive_send_deferred_count_slave`: Number of adaptive send calls not actually sent by this replica.
- `Ndb_api_adaptive_send_forced_count`: Number of adaptive sends with forced-send set sent by this MySQL Server (SQL node).
- `Ndb_api_adaptive_send_forced_count_session`: Number of adaptive sends with forced-send set in this client session.
- `Ndb_api_adaptive_send_forced_count_replica`: Number of adaptive sends with forced-send set sent by this replica.
- `Ndb_api_adaptive_send_forced_count_slave`: Number of adaptive sends with forced-send set sent by this replica.
- `Ndb_api_adaptive_send_unforced_count`: Number of adaptive sends without forced-send sent by this MySQL Server (SQL node).
- `Ndb_api_adaptive_send_unforced_count_session`: Number of adaptive sends without forced-send in this client session.
- `Ndb_api_adaptive_send_unforced_count_replica`: Number of adaptive sends without forced-send sent by this replica.
- `Ndb_api_adaptive_send_unforced_count_slave`: Number of adaptive sends without forced-send sent by this replica.
- `Ndb_api_bytes_received_count`: Quantity of data (in bytes) received from data nodes by this MySQL Server (SQL node).
- `Ndb_api_bytes_received_count_session`: Quantity of data (in bytes) received from data nodes in this client session.
- `Ndb_api_bytes_received_count_replica`: Quantity of data (in bytes) received from data nodes by this replica.
- `Ndb_api_bytes_received_count_slave`: Quantity of data (in bytes) received from data nodes by this replica.
- `Ndb_api_bytes_sent_count`: Quantity of data (in bytes) sent to data nodes by this MySQL Server (SQL node).
- `Ndb_api_bytes_sent_count_session`: Quantity of data (in bytes) sent to data nodes in this client session.
- `Ndb_api_bytes_sent_count_replica`: Quantity of data (in bytes) sent to data nodes by this replica.
- `Ndb_api_bytes_sent_count_slave`: Quantity of data (in bytes) sent to data nodes by this replica.
- `Ndb_api_event_bytes_count`: Number of bytes of events received by this MySQL Server (SQL node).
- `Ndb_api_event_bytes_count_injector`: Number of bytes of event data received by NDB binary log injector thread.

- [Ndb_api_event_data_count](#): Number of row change events received by this MySQL Server (SQL node).
- [Ndb_api_event_data_count_injector](#): Number of row change events received by NDB binary log injector thread.
- [Ndb_api_event_nondata_count](#): Number of events received, other than row change events, by this MySQL Server (SQL node).
- [Ndb_api_event_nondata_count_injector](#): Number of events received, other than row change events, by NDB binary log injector thread.
- [Ndb_api_pk_op_count](#): Number of operations based on or using primary keys by this MySQL Server (SQL node).
- [Ndb_api_pk_op_count_session](#): Number of operations based on or using primary keys in this client session.
- [Ndb_api_pk_op_count_replica](#): Number of operations based on or using primary keys by this replica.
- [Ndb_api_pk_op_count_slave](#): Number of operations based on or using primary keys by this replica.
- [Ndb_api_pruned_scan_count](#): Number of scans that have been pruned to one partition by this MySQL Server (SQL node).
- [Ndb_api_pruned_scan_count_session](#): Number of scans that have been pruned to one partition in this client session.
- [Ndb_api_pruned_scan_count_replica](#): Number of scans that have been pruned to one partition by this replica.
- [Ndb_api_pruned_scan_count_slave](#): Number of scans that have been pruned to one partition by this replica.
- [Ndb_api_range_scan_count](#): Number of range scans that have been started by this MySQL Server (SQL node).
- [Ndb_api_range_scan_count_session](#): Number of range scans that have been started in this client session.
- [Ndb_api_range_scan_count_replica](#): Number of range scans that have been started by this replica.
- [Ndb_api_range_scan_count_slave](#): Number of range scans that have been started by this replica.
- [Ndb_api_read_row_count](#): Total number of rows that have been read by this MySQL Server (SQL node).
- [Ndb_api_read_row_count_session](#): Total number of rows that have been read in this client session.
- [Ndb_api_read_row_count_replica](#): Total number of rows that have been read by this replica.
- [Ndb_api_read_row_count_slave](#): Total number of rows that have been read by this replica.
- [Ndb_api_scan_batch_count](#): Number of batches of rows received by this MySQL Server (SQL node).
- [Ndb_api_scan_batch_count_session](#): Number of batches of rows received in this client session.

- `Ndb_api_scan_batch_count_replica`: Number of batches of rows received by this replica.
- `Ndb_api_scan_batch_count_slave`: Number of batches of rows received by this replica.
- `Ndb_api_table_scan_count`: Number of table scans that have been started, including scans of internal tables, by this MySQL Server (SQL node).
- `Ndb_api_table_scan_count_session`: Number of table scans that have been started, including scans of internal tables, in this client session.
- `Ndb_api_table_scan_count_replica`: Number of table scans that have been started, including scans of internal tables, by this replica.
- `Ndb_api_table_scan_count_slave`: Number of table scans that have been started, including scans of internal tables, by this replica.
- `Ndb_api_trans_abort_count`: Number of transactions aborted by this MySQL Server (SQL node).
- `Ndb_api_trans_abort_count_session`: Number of transactions aborted in this client session.
- `Ndb_api_trans_abort_count_replica`: Number of transactions aborted by this replica.
- `Ndb_api_trans_abort_count_slave`: Number of transactions aborted by this replica.
- `Ndb_api_trans_close_count`: Number of transactions aborted (may be greater than sum of `TransCommitCount` and `TransAbortCount`) by this MySQL Server (SQL node).
- `Ndb_api_trans_close_count_session`: Number of transactions aborted (may be greater than sum of `TransCommitCount` and `TransAbortCount`) in this client session.
- `Ndb_api_trans_close_count_replica`: Number of transactions aborted (may be greater than sum of `TransCommitCount` and `TransAbortCount`) by this replica.
- `Ndb_api_trans_close_count_slave`: Number of transactions aborted (may be greater than sum of `TransCommitCount` and `TransAbortCount`) by this replica.
- `Ndb_api_trans_commit_count`: Number of transactions committed by this MySQL Server (SQL node).
- `Ndb_api_trans_commit_count_session`: Number of transactions committed in this client session.
- `Ndb_api_trans_commit_count_replica`: Number of transactions committed by this replica.
- `Ndb_api_trans_commit_count_slave`: Number of transactions committed by this replica.
- `Ndb_api_trans_local_read_row_count`: Total number of rows that have been read by this MySQL Server (SQL node).
- `Ndb_api_trans_local_read_row_count_session`: Total number of rows that have been read in this client session.
- `Ndb_api_trans_local_read_row_count_replica`: Total number of rows that have been read by this replica.
- `Ndb_api_trans_local_read_row_count_slave`: Total number of rows that have been read by this replica.
- `Ndb_api_trans_start_count`: Number of transactions started by this MySQL Server (SQL node).
- `Ndb_api_trans_start_count_session`: Number of transactions started in this client session.

- [Ndb_api_trans_start_count_replica](#): Number of transactions started by this replica.
- [Ndb_api_trans_start_count_slave](#): Number of transactions started by this replica.
- [Ndb_api_uk_op_count](#): Number of operations based on or using unique keys by this MySQL Server (SQL node).
- [Ndb_api_uk_op_count_session](#): Number of operations based on or using unique keys in this client session.
- [Ndb_api_uk_op_count_replica](#): Number of operations based on or using unique keys by this replica.
- [Ndb_api_uk_op_count_slave](#): Number of operations based on or using unique keys by this replica.
- [Ndb_api_wait_exec_complete_count](#): Number of times thread has been blocked while waiting for operation execution to complete by this MySQL Server (SQL node).
- [Ndb_api_wait_exec_complete_count_session](#): Number of times thread has been blocked while waiting for operation execution to complete in this client session.
- [Ndb_api_wait_exec_complete_count_replica](#): Number of times thread has been blocked while waiting for operation execution to complete by this replica.
- [Ndb_api_wait_exec_complete_count_slave](#): Number of times thread has been blocked while waiting for operation execution to complete by this replica.
- [Ndb_api_wait_meta_request_count](#): Number of times thread has been blocked waiting for metadata-based signal by this MySQL Server (SQL node).
- [Ndb_api_wait_meta_request_count_session](#): Number of times thread has been blocked waiting for metadata-based signal in this client session.
- [Ndb_api_wait_meta_request_count_replica](#): Number of times thread has been blocked waiting for metadata-based signal by this replica.
- [Ndb_api_wait_meta_request_count_slave](#): Number of times thread has been blocked waiting for metadata-based signal by this replica.
- [Ndb_api_wait_nanos_count](#): Total time (in nanoseconds) spent waiting for some type of signal from data nodes by this MySQL Server (SQL node).
- [Ndb_api_wait_nanos_count_session](#): Total time (in nanoseconds) spent waiting for some type of signal from data nodes in this client session.
- [Ndb_api_wait_nanos_count_replica](#): Total time (in nanoseconds) spent waiting for some type of signal from data nodes by this replica.
- [Ndb_api_wait_nanos_count_slave](#): Total time (in nanoseconds) spent waiting for some type of signal from data nodes by this replica.
- [Ndb_api_wait_scan_result_count](#): Number of times thread has been blocked while waiting for scan-based signal by this MySQL Server (SQL node).
- [Ndb_api_wait_scan_result_count_session](#): Number of times thread has been blocked while waiting for scan-based signal in this client session.
- [Ndb_api_wait_scan_result_count_replica](#): Number of times thread has been blocked while waiting for scan-based signal by this replica.

- `Ndb_api_wait_scan_result_count_slave`: Number of times thread has been blocked while waiting for scan-based signal by this replica.
- `ndb_autoincrement_prefetch_sz`: NDB auto-increment prefetch size.
- `ndb_cache_check_time`: Number of milliseconds between checks of cluster SQL nodes made by MySQL query cache.
- `ndb_clear_apply_status`: Causes RESET SLAVE/RESET REPLICA to clear all rows from `ndb_apply_status` table; ON by default.
- `Ndb_cluster_node_id`: Node ID of this server when acting as NDB Cluster SQL node.
- `Ndb_config_from_host`: NDB Cluster management server host name or IP address.
- `Ndb_config_from_port`: Port for connecting to NDB Cluster management server.
- `Ndb_config_generation`: Generation number of the current configuration of the cluster.
- `Ndb_conflict_fn_epoch`: Number of rows that have been found in conflict by `NDB$EPOCH()` conflict detection function.
- `Ndb_conflict_fn_epoch2`: Number of rows that have been found in conflict by `NDB$EPOCH2()` conflict detection function.
- `Ndb_conflict_fn_epoch2_trans`: Number of rows that have been found in conflict by `NDB$EPOCH2_TRANS()` conflict detection function.
- `Ndb_conflict_fn_epoch_trans`: Number of rows that have been found in conflict by `NDB$EPOCH_TRANS()` conflict detection function.
- `Ndb_conflict_fn_max`: Number of times that conflict resolution based on "greater timestamp wins" has been applied when server is part of an NDB Cluster involved in cluster replication.
- `Ndb_conflict_fn_old`: Number of times that "same timestamp wins" conflict resolution has been applied when this server is part of an NDB Cluster involved in cluster replication.
- `Ndb_conflict_last_conflict_epoch`: Most recent NDB epoch on this replica in which some conflict was detected.
- `Ndb_conflict_last_stable_epoch`: Number of rows found to be in conflict by transactional conflict function.
- `Ndb_conflict_reflected_op_discard_count`: Number of reflected operations that were not applied due error during execution.
- `Ndb_conflict_reflected_op_prepare_count`: Number of reflected operations received that have been prepared for execution.
- `Ndb_conflict_refresh_op_count`: Number of refresh operations that have been prepared.
- `ndb_conflict_role`: Role for replica to play in conflict detection and resolution. Value is one of PRIMARY, SECONDARY, PASS, or NONE (default). Can be changed only when replication SQL thread is stopped. See documentation for further information.
- `Ndb_conflict_trans_conflict_commit_count`: Number of epoch transactions committed after requiring transactional conflict handling.
- `Ndb_conflict_trans_detect_iter_count`: Number of internal iterations required to commit epoch transaction. Should be (slightly) greater than or equal to `Ndb_conflict_trans_conflict_commit_count`.

- `Ndb_conflict_trans_reject_count`: Number of transactions rejected after being found in conflict by transactional conflict function.
- `Ndb_conflict_trans_row_conflict_count`: Number of rows found in conflict by transactional conflict function. Includes any rows included in or dependent on conflicting transactions.
- `Ndb_conflict_trans_row_reject_count`: Total number of rows realigned after being found in conflict by transactional conflict function. Includes `Ndb_conflict_trans_row_conflict_count` and any rows included in or dependent on conflicting transactions.
- `ndb_data_node_neighbour`: Specifies cluster data node "closest" to this MySQL Server, for transaction hinting and fully replicated tables.
- `ndb_default_column_format`: Sets default row format and column format (FIXED or DYNAMIC) used for new NDB tables.
- `ndb_deferred_constraints`: Specifies that constraint checks should be deferred (where these are supported). Not normally needed or used; for testing purposes only.
- `ndb_dbg_check_shares`: Check for any lingering shares (debug builds only).
- `ndb-schema-dist-timeout`: How long to wait before detecting timeout during schema distribution.
- `ndb_distribution`: Default distribution for new tables in NDBCLUSTER (KEYHASH or LINHASH, default is KEYHASH).
- `Ndb_epoch_delete_delete_count`: Number of delete-delete conflicts detected (delete operation is applied, but row does not exist).
- `ndb_eventbuffer_free_percent`: Percentage of free memory that should be available in event buffer before resumption of buffering, after reaching limit set by `ndb_eventbuffer_max_alloc`.
- `ndb_eventbuffer_max_alloc`: Maximum memory that can be allocated for buffering events by NDB API. Defaults to 0 (no limit).
- `Ndb_execute_count`: Number of round trips to NDB kernel made by operations.
- `ndb_extra_logging`: Controls logging of NDB Cluster schema, connection, and data distribution events in MySQL error log.
- `ndb_force_send`: Forces sending of buffers to NDB immediately, without waiting for other threads.
- `ndb_fully_replicated`: Whether new NDB tables are fully replicated.
- `ndb_index_stat_enable`: Use NDB index statistics in query optimization.
- `ndb_index_stat_option`: Comma-separated list of tunable options for NDB index statistics; list should contain no spaces.
- `ndb_join_pushdown`: Enables pushing down of joins to data nodes.
- `Ndb_last_commit_epoch_server`: Epoch most recently committed by NDB.
- `Ndb_last_commit_epoch_session`: Epoch most recently committed by this NDB client.
- `ndb_log_apply_status`: Whether or not MySQL server acting as replica logs `mysql.ndb_apply_status` updates received from its immediate source in its own binary log, using its own server ID.
- `ndb_log_bin`: Write updates to NDB tables in binary log. Effective only if binary logging is enabled with `--log-bin`.

- `ndb_log_binlog_index`: Insert mapping between epochs and binary log positions into `ndb_binlog_index` table. Defaults to ON. Effective only if binary logging is enabled.
- `ndb_log_empty_epochs`: When enabled, epochs in which there were no changes are written to `ndb_apply_status` and `ndb_binlog_index` tables, even when `log_replica_updates` or `log_slave_updates` is enabled.
- `ndb_log_empty_update`: When enabled, updates which produce no changes are written to `ndb_apply_status` and `ndb_binlog_index` tables, even when `log_replica_updates` or `log_slave_updates` is enabled.
- `ndb_log_exclusive_reads`: Log primary key reads with exclusive locks; allow conflict resolution based on read conflicts.
- `ndb_log_orig`: Whether id and epoch of originating server are recorded in `mysql.ndb_binlog_index` table. Set using `--ndb-log-orig` option when starting mysqld.
- `ndb_log_transaction_id`: Whether NDB transaction IDs are written into binary log (Read-only).
- `ndb-log-update-minimal`: Log updates in minimal format.
- `ndb-log-updated-only`: Log complete rows (ON) or updates only (OFF).
- `ndb_metadata_check`: Enable auto-detection of NDB metadata changes with respect to MySQL data dictionary; enabled by default.
- `Ndb_metadata_blacklist_size`: Number of NDB metadata objects that NDB binlog thread has failed to synchronize; renamed in NDB 8.0.22 as `Ndb_metadata_excluded_count`.
- `ndb_metadata_check_interval`: Interval in seconds to perform check for NDB metadata changes with respect to MySQL data dictionary.
- `Ndb_metadata_detected_count`: Number of times NDB metadata change monitor thread has detected changes.
- `Ndb_metadata_excluded_count`: Number of NDB metadata objects that NDB binlog thread has failed to synchronize.
- `ndb_metadata_sync`: Triggers immediate synchronization of all changes between NDB dictionary and MySQL data dictionary; causes `ndb_metadata_check` and `ndb_metadata_check_interval` values to be ignored. Resets to false when synchronization is complete.
- `Ndb_metadata_synced_count`: Number of NDB metadata objects which have been synchronized.
- `Ndb_number_of_data_nodes`: Number of data nodes in this NDB cluster; set only if server participates in cluster.
- `ndb-optimization-delay`: Number of milliseconds to wait between processing sets of rows by `OPTIMIZE TABLE` on NDB tables.
- `ndb_optimized_node_selection`: Determines how SQL node chooses cluster data node to use as transaction coordinator.
- `Ndb_pruned_scan_count`: Number of scans executed by NDB since cluster was last started where partition pruning could be used.
- `Ndb_pushed_queries_defined`: Number of joins that API nodes have attempted to push down to data nodes.
- `Ndb_pushed_queries_dropped`: Number of joins that API nodes have tried to push down, but failed.

- [Ndb_pushed_queries_executed](#): Number of joins successfully pushed down and executed on data nodes.
- [Ndb_pushed_reads](#): Number of reads executed on data nodes by pushed-down joins.
- [ndb_read_backup](#): Enable read from any replica for all NDB tables; use `NDB_TABLE=READ_BACKUP={0|1}` with `CREATE TABLE` or `ALTER TABLE` to enable or disable for individual NDB tables.
- [ndb_recv_thread_activation_threshold](#): Activation threshold when receive thread takes over polling of cluster connection (measured in concurrently active threads).
- [ndb_recv_thread_cpu_mask](#): CPU mask for locking receiver threads to specific CPUs; specified as hexadecimal. See documentation for details.
- [Ndb_replica_max_replicated_epoch](#): Most recently committed NDB epoch on this replica. When this value is greater than or equal to `Ndb_conflict_last_conflict_epoch`, no conflicts have yet been detected.
- [ndb_report_thresh_binlog_epoch_slip](#): NDB 7.5.4 and later: Threshold for number of epochs completely buffered, but not yet consumed by binlog injector thread which when exceeded generates `BUFFERED_EPOCHS_OVER_THRESHOLD` event buffer status message; prior to NDB 7.5.4: Threshold for number of epochs to lag behind before reporting binary log status.
- [ndb_report_thresh_binlog_mem_usage](#): Threshold for percentage of free memory remaining before reporting binary log status.
- [ndb_row_checksum](#): When enabled, set row checksums; enabled by default.
- [Ndb_scan_count](#): Total number of scans executed by NDB since cluster was last started.
- [ndb_schema_dist_lock_wait_timeout](#): Time during schema distribution to wait for lock before returning error.
- [ndb_schema_dist_timeout](#): Time to wait before detecting timeout during schema distribution.
- [ndb_schema_dist_upgrade_allowed](#): Allow schema distribution table upgrade when connecting to NDB.
- [ndb_show_foreign_key_mock_tables](#): Show mock tables used to support `foreign_key_checks=0`.
- [ndb_slave_conflict_role](#): Role for replica to play in conflict detection and resolution. Value is one of `PRIMARY`, `SECONDARY`, `PASS`, or `NONE` (default). Can be changed only when replication SQL thread is stopped. See documentation for further information.
- [Ndb_slave_max_replicated_epoch](#): Most recently committed NDB epoch on this replica. When this value is greater than or equal to `Ndb_conflict_last_conflict_epoch`, no conflicts have yet been detected.
- [Ndb_system_name](#): Configured cluster system name; empty if server not connected to NDB.
- [ndb_table_no_logging](#): NDB tables created when this setting is enabled are not checkpointed to disk (although table schema files are created). Setting in effect when table is created with or altered to use `NDBCLUSTER` persists for table's lifetime.
- [ndb_table_temporary](#): NDB tables are not persistent on disk: no schema files are created and tables are not logged.
- [Ndb_trans_hint_count_session](#): Number of transactions using hints that have been started in this session.

- `ndb_use_copying_alter_table`: Use copying ALTER TABLE operations in NDB Cluster.
- `ndb_use_exact_count`: Use exact row count when planning queries.
- `ndb_use_transactions`: Forces NDB to use a count of records during SELECT COUNT(*) query planning to speed up this type of query.
- `ndb_version`: Shows build and NDB engine version as an integer.
- `ndb_version_string`: Shows build information including NDB engine version in ndb-x.y.z format.
- `ndbcluster`: Enable NDB Cluster (if this version of MySQL supports it). Disabled by `--skip-ndbcluster`.
- `ndbinfo`: Enable ndbinfo plugin, if supported.
- `ndbinfo_database`: Name used for NDB information database; read only.
- `ndbinfo_max_bytes`: Used for debugging only.
- `ndbinfo_max_rows`: Used for debugging only.
- `ndbinfo_offline`: Put ndbinfo database into offline mode, in which no rows are returned from tables or views.
- `ndbinfo_show_hidden`: Whether to show ndbinfo internal base tables in mysql client; default is OFF.
- `ndbinfo_table_prefix`: Prefix to use for naming ndbinfo internal base tables; read only.
- `ndbinfo_version`: ndbinfo engine version; read only.
- `replica_allow_batching`: Turns update batching on and off for replica.
- `server_id_bits`: Number of least significant bits in server_id actually used for identifying server, permitting NDB API applications to store application data in most significant bits. server_id must be less than 2 to power of this value.
- `skip-ndbcluster`: Disable NDB Cluster storage engine.
- `slave_allow_batching`: Turns update batching on and off for replica.
- `transaction_allow_batching`: Allows batching of statements within one transaction. Disable AUTOCOMMIT to use.

23.4.3 NDB Cluster Configuration Files

Configuring NDB Cluster requires working with two files:

- `my.cnf`: Specifies options for all NDB Cluster executables. This file, with which you should be familiar with from previous work with MySQL, must be accessible by each executable running in the cluster.
- `config.ini`: This file, sometimes known as the *global configuration file*, is read only by the NDB Cluster management server, which then distributes the information contained therein to all processes participating in the cluster. `config.ini` contains a description of each node involved in the cluster. This includes configuration parameters for data nodes and configuration parameters for connections between all nodes in the cluster. For a quick reference to the sections that can appear in this file, and what sorts of configuration parameters may be placed in each section, see [Sections of the config.ini File](#).

Caching of configuration data. NDB uses *stateful configuration*. Rather than reading the global configuration file every time the management server is restarted, the management server caches the

configuration the first time it is started, and thereafter, the global configuration file is read only when one of the following conditions is true:

- **The management server is started using the `--initial` option.** When `--initial` is used, the global configuration file is re-read, any existing cache files are deleted, and the management server creates a new configuration cache.
- **The management server is started using the `--reload` option.** The `--reload` option causes the management server to compare its cache with the global configuration file. If they differ, the management server creates a new configuration cache; any existing configuration cache is preserved, but not used. If the management server's cache and the global configuration file contain the same configuration data, then the existing cache is used, and no new cache is created.
- **The management server is started using `--config-cache=FALSE`.** This disables `--config-cache` (enabled by default), and can be used to force the management server to bypass configuration caching altogether. In this case, the management server ignores any configuration files that may be present, always reading its configuration data from the `config.ini` file instead.
- **No configuration cache is found.** In this case, the management server reads the global configuration file and creates a cache containing the same configuration data as found in the file.

Configuration cache files. The management server by default creates configuration cache files in a directory named `mysql-cluster` in the MySQL installation directory. (If you build NDB Cluster from source on a Unix system, the default location is `/usr/local/mysql-cluster`.) This can be overridden at runtime by starting the management server with the `--configdir` option. Configuration cache files are binary files named according to the pattern `ndb_node_id_config.bin.seq_id`, where `node_id` is the management server's node ID in the cluster, and `seq_id` is a cache identifier. Cache files are numbered sequentially using `seq_id`, in the order in which they are created. The management server uses the latest cache file as determined by the `seq_id`.

Note

It is possible to roll back to a previous configuration by deleting later configuration cache files, or by renaming an earlier cache file so that it has a higher `seq_id`. However, since configuration cache files are written in a binary format, you should not attempt to edit their contents by hand.

For more information about the `--configdir`, `--config-cache`, `--initial`, and `--reload` options for the NDB Cluster management server, see [Section 23.5.4, “ndb_mgmd — The NDB Cluster Management Server Daemon”](#).

We are continuously making improvements in NDB Cluster configuration and attempting to simplify this process. Although we strive to maintain backward compatibility, there may be times when introduce an incompatible change. In such cases we try to let NDB Cluster users know in advance if a change is not backward compatible. If you find such a change and we have not documented it, please report it in the MySQL bugs database using the instructions given in [Section 1.6, “How to Report Bugs or Problems”](#).

23.4.3.1 NDB Cluster Configuration: Basic Example

To support NDB Cluster, you should update `my.cnf` as shown in the following example. You may also specify these parameters on the command line when invoking the executables.

Note

The options shown here should not be confused with those that are used in `config.ini` global configuration files. Global configuration options are discussed later in this section.

```
# my.cnf
# example additions to my.cnf for NDB Cluster
# (valid in MySQL 8.0)

# enable ndbcluster storage engine, and provide connection string for
# management server host (default port is 1186)
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com

# provide connection string for management server host (default port: 1186)
[ndbd]
connect-string=ndb_mgmd.mysql.com

# provide connection string for management server host (default port: 1186)
[ndb_mgm]
connect-string=ndb_mgmd.mysql.com

# provide location of cluster configuration file
# IMPORTANT: When starting the management server with this option in the
# configuration file, the use of --initial or --reload on the command line when
# invoking ndb_mgmd is also required.
[ndb_mgmd]
config-file=/etc/config.ini
```

(For more information on connection strings, see [Section 23.4.3.3, “NDB Cluster Connection Strings”](#).)

```
# my.cnf
# example additions to my.cnf for NDB Cluster
# (works on all versions)

# enable ndbcluster storage engine, and provide connection string for management
# server host to the default port 1186
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

Important

Once you have started a `mysqld` process with the `NDBCLUSTER` and `ndb-connectstring` parameters in the `[mysqld]` in the `my.cnf` file as shown previously, you cannot execute any `CREATE TABLE` or `ALTER TABLE` statements without having actually started the cluster. Otherwise, these statements fail with an error. *This is by design.*

You may also use a separate `[mysql_cluster]` section in the cluster `my.cnf` file for settings to be read and used by all executables:

```
# cluster-specific settings
[mysql_cluster]
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

For additional [NDB](#) variables that can be set in the `my.cnf` file, see [NDB Cluster System Variables](#).

The NDB Cluster global configuration file is by convention named `config.ini` (but this is not required). If needed, it is read by `ndb_mgmd` at startup and can be placed in any location that can be read by it. The location and name of the configuration are specified using `--config-file=path_name` with `ndb_mgmd` on the command line. This option has no default value, and is ignored if `ndb_mgmd` uses the configuration cache.

The global configuration file for NDB Cluster uses INI format, which consists of sections preceded by section headings (surrounded by square brackets), followed by the appropriate parameter names and

values. One deviation from the standard INI format is that the parameter name and value can be separated by a colon (:) as well as the equal sign (=); however, the equal sign is preferred. Another deviation is that sections are not uniquely identified by section name. Instead, unique sections (such as two different nodes of the same type) are identified by a unique ID specified as a parameter within the section.

Default values are defined for most parameters, and can also be specified in `config.ini`. To create a default value section, simply add the word `default` to the section name. For example, an `[ndbd]` section contains parameters that apply to a particular data node, whereas an `[ndbd default]` section contains parameters that apply to all data nodes. Suppose that all data nodes should use the same data memory size. To configure them all, create an `[ndbd default]` section that contains a `DataMemory` line to specify the data memory size.

If used, the `[ndbd default]` section must precede any `[ndbd]` sections in the configuration file. This is also true for `default` sections of any other type.

Note

In some older releases of NDB Cluster, there was no default value for `NoOfReplicas`, which always had to be specified explicitly in the `[ndbd default]` section. Although this parameter now has a default value of 2, which is the recommended setting in most common usage scenarios, it is still recommended practice to set this parameter explicitly.

The global configuration file must define the computers and nodes involved in the cluster and on which computers these nodes are located. An example of a simple configuration file for a cluster consisting of one management server, two data nodes and two MySQL servers is shown here:

```
# file "config.ini" - 2 data nodes and 2 SQL nodes
# This file is placed in the startup directory of ndb_mgmd (the
# management server)
# The first MySQL Server can be started from any host. The second
# can be started only on the host mysqld_5.mysql.com

[ndbd default]
NoOfReplicas= 2
DataDir= /var/lib/mysql-cluster

[ndb_mgmd]
Hostname= ndb_mgmd.mysql.com
DataDir= /var/lib/mysql-cluster

[ndbd]
HostName= ndbd_2.mysql.com

[ndbd]
HostName= ndbd_3.mysql.com

[mysqld]
[mysqld]
HostName= mysqld_5.mysql.com
```

Note

The preceding example is intended as a minimal starting configuration for purposes of familiarization with NDB Cluster, and is almost certain not to be sufficient for production settings. See [Section 23.4.3.2, “Recommended Starting Configuration for NDB Cluster”](#), which provides a more complete example starting configuration.

Each node has its own section in the `config.ini` file. For example, this cluster has two data nodes, so the preceding configuration file contains two `[ndbd]` sections defining these nodes.

**Note**

Do not place comments on the same line as a section heading in the `config.ini` file; this causes the management server not to start because it cannot parse the configuration file in such cases.

Sections of the config.ini File

There are six different sections that you can use in the `config.ini` configuration file, as described in the following list:

- `[computer]`: Defines cluster hosts. This is not required to configure a viable NDB Cluster, but be may used as a convenience when setting up a large cluster. See [Section 23.4.3.4, “Defining Computers in an NDB Cluster”](#), for more information.
- `[ndbd]`: Defines a cluster data node (`ndbd` process). See [Section 23.4.3.6, “Defining NDB Cluster Data Nodes”](#), for details.
- `[mysqld]`: Defines the cluster's MySQL server nodes (also called SQL or API nodes). For a discussion of SQL node configuration, see [Section 23.4.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”](#).
- `[mgm]` or `[ndb_mgmd]`: Defines a cluster management server (MGM) node. For information concerning the configuration of management nodes, see [Section 23.4.3.5, “Defining an NDB Cluster Management Server”](#).
- `[tcp]`: Defines a TCP/IP connection between cluster nodes, with TCP/IP being the default transport protocol. Normally, `[tcp]` or `[tcp default]` sections are not required to set up an NDB Cluster, as the cluster handles this automatically; however, it may be necessary in some situations to override the defaults provided by the cluster. See [Section 23.4.3.10, “NDB Cluster TCP/IP Connections”](#), for information about available TCP/IP configuration parameters and how to use them. (You may also find [Section 23.4.3.11, “NDB Cluster TCP/IP Connections Using Direct Connections”](#) to be of interest in some cases.)
- `[shm]`: Defines shared-memory connections between nodes. In MySQL 8.0, it is enabled by default, but should still be considered experimental. For a discussion of SHM interconnects, see [Section 23.4.3.12, “NDB Cluster Shared-Memory Connections”](#).
- `[sci]`: Defines Scalable Coherent Interface connections between cluster data nodes. Not supported in NDB 8.0.

You can define `default` values for each section. If used, a `default` section should come before any other sections of that type. For example, an `[ndbd default]` section should appear in the configuration file before any `[ndbd]` sections.

NDB Cluster parameter names are case-insensitive, unless specified in MySQL Server `my.cnf` or `my.ini` files.

23.4.3.2 Recommended Starting Configuration for NDB Cluster

Achieving the best performance from an NDB Cluster depends on a number of factors including the following:

- NDB Cluster software version
- Numbers of data nodes and SQL nodes
- Hardware

- Operating system
- Amount of data to be stored
- Size and type of load under which the cluster is to operate

Therefore, obtaining an optimum configuration is likely to be an iterative process, the outcome of which can vary widely with the specifics of each NDB Cluster deployment. Changes in configuration are also likely to be indicated when changes are made in the platform on which the cluster is run, or in applications that use the NDB Cluster's data. For these reasons, it is not possible to offer a single configuration that is ideal for all usage scenarios. However, in this section, we provide a recommended base configuration.

Starting config.ini file. The following `config.ini` file is a recommended starting point for configuring a cluster running NDB Cluster 8.0:

```
# TCP PARAMETERS

[tcp default]
SendBufferMemory=2M
ReceiveBufferMemory=2M

# Increasing the sizes of these 2 buffers beyond the default values
# helps prevent bottlenecks due to slow disk I/O.

# MANAGEMENT NODE PARAMETERS

[ndb_mgmd default]
DataDir=path/to/management/server/data/directory

# It is possible to use a different data directory for each management
# server, but for ease of administration it is preferable to be
# consistent.

[ndb_mgmd]
HostName=management-server-A-hostname
# NodeId=management-server-A-nodeid

[ndb_mgmd]
HostName=management-server-B-hostname
# NodeId=management-server-B-nodeid

# Using 2 management servers helps guarantee that there is always an
# arbitrator in the event of network partitioning, and so is
# recommended for high availability. Each management server must be
# identified by a HostName. You may for the sake of convenience specify
# a NodeId for any management server, although one is allocated
# for it automatically; if you do so, it must be in the range 1-255
# inclusive and must be unique among all IDs specified for cluster
# nodes.

# DATA NODE PARAMETERS

[ndbd default]
NoOfReplicas=2

# Using two fragment replicas is recommended to guarantee availability of data;
# using only one fragment replica does not provide any redundancy, which means
# that the failure of a single data node causes the entire cluster to shut down.
# It is also possible (but not required) in NDB 8.0 to use more than two
# fragment replicas, although two fragment replicas are sufficient to provide
# high availability.

LockPagesInMainMemory=1

# On Linux and Solaris systems, setting this parameter locks data node
```

NDB Cluster Configuration Files

```
# processes into memory. Doing so prevents them from swapping to disk,
# which can severely degrade cluster performance.

DataMemory=3456M

# The value provided for DataMemory assumes 4 GB RAM
# per data node. However, for best results, you should first calculate
# the memory that would be used based on the data you actually plan to
# store (you may find the ndb_size.pl utility helpful in estimating
# this), then allow an extra 20% over the calculated values. Naturally,
# you should ensure that each data node host has at least as much
# physical memory as the sum of these two values.

# ODirect=1

# Enabling this parameter causes NDBCLUSTER to try using O_DIRECT
# writes for local checkpoints and redo logs; this can reduce load on
# CPUs. We recommend doing so when using NDB Cluster on systems running
# Linux kernel 2.6 or later.

NoOfFragmentLogFiles=300
DataDir=path/to/data/node/data/directory
MaxNoOfConcurrentOperations=100000

SchedulerSpinTimer=400
SchedulerExecutionTimer=100
RealTimeScheduler=1
# Setting these parameters allows you to take advantage of real-time scheduling
# of NDB threads to achieve increased throughput when using ndbd. They
# are not needed when using ndbmtd; in particular, you should not set
# RealTimeScheduler for ndbmtd data nodes.

TimeBetweenGlobalCheckpoints=1000
TimeBetweenEpochs=200
RedoBuffer=32M

# CompressedLCP=1
# CompressedBackup=1
# Enabling CompressedLCP and CompressedBackup causes, respectively, local
# checkpoint files and backup files to be compressed, which can result in a space
# savings of up to 50% over noncompressed LCPs and backups.

# MaxNoOfLocalScans=64
MaxNoOfTables=1024
MaxNoOfOrderedIndexes=256

[ndbd]
HostName=data-node-A-hostname
# NodeId=data-node-A-nodeid

LockExecuteThreadToCPU=1
LockMaintThreadsToCPU=0
# On systems with multiple CPUs, these parameters can be used to lock NDBCLUSTER
# threads to specific CPUs

[ndbd]
HostName=data-node-B-hostname
# NodeId=data-node-B-nodeid

LockExecuteThreadToCPU=1
LockMaintThreadsToCPU=0

# You must have an [ndbd] section for every data node in the cluster;
# each of these sections must include a HostName. Each section may
# optionally include a NodeId for convenience, but in most cases, it is
# sufficient to allow the cluster to allocate node IDs dynamically. If
# you do specify the node ID for a data node, it must be in the range 1
```

```

# to 144 inclusive and must be unique among all IDs specified for
# cluster nodes.

# SQL NODE / API NODE PARAMETERS

[mysqld]
# HostName=sql-node-A-hostname
# NodeId=sql-node-A-nodeid

[mysqld]

[mysqld]

# Each API or SQL node that connects to the cluster requires a [mysqld]
# or [api] section of its own. Each such section defines a connection
# "slot"; you should have at least as many of these sections in the
# config.ini file as the total number of API nodes and SQL nodes that
# you wish to have connected to the cluster at any given time. There is
# no performance or other penalty for having extra slots available in
# case you find later that you want or need more API or SQL nodes to
# connect to the cluster at the same time.
# If no HostName is specified for a given [mysqld] or [api] section,
# then any API or SQL node may use that slot to connect to the
# cluster. You may wish to use an explicit HostName for one connection slot
# to guarantee that an API or SQL node from that host can always
# connect to the cluster. If you wish to prevent API or SQL nodes from
# connecting from other than a desired host or hosts, then use a
# HostName for every [mysqld] or [api] section in the config.ini file.
# You can if you wish define a node ID (NodeId parameter) for any API or
# SQL node, but this is not necessary; if you do so, it must be in the
# range 1 to 255 inclusive and must be unique among all IDs specified
# for cluster nodes.

```

Recommended my.cnf options for SQL nodes. MySQL Servers acting as NDB Cluster SQL nodes must always be started with the `--ndbcluster` and `--ndb-connectstring` options, either on the command line or in `my.cnf`. In addition, set the following options for all `mysqld` processes in the cluster, unless your setup requires otherwise:

- `--ndb-use-exact-count=0`
- `--ndb-index-stat-enable=0`
- `--ndb-force-send=1`
- `--optimizer-switch=engine_condition_pushdown=on`

23.4.3.3 NDB Cluster Connection Strings

With the exception of the NDB Cluster management server (`ndb_mgmd`), each node that is part of an NDB Cluster requires a *connection string* that points to the management server's location. This connection string is used in establishing a connection to the management server as well as in performing other tasks depending on the node's role in the cluster. The syntax for a connection string is as follows:

```

[nodeid=node_id, ]host-definition[, host-definition[, ...]]

host-definition:
    host_name[:port_number]

```

`node_id` is an integer greater than or equal to 1 which identifies a node in `config.ini`. `host_name` is a string representing a valid Internet host name or IP address. `port_number` is an integer referring to a TCP/IP port number.

```

example 1 (long):      "nodeid=2,myhost1:1100,myhost2:1100,198.51.100.3:1200"

```

```
example 2 (short): "myhost1"
```

`localhost:1186` is used as the default connection string value if none is provided. If `port_num` is omitted from the connection string, the default port is 1186. This port should always be available on the network because it has been assigned by IANA for this purpose (see <http://www.iana.org/assignments/port-numbers> for details).

By listing multiple host definitions, it is possible to designate several redundant management servers. An NDB Cluster data or API node attempts to contact successive management servers on each host in the order specified, until a successful connection has been established.

It is also possible to specify in a connection string one or more bind addresses to be used by nodes having multiple network interfaces for connecting to management servers. A bind address consists of a hostname or network address and an optional port number. This enhanced syntax for connection strings is shown here:

```
[nodeid=node_id, ]
  [bind-address=host-definition, ]
  host-definition[; bind-address=host-definition]
  host-definition[; bind-address=host-definition]
  [, ...]

host-definition:
  host_name[:port_number]
```

If a single bind address is used in the connection string *prior* to specifying any management hosts, then this address is used as the default for connecting to any of them (unless overridden for a given management server; see later in this section for an example). For example, the following connection string causes the node to use `198.51.100.242` regardless of the management server to which it connects:

```
bind-address=198.51.100.242, poseidon:1186, perch:1186
```

If a bind address is specified *following* a management host definition, then it is used only for connecting to that management node. Consider the following connection string:

```
poseidon:1186;bind-address=localhost, perch:1186;bind-address=198.51.100.242
```

In this case, the node uses `localhost` to connect to the management server running on the host named `poseidon` and `198.51.100.242` to connect to the management server running on the host named `perch`.

You can specify a default bind address and then override this default for one or more specific management hosts. In the following example, `localhost` is used for connecting to the management server running on host `poseidon`; since `198.51.100.242` is specified first (before any management server definitions), it is the default bind address and so is used for connecting to the management servers on hosts `perch` and `orca`:

```
bind-address=198.51.100.242,poseidon:1186;bind-address=localhost,perch:1186,orca:2200
```

There are a number of different ways to specify the connection string:

- Each executable has its own command-line option which enables specifying the management server at startup. (See the documentation for the respective executable.)
- It is also possible to set the connection string for all nodes in the cluster at once by placing it in a `[mysql_cluster]` section in the management server's `my.cnf` file.
- For backward compatibility, two other options are available, using the same syntax:

1. Set the `NDB_CONNECTSTRING` environment variable to contain the connection string.
2. Write the connection string for each executable into a text file named `Ndb.cfg` and place this file in the executable's startup directory.

However, these are now deprecated and should not be used for new installations.

The recommended method for specifying the connection string is to set it on the command line or in the `my.cnf` file for each executable.

23.4.3.4 Defining Computers in an NDB Cluster

The `[computer]` section has no real significance other than serving as a way to avoid the need of defining host names for each node in the system. All parameters mentioned here are required.

- `Id`

| | |
|------------------------------|-----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | string |
| Default | [...] |
| Range | ... |
| Restart Type | IS (NDB 8.0.13) |

This is a unique identifier, used to refer to the host computer elsewhere in the configuration file.

Important

The computer ID is *not* the same as the node ID used for a management, API, or data node. Unlike the case with node IDs, you cannot use `NodeId` in place of `Id` in the `[computer]` section of the `config.ini` file.

- `HostName`

| | |
|------------------------------|--------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | name or IP address |
| Default | [...] |
| Range | ... |
| Restart Type | N (NDB 8.0.13) |

This is the computer's hostname or IP address.

Restart types. Information about the restart types used by the parameter descriptions in this section is shown in the following table:

Table 23.8 NDB Cluster restart types

| Symbol | Restart Type | Description |
|--------|--------------|--|
| N | Node | The parameter can be updated using a rolling restart (see Section 23.6.5, “Performing a Rolling Restart of an NDB Cluster”) |

| Symbol | Restart Type | Description |
|--------|--------------|--|
| S | System | All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter |
| I | Initial | Data nodes must be restarted using the <code>--initial</code> option |

23.4.3.5 Defining an NDB Cluster Management Server

The `[ndb_mgmd]` section is used to configure the behavior of the management server. If multiple management servers are employed, you can specify parameters common to all of them in an `[ndb_mgmd default]` section. `[mgm]` and `[mgm default]` are older aliases for these, supported for backward compatibility.

All parameters in the following list are optional and assume their default values if omitted.

Note

If neither the `ExecuteOnComputer` nor the `HostName` parameter is present, the default value `localhost` is assumed for both.

- `Id`

| | |
|------------------------------|-----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | unsigned |
| Default | [...] |
| Range | 1 - 255 |
| Restart Type | IS (NDB 8.0.13) |

Each node in the cluster has a unique identity. For a management node, this is represented by an integer value in the range 1 to 255, inclusive. This ID is used by all internal cluster messages for addressing the node, and so must be unique for each NDB Cluster node, regardless of the type of node.

Note

Data node IDs must be less than 145. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for management nodes (and API nodes) to values greater than 144.

The use of the `Id` parameter for identifying management nodes is deprecated in favor of `NodeId`. Although `Id` continues to be supported for backward compatibility, it now generates a warning and is subject to removal in a future version of NDB Cluster.

- `NodeId`

| | |
|------------------------------|-----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | unsigned |
| Default | [...] |
| Range | 1 - 255 |
| Restart Type | IS (NDB 8.0.13) |

Each node in the cluster has a unique identity. For a management node, this is represented by an integer value in the range 1 to 255 inclusive. This ID is used by all internal cluster messages for addressing the node, and so must be unique for each NDB Cluster node, regardless of the type of node.

Note

Data node IDs must be less than 145. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for management nodes (and API nodes) to values greater than 144.

`NodeId` is the preferred parameter name to use when identifying management nodes. Although the older `Id` continues to be supported for backward compatibility, it is now deprecated and generates a warning when used; it is also subject to removal in a future NDB Cluster release.

- [ExecuteOnComputer](#)

| | |
|------------------------------|------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | name |
| Default | [...] |
| Range | ... |
| Deprecated | Yes (in NDB 7.5) |
| Restart Type | S (NDB 8.0.13) |

This refers to the `Id` set for one of the computers defined in a `[computer]` section of the `config.ini` file.

Important

This parameter is deprecated, and is subject to removal in a future release. Use the `HostName` parameter instead.

- [PortNumber](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | unsigned |
| Default | 1186 |
| Range | 0 - 64K |
| Restart Type | S (NDB 8.0.13) |

This is the port number on which the management server listens for configuration requests and management commands.

-

The node ID for this node can be given out only to connections that explicitly request it. A management server that requests “any” node ID cannot use this one. This parameter can be used when running multiple management servers on the same host, and `HostName` is not sufficient for distinguishing among processes. Intended for use in testing.

- [HostName](#)

| | |
|--------------------|------------|
| Version (or later) | NDB 8.0.13 |
|--------------------|------------|

| | |
|------------------------------|--------------------|
| Type or units | name or IP address |
| Default | [...] |
| Range | ... |
| Restart Type | N (NDB 8.0.13) |

Specifying this parameter defines the hostname of the computer on which the management node is to reside. To specify a hostname other than `localhost`, either this parameter or `ExecuteOnComputer` is required.

- [LocationDomainId](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | integer |
| Default | 0 |
| Range | 0 - 16 |
| Restart Type | S (NDB 8.0.13) |

Assigns a management node to a specific [availability domain](#) (also known as an availability zone) within a cloud. By informing `NDB` which nodes are in which availability domains, performance can be improved in a cloud environment in the following ways:

- If requested data is not found on the same node, reads can be directed to another node in the same availability domain.
- Communication between nodes in different availability domains are guaranteed to use `NDB` transporters' WAN support without any further manual intervention.
- The transporter's group number can be based on which availability domain is used, such that also SQL and other API nodes communicate with local data nodes in the same availability domain whenever possible.
- The arbitrator can be selected from an availability domain in which no data nodes are present, or, if no such availability domain can be found, from a third availability domain.

`LocationDomainId` takes an integer value between 0 and 16 inclusive, with 0 being the default; using 0 is the same as leaving the parameter unset.

- [LogDestination](#)

| | |
|--------------------|--|
| Version (or later) | NDB 8.0.13 |
| Type or units | {CONSOLE SYSLOG FILE} |
| Default | FILE: filename=ndb_nodeid_cluster.log, maxsize=1000000, maxfiles=6 |
| Range | ... |

| | |
|--------------|----------------|
| Restart Type | N (NDB 8.0.13) |
|--------------|----------------|

This parameter specifies where to send cluster logging information. There are three options in this regard—`CONSOLE`, `SYSLOG`, and `FILE`—with `FILE` being the default:

- `CONSOLE` outputs the log to `stdout`:

```
CONSOLE
```

- `SYSLOG` sends the log to a `syslog` facility, possible values being one of `auth`, `authpriv`, `cron`, `daemon`, `ftp`, `kern`, `lpr`, `mail`, `news`, `syslog`, `user`, `uucp`, `local0`, `local1`, `local2`, `local3`, `local4`, `local5`, `local6`, or `local7`.

Note

Not every facility is necessarily supported by every operating system.

```
SYSLOG:facility=syslog
```

- `FILE` pipes the cluster log output to a regular file on the same machine. The following values can be specified:

- `filename`: The name of the log file.

The default log file name used in such cases is `ndb_nodeid_cluster.log`.

- `maxsize`: The maximum size (in bytes) to which the file can grow before logging rolls over to a new file. When this occurs, the old log file is renamed by appending `.N` to the file name, where `N` is the next number not yet used with this name.
- `maxfiles`: The maximum number of log files.

```
FILE:filename=cluster.log,maxsize=1000000,maxfiles=6
```

The default value for the `FILE` parameter is

`FILE:filename=ndb_node_id_cluster.log,maxsize=1000000,maxfiles=6`, where `node_id` is the ID of the node.

It is possible to specify multiple log destinations separated by semicolons as shown here:

```
CONSOLE;SYSLOG:facility=local0;FILE:filename=/var/log/mgmd
```

- `ArbitrationRank`

| | |
|--------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | 0-2 |
| Default | 1 |
| Range | 0 - 2 |
| Restart Type | N (NDB 8.0.13) |

This parameter is used to define which nodes can act as arbitrators. Only management nodes and SQL nodes can be arbitrators. `ArbitrationRank` can take one of the following values:

- `0`: The node is never used as an arbitrator.

- 1: The node has high priority; that is, it is preferred as an arbitrator over low-priority nodes.
- 2: Indicates a low-priority node which is used as an arbitrator only if a node with a higher priority is not available for that purpose.

Normally, the management server should be configured as an arbitrator by setting its `ArbitrationRank` to 1 (the default for management nodes) and those for all SQL nodes to 0 (the default for SQL nodes).

You can disable arbitration completely either by setting `ArbitrationRank` to 0 on all management and SQL nodes, or by setting the `Arbitration` parameter in the `[ndbd default]` section of the `config.ini` global configuration file. Setting `Arbitration` causes any settings for `ArbitrationRank` to be disregarded.

- `ArbitrationDelay`

| | |
|--------------------|-----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | milliseconds |
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

An integer value which causes the management server's responses to arbitration requests to be delayed by that number of milliseconds. By default, this value is 0; it is normally not necessary to change it.

- `DataDir`

| | |
|--------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | path |
| Default | . |
| Range | ... |
| Restart Type | N (NDB 8.0.13) |

This specifies the directory where output files from the management server are placed. These files include cluster log files, process output files, and the daemon's process ID (PID) file. (For log files, this location can be overridden by setting the `FILE` parameter for `LogDestination`, as discussed previously in this section.)

The default value for this parameter is the directory in which `ndb_mgmd` is located.

- `PortNumberStats`

| | |
|--------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | unsigned |
| Default | [...] |
| Range | 0 - 64K |
| Restart Type | N (NDB 8.0.13) |

This parameter specifies the port number used to obtain statistical information from an NDB Cluster management server. It has no default value.

- [Wan](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | boolean |
| Default | false |
| Range | true, false |
| Restart Type | N (NDB 8.0.13) |

Use WAN TCP setting as default.

- [HeartbeatThreadPriority](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | string |
| Default | [...] |
| Range | ... |
| Restart Type | N (NDB 8.0.13) |

Set the scheduling policy and priority of heartbeat threads for management and API nodes.

The syntax for setting this parameter is shown here:

```
HeartbeatThreadPriority = policy[, priority]

policy:
{FIFO | RR}
```

When setting this parameter, you must specify a policy. This is one of [FIFO](#) (first in, first out) or [RR](#) (round robin). The policy value is followed optionally by the priority (an integer).

- [ExtraSendBufferMemory](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | bytes |
| Default | 0 |
| Range | 0 - 32G |
| Restart Type | N (NDB 8.0.13) |

This parameter specifies the amount of transporter send buffer memory to allocate in addition to any that has been set using [TotalSendBufferMemory](#), [SendBufferMemory](#), or both.

- [TotalSendBufferMemory](#)

| | |
|--------------------|--------------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | bytes |
| Default | 0 |
| Range | 256K - 4294967039 (0xFFFFFFFF) |

| | |
|------------------------------|----------------|
| Restart Type | N (NDB 8.0.13) |
|------------------------------|----------------|

This parameter is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see [Section 23.4.3.14, “Configuring NDB Cluster Send Buffer Parameters”](#).

- [HeartbeatIntervalMgmdMgmd](#)

| | |
|------------------------------|-------------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | milliseconds |
| Default | 1500 |
| Range | 100 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

Specify the interval between heartbeat messages used to determine whether another management node is on contact with this one. The management node waits after 3 of these intervals to declare the connection dead; thus, the default setting of 1500 milliseconds causes the management node to wait for approximately 1600 ms before timing out.

Note

After making changes in a management node's configuration, it is necessary to perform a rolling restart of the cluster for the new configuration to take effect.

To add new management servers to a running NDB Cluster, it is also necessary to perform a rolling restart of all cluster nodes after modifying any existing `config.ini` files. For more information about issues arising when using multiple management nodes, see [Section 23.2.7.10, “Limitations Relating to Multiple NDB Cluster Nodes”](#).

Restart types. Information about the restart types used by the parameter descriptions in this section is shown in the following table:

Table 23.9 NDB Cluster restart types

| Symbol | Restart Type | Description |
|--------|--------------|--|
| N | Node | The parameter can be updated using a rolling restart (see Section 23.6.5, “Performing a Rolling Restart of an NDB Cluster”) |
| S | System | All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter |
| I | Initial | Data nodes must be restarted using the <code>--initial</code> option |

23.4.3.6 Defining NDB Cluster Data Nodes

The `[ndbd]` and `[ndbd default]` sections are used to configure the behavior of the cluster's data nodes.

`[ndbd]` and `[ndbd default]` are always used as the section names whether you are using `ndbd` or `ndbmtbd` binaries for the data node processes.

There are many parameters which control buffer sizes, pool sizes, timeouts, and so forth. The only mandatory parameter is either one of `ExecuteOnComputer` or `HostName`; this must be defined in the local `[ndbd]` section.

The parameter `NoOfReplicas` should be defined in the `[ndbd default]` section, as it is common to all Cluster data nodes. It is not strictly necessary to set `NoOfReplicas`, but it is good practice to set it explicitly.

Most data node parameters are set in the `[ndbd default]` section. Only those parameters explicitly stated as being able to set local values are permitted to be changed in the `[ndbd]` section. Where present, `HostName`, `NodeId` and `ExecuteOnComputer` *must* be defined in the local `[ndbd]` section, and not in any other section of `config.ini`. In other words, settings for these parameters are specific to one data node.

For those parameters affecting memory usage or buffer sizes, it is possible to use `K`, `M`, or `G` as a suffix to indicate units of 1024, 1024×1024, or 1024×1024×1024. (For example, `100K` means 100 × 1024 = 102400.)

Parameter names and values are case-insensitive, unless used in a MySQL Server `my.cnf` or `my.ini` file, in which case they are case-sensitive.

Information about configuration parameters specific to NDB Cluster Disk Data tables can be found later in this section (see [Disk Data Configuration Parameters](#)).

All of these parameters also apply to `ndbmtbd` (the multithreaded version of `ndbd`). Three additional data node configuration parameters—`MaxNoOfExecutionThreads`, `ThreadConfig`, and `NoOfFragmentLogParts`—apply to `ndbmtbd` only; these have no effect when used with `ndbd`. For more information, see [Multi-Threading Configuration Parameters \(ndbmtbd\)](#). See also [Section 23.5.3, “ndbmtbd — The NDB Cluster Data Node Daemon \(Multi-Threaded\)”](#).

Identifying data nodes. The `NodeId` or `Id` value (that is, the data node identifier) can be allocated on the command line when the node is started or in the configuration file.

- `NodeId`

| | |
|------------------------------|-----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | unsigned |
| Default | [...] |
| Range | 1 - 48 |
| Version (or later) | NDB 8.0.18 |
| Type or units | unsigned |
| Default | [...] |
| Range | 1 - 144 |
| Restart Type | IS (NDB 8.0.13) |

A unique node ID is used as the node's address for all cluster internal messages. For data nodes, this is an integer in the range 1 to 144 inclusive. Each node in the cluster must have a unique identifier.

[NodeId](#) is the only supported parameter name to use when identifying data nodes.

- [ExecuteOnComputer](#)

| | |
|------------------------------|------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | name |
| Default | [...] |
| Range | ... |
| Deprecated | Yes (in NDB 7.5) |
| Restart Type | S (NDB 8.0.13) |

This refers to the [Id](#) set for one of the computers defined in a [\[computer\]](#) section.

Important

This parameter is deprecated, and is subject to removal in a future release. Use the [HostName](#) parameter instead.

-

The node ID for this node can be given out only to connections that explicitly request it. A management server that requests “any” node ID cannot use this one. This parameter can be used when running multiple management servers on the same host, and [HostName](#) is not sufficient for distinguishing among processes. Intended for use in testing.

- [HostName](#)

| | |
|------------------------------|--------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | name or IP address |
| Default | localhost |
| Range | ... |
| Restart Type | N (NDB 8.0.13) |

Specifying this parameter defines the hostname of the computer on which the data node is to reside. To specify a hostname other than [localhost](#), either this parameter or [ExecuteOnComputer](#) is required.

- [ServerPort](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | unsigned |
| Default | [...] |
| Range | 1 - 64K |
| Restart Type | S (NDB 8.0.13) |

Each node in the cluster uses a port to connect to other nodes. By default, this port is allocated dynamically in such a way as to ensure that no two nodes on the same host computer receive the same port number, so it should normally not be necessary to specify a value for this parameter.

However, if you need to be able to open specific ports in a firewall to permit communication between data nodes and API nodes (including SQL nodes), you can set this parameter to the number of

the desired port in an `[ndbd]` section or (if you need to do this for multiple data nodes) the `[ndbd default]` section of the `config.ini` file, and then open the port having that number for incoming connections from SQL nodes, API nodes, or both.

Note

Connections from data nodes to management nodes is done using the `ndb_mgmd` management port (the management server's `PortNumber`) so outgoing connections to that port from any data nodes should always be permitted.

- `TcpBind_INADDR_ANY`

Setting this parameter to `TRUE` or `1` binds `IP_ADDR_ANY` so that connections can be made from anywhere (for autogenerated connections). The default is `FALSE` (`0`).

- `NodeGroup`

| | |
|------------------------------|-----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | unsigned |
| Default | [...] |
| Range | 0 - 65536 |
| Restart Type | IS (NDB 8.0.13) |

This parameter can be used to assign a data node to a specific node group. It is read only when the cluster is started for the first time, and cannot be used to reassign a data node to a different node group online. It is generally not desirable to use this parameter in the `[ndbd default]` section of the `config.ini` file, and care must be taken not to assign nodes to node groups in such a way that an invalid numbers of nodes are assigned to any node groups.

The `NodeGroup` parameter is chiefly intended for use in adding a new node group to a running NDB Cluster without having to perform a rolling restart. For this purpose, you should set it to 65536 (the maximum value). You are not required to set a `NodeGroup` value for all cluster data nodes, only for those nodes which are to be started and added to the cluster as a new node group at a later time. For more information, see [Section 23.6.7.3, “Adding NDB Cluster Data Nodes Online: Detailed Example”](#).

- `LocationDomainId`

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | integer |
| Default | 0 |
| Range | 0 - 16 |
| Restart Type | S (NDB 8.0.13) |

Assigns a data node to a specific [availability domain](#) (also known as an availability zone) within a cloud. By informing NDB which nodes are in which availability domains, performance can be improved in a cloud environment in the following ways:

- If requested data is not found on the same node, reads can be directed to another node in the same availability domain.

- Communication between nodes in different availability domains are guaranteed to use [NDB transporters](#)' WAN support without any further manual intervention.
- The transporter's group number can be based on which availability domain is used, such that also SQL and other API nodes communicate with local data nodes in the same availability domain whenever possible.
- The arbitrator can be selected from an availability domain in which no data nodes are present, or, if no such availability domain can be found, from a third availability domain.

[LocationDomainId](#) takes an integer value between 0 and 16 inclusive, with 0 being the default; using 0 is the same as leaving the parameter unset.

- [NoOfReplicas](#)

| | |
|------------------------------|-----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | integer |
| Default | 2 |
| Range | 1 - 2 |
| Version (or later) | NDB 8.0.19 |
| Type or units | integer |
| Default | 2 |
| Range | 1 - 4 |
| Restart Type | IS (NDB 8.0.13) |

This global parameter can be set only in the `[ndbd default]` section, and defines the number of fragment replicas for each table stored in the cluster. This parameter also specifies the size of node groups. A node group is a set of nodes all storing the same information.

Node groups are formed implicitly. The first node group is formed by the set of data nodes with the lowest node IDs, the next node group by the set of the next lowest node identities, and so on. By way of example, assume that we have 4 data nodes and that [NoOfReplicas](#) is set to 2. The four data nodes have node IDs 2, 3, 4 and 5. Then the first node group is formed from nodes 2 and 3, and the second node group by nodes 4 and 5. It is important to configure the cluster in such a manner that nodes in the

same node groups are not placed on the same computer because a single hardware failure would cause the entire cluster to fail.

If no node IDs are provided, the order of the data nodes is the determining factor for the node group. Whether or not explicit assignments are made, they can be viewed in the output of the management client's `SHOW` command.

The default value for `NoOfReplicas` is 2. This is the recommended value for most production environments. In NDB 8.0, setting this parameter's value to 3 or 4 is fully tested and supported in production.

Warning

Setting `NoOfReplicas` to 1 means that there is only a single copy of all Cluster data; in this case, the loss of a single data node causes the cluster to fail because there are no additional copies of the data stored by that node.

The number of data nodes in the cluster must be evenly divisible by the value of this parameter. For example, if there are two data nodes, then `NoOfReplicas` must be equal to either 1 or 2, since 2/3 and 2/4 both yield fractional values; if there are four data nodes, then `NoOfReplicas` must be equal to 1, 2, or 4.

- `DataDir`

| | |
|------------------------------|-----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | path |
| Default | . |
| Range | ... |
| Restart Type | IN (NDB 8.0.13) |

This parameter specifies the directory where trace files, log files, pid files and error logs are placed.

The default is the data node process working directory.

- `FileSystemPath`

| | |
|------------------------------|----------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | path |
| Default | <code>DataDir</code> |
| Range | ... |
| Restart Type | IN (NDB 8.0.13) |

This parameter specifies the directory where all files created for metadata, REDO logs, UNDO logs (for Disk Data tables), and data files are placed. The default is the directory specified by `DataDir`.

Note

This directory must exist before the `ndbd` process is initiated.

The recommended directory hierarchy for NDB Cluster includes `/var/lib/mysql-cluster`, under which a directory for the node's file system is created. The name of this subdirectory contains the node ID. For example, if the node ID is 2, this subdirectory is named `ndb_2_fs`.

- [BackupDataDir](#)

| | |
|------------------------------|-----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | path |
| Default | FileSystemPath |
| Range | ... |
| Restart Type | IN (NDB 8.0.13) |

This parameter specifies the directory in which backups are placed.

Important

The string `'/BACKUP'` is always appended to this value. For example, if you set the value of `BackupDataDir` to `/var/lib/cluster-data`, then all backups are stored under `/var/lib/cluster-data/BACKUP`. This also means that the *effective* default backup location is the directory named `BACKUP` under the location specified by the `FileSystemPath` parameter.

Data Memory, Index Memory, and String Memory

`DataMemory` and `IndexMemory` are `[ndbd]` parameters specifying the size of memory segments used to store the actual records and their indexes. In setting values for these, it is important to understand how `DataMemory` is used, as it usually needs to be updated to reflect actual usage by the cluster.

Note

`IndexMemory` is deprecated, and subject to removal in a future version of NDB Cluster. See the descriptions that follow for further information.

- [DataMemory](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | bytes |
| Default | 98M |
| Range | 1M - 1T |
| Version (or later) | NDB 8.0.19 |
| Type or units | bytes |
| Default | 98M |
| Range | 1M - 16T |
| Restart Type | N (NDB 8.0.13) |

This parameter defines the amount of space (in bytes) available for storing database records. The entire amount specified by this value is allocated in memory, so it is extremely important that the machine has sufficient physical memory to accommodate it.

The memory allocated by `DataMemory` is used to store both the actual records and indexes. There is a 16-byte overhead on each record; an additional amount for each record is incurred because it is stored in a 32KB page with 128 byte page overhead (see below). There is also a small amount wasted per page due to the fact that each record is stored in only one page.

For variable-size table attributes, the data is stored on separate data pages, allocated from [DataMemory](#). Variable-length records use a fixed-size part with an extra overhead of 4 bytes to reference the variable-size part. The variable-size part has 2 bytes overhead plus 2 bytes per attribute.

In NDB 8.0, the maximum record size is 30000 bytes.

Resources assigned to [DataMemory](#) are used for storing all data and indexes. (Any memory configured as [IndexMemory](#) is automatically added to that used by [DataMemory](#) to form a common resource pool.)

Currently, NDB Cluster can use a maximum of 512 MB for hash indexes per partition, which means in some cases it is possible to get `Table is full` errors in MySQL client applications even when `ndb_mgm -e "ALL REPORT MEMORYUSAGE"` shows significant free [DataMemory](#). This can also pose a problem with data node restarts on nodes that are heavily loaded with data.

You can control the number of partitions per local data manager for a given table by setting the [NDB_TABLE](#) option `PARTITION_BALANCE` to one of the values `FOR_RA_BY_LDM`, `FOR_RA_BY_LDM_X_2`, `FOR_RA_BY_LDM_X_3`, or `FOR_RA_BY_LDM_X_4`, for 1, 2, 3, or 4 partitions per LDM, respectively, when creating the table (see [Section 13.1.20.11](#), “[Setting NDB_TABLE Options](#)”).

Note

In previous versions of NDB Cluster it was possible to create extra partitions for NDB Cluster tables and thus have more memory available for hash indexes by using the `MAX_ROWS` option for `CREATE TABLE`. While still supported for backward compatibility, using `MAX_ROWS` for this purpose is deprecated; you should use `PARTITION_BALANCE` instead.

You can also use the `MinFreePct` configuration parameter to help avoid problems with node restarts.

The memory space allocated by [DataMemory](#) consists of 32KB pages, which are allocated to table fragments. Each table is normally partitioned into the same number of fragments as there are data nodes in the cluster. Thus, for each node, there are the same number of fragments as are set in [NoOfReplicas](#).

Once a page has been allocated, it is currently not possible to return it to the pool of free pages, except by deleting the table. (This also means that [DataMemory](#) pages, once allocated to a given table, cannot be used by other tables.) Performing a data node recovery also compresses the partition because all records are inserted into empty partitions from other live nodes.

The [DataMemory](#) memory space also contains UNDO information: For each update, a copy of the unaltered record is allocated in the [DataMemory](#). There is also a reference to each copy in the ordered table indexes. Unique hash indexes are updated only when the unique index columns are updated, in which case a new entry in the index table is inserted and the old entry is deleted upon commit. For this reason, it is also necessary to allocate enough memory to handle the largest transactions performed by

applications using the cluster. In any case, performing a few large transactions holds no advantage over using many smaller ones, for the following reasons:

- Large transactions are not any faster than smaller ones
- Large transactions increase the number of operations that are lost and must be repeated in event of transaction failure
- Large transactions use more memory

The default value for `DataMemory` in NDB 8.0 is 98MB. The minimum value is 1MB. There is no maximum size, but in reality the maximum size has to be adapted so that the process does not start swapping when the limit is reached. This limit is determined by the amount of physical RAM available on the machine and by the amount of memory that the operating system may commit to any one process. 32-bit operating systems are generally limited to 2–4GB per process; 64-bit operating systems can use more. For large databases, it may be preferable to use a 64-bit operating system for this reason.

- `IndexMemory`

| | |
|--------------------|------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | bytes |
| Default | 0 |
| Range | 1M - 1T |
| Deprecated | Yes (in NDB 7.6) |
| Restart Type | N (NDB 8.0.13) |

The `IndexMemory` parameter is deprecated (and subject to future removal); any memory assigned to `IndexMemory` is allocated instead to the same pool as `DataMemory`, which is solely responsible for all resources needed for storing data and indexes in memory. In NDB 8.0, the use of `IndexMemory` in the cluster configuration file triggers a warning from the management server.

You can estimate the size of a hash index using this formula:

```
size = ( (fragments * 32K) + (rows * 18) )
      * fragment_replicas
```

`fragments` is the number of fragments, `fragment_replicas` is the number of fragment replicas (normally 2), and `rows` is the number of rows. If a table has one million rows, eight fragments, and two fragment replicas, the expected index memory usage is calculated as shown here:

```
((8 * 32K) + (1000000 * 18)) * 2 = ((8 * 32768) + (1000000 * 18)) * 2
= (262144 + 18000000) * 2
= 18262144 * 2 = 36524288 bytes = ~35MB
```

Index statistics for ordered indexes (when these are enabled) are stored in the `mysql.ndb_index_stat_sample` table. Since this table has a hash index, this adds to index memory usage. An upper bound to the number of rows for a given ordered index can be calculated as follows:

```
sample_size= key_size + ((key_attributes + 1) * 4)

sample_rows = IndexStatSaveSize
              * ((0.01 * IndexStatSaveScale * log2(rows * sample_size)) + 1)
```

/ sample_size

In the preceding formula, *key_size* is the size of the ordered index key in bytes, *key_attributes* is the number of attributes in the ordered index key, and *rows* is the number of rows in the base table.

Assume that table *t1* has 1 million rows and an ordered index named *ix1* on two four-byte integers. Assume in addition that *IndexStatSaveSize* and *IndexStatSaveScale* are set to their default values (32K and 100, respectively). Using the previous 2 formulas, we can calculate as follows:

```
sample_size = 8 + ((1 + 2) * 4) = 20 bytes

sample_rows = 32K
              * ((0.01 * 100 * log2(1000000*20)) + 1)
              / 20
              = 32768 * ( (1 * ~16.811) +1) / 20
              = 32768 * ~17.811 / 20
              = ~29182 rows
```

The expected index memory usage is thus $2 * 18 * 29182 = \sim 1050550$ bytes.

In NDB 8.0, the minimum and default value for this parameter is 0 (zero).

- [StringMemory](#)

| | |
|--------------------|-----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | % or bytes |
| Default | 25 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Restart Type | S (NDB 8.0.13) |

This parameter determines how much memory is allocated for strings such as table names, and is specified in an `[ndbd]` or `[ndbd default]` section of the `config.ini` file. A value between 0 and 100 inclusive is interpreted as a percent of the maximum default value, which is calculated based on a number of factors including the number of tables, maximum table name size, maximum size of `.FRM` files, `MaxNoOfTriggers`, maximum column name size, and maximum default column value.

A value greater than 100 is interpreted as a number of bytes.

The default value is 25—that is, 25 percent of the default maximum.

Under most circumstances, the default value should be sufficient, but when you have a great many NDB tables (1000 or more), it is possible to get Error 773 `Out of string memory, please modify StringMemory config parameter: Permanent error: Schema error`, in which case you should increase this value. 25 (25 percent) is not excessive, and should prevent this error from recurring in all but the most extreme conditions.

The following example illustrates how memory is used for a table. Consider this table definition:

```
CREATE TABLE example (
  a INT NOT NULL,
  b INT NOT NULL,
  c INT NOT NULL,
  PRIMARY KEY(a),
  UNIQUE(b)
) ENGINE=NDBCLUSTER;
```

For each record, there are 12 bytes of data plus 12 bytes overhead. Having no nullable columns saves 4 bytes of overhead. In addition, we have two ordered indexes on columns *a* and *b* consuming roughly 10

bytes each per record. There is a primary key hash index on the base table using roughly 29 bytes per record. The unique constraint is implemented by a separate table with `b` as primary key and `a` as a column. This other table consumes an additional 29 bytes of index memory per record in the `example` table as well 8 bytes of record data plus 12 bytes of overhead.

Thus, for one million records, we need 58MB for index memory to handle the hash indexes for the primary key and the unique constraint. We also need 64MB for the records of the base table and the unique index table, plus the two ordered index tables.

You can see that hash indexes takes up a fair amount of memory space; however, they provide very fast access to the data in return. They are also used in NDB Cluster to handle uniqueness constraints.

Currently, the only partitioning algorithm is hashing and ordered indexes are local to each node. Thus, ordered indexes cannot be used to handle uniqueness constraints in the general case.

An important point for both `IndexMemory` and `DataMemory` is that the total database size is the sum of all data memory and all index memory for each node group. Each node group is used to store replicated information, so if there are four nodes with two fragment replicas, there are two node groups. Thus, the total data memory available is $2 \times \text{DataMemory}$ for each data node.

It is highly recommended that `DataMemory` and `IndexMemory` be set to the same values for all nodes. Data distribution is even over all nodes in the cluster, so the maximum amount of space available for any node can be no greater than that of the smallest node in the cluster.

`DataMemory` can be changed, but decreasing it can be risky; doing so can easily lead to a node or even an entire NDB Cluster that is unable to restart due to there being insufficient memory space. Increasing these values should be acceptable, but it is recommended that such upgrades are performed in the same manner as a software upgrade, beginning with an update of the configuration file, and then restarting the management server followed by restarting each data node in turn.

MinFreePct. A proportion (5% by default) of data node resources including `DataMemory` is kept in reserve to insure that the data node does not exhaust its memory when performing a restart. This can be adjusted using the `MinFreePct` data node configuration parameter (default 5).

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | unsigned |
| Default | 5 |
| Range | 0 - 100 |
| Restart Type | N (NDB 8.0.13) |

Updates do not increase the amount of index memory used. Inserts take effect immediately; however, rows are not actually deleted until the transaction is committed.

Transaction parameters. The next few `[ndbd]` parameters that we discuss are important because they affect the number of parallel transactions and the sizes of transactions that can be handled by the system. `MaxNoOfConcurrentTransactions` sets the number of parallel transactions possible in a node. `MaxNoOfConcurrentOperations` sets the number of records that can be in update phase or locked simultaneously.

Both of these parameters (especially `MaxNoOfConcurrentOperations`) are likely targets for users setting specific values and not using the default value. The default value is set for systems using small transactions, to ensure that these do not use excessive memory.

`MaxDMLOperationsPerTransaction` sets the maximum number of DML operations that can be performed in a given transaction.

- `MaxNoOfConcurrentTransactions`

| | |
|--------------------|------------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | integer |
| Default | 4096 |
| Range | 32 - 4294967039 (0xFFFFFFFF) |
| Deprecated | NDB 8.0.19 |
| Restart Type | N (NDB 8.0.13) |

Each cluster data node requires a transaction record for each active transaction in the cluster. The task of coordinating transactions is distributed among all of the data nodes. The total number of transaction records in the cluster is the number of transactions in any given node times the number of nodes in the cluster.

Transaction records are allocated to individual MySQL servers. Each connection to a MySQL server requires at least one transaction record, plus an additional transaction object per table accessed by that connection. This means that a reasonable minimum for the total number of transactions in the cluster can be expressed as

```
TotalNoOfConcurrentTransactions =
    (maximum number of tables accessed in any single transaction + 1)
    * number of SQL nodes
```

Suppose that there are 10 SQL nodes using the cluster. A single join involving 10 tables requires 11 transaction records; if there are 10 such joins in a transaction, then $10 * 11 = 110$ transaction records are required for this transaction, per MySQL server, or $110 * 10 = 1100$ transaction records total. Each data node can be expected to handle `TotalNoOfConcurrentTransactions` / number of data nodes. For an NDB Cluster having 4 data nodes, this would mean setting `MaxNoOfConcurrentTransactions` on each data node to $1100 / 4 = 275$. In addition, you should provide for failure recovery by ensuring that a single node group can accommodate all concurrent transactions; in other words, that each data node's `MaxNoOfConcurrentTransactions` is sufficient to cover a number of transactions equal to `TotalNoOfConcurrentTransactions` / number of node groups. If this cluster has a single node group, then `MaxNoOfConcurrentTransactions` should be set to 1100 (the same as the total number of concurrent transactions for the entire cluster).

In addition, each transaction involves at least one operation; for this reason, the value set for `MaxNoOfConcurrentTransactions` should always be no more than the value of `MaxNoOfConcurrentOperations`.

This parameter must be set to the same value for all cluster data nodes. This is due to the fact that, when a data node fails, the oldest surviving node re-creates the transaction state of all transactions that were ongoing in the failed node.

It is possible to change this value using a rolling restart, but the amount of traffic on the cluster must be such that no more transactions occur than the lower of the old and new levels while this is taking place.

The default value is 4096.

- `MaxNoOfConcurrentOperations`

| | |
|--------------------|------------|
| Version (or later) | NDB 8.0.13 |
|--------------------|------------|

| | |
|---------------|------------------------------|
| Type or units | integer |
| Default | 32K |
| Range | 32 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

It is a good idea to adjust the value of this parameter according to the size and number of transactions. When performing transactions which involve only a few operations and records, the default value for this parameter is usually sufficient. Performing large transactions involving many records usually requires that you increase its value.

Records are kept for each transaction updating cluster data, both in the transaction coordinator and in the nodes where the actual updates are performed. These records contain state information needed to find UNDO records for rollback, lock queues, and other purposes.

This parameter should be set at a minimum to the number of records to be updated simultaneously in transactions, divided by the number of cluster data nodes. For example, in a cluster which has four data nodes and which is expected to handle one million concurrent updates using transactions, you should set this value to $1000000 / 4 = 250000$. To help provide resiliency against failures, it is suggested that you set this parameter to a value that is high enough to permit an individual data node to handle the load for its node group. In other words, you should set the value equal to `total number of concurrent operations / number of node groups`. (In the case where there is a single node group, this is the same as the total number of concurrent operations for the entire cluster.)

Because each transaction always involves at least one operation, the value of `MaxNoOfConcurrentOperations` should always be greater than or equal to the value of `MaxNoOfConcurrentTransactions`.

Read queries which set locks also cause operation records to be created. Some extra space is allocated within individual nodes to accommodate cases where the distribution is not perfect over the nodes.

When queries make use of the unique hash index, there are actually two operation records used per record in the transaction. The first record represents the read in the index table and the second handles the operation on the base table.

The default value is 32768.

This parameter actually handles two values that can be configured separately. The first of these specifies how many operation records are to be placed with the transaction coordinator. The second part specifies how many operation records are to be local to the database.

A very large transaction performed on an eight-node cluster requires as many operation records in the transaction coordinator as there are reads, updates, and deletes involved in the transaction. However, the operation records of the are spread over all eight nodes. Thus, if it is necessary to configure the system for one very large transaction, it is a good idea to configure the two parts separately. `MaxNoOfConcurrentOperations` is always used to calculate the number of operation records in the transaction coordinator portion of the node.

It is also important to have an idea of the memory requirements for operation records. These consume about 1KB per record.

- `MaxNoOfLocalOperations`

| | |
|--------------------|------------|
| Version (or later) | NDB 8.0.13 |
|--------------------|------------|

| | |
|------------------------------|------------------------------|
| Type or units | integer |
| Default | UNDEFINED |
| Range | 32 - 4294967039 (0xFFFFFFFF) |
| Deprecated | NDB 8.0.19 |
| Restart Type | N (NDB 8.0.13) |

By default, this parameter is calculated as $1.1 \times \text{MaxNoOfConcurrentOperations}$. This fits systems with many simultaneous transactions, none of them being very large. If there is a need to handle one very large transaction at a time and there are many nodes, it is a good idea to override the default value by explicitly specifying this parameter.

This parameter is deprecated in NDB 8.0, and is subject to removal in a future NDB Cluster release. In addition, this parameter is incompatible with the [TransactionMemory](#) parameter; if you try to set values for both parameters in the cluster configuration file ([config.ini](#)), the management server refuses to start.

- [MaxDMLOperationsPerTransaction](#)

| | |
|------------------------------|------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | operations (DML) |
| Default | 4294967295 |
| Range | 32 - 4294967295 |
| Restart Type | N (NDB 8.0.13) |

This parameter limits the size of a transaction. The transaction is aborted if it requires more than this many DML operations. The minimum number of operations per transaction is 32; however, you can set [MaxDMLOperationsPerTransaction](#) to 0 to disable any limitation on the number of DML operations per transaction. The maximum (and default) is 4294967295.

The value of this parameter cannot exceed that set for [MaxNoOfConcurrentOperations](#).

Transaction temporary storage. The next set of [\[ndbd\]](#) parameters is used to determine temporary storage when executing a statement that is part of a Cluster transaction. All records are released when the statement is completed and the cluster is waiting for the commit or rollback.

The default values for these parameters are adequate for most situations. However, users with a need to support transactions involving large numbers of rows or operations may need to increase these values to enable better parallelism in the system, whereas users whose applications require relatively small transactions can decrease the values to save memory.

- [MaxNoOfConcurrentIndexOperations](#)

| | |
|------------------------------|-----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | integer |
| Default | 8K |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Deprecated | NDB 8.0.19 |
| Restart Type | N (NDB 8.0.13) |

For queries using a unique hash index, another temporary set of operation records is used during a query's execution phase. This parameter sets the size of that pool of records. Thus, this record is allocated only while executing a part of a query. As soon as this part has been executed, the record is released. The state needed to handle aborts and commits is handled by the normal operation records, where the pool size is set by the parameter [MaxNoOfConcurrentOperations](#).

The default value of this parameter is 8192. Only in rare cases of extremely high parallelism using unique hash indexes should it be necessary to increase this value. Using a smaller value is possible and can save memory if the DBA is certain that a high degree of parallelism is not required for the cluster.

This parameter is deprecated in NDB 8.0, and is subject to removal in a future NDB Cluster release. In addition, this parameter is incompatible with the [TransactionMemory](#) parameter; if you try to set values for both parameters in the cluster configuration file ([config.ini](#)), the management server refuses to start.

- [MaxNoOfFiredTriggers](#)

| | |
|------------------------------|-----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | integer |
| Default | 4000 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Deprecated | NDB 8.0.19 |
| Restart Type | N (NDB 8.0.13) |

The default value of [MaxNoOfFiredTriggers](#) is 4000, which is sufficient for most situations. In some cases it can even be decreased if the DBA feels certain the need for parallelism in the cluster is not high.

A record is created when an operation is performed that affects a unique hash index. Inserting or deleting a record in a table with unique hash indexes or updating a column that is part of a unique hash index fires an insert or a delete in the index table. The resulting record is used to represent this index table operation while waiting for the original operation that fired it to complete. This operation is short-lived but can still require a large number of records in its pool for situations with many parallel write operations on a base table containing a set of unique hash indexes.

This parameter is deprecated in NDB 8.0, and is subject to removal in a future NDB Cluster release. In addition, this parameter is incompatible with the [TransactionMemory](#) parameter; if you try to set values for both parameters in the cluster configuration file ([config.ini](#)), the management server refuses to start.

- [TransactionBufferMemory](#)

| | |
|--------------------|------------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | bytes |
| Default | 1M |
| Range | 1K - 4294967039 (0xFFFFFFFF) |

| | |
|------------------------------|----------------|
| Restart Type | N (NDB 8.0.13) |
|------------------------------|----------------|

The memory affected by this parameter is used for tracking operations fired when updating index tables and reading unique indexes. This memory is used to store the key and column information for these operations. It is only very rarely that the value for this parameter needs to be altered from the default.

The default value for [TransactionBufferMemory](#) is 1MB.

Normal read and write operations use a similar buffer, whose usage is even more short-lived. The compile-time parameter [ZATTRBUF_FILESIZE](#) (found in `ndb/src/kernel/blocks/Dbtc/Dbtc.hpp`) set to 4000 × 128 bytes (500KB). A similar buffer for key information, [ZDATABUF_FILESIZE](#) (also in `Dbtc.hpp`) contains 4000 × 16 = 62.5KB of buffer space. `Dbtc` is the module that handles transaction coordination.

Transaction resource allocation parameters. The parameters in the following list are used to allocate transaction resources in the transaction coordinator (`DBTC`). Leaving any one of these set to the default (0) dedicates transaction memory for 25% of estimated total data node usage for the corresponding resource. The actual maximum possible values for these parameters are typically limited by the amount of memory available to the data node; setting them has no impact on the total amount of memory allocated to the data node. In addition, you should keep in mind that they control numbers of reserved internal records for the data node independent of any settings for [MaxDMLOperationsPerTransaction](#), [MaxNoOfConcurrentIndexOperations](#), [MaxNoOfConcurrentOperations](#), [MaxNoOfConcurrentScans](#), [MaxNoOfConcurrentTransactions](#), [MaxNoOfFiredTriggers](#), [MaxNoOfLocalScans](#), or [TransactionBufferMemory](#) (see [Transaction parameters](#) and [Transaction temporary storage](#)).

- [ReservedConcurrentIndexOperations](#)

| | |
|------------------------------|-----------------------------|
| Version (or later) | NDB 8.0.16 |
| Type or units | numeric |
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Added | NDB 8.0.16 |
| Restart Type | N (NDB 8.0.13) |

Number of simultaneous index operations having dedicated resources on one data node.

- [ReservedConcurrentOperations](#)

| | |
|------------------------------|-----------------------------|
| Version (or later) | NDB 8.0.16 |
| Type or units | numeric |
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Added | NDB 8.0.16 |
| Restart Type | N (NDB 8.0.13) |

Number of simultaneous operations having dedicated resources in transaction coordinators on one data node.

- [ReservedConcurrentScans](#)

| | |
|------------------------------|-----------------------------|
| Version (or later) | NDB 8.0.16 |
| Type or units | numeric |
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Added | NDB 8.0.16 |
| Restart Type | N (NDB 8.0.13) |

Number of simultaneous scans having dedicated resources on one data node.

- [ReservedConcurrentTransactions](#)

| | |
|------------------------------|-----------------------------|
| Version (or later) | NDB 8.0.16 |
| Type or units | numeric |
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Added | NDB 8.0.16 |
| Restart Type | N (NDB 8.0.13) |

Number of simultaneous transactions having dedicated resources on one data node.

- [ReservedFiredTriggers](#)

| | |
|------------------------------|-----------------------------|
| Version (or later) | NDB 8.0.16 |
| Type or units | numeric |
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Added | NDB 8.0.16 |
| Restart Type | N (NDB 8.0.13) |

Number of triggers that have dedicated resources on one ndbd(DB) node.

- [ReservedLocalScans](#)

| | |
|------------------------------|-----------------------------|
| Version (or later) | NDB 8.0.16 |
| Type or units | numeric |
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Added | NDB 8.0.16 |
| Restart Type | N (NDB 8.0.13) |

Number of simultaneous fragment scans having dedicated resources on one data node.

- [ReservedTransactionBufferMemory](#)

| | |
|--------------------|------------|
| Version (or later) | NDB 8.0.16 |
| Type or units | numeric |

| | |
|------------------------------|-----------------------------|
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Added | NDB 8.0.16 |
| Deprecated | NDB 8.0.19 |
| Restart Type | N (NDB 8.0.13) |

Dynamic buffer space (in bytes) for key and attribute data allocated to each data node.

- [TransactionMemory](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.19 |
| Type or units | bytes |
| Default | 0 |
| Range | 0 - 16384G |
| Added | NDB 8.0.19 |
| Restart Type | N (NDB 8.0.13) |

This parameter determines the memory (in bytes) allocated for transactions on each data node. Setting of transaction memory can be handled in any one of the three ways listed here:

- A number of configuration parameters are incompatible with [TransactionMemory](#). If any of these are set, transaction memory is calculated as it was previous to NDB 8.0. You should be aware that it is not possible to set any of these parameters concurrently with [TransactionMemory](#); if you attempt to do so, the management server is unable to start (see [Parameters incompatible with TransactionMemory](#)).
- If [TransactionMemory](#) is set, this value is used for determining transaction memory.
- If neither any incompatible parameters are set nor [TransactionMemory](#) is set, transaction memory is set by NDB to 10% of the value of the [DataMemory](#) configuration parameter.

Parameters incompatible with TransactionMemory. The following parameters cannot be used concurrently with [TransactionMemory](#) and are deprecated in NDB 8.0:

- [MaxNoOfConcurrentIndexOperations](#)
- [MaxNoOfFiredTriggers](#)
- [MaxNoOfLocalOperations](#)
- [MaxNoOfLocalScans](#)

Explicitly setting any of the parameters just listed when [TransactionMemory](#) has also been set in the cluster configuration file ([config.ini](#)) keeps the management node from starting.

For more information regarding resource allocation in NDB Cluster data nodes, see [Section 23.4.3.13](#), “Data Node Memory Management”.

Scans and buffering. There are additional [[ndbd](#)] parameters in the [Dblqh](#) module (in [ndb/src/kernel/blocks/Dblqh/Dblqh.hpp](#)) that affect reads and updates. These include [ZATTRINBUF_FILESIZE](#), set by default to 10000 × 128 bytes (1250KB) and [ZDATABUF_FILE_SIZE](#), set by default to 10000*16 bytes (roughly 156KB) of buffer space. To date, there have been neither any

reports from users nor any results from our own extensive tests suggesting that either of these compile-time limits should be increased.

- [BatchSizePerLocalScan](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | integer |
| Default | 256 |
| Range | 1 - 992 |
| Deprecated | NDB 8.0.19 |
| Restart Type | N (NDB 8.0.13) |

This parameter is used to calculate the number of lock records used to handle concurrent scan operations.

[BatchSizePerLocalScan](#) has a strong connection to the [BatchSize](#) defined in the SQL nodes.

Deprecated in NDB 8.0.

- [LongMessageBuffer](#)

| | |
|------------------------------|--------------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | bytes |
| Default | 64M |
| Range | 512K - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

This is an internal buffer used for passing messages within individual nodes and between nodes. The default is 64MB.

This parameter seldom needs to be changed from the default.

- [MaxFKBuildBatchSize](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | integer |
| Default | 64 |
| Range | 16 - 512 |
| Restart Type | N (NDB 8.0.13) |

Maximum scan batch size used for building foreign keys. Increasing the value set for this parameter may speed up building of foreign key builds at the expense of greater impact to ongoing traffic.

- [MaxNoOfConcurrentScans](#)

| | |
|--------------------|------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | integer |
| Default | 256 |
| Range | 2 - 500 |

| | |
|------------------------------|----------------|
| Restart Type | N (NDB 8.0.13) |
|------------------------------|----------------|

This parameter is used to control the number of parallel scans that can be performed in the cluster. Each transaction coordinator can handle the number of parallel scans defined for this parameter. Each scan query is performed by scanning all partitions in parallel. Each partition scan uses a scan record in the node where the partition is located, the number of records being the value of this parameter times the number of nodes. The cluster should be able to sustain [MaxNoOfConcurrentScans](#) scans concurrently from all nodes in the cluster.

Scans are actually performed in two cases. The first of these cases occurs when no hash or ordered indexes exists to handle the query, in which case the query is executed by performing a full table scan. The second case is encountered when there is no hash index to support the query but there is an ordered index. Using the ordered index means executing a parallel range scan. The order is kept on the local partitions only, so it is necessary to perform the index scan on all partitions.

The default value of [MaxNoOfConcurrentScans](#) is 256. The maximum value is 500.

- [MaxNoOfLocalScans](#)

| | |
|------------------------------|--|
| Version (or later) | NDB 8.0.13 |
| Type or units | integer |
| Default | $4 * \text{MaxNoOfConcurrentScans} * [\# \text{ of data nodes}] + 2$ |
| Range | 32 - 4294967039 (0xFFFFFFFF) |
| Deprecated | NDB 8.0.19 |
| Restart Type | N (NDB 8.0.13) |

Specifies the number of local scan records if many scans are not fully parallelized. When the number of local scan records is not provided, it is calculated as shown here:

$$4 * \text{MaxNoOfConcurrentScans} * [\# \text{ data nodes}] + 2$$

This parameter is deprecated in NDB 8.0, and is subject to removal in a future NDB Cluster release. In addition, this parameter is incompatible with the [TransactionMemory](#) parameter; if you try to set values for both parameters in the cluster configuration file ([config.ini](#)), the management server refuses to start.

- [MaxParallelCopyInstances](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | integer |
| Default | 0 |
| Range | 0 - 64 |
| Restart Type | N (NDB 8.0.13) |

This parameter sets the parallelization used in the copy phase of a node restart or system restart, when a node that is currently just starting is synchronised with a node that already has current data by copying over any changed records from the node that is up to date. Because full parallelism in such cases can lead to overload situations, [MaxParallelCopyInstances](#) provides a means to decrease it. This parameter's default value 0. This value means that the effective parallelism is equal to the number of LDM instances in the node just starting as well as the node updating it.

- [MaxParallelScansPerFragment](#)

| | |
|------------------------------|-----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | bytes |
| Default | 256 |
| Range | 1 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

It is possible to configure the maximum number of parallel scans ([TUP](#) scans and [TUX](#) scans) allowed before they begin queuing for serial handling. You can increase this to take advantage of any unused CPU when performing large number of scans in parallel and improve their performance.

- [MaxReorgBuildBatchSize](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | integer |
| Default | 64 |
| Range | 16 - 512 |
| Restart Type | N (NDB 8.0.13) |

Maximum scan batch size used for reorganization of table partitions. Increasing the value set for this parameter may speed up reorganization at the expense of greater impact to ongoing traffic.

- [MaxUIBuildBatchSize](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | integer |
| Default | 64 |
| Range | 16 - 512 |
| Restart Type | N (NDB 8.0.13) |

Maximum scan batch size used for building unique keys. Increasing the value set for this parameter may speed up such builds at the expense of greater impact to ongoing traffic.

Memory Allocation

- [MaxAllocate](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | unsigned |
| Default | 32M |
| Range | 1M - 1G |
| Deprecated | NDB 8.0.27 |
| Restart Type | N (NDB 8.0.13) |

This parameter was used in older versions of NDB Cluster, but has no effect in NDB 8.0. It is deprecated as of NDB 8.0.27, and subject to removal in a future release.

Multiple Transporters

Beginning with version 8.0.20, **NDB** allocates multiple transporters for communication between pairs of data nodes. The number of transporters so allocated can be influenced by setting an appropriate value for the `NodeGroupTransporters` parameter introduced in that release.

`NodeGroupTransporters`

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.20 |
| Type or units | integer |
| Default | 0 |
| Range | 0 - 32 |
| Added | NDB 8.0.20 |
| Restart Type | N (NDB 8.0.13) |

This parameter determines the number of transporters used between nodes in the same node group. The default value (0) means that the number of transporters used is the same as the number of LDMs in the node. This should be sufficient for most use cases; thus it should seldom be necessary to change this value from its default.

Setting `NodeGroupTransporters` to a number greater than the number of LDM threads or the number of TC threads, whichever is higher, causes **NDB** to use the maximum of these two numbers of threads. This means that a value greater than this is effectively ignored.

Hash Map Size

`DefaultHashMapSize`

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | LDM threads |
| Default | 240 |
| Range | 0 - 3840 |
| Restart Type | N (NDB 8.0.13) |

The original intended use for this parameter was to facilitate upgrades and especially downgrades to and from very old releases with differing default hash map sizes. This is not an issue when upgrading from NDB Cluster 7.3 (or later) to later versions.

Decreasing this parameter online after any tables have been created or modified with `DefaultHashMapSize` equal to 3840 is not currently supported.

Logging and checkpointing. The following `[ndbd]` parameters control log and checkpoint behavior.

- `FragmentLogFileSize`

| | |
|------------------------------|-----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | bytes |
| Default | 16M |
| Range | 4M - 1G |
| Restart Type | IN (NDB 8.0.13) |

Setting this parameter enables you to control directly the size of redo log files. This can be useful in situations when NDB Cluster is operating under a high load and it is unable to close fragment log files quickly enough before attempting to open new ones (only 2 fragment log files can be open at one time); increasing the size of the fragment log files gives the cluster more time before having to open each new fragment log file. The default value for this parameter is 16M.

For more information about fragment log files, see the description for [NoOfFragmentLogFiles](#).

- [InitialNoOfOpenFiles](#)

| | |
|------------------------------|------------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | files |
| Default | 27 |
| Range | 20 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

This parameter sets the initial number of internal threads to allocate for open files.

The default value is 27.

- [InitFragmentLogFiles](#)

| | |
|------------------------------|-----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | [see values] |
| Default | SPARSE |
| Range | SPARSE, FULL |
| Restart Type | IN (NDB 8.0.13) |

By default, fragment log files are created sparsely when performing an initial start of a data node—that is, depending on the operating system and file system in use, not all bytes are necessarily written to disk. However, it is possible to override this behavior and force all bytes to be written, regardless of the platform and file system type being used, by means of this parameter. [InitFragmentLogFiles](#) takes either of two values:

- [SPARSE](#). Fragment log files are created sparsely. This is the default value.
- [FULL](#). Force all bytes of the fragment log file to be written to disk.

Depending on your operating system and file system, setting [InitFragmentLogFiles=FULL](#) may help eliminate I/O errors on writes to the REDO log.

- [EnablePartialLcp](#)

| | |
|--------------------|------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | boolean |
| Default | true |
| Range | ... |

| | |
|------------------------------|----------------|
| Restart Type | N (NDB 8.0.13) |
|------------------------------|----------------|

When `true`, enable partial local checkpoints: This means that each LCP records only part of the full database, plus any records containing rows changed since the last LCP; if no rows have changed, the LCP updates only the LCP control file and does not update any data files.

If `EnablePartialLcp` is disabled (`false`), each LCP uses only a single file and writes a full checkpoint; this requires the least amount of disk space for LCPs, but increases the write load for each LCP. The default value is enabled (`true`). The proportion of space used by partial LCPS can be modified by the setting for the `RecoveryWork` configuration parameter.

For more information about files and directories used for full and partial LCPs, see [NDB Cluster Data Node File System Directory](#).

Setting this parameter to `false` also disables the calculation of disk write speed used by the adaptive LCP control mechanism.

- [LcpScanProgressTimeout](#)

| | |
|------------------------------|-----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | second |
| Default | 60 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Version (or later) | NDB 8.0.19 |
| Type or units | second |
| Default | 180 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

A local checkpoint fragment scan watchdog checks periodically for no progress in each fragment scan performed as part of a local checkpoint, and shuts down the node if there is no progress after a given amount of time has elapsed. This interval can be set using the `LcpScanProgressTimeout` data node configuration parameter, which sets the maximum time for which the local checkpoint can be stalled before the LCP fragment scan watchdog shuts down the node.

The default value is 60 seconds (providing compatibility with previous releases). Setting this parameter to 0 disables the LCP fragment scan watchdog altogether.

- [MaxNoOfOpenFiles](#)

| | |
|------------------------------|------------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | unsigned |
| Default | 0 |
| Range | 20 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

This parameter sets a ceiling on how many internal threads to allocate for open files. *Any situation requiring a change in this parameter should be reported as a bug.*

The default value is 0. However, the minimum value to which this parameter can be set is 20.

- [MaxNoOfSavedMessages](#)

| | |
|------------------------------|-----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | integer |
| Default | 25 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

This parameter sets the maximum number of errors written in the error log as well as the maximum number of trace files that are kept before overwriting the existing ones. Trace files are generated when, for whatever reason, the node crashes.

The default is 25, which sets these maximums to 25 error messages and 25 trace files.

- [MaxLCPStartDelay](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | seconds |
| Default | 0 |
| Range | 0 - 600 |
| Restart Type | N (NDB 8.0.13) |

In parallel data node recovery, only table data is actually copied and synchronized in parallel; synchronization of metadata such as dictionary and checkpoint information is done in a serial fashion. In addition, recovery of dictionary and checkpoint information cannot be executed in parallel with performing of local checkpoints. This means that, when starting or restarting many data nodes concurrently, data nodes may be forced to wait while a local checkpoint is performed, which can result in longer node recovery times.

It is possible to force a delay in the local checkpoint to permit more (and possibly all) data nodes to complete metadata synchronization; once each data node's metadata synchronization is complete, all of the data nodes can recover table data in parallel, even while the local checkpoint is being executed. To force such a delay, set [MaxLCPStartDelay](#), which determines the number of seconds the cluster can wait to begin a local checkpoint while data nodes continue to synchronize metadata. This parameter should be set in the `[ndbd default]` section of the `config.ini` file, so that it is the same for all data nodes. The maximum value is 600; the default is 0.

- [NoOfFragmentLogFiles](#)

| | |
|------------------------------|-----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | integer |
| Default | 16 |
| Range | 3 - 4294967039 (0xFFFFFFFF) |
| Restart Type | IN (NDB 8.0.13) |

This parameter sets the number of REDO log files for the node, and thus the amount of space allocated to REDO logging. Because the REDO log files are organized in a ring, it is extremely important that the first and last log files in the set (sometimes referred to as the “head” and “tail” log files, respectively)

do not meet. When these approach one another too closely, the node begins aborting all transactions encompassing updates due to a lack of room for new log records.

A REDO log record is not removed until both required local checkpoints have been completed since that log record was inserted. Checkpointing frequency is determined by its own set of configuration parameters discussed elsewhere in this chapter.

The default parameter value is 16, which by default means 16 sets of 4 16MB files for a total of 1024MB. The size of the individual log files is configurable using the `FragmentLogFileSize` parameter. In scenarios requiring a great many updates, the value for `NoOfFragmentLogFiles` may need to be set as high as 300 or even higher to provide sufficient space for REDO logs.

If the checkpointing is slow and there are so many writes to the database that the log files are full and the log tail cannot be cut without jeopardizing recovery, all updating transactions are aborted with internal error code 410 (`Out of log file space temporarily`). This condition prevails until a checkpoint has completed and the log tail can be moved forward.

Important

This parameter cannot be changed “on the fly”; you must restart the node using `--initial`. If you wish to change this value for all data nodes in a running cluster, you can do so using a rolling node restart (using `--initial` when starting each data node).

- `RecoveryWork`

| | |
|--------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | integer |
| Default | 60 |
| Range | 25 - 100 |
| Restart Type | N (NDB 8.0.13) |

Percentage of storage overhead for LCP files. This parameter has an effect only when `EnablePartialLcp` is true, that is, only when partial local checkpoints are enabled. A higher value means:

- Fewer records are written for each LCP, LCPs use more space
- More work is needed during restarts

A lower value for `RecoveryWork` means:

- More records are written during each LCP, but LCPs require less space on disk.
- Less work during restart and thus faster restarts, at the expense of more work during normal operations

For example, setting `RecoveryWork` to 60 means that the total size of an LCP is roughly $1 + 0.6 = 1.6$ times the size of the data to be checkpointed. This means that 60% more work is required during the restore phase of a restart compared to the work done during a restart that uses full checkpoints. (This is more than compensated for during other phases of the restart such that the restart as a whole is still faster when using partial LCPs than when using full LCPs.) In order not to fill up the redo log, it is necessary to write at $1 + (1 / \text{RecoveryWork})$ times the rate of data changes during checkpoints—thus, when `RecoveryWork` = 60, it is necessary to write at approximately $1 + (1 / 0.6) = 2.67$ times the

change rate. In other words, if changes are being written at 10 MByte per second, the checkpoint needs to be written at roughly 26.7 MByte per second.

Setting `RecoveryWork` = 40 means that only 1.4 times the total LCP size is needed (and thus the restore phase takes 10 to 15 percent less time. In this case, the checkpoint write rate is 3.5 times the rate of change.

The NDB source distribution includes a test program for simulating LCPs. `lcp_simulator.cc` can be found in `storage/ndb/src/kernel/blocks/backup/`. To compile and run it on Unix platforms, execute the commands shown here:

```
shell> gcc lcp_simulator.cc
shell> ./a.out
```

This program has no dependencies other than `stdio.h`, and does not require a connection to an NDB cluster or a MySQL server. By default, it simulates 300 LCPs (three sets of 100 LCPs, each consisting of inserts, updates, and deletes, in turn), reporting the size of the LCP after each one. You can alter the simulation by changing the values of `recovery_work`, `insert_work`, and `delete_work` in the source and recompiling. For more information, see the source of the program.

- `InsertRecoveryWork`

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | integer |
| Default | 40 |
| Range | 0 - 70 |
| Restart Type | N (NDB 8.0.13) |

Percentage of `RecoveryWork` used for inserted rows. A higher value increases the number of writes during a local checkpoint, and decreases the total size of the LCP. A lower value decreases the number of writes during an LCP, but results in more space being used for the LCP, which means that recovery takes longer. This parameter has an effect only when `EnablePartialLcp` is true, that is, only when partial local checkpoints are enabled.

- `EnableRedoControl`

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | boolean |
| Default | false |
| Range | ... |
| Restart Type | N (NDB 8.0.13) |

Enable adaptive checkpointing speed for controlling redo log usage. Set to `false` to disable (the default). Setting `EnablePartialLcp` to `false` also disables the adaptive calculation.

When enabled, `EnableRedoControl` allows the data nodes greater flexibility with regard to the rate at which they write LCPs to disk. More specifically, enabling this parameter means that higher write rates can be employed, so that LCPs can complete and Redo logs be trimmed more quickly, thereby reducing recovery time and disk space requirements. This functionality allows data nodes to make better use

of the higher rate of I/O and greater bandwidth available from modern solid-state storage devices and protocols, such as solid-state drives (SSDs) using Non-Volatile Memory Express (NVMe).

The parameter currently defaults to `false` (disabled) due to the fact that NDB is still deployed widely on systems whose I/O or bandwidth is constrained relative to those employing solid-state technology, such as those using conventional hard disks (HDDs). In settings such as these, the `EnableRedoControl` mechanism can easily cause the I/O subsystem to become saturated, increasing wait times for data node input and output. In particular, this can cause issues with NDB Disk Data tables which have tablespaces or log file groups sharing a constrained IO subsystem with data node LCP and redo log files; such problems potentially include node or cluster failure due to GCP stop errors.

Metadata objects. The next set of `[ndbd]` parameters defines pool sizes for metadata objects, used to define the maximum number of attributes, tables, indexes, and trigger objects used by indexes, events, and replication between clusters.

Note

These act merely as “suggestions” to the cluster, and any that are not specified revert to the default values shown.

- `MaxNoOfAttributes`

| | |
|--------------------|------------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | integer |
| Default | 1000 |
| Range | 32 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

This parameter sets a suggested maximum number of attributes that can be defined in the cluster; like `MaxNoOfTables`, it is not intended to function as a hard upper limit.

(In older NDB Cluster releases, this parameter was sometimes treated as a hard limit for certain operations. This caused problems with NDB Cluster Replication, when it was possible to create more tables than could be replicated, and sometimes led to confusion when it was possible [or not possible, depending on the circumstances] to create more than `MaxNoOfAttributes` attributes.)

The default value is 1000, with the minimum possible value being 32. The maximum is 4294967039. Each attribute consumes around 200 bytes of storage per node due to the fact that all metadata is fully replicated on the servers.

When setting `MaxNoOfAttributes`, it is important to prepare in advance for any `ALTER TABLE` statements that you might want to perform in the future. This is due to the fact, during the execution of `ALTER TABLE` on a Cluster table, 3 times the number of attributes as in the original table are used, and a good practice is to permit double this amount. For example, if the NDB Cluster table having the greatest number of attributes (`greatest_number_of_attributes`) has 100 attributes, a good starting point for the value of `MaxNoOfAttributes` would be $6 * \text{greatest_number_of_attributes} = 600$.

You should also estimate the average number of attributes per table and multiply this by `MaxNoOfTables`. If this value is larger than the value obtained in the previous paragraph, you should use the larger value instead.

Assuming that you can create all desired tables without any problems, you should also verify that this number is sufficient by trying an actual `ALTER TABLE` after configuring the parameter. If this is not successful, increase `MaxNoOfAttributes` by another multiple of `MaxNoOfTables` and test it again.

- `MaxNoOfTables`

| | |
|--------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | integer |
| Default | 128 |
| Range | 8 - 20320 |
| Restart Type | N (NDB 8.0.13) |

A table object is allocated for each table and for each unique hash index in the cluster. This parameter sets a suggested maximum number of table objects for the cluster as a whole; like `MaxNoOfAttributes`, it is not intended to function as a hard upper limit.

(In older NDB Cluster releases, this parameter was sometimes treated as a hard limit for certain operations. This caused problems with NDB Cluster Replication, when it was possible to create more tables than could be replicated, and sometimes led to confusion when it was possible [or not possible, depending on the circumstances] to create more than `MaxNoOfTables` tables.)

For each attribute that has a `BLOB` data type an extra table is used to store most of the `BLOB` data. These tables also must be taken into account when defining the total number of tables.

The default value of this parameter is 128. The minimum is 8 and the maximum is 20320. Each table object consumes approximately 20KB per node.

Note

The sum of `MaxNoOfTables`, `MaxNoOfOrderedIndexes`, and `MaxNoOfUniqueHashIndexes` must not exceed $2^{32} - 2$ (4294967294).

- `MaxNoOfOrderedIndexes`

| | |
|--------------------|-----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | integer |
| Default | 128 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

For each ordered index in the cluster, an object is allocated describing what is being indexed and its storage segments. By default, each index so defined also defines an ordered index. Each unique index and primary key has both an ordered index and a hash index. `MaxNoOfOrderedIndexes` sets the total number of ordered indexes that can be in use in the system at any one time.

The default value of this parameter is 128. Each index object consumes approximately 10KB of data per node.

Note

The sum of `MaxNoOfTables`, `MaxNoOfOrderedIndexes`, and `MaxNoOfUniqueHashIndexes` must not exceed $2^{32} - 2$ (4294967294).

- [MaxNoOfUniqueHashIndexes](#)

| | |
|------------------------------|-----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | integer |
| Default | 64 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

For each unique index that is not a primary key, a special table is allocated that maps the unique key to the primary key of the indexed table. By default, an ordered index is also defined for each unique index. To prevent this, you must specify the `USING HASH` option when defining the unique index.

The default value is 64. Each index consumes approximately 15KB per node.

Note

The sum of `MaxNoOfTables`, `MaxNoOfOrderedIndexes`, and `MaxNoOfUniqueHashIndexes` must not exceed $2^{32} - 2$ (4294967294).

- [MaxNoOfTriggers](#)

| | |
|------------------------------|-----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | integer |
| Default | 768 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

Internal update, insert, and delete triggers are allocated for each unique hash index. (This means that three triggers are created for each unique hash index.) However, an *ordered* index requires only a single trigger object. Backups also use three trigger objects for each normal table in the cluster.

Replication between clusters also makes use of internal triggers.

This parameter sets the maximum number of trigger objects in the cluster.

The default value is 768.

- [MaxNoOfSubscriptions](#)

| | |
|------------------------------|-----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | unsigned |
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

Each NDB table in an NDB Cluster requires a subscription in the NDB kernel. For some NDB API applications, it may be necessary or desirable to change this parameter. However, for normal usage with MySQL servers acting as SQL nodes, there is not any need to do so.

The default value for `MaxNoOfSubscriptions` is 0, which is treated as equal to `MaxNoOfTables`. Each subscription consumes 108 bytes.

- [MaxNoOfSubscribers](#)

| | |
|------------------------------|-----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | unsigned |
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

This parameter is of interest only when using NDB Cluster Replication. The default value is 0. Prior to NDB 8.0.26, this was treated as $2 * \text{MaxNoOfTables}$; beginning with NDB 8.0.26, it is treated as $2 * \text{MaxNoOfTables} + 2 * [\text{number of API nodes}]$. There is one subscription per NDB table for each of two MySQL servers (one acting as the replication source and the other as the replica). Each subscriber uses 16 bytes of memory.

When using circular replication, multi-source replication, and other replication setups involving more than 2 MySQL servers, you should increase this parameter to the number of `mysqld` processes included in replication (this is often, but not always, the same as the number of clusters). For example, if you have a circular replication setup using three NDB Clusters, with one `mysqld` attached to each cluster, and each of these `mysqld` processes acts as a source and as a replica, you should set `MaxNoOfSubscribers` equal to $3 * \text{MaxNoOfTables}$.

For more information, see [Section 23.7, “NDB Cluster Replication”](#).

- [MaxNoOfConcurrentSubOperations](#)

| | |
|------------------------------|-----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | unsigned |
| Default | 256 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

This parameter sets a ceiling on the number of operations that can be performed by all API nodes in the cluster at one time. The default value (256) is sufficient for normal operations, and might need to be adjusted only in scenarios where there are a great many API nodes each performing a high volume of operations concurrently.

Boolean parameters. The behavior of data nodes is also affected by a set of `[ndbd]` parameters taking on boolean values. These parameters can each be specified as `TRUE` by setting them equal to `1` or `Y`, and as `FALSE` by setting them equal to `0` or `N`.

- [CompressedLCP](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | boolean |
| Default | false |
| Range | true, false |
| Restart Type | N (NDB 8.0.13) |

Setting this parameter to `1` causes local-checkpoint files to be compressed. The compression used is equivalent to `gzip --fast`, and can save 50% or more of the space required on the data node to store

uncompressed checkpoint files. Compressed LCPs can be enabled for individual data nodes, or for all data nodes (by setting this parameter in the `[ndbd default]` section of the `config.ini` file).

Important

You cannot restore a compressed local checkpoint to a cluster running a MySQL version that does not support this feature.

The default value is 0 (disabled).

- [CrashOnCorruptedTuple](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | boolean |
| Default | true |
| Range | true, false |
| Restart Type | N (NDB 8.0.13) |

When this parameter is enabled (the default), it forces a data node to shut down whenever it encounters a corrupted tuple.

- [Diskless](#)

| | |
|------------------------------|------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | true false (1 0) |
| Default | false |
| Range | true, false |
| Restart Type | IS (NDB 8.0.13) |

It is possible to specify NDB Cluster tables as *diskless*, meaning that tables are not checkpointed to disk and that no logging occurs. Such tables exist only in main memory. A consequence of using diskless tables is that neither the tables nor the records in those tables survive a crash. However, when operating in diskless mode, it is possible to run `ndbd` on a diskless computer.

Important

This feature causes the *entire* cluster to operate in diskless mode.

When this feature is enabled, Cluster online backup is disabled. In addition, a partial start of the cluster is not possible.

`Diskless` is disabled by default.

- [LateAlloc](#)

| | |
|--------------------|------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | numeric |
| Default | 1 |
| Range | 0 - 1 |

| | |
|--------------|----------------|
| Restart Type | N (NDB 8.0.13) |
|--------------|----------------|

Allocate memory for this data node after a connection to the management server has been established. Enabled by default.

- [LockPagesInMainMemory](#)

| | |
|--------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | numeric |
| Default | 0 |
| Range | 0 - 2 |
| Restart Type | N (NDB 8.0.13) |

For a number of operating systems, including Solaris and Linux, it is possible to lock a process into memory and so avoid any swapping to disk. This can be used to help guarantee the cluster's real-time characteristics.

This parameter takes one of the integer values `0`, `1`, or `2`, which act as shown in the following list:

- `0`: Disables locking. This is the default value.
- `1`: Performs the lock after allocating memory for the process.
- `2`: Performs the lock before memory for the process is allocated.

If the operating system is not configured to permit unprivileged users to lock pages, then the data node process making use of this parameter may have to be run as system root. ([LockPagesInMainMemory](#) uses the `mlockall` function. From Linux kernel 2.6.9, unprivileged users can lock memory as limited by `max locked memory`. For more information, see `ulimit -l` and <http://linux.die.net/man/2/mlock>).

Note

In older NDB Cluster releases, this parameter was a Boolean. `0` or `false` was the default setting, and disabled locking. `1` or `true` enabled locking of the process after its memory was allocated. NDB Cluster 8.0 treats `true` or `false` for the value of this parameter as an error.

Important

Beginning with `glibc` 2.10, `glibc` uses per-thread arenas to reduce lock contention on a shared pool, which consumes real memory. In general, a data node process does not need per-thread arenas, since it does not perform any memory allocation after startup. (This difference in allocators does not appear to affect performance significantly.)

The `glibc` behavior is intended to be configurable via the `MALLOC_ARENA_MAX` environment variable, but a bug in this mechanism prior to `glibc` 2.16 meant that this variable could not be set to less than 8, so that the wasted memory could not be reclaimed. (Bug #15907219; see also http://sourceware.org/bugzilla/show_bug.cgi?id=13137 for more information concerning this issue.)

One possible workaround for this problem is to use the `LD_PRELOAD` environment variable to preload a `jemalloc` memory allocation library to take the place of that supplied with `glibc`.

- `ODirect`

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | boolean |
| Default | false |
| Range | true, false |
| Restart Type | N (NDB 8.0.13) |

Enabling this parameter causes NDB to attempt using `O_DIRECT` writes for LCP, backups, and redo logs, often lowering `kswapd` and CPU usage. When using NDB Cluster on Linux, enable `ODirect` if you are using a 2.6 or later kernel.

`ODirect` is disabled by default.

- `ODirectSyncFlag`

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | boolean |
| Default | false |
| Range | true, false |
| Restart Type | N (NDB 8.0.13) |

When this parameter is enabled, redo log writes are performed such that each completed file system write is handled as a call to `fsync`. The setting for this parameter is ignored if at least one of the following conditions is true:

- `ODirect` is not enabled.
- `InitFragmentLogFiles` is set to `SPARSE`.

Disabled by default.

- `RestartOnErrorInsert`

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | error code |
| Default | 2 |
| Range | 0 - 4 |
| Restart Type | N (NDB 8.0.13) |

This feature is accessible only when building the debug version where it is possible to insert errors in the execution of individual blocks of code as part of testing.

This feature is disabled by default.

- `StopOnError`

| | |
|--------------------|------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | boolean |
| Default | 1 |

| | |
|------------------------------|----------------|
| Range | 0, 1 |
| Restart Type | N (NDB 8.0.13) |

This parameter specifies whether a data node process should exit or perform an automatic restart when an error condition is encountered.

This parameter's default value is 1; this means that, by default, an error causes the data node process to halt.

When an error is encountered and `StopOnError` is 0, the data node process is restarted.

Users of MySQL Cluster Manager should note that, when `StopOnError` equals 1, this prevents the MySQL Cluster Manager agent from restarting any data nodes after it has performed its own restart and recovery. See [Starting and Stopping the Agent on Linux](#), for more information.

- [UseShm](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | boolean |
| Default | false |
| Range | true, false |
| Restart Type | N (NDB 8.0.13) |

Enable a shared memory connection between this data node and the API node also running on this host. Set to 1 to enable.

Controlling Timeouts, Intervals, and Disk Paging

There are a number of `[ndbd]` parameters specifying timeouts and intervals between various actions in Cluster data nodes. Most of the timeout values are specified in milliseconds. Any exceptions to this are mentioned where applicable.

- [TimeBetweenWatchDogCheck](#)

| | |
|------------------------------|------------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | milliseconds |
| Default | 6000 |
| Range | 70 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

To prevent the main thread from getting stuck in an endless loop at some point, a “watchdog” thread checks the main thread. This parameter specifies the number of milliseconds between checks. If the process remains in the same state after three checks, the watchdog thread terminates it.

This parameter can easily be changed for purposes of experimentation or to adapt to local conditions. It can be specified on a per-node basis although there seems to be little reason for doing so.

The default timeout is 6000 milliseconds (6 seconds).

- [TimeBetweenWatchDogCheckInitial](#)

| | |
|--------------------|------------|
| Version (or later) | NDB 8.0.13 |
|--------------------|------------|

| | |
|------------------------------|------------------------------|
| Type or units | milliseconds |
| Default | 6000 |
| Range | 70 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

This is similar to the [TimeBetweenWatchDogCheck](#) parameter, except that [TimeBetweenWatchDogCheckInitial](#) controls the amount of time that passes between execution checks inside a storage node in the early start phases during which memory is allocated.

The default timeout is 6000 milliseconds (6 seconds).

- [StartPartialTimeout](#)

| | |
|------------------------------|-----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | milliseconds |
| Default | 30000 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

This parameter specifies how long the Cluster waits for all data nodes to come up before the cluster initialization routine is invoked. This timeout is used to avoid a partial Cluster startup whenever possible.

This parameter is overridden when performing an initial start or initial restart of the cluster.

The default value is 30000 milliseconds (30 seconds). 0 disables the timeout, in which case the cluster may start only if all nodes are available.

- [StartPartitionedTimeout](#)

| | |
|------------------------------|-----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | milliseconds |
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

If the cluster is ready to start after waiting for [StartPartialTimeout](#) milliseconds but is still possibly in a partitioned state, the cluster waits until this timeout has also passed. If [StartPartitionedTimeout](#) is set to 0, the cluster waits indefinitely ($2^{32}-1$ ms, or approximately 49.71 days).

This parameter is overridden when performing an initial start or initial restart of the cluster.

- [StartFailureTimeout](#)

| | |
|--------------------|-----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | milliseconds |
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |

| | |
|------------------------------|----------------|
| Restart Type | N (NDB 8.0.13) |
|------------------------------|----------------|

If a data node has not completed its startup sequence within the time specified by this parameter, the node startup fails. Setting this parameter to 0 (the default value) means that no data node timeout is applied.

For nonzero values, this parameter is measured in milliseconds. For data nodes containing extremely large amounts of data, this parameter should be increased. For example, in the case of a data node containing several gigabytes of data, a period as long as 10–15 minutes (that is, 600000 to 1000000 milliseconds) might be required to perform a node restart.

- [StartNoNodeGroupTimeout](#)

| | |
|------------------------------|-----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | milliseconds |
| Default | 15000 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

When a data node is configured with `Nodegroup = 65536`, is regarded as not being assigned to any node group. When that is done, the cluster waits `StartNoNodegroupTimeout` milliseconds, then treats such nodes as though they had been added to the list passed to the `--nowait-nodes` option, and starts. The default value is `15000` (that is, the management server waits 15 seconds). Setting this parameter equal to `0` means that the cluster waits indefinitely.

`StartNoNodegroupTimeout` must be the same for all data nodes in the cluster; for this reason, you should always set it in the `[ndbd default]` section of the `config.ini` file, rather than for individual data nodes.

See [Section 23.6.7, “Adding NDB Cluster Data Nodes Online”](#), for more information.

- [HeartbeatIntervalDbDb](#)

| | |
|------------------------------|------------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | milliseconds |
| Default | 5000 |
| Range | 10 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

One of the primary methods of discovering failed nodes is by the use of heartbeats. This parameter states how often heartbeat signals are sent and how often to expect to receive them. Heartbeats cannot be disabled.

After missing four heartbeat intervals in a row, the node is declared dead. Thus, the maximum time for discovering a failure through the heartbeat mechanism is five times the heartbeat interval.

The default heartbeat interval is 5000 milliseconds (5 seconds). This parameter must not be changed drastically and should not vary widely between nodes. If one node uses 5000 milliseconds and the node

watching it uses 1000 milliseconds, obviously the node is declared dead very quickly. This parameter can be changed during an online software upgrade, but only in small increments.

See also [Network communication and latency](#), as well as the description of the [ConnectCheckIntervalDelay](#) configuration parameter.

- [HeartbeatIntervalDbApi](#)

| | |
|------------------------------|-------------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | milliseconds |
| Default | 1500 |
| Range | 100 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

Each data node sends heartbeat signals to each MySQL server (SQL node) to ensure that it remains in contact. If a MySQL server fails to send a heartbeat in time it is declared “dead,” in which case all ongoing transactions are completed and all resources released. The SQL node cannot reconnect until all activities initiated by the previous MySQL instance have been completed. The three-heartbeat criteria for this determination are the same as described for [HeartbeatIntervalDbDb](#).

The default interval is 1500 milliseconds (1.5 seconds). This interval can vary between individual data nodes because each data node watches the MySQL servers connected to it, independently of all other data nodes.

For more information, see [Network communication and latency](#).

- [HeartbeatOrder](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | numeric |
| Default | 0 |
| Range | 0 - 65535 |
| Restart Type | S (NDB 8.0.13) |

Data nodes send heartbeats to one another in a circular fashion whereby each data node monitors the previous one. If a heartbeat is not detected by a given data node, this node declares the previous data node in the circle “dead” (that is, no longer accessible by the cluster). The determination that a data node is dead is done globally; in other words; once a data node is declared dead, it is regarded as such by all nodes in the cluster.

It is possible for heartbeats between data nodes residing on different hosts to be too slow compared to heartbeats between other pairs of nodes (for example, due to a very low heartbeat interval or temporary connection problem), such that a data node is declared dead, even though the node can still function as part of the cluster. .

In this type of situation, it may be that the order in which heartbeats are transmitted between data nodes makes a difference as to whether or not a particular data node is declared dead. If this declaration

occurs unnecessarily, this can in turn lead to the unnecessary loss of a node group and as thus to a failure of the cluster.

Consider a setup where there are 4 data nodes A, B, C, and D running on 2 host computers `host1` and `host2`, and that these data nodes make up 2 node groups, as shown in the following table:

Table 23.10 Four data nodes A, B, C, D running on two host computers `host1`, `host2`; each data node belongs to one of two node groups.

| Node Group | Nodes Running on <code>host1</code> | Nodes Running on <code>host2</code> |
|---------------|-------------------------------------|-------------------------------------|
| Node Group 0: | Node A | Node B |
| Node Group 1: | Node C | Node D |

Suppose the heartbeats are transmitted in the order A->B->C->D->A. In this case, the loss of the heartbeat between the hosts causes node B to declare node A dead and node C to declare node B dead. This results in loss of Node Group 0, and so the cluster fails. On the other hand, if the order of transmission is A->B->D->C->A (and all other conditions remain as previously stated), the loss of the heartbeat causes nodes A and D to be declared dead; in this case, each node group has one surviving node, and the cluster survives.

The `HeartbeatOrder` configuration parameter makes the order of heartbeat transmission user-configurable. The default value for `HeartbeatOrder` is zero; allowing the default value to be used on all data nodes causes the order of heartbeat transmission to be determined by `NDB`. If this parameter is used, it must be set to a nonzero value (maximum 65535) for every data node in the cluster, and this value must be unique for each data node; this causes the heartbeat transmission to proceed from data node to data node in the order of their `HeartbeatOrder` values from lowest to highest (and then directly from the data node having the highest `HeartbeatOrder` to the data node having the lowest value, to complete the circle). The values need not be consecutive. For example, to force the heartbeat transmission order A->B->D->C->A in the scenario outlined previously, you could set the `HeartbeatOrder` values as shown here:

Table 23.11 `HeartbeatOrder` values to force a heartbeat transition order of A->B->D->C->A.

| Node | <code>HeartbeatOrder</code> Value |
|------|-----------------------------------|
| A | 10 |
| B | 20 |
| C | 30 |
| D | 25 |

To use this parameter to change the heartbeat transmission order in a running NDB Cluster, you must first set `HeartbeatOrder` for each data node in the cluster in the global configuration (`config.ini`) file (or files). To cause the change to take effect, you must perform either of the following:

- A complete shutdown and restart of the entire cluster.
- 2 rolling restarts of the cluster in succession. *All nodes must be restarted in the same order in both rolling restarts.*

You can use `DUMP 908` to observe the effect of this parameter in the data node logs.

- `ConnectCheckIntervalDelay`

| | |
|------------------------------|-----------------------------|
| Type or units | milliseconds |
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

This parameter enables connection checking between data nodes after one of them has failed heartbeat checks for 5 intervals of up to `HeartbeatIntervalDbDb` milliseconds.

Such a data node that further fails to respond within an interval of `ConnectCheckIntervalDelay` milliseconds is considered suspect, and is considered dead after two such intervals. This can be useful in setups with known latency issues.

The default value for this parameter is 0 (disabled).

- [TimeBetweenLocalCheckpoints](#)

| | |
|------------------------------|---|
| Version (or later) | NDB 8.0.13 |
| Type or units | number of 4-byte words, as base-2 logarithm |
| Default | 20 |
| Range | 0 - 31 |
| Restart Type | N (NDB 8.0.13) |

This parameter is an exception in that it does not specify a time to wait before starting a new local checkpoint; rather, it is used to ensure that local checkpoints are not performed in a cluster where relatively few updates are taking place. In most clusters with high update rates, it is likely that a new local checkpoint is started immediately after the previous one has been completed.

The size of all write operations executed since the start of the previous local checkpoints is added. This parameter is also exceptional in that it is specified as the base-2 logarithm of the number of 4-byte words, so that the default value 20 means 4MB (4×2^{20}) of write operations, 21 would mean 8MB, and so on up to a maximum value of 31, which equates to 8GB of write operations.

All the write operations in the cluster are added together. Setting `TimeBetweenLocalCheckpoints` to 6 or less means that local checkpoints are executed continuously without pause, independent of the cluster's workload.

- [TimeBetweenGlobalCheckpoints](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | milliseconds |
| Default | 2000 |
| Range | 20 - 32000 |
| Restart Type | N (NDB 8.0.13) |

When a transaction is committed, it is committed in main memory in all nodes on which the data is mirrored. However, transaction log records are not flushed to disk as part of the commit. The reasoning behind this behavior is that having the transaction safely committed on at least two autonomous host machines should meet reasonable standards for durability.

It is also important to ensure that even the worst of cases—a complete crash of the cluster—is handled properly. To guarantee that this happens, all transactions taking place within a given interval are put into

a global checkpoint, which can be thought of as a set of committed transactions that has been flushed to disk. In other words, as part of the commit process, a transaction is placed in a global checkpoint group. Later, this group's log records are flushed to disk, and then the entire group of transactions is safely committed to disk on all computers in the cluster.

In NDB 8.0, we recommended when you are using solid-state disks (especially those employing NVMe) with Disk Data tables that you reduce this value. In such cases, you should also ensure that [MaxDiskDataLatency](#) is set to a proper level.

This parameter defines the interval between global checkpoints. The default is 2000 milliseconds.

- [TimeBetweenGlobalCheckpointsTimeout](#)

| | |
|------------------------------|------------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | milliseconds |
| Default | 120000 |
| Range | 10 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

This parameter defines the minimum timeout between global checkpoints. The default is 120000 milliseconds.

- [TimeBetweenEpochs](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | milliseconds |
| Default | 100 |
| Range | 0 - 32000 |
| Restart Type | N (NDB 8.0.13) |

This parameter defines the interval between synchronization epochs for NDB Cluster Replication. The default value is 100 milliseconds.

[TimeBetweenEpochs](#) is part of the implementation of “micro-GCPs”, which can be used to improve the performance of NDB Cluster Replication.

- [TimeBetweenEpochsTimeout](#)

| | |
|--------------------|--------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | milliseconds |
| Default | 0 |
| Range | 0 - 256000 |

| | |
|------------------------------|----------------|
| Restart Type | N (NDB 8.0.13) |
|------------------------------|----------------|

This parameter defines a timeout for synchronization epochs for NDB Cluster Replication. If a node fails to participate in a global checkpoint within the time determined by this parameter, the node is shut down. The default value is 0; in other words, the timeout is disabled.

[TimeBetweenEpochsTimeout](#) is part of the implementation of “micro-GCPs”, which can be used to improve the performance of NDB Cluster Replication.

The current value of this parameter and a warning are written to the cluster log whenever a GCP save takes longer than 1 minute or a GCP commit takes longer than 10 seconds.

Setting this parameter to zero has the effect of disabling GCP stops caused by save timeouts, commit timeouts, or both. The maximum possible value for this parameter is 256000 milliseconds.

- [MaxBufferedEpochs](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | epochs |
| Default | 100 |
| Range | 0 - 100000 |
| Restart Type | N (NDB 8.0.13) |

The number of unprocessed epochs by which a subscribing node can lag behind. Exceeding this number causes a lagging subscriber to be disconnected.

The default value of 100 is sufficient for most normal operations. If a subscribing node does lag enough to cause disconnections, it is usually due to network or scheduling issues with regard to processes or threads. (In rare circumstances, the problem may be due to a bug in the [NDB](#) client.) It may be desirable to set the value lower than the default when epochs are longer.

Disconnection prevents client issues from affecting the data node service, running out of memory to buffer data, and eventually shutting down. Instead, only the client is affected as a result of the disconnect (by, for example gap events in the binary log), forcing the client to reconnect or restart the process.

- [MaxBufferedEpochBytes](#)

| | |
|------------------------------|---|
| Version (or later) | NDB 8.0.13 |
| Type or units | bytes |
| Default | 26214400 |
| Range | 26214400 (0x01900000) - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

The total number of bytes allocated for buffering epochs by this node.

- [TimeBetweenInactiveTransactionAbortCheck](#)

| | |
|--------------------|--------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | milliseconds |
| Default | 1000 |

| | |
|------------------------------|--------------------------------|
| Range | 1000 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

Timeout handling is performed by checking a timer on each transaction once for every interval specified by this parameter. Thus, if this parameter is set to 1000 milliseconds, every transaction is checked for timing out once per second.

The default value is 1000 milliseconds (1 second).

- [TransactionInactiveTimeout](#)

| | |
|------------------------------|-----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | milliseconds |
| Default | 4294967039 (0xFFFFFFFF) |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

This parameter states the maximum time that is permitted to lapse between operations in the same transaction before the transaction is aborted.

The default for this parameter is 4G (also the maximum). For a real-time database that needs to ensure that no transaction keeps locks for too long, this parameter should be set to a relatively small value. Setting it to 0 means that the application never times out. The unit is milliseconds.

- [TransactionDeadlockDetectionTimeout](#)

| | |
|------------------------------|------------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | milliseconds |
| Default | 1200 |
| Range | 50 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

When a node executes a query involving a transaction, the node waits for the other nodes in the cluster to respond before continuing. This parameter sets the amount of time that the transaction can spend executing within a data node, that is, the time that the transaction coordinator waits for each data node participating in the transaction to execute a request.

A failure to respond can occur for any of the following reasons:

- The node is “dead”
- The operation has entered a lock queue
- The node requested to perform the action could be heavily overloaded.

This timeout parameter states how long the transaction coordinator waits for query execution by another node before aborting the transaction, and is important for both node failure handling and deadlock detection.

The default timeout value is 1200 milliseconds (1.2 seconds).

- [DiskSyncSize](#)

| | |
|------------------------------|-------------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | bytes |
| Default | 4M |
| Range | 32K - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

This is the maximum number of bytes to store before flushing data to a local checkpoint file. This is done to prevent write buffering, which can impede performance significantly. This parameter is *not* intended to take the place of [TimeBetweenLocalCheckpoints](#).

Note

When [ODirect](#) is enabled, it is not necessary to set [DiskSyncSize](#); in fact, in such cases its value is simply ignored.

The default value is 4M (4 megabytes).

- [MaxDiskWriteSpeed](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | numeric |
| Default | 20M |
| Range | 1M - 1024G |
| Restart Type | S (NDB 8.0.13) |

Set the maximum rate for writing to disk, in bytes per second, by local checkpoints and backup operations when no restarts (by this data node or any other data node) are taking place in this NDB Cluster.

For setting the maximum rate of disk writes allowed while this data node is restarting, use [MaxDiskWriteSpeedOwnRestart](#). For setting the maximum rate of disk writes allowed while other data nodes are restarting, use [MaxDiskWriteSpeedOtherNodeRestart](#). The minimum speed for disk writes by all LCPs and backup operations can be adjusted by setting [MinDiskWriteSpeed](#).

- [MaxDiskWriteSpeedOtherNodeRestart](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | numeric |
| Default | 50M |
| Range | 1M - 1024G |
| Restart Type | S (NDB 8.0.13) |

Set the maximum rate for writing to disk, in bytes per second, by local checkpoints and backup operations when one or more data nodes in this NDB Cluster are restarting, other than this node.

For setting the maximum rate of disk writes allowed while this data node is restarting, use [MaxDiskWriteSpeedOwnRestart](#). For setting the maximum rate of disk writes allowed when no data

nodes are restarting anywhere in the cluster, use [MaxDiskWriteSpeed](#). The minimum speed for disk writes by all LCPs and backup operations can be adjusted by setting [MinDiskWriteSpeed](#).

- [MaxDiskWriteSpeedOwnRestart](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | numeric |
| Default | 200M |
| Range | 1M - 1024G |
| Restart Type | S (NDB 8.0.13) |

Set the maximum rate for writing to disk, in bytes per second, by local checkpoints and backup operations while this data node is restarting.

For setting the maximum rate of disk writes allowed while other data nodes are restarting, use [MaxDiskWriteSpeedOtherNodeRestart](#). For setting the maximum rate of disk writes allowed when no data nodes are restarting anywhere in the cluster, use [MaxDiskWriteSpeed](#). The minimum speed for disk writes by all LCPs and backup operations can be adjusted by setting [MinDiskWriteSpeed](#).

- [MinDiskWriteSpeed](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | numeric |
| Default | 10M |
| Range | 1M - 1024G |
| Restart Type | S (NDB 8.0.13) |

Set the minimum rate for writing to disk, in bytes per second, by local checkpoints and backup operations.

The maximum rates of disk writes allowed for LCPs and backups under various conditions are adjustable using the parameters [MaxDiskWriteSpeed](#), [MaxDiskWriteSpeedOwnRestart](#), and [MaxDiskWriteSpeedOtherNodeRestart](#). See the descriptions of these parameters for more information.

- [ArbitrationTimeout](#)

| | |
|------------------------------|------------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | milliseconds |
| Default | 7500 |
| Range | 10 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

This parameter specifies how long data nodes wait for a response from the arbitrator to an arbitration message. If this is exceeded, the network is assumed to have split.

The default value is 7500 milliseconds (7.5 seconds).

- [Arbitration](#)

| | |
|--------------------|------------|
| Version (or later) | NDB 8.0.13 |
|--------------------|------------|

| | |
|------------------------------|---------------------------------|
| Type or units | enumeration |
| Default | Default |
| Range | Default, Disabled, WaitExternal |
| Restart Type | N (NDB 8.0.13) |

The [Arbitration](#) parameter enables a choice of arbitration schemes, corresponding to one of 3 possible values for this parameter:

- **Default.** This enables arbitration to proceed normally, as determined by the [ArbitrationRank](#) settings for the management and API nodes. This is the default value.
- **Disabled.** Setting [Arbitration = Disabled](#) in the `[ndbd default]` section of the `config.ini` file to accomplish the same task as setting [ArbitrationRank](#) to 0 on all management and API nodes. When [Arbitration](#) is set in this way, any [ArbitrationRank](#) settings are ignored.
- **WaitExternal.** The [Arbitration](#) parameter also makes it possible to configure arbitration in such a way that the cluster waits until after the time determined by [ArbitrationTimeout](#) has passed for an external cluster manager application to perform arbitration instead of handling arbitration internally. This can be done by setting [Arbitration = WaitExternal](#) in the `[ndbd default]` section of the `config.ini` file. For best results with the [WaitExternal](#) setting, it is recommended that [ArbitrationTimeout](#) be 2 times as long as the interval required by the external cluster manager to perform arbitration.

Important

This parameter should be used only in the `[ndbd default]` section of the cluster configuration file. The behavior of the cluster is unspecified when [Arbitration](#) is set to different values for individual data nodes.

- [RestartSubscriberConnectTimeout](#)

| | |
|------------------------------|-----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | ms |
| Default | 12000 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

This parameter determines the time that a data node waits for subscribing API nodes to connect. Once this timeout expires, any “missing” API nodes are disconnected from the cluster. To disable this timeout, set [RestartSubscriberConnectTimeout](#) to 0.

While this parameter is specified in milliseconds, the timeout itself is resolved to the next-greatest whole second.

- [KeepAliveSendInterval](#)

| | |
|--------------------|-----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | integer |
| Default | 60000 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |

| | |
|------------------------------|----------------|
| Added | NDB 8.0.27 |
| Restart Type | N (NDB 8.0.13) |

Beginning with NDB 8.0.27, it is possible to enable and control the interval between keep-alive signals sent between data nodes by setting this parameter. The default for `KeepAliveSendInterval` is 60000 milliseconds (one minute); setting it to 0 disables keep-alive signals. Values between 1 and 10 inclusive are treated as 10.

This parameter may prove useful in environments which monitor and disconnect idle TCP connections, possibly causing unnecessary data node failures when the cluster is idle.

Buffering and logging. Several `[ndbd]` configuration parameters enable the advanced user to have more control over the resources used by node processes and to adjust various buffer sizes at need.

These buffers are used as front ends to the file system when writing log records to disk. If the node is running in diskless mode, these parameters can be set to their minimum values without penalty due to the fact that disk writes are “faked” by the NDB storage engine’s file system abstraction layer.

- [UndoIndexBuffer](#)

| | |
|------------------------------|------------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | unsigned |
| Default | 2M |
| Range | 1M - 4294967039 (0xFFFFFFFF) |
| Deprecated | NDB 8.0.27 |
| Restart Type | N (NDB 8.0.13) |

This parameter formerly set the size of the undo index buffer, but has no effect in current versions of NDB Cluster.

In NDB 8.0.27 and later, the use of this parameter in the cluster configuration file raises a deprecation warning; you should expect it to be removed in a future NDB Cluster release.

- [UndoDataBuffer](#)

| | |
|------------------------------|------------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | unsigned |
| Default | 16M |
| Range | 1M - 4294967039 (0xFFFFFFFF) |
| Deprecated | NDB 8.0.27 |
| Restart Type | N (NDB 8.0.13) |

This parameter formerly set the size of the undo data buffer, but has no effect in current versions of NDB Cluster.

In NDB 8.0.27 and later, the use of this parameter in the cluster configuration file raises a deprecation warning; you should expect it to be removed in a future NDB Cluster release.

- [RedoBuffer](#)

| | |
|--------------------|------------|
| Version (or later) | NDB 8.0.13 |
|--------------------|------------|

| | |
|------------------------------|------------------------------|
| Type or units | bytes |
| Default | 32M |
| Range | 1M - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

All update activities also need to be logged. The REDO log makes it possible to replay these updates whenever the system is restarted. The NDB recovery algorithm uses a “fuzzy” checkpoint of the data together with the UNDO log, and then applies the REDO log to play back all changes up to the restoration point.

[RedoBuffer](#) sets the size of the buffer in which the REDO log is written. The default value is 32MB; the minimum value is 1MB.

If this buffer is too small, the NDB storage engine issues error code 1221 ([REDO log buffers overloaded](#)). For this reason, you should exercise care if you attempt to decrease the value of [RedoBuffer](#) as part of an online change in the cluster's configuration.

[ndbmt](#) allocates a separate buffer for each LDM thread (see [ThreadConfig](#)). For example, with 4 LDM threads, an [ndbmt](#) data node actually has 4 buffers and allocates [RedoBuffer](#) bytes to each one, for a total of $4 * \text{RedoBuffer}$ bytes.

- [EventLogBufferSize](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | bytes |
| Default | 8192 |
| Range | 0 - 64K |
| Restart Type | S (NDB 8.0.13) |

Controls the size of the circular buffer used for NDB log events within data nodes.

Controlling log messages. In managing the cluster, it is very important to be able to control the number of log messages sent for various event types to [stdout](#). For each event category, there are 16 possible event levels (numbered 0 through 15). Setting event reporting for a given event category to level 15 means all event reports in that category are sent to [stdout](#); setting it to 0 means that no event reports in that category are made.

By default, only the startup message is sent to [stdout](#), with the remaining event reporting level defaults being set to 0. The reason for this is that these messages are also sent to the management server's cluster log.

An analogous set of levels can be set for the management client to determine which event levels to record in the cluster log.

- [LogLevelStartup](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | integer |
| Default | 1 |
| Range | 0 - 15 |
| Restart Type | N (NDB 8.0.13) |

The reporting level for events generated during startup of the process.

The default level is 1.

- [LogLevelShutdown](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | integer |
| Default | 0 |
| Range | 0 - 15 |
| Restart Type | N (NDB 8.0.13) |

The reporting level for events generated as part of graceful shutdown of a node.

The default level is 0.

- [LogLevelStatistic](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | integer |
| Default | 0 |
| Range | 0 - 15 |
| Restart Type | N (NDB 8.0.13) |

The reporting level for statistical events such as number of primary key reads, number of updates, number of inserts, information relating to buffer usage, and so on.

The default level is 0.

- [LogLevelCheckpoint](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | log level |
| Default | 0 |
| Range | 0 - 15 |
| Restart Type | N (NDB 8.0.13) |

The reporting level for events generated by local and global checkpoints.

The default level is 0.

- [LogLevelNodeRestart](#)

| | |
|--------------------|------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | integer |
| Default | 0 |
| Range | 0 - 15 |

| | |
|------------------------------|----------------|
| Restart Type | N (NDB 8.0.13) |
|------------------------------|----------------|

The reporting level for events generated during node restart.

The default level is 0.

- [LogLevelConnection](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | integer |
| Default | 0 |
| Range | 0 - 15 |
| Restart Type | N (NDB 8.0.13) |

The reporting level for events generated by connections between cluster nodes.

The default level is 0.

- [LogLevelError](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | integer |
| Default | 0 |
| Range | 0 - 15 |
| Restart Type | N (NDB 8.0.13) |

The reporting level for events generated by errors and warnings by the cluster as a whole. These errors do not cause any node failure but are still considered worth reporting.

The default level is 0.

- [LogLevelCongestion](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | level |
| Default | 0 |
| Range | 0 - 15 |
| Restart Type | N (NDB 8.0.13) |

The reporting level for events generated by congestion. These errors do not cause node failure but are still considered worth reporting.

The default level is 0.

- [LogLevelInfo](#)

| | |
|--------------------|------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | integer |
| Default | 0 |

| | |
|--------------|----------------|
| Range | 0 - 15 |
| Restart Type | N (NDB 8.0.13) |

The reporting level for events generated for information about the general state of the cluster.

The default level is 0.

- [MemReportFrequency](#)

| | |
|--------------------|-----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | unsigned |
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

This parameter controls how often data node memory usage reports are recorded in the cluster log; it is an integer value representing the number of seconds between reports.

Each data node's data memory and index memory usage is logged as both a percentage and a number of 32 KB pages of [DataMemory](#), as set in the `config.ini` file. For example, if [DataMemory](#) is equal to 100 MB, and a given data node is using 50 MB for data memory storage, the corresponding line in the cluster log might look like this:

```
2006-12-24 01:18:16 [MgmSrvr] INFO -- Node 2: Data usage is 50%(1280 32K pages of total 2560)
```

[MemReportFrequency](#) is not a required parameter. If used, it can be set for all cluster data nodes in the `[ndbd default]` section of `config.ini`, and can also be set or overridden for individual data nodes in the corresponding `[ndbd]` sections of the configuration file. The minimum value—which is also the default value—is 0, in which case memory reports are logged only when memory usage reaches certain percentages (80%, 90%, and 100%), as mentioned in the discussion of statistics events in [Section 23.6.3.2, “NDB Cluster Log Events”](#).

- [StartupStatusReportFrequency](#)

| | |
|--------------------|-----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | seconds |
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

When a data node is started with the `--initial`, it initializes the redo log file during Start Phase 4 (see [Section 23.6.4, “Summary of NDB Cluster Start Phases”](#)). When very large values are set for `NoOfFragmentLogFiles`, `FragmentLogFileSize`, or both, this initialization can take a long time. You can force reports on the progress of this process to be logged periodically, by means of the [StartupStatusReportFrequency](#) configuration parameter. In this case, progress is reported in the cluster log, in terms of both the number of files and the amount of space that have been initialized, as shown here:

```
2009-06-20 16:39:23 [MgmSrvr] INFO -- Node 1: Local redo log file initialization status:
#Total files: 80, Completed: 60
#Total MBytes: 20480, Completed: 15557
2009-06-20 16:39:23 [MgmSrvr] INFO -- Node 2: Local redo log file initialization status:
#Total files: 80, Completed: 60
```

```
#Total MBytes: 20480, Completed: 15570
```

These reports are logged each `StartupStatusReportFrequency` seconds during Start Phase 4. If `StartupStatusReportFrequency` is 0 (the default), then reports are written to the cluster log only when at the beginning and at the completion of the redo log file initialization process.

Data Node Debugging Parameters

The following parameters are intended for use during testing or debugging of data nodes, and not for use in production.

- `DictTrace`

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | bytes |
| Default | undefined |
| Range | 0 - 100 |
| Restart Type | N (NDB 8.0.13) |

It is possible to cause logging of traces for events generated by creating and dropping tables using `DictTrace`. This parameter is useful only in debugging NDB kernel code. `DictTrace` takes an integer value. 0 is the default, and means no logging is performed; 1 enables trace logging, and 2 enables logging of additional `DBDICT` debugging output.

- `WatchdogImmediateKill`

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | boolean |
| Default | false |
| Range | true, false |
| Restart Type | N (NDB 8.0.13) |

You can cause threads to be killed immediately whenever watchdog issues occur by enabling the `WatchdogImmediateKill` data node configuration parameter. This parameter should be used only when debugging or troubleshooting, to obtain trace files reporting exactly what was occurring the instant that execution ceased.

Backup parameters. The `[ndbd]` parameters discussed in this section define memory buffers set aside for execution of online backups.

- `BackupDataBufferSize`

| | |
|------------------------------|--------------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | bytes |
| Default | 16M |
| Range | 512K - 4294967039 (0xFFFFFFFF) |
| Deprecated | Yes (in NDB 7.6) |
| Restart Type | N (NDB 8.0.13) |

In creating a backup, there are two buffers used for sending data to the disk. The backup data buffer is used to fill in data recorded by scanning a node's tables. Once this buffer has been filled to the level

specified as `BackupWriteSize`, the pages are sent to disk. While flushing data to disk, the backup process can continue filling this buffer until it runs out of space. When this happens, the backup process pauses the scan and waits until some disk writes have completed freeing up memory so that scanning may continue.

The default value for this parameter is 16MB. The minimum is 512K.

- `BackupDiskWriteSpeedPct`

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | percent |
| Default | 50 |
| Range | 0 - 90 |
| Restart Type | N (NDB 8.0.13) |

During normal operation, data nodes attempt to maximize the disk write speed used for local checkpoints and backups while remaining within the bounds set by `MinDiskWriteSpeed` and `MaxDiskWriteSpeed`. Disk write throttling gives each LDM thread an equal share of the total budget. This allows parallel LCPs to take place without exceeding the disk I/O budget. Because a backup is executed by only one LDM thread, this effectively caused a budget cut, resulting in longer backup completion times, and—if the rate of change is sufficiently high—in failure to complete the backup when the backup log buffer fill rate is higher than the achievable write rate.

This problem can be addressed by using the `BackupDiskWriteSpeedPct` configuration parameter, which takes a value in the range 0-90 (inclusive) which is interpreted as the percentage of the node's maximum write rate budget that is reserved prior to sharing out the remainder of the budget among LDM threads for LCPs. The LDM thread running the backup receives the whole write rate budget for the backup, plus its (reduced) share of the write rate budget for local checkpoints.

The default value for this parameter is 50 (interpreted as 50%).

- `BackupLogBufferSize`

| | |
|------------------------------|------------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | bytes |
| Default | 16M |
| Range | 2M - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

The backup log buffer fulfills a role similar to that played by the backup data buffer, except that it is used for generating a log of all table writes made during execution of the backup. The same principles apply for writing these pages as with the backup data buffer, except that when there is no more space in the backup log buffer, the backup fails. For that reason, the size of the backup log buffer must be large enough to handle the load caused by write activities while the backup is being made. See [Section 23.6.8.3, "Configuration for NDB Cluster Backups"](#).

The default value for this parameter should be sufficient for most applications. In fact, it is more likely for a backup failure to be caused by insufficient disk write speed than it is for the backup log buffer to

become full. If the disk subsystem is not configured for the write load caused by applications, the cluster is unlikely to be able to perform the desired operations.

It is preferable to configure cluster nodes in such a manner that the processor becomes the bottleneck rather than the disks or the network connections.

The default value for this parameter is 16MB.

- [BackupMemory](#)

| | |
|------------------------------|-----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | bytes |
| Default | 32M |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Deprecated | Yes (in NDB 7.4) |
| Restart Type | N (NDB 8.0.13) |

This parameter is deprecated, and subject to removal in a future version of NDB Cluster. Any setting made for it is ignored.

- [BackupReportFrequency](#)

| | |
|------------------------------|-----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | seconds |
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

This parameter controls how often backup status reports are issued in the management client during a backup, as well as how often such reports are written to the cluster log (provided cluster event logging is configured to permit it—see [Logging and checkpointing](#)). [BackupReportFrequency](#) represents the time in seconds between backup status reports.

The default value is 0.

- [BackupWriteSize](#)

| | |
|------------------------------|-------------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | bytes |
| Default | 256K |
| Range | 32K - 4294967039 (0xFFFFFFFF) |
| Deprecated | Yes (in NDB 7.6) |
| Restart Type | N (NDB 8.0.13) |

This parameter specifies the default size of messages written to disk by the backup log and backup data buffers.

The default value for this parameter is 256KB.

- [BackupMaxWriteSize](#)

| | |
|------------------------------|--------------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | bytes |
| Default | 1M |
| Range | 256K - 4294967039 (0xFFFFFFFF) |
| Deprecated | Yes (in NDB 7.6) |
| Restart Type | N (NDB 8.0.13) |

This parameter specifies the maximum size of messages written to disk by the backup log and backup data buffers.

The default value for this parameter is 1MB.

- [CompressedBackup](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | boolean |
| Default | false |
| Range | true, false |
| Restart Type | N (NDB 8.0.13) |

Enabling this parameter causes backup files to be compressed. The compression used is equivalent to `gzip --fast`, and can save 50% or more of the space required on the data node to store uncompressed backup files. Compressed backups can be enabled for individual data nodes, or for all data nodes (by setting this parameter in the `[ndbd default]` section of the `config.ini` file).

Important

You cannot restore a compressed backup to a cluster running a MySQL version that does not support this feature.

The default value is 0 (disabled).

- [RequireEncryptedBackup](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.22 |
| Type or units | integer |
| Default | 0 |
| Range | 0 - 1 |
| Added | NDB 8.0.22 |
| Restart Type | N (NDB 8.0.13) |

If set to 1, backups must be encrypted. While it is possible to set this parameter for each data node individually, it is recommended that you set it in the `[ndbd default]` section of the `config.ini` global configuration file. For more information about performing encrypted backups, see [Section 23.6.8.2, “Using The NDB Cluster Management Client to Create a Backup”](#).

Added in NDB 8.0.22.

**Note**

The location of the backup files is determined by the `BackupDataDir` data node configuration parameter.

Additional requirements. When specifying these parameters, the following relationships must hold true. Otherwise, the data node cannot start.

- `BackupDataBufferSize >= BackupWriteSize + 188KB`
- `BackupLogBufferSize >= BackupWriteSize + 16KB`
- `BackupMaxWriteSize >= BackupWriteSize`

NDB Cluster Realtime Performance Parameters

The `[ndbd]` parameters discussed in this section are used in scheduling and locking of threads to specific CPUs on multiprocessor data node hosts.

**Note**

To make use of these parameters, the data node process must be run as system root.

- `BuildIndexThreads`

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | numeric |
| Default | 128 |
| Range | 0 - 128 |
| Restart Type | N (NDB 8.0.13) |

This parameter determines the number of threads to create when rebuilding ordered indexes during a system or node start, as well as when running `ndb_restore --rebuild-indexes`. It is supported only when there is more than one fragment for the table per data node (for example, when `COMMENT="NDB_TABLE=PARTITION_BALANCE=FOR_RA_BY_LDM_X_2"` is used with `CREATE TABLE`).

Setting this parameter to 0 (the default) disables multithreaded building of ordered indexes.

This parameter is supported when using `ndbd` or `ndbmt.d`.

You can enable multithreaded builds during data node initial restarts by setting the `TwoPassInitialNodeRestartCopy` data node configuration parameter to `TRUE`.

- `LockExecuteThreadToCPU`

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | set of CPU IDs |
| Default | 0 |
| Range | ... |
| Restart Type | N (NDB 8.0.13) |

When used with `ndbd`, this parameter (now a string) specifies the ID of the CPU assigned to handle the `NDBCLUSTER` execution thread. When used with `ndbmt_d`, the value of this parameter is a comma-separated list of CPU IDs assigned to handle execution threads. Each CPU ID in the list should be an integer in the range 0 to 65535 (inclusive).

The number of IDs specified should match the number of execution threads determined by `MaxNoOfExecutionThreads`. However, there is no guarantee that threads are assigned to CPUs in any given order when using this parameter. You can obtain more finely-grained control of this type using `ThreadConfig`.

`LockExecuteThreadToCPU` has no default value.

- `LockMaintThreadsToCPU`

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | CPU ID |
| Default | 0 |
| Range | 0 - 64K |
| Restart Type | N (NDB 8.0.13) |

This parameter specifies the ID of the CPU assigned to handle `NDBCLUSTER` maintenance threads.

The value of this parameter is an integer in the range 0 to 65535 (inclusive). *There is no default value.*

- `Numa`

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | numeric |
| Default | 1 |
| Range | ... |
| Restart Type | N (NDB 8.0.13) |

This parameter determines whether Non-Uniform Memory Access (NUMA) is controlled by the operating system or by the data node process, whether the data node uses `ndbd` or `ndbmt_d`. By default, `NDB` attempts to use an interleaved NUMA memory allocation policy on any data node where the host operating system provides NUMA support.

Setting `Numa = 0` means that the datanode process does not itself attempt to set a policy for memory allocation, and permits this behavior to be determined by the operating system, which may be further guided by the separate `numactl` tool. That is, `Numa = 0` yields the system default behavior, which can be customised by `numactl`. For many Linux systems, the system default behavior is to allocate socket-local memory to any given process at allocation time. This can be problematic when using `ndbmt_d`; this is because `ndbmt_d` allocates all memory at startup, leading to an imbalance, giving different access speeds for different sockets, especially when locking pages in main memory.

Setting `Numa = 1` means that the data node process uses `libnuma` to request interleaved memory allocation. (This can also be accomplished manually, on the operating system level, using `numactl`.) Using interleaved allocation in effect tells the data node process to ignore non-uniform memory access but does not attempt to take any advantage of fast local memory; instead, the data node process tries to

avoid imbalances due to slow remote memory. If interleaved allocation is not desired, set `Numa` to 0 so that the desired behavior can be determined on the operating system level.

The `Numa` configuration parameter is supported only on Linux systems where `libnuma.so` is available.

- `RealtimeScheduler`

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | boolean |
| Default | false |
| Range | true, false |
| Restart Type | N (NDB 8.0.13) |

Setting this parameter to 1 enables real-time scheduling of data node threads.

The default is 0 (scheduling disabled).

- `SchedulerExecutionTimer`

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | μ s |
| Default | 50 |
| Range | 0 - 11000 |
| Restart Type | N (NDB 8.0.13) |

This parameter specifies the time in microseconds for threads to be executed in the scheduler before being sent. Setting it to 0 minimizes the response time; to achieve higher throughput, you can increase the value at the expense of longer response times.

The default is 50 μ sec, which our testing shows to increase throughput slightly in high-load cases without materially delaying requests.

- `SchedulerResponsiveness`

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | integer |
| Default | 5 |
| Range | 0 - 10 |
| Restart Type | N (NDB 8.0.13) |

Set the balance in the NDB scheduler between speed and throughput. This parameter takes an integer whose value is in the range 0-10 inclusive, with 5 as the default. Higher values provide better response times relative to throughput. Lower values provide increased throughput at the expense of longer response times.

- `SchedulerSpinTimer`

| | |
|--------------------|------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | μ s |
| Default | 0 |

| | |
|--------------|----------------|
| Range | 0 - 500 |
| Restart Type | N (NDB 8.0.13) |

This parameter specifies the time in microseconds for threads to be executed in the scheduler before sleeping.

Starting with NDB 8.0.20, if `SpinMethod` is set, any setting for this parameter is ignored.

- `SpinMethod`

| | |
|--------------------|--|
| Version (or later) | NDB 8.0.20 |
| Type or units | enumeration |
| Default | StaticSpinning |
| Range | CostBasedSpinning, LatencyOptimisedSpinning, DatabaseMachineSpinning, StaticSpinning |
| Added | NDB 8.0.20 |
| Restart Type | N (NDB 8.0.13) |

This parameter is present beginning in NDB 8.0.20, but has no effect prior to NDB 8.0.24. It provides a simple interface to control adaptive spinning on data nodes, with four possible values furnishing presets for spin parameter values, as shown in the following list:

1. `StaticSpinning` (default): Sets `EnableAdaptiveSpinning` to `false` and `SchedulerSpinTimer` to 0. (`SetAllowedSpinOverhead` is not relevant in this case.)
2. `CostBasedSpinning`: Sets `EnableAdaptiveSpinning` to `true`, `SchedulerSpinTimer` to 100, and `SetAllowedSpinOverhead` to 200.
3. `LatencyOptimisedSpinning`: Sets `EnableAdaptiveSpinning` to `true`, `SchedulerSpinTimer` to 200, and `SetAllowedSpinOverhead` to 1000.
4. `DatabaseMachineSpinning`: Sets `EnableAdaptiveSpinning` to `true`, `SchedulerSpinTimer` to 500, and `SetAllowedSpinOverhead` to 10000. This is intended for use in cases where threads own their own CPUs.

The spin parameters modified by `SpinMethod` are described in the following list:

- `SchedulerSpinTimer`: This is the same as the data node configuration parameter of that name. The setting applied to this parameter by `SpinMethod` overrides any value set in the `config.ini` file.
- `EnableAdaptiveSpinning`: Enables or disables adaptive spinning. Disabling it causes spinning to be performed without making any checks for CPU resources. This parameter cannot be set directly in the cluster configuration file, and under most circumstances should not need to be, but can be enabled directly using `DUMP 104004 1` or disabled with `DUMP 104004 0` in the `ndb_mgm` management client.
- `SetAllowedSpinOverhead`: Sets the amount of CPU time to allow for gaining latency. This parameter cannot be set directly in the `config.ini` file. In most cases, the setting applied by `SpinMethod` should be satisfactory, but if it is necessary to change it directly, you can use `DUMP`

104002 *overhead* to do so, where *overhead* is a value ranging from 0 to 10000, inclusive; see the description of the indicated `DUMP` command for details.

On platforms lacking usable spin instructions, such as PowerPC and some SPARC platforms, spin time is set to 0 in all situations, and values for `SpinMethod` other than `StaticSpinning` are ignored.

- `TwoPassInitialNodeRestartCopy`

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | boolean |
| Default | true |
| Range | true, false |
| Restart Type | N (NDB 8.0.13) |

Multithreaded building of ordered indexes can be enabled for initial restarts of data nodes by setting this configuration parameter to `true` (the default value), which enables two-pass copying of data during initial node restarts.

You must also set `BuildIndexThreads` to a nonzero value.

Multi-Threading Configuration Parameters (ndbmt). `ndbmt` runs by default as a single-threaded process and must be configured to use multiple threads, using either of two methods, both of which require setting configuration parameters in the `config.ini` file. The first method is simply to set an appropriate value for the `MaxNoOfExecutionThreads` configuration parameter. A second method, makes it possible to set up more complex rules for `ndbmt` multithreading using `ThreadConfig`. The next few paragraphs provide information about these parameters and their use with multithreaded data nodes.

Note

A backup using parallelism on the data nodes requires that multiple LDMs are in use on all data nodes in the cluster prior to taking the backup. For more information, see [Section 23.6.8.5, “Taking an NDB Backup with Parallel Data Nodes”](#), as well as [Section 23.5.23.3, “Restoring from a backup taken in parallel”](#).

- `AutomaticThreadConfig`

| | |
|------------------------------|-----------------|
| Version (or later) | NDB 8.0.23 |
| Type or units | boolean |
| Default | false |
| Range | true, false |
| Added | NDB 8.0.23 |
| Restart Type | IS (NDB 8.0.13) |

When set to 1, enables automatic thread configuration employing the number of CPUs available to a data node taking into account any limits set by `taskset`, `numactl`, virtual machines, Docker, and other such means of controlling which CPUs are available to a given application (on Windows platforms, automatic thread configuration uses all CPUs which are online); alternatively, you can set `NumCPUs` to the desired number of CPUs (up to 1024, the maximum number of CPUs that can be handled by automatic thread configuration). Any settings for `ThreadConfig` and `MaxNoOfExecutionThreads` are ignored.

- `ClassicFragmentation`

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.23 |
| Type or units | boolean |
| Default | true |
| Range | true, false |
| Added | NDB 8.0.23 |
| Restart Type | N (NDB 8.0.13) |

When enabled (set to `true`), NDB uses flexible distribution of table fragments among LDMS. This means that the default number of partitions per node is equal to `PartitionsPerNode`, rather than to the minimum number of LDM threads per data node, and that each table has a number of partitions equal to 4 (the default for `PartitionsPerNode`) times the number of data nodes.

For new clusters for which a downgrade to NDB 8.0.22 or earlier is never expected to occur, setting `ClassicFragmentation` to `false` when first setting up the cluster is preferable; this ensures that all partitions are spread out evenly between all LDMS.

- [EnableMultithreadedBackup](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | unsigned |
| Default | 1 |
| Range | 0 - 1 |
| Added | NDB 8.0.16 |
| Restart Type | N (NDB 8.0.13) |

Enables multi-threaded backup. If each data node has at least 2 LDMS, all LDM threads participate in the backup, which is created using one subdirectory per LDM thread, and each subdirectory containing `.ctl`, `.Data`, and `.log` backup files.

This parameter is normally enabled (set to 1) for `ndbmttd`. To force a single-threaded backup that can be restored easily using older versions of `ndb_restore`, disable multi-threaded backup by setting this parameter to 0. This must be done for each data node in the cluster.

See [Section 23.6.8.5, "Taking an NDB Backup with Parallel Data Nodes"](#), and [Section 23.5.23.3, "Restoring from a backup taken in parallel"](#), for more information.

- [MaxNoOfExecutionThreads](#)

| | |
|--------------------|------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | integer |
| Default | 2 |
| Range | 2 - 72 |

| | |
|--------------|----------------|
| Restart Type | S (NDB 8.0.13) |
|--------------|----------------|

This parameter directly controls the number of execution threads used by `ndbmysqld`, up to a maximum of 72. Although this parameter is set in `[ndbd]` or `[ndbd default]` sections of the `config.ini` file, it is exclusive to `ndbmysqld` and does not apply to `ndbd`.

Setting `MaxNoOfExecutionThreads` sets the number of threads for each type as determined by a matrix in the file `storage/ndb/src/kernel/vm/mt_thr_config.cpp`. This table shows these numbers of threads for possible values of `MaxNoOfExecutionThreads`.

Table 23.12 `MaxNoOfExecutionThreads` values and the corresponding number of threads by thread type (LQH, TC, Send, Receive).

| <code>MaxNoOfExecutionThreads</code> Value | LQH Threads | TC Threads | Send Threads | Receive Threads |
|--|-------------|------------|--------------|-----------------|
| 0 .. 3 | 1 | 0 | 0 | 1 |
| 4 .. 6 | 2 | 0 | 0 | 1 |
| 7 .. 8 | 4 | 0 | 0 | 1 |
| 9 | 4 | 2 | 0 | 1 |
| 10 | 4 | 2 | 1 | 1 |
| 11 | 4 | 3 | 1 | 1 |
| 12 | 6 | 2 | 1 | 1 |
| 13 | 6 | 3 | 1 | 1 |
| 14 | 6 | 3 | 1 | 2 |
| 15 | 6 | 3 | 2 | 2 |
| 16 | 8 | 3 | 1 | 2 |
| 17 | 8 | 4 | 1 | 2 |
| 18 | 8 | 4 | 2 | 2 |
| 19 | 8 | 5 | 2 | 2 |
| 20 | 10 | 4 | 2 | 2 |
| 21 | 10 | 5 | 2 | 2 |
| 22 | 10 | 5 | 2 | 3 |
| 23 | 10 | 6 | 2 | 3 |
| 24 | 12 | 5 | 2 | 3 |
| 25 | 12 | 6 | 2 | 3 |
| 26 | 12 | 6 | 3 | 3 |
| 27 | 12 | 7 | 3 | 3 |
| 28 | 12 | 7 | 3 | 4 |
| 29 | 12 | 8 | 3 | 4 |
| 30 | 12 | 8 | 4 | 4 |
| 31 | 12 | 9 | 4 | 4 |
| 32 | 16 | 8 | 3 | 3 |
| 33 | 16 | 8 | 3 | 4 |

NDB Cluster Configuration Files

| MaxNoOfExecutionThreads Value | DM Threads | TC Threads | Send Threads | Receive Threads |
|----------------------------------|------------|------------|--------------|-----------------|
| 34 | 16 | 8 | 4 | 4 |
| 35 | 16 | 9 | 4 | 4 |
| 36 | 16 | 10 | 4 | 4 |

| MaxNoOfExecutionThreads Value | LDM Threads | TC Threads | Send Threads | Receive Threads |
|-------------------------------|-------------|------------|--------------|-----------------|
| 71 | 32 | 20 | 8 | 9 |
| 72 | 32 | 20 | 8 | 10 |

There is always one SUMA (replication) thread.

`NoOfFragmentLogParts` should be set equal to the number of LDM threads used by `ndbmt_d`, as determined by the setting for this parameter. This ratio should not be any greater than 4:1; a configuration in which this is the case is specifically disallowed.

The number of LDM threads also determines the number of partitions used by an NDB table that is not explicitly partitioned; this is the number of LDM threads times the number of data nodes in the cluster. (If `ndbd` is used on the data nodes rather than `ndbmt_d`, then there is always a single LDM thread; in this case, the number of partitions created automatically is simply equal to the number of data nodes. See [Section 23.2.2, “NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions”](#), for more information.

Adding large tablespaces for Disk Data tables when using more than the default number of LDM threads may cause issues with resource and CPU usage if the disk page buffer is insufficiently large; see the description of the `DiskPageBufferMemory` configuration parameter, for more information.

The thread types are described later in this section (see `ThreadConfig`).

Setting this parameter outside the permitted range of values causes the management server to abort on startup with the error `Error line number: Illegal value value for parameter MaxNoOfExecutionThreads`.

For `MaxNoOfExecutionThreads`, a value of 0 or 1 is rounded up internally by NDB to 2, so that 2 is considered this parameter's default and minimum value.

`MaxNoOfExecutionThreads` is generally intended to be set equal to the number of CPU threads available, and to allocate a number of threads of each type suitable to typical workloads. It does not assign particular threads to specified CPUs. For cases where it is desirable to vary from the settings provided, or to bind threads to CPUs, you should use `ThreadConfig` instead, which allows you to allocate each thread directly to a desired type, CPU, or both.

The multithreaded data node process always spawns, at a minimum, the threads listed here:

- 1 local query handler (LDM) thread
- 1 receive thread
- 1 subscription manager (SUMA or replication) thread

For a `MaxNoOfExecutionThreads` value of 8 or less, no TC threads are created, and TC handling is instead performed by the main thread.

Changing the number of LDM threads normally requires a system restart, whether it is changed using this parameter or `ThreadConfig`, but it is possible to effect the change using a node initial restart (*NI*) provided the following two conditions are met:

- Each LDM thread handles a maximum of 8 fragments, and

- The total number of table fragments is an integer multiple of the number of LDM threads.

In NDB 8.0, an initial restart is *not* required to effect a change in this parameter, as it was in some older versions of NDB Cluster.

- [NoOfFragmentLogParts](#)

| | |
|------------------------------|---------------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | numeric |
| Default | 4 |
| Range | 4, 6, 8, 10, 12, 16, 20, 24, 32 |
| Restart Type | IN (NDB 8.0.13) |

Set the number of log file groups for redo logs belonging to this [ndbmt.d](#). The value of this parameter should be set equal to the number of LDM threads used by [ndbmt.d](#) as determined by the setting for [MaxNoOfExecutionThreads](#). A configuration using more than 4 redo log parts per LDM is disallowed.

See the description of [MaxNoOfExecutionThreads](#) for more information.

- [NumCPUs](#)

| | |
|------------------------------|-----------------|
| Version (or later) | NDB 8.0.23 |
| Type or units | integer |
| Default | 0 |
| Range | 0 - 1024 |
| Added | NDB 8.0.23 |
| Restart Type | IS (NDB 8.0.13) |

Cause automatic thread configuration to use only this many CPUs. Has no effect if [AutomaticThreadConfig](#) is not enabled.

- [PartitionsPerNode](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.23 |
| Type or units | integer |
| Default | 2 |
| Range | 1 - 32 |
| Added | NDB 8.0.23 |
| Restart Type | N (NDB 8.0.13) |

Sets the number of partitions used on each node when creating a new [NDB](#) table. This makes it possible to avoid splitting up tables into an excessive number of partitions when the number of local data managers (LDMs) grows high.

While it is possible to set this parameter to different values on different data nodes and there are no known issues with doing so, there is also not likely to be any advantage in doing so, and so it is recommended simply to set it once, for all data nodes, in the [\[ndbd default\]](#) section of the global [config.ini](#) file.

- [ThreadConfig](#)

| | |
|--------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | string |
| Default | " |
| Range | ... |
| Restart Type | S (NDB 8.0.13) |

This parameter is used with [ndbmt](#) to assign threads of different types to different CPUs. Its value is a string whose format has the following syntax:

```
ThreadConfig := entry[,entry[,...]]
entry := type={param[,param[,...]]}
type (NDB 8.0.22 and earlier) := ldm | main | recv | send | rep | io | tc | watchdog | idxbld
type (NDB 8.0.23 and later) := ldm | query | recover | main | recv | send | rep | io | tc | watchdog | i
param := count=number
| cpubind=cpu_list
| cpuset=cpu_list
| spintime=number
| realtime={0|1}
| nosend={0|1}
| thread_prio={0..10}
| cpubind_exclusive=cpu_list
| cpuset_exclusive=cpu_list
```

The curly braces (`{...}`) surrounding the list of parameters are required, even if there is only one parameter in the list.

A [param](#) (parameter) specifies any or all of the following information:

- The number of threads of the given type ([count](#)).
- The set of CPUs to which the threads of the given type are to be nonexclusively bound. This is determined by either one of [cpubind](#) or [cpuset](#). [cpubind](#) causes each thread to be bound (nonexclusively) to a CPU in the set; [cpuset](#) means that each thread is bound (nonexclusively) to the set of CPUs specified.

On Solaris, you can instead specify a set of CPUs to which the threads of the given type are to be bound exclusively. [cpubind_exclusive](#) causes each thread to be bound exclusively to a CPU in the set; [cpuset_exclusive](#) means that each thread is bound exclusively to the set of CPUs specified.

Only one of [cpubind](#), [cpuset](#), [cpubind_exclusive](#), or [cpuset_exclusive](#) can be provided in a single configuration.

- [spintime](#) determines the wait time in microseconds the thread spins before going to sleep.

The default value for [spintime](#) is the value of the [SchedulerSpinTimer](#) data node configuration parameter.

[spintime](#) does not apply to I/O threads, watchdog, or offline index build threads, and so cannot be set for these thread types.

- `realtime` can be set to 0 or 1. If it is set to 1, the threads run with real-time priority. This also means that `thread_prio` cannot be set.

The `realtime` parameter is set by default to the value of the `RealtimeScheduler` data node configuration parameter.

`realtime` cannot be set for offline index build threads.

- By setting `nosend` to 1, you can prevent a `main`, `ldm`, `rep`, or `tc` thread from assisting the send threads. This parameter is 0 by default, and cannot be used with other types of threads.
- `thread_prio` is a thread priority level that can be set from 0 to 10, with 10 representing the greatest priority. The default is 5. The precise effects of this parameter are platform-specific, and are described later in this section.

The thread priority level cannot be set for offline index build threads.

thread_prio settings and effects by platform. The implementation of `thread_prio` differs between Linux/FreeBSD, Solaris, and Windows. In the following list, we discuss its effects on each of these platforms in turn:

- *Linux and FreeBSD:* We map `thread_prio` to a value to be supplied to the `nice` system call. Since a lower niceness value for a process indicates a higher process priority, increasing `thread_prio` has the effect of lowering the `nice` value.

Table 23.13 Mapping of thread_prio to nice values on Linux and FreeBSD

| <code>thread_prio</code> value | <code>nice</code> value |
|--------------------------------|-------------------------|
| 0 | 19 |
| 1 | 16 |
| 2 | 12 |
| 3 | 8 |
| 4 | 4 |
| 5 | 0 |
| 6 | -4 |
| 7 | -8 |
| 8 | -12 |
| 9 | -16 |
| 10 | -20 |

Some operating systems may provide for a maximum process niceness level of 20, but this is not supported by all targeted versions; for this reason, we choose 19 as the maximum `nice` value that can be set.

- *Solaris*: Setting `thread_prio` on Solaris sets the Solaris FX priority, with mappings as shown in the following table:

Table 23.14 Mapping of `thread_prio` to FX priority on Solaris

| <code>thread_prio</code> value | Solaris FX priority |
|--------------------------------|---------------------|
| 0 | 15 |
| 1 | 20 |
| 2 | 25 |
| 3 | 30 |
| 4 | 35 |
| 5 | 40 |
| 6 | 45 |
| 7 | 50 |
| 8 | 55 |
| 9 | 59 |
| 10 | 60 |

A `thread_prio` setting of 9 is mapped on Solaris to the special FX priority value 59, which means that the operating system also attempts to force the thread to run alone on its own CPU core.

- *Windows*: We map `thread_prio` to a Windows thread priority value passed to the Windows API `SetThreadPriority()` function. This mapping is shown in the following table:

Table 23.15 Mapping of `thread_prio` to Windows thread priority

| <code>thread_prio</code> value | Windows thread priority |
|--------------------------------|---|
| 0 - 1 | <code>THREAD_PRIORITY_LOWEST</code> |
| 2 - 3 | <code>THREAD_PRIORITY_BELOW_NORMAL</code> |
| 4 - 5 | <code>THREAD_PRIORITY_NORMAL</code> |
| 6 - 7 | <code>THREAD_PRIORITY_ABOVE_NORMAL</code> |
| 8 - 10 | <code>THREAD_PRIORITY_HIGHEST</code> |

The `type` attribute represents an NDB thread type. The thread types supported, and the range of permitted `count` values for each, are provided in the following list:

- `ldm`: Local query handler (`DBLQH` kernel block) that handles data. The more LDM threads that are used, the more highly partitioned the data becomes. (Beginning with NDB 8.0.23, when `ClassicFragmentation` is set to 0, the number of partitions is independent of the number of LDM threads, and depends on the value of `PartitionsPerNode` instead.) Each LDM thread maintains its own sets of data and index partitions, as well as its own redo log. Prior to NDB 8.0.23, the value set for `ldm` must be one of the values 1, 2, 4, 6, 8, 12, 16, 24, or 32. In NDB 8.0.23 and later, it is possible to set `ldm` to any value in the range 1 to 332 inclusive; it also becomes possible to set it to 0, provided that `main`, `rep`, and `tc` are also 0, and that `recv` is set to 1; doing this causes `ndbmt` to emulate `ndbd`.

Each LDM thread is normally grouped with 1 query thread to form an LDM group. A set of 4 to 8 LDM groups is grouped into a round robin groups. Each LDM thread can be assisted in execution by any

query or threads in the same round robin group. NDB attempts to form round robin groups such that all threads in each round robin group are locked to CPUs that are attached to the same L3 cache, within the limits of the range stated for a round robin group's size.

Changing the number of LDM threads normally requires a system restart to be effective and safe for cluster operations; this requirement is relaxed in certain cases, as explained later in this section. This is also true when this is done using `MaxNoOfExecutionThreads`.

Adding large tablespaces (hundreds of gigabytes or more) for Disk Data tables when using more than the default number of LDMs may cause issues with resource and CPU usage if `DiskPageBufferMemory` is not sufficiently large.

- `query` (Added in NDB 8.0.23): A query thread is tied to an LDM and together with it forms an LDM group; acts only on `READ COMMITTED` queries. The number of query threads must be set to 0, 1, 2, or 3 times the number of LDM threads. Query threads are not used, unless this is overridden by setting `query` to a nonzero value, or by enabling the `AutomaticThreadConfig` parameter, in which case LDMs behave as they did prior to NDB 8.0.23.

A query thread also acts as a recovery thread (see next item), although the reverse is not true.

Changing the number of query threads requires a node restart.

- `recover` (Added in NDB 8.0.23): A recovery thread restores data from a fragment as part of an LCP.

Changing the number of recovery threads requires a node restart.

- `tc`: Transaction coordinator thread (`DBTC` kernel block) containing the state of an ongoing transaction. In NDB 8.0.23 and later, the maximum number of TC threads is 128; previously, this was 32.

Optimally, every new transaction can be assigned to a new TC thread. In most cases 1 TC thread per 2 LDM threads is sufficient to guarantee that this can happen. In cases where the number of writes is relatively small when compared to the number of reads, it is possible that only 1 TC thread per 4 LQH threads is required to maintain transaction states. Conversely, in applications that perform a great many updates, it may be necessary for the ratio of TC threads to LDM threads to approach 1 (for example, 3 TC threads to 4 LDM threads).

Setting `tc` to 0 causes TC handling to be done by the main thread. In most cases, this is effectively the same as setting it to 1.

Range: 0-64 (*NDB 8.0.22 and earlier: 0 - 32*)

- **main**: Data dictionary and transaction coordinator (**DBDIH** and **DBTC** kernel blocks), providing schema management. Prior to NDB 8.0.23, this was always handled by a single dedicated thread, beginning with NDB 8.0.23, it is also possible to specify zero or two main threads.

Range:

- *NDB 8.0.22 and earlier*: 1 only.

NDB 8.0.23 and later: 0-2.

Setting **main** to 0 and **rep** to 1 causes the **main** blocks to be placed into the **rep** thread; the combined thread is shown in the **ndbinfo.threads** table as **main_rep**. This is effectively the same as setting **rep** equal to 1 and **main** equal to 0.

It is also possible to set both **main** and **rep** to 0, in which case both threads are placed in the first **recv** thread; the resulting combined thread is named **main_rep_recv** in the **threads** table.

- **recv**: Receive thread (**CMVMI** kernel block). Each receive thread handles one or more sockets for communicating with other nodes in an NDB Cluster, with one socket per node. NDB Cluster supports multiple receive threads; the maximum is 16 such threads.

Range:

- *NDB 8.0.22 and earlier*: 1 - 16

- *NDB 8.0.23 and later*: 1 - 64

- **send**: Send thread (**CMVMI** kernel block). To increase throughput, it is possible to perform sends from one or more separate, dedicated threads (maximum 8).

In NDB 8.0.20 and later, due to changes in the multithreading implementation, using many send threads can have an adverse effect on scalability.

Previously, all threads handled their own sending directly; this can still be made to happen by setting the number of send threads to 0 (this also happens when **MaxNoOfExecutionThreads** is set less than 10). While doing so can have an adverse impact on throughput, it can also in some cases provide decreased latency.

Range:

- *NDB 8.0.22 and earlier*: 0 - 16

- *NDB 8.0.23 and later*: 0 - 64

- `rep`: Replication thread (SUMA kernel block). Prior to NDB 8.0.23, asynchronous replication operations are always handled by a single, dedicated thread. Beginning with NDB 8.0.23, this thread can be combined with the main thread (see range information).

Range:

- *NDB 8.0.22 and earlier*: 1 only.
- *NDB 8.0.23 and later*: 0-1.

Setting `rep` to 0 and `main` to 1 causes the `rep` blocks to be placed into the `main` thread; the combined thread is shown in the `ndbinfo.threads` table as `main_rep`. This is effectively the same as setting `main` equal to 1 and `rep` equal to 0.

It is also possible to set both `main` and `rep` to 0, in which case both threads are placed in the first `recv` thread; the resulting combined thread is named `main_rep_recv` in the `threads` table.

- `io`: File system and other miscellaneous operations. These are not demanding tasks, and are always handled as a group by a single, dedicated I/O thread.

Range: 1 only.

- `watchdog`: Parameters settings associated with this type are actually applied to several threads, each having a specific use. These threads include the `SocketServer` thread, which receives connection setups from other nodes; the `SocketClient` thread, which attempts to set up connections to other nodes; and the thread watchdog thread that checks that threads are progressing.

Range: 1 only.

- `idxbld`: Offline index build threads. Unlike the other thread types listed previously, which are permanent, these are temporary threads which are created and used only during node or system restarts, or when running `ndb_restore --rebuild-indexes`. They may be bound to CPU sets which overlap with CPU sets bound to permanent thread types.

`thread_prio`, `realtime`, and `spintime` values cannot be set for offline index build threads. In addition, `count` is ignored for this type of thread.

If `idxbld` is not specified, the default behavior is as follows:

- Offline index build threads are not bound if the I/O thread is also not bound, and these threads use any available cores.
- If the I/O thread is bound, then the offline index build threads are bound to the entire set of bound threads, due to the fact that there should be no other tasks for these threads to perform.

Range: 0 - 1.

Changing `ThreadConfig` normally requires a system initial restart, but this requirement can be relaxed under certain circumstances:

- If, following the change, the number of LDM threads remains the same as before, nothing more than a simple node restart (rolling restart, or *N*) is required to implement the change.

- Otherwise (that is, if the number of LDM threads changes), it is still possible to effect the change using a node initial restart (*NI*) provided the following two conditions are met:
 - a. Each LDM thread handles a maximum of 8 fragments, and
 - b. The total number of table fragments is an integer multiple of the number of LDM threads.

In any other case, a system initial restart is needed to change this parameter.

NDB can distinguish between thread types by both of the following criteria:

- Whether the thread is an execution thread. Threads of type `main`, `ldm`, `query` (NDB 8.0.23 and later), `recv`, `rep`, `tc`, and `send` are execution threads; `io`, `recover` (NDB 8.0.23 and later), `watchdog`, and `idxbld` threads are not considered execution threads.
- Whether the allocation of threads to a given task is permanent or temporary. Currently all thread types except `idxbld` are considered permanent; `idxbld` threads are regarded as temporary threads.

Simple examples:

```
# Example 1.
ThreadConfig=ldm={count=2,cpubind=1,2},main={cpubind=12},rep={cpubind=11}

# Example 2.
Threadconfig=main={cpubind=0},ldm={count=4,cpubind=1,2,5,6},io={cpubind=3}
```

It is usually desirable when configuring thread usage for a data node host to reserve one or more number of CPUs for operating system and other tasks. Thus, for a host machine with 24 CPUs, you might want to use 20 CPU threads (leaving 4 for other uses), with 8 LDM threads, 4 TC threads (half the number of LDM threads), 3 send threads, 3 receive threads, and 1 thread each for schema management, asynchronous replication, and I/O operations. (This is almost the same distribution of threads used when `MaxNoOfExecutionThreads` is set equal to 20.) The following `ThreadConfig` setting performs these assignments, additionally binding all of these threads to specific CPUs:

```
ThreadConfig=ldm{count=8,cpubind=1,2,3,4,5,6,7,8},main={cpubind=9},io={cpubind=9}, \
rep={cpubind=10},tc{count=4,cpubind=11,12,13,14},recv={count=3,cpubind=15,16,17}, \
send{count=3,cpubind=18,19,20}
```

It should be possible in most cases to bind the main (schema management) thread and the I/O thread to the same CPU, as we have done in the example just shown.

The following example incorporates groups of CPUs defined using both `cpuset` and `cpubind`, as well as use of thread prioritization.

```
ThreadConfig=ldm={count=4,cpuset=0-3,thread_prio=8,spintime=200}, \
ldm={count=4,cpubind=4-7,thread_prio=8,spintime=200}, \
tc={count=4,cpuset=8-9,thread_prio=6},send={count=2,thread_prio=10,cpubind=10-11}, \
main={count=1,cpubind=10},rep={count=1,cpubind=11}
```

In this case we create two LDM groups; the first uses `cpubind` and the second uses `cpuset`. `thread_prio` and `spintime` are set to the same values for each group. This means there are eight LDM threads in total. (You should ensure that `NoOfFragmentLogParts` is also set to 8.) The four TC threads use only two CPUs; it is possible when using `cpuset` to specify fewer CPUs than threads in the

group. (This is not true for `cpubind`.) The send threads use two threads using `cpubind` to bind these threads to CPUs 10 and 11. The main and rep threads can reuse these CPUs.

This example shows how `ThreadConfig` and `NoOfFragmentLogParts` might be set up for a 24-CPU host with hyperthreading, leaving CPUs 10, 11, 22, and 23 available for operating system functions and interrupts:

```
NoOfFragmentLogParts=10
ThreadConfig=ldm={count=10,cpubind=0-4,12-16,thread_prio=9,spintime=200}, \
tc={count=4,cpuset=6-7,18-19,thread_prio=8},send={count=1,cpuset=8}, \
recv={count=1,cpuset=20},main={count=1,cpuset=9,21},rep={count=1,cpuset=9,21}, \
io={count=1,cpuset=9,21,thread_prio=8},watchdog={count=1,cpuset=9,21,thread_prio=9}
```

The next few examples include settings for `idxbld`. The first two of these demonstrate how a CPU set defined for `idxbld` can overlap those specified for other (permanent) thread types, the first using `cpuset` and the second using `cpubind`:

```
ThreadConfig=main,ldm={count=4,cpuset=1-4},tc={count=4,cpuset=5,6,7}, \
io={cpubind=8},idxbld={cpuset=1-8}

ThreadConfig=main,ldm={count=1,cpubind=1},idxbld={count=1,cpubind=1}
```

The next example specifies a CPU for the I/O thread, but not for the index build threads:

```
ThreadConfig=main,ldm={count=4,cpuset=1-4},tc={count=4,cpuset=5,6,7}, \
io={cpubind=8}
```

Since the `ThreadConfig` setting just shown locks threads to eight cores numbered 1 through 8, it is equivalent to the setting shown here:

```
ThreadConfig=main,ldm={count=4,cpuset=1-4},tc={count=4,cpuset=5,6,7}, \
io={cpubind=8},idxbld={cpuset=1,2,3,4,5,6,7,8}
```

In order to take advantage of the enhanced stability that the use of `ThreadConfig` offers, it is necessary to insure that CPUs are isolated, and that they not subject to interrupts, or to being scheduled for other tasks by the operating system. On many Linux systems, you can do this by setting `IRQBALANCE_BANNED_CPUS` in `/etc/sysconfig/irqbalance` to `0xFFFFF0`, and by using the `isolcpus` boot option in `grub.conf`. For specific information, see your operating system or platform documentation.

Disk Data Configuration Parameters. Configuration parameters affecting Disk Data behavior include the following:

- `DiskPageBufferEntries`

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | 32K pages |
| Default | 10 |
| Range | 1 - 1000 |
| Version (or later) | NDB 8.0.19 |
| Type or units | bytes |
| Default | 64MB |
| Range | 4MB - 16TB |
| Restart Type | N (NDB 8.0.13) |

This is the number of page entries (page references) to allocate. It is specified as a number of 32K pages in `DiskPageBufferMemory`. The default is sufficient for most cases but you may need to increase the value of this parameter if you encounter problems with very large transactions on Disk Data tables. Each page entry requires approximately 100 bytes.

- `DiskPageBufferMemory`

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | bytes |
| Default | 64M |
| Range | 4M - 1T |
| Version (or later) | NDB 8.0.19 |
| Type or units | bytes |
| Default | 64M |
| Range | 4M - 16T |
| Restart Type | N (NDB 8.0.13) |

This determines the amount of space used for caching pages on disk, and is set in the `[ndbd]` or `[ndbd default]` section of the `config.ini` file.

Note

Previously, this parameter was specified as a number of 32 KB pages. In NDB 8.0, it is specified as a number of bytes.

If the value for `DiskPageBufferMemory` is set too low in conjunction with using more than the default number of LDM threads in `ThreadConfig` (for example `{ldm=6...}`), problems can arise when trying to add a large (for example 500G) data file to a disk-based NDB table, wherein the process takes indefinitely long while occupying one of the CPU cores.

This is due to the fact that, as part of adding a data file to a tablespace, extent pages are locked into memory in an extra PGMAN worker thread, for quick metadata access. When adding a large file, this worker has insufficient memory for all of the data file metadata. In such cases, you should either increase `DiskPageBufferMemory`, or add smaller tablespace files. You may also need to adjust `DiskPageBufferEntries`.

You can query the `ndbinfo.diskpagebuffer` table to help determine whether the value for this parameter should be increased to minimize unnecessary disk seeks. See [Section 23.6.14.27, “The ndbinfo diskpagebuffer Table”](#), for more information.

- `SharedGlobalMemory`

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | bytes |
| Default | 128M |
| Range | 0 - 64T |
| Restart Type | N (NDB 8.0.13) |

This parameter determines the amount of memory that is used for log buffers, disk operations (such as page requests and wait queues), and metadata for tablespaces, log file groups, `UNDO` files, and

data files. The shared global memory pool also provides memory used for satisfying the memory requirements of the `UNDO_BUFFER_SIZE` option used with `CREATE LOGFILE GROUP` and `ALTER LOGFILE GROUP` statements, including any default value implied for this options by the setting of the `InitialLogFileGroup` data node configuration parameter. `SharedGlobalMemory` can be set in the `[ndbd]` or `[ndbd default]` section of the `config.ini` configuration file, and is measured in bytes.

The default value is `128M`.

- `DiskIOThreadPool`

| | |
|--------------------|-----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | threads |
| Default | 2 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

This parameter determines the number of unbound threads used for Disk Data file access. Before `DiskIOThreadPool` was introduced, exactly one thread was spawned for each Disk Data file, which could lead to performance issues, particularly when using very large data files. With `DiskIOThreadPool`, you can—for example—access a single large data file using several threads working in parallel.

This parameter applies to Disk Data I/O threads only.

The optimum value for this parameter depends on your hardware and configuration, and includes these factors:

- **Physical distribution of Disk Data files.** You can obtain better performance by placing data files, undo log files, and the data node file system on separate physical disks. If you do this with some or all of these sets of files, then you can (and should) set `DiskIOThreadPool` higher to enable separate threads to handle the files on each disk.

In NDB 8.0, you should also disable `DiskDataUsingSameDisk` when using a separate disk or disks for Disk Data files; this increases the rate at which checkpoints of Disk Data tablespaces can be performed.

- **Disk performance and types.** The number of threads that can be accommodated for Disk Data file handling is also dependent on the speed and throughput of the disks. Faster disks and higher throughput allow for more disk I/O threads. Our test results indicate that solid-state disk drives can handle many more disk I/O threads than conventional disks, and thus higher values for `DiskIOThreadPool`.

Decreasing `TimeBetweenGlobalCheckpoints` is also recommended when using solid-state disk drives, in particular those using NVMe. See also [Disk Data latency parameters](#).

The default value for this parameter is 2.

- **Disk Data file system parameters.** The parameters in the following list make it possible to place NDB Cluster Disk Data files in specific directories without the need for using symbolic links.
- `FileSystemPathDD`

| | |
|--------------------|------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | filename |

| | |
|------------------------------|-----------------|
| Default | FileSystemPath |
| Range | ... |
| Restart Type | IN (NDB 8.0.13) |

If this parameter is specified, then NDB Cluster Disk Data data files and undo log files are placed in the indicated directory. This can be overridden for data files, undo log files, or both, by specifying values for `FileSystemPathDataFiles`, `FileSystemPathUndoFiles`, or both, as explained for these parameters. It can also be overridden for data files by specifying a path in the `ADD DATAFILE` clause of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement, and for undo log files by specifying a path in the `ADD UNDOFILE` clause of a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement. If `FileSystemPathDD` is not specified, then `FileSystemPath` is used.

If a `FileSystemPathDD` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

- `FileSystemPathDataFiles`

| | |
|------------------------------|------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | filename |
| Default | FileSystemPathDD |
| Range | ... |
| Restart Type | IN (NDB 8.0.13) |

If this parameter is specified, then NDB Cluster Disk Data data files are placed in the indicated directory. This overrides any value set for `FileSystemPathDD`. This parameter can be overridden for a given data file by specifying a path in the `ADD DATAFILE` clause of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement used to create that data file. If `FileSystemPathDataFiles` is not specified, then `FileSystemPathDD` is used (or `FileSystemPath`, if `FileSystemPathDD` has also not been set).

If a `FileSystemPathDataFiles` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

- `FileSystemPathUndoFiles`

| | |
|------------------------------|------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | filename |
| Default | FileSystemPathDD |
| Range | ... |
| Restart Type | IN (NDB 8.0.13) |

If this parameter is specified, then NDB Cluster Disk Data undo log files are placed in the indicated directory. This overrides any value set for `FileSystemPathDD`. This parameter can be overridden for a given data file by specifying a path in the `ADD UNDO` clause of a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement used to create that data file. If `FileSystemPathUndoFiles` is

not specified, then `FileSystemPathDD` is used (or `FileSystemPath`, if `FileSystemPathDD` has also not been set).

If a `FileSystemPathUndoFiles` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

For more information, see [Section 23.6.10.1, “NDB Cluster Disk Data Objects”](#).

- **Disk Data object creation parameters.** The next two parameters enable you—when starting the cluster for the first time—to cause a Disk Data log file group, tablespace, or both, to be created without the use of SQL statements.
- `InitialLogFileGroup`

| | |
|--------------------|---------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | string |
| Default | [see documentation] |
| Range | ... |
| Restart Type | S (NDB 8.0.13) |

This parameter can be used to specify a log file group that is created when performing an initial start of the cluster. `InitialLogFileGroup` is specified as shown here:

```
InitialLogFileGroup = [name=name;] [undo_buffer_size=size;] file-specification-list

file-specification-list:
    file-specification[; file-specification[; ...]]

file-specification:
    filename:size
```

The `name` of the log file group is optional and defaults to `DEFAULT-LG`. The `undo_buffer_size` is also optional; if omitted, it defaults to `64M`. Each `file-specification` corresponds to an undo log file, and at least one must be specified in the `file-specification-list`. Undo log files are placed according to any values that have been set for `FileSystemPath`, `FileSystemPathDD`, and `FileSystemPathUndoFiles`, just as if they had been created as the result of a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement.

Consider the following:

```
InitialLogFileGroup = name=LG1; undo_buffer_size=128M; undo1.log:250M; undo2.log:150M
```

This is equivalent to the following SQL statements:

```
CREATE LOGFILE GROUP LG1
  ADD UNDOFILE 'undo1.log'
  INITIAL_SIZE 250M
  UNDO_BUFFER_SIZE 128M
  ENGINE NDBCLUSTER;

ALTER LOGFILE GROUP LG1
  ADD UNDOFILE 'undo2.log'
  INITIAL_SIZE 150M
```

```
ENGINE NDBCLUSTER;
```

This logfile group is created when the data nodes are started with `--initial`.

Resources for the initial log file group are added to the global memory pool along with those indicated by the value of `SharedGlobalMemory`.

This parameter, if used, should always be set in the `[ndbd default]` section of the `config.ini` file. The behavior of an NDB Cluster when different values are set on different data nodes is not defined.

- `InitialTablespace`

| | |
|--------------------|---------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | string |
| Default | [see documentation] |
| Range | ... |
| Restart Type | S (NDB 8.0.13) |

This parameter can be used to specify an NDB Cluster Disk Data tablespace that is created when performing an initial start of the cluster. `InitialTablespace` is specified as shown here:

```
InitialTablespace = [name=name;] [extent_size=size;] file-specification-list
```

The `name` of the tablespace is optional and defaults to `DEFAULT-TS`. The `extent_size` is also optional; it defaults to `1M`. The `file-specification-list` uses the same syntax as shown with the `InitialLogfileGroup` parameter, the only difference being that each `file-specification` used with `InitialTablespace` corresponds to a data file. At least one must be specified in the `file-specification-list`. Data files are placed according to any values that have been set for `FileSystemPath`, `FileSystemPathDD`, and `FileSystemPathDataFiles`, just as if they had been created as the result of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement.

For example, consider the following line specifying `InitialTablespace` in the `[ndbd default]` section of the `config.ini` file (as with `InitialLogfileGroup`, this parameter should always be set in the `[ndbd default]` section, as the behavior of an NDB Cluster when different values are set on different data nodes is not defined):

```
InitialTablespace = name=TS1; extent_size=8M; data1.dat:2G; data2.dat:4G
```

This is equivalent to the following SQL statements:

```
CREATE TABLESPACE TS1
  ADD DATAFILE 'data1.dat'
  EXTENT_SIZE 8M
  INITIAL_SIZE 2G
  ENGINE NDBCLUSTER;

ALTER TABLESPACE TS1
  ADD DATAFILE 'data2.dat'
  INITIAL_SIZE 4G
  ENGINE NDBCLUSTER;
```

This tablespace is created when the data nodes are started with `--initial`, and can be used whenever creating NDB Cluster Disk Data tables thereafter.

- **Disk Data latency parameters.** The two parameters listed here can be used to improve handling of latency issues with NDB Cluster Disk Data tables.

- [MaxDiskDataLatency](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.19 |
| Type or units | ms |
| Default | 0 |
| Range | 0 - 8000 |
| Added | NDB 8.0.19 |
| Restart Type | N (NDB 8.0.13) |

This parameter controls the maximum allowed mean latency for disk access (maximum 8000 milliseconds). When this limit is reached, [NDB](#) begins to abort transactions in order to decrease pressure on the Disk Data I/O subsystem. Use `0` to disable the latency check.

- [DiskDataUsingSameDisk](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.19 |
| Type or units | boolean |
| Default | true |
| Range | ... |
| Added | NDB 8.0.19 |
| Restart Type | N (NDB 8.0.13) |

Set this parameter to `false` if your Disk Data tablespaces use one or more separate disks. Doing so allows checkpoints to tablespaces to be executed at a higher rate than normally used for when disks are shared.

When [DiskDataUsingSameDisk](#) is `true`, [NDB](#) decreases the rate of Disk Data checkpointing whenever an in-memory checkpoint is in progress to help ensure that disk load remains constant.

Disk Data and GCP Stop errors. Errors encountered when using Disk Data tables such as [Node `nodeid` killed this node because GCP stop was detected](#) (error 2303) are often referred to as “GCP stop errors”. Such errors occur when the redo log is not flushed to disk quickly enough; this is usually due to slow disks and insufficient disk throughput.

You can help prevent these errors from occurring by using faster disks, and by placing Disk Data files on a separate disk from the data node file system. Reducing the value of [TimeBetweenGlobalCheckpoints](#) tends to decrease the amount of data to be written for each global checkpoint, and so may provide some protection against redo log buffer overflows when trying to write a global checkpoint; however, reducing this value also permits less time in which to write the GCP, so this must be done with caution.

In addition to the considerations given for [DiskPageBufferMemory](#) as explained previously, it is also very important that the [DiskIOThreadPool](#) configuration parameter be set correctly; having [DiskIOThreadPool](#) set too high is very likely to cause GCP stop errors (Bug #37227).

GCP stops can be caused by save or commit timeouts; the [TimeBetweenEpochsTimeout](#) data node configuration parameter determines the timeout for commits. However, it is possible to disable both types of timeouts by setting this parameter to 0.

Parameters for configuring send buffer memory allocation. Send buffer memory is allocated dynamically from a memory pool shared between all transporters, which means that the size of the send

buffer can be adjusted as necessary. (Previously, the NDB kernel used a fixed-size send buffer for every node in the cluster, which was allocated when the node started and could not be changed while the node was running.) The `TotalSendBufferMemory` and `OverLoadLimit` data node configuration parameters permit the setting of limits on this memory allocation. For more information about the use of these parameters (as well as `SendBufferMemory`), see [Section 23.4.3.14, “Configuring NDB Cluster Send Buffer Parameters”](#).

- `ExtraSendBufferMemory`

This parameter specifies the amount of transporter send buffer memory to allocate in addition to any set using `TotalSendBufferMemory`, `SendBufferMemory`, or both.

- `TotalSendBufferMemory`

This parameter is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see [Section 23.4.3.14, “Configuring NDB Cluster Send Buffer Parameters”](#).

See also [Section 23.6.7, “Adding NDB Cluster Data Nodes Online”](#).

Redo log over-commit handling. It is possible to control a data node's handling of operations when too much time is taken flushing redo logs to disk. This occurs when a given redo log flush takes longer than `RedoOverCommitLimit` seconds, more than `RedoOverCommitCounter` times, causing any pending transactions to be aborted. When this happens, the API node that sent the transaction can handle the operations that should have been committed either by queuing the operations and re-trying them, or by aborting them, as determined by `DefaultOperationRedoProblemAction`. The data node configuration parameters for setting the timeout and number of times it may be exceeded before the API node takes this action are described in the following list:

- `RedoOverCommitCounter`

| | |
|------------------------------|-----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | numeric |
| Default | 3 |
| Range | 1 - 4294967039 (0xFFFFFFFF) |
| Version (or later) | NDB 8.0.19 |
| Type or units | numeric |
| Default | 3 |
| Range | 1 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

When `RedoOverCommitLimit` is exceeded when trying to write a given redo log to disk this many times or more, any transactions that were not committed as a result are aborted, and an API node where any of these transactions originated handles the operations making up those transactions according to its value for `DefaultOperationRedoProblemAction` (by either queuing the operations to be re-tried, or aborting them).

- `RedoOverCommitLimit`

| | |
|--------------------|------------|
| Version (or later) | NDB 8.0.13 |
|--------------------|------------|

| | |
|------------------------------|-----------------------------|
| Type or units | seconds |
| Default | 20 |
| Range | 1 - 4294967039 (0xFFFFFFFF) |
| Version (or later) | NDB 8.0.19 |
| Type or units | seconds |
| Default | 20 |
| Range | 1 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

This parameter sets an upper limit in seconds for trying to write a given redo log to disk before timing out. The number of times the data node tries to flush this redo log, but takes longer than [RedoOverCommitLimit](#), is kept and compared with [RedoOverCommitCounter](#), and when flushing takes too long more times than the value of that parameter, any transactions that were not committed as a result of the flush timeout are aborted. When this occurs, the API node where any of these transactions originated handles the operations making up those transactions according to its [DefaultOperationRedoProblemAction](#) setting (it either queues the operations to be re-tried, or aborts them).

Controlling restart attempts. It is possible to exercise finely-grained control over restart attempts by data nodes when they fail to start using the [MaxStartFailRetries](#) and [StartFailRetryDelay](#) data node configuration parameters.

[MaxStartFailRetries](#) limits the total number of retries made before giving up on starting the data node, [StartFailRetryDelay](#) sets the number of seconds between retry attempts. These parameters are listed here:

- [StartFailRetryDelay](#)

| | |
|------------------------------|-----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | unsigned |
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

Use this parameter to set the number of seconds between restart attempts by the data node in the event on failure on startup. The default is 0 (no delay).

Both this parameter and [MaxStartFailRetries](#) are ignored unless [StopOnError](#) is equal to 0.

- [MaxStartFailRetries](#)

| | |
|------------------------------|-----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | unsigned |
| Default | 3 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

Use this parameter to limit the number restart attempts made by the data node in the event that it fails on startup. The default is 3 attempts.

Both this parameter and [StartFailRetryDelay](#) are ignored unless [StopOnError](#) is equal to 0.

NDB index statistics parameters. The parameters in the following list relate to NDB index statistics generation.

- [IndexStatAutoCreate](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | integer |
| Default | 0 |
| Range | 0, 1 |
| Version (or later) | NDB 8.0.27 |
| Type or units | integer |
| Default | 1 |
| Range | 0, 1 |
| Restart Type | N (NDB 8.0.13) |

Enable (set equal to 1) or disable (set equal to 0) automatic statistics collection when indexes are created.

- [IndexStatAutoUpdate](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | integer |
| Default | 0 |
| Range | 0, 1 |
| Version (or later) | NDB 8.0.27 |
| Type or units | integer |
| Default | 1 |
| Range | 0, 1 |
| Restart Type | N (NDB 8.0.13) |

Enable (set equal to 1) or disable (set equal to 0) monitoring of indexes for changes, and trigger automatic statistics updates when these are detected. The degree of change needed to trigger the updates are determined by the settings for the [IndexStatTriggerPct](#) and [IndexStatTriggerScale](#) options.

- [IndexStatSaveSize](#)

| | |
|------------------------------|-----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | bytes |
| Default | 32768 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Restart Type | IN (NDB 8.0.13) |

Maximum space in bytes allowed for the saved statistics of any given index in the NDB system tables and in the `mysqld` memory cache.

At least one sample is always produced, regardless of any size limit. This size is scaled by `IndexStatSaveScale`.

The size specified by `IndexStatSaveSize` is scaled by the value of `IndexStatTriggerPct` for a large index, times 0.01. This is further multiplied by the logarithm to the base 2 of the index size. Setting `IndexStatTriggerPct` equal to 0 disables the scaling effect.

- `IndexStatSaveScale`

| | |
|------------------------------|-----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | percentage |
| Default | 100 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Restart Type | IN (NDB 8.0.13) |

The size specified by `IndexStatSaveSize` is scaled by the value of `IndexStatTriggerPct` for a large index, times 0.01. This is further multiplied by the logarithm to the base 2 of the index size. Setting `IndexStatTriggerPct` equal to 0 disables the scaling effect.

- `IndexStatTriggerPct`

| | |
|------------------------------|-----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | percentage |
| Default | 100 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Restart Type | IN (NDB 8.0.13) |

Percentage change in updates that triggers an index statistics update. The value is scaled by `IndexStatTriggerScale`. You can disable this trigger altogether by setting `IndexStatTriggerPct` to 0.

- `IndexStatTriggerScale`

| | |
|------------------------------|-----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | percentage |
| Default | 100 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Restart Type | IN (NDB 8.0.13) |

Scale `IndexStatTriggerPct` by this amount times 0.01 for a large index. A value of 0 disables scaling.

- `IndexStatUpdateDelay`

| | |
|--------------------|------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | seconds |

| | |
|------------------------------|-----------------------------|
| Default | 60 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Restart Type | IN (NDB 8.0.13) |

Minimum delay in seconds between automatic index statistics updates for a given index. Setting this variable to 0 disables any delay. The default is 60 seconds.

Restart types. Information about the restart types used by the parameter descriptions in this section is shown in the following table:

Table 23.16 NDB Cluster restart types

| Symbol | Restart Type | Description |
|--------|--------------|--|
| N | Node | The parameter can be updated using a rolling restart (see Section 23.6.5, “Performing a Rolling Restart of an NDB Cluster”) |
| S | System | All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter |
| I | Initial | Data nodes must be restarted using the <code>--initial</code> option |

23.4.3.7 Defining SQL and Other API Nodes in an NDB Cluster

The `[mysqld]` and `[api]` sections in the `config.ini` file define the behavior of the MySQL servers (SQL nodes) and other applications (API nodes) used to access cluster data. None of the parameters shown is required. If no computer or host name is provided, any host can use this SQL or API node.

Generally speaking, a `[mysqld]` section is used to indicate a MySQL server providing an SQL interface to the cluster, and an `[api]` section is used for applications other than `mysqld` processes accessing cluster data, but the two designations are actually synonymous; you can, for instance, list parameters for a MySQL server acting as an SQL node in an `[api]` section.

Note

For a discussion of MySQL server options for NDB Cluster, see [MySQL Server Options for NDB Cluster](#). For information about MySQL server system variables relating to NDB Cluster, see [NDB Cluster System Variables](#).

- `Id`

| | |
|------------------------------|-----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | unsigned |
| Default | [...] |
| Range | 1 - 255 |
| Restart Type | IS (NDB 8.0.13) |

The `Id` is an integer value used to identify the node in all cluster internal messages. The permitted range of values is 1 to 255 inclusive. This value must be unique for each node in the cluster, regardless of the type of node.

Note

In NDB 8.0, data node IDs must be less than 145. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for API nodes (and management nodes) to values greater than 144. (Previously, the maximum supported value for a data node ID was 48.)

`NodeId` is the preferred parameter name to use when identifying API nodes. (`Id` continues to be supported for backward compatibility, but is now deprecated and generates a warning when used. It is also subject to future removal.)

- [ConnectionMap](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | string |
| Default | [...] |
| Range | ... |
| Restart Type | N (NDB 8.0.13) |

Specifies which data nodes to connect.

- [NodeId](#)

| | |
|------------------------------|-----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | unsigned |
| Default | [...] |
| Range | 1 - 255 |
| Restart Type | IS (NDB 8.0.13) |

The `NodeId` is an integer value used to identify the node in all cluster internal messages. The permitted range of values is 1 to 255 inclusive. This value must be unique for each node in the cluster, regardless of the type of node.

Note

In NDB 8.0, data node IDs must be less than 145. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for API nodes (and management nodes) to values greater than 144. (Previously, the maximum supported value for a data node ID was 48.)

`NodeId` is the preferred parameter name to use when identifying management nodes. An alias, `Id`, was used for this purpose in very old versions of NDB Cluster, and continues to be supported for backward compatibility; it is now deprecated and generates a warning when used, and is subject to removal in a future release of NDB Cluster.

- [ExecuteOnComputer](#)

| | |
|--------------------|------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | name |
| Default | [...] |

| | |
|------------------------------|------------------|
| Range | ... |
| Deprecated | Yes (in NDB 7.5) |
| Restart Type | S (NDB 8.0.13) |

This refers to the `id` set for one of the computers (hosts) defined in a `[computer]` section of the configuration file.

Important

This parameter is deprecated, and is subject to removal in a future release. Use the `HostName` parameter instead.

-

The node ID for this node can be given out only to connections that explicitly request it. A management server that requests “any” node ID cannot use this one. This parameter can be used when running multiple management servers on the same host, and `HostName` is not sufficient for distinguishing among processes. Intended for use in testing.

- [HostName](#)

| | |
|------------------------------|--------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | name or IP address |
| Default | [...] |
| Range | ... |
| Restart Type | N (NDB 8.0.13) |

Specifying this parameter defines the hostname of the computer on which the SQL node (API node) is to reside. To specify a hostname, either this parameter or `ExecuteOnComputer` is required.

If no `HostName` or `ExecuteOnComputer` is specified in a given `[mysql]` or `[api]` section of the `config.ini` file, then an SQL or API node may connect using the corresponding “slot” from any host which can establish a network connection to the management server host machine. *This differs from the default behavior for data nodes, where `localhost` is assumed for `HostName` unless otherwise specified.*

- [LocationDomainId](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | integer |
| Default | 0 |
| Range | 0 - 16 |
| Restart Type | S (NDB 8.0.13) |

Assigns an SQL or other API node to a specific [availability domain](#) (also known as an availability zone) within a cloud. By informing `NDB` which nodes are in which availability domains, performance can be improved in a cloud environment in the following ways:

- If requested data is not found on the same node, reads can be directed to another node in the same availability domain.

- Communication between nodes in different availability domains are guaranteed to use [NDB transporters](#)' WAN support without any further manual intervention.
- The transporter's group number can be based on which availability domain is used, such that also SQL and other API nodes communicate with local data nodes in the same availability domain whenever possible.
- The arbitrator can be selected from an availability domain in which no data nodes are present, or, if no such availability domain can be found, from a third availability domain.

[LocationDomainId](#) takes an integer value between 0 and 16 inclusive, with 0 being the default; using 0 is the same as leaving the parameter unset.

- [ArbitrationRank](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | 0-2 |
| Default | 0 |
| Range | 0 - 2 |
| Restart Type | N (NDB 8.0.13) |

This parameter defines which nodes can act as arbitrators. Both management nodes and SQL nodes can be arbitrators. A value of 0 means that the given node is never used as an arbitrator, a value of 1 gives the node high priority as an arbitrator, and a value of 2 gives it low priority. A normal configuration uses the management server as arbitrator, setting its [ArbitrationRank](#) to 1 (the default for management nodes) and those for all SQL nodes to 0 (the default for SQL nodes).

By setting [ArbitrationRank](#) to 0 on all management and SQL nodes, you can disable arbitration completely. You can also control arbitration by overriding this parameter; to do so, set the [Arbitration](#) parameter in the `[ndbd default]` section of the `config.ini` global configuration file.

- [ArbitrationDelay](#)

| | |
|------------------------------|-----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | milliseconds |
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

Setting this parameter to any other value than 0 (the default) means that responses by the arbitrator to arbitration requests are delayed by the stated number of milliseconds. It is usually not necessary to change this value.

- [BatchByteSize](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | bytes |
| Default | 16K |
| Range | 1K - 1M |
| Restart Type | N (NDB 8.0.13) |

For queries that are translated into full table scans or range scans on indexes, it is important for best performance to fetch records in properly sized batches. It is possible to set the proper size both in terms of number of records ([BatchSize](#)) and in terms of bytes ([BatchByteSize](#)). The actual batch size is limited by both parameters.

The speed at which queries are performed can vary by more than 40% depending upon how this parameter is set.

This parameter is measured in bytes. The default value is 16K.

- [BatchSize](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | records |
| Default | 256 |
| Range | 1 - 992 |
| Restart Type | N (NDB 8.0.13) |

This parameter is measured in number of records and is by default set to 256. The maximum size is 992.

- [ExtraSendBufferMemory](#)

| | |
|------------------------------|-----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | bytes |
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

This parameter specifies the amount of transporter send buffer memory to allocate in addition to any that has been set using [TotalSendBufferMemory](#), [SendBufferMemory](#), or both.

- [HeartbeatThreadPriority](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | string |
| Default | [...] |
| Range | ... |
| Restart Type | N (NDB 8.0.13) |

Use this parameter to set the scheduling policy and priority of heartbeat threads for management and API nodes. The syntax for setting this parameter is shown here:

```
HeartbeatThreadPriority = policy[, priority]
```

```
policy:
{FIFO | RR}
```

When setting this parameter, you must specify a policy. This is one of [FIFO](#) (first in, first in) or [RR](#) (round robin). This followed optionally by the priority (an integer).

- [MaxScanBatchSize](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | bytes |
| Default | 256K |
| Range | 32K - 16M |
| Restart Type | N (NDB 8.0.13) |

The batch size is the size of each batch sent from each data node. Most scans are performed in parallel to protect the MySQL Server from receiving too much data from many nodes in parallel; this parameter sets a limit to the total batch size over all nodes.

The default value of this parameter is set to 256KB. Its maximum size is 16MB.

- [TotalSendBufferMemory](#)

| | |
|------------------------------|--------------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | bytes |
| Default | 0 |
| Range | 256K - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

This parameter is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see [Section 23.4.3.14, “Configuring NDB Cluster Send Buffer Parameters”](#).

- [AutoReconnect](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | boolean |
| Default | false |
| Range | true, false |
| Restart Type | N (NDB 8.0.13) |

This parameter is `false` by default. This forces disconnected API nodes (including MySQL Servers acting as SQL nodes) to use a new connection to the cluster rather than attempting to re-use an existing one, as re-use of connections can cause problems when using dynamically-allocated node IDs. (Bug #45921)

Note

This parameter can be overridden using the NDB API. For more information, see [Ndb_cluster_connection::set_auto_reconnect\(\)](#), and [Ndb_cluster_connection::get_auto_reconnect\(\)](#).

- [DefaultOperationRedoProblemAction](#)

| | |
|--------------------|------------|
| Version (or later) | NDB 8.0.13 |
|--------------------|------------|

| | |
|------------------------------|----------------|
| Type or units | enumeration |
| Default | QUEUE |
| Range | ABORT, QUEUE |
| Restart Type | N (NDB 8.0.13) |

This parameter (along with [RedoOverCommitLimit](#) and [RedoOverCommitCounter](#)) controls the data node's handling of operations when too much time is taken flushing redo logs to disk. This occurs when a given redo log flush takes longer than [RedoOverCommitLimit](#) seconds, more than [RedoOverCommitCounter](#) times, causing any pending transactions to be aborted.

When this happens, the node can respond in either of two ways, according to the value of [DefaultOperationRedoProblemAction](#), listed here:

- **ABORT**: Any pending operations from aborted transactions are also aborted.
- **QUEUE**: Pending operations from transactions that were aborted are queued up to be re-tried. This is the default. Pending operations are still aborted when the redo log runs out of space—that is, when [P_TAIL_PROBLEM](#) errors occur.
- [DefaultHashMapSize](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | buckets |
| Default | 3840 |
| Range | 0 - 3840 |
| Restart Type | N (NDB 8.0.13) |

The size of the table hash maps used by NDB is configurable using this parameter. [DefaultHashMapSize](#) can take any of three possible values (0, 240, 3840). These values and their effects are described in the following table.

Table 23.17 DefaultHashMapSize parameter values

| Value | Description / Effect |
|-------|--|
| 0 | Use the lowest value set, if any, for this parameter among all data nodes and API nodes in the cluster; if it is not set on any data or API node, use the default value. |
| 240 | Old default hash map size |
| 3840 | Hash map size used by default in NDB 8.0 |

The original intended use for this parameter was to facilitate upgrades and downgrades to and from older NDB Cluster versions, in which the hash map size differed, due to the fact that this change was not otherwise backward compatible. This is not an issue when upgrading to or downgrading from NDB Cluster 8.0.

- [Wan](#)

| | |
|--------------------|------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | boolean |

| | |
|------------------------------|----------------|
| Default | false |
| Range | true, false |
| Restart Type | N (NDB 8.0.13) |

Use WAN TCP setting as default.

- [ConnectBackoffMaxTime](#)

| | |
|------------------------------|-----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | integer |
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

In an NDB Cluster with many unstarted data nodes, the value of this parameter can be raised to circumvent connection attempts to data nodes which have not yet begun to function in the cluster, as well as moderate high traffic to management nodes. As long as the API node is not connected to any new data nodes, the value of the [StartConnectBackoffMaxTime](#) parameter is applied; otherwise, [ConnectBackoffMaxTime](#) is used to determine the length of time in milliseconds to wait between connection attempts.

Time elapsed *during* node connection attempts is not taken into account when calculating elapsed time for this parameter. The timeout is applied with approximately 100 ms resolution, starting with a 100 ms delay; for each subsequent attempt, the length of this period is doubled until it reaches [ConnectBackoffMaxTime](#) milliseconds, up to a maximum of 100000 ms (100s).

Once the API node is connected to a data node and that node reports (in a heartbeat message) that it has connected to other data nodes, connection attempts to those data nodes are no longer affected by this parameter, and are made every 100 ms thereafter until connected. Once a data node has started, it can take up [HeartbeatIntervalDbApi](#) for the API node to be notified that this has occurred.

- [StartConnectBackoffMaxTime](#)

| | |
|------------------------------|-----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | integer |
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

In an NDB Cluster with many unstarted data nodes, the value of this parameter can be raised to circumvent connection attempts to data nodes which have not yet begun to function in the cluster, as well as moderate high traffic to management nodes. As long as the API node is not connected to any new data nodes, the value of the [StartConnectBackoffMaxTime](#) parameter is applied; otherwise, [ConnectBackoffMaxTime](#) is used to determine the length of time in milliseconds to wait between connection attempts.

Time elapsed *during* node connection attempts is not taken into account when calculating elapsed time for this parameter. The timeout is applied with approximately 100 ms resolution, starting with

a 100 ms delay; for each subsequent attempt, the length of this period is doubled until it reaches `StartConnectBackoffMaxTime` milliseconds, up to a maximum of 100000 ms (100s).

Once the API node is connected to a data node and that node reports (in a heartbeat message) that it has connected to other data nodes, connection attempts to those data nodes are no longer affected by this parameter, and are made every 100 ms thereafter until connected. Once a data node has started, it can take up `HeartbeatIntervalDbApi` for the API node to be notified that this has occurred.

API Node Debugging Parameters. You can use the `ApiVerbose` configuration parameter to enable debugging output from a given API node. This parameter takes an integer value. 0 is the default, and disables such debugging; 1 enables debugging output to the cluster log; 2 adds `DBDICT` debugging output as well. (Bug #20638450) See also [DUMP 1229](#).

You can also obtain information from a MySQL server running as an NDB Cluster SQL node using `SHOW STATUS` in the `mysql` client, as shown here:

```
mysql> SHOW STATUS LIKE 'ndb%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ndb_cluster_node_id | 5 |
| Ndb_config_from_host | 198.51.100.112 |
| Ndb_config_from_port | 1186 |
| Ndb_number_of_storage_nodes | 4 |
+-----+-----+
4 rows in set (0.02 sec)
```

For information about the status variables appearing in the output from this statement, see [NDB Cluster Status Variables](#).

Note

To add new SQL or API nodes to the configuration of a running NDB Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new `[mysqld]` or `[api]` sections to the `config.ini` file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.

It is *not* necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.

Restart types. Information about the restart types used by the parameter descriptions in this section is shown in the following table:

Table 23.18 NDB Cluster restart types

| Symbol | Restart Type | Description |
|--------|--------------|--|
| N | Node | The parameter can be updated using a rolling restart (see Section 23.6.5, “Performing a Rolling Restart of an NDB Cluster”) |
| S | System | All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter |

| Symbol | Restart Type | Description |
|--------|--------------|--|
| I | Initial | Data nodes must be restarted using the <code>--initial</code> option |

23.4.3.8 Defining the System

The `[system]` section is used for parameters applying to the cluster as a whole. The `Name` system parameter is used with MySQL Enterprise Monitor; `ConfigGenerationNumber` and `PrimaryMGMNode` are not used in production environments. Except when using NDB Cluster with MySQL Enterprise Monitor, is not necessary to have a `[system]` section in the `config.ini` file.

More information about these parameters can be found in the following list:

- [ConfigGenerationNumber](#)

| | |
|------------------------------|-----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | unsigned |
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

Configuration generation number. This parameter is currently unused.

- [Name](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | string |
| Default | [...] |
| Range | ... |
| Restart Type | N (NDB 8.0.13) |

Set a name for the cluster. This parameter is required for deployments with MySQL Enterprise Monitor; it is otherwise unused.

You can obtain the value of this parameter by checking the `Ndb_system_name` status variable. In NDB API applications, you can also retrieve it using `get_system_name()`.

- [PrimaryMGMNode](#)

| | |
|------------------------------|-----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | unsigned |
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

Node ID of the primary management node. This parameter is currently unused.

Restart types. Information about the restart types used by the parameter descriptions in this section is shown in the following table:

Table 23.19 NDB Cluster restart types

| Symbol | Restart Type | Description |
|--------|--------------|--|
| N | Node | The parameter can be updated using a rolling restart (see Section 23.6.5, “Performing a Rolling Restart of an NDB Cluster”) |
| S | System | All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter |
| I | Initial | Data nodes must be restarted using the <code>--initial</code> option |

23.4.3.9 MySQL Server Options and Variables for NDB Cluster

This section provides information about MySQL server options, server and status variables that are specific to NDB Cluster. For general information on using these, and for other options and variables not specific to NDB Cluster, see [Section 5.1, “The MySQL Server”](#).

For NDB Cluster configuration parameters used in the cluster configuration file (usually named `config.ini`), see [Section 23.4, “Configuration of NDB Cluster”](#).

MySQL Server Options for NDB Cluster

This section provides descriptions of `mysqld` server options relating to NDB Cluster. For information about `mysqld` options not specific to NDB Cluster, and for general information about the use of options with `mysqld`, see [Section 5.1.7, “Server Command Options”](#).

For information about command-line options used with other NDB Cluster processes, see [Section 23.5, “NDB Cluster Programs”](#).

- `--ndbcluster`

| | |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--ndbcluster[=value]</code> |
| Disabled by | <code>skip-ndbcluster</code> |
| Type | Enumeration |
| Default Value | ON |
| Valid Values | OFF FORCE |

The `NDBCLUSTER` storage engine is necessary for using NDB Cluster. If a `mysqld` binary includes support for the `NDBCLUSTER` storage engine, the engine is disabled by default. Use the `--ndbcluster` option to enable it. Use `--skip-ndbcluster` to explicitly disable the engine.

The `--ndbcluster` option is ignored (and the `NDB` storage engine is *not* enabled) if `--initialize` is also used. (It is neither necessary nor desirable to use this option together with `--initialize`.)

- `--ndb-allow-copying-alter-table=[ON|OFF]`

| | |
|---------------------|---|
| Command-Line Format | <code>--ndb-allow-copying-alter-table[={OFF ON}]</code> |
|---------------------|---|

| | |
|----------------------|--|
| System Variable | <code>ndb_allow_copying_alter_table</code> |
| Scope | Global, Session |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Boolean |
| Default Value | ON |

Let `ALTER TABLE` and other DDL statements use copying operations on NDB tables. Set to `OFF` to keep this from happening; doing so may improve performance of critical applications.

- `--ndb-batch-size=#`

| | |
|----------------------|-------------------------------|
| Command-Line Format | <code>--ndb-batch-size</code> |
| System Variable | <code>ndb_batch_size</code> |
| Scope | Global |
| Dynamic | No |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value | 32768 |
| Minimum Value | 0 |
| Maximum Value | 31536000 |

This sets the size in bytes that is used for NDB transaction batches.

- `--ndb-cluster-connection-pool=#`

| | |
|----------------------|--|
| Command-Line Format | <code>--ndb-cluster-connection-pool</code> |
| System Variable | <code>ndb_cluster_connection_pool</code> |
| System Variable | <code>ndb_cluster_connection_pool</code> |
| Scope | Global |
| Scope | Global |
| Dynamic | No |
| Dynamic | No |
| SET_VAR Hint Applies | No |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value | 1 |
| Minimum Value | 1 |
| Maximum Value | 63 |

By setting this option to a value greater than 1 (the default), a `mysqld` process can use multiple connections to the cluster, effectively mimicking several SQL nodes. Each connection requires its own

[`api`] or [`mysqld`] section in the cluster configuration (`config.ini`) file, and counts against the maximum number of API connections supported by the cluster.

Suppose that you have 2 cluster host computers, each running an SQL node whose `mysqld` process was started with `--ndb-cluster-connection-pool=4`; this means that the cluster must have 8 API slots available for these connections (instead of 2). All of these connections are set up when the SQL node connects to the cluster, and are allocated to threads in a round-robin fashion.

This option is useful only when running `mysqld` on host machines having multiple CPUs, multiple cores, or both. For best results, the value should be smaller than the total number of cores available on the host machine. Setting it to a value greater than this is likely to degrade performance severely.

Important

Because each SQL node using connection pooling occupies multiple API node slots—each slot having its own node ID in the cluster—you must *not* use a node ID as part of the cluster connection string when starting any `mysqld` process that employs connection pooling.

Setting a node ID in the connection string when using the `--ndb-cluster-connection-pool` option causes node ID allocation errors when the SQL node attempts to connect to the cluster.

- `--ndb-cluster-connection-pool-nodeids=list`

| | |
|-----------------------------------|--|
| Command-Line Format | <code>--ndb-cluster-connection-pool-nodeids</code> |
| System Variable | <code>ndb_cluster_connection_pool_nodeids</code> |
| Scope | Global |
| Dynamic | No |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Set |
| Default Value | |

Specifies a comma-separated list of node IDs for connections to the cluster used by an SQL node. The number of nodes in this list must be the same as the value set for the `--ndb-cluster-connection-pool` option.

- `--ndb-blob-read-batch-bytes=bytes`

| | |
|-----------------------------------|--|
| Command-Line Format | <code>--ndb-blob-read-batch-bytes</code> |
| System Variable | <code>ndb_blob_read_batch_bytes</code> |
| Scope | Global, Session |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Integer |
| Default Value | 65536 |
| Minimum Value | 0 |

| | |
|---------------|------------|
| Maximum Value | 4294967295 |
|---------------|------------|

This option can be used to set the size (in bytes) for batching of **BLOB** data reads in NDB Cluster applications. When this batch size is exceeded by the amount of **BLOB** data to be read within the current transaction, any pending **BLOB** read operations are immediately executed.

The maximum value for this option is 4294967295; the default is 65536. Setting it to 0 has the effect of disabling **BLOB** read batching.

Note

In NDB API applications, you can control **BLOB** write batching with the `setMaxPendingBlobReadBytes()` and `getMaxPendingBlobReadBytes()` methods.

- `--ndb-lob-write-batch-bytes=bytes`

| | |
|-----------------------------------|--|
| Command-Line Format | <code>--ndb-lob-write-batch-bytes</code> |
| System Variable | <code>ndb_lob_write_batch_bytes</code> |
| Scope | Global, Session |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Integer |
| Default Value | 65536 |
| Minimum Value | 0 |
| Maximum Value | 4294967295 |

This option can be used to set the size (in bytes) for batching of **BLOB** data writes in NDB Cluster applications. When this batch size is exceeded by the amount of **BLOB** data to be written within the current transaction, any pending **BLOB** write operations are immediately executed.

The maximum value for this option is 4294967295; the default is 65536. Setting it to 0 has the effect of disabling **BLOB** write batching.

Note

In NDB API applications, you can control **BLOB** write batching with the `setMaxPendingBlobWriteBytes()` and `getMaxPendingBlobWriteBytes()` methods.

- `--ndb-connectstring=connection_string`

| | |
|---------------------|----------------------------------|
| Command-Line Format | <code>--ndb-connectstring</code> |
| Type | String |

When using the `NDBCLUSTER` storage engine, this option specifies the management server that distributes cluster configuration data. See [Section 23.4.3.3, “NDB Cluster Connection Strings”](#), for syntax.

- `--ndb-default-column-format={FIXED|DYNAMIC}`

| | |
|----------------------|--|
| Command-Line Format | <code>--ndb-default-column-format={FIXED DYNAMIC}</code> |
| System Variable | <code>ndb_default_column_format</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Enumeration |
| Default Value | <code>FIXED</code> |
| Valid Values | <code>FIXED</code> <code>DYNAMIC</code> |

Sets the default `COLUMN_FORMAT` and `ROW_FORMAT` for new tables (see [Section 13.1.20, “CREATE TABLE Statement”](#)). The default is `FIXED`.

- `--ndb-deferred-constraints={0|1}`

| | |
|----------------------|---|
| Command-Line Format | <code>--ndb-deferred-constraints</code> |
| System Variable | <code>ndb_deferred_constraints</code> |
| Scope | Global, Session |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value | 0 |
| Minimum Value | 0 |
| Maximum Value | 1 |

Controls whether or not constraint checks on unique indexes are deferred until commit time, where such checks are supported. 0 is the default.

This option is not normally needed for operation of NDB Cluster or NDB Cluster Replication, and is intended primarily for use in testing.

- `--ndb-schema-dist-timeout=#`

| | |
|----------------------|--|
| Command-Line Format | <code>--ndb-schema-dist-timeout=#</code> |
| Introduced | 8.0.17-ndb-8.0.17 |
| System Variable | <code>ndb_schema_dist_timeout</code> |
| Scope | Global |
| Dynamic | No |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value | 120 |
| Minimum Value | 5 |

NDB Cluster Configuration Files

| | |
|---------------|---------|
| Maximum Value | 1200 |
| Unit | seconds |

Specifies the maximum time in seconds that this `mysqld` waits for a schema operation to complete before marking it as having timed out.

- `--ndb-distribution={KEYHASH|LINHASH}`

| | |
|----------------------|---|
| Command-Line Format | <code>--ndb-distribution={KEYHASH LINHASH}</code> |
| System Variable | <code>ndb_distribution</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Enumeration |
| Default Value | KEYHASH |
| Valid Values | LINHASH KEYHASH |

Controls the default distribution method for NDB tables. Can be set to either of `KEYHASH` (key hashing) or `LINHASH` (linear hashing). `KEYHASH` is the default.

- `--ndb-log-apply-status`

| | |
|----------------------|--|
| Command-Line Format | <code>--ndb-log-apply-status[={OFF ON}]</code> |
| System Variable | <code>ndb_log_apply_status</code> |
| Scope | Global |
| Dynamic | No |
| SET_VAR Hint Applies | No |
| Type | Boolean |
| Default Value | OFF |

Causes a replica `mysqld` to log any updates received from its immediate source to the `mysql.ndb_apply_status` table in its own binary log using its own server ID rather than the server ID of the source. In a circular or chain replication setting, this allows such updates to propagate to the `mysql.ndb_apply_status` tables of any MySQL servers configured as replicas of the current `mysqld`.

In a chain replication setup, using this option allows downstream (replica) clusters to be aware of their positions relative to all of their upstream contributors (sources).

In a circular replication setup, this option causes changes to `ndb_apply_status` tables to complete the entire circuit, eventually propagating back to the originating NDB Cluster. This also allows a cluster acting as a replication source to see when its changes (epochs) have been applied to the other clusters in the circle.

This option has no effect unless the MySQL server is started with the `--ndbcluster` option.

- `--ndb-log-empty-epochs={ON|OFF}`

| | |
|----------------------|--|
| Command-Line Format | <code>--ndb-log-empty-epochs[={OFF ON}]</code> |
| System Variable | <code>ndb_log_empty_epochs</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Boolean |
| Default Value | <code>OFF</code> |

Causes epochs during which there were no changes to be written to the `ndb_apply_status` and `ndb_binlog_index` tables, even when `log_replica_updates` or `log_slave_updates` is enabled.

By default this option is disabled. Disabling `--ndb-log-empty-epochs` causes epoch transactions with no changes not to be written to the binary log, although a row is still written even for an empty epoch in `ndb_binlog_index`.

Because `--ndb-log-empty-epochs=1` causes the size of the `ndb_binlog_index` table to increase independently of the size of the binary log, users should be prepared to manage the growth of this table, even if they expect the cluster to be idle a large part of the time.

- `--ndb-log-empty-update={ON|OFF}`

| | |
|----------------------|--|
| Command-Line Format | <code>--ndb-log-empty-update[={OFF ON}]</code> |
| System Variable | <code>ndb_log_empty_update</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Boolean |
| Default Value | <code>OFF</code> |

Causes updates that produced no changes to be written to the `ndb_apply_status` and `ndb_binlog_index` tables, even when `log_replica_updates` or `log_slave_updates` is enabled.

By default this option is disabled (`OFF`). Disabling `--ndb-log-empty-update` causes updates with no changes not to be written to the binary log.

- `--ndb-log-exclusive-reads={0|1}`

| | |
|----------------------|---|
| Command-Line Format | <code>--ndb-log-exclusive-reads[={OFF ON}]</code> |
| System Variable | <code>ndb_log_exclusive_reads</code> |
| Scope | Global, Session |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Boolean |

| | |
|---------------|---|
| Default Value | 0 |
|---------------|---|

Starting the server with this option causes primary key reads to be logged with exclusive locks, which allows for NDB Cluster Replication conflict detection and resolution based on read conflicts. You can also enable and disable these locks at runtime by setting the value of the `ndb_log_exclusive_reads` system variable to 1 or 0, respectively. 0 (disable locking) is the default.

For more information, see [Read conflict detection and resolution](#).

- `--ndb-log-fail-terminate`

| | |
|----------------------|---------------------------------------|
| Command-Line Format | <code>--ndb-log-fail-terminate</code> |
| Introduced | 8.0.21-ndb-8.0.21 |
| System Variable | <code>ndb_log_fail_terminate</code> |
| Scope | Global |
| Dynamic | No |
| SET_VAR Hint Applies | No |
| Type | Boolean |
| Default Value | FALSE |

When this option is specified, and complete logging of all found row events is not possible, the `mysqld` process is terminated.

- `--ndb-log-orig`

| | |
|----------------------|---|
| Command-Line Format | <code>--ndb-log-orig[={OFF ON}]</code> |
| System Variable | <code>ndb_log_orig</code> |
| Scope | Global |
| Dynamic | No |
| SET_VAR Hint Applies | No |
| Type | Boolean |
| Default Value | OFF |

Log the originating server ID and epoch in the `ndb_binlog_index` table.

Note

This makes it possible for a given epoch to have multiple rows in `ndb_binlog_index`, one for each originating epoch.

For more information, see [Section 23.7.4, “NDB Cluster Replication Schema and Tables”](#).

- `--ndb-log-transaction-id`

| | |
|---------------------|---|
| Command-Line Format | <code>--ndb-log-transaction-id[={OFF ON}]</code> |
| System Variable | <code>ndb_log_transaction_id</code> |
| Scope | Global |
| Dynamic | No |

| | |
|-----------------------------------|------------------|
| <code>SET_VAR</code> Hint Applies | No |
| Type | Boolean |
| Default Value | <code>OFF</code> |

Causes a replica `mysqld` to write the NDB transaction ID in each row of the binary log. The default value is `FALSE`.

This option is not supported in mainline MySQL Server 8.0. It is required to enable NDB Cluster Replication conflict detection and resolution using the `NDB$EPOCH_TRANS()` function (see [NDB \\$EPOCH_TRANS\(\)](#)). For more information, see [Section 23.7.11, “NDB Cluster Replication Conflict Resolution”](#).

The deprecated `log_bin_use_v1_row_events` system variable, which defaults to `OFF`, must not be set to `ON` when you use `--ndb-log-transaction-id`.

- `--ndb-log-update-as-write`

| | |
|-----------------------------------|--|
| Command-Line Format | <code>--ndb-log-update-as-write[={OFF ON}]</code> |
| System Variable | <code>ndb_log_update_as_write</code> |
| Scope | Global |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Boolean |
| Default Value | <code>ON</code> |

Whether updates on the source are written to the binary log as updates (`OFF`) or writes (`ON`). Used in NDB Replication conflict resolution; for more information, see [Logging Changed Data as Updates](#).

- `--ndb-log-updated-only`

| | |
|-----------------------------------|---|
| Command-Line Format | <code>--ndb-log-updated-only[={OFF ON}]</code> |
| System Variable | <code>ndb_log_updated_only</code> |
| Scope | Global |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Boolean |
| Default Value | <code>ON</code> |

Whether `mysqld` writes complete rows (`ON`) or updates only (`OFF`) to the binary log. Used in NDB Replication conflict resolution; see [Logging Full or Partial Rows](#), for more information.

- `--ndb-log-update-minimal`

| | |
|-----------------------------------|---|
| Command-Line Format | <code>--ndb-log-update-minimal[={OFF ON}]</code> |
| System Variable | <code>ndb_log_update_minimal</code> |
| Scope | Global |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |

| | |
|---------------|---------|
| Type | Boolean |
| Default Value | OFF |

Log updates in a minimal fashion, by writing only the primary key values in the before image, and only the changed columns in the after image. This may cause compatibility problems if replicating to storage engines other than NDB.

- `--ndb-mgmd-host=host[:port]`

| | |
|---------------------|---|
| Command-Line Format | <code>--ndb-mgmd-host=host_name[:port_num]</code> |
| Type | String |
| Default Value | <code>localhost:1186</code> |

Can be used to set the host and port number of a single management server for the program to connect to. If the program requires node IDs or references to multiple management servers (or both) in its connection information, use the `--ndb-connectstring` option instead.

- `--ndb-nodeid=#`

| | |
|---------------------|----------------------------------|
| Command-Line Format | <code>--ndb-nodeid=#</code> |
| Status Variable | <code>Ndb_cluster_node_id</code> |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Minimum Value | 1 |
| Maximum Value | 255 |
| Maximum Value | 63 |

Set this MySQL server's node ID in an NDB Cluster.

The `--ndb-nodeid` option overrides any node ID set with `--ndb-connectstring`, regardless of the order in which the two options are used.

In addition, if `--ndb-nodeid` is used, then either a matching node ID must be found in a `[mysqld]` or `[api]` section of `config.ini`, or there must be an “open” `[mysqld]` or `[api]` section in the file (that is, a section without a `NodeId` or `Id` parameter specified). This is also true if the node ID is specified as part of the connection string.

Regardless of how the node ID is determined, its is shown as the value of the global status variable `Ndb_cluster_node_id` in the output of `SHOW STATUS`, and as `cluster_node_id` in the `connection` row of the output of `SHOW ENGINE NDBCLUSTER STATUS`.

For more information about node IDs for NDB Cluster SQL nodes, see [Section 23.4.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”](#).

- `--ndbinfo={ON|OFF|FORCE}`

| | |
|---------------------|--|
| Command-Line Format | <code>--ndbinfo[=value]</code> (≥ 8.0.13-ndb-8.0.13) |
| Introduced | 8.0.13-ndb-8.0.13 |
| Type | Enumeration |

| | |
|---------------|--------------------|
| Default Value | ON |
| Valid Values | ON OFF FORCE |

Enables the plugin for the `ndbinfo` information database. By default this is ON whenever `NDBCLUSTER` is enabled.

- `--ndb-optimization-delay=milliseconds`

| | |
|----------------------|---|
| Command-Line Format | <code>--ndb-optimization-delay=#</code> |
| System Variable | <code>ndb_optimization_delay</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value | 10 |
| Minimum Value | 0 |
| Maximum Value | 100000 |

Set the number of milliseconds to wait between sets of rows by `OPTIMIZE TABLE` statements on `NDB` tables. The default is 10.

- `--ndb-optimized-node-selection`

| | |
|---------------------|---|
| Command-Line Format | <code>--ndb-optimized-node-selection</code> |
|---------------------|---|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--ndb-transid-mysql-connection-map=state`

| | |
|---------------------|---|
| Command-Line Format | <code>--ndb-transid-mysql-connection-map[=state]</code> |
| Type | Enumeration |
| Default Value | ON |
| Valid Values | ON OFF FORCE |

Enables or disables the plugin that handles the `ndb_transid_mysql_connection_map` table in the `INFORMATION_SCHEMA` database. Takes one of the values `ON`, `OFF`, or `FORCE`. `ON` (the default) enables the plugin. `OFF` disables the plugin, which makes `ndb_transid_mysql_connection_map` inaccessible. `FORCE` keeps the MySQL Server from starting if the plugin fails to load and start.

You can see whether the `ndb_transid_mysql_connection_map` table plugin is running by checking the output of `SHOW PLUGINS`.

- `--ndb-wait-connected=seconds`

| | |
|-------------------------------------|-------------------------------------|
| Command-Line Format | <code>--ndb-wait-connected=#</code> |
| System Variable | <code>ndb_wait_connected</code> |
| Scope | Global |
| Dynamic | No |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value (≥ 8.0.27-ndb-8.0.27) | 120 |
| Default Value (≤ 8.0.26-ndb-8.0.26) | 30 |
| Default Value | 30 |
| Minimum Value | 0 |
| Maximum Value | 31536000 |

This option sets the period of time that the MySQL server waits for connections to NDB Cluster management and data nodes to be established before accepting MySQL client connections. The time is specified in seconds. The default value is 30.

- `--ndb-wait-setup=seconds`

| | |
|-------------------------------------|---------------------------------|
| Command-Line Format | <code>--ndb-wait-setup=#</code> |
| System Variable | <code>ndb_wait_setup</code> |
| Scope | Global |
| Dynamic | No |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value (≥ 8.0.27-ndb-8.0.27) | 120 |
| Default Value (≤ 8.0.26-ndb-8.0.26) | 30 |
| Default Value | 30 |
| Default Value | 15 |
| Default Value | 15 |
| Minimum Value | 0 |
| Maximum Value | 31536000 |

This variable shows the period of time that the MySQL server waits for the NDB storage engine to complete setup before timing out and treating NDB as unavailable. The time is specified in seconds. The default value is 30.

- `--skip-ndbcluster`

| | |
|---------------------|--------------------------------|
| Command-Line Format | <code>--skip-ndbcluster</code> |
|---------------------|--------------------------------|

Disable the `NDBCLUSTER` storage engine. This is the default for binaries that were built with `NDBCLUSTER` storage engine support; the server allocates memory and other resources for this storage engine only if the `--ndbcluster` option is given explicitly. See [Section 23.4.1, “Quick Test Setup of NDB Cluster”](#), for an example.

NDB Cluster System Variables

This section provides detailed information about MySQL server system variables that are specific to NDB Cluster and the [NDB](#) storage engine. For system variables not specific to NDB Cluster, see [Section 5.1.8, “Server System Variables”](#). For general information on using system variables, see [Section 5.1.9, “Using System Variables”](#).

- `ndb_autoincrement_prefetch_sz`

| | |
|---|--|
| Command-Line Format | <code>--ndb-autoincrement-prefetch-sz=#</code> |
| System Variable | <code>ndb_autoincrement_prefetch_sz</code> |
| Scope | Global, Session |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Integer |
| Default Value (\geq 8.0.19-ndb-8.0.19) | 512 |
| Default Value (\leq 8.0.18-ndb-8.0.18) | 1 |
| Minimum Value | 1 |
| Maximum Value | 65536 |

Determines the probability of gaps in an autoincremented column. Set it to `1` to minimize this. Setting it to a high value for optimization makes inserts faster, but decreases the likelihood of consecutive autoincrement numbers being used in a batch of inserts.

This variable affects only the number of `AUTO_INCREMENT` IDs that are fetched between statements; within a given statement, at least 32 IDs are obtained at a time.

Important

This variable does not affect inserts performed using `INSERT ... SELECT`.

- `ndb_cache_check_time`

| | |
|-----------------------------------|---------------------------------------|
| Command-Line Format | <code>--ndb-cache-check-time=#</code> |
| Deprecated | Yes |
| System Variable | <code>ndb_cache_check_time</code> |
| Scope | Global |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Integer |
| Default Value | 0 |

The number of milliseconds that elapse between checks of NDB Cluster SQL nodes by the MySQL query cache. Setting this to 0 (the default and minimum value) means that the query cache checks for validation on every query.

The recommended maximum value for this variable is 1000, which means that the check is performed once per second. A larger value means that the check is performed and possibly invalidated due to

updates on different SQL nodes less often. It is generally not desirable to set this to a value greater than 2000.

Note

The query cache `ndb_cache_check_time` are deprecated in MySQL 5.7; the query cache was removed in MySQL 8.0.

- `ndb_clear_apply_status`

| | |
|----------------------|--|
| Command-Line Format | <code>--ndb-clear-apply-status[={OFF ON}]</code> |
| System Variable | <code>ndb_clear_apply_status</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Boolean |
| Default Value | ON |

By the default, executing `RESET SLAVE` causes an NDB Cluster replica to purge all rows from its `ndb_apply_status` table. You can disable this by setting `ndb_clear_apply_status=OFF`.

- `ndb_conflict_role`

| | |
|----------------------|--|
| Command-Line Format | <code>--ndb-conflict-role=value</code> |
| Introduced | 8.0.23-ndb-8.0.23 |
| System Variable | <code>ndb_conflict_role</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Enumeration |
| Default Value | NONE |
| Valid Values | NONE PRIMARY SECONDARY PASS |

Determines the role of this SQL node (and NDB Cluster) in a circular (“active-active”) replication setup. `ndb_slave_conflict_role` can take any one of the values `PRIMARY`, `SECONDARY`, `PASS`, or `NULL` (the default). The replica SQL thread must be stopped before you can change `ndb_slave_conflict_role`. In addition, it is not possible to change directly between `PASS` and either of `PRIMARY` or `SECONDARY` directly; in such cases, you must ensure that the SQL thread is stopped, then execute `SET @@GLOBAL.ndb_slave_conflict_role = 'NONE'` first.

This variable replaces `ndb_slave_conflict_role`, which is deprecated as of NDB 8.0.23.

For more information, see [Section 23.7.11, “NDB Cluster Replication Conflict Resolution”](#).

- [ndb_data_node_neighbour](#)

| | |
|----------------------|--|
| Command-Line Format | <code>--ndb-data-node-neighbour=#</code> |
| System Variable | ndb_data_node_neighbour |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value | 0 |
| Minimum Value | 0 |
| Maximum Value | 255 |

Sets the ID of a “nearest” data node—that is, a preferred nonlocal data node is chosen to execute the transaction, rather than one running on the same host as the SQL or API node. This used to ensure that when a fully replicated table is accessed, we access it on this data node, to ensure that the local copy of the table is always used whenever possible. This can also be used for providing hints for transactions.

This can improve data access times in the case of a node that is physically closer than and thus has higher network throughput than others on the same host.

See [Section 13.1.20.11, “Setting NDB_TABLE Options”](#), for further information.

Note

An equivalent method `set_data_node_neighbour()` is provided for use in NDB API applications.

- [ndb_dbg_check_shares](#)

| | |
|----------------------|---------------------------------------|
| Command-Line Format | <code>--ndb-dbg-check-shares=#</code> |
| Introduced | 8.0.13-ndb-8.0.13 |
| System Variable | ndb_dbg_check_shares |
| Scope | Global, Session |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value | 0 |
| Minimum Value | 0 |
| Maximum Value | 1 |

When set to 1, check that no shares are lingering. Available in debug builds only.

- [ndb_default_column_format](#)

| | |
|---------------------|--|
| Command-Line Format | <code>--ndb-default-column-format={FIXED DYNAMIC}</code> |
| System Variable | ndb_default_column_format |

| | |
|----------------------|------------------|
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Enumeration |
| Default Value | FIXED |
| Valid Values | FIXED DYNAMIC |

Sets the default `COLUMN_FORMAT` and `ROW_FORMAT` for new tables (see Section 13.1.20, “CREATE TABLE Statement”). The default is `FIXED`.

- `ndb_deferred_constraints`

| | |
|----------------------|---|
| Command-Line Format | <code>--ndb-deferred-constraints=#</code> |
| System Variable | <code>ndb_deferred_constraints</code> |
| Scope | Global, Session |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value | 0 |
| Minimum Value | 0 |
| Maximum Value | 1 |

Controls whether or not constraint checks are deferred, where these are supported. 0 is the default.

This variable is not normally needed for operation of NDB Cluster or NDB Cluster Replication, and is intended primarily for use in testing.

- `ndb_distribution`

| | |
|----------------------|---|
| Command-Line Format | <code>--ndb-distribution={KEYHASH LINHASH}</code> |
| System Variable | <code>ndb_distribution</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Enumeration |
| Default Value | KEYHASH |
| Valid Values | LINHASH KEYHASH |

Controls the default distribution method for NDB tables. Can be set to either of `KEYHASH` (key hashing) or `LINHASH` (linear hashing). `KEYHASH` is the default.

- [ndb_eventbuffer_free_percent](#)

| | |
|----------------------|---|
| Command-Line Format | <code>--ndb-eventbuffer-free-percent=#</code> |
| System Variable | <code>ndb_eventbuffer_free_percent</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value | 20 |
| Minimum Value | 1 |
| Maximum Value | 99 |

Sets the percentage of the maximum memory allocated to the event buffer (`ndb_eventbuffer_max_alloc`) that should be available in event buffer after reaching the maximum, before starting to buffer again.

- [ndb_eventbuffer_max_alloc](#)

| | |
|----------------------|--|
| Command-Line Format | <code>--ndb-eventbuffer-max-alloc=#</code> |
| System Variable | <code>ndb_eventbuffer_max_alloc</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value | 0 |
| Minimum Value | 0 |
| Maximum Value | 4294967295 |

Sets the maximum amount memory (in bytes) that can be allocated for buffering events by the NDB API. 0 means that no limit is imposed, and is the default.

- [ndb_extra_logging](#)

| | |
|----------------------|----------------------------------|
| Command-Line Format | <code>ndb_extra_logging=#</code> |
| System Variable | <code>ndb_extra_logging</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value | 1 |

This variable enables recording in the MySQL error log of information specific to the [NDB](#) storage engine.

When this variable is set to 0, the only information specific to [NDB](#) that is written to the MySQL error log relates to transaction handling. If it set to a value greater than 0 but less than 10, [NDB](#) table schema and connection events are also logged, as well as whether or not conflict resolution is in use, and other [NDB](#) errors and information. If the value is set to 10 or more, information about [NDB](#) internals, such as the4257

progress of data distribution among cluster nodes, is also written to the MySQL error log. The default is 1.

- `ndb_force_send`

| | |
|----------------------|--|
| Command-Line Format | <code>--ndb-force-send[={OFF ON}]</code> |
| System Variable | <code>ndb_force_send</code> |
| Scope | Global, Session |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Boolean |
| Default Value | ON |

Forces sending of buffers to NDB immediately, without waiting for other threads. Defaults to ON.

- `ndb_fully_replicated`

| | |
|----------------------|--|
| Command-Line Format | <code>--ndb-fully-replicated[={OFF ON}]</code> |
| System Variable | <code>ndb_fully_replicated</code> |
| Scope | Global, Session |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Boolean |
| Default Value | OFF |

Determines whether new NDB tables are fully replicated. This setting can be overridden for an individual table using `COMMENT="NDB_TABLE=FULLY_REPLICATED=..."` in a `CREATE TABLE` or `ALTER TABLE` statement; see [Section 13.1.20.11, "Setting NDB_TABLE Options"](#), for syntax and other information.

- `ndb_index_stat_enable`

| | |
|----------------------|---|
| Command-Line Format | <code>--ndb-index-stat-enable[={OFF ON}]</code> |
| System Variable | <code>ndb_index_stat_enable</code> |
| Scope | Global, Session |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Boolean |
| Default Value | ON |

Use NDB index statistics in query optimization. The default is ON.

Prior to NDB 8.0.27, starting the server with `--ndb-index-stat-enable` set to OFF prevented the creation of the index statistics tables. In NDB 8.0.27 and later, these tables are always created when the server starts, regardless of this option's value.

- `ndb_index_stat_option`

| | |
|----------------------|---|
| Command-Line Format | <code>--ndb-index-stat-option=value</code> |
| System Variable | <code>ndb_index_stat_option</code> |
| Scope | Global, Session |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | String |
| Default Value | <code>loop_checkon=1000ms,loop_idle=1000ms,loop_busy_update_batch=1,read_batch=4,idle_batch=32,check_batch=8,check_delay=1m,delete_batch=8,clean_delay=0,error_batch=4,error_delay=1m,evict_batch=8,evict_delay=1m,cache_lowpct=90</code> |

This variable is used for providing tuning options for NDB index statistics generation. The list consist of comma-separated name-value pairs of option names and values, and this list must not contain any space characters.

Options not used when setting `ndb_index_stat_option` are not changed from their default values. For example, you can set `ndb_index_stat_option = 'loop_idle=1000ms,cache_limit=32M'`.

Time values can be optionally suffixed with `h` (hours), `m` (minutes), or `s` (seconds). Millisecond values can optionally be specified using `ms`; millisecond values cannot be specified using `h`, `m`, or `s`.) Integer values can be suffixed with `K`, `M`, or `G`.

The names of the options that can be set using this variable are shown in the table that follows. The table also provides brief descriptions of the options, their default values, and (where applicable) their minimum and maximum values.

Table 23.20 `ndb_index_stat_option` options and values

| Name | Description | Default/Units | Minimum/Maximum |
|---------------------------|---|---------------|-----------------|
| <code>loop_enable</code> | | 1000 ms | 0/4G |
| <code>loop_idle</code> | Time to sleep when idle | 1000 ms | 0/4G |
| <code>loop_busy</code> | Time to sleep when more work is waiting | 100 ms | 0/4G |
| <code>update_batch</code> | | 1 | 0/4G |
| <code>read_batch</code> | | 4 | 1/4G |
| <code>idle_batch</code> | | 32 | 1/4G |
| <code>check_batch</code> | | 8 | 1/4G |
| <code>check_delay</code> | How often to check for new statistics | 10 m | 1/4G |
| <code>delete_batch</code> | | 8 | 0/4G |
| <code>clean_delay</code> | | 1 m | 0/4G |
| <code>error_batch</code> | | 4 | 1/4G |
| <code>error_delay</code> | | 1 m | 1/4G |

| Name | Description | Default/Units | Minimum/Maximum |
|---------------------------|--|---------------|-----------------|
| <code>evict_batch</code> | | 8 | 1/4G |
| <code>evict_delay</code> | Clean LRU cache, from read time | 1 m | 0/4G |
| <code>cache_limit</code> | Maximum amount of memory in bytes used for cached index statistics by this <code>mysqld</code> ; clean up the cache when this is exceeded. | 32 M | 0/4G |
| <code>cache_lowpct</code> | | 90 | 0/100 |
| <code>zero_total</code> | Setting this to 1 resets all accumulating counters in <code>ndb_index_stat_status</code> to 0. This option value is also reset to 0 when this is done. | 0 | 0/1 |

- `ndb_join_pushdown`

| | |
|-----------------------------------|--------------------------------|
| System Variable | <code>ndb_join_pushdown</code> |
| Scope | Global, Session |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Boolean |
| Default Value | <code>ON</code> |

This variable controls whether joins on `NDB` tables are pushed down to the `NDB` kernel (data nodes). Previously, a join was handled using multiple accesses of `NDB` by the SQL node; however, when `ndb_join_pushdown` is enabled, a pushable join is sent in its entirety to the data nodes, where it can be distributed among the data nodes and executed in parallel on multiple copies of the data, with

a single, merged result being returned to `mysqld`. This can reduce greatly the number of round trips between an SQL node and the data nodes required to handle such a join.

By default, `ndb_join_pushdown` is enabled.

Conditions for NDB pushdown joins. In order for a join to be pushable, it must meet the following conditions:

1. Only columns can be compared, and all columns to be joined must use *exactly* the same data type. This means that (for example) a join on an `INT` column and a `BIGINT` column also cannot be pushed down.

Previously, expressions such as `t1.a = t2.a + constant` could not be pushed down. This restriction is lifted in NDB 8.0. The result of any operations on any column to be compared must yield the same type as the column itself.

Expressions comparing columns from the same table can also be pushed down. The columns (or the result of any operations on those columns) must be of exactly the same type, including the same signedness, length, character set and collation, precision, and scale, where these are applicable.

2. Queries referencing `BLOB` or `TEXT` columns are not supported.
3. Explicit locking is not supported; however, the NDB storage engine's characteristic implicit row-based locking is enforced.

This means that a join using `FOR UPDATE` cannot be pushed down.

4. In order for a join to be pushed down, child tables in the join must be accessed using one of the `ref`, `eq_ref`, or `const` access methods, or some combination of these methods.

Outer joined child tables can only be pushed using `eq_ref`.

If the root of the pushed join is an `eq_ref` or `const`, only child tables joined by `eq_ref` can be appended. (A table joined by `ref` is likely to become the root of another pushed join.)

If the query optimizer decides on `Using join cache` for a candidate child table, that table cannot be pushed as a child. However, it may be the root of another set of pushed tables.

5. Joins referencing tables explicitly partitioned by `[LINEAR] HASH, LIST, or RANGE` currently cannot be pushed down.

You can see whether a given join can be pushed down by checking it with `EXPLAIN`; when the join can be pushed down, you can see references to the `pushed join` in the `Extra` column of the output, as shown in this example:

```
mysql> EXPLAIN
->      SELECT e.first_name, e.last_name, t.title, d.dept_name
->      FROM employees e
->      JOIN dept_emp de ON e.emp_no=de.emp_no
->      JOIN departments d ON d.dept_no=de.dept_no
->      JOIN titles t ON e.emp_no=t.emp_no\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: d
         type: ALL
possible_keys: PRIMARY
          key: NULL
         key_len: NULL
```

```

        ref: NULL
        rows: 9
        Extra: Parent of 4 pushed join@1
***** 2. row *****
        id: 1
        select_type: SIMPLE
        table: de
        type: ref
possible_keys: PRIMARY,emp_no,dept_no
        key: dept_no
        key_len: 4
        ref: employees.d.dept_no
        rows: 5305
        Extra: Child of 'd' in pushed join@1
***** 3. row *****
        id: 1
        select_type: SIMPLE
        table: e
        type: eq_ref
possible_keys: PRIMARY
        key: PRIMARY
        key_len: 4
        ref: employees.de.emp_no
        rows: 1
        Extra: Child of 'de' in pushed join@1
***** 4. row *****
        id: 1
        select_type: SIMPLE
        table: t
        type: ref
possible_keys: PRIMARY,emp_no
        key: emp_no
        key_len: 4
        ref: employees.de.emp_no
        rows: 19
        Extra: Child of 'e' in pushed join@1
4 rows in set (0.00 sec)

```

Note

If inner joined child tables are joined by *ref*, and the result is ordered or grouped by a sorted index, this index cannot provide sorted rows, which forces writing to a sorted tempfile.

Two additional sources of information about pushed join performance are available:

1. The status variables `Ndb_pushed_queries_defined`, `Ndb_pushed_queries_dropped`, `Ndb_pushed_queries_executed`, and `Ndb_pushed_reads`.
2. The counters in the `ndbinfo.counters` table that belong to the `DBSPJ` kernel block.

- `ndb_log_apply_status`

| | |
|----------------------|--|
| Command-Line Format | <code>--ndb-log-apply-status[={OFF ON}]</code> |
| System Variable | <code>ndb_log_apply_status</code> |
| Scope | Global |
| Dynamic | No |
| SET_VAR Hint Applies | No |
| Type | Boolean |
| Default Value | OFF |

A read-only variable which shows whether the server was started with the `--ndb-log-apply-status` option.

- `ndb_log_bin`

| | |
|-------------------------------------|---------------------------------------|
| Command-Line Format | <code>--ndb-log-bin[={OFF ON}]</code> |
| System Variable | <code>ndb_log_bin</code> |
| Scope | Global, Session |
| Dynamic | No |
| SET_VAR Hint Applies | No |
| Type | Boolean |
| Default Value (≥ 8.0.16-ndb-8.0.16) | OFF |
| Default Value (≤ 8.0.15-ndb-8.0.15) | ON |

Causes updates to NDB tables to be written to the binary log. The setting for this variable has no effect if binary logging is not already enabled on the server using `log_bin`. In NDB 8.0, `ndb_log_bin` defaults to 0 (FALSE).

- `ndb_log_binlog_index`

| | |
|----------------------|--|
| Command-Line Format | <code>--ndb-log-binlog-index[={OFF ON}]</code> |
| System Variable | <code>ndb_log_binlog_index</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Boolean |
| Default Value | ON |

Causes a mapping of epochs to positions in the binary log to be inserted into the `ndb_binlog_index` table. Setting this variable has no effect if binary logging is not already enabled for the server using `log_bin`. (In addition, `ndb_log_bin` must not be disabled.) `ndb_log_binlog_index` defaults to 1 (ON); normally, there is never any need to change this value in a production environment.

- `ndb_log_empty_epochs`

| | |
|----------------------|--|
| Command-Line Format | <code>--ndb-log-empty-epochs[={OFF ON}]</code> |
| System Variable | <code>ndb_log_empty_epochs</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Boolean |
| Default Value | OFF |

When this variable is set to 0, epoch transactions with no changes are not written to the binary log, although a row is still written even for an empty epoch in `ndb_binlog_index`.

- `ndb_log_empty_update`

| | |
|-----------------------------------|--|
| Command-Line Format | <code>--ndb-log-empty-update[={OFF ON}]</code> |
| System Variable | <code>ndb_log_empty_update</code> |
| Scope | Global |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Boolean |
| Default Value | <code>OFF</code> |

When this variable is set to `ON` (1), update transactions with no changes are written to the binary log, even when `log_replica_updates` or `log_slave_updates` is enabled.

- `ndb_log_exclusive_reads`

| | |
|-----------------------------------|---|
| Command-Line Format | <code>--ndb-log-exclusive-reads[={OFF ON}]</code> |
| System Variable | <code>ndb_log_exclusive_reads</code> |
| Scope | Global, Session |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Boolean |
| Default Value | 0 |

This variable determines whether primary key reads are logged with exclusive locks, which allows for NDB Cluster Replication conflict detection and resolution based on read conflicts. To enable these locks, set the value of `ndb_log_exclusive_reads` to 1. 0, which disables such locking, is the default.

For more information, see [Read conflict detection and resolution](#).

- `ndb_log_orig`

| | |
|-----------------------------------|--|
| Command-Line Format | <code>--ndb-log-orig[={OFF ON}]</code> |
| System Variable | <code>ndb_log_orig</code> |
| Scope | Global |
| Dynamic | No |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Boolean |
| Default Value | <code>OFF</code> |

Shows whether the originating server ID and epoch are logged in the `ndb_binlog_index` table. Set using the `--ndb-log-orig` server option.

- `ndb_log_transaction_id`

| | |
|-----------------|-------------------------------------|
| System Variable | <code>ndb_log_transaction_id</code> |
| Scope | Global |
| Dynamic | No |

| | |
|--------------------------------------|------------------|
| SET_VAR Hint Applies | No |
| Type | Boolean |
| Default Value | <code>OFF</code> |

This read-only, Boolean system variable shows whether a replica `mysqld` writes NDB transaction IDs in the binary log (required to use “active-active” NDB Cluster Replication with `NDB$EPOCH_TRANS()` conflict detection). To change the setting, use the `--ndb-log-transaction-id` option.

`ndb_log_transaction_id` is not supported in mainline MySQL Server 8.0.

For more information, see [Section 23.7.11, “NDB Cluster Replication Conflict Resolution”](#).

- [ndb_metadata_check](#)

| | |
|--------------------------------------|--|
| Command-Line Format | <code>--ndb-metadata-check[={OFF ON}]</code> |
| Introduced | 8.0.16-ndb-8.0.16 |
| System Variable | ndb_metadata_check |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Boolean |
| Default Value | <code>ON</code> |

NDB uses a background thread to check for metadata changes each `ndb_metadata_check_interval` seconds as compared with the MySQL data dictionary. This metadata change detection thread can be disabled by setting `ndb_metadata_check` to `OFF`. The thread is enabled by default.

- [ndb_metadata_check_interval](#)

| | |
|--------------------------------------|--|
| Command-Line Format | <code>--ndb-metadata-check-interval=#</code> |
| Introduced | 8.0.16-ndb-8.0.16 |
| System Variable | ndb_metadata_check_interval |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value | <code>60</code> |
| Minimum Value | <code>0</code> |
| Maximum Value | <code>31536000</code> |
| Unit | <code>seconds</code> |

NDB runs a metadata change detection thread in the background to determine when the NDB dictionary has changed with respect to the MySQL data dictionary. By default, the interval between such checks is 60 seconds; this can be adjusted by setting the value of `ndb_metadata_check_interval`. To enable or disable the thread, use `ndb_metadata_check`.

- `ndb_metadata_sync`

| | |
|-----------------------------------|--------------------------------|
| Introduced | 8.0.19-ndb-8.0.19 |
| System Variable | <code>ndb_metadata_sync</code> |
| Scope | Global |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Boolean |
| Default Value | <code>false</code> |

Setting this variable causes the change monitor thread to override any values set for `ndb_metadata_check` or `ndb_metadata_check_interval`, and to enter a period of continuous change detection. When the thread ascertains that there are no more changes to be detected, it stalls until the binary logging thread has finished synchronization of all detected objects. `ndb_metadata_sync` is then set to `false`, and the change monitor thread reverts to the behavior determined by the settings for `ndb_metadata_check` and `ndb_metadata_check_interval`.

In NDB 8.0.22 and later, setting this variable to `true` causes the list of excluded objects to be cleared, and setting it to `false` clears the list of objects to be retried.

- `ndb_optimized_node_selection`

| | |
|-----------------------------------|---|
| Command-Line Format | <code>--ndb-optimized-node-selection=#</code> |
| System Variable | <code>ndb_optimized_node_selection</code> |
| Scope | Global |
| Dynamic | No |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Integer |
| Default Value | 3 |
| Minimum Value | 0 |
| Maximum Value | 3 |

There are two forms of optimized node selection, described here:

1. The SQL node uses *proximity* to determine the transaction coordinator; that is, the “closest” data node to the SQL node is chosen as the transaction coordinator. For this purpose, a data node having a shared memory connection with the SQL node is considered to be “closest” to the SQL node; the next closest (in order of decreasing proximity) are: TCP connection to `localhost`, followed by TCP connection from a host other than `localhost`.
2. The SQL thread uses *distribution awareness* to select the data node. That is, the data node housing the cluster partition accessed by the first statement of a given transaction is used as the transaction

coordinator for the entire transaction. (This is effective only if the first statement of the transaction accesses no more than one cluster partition.)

This option takes one of the integer values 0, 1, 2, or 3. 3 is the default. These values affect node selection as follows:

- 0: Node selection is not optimized. Each data node is employed as the transaction coordinator 8 times before the SQL thread proceeds to the next data node.
- 1: Proximity to the SQL node is used to determine the transaction coordinator.
- 2: Distribution awareness is used to select the transaction coordinator. However, if the first statement of the transaction accesses more than one cluster partition, the SQL node reverts to the round-robin behavior seen when this option is set to 0.
- 3: If distribution awareness can be employed to determine the transaction coordinator, then it is used; otherwise proximity is used to select the transaction coordinator. (This is the default behavior.)

Proximity is determined as follows:

1. Start with the value set for the `Group` parameter (default 55).
2. For an API node sharing the same host with other API nodes, decrement the value by 1. Assuming the default value for `Group`, the effective value for data nodes on same host as the API node is 54, and for remote data nodes 55.
3. Setting `ndb_data_node_neighbour` further decreases the effective `Group` value by 50, causing this node to be regarded as the nearest node. This is needed only when all data nodes are on hosts other than that hosts the API node and it is desirable to dedicate one of them to the API node. In normal cases, the default adjustment described previously is sufficient.

Frequent changes in `ndb_data_node_neighbour` are not advisable, since this changes the state of the cluster connection and thus may disrupt the selection algorithm for new transactions from each thread until it stabilizes.

- `ndb_read_backup`

| | |
|-------------------------------------|--|
| Command-Line Format | <code>--ndb-read-backup[={OFF ON}]</code> |
| System Variable | <code>ndb_read_backup</code> |
| Scope | Global |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Boolean |
| Default Value (≥ 8.0.19-ndb-8.0.19) | ON |
| Default Value (≤ 8.0.18-ndb-8.0.18) | OFF |

Enable read from any fragment replica for any NDB table subsequently created; doing so greatly improves the table read performance at a relatively small cost to writes.

To enable or disable read from any fragment replica for an individual table, you can set the `NDB_TABLE` option `READ_BACKUP` for the table accordingly, in a `CREATE TABLE` or `ALTER TABLE` statement; see [Section 13.1.20.11, “Setting NDB_TABLE Options”](#), for more information.

- `ndb_recv_thread_activation_threshold`

| | |
|-----------------------------------|---|
| Command-Line Format | <code>--ndb-recv-thread-activation-threshold=#</code> |
| System Variable | <code>ndb_recv_thread_activation_threshold</code> |
| Scope | Global |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Integer |
| Default Value | 8 |
| Minimum Value | 0 (<code>MIN_ACTIVATION_THRESHOLD</code>) |
| Maximum Value | 16 (<code>MAX_ACTIVATION_THRESHOLD</code>) |

When this number of concurrently active threads is reached, the receive thread takes over polling of the cluster connection.

This variable is global in scope. It can also be set at startup.

- `ndb_recv_thread_cpu_mask`

| | |
|-----------------------------------|--|
| Command-Line Format | <code>--ndb-recv-thread-cpu-mask=mask</code> |
| System Variable | <code>ndb_recv_thread_cpu_mask</code> |
| Scope | Global |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Bitmap |
| Default Value | [empty] |

CPU mask for locking receiver threads to specific CPUs. This is specified as a hexadecimal bitmask. For example, `0x33` means that one CPU is used per receiver thread. An empty string is the default; setting `ndb_recv_thread_cpu_mask` to this value removes any receiver thread locks previously set.

This variable is global in scope. It can also be set at startup.

- `ndb_report_thresh_binlog_epoch_slip`

| | |
|-----------------------------------|--|
| Command-Line Format | <code>--ndb-report-thresh-binlog-epoch-slip=#</code> |
| System Variable | <code>ndb_report_thresh_binlog_epoch_slip</code> |
| Scope | Global |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Integer |
| Default Value | 10 |
| Minimum Value | 0 |

| | |
|---------------|-----|
| Maximum Value | 256 |
|---------------|-----|

This represents the threshold for the number of epochs completely buffered in the event buffer, but not yet consumed by the binlog injector thread. When this degree of slippage (lag) is exceeded, an event buffer status message is reported, with `BUFFERED_EPOCHS_OVER_THRESHOLD` supplied as the reason (see [Section 23.6.2.3, “Event Buffer Reporting in the Cluster Log”](#)). Slip is increased when an epoch is received from data nodes and buffered completely in the event buffer; it is decreased when an epoch is consumed by the binlog injector thread, it is reduced. Empty epochs are buffered and queued, and so included in this calculation only when this is enabled using the `Ndb::setEventBufferQueueEmptyEpoch()` method from the NDB API.

- [ndb_report_thresh_binlog_mem_usage](#)

| | |
|-----------------------------------|---|
| Command-Line Format | <code>--ndb-report-thresh-binlog-mem-usage=#</code> |
| System Variable | <code>ndb_report_thresh_binlog_mem_usage</code> |
| Scope | Global |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Integer |
| Default Value | 10 |
| Minimum Value | 0 |
| Maximum Value | 10 |

This is a threshold on the percentage of free memory remaining before reporting binary log status. For example, a value of 10 (the default) means that if the amount of available memory for receiving binary log data from the data nodes falls below 10%, a status message is sent to the cluster log.

- [ndb_row_checksum](#)

| | |
|-----------------------------------|-------------------------------|
| System Variable | <code>ndb_row_checksum</code> |
| Scope | Global, Session |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Integer |
| Default Value | 1 |
| Minimum Value | 0 |
| Maximum Value | 1 |

Traditionally, NDB has created tables with row checksums, which checks for hardware issues at the expense of performance. Setting `ndb_row_checksum` to 0 means that row checksums are *not* used for new or altered tables, which has a significant impact on performance for all types of queries. This variable is set to 1 by default, to provide backward-compatible behavior.

- [ndb_schema_dist_lock_wait_timeout](#)

| | |
|---------------------|--|
| Command-Line Format | <code>--ndb-schema-dist-lock-wait-timeout=value</code> |
|---------------------|--|

| | |
|--------------------------------------|---|
| Introduced | 8.0.18-ndb-8.0.18 |
| System Variable | ndb_schema_dist_lock_wait_timeout |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value | 30 |
| Minimum Value | 0 |
| Maximum Value | 1200 |
| Unit | seconds |

Number of seconds to wait during schema distribution for the metadata lock taken on each SQL node in order to change its local data dictionary to reflect the DDL statement change. After this time has elapsed, a warning is returned to the effect that a given SQL node's data dictionary was not updated with the change. This avoids having the binary logging thread wait an excessive length of time while handling schema operations.

- [ndb_schema_dist_timeout](#)

| | |
|--------------------------------------|---|
| Command-Line Format | --ndb-schema-dist-timeout=value |
| Introduced | 8.0.16-ndb-8.0.16 |
| System Variable | ndb_schema_dist_timeout |
| Scope | Global |
| Dynamic | No |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value | 120 |
| Minimum Value | 5 |
| Maximum Value | 1200 |
| Unit | seconds |

Number of seconds to wait before detecting a timeout during schema distribution. This can indicate that other SQL nodes are experiencing excessive activity, or that they are somehow being prevented from acquiring necessary resources at this time.

- [ndb_schema_dist_upgrade_allowed](#)

| | |
|--------------------------------------|---|
| Command-Line Format | --ndb-schema-dist-upgrade-allowed=value |
| Introduced | 8.0.17-ndb-8.0.17 |
| System Variable | ndb_schema_dist_upgrade_allowed |
| Scope | Global |
| Dynamic | No |
| SET_VAR Hint Applies | No |

| | |
|---------------|-------------------|
| Type | Boolean |
| Default Value | <code>true</code> |

Allow upgrading of the schema distribution table when connecting to [NDB](#). When true (the default), this change is deferred until all SQL nodes have been upgraded to the same version of the NDB Cluster software.

Note

The performance of the schema distribution may be somewhat degraded until the upgrade has been performed.

- [ndb_show_foreign_key_mock_tables](#)

| | |
|--------------------------------------|--|
| Command-Line Format | <code>--ndb-show-foreign-key-mock-tables[={OFF ON}]</code> |
| System Variable | ndb_show_foreign_key_mock_tables |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Boolean |
| Default Value | <code>OFF</code> |

Show the mock tables used by [NDB](#) to support `foreign_key_checks=0`. When this is enabled, extra warnings are shown when creating and dropping the tables. The real (internal) name of the table can be seen in the output of `SHOW CREATE TABLE`.

- [ndb_slave_conflict_role](#)

| | |
|--------------------------------------|--|
| Command-Line Format | <code>--ndb-slave-conflict-role=value</code> |
| Deprecated | 8.0.23-ndb-8.0.23 |
| System Variable | ndb_slave_conflict_role |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Enumeration |
| Default Value | <code>NONE</code> |
| Valid Values | <code>NONE</code> <code>PRIMARY</code> <code>SECONDARY</code> <code>PASS</code> |

Deprecated in NDB 8.0.23, and subject to removal in a future release. Use [ndb_conflict_role](#) instead.

- `ndb_table_no_logging`

| | |
|-----------------------------------|-----------------------------------|
| System Variable | <code>ndb_table_no_logging</code> |
| Scope | Session |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Boolean |
| Default Value | OFF |

When this variable is set to `ON` or `1`, it causes `NDB` tables not to be checkpointed to disk. More specifically, this setting applies to tables which are created or altered using `ENGINE NDB` when `ndb_table_no_logging` is enabled, and continues to apply for the lifetime of the table, even if `ndb_table_no_logging` is later changed. Suppose that `A`, `B`, `C`, and `D` are tables that we create (and perhaps also alter), and that we also change the setting for `ndb_table_no_logging` as shown here:

```
SET @@ndb_table_no_logging = 1;

CREATE TABLE A ... ENGINE NDB;

CREATE TABLE B ... ENGINE MYISAM;
CREATE TABLE C ... ENGINE MYISAM;

ALTER TABLE B ENGINE NDB;

SET @@ndb_table_no_logging = 0;

CREATE TABLE D ... ENGINE NDB;
ALTER TABLE C ENGINE NDB;

SET @@ndb_table_no_logging = 1;
```

After the previous sequence of events, tables `A` and `B` are not checkpointed; `A` was created with `ENGINE NDB` and `B` was altered to use `NDB`, both while `ndb_table_no_logging` was enabled. However, tables `C` and `D` are logged; `C` was altered to use `NDB` and `D` was created using `ENGINE NDB`, both while `ndb_table_no_logging` was disabled. Setting `ndb_table_no_logging` back to `1` or `ON` does *not* cause table `C` or `D` to be checkpointed.

Note

`ndb_table_no_logging` has no effect on the creation of `NDB` table schema files; to suppress these, use `ndb_table_temporary` instead.

- `ndb_table_temporary`

| | |
|-----------------------------------|----------------------------------|
| System Variable | <code>ndb_table_temporary</code> |
| Scope | Session |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Boolean |

| | |
|---------------|-----|
| Default Value | OFF |
|---------------|-----|

When set to `ON` or `1`, this variable causes `NDB` tables not to be written to disk: This means that no table schema files are created, and that the tables are not logged.

Note

Setting this variable currently has no effect. This is a known issue; see Bug #34036.

- `ndb_use_copying_alter_table`

| | |
|----------------------|--|
| System Variable | <code>ndb_use_copying_alter_table</code> |
| Scope | Global, Session |
| Dynamic | No |
| SET_VAR Hint Applies | No |

Forces `NDB` to use copying of tables in the event of problems with online `ALTER TABLE` operations. The default value is `OFF`.

- `ndb_use_exact_count`

| | |
|----------------------|----------------------------------|
| System Variable | <code>ndb_use_exact_count</code> |
| Scope | Global, Session |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Boolean |
| Default Value | OFF |

Forces `NDB` to use a count of records during `SELECT COUNT(*)` query planning to speed up this type of query. The default value is `OFF`, which allows for faster queries overall.

- `ndb_use_transactions`

| | |
|----------------------|--|
| Command-Line Format | <code>--ndb-use-transactions[={OFF ON}]</code> |
| System Variable | <code>ndb_use_transactions</code> |
| Scope | Global, Session |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Boolean |
| Default Value | ON |

You can disable `NDB` transaction support by setting this variable's values to `OFF` (not recommended). The default is `ON`.

- `ndb_version`

| | |
|-----------------|--------------------------|
| System Variable | <code>ndb_version</code> |
| Scope | Global |

| | |
|--------------------------------------|--------|
| Dynamic | No |
| SET_VAR Hint Applies | No |
| Type | String |
| Default Value | |

NDB engine version, as a composite integer.

- [ndb_version_string](#)

| | |
|--------------------------------------|------------------------------------|
| System Variable | ndb_version_string |
| Scope | Global |
| Dynamic | No |
| SET_VAR Hint Applies | No |
| Type | String |
| Default Value | |

NDB engine version in `ndb-x.y.z` format.

- [replica_allow_batching](#)

| | |
|--------------------------------------|--|
| Command-Line Format | <code>--replica-allow-batching[={OFF ON}]</code> |
| Introduced | 8.0.26-ndb-8.0.26 |
| System Variable | replica_allow_batching |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Boolean |
| Default Value | <code>OFF</code> |

Whether or not batched updates are enabled on NDB Cluster replicas. From MySQL 8.0.26, use [replica_allow_batching](#) in place of [slave_allow_batching](#), which is deprecated from that release. In releases before MySQL 8.0.26, use [slave_allow_batching](#).

Setting this variable has an effect only when using replication with the NDB storage engine; in MySQL Server 8.0, it is present but does nothing. For more information, see [Section 23.7.6, “Starting NDB Cluster Replication \(Single Replication Channel\)”](#).

- [server_id_bits](#)

| | |
|--------------------------------------|---------------------------------|
| Command-Line Format | <code>--server-id-bits=#</code> |
| System Variable | server_id_bits |
| Scope | Global |
| Dynamic | No |
| SET_VAR Hint Applies | No |
| Type | Integer |
| Default Value | <code>32</code> |

| | |
|---------------|----|
| Minimum Value | 7 |
| Maximum Value | 32 |

This variable indicates the number of least significant bits within the 32-bit `server_id` which actually identify the server. Indicating that the server is actually identified by fewer than 32 bits makes it possible for some of the remaining bits to be used for other purposes, such as storing user data generated by applications using the NDB API's Event API within the `AnyValue` of an `OperationOptions` structure (NDB Cluster uses the `AnyValue` to store the server ID).

When extracting the effective server ID from `server_id` for purposes such as detection of replication loops, the server ignores the remaining bits. The `server_id_bits` variable is used to mask out any irrelevant bits of `server_id` in the I/O and SQL threads when deciding whether an event should be ignored based on the server ID.

This data can be read from the binary log by `mysqlbinlog`, provided that it is run with its own `server_id_bits` variable set to 32 (the default).

If the value of `server_id` greater than or equal to 2 to the power of `server_id_bits`; otherwise, `mysqld` refuses to start.

This system variable is supported only by NDB Cluster. It is not supported in the standard MySQL 8.0 Server.

- `slave_allow_batching`

| | |
|-----------------------------------|--|
| Command-Line Format | <code>--slave-allow-batching[={OFF ON}]</code> |
| Deprecated | 8.0.26-ndb-8.0.26 |
| System Variable | <code>slave_allow_batching</code> |
| Scope | Global |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Boolean |
| Default Value | <code>OFF</code> |

Whether or not batched updates are enabled on NDB Cluster replicas. From MySQL 8.0.26, `slave_allow_batching` is deprecated and the alias `replica_allow_batching` should be used instead. In releases before MySQL 8.0.26, use `slave_allow_batching`.

Setting this variable has an effect only when using replication with the NDB storage engine; in MySQL Server 8.0, it is present but does nothing. For more information, see [Section 23.7.6, “Starting NDB Cluster Replication \(Single Replication Channel\)”](#).

- `transaction_allow_batching`

| | |
|-----------------------------------|---|
| System Variable | <code>transaction_allow_batching</code> |
| Scope | Session |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Boolean |
| Default Value | <code>OFF</code> |

When set to `1` or `ON`, this variable enables batching of statements within the same transaction. To use this variable, `autocommit` must first be disabled by setting it to `0` or `OFF`; otherwise, setting `transaction_allow_batching` has no effect.

It is safe to use this variable with transactions that performs writes only, as having it enabled can lead to reads from the “before” image. You should ensure that any pending transactions are committed (using an explicit `COMMIT` if desired) before issuing a `SELECT`.

Important

`transaction_allow_batching` should not be used whenever there is the possibility that the effects of a given statement depend on the outcome of a previous statement within the same transaction.

This variable is currently supported for NDB Cluster only.

The system variables in the following list all relate to the `ndbinfo` information database.

- `ndbinfo_database`

| | |
|-----------------------------------|-------------------------------|
| System Variable | <code>ndbinfo_database</code> |
| Scope | Global |
| Dynamic | No |
| <code>SET_VAR</code> Hint Applies | No |
| Type | String |
| Default Value | <code>ndbinfo</code> |

Shows the name used for the NDB information database; the default is `ndbinfo`. This is a read-only variable whose value is determined at compile time.

- `ndbinfo_max_bytes`

| | |
|-----------------------------------|------------------------------------|
| Command-Line Format | <code>--ndbinfo-max-bytes=#</code> |
| System Variable | <code>ndbinfo_max_bytes</code> |
| Scope | Global, Session |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |
| Type | Integer |
| Default Value | <code>0</code> |

Used in testing and debugging only.

- `ndbinfo_max_rows`

| | |
|-----------------------------------|-----------------------------------|
| Command-Line Format | <code>--ndbinfo-max-rows=#</code> |
| System Variable | <code>ndbinfo_max_rows</code> |
| Scope | Global, Session |
| Dynamic | Yes |
| <code>SET_VAR</code> Hint Applies | No |

| | |
|---------------|---------|
| Type | Integer |
| Default Value | 10 |

Used in testing and debugging only.

- `ndbinfo_offline`

| | |
|----------------------|------------------------------|
| System Variable | <code>ndbinfo_offline</code> |
| Scope | Global |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Boolean |
| Default Value | OFF |

Place the `ndbinfo` database into offline mode, in which tables and views can be opened even when they do not actually exist, or when they exist but have different definitions in NDB. No rows are returned from such tables (or views).

- `ndbinfo_show_hidden`

| | |
|----------------------|---|
| Command-Line Format | <code>--ndbinfo-show-hidden[={OFF ON}]</code> |
| System Variable | <code>ndbinfo_show_hidden</code> |
| Scope | Global, Session |
| Dynamic | Yes |
| SET_VAR Hint Applies | No |
| Type | Boolean |
| Default Value | OFF |
| Valid Values | ON OFF |

Whether or not the `ndbinfo` database's underlying internal tables are shown in the `mysql` client. The default is OFF.

- `ndbinfo_table_prefix`

| | |
|----------------------|-----------------------------------|
| System Variable | <code>ndbinfo_table_prefix</code> |
| Scope | Global |
| Dynamic | No |
| SET_VAR Hint Applies | No |
| Type | String |
| Default Value | <code>ndb\$</code> |

The prefix used in naming the `ndbinfo` database's base tables (normally hidden, unless exposed by setting `ndbinfo_show_hidden`). This is a read-only variable whose default value is `ndb$`; the prefix itself is determined at compile time.

- `ndbinfo_version`

| | |
|-----------------------------------|------------------------------|
| System Variable | <code>ndbinfo_version</code> |
| Scope | Global |
| Dynamic | No |
| <code>SET_VAR</code> Hint Applies | No |
| Type | String |
| Default Value | |

Shows the version of the `ndbinfo` engine in use; read-only.

NDB Cluster Status Variables

This section provides detailed information about MySQL server status variables that relate to NDB Cluster and the `NDB` storage engine. For status variables not specific to NDB Cluster, and for general information on using status variables, see [Section 5.1.10, “Server Status Variables”](#).

- `Handler_discover`

The MySQL server can ask the `NDBCLUSTER` storage engine if it knows about a table with a given name. This is called discovery. `Handler_discover` indicates the number of times that tables have been discovered using this mechanism.

- `Ndb_api_adaptive_send_deferred_count`

Number of adaptive send calls that were not actually sent.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_adaptive_send_deferred_count_session`

Number of adaptive send calls that were not actually sent.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_adaptive_send_deferred_count_replica`

Number of adaptive send calls that were not actually sent by this replica.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_adaptive_send_deferred_count_slave`

Note

Deprecated in NDB 8.0.23; use `Ndb_api_adaptive_send_deferred_count_replica` instead.

Number of adaptive send calls that were not actually sent by this replica.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_adaptive_send_forced_count`

Number of adaptive send calls using forced-send sent by this MySQL Server (SQL node).

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_adaptive_send_forced_count_session`

Number of adaptive send calls using forced-send sent in this client session.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_adaptive_send_forced_count_replica`

Number of adaptive send calls using forced-send sent by this replica.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_adaptive_send_forced_count_slave`

**Note**

Deprecated in NDB 8.0.23; use `Ndb_api_adaptive_send_forced_count_replica` instead.

Number of adaptive send calls using forced-send sent by this replica.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_adaptive_send_unforced_count`

Number of adaptive send calls without forced-send sent by this MySQL server (SQL node).

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_adaptive_send_unforced_count_session`

Number of adaptive send calls without forced-send sent in this client session.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_adaptive_send_unforced_count_replica`

Number of adaptive send calls without forced-send sent by this replica.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_adaptive_send_unforced_count_slave`

**Note**

Deprecated in NDB 8.0.23; use `Ndb_api_adaptive_send_unforced_count_replica` instead.

Number of adaptive send calls without forced-send sent by this replica.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_bytes_sent_count_session`

Amount of data (in bytes) sent to the data nodes in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_bytes_sent_count_replica`

Amount of data (in bytes) sent to the data nodes by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_bytes_sent_count_slave`

Note

Deprecated in NDB 8.0.23; use `Ndb_api_bytes_sent_count_replica` instead.

Amount of data (in bytes) sent to the data nodes by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_bytes_sent_count`

Amount of data (in bytes) sent to the data nodes by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_bytes_received_count_session`

Amount of data (in bytes) received from the data nodes in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_bytes_received_count_replica`

Amount of data (in bytes) received from the data nodes by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_bytes_received_count_slave`

**Note**

Deprecated in NDB 8.0.23; use `Ndb_api_bytes_received_count_replica` instead.

Amount of data (in bytes) received from the data nodes by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_bytes_received_count`

Amount of data (in bytes) received from the data nodes by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_event_data_count_injector`

The number of row change events received by the NDB binlog injector thread.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_event_data_count`

The number of row change events received by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_event_nondata_count_injector`

The number of events received, other than row change events, by the NDB binary log injector thread.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_event_nondata_count`

The number of events received, other than row change events, by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_event_bytes_count_injector`

The number of bytes of events received by the NDB binlog injector thread.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_event_bytes_count`

The number of bytes of events received by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_pk_op_count_session`

The number of operations in this client session based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_pk_op_count_replica`

The number of operations by this replica based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_pk_op_count_slave`

**Note**

Deprecated in NDB 8.0.23; use `Ndb_api_pk_op_count_replica` instead.

The number of operations by this replica based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_pk_op_count`

The number of operations by this MySQL Server (SQL node) based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_pruned_scan_count_session`

The number of scans in this client session that have been pruned to a single partition.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_pruned_scan_count_replica`

The number of scans by this replica that have been pruned to a single partition.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_pruned_scan_count_slave`

**Note**

Deprecated in NDB 8.0.23; use `Ndb_api_pruned_scan_count_replica` instead.

The number of scans by this replica that have been pruned to a single partition.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_pruned_scan_count`

The number of scans by this MySQL Server (SQL node) that have been pruned to a single partition.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_range_scan_count_session`

The number of range scans that have been started in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_range_scan_count_replica`

The number of range scans that have been started by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_range_scan_count_slave`

**Note**

Deprecated in NDB 8.0.23; use `Ndb_api_range_scan_count_replica` instead.

The number of range scans that have been started by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_range_scan_count`

The number of range scans that have been started by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_read_row_count_session`

The total number of rows that have been read in this client session. This includes all rows read by any primary key, unique key, or scan operation made in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_read_row_count_replica`

The total number of rows that have been read by this replica. This includes all rows read by any primary key, unique key, or scan operation made by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_read_row_count_slave`

**Note**

Deprecated in NDB 8.0.23; use `Ndb_api_read_row_count_replica` instead.

The total number of rows that have been read by this replica. This includes all rows read by any primary key, unique key, or scan operation made by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_read_row_count`

The total number of rows that have been read by this MySQL Server (SQL node). This includes all rows read by any primary key, unique key, or scan operation made by this MySQL Server (SQL node).

You should be aware that this value may not be completely accurate with regard to rows read by `SELECT COUNT(*)` queries, due to the fact that, in this case, the MySQL server actually reads pseudo-rows in the form `[table fragment ID]:[number of rows in fragment]` and sums the rows per fragment for all fragments in the table to derive an estimated count for all rows. `Ndb_api_read_row_count` uses this estimate and not the actual number of rows in the table.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb_api_scan_batch_count_session](#)

The number of batches of rows received in this client session. 1 batch is defined as 1 set of scan results from a single fragment.

Although this variable can be read using either [SHOW GLOBAL STATUS](#) or [SHOW SESSION STATUS](#), it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb_api_scan_batch_count_replica](#)

The number of batches of rows received by this replica. 1 batch is defined as 1 set of scan results from a single fragment.

Although this variable can be read using either [SHOW GLOBAL STATUS](#) or [SHOW SESSION STATUS](#), it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb_api_scan_batch_count_slave](#)

**Note**

Deprecated in NDB 8.0.23; use [Ndb_api_scan_batch_count_replica](#) instead.

The number of batches of rows received by this replica. 1 batch is defined as 1 set of scan results from a single fragment.

Although this variable can be read using either [SHOW GLOBAL STATUS](#) or [SHOW SESSION STATUS](#), it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb_api_scan_batch_count](#)

The number of batches of rows received by this MySQL Server (SQL node). 1 batch is defined as 1 set of scan results from a single fragment.

Although this variable can be read using either [SHOW GLOBAL STATUS](#) or [SHOW SESSION STATUS](#), it is effectively global in scope.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb_api_table_scan_count_session](#)

The number of table scans that have been started in this client session, including scans of internal tables,.

Although this variable can be read using either [SHOW GLOBAL STATUS](#) or [SHOW SESSION STATUS](#), it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- [Ndb_api_table_scan_count_replica](#)

The number of table scans that have been started by this replica, including scans of internal tables.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_table_scan_count_slave`

**Note**

Deprecated in NDB 8.0.23; use `Ndb_api_table_scan_count_replica` instead.

The number of table scans that have been started by this replica, including scans of internal tables.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_table_scan_count`

The number of table scans that have been started by this MySQL Server (SQL node), including scans of internal tables,.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_abort_count_session`

The number of transactions aborted in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_abort_count_replica`

The number of transactions aborted by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_abort_count_slave`

**Note**

Deprecated in NDB 8.0.23; use `Ndb_api_trans_abort_count_replica` instead.

The number of transactions aborted by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_abort_count`

The number of transactions aborted by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_close_count_session`

The number of transactions closed in this client session. This value may be greater than the sum of `Ndb_api_trans_commit_count_session` and `Ndb_api_trans_abort_count_session`, since some transactions may have been rolled back.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_close_count_replica`

The number of transactions closed by this replica. This value may be greater than the sum of `Ndb_api_trans_commit_count_replica` and `Ndb_api_trans_abort_count_replica`, since some transactions may have been rolled back.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_close_count_slave`

**Note**

Deprecated in NDB 8.0.23; use `Ndb_api_trans_close_count_replica` instead.

The number of transactions closed by this replica. This value may be greater than the sum of `Ndb_api_trans_commit_count_replica` and `Ndb_api_trans_abort_count_replica`, since some transactions may have been rolled back.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_close_count`

The number of transactions closed by this MySQL Server (SQL node). This value may be greater than the sum of `Ndb_api_trans_commit_count` and `Ndb_api_trans_abort_count`, since some transactions may have been rolled back.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_commit_count_session`

The number of transactions committed in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_commit_count_replica`

The number of transactions committed by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_commit_count_slave`

**Note**

Deprecated in NDB 8.0.23; use `Ndb_api_trans_commit_count_replica` instead.

The number of transactions committed by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_commit_count`

The number of transactions committed by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_local_read_row_count_session`

The total number of rows that have been read in this client session. This includes all rows read by any primary key, unique key, or scan operation made in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_local_read_row_count_replica`

The total number of rows that have been read by this replica. This includes all rows read by any primary key, unique key, or scan operation made by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_local_read_row_count_slave`

**Note**

Deprecated in NDB 8.0.23; use `Ndb_api_trans_local_read_row_count_replica` instead.

The total number of rows that have been read by this replica. This includes all rows read by any primary key, unique key, or scan operation made by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_local_read_row_count`

The total number of rows that have been read by this MySQL Server (SQL node). This includes all rows read by any primary key, unique key, or scan operation made by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_start_count_session`

The number of transactions started in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_start_count_replica`

The number of transactions started by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_start_count_slave`

Note

Deprecated in NDB 8.0.23; use `Ndb_api_trans_start_count_replica` instead.

The number of transactions started by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_start_count`

The number of transactions started by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_uk_op_count_session`

The number of operations in this client session based on or using unique keys.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_uk_op_count_replica`

The number of operations by this replica based on or using unique keys.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_uk_op_count_slave`

**Note**

Deprecated in NDB 8.0.23; use `Ndb_api_uk_op_count_replica` instead.

The number of operations by this replica based on or using unique keys.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_uk_op_count`

The number of operations by this MySQL Server (SQL node) based on or using unique keys.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_exec_complete_count_session`

The number of times a thread has been blocked in this client session while waiting for execution of an operation to complete. This includes all `execute()` calls as well as implicit executes for blob and auto-increment operations not visible to clients.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_exec_complete_count_replica`

The number of times a thread has been blocked by this replica while waiting for execution of an operation to complete. This includes all `execute()` calls as well as implicit executes for blob and auto-increment operations not visible to clients.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_exec_complete_count_slave`

**Note**

Deprecated in NDB 8.0.23; use `Ndb_api_wait_exec_complete_count_replica` instead.

The number of times a thread has been blocked by this replica while waiting for execution of an operation to complete. This includes all `execute()` calls as well as implicit executes for blob and auto-increment operations not visible to clients.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_exec_complete_count`

The number of times a thread has been blocked by this MySQL Server (SQL node) while waiting for execution of an operation to complete. This includes all `execute()` calls as well as implicit executes for blob and auto-increment operations not visible to clients.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_meta_request_count_session`

The number of times a thread has been blocked in this client session waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_meta_request_count_replica`

The number of times a thread has been blocked by this replica waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_meta_request_count_slave`

**Note**

Deprecated in NDB 8.0.23; use `Ndb_api_wait_meta_request_count_replica` instead.

The number of times a thread has been blocked by this replica waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_meta_request_count`

The number of times a thread has been blocked by this MySQL Server (SQL node) waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_nanos_count_session`

Total time (in nanoseconds) spent in this client session waiting for any type of signal from the data nodes.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_nanos_count_replica`

Total time (in nanoseconds) spent by this replica waiting for any type of signal from the data nodes.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_nanos_count_slave`

**Note**

Deprecated in NDB 8.0.23; use `Ndb_api_wait_nanos_count_replica` instead.

Total time (in nanoseconds) spent by this replica waiting for any type of signal from the data nodes.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_nanos_count`

Total time (in nanoseconds) spent by this MySQL Server (SQL node) waiting for any type of signal from the data nodes.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_scan_result_count_session`

The number of times a thread has been blocked in this client session while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_scan_result_count_replica`

The number of times a thread has been blocked by this replica while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_scan_result_count_slave`

**Note**

Deprecated in NDB 8.0.23; use `Ndb_api_wait_scan_result_count_replica` instead.

The number of times a thread has been blocked by this replica while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_scan_result_count`

The number of times a thread has been blocked by this MySQL Server (SQL node) while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 23.6.13, “NDB API Statistics Counters and Variables”](#).

- `Ndb_cluster_node_id`

If the server is acting as an NDB Cluster node, then the value of this variable is its node ID in the cluster.

If the server is not part of an NDB Cluster, then the value of this variable is 0.

- `Ndb_config_from_host`

If the server is part of an NDB Cluster, the value of this variable is the host name or IP address of the Cluster management server from which it gets its configuration data.

If the server is not part of an NDB Cluster, then the value of this variable is an empty string.

- `Ndb_config_from_port`

If the server is part of an NDB Cluster, the value of this variable is the number of the port through which it is connected to the Cluster management server from which it gets its configuration data.

If the server is not part of an NDB Cluster, then the value of this variable is 0.

- `Ndb_config_generation`

Shows the generation number of the cluster's current configuration. This can be used as an indicator to determine whether the configuration of the cluster has changed since this SQL node last connected to the cluster.

- `Ndb_conflict_fn_max_del_win`

Shows the number of times that a row was rejected on the current SQL node due to NDB Cluster Replication conflict resolution using `NDB$MAX_DELETE_WIN()`, since the last time that this `mysqld` was started.

For more information, see [Section 23.7.11, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_fn_max`

Used in NDB Cluster Replication conflict resolution, this variable shows the number of times that a row was not applied on the current SQL node due to “greatest timestamp wins” conflict resolution since the last time that this `mysqld` was started.

For more information, see [Section 23.7.11, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_fn_old`

Used in NDB Cluster Replication conflict resolution, this variable shows the number of times that a row was not applied as the result of “same timestamp wins” conflict resolution on a given `mysqld` since the last time it was restarted.

For more information, see [Section 23.7.11, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_fn_epoch`

Used in NDB Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using `NDB$EPOCH()` conflict resolution on a given `mysqld` since the last time it was restarted.

For more information, see [Section 23.7.11, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_fn_epoch2`

Shows the number of rows found to be in conflict in NDB Cluster Replication conflict resolution, when using `NDB$EPOCH2()`, on the source designated as the primary since the last time it was restarted.

For more information, see `NDB$EPOCH2()`.

- `Ndb_conflict_fn_epoch_trans`

Used in NDB Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using `NDB$EPOCH_TRANS()` conflict resolution on a given `mysqld` since the last time it was restarted.

For more information, see [Section 23.7.11, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_fn_epoch2_trans`

Used in NDB Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using `NDB$EPOCH_TRANS2()` conflict resolution on a given `mysqld` since the last time it was restarted.

For more information, see `NDB$EPOCH2_TRANS()`.

- `Ndb_conflict_last_conflict_epoch`

The most recent epoch in which a conflict was detected on this replica. You can compare this value with `Ndb_replica_max_replicated_epoch`; if `Ndb_replica_max_replicated_epoch` is greater than `Ndb_conflict_last_conflict_epoch`, no conflicts have yet been detected.

See [Section 23.7.11, “NDB Cluster Replication Conflict Resolution”](#), for more information.

- `Ndb_conflict_reflected_op_discard_count`

When using NDB Cluster Replication conflict resolution, this is the number of reflected operations that were not applied on the secondary, due to encountering an error during execution.

See [Section 23.7.11, “NDB Cluster Replication Conflict Resolution”](#), for more information.

- `Ndb_conflict_reflected_op_prepare_count`

When using conflict resolution with NDB Cluster Replication, this status variable contains the number of reflected operations that have been defined (that is, prepared for execution on the secondary).

See [Section 23.7.11, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_refresh_op_count`

When using conflict resolution with NDB Cluster Replication, this gives the number of refresh operations that have been prepared for execution on the secondary.

See [Section 23.7.11, “NDB Cluster Replication Conflict Resolution”](#), for more information.

- `Ndb_conflict_last_stable_epoch`

Number of rows found to be in conflict by a transactional conflict function

See [Section 23.7.11, “NDB Cluster Replication Conflict Resolution”](#), for more information.

- `Ndb_conflict_trans_row_conflict_count`

Used in NDB Cluster Replication conflict resolution, this status variable shows the number of rows found to be directly in-conflict by a transactional conflict function on a given `mysqld` since the last time it was restarted.

Currently, the only transactional conflict detection function supported by NDB Cluster is `NDB$EPOCH_TRANS()`, so this status variable is effectively the same as `Ndb_conflict_fn_epoch_trans`.

For more information, see [Section 23.7.11, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_trans_row_reject_count`

Used in NDB Cluster Replication conflict resolution, this status variable shows the total number of rows realigned due to being determined as conflicting by a transactional conflict detection function. This includes not only `Ndb_conflict_trans_row_conflict_count`, but any rows in or dependent on conflicting transactions.

For more information, see [Section 23.7.11, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_trans_reject_count`

Used in NDB Cluster Replication conflict resolution, this status variable shows the number of transactions found to be in conflict by a transactional conflict detection function.

For more information, see [Section 23.7.11, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_trans_detect_iter_count`

Used in NDB Cluster Replication conflict resolution, this shows the number of internal iterations required to commit an epoch transaction. Should be (slightly) greater than or equal to `Ndb_conflict_trans_conflict_commit_count`.

For more information, see [Section 23.7.11, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_trans_conflict_commit_count`

Used in NDB Cluster Replication conflict resolution, this shows the number of epoch transactions committed after they required transactional conflict handling.

For more information, see [Section 23.7.11, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_epoch_delete_delete_count`

When using delete-delete conflict detection, this is the number of delete-delete conflicts detected, where a delete operation is applied, but the indicated row does not exist.

- `Ndb_execute_count`

Provides the number of round trips to the [NDB](#) kernel made by operations.

- [Ndb_last_commit_epoch_server](#)

The epoch most recently committed by [NDB](#).

- [Ndb_last_commit_epoch_session](#)

The epoch most recently committed by this [NDB](#) client.

- [Ndb_metadata_detected_count](#)

The number of times since this server was last started that the [NDB](#) metadata change detection thread has discovered changes with respect to the MySQL data dictionary.

- [Ndb_metadata_excluded_count](#)

The number of metadata objects that the [NDB](#) binlog thread has been unable to synchronize on this SQL node since it was last restarted.

Should an object be excluded, it is not again considered for automatic synchronization until the user corrects the mismatch manually. This can be done by attempting to use the table with a statement such as `SHOW CREATE TABLE table`, `SELECT * FROM table`, or any other statement that would trigger table discovery.

Prior to [NDB 8.0.22](#), this variable was named [Ndb_metadata_blacklist_size](#).

- [Ndb_metadata_synced_count](#)

The number of [NDB](#) metadata objects which have been synchronized on this SQL node since it was last restarted.

- [Ndb_number_of_data_nodes](#)

If the server is part of an [NDB](#) Cluster, the value of this variable is the number of data nodes in the cluster.

If the server is not part of an [NDB](#) Cluster, then the value of this variable is 0.

- [Ndb_pushed_queries_defined](#)

The total number of joins pushed down to the [NDB](#) kernel for distributed handling on the data nodes.

**Note**

Joins tested using [EXPLAIN](#) that can be pushed down contribute to this number.

- [Ndb_pushed_queries_dropped](#)

The number of joins that were pushed down to the [NDB](#) kernel but that could not be handled there.

- [Ndb_pushed_queries_executed](#)

The number of joins successfully pushed down to [NDB](#) and executed there.

- [Ndb_pushed_reads](#)

The number of rows returned to `mysqld` from the [NDB](#) kernel by joins that were pushed down.

**Note**

Executing `EXPLAIN` on joins that can be pushed down to NDB does not add to this number.

- `Ndb_pruned_scan_count`

This variable holds a count of the number of scans executed by NDBCLUSTER since the NDB Cluster was last started where NDBCLUSTER was able to use partition pruning.

Using this variable together with `Ndb_scan_count` can be helpful in schema design to maximize the ability of the server to prune scans to a single table partition, thereby involving replica only a single data node.

- `Ndb_replica_max_replicated_epoch`

The most recently committed epoch on this replica. You can compare this value with `Ndb_conflict_last_conflict_epoch`; if `Ndb_replica_max_replicated_epoch` is the greater of the two, no conflicts have yet been detected.

For more information, see [Section 23.7.11, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_scan_count`

This variable holds a count of the total number of scans executed by NDBCLUSTER since the NDB Cluster was last started.

- `Ndb_slave_max_replicated_epoch`

**Note**

Deprecated in NDB 8.0.23; use `Ndb_slave_max_replicated_epoch` instead.

The most recently committed epoch on this replica. You can compare this value with `Ndb_conflict_last_conflict_epoch`; if `Ndb_slave_max_replicated_epoch` is the greater of the two, no conflicts have yet been detected.

For more information, see [Section 23.7.11, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_system_name`

If this MySQL Server is connected to an NDB cluster, this read-only variable shows the cluster system name. Otherwise, the value is an empty string.

- `Ndb_trans_hint_count_session`

The number of transactions using hints that have been started in the current session. Compare with `Ndb_api_trans_start_count_session` to obtain the proportion of all NDB transactions able to use hints.

23.4.3.10 NDB Cluster TCP/IP Connections

TCP/IP is the default transport mechanism for all connections between nodes in an NDB Cluster. Normally it is not necessary to define TCP/IP connections; NDB Cluster automatically sets up such connections for all data nodes, management nodes, and SQL or API nodes.

**Note**

For an exception to this rule, see [Section 23.4.3.11, “NDB Cluster TCP/IP Connections Using Direct Connections”](#).

To override the default connection parameters, it is necessary to define a connection using one or more `[tcp]` sections in the `config.ini` file. Each `[tcp]` section explicitly defines a TCP/IP connection between two NDB Cluster nodes, and must contain at a minimum the parameters `NodeId1` and `NodeId2`, as well as any connection parameters to override.

It is also possible to change the default values for these parameters by setting them in the `[tcp default]` section.

**Important**

Any `[tcp]` sections in the `config.ini` file should be listed *last*, following all other sections in the file. However, this is not required for a `[tcp default]` section. This requirement is a known issue with the way in which the `config.ini` file is read by the NDB Cluster management server.

Connection parameters which can be set in `[tcp]` and `[tcp default]` sections of the `config.ini` file are listed here:

- [AllowUnresolvedHostNames](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.22 |
| Type or units | boolean |
| Default | false |
| Range | true, false |
| Added | NDB 8.0.22 |
| Restart Type | N (NDB 8.0.13) |

By default, when a management node fails to resolve a host name while trying to connect, this results in a fatal error. This behavior can be overridden by setting `AllowUnresolvedHostNames` to `true` in the `[tcp default]` section of the global configuration file (usually named `config.ini`), in which case failure to resolve a host name is treated as a warning and `ndb_mgmd` startup continues uninterrupted.

- [Checksum](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | boolean |
| Default | false |
| Range | true, false |
| Restart Type | N (NDB 8.0.13) |

This parameter is disabled by default. When it is enabled (set to `Y` or `1`), checksums for all messages are calculated before they placed in the send buffer. This feature ensures that messages are not corrupted while waiting in the send buffer, or by the transport mechanism.

- [Group](#)

When `ndb_optimized_node_selection` is enabled, node proximity is used in some cases to select which node to connect to. This parameter can be used to influence proximity by setting it to a lower value, which is interpreted as “closer”. See the description of the system variable for more information.

- `HostName1`

| | |
|------------------------------|--------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | name or IP address |
| Default | [...] |
| Range | ... |
| Restart Type | N (NDB 8.0.13) |

The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given TCP connection between two nodes. The values used for these parameters can be host names or IP addresses.

- `HostName2`

| | |
|------------------------------|--------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | name or IP address |
| Default | [...] |
| Range | ... |
| Restart Type | N (NDB 8.0.13) |

The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given TCP connection between two nodes. The values used for these parameters can be host names or IP addresses.

- `NodeId1`

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | numeric |
| Default | [none] |
| Range | 1 - 255 |
| Restart Type | N (NDB 8.0.13) |

To identify a connection between two nodes it is necessary to provide their node IDs in the `[tcp]` section of the configuration file as the values of `NodeId1` and `NodeId2`. These are the same unique `Id` values for each of these nodes as described in [Section 23.4.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”](#).

- `NodeId2`

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | numeric |
| Default | [none] |
| Range | 1 - 255 |
| Restart Type | N (NDB 8.0.13) |

To identify a connection between two nodes it is necessary to provide their node IDs in the `[tcp]` section of the configuration file as the values of `NodeId1` and `NodeId2`. These are the same unique `Id` values for each of these nodes as described in [Section 23.4.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”](#).

- `NodeIdServer`

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | numeric |
| Default | [none] |
| Range | 1 - 63 |
| Restart Type | N (NDB 8.0.13) |

Set the server side of a TCP connection.

- `OverloadLimit`

| | |
|------------------------------|-----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | bytes |
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

When more than this many unsent bytes are in the send buffer, the connection is considered overloaded.

This parameter can be used to determine the amount of unsent data that must be present in the send buffer before the connection is considered overloaded. See [Section 23.4.3.14, “Configuring NDB Cluster Send Buffer Parameters”](#), for more information.

- `PreferIPVersion`

| | |
|------------------------------|-----------------|
| Version (or later) | NDB 8.0.26 |
| Type or units | enumeration |
| Default | 4 |
| Range | 4, 6 |
| Added | NDB 8.0.26 |
| Restart Type | IS (NDB 8.0.13) |

Determines the preference of DNS resolution for IP version 4 or version 6. Because the configuration retrieval mechanism employed by NDB Cluster requires that all connections use the same preference, this parameter should be set in the `[tcp default]` of the `config.ini` global configuration file.

- `PreSendChecksum`

| | |
|--------------------|-------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | boolean |
| Default | false |
| Range | true, false |

| | |
|------------------------------|----------------|
| Restart Type | N (NDB 8.0.13) |
|------------------------------|----------------|

If this parameter and [Checksum](#) are both enabled, perform pre-send checksum checks, and check all TCP signals between nodes for errors. Has no effect if [Checksum](#) is not also enabled.

- [Proxy](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | string |
| Default | [...] |
| Range | ... |
| Restart Type | N (NDB 8.0.13) |

Set a proxy for the TCP connection.

- [ReceiveBufferMemory](#)

| | |
|------------------------------|-------------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | bytes |
| Default | 2M |
| Range | 16K - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

Specifies the size of the buffer used when receiving data from the TCP/IP socket.

The default value of this parameter is 2MB. The minimum possible value is 16KB; the theoretical maximum is 4GB.

- [SendBufferMemory](#)

| | |
|------------------------------|--------------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | unsigned |
| Default | 2M |
| Range | 256K - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

TCP transporters use a buffer to store all messages before performing the send call to the operating system. When this buffer reaches 64KB its contents are sent; these are also sent when a round of messages have been executed. To handle temporary overload situations it is also possible to define a bigger send buffer.

If this parameter is set explicitly, then the memory is not dedicated to each transporter; instead, the value used denotes the hard limit for how much memory (out of the total available memory—that is, [TotalSendBufferMemory](#)) that may be used by a single transporter. For more information about configuring dynamic transporter send buffer memory allocation in NDB Cluster, see [Section 23.4.3.14, “Configuring NDB Cluster Send Buffer Parameters”](#).

The default size of the send buffer is 2MB, which is the size recommended in most situations. The minimum size is 64 KB; the theoretical maximum is 4 GB.

- [SendSignalId](#)

| | |
|------------------------------|----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | boolean |
| Default | false (debug builds: true) |
| Range | true, false |
| Restart Type | N (NDB 8.0.13) |

To be able to retrace a distributed message datagram, it is necessary to identify each message. When this parameter is set to `Y`, message IDs are transported over the network. This feature is disabled by default in production builds, and enabled in `-debug` builds.

- [TcpBind_INADDR_ANY](#)

Setting this parameter to `TRUE` or `1` binds `IP_ADDR_ANY` so that connections can be made from anywhere (for autogenerated connections). The default is `FALSE` (`0`).

- [TcpSpinTime](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.20 |
| Type or units | μ sec |
| Default | 0 |
| Range | 0 - 2000 |
| Added | NDB 8.0.20 |
| Restart Type | N (NDB 8.0.13) |

Controls spin for a TCP transporter; no enable, set to a nonzero value. This works for both the data node and management or SQL node side of the connection.

- [TCP_MAXSEG_SIZE](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | unsigned |
| Default | 0 |
| Range | 0 - 2G |
| Restart Type | N (NDB 8.0.13) |

Determines the size of the memory set during TCP transporter initialization. The default is recommended for most common usage cases.

- [TCP_RCV_BUF_SIZE](#)

| | |
|--------------------|------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | unsigned |
| Default | 0 |
| Range | 0 - 2G |

| | |
|--------------|----------------|
| Restart Type | N (NDB 8.0.13) |
|--------------|----------------|

Determines the size of the receive buffer set during TCP transporter initialization. The default and minimum value is 0, which allows the operating system or platform to set this value. The default is recommended for most common usage cases.

- [TCP_SND_BUF_SIZE](#)

| | |
|--------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | unsigned |
| Default | 0 |
| Range | 0 - 2G |
| Restart Type | N (NDB 8.0.13) |

Determines the size of the send buffer set during TCP transporter initialization. The default and minimum value is 0, which allows the operating system or platform to set this value. The default is recommended for most common usage cases.

Restart types. Information about the restart types used by the parameter descriptions in this section is shown in the following table:

Table 23.21 NDB Cluster restart types

| Symbol | Restart Type | Description |
|--------|--------------|--|
| N | Node | The parameter can be updated using a rolling restart (see Section 23.6.5, “Performing a Rolling Restart of an NDB Cluster”) |
| S | System | All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter |
| I | Initial | Data nodes must be restarted using the <code>--initial</code> option |

23.4.3.11 NDB Cluster TCP/IP Connections Using Direct Connections

Setting up a cluster using direct connections between data nodes requires specifying explicitly the crossover IP addresses of the data nodes so connected in the `[tcp]` section of the cluster `config.ini` file.

In the following example, we envision a cluster with at least four hosts, one each for a management server, an SQL node, and two data nodes. The cluster as a whole resides on the `172.23.72.*` subnet of a LAN. In addition to the usual network connections, the two data nodes are connected directly using a standard crossover cable, and communicate with one another directly using IP addresses in the `1.1.0.*` address range as shown:

```
# Management Server
[ndb_mgmd]
Id=1
HostName=172.23.72.20
```

```
# SQL Node
[mysqld]
Id=2
HostName=172.23.72.21

# Data Nodes
[ndbd]
Id=3
HostName=172.23.72.22

[ndbd]
Id=4
HostName=172.23.72.23

# TCP/IP Connections
[tcp]
NodeId1=3
NodeId2=4
HostName1=1.1.0.1
HostName2=1.1.0.2
```

The `HostName1` and `HostName2` parameters are used only when specifying direct connections.

The use of direct TCP connections between data nodes can improve the cluster's overall efficiency by enabling the data nodes to bypass an Ethernet device such as a switch, hub, or router, thus cutting down on the cluster's latency.

Note

To take the best advantage of direct connections in this fashion with more than two data nodes, you must have a direct connection between each data node and every other data node in the same node group.

23.4.3.12 NDB Cluster Shared-Memory Connections

Communications between NDB cluster nodes are normally handled using TCP/IP. The shared memory (SHM) transporter is distinguished by the fact that signals are transmitted by writing in memory rather than on a socket. The shared-memory transporter (SHM) can improve performance by negating up to 20% of the overhead required by a TCP connection when running an API node (usually an SQL node) and a data node together on the same host. You can enable a shared memory connection in either of the two ways listed here:

- By setting the `UseShm` data node configuration parameter to `1`, and setting `HostName` for the data node and `HostName` for the API node to the same value.
- By using `[shm]` sections in the cluster configuration file, each containing settings for `NodeId1` and `NodeId2`. This method is described in more detail later in this section.

Suppose a cluster is running a data node which has node ID 1 and an SQL node having node ID 51 on the same host computer at 10.0.0.1. To enable an SHM connection between these two nodes, all that is necessary is to insure that the following entries are included in the cluster configuration file:

```
[ndbd]
NodeId=1
HostName=10.0.0.1
UseShm=1

[mysqld]
NodeId=51
```

```
HostName=10.0.0.1
```

Important

The two entries just shown are in addition to any other entries and parameter settings needed by the cluster. A more complete example is shown later in this section.

Before starting data nodes that use SHM connections, it is also necessary to make sure that the operating system on each computer hosting such a data node has sufficient memory allocated to shared memory segments. See the documentation for your operating platform for information regarding this. In setups where multiple hosts are each running a data node and an API node, it is possible to enable shared memory on all such hosts by setting `UseShm` in the `[ndbd default]` section of the configuration file. This is shown in the example later in this section.

While not strictly required, tuning for all SHM connections in the cluster can be done by setting one or more of the following parameters in the `[shm default]` section of the cluster configuration (`config.ini`) file:

- `ShmSize`: Shared memory size
- `ShmSpinTime`: Time in μ s to spin before sleeping
- `SendBufferMemory`: Size of buffer for signals sent from this node, in bytes.
- `SendSignalId`: Indicates that a signal ID is included in each signal sent through the transporter.
- `Checksum`: Indicates that a checksum is included in each signal sent through the transporter.
- `PreSendChecksum`: Checks of the checksum are made prior to sending the signal; Checksum must also be enabled for this to work

This example shows a simple setup with SHM connections defined on multiple hosts, in an NDB Cluster using 3 computers listed here by host name, hosting the node types shown:

1. `10.0.0.0`: The management server
2. `10.0.0.1`: A data node and an SQL node
3. `10.0.0.2`: A data node and an SQL node

In this scenario, each data node communicates with both the management server and the other data node using TCP transporters; each SQL node uses a shared memory transporter to communicate with the data nodes that is local to it, and a TCP transporter to communicate with the remote data node. A basic configuration reflecting this setup is enabled by the `config.ini` file whose contents are shown here:

```
[ndbd default]
DataDir=/path/to/datadir
UseShm=1

[shm default]
ShmSize=8M
ShmSpintime=200
SendBufferMemory=4M

[tcp default]
SendBufferMemory=8M

[ndb_mgmd]
NodeId=49
Hostname=10.0.0.0
DataDir=/path/to/datadir
```

```
[ndbd]
NodeId=1
Hostname=10.0.0.1
DataDir=/path/to/datadir

[ndbd]
NodeId=2
Hostname=10.0.0.2
DataDir=/path/to/datadir

[mysqld]
NodeId=51
Hostname=10.0.0.1

[mysqld]
NodeId=52
Hostname=10.0.0.2

[api]
[api]
```

Parameters affecting all shared memory transporters are set in the `[shm default]` section; these can be overridden on a per-connection basis in one or more `[shm]` sections. Each such section must be associated with a given SHM connection using `NodeId1` and `NodeId2`; the values required for these parameters are the node IDs of the two nodes connected by the transporter. You can also identify the nodes by host name using `HostName1` and `HostName2`, but these parameters are not required.

The API nodes for which no host names are set use the TCP transporter to communicate with data nodes independent of the hosts on which they are started; the parameters and values set in the `[tcp default]` section of the configuration file apply to all TCP transporters in the cluster.

For optimum performance, you can define a spin time for the SHM transporter (`ShmSpinTime` parameter); this affects both the data node receiver thread and the poll owner (receive thread or user thread) in NDB.

- [Checksum](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | boolean |
| Default | true |
| Range | true, false |
| Restart Type | N (NDB 8.0.13) |

This parameter is a boolean (Y/N) parameter which is disabled by default. When it is enabled, checksums for all messages are calculated before being placed in the send buffer.

This feature prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.

- [Group](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | unsigned |
| Default | 35 |
| Range | 0 - 200 |
| Restart Type | N (NDB 8.0.13) |

Determines the group proximity; a smaller value is interpreted as being closer. The default value is sufficient for most conditions.

- [HostName1](#)

| | |
|------------------------------|--------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | name or IP address |
| Default | [...] |
| Range | ... |
| Restart Type | N (NDB 8.0.13) |

The [HostName1](#) and [HostName2](#) parameters can be used to specify specific network interfaces to be used for a given SHM connection between two nodes. The values used for these parameters can be host names or IP addresses.

- [HostName2](#)

| | |
|------------------------------|--------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | name or IP address |
| Default | [...] |
| Range | ... |
| Restart Type | N (NDB 8.0.13) |

The [HostName1](#) and [HostName2](#) parameters can be used to specify specific network interfaces to be used for a given SHM connection between two nodes. The values used for these parameters can be host names or IP addresses.

- [NodeId1](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | numeric |
| Default | [none] |
| Range | 1 - 255 |
| Restart Type | N (NDB 8.0.13) |

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as [NodeId1](#) and [NodeId2](#).

- [NodeId2](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | numeric |
| Default | [none] |
| Range | 1 - 255 |
| Restart Type | N (NDB 8.0.13) |

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as [NodeId1](#) and [NodeId2](#).

- [NodeIdServer](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | numeric |
| Default | [none] |
| Range | 1 - 63 |
| Restart Type | N (NDB 8.0.13) |

Identify the server end of a shared memory connection. By default, this is the node ID of the data node.

- [OverloadLimit](#)

| | |
|------------------------------|-----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | bytes |
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

When more than this many unsent bytes are in the send buffer, the connection is considered overloaded. See [Section 23.4.3.14, “Configuring NDB Cluster Send Buffer Parameters”](#), and [Section 23.6.14.55, “The ndbinfo transporters Table”](#), for more information.

- [PreSendChecksum](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | boolean |
| Default | false |
| Range | true, false |
| Restart Type | N (NDB 8.0.13) |

If this parameter and [Checksum](#) are both enabled, perform pre-send checksum checks, and check all SHM signals between nodes for errors. Has no effect if [Checksum](#) is not also enabled.

- [SendBufferMemory](#)

| | |
|------------------------------|--------------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | integer |
| Default | 2M |
| Range | 256K - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

Size (in bytes) of the shared memory buffer for signals sent from this node using a shared memory connection.

- [SendSignalId](#)

| | |
|--------------------|------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | boolean |

| | |
|------------------------------|----------------|
| Default | false |
| Range | true, false |
| Restart Type | N (NDB 8.0.13) |

To retrace the path of a distributed message, it is necessary to provide each message with a unique identifier. Setting this parameter to `y` causes these message IDs to be transported over the network as well. This feature is disabled by default in production builds, and enabled in `-debug` builds.

- [ShmKey](#)

| | |
|------------------------------|-----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | unsigned |
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

When setting up shared memory segments, a node ID, expressed as an integer, is used to identify uniquely the shared memory segment to use for the communication. There is no default value. If [UseShm](#) is enabled, the shared memory key is calculated automatically by [NDB](#).

- [ShmSize](#)

| | |
|------------------------------|-------------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | bytes |
| Default | 4M |
| Range | 64K - 4294967039 (0xFFFFFFFF) |
| Restart Type | N (NDB 8.0.13) |

Each SHM connection has a shared memory segment where messages between nodes are placed by the sender and read by the reader. The size of this segment is defined by [ShmSize](#). The default value is 4MB.

- [ShmSpinTime](#)

| | |
|------------------------------|----------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | integer |
| Default | 0 |
| Range | 0 - 2000 |
| Restart Type | N (NDB 8.0.13) |

When receiving, the time to wait before sleeping, in microseconds.

- [SigNum](#)

| | |
|--------------------|-----------------------------|
| Version (or later) | NDB 8.0.13 |
| Type or units | unsigned |
| Default | [...] |
| Range | 0 - 4294967039 (0xFFFFFFFF) |

| | |
|------------------------------|------------------|
| Deprecated | Yes (in NDB 7.6) |
| Restart Type | N (NDB 8.0.13) |

This parameter was used formerly to override operating system signal numbers; in NDB 8.0, it is no longer used, and any setting for it is ignored.

Restart types. Information about the restart types used by the parameter descriptions in this section is shown in the following table:

Table 23.22 NDB Cluster restart types

| Symbol | Restart Type | Description |
|--------|--------------|--|
| N | Node | The parameter can be updated using a rolling restart (see Section 23.6.5, “Performing a Rolling Restart of an NDB Cluster”) |
| S | System | All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter |
| I | Initial | Data nodes must be restarted using the <code>--initial</code> option |

23.4.3.13 Data Node Memory Management

All memory allocation for a data node is performed when the node is started. This ensures that the data node can run in a stable manner without using swap memory, so that NDB can be used for latency-sensitive (realtime) applications. The following types of memory are allocated on data node startup:

- Data memory
- Shared global memory
- Redo log buffers
- Job buffers
- Send buffers
- Page cache for disk data records
- Schema transaction memory
- Transaction memory
- Undo log buffer
- Query memory
- Block objects
- Schema memory
- Block data structures
- Long signal memory

- Shared memory communication buffers

The [NDB](#) memory manager, which regulates most data node memory, handles the following memory resources:

- Data Memory ([DataMemory](#))
- Redo log buffers ([RedoBuffer](#))
- Job buffers
- Send buffers ([SendBufferMemory](#), [TotalSendBufferMemory](#), [ExtraSendBufferMemory](#), [ReservedSendBufferMemory](#))
- Disk Data record page cache ([DiskPageBufferMemory](#), [DiskPageBufferEntries](#))
- Transaction memory ([TransactionMemory](#))
- Query memory
- Disk access records
- File buffers

Each of these resources is set up with a reserved memory area and a maximum memory area. The reserved memory area can be used only by the resource for which it is reserved and cannot be shared with other resources; a given resource can never allocate more than the maximum memory allowed for the resource. A resource that has no maximum memory can expand to use all the shared memory in the memory manager.

The size of the global shared memory for these resources is controlled by the [SharedGlobalMemory](#) configuration parameter (default: 128 MB).

Data memory is always reserved and never acquires any memory from shared memory. It is controlled using the [DataMemory](#) configuration parameter, whose maximum is 16384 GB. [DataMemory](#) is where records are stored, including hash indexes (approximately 15 bytes per row), ordered indexes (10-12 bytes per row per index), and row headers (16-32 bytes per row).

Redo log buffers also use reserved memory only; this is controlled by the [RedoBuffer](#) configuration parameter, which sets the size of the redo log buffer per LDM thread. This means that the actual amount of memory used is the value of this parameter multiplied by the number of LDM threads in the data node.

Job buffers use reserved memory only; the size of this memory is calculated by [NDB](#), based on the numbers of threads of various types.

Send buffers have a reserved part but can also allocate an additional 25% of shared global memory. The send buffer reserved size is calculated in two steps:

1. Use the value of the [TotalSendBufferMemory](#) configuration parameter (no default value) or the sum of the individual send buffers used by all individual connections to the data node. A data node is connected to all other data nodes, to all API nodes, and to all management nodes. This means that, in a cluster with 2 data nodes, 2 management nodes, and 10 API nodes each data node has 13 node connections. Since the default value for [SendBufferMemory](#) for a data node connection is 2 MByte, this works out to 26 MB total.
2. To obtain the total reserved size for the send buffer, the value of the [ExtraSendBufferMemory](#) configuration parameter, if any (default value 0), is added to the value obtained in the previous step.

In other words, if [TotalSendBufferMemory](#) has been set, the send buffer size is [TotalSendBufferMemory](#) + [ExtraSendBufferMemory](#); otherwise, the size of the

send buffer is equal to $([number\ of\ node\ connections] * SendBufferMemory) + ExtraSendBufferMemory$.

The page cache for disk data records uses a reserved resource only; the size of this resource is controlled by the `DiskPageBufferMemory` configuration parameter (default 64 MB). Memory for 32 KB disk page entries is also allocated; the number of these is determined by the `DiskPageBufferEntries` configuration parameter (default 10).

Transaction memory has a reserved part that either is calculated by `NDB`, or is set explicitly using the `TransactionMemory` configuration parameter, introduced in NDB 8.0 (previously, this value was always calculated by `NDB`); transaction memory can also use an unlimited amount of shared global memory. Transaction memory is used for all operational resources handling transactions, scans, locks, scan buffers, and trigger operations. It also holds table rows as they are updated, before the next commit writes them to data memory.

Previously, operational records used dedicated resources whose sizes were controlled by a number of configuration parameters. In NDB 8.0, these are all allocated from a common transaction memory resource and can also use resources from global shared memory. the size of this resource can be controlled using a single `TransactionMemory` configuration parameter.

Reserved memory for undo log buffers can be set using the `InitialLogFileGroup` configuration parameter. If an undo log buffer is created as part of a `CREATE LOGFILE GROUP` SQL statement, the memory is taken from the transaction memory.

A number of resources relating to metadata for Disk Data resources also have no reserved part, and use shared global memory only. Shared global shared memory is thus shared between send buffers, transaction memory, and Disk Data metadata.

If `TransactionMemory` is not set, it is calculated based on the following parameters:

- `MaxNoOfConcurrentOperations`
- `MaxNoOfConcurrentTransactions`
- `MaxNoOfFiredTriggers`
- `MaxNoOfLocalOperations`
- `MaxNoOfConcurrentIndexOperations`
- `MaxNoOfConcurrentScans`
- `MaxNoOfLocalScans`
- `BatchSizePerLocalScan`
- `TransactionBufferMemory`

When `TransactionMemory` is set explicitly, none of the configuration parameters just listed are used to calculate memory size. In addition, the parameters `MaxNoOfConcurrentIndexOperations`, `MaxNoOfFiredTriggers`, `MaxNoOfLocalOperations`, and `MaxNoOfLocalScans` are incompatible with `TransactionMemory` and cannot be set concurrently with it; if `TransactionMemory` is set and any of these four parameters are also set in the `config.ini` configuration file, the management server cannot start. These four parameters are deprecated in NDB 8.0; expect them to be removed from a future release of MySQL NDB Cluster.

The transaction memory resource contains a large number of memory pools. Each memory pool represents an object type and contains a set of objects; each pool includes a reserved part allocated to

the pool at startup; this reserved memory is never returned to shared global memory. Reserved records are found using a data structure having only a single level for fast retrieval, which means that a number of records in each pool should be reserved. The number of reserved records in each pool has some impact on performance and reserved memory allocation, but is generally necessary only in certain very advanced use cases to set the reserved sizes explicitly.

The size of the reserved part of the pool can be controlled by setting the following configuration parameters:

- [ReservedConcurrentIndexOperations](#)
- [ReservedFiredTriggers](#)
- [ReservedConcurrentOperations](#)
- [ReservedLocalScans](#)
- [ReservedConcurrentTransactions](#)
- [ReservedConcurrentScans](#)
- [ReservedTransactionBufferMemory](#)

If the parameters just listed are not set, the reserved setting is 25% of transaction memory. The number of reserved records is per data node; these records are split among the threads handling them (LDM and TC threads) on each node. In most cases, it is sufficient to set [TransactionMemory](#) alone, and to allow the number of records in pools to be governed by its value.

[MaxNoOfConcurrentScans](#) limits the number of concurrent scans that can be active in each TC thread. This is important in guarding against cluster overload.

[MaxNoOfConcurrentOperations](#) limits the number of operations that can be active at any one time in updating transactions. (Simple reads are not affected by this parameter.) This number needs to be limited because it is necessary to preallocate memory for node failure handling, and a resource must be available for handling the maximum number of active operations in one TC thread when contending with node failures. It is imperative that [MaxNoOfConcurrentOperations](#) be set to the same number on all nodes (this can be done most easily by setting a value for it once, in the `[ndbd default]` section of the `config.ini` global configuration file). While its value can be increased using a rolling restart (see [Section 23.6.5, “Performing a Rolling Restart of an NDB Cluster”](#)), decreasing it in this way is not considered safe due to the possibility of a node failure occurring during the rolling restart.

It is possible to limit the size of a single transaction in NDB Cluster through the [MaxDMLOperationsPerTransaction](#) parameter. If this is not set, the size of one transaction is limited by [MaxNoOfConcurrentOperations](#) since this parameter limits the total number of concurrent operations per TC thread.

Schema memory size is controlled by the following set of configuration parameters:

- [MaxNoOfSubscriptions](#)
- [MaxNoOfSubscribers](#)
- [MaxNoOfConcurrentSubOperations](#)
- [MaxNoOfAttributes](#)
- [MaxNoOfTables](#)
- [MaxNoOfOrderedIndexes](#)

- [MaxNoOfUniqueHashIndexes](#)
- [MaxNoOfTriggers](#)

The number of nodes and the number of LDM threads also have a major impact on the size of schema memory since the number of partitions in each table and each partition (and its fragment replicas) have to be represented in schema memory.

In addition, a number of other records are allocated during startup. These are relatively small. Each block in each thread contains block objects that use memory. This memory size is also normally quite small compared to the other data node memory structures.

23.4.3.14 Configuring NDB Cluster Send Buffer Parameters

The NDB kernel employs a unified send buffer whose memory is allocated dynamically from a pool shared by all transporters. This means that the size of the send buffer can be adjusted as necessary. Configuration of the unified send buffer can be accomplished by setting the following parameters:

- **TotalSendBufferMemory.** This parameter can be set for all types of NDB Cluster nodes—that is, it can be set in the `[ndbd]`, `[mgm]`, and `[api]` (or `[mysql]`) sections of the `config.ini` file. It represents the total amount of memory (in bytes) to be allocated by each node for which it is set for use among all configured transporters. If set, its minimum is 256KB; the maximum is 4294967039.

To be backward-compatible with existing configurations, this parameter takes as its default value the sum of the maximum send buffer sizes of all configured transporters, plus an additional 32KB (one page) per transporter. The maximum depends on the type of transporter, as shown in the following table:

Table 23.23 Transporter types with maximum send buffer sizes

| Transporter | Maximum Send Buffer Size (bytes) |
|-------------|--|
| TCP | <code>SendBufferMemory</code> (default = 2M) |
| SHM | 20K |

This enables existing configurations to function in close to the same way as they did with NDB Cluster 6.3 and earlier, with the same amount of memory and send buffer space available to each transporter. However, memory that is unused by one transporter is not available to other transporters.

- **OverloadLimit.** This parameter is used in the `config.ini` file `[tcp]` section, and denotes the amount of unsent data (in bytes) that must be present in the send buffer before the connection is considered overloaded. When such an overload condition occurs, transactions that affect the overloaded connection fail with NDB API Error 1218 ([Send Buffers overloaded in NDB kernel](#)) until the overload status passes. The default value is 0, in which case the effective overload limit is calculated as `SendBufferMemory * 0.8` for a given connection. The maximum value for this parameter is 4G.
- **SendBufferMemory.** This value denotes a hard limit for the amount of memory that may be used by a single transporter out of the entire pool specified by `TotalSendBufferMemory`. However, the sum of `SendBufferMemory` for all configured transporters may be greater than the `TotalSendBufferMemory` that is set for a given node. This is a way to save memory when many nodes are in use, as long as the maximum amount of memory is never required by all transporters at the same time.

You can use the `ndbinfo.transporters` table to monitor send buffer memory usage, and to detect slowdown and overload conditions that can adversely affect performance.

23.4.4 Using High-Speed Interconnects with NDB Cluster

Even before design of `NDBCLUSTER` began in 1996, it was evident that one of the major problems to be encountered in building parallel databases would be communication between the nodes in the network. For this reason, `NDBCLUSTER` was designed from the very beginning to permit the use of a number of different data transport mechanisms. In this Manual, we use the term *transporter* for these.

The NDB Cluster codebase provides for four different transporters:

- *TCP/IP using 100 Mbps or gigabit Ethernet*, as discussed in [Section 23.4.3.10, “NDB Cluster TCP/IP Connections”](#).
- *Direct (machine-to-machine) TCP/IP*; although this transporter uses the same TCP/IP protocol as mentioned in the previous item, it requires setting up the hardware differently and is configured differently as well. For this reason, it is considered a separate transport mechanism for NDB Cluster. See [Section 23.4.3.11, “NDB Cluster TCP/IP Connections Using Direct Connections”](#), for details.
- *Shared memory (SHM)*. For more information about SHM, see [Section 23.4.3.12, “NDB Cluster Shared-Memory Connections”](#).
- *Scalable Coherent Interface (SCI)*.

Note

Using SCI transporters in NDB Cluster requires specialized hardware, software, and MySQL binaries not available with NDB 8.0.

Most users today employ TCP/IP over Ethernet because it is ubiquitous. TCP/IP is also by far the best-tested transporter for use with NDB Cluster.

Regardless of the transporter used, `NDB` attempts to make sure that communication with data node processes is done using chunks that are as large as possible since this benefits all types of data transmission.

23.5 NDB Cluster Programs

Using and managing an NDB Cluster requires several specialized programs, which we describe in this chapter. We discuss the purposes of these programs in an NDB Cluster, how to use the programs, and what startup options are available for each of them.

These programs include the NDB Cluster data, management, and SQL node processes (`ndbd`, `ndbmt`, `ndb_mgmd`, and `mysqld`) and the management client (`ndb_mgm`).

Information about the program `ndb_setup.py` (now deprecated), used to start the NDB Cluster Auto-Installer, is also included in this section. You should be aware that [Section 23.5.26, “ndb_setup.py — Start browser-based Auto-Installer for NDB Cluster \(DEPRECATED\)”](#), contains information about the command-line client only; for information about using the GUI installer spawned by this program to configure and deploy an NDB Cluster, see [The NDB Cluster Auto-Installer \(NDB 7.5\) \(No longer supported\)](#).

For information about using `mysqld` as an NDB Cluster process, see [Section 23.6.9, “MySQL Server Usage for NDB Cluster”](#).

Other `NDB` utility, diagnostic, and example programs are included with the NDB Cluster distribution. These include `ndb_restore`, `ndb_show_tables`, and `ndb_config`. These programs are also covered in this section.

The final portion of this section contains tables of options that are common to all the various NDB Cluster programs.

23.5.1 ndbd — The NDB Cluster Data Node Daemon

`ndbd` is the process that is used to handle all the data in tables using the NDB Cluster storage engine. This is the process that empowers a data node to accomplish distributed transaction handling, node recovery, checkpointing to disk, online backup, and related tasks.

In an NDB Cluster, a set of `ndbd` processes cooperate in handling data. These processes can execute on the same computer (host) or on different computers. The correspondences between data nodes and Cluster hosts is completely configurable.

Options that can be used with `ndbd` are shown in the following table. Additional descriptions follow the table.

Table 23.24 Command-line options used with the program `ndbd`

| Format | Description | Added, Deprecated, or Removed |
|---|--|--|
| <code>--bind-address=name</code> | Local bind address | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--character-sets-dir=path</code> | Directory containing character sets | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-delay=#</code> | Time to wait between attempts to contact a management server, in seconds; 0 means do not wait between attempts | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-retries=#</code> | Set the number of times to retry a connection before giving up; 0 means 1 attempt only (and no retries) | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-retry-delay=#</code> | Time to wait between attempts to contact a management server, in seconds; 0 means do not wait between attempts | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-string=connection-string,</code> <code>-c</code> | Same as <code>--ndb-connectstring</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--core-file</code> | Write core file on error; used in debugging | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--daemon,</code> <code>-d</code> | Start <code>ndbd</code> as daemon (default); override with <code>--nodaemon</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-extra-file=path</code> | Read given file after global files are read | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-file=path</code> | Read default options from given file only | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-group-suffix=string</code> | Also read groups with <code>concat(group, suffix)</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--foreground</code> | Run <code>ndbd</code> in foreground, provided for debugging purposes (implies <code>--nodaemon</code>) | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--help,</code> | Display help text and exit | (Supported in all NDB releases based on MySQL 8.0) |

| Format | Description | Added, Deprecated, or Removed |
|--|--|--|
| -? | | |
| --initial | Perform initial start of ndbd, including file system cleanup; consult documentation before using this option | (Supported in all NDB releases based on MySQL 8.0) |
| --initial-start | Perform partial initial start (requires --nowait-nodes) | (Supported in all NDB releases based on MySQL 8.0) |
| --install[=name] | Used to install data node process as Windows service; does not apply on other platforms | (Supported in all NDB releases based on MySQL 8.0) |
| --logbuffer-size=# | Control size of log buffer; for use when debugging with many log messages being generated; default is sufficient for normal operations | (Supported in all NDB releases based on MySQL 8.0) |
| --login-path=path | Read given path from login file | (Supported in all NDB releases based on MySQL 8.0) |
| --ndb-connectstring=connection-string, | Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". | (Supported in all NDB releases based on MySQL 8.0) |
| -c | Overrides entries in NDB_CONNECTSTRING and my.cnf | |
| --ndb-mgmd-host=connection-string, | Same as --ndb-connectstring | (Supported in all NDB releases based on MySQL 8.0) |
| -c | | |
| --ndb-nodeid=# | Set node ID for this node, overriding any ID set by --ndb-connectstring | (Supported in all NDB releases based on MySQL 8.0) |
| --nodaemon | Do not start ndbd as daemon; provided for testing purposes | (Supported in all NDB releases based on MySQL 8.0) |
| --no-defaults | Do not read default options from any option file other than login file | (Supported in all NDB releases based on MySQL 8.0) |
| --nostart, | Do not start ndbd immediately; ndbd waits for command to start from ndb_mgm | (Supported in all NDB releases based on MySQL 8.0) |
| -n | | |
| --nowait-nodes=list | Do not wait for these data nodes to start (takes comma-separated list of node IDs); requires --ndb-nodeid | (Supported in all NDB releases based on MySQL 8.0) |
| --ndb-optimized-node-selection | Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable | (Supported in all NDB releases based on MySQL 8.0) |

| Format | Description | Added, Deprecated, or Removed |
|--|--|--|
| <code>--print-defaults</code> | Print program argument list and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--remove[=name]</code> | Used to remove data node process that was previously installed as Windows service; does not apply on other platforms | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--usage,</code> <code>-?</code> | Display help text and exit; same as <code>--help</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--verbose,</code> <code>-v</code> | Write extra debugging information to node log | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--version,</code> <code>-V</code> | Display version information and exit | (Supported in all NDB releases based on MySQL 8.0) |

Note

All of these options also apply to the multithreaded version of this program (`ndbmt`) and you may substitute “`ndbmt`” for “`ndbd`” wherever the latter occurs in this section.

- `--bind-address`

| | |
|---------------------|----------------------------------|
| Command-Line Format | <code>--bind-address=name</code> |
| Type | String |
| Default Value | |

Causes `ndbd` to bind to a specific network interface (host name or IP address). This option has no default value.

- `--character-sets-dir`

| | |
|---------------------|--|
| Command-Line Format | <code>--character-sets-dir=path</code> |
|---------------------|--|

Directory containing character sets.

- `--connect-delay=#`

| | |
|---------------------|--------------------------------|
| Command-Line Format | <code>--connect-delay=#</code> |
| Deprecated | Yes |
| Type | Numeric |
| Default Value | 5 |
| Minimum Value | 0 |
| Maximum Value | 3600 |

Determines the time to wait between attempts to contact a management server when starting (the number of attempts is controlled by the `--connect-retries` option). The default is 5 seconds. 4321

This option is deprecated, and is subject to removal in a future release of NDB Cluster. Use `--connect-retry-delay` instead.

- `--connect-retries=#`

| | |
|---------------------|----------------------------------|
| Command-Line Format | <code>--connect-retries=#</code> |
| Type | Numeric |
| Default Value | 12 |
| Minimum Value | 0 |
| Maximum Value | 65535 |

Set the number of times to retry a connection before giving up; 0 means 1 attempt only (and no retries). The default is 12 attempts. The time to wait between attempts is controlled by the `--connect-retry-delay` option.

- `--connect-retry-delay=#`

| | |
|---------------------|--------------------------------------|
| Command-Line Format | <code>--connect-retry-delay=#</code> |
| Type | Numeric |
| Default Value | 5 |
| Minimum Value | 0 |
| Maximum Value | 4294967295 |

Determines the time to wait between attempts to contact a management server when starting (the time between attempts is controlled by the `--connect-retries` option). The default is 5 seconds.

This option takes the place of the `--connect-delay` option, which is now deprecated and subject to removal in a future release of NDB Cluster.

- `--connect-string`

| | |
|---------------------|---|
| Command-Line Format | <code>--connect-string=connection-string</code> |
| Type | String |
| Default Value | [none] |

Same as `--ndb-connectstring`.

- `--core-file`

| | |
|---------------------|--------------------------|
| Command-Line Format | <code>--core-file</code> |
|---------------------|--------------------------|

Write core file on error; used in debugging.

- `--daemon, -d`

| | |
|---------------------|-----------------------|
| Command-Line Format | <code>--daemon</code> |
| Type | Boolean |

| | |
|---------------|------|
| Default Value | TRUE |
|---------------|------|

Instructs `ndbd` or `ndbmt` to execute as a daemon process. This is the default behavior. `--nodaemon` can be used to prevent the process from running as a daemon.

This option has no effect when running `ndbd` or `ndbmt` on Windows platforms.

- `--defaults-extra-file`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-extra-file=path</code> |
| Type | String |
| Default Value | [none] |

Read given file after global files are read.

- `--defaults-file`

| | |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--defaults-file=path</code> |
| Type | String |
| Default Value | [none] |

Read default options from given file only.

- `--defaults-group-suffix`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-group-suffix=string</code> |
| Type | String |
| Default Value | [none] |

Also read groups with `concat(group, suffix)`.

- `--foreground`

| | |
|---------------------|---------------------------|
| Command-Line Format | <code>--foreground</code> |
| Type | Boolean |
| Default Value | FALSE |

Causes `ndbd` or `ndbmt` to execute as a foreground process, primarily for debugging purposes. This option implies the `--nodaemon` option.

This option has no effect when running `ndbd` or `ndbmt` on Windows platforms.

- `--help`

| | |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
|---------------------|---------------------|

Display help text and exit.

- `--initial`

| | |
|---------------------|------------------------|
| Command-Line Format | <code>--initial</code> |
| Type | Boolean |

| | |
|---------------|-------|
| Default Value | FALSE |
|---------------|-------|

Instructs `ndbd` to perform an initial start. An initial start erases any files created for recovery purposes by earlier instances of `ndbd`. It also re-creates recovery log files. On some operating systems, this process can take a substantial amount of time.

An `--initial` start is to be used *only* when starting the `ndbd` process under very special circumstances; this is because this option causes all files to be removed from the NDB Cluster file system and all redo log files to be re-created. These circumstances are listed here:

- When performing a software upgrade which has changed the contents of any files.
- When restarting the node with a new version of `ndbd`.
- As a measure of last resort when for some reason the node restart or system restart repeatedly fails. In this case, be aware that this node can no longer be used to restore data due to the destruction of the data files.

Warning

To avoid the possibility of eventual data loss, it is recommended that you *not* use the `--initial` option together with `StopOnError = 0`. Instead, set `StopOnError` to 0 in `config.ini` only after the cluster has been started, then restart the data nodes normally—that is, without the `--initial` option. See the description of the `StopOnError` parameter for a detailed explanation of this issue. (Bug #24945638)

Use of this option prevents the `StartPartialTimeout` and `StartPartitionedTimeout` configuration parameters from having any effect.

Important

This option does *not* affect backup files that have already been created by the affected node.

Prior to NDB 8.0.21, the `--initial` option also did not affect any Disk Data files. In NDB 8.0.21 and later, when used to perform an initial restart of the cluster, the option causes the removal of all data files associated with Disk Data tablespaces and undo log files associated with log file groups that existed previously on this data node (see [Section 23.6.10, “NDB Cluster Disk Data Tables”](#)).

This option also has no effect on recovery of data by a data node that is just starting (or restarting) from data nodes that are already running (unless they also were started with `--initial`, as part of an initial restart). This recovery of data occurs automatically, and requires no user intervention in an NDB Cluster that is running normally.

It is permissible to use this option when starting the cluster for the very first time (that is, before any data node files have been created); however, it is *not* necessary to do so.

- `--initial-start`

| | |
|---------------------|------------------------------|
| Command-Line Format | <code>--initial-start</code> |
| Type | Boolean |

| | |
|---------------|-------|
| Default Value | FALSE |
|---------------|-------|

This option is used when performing a partial initial start of the cluster. Each node should be started with this option, as well as `--nowait-nodes`.

Suppose that you have a 4-node cluster whose data nodes have the IDs 2, 3, 4, and 5, and you wish to perform a partial initial start using only nodes 2, 4, and 5—that is, omitting node 3:

```
shell> ndbd --ndb-nodeid=2 --nowait-nodes=3 --initial-start
shell> ndbd --ndb-nodeid=4 --nowait-nodes=3 --initial-start
shell> ndbd --ndb-nodeid=5 --nowait-nodes=3 --initial-start
```

When using this option, you must also specify the node ID for the data node being started with the `--ndb-nodeid` option.

Important

Do not confuse this option with the `--nowait-nodes` option for `ndb_mgmd`, which can be used to enable a cluster configured with multiple management servers to be started without all management servers being online.

- `--install[=name]`

| | |
|---------------------|-------------------------------|
| Command-Line Format | <code>--install[=name]</code> |
| Platform Specific | Windows |
| Type | String |
| Default Value | <code>ndbd</code> |

Causes `ndbd` to be installed as a Windows service. Optionally, you can specify a name for the service; if not set, the service name defaults to `ndbd`. Although it is preferable to specify other `ndbd` program options in a `my.ini` or `my.cnf` configuration file, it is possible to use together with `--install`. However, in such cases, the `--install` option must be specified first, before any other options are given, for the Windows service installation to succeed.

It is generally not advisable to use this option together with the `--initial` option, since this causes the data node file system to be wiped and rebuilt every time the service is stopped and started. Extreme care should also be taken if you intend to use any of the other `ndbd` options that affect the starting of data nodes—including `--initial-start`, `--nostart`, and `--nowait-nodes`—together with `--install`, and you should make absolutely certain you fully understand and allow for any possible consequences of doing so.

The `--install` option has no effect on non-Windows platforms.

- `--logbuffer-size=#`

| | |
|---------------------|---------------------------------|
| Command-Line Format | <code>--logbuffer-size=#</code> |
| Type | Integer |
| Default Value | 32768 |
| Minimum Value | 2048 |

| | |
|---------------|------------|
| Maximum Value | 4294967295 |
|---------------|------------|

Sets the size of the data node log buffer. When debugging with high amounts of extra logging, it is possible for the log buffer to run out of space if there are too many log messages, in which case some log messages can be lost. This should not occur during normal operations.

- `--login-path`

| | |
|---------------------|--------------------------------|
| Command-Line Format | <code>--login-path=path</code> |
| Type | String |
| Default Value | [none] |

Read given path from login file.

- `--ndb-connectstring`

| | |
|---------------------|--|
| Command-Line Format | <code>--ndb-connectstring=connection-string</code> |
| Type | String |
| Default Value | [none] |

Set connect string for connecting to `ndb_mgmd`. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in `NDB_CONNECTSTRING` and `my.cnf`.

- `--ndb-mgmd-host`

| | |
|---------------------|--|
| Command-Line Format | <code>--ndb-mgmd-host=connection-string</code> |
| Type | String |
| Default Value | [none] |

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

| | |
|---------------------|-----------------------------|
| Command-Line Format | <code>--ndb-nodeid=#</code> |
| Type | Integer |
| Default Value | [none] |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

| | |
|---------------------|---|
| Command-Line Format | <code>--ndb-optimized-node-selection</code> |
|---------------------|---|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--nodaemon`

| | |
|---------------------|-------------------------|
| Command-Line Format | <code>--nodaemon</code> |
| Type | Boolean |
| Default Value | FALSE |

Prevents `ndbd` or `ndbmt` from executing as a daemon process. This option overrides the `--daemon` option. This is useful for redirecting output to the screen when debugging the binary.

The default behavior for `ndbd` and `ndbmt` on Windows is to run in the foreground, making this option unnecessary on Windows platforms, where it has no effect.

- `--no-defaults`

| | |
|---------------------|----------------------------|
| Command-Line Format | <code>--no-defaults</code> |
|---------------------|----------------------------|

Do not read default options from any option file other than login file.

- `--nostart, -n`

| | |
|---------------------|------------------------|
| Command-Line Format | <code>--nostart</code> |
| Type | Boolean |
| Default Value | <code>FALSE</code> |

Instructs `ndbd` not to start automatically. When this option is used, `ndbd` connects to the management server, obtains configuration data from it, and initializes communication objects. However, it does not actually start the execution engine until specifically requested to do so by the management server. This can be accomplished by issuing the proper `START` command in the management client (see [Section 23.6.1, “Commands in the NDB Cluster Management Client”](#)).

- `--nowait-nodes=node_id_1[, node_id_2[, ...]]`

| | |
|---------------------|----------------------------------|
| Command-Line Format | <code>--nowait-nodes=list</code> |
| Type | String |
| Default Value | |

This option takes a list of data nodes for which the cluster does not wait, prior to starting.

This can be used to start the cluster in a partitioned state. For example, to start the cluster with only half of the data nodes (nodes 2, 3, 4, and 5) running in a 4-node cluster, you can start each `ndbd` process with `--nowait-nodes=3,5`. In this case, the cluster starts as soon as nodes 2 and 4 connect, and does *not* wait `StartPartitionedTimeout` milliseconds for nodes 3 and 5 to connect as it would otherwise.

If you wanted to start up the same cluster as in the previous example without one `ndbd` (say, for example, that the host machine for node 3 has suffered a hardware failure) then start nodes 2, 4, and 5 with `--nowait-nodes=3`. Then the cluster starts as soon as nodes 2, 4, and 5 connect, and does not wait for node 3 to start.

- `--print-defaults`

| | |
|---------------------|-------------------------------|
| Command-Line Format | <code>--print-defaults</code> |
|---------------------|-------------------------------|

Print program argument list and exit.

- `--remove[=name]`

| | |
|---------------------|------------------------------|
| Command-Line Format | <code>--remove[=name]</code> |
| Platform Specific | Windows |

| | |
|---------------|--------|
| Type | String |
| Default Value | ndbd |

Causes an `ndbd` process that was previously installed as a Windows service to be removed. Optionally, you can specify a name for the service to be uninstalled; if not set, the service name defaults to `ndbd`.

The `--remove` option has no effect on non-Windows platforms.

- `--usage`

| | |
|---------------------|----------------------|
| Command-Line Format | <code>--usage</code> |
|---------------------|----------------------|

Display help text and exit; same as `--help`.

- `--verbose, -v`

Causes extra debug output to be written to the node log.

You can also use `NODELOG DEBUG ON` and `NODELOG DEBUG OFF` to enable and disable this extra logging while the data node is running.

- `--version`

| | |
|---------------------|------------------------|
| Command-Line Format | <code>--version</code> |
|---------------------|------------------------|

Display version information and exit.

`ndbd` generates a set of log files which are placed in the directory specified by `DataDir` in the `config.ini` configuration file.

These log files are listed below. `node_id` is and represents the node's unique identifier. For example, `ndb_2_error.log` is the error log generated by the data node whose node ID is 2.

- `ndb_node_id_error.log` is a file containing records of all crashes which the referenced `ndbd` process has encountered. Each record in this file contains a brief error string and a reference to a trace file for this crash. A typical entry in this file might appear as shown here:

```
Date/Time: Saturday 30 July 2004 - 00:20:01
Type of error: error
Message: Internal program error (failed ndbrequire)
Fault ID: 2341
Problem data: DbtupFixAlloc.cpp
Object of reference: DBTUP (Line: 173)
ProgramName: NDB Kernel
ProcessID: 14909
TraceFile: ndb_2_trace.log.2
***EOM***
```

Listings of possible `ndbd` exit codes and messages generated when a data node process shuts down prematurely can be found in [Data Node Error Messages](#).

Important

*The last entry in the error log file is not necessarily the newest one (nor is it likely to be). Entries in the error log are *not* listed in chronological order; rather, they correspond to the order of the trace files as determined in the*

`ndb_node_id_trace.log.next` file (see below). Error log entries are thus overwritten in a cyclical and not sequential fashion.

- `ndb_node_id_trace.log.trace_id` is a trace file describing exactly what happened just before the error occurred. This information is useful for analysis by the NDB Cluster development team.

It is possible to configure the number of these trace files that are created before old files are overwritten. `trace_id` is a number which is incremented for each successive trace file.

- `ndb_node_id_trace.log.next` is the file that keeps track of the next trace file number to be assigned.
- `ndb_node_id_out.log` is a file containing any data output by the `ndbd` process. This file is created only if `ndbd` is started as a daemon, which is the default behavior.
- `ndb_node_id.pid` is a file containing the process ID of the `ndbd` process when started as a daemon. It also functions as a lock file to avoid the starting of nodes with the same identifier.
- `ndb_node_id_signal.log` is a file used only in debug versions of `ndbd`, where it is possible to trace all incoming, outgoing, and internal messages with their data in the `ndbd` process.

It is recommended not to use a directory mounted through NFS because in some environments this can cause problems whereby the lock on the `.pid` file remains in effect even after the process has terminated.

To start `ndbd`, it may also be necessary to specify the host name of the management server and the port on which it is listening. Optionally, one may also specify the node ID that the process is to use.

```
shell> ndbd --connect-string="nodeid=2;host=ndb_mgmd.mysql.com:1186"
```

See [Section 23.4.3.3, “NDB Cluster Connection Strings”](#), for additional information about this issue. For more information about data node configuration parameters, see [Section 23.4.3.6, “Defining NDB Cluster Data Nodes”](#).

When `ndbd` starts, it actually initiates two processes. The first of these is called the “angel process”; its only job is to discover when the execution process has been completed, and then to restart the `ndbd` process if it is configured to do so. Thus, if you attempt to kill `ndbd` using the Unix `kill` command, it is necessary to kill both processes, beginning with the angel process. The preferred method of terminating an `ndbd` process is to use the management client and stop the process from there.

The execution process uses one thread for reading, writing, and scanning data, as well as all other activities. This thread is implemented asynchronously so that it can easily handle thousands of concurrent actions. In addition, a watch-dog thread supervises the execution thread to make sure that it does not hang in an endless loop. A pool of threads handles file I/O, with each thread able to handle one open file. Threads can also be used for transporter connections by the transporters in the `ndbd` process. In a multi-processor system performing a large number of operations (including updates), the `ndbd` process can consume up to 2 CPUs if permitted to do so.

For a machine with many CPUs it is possible to use several `ndbd` processes which belong to different node groups; however, such a configuration is still considered experimental and is not supported for MySQL 8.0 in a production setting. See [Section 23.2.7, “Known Limitations of NDB Cluster”](#).

23.5.2 ndbinfo_select_all — Select From ndbinfo Tables

`ndbinfo_select_all` is a client program that selects all rows and columns from one or more tables in the `ndbinfo` database

Not all `ndbinfo` tables available in the `mysql` client can be read by this program. In addition, `ndbinfo_select_all` can show information about some tables internal to `ndbinfo` which cannot be accessed using SQL, including the `tables` and `columns` metadata tables.

To select from one or more `ndbinfo` tables using `ndbinfo_select_all`, it is necessary to supply the names of the tables when invoking the program as shown here:

```
shell> ndbinfo_select_all table_name1 [table_name2] [...]
```

For example:

```
shell> ndbinfo_select_all logbuffers logspaces
== logbuffers ==
node_id log_type      log_id  log_part      total  used   high
5      0      0      0      33554432    262144  0
6      0      0      0      33554432    262144  0
7      0      0      0      33554432    262144  0
8      0      0      0      33554432    262144  0
== logspaces ==
node_id log_type      log_id  log_part      total  used   high
5      0      0      0      268435456   0      0
5      0      0      1      268435456   0      0
5      0      0      2      268435456   0      0
5      0      0      3      268435456   0      0
6      0      0      0      268435456   0      0
6      0      0      1      268435456   0      0
6      0      0      2      268435456   0      0
6      0      0      3      268435456   0      0
7      0      0      0      268435456   0      0
7      0      0      1      268435456   0      0
7      0      0      2      268435456   0      0
7      0      0      3      268435456   0      0
8      0      0      0      268435456   0      0
8      0      0      1      268435456   0      0
8      0      0      2      268435456   0      0
8      0      0      3      268435456   0      0
shell>
```

Options that can be used with `ndbinfo_select_all` are shown in the following table. Additional descriptions follow the table.

Table 23.25 Command-line options used with the program `ndbinfo_select_all`

| Format | Description | Added, Deprecated, or Removed |
|---|---|--|
| <code>--character-sets-dir=path</code> | Directory containing character sets | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-retries=#</code> | Number of times to retry connection before giving up | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-retry-delay=#</code> | Number of seconds to wait between attempts to contact management server | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-string=connection-string,</code> <code>-c</code> | Same as <code>--ndb-connectstring</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--core-file</code> | Write core file on error; used in debugging | (Supported in all NDB releases based on MySQL 8.0) |

| Format | Description | Added, Deprecated, or Removed |
|--|--|--|
| <code>--database=db_name,</code> <code>-d</code> | Name of database where table is located | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-extra-file=path</code> | Read given file after global files are read | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-file=path</code> | Read default options from given file only | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-group-suffix=string</code> | Also read groups with <code>concat(group, suffix)</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--delay=#</code> | Set delay in seconds between loops | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--help,</code> <code>-?</code> | Display help text and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--login-path=path</code> | Read given path from login file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--loops=#,</code> <code>-l</code> | Set number of times to perform select | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-connectstring=connection-string,</code> <code>-c</code> | Set connect string for connecting to <code>ndb_mgmd</code> . Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in <code>NDB_CONNECTSTRING</code> and <code>my.cnf</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-mgmd-host=connection-string,</code> <code>-c</code> | Same as <code>--ndb-connectstring</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-nodeid=#</code> | Set node ID for this node, overriding any ID set by <code>--ndb-connectstring</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--no-defaults</code> | Do not read default options from any option file other than login file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-optimized-node-selection</code> | Enable optimizations for selection of nodes for transactions. Enabled by default; use <code>--skip-ndb-optimized-node-selection</code> to disable | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--parallelism=#,</code> <code>-p</code> | Set degree of parallelism | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--print-defaults</code> | Print program argument list and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--usage,</code> | Display help text and exit; same as <code>--help</code> | (Supported in all NDB releases based on MySQL 8.0) |

| Format | Description | Added, Deprecated, or Removed |
|------------------------|--------------------------------------|--|
| -? --version, -V | Display version information and exit | (Supported in all NDB releases based on MySQL 8.0) |

- `--character-sets-dir`

| | |
|---------------------|--|
| Command-Line Format | <code>--character-sets-dir=path</code> |
|---------------------|--|

Directory containing character sets.

- `--core-file`

| | |
|---------------------|--------------------------|
| Command-Line Format | <code>--core-file</code> |
|---------------------|--------------------------|

Write core file on error; used in debugging.

- `--connect-retries`

| | |
|---------------------|----------------------------------|
| Command-Line Format | <code>--connect-retries=#</code> |
| Type | Integer |
| Default Value | 12 |
| Minimum Value | 0 |
| Maximum Value | 12 |

Number of times to retry connection before giving up.

- `--connect-retry-delay`

| | |
|---------------------|--------------------------------------|
| Command-Line Format | <code>--connect-retry-delay=#</code> |
| Type | Integer |
| Default Value | 5 |
| Minimum Value | 0 |
| Maximum Value | 5 |

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

| | |
|---------------------|---|
| Command-Line Format | <code>--connect-string=connection-string</code> |
| Type | String |
| Default Value | [none] |

Same as `--ndb-connectstring`.

- `--defaults-extra-file`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-extra-file=path</code> |
|---------------------|---|

| | |
|---------------|--------|
| Type | String |
| Default Value | [none] |

Read given file after global files are read.

- `--defaults-file`

| | |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--defaults-file=path</code> |
| Type | String |
| Default Value | [none] |

Read default options from given file only.

- `--defaults-group-suffix`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-group-suffix=string</code> |
| Type | String |
| Default Value | [none] |

Also read groups with `concat(group, suffix)`.

- `--delay=seconds`

| | |
|---------------------|------------------------|
| Command-Line Format | <code>--delay=#</code> |
| Type | Numeric |
| Default Value | 5 |
| Minimum Value | 0 |
| Maximum Value | MAX_INT |

This option sets the number of seconds to wait between executing loops. Has no effect if `--loops` is set to 0 or 1.

- `--help`

| | |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
|---------------------|---------------------|

Display help text and exit.

- `--login-path`

| | |
|---------------------|--------------------------------|
| Command-Line Format | <code>--login-path=path</code> |
| Type | String |
| Default Value | [none] |

Read given path from login file.

- `--loops=number, -l number`

| | |
|---------------------|------------------------|
| Command-Line Format | <code>--loops=#</code> |
| Type | Numeric |

| | |
|---------------|---------|
| Default Value | 1 |
| Minimum Value | 0 |
| Maximum Value | MAX_INT |

This option sets the number of times to execute the select. Use `--delay` to set the time between loops.

- `--ndb-connectstring`

| | |
|---------------------|--|
| Command-Line Format | <code>--ndb-connectstring=connection-string</code> |
| Type | String |
| Default Value | [none] |

Set connect string for connecting to `ndb_mgmd`. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in `NDB_CONNECTSTRING` and `my.cnf`.

- `--ndb-mgmd-host`

| | |
|---------------------|--|
| Command-Line Format | <code>--ndb-mgmd-host=connection-string</code> |
| Type | String |
| Default Value | [none] |

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

| | |
|---------------------|-----------------------------|
| Command-Line Format | <code>--ndb-nodeid=#</code> |
| Type | Integer |
| Default Value | [none] |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

| | |
|---------------------|---|
| Command-Line Format | <code>--ndb-optimized-node-selection</code> |
|---------------------|---|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--no-defaults`

| | |
|---------------------|----------------------------|
| Command-Line Format | <code>--no-defaults</code> |
|---------------------|----------------------------|

Do not read default options from any option file other than login file.

- `--print-defaults`

| | |
|---------------------|-------------------------------|
| Command-Line Format | <code>--print-defaults</code> |
|---------------------|-------------------------------|

- `--usage`

| | |
|---------------------|----------------------|
| Command-Line Format | <code>--usage</code> |
|---------------------|----------------------|

Display help text and exit; same as `--help`.

- `--version`

| | |
|---------------------|------------------------|
| Command-Line Format | <code>--version</code> |
|---------------------|------------------------|

Display version information and exit.

23.5.3 ndbmttd — The NDB Cluster Data Node Daemon (Multi-Threaded)

`ndbmttd` is a multithreaded version of `ndbd`, the process that is used to handle all the data in tables using the `NDBCLUSTER` storage engine. `ndbmttd` is intended for use on host computers having multiple CPU cores. Except where otherwise noted, `ndbmttd` functions in the same way as `ndbd`; therefore, in this section, we concentrate on the ways in which `ndbmttd` differs from `ndbd`, and you should consult [Section 23.5.1, “ndbd — The NDB Cluster Data Node Daemon”](#), for additional information about running NDB Cluster data nodes that apply to both the single-threaded and multithreaded versions of the data node process.

Command-line options and configuration parameters used with `ndbd` also apply to `ndbmttd`. For more information about these options and parameters, see [Section 23.5.1, “ndbd — The NDB Cluster Data Node Daemon”](#), and [Section 23.4.3.6, “Defining NDB Cluster Data Nodes”](#), respectively.

`ndbmttd` is also file system-compatible with `ndbd`. In other words, a data node running `ndbd` can be stopped, the binary replaced with `ndbmttd`, and then restarted without any loss of data. (However, when doing this, you must make sure that `MaxNoOfExecutionThreads` is set to an appropriate value before restarting the node if you wish for `ndbmttd` to run in multithreaded fashion.) Similarly, an `ndbmttd` binary can be replaced with `ndbd` simply by stopping the node and then starting `ndbd` in place of the multithreaded binary. It is not necessary when switching between the two to start the data node binary using `--initial`.

Using `ndbmttd` differs from using `ndbd` in two key respects:

1. Because `ndbmttd` runs by default in single-threaded mode (that is, it behaves like `ndbd`), you must configure it to use multiple threads. This can be done by setting an appropriate value in the `config.ini` file for the `MaxNoOfExecutionThreads` configuration parameter or the `ThreadConfig` configuration parameter. Using `MaxNoOfExecutionThreads` is simpler, but `ThreadConfig` offers more flexibility. For more information about these configuration parameters and their use, see [Multi-Threading Configuration Parameters \(ndbmttd\)](#).
2. Trace files are generated by critical errors in `ndbmttd` processes in a somewhat different fashion from how these are generated by `ndbd` failures. These differences are discussed in more detail in the next few paragraphs.

Like `ndbd`, `ndbmttd` generates a set of log files which are placed in the directory specified by `DataDir` in the `config.ini` configuration file. Except for trace files, these are generated in the same way and have the same names as those generated by `ndbd`.

In the event of a critical error, `ndbmttd` generates trace files describing what happened just prior to the error's occurrence. These files, which can be found in the data node's `DataDir`, are useful for analysis of problems by the NDB Cluster Development and Support teams. One trace file is generated for each `ndbmttd` thread. The names of these files have the following pattern:

```
ndb_node_id_trace.log.trace_id_tthread_id,
```

In this pattern, *node_id* stands for the data node's unique node ID in the cluster, *trace_id* is a trace sequence number, and *thread_id* is the thread ID. For example, in the event of the failure of an `ndbmt_d` process running as an NDB Cluster data node having the node ID 3 and with `MaxNoOfExecutionThreads` equal to 4, four trace files are generated in the data node's data directory. If this is the first time this node has failed, then these files are named `ndb_3_trace.log.1_t1`, `ndb_3_trace.log.1_t2`, `ndb_3_trace.log.1_t3`, and `ndb_3_trace.log.1_t4`. Internally, these trace files follow the same format as `ndbd` trace files.

The `ndbd` exit codes and messages that are generated when a data node process shuts down prematurely are also used by `ndbmt_d`. See [Data Node Error Messages](#), for a listing of these.

Note

It is possible to use `ndbd` and `ndbmt_d` concurrently on different data nodes in the same NDB Cluster. However, such configurations have not been tested extensively; thus, we cannot recommend doing so in a production setting at this time.

23.5.4 ndb_mgmd — The NDB Cluster Management Server Daemon

The management server is the process that reads the cluster configuration file and distributes this information to all nodes in the cluster that request it. It also maintains a log of cluster activities. Management clients can connect to the management server and check the cluster's status.

All options that can be used with `ndb_mgmd` are shown in the following table. Additional descriptions follow the table.

Table 23.26 Command-line options used with the program `ndb_mgmd`

| Format | Description | Added, Deprecated, or Removed |
|--|---|--|
| <code>--bind-address=host</code> | Local bind address | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--character-sets-dir=path</code> | Directory containing character sets | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--cluster-config-suffix=name</code> | Override defaults group suffix when reading cluster_config sections in my.cnf file; used in testing | ADDED: NDB 8.0.24 |
| <code>--config-cache[=TRUE FALSE]</code> | Enable management server configuration cache; true by default | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--config-file=file,</code> <code>-f</code> | Specify cluster configuration file; also specify <code>--reload</code> or <code>--initial</code> to override configuration cache if present | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--configdir=directory,</code> <code>--config-dir=directory</code> | Specify cluster management server configuration cache directory | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-retries=#</code> | Number of times to retry connection before giving up | (Supported in all NDB releases based on MySQL 8.0) |

| Format | Description | Added, Deprecated, or Removed |
|--|--|--|
| <code>--connect-retry-delay=#</code> | Number of seconds to wait between attempts to contact management server | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-string=connection-string,</code> <code>-c</code> | Same as <code>--ndb-connectstring</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--core-file</code> | Write core file on error; used in debugging | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--daemon,</code> <code>-d</code> | Run <code>ndb_mgmd</code> in daemon mode (default) | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-extra-file=path</code> | Read given file after global files are read | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-file=path</code> | Read default options from given file only | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-group-suffix=string</code> | Also read groups with <code>concat(group, suffix)</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--help,</code> <code>-?</code> | Display help text and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--initial</code> | Causes management server to reload configuration data from configuration file, bypassing configuration cache | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--install[=name]</code> | Used to install management server process as Windows service; does not apply on other platforms | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--interactive</code> | Run <code>ndb_mgmd</code> in interactive mode (not officially supported in production; for testing purposes only) | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--log-name=name</code> | Name to use when writing cluster log messages applying to this node | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--login-path=path</code> | Read given path from login file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--mycnf</code> | Read cluster configuration data from <code>my.cnf</code> file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-connectstring=connection-string,</code> <code>-c</code> | Set connect string for connecting to <code>ndb_mgmd</code> . Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in <code>NDB_CONNECTSTRING</code> and <code>my.cnf</code> | (Supported in all NDB releases based on MySQL 8.0) |

| Format | Description | Added, Deprecated, or Removed |
|---|---|--|
| <code>--ndb-mgmd-host=connection-string,</code> | Same as <code>--ndb-connectstring</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>-c</code> | | |
| <code>--ndb-nodeid=#</code> | Set node ID for this node, overriding any ID set by <code>--ndb-connectstring</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-optimized-node-selection</code> | Enable optimizations for selection of nodes for transactions. Enabled by default; use <code>--skip-ndb-optimized-node-selection</code> to disable | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--no-defaults</code> | Do not read default options from any option file other than login file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--no-nodeid-checks</code> | Do not provide any node ID checks | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--nodaemon</code> | Do not run <code>ndb_mgmd</code> as a daemon | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--nowait-nodes=list</code> | Do not wait for management nodes specified when starting this management server; requires <code>--ndb-nodeid</code> option | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--print-defaults</code> | Print program argument list and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--print-full-config,</code> | Print full configuration and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>-P</code> | | |
| <code>--reload</code> | Causes management server to compare configuration file with configuration cache | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--remove[=name]</code> | Used to remove management server process that was previously installed as Windows service, optionally specifying name of service to be removed; does not apply on other platforms | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--usage,</code> | Display help text and exit; same as <code>--help</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>-?</code> | | |
| <code>--skip-config-file</code> | Do not use configuration file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--verbose,</code> | Write additional information to log | (Supported in all NDB releases based on MySQL 8.0) |
| <code>-v</code> | | |
| <code>--version,</code> | Display version information and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>-V</code> | | |

- `--bind-address=host`

| | |
|---------------------|----------------------------------|
| Command-Line Format | <code>--bind-address=host</code> |
| Type | String |
| Default Value | [none] |

Causes the management server to bind to a specific network interface (host name or IP address). This option has no default value.

- `--character-sets-dir`

| | |
|---------------------|--|
| Command-Line Format | <code>--character-sets-dir=path</code> |
|---------------------|--|

Directory containing character sets.

- `cluster-config-suffix`

| | |
|---------------------|---|
| Command-Line Format | <code>--cluster-config-suffix=name</code> |
| Introduced | 8.0.24-ndb-8.0.24 |
| Type | String |
| Default Value | [none] |

Override defaults group suffix when reading cluster configuration sections in `my.cnf`; used in testing.

- `--config-cache`

| | |
|---------------------|--|
| Command-Line Format | <code>--config-cache[=TRUE FALSE]</code> |
| Type | Boolean |
| Default Value | TRUE |

This option, whose default value is 1 (or TRUE, or ON), can be used to disable the management server's configuration cache, so that it reads its configuration from `config.ini` every time it starts (see [Section 23.4.3, “NDB Cluster Configuration Files”](#)). You can do this by starting the `ndb_mgmd` process with any one of the following options:

- `--config-cache=0`
- `--config-cache=FALSE`
- `--config-cache=OFF`
- `--skip-config-cache`

Using one of the options just listed is effective only if the management server has no stored configuration at the time it is started. If the management server finds any configuration cache files, then the `--config-cache` option or the `--skip-config-cache` option is ignored. Therefore, to disable configuration caching, the option should be used the *first* time that the management server is started. Otherwise—that is, if you wish to disable configuration caching for a management server that has *already* created a configuration cache—you must stop the management server, delete any existing

configuration cache files manually, then restart the management server with `--skip-config-cache` (or with `--config-cache` set equal to 0, `OFF`, or `FALSE`).

Configuration cache files are normally created in a directory named `mysql-cluster` under the installation directory (unless this location has been overridden using the `--configdir` option). Each time the management server updates its configuration data, it writes a new cache file. The files are named sequentially in order of creation using the following format:

```
ndb_node-id_config.bin.seq-number
```

`node-id` is the management server's node ID; `seq-number` is a sequence number, beginning with 1. For example, if the management server's node ID is 5, then the first three configuration cache files would, when they are created, be named `ndb_5_config.bin.1`, `ndb_5_config.bin.2`, and `ndb_5_config.bin.3`.

If your intent is to purge or reload the configuration cache without actually disabling caching, you should start `ndb_mgmd` with one of the options `--reload` or `--initial` instead of `--skip-config-cache`.

To re-enable the configuration cache, simply restart the management server, but without the `--config-cache` or `--skip-config-cache` option that was used previously to disable the configuration cache.

`ndb_mgmd` does not check for the configuration directory (`--configdir`) or attempts to create one when `--skip-config-cache` is used. (Bug #13428853)

- `--config-file=filename, -f filename`

| | |
|---------------------|---------------------------------|
| Command-Line Format | <code>--config-file=file</code> |
| Disabled by | <code>skip-config-file</code> |
| Type | File name |
| Default Value | [none] |

Instructs the management server as to which file it should use for its configuration file. By default, the management server looks for a file named `config.ini` in the same directory as the `ndb_mgmd` executable; otherwise the file name and location must be specified explicitly.

This option has no default value, and is ignored unless the management server is forced to read the configuration file, either because `ndb_mgmd` was started with the `--reload` or `--initial` option, or because the management server could not find any configuration cache.

The `--config-file` option is also read if `ndb_mgmd` was started with `--config-cache=OFF`. See [Section 23.4.3, “NDB Cluster Configuration Files”](#), for more information.

- `--configdir=dir_name`

| | |
|---------------------|---|
| Command-Line Format | <code>--configdir=directory</code> <code>--config-dir=directory</code> |
| Type | File name |

| | |
|---------------|---|
| Default Value | <code>\$INSTALLDIR/mysql-cluster</code> |
|---------------|---|

Specifies the cluster management server's configuration cache directory. `--config-dir` is an alias for this option.

In NDB 8.0.27 and later, this must be an absolute path. Otherwise, the management server refuses to start.

- `--connect-retries`

| | |
|---------------------|----------------------------------|
| Command-Line Format | <code>--connect-retries=#</code> |
| Type | Integer |
| Default Value | 12 |
| Minimum Value | 0 |
| Maximum Value | 12 |

Number of times to retry connection before giving up.

- `--connect-retry-delay`

| | |
|---------------------|--------------------------------------|
| Command-Line Format | <code>--connect-retry-delay=#</code> |
| Type | Integer |
| Default Value | 5 |
| Minimum Value | 0 |
| Maximum Value | 5 |

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

| | |
|---------------------|---|
| Command-Line Format | <code>--connect-string=connection-string</code> |
| Type | String |
| Default Value | [none] |

Same as `--ndb-connectstring`.

- `--core-file`

| | |
|---------------------|--------------------------|
| Command-Line Format | <code>--core-file</code> |
|---------------------|--------------------------|

Write core file on error; used in debugging.

- `--daemon, -d`

| | |
|---------------------|-----------------------|
| Command-Line Format | <code>--daemon</code> |
| Type | Boolean |
| Default Value | TRUE |

Instructs `ndb_mgmd` to start as a daemon process. This is the default behavior.

This option has no effect when running `ndb_mgmd` on Windows platforms.

- `--defaults-extra-file`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-extra-file=path</code> |
| Type | String |
| Default Value | [none] |

Read given file after global files are read.

- `--defaults-file`

| | |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--defaults-file=path</code> |
| Type | String |
| Default Value | [none] |

Read default options from given file only.

- `--defaults-group-suffix`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-group-suffix=string</code> |
| Type | String |
| Default Value | [none] |

Also read groups with `concat(group, suffix)`.

- `--help`

| | |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
|---------------------|---------------------|

Display help text and exit.

- `--initial`

| | |
|---------------------|------------------------|
| Command-Line Format | <code>--initial</code> |
| Type | Boolean |
| Default Value | FALSE |

Configuration data is cached internally, rather than being read from the cluster global configuration file each time the management server is started (see [Section 23.4.3, “NDB Cluster Configuration Files”](#)). Using the `--initial` option overrides this behavior, by forcing the management server to delete any existing cache files, and then to re-read the configuration data from the cluster configuration file and to build a new cache.

This differs in two ways from the `--reload` option. First, `--reload` forces the server to check the configuration file against the cache and reload its data only if the contents of the file are different from the cache. Second, `--reload` does not delete any existing cache files.

If `ndb_mgmd` is invoked with `--initial` but cannot find a global configuration file, the management server cannot start.

performing a rolling restart of an NDB Cluster with multiple management nodes. See [Section 23.6.5, “Performing a Rolling Restart of an NDB Cluster”](#), for more information.

When used together with the `--config-file` option, the cache is cleared only if the configuration file is actually found.

- `--install[=name]`

| | |
|---------------------|-------------------------------|
| Command-Line Format | <code>--install[=name]</code> |
| Platform Specific | Windows |
| Type | String |
| Default Value | <code>ndb_mgmd</code> |

Causes `ndb_mgmd` to be installed as a Windows service. Optionally, you can specify a name for the service; if not set, the service name defaults to `ndb_mgmd`. Although it is preferable to specify other `ndb_mgmd` program options in a `my.ini` or `my.cnf` configuration file, it is possible to use them together with `--install`. However, in such cases, the `--install` option must be specified first, before any other options are given, for the Windows service installation to succeed.

It is generally not advisable to use this option together with the `--initial` option, since this causes the configuration cache to be wiped and rebuilt every time the service is stopped and started. Care should also be taken if you intend to use any other `ndb_mgmd` options that affect the starting of the management server, and you should make absolutely certain you fully understand and allow for any possible consequences of doing so.

The `--install` option has no effect on non-Windows platforms.

- `--interactive`

| | |
|---------------------|----------------------------|
| Command-Line Format | <code>--interactive</code> |
| Type | Boolean |
| Default Value | <code>FALSE</code> |

Starts `ndb_mgmd` in interactive mode; that is, an `ndb_mgm` client session is started as soon as the management server is running. This option does not start any other NDB Cluster nodes.

- `--log-name=name`

| | |
|---------------------|------------------------------|
| Command-Line Format | <code>--log-name=name</code> |
| Type | String |
| Default Value | <code>MgmtSrvr</code> |

Provides a name to be used for this node in the cluster log.

- `--login-path`

| | |
|---------------------|--------------------------------|
| Command-Line Format | <code>--login-path=path</code> |
| Type | String |
| Default Value | <code>[none]</code> |

Read given path from login file.

- `--mycnf`

| | |
|---------------------|----------------------|
| Command-Line Format | <code>--mycnf</code> |
| Type | Boolean |
| Default Value | <code>FALSE</code> |

Read configuration data from the `my.cnf` file.

- `--ndb-connectstring`

| | |
|---------------------|--|
| Command-Line Format | <code>--ndb-connectstring=connection-string</code> |
| Type | String |
| Default Value | <code>[none]</code> |

Set connection string. Syntax: `[nodeid=id;][host=]hostname[:port]`. Overrides entries in `NDB_CONNECTSTRING` and `my.cnf`. Ignored if `--config-file` is specified; beginning with NDB 8.0.27, a warning is issued when both options are used.

- `--ndb-mgmd-host`

| | |
|---------------------|--|
| Command-Line Format | <code>--ndb-mgmd-host=connection-string</code> |
| Type | String |
| Default Value | <code>[none]</code> |

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

| | |
|---------------------|-----------------------------|
| Command-Line Format | <code>--ndb-nodeid=#</code> |
| Type | Integer |
| Default Value | <code>[none]</code> |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

| | |
|---------------------|---|
| Command-Line Format | <code>--ndb-optimized-node-selection</code> |
|---------------------|---|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--no-nodeid-checks`

| | |
|---------------------|---------------------------------|
| Command-Line Format | <code>--no-nodeid-checks</code> |
| Type | Boolean |
| Default Value | <code>FALSE</code> |

- `--nodaemon`

| | |
|---------------------|-------------------------|
| Command-Line Format | <code>--nodaemon</code> |
| Type | Boolean |
| Default Value | <code>FALSE</code> |

Instructs `ndb_mgmd` not to start as a daemon process.

The default behavior for `ndb_mgmd` on Windows is to run in the foreground, making this option unnecessary on Windows platforms.

- `--no-defaults`

| | |
|---------------------|----------------------------|
| Command-Line Format | <code>--no-defaults</code> |
|---------------------|----------------------------|

Do not read default options from any option file other than login file.

- `--nowait-nodes`

| | |
|---------------------|----------------------------------|
| Command-Line Format | <code>--nowait-nodes=list</code> |
| Type | Numeric |
| Default Value | <code>[none]</code> |
| Minimum Value | <code>1</code> |
| Maximum Value | <code>255</code> |

When starting an NDB Cluster is configured with two management nodes, each management server normally checks to see whether the other `ndb_mgmd` is also operational and whether the other management server's configuration is identical to its own. However, it is sometimes desirable to start the cluster with only one management node (and perhaps to allow the other `ndb_mgmd` to be started later). This option causes the management node to bypass any checks for any other management nodes whose node IDs are passed to this option, permitting the cluster to start as though configured to use only the management node that was started.

For purposes of illustration, consider the following portion of a `config.ini` file (where we have omitted most of the configuration parameters that are not relevant to this example):

```
[ndbd]
NodeId = 1
HostName = 198.51.100.101

[ndbd]
NodeId = 2
HostName = 198.51.100.102

[ndbd]
NodeId = 3
HostName = 198.51.100.103

[ndbd]
NodeId = 4
HostName = 198.51.100.104

[ndb_mgmd]
NodeId = 10
HostName = 198.51.100.150

[ndb_mgmd]
```

```

NodeId = 11
HostName = 198.51.100.151

[api]
NodeId = 20
HostName = 198.51.100.200

[api]
NodeId = 21
HostName = 198.51.100.201

```

Assume that you wish to start this cluster using only the management server having node ID 10 and running on the host having the IP address 198.51.100.150. (Suppose, for example, that the host computer on which you intend to the other management server is temporarily unavailable due to a hardware failure, and you are waiting for it to be repaired.) To start the cluster in this way, use a command line on the machine at 198.51.100.150 to enter the following command:

```
shell> ndb_mgmd --ndb-nodeid=10 --nowait-nodes=11
```

As shown in the preceding example, when using `--nowait-nodes`, you must also use the `--ndb-nodeid` option to specify the node ID of this `ndb_mgmd` process.

You can then start each of the cluster's data nodes in the usual way. If you wish to start and use the second management server in addition to the first management server at a later time without restarting the data nodes, you must start each data node with a connection string that references both management servers, like this:

```
shell> ndbd -c 198.51.100.150,198.51.100.151
```

The same is true with regard to the connection string used with any `mysqld` processes that you wish to start as NDB Cluster SQL nodes connected to this cluster. See [Section 23.4.3.3, “NDB Cluster Connection Strings”](#), for more information.

When used with `ndb_mgmd`, this option affects the behavior of the management node with regard to other management nodes only. Do not confuse it with the `--nowait-nodes` option used with `ndbd` or `ndbmt` to permit a cluster to start with fewer than its full complement of data nodes; when used with data nodes, this option affects their behavior only with regard to other data nodes.

Multiple management node IDs may be passed to this option as a comma-separated list. Each node ID must be no less than 1 and no greater than 255. In practice, it is quite rare to use more than two management servers for the same NDB Cluster (or to have any need for doing so); in most cases you need to pass to this option only the single node ID for the one management server that you do not wish to use when starting the cluster.

Note

When you later start the “missing” management server, its configuration must match that of the management server that is already in use by the cluster. Otherwise, it fails the configuration check performed by the existing management server, and does not start.

- `--print-defaults`

| | |
|---------------------|-------------------------------|
| Command-Line Format | <code>--print-defaults</code> |
|---------------------|-------------------------------|

Print program argument list and exit.

- `--print-full-config, -P`

| | |
|---------------------|----------------------------------|
| Command-Line Format | <code>--print-full-config</code> |
| Type | Boolean |
| Default Value | <code>FALSE</code> |

Shows extended information regarding the configuration of the cluster. With this option on the command line the `ndb_mgmd` process prints information about the cluster setup including an extensive list of the cluster configuration sections as well as parameters and their values. Normally used together with the `--config-file (-f)` option.

- `--reload`

| | |
|---------------------|-----------------------|
| Command-Line Format | <code>--reload</code> |
| Type | Boolean |
| Default Value | <code>FALSE</code> |

NDB Cluster configuration data is stored internally rather than being read from the cluster global configuration file each time the management server is started (see [Section 23.4.3, “NDB Cluster Configuration Files”](#)). Using this option forces the management server to check its internal data store against the cluster configuration file and to reload the configuration if it finds that the configuration file does not match the cache. Existing configuration cache files are preserved, but not used.

This differs in two ways from the `--initial` option. First, `--initial` causes all cache files to be deleted. Second, `--initial` forces the management server to re-read the global configuration file and construct a new cache.

If the management server cannot find a global configuration file, then the `--reload` option is ignored.

When `--reload` is used, the management server must be able to communicate with data nodes and any other management servers in the cluster before it attempts to read the global configuration file; otherwise, the management server fails to start. This can happen due to changes in the networking environment, such as new IP addresses for nodes or an altered firewall configuration. In such cases, you must use `--initial` instead to force the existing cached configuration to be discarded and reloaded from the file. See [Section 23.6.5, “Performing a Rolling Restart of an NDB Cluster”](#), for additional information.

- `--remove [=name]`

| | |
|---------------------|-------------------------------|
| Command-Line Format | <code>--remove [=name]</code> |
| Platform Specific | Windows |
| Type | String |
| Default Value | <code>ndb_mgmd</code> |

Remove a management server process that has been installed as a Windows service, optionally specifying the name of the service to be removed. Applies only to Windows platforms.

- `--skip-config-file`

| | |
|---------------------|---------------------------------|
| Command-Line Format | <code>--skip-config-file</code> |
| Type | Boolean |

| | |
|---------------|-------|
| Default Value | FALSE |
|---------------|-------|

Do not read cluster configuration file; ignore `--initial` and `--reload` options if specified.

- `--usage`

| | |
|---------------------|----------------------|
| Command-Line Format | <code>--usage</code> |
|---------------------|----------------------|

Display help text and exit; same as `--help`.

- `--verbose, -v`

| | |
|---------------------|------------------------|
| Command-Line Format | <code>--verbose</code> |
| Type | Boolean |
| Default Value | FALSE |

Remove a management server process that has been installed as a Windows service, optionally specifying the name of the service to be removed. Applies only to Windows platforms.

- `--version`

| | |
|---------------------|------------------------|
| Command-Line Format | <code>--version</code> |
|---------------------|------------------------|

Display version information and exit.

It is not strictly necessary to specify a connection string when starting the management server. However, if you are using more than one management server, a connection string should be provided and each node in the cluster should specify its node ID explicitly.

See [Section 23.4.3.3, “NDB Cluster Connection Strings”](#), for information about connection strings. [Section 23.5.4, “ndb_mgmd — The NDB Cluster Management Server Daemon”](#), describes other options for `ndb_mgmd`.

The following files are created or used by `ndb_mgmd` in its starting directory, and are placed in the `DataDir` as specified in the `config.ini` configuration file. In the list that follows, `node_id` is the unique node identifier.

- `config.ini` is the configuration file for the cluster as a whole. This file is created by the user and read by the management server. [Section 23.4, “Configuration of NDB Cluster”](#), discusses how to set up this file.
- `ndb_node_id_cluster.log` is the cluster events log file. Examples of such events include checkpoint startup and completion, node startup events, node failures, and levels of memory usage. A complete listing of cluster events with descriptions may be found in [Section 23.6, “Management of NDB Cluster”](#).

By default, when the size of the cluster log reaches one million bytes, the file is renamed to `ndb_node_id_cluster.log.seq_id`, where `seq_id` is the sequence number of the cluster log file. (For example: If files with the sequence numbers 1, 2, and 3 already exist, the next log file is named using the number 4.) You can change the size and number of files, and other characteristics of the cluster log, using the `LogDestination` configuration parameter.

- `ndb_node_id_out.log` is the file used for `stdout` and `stderr` when running the management server as a daemon.
- `ndb_node_id.pid` is the process ID file used when running the management server as a daemon.

23.5.5 ndb_mgm — The NDB Cluster Management Client

The `ndb_mgm` management client process is actually not needed to run the cluster. Its value lies in providing a set of commands for checking the cluster's status, starting backups, and performing other administrative functions. The management client accesses the management server using a C API. Advanced users can also employ this API for programming dedicated management processes to perform tasks similar to those performed by `ndb_mgm`.

To start the management client, it is necessary to supply the host name and port number of the management server:

```
shell> ndb_mgm [host_name [port_num]]
```

For example:

```
shell> ndb_mgm ndb_mgmd.mysql.com 1186
```

The default host name and port number are `localhost` and 1186, respectively.

All options that can be used with `ndb_mgm` are shown in the following table. Additional descriptions follow the table.

Table 23.27 Command-line options used with the program `ndb_mgm`

| Format | Description | Added, Deprecated, or Removed |
|---|--|--|
| <code>--backup-password-from-stdin[=value]</code> | Get decryption password in a secure fashion from STDIN; use together with <code>--execute</code> and <code>START BACKUP</code> command | ADDED: NDB 8.0.24 |
| <code>--character-sets-dir=path</code> | Directory containing character sets | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-retries=#</code> | Set number of times to retry connection before giving up; 0 means 1 attempt only (and no retries) | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-retry-delay=#</code> | Number of seconds to wait between attempts to contact management server | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-string=connection-string,</code> <code>-c</code> | Same as <code>--ndb-connectstring</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--core-file</code> | Write core file on error; used in debugging | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-extra-file=path</code> | Read given file after global files are read | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-file=path</code> | Read default options from given file only | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-group-suffix=string</code> | Also read groups with <code>concat(group, suffix)</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--encrypt-backup[=TRUE FALSE]</code> | Cause <code>START BACKUP</code> to encrypt whenever making a | ADDED: NDB 8.0.24 |

| Format | Description | Added, Deprecated, or Removed |
|---|--|--|
| <code>--execute=name,</code> | backup, prompting for password if not supplied by user | |
| <code>-e</code> | Execute command and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--help,</code> | Display help text and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>-?</code> | | |
| <code>--login-path=path</code> | Read given path from login file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-connectstring=connection-string,</code> | Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;] [host=]hostname[:port]". | (Supported in all NDB releases based on MySQL 8.0) |
| <code>-c</code> | Overrides entries in NDB_CONNECTSTRING and my.cnf | |
| <code>--ndb-mgmd-host=connection-string,</code> | Same as --ndb-connectstring | (Supported in all NDB releases based on MySQL 8.0) |
| <code>-c</code> | | |
| <code>--ndb-nodeid=#</code> | Set node ID for this node, overriding any ID set by --ndb-connectstring | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-optimized-node-selection</code> | Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--no-defaults</code> | Do not read default options from any option file other than login file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--print-defaults</code> | Print program argument list and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--try-reconnect=#,</code> | Set number of times to retry connection before giving up; synonym for --connect-retries | (Supported in all NDB releases based on MySQL 8.0) |
| <code>-t</code> | | |
| <code>--usage,</code> | Display help text and exit; same as --help | (Supported in all NDB releases based on MySQL 8.0) |
| <code>-?</code> | | |
| <code>--version,</code> | Display version information and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>-V</code> | | |

- `--backup-password-from-stdin[=TRUE|FALSE]`

| | |
|---------------------|---|
| Command-Line Format | <code>--backup-password-from-stdin[=value]</code> |
| Introduced | 8.0.24-ndb-8.0.24 |

| | |
|---------------|---------|
| Type | Boolean |
| Default Value | FALSE |

This option enables input of the backup password from the system shell (`stdin`) when using `--execute "START BACKUP"` or similar to create a backup. Use of this option requires use of `--execute` as well.

- `--character-sets-dir`

| | |
|---------------------|--|
| Command-Line Format | <code>--character-sets-dir=path</code> |
|---------------------|--|

Directory containing character sets.

- `--connect-retries=#`

| | |
|---------------------|----------------------------------|
| Command-Line Format | <code>--connect-retries=#</code> |
| Type | Numeric |
| Default Value | 3 |
| Minimum Value | 0 |
| Maximum Value | 4294967295 |

This option specifies the number of times following the first attempt to retry a connection before giving up (the client always tries the connection at least once). The length of time to wait per attempt is set using `--connect-retry-delay`.

This option is synonymous with the `--try-reconnect` option, which is now deprecated.

- `--connect-retry-delay`

| | |
|---------------------|--------------------------------------|
| Command-Line Format | <code>--connect-retry-delay=#</code> |
| Type | Integer |
| Default Value | 5 |
| Minimum Value | 0 |
| Maximum Value | 5 |

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

| | |
|---------------------|---|
| Command-Line Format | <code>--connect-string=connection-string</code> |
| Type | String |
| Default Value | [none] |

Same as `--ndb-connectstring`.

- `--core-file`

| | | |
|---------------------|--------------------------|------|
| Command-Line Format | <code>--core-file</code> | 4351 |
|---------------------|--------------------------|------|

Write core file on error; used in debugging.

- `--defaults-extra-file`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-extra-file=path</code> |
| Type | String |
| Default Value | [none] |

Read given file after global files are read.

- `--defaults-file`

| | |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--defaults-file=path</code> |
| Type | String |
| Default Value | [none] |

Read default options from given file only.

- `--defaults-group-suffix`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-group-suffix=string</code> |
| Type | String |
| Default Value | [none] |

Also read groups with `concat(group, suffix)`.

- `--encrypt-backup`

| | |
|---------------------|---|
| Command-Line Format | <code>--encrypt-backup[=TRUE FALSE]</code> |
| Introduced | 8.0.24-ndb-8.0.24 |
| Type | Boolean |
| Default Value | TRUE |

When used, this option causes all backups to be encrypted. To make this happen whenever `ndb_mgm` is run, put the option in the `[ndb_mgm]` section of the `my.cnf` file.

- `--execute=command, -e command`

| | |
|---------------------|-----------------------------|
| Command-Line Format | <code>--execute=name</code> |
|---------------------|-----------------------------|

This option can be used to send a command to the NDB Cluster management client from the system shell. For example, either of the following is equivalent to executing `SHOW` in the management client:

```
shell> ndb_mgm -e "SHOW"
shell> ndb_mgm --execute="SHOW"
```

This is analogous to how the `--execute` or `-e` option works with the `mysql` command-line client. See [Section 4.2.2.1, “Using Options on the Command Line”](#).

Note

If the management client command to be passed using this option contains any space characters, then the command *must* be enclosed in quotation marks.

Either single or double quotation marks may be used. If the management client command contains no space characters, the quotation marks are optional.

- `--help`

| | |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
|---------------------|---------------------|

Display help text and exit.

- `--login-path`

| | |
|---------------------|--------------------------------|
| Command-Line Format | <code>--login-path=path</code> |
| Type | String |
| Default Value | [none] |

Read given path from login file.

- `--ndb-connectstring`

| | |
|---------------------|--|
| Command-Line Format | <code>--ndb-connectstring=connection-string</code> |
| Type | String |
| Default Value | [none] |

Set connect string for connecting to `ndb_mgmd`. Syntax: `[nodeid=id;][host=]hostname[:port]`. Overrides entries in `NDB_CONNECTSTRING` and `my.cnf`.

- `--ndb-nodeid`

| | |
|---------------------|-----------------------------|
| Command-Line Format | <code>--ndb-nodeid=#</code> |
| Type | Integer |
| Default Value | [none] |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-mgmd-host`

| | |
|---------------------|--|
| Command-Line Format | <code>--ndb-mgmd-host=connection-string</code> |
| Type | String |
| Default Value | [none] |

Same as `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

| | |
|---------------------|---|
| Command-Line Format | <code>--ndb-optimized-node-selection</code> |
|---------------------|---|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--no-defaults`

| | |
|---------------------|----------------------------|
| Command-Line Format | <code>--no-defaults</code> |
|---------------------|----------------------------|

Do not read default options from any option file other than login file.

- `--print-defaults`

| | |
|---------------------|-------------------------------|
| Command-Line Format | <code>--print-defaults</code> |
|---------------------|-------------------------------|

Print program argument list and exit.

- `--try-reconnect=number`

| | |
|---------------------|--------------------------------|
| Command-Line Format | <code>--try-reconnect=#</code> |
| Deprecated | Yes |
| Type | Numeric |
| Type | Integer |
| Default Value | 12 |
| Default Value | 3 |
| Minimum Value | 0 |
| Maximum Value | 4294967295 |

If the connection to the management server is broken, the node tries to reconnect to it every 5 seconds until it succeeds. By using this option, it is possible to limit the number of attempts to *number* before giving up and reporting an error instead.

This option is deprecated and subject to removal in a future release. Use `--connect-retries`, instead.

- `--usage`

| | |
|---------------------|----------------------|
| Command-Line Format | <code>--usage</code> |
|---------------------|----------------------|

Display help text and exit; same as `--help`.

- `--version`

| | |
|---------------------|------------------------|
| Command-Line Format | <code>--version</code> |
|---------------------|------------------------|

Display version information and exit.

Additional information about using `ndb_mgm` can be found in [Section 23.6.1, “Commands in the NDB Cluster Management Client”](#).

23.5.6 ndb_blob_tool — Check and Repair BLOB and TEXT columns of NDB Cluster Tables

This tool can be used to check for and remove orphaned BLOB column parts from NDB tables, as well as to generate a file listing any orphaned parts. It is sometimes useful in diagnosing and repairing corrupted or damaged NDB tables containing BLOB or TEXT columns.

The basic syntax for `ndb_blob_tool` is shown here:

```
ndb_blob_tool [options] table [column, ...]
```

Unless you use the `--help` option, you must specify an action to be performed by including one or more of the options `--check-orphans`, `--delete-orphans`, or `--dump-file`. These options cause `ndb_blob_tool` to check for orphaned BLOB parts, remove any orphaned BLOB parts, and generate a dump file listing orphaned BLOB parts, respectively, and are described in more detail later in this section.

You must also specify the name of a table when invoking `ndb_blob_tool`. In addition, you can optionally follow the table name with the (comma-separated) names of one or more `BLOB` or `TEXT` columns from that table. If no columns are listed, the tool works on all of the table's `BLOB` and `TEXT` columns. If you need to specify a database, use the `--database (-d)` option.

The `--verbose` option provides additional information in the output about the tool's progress.

All options that can be used with `ndb_mgmd` are shown in the following table. Additional descriptions follow the table.

Table 23.28 Command-line options used with the program `ndb_blob_tool`

| Format | Description | Added, Deprecated, or Removed |
|---|--|--|
| <code>--add-missing</code> | Write dummy blob parts to take place of those which are missing | ADDED: NDB 8.0.20 |
| <code>--character-sets-dir=path</code> | Directory containing character sets | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--check-missing</code> | Check for blobs having inline parts but missing one or more parts from parts table | ADDED: NDB 8.0.20 |
| <code>--check-orphans</code> | Check for blob parts having no corresponding inline parts | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-retries=#</code> | Number of times to retry connection before giving up | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-retry-delay=#</code> | Number of seconds to wait between attempts to contact management server | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-string=connection-string,</code> <code>-c</code> | Same as <code>--ndb-connectstring</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--core-file</code> | Write core file on error; used in debugging | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--database=db_name,</code> <code>-d</code> | Database to find the table in | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-extra-file=path</code> | Read given file after global files are read | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-file=path</code> | Read default options from given file only | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-group-suffix=string</code> | Also read groups with <code>concat(group, suffix)</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--delete-orphans</code> | Delete blob parts having no corresponding inline parts | (Supported in all NDB releases based on MySQL 8.0) |

| Format | Description | Added, Deprecated, or Removed |
|--|---|--|
| <code>--dump-file=file</code> | Write orphan keys to specified file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--help,</code> <code>-?</code> | Display help text and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--login-path=path</code> | Read given path from login file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-connectstring=connection-string,</code> <code>-c</code> | Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-mgmd-host=connection-string,</code> <code>-c</code> | Same as <code>--ndb-connectstring</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-nodeid=#</code> | Set node ID for this node, overriding any ID set by <code>--ndb-connectstring</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-optimized-node-selection</code> | Enable optimizations for selection of nodes for transactions. Enabled by default; use <code>--skip-ndb-optimized-node-selection</code> to disable | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--no-defaults</code> | Do not read default options from any option file other than login file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--print-defaults</code> | Print program argument list and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--usage,</code> <code>-?</code> | Display help text and exit; same as <code>--help</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--verbose,</code> <code>-v</code> | Verbose output | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--version,</code> <code>-V</code> | Display version information and exit | (Supported in all NDB releases based on MySQL 8.0) |

- `--add-missing`

| | |
|---------------------|----------------------------|
| Command-Line Format | <code>--add-missing</code> |
| Introduced | 8.0.20-ndb-8.0.20 |
| Type | Boolean |

| | |
|---------------|-------|
| Default Value | FALSE |
|---------------|-------|

For each inline part in NDB Cluster tables which has no corresponding BLOB part, write a dummy BLOB part of the required length, consisting of spaces.

- `--character-sets-dir`

| | |
|---------------------|--|
| Command-Line Format | <code>--character-sets-dir=path</code> |
|---------------------|--|

Directory containing character sets.

- `--check-missing`

| | |
|---------------------|------------------------------|
| Command-Line Format | <code>--check-missing</code> |
| Introduced | 8.0.20-ndb-8.0.20 |
| Type | Boolean |
| Default Value | FALSE |

Check for inline parts in NDB Cluster tables which have no corresponding BLOB parts.

- `--check-orphans`

| | |
|---------------------|------------------------------|
| Command-Line Format | <code>--check-orphans</code> |
| Type | Boolean |
| Default Value | FALSE |

Check for BLOB parts in NDB Cluster tables which have no corresponding inline parts.

- `--connect-retries`

| | |
|---------------------|----------------------------------|
| Command-Line Format | <code>--connect-retries=#</code> |
| Type | Integer |
| Default Value | 12 |
| Minimum Value | 0 |
| Maximum Value | 12 |

Number of times to retry connection before giving up.

- `--connect-retry-delay`

| | |
|---------------------|--------------------------------------|
| Command-Line Format | <code>--connect-retry-delay=#</code> |
| Type | Integer |
| Default Value | 5 |
| Minimum Value | 0 |
| Maximum Value | 5 |

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

| | |
|---------------------|---|
| Command-Line Format | <code>--connect-string=connection-string</code> |
| Type | String |
| Default Value | [none] |

Same as `--ndb-connectstring`.

- `--core-file`

| | |
|---------------------|--------------------------|
| Command-Line Format | <code>--core-file</code> |
|---------------------|--------------------------|

Write core file on error; used in debugging.

- `--database=db_name, -d`

| | |
|---------------------|---------------------------------|
| Command-Line Format | <code>--database=db_name</code> |
| Type | String |
| Default Value | [none] |

Specify the database to find the table in.

- `--defaults-extra-file`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-extra-file=path</code> |
| Type | String |
| Default Value | [none] |

Read given file after global files are read.

- `--defaults-file`

| | |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--defaults-file=path</code> |
| Type | String |
| Default Value | [none] |

Read default options from given file only.

- `--defaults-group-suffix`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-group-suffix=string</code> |
| Type | String |
| Default Value | [none] |

Also read groups with `concat(group, suffix)`.

- `--delete-orphans`

| | |
|---------------------|-------------------------------|
| Command-Line Format | <code>--delete-orphans</code> |
| Type | Boolean |
| Default Value | FALSE |

Remove BLOB parts from NDB Cluster tables which have no corresponding inline parts.

- `--dump-file=file`

| | |
|---------------------|-------------------------------|
| Command-Line Format | <code>--dump-file=file</code> |
| Type | File name |
| Default Value | [none] |

Writes a list of orphaned BLOB column parts to *file*. The information written to the file includes the table key and BLOB part number for each orphaned BLOB part.

- `--help`

| | |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
|---------------------|---------------------|

Display help text and exit.

- `--login-path`

| | |
|---------------------|--------------------------------|
| Command-Line Format | <code>--login-path=path</code> |
| Type | String |
| Default Value | [none] |

Read given path from login file.

- `--ndb-connectstring`

| | |
|---------------------|--|
| Command-Line Format | <code>--ndb-connectstring=connection-string</code> |
| Type | String |
| Default Value | [none] |

Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf.

- `--ndb-mgmd-host`

| | |
|---------------------|--|
| Command-Line Format | <code>--ndb-mgmd-host=connection-string</code> |
| Type | String |
| Default Value | [none] |

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

| | |
|---------------------|-----------------------------|
| Command-Line Format | <code>--ndb-nodeid=#</code> |
| Type | Integer |
| Default Value | [none] |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

| | |
|---------------------|---|
| Command-Line Format | <code>--ndb-optimized-node-selection</code> |
|---------------------|---|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--no-defaults`

| | |
|---------------------|----------------------------|
| Command-Line Format | <code>--no-defaults</code> |
|---------------------|----------------------------|

Do not read default options from any option file other than login file.

- `--print-defaults`

| | |
|---------------------|-------------------------------|
| Command-Line Format | <code>--print-defaults</code> |
|---------------------|-------------------------------|

Print program argument list and exit.

- `--usage`

| | |
|---------------------|----------------------|
| Command-Line Format | <code>--usage</code> |
|---------------------|----------------------|

Display help text and exit; same as `--help`.

- `--verbose`

| | |
|---------------------|------------------------|
| Command-Line Format | <code>--verbose</code> |
| Type | Boolean |
| Default Value | <code>FALSE</code> |

Provide extra information in the tool's output regarding its progress.

- `--version`

| | |
|---------------------|------------------------|
| Command-Line Format | <code>--version</code> |
|---------------------|------------------------|

Display version information and exit.

Example

First we create an NDB table in the `test` database, using the `CREATE TABLE` statement shown here:

```
USE test;

CREATE TABLE btest (
  c0 BIGINT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
  c1 TEXT,
  c2 BLOB
) ENGINE=NDB;
```

Then we insert a few rows into this table, using a series of statements similar to this one:

```
INSERT INTO btest VALUES (NULL, 'x', REPEAT('x', 1000));
```

When run with `--check-orphans` against this table, `ndb_blob_tool` generates the following output:

```
shell> ndb_blob_tool --check-orphans --verbose -d test btest
```

```
connected
processing 2 blobs
processing blob #0 c1 NDB$BLOB_19_1
NDB$BLOB_19_1: nextResult: res=1
total parts: 0
orphan parts: 0
processing blob #1 c2 NDB$BLOB_19_2
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=1
total parts: 10
orphan parts: 0
disconnected

NDBT_ProgramExit: 0 - OK
```

The tool reports that there are no NDB BLOB column parts associated with column `c1`, even though `c1` is a `TEXT` column. This is due to the fact that, in an NDB table, only the first 256 bytes of a `BLOB` or `TEXT` column value are stored inline, and only the excess, if any, is stored separately; thus, if there are no values using more than 256 bytes in a given column of one of these types, no `BLOB` column parts are created by NDB for this column. See [Section 11.7, “Data Type Storage Requirements”](#), for more information.

23.5.7 ndb_config — Extract NDB Cluster Configuration Information

This tool extracts current configuration information for data nodes, SQL nodes, and API nodes from one of a number of sources: an NDB Cluster management node, or its `config.ini` or `my.cnf` file. By default, the management node is the source for the configuration data; to override the default, execute `ndb_config` with the `--config-file` or `--mycnf` option. It is also possible to use a data node as the source by specifying its node ID with `--config_from_node=node_id`.

`ndb_config` can also provide an offline dump of all configuration parameters which can be used, along with their default, maximum, and minimum values and other information. The dump can be produced in either text or XML format; for more information, see the discussion of the `--configinfo` and `--xml` options later in this section).

You can filter the results by section (`DB`, `SYSTEM`, or `CONNECTIONS`) using one of the options `--nodes`, `--system`, or `--connections`.

All options that can be used with `ndb_config` are shown in the following table. Additional descriptions follow the table.

Table 23.29 Command-line options used with the program `ndb_config`

| Format | Description | Added, Deprecated, or Removed |
|---|---|--|
| <code>--character-sets-dir=path</code> | Directory containing character sets | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--cluster-config-suffix=name</code> | Override defaults group suffix when reading <code>cluster_config</code> sections in <code>my.cnf</code> file; used in testing | ADDED: NDB 8.0.24 |

| Format | Description | Added, Deprecated, or Removed |
|--|--|--|
| <code>--config-file=file_name</code> | Set the path to config.ini file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--config-from-node=#</code> | Obtain configuration data from the node having this ID (must be a data node) | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--configinfo</code> | Dumps information about all NDB configuration parameters in text format with default, maximum, and minimum values. Use with <code>--xml</code> to obtain XML output | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connections</code> | Print connections information ([tcp], [tcp default], [sci], [sci default], [shm], or [shm default] sections of cluster configuration file) only. Cannot be used with <code>--system</code> or <code>--nodes</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-retries=#</code> | Number of times to retry connection before giving up | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-retry-delay=#</code> | Number of seconds to wait between attempts to contact management server | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-string=connection-string,</code> | Same as <code>--ndb-connectstring</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>-c</code> | | |
| <code>--core-file</code> | Write core file on error; used in debugging | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-extra-file=path</code> | Read given file after global files are read | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-file=path</code> | Read default options from given file only | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-group-suffix=string</code> | Also read groups with <code>concat(group, suffix)</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--diff-default</code> | Print only configuration parameters that have non-default values | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--fields=string,</code> | Field separator | (Supported in all NDB releases based on MySQL 8.0) |
| <code>-f</code> | | |
| <code>--help,</code> | Display help text and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>-?</code> | | |
| <code>--host=name</code> | Specify host | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--login-path=path</code> | Read given path from login file | (Supported in all NDB releases based on MySQL 8.0) |

| Format | Description | Added, Deprecated, or Removed |
|--|---|--|
| <code>--mycnf</code> | Read configuration data from my.cnf file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-connectstring=connection-string,</code> <code>-c</code> | Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;] [host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-mgmd-host=connection-string,</code> <code>-c</code> | Same as --ndb-connectstring | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-nodeid=#</code> | Set node ID for this node, overriding any ID set by --ndb-connectstring | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-optimized-node-selection</code> | Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--no-defaults</code> | Do not read default options from any option file other than login file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--nodeid</code> | Get configuration of node with this ID | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--nodes</code> | Print node information ([ndbd] or [ndbd default] section of cluster configuration file) only. Cannot be used with --system or --connections | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--query=string,</code> <code>-q</code> | One or more query options (attributes) | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--query-all,</code> <code>-a</code> | Dumps all parameters and values to a single comma-delimited string | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--print-defaults</code> | Print program argument list and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--rows=string,</code> <code>-r</code> | Row separator | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--system</code> | Print SYSTEM section information only (see ndb_config --configinfo output). Cannot be used with --nodes or --connections | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--type=name</code> | Specify node type | (Supported in all NDB releases based on MySQL 8.0) |

| Format | Description | Added, Deprecated, or Removed |
|--|--|--|
| <code>--usage,</code> <code>-?</code> | Display help text and exit; same as <code>--help</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--version,</code> <code>-V</code> | Display version information and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--configinfo --xml</code> | Use <code>--xml</code> with <code>--configinfo</code> to obtain a dump of all NDB configuration parameters in XML format with default, maximum, and minimum values | (Supported in all NDB releases based on MySQL 8.0) |

- `cluster-config-suffix`

| | |
|---------------------|---|
| Command-Line Format | <code>--cluster-config-suffix=name</code> |
| Introduced | 8.0.24-ndb-8.0.24 |
| Type | String |
| Default Value | [none] |

Override defaults group suffix when reading cluster configuration sections in `my.cnf`; used in testing.

- `--configinfo`

The `--configinfo` option causes `ndb_config` to dump a list of each NDB Cluster configuration parameter supported by the NDB Cluster distribution of which `ndb_config` is a part, including the following information:

- A brief description of each parameter's purpose, effects, and usage
- The section of the `config.ini` file where the parameter may be used
- The parameter's data type or unit of measurement
- Where applicable, the parameter's default, minimum, and maximum values
- NDB Cluster release version and build information

By default, this output is in text format. Part of this output is shown here:

```
shell> ndb_config --configinfo

***** SYSTEM *****

Name (String)
Name of system (NDB Cluster)
MANDATORY

PrimaryMGMNode (Non-negative Integer)
Node id of Primary ndb_mgmd(MGM) node
Default: 0 (Min: 0, Max: 4294967039)

ConfigGenerationNumber (Non-negative Integer)
Configuration generation number
Default: 0 (Min: 0, Max: 4294967039)
```

```

***** DB *****

MaxNoOfSubscriptions (Non-negative Integer)
Max no of subscriptions (default 0 == MaxNoOfTables)
Default: 0 (Min: 0, Max: 4294967039)

MaxNoOfSubscribers (Non-negative Integer)
Max no of subscribers (default 0 == 2 * MaxNoOfTables)
Default: 0 (Min: 0, Max: 4294967039)

...

```

Use this option together with the `--xml` option to obtain output in XML format.

- `--config-file=path-to-file`

| | |
|---------------------|--------------------------------------|
| Command-Line Format | <code>--config-file=file_name</code> |
| Type | File name |
| Default Value | |

Gives the path to the management server's configuration file (`config.ini`). This may be a relative or absolute path. If the management node resides on a different host from the one on which `ndb_config` is invoked, then an absolute path must be used.

- `--config_from_node=#`

| | |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--config-from-node=#</code> |
| Type | Numeric |
| Default Value | <code>none</code> |
| Minimum Value | <code>1</code> |
| Maximum Value | <code>48</code> |

Obtain the cluster's configuration data from the data node that has this ID.

If the node having this ID is not a data node, `ndb_config` fails with an error. (To obtain configuration data from the management node instead, simply omit this option.)

- `--connections`

| | |
|---------------------|----------------------------|
| Command-Line Format | <code>--connections</code> |
| Type | Boolean |
| Default Value | <code>FALSE</code> |

Tells `ndb_config` to print `CONNECTIONS` information only—that is, information about parameters found in the `[tcp]`, `[tcp default]`, `[shm]`, or `[shm default]` sections of the cluster configuration file (see [Section 23.4.3.10](#), “NDB Cluster TCP/IP Connections”, and [Section 23.4.3.12](#), “NDB Cluster Shared-Memory Connections”, for more information).

This option is mutually exclusive with `--nodes` and `--system`; only one of these 3 options can be used.

- `--diff-default`

| | |
|---------------------|-----------------------------|
| Command-Line Format | <code>--diff-default</code> |
| Type | Boolean |

| | |
|---------------|-------|
| Default Value | FALSE |
|---------------|-------|

Print only configuration parameters that have non-default values.

- `--fields=delimiter, -f delimiter`

| | |
|---------------------|------------------------------|
| Command-Line Format | <code>--fields=string</code> |
| Type | String |
| Default Value | |

Specifies a *delimiter* string used to separate the fields in the result. The default is `,` (the comma character).

Note

If the *delimiter* contains spaces or escapes (such as `\n` for the linefeed character), then it must be quoted.

- `--host=hostname`

| | |
|---------------------|--------------------------|
| Command-Line Format | <code>--host=name</code> |
| Type | String |
| Default Value | |

Specifies the host name of the node for which configuration information is to be obtained.

Note

While the hostname `localhost` usually resolves to the IP address `127.0.0.1`, this may not necessarily be true for all operating platforms and configurations. This means that it is possible, when `localhost` is used in `config.ini`, for `ndb_config --host=localhost` to fail if `ndb_config` is run on a different host where `localhost` resolves to a different address (for example, on some versions of SUSE Linux, this is `127.0.0.2`). In general, for best results, you should use numeric IP addresses for all NDB Cluster configuration values relating to hosts, or verify that all NDB Cluster hosts handle `localhost` in the same fashion.

- `--mycnf`

| | |
|---------------------|----------------------|
| Command-Line Format | <code>--mycnf</code> |
| Type | Boolean |
| Default Value | FALSE |

Read configuration data from the `my.cnf` file.

- `--ndb-connectstring=connection_string, -c connection_string`

| | |
|---------------------|--|
| Command-Line Format | <code>--ndb-connectstring=connection-string</code> |
| Type | String |

| | |
|---------------|--------|
| Default Value | [none] |
|---------------|--------|

Specifies the connection string to use in connecting to the management server. The format for the connection string is the same as described in [Section 23.4.3.3, “NDB Cluster Connection Strings”](#), and defaults to `localhost:1186`.

- `--no-defaults`

| | |
|---------------------|----------------------------|
| Command-Line Format | <code>--no-defaults</code> |
|---------------------|----------------------------|

Do not read default options from any option file other than login file.

- `--nodeid=node_id`

| | |
|---------------------|-----------------------------|
| Command-Line Format | <code>--ndb-nodeid=#</code> |
| Type | Integer |
| Default Value | [none] |

Specify the node ID of the node for which configuration information is to be obtained.

- `--nodes`

| | |
|---------------------|----------------------|
| Command-Line Format | <code>--nodes</code> |
| Type | Boolean |
| Default Value | FALSE |

Tells `ndb_config` to print information relating only to parameters defined in an `[ndbd]` or `[ndbd default]` section of the cluster configuration file (see [Section 23.4.3.6, “Defining NDB Cluster Data Nodes”](#)).

This option is mutually exclusive with `--connections` and `--system`; only one of these 3 options can be used.

- `--query=query-options, -q query-options`

| | |
|---------------------|-----------------------------|
| Command-Line Format | <code>--query=string</code> |
| Type | String |
| Default Value | |

This is a comma-delimited list of *query options*—that is, a list of one or more node attributes to be returned. These include `nodeid` (node ID), `type` (node type—that is, `ndbd`, `mysqld`, or `ndb_mgmd`), and any configuration parameters whose values are to be obtained.

For example, `--query=nodeid,type,datamemory,datadir` returns the node ID, node type, `DataMemory`, and `DataDir` for each node.

Note

If a given parameter is not applicable to a certain type of node, then an empty string is returned for the corresponding value. See the examples later in this section for more information.

- `--query-all, -a`

| | |
|---------------------|--------------------------|
| Command-Line Format | <code>--query-all</code> |
| Type | String |
| Default Value | |

Returns a comma-delimited list of all query options (node attributes; note that this list is a single string).

- `--rows=separator, -r separator`

| | |
|---------------------|----------------------------|
| Command-Line Format | <code>--rows=string</code> |
| Type | String |
| Default Value | |

Specifies a *separator* string used to separate the rows in the result. The default is a space character.

Note

If the *separator* contains spaces or escapes (such as `\n` for the linefeed character), then it must be quoted.

- `--system`

| | |
|---------------------|-----------------------|
| Command-Line Format | <code>--system</code> |
| Type | Boolean |
| Default Value | <code>FALSE</code> |

Tells `ndb_config` to print `SYSTEM` information only. This consists of system variables that cannot be changed at run time; thus, there is no corresponding section of the cluster configuration file for them. They can be seen (prefixed with `***** SYSTEM *****`) in the output of `ndb_config --configinfo`.

This option is mutually exclusive with `--nodes` and `--connections`; only one of these 3 options can be used.

- `--type=node_type`

| | |
|---------------------|---|
| Command-Line Format | <code>--type=name</code> |
| Type | Enumeration |
| Default Value | <code>[none]</code> |
| Valid Values | <code>ndbd</code> <code>mysqld</code> <code>ndb_mgmd</code> |

Filters results so that only configuration values applying to nodes of the specified *node_type* (`ndbd`, `mysqld`, or `ndb_mgmd`) are returned.

- `--usage`, `--help`, or `-?`

| | |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
|---------------------|---------------------|

Causes `ndb_config` to print a list of available options, and then exit.

- `--version`, `-V`

| | |
|---------------------|------------------------|
| Command-Line Format | <code>--version</code> |
|---------------------|------------------------|

Causes `ndb_config` to print a version information string, and then exit.

- `--configinfo --xml`

| | |
|---------------------|---------------------------------|
| Command-Line Format | <code>--configinfo --xml</code> |
| Type | Boolean |
| Default Value | <code>false</code> |

Cause `ndb_config --configinfo` to provide output as XML by adding this option. A portion of such output is shown in this example:

```
shell> ndb_config --configinfo --xml

<configvariables protocolversion="1" ndbversionstring="5.7.35-ndb-7.5.24"
                 ndbversion="460032" ndbversionmajor="7" ndbversionminor="5"
                 ndbversionbuild="0">
  <section name="SYSTEM">
    <param name="Name" comment="Name of system (NDB Cluster)" type="string"
           mandatory="true"/>
    <param name="PrimaryMGMDNode" comment="Node id of Primary ndb_mgmd(MGM) node"
           type="unsigned" default="0" min="0" max="4294967039"/>
    <param name="ConfigGenerationNumber" comment="Configuration generation number"
           type="unsigned" default="0" min="0" max="4294967039"/>
  </section>
  <section name="MYSQLD" primarykeys="NodeId">
    <param name="wan" comment="Use WAN TCP setting as default" type="bool"
           default="false"/>
    <param name="HostName" comment="Name of computer for this node"
           type="string" default=""/>
    <param name="Id" comment="NodeId" type="unsigned" mandatory="true"
           min="1" max="255" deprecated="true"/>
    <param name="NodeId" comment="Number identifying application node (mysqld(API))"
           type="unsigned" mandatory="true" min="1" max="255"/>
    <param name="ExecuteOnComputer" comment="HostName" type="string"
           deprecated="true"/>
    ...
  </section>
  ...
</configvariables>
```

Note

Normally, the XML output produced by `ndb_config --configinfo --xml` is formatted using one line per element; we have added extra whitespace in the previous example, as well as the next one, for reasons of legibility. This should not make any difference to applications using this output, since most XML4369

processors either ignore nonessential whitespace as a matter of course, or can be instructed to do so.

The XML output also indicates when changing a given parameter requires that data nodes be restarted using the `--initial` option. This is shown by the presence of an `initial="true"` attribute in the corresponding `<param>` element. In addition, the restart type (`system` or `node`) is also shown; if a given parameter requires a system restart, this is indicated by the presence of a `restart="system"` attribute in the corresponding `<param>` element. For example, changing the value set for the `Diskless` parameter requires a system initial restart, as shown here (with the `restart` and `initial` attributes highlighted for visibility):

```
<param name="Diskless" comment="Run wo/ disk" type="bool" default="false"
      restart="system" initial="true"/>
```

Currently, no `initial` attribute is included in the XML output for `<param>` elements corresponding to parameters which do not require initial restarts; in other words, `initial="false"` is the default, and the value `false` should be assumed if the attribute is not present. Similarly, the default restart type is `node` (that is, an online or “rolling” restart of the cluster), but the `restart` attribute is included only if the restart type is `system` (meaning that all cluster nodes must be shut down at the same time, then restarted).

Deprecated parameters are indicated in the XML output by the `deprecated` attribute, as shown here:

```
<param name="NoOfDiskPagesToDiskAfterRestartACC" comment="DiskCheckpointSpeed"
      type="unsigned" default="20" min="1" max="4294967039" deprecated="true"/>
```

In such cases, the `comment` refers to one or more parameters that supersede the deprecated parameter. Similarly to `initial`, the `deprecated` attribute is indicated only when the parameter is deprecated, with `deprecated="true"`, and does not appear at all for parameters which are not deprecated. (Bug #21127135)

Parameters that are required are indicated with `mandatory="true"`, as shown here:

```
<param name="NodeId"
      comment="Number identifying application node (mysqld(API))"
      type="unsigned" mandatory="true" min="1" max="255"/>
```

In much the same way that the `initial` or `deprecated` attribute is displayed only for a parameter that requires an initial restart or that is deprecated, the `mandatory` attribute is included only if the given parameter is actually required.

Important

The `--xml` option can be used only with the `--configinfo` option. Using `--xml` without `--configinfo` fails with an error.

Unlike the options used with this program to obtain current configuration data, `--configinfo` and `--xml` use information obtained from the NDB Cluster sources when `ndb_config` was compiled. For this reason, no connection to a running NDB Cluster or access to a `config.ini` or `my.cnf` file is required for these two options.

- `--print-defaults`

| | |
|---------------------|-------------------------------|
| Command-Line Format | <code>--print-defaults</code> |
|---------------------|-------------------------------|

Print program argument list and exit.

- `--defaults-file`

| | |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--defaults-file=path</code> |
| Type | String |
| Default Value | [none] |

Read default options from given file only.

- `--defaults-extra-file`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-extra-file=path</code> |
| Type | String |
| Default Value | [none] |

Read given file after global files are read.

- `--defaults-group-suffix`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-group-suffix=string</code> |
| Type | String |
| Default Value | [none] |

Also read groups with `concat(group, suffix)`.

- `--login-path`

| | |
|---------------------|--------------------------------|
| Command-Line Format | <code>--login-path=path</code> |
| Type | String |
| Default Value | [none] |

Read given path from login file.

- `--help`

| | |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
|---------------------|---------------------|

Display help text and exit.

- `--connect-string`

| | |
|---------------------|---|
| Command-Line Format | <code>--connect-string=connection-string</code> |
| Type | String |
| Default Value | [none] |

Same as `--ndb-connectstring`.

- `--ndb-mgmd-host`

| | |
|---------------------|--|
| Command-Line Format | <code>--ndb-mgmd-host=connection-string</code> |
| Type | String |

| | |
|---------------|--------|
| Default Value | [none] |
|---------------|--------|

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

| | |
|---------------------|-----------------------------|
| Command-Line Format | <code>--ndb-nodeid=#</code> |
| Type | Integer |
| Default Value | [none] |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--core-file`

| | |
|---------------------|--------------------------|
| Command-Line Format | <code>--core-file</code> |
|---------------------|--------------------------|

Write core file on error; used in debugging.

- `--character-sets-dir`

| | |
|---------------------|--|
| Command-Line Format | <code>--character-sets-dir=path</code> |
|---------------------|--|

Directory containing character sets.

- `--connect-retries`

| | |
|---------------------|----------------------------------|
| Command-Line Format | <code>--connect-retries=#</code> |
| Type | Integer |
| Default Value | 12 |
| Minimum Value | 0 |
| Maximum Value | 12 |

Number of times to retry connection before giving up.

- `--connect-retry-delay`

| | |
|---------------------|--------------------------------------|
| Command-Line Format | <code>--connect-retry-delay=#</code> |
| Type | Integer |
| Default Value | 5 |
| Minimum Value | 0 |
| Maximum Value | 5 |

Number of seconds to wait between attempts to contact management server.

- `--ndb-optimized-node-selection`

| | |
|---------------------|---|
| Command-Line Format | <code>--ndb-optimized-node-selection</code> |
|---------------------|---|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

Combining other `ndb_config` options (such as `--query` or `--type`) with `--configinfo` (with or without the `--xml` option) is not supported. Currently, if you attempt to do so, the usual result is that all other options besides `--configinfo` or `--xml` are simply ignored. *However, this behavior is not guaranteed and is subject to change at any time.* In addition, since `ndb_config`, when used with the `--configinfo` option, does not access the NDB Cluster or read any files, trying to specify additional options such as `--ndb-connectstring` or `--config-file` with `--configinfo` serves no purpose.

Examples

1. To obtain the node ID and type of each node in the cluster:

```
shell> ./ndb_config --query=nodeid,type --fields=':' --rows='\n'
1:ndbd
2:ndbd
3:ndbd
4:ndbd
5:ndb_mgmd
6:mysqld
7:mysqld
8:mysqld
9:mysqld
```

In this example, we used the `--fields` options to separate the ID and type of each node with a colon character (:), and the `--rows` options to place the values for each node on a new line in the output.

2. To produce a connection string that can be used by data, SQL, and API nodes to connect to the management server:

```
shell> ./ndb_config --config-file=usr/local/mysql/cluster-data/config.ini \
--query=hostname,portnumber --fields=: --rows=, --type=ndb_mgmd
198.51.100.179:1186
```

3. This invocation of `ndb_config` checks only data nodes (using the `--type` option), and shows the values for each node's ID and host name, as well as the values set for its `DataMemory` and `DataDir` parameters:

```
shell> ./ndb_config --type=ndbd --query=nodeid,host,datememory,datadir -f ' : ' -r '\n'
1 : 198.51.100.193 : 83886080 : /usr/local/mysql/cluster-data
2 : 198.51.100.112 : 83886080 : /usr/local/mysql/cluster-data
3 : 198.51.100.176 : 83886080 : /usr/local/mysql/cluster-data
4 : 198.51.100.119 : 83886080 : /usr/local/mysql/cluster-data
```

In this example, we used the short options `-f` and `-r` for setting the field delimiter and row separator, respectively, as well as the short option `-q` to pass a list of parameters to be obtained.

4. To exclude results from any host except one in particular, use the `--host` option:

```
shell> ./ndb_config --host=198.51.100.176 -f : -r '\n' -q id,type
3:ndbd
5:ndb_mgmd
```

In this example, we also used the short form `-q` to determine the attributes to be queried.

Similarly, you can limit results to a node with a specific ID using the `--nodeid` option.

23.5.8 ndb_delete_all — Delete All Rows from an NDB Table

`ndb_delete_all` deletes all rows from the given NDB table. In some cases, this can be much faster than `DELETE` or even `TRUNCATE TABLE`.

Usage

```
ndb_delete_all -c connection_string tbl_name -d db_name
```

This deletes all rows from the table named *tbl_name* in the database named *db_name*. It is exactly equivalent to executing `TRUNCATE db_name.tbl_name` in MySQL.

Options that can be used with `ndb_delete_all` are shown in the following table. Additional descriptions follow the table.

Table 23.30 Command-line options used with the program `ndb_delete_all`

| Format | Description | Added, Deprecated, or Removed |
|--|--|--|
| <code>--character-sets-dir=path</code> | Directory containing character sets | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-retries=#</code> | Number of times to retry connection before giving up | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-retry-delay=#</code> | Number of seconds to wait between attempts to contact management server | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-string=connection-string,</code> <code>-c</code> | Same as <code>--ndb-connectstring</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--core-file</code> | Write core file on error; used in debugging | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--database=dbname,</code> <code>-d</code> | Name of the database in which the table is found | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-extra-file=path</code> | Read given file after global files are read | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-file=path</code> | Read default options from given file only | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-group-suffix=string</code> | Also read groups with <code>concat(group, suffix)</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--diskscan</code> | Run disk scan | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--help,</code> <code>-?</code> | Display help text and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--login-path=path</code> | Read given path from login file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-connectstring=connection-string,</code> <code>-c</code> | Set connect string for connecting to <code>ndb_mgmd</code> . Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in <code>NDB_CONNECTSTRING</code> and <code>my.cnf</code> | (Supported in all NDB releases based on MySQL 8.0) |

| Format | Description | Added, Deprecated, or Removed |
|---|---|--|
| <code>--ndb-mgmd-host=connection-string,</code> <code>-c</code> <code>--ndb-nodeid=#</code> | Same as <code>--ndb-connectstring</code> Set node ID for this node, overriding any ID set by <code>--ndb-connectstring</code> | (Supported in all NDB releases based on MySQL 8.0) (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-optimized-node-selection</code> | Enable optimizations for selection of nodes for transactions. Enabled by default; use <code>--skip-ndb-optimized-node-selection</code> to disable | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--no-defaults</code> | Do not read default options from any option file other than login file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--print-defaults</code> | Print program argument list and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--transactional,</code> <code>-t</code> | Perform the delete in a single transaction (may run out of operations) | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--tupscan</code> | Run tup scan | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--usage,</code> <code>-?</code> | Display help text and exit; same as <code>--help</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--version,</code> <code>-V</code> | Display version information and exit | (Supported in all NDB releases based on MySQL 8.0) |

- `--character-sets-dir`

| | |
|---------------------|--|
| Command-Line Format | <code>--character-sets-dir=path</code> |
|---------------------|--|

Directory containing character sets.

- `--connect-retries`

| | |
|---------------------|----------------------------------|
| Command-Line Format | <code>--connect-retries=#</code> |
| Type | Integer |
| Default Value | 12 |
| Minimum Value | 0 |
| Maximum Value | 12 |

Number of times to retry connection before giving up.

- `--connect-retry-delay`

| | |
|---------------------|--------------------------------------|
| Command-Line Format | <code>--connect-retry-delay=#</code> |
|---------------------|--------------------------------------|

| | |
|---------------|---------|
| Type | Integer |
| Default Value | 5 |
| Minimum Value | 0 |
| Maximum Value | 5 |

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

| | |
|---------------------|---|
| Command-Line Format | <code>--connect-string=connection-string</code> |
| Type | String |
| Default Value | [none] |

Same as `--ndb-connectstring`.

- `--core-file`

| | |
|---------------------|--------------------------|
| Command-Line Format | <code>--core-file</code> |
|---------------------|--------------------------|

Write core file on error; used in debugging.

- `--database, -d`

| | |
|---------------------|--------------------------------|
| Command-Line Format | <code>--database=dbname</code> |
| Type | String |
| Default Value | TEST_DB |

Name of the database containing the table to delete from.

- `--defaults-extra-file`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-extra-file=path</code> |
| Type | String |
| Default Value | [none] |

Read given file after global files are read.

- `--defaults-file`

| | |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--defaults-file=path</code> |
| Type | String |
| Default Value | [none] |

Read default options from given file only.

- `--defaults-group-suffix`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-group-suffix=string</code> |
| Type | String |
| Default Value | [none] |

Also read groups with `concat(group, suffix)`.

- `--diskscan`

| | |
|---------------------|-------------------------|
| Command-Line Format | <code>--diskscan</code> |
| Type | Boolean |
| Default Value | <code>FALSE</code> |

Run a disk scan.

- `--help`

| | |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
|---------------------|---------------------|

Display help text and exit.

- `--login-path`

| | |
|---------------------|--------------------------------|
| Command-Line Format | <code>--login-path=path</code> |
| Type | String |
| Default Value | <code>[none]</code> |

Read given path from login file.

- `--ndb-connectstring`

| | |
|---------------------|--|
| Command-Line Format | <code>--ndb-connectstring=connection-string</code> |
| Type | String |
| Default Value | <code>[none]</code> |

Set connect string for connecting to `ndb_mgmd`. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in `NDB_CONNECTSTRING` and `my.cnf`.

- `--ndb-mgmd-host`

| | |
|---------------------|--|
| Command-Line Format | <code>--ndb-mgmd-host=connection-string</code> |
| Type | String |
| Default Value | <code>[none]</code> |

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

| | |
|---------------------|-----------------------------|
| Command-Line Format | <code>--ndb-nodeid=#</code> |
| Type | Integer |
| Default Value | <code>[none]</code> |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

| | |
|---------------------|---|
| Command-Line Format | <code>--ndb-optimized-node-selection</code> |
|---------------------|---|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--no-defaults`

| | |
|---------------------|----------------------------|
| Command-Line Format | <code>--no-defaults</code> |
|---------------------|----------------------------|

Do not read default options from any option file other than login file.

- `--print-defaults`

| | |
|---------------------|-------------------------------|
| Command-Line Format | <code>--print-defaults</code> |
|---------------------|-------------------------------|

Print program argument list and exit.

- `--transactional, -t`

Use of this option causes the delete operation to be performed as a single transaction.

Warning

With very large tables, using this option may cause the number of operations available to the cluster to be exceeded.

- `--tupscan`

Run a tuple scan.

- `--usage`

| | |
|---------------------|----------------------|
| Command-Line Format | <code>--usage</code> |
|---------------------|----------------------|

Display help text and exit; same as `--help`.

- `--version`

| | |
|---------------------|------------------------|
| Command-Line Format | <code>--version</code> |
|---------------------|------------------------|

Display version information and exit.

In NDB 7.6 and earlier, this program printed `NDBT_ProgramExit - status` upon completion of its run, due to an unnecessary dependency on the `NDBT` testing library. This dependency has been removed in NDB 8.0, eliminating the extraneous output.

23.5.9 ndb_desc — Describe NDB Tables

`ndb_desc` provides a detailed description of one or more `NDB` tables.

Usage

```
ndb_desc -c connection_string tbl_name -d db_name [options]
ndb_desc -c connection_string index_name -d db_name -t tbl_name
```

Additional options that can be used with `ndb_desc` are listed later in this section.

Sample Output

MySQL table creation and population statements:

```
USE test;

CREATE TABLE fish (
  id INT NOT NULL AUTO_INCREMENT,
  name VARCHAR(20) NOT NULL,
  length_mm INT NOT NULL,
  weight_gm INT NOT NULL,

  PRIMARY KEY pk (id),
  UNIQUE KEY uk (name)
) ENGINE=NDB;

INSERT INTO fish VALUES
  (NULL, 'guppy', 35, 2), (NULL, 'tuna', 2500, 150000),
  (NULL, 'shark', 3000, 110000), (NULL, 'manta ray', 1500, 50000),
  (NULL, 'grouper', 900, 125000), (NULL, 'puffer', 250, 2500);
```

Output from `ndb_desc`:

```
shell> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 2
Fragment type: HashMapPartition
K Value: 6

1                4                4             32768                32768                   0

NDBT_ProgramExit: 0 - OK
```

Information about multiple tables can be obtained in a single invocation of `ndb_desc` by using their names, separated by spaces. All of the tables must be in the same database.

You can obtain additional information about a specific index using the `--table` (short form: `-t`) option and supplying the name of the index as the first argument to `ndb_desc`, as shown here:

```
shell> ./ndb_desc uk -d test -t fish
-- uk --
Version: 2
Base table: fish
Number of attributes: 1
Logging: 0
Index type: OrderedIndex
Index status: Retrieved
-- Attributes --
name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
-- IndexTable 10/uk --
Version: 2
Fragment type: FragUndefined
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: yes
Number of attributes: 2
Number of primary keys: 1
Length of frm data: 0
Max Rows: 0
Row Checksum: 1
Row GCI: 1
SingleUserMode: 2
ForceVarPart: 0
PartitionCount: 2
FragmentCount: 2
FragmentCountType: ONE_PER_LDM_PER_NODE
ExtraRowGciBits: 0
ExtraRowAuthorBits: 0
TableStatus: Retrieved
Table options:
-- Attributes --
name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
NDB$TNODE Unsigned [64] PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY
-- Indexes --
PRIMARY KEY(NDB$TNODE) - UniqueHashIndex
NDBT_ProgramExit: 0 - OK
```

When an index is specified in this way, the `--extra-partition-info` and `--extra-node-info` options have no effect.

The `Version` column in the output contains the table's schema object version. For information about interpreting this value, see [NDB Schema Object Versions](#).

Three of the table properties that can be set using `NDB_TABLE` comments embedded in `CREATE TABLE` and `ALTER TABLE` statements are also visible in `ndb_desc` output. The table's `FRAGMENT_COUNT_TYPE` is always shown in the `FragmentCountType` column. `READ_ONLY` and `FULLY_REPLICATED`, if set to 1, are shown in the `Table options` column. You can see this after executing the following `ALTER TABLE` statement in the `mysql` client:

```
mysql> ALTER TABLE fish COMMENT='NDB_TABLE=READ_ONLY=1,FULLY_REPLICATED=1';
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
+-----+-----+-----+
| Level | Code | Message
```

```

+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| Warning | 1296 | Got error 4503 'Table property is FRAGMENT_COUNT_TYPE=ONE_PER_LDM_PER_NODE but not in c
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
1 row in set (0.00 sec)

```

The warning is issued because `READ_ONLY=1` requires that the table's fragment count type is (or be set to) `ONE_PER_LDM_PER_NODE_GROUP`; NDB sets this automatically in such cases. You can check that the `ALTER TABLE` statement has the desired effect using `SHOW CREATE TABLE`:

```

mysql> SHOW CREATE TABLE fish\G
***** 1. row *****
      Table: fish
Create Table: CREATE TABLE `fish` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `name` varchar(20) NOT NULL,
  `length_mm` int(11) NOT NULL,
  `weight_gm` int(11) NOT NULL,
  PRIMARY KEY (`id`),
  UNIQUE KEY `uk` (`name`)
) ENGINE=ndbcluster DEFAULT CHARSET=latin1
COMMENT='NDB_TABLE=READ_BACKUP=1,FULLY_REPLICATED=1'
1 row in set (0.01 sec)

```

Because `FRAGMENT_COUNT_TYPE` was not set explicitly, its value is not shown in the comment text printed by `SHOW CREATE TABLE`. `ndb_desc`, however, displays the updated value for this attribute. The `Table options` column shows the binary properties just enabled. You can see this in the output shown here (emphasized text):

```

shell> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 4
Fragment type: HashMapPartition
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 4
Number of primary keys: 1
Length of frm data: 380
Max Rows: 0
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
PartitionCount: 1
FragmentCount: 1
FragmentCountType: ONE_PER_LDM_PER_NODE_GROUP
ExtraRowGciBits: 0
ExtraRowAuthorBits: 0
TableStatus: Retrieved
Table options: readbackup, fullyreplicated
HashMap: DEFAULT-HASHMAP-3840-1
-- Attributes --
id Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY DYNAMIC
length_mm Int NOT NULL AT=FIXED ST=MEMORY DYNAMIC
weight_gm Int NOT NULL AT=FIXED ST=MEMORY DYNAMIC
-- Indexes --
PRIMARY KEY(id) - UniqueHashIndex
PRIMARY(id) - OrderedIndex
uk(name) - OrderedIndex
uk$unique(name) - UniqueHashIndex
-- Per partition info --
Partition      Row count      Commit count      Frag fixed memory      Frag varsized memory      Extent_spa
NDBT_ProgramExit: 0 - OK

```

For more information about these table properties, see [Section 13.1.20.11, “Setting NDB_TABLE Options”](#).

The `Extent_space` and `Free extent_space` columns are applicable only to NDB tables having columns on disk; for tables having only in-memory columns, these columns always contain the value 0.

To illustrate their use, we modify the previous example. First, we must create the necessary Disk Data objects, as shown here:

```
CREATE LOGFILE GROUP lg_1
  ADD UNDOFILE 'undo_1.log'
  INITIAL_SIZE 16M
  UNDO_BUFFER_SIZE 2M
  ENGINE NDB;

ALTER LOGFILE GROUP lg_1
  ADD UNDOFILE 'undo_2.log'
  INITIAL_SIZE 12M
  ENGINE NDB;

CREATE TABLESPACE ts_1
  ADD DATAFILE 'data_1.dat'
  USE LOGFILE GROUP lg_1
  INITIAL_SIZE 32M
  ENGINE NDB;

ALTER TABLESPACE ts_1
  ADD DATAFILE 'data_2.dat'
  INITIAL_SIZE 48M
  ENGINE NDB;
```

(For more information on the statements just shown and the objects created by them, see [Section 23.6.10.1, “NDB Cluster Disk Data Objects”](#), as well as [Section 13.1.16, “CREATE LOGFILE GROUP Statement”](#), and [Section 13.1.21, “CREATE TABLESPACE Statement”](#).)

Now we can create and populate a version of the `fish` table that stores 2 of its columns on disk (deleting the previous version of the table first, if it already exists):

```
DROP TABLE IF EXISTS fish;

CREATE TABLE fish (
  id INT NOT NULL AUTO_INCREMENT,
  name VARCHAR(20) NOT NULL,
  length_mm INT NOT NULL,
  weight_gm INT NOT NULL,

  PRIMARY KEY pk (id),
  UNIQUE KEY uk (name)
) TABLESPACE ts_1 STORAGE DISK
ENGINE=NDB;

INSERT INTO fish VALUES
  (NULL, 'guppy', 35, 2), (NULL, 'tuna', 2500, 150000),
  (NULL, 'shark', 3000, 110000), (NULL, 'manta ray', 1500, 50000),
  (NULL, 'grouper', 900, 125000), (NULL, 'puffer', 250, 2500);
```

When run against this version of the table, `ndb_desc` displays the following output:

```
shell> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 1
Fragment type: HashMapPartition
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
```

```

Number of attributes: 4
Number of primary keys: 1
Length of frm data: 1001
Max Rows: 0
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
PartitionCount: 2
FragmentCount: 2
PartitionBalance: FOR_RP_BY_LDM
ExtraRowGciBits: 0
ExtraRowAuthorBits: 0
TableStatus: Retrieved
Table options: readbackup
HashMap: DEFAULT-HASHMAP-3840-2
Tablespace id: 16
Tablespace: ts_1
-- Attributes --
id Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
name Varchar(80;utf8mb4_0900_ai_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
length_mm Int NOT NULL AT=FIXED ST=DISK
weight_gm Int NOT NULL AT=FIXED ST=DISK
-- Indexes --
PRIMARY KEY(id) - UniqueHashIndex
PRIMARY(id) - OrderedIndex
uk(name) - OrderedIndex
uk$unique(name) - UniqueHashIndex
-- Per partition info --
Partition      Row count      Commit count      Frag fixed memory      Frag var sized memory      Extent_spa
0              2              2                 32768                  32768                      1048576
1              4              4                 32768                  32768                      1048576

NDBT_ProgramExit: 0 - OK

```

This means that 1048576 bytes are allocated from the tablespace for this table on each partition, of which 1044440 bytes remain free for additional storage. In other words, $1048576 - 1044440 = 4136$ bytes per partition is currently being used to store the data from this table's disk-based columns. The number of bytes shown as `Free extent_space` is available for storing on-disk column data from the `fish` table only; for this reason, it is not visible when selecting from the `INFORMATION_SCHEMA.FILES` table.

`Tablespace id` and `Tablespace` are displayed for Disk Data tables beginning with NDB 8.0.21.

For fully replicated tables, `ndb_desc` shows only the nodes holding primary partition fragment replicas; nodes with copy fragment replicas (only) are ignored. You can obtain such information, using the `mysql` client, from the `table_distribution_status`, `table_fragments`, `table_info`, and `table_replicas` tables in the `ndbinfo` database.

All options that can be used with `ndb_desc` are shown in the following table. Additional descriptions follow the table.

Table 23.31 Command-line options used with the program `ndb_desc`

| Format | Description | Added, Deprecated, or Removed |
|---|--|--|
| <code>--auto-inc</code> , <code>-a</code> | Show next value for AUTO_INCREMENT oolumn if table has one | ADDED: NDB 8.0.21 |
| <code>--blob-info</code> , <code>-b</code> | Include partition information for BLOB tables in output. Requires that the <code>-p</code> option also be used | (Supported in all NDB releases based on MySQL 8.0) |

| Format | Description | Added, Deprecated, or Removed |
|---|---|--|
| <code>--character-sets-dir=path</code> | Directory containing character sets | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-retries=#</code> | Number of times to retry connection before giving up | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-retry-delay=#</code> | Number of seconds to wait between attempts to contact management server | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-string=connection-string,</code> | Same as <code>--ndb-connectstring</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>-c</code> | | |
| <code>--context,</code> | Show extra information for table such as database, schema, name, internal ID | ADDED: NDB 8.0.21 |
| <code>-x</code> | | |
| <code>--core-file</code> | Write core file on error; used in debugging | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--database=dbname,</code> | Name of database containing table | (Supported in all NDB releases based on MySQL 8.0) |
| <code>-d</code> | | |
| <code>--defaults-extra-file=path</code> | Read given file after global files are read | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-file=path</code> | Read default options from given file only | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-group-suffix=string</code> | Also read groups with <code>concat(group, suffix)</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--extra-node-info,</code> | Include partition-to-data-node mappings in output. Requires that the <code>-p</code> option also be used | (Supported in all NDB releases based on MySQL 8.0) |
| <code>-n</code> | | |
| <code>--extra-partition-info,</code> | Display information about partitions | (Supported in all NDB releases based on MySQL 8.0) |
| <code>-p</code> | | |
| <code>--help,</code> | Display help text and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>-?</code> | | |
| <code>--login-path=path</code> | Read given path from login file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-connectstring=connection-string,</code> | Set connect string for connecting to <code>ndb_mgmd</code> . Syntax: "[nodeid=id;] [host=]hostname[:port]". Overrides entries in <code>NDB_CONNECTSTRING</code> and <code>my.cnf</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>-c</code> | | |
| <code>--ndb-mgmd-host=connection-string,</code> | Same as <code>--ndb-connectstring</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>-c</code> | | |

| Format | Description | Added, Deprecated, or Removed |
|---|---|--|
| <code>--ndb-nodeid=#</code> | Set node ID for this node, overriding any ID set by <code>--ndb-connectstring</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-optimized-node-selection</code> | Enable optimizations for selection of nodes for transactions. Enabled by default; use <code>--skip-ndb-optimized-node-selection</code> to disable | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--no-defaults</code> | Do not read default options from any option file other than login file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--print-defaults</code> | Print program argument list and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--retries=#,</code> <code>-r</code> | Number of times to retry the connection (once per second) | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--table=tbl_name,</code> <code>-t</code> | Specify the table in which to find an index. When this option is used, <code>-p</code> and <code>-n</code> have no effect and are ignored | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--unqualified,</code> <code>-u</code> | Use unqualified table names | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--usage,</code> <code>-?</code> | Display help text and exit; same as <code>--help</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--version,</code> <code>-V</code> | Display version information and exit | (Supported in all NDB releases based on MySQL 8.0) |

- `--auto-inc, -a`

Show the next value for a table's `AUTO_INCREMENT` column, if it has one.

- `--blob-info, -b`

Include information about subordinate `BLOB` and `TEXT` columns.

Use of this option also requires the use of the `--extra-partition-info (-p)` option.

- `--character-sets-dir`

| | |
|---------------------|--|
| Command-Line Format | <code>--character-sets-dir=path</code> |
|---------------------|--|

Directory containing character sets.

- `--connect-retries`

| | |
|---------------------|----------------------------------|
| Command-Line Format | <code>--connect-retries=#</code> |
| Type | Integer |
| Default Value | 12 |

| | |
|---------------|----|
| Minimum Value | 0 |
| Maximum Value | 12 |

Number of times to retry connection before giving up.

- `--connect-retry-delay`

| | |
|---------------------|--------------------------------------|
| Command-Line Format | <code>--connect-retry-delay=#</code> |
| Type | Integer |
| Default Value | 5 |
| Minimum Value | 0 |
| Maximum Value | 5 |

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

| | |
|---------------------|---|
| Command-Line Format | <code>--connect-string=connection-string</code> |
| Type | String |
| Default Value | [none] |

Same as `--ndb-connectstring`.

- `--context, -x`

Show additional contextual information for the table such as schema, database name, table name, and the table's internal ID.

- `--core-file`

| | |
|---------------------|--------------------------|
| Command-Line Format | <code>--core-file</code> |
|---------------------|--------------------------|

Write core file on error; used in debugging.

- `--database=db_name, -d`

Specify the database in which the table should be found.

- `--defaults-extra-file`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-extra-file=path</code> |
| Type | String |
| Default Value | [none] |

Read given file after global files are read.

- `--defaults-file`

| | |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--defaults-file=path</code> |
| Type | String |
| Default Value | [none] |

Read default options from given file only.

- `--defaults-group-suffix`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-group-suffix=string</code> |
| Type | String |
| Default Value | [none] |

Also read groups with `concat(group, suffix)`.

- `--extra-node-info, -n`

Include information about the mappings between table partitions and the data nodes upon which they reside. This information can be useful for verifying distribution awareness mechanisms and supporting more efficient application access to the data stored in NDB Cluster.

Use of this option also requires the use of the `--extra-partition-info (-p)` option.

- `--extra-partition-info, -p`

Print additional information about the table's partitions.

- `--help`

| | |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
|---------------------|---------------------|

Display help text and exit.

- `--login-path`

| | |
|---------------------|--------------------------------|
| Command-Line Format | <code>--login-path=path</code> |
| Type | String |
| Default Value | [none] |

Read given path from login file.

- `--ndb-connectstring`

| | |
|---------------------|--|
| Command-Line Format | <code>--ndb-connectstring=connection-string</code> |
| Type | String |
| Default Value | [none] |

Set connect string for connecting to `ndb_mgmd`. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in `NDB_CONNECTSTRING` and `my.cnf`.

- `--ndb-mgmd-host`

| | |
|---------------------|--|
| Command-Line Format | <code>--ndb-mgmd-host=connection-string</code> |
| Type | String |
| Default Value | [none] |

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

| | |
|---------------------|-----------------------------|
| Command-Line Format | <code>--ndb-nodeid=#</code> |
| Type | Integer |
| Default Value | [none] |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

| | |
|---------------------|---|
| Command-Line Format | <code>--ndb-optimized-node-selection</code> |
|---------------------|---|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--no-defaults`

| | |
|---------------------|----------------------------|
| Command-Line Format | <code>--no-defaults</code> |
|---------------------|----------------------------|

Do not read default options from any option file other than login file.

- `--print-defaults`

| | |
|---------------------|-------------------------------|
| Command-Line Format | <code>--print-defaults</code> |
|---------------------|-------------------------------|

Print program argument list and exit.

- `--retries=#, -r`

Try to connect this many times before giving up. One connect attempt is made per second.

- `--table=tbl_name, -t`

Specify the table in which to look for an index.

- `--unqualified, -u`

Use unqualified table names.

- `--usage`

| | |
|---------------------|----------------------|
| Command-Line Format | <code>--usage</code> |
|---------------------|----------------------|

Display help text and exit; same as `--help`.

- `--version`

| | |
|---------------------|------------------------|
| Command-Line Format | <code>--version</code> |
|---------------------|------------------------|

Display version information and exit.

`ndb_drop_index` drops the specified index from an NDB table. *It is recommended that you use this utility only as an example for writing NDB API applications*—see the Warning later in this section for details.

Usage

```
ndb_drop_index -c connection_string table_name index -d db_name
```

The statement shown above drops the index named *index* from the *table* in the *database*.

Options that can be used with `ndb_drop_index` are shown in the following table. Additional descriptions follow the table.

Table 23.32 Command-line options used with the program `ndb_drop_index`

| Format | Description | Added, Deprecated, or Removed |
|--|--|--|
| <code>--character-sets-dir=path</code> | Directory containing character sets | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-retries=#</code> | Number of times to retry connection before giving up | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-retry-delay=#</code> | Number of seconds to wait between attempts to contact management server | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-string=connection-string,</code> <code>-c</code> | Same as <code>--ndb-connectstring</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--core-file</code> | Write core file on error; used in debugging | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--database=dbname,</code> <code>-d</code> | Name of database in which table is found | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-extra-file=path</code> | Read given file after global files are read | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-file=path</code> | Read default options from given file only | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-group-suffix=string</code> | Also read groups with <code>concat(group, suffix)</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--help,</code> <code>-?</code> | Display help text and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--login-path=path</code> | Read given path from login file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-connectstring=connection-string,</code> <code>-c</code> | Set connect string for connecting to <code>ndb_mgmd</code> . Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in <code>NDB_CONNECTSTRING</code> and <code>my.cnf</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-mgmd-host=connection-string,</code> | Same as <code>--ndb-connectstring</code> | (Supported in all NDB releases based on MySQL 8.0) |

| Format | Description | Added, Deprecated, or Removed |
|--|---|--|
| <code>-c</code> <code>--ndb-nodeid=#</code> | Set node ID for this node, overriding any ID set by <code>--ndb-connectstring</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-optimized-node-selection</code> | Enable optimizations for selection of nodes for transactions. Enabled by default; use <code>--skip-ndb-optimized-node-selection</code> to disable | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--no-defaults</code> | Do not read default options from any option file other than login file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--print-defaults</code> | Print program argument list and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--usage,</code> <code>-?</code> | Display help text and exit; same as <code>--help</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--version,</code> <code>-V</code> | Display version information and exit | (Supported in all NDB releases based on MySQL 8.0) |

- `--character-sets-dir`

| | |
|---------------------|--|
| Command-Line Format | <code>--character-sets-dir=path</code> |
|---------------------|--|

Directory containing character sets.

- `--connect-retries`

| | |
|---------------------|----------------------------------|
| Command-Line Format | <code>--connect-retries=#</code> |
| Type | Integer |
| Default Value | 12 |
| Minimum Value | 0 |
| Maximum Value | 12 |

Number of times to retry connection before giving up.

- `--connect-retry-delay`

| | |
|---------------------|--------------------------------------|
| Command-Line Format | <code>--connect-retry-delay=#</code> |
| Type | Integer |
| Default Value | 5 |
| Minimum Value | 0 |
| Maximum Value | 5 |

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

| | |
|---------------------|---|
| Command-Line Format | <code>--connect-string=connection-string</code> |
| Type | String |
| Default Value | [none] |

Same as `--ndb-connectstring`.

- `--core-file`

| | |
|---------------------|--------------------------|
| Command-Line Format | <code>--core-file</code> |
|---------------------|--------------------------|

Write core file on error; used in debugging.

- `--database, -d`

| | |
|---------------------|--------------------------------|
| Command-Line Format | <code>--database=dbname</code> |
| Type | String |
| Default Value | TEST_DB |

Name of the database in which the table resides.

- `--defaults-extra-file`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-extra-file=path</code> |
| Type | String |
| Default Value | [none] |

Read given file after global files are read.

- `--defaults-file`

| | |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--defaults-file=path</code> |
| Type | String |
| Default Value | [none] |

Read default options from given file only.

- `--defaults-group-suffix`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-group-suffix=string</code> |
| Type | String |
| Default Value | [none] |

Also read groups with `concat(group, suffix)`.

- `--help`

| | |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
|---------------------|---------------------|

Display help text and exit.

- `--login-path`

| | |
|---------------------|--------------------------------|
| Command-Line Format | <code>--login-path=path</code> |
| Type | String |
| Default Value | [none] |

Read given path from login file.

- `--ndb-connectstring`

| | |
|---------------------|--|
| Command-Line Format | <code>--ndb-connectstring=connection-string</code> |
| Type | String |
| Default Value | [none] |

Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf.

- `--ndb-mgmd-host`

| | |
|---------------------|--|
| Command-Line Format | <code>--ndb-mgmd-host=connection-string</code> |
| Type | String |
| Default Value | [none] |

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

| | |
|---------------------|-----------------------------|
| Command-Line Format | <code>--ndb-nodeid=#</code> |
| Type | Integer |
| Default Value | [none] |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

| | |
|---------------------|---|
| Command-Line Format | <code>--ndb-optimized-node-selection</code> |
|---------------------|---|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--no-defaults`

| | |
|---------------------|----------------------------|
| Command-Line Format | <code>--no-defaults</code> |
|---------------------|----------------------------|

Do not read default options from any option file other than login file.

- `--print-defaults`

| | |
|---------------------|-------------------------------|
| Command-Line Format | <code>--print-defaults</code> |
|---------------------|-------------------------------|

Print program argument list and exit.

- `--usage`

| | |
|---------------------|----------------------|
| Command-Line Format | <code>--usage</code> |
|---------------------|----------------------|

Display help text and exit; same as `--help`.

- `--version`

| | |
|---------------------|------------------------|
| Command-Line Format | <code>--version</code> |
|---------------------|------------------------|

Display version information and exit.

Warning

Operations performed on Cluster table indexes using the NDB API are not visible to MySQL and make the table unusable by a MySQL server. If you use this program to drop an index, then try to access the table from an SQL node, an error results, as shown here:

```

shell> ./ndb_drop_index -c localhost dogs ix -d ctest1
Dropping index dogs/idx...OK

NDBT_ProgramExit: 0 - OK

shell> ./mysql -u jon -p ctest1
Enter password: *****
Reading table information for completion of table and column names
You can turn off this feature to get a quicker startup with -A

Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 7 to server version: 5.7.35-ndb-7.5.24

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SHOW TABLES;
+-----+
| Tables_in_ctest1 |
+-----+
| a                 |
| bt1               |
| bt2               |
| dogs              |
| employees         |
| fish              |
+-----+
6 rows in set (0.00 sec)

mysql> SELECT * FROM dogs;
ERROR 1296 (HY000): Got error 4243 'Index not found' from NDBCLUSTER
    
```

In such a case, your *only* option for making the table available to MySQL again is to drop the table and re-create it. You can use either the SQL statement `DROP TABLE` or the `ndb_drop_table` utility (see [Section 23.5.11, “ndb_drop_table — Drop an NDB Table”](#)) to drop the table.

23.5.11 ndb_drop_table — Drop an NDB Table

`ndb_drop_table` drops the specified NDB table. (If you try to use this on a table created with a storage engine other than NDB, the attempt fails with the error `723: No such table exists.`) This operation is extremely fast; in some cases, it can be an order of magnitude faster than using a MySQL `DROP TABLE` statement on an NDB table.

Usage

```
ndb_drop_table -c connection_string tbl_name -d db_name
```

Options that can be used with `ndb_drop_table` are shown in the following table. Additional descriptions follow the table.

Table 23.33 Command-line options used with the program `ndb_drop_table`

| Format | Description | Added, Deprecated, or Removed |
|--|---|--|
| <code>--character-sets-dir=path</code> | Directory containing character sets | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-retries=#</code> | Number of times to retry connection before giving up | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-retry-delay=#</code> | Number of seconds to wait between attempts to contact management server | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-string=connection-string,</code> <code>-c</code> | Same as <code>--ndb-connectstring</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--core-file</code> | Write core file on error; used in debugging | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--database=dbname,</code> <code>-d</code> | Name of database in which table is found | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-extra-file=path</code> | Read given file after global files are read | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-file=path</code> | Read default options from given file only | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-group-suffix=string</code> | Also read groups with <code>concat(group, suffix)</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--help,</code> <code>-?</code> | Display help text and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--login-path=path</code> | Read given path from login file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-connectstring=connection-string,</code> <code>-c</code> | Set connect string for connecting to <code>ndb_mgmd</code> . Syntax: "[nodeid=id;] [host=]hostname[:port]". Overrides entries in <code>NDB_CONNECTSTRING</code> and <code>my.cnf</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-mgmd-host=connection-string,</code> <code>-c</code> | Same as <code>--ndb-connectstring</code> | (Supported in all NDB releases based on MySQL 8.0) |

| Format | Description | Added, Deprecated, or Removed |
|---|---|--|
| <code>--ndb-nodeid=#</code> | Set node ID for this node, overriding any ID set by <code>--ndb-connectstring</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-optimized-node-selection</code> | Enable optimizations for selection of nodes for transactions. Enabled by default; use <code>--skip-ndb-optimized-node-selection</code> to disable | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--no-defaults</code> | Do not read default options from any option file other than login file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--print-defaults</code> | Print program argument list and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--usage,</code> <code>-?</code> | Display help text and exit; same as <code>--help</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--version,</code> <code>-V</code> | Display version information and exit | (Supported in all NDB releases based on MySQL 8.0) |

- `--character-sets-dir`

| | |
|---------------------|--|
| Command-Line Format | <code>--character-sets-dir=path</code> |
|---------------------|--|

Directory containing character sets.

- `--connect-retries`

| | |
|---------------------|----------------------------------|
| Command-Line Format | <code>--connect-retries=#</code> |
| Type | Integer |
| Default Value | 12 |
| Minimum Value | 0 |
| Maximum Value | 12 |

Number of times to retry connection before giving up.

- `--connect-retry-delay`

| | |
|---------------------|--------------------------------------|
| Command-Line Format | <code>--connect-retry-delay=#</code> |
| Type | Integer |
| Default Value | 5 |
| Minimum Value | 0 |
| Maximum Value | 5 |

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

| | |
|---------------------|---|
| Command-Line Format | <code>--connect-string=connection-string</code> |
| Type | String |
| Default Value | [none] |

Same as `--ndb-connectstring`.

- `--core-file`

| | |
|---------------------|--------------------------|
| Command-Line Format | <code>--core-file</code> |
|---------------------|--------------------------|

Write core file on error; used in debugging.

- `--database, -d`

| | |
|---------------------|--------------------------------|
| Command-Line Format | <code>--database=dbname</code> |
| Type | String |
| Default Value | TEST_DB |

Name of the database in which the table resides.

- `--defaults-extra-file`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-extra-file=path</code> |
| Type | String |
| Default Value | [none] |

Read given file after global files are read.

- `--defaults-file`

| | |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--defaults-file=path</code> |
| Type | String |
| Default Value | [none] |

Read default options from given file only.

- `--defaults-group-suffix`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-group-suffix=string</code> |
| Type | String |
| Default Value | [none] |

Also read groups with `concat(group, suffix)`.

- `--help`

| | |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
|---------------------|---------------------|

Display help text and exit.

- `--login-path`

| | |
|---------------------|--------------------------------|
| Command-Line Format | <code>--login-path=path</code> |
| Type | String |
| Default Value | [none] |

Read given path from login file.

- `--ndb-connectstring`

| | |
|---------------------|--|
| Command-Line Format | <code>--ndb-connectstring=connection-string</code> |
| Type | String |
| Default Value | [none] |

Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf.

- `--ndb-mgmd-host`

| | |
|---------------------|--|
| Command-Line Format | <code>--ndb-mgmd-host=connection-string</code> |
| Type | String |
| Default Value | [none] |

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

| | |
|---------------------|-----------------------------|
| Command-Line Format | <code>--ndb-nodeid=#</code> |
| Type | Integer |
| Default Value | [none] |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

| | |
|---------------------|---|
| Command-Line Format | <code>--ndb-optimized-node-selection</code> |
|---------------------|---|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--no-defaults`

| | |
|---------------------|----------------------------|
| Command-Line Format | <code>--no-defaults</code> |
|---------------------|----------------------------|

Do not read default options from any option file other than login file.

- `--print-defaults`

| | |
|---------------------|-------------------------------|
| Command-Line Format | <code>--print-defaults</code> |
|---------------------|-------------------------------|

Print program argument list and exit.

- `--usage`

| | |
|---------------------|----------------------|
| Command-Line Format | <code>--usage</code> |
|---------------------|----------------------|

Display help text and exit; same as `--help`.

- `--version`

| | |
|---------------------|------------------------|
| Command-Line Format | <code>--version</code> |
|---------------------|------------------------|

Display version information and exit.

23.5.12 ndb_error_reporter — NDB Error-Reporting Utility

`ndb_error_reporter` creates an archive from data node and management node log files that can be used to help diagnose bugs or other problems with a cluster. *It is highly recommended that you make use of this utility when filing reports of bugs in NDB Cluster.*

Options that can be used with `ndb_error_reporter` are shown in the following table. Additional descriptions follow the table.

Table 23.34 Command-line options used with the program `ndb_error_reporter`

| Format | Description | Added, Deprecated, or Removed |
|--|--|--|
| <code>--connection-timeout=timeout</code> | Number of seconds to wait when connecting to nodes before timing out | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--dry-scp</code> | Disable scp with remote hosts; used only for testing | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--fs</code> | Include file system data in error report; can use a large amount of disk space | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--help</code> , <code>-?</code> | Display help text and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--skip-nodegroup=nodegroup_id</code> | Skip all nodes in the node group having this ID | (Supported in all NDB releases based on MySQL 8.0) |

Usage

```
ndb_error_reporter path/to/config-file [username] [options]
```

This utility is intended for use on a management node host, and requires the path to the management host configuration file (usually named `config.ini`). Optionally, you can supply the name of a user that is able to access the cluster's data nodes using SSH, to copy the data node log files. `ndb_error_reporter` then includes all of these files in archive that is created in the same directory in which it is run. The archive is named `ndb_error_report_YYYYMMDDhhmmss.tar.bz2`, where `YYYYMMDDhhmmss` is a datetime string.

`ndb_error_reporter` also accepts the options listed here:

- `--connection-timeout=timeout`

| | |
|---------------------|---|
| Command-Line Format | <code>--connection-timeout=timeout</code> |
| Type | Integer |

| | |
|---------------|---|
| Default Value | 0 |
|---------------|---|

Wait this many seconds when trying to connect to nodes before timing out.

- `--dry-scp`

| | |
|---------------------|------------------------|
| Command-Line Format | <code>--dry-scp</code> |
| Type | Boolean |
| Default Value | TRUE |

Run `ndb_error_reporter` without using scp from remote hosts. Used for testing only.

- `--help`

| | |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
|---------------------|---------------------|

Display help text and exit.

- `--fs`

| | |
|---------------------|-------------------|
| Command-Line Format | <code>--fs</code> |
| Type | Boolean |
| Default Value | FALSE |

Copy the data node file systems to the management host and include them in the archive.

Because data node file systems can be extremely large, even after being compressed, we ask that you please do *not* send archives created using this option to Oracle unless you are specifically requested to do so.

- `--skip-nodegroup=nodegroup_id`

| | |
|---------------------|---|
| Command-Line Format | <code>--connection-timeout=timeout</code> |
| Type | Integer |
| Default Value | 0 |

Skip all nodes belong to the node group having the supplied node group ID.

23.5.13 ndb_import — Import CSV Data Into NDB

`ndb_import` imports CSV-formatted data, such as that produced by `mysqldump --tab`, directly into NDB using the NDB API. `ndb_import` requires a connection to an NDB management server (`ndb_mgmd`) to function; it does not require a connection to a MySQL Server.

Usage

```
ndb_import db_name file_name options
```

`ndb_import` requires two arguments. `db_name` is the name of the database where the table into which to import the data is found; `file_name` is the name of the CSV file from which to read the data; this must include the path to this file if it is not in the current directory. The name of the file must match that of the table; the file's extension, if any, is not taken into consideration. Options supported by `ndb_import` include those for specifying field separators, escapes, and line terminators, and are described later in this

section. `ndb_import` must be able to connect to an NDB Cluster management server; for this reason, there must be an unused `[api]` slot in the cluster `config.ini` file.

To duplicate an existing table that uses a different storage engine, such as InnoDB, as an NDB table, use the `mysql` client to perform a `SELECT INTO OUTFILE` statement to export the existing table to a CSV file, then to execute a `CREATE TABLE LIKE` statement to create a new table having the same structure as the existing table, then perform `ALTER TABLE ... ENGINE=NDB` on the new table; after this, from the system shell, invoke `ndb_import` to load the data into the new NDB table. For example, an existing InnoDB table named `myinnodb_table` in a database named `myinnodb` can be exported into an NDB table named `myndb_table` in a database named `myndb` as shown here, assuming that you are already logged in as a MySQL user with the appropriate privileges:

1. In the `mysql` client:

```
mysql> USE myinnodb;

mysql> SELECT * INTO OUTFILE '/tmp/myndb_table.csv'
>   FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"' ESCAPED BY '\\'
>   LINES TERMINATED BY '\n'
>   FROM myinnodbtable;

mysql> CREATE DATABASE myndb;

mysql> USE myndb;

mysql> CREATE TABLE myndb_table LIKE myinnodb.myinnodb_table;

mysql> ALTER TABLE myndb_table ENGINE=NDB;

mysql> EXIT;
Bye
shell>
```

Once the target database and table have been created, a running `mysqld` is no longer required. You can stop it using `mysqladmin shutdown` or another method before proceeding, if you wish.

2. In the system shell:

```
# if you are not already in the MySQL bin directory:
shell> cd path-to-mysql-bin-dir

shell> ndb_import myndb /tmp/myndb_table.csv --fields-optionally-enclosed-by='"' \
--fields-terminated-by="," --fields-escaped-by='\\'
```

The output should resemble what is shown here:

```
job-1 import myndb.myndb_table from /tmp/myndb_table.csv
job-1 [running] import myndb.myndb_table from /tmp/myndb_table.csv
job-1 [success] import myndb.myndb_table from /tmp/myndb_table.csv
job-1 imported 19984 rows in 0h0m9s at 2277 rows/s
jobs summary: defined: 1 run: 1 with success: 1 with failure: 0
shell>
```

All options that can be used with `ndb_import` are shown in the following table. Additional descriptions follow the table.

Table 23.35 Command-line options used with the program `ndb_import`

| Format | Description | Added, Deprecated, or Removed |
|-------------------------------|--|--|
| <code>--abort-on-error</code> | Dump core on any fatal error; used for debugging | (Supported in all NDB releases based on MySQL 8.0) |

| Format | Description | Added, Deprecated, or Removed |
|--|--|--|
| <code>--ai-increment=#</code> | For table with hidden PK, specify autoincrement increment. See <code>mysqld</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ai-offset=#</code> | For table with hidden PK, specify autoincrement offset. See <code>mysqld</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ai-prefetch-sz=#</code> | For table with hidden PK, specify number of autoincrement values that are prefetched. See <code>mysqld</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--character-sets-dir=path</code> | Directory containing character sets | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-retries=#</code> | Number of times to retry connection before giving up | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-retry-delay=#</code> | Number of seconds to wait between attempts to contact management server | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-string=connection-string,</code> | Same as <code>--ndb-connectstring</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>-c</code> | | |
| <code>--connections=#</code> | Number of cluster connections to create | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--continue</code> | When job fails, continue to next job | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--core-file</code> | Write core file on error; used in debugging | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--db-workers=#</code> | Number of threads, per data node, executing database operations | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-extra-file=path</code> | Read given file after global files are read | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-file=path</code> | Read default options from given file only | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-group-suffix=string</code> | Also read groups with <code>concat(group, suffix)</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--errins-type=name</code> | Error insert type, for testing purposes; use "list" to obtain all possible values | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--errins-delay=#</code> | Error insert delay in milliseconds; random variation is added | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--fields-enclosed-by=char</code> | Same as <code>FIELDS ENCLOSED BY</code> option for <code>LOAD DATA</code> statements. For CSV input this is same as using <code>--fields-optionally-enclosed-by</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--fields-escaped-by=name</code> | Same as <code>FIELDS ESCAPED BY</code> option for <code>LOAD DATA</code> statements | (Supported in all NDB releases based on MySQL 8.0) |

| Format | Description | Added, Deprecated, or Removed |
|--|--|--|
| <code>--fields-optionally-enclosed-by=char</code> | Same as FIELDS OPTIONALLY ENCLOSED BY option for LOAD DATA statements | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--fields-terminated-by=char</code> | Same as FIELDS TERMINATED BY option for LOAD DATA statements | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--help,</code> <code>-?</code> | Display help text and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--idlesleep=#</code> | Number of milliseconds to sleep waiting for more to do | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--idlespin=#</code> | Number of times to re-try before idlesleep | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ignore-lines=#</code> | Ignore first # lines in input file. Used to skip a non-data header | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--input-type=name</code> | Input type: random or csv | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--input-workers=#</code> | Number of threads processing input. Must be 2 or more if --input-type is csv | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--keep-state</code> | State files (except non-empty *.rej files) are normally removed on job completion. Using this option causes all state files to be preserved instead | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--lines-terminated-by=name</code> | Same as LINES TERMINATED BY option for LOAD DATA statements | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--login-path=path</code> | Read given path from login file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--max-rows=#</code> | Import only this number of input data rows; default is 0, which imports all rows | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--monitor=#</code> | Periodically print status of running job if something has changed (status, rejected rows, temporary errors). Value 0 disables. Value 1 prints any change seen. Higher values reduce status printing exponentially up to some pre-defined limit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-connectstring=connection-string,</code> <code>-c</code> | Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in | (Supported in all NDB releases based on MySQL 8.0) |

| Format | Description | Added, Deprecated, or Removed |
|---|--|--|
| <code>--ndb-mgmd-host=connection-string,</code> | NDB_CONNECTSTRING and my.cnf Same as <code>--ndb-connectstring</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>-c</code> | | |
| <code>--ndb-nodeid=#</code> | Set node ID for this node, overriding any ID set by <code>--ndb-connectstring</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-optimized-node-selection</code> | Enable optimizations for selection of nodes for transactions. Enabled by default; use <code>--skip-ndb-optimized-node-selection</code> to disable | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--no-asynch</code> | Run database operations as batches, in single transactions | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--no-defaults</code> | Do not read default options from any option file other than login file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--no-hint</code> | Do not use distribution key hint to select data node (TC) | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--opbatch=#</code> | A db execution batch is a set of transactions and operations sent to NDB kernel. This option limits NDB operations (including blob operations) in a db execution batch. Therefore it also limits number of asynch transactions. Value 0 is not valid | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--opbytes=#</code> | Limit bytes in execution batch (default 0 = no limit) | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--output-type=name</code> | Output type: ndb is default, null used for testing | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--output-workers=#</code> | Number of threads processing output or relaying database operations | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--pagesize=#</code> | Align I/O buffers to given size | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--pagecnt=#</code> | Size of I/O buffers as multiple of page size. CSV input worker allocates a double-sized buffer | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--polltimeout=#</code> | Timeout per poll for completed asynchronous transactions; polling continues until all polls are completed, or error occurs | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--print-defaults</code> | Print program argument list and exit | (Supported in all NDB releases based on MySQL 8.0) |

| Format | Description | Added, Deprecated, or Removed |
|--|---|--|
| <code>--rejects=#</code> | Limit number of rejected rows (rows with permanent error) in data load. Default is 0 which means that any rejected row causes a fatal error. The row exceeding the limit is also added to *.rej | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--resume</code> | If job aborted (temporary error, user interrupt), resume with rows not yet processed | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--rowbatch=#</code> | Limit rows in row queues (default 0 = no limit); must be 1 or more if --input-type is random | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--rowbytes=#</code> | Limit bytes in row queues (0 = no limit) | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--state-dir=name</code> | Where to write state files; current directory is default | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--stats</code> | Save performance related options and internal statistics in *.sto and *.stt files. These files are kept on successful completion even if --keep-state is not used | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--tempdelay=#</code> | Number of milliseconds to sleep between temporary errors | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--temperrors=#</code> | Number of times a transaction can fail due to a temporary error, per execution batch; 0 means any temporary error is fatal. Such errors do not cause any rows to be written to .rej file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--usage,</code> <code>-?</code> | Display help text and exit; same as --help | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--verbose,</code> <code>-v</code> | Enable verbose output | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--version,</code> <code>-V</code> | Display version information and exit | (Supported in all NDB releases based on MySQL 8.0) |

- `--abort-on-error`

| | |
|---------------------|-------------------------------|
| Command-Line Format | <code>--abort-on-error</code> |
| Type | Boolean |
| Default Value | <code>FALSE</code> |

Dump core on any fatal error; used for debugging only.

- `--ai-increment=#`

| | |
|---------------------|-------------------------------|
| Command-Line Format | <code>--ai-increment=#</code> |
| Type | Integer |
| Default Value | 1 |
| Minimum Value | 1 |
| Maximum Value | 4294967295 |

For a table with a hidden primary key, specify the autoincrement increment, like the `auto_increment_increment` system variable does in the MySQL Server.

- `--ai-offset=#`

| | |
|---------------------|----------------------------|
| Command-Line Format | <code>--ai-offset=#</code> |
| Type | Integer |
| Default Value | 1 |
| Minimum Value | 1 |
| Maximum Value | 4294967295 |

For a table with hidden primary key, specify the autoincrement offset. Similar to the `auto_increment_offset` system variable.

- `--ai-prefetch-sz=#`

| | |
|---------------------|---------------------------------|
| Command-Line Format | <code>--ai-prefetch-sz=#</code> |
| Type | Integer |
| Default Value | 1024 |
| Minimum Value | 1 |
| Maximum Value | 4294967295 |

For a table with a hidden primary key, specify the number of autoincrement values that are prefetched. Behaves like the `ndb_autoincrement_prefetch_sz` system variable does in the MySQL Server.

- `--connections=#`

| | |
|---------------------|------------------------------|
| Command-Line Format | <code>--connections=#</code> |
| Type | Integer |
| Default Value | 1 |
| Minimum Value | 1 |
| Maximum Value | 4294967295 |

Number of cluster connections to create.

- `--continue`

| | |
|---------------------|-------------------------|
| Command-Line Format | <code>--continue</code> |
| Type | Boolean |
| Default Value | FALSE |

When a job fails, continue to the next job.

- `--db-workers=#`

| | |
|---------------------|-----------------------------|
| Command-Line Format | <code>--db-workers=#</code> |
| Type | Integer |
| Default Value | 4 |
| Minimum Value | 1 |
| Maximum Value | 4294967295 |

Number of threads, per data node, executing database operations.

- `--errins-type=name`

| | |
|---------------------|--|
| Command-Line Format | <code>--errins-type=name</code> |
| Type | Enumeration |
| Default Value | [none] |
| Valid Values | <code>stopjob</code> <code>stopall</code> <code>sigint</code> <code>list</code> |

Error insert type; use `list` as the `name` value to obtain all possible values. This option is used for testing purposes only.

- `--errins-delay=#`

| | |
|---------------------|-------------------------------|
| Command-Line Format | <code>--errins-delay=#</code> |
| Type | Integer |
| Default Value | 1000 |
| Minimum Value | 0 |
| Maximum Value | 4294967295 |
| Unit | ms |

Error insert delay in milliseconds; random variation is added. This option is used for testing purposes only.

- `--fields-enclosed-by=char`

| | |
|---------------------|--|
| Command-Line Format | <code>--fields-enclosed-by=char</code> |
| Type | String |

| | |
|---------------|--------|
| Default Value | [none] |
|---------------|--------|

This works in the same way as the `FIELDS ENCLOSED BY` option does for the `LOAD DATA` statement, specifying a character to be interpreted as quoting field values. For CSV input, this is the same as `--fields-optionally-enclosed-by`.

- `--fields-escaped-by=name`

| | |
|---------------------|---------------------------------------|
| Command-Line Format | <code>--fields-escaped-by=name</code> |
| Type | String |
| Default Value | \ |

Specify an escape character in the same way as the `FIELDS ESCAPED BY` option does for the SQL `LOAD DATA` statement.

- `--fields-optionally-enclosed-by=char`

| | |
|---------------------|---|
| Command-Line Format | <code>--fields-optionally-enclosed-by=char</code> |
| Type | String |
| Default Value | [none] |

This works in the same way as the `FIELDS OPTIONALLY ENCLOSED BY` option does for the `LOAD DATA` statement, specifying a character to be interpreted as optionally quoting field values. For CSV input, this is the same as `--fields-enclosed-by`.

- `--fields-terminated-by=char`

| | |
|---------------------|--|
| Command-Line Format | <code>--fields-terminated-by=char</code> |
| Type | String |
| Default Value | \t |

This works in the same way as the `FIELDS TERMINATED BY` option does for the `LOAD DATA` statement, specifying a character to be interpreted as the field separator.

- `--idlesleep=#`

| | |
|---------------------|----------------------------|
| Command-Line Format | <code>--idlesleep=#</code> |
| Type | Integer |
| Default Value | 1 |
| Minimum Value | 1 |
| Maximum Value | 4294967295 |
| Unit | ms |

Number of milliseconds to sleep waiting for more work to perform.

- `--idlespin=#`

| | |
|---------------------|---------------------------|
| Command-Line Format | <code>--idlespin=#</code> |
| Type | Integer |
| Default Value | 0 |

| | |
|---------------|------------|
| Minimum Value | 0 |
| Maximum Value | 4294967295 |

Number of times to retry before sleeping.

- `--ignore-lines=#`

| | |
|---------------------|-------------------------------|
| Command-Line Format | <code>--ignore-lines=#</code> |
| Type | Integer |
| Default Value | 0 |
| Minimum Value | 0 |
| Maximum Value | 4294967295 |

Cause `ndb_import` to ignore the first `#` lines of the input file. This can be employed to skip a file header that does not contain any data.

- `--input-type=name`

| | |
|---------------------|---|
| Command-Line Format | <code>--input-type=name</code> |
| Type | Enumeration |
| Default Value | <code>csv</code> |
| Valid Values | <code>random</code> <code>csv</code> |

Set the type of input type. The default is `csv`; `random` is intended for testing purposes only. .

- `--input-workers=#`

| | |
|---------------------|--------------------------------|
| Command-Line Format | <code>--input-workers=#</code> |
| Type | Integer |
| Default Value | 4 |
| Minimum Value | 1 |
| Maximum Value | 4294967295 |

Set the number of threads processing input.

- `--keep-state`

| | |
|---------------------|---------------------------|
| Command-Line Format | <code>--keep-state</code> |
| Type | Boolean |
| Default Value | <code>false</code> |

By default, `ndb_import` removes all state files (except non-empty `*.rej` files) when it completes a job. Specify this option (nor argument is required) to force the program to retain all state files instead.

- `--lines-terminated-by=name`

| | |
|---------------------|---|
| Command-Line Format | <code>--lines-terminated-by=name</code> |
|---------------------|---|

| | |
|---------------|--------|
| Type | String |
| Default Value | \n |

This works in the same way as the `LINES TERMINATED BY` option does for the `LOAD DATA` statement, specifying a character to be interpreted as end-of-line.

- `--log-level=#`

| | |
|---------------------|----------------------------|
| Command-Line Format | <code>--log-level=#</code> |
| Type | Integer |
| Default Value | 0 |
| Minimum Value | 0 |
| Maximum Value | 2 |

Performs internal logging at the given level. This option is intended primarily for internal and development use.

In debug builds of NDB only, the logging level can be set using this option to a maximum of 4.

- `--max-rows=#`

| | |
|---------------------|---------------------------|
| Command-Line Format | <code>--max-rows=#</code> |
| Type | Integer |
| Default Value | 0 |
| Minimum Value | 0 |
| Maximum Value | 4294967295 |
| Unit | bytes |

Import only this number of input data rows; the default is 0, which imports all rows.

- `--monitor=#`

| | |
|---------------------|--------------------------|
| Command-Line Format | <code>--monitor=#</code> |
| Type | Integer |
| Default Value | 2 |
| Minimum Value | 0 |
| Maximum Value | 4294967295 |
| Unit | bytes |

Periodically print the status of a running job if something has changed (status, rejected rows, temporary errors). Set to 0 to disable this reporting. Setting to 1 prints any change that is seen. Higher values reduce the frequency of this status reporting.

- `--no-async`

| | |
|---------------------|-------------------------|
| Command-Line Format | <code>--no-async</code> |
| Type | Boolean |
| Default Value | FALSE |

Run database operations as batches, in single transactions.

- `--no-hint`

| | |
|---------------------|------------------------|
| Command-Line Format | <code>--no-hint</code> |
| Type | Boolean |
| Default Value | <code>FALSE</code> |

Do not use distribution key hinting to select a data node.

- `--opbatch=#`

| | |
|---------------------|--------------------------|
| Command-Line Format | <code>--opbatch=#</code> |
| Type | Integer |
| Default Value | <code>256</code> |
| Minimum Value | <code>1</code> |
| Maximum Value | <code>4294967295</code> |
| Unit | <code>bytes</code> |

Set a limit on the number of operations (including blob operations), and thus the number of asynchronous transactions, per execution batch.

- `--opbytes=#`

| | |
|---------------------|--------------------------|
| Command-Line Format | <code>--opbytes=#</code> |
| Type | Integer |
| Default Value | <code>0</code> |
| Minimum Value | <code>0</code> |
| Maximum Value | <code>4294967295</code> |
| Unit | <code>bytes</code> |

Set a limit on the number of bytes per execution batch. Use 0 for no limit.

- `--output-type=name`

| | |
|---------------------|---------------------------------|
| Command-Line Format | <code>--output-type=name</code> |
| Type | Enumeration |
| Default Value | <code>ndb</code> |
| Valid Values | <code>null</code> |

Set the output type. `ndb` is the default. `null` is used only for testing.

- `--output-workers=#`

| | |
|---------------------|---------------------------------|
| Command-Line Format | <code>--output-workers=#</code> |
| Type | Integer |
| Default Value | <code>2</code> |

| | |
|---------------|------------|
| Minimum Value | 1 |
| Maximum Value | 4294967295 |

Set the number of threads processing output or relaying database operations.

- `--pagesize=#`

| | |
|---------------------|---------------------------|
| Command-Line Format | <code>--pagesize=#</code> |
| Type | Integer |
| Default Value | 4096 |
| Minimum Value | 1 |
| Maximum Value | 4294967295 |
| Unit | bytes |

Align I/O buffers to the given size.

- `--pagecnt=#`

| | |
|---------------------|--------------------------|
| Command-Line Format | <code>--pagecnt=#</code> |
| Type | Integer |
| Default Value | 64 |
| Minimum Value | 1 |
| Maximum Value | 4294967295 |

Set the size of I/O buffers as multiple of page size. The CSV input worker allocates buffer that is doubled in size.

- `--polltimeout=#`

| | |
|---------------------|------------------------------|
| Command-Line Format | <code>--polltimeout=#</code> |
| Type | Integer |
| Default Value | 1000 |
| Minimum Value | 1 |
| Maximum Value | 4294967295 |
| Unit | ms |

Set a timeout per poll for completed asynchronous transactions; polling continues until all polls are completed, or until an error occurs.

- `--rejects=#`

| | |
|---------------------|--------------------------|
| Command-Line Format | <code>--rejects=#</code> |
| Type | Integer |
| Default Value | 0 |
| Minimum Value | 0 |

| | |
|---------------|------------|
| Maximum Value | 4294967295 |
|---------------|------------|

Limit the number of rejected rows (rows with permanent errors) in the data load. The default is 0, which means that any rejected row causes a fatal error. Any rows causing the limit to be exceeded are added to the `.rej` file.

The limit imposed by this option is effective for the duration of the current run. A run restarted using `--resume` is considered a “new” run for this purpose.

- `--resume`

| | |
|---------------------|-----------------------|
| Command-Line Format | <code>--resume</code> |
| Type | Boolean |
| Default Value | FALSE |

If a job is aborted (due to a temporary db error or when interrupted by the user), resume with any rows not yet processed.

- `--rowbatch=#`

| | |
|---------------------|---------------------------|
| Command-Line Format | <code>--rowbatch=#</code> |
| Type | Integer |
| Default Value | 0 |
| Minimum Value | 0 |
| Maximum Value | 4294967295 |
| Unit | rows |

Set a limit on the number of rows per row queue. Use 0 for no limit.

- `--rowbytes=#`

| | |
|---------------------|---------------------------|
| Command-Line Format | <code>--rowbytes=#</code> |
| Type | Integer |
| Default Value | 262144 |
| Minimum Value | 0 |
| Maximum Value | 4294967295 |
| Unit | bytes |

Set a limit on the number of bytes per row queue. Use 0 for no limit.

- `--stats`

| | |
|---------------------|----------------------|
| Command-Line Format | <code>--stats</code> |
| Type | Boolean |
| Default Value | false |

Save information about options related to performance and other internal statistics in files named `*.sto` and `*.stt`. These files are always kept on successful completion (even if `--keep-state` is not also specified).

- `--state-dir=name`

| | |
|---------------------|-------------------------------|
| Command-Line Format | <code>--state-dir=name</code> |
| Type | String |
| Default Value | . |

Where to write the state files (`tbl_name.map`, `tbl_name.rej`, `tbl_name.res`, and `tbl_name.stt`) produced by a run of the program; the default is the current directory.

- `--tempdelay=#`

| | |
|---------------------|----------------------------|
| Command-Line Format | <code>--tempdelay=#</code> |
| Type | Integer |
| Default Value | 10 |
| Minimum Value | 0 |
| Maximum Value | 4294967295 |
| Unit | ms |

Number of milliseconds to sleep between temporary errors.

- `--temperrors=#`

| | |
|---------------------|-----------------------------|
| Command-Line Format | <code>--temperrors=#</code> |
| Type | Integer |
| Default Value | 0 |
| Minimum Value | 0 |
| Maximum Value | 4294967295 |

Number of times a transaction can fail due to a temporary error, per execution batch. The default is 0, which means that any temporary error is fatal. Temporary errors do not cause any rows to be added to the `.rej` file.

- `--verbose, -v`

| | |
|---------------------|------------------------|
| Command-Line Format | <code>--verbose</code> |
| Type | Boolean |
| Default Value | false |

Enable verbose output.

- `--print-defaults`

| | |
|---------------------|-------------------------------|
| Command-Line Format | <code>--print-defaults</code> |
|---------------------|-------------------------------|

Print program argument list and exit.

- `--no-defaults`

| | |
|---------------------|----------------------------|
| Command-Line Format | <code>--no-defaults</code> |
|---------------------|----------------------------|

Do not read default options from any option file other than login file.

- `--defaults-file`

| | |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--defaults-file=path</code> |
| Type | String |
| Default Value | [none] |

Read default options from given file only.

- `--defaults-extra-file`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-extra-file=path</code> |
| Type | String |
| Default Value | [none] |

Read given file after global files are read.

- `--defaults-group-suffix`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-group-suffix=string</code> |
| Type | String |
| Default Value | [none] |

Also read groups with `concat(group, suffix)`.

- `--login-path`

| | |
|---------------------|--------------------------------|
| Command-Line Format | <code>--login-path=path</code> |
| Type | String |
| Default Value | [none] |

Read given path from login file.

- `--help`

| | |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
|---------------------|---------------------|

Display help text and exit.

- `--usage`

| | |
|---------------------|----------------------|
| Command-Line Format | <code>--usage</code> |
|---------------------|----------------------|

Display help text and exit; same as `--help`.

- `--version`

| | |
|---------------------|------------------------|
| Command-Line Format | <code>--version</code> |
|---------------------|------------------------|

Display version information and exit.

- `--ndb-connectstring`

| | |
|---------------------|--|
| Command-Line Format | <code>--ndb-connectstring=connection-string</code> |
| Type | String |
| Default Value | [none] |

Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf.

- `--connect-string`

| | |
|---------------------|---|
| Command-Line Format | <code>--connect-string=connection-string</code> |
| Type | String |
| Default Value | [none] |

Same as `--ndb-connectstring`.

- `--ndb-mgmd-host`

| | |
|---------------------|--|
| Command-Line Format | <code>--ndb-mgmd-host=connection-string</code> |
| Type | String |
| Default Value | [none] |

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

| | |
|---------------------|-----------------------------|
| Command-Line Format | <code>--ndb-nodeid=#</code> |
| Type | Integer |
| Default Value | [none] |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--core-file`

| | |
|---------------------|--------------------------|
| Command-Line Format | <code>--core-file</code> |
|---------------------|--------------------------|

Write core file on error; used in debugging.

- `--character-sets-dir`

| | |
|---------------------|--|
| Command-Line Format | <code>--character-sets-dir=path</code> |
|---------------------|--|

Directory containing character sets.

- `--connect-retries`

| | |
|---------------------|----------------------------------|
| Command-Line Format | <code>--connect-retries=#</code> |
| Type | Integer |
| Default Value | 12 |
| Minimum Value | 0 |
| Maximum Value | 12 |

Number of times to retry connection before giving up.

- `--connect-retry-delay`

| | |
|---------------------|--------------------------------------|
| Command-Line Format | <code>--connect-retry-delay=#</code> |
| Type | Integer |
| Default Value | 5 |
| Minimum Value | 0 |
| Maximum Value | 5 |

Number of seconds to wait between attempts to contact management server.

- `--ndb-optimized-node-selection`

| | |
|---------------------|---|
| Command-Line Format | <code>--ndb-optimized-node-selection</code> |
|---------------------|---|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

As with `LOAD DATA`, options for field and line formatting much match those used to create the CSV file, whether this was done using `SELECT INTO ... OUTFILE`, or by some other means. There is no equivalent to the `LOAD DATA` statement `STARTING WITH` option.

23.5.14 ndb_index_stat — NDB Index Statistics Utility

`ndb_index_stat` provides per-fragment statistical information about indexes on NDB tables. This includes cache version and age, number of index entries per partition, and memory consumption by indexes.

Usage

To obtain basic index statistics about a given NDB table, invoke `ndb_index_stat` as shown here, with the name of the table as the first argument and the name of the database containing this table specified immediately following it, using the `--database (-d)` option:

```
ndb_index_stat table -d database
```

In this example, we use `ndb_index_stat` to obtain such information about an NDB table named `mytable` in the `test` database:

```
shell> ndb_index_stat -d test mytable
table:City index:PRIMARY fragCount:2
sampleVersion:3 loadTime:1399585986 sampleCount:1994 keyBytes:7976
query cache: valid:1 sampleCount:1994 totalBytes:27916
times in ms: save: 7.133 sort: 1.974 sort per sample: 0.000

NDBT_ProgramExit: 0 - OK
```

`sampleVersion` is the version number of the cache from which the statistics data is taken. Running `ndb_index_stat` with the `--update` option causes `sampleVersion` to be incremented.

`loadTime` shows when the cache was last updated. This is expressed as seconds since the Unix Epoch.

`sampleCount` is the number of index entries found per partition. You can estimate the total number of entries by multiplying this by the number of fragments (shown as `fragCount`).

`sampleCount` can be compared with the cardinality of `SHOW INDEX` or `INFORMATION_SCHEMA.STATISTICS`, although the latter two provide a view of the table as a whole, while `ndb_index_stat` provides a per-fragment average.

`keyBytes` is the number of bytes used by the index. In this example, the primary key is an integer, which requires four bytes for each index, so `keyBytes` can be calculated in this case as shown here:

```
keyBytes = sampleCount * (4 bytes per index) = 1994 * 4 = 7976
```

This information can also be obtained using the corresponding column definitions from `INFORMATION_SCHEMA.COLUMNS` (this requires a MySQL Server and a MySQL client application).

`totalBytes` is the total memory consumed by all indexes on the table, in bytes.

Timings shown in the preceding examples are specific to each invocation of `ndb_index_stat`.

The `--verbose` option provides some additional output, as shown here:

```
shell> ndb_index_stat -d test mytable --verbose
random seed 1337010518
connected
loop 1 of 1
table:mytable index:PRIMARY fragCount:4
sampleVersion:2 loadTime:1336751773 sampleCount:0 keyBytes:0
read stats
query cache created
query cache: valid:1 sampleCount:0 totalBytes:0
times in ms: save: 20.766 sort: 0.001
disconnected

NDBT_ProgramExit: 0 - OK

shell>
```

If the only output from the program is `NDBT_ProgramExit: 0 - OK`, this may indicate that no statistics yet exist. To force them to be created (or updated if they already exist), invoke `ndb_index_stat` with the `--update` option, or execute `ANALYZE TABLE` on the table in the `mysql` client.

Options

The following table includes options that are specific to the NDB Cluster `ndb_index_stat` utility. Additional descriptions are listed following the table.

Table 23.36 Command-line options used with the program `ndb_index_stat`

| Format | Description | Added, Deprecated, or Removed |
|--|--|--|
| <code>--character-sets-dir=path</code> | Directory containing character sets | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-retries=#</code> | Number of times to retry connection before giving up | (Supported in all NDB releases based on MySQL 8.0) |

| Format | Description | Added, Deprecated, or Removed |
|--|--|--|
| <code>--connect-retry-delay=#</code> | Number of seconds to wait between attempts to contact management server | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-string=connection-string,</code> <code>-c</code> | Same as <code>--ndb-connectstring</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--core-file</code> | Write core file on error; used in debugging | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--database=name,</code> <code>-d</code> | Name of database containing table | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-extra-file=path</code> | Read given file after global files are read | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-file=path</code> | Read default options from given file only | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-group-suffix=string</code> | Also read groups with <code>concat(group, suffix)</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--delete</code> | Delete index statistics for table, stopping any auto-update previously configured | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--dump</code> | Print query cache | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--help,</code> <code>-?</code> | Display help text and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--login-path=path</code> | Read given path from login file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--loops=#</code> | Set the number of times to perform given command; default is 0 | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-connectstring=connection-string,</code> <code>-c</code> | Set connect string for connecting to <code>ndb_mgmd</code> . Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in <code>NDB_CONNECTSTRING</code> and <code>my.cnf</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-mgmd-host=connection-string,</code> <code>-c</code> | Same as <code>--ndb-connectstring</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-nodeid=#</code> | Set node ID for this node, overriding any ID set by <code>--ndb-connectstring</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-optimized-node-selection</code> | Enable optimizations for selection of nodes for transactions. Enabled | (Supported in all NDB releases based on MySQL 8.0) |

| Format | Description | Added, Deprecated, or Removed |
|--|---|--|
| | by default; use <code>--skip-ndb-optimized-node-selection</code> to disable | |
| <code>--no-defaults</code> | Do not read default options from any option file other than login file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--print-defaults</code> | Print program argument list and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--query=#</code> | Perform random range queries on first key attr (must be int unsigned) | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--sys-drop</code> | Drop any statistics tables and events in NDB kernel (all statistics are lost) | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--sys-create</code> | Create all statistics tables and events in NDB kernel, if none of them already exist | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--sys-create-if-not-exist</code> | Create any statistics tables and events in NDB kernel that do not already exist | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--sys-create-if-not-valid</code> | Create any statistics tables or events that do not already exist in the NDB kernel, after dropping any that are invalid | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--sys-check</code> | Verify that NDB system index statistics and event tables exist | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--sys-skip-tables</code> | Do not apply <code>sys-*</code> options to tables | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--sys-skip-events</code> | Do not apply <code>sys-*</code> options to events | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--update</code> | Update index statistics for table, restarting any auto-update previously configured | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--usage,</code> <code>-?</code> | Display help text and exit; same as <code>--help</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--verbose,</code> <code>-v</code> | Turn on verbose output | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--version,</code> <code>-V</code> | Display version information and exit | (Supported in all NDB releases based on MySQL 8.0) |

- `--character-sets-dir`

| | |
|---------------------|--|
| Command-Line Format | <code>--character-sets-dir=path</code> |
|---------------------|--|

Directory containing character sets.

- `--connect-retries`

| | |
|---------------------|----------------------------------|
| Command-Line Format | <code>--connect-retries=#</code> |
| Type | Integer |
| Default Value | 12 |
| Minimum Value | 0 |
| Maximum Value | 12 |

Number of times to retry connection before giving up.

- `--connect-retry-delay`

| | |
|---------------------|--------------------------------------|
| Command-Line Format | <code>--connect-retry-delay=#</code> |
| Type | Integer |
| Default Value | 5 |
| Minimum Value | 0 |
| Maximum Value | 5 |

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

| | |
|---------------------|---|
| Command-Line Format | <code>--connect-string=connection-string</code> |
| Type | String |
| Default Value | [none] |

Same as `--ndb-connectstring`.

- `--core-file`

| | |
|---------------------|--------------------------|
| Command-Line Format | <code>--core-file</code> |
|---------------------|--------------------------|

Write core file on error; used in debugging.

- `--database=name, -d name`

| | |
|---------------------|------------------------------|
| Command-Line Format | <code>--database=name</code> |
| Type | String |
| Default Value | [none] |
| Minimum Value | |
| Maximum Value | |

The name of the database that contains the table being queried.

- `--defaults-extra-file`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-extra-file=path</code> |
| Type | String |
| Default Value | [none] |

Read given file after global files are read.

- `--defaults-file`

| | |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--defaults-file=path</code> |
| Type | String |
| Default Value | [none] |

Read default options from given file only.

- `--defaults-group-suffix`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-group-suffix=string</code> |
| Type | String |
| Default Value | [none] |

Also read groups with `concat(group, suffix)`.

- `--delete`

| | |
|---------------------|-----------------------|
| Command-Line Format | <code>--delete</code> |
| Type | Boolean |
| Default Value | <code>false</code> |
| Minimum Value | |
| Maximum Value | |

Delete the index statistics for the given table, stopping any auto-update that was previously configured.

- `--dump`

| | |
|---------------------|---------------------|
| Command-Line Format | <code>--dump</code> |
| Type | Boolean |
| Default Value | <code>false</code> |
| Minimum Value | |
| Maximum Value | |

Dump the contents of the query cache.

- `--help`

| | |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
|---------------------|---------------------|

Display help text and exit.

- `--login-path`

| | |
|---------------------|--------------------------------|
| Command-Line Format | <code>--login-path=path</code> |
| Type | String |
| Default Value | [none] |

Read given path from login file.

- `--loops=#`

| | |
|---------------------|------------------------|
| Command-Line Format | <code>--loops=#</code> |
| Type | Numeric |
| Default Value | 0 |
| Minimum Value | 0 |
| Maximum Value | <code>MAX_INT</code> |

Repeat commands this number of times (for use in testing).

- `--ndb-connectstring`

| | |
|---------------------|--|
| Command-Line Format | <code>--ndb-connectstring=connection-string</code> |
| Type | String |
| Default Value | <code>[none]</code> |

Set connect string for connecting to `ndb_mgmd`. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in `NDB_CONNECTSTRING` and `my.cnf`.

- `--ndb-mgmd-host`

| | |
|---------------------|--|
| Command-Line Format | <code>--ndb-mgmd-host=connection-string</code> |
| Type | String |
| Default Value | <code>[none]</code> |

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

| | |
|---------------------|-----------------------------|
| Command-Line Format | <code>--ndb-nodeid=#</code> |
| Type | Integer |
| Default Value | <code>[none]</code> |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

| | |
|---------------------|---|
| Command-Line Format | <code>--ndb-optimized-node-selection</code> |
|---------------------|---|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--no-defaults`

| | |
|---------------------|----------------------------|
| Command-Line Format | <code>--no-defaults</code> |
|---------------------|----------------------------|

Do not read default options from any option file other than login file.

- `--print-defaults`

| | |
|---------------------|-------------------------------|
| Command-Line Format | <code>--print-defaults</code> |
|---------------------|-------------------------------|

Print program argument list and exit.

- `--query=#`

| | |
|---------------------|------------------------|
| Command-Line Format | <code>--query=#</code> |
| Type | Numeric |
| Default Value | 0 |
| Minimum Value | 0 |
| Maximum Value | <code>MAX_INT</code> |

Perform random range queries on first key attribute (must be int unsigned).

- `--sys-drop`

| | |
|---------------------|-------------------------|
| Command-Line Format | <code>--sys-drop</code> |
| Type | Boolean |
| Default Value | <code>false</code> |
| Minimum Value | |
| Maximum Value | |

Drop all statistics tables and events in the NDB kernel. *This causes all statistics to be lost.*

- `--sys-create`

| | |
|---------------------|---------------------------|
| Command-Line Format | <code>--sys-create</code> |
| Type | Boolean |
| Default Value | <code>false</code> |
| Minimum Value | |
| Maximum Value | |

Create all statistics tables and events in the NDB kernel. This works only if none of them exist previously.

- `--sys-create-if-not-exist`

| | |
|---------------------|--|
| Command-Line Format | <code>--sys-create-if-not-exist</code> |
| Type | Boolean |
| Default Value | <code>false</code> |
| Minimum Value | |
| Maximum Value | |

Create any NDB system statistics tables or events (or both) that do not already exist when the program is invoked.

- `--sys-create-if-not-valid`

| | |
|---------------------|--|
| Command-Line Format | <code>--sys-create-if-not-valid</code> |
|---------------------|--|

| | |
|---------------|---------|
| Type | Boolean |
| Default Value | false |
| Minimum Value | |
| Maximum Value | |

Create any NDB system statistics tables or events that do not already exist, after dropping any that are invalid.

- `--sys-check`

| | |
|---------------------|--------------------------|
| Command-Line Format | <code>--sys-check</code> |
| Type | Boolean |
| Default Value | false |
| Minimum Value | |
| Maximum Value | |

Verify that all required system statistics tables and events exist in the NDB kernel.

- `--sys-skip-tables`

| | |
|---------------------|--------------------------------|
| Command-Line Format | <code>--sys-skip-tables</code> |
| Type | Boolean |
| Default Value | false |
| Minimum Value | |
| Maximum Value | |

Do not apply any `--sys-*` options to any statistics tables.

- `--sys-skip-events`

| | |
|---------------------|--------------------------------|
| Command-Line Format | <code>--sys-skip-events</code> |
| Type | Boolean |
| Default Value | false |
| Minimum Value | |
| Maximum Value | |

Do not apply any `--sys-*` options to any events.

- `--update`

| | |
|---------------------|-----------------------|
| Command-Line Format | <code>--update</code> |
| Type | Boolean |
| Default Value | false |
| Minimum Value | |

| | |
|---------------|--|
| Maximum Value | |
|---------------|--|

Update the index statistics for the given table, and restart any auto-update that was previously configured.

- `--usage`

| | |
|---------------------|----------------------|
| Command-Line Format | <code>--usage</code> |
|---------------------|----------------------|

Display help text and exit; same as `--help`.

- `--verbose`

| | |
|---------------------|------------------------|
| Command-Line Format | <code>--verbose</code> |
| Type | Boolean |
| Default Value | <code>false</code> |
| Minimum Value | |
| Maximum Value | |

Turn on verbose output.

- `--version`

| | |
|---------------------|------------------------|
| Command-Line Format | <code>--version</code> |
|---------------------|------------------------|

Display version information and exit.

ndb_index_stat system options. The following options are used to generate and update the statistics tables in the NDB kernel. None of these options can be mixed with statistics options (see [ndb_index_stat statistics options](#)).

- `--sys-drop`
- `--sys-create`
- `--sys-create-if-not-exist`
- `--sys-create-if-not-valid`
- `--sys-check`
- `--sys-skip-tables`
- `--sys-skip-events`

ndb_index_stat statistics options. The options listed here are used to generate index statistics. They work with a given table and database. They cannot be mixed with system options (see [ndb_index_stat system options](#)).

- `--database`
- `--delete`
- `--update`
- `--dump`

- `--query`

23.5.15 ndb_move_data — NDB Data Copy Utility

`ndb_move_data` copies data from one NDB table to another.

Usage

The program is invoked with the names of the source and target tables; either or both of these may be qualified optionally with the database name. Both tables must use the NDB storage engine.

```
ndb_move_data options source target
```

Options that can be used with `ndb_move_data` are shown in the following table. Additional descriptions follow the table.

Table 23.37 Command-line options used with the program `ndb_move_data`

| Format | Description | Added, Deprecated, or Removed |
|--|---|--|
| <code>--abort-on-error</code> | Dump core on permanent error (debug option) | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--character-sets-dir=name</code> | Directory where character sets are | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-retries=#</code> | Number of times to retry connection before giving up | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-retry-delay=#</code> | Number of seconds to wait between attempts to contact management server | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-string=connection-string,</code> | Same as <code>--ndb-connectstring</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>-c</code> | | |
| <code>--core-file</code> | Write core file on error; used in debugging | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--database=dbname,</code> | Name of database in which table is found | (Supported in all NDB releases based on MySQL 8.0) |
| <code>-d</code> | | |
| <code>--defaults-extra-file=path</code> | Read given file after global files are read | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-file=path</code> | Read default options from given file only | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-group-suffix=string</code> | Also read groups with <code>concat(group, suffix)</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--drop-source</code> | Drop source table after all rows have been moved | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--error-insert</code> | Insert random temporary errors (testing option) | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--exclude-missing-columns</code> | Ignore extra columns in source or target table | (Supported in all NDB releases based on MySQL 8.0) |

| Format | Description | Added, Deprecated, or Removed |
|--|--|--|
| <code>--help,</code> <code>-?</code> | Display help text and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--login-path=path</code> | Read given path from login file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--lossy-conversions,</code> <code>-l</code> | Allow attribute data to be truncated when converted to smaller type | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-connectstring=connection-string,</code> <code>-c</code> | Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-mgmd-host=connection-string,</code> <code>-c</code> | Same as --ndb-connectstring | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-nodeid=#</code> | Set node ID for this node, overriding any ID set by --ndb-connectstring | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-optimized-node-selection</code> | Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--no-defaults</code> | Do not read default options from any option file other than login file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--print-defaults</code> | Print program argument list and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--promote-attributes,</code> <code>-A</code> | Allow attribute data to be converted to larger type | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--staging-tries=x[,y[,z]]</code> | Specify tries on temporary errors; format is x[,y[,z]] where x=max tries (0=no limit), y=min delay (ms), z=max delay (ms) | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--usage,</code> <code>-?</code> | Display help text and exit; same as --help | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--verbose</code> | Enable verbose messages | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--version,</code> <code>-V</code> | Display version information and exit | (Supported in all NDB releases based on MySQL 8.0) |

- `--abort-on-error`

| | |
|---------------------|-------------------------------|
| Command-Line Format | <code>--abort-on-error</code> |
| Type | Boolean |
| Default Value | <code>FALSE</code> |

Dump core on permanent error (debug option).

- `--character-sets-dir=name`

| | |
|---------------------|--|
| Command-Line Format | <code>--character-sets-dir=name</code> |
| Type | String |
| Default Value | <code>[none]</code> |

Directory where character sets are.

- `--connect-retry-delay`

| | |
|---------------------|--------------------------------------|
| Command-Line Format | <code>--connect-retry-delay=#</code> |
| Type | Integer |
| Default Value | <code>5</code> |
| Minimum Value | <code>0</code> |
| Maximum Value | <code>5</code> |

Number of seconds to wait between attempts to contact management server.

- `--connect-retries`

| | |
|---------------------|----------------------------------|
| Command-Line Format | <code>--connect-retries=#</code> |
| Type | Integer |
| Default Value | <code>12</code> |
| Minimum Value | <code>0</code> |
| Maximum Value | <code>12</code> |

Number of times to retry connection before giving up.

- `--connect-string`

| | |
|---------------------|---|
| Command-Line Format | <code>--connect-string=connection-string</code> |
| Type | String |
| Default Value | <code>[none]</code> |

Same as `--ndb-connectstring`.

- `--core-file`

| | |
|---------------------|--------------------------|
| Command-Line Format | <code>--core-file</code> |
|---------------------|--------------------------|

Write core file on error; used in debugging.

- `--database=dbname, -d`

| | |
|---------------------|--------------------------------|
| Command-Line Format | <code>--database=dbname</code> |
| Type | String |
| Default Value | <code>TEST_DB</code> |

Name of the database in which the table is found.

- `--defaults-extra-file`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-extra-file=path</code> |
| Type | String |
| Default Value | <code>[none]</code> |

Read given file after global files are read.

- `--defaults-file`

| | |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--defaults-file=path</code> |
| Type | String |
| Default Value | <code>[none]</code> |

Read default options from given file only.

- `--defaults-group-suffix`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-group-suffix=string</code> |
| Type | String |
| Default Value | <code>[none]</code> |

Also read groups with `concat(group, suffix)`.

- `--drop-source`

| | |
|---------------------|----------------------------|
| Command-Line Format | <code>--drop-source</code> |
| Type | Boolean |
| Default Value | <code>FALSE</code> |

Drop source table after all rows have been moved.

- `--error-insert`

| | |
|---------------------|-----------------------------|
| Command-Line Format | <code>--error-insert</code> |
| Type | Boolean |
| Default Value | <code>FALSE</code> |

Insert random temporary errors (testing option).

- `--exclude-missing-columns`

| | |
|---------------------|--|
| Command-Line Format | <code>--exclude-missing-columns</code> |
|---------------------|--|

| | |
|---------------|---------|
| Type | Boolean |
| Default Value | FALSE |

Ignore extra columns in source or target table.

- `--help`

| | |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
|---------------------|---------------------|

Display help text and exit.

- `--login-path`

| | |
|---------------------|--------------------------------|
| Command-Line Format | <code>--login-path=path</code> |
| Type | String |
| Default Value | [none] |

Read given path from login file.

- `--lossy-conversions, -l`

| | |
|---------------------|----------------------------------|
| Command-Line Format | <code>--lossy-conversions</code> |
| Type | Boolean |
| Default Value | FALSE |

Allow attribute data to be truncated when converted to a smaller type.

- `--ndb-connectstring`

| | |
|---------------------|--|
| Command-Line Format | <code>--ndb-connectstring=connection-string</code> |
| Type | String |
| Default Value | [none] |

Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf.

- `--ndb-mgmd-host`

| | |
|---------------------|--|
| Command-Line Format | <code>--ndb-mgmd-host=connection-string</code> |
| Type | String |
| Default Value | [none] |

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

| | |
|---------------------|-----------------------------|
| Command-Line Format | <code>--ndb-nodeid=#</code> |
| Type | Integer |
| Default Value | [none] |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

| | |
|---------------------|---|
| Command-Line Format | <code>--ndb-optimized-node-selection</code> |
|---------------------|---|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--no-defaults`

| | |
|---------------------|----------------------------|
| Command-Line Format | <code>--no-defaults</code> |
|---------------------|----------------------------|

Do not read default options from any option file other than login file.

- `--print-defaults`

| | |
|---------------------|-------------------------------|
| Command-Line Format | <code>--print-defaults</code> |
|---------------------|-------------------------------|

Print program argument list and exit.

- `--promote-attributes, -A`

| | |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--promote-attributes</code> |
| Type | Boolean |
| Default Value | FALSE |

Allow attribute data to be converted to a larger type.

- `--staging-tries=x[,y[,z]]`

| | |
|---------------------|--|
| Command-Line Format | <code>--staging-tries=x[,y[,z]]</code> |
| Type | String |
| Default Value | 0,1000,60000 |

Specify tries on temporary errors. Format is x[,y[,z]] where x=max tries (0=no limit), y=min delay (ms), z=max delay (ms).

- `--usage`

| | |
|---------------------|----------------------|
| Command-Line Format | <code>--usage</code> |
|---------------------|----------------------|

Display help text and exit; same as `--help`.

- `--verbose`

| | |
|---------------------|------------------------|
| Command-Line Format | <code>--verbose</code> |
| Type | Boolean |
| Default Value | FALSE |

Enable verbose messages.

- `--version`

| | |
|---------------------|------------------------|
| Command-Line Format | <code>--version</code> |
|---------------------|------------------------|

Display version information and exit.

23.5.16 ndb_perror — Obtain NDB Error Message Information

`ndb_perror` shows information about an NDB error, given its error code. This includes the error message, the type of error, and whether the error is permanent or temporary. This is intended as a drop-in replacement for `perror --ndb`, which is no longer supported.

Usage

```
ndb_perror [options] error_code
```

`ndb_perror` does not need to access a running NDB Cluster, or any nodes (including SQL nodes). To view information about a given NDB error, invoke the program, using the error code as an argument, like this:

```
shell> ndb_perror 323
NDB error code 323: Invalid nodegroup id, nodegroup already existing: Permanent error: Application error
```

To display only the error message, invoke `ndb_perror` with the `--silent` option (short form `-s`), as shown here:

```
shell> ndb_perror -s 323
Invalid nodegroup id, nodegroup already existing: Permanent error: Application error
```

Like `perror`, `ndb_perror` accepts multiple error codes:

```
shell> ndb_perror 321 1001
NDB error code 321: Invalid nodegroup id: Permanent error: Application error
NDB error code 1001: Illegal connect string
```

Additional program options for `ndb_perror` are described later in this section.

`ndb_perror` replaces `perror --ndb`, which is no longer supported by NDB Cluster. To make substitution easier in scripts and other applications that might depend on `perror` for obtaining NDB error information, `ndb_perror` supports its own “dummy” `--ndb` option, which does nothing.

The following table includes all options that are specific to the NDB Cluster program `ndb_perror`. Additional descriptions follow the table.

Table 23.38 Command-line options used with the program `ndb_perror`

| Format | Description | Added, Deprecated, or Removed |
|---|--|--|
| <code>--defaults-extra-file=path</code> | Read given file after global files are read | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-file=path</code> | Read default options from given file only | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-group-suffix=string</code> | Also read groups with <code>concat(group, suffix)</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--help,</code> <code>-?</code> | Display help text | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--login-path=path</code> | Read given path from login file | (Supported in all NDB releases based on MySQL 8.0) |

| Format | Description | Added, Deprecated, or Removed |
|--|---|--|
| <code>--ndb</code> | For compatibility with applications depending on old versions of perror; does nothing | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--no-defaults</code> | Do not read default options from any option file other than login file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--print-defaults</code> | Print program argument list and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--silent,</code> <code>-s</code> | Show error message only | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--version,</code> <code>-V</code> | Print program version information and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--verbose,</code> <code>-v</code> | Verbose output; disable with <code>--silent</code> | (Supported in all NDB releases based on MySQL 8.0) |

Additional Options

- `--defaults-extra-file`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-extra-file=path</code> |
| Type | String |
| Default Value | [none] |

Read given file after global files are read.

- `--defaults-file`

| | |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--defaults-file=path</code> |
| Type | String |
| Default Value | [none] |

Read default options from given file only.

- `--defaults-group-suffix`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-group-suffix=string</code> |
| Type | String |
| Default Value | [none] |

Also read groups with `concat(group, suffix)`.

- `--help, -?`

| | |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
| Type | Boolean |
| Default Value | TRUE |

Display program help text and exit.

- `--login-path`

| | |
|---------------------|--------------------------------|
| Command-Line Format | <code>--login-path=path</code> |
| Type | String |
| Default Value | [none] |

Read given path from login file.

- `--ndb`

| | |
|---------------------|--------------------|
| Command-Line Format | <code>--ndb</code> |
| Type | Boolean |
| Default Value | TRUE |

For compatibility with applications depending on old versions of `perror` that use that program's `--ndb` option. The option when used with `ndb_perror` does nothing, and is ignored by it.

- `--no-defaults`

| | |
|---------------------|----------------------------|
| Command-Line Format | <code>--no-defaults</code> |
|---------------------|----------------------------|

Do not read default options from any option file other than login file.

- `--print-defaults`

| | |
|---------------------|-------------------------------|
| Command-Line Format | <code>--print-defaults</code> |
|---------------------|-------------------------------|

Print program argument list and exit.

- `--silent, -s`

| | |
|---------------------|-----------------------|
| Command-Line Format | <code>--silent</code> |
| Type | Boolean |
| Default Value | TRUE |

Show error message only.

- `--version, -V`

| | |
|---------------------|------------------------|
| Command-Line Format | <code>--version</code> |
| Type | Boolean |
| Default Value | TRUE |

Print program version information and exit.

- `--verbose, -v`

| | |
|---------------------|------------------------|
| Command-Line Format | <code>--verbose</code> |
| Type | Boolean |

| | |
|---------------|------|
| Default Value | TRUE |
|---------------|------|

Verbose output; disable with `--silent`.

23.5.17 ndb_print_backup_file — Print NDB Backup File Contents

`ndb_print_backup_file` obtains diagnostic information from a cluster backup file.

Table 23.39 Command-line options used with the program `ndb_print_backup_file`

| Format | Description | Added, Deprecated, or Removed |
|--|--|--|
| <code>--backup-password=string,</code> <code>-P</code> | Use this password to decrypt file | ADDED: NDB 8.0.22 |
| <code>--backup-password-from-stdin[=value]</code> | Get decryption password in a secure fashion from STDIN | ADDED: NDB 8.0.24 |
| <code>--control-directory-number=#,</code> <code>-c</code> | Control directory number | ADDED: NDB 8.0.24 |
| <code>--defaults-extra-file=path</code> | Read given file after global files are read | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-file=path</code> | Read default options from given file only | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-group-suffix=string</code> | Also read groups with <code>concat(group, suffix)</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--fragment-id=#,</code> <code>-f</code> | Fragment ID | ADDED: NDB 8.0.24 |
| <code>--help,</code> <code>--usage,</code> <code>-h,</code> <code>-?</code> | Print usage information | ADDED: NDB 8.0.24 |
| <code>--login-path=path</code> | Read given path from login file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--no-defaults</code> | Do not read default options from any option file other than login file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--no-print-rows,</code> <code>-u</code> | Do not print rows | ADDED: NDB 8.0.24 |
| <code>--print-defaults</code> | Print program argument list and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--print-header-words,</code> <code>-h</code> | Print header words | ADDED: NDB 8.0.24 |
| <code>--print-restored-rows</code> | Print restored rows | ADDED: NDB 8.0.24 |

| Format | Description | Added, Deprecated, or Removed |
|---|---|--|
| <code>--print-rows</code> , <code>-U</code> | Print rows. Enabled by default; disable with <code>--no-print-rows</code> | ADDED: NDB 8.0.24 |
| <code>--print-rows-per-page</code> | Print rows per page | ADDED: NDB 8.0.24 |
| <code>--rowid-file</code> , <code>-n</code> | File containing row ID to check for | ADDED: NDB 8.0.24 |
| <code>--show-ignored-rows</code> , <code>-i</code> | Show ignored rows | ADDED: NDB 8.0.24 |
| <code>--table-id</code> , <code>-t</code> | Table ID | ADDED: NDB 8.0.24 |
| <code>--usage</code> , <code>-?</code> | Display help text and exit; same as <code>--help</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--verbose[=#]</code> , <code>-v</code> | Verbosity level | ADDED: NDB 8.0.24 |
| <code>--version</code> , <code>-V</code> | Display version information and exit | (Supported in all NDB releases based on MySQL 8.0) |

Usage

```
ndb_print_backup_file [-P password] file_name
```

file_name is the name of a cluster backup file. This can be any of the files (`.Data`, `.ctl`, or `.log` file) found in a cluster backup directory. These files are found in the data node's backup directory under the subdirectory `BACKUP-#`, where `#` is the sequence number for the backup. For more information about cluster backup files and their contents, see [Section 23.6.8.1, “NDB Cluster Backup Concepts”](#).

Like `ndb_print_schema_file` and `ndb_print_sys_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_backup_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

In NDB 8.0, this program can also be used to read undo log files.

Options

Prior to NDB 8.0.24, `ndb_print_backup_file` supported only the `-P` option. Beginning with NDB 8.0.24, the program supports a number of options, which are described in the following list.

- `--backup-password`

| | |
|---------------------|---------------------------------------|
| Command-Line Format | <code>--backup-password=string</code> |
| Introduced | 8.0.22-ndb-8.0.22 |
| Type | String |
| Default Value | [none] |

Specify the password needed to decrypt an encrypted backup.

The long form of this option is available beginning with NDB 8.0.24.

- `--backup-password-from-stdin`

| | |
|---------------------|---|
| Command-Line Format | <code>--backup-password-from-stdin[=value]</code> |
| Introduced | 8.0.24-ndb-8.0.24 |
| Type | Boolean |
| Default Value | <code>FALSE</code> |

Allow input of the password from standard input, similar to entering a password after invoking `mysql --password` with no password supplied.

- `--control-directory-number`

| | |
|---------------------|---|
| Command-Line Format | <code>--control-directory-number=#</code> |
| Introduced | 8.0.24-ndb-8.0.24 |
| Type | Integer |
| Default Value | <code>0</code> |

Control file directory number. Used together with `--print-restored-rows`.

- `--defaults-extra-file`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-extra-file=path</code> |
| Type | String |
| Default Value | <code>[none]</code> |

Read given file after global files are read.

- `--defaults-file`

| | |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--defaults-file=path</code> |
| Type | String |
| Default Value | <code>[none]</code> |

Read default options from given file only.

- `--defaults-group-suffix`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-group-suffix=string</code> |
| Type | String |
| Default Value | <code>[none]</code> |

Also read groups with `concat(group, suffix)`.

- `--fragment-id`

| | |
|---------------------|------------------------------|
| Command-Line Format | <code>--fragment-id=#</code> |
|---------------------|------------------------------|

| | |
|---------------|-------------------|
| Introduced | 8.0.24-ndb-8.0.24 |
| Type | Integer |
| Default Value | 0 |

Fragment ID. Used together with `--print-restored-rows`.

- `--help`

| | |
|---------------------|---|
| Command-Line Format | <code>--help</code> <code>--usage</code> |
| Introduced | 8.0.24-ndb-8.0.24 |
| Type | Boolean |
| Default Value | |

Print program usage information.

- `--login-path`

| | |
|---------------------|--------------------------------|
| Command-Line Format | <code>--login-path=path</code> |
| Type | String |
| Default Value | [none] |

Read given path from login file.

- `--no-defaults`

| | |
|---------------------|----------------------------|
| Command-Line Format | <code>--no-defaults</code> |
|---------------------|----------------------------|

Do not read default options from any option file other than login file.

- `--no-print-rows`

| | |
|---------------------|------------------------------|
| Command-Line Format | <code>--no-print-rows</code> |
| Introduced | 8.0.24-ndb-8.0.24 |
| Type | Boolean |
| Default Value | FALSE |

Do not include rows in output.

- `--print-defaults`

| | |
|---------------------|-------------------------------|
| Command-Line Format | <code>--print-defaults</code> |
|---------------------|-------------------------------|

Print program argument list and exit.

- `--print-header-words`

| | |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--print-header-words</code> |
| Introduced | 8.0.24-ndb-8.0.24 |
| Type | Boolean |

| | |
|---------------|-------|
| Default Value | FALSE |
|---------------|-------|

Include header words in output.

- `--print-restored-rows`

| | |
|---------------------|------------------------------------|
| Command-Line Format | <code>--print-restored-rows</code> |
| Introduced | 8.0.24-ndb-8.0.24 |
| Type | Boolean |
| Default Value | FALSE |

Include restored rows in output, using the file `LCP/c/TtFf.ctl`, for which the values are set as follows:

- `c` is the control file number set using `--control-directory-number`
- `t` is the table ID set using `--table-id`
- `f` is the fragment ID set using `--fragment-id`

- `--print-rows`

| | |
|---------------------|---------------------------|
| Command-Line Format | <code>--print-rows</code> |
| Introduced | 8.0.24-ndb-8.0.24 |
| Type | Boolean |
| Default Value | TRUE |

Print rows. This option is enabled by default; to disable it, use `--no-print-rows`.

- `--print-rows-per-page`

| | |
|---------------------|------------------------------------|
| Command-Line Format | <code>--print-rows-per-page</code> |
| Introduced | 8.0.24-ndb-8.0.24 |
| Type | Boolean |
| Default Value | FALSE |

Print rows per page.

- `--rowid-file`

| | |
|---------------------|---------------------------|
| Command-Line Format | <code>--rowid-file</code> |
| Introduced | 8.0.24-ndb-8.0.24 |
| Type | File name |
| Default Value | [none] |

File to check for row ID.

- `--show-ignored-rows`

| | |
|---------------------|----------------------------------|
| Command-Line Format | <code>--show-ignored-rows</code> |
| Introduced | 8.0.24-ndb-8.0.24 |

| | |
|---------------|---------|
| Type | Boolean |
| Default Value | FALSE |

Show ignored rows.

- `--table-id`

| | |
|---------------------|-------------------------|
| Command-Line Format | <code>--table-id</code> |
| Introduced | 8.0.24-ndb-8.0.24 |
| Type | Boolean |
| Default Value | FALSE |

Table ID. Used together with `--print-restored-rows`.

- `--usage`

| | |
|---------------------|----------------------|
| Command-Line Format | <code>--usage</code> |
|---------------------|----------------------|

Display help text and exit; same as `--help`.

- `--verbose`

| | |
|---------------------|----------------------------|
| Command-Line Format | <code>--verbose[=#]</code> |
| Introduced | 8.0.24-ndb-8.0.24 |
| Type | Integer |
| Default Value | 0 |

Verbosity level of output. A greater value indicates increased verbosity.

- `--version`

| | |
|---------------------|------------------------|
| Command-Line Format | <code>--version</code> |
|---------------------|------------------------|

Display version information and exit.

23.5.18 ndb_print_file — Print NDB Disk Data File Contents

`ndb_print_file` obtains information from an NDB Cluster Disk Data file.

Usage

```
ndb_print_file [-v] [-q] file_name+
```

file_name is the name of an NDB Cluster Disk Data file. Multiple filenames are accepted, separated by spaces.

Like `ndb_print_schema_file` and `ndb_print_sys_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_file` must be run on an NDB Cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

Additional Options

`ndb_print_file` supports the following options:

- `-v`: Make output verbose.
- `-q`: Suppress output (quiet mode).
- `--help`, `-h`, `-?`: Print help message.

For more information, see [Section 23.6.10, “NDB Cluster Disk Data Tables”](#).

23.5.19 ndb_print_frag_file — Print NDB Fragment List File Contents

`ndb_print_frag_file` obtains information from a cluster fragment list file. It is intended for use in helping to diagnose issues with data node restarts.

Usage

```
ndb_print_frag_file file_name
```

file_name is the name of a cluster fragment list file, which matches the pattern `SX.FragList`, where *X* is a digit in the range 2-9 inclusive, and are found in the data node file system of the data node having the node ID *nodeid*, in directories named `ndb_nodeid_fs/DN/DBDIH/`, where *N* is 1 or 2. Each fragment file contains records of the fragments belonging to each NDB table. For more information about cluster fragment files, see [NDB Cluster Data Node File System Directory](#).

Like `ndb_print_backup_file`, `ndb_print_sys_file`, and `ndb_print_schema_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server), `ndb_print_frag_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

Additional Options

None.

Sample Output

```
shell> ndb_print_frag_file /usr/local/mysql/data/ndb_3_fs/D1/DBDIH/S2.FragList
Filename: /usr/local/mysql/data/ndb_3_fs/D1/DBDIH/S2.FragList with size 8192
noOfPages = 1 noOfWords = 182
Table Data
-----
Num Frags: 2 NoOfReplicas: 2 hashpointer: 4294967040
kvalue: 6 mask: 0x00000000 method: HashMap

LcpNo[1]: maxGciCompleted: 0 maxGciStarted: 0 lcpId: 0 lcpStatus: invalid

```

23.5.20 ndb_print_schema_file — Print NDB Schema File Contents

`ndb_print_schema_file` obtains diagnostic information from a cluster schema file.

Usage

```
ndb_print_schema_file file_name
```

file_name is the name of a cluster schema file. For more information about cluster schema files, see [NDB Cluster Data Node File System Directory](#).

Like `ndb_print_backup_file` and `ndb_print_sys_file` (and unlike most of the other *NDB* utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_schema_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

Additional Options

None.

23.5.21 ndb_print_sys_file — Print NDB System File Contents

`ndb_print_sys_file` obtains diagnostic information from an NDB Cluster system file.

Usage

```
ndb_print_sys_file file_name
```

file_name is the name of a cluster system file (sysfile). Cluster system files are located in a data node's data directory (`DataDir`); the path under this directory to system files matches the pattern `ndb_#_fs/D#/DBDIH/P#.sysfile`. In each case, the `#` represents a number (not necessarily the same number). For more information, see [NDB Cluster Data Node File System Directory](#).

Like `ndb_print_backup_file` and `ndb_print_schema_file` (and unlike most of the other *NDB* utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_backup_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

Additional Options

None.

23.5.22 ndb_redo_log_reader — Check and Print Content of Cluster Redo Log

Reads a redo log file, checking it for errors, printing its contents in a human-readable format, or both. `ndb_redo_log_reader` is intended for use primarily by NDB Cluster developers and Support personnel in debugging and diagnosing problems.

This utility remains under development, and its syntax and behavior are subject to change in future NDB Cluster releases.

The C++ source files for `ndb_redo_log_reader` can be found in the directory `/storage/ndb/src/kernel/blocks/dblqh/redoLogReader`.

Options that can be used with `ndb_redo_log_reader` are shown in the following table. Additional descriptions follow the table.

Table 23.40 Command-line options used with the program `ndb_redo_log_reader`

| Format | Description | Added, Deprecated, or Removed |
|-------------------------------|--|--|
| <code>-dump</code> | Print dump info | (Supported in all NDB releases based on MySQL 8.0) |
| <code>-filedescriptors</code> | Print file descriptors only | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--help</code> | Print usage information | (Supported in all NDB releases based on MySQL 8.0) |
| <code>-lap</code> | Provide lap info, with max GCI started and completed | (Supported in all NDB releases based on MySQL 8.0) |
| <code>-mbyte #</code> | Starting megabyte | (Supported in all NDB releases based on MySQL 8.0) |
| <code>-mbyteheaders</code> | Show only first page header of each megabyte in file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>-nocheck</code> | Do not check records for errors | (Supported in all NDB releases based on MySQL 8.0) |
| <code>-noprint</code> | Do not print records | (Supported in all NDB releases based on MySQL 8.0) |
| <code>-page #</code> | Start with this page | (Supported in all NDB releases based on MySQL 8.0) |
| <code>-pageheaders</code> | Show page headers only | (Supported in all NDB releases based on MySQL 8.0) |
| <code>-pageindex #</code> | Start with this page index | (Supported in all NDB releases based on MySQL 8.0) |
| <code>-twiddle</code> | Bit-shifted dump | (Supported in all NDB releases based on MySQL 8.0) |

Usage

```
ndb_redo_log_reader file_name [options]
```

file_name is the name of a cluster redo log file. redo log files are located in the numbered directories under the data node's data directory (`DataDir`); the path under this directory to the redo log files matches the pattern `ndb_nodeid_fs/D#/DBLQH/S#.FragLog.nodeid` is the data node's node ID. The two instances of `#` each represent a number (not necessarily the same number); the number following `D` is in the range 8-39 inclusive; the range of the number following `S` varies according to the value of the `NoOfFragmentLogFiles` configuration parameter, whose default value is 16; thus, the default range of the number in the file name is 0-15 inclusive. For more information, see [NDB Cluster Data Node File System Directory](#).

The name of the file to be read may be followed by one or more of the options listed here:

- `-dump`

| | |
|---------------------|--------------------|
| Command-Line Format | <code>-dump</code> |
| Type | Boolean |
| Default Value | <code>FALSE</code> |

Print dump info.

- | | |
|---------------------|-------------------------------|
| Command-Line Format | <code>-filedescriptors</code> |
| Type | Boolean |
| Default Value | <code>FALSE</code> |

`-filedescriptors`: Print file descriptors only.

- | | |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
|---------------------|---------------------|

`--help`: Print usage information.

- `-lap`

| | |
|---------------------|--------------------|
| Command-Line Format | <code>-lap</code> |
| Type | Boolean |
| Default Value | <code>FALSE</code> |

Provide lap info, with max GCI started and completed.

- | | |
|---------------------|-----------------------|
| Command-Line Format | <code>-mbyte #</code> |
| Type | Numeric |
| Default Value | 0 |
| Minimum Value | 0 |
| Maximum Value | 15 |

`-mbyte #`: Starting megabyte.

`#` is an integer in the range 0 to 15, inclusive.

- | | |
|---------------------|----------------------------|
| Command-Line Format | <code>-mbyteheaders</code> |
| Type | Boolean |
| Default Value | <code>FALSE</code> |

`-mbyteheaders`: Show only the first page header of every megabyte in the file.

- | | |
|---------------------|-----------------------|
| Command-Line Format | <code>-noprint</code> |
| Type | Boolean |
| Default Value | <code>FALSE</code> |

`-noprint`: Do not print the contents of the log file.

- | | |
|---------------------|-----------------------|
| Command-Line Format | <code>-nocheck</code> |
|---------------------|-----------------------|

| | |
|---------------|---------|
| Type | Boolean |
| Default Value | FALSE |

`-nocheck`: Do not check the log file for errors.

- | | |
|---------------------|----------------------|
| Command-Line Format | <code>-page #</code> |
| Type | Integer |
| Default Value | 0 |
| Minimum Value | 0 |
| Maximum Value | 31 |

`-page #`: Start at this page.

`#` is an integer in the range 0 to 31, inclusive.

- | | |
|---------------------|---------------------------|
| Command-Line Format | <code>-pageheaders</code> |
| Type | Boolean |
| Default Value | FALSE |

`-pageheaders`: Show page headers only.

- | | |
|---------------------|---------------------------|
| Command-Line Format | <code>-pageindex #</code> |
| Type | Integer |
| Default Value | 12 |
| Minimum Value | 12 |
| Maximum Value | 8191 |

`-pageindex #`: Start at this page index.

`#` is an integer between 12 and 8191, inclusive.

- `-twiddle`

| | |
|---------------------|-----------------------|
| Command-Line Format | <code>-twiddle</code> |
| Type | Boolean |
| Default Value | FALSE |

Bit-shifted dump.

Like `ndb_print_backup_file` and `ndb_print_schema_file` (and unlike most of the NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_redo_log_reader` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

23.5.23 ndb_restore — Restore an NDB Cluster Backup

The NDB Cluster restoration program is implemented as a separate command-line utility `ndb_restore`, which can normally be found in the MySQL `bin` directory. This program reads the files created as a result of the backup and inserts the stored information into the database.

In NDB 7.6 and earlier, this program printed `NDBT_ProgramExit - status` upon completion of its run, due to an unnecessary dependency on the `NDBT` testing library. This dependency has been removed in NDB 8.0, eliminating the extraneous output.

`ndb_restore` must be executed once for each of the backup files that were created by the `START BACKUP` command used to create the backup (see [Section 23.6.8.2, “Using The NDB Cluster Management Client to Create a Backup”](#)). This is equal to the number of data nodes in the cluster at the time that the backup was created.

Note

Before using `ndb_restore`, it is recommended that the cluster be running in single user mode, unless you are restoring multiple data nodes in parallel. See [Section 23.6.6, “NDB Cluster Single User Mode”](#), for more information.

Options that can be used with `ndb_restore` are shown in the following table. Additional descriptions follow the table.

Table 23.41 Command-line options used with the program `ndb_restore`

| Format | Description | Added, Deprecated, or Removed |
|---|---|--|
| <code>--allow-pk-changes[=0 1]</code> | Allow changes to set of columns making up table's primary key | ADDED: NDB 8.0.21 |
| <code>--append</code> | Append data to tab-delimited file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--backup-password=string</code> | Supply a password for decrypting an encrypted backup with <code>--decrypt</code> ; see documentation for allowed values | ADDED: NDB 8.0.22 |
| <code>--backup-password-from-stdin[=value]</code> | Get decryption password in a secure fashion from STDIN; use together with <code>--decrypt</code> option | ADDED: NDB 8.0.24 |
| <code>--backup-path=dir_name</code> | Path to backup files directory | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--backupid=#,</code> <code>-b</code> | Restore from backup having this ID | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--character-sets-dir=path</code> | Directory containing character sets | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect,</code> <code>-c</code> | Alias for <code>--connectstring</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-retries=#</code> | Number of times to retry connection before giving up | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-retry-delay=#</code> | Number of seconds to wait between attempts to contact management server | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-string=connection-string,</code> <code>-c</code> | Same as <code>--ndb-connectstring</code> | (Supported in all NDB releases based on MySQL 8.0) |

| Format | Description | Added, Deprecated, or Removed |
|---|--|--|
| <code>--core-file</code> | Write core file on error; used in debugging | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--decrypt</code> | Decrypt an encrypted backup; requires <code>--backup-password</code> | ADDED: NDB 8.0.22 |
| <code>--defaults-extra-file=path</code> | Read given file after global files are read | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-file=path</code> | Read default options from given file only | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-group-suffix=string</code> | Also read groups with <code>concat(group, suffix)</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--disable-indexes</code> | Causes indexes from backup to be ignored; may decrease time needed to restore data | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--dont-ignore-systab-0,</code> <code>-f</code> | Do not ignore system table during restore; experimental only; not for production use | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--exclude-databases=db-list</code> | List of one or more databases to exclude (includes those not named) | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--exclude-intermediate-sql-tables[=TRUE FALSE]</code> | If TRUE (default), do not restore any intermediate tables (having names prefixed with '#sql-') that were left over from copying ALTER TABLE operations | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--exclude-missing-columns</code> | Causes columns from backup version of table that are missing from version of table in database to be ignored | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--exclude-missing-tables</code> | Causes tables from backup that are missing from database to be ignored | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--exclude-tables=table-list</code> | List of one or more tables to exclude (includes those in same database that are not named); each table reference must include database name | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--fields-enclosed-by=char</code> | Fields are enclosed by this character | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--fields-optionally-enclosed-by</code> | Fields are optionally enclosed by this character | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--fields-terminated-by=char</code> | Fields are terminated by this character | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--help,</code> <code>-?</code> | Display help text and exit | (Supported in all NDB releases based on MySQL 8.0) |

| Format | Description | Added, Deprecated, or Removed |
|--|--|--|
| <code>--hex</code> | Print binary types in hexadecimal format | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ignore-extended-pk-updates[=0 1]</code> | Ignore log entries containing updates to columns now included in extended primary key | ADDED: NDB 8.0.21 |
| <code>--include-databases=db-list</code> | List of one or more databases to restore (excludes those not named) | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--include-stored-grants</code> | Restore shared users and grants to <code>ndb_sql_metadata</code> table | ADDED: NDB 8.0.19 |
| <code>--include-tables=table-list</code> | List of one or more tables to restore (excludes those in same database that are not named); each table reference must include database name | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--lines-terminated-by=char</code> | Lines are terminated by this character | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--login-path=path</code> | Read given path from login file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--lossy-conversions,</code> <code>-L</code> | Allow lossy conversions of column values (type demotions or changes in sign) when restoring data from backup | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--no-binlog</code> | If mysqld is connected and using binary logging, do not log restored data | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--no-defaults</code> | Do not read default options from any option file other than login file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--no-restore-disk-objects,</code> <code>-d</code> | Do not restore objects relating to Disk Data | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--no-upgrade,</code> <code>-u</code> | Do not upgrade array type for varsize attributes which do not already resize VAR data, and do not change column attributes | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-connectstring=connection-string,</code> <code>-c</code> | Set connect string for connecting to <code>ndb_mgmd</code> . Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in <code>NDB_CONNECTSTRING</code> and <code>my.cnf</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-mgmd-host=connection-string,</code> <code>-c</code> | Same as <code>--ndb-connectstring</code> | (Supported in all NDB releases based on MySQL 8.0) |

| Format | Description | Added, Deprecated, or Removed |
|---|--|--|
| <code>--ndb-nodegroup-map=map,</code> <code>-z</code> | Specify node group map; unused, unsupported | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-nodeid=#</code> | Set node ID for this node, overriding any ID set by <code>--ndb-connectstring</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-optimized-node-selection</code> | Enable optimizations for selection of nodes for transactions. Enabled by default; use <code>--skip-ndb-optimized-node-selection</code> to disable | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--nodeid=#,</code> <code>-n</code> | ID of node where backup was taken | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--num-slices=#</code> | Number of slices to apply when restoring by slice | ADDED: NDB 8.0.20 |
| <code>--parallelism=#,</code> <code>-p</code> | Number of parallel transactions to use while restoring data | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--preserve-trailing-spaces,</code> <code>-P</code> | Allow preservation of trailing spaces (including padding) when promoting fixed-width string types to variable-width types | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--print</code> | Print metadata, data, and log to stdout (equivalent to <code>--print-meta --print-data --print-log</code>) | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--print-data</code> | Print data to stdout | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--print-defaults</code> | Print program argument list and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--print-log</code> | Print log to stdout | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--print-meta</code> | Print metadata to stdout | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--print-sql-log</code> | Write SQL log to stdout; default is FALSE | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--progress-frequency=#</code> | Print status of restore each given number of seconds | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--promote-attributes,</code> <code>-A</code> | Allow attributes to be promoted when restoring data from backup | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--rebuild-indexes</code> | Causes multithreaded rebuilding of ordered indexes found in backup; number of threads used is determined by setting <code>BuildIndexThreads</code> | (Supported in all NDB releases based on MySQL 8.0) |

| Format | Description | Added, Deprecated, or Removed |
|--|---|--|
| <code>--remap-column=[db].[tbl].[col]:[fn]:[args]</code> | Apply offset to value of specified column using indicated function and arguments | ADDED: NDB 8.0.21 |
| <code>--restore-data,</code> <code>-r</code> | Restore table data and logs into NDB Cluster using NDB API | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--restore-epoch,</code> <code>-e</code> | Restore epoch info into status table; useful on replica cluster for starting replication; updates or inserts row in <code>mysql.ndb_apply_status</code> with ID 0 | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--restore-meta,</code> <code>-m</code> | Restore metadata to NDB Cluster using NDB API | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--restore-privilege-tables</code> | Restore MySQL privilege tables that were previously moved to NDB | DEPRECATED: NDB 8.0.16 |
| <code>--rewrite-database=olddb,newdb</code> | Restore to differently named database | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--skip-broken-objects</code> | Ignore missing blob tables in backup file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--skip-table-check,</code> <code>-s</code> | Skip table structure check during restore | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--skip-unknown-objects</code> | Causes schema objects not recognized by <code>ndb_restore</code> to be ignored when restoring backup made from newer NDB version to older version | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--slice-id=#</code> | Slice ID, when restoring by slices | ADDED: NDB 8.0.20 |
| <code>--tab=dir_name,</code> <code>-T dir_name</code> | Creates a tab-separated .txt file for each table in path provided | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--usage,</code> <code>-?</code> | Display help text and exit; same as <code>--help</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--verbose=#</code> | Level of verbosity in output | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--version,</code> <code>-V</code> | Display version information and exit | (Supported in all NDB releases based on MySQL 8.0) |

- `--allow-pk-changes`

| | |
|---------------------|---------------------------------------|
| Command-Line Format | <code>--allow-pk-changes[=0 1]</code> |
| Introduced | 8.0.21-ndb-8.0.21 |
| Type | Integer |

| | |
|---------------|---|
| Default Value | 0 |
| Minimum Value | 0 |
| Maximum Value | 1 |

When this option is set to 1, `ndb_restore` allows the primary keys in a table definition to differ from that of the same table in the backup. This may be desirable when backing up and restoring between different schema versions with primary key changes on one or more tables, and it appears that performing the restore operation using `ndb_restore` is simpler or more efficient than issuing many `ALTER TABLE` statements after restoring table schemas and data.

The following changes in primary key definitions are supported by `--allow-pk-changes`:

- **Extending the primary key:** A non-nullable column that exists in the table schema in the backup becomes part of the table's primary key in the database.

Important

When extending a table's primary key, any columns which become part of primary key must not be updated while the backup is being taken; any such updates discovered by `ndb_restore` cause the restore operation to fail, even when no change in value takes place. In some cases, it may be possible to override this behavior using the `--ignore-extended-pk-updates` option; see the description of this option for more information.

- **Contracting the primary key (1):** A column that is already part of the table's primary key in the backup schema is no longer part of the primary key, but remains in the table.
- **Contracting the primary key (2):** A column that is already part of the table's primary key in the backup schema is removed from the table entirely.

These differences can be combined with other schema differences supported by `ndb_restore`, including changes to blob and text columns requiring the use of staging tables.

Basic steps in a typical scenario using primary key schema changes are listed here:

1. Restore table schemas using `ndb_restore --restore-meta`
2. Alter schema to that desired, or create it
3. Back up the desired schema
4. Run `ndb_restore --disable-indexes` using the backup from the previous step, to drop indexes and constraints
5. Run `ndb_restore --allow-pk-changes` (possibly along with `--ignore-extended-pk-updates`, `--disable-indexes`, and possibly other options as needed) to restore all data
6. Run `ndb_restore --rebuild-indexes` using the backup made with the desired schema, to rebuild indexes and constraints

When extending the primary key, it may be necessary for `ndb_restore` to use a temporary secondary unique index during the restore operation to map from the old primary key to the new one. Such an index is created only when necessary to apply events from the backup log to a table which has an extended primary key. This index is named `NDB$RESTORE_PK_MAPPING`, and is created on each table requiring it; it can be shared, if necessary, by multiple instances of `ndb_restore` instances running in parallel.

(Running `ndb_restore --rebuild-indexes` at the end of the restore process causes this index to be dropped.)

- `--append`

| | |
|---------------------|-----------------------|
| Command-Line Format | <code>--append</code> |
|---------------------|-----------------------|

When used with the `--tab` and `--print-data` options, this causes the data to be appended to any existing files having the same names.

- `--backup-path=dir_name`

| | |
|---------------------|-------------------------------------|
| Command-Line Format | <code>--backup-path=dir_name</code> |
| Type | Directory name |
| Default Value | <code>./</code> |

The path to the backup directory is required; this is supplied to `ndb_restore` using the `--backup-path` option, and must include the subdirectory corresponding to the ID backup of the backup to be restored. For example, if the data node's `DataDir` is `/var/lib/mysql-cluster`, then the backup directory is `/var/lib/mysql-cluster/BACKUP`, and the backup files for the backup with the ID 3 can be found in `/var/lib/mysql-cluster/BACKUP/BACKUP-3`. The path may be absolute or relative to the directory in which the `ndb_restore` executable is located, and may be optionally prefixed with `backup-path=`.

It is possible to restore a backup to a database with a different configuration than it was created from. For example, suppose that a backup with backup ID 12, created in a cluster with two storage nodes having the node IDs 2 and 3, is to be restored to a cluster with four nodes. Then `ndb_restore` must be run twice—once for each storage node in the cluster where the backup was taken. However, `ndb_restore` cannot always restore backups made from a cluster running one version of MySQL to a cluster running a different MySQL version.

Important

It is not possible to restore a backup made from a newer version of NDB Cluster using an older version of `ndb_restore`. You can restore a backup made from a newer version of MySQL to an older cluster, but you must use a copy of `ndb_restore` from the newer NDB Cluster version to do so.

For example, to restore a cluster backup taken from a cluster running NDB Cluster 7.5.24 to a cluster running NDB Cluster 7.4.33, you must use the `ndb_restore` that comes with the NDB Cluster 7.5.24 distribution.

For more rapid restoration, the data may be restored in parallel, provided that there is a sufficient number of cluster connections available. That is, when restoring to multiple nodes in parallel, you must have an `[api]` or `[mysqld]` section in the cluster `config.ini` file available for each concurrent `ndb_restore` process. However, the data files must always be applied before the logs.

- `--backup-password=password`

| | |
|---------------------|---------------------------------------|
| Command-Line Format | <code>--backup-password=string</code> |
| Introduced | 8.0.22-ndb-8.0.22 |
| Type | String |

| | |
|---------------|--------|
| Default Value | [none] |
|---------------|--------|

This option specifies a password to be used when decrypting an encrypted backup with the `--decrypt` option. This must be the same password that was used to encrypt the backup.

The password can be up to 256 characters in length, and must be enclosed by single or double quotation marks. It can contain any of the ASCII characters having character codes 32, 35, 38, 40-91, 93, 95, and 97-126; in other words, it can use any printable ASCII characters except for `!`, `'`, `"`, `$`, `%`, `\`, and `^`.

In MySQL 8.0.24 and later, it is possible to omit the password, in which case `ndb_restore` waits for it to be supplied from `stdin`, as when using `--backup-password-from-stdin`.

- `--backup-password-from-stdin[=TRUE|FALSE]`

| | |
|---------------------|---|
| Command-Line Format | <code>--backup-password-from-stdin[=value]</code> |
| Introduced | 8.0.24-ndb-8.0.24 |
| Type | Boolean |
| Default Value | FALSE |

When used in place of `--backup-password`, this option enables input of the backup password from the system shell (`stdin`), similar to how this is done when supplying the password interactively to `mysql` when using the `--password` without supplying the password on the command line.

- `--backupid=#, -b`

| | |
|---------------------|---------------------------|
| Command-Line Format | <code>--backupid=#</code> |
| Type | Numeric |
| Default Value | none |

This option is used to specify the ID or sequence number of the backup, and is the same number shown by the management client in the `Backup backup_id completed` message displayed upon completion of a backup. (See [Section 23.6.8.2, “Using The NDB Cluster Management Client to Create a Backup”](#).)

Important

When restoring cluster backups, you must be sure to restore all data nodes from backups having the same backup ID. Using files from different backups results at best in restoring the cluster to an inconsistent state, and is likely to fail altogether.

In NDB 8.0, this option is required.

- `--character-sets-dir`

| | |
|---------------------|--|
| Command-Line Format | <code>--character-sets-dir=path</code> |
|---------------------|--|

Directory containing character sets.

- `--connect, -c`

| | |
|---------------------|------------------------|
| Command-Line Format | <code>--connect</code> |
| Type | String |

| | |
|---------------|----------------|
| Default Value | localhost:1186 |
|---------------|----------------|

Alias for `--ndb-connectstring`.

- `--connect-retries`

| | |
|---------------------|----------------------------------|
| Command-Line Format | <code>--connect-retries=#</code> |
| Type | Integer |
| Default Value | 12 |
| Minimum Value | 0 |
| Maximum Value | 12 |

Number of times to retry connection before giving up.

- `--connect-retry-delay`

| | |
|---------------------|--------------------------------------|
| Command-Line Format | <code>--connect-retry-delay=#</code> |
| Type | Integer |
| Default Value | 5 |
| Minimum Value | 0 |
| Maximum Value | 5 |

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

| | |
|---------------------|---|
| Command-Line Format | <code>--connect-string=connection-string</code> |
| Type | String |
| Default Value | [none] |

Same as `--ndb-connectstring`.

- `--core-file`

| | |
|---------------------|--------------------------|
| Command-Line Format | <code>--core-file</code> |
|---------------------|--------------------------|

Write core file on error; used in debugging.

- `--decrypt`

| | |
|---------------------|------------------------|
| Command-Line Format | <code>--decrypt</code> |
| Introduced | 8.0.22-ndb-8.0.22 |

Decrypt an encrypted backup using the password supplied by the `--backup-password` option.

- `--defaults-extra-file`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-extra-file=path</code> |
| Type | String |
| Default Value | [none] |

Read given file after global files are read.

- `--defaults-file`

| | |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--defaults-file=path</code> |
| Type | String |
| Default Value | [none] |

Read default options from given file only.

- `--defaults-group-suffix`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-group-suffix=string</code> |
| Type | String |
| Default Value | [none] |

Also read groups with `concat(group, suffix)`.

- `--disable-indexes`

| | |
|---------------------|--------------------------------|
| Command-Line Format | <code>--disable-indexes</code> |
|---------------------|--------------------------------|

Disable restoration of indexes during restoration of the data from a native NDB backup. Afterwards, you can restore indexes for all tables at once with multithreaded building of indexes using `--rebuild-indexes`, which should be faster than rebuilding indexes concurrently for very large tables.

In NDB 8.0.27 and later, this option also drops any foreign keys specified in the backup.

- `--dont-ignore-systab-0, -f`

| | |
|---------------------|-------------------------------------|
| Command-Line Format | <code>--dont-ignore-systab-0</code> |
|---------------------|-------------------------------------|

Normally, when restoring table data and metadata, `ndb_restore` ignores the copy of the NDB system table that is present in the backup. `--dont-ignore-systab-0` causes the system table to be restored. *This option is intended for experimental and development use only, and is not recommended in a production environment.*

- `--exclude-databases=db-list`

| | |
|---------------------|--|
| Command-Line Format | <code>--exclude-databases=db-list</code> |
| Type | String |
| Default Value | |

Comma-delimited list of one or more databases which should not be restored.

This option is often used in combination with `--exclude-tables`; see that option's description for further information and examples.

- `--exclude-intermediate-sql-tables[=TRUE|FALSE]`

| | |
|---------------------|---|
| Command-Line Format | <code>--exclude-intermediate-sql-tables[=TRUE FALSE]</code> |
|---------------------|---|

| | |
|---------------|---------|
| Type | Boolean |
| Default Value | TRUE |

When performing copying `ALTER TABLE` operations, `mysqld` creates intermediate tables (whose names are prefixed with `#sql-`). When `TRUE`, the `--exclude-intermediate-sql-tables` option keeps `ndb_restore` from restoring such tables that may have been left over from these operations. This option is `TRUE` by default.

- `--exclude-missing-columns`

| | |
|---------------------|--|
| Command-Line Format | <code>--exclude-missing-columns</code> |
|---------------------|--|

It is possible to restore only selected table columns using this option, which causes `ndb_restore` to ignore any columns missing from tables being restored as compared to the versions of those tables found in the backup. This option applies to all tables being restored. If you wish to apply this option only to selected tables or databases, you can use it in combination with one or more of the `--include-*` or `--exclude-*` options described elsewhere in this section to do so, then restore data to the remaining tables using a complementary set of these options.

- `--exclude-missing-tables`

| | |
|---------------------|---------------------------------------|
| Command-Line Format | <code>--exclude-missing-tables</code> |
|---------------------|---------------------------------------|

It is possible to restore only selected tables using this option, which causes `ndb_restore` to ignore any tables from the backup that are not found in the target database.

- `--exclude-tables=table-list`

| | |
|---------------------|--|
| Command-Line Format | <code>--exclude-tables=table-list</code> |
| Type | String |
| Default Value | |

List of one or more tables to exclude; each table reference must include the database name. Often used together with `--exclude-databases`.

When `--exclude-databases` or `--exclude-tables` is used, only those databases or tables named by the option are excluded; all other databases and tables are restored by `ndb_restore`.

This table shows several invocations of `ndb_restore` using `--exclude-*` options (other options possibly required have been omitted for clarity), and the effects these options have on restoring from an NDB Cluster backup:

Table 23.42 Several invocations of `ndb_restore` using `--exclude-*` options, and the effects these options have on restoring from an NDB Cluster backup.

| Option | Result |
|---|---|
| <code>--exclude-databases=db1</code> | All tables in all databases except <code>db1</code> are restored; no tables in <code>db1</code> are restored |
| <code>--exclude-databases=db1,db2</code> (or <code>--exclude-databases=db1 --exclude-databases=db2</code>) | All tables in all databases except <code>db1</code> and <code>db2</code> are restored; no tables in <code>db1</code> or <code>db2</code> are restored |

| Option | Result |
|---|--|
| <code>--exclude-tables=db1.t1</code> | All tables except <code>t1</code> in database <code>db1</code> are restored; all other tables in <code>db1</code> are restored; all tables in all other databases are restored |
| <code>--exclude-tables=db1.t2,db2.t1</code> (or <code>--exclude-tables=db1.t2 --exclude-tables=db2.t1</code>) | All tables in database <code>db1</code> except for <code>t2</code> and all tables in database <code>db2</code> except for table <code>t1</code> are restored; no other tables in <code>db1</code> or <code>db2</code> are restored; all tables in all other databases are restored |

You can use these two options together. For example, the following causes all tables in all databases *except for* databases `db1` and `db2`, and tables `t1` and `t2` in database `db3`, to be restored:

```
shell> ndb_restore [...] --exclude-databases=db1,db2 --exclude-tables=db3.t1,db3.t2
```

(Again, we have omitted other possibly necessary options in the interest of clarity and brevity from the example just shown.)

You can use `--include-*` and `--exclude-*` options together, subject to the following rules:

- The actions of all `--include-*` and `--exclude-*` options are cumulative.
- All `--include-*` and `--exclude-*` options are evaluated in the order passed to `ndb_restore`, from right to left.
- In the event of conflicting options, the first (rightmost) option takes precedence. In other words, the first option (going from right to left) that matches against a given database or table “wins”.

For example, the following set of options causes `ndb_restore` to restore all tables from database `db1` except `db1.t1`, while restoring no other tables from any other databases:

```
--include-databases=db1 --exclude-tables=db1.t1
```

However, reversing the order of the options just given simply causes all tables from database `db1` to be restored (including `db1.t1`, but no tables from any other database), because the `--include-databases` option, being farthest to the right, is the first match against database `db1` and thus takes precedence over any other option that matches `db1` or any tables in `db1`:

```
--exclude-tables=db1.t1 --include-databases=db1
```

- `--fields-enclosed-by=char`

| | |
|---------------------|--|
| Command-Line Format | <code>--fields-enclosed-by=char</code> |
| Type | String |
| Default Value | |

Each column value is enclosed by the string passed to this option (regardless of data type; see the description of `--fields-optionally-enclosed-by`).

- `--fields-optionally-enclosed-by`

| | |
|---------------------|--|
| Command-Line Format | <code>--fields-optionally-enclosed-by</code> |
| Type | String |
| Default Value | |

The string passed to this option is used to enclose column values containing character data (such as CHAR, VARCHAR, BINARY, TEXT, or ENUM).

- `--fields-terminated-by=char`

| | |
|---------------------|--|
| Command-Line Format | <code>--fields-terminated-by=char</code> |
| Type | String |
| Default Value | <code>\t (tab)</code> |

The string passed to this option is used to separate column values. The default value is a tab character (`\t`).

- `--help`

| | |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
|---------------------|---------------------|

Display help text and exit.

- `--hex`

| | |
|---------------------|--------------------|
| Command-Line Format | <code>--hex</code> |
|---------------------|--------------------|

If this option is used, all binary values are output in hexadecimal format.

- `--ignore-extended-pk-updates`

| | |
|---------------------|---|
| Command-Line Format | <code>--ignore-extended-pk-updates[=0 1]</code> |
| Introduced | 8.0.21-ndb-8.0.21 |
| Type | Integer |
| Default Value | 0 |
| Minimum Value | 0 |
| Maximum Value | 1 |

When using `--allow-pk-changes`, columns which become part of a table's primary key must not be updated while the backup is being taken; such columns should keep the same values from the time values are inserted into them until the rows containing the values are deleted. If `ndb_restore` encounters updates to these columns when restoring a backup, the restore fails. Because some applications may set values for all columns when updating a row, even when some column values are not changed, the backup may include log events appearing to update columns which are not in fact modified. In such cases you can set `--ignore-extended-pk-updates` to 1, forcing `ndb_restore` to ignore such updates.

Important

When causing these updates to be ignored, the user is responsible for ensuring that there are no updates to the values of any columns that become part of the primary key.

For more information, see the description of `--allow-pk-changes`.

- `--include-databases=db-list`

| | |
|---------------------|--|
| Command-Line Format | <code>--include-databases=db-list</code> |
| Type | String |
| Default Value | |

Comma-delimited list of one or more databases to restore. Often used together with `--include-tables`; see the description of that option for further information and examples.

- `--include-stored-grants`

| | |
|---------------------|--------------------------------------|
| Command-Line Format | <code>--include-stored-grants</code> |
| Introduced | 8.0.19-ndb-8.0.19 |
| Type | Boolean |
| Default Value | <code>FALSE</code> |

In NDB 8.0, `ndb_restore` does not by default restore shared users and grants (see [Section 23.6.12, “Distributed MySQL Privileges with NDB_STORED_USER”](#)) to the `ndb_sql_metadata` table. Specifying this option causes it to do so.

- `--include-tables=table-list`

| | |
|---------------------|--|
| Command-Line Format | <code>--include-tables=table-list</code> |
| Type | String |
| Default Value | |

Comma-delimited list of tables to restore; each table reference must include the database name.

When `--include-databases` or `--include-tables` is used, only those databases or tables named by the option are restored; all other databases and tables are excluded by `ndb_restore`, and are not restored.

The following table shows several invocations of `ndb_restore` using `--include-*` options (other options possibly required have been omitted for clarity), and the effects these have on restoring from an NDB Cluster backup:

Table 23.43 Several invocations of `ndb_restore` using `--include-*` options, and their effects on restoring from an NDB Cluster backup.

| Option | Result |
|---|--|
| <code>--include-databases=db1</code> | Only tables in database <code>db1</code> are restored; all tables in all other databases are ignored |
| <code>--include-databases=db1,db2</code> (or <code>--include-databases=db1 --include-databases=db2</code>) | Only tables in databases <code>db1</code> and <code>db2</code> are restored; all tables in all other databases are ignored |
| <code>--include-tables=db1.t1</code> | Only table <code>t1</code> in database <code>db1</code> is restored; no other tables in <code>db1</code> or in any other database are restored |

| Option | Result |
|--|--|
| <code>--include-tables=db1.t2,db2.t1</code> (or <code>--include-tables=db1.t2 --include-tables=db2.t1</code>) | Only the table <code>t2</code> in database <code>db1</code> and the table <code>t1</code> in database <code>db2</code> are restored; no other tables in <code>db1</code> , <code>db2</code> , or any other database are restored |

You can also use these two options together. For example, the following causes all tables in databases `db1` and `db2`, together with the tables `t1` and `t2` in database `db3`, to be restored (and no other databases or tables):

```
shell> ndb_restore [...] --include-databases=db1,db2 --include-tables=db3.t1,db3.t2
```

(Again we have omitted other, possibly required, options in the example just shown.)

It also possible to restore only selected databases, or selected tables from a single database, without any `--include-*` (or `--exclude-*`) options, using the syntax shown here:

```
ndb_restore other_options db_name,[db_name[,...] | tbl_name[,tbl_name][,...]]
```

In other words, you can specify either of the following to be restored:

- All tables from one or more databases
- One or more tables from a single database
- `--lines-terminated-by=char`

| | |
|---------------------|---|
| Command-Line Format | <code>--lines-terminated-by=char</code> |
| Type | String |
| Default Value | <code>\n</code> (linebreak) |

Specifies the string used to end each line of output. The default is a linefeed character (`\n`).

- `--login-path`

| | |
|---------------------|--------------------------------|
| Command-Line Format | <code>--login-path=path</code> |
| Type | String |
| Default Value | <code>[none]</code> |

Read given path from login file.

- `--lossy-conversions, -L`

| | |
|---------------------|--|
| Command-Line Format | <code>--lossy-conversions</code> |
| Type | Boolean |
| Default Value | <code>FALSE</code> (If option is not used) |

This option is intended to complement the `--promote-attributes` option. Using `--lossy-conversions` allows lossy conversions of column values (type demotions or changes in sign) when restoring data from backup. With some exceptions, the rules governing demotion are the same as for

MySQL replication; see [Replication of Columns Having Different Data Types](#), for information about specific type conversions currently supported by attribute demotion.

Beginning with NDB 8.0.26, this option also makes it possible to restore a `NULL` column as `NOT NULL`. The column must not contain any `NULL` entries; otherwise `ndb_restore` stops with an error.

`ndb_restore` reports any truncation of data that it performs during lossy conversions once per attribute and column.

- `--no-binlog`

| | |
|---------------------|--------------------------|
| Command-Line Format | <code>--no-binlog</code> |
|---------------------|--------------------------|

This option prevents any connected SQL nodes from writing data restored by `ndb_restore` to their binary logs.

- `--no-restore-disk-objects, -d`

| | |
|---------------------|--|
| Command-Line Format | <code>--no-restore-disk-objects</code> |
| Type | Boolean |
| Default Value | <code>FALSE</code> |

This option stops `ndb_restore` from restoring any NDB Cluster Disk Data objects, such as tablespaces and log file groups; see [Section 23.6.10, “NDB Cluster Disk Data Tables”](#), for more information about these.

- `--no-upgrade, -u`

| | |
|---------------------|---------------------------|
| Command-Line Format | <code>--no-upgrade</code> |
|---------------------|---------------------------|

When using `ndb_restore` to restore a backup, `VARCHAR` columns created using the old fixed format are resized and recreated using the variable-width format now employed. This behavior can be overridden by specifying `--no-upgrade`.

- `--ndb-connectstring`

| | |
|---------------------|--|
| Command-Line Format | <code>--ndb-connectstring=connection-string</code> |
| Type | String |
| Default Value | <code>[none]</code> |

Set connect string for connecting to `ndb_mgmd`. Syntax: “[nodeid=id;][host=]hostname[:port]”. Overrides entries in `NDB_CONNECTSTRING` and `my.cnf`.

- `--ndb-mgmd-host`

| | |
|---------------------|--|
| Command-Line Format | <code>--ndb-mgmd-host=connection-string</code> |
| Type | String |
| Default Value | <code>[none]</code> |

Same as `--ndb-connectstring`.

- `--ndb-nodegroup-map=map, -z`

| | |
|---------------------|--------------------------------------|
| Command-Line Format | <code>--ndb-nodegroup-map=map</code> |
|---------------------|--------------------------------------|

Intended for restoring a backup taken from one node group to a different node group, but never completely implemented; unsupported.

All code supporting this option was removed in NDB 8.0.27; in this and later versions, any value set for it is ignored, and the option itself does nothing.

- `--ndb-nodeid`

| | |
|---------------------|-----------------------------|
| Command-Line Format | <code>--ndb-nodeid=#</code> |
| Type | Integer |
| Default Value | [none] |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

| | |
|---------------------|---|
| Command-Line Format | <code>--ndb-optimized-node-selection</code> |
|---------------------|---|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--no-defaults`

| | |
|---------------------|----------------------------|
| Command-Line Format | <code>--no-defaults</code> |
|---------------------|----------------------------|

Do not read default options from any option file other than login file.

- `--nodeid=#, -n`

| | |
|---------------------|-------------------------|
| Command-Line Format | <code>--nodeid=#</code> |
| Type | Numeric |
| Default Value | none |

Specify the node ID of the data node on which the backup was taken.

When restoring to a cluster with different number of data nodes from that where the backup was taken, this information helps identify the correct set or sets of files to be restored to a given node. (In such cases, multiple files usually need to be restored to a single data node.) See [Section 23.5.23.2, “Restoring to a different number of data nodes”](#), for additional information and examples.

In NDB 8.0, this option is required.

- `--num-slices=#`

| | |
|---------------------|-----------------------------|
| Command-Line Format | <code>--num-slices=#</code> |
| Introduced | 8.0.20-ndb-8.0.20 |
| Type | Integer |
| Default Value | 1 |

| | |
|---------------|------|
| Minimum Value | 1 |
| Maximum Value | 1024 |

When restoring a backup by slices, this option sets the number of slices into which to divide the backup. This allows multiple instances of `ndb_restore` to restore disjoint subsets in parallel, potentially reducing the amount of time required to perform the restore operation.

A *slice* is a subset of the data in a given backup; that is, it is a set of fragments having the same slice ID, specified using the `--slice-id` option. The two options must always be used together, and the value set by `--slice-id` must always be less than the number of slices.

`ndb_restore` encounters fragments and assigns each one a fragment counter. When restoring by slices, a slice ID is assigned to each fragment; this slice ID is in the range 0 to 1 less than the number of slices. For a table that is not a `BLOB` table, the slice to which a given fragment belongs is determined using the formula shown here:

```
[slice_ID] = [fragment_counter] % [number_of_slices]
```

For a `BLOB` table, a fragment counter is not used; the fragment number is used instead, along with the ID of the main table for the `BLOB` table (recall that `NDB` stores `BLOB` values in a separate table internally). In this case, the slice ID for a given fragment is calculated as shown here:

```
[slice_ID] =  
([main_table_ID] + [fragment_ID]) % [number_of_slices]
```

Thus, restoring by *N* slices means running *N* instances of `ndb_restore`, all with `--num-slices=N` (along with any other necessary options) and one each with `--slice-id=1`, `--slice-id=2`, `--slice-id=3`, and so on through `slice-id=N-1`.

Example. Assume that you want to restore a backup named `BACKUP-1`, found in the default directory `/var/lib/mysql-cluster/BACKUP/BACKUP-3` on the node file system on each data node, to a cluster with four data nodes having the node IDs 1, 2, 3, and 4. To perform this operation using five slices, execute the sets of commands shown in the following list:

1. Restore the cluster metadata using `ndb_restore` as shown here:

```
shell> ndb_restore -b 1 -n 1 -m --disable-indexes --backup-path=/home/ndbuser/backups
```

2. Restore the cluster data to the data nodes invoking `ndb_restore` as shown here:

```
shell> ndb_restore -b 1 -n 1 -r --num-slices=5 --slice-id=0 --backup-path=/var/lib/mysql-cluster/BACKUP-3
shell> ndb_restore -b 1 -n 1 -r --num-slices=5 --slice-id=1 --backup-path=/var/lib/mysql-cluster/BACKUP-3
shell> ndb_restore -b 1 -n 1 -r --num-slices=5 --slice-id=2 --backup-path=/var/lib/mysql-cluster/BACKUP-3
shell> ndb_restore -b 1 -n 1 -r --num-slices=5 --slice-id=3 --backup-path=/var/lib/mysql-cluster/BACKUP-3
shell> ndb_restore -b 1 -n 1 -r --num-slices=5 --slice-id=4 --backup-path=/var/lib/mysql-cluster/BACKUP-3

shell> ndb_restore -b 1 -n 2 -r --num-slices=5 --slice-id=0 --backup-path=/var/lib/mysql-cluster/BACKUP-3
shell> ndb_restore -b 1 -n 2 -r --num-slices=5 --slice-id=1 --backup-path=/var/lib/mysql-cluster/BACKUP-3
shell> ndb_restore -b 1 -n 2 -r --num-slices=5 --slice-id=2 --backup-path=/var/lib/mysql-cluster/BACKUP-3
shell> ndb_restore -b 1 -n 2 -r --num-slices=5 --slice-id=3 --backup-path=/var/lib/mysql-cluster/BACKUP-3
shell> ndb_restore -b 1 -n 2 -r --num-slices=5 --slice-id=4 --backup-path=/var/lib/mysql-cluster/BACKUP-3

shell> ndb_restore -b 1 -n 3 -r --num-slices=5 --slice-id=0 --backup-path=/var/lib/mysql-cluster/BACKUP-3
shell> ndb_restore -b 1 -n 3 -r --num-slices=5 --slice-id=1 --backup-path=/var/lib/mysql-cluster/BACKUP-3
shell> ndb_restore -b 1 -n 3 -r --num-slices=5 --slice-id=2 --backup-path=/var/lib/mysql-cluster/BACKUP-3
shell> ndb_restore -b 1 -n 3 -r --num-slices=5 --slice-id=3 --backup-path=/var/lib/mysql-cluster/BACKUP-3
shell> ndb_restore -b 1 -n 3 -r --num-slices=5 --slice-id=4 --backup-path=/var/lib/mysql-cluster/BACKUP-3

shell> ndb_restore -b 1 -n 4 -r --num-slices=5 --slice-id=0 --backup-path=/var/lib/mysql-cluster/BACKUP-3
shell> ndb_restore -b 1 -n 4 -r --num-slices=5 --slice-id=1 --backup-path=/var/lib/mysql-cluster/BACKUP-3
```

```
shell> ndb_restore -b 1 -n 4 -r --num-slices=5 --slice-id=2 --backup-path=/var/lib/mysql-cluster/BACKUP/E
shell> ndb_restore -b 1 -n 4 -r --num-slices=5 --slice-id=3 --backup-path=/var/lib/mysql-cluster/BACKUP/E
shell> ndb_restore -b 1 -n 4 -r --num-slices=5 --slice-id=4 --backup-path=/var/lib/mysql-cluster/BACKUP/E
```

All of the commands just shown in this step can be executed in parallel, provided there are enough slots for connections to the cluster (see the description for the `--backup-path` option).

3. Restore indexes as usual, as shown here:

```
shell> ndb_restore -b 1 -n 1 --rebuild-indexes --backup-path=/var/lib/mysql-cluster/BACKUP/BACKUP-1
```

4. Finally, restore the epoch, using the command shown here:

```
shell> ndb_restore -b 1 -n 1 --restore-epoch --backup-path=/var/lib/mysql-cluster/BACKUP/BACKUP-1
```

You should use slicing to restore the cluster data only; it is not necessary to employ `--num-slices` or `--slice-id` when restoring the metadata, indexes, or epoch information. If either or both of these options are used with the `ndb_restore` options controlling restoration of these, the program ignores them.

The effects of using the `--parallelism` option on the speed of restoration are independent of those produced by slicing or parallel restoration using multiple instances of `ndb_restore` (`--parallelism` specifies the number of parallel transactions executed by a *single* `ndb_restore` thread), but it can be used together with either or both of these. You should be aware that increasing `--parallelism` causes `ndb_restore` to impose a greater load on the cluster; if the system can handle this, restoration should complete even more quickly.

The value of `--num-slices` is not directly dependent on values relating to hardware such as number of CPUs or CPU cores, amount of RAM, and so forth, nor does it depend on the number of LDMS.

It is possible to employ different values for this option on different data nodes as part of the same restoration; doing so should not in and of itself produce any ill effects.

- `--parallelism=#, -p`

| | |
|---------------------|------------------------------|
| Command-Line Format | <code>--parallelism=#</code> |
| Type | Numeric |
| Default Value | 128 |
| Minimum Value | 1 |
| Maximum Value | 1024 |

`ndb_restore` uses single-row transactions to apply many rows concurrently. This parameter determines the number of parallel transactions (concurrent rows) that an instance of `ndb_restore` tries to use. By default, this is 128; the minimum is 1, and the maximum is 1024.

The work of performing the inserts is parallelized across the threads in the data nodes involved. This mechanism is employed for restoring bulk data from the `.Data` file—that is, the fuzzy snapshot of the data; it is not used for building or rebuilding indexes. The change log is applied serially; index drops and builds are DDL operations and handled separately. There is no thread-level parallelism on the client side of the restore.

- `--preserve-trailing-spaces, -P`

| | |
|---------------------|---|
| Command-Line Format | <code>--preserve-trailing-spaces</code> |
|---------------------|---|

Cause trailing spaces to be preserved when promoting a fixed-width character data type to its variable-width equivalent—that is, when promoting a `CHAR` column value to `VARCHAR`, or a `BINARY` column value to `VARBINARY`. Otherwise, any trailing spaces are dropped from such column values when they are inserted into the new columns.

Note

Although you can promote `CHAR` columns to `VARCHAR` and `BINARY` columns to `VARBINARY`, you cannot promote `VARCHAR` columns to `CHAR` or `VARBINARY` columns to `BINARY`.

- `--print`

| | |
|---------------------|----------------------|
| Command-Line Format | <code>--print</code> |
| Type | Boolean |
| Default Value | <code>FALSE</code> |

Causes `ndb_restore` to print all data, metadata, and logs to `stdout`. Equivalent to using the `--print-data`, `--print-meta`, and `--print-log` options together.

Note

Use of `--print` or any of the `--print_*` options is in effect performing a dry run. Including one or more of these options causes any output to be redirected to `stdout`; in such cases, `ndb_restore` makes no attempt to restore data or metadata to an NDB Cluster.

- `--print-data`

| | |
|---------------------|---------------------------|
| Command-Line Format | <code>--print-data</code> |
| Type | Boolean |
| Default Value | <code>FALSE</code> |

Cause `ndb_restore` to direct its output to `stdout`. Often used together with one or more of `--tab`, `--fields-enclosed-by`, `--fields-optionally-enclosed-by`, `--fields-terminated-by`, `--hex`, and `--append`.

`TEXT` and `BLOB` column values are always truncated. Such values are truncated to the first 256 bytes in the output. This cannot currently be overridden when using `--print-data`.

- `--print-defaults`

| | |
|---------------------|-------------------------------|
| Command-Line Format | <code>--print-defaults</code> |
|---------------------|-------------------------------|

Print program argument list and exit.

- `--print-log`

| | |
|---------------------|--------------------------|
| Command-Line Format | <code>--print-log</code> |
|---------------------|--------------------------|

| | |
|---------------|---------|
| Type | Boolean |
| Default Value | FALSE |

Cause `ndb_restore` to output its log to `stdout`.

- `--print-meta`

| | |
|---------------------|---------------------------|
| Command-Line Format | <code>--print-meta</code> |
| Type | Boolean |
| Default Value | FALSE |

Print all metadata to `stdout`.

- `print-sql-log`

| | |
|---------------------|------------------------------|
| Command-Line Format | <code>--print-sql-log</code> |
| Type | Boolean |
| Default Value | FALSE |

Log SQL statements to `stdout`. Use the option to enable; normally this behavior is disabled. The option checks before attempting to log whether all the tables being restored have explicitly defined primary keys; queries on a table having only the hidden primary key implemented by NDB cannot be converted to valid SQL.

This option does not work with tables having `BLOB` columns.

- `--progress-frequency=N`

| | |
|---------------------|-------------------------------------|
| Command-Line Format | <code>--progress-frequency=#</code> |
| Type | Numeric |
| Default Value | 0 |
| Minimum Value | 0 |
| Maximum Value | 65535 |

Print a status report each `N` seconds while the backup is in progress. 0 (the default) causes no status reports to be printed. The maximum is 65535.

- `--promote-attributes, -A`

| | |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--promote-attributes</code> |
|---------------------|-----------------------------------|

`ndb_restore` supports limited *attribute promotion* in much the same way that it is supported by MySQL replication; that is, data backed up from a column of a given type can generally be restored to a column using a “larger, similar” type. For example, data from a `CHAR(20)` column can be restored to a column declared as `VARCHAR(20)`, `VARCHAR(30)`, or `CHAR(30)`; data from a `MEDIUMINT` column can be

restored to a column of type `INT` or `BIGINT`. See [Replication of Columns Having Different Data Types](#), for a table of type conversions currently supported by attribute promotion.

Beginning with NDB 8.0.26, this option also makes it possible to restore a `NOT NULL` column as `NULL`.

Attribute promotion by `ndb_restore` must be enabled explicitly, as follows:

1. Prepare the table to which the backup is to be restored. `ndb_restore` cannot be used to re-create the table with a different definition from the original; this means that you must either create the table manually, or alter the columns which you wish to promote using `ALTER TABLE` after restoring the table metadata but before restoring the data.
2. Invoke `ndb_restore` with the `--promote-attributes` option (short form `-A`) when restoring the table data. Attribute promotion does not occur if this option is not used; instead, the restore operation fails with an error.

When converting between character data types and `TEXT` or `BLOB`, only conversions between character types (`CHAR` and `VARCHAR`) and binary types (`BINARY` and `VARBINARY`) can be performed at the same time. For example, you cannot promote an `INT` column to `BIGINT` while promoting a `VARCHAR` column to `TEXT` in the same invocation of `ndb_restore`.

Converting between `TEXT` columns using different character sets is not supported, and is expressly disallowed.

When performing conversions of character or binary types to `TEXT` or `BLOB` with `ndb_restore`, you may notice that it creates and uses one or more staging tables named `table_name$STnode_id`. These tables are not needed afterwards, and are normally deleted by `ndb_restore` following a successful restoration.

- `--rebuild-indexes`

| | |
|---------------------|--------------------------------|
| Command-Line Format | <code>--rebuild-indexes</code> |
|---------------------|--------------------------------|

Enable multithreaded rebuilding of the ordered indexes while restoring a native NDB backup. The number of threads used for building ordered indexes by `ndb_restore` with this option is controlled by the `BuildIndexThreads` data node configuration parameter and the number of LDMs.

It is necessary to use this option only for the first run of `ndb_restore`; this causes all ordered indexes to be rebuilt without using `--rebuild-indexes` again when restoring subsequent nodes. You should use this option prior to inserting new rows into the database; otherwise, it is possible for a row to be inserted that later causes a unique constraint violation when trying to rebuild the indexes.

Building of ordered indices is parallelized with the number of LDMs by default. Offline index builds performed during node and system restarts can be made faster using the `BuildIndexThreads` data node configuration parameter; this parameter has no effect on dropping and rebuilding of indexes by `ndb_restore`, which is performed online.

Rebuilding of unique indexes uses disk write bandwidth for redo logging and local checkpointing. An insufficient amount of this bandwidth can lead to redo buffer overload or log overload errors. In such cases you can run `ndb_restore --rebuild-indexes` again; the process resumes at the point where the error occurred. You can also do this when you have encountered temporary errors. You can repeat execution of `ndb_restore --rebuild-indexes` indefinitely; you may be able to stop such errors by reducing the value of `--parallelism`. If the problem is insufficient space, you can increase the size of the redo log (`FragmentLogFileSize` node configuration parameter), or you can increase the speed at

which LCPs are performed (`MaxDiskWriteSpeed` and related parameters), in order to free space more quickly.

- `--remap-column=db.tbl.col:fn:args`

| | |
|---------------------|--|
| Command-Line Format | <code>--remap-column=[db].[tbl].[col]:[fn]:[args]</code> |
| Introduced | 8.0.21-ndb-8.0.21 |
| Type | String |
| Default Value | [none] |

When used together with `--restore-data`, this option applies a function to the value of the indicated column. Values in the argument string are listed here:

- `db`: Database name, following any renames performed by `--rewrite-database`.
- `tbl`: Table name.
- `col`: Name of the column to be updated. This column must be of type `INT` or `BIGINT`. The column can also be but is not required to be `UNSIGNED`.
- `fn`: Function name; currently, the only supported name is `offset`.
- `args`: Arguments supplied to the function. Currently, only a single argument, the size of the offset to be added by the `offset` function, is supported. Negative values are supported. The size of the argument cannot exceed that of the signed variant of the column's type; for example, if `col` is an `INT` column, then the allowed range of the argument passed to the `offset` function is `-2147483648` to `2147483647` (see [Section 11.1.2, "Integer Types \(Exact Value\) - INTEGER, INT, SMALLINT, TINYINT, MEDIUMINT, BIGINT"](#)).

If applying the offset value to the column would cause an overflow or underflow, the restore operation fails. This could happen, for example, if the column is a `BIGINT`, and the option attempts to apply an offset value of 8 on a row in which the column value is 4294967291, since $4294967291 + 8 = 4294967299 > 4294967295$.

This option can be useful when you wish to merge data stored in multiple source instances of NDB Cluster (all using the same schema) into a single destination NDB Cluster, using NDB native backup (see [Section 23.6.8.2, "Using The NDB Cluster Management Client to Create a Backup"](#)) and `ndb_restore` to merge the data, where primary and unique key values are overlapping between source clusters, and it is necessary as part of the process to remap these values to ranges that do not overlap. It may also be necessary to preserve other relationships between tables. To fulfill such requirements, it is possible to use the option multiple times in the same invocation of `ndb_restore` to remap columns of different tables, as shown here:

```
shell> ndb_restore --restore-data --remap-column=hr.employee.id:offset:1000 \
--remap-column=hr.manager.id:offset:1000 --remap-column=hr.firstaiders.id:offset:1000
```

(Other options not shown here may also be used.)

`--remap-column` can also be used to update multiple columns of the same table. Combinations of multiple tables and columns are possible. Different offset values can also be used for different columns of the same table, like this:

```
shell> ndb_restore --restore-data --remap-column=hr.employee.salary:offset:10000 \
```

```
--remap-column=hr.employee.hours:offset:-10
```

When source backups contain duplicate tables which should not be merged, you can handle this by using `--exclude-tables`, `--exclude-databases`, or by some other means in your application.

Information about the structure and other characteristics of tables to be merged can be obtained using `SHOW CREATE TABLE`; the `ndb_desc` tool; and `MAX()`, `MIN()`, `LAST_INSERT_ID()`, and other MySQL functions.

Replication of changes from merged to unmerged tables, or from unmerged to merged tables, in separate instances of NDB Cluster is not supported.

- `--restore-data, -r`

| | |
|---------------------|-----------------------------|
| Command-Line Format | <code>--restore-data</code> |
| Type | Boolean |
| Default Value | <code>FALSE</code> |

Output NDB table data and logs.

- `--restore-epoch, -e`

| | |
|---------------------|------------------------------|
| Command-Line Format | <code>--restore-epoch</code> |
|---------------------|------------------------------|

Add (or restore) epoch information to the cluster replication status table. This is useful for starting replication on an NDB Cluster replica. When this option is used, the row in the `mysql.ndb_apply_status` having 0 in the `id` column is updated if it already exists; such a row is inserted if it does not already exist. (See [Section 23.7.9, “NDB Cluster Backups With NDB Cluster Replication”](#).)

- `--restore-meta, -m`

| | |
|---------------------|-----------------------------|
| Command-Line Format | <code>--restore-meta</code> |
| Type | Boolean |
| Default Value | <code>FALSE</code> |

This option causes `ndb_restore` to print NDB table metadata.

The first time you run the `ndb_restore` restoration program, you also need to restore the metadata. In other words, you must re-create the database tables—this can be done by running it with the `--restore-meta (-m)` option. Restoring the metadata need be done only on a single data node; this is sufficient to restore it to the entire cluster.

In older versions of NDB Cluster, tables whose schemas were restored using this option used the same number of partitions as they did on the original cluster, even if it had a differing number of data nodes from the new cluster. In NDB 8.0, when restoring metadata, this is no longer an issue; `ndb_restore`

now uses the default number of partitions for the target cluster, unless the number of local data manager threads is also changed from what it was for data nodes in the original cluster.

When using this option in NDB 8.0, it is recommended that auto synchronization be disabled by setting `ndb_metadata_check=OFF` until `ndb_restore` has completed restoring the metadata, after which it can be turned on again to synchronize objects newly created in the NDB dictionary.

Note

The cluster should have an empty database when starting to restore a backup. (In other words, you should start the data nodes with `--initial` prior to performing the restore.)

- `--restore-privilege-tables`

| | |
|---------------------|--|
| Command-Line Format | <code>--restore-privilege-tables</code> |
| Deprecated | 8.0.16-ndb-8.0.16 |
| Type | Boolean |
| Default Value | <code>FALSE</code> (If option is not used) |

`ndb_restore` does not by default restore distributed MySQL privilege tables created in releases of NDB Cluster prior to version 8.0, which does not support distributed privileges as implemented in NDB 7.6 and earlier. This option causes `ndb_restore` to restore them.

In NDB 8.0, such tables are not used for access control; as part of the MySQL server's upgrade process, the server creates InnoDB copies of these tables local to itself. For more information, see [Section 23.3.7, “Upgrading and Downgrading NDB Cluster”](#), as well as [Section 6.2.3, “Grant Tables”](#).

- `--rewrite-database=olddb,newdb`

| | |
|---------------------|---|
| Command-Line Format | <code>--rewrite-database=olddb,newdb</code> |
| Type | String |
| Default Value | <code>none</code> |

This option makes it possible to restore to a database having a different name from that used in the backup. For example, if a backup is made of a database named `products`, you can restore the data it contains to a database named `inventory`, use this option as shown here (omitting any other options that might be required):

```
shell> ndb_restore --rewrite-database=product,inventory
```

The option can be employed multiple times in a single invocation of `ndb_restore`. Thus it is possible to restore simultaneously from a database named `db1` to a database named `db2` and from a database named `db3` to one named `db4` using `--rewrite-database=db1,db2 --rewrite-database=db3,db4`. Other `ndb_restore` options may be used between multiple occurrences of `--rewrite-database`.

In the event of conflicts between multiple `--rewrite-database` options, the last `--rewrite-database` option used, reading from left to right, is the one that takes effect. For example, if `--rewrite-database=db1,db2 --rewrite-database=db1,db3` is used, only `--rewrite-database=db1,db3` is honored, and `--rewrite-database=db1,db2` is ignored. It is also possible to restore from multiple databases to a single database, so that `--rewrite-database=db1,db3 --rewrite-database=db2,db3` restores all tables and data from databases `db1` and `db2` into database `db3`.

Important

When restoring from multiple backup databases into a single target database using `--rewrite-database`, no check is made for collisions between table or other object names, and the order in which rows are restored is not guaranteed. This means that it is possible in such cases for rows to be overwritten and updates to be lost.

- `--skip-broken-objects`

| | |
|---------------------|------------------------------------|
| Command-Line Format | <code>--skip-broken-objects</code> |
|---------------------|------------------------------------|

This option causes `ndb_restore` to ignore corrupt tables while reading a native NDB backup, and to continue restoring any remaining tables (that are not also corrupted). Currently, the `--skip-broken-objects` option works only in the case of missing blob parts tables.

- `--skip-table-check, -s`

| | |
|---------------------|---------------------------------|
| Command-Line Format | <code>--skip-table-check</code> |
|---------------------|---------------------------------|

It is possible to restore data without restoring table metadata. By default when doing this, `ndb_restore` fails with an error if a mismatch is found between the table data and the table schema; this option overrides that behavior.

Some of the restrictions on mismatches in column definitions when restoring data using `ndb_restore` are relaxed; when one of these types of mismatches is encountered, `ndb_restore` does not stop with an error as it did previously, but rather accepts the data and inserts it into the target table while issuing a warning to the user that this is being done. This behavior occurs whether or not either of the options `--skip-table-check` or `--promote-attributes` is in use. These differences in column definitions are of the following types:

- Different `COLUMN_FORMAT` settings (`FIXED`, `DYNAMIC`, `DEFAULT`)
- Different `STORAGE` settings (`MEMORY`, `DISK`)
- Different default values
- Different distribution key settings
- `--skip-unknown-objects`

| | |
|---------------------|-------------------------------------|
| Command-Line Format | <code>--skip-unknown-objects</code> |
|---------------------|-------------------------------------|

This option causes `ndb_restore` to ignore any schema objects it does not recognize while reading a native NDB backup. This can be used for restoring a backup made from a cluster running (for example) NDB 7.6 to a cluster running NDB Cluster 7.5.

- `--slice-id=#`

| | |
|---------------------|---------------------------|
| Command-Line Format | <code>--slice-id=#</code> |
| Introduced | 8.0.20-ndb-8.0.20 |
| Type | Integer |
| Default Value | 0 |

| | |
|---------------|------|
| Minimum Value | 0 |
| Maximum Value | 1023 |

When restoring by slices, this is the ID of the slice to restore. This option is always used together with `--num-slices`, and its value must be always less than that of `--num-slices`.

For more information, see the description of the `--num-slices` elsewhere in this section.

- `--tab=dir_name, -T dir_name`

| | |
|---------------------|-----------------------------|
| Command-Line Format | <code>--tab=dir_name</code> |
| Type | Directory name |

Causes `--print-data` to create dump files, one per table, each named `tbl_name.txt`. It requires as its argument the path to the directory where the files should be saved; use `.` for the current directory.

- `--usage`

| | |
|---------------------|----------------------|
| Command-Line Format | <code>--usage</code> |
|---------------------|----------------------|

Display help text and exit; same as `--help`.

- `--verbose=#`

| | |
|---------------------|--------------------------|
| Command-Line Format | <code>--verbose=#</code> |
| Type | Numeric |
| Default Value | 1 |
| Minimum Value | 0 |
| Maximum Value | 255 |

Sets the level for the verbosity of the output. The minimum is 0; the maximum is 255. The default value is 1.

- `--version`

| | |
|---------------------|------------------------|
| Command-Line Format | <code>--version</code> |
|---------------------|------------------------|

Display version information and exit.

Typical options for this utility are shown here:

```
ndb_restore [-c connection_string] -n node_id -b backup_id \
  [-m] -r --backup-path=/path/to/backup/files
```

Normally, when restoring from an NDB Cluster backup, `ndb_restore` requires at a minimum the `--nodeid` (short form: `-n`), `--backupid` (short form: `-b`), and `--backup-path` options.

The `-c` option is used to specify a connection string which tells `ndb_restore` where to locate the cluster management server (see [Section 23.4.3.3, “NDB Cluster Connection Strings”](#)). If this option is not used, then `ndb_restore` attempts to connect to a management server on `localhost:1186`. This utility acts as a cluster API node, and so requires a free connection “slot” to connect to the cluster management server. This means that there must be at least one `[api]` or `[mysqld]` section that can be used by it

in the cluster `config.ini` file. It is a good idea to keep at least one empty `[api]` or `[mysqld]` section in `config.ini` that is not being used for a MySQL server or other application for this reason (see [Section 23.4.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”](#)).

In NDB 8.0.22 and later, `ndb_restore` can decrypt an encrypted backup using `--decrypt` and `--backup-password`. Both options must be specified to perform decryption. See the documentation for the `START BACKUP` management client command for information on creating encrypted backups.

You can verify that `ndb_restore` is connected to the cluster by using the `SHOW` command in the `ndb_mgm` management client. You can also accomplish this from a system shell, as shown here:

```
shell> ndb_mgm -e "SHOW"
```

Error reporting.

`ndb_restore` reports both temporary and permanent errors. In the case of temporary errors, it may be able to recover from them, and reports `Restore successful, but encountered temporary error, please look at configuration` in such cases.

Important

After using `ndb_restore` to initialize an NDB Cluster for use in circular replication, binary logs on the SQL node acting as the replica are not automatically created, and you must cause them to be created manually. To cause the binary logs to be created, issue a `SHOW TABLES` statement on that SQL node before running `START SLAVE`. This is a known issue in NDB Cluster.

23.5.23.1 Restoring an NDB Backup to a Different Version of NDB Cluster

The following two sections provide information about restoring a native NDB backup to a different version of NDB Cluster from the version in which the backup was taken.

In addition, you should consult [Section 23.3.7, “Upgrading and Downgrading NDB Cluster”](#), for other issues you may encounter when attempting to restore an NDB backup to a cluster running a different version of the NDB software.

It is also advisable to review [What is New in NDB Cluster 8.0](#), as well as [Section 2.11.4, “Changes in MySQL 8.0”](#), for other changes between NDB 8.0 and previous versions of NDB Cluster that may be relevant to your particular circumstances.

Restoring an NDB backup to a previous version of NDB Cluster

You may encounter issues when restoring a backup taken from a later version of NDB Cluster to a previous one, due to the use of features which do not exist in the earlier version. Some of these issues are listed here:

- **utf8mb4_ai_ci character set.** Tables created in NDB 8.0 by default use the `utf8mb4_ai_ci` character set, which is not available in NDB 7.6 and earlier, and so cannot be read by an `ndb_restore` binary from one of these earlier versions. In such cases, it is necessary to alter any tables using `utf8mb4_ai_ci` so that they use a character set supported in the older version prior to performing the backup.
- **Table metadata format.** Due to changes in how the MySQL Server and NDB handle table metadata, tables created or altered using the included MySQL server binary from NDB 8.0 cannot be restored using `ndb_restore` to NDB 7.6 or an earlier version of NDB Cluster. Such tables use `.sdi` files which are not understood by older versions of `mysqld`.

A backup taken in NDB 8.0 of tables which were created in NDB 7.6 or earlier, and which have not been altered since upgrading to NDB 8.0, should be restorable to older versions of NDB Cluster.

Since it is possible to restore metadata and table data separately, you can in such cases restore the table schemas from a dump made using `mysqldump`, or by executing the necessary `CREATE TABLE` statements manually, then import only the table data using `ndb_restore` with the `--restore-data` option.

- **Multi-threaded backups.** Multi-threaded backups taken in NDB 8.0 can be restored to an cluster running an earlier version of NDB in either of the following two ways:
 - Using an `ndb_restore` binary from NDB 8.0, perform a parallel restore. See [Restoring a parallel backup in parallel](#).
 - Restore the backups serially; in this case, a later version of `ndb_restore` is not required. See [Restoring a parallel backup serially](#).
- **Encrypted backups.** Encrypted backups created in NDB 8.0.22 and later cannot be restored using `ndb_restore` from NDB 8.0.21 or earlier.
- **NDB_STORED_USER privilege.** The `NDB_STORED_USER` privilege is supported only in NDB 8.0.
- **Maximum number of data nodes.** NDB Cluster 8.0 supports up to 144 data nodes, while earlier versions support a maximum of only 48 data nodes. See [Restoring to Fewer Nodes Than the Original](#), for information with situations in which this incompatibility causes an issue.

Restoring an NDB backup to a later version of NDB Cluster

In general, it should be possible to restore a backup created using the `ndb_mgm` client `START BACKUP` command in an older version of NDB to a newer version, provided that you use the `ndb_restore` binary that comes with the newer version. (It may be possible to use the older version of `ndb_restore`, but this is not recommended.) Additional potential issues are listed here:

- When restoring the metadata from a backup (`--restore-meta` option), `ndb_restore` normally attempts to reproduce the captured table schema exactly as it was when the backup was taken.

Tables created in versions of NDB prior to 8.0 use `.frm` files for their metadata. These files can be read by the `mysqld` in NDB 8.0, which can use the information contained therein to create the `.sdi` files used by the MySQL data dictionary in later versions.

- When restoring an older backup to a newer version of NDB, it may not be possible to take advantage of newer features such as hashmap partitioning, greater number of hashmap buckets, read backup, and different partitioning layouts. For this reason, it may be preferable to restore older schemas using `mysqldump` and the `mysql` client, which allows NDB to make use of the new schema features.
- Tables using the old temporal types which did not support fractional seconds (used prior to MySQL 5.6.4 and NDB 7.3.31) cannot be restored to NDB 8.0 using `ndb_restore`. You can check such tables using `CHECK TABLE`, and then upgrade them to the newer temporal column format, if necessary, using `REPAIR TABLE` in the `mysql` client; this must be done prior to taking the backup. See [Section 2.11.5, “Preparing Your Installation for Upgrade”](#), for more information.

You also also restore such tables using a dump created with `mysqldump`.

- Distributed grant tables created in NDB 7.6 and earlier are not supported in NDB 8.0. Such tables can be restored to an NDB 8.0 cluster, but they have no effect on access control.

23.5.23.2 Restoring to a different number of data nodes

It is possible to restore from an NDB backup to a cluster having a different number of data nodes than the original from which the backup was taken. The following two sections discuss, respectively, the cases where the target cluster has a lesser or greater number of data nodes than the source of the backup.

Restoring to Fewer Nodes Than the Original

You can restore to a cluster having fewer data nodes than the original provided that the larger number of nodes is an even multiple of the smaller number. In the following example, we use a backup taken on a cluster having four data nodes to a cluster having two data nodes.

1. The management server for the original cluster is on host `host10`. The original cluster has four data nodes, with the node IDs and host names shown in the following extract from the management server's `config.ini` file:

```
[ndbd]
NodeId=2
HostName=host2

[ndbd]
NodeId=4
HostName=host4

[ndbd]
NodeId=6
HostName=host6

[ndbd]
NodeId=8
HostName=host8
```

We assume that each data node was originally started with `ndbmtbd --ndb-connectstring=host10` or the equivalent.

2. Perform a backup in the normal manner. See [Section 23.6.8.2, “Using The NDB Cluster Management Client to Create a Backup”](#), for information about how to do this.
3. The files created by the backup on each data node are listed here, where *N* is the node ID and *B* is the backup ID.
 - `BACKUP-B-0.N.Data`
 - `BACKUP-B.Nctl`
 - `BACKUP-B.N.log`

These files are found under `BackupDataDir/BACKUP/BACKUP-B`, on each data node. For the rest of this example, we assume that the backup ID is 1.

Have all of these files available for later copying to the new data nodes (where they can be accessed on the data node's local file system by `ndb_restore`). It is simplest to copy them all to a single location; we assume that this is what you have done.

4. The management server for the target cluster is on host `host20`, and the target has two data nodes, with the node IDs and host names shown, from the management server `config.ini` file on `host20`:

```
[ndbd]
NodeId=3
hostname=host3
```

```
[ndbd]
NodeId=5
hostname=host5
```

Each of the data node processes on `host3` and `host5` should be started with `ndbmtbd -c host20 --initial` or the equivalent, so that the new (target) cluster starts with clean data node file systems.

5. Copy two different sets of two backup files to each of the target data nodes. For this example, copy the backup files from nodes 2 and 4 from the original cluster to node 3 in the target cluster. These files are listed here:

- `BACKUP-1-0.2.Data`
- `BACKUP-1.2.ctl`
- `BACKUP-1.2.log`
- `BACKUP-1-0.4.Data`
- `BACKUP-1.4.ctl`
- `BACKUP-1.4.log`

Then copy the backup files from nodes 6 and 8 to node 5; these files are shown in the following list:

- `BACKUP-1-0.6.Data`
- `BACKUP-1.6.ctl`
- `BACKUP-1.6.log`
- `BACKUP-1-0.8.Data`
- `BACKUP-1.8.ctl`
- `BACKUP-1.8.log`

For the remainder of this example, we assume that the respective backup files have been saved to the directory `/BACKUP-1` on each of nodes 3 and 5.

6. On each of the two target data nodes, you must restore from both sets of backups. First, restore the backups from nodes 2 and 4 to node 3 by invoking `ndb_restore` on `host3` as shown here:

```
shell> ndb_restore -c host20 --nodeid=2 --backupid=1 --restore-data --backup-path=/BACKUP-1
shell> ndb_restore -c host20 --nodeid=4 --backupid=1 --restore-data --backup-path=/BACKUP-1
```

Then restore the backups from nodes 6 and 8 to node 5 by invoking `ndb_restore` on `host5`, like this:

```
shell> ndb_restore -c host20 --nodeid=6 --backupid=1 --restore-data --backup-path=/BACKUP-1
shell> ndb_restore -c host20 --nodeid=8 --backupid=1 --restore-data --backup-path=/BACKUP-1
```

Restoring to More Nodes Than the Original

The node ID specified for a given `ndb_restore` command is that of the node in the original backup and not that of the data node to restore it to. When performing a backup using the method described in this section, `ndb_restore` connects to the management server and obtains a list of data nodes in the cluster

the backup is being restored to. The restored data is distributed accordingly, so that the number of nodes in the target cluster does not need to be known or calculated when performing the backup.

Note

When changing the total number of LCP threads or LQH threads per node group, you should recreate the schema from backup created using `mysqldump`.

1. *Create the backup of the data.* You can do this by invoking the `ndb_mgm` client `START BACKUP` command from the system shell, like this:

```
shell> ndb_mgm -e "START BACKUP 1"
```

This assumes that the desired backup ID is 1.

2. *Create a backup of the schema.* This step is necessary only if the total number of LCP threads or LQH threads per node group is changed.

```
shell> mysqldump --no-data --routines --events --triggers --databases > myschema.sql
```

Important

Once you have created the NDB native backup using `ndb_mgm`, you must not make any schema changes before creating the backup of the schema, if you do so.

3. *Copy the backup directory to the new cluster.* For example if the backup you want to restore has ID 1 and `BackupDataDir = /backups/node_nodeid`, then the path to the backup on this node is `/backups/node_1/BACKUP/BACKUP-1`. Inside this directory there are three files, listed here:

- `BACKUP-1-0.1.Data`
- `BACKUP-1.1ctl`
- `BACKUP-1.1.log`

You should copy the entire directory to the new node.

If you needed to create a schema file, copy this to a location on an SQL node where it can be read by `mysqld`.

There is no requirement for the backup to be restored from a specific node or nodes.

To restore from the backup just created, perform the following steps:

1. *Restore the schema.*

- If you created a separate schema backup file using `mysqldump`, import this file using the `mysql` client, similar to what is shown here:

```
shell> mysql < myschema.sql
```

When importing the schema file, you may need to specify the `--user` and `--password` options (and possibly others) in addition to what is shown, in order for the `mysql` client to be able to connect to the MySQL server.

- If you did *not* need to create a schema file, you can re-create the schema using `ndb_restore --restore-meta` (short form `-m`), similar to what is shown here:

```
shell> ndb_restore --nodeid=1 --backupid=1 --restore-meta --backup-path=/backups/node_1/BACKUP/BACKUP-1
```

`ndb_restore` must be able to contact the management server; add the `--ndb-connectstring` option if and as needed to make this possible.

2. *Restore the data.* This needs to be done once for each data node in the original cluster, each time using that data node's node ID. Assuming that there were 4 data nodes originally, the set of commands required would look something like this:

```
ndb_restore --nodeid=1 --backupid=1 --restore-data --backup-path=/backups/node_1/BACKUP/BACKUP-1 --disable-
ndb_restore --nodeid=2 --backupid=1 --restore-data --backup-path=/backups/node_2/BACKUP/BACKUP-1 --disable-
ndb_restore --nodeid=3 --backupid=1 --restore-data --backup-path=/backups/node_3/BACKUP/BACKUP-1 --disable-
ndb_restore --nodeid=4 --backupid=1 --restore-data --backup-path=/backups/node_4/BACKUP/BACKUP-1 --disable-
```

These can be run in parallel.

Be sure to add the `--ndb-connectstring` option as needed.

3. *Rebuild the indexes.* These were disabled by the `--disable-indexes` option used in the commands just shown. Recreating the indexes avoids errors due to the restore not being consistent at all points. Rebuilding the indexes can also improve performance in some cases. To rebuild the indexes, execute the following command once, on a single node:

```
shell> ndb_restore --nodeid=1 --backupid=1 --backup-path=/backups/node_1/BACKUP/BACKUP-1 --rebuild-indexes
```

As mentioned previously, you may need to add the `--ndb-connectstring` option, so that `ndb_restore` can contact the management server.

23.5.23.3 Restoring from a backup taken in parallel

NDB Cluster 8.0 supports parallel backups on each data node using `ndbmt` with multiple LDMs (see [Section 23.6.8.5, "Taking an NDB Backup with Parallel Data Nodes"](#)). The next two sections describe how to restore backups that were taken in this fashion.

Restoring a parallel backup in parallel

Restoring a parallel backup in parallel requires an `ndb_restore` binary from an NDB 8.0 distribution. The process is not substantially different from that outlined in the general usage section under the description of the `ndb_restore` program, and consists of executing `ndb_restore` twice, similarly to what is shown here:

```
shell> ndb_restore -n 1 -b 1 -m --backup-path=path/to/backup_dir/BACKUP/BACKUP-backup_id
shell> ndb_restore -n 1 -b 1 -r --backup-path=path/to/backup_dir/BACKUP/BACKUP-backup_id
```

`backup_id` is the ID of the backup to be restored. In the general case, no additional special arguments are required; `ndb_restore` always checks for the existence of parallel subdirectories under the directory indicated by the `--backup-path` option and restores the metadata (serially) and then the table data (in parallel).

Restoring a parallel backup serially

It is possible to restore a backup that was made using parallelism on the data nodes in serial fashion. To do this, invoke `ndb_restore` with `--backup-path` pointing to the subdirectories created by each LDM under the main backup directory, once to any one of the subdirectories to restore the metadata (it does not matter which one, since each subdirectory contains a complete copy of the metadata), then to each of the subdirectories in turn to restore the data. Suppose that we want to restore the backup having backup ID 100 that was taken with four LDMs, and that the `BackupDataDir` is `/opt`. To restore the metadata in this case, we can invoke `ndb_restore` like this:

```
shell> ndb_restore -n 1 -b 1 -m --backup-path=opt/BACKUP/BACKUP-100/BACKUP-100-PART-1-OF-4
```

To restore the table data, execute `ndb_restore` four times, each time using one of the subdirectories in turn, as shown here:

```
shell> ndb_restore -n 1 -b 1 -r --backup-path=opt/BACKUP/BACKUP-100/BACKUP-100-PART-1-OF-4
shell> ndb_restore -n 1 -b 1 -r --backup-path=opt/BACKUP/BACKUP-100/BACKUP-100-PART-2-OF-4
shell> ndb_restore -n 1 -b 1 -r --backup-path=opt/BACKUP/BACKUP-100/BACKUP-100-PART-3-OF-4
shell> ndb_restore -n 1 -b 1 -r --backup-path=opt/BACKUP/BACKUP-100/BACKUP-100-PART-4-OF-4
```

You can employ the same technique to restore a parallel backup to an older version of NDB Cluster (7.6 or earlier) that does not support parallel backups, using the `ndb_restore` binary supplied with the older version of the NDB Cluster software.

23.5.24 ndb_select_all — Print Rows from an NDB Table

`ndb_select_all` prints all rows from an NDB table to `stdout`.

Usage

```
ndb_select_all -c connection_string tbl_name -d db_name [> file_name]
```

Options that can be used with `ndb_select_all` are shown in the following table. Additional descriptions follow the table.

Table 23.44 Command-line options used with the program `ndb_select_all`

| Format | Description | Added, Deprecated, or Removed |
|---|---|--|
| <code>--character-sets-dir=path</code> | Directory containing character sets | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-retries=#</code> | Number of times to retry connection before giving up | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-retry-delay=#</code> | Number of seconds to wait between attempts to contact management server | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-string=connection-string,</code> <code>-c</code> | Same as <code>--ndb-connectstring</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--core-file</code> | Write core file on error; used in debugging | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--database=dbname,</code> <code>-d</code> | Name of database in which table is found | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-extra-file=path</code> | Read given file after global files are read | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-file=path</code> | Read default options from given file only | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-group-suffix=string</code> | Also read groups with <code>concat(group, suffix)</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--delimiter=char,</code> <code>-D</code> | Set column delimiter | (Supported in all NDB releases based on MySQL 8.0) |

| Format | Description | Added, Deprecated, or Removed |
|--|---|--|
| <code>--descending,</code> <code>-z</code> | Sort resultset in descending order (requires <code>--order</code>) | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--disk</code> | Print disk references (useful only for Disk Data tables having nonindexed columns) | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--gci</code> | Include GCI in output | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--gci64</code> | Include GCI and row epoch in output | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--header,</code> <code>-h</code> | Print header (set to 0 FALSE to disable headers in output) | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--lock=#,</code> <code>-l</code> | Lock type | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--login-path=path</code> | Read given path from login file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--help,</code> <code>-?</code> | Display help text and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-connectstring=connection-string,</code> <code>-c</code> | Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-mgmd-host=connection-string,</code> <code>-c</code> | Same as <code>--ndb-connectstring</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-nodeid=#</code> | Set node ID for this node, overriding any ID set by <code>--ndb-connectstring</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-optimized-node-selection</code> | Enable optimizations for selection of nodes for transactions. Enabled by default; use <code>--skip-ndb-optimized-node-selection</code> to disable | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--no-defaults</code> | Do not read default options from any option file other than login file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--nodata</code> | Do not print table column data | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--order=index,</code> <code>-o</code> | Sort resultset according to index having this name | (Supported in all NDB releases based on MySQL 8.0) |

| Format | Description | Added, Deprecated, or Removed |
|---|---|--|
| <code>--parallelism=#</code> , <code>-p</code> | Degree of parallelism | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--print-defaults</code> | Print program argument list and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--rowid</code> | Print row ID | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--tupscan</code> , <code>-t</code> | Scan in tup order | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--usage</code> , <code>-?</code> | Display help text and exit; same as <code>--help</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--useHexFormat</code> , <code>-x</code> | Output numbers in hexadecimal format | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--version</code> , <code>-V</code> | Display version information and exit | (Supported in all NDB releases based on MySQL 8.0) |

- `--character-sets-dir`

| | |
|---------------------|--|
| Command-Line Format | <code>--character-sets-dir=path</code> |
|---------------------|--|

Directory containing character sets.

- `--connect-retries`

| | |
|---------------------|----------------------------------|
| Command-Line Format | <code>--connect-retries=#</code> |
| Type | Integer |
| Default Value | 12 |
| Minimum Value | 0 |
| Maximum Value | 12 |

Number of times to retry connection before giving up.

- `--connect-retry-delay`

| | |
|---------------------|--------------------------------------|
| Command-Line Format | <code>--connect-retry-delay=#</code> |
| Type | Integer |
| Default Value | 5 |
| Minimum Value | 0 |
| Maximum Value | 5 |

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

| | |
|---------------------|---|
| Command-Line Format | <code>--connect-string=connection-string</code> |
| Type | String |
| Default Value | [none] |

Same as `--ndb-connectstring`.

- `--core-file`

| | |
|---------------------|--------------------------|
| Command-Line Format | <code>--core-file</code> |
|---------------------|--------------------------|

Write core file on error; used in debugging.

- `--database=dbname, -d dbname`

Name of the database in which the table is found. The default value is `TEST_DB`.

- `--descending, -z`

Sorts the output in descending order. This option can be used only in conjunction with the `-o` (`--order`) option.

- `--defaults-extra-file`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-extra-file=path</code> |
| Type | String |
| Default Value | [none] |

Read given file after global files are read.

- `--defaults-file`

| | |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--defaults-file=path</code> |
| Type | String |
| Default Value | [none] |

Read default options from given file only.

- `--defaults-group-suffix`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-group-suffix=string</code> |
| Type | String |
| Default Value | [none] |

Also read groups with `concat(group, suffix)`.

- `--delimiter=character, -D character`

Causes the `character` to be used as a column delimiter. Only table data columns are separated by this delimiter.

The default delimiter is the tab character.

- `--disk`

Adds a disk reference column to the output. The column is nonempty only for Disk Data tables having nonindexed columns.

- `--gci`

Adds a `GCI` column to the output showing the global checkpoint at which each row was last updated. See [Section 23.2, “NDB Cluster Overview”](#), and [Section 23.6.3.2, “NDB Cluster Log Events”](#), for more information about checkpoints.

- `--gci64`

Adds a `ROW$GCI64` column to the output showing the global checkpoint at which each row was last updated, as well as the number of the epoch in which this update occurred.

- `--help`

| | |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
|---------------------|---------------------|

Display help text and exit.

- `--lock=lock_type, -l lock_type`

Employs a lock when reading the table. Possible values for `lock_type` are:

- 0: Read lock
- 1: Read lock with hold
- 2: Exclusive read lock

There is no default value for this option.

- `--login-path`

| | |
|---------------------|--------------------------------|
| Command-Line Format | <code>--login-path=path</code> |
| Type | String |
| Default Value | [none] |

Read given path from login file.

- `--header=FALSE`

Excludes column headers from the output.

- `--nodata`

Causes any table data to be omitted.

- `--ndb-connectstring`

| | |
|---------------------|--|
| Command-Line Format | <code>--ndb-connectstring=connection-string</code> |
| Type | String |

| | |
|---------------|--------|
| Default Value | [none] |
|---------------|--------|

Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf.

- `--ndb-mgmd-host`

| | |
|---------------------|--|
| Command-Line Format | <code>--ndb-mgmd-host=connection-string</code> |
| Type | String |
| Default Value | [none] |

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

| | |
|---------------------|-----------------------------|
| Command-Line Format | <code>--ndb-nodeid=#</code> |
| Type | Integer |
| Default Value | [none] |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

| | |
|---------------------|---|
| Command-Line Format | <code>--ndb-optimized-node-selection</code> |
|---------------------|---|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--no-defaults`

| | |
|---------------------|----------------------------|
| Command-Line Format | <code>--no-defaults</code> |
|---------------------|----------------------------|

Do not read default options from any option file other than login file.

- `--order=index_name, -o index_name`

Orders the output according to the index named `index_name`.

Note

This is the name of an index, not of a column; the index must have been explicitly named when created.

- `parallelism=#, -p #`

Specifies the degree of parallelism.

- `--print-defaults`

| | |
|---------------------|-------------------------------|
| Command-Line Format | <code>--print-defaults</code> |
|---------------------|-------------------------------|

Print program argument list and exit.

- `--rowid`
Adds a `ROWID` column providing information about the fragments in which rows are stored.
- `--tupscan, -t`
Scan the table in the order of the tuples.

- `--usage`

| | |
|---------------------|----------------------|
| Command-Line Format | <code>--usage</code> |
|---------------------|----------------------|

Display help text and exit; same as `--help`.

- `--useHexFormat -x`

Causes all numeric values to be displayed in hexadecimal format. This does not affect the output of numerals contained in strings or datetime values.

- `--version`

| | |
|---------------------|------------------------|
| Command-Line Format | <code>--version</code> |
|---------------------|------------------------|

Display version information and exit.

Sample Output

Output from a MySQL `SELECT` statement:

```
mysql> SELECT * FROM ctest1.fish;
+----+-----+
| id | name      |
+----+-----+
| 3  | shark     |
| 6  | puffer    |
| 2  | tuna     |
| 4  | manta ray |
| 5  | grouper  |
| 1  | guppy    |
+----+-----+
6 rows in set (0.04 sec)
```

Output from the equivalent invocation of `ndb_select_all`:

```
shell> ./ndb_select_all -c localhost fish -d ctest1
id      name
3       [shark]
6       [puffer]
2       [tuna]
4       [manta ray]
5       [grouper]
1       [guppy]
6 rows returned

NDBT_ProgramExit: 0 - OK
```

All string values are enclosed by square brackets (`[...]`) in the output of `ndb_select_all`. For another example, consider the table created and populated as shown here:

```
CREATE TABLE dogs (
  id INT(11) NOT NULL AUTO_INCREMENT,
  name VARCHAR(25) NOT NULL,
  breed VARCHAR(50) NOT NULL,
```

```

PRIMARY KEY pk (id),
KEY ix (name)
)
TABLESPACE ts STORAGE DISK
ENGINE=NDBCLUSTER;

INSERT INTO dogs VALUES
('', 'Lassie', 'collie'),
('', 'Scooby-Doo', 'Great Dane'),
('', 'Rin-Tin-Tin', 'Alsatian'),
('', 'Rosscoe', 'Mutt');
```

This demonstrates the use of several additional `ndb_select_all` options:

```

shell> ./ndb_select_all -d ctest1 dogs -o ix -z --gci --disk
GCI      id name          breed          DISK_REF
834461   2 [Scooby-Doo] [Great Dane] [ m_file_no: 0 m_page: 98 m_page_idx: 0 ]
834878   4 [Rosscoe]     [Mutt]         [ m_file_no: 0 m_page: 98 m_page_idx: 16 ]
834463   3 [Rin-Tin-Tin] [Alsatian]    [ m_file_no: 0 m_page: 34 m_page_idx: 0 ]
835657   1 [Lassie]     [Collie]       [ m_file_no: 0 m_page: 66 m_page_idx: 0 ]
4 rows returned

NDBT_ProgramExit: 0 - OK
```

23.5.25 ndb_select_count — Print Row Counts for NDB Tables

`ndb_select_count` prints the number of rows in one or more NDB tables. With a single table, the result is equivalent to that obtained by using the MySQL statement `SELECT COUNT(*) FROM tbl_name`.

Usage

```
ndb_select_count [-c connection_string] -ddb_name tbl_name[, tbl_name2[, ...]]
```

Options that can be used with `ndb_select_count` are shown in the following table. Additional descriptions follow the table.

Table 23.45 Command-line options used with the program `ndb_select_count`

| Format | Description | Added, Deprecated, or Removed |
|---|---|--|
| <code>--character-sets-dir=path</code> | Directory containing character sets | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-retries=#</code> | Number of times to retry connection before giving up | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-retry-delay=#</code> | Number of seconds to wait between attempts to contact management server | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-string=connection-string,</code> <code>-c</code> | Same as <code>--ndb-connectstring</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--core-file</code> | Write core file on error; used in debugging | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--database=dbname,</code> <code>-d</code> | Name of database in which table is found | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-extra-file=path</code> | Read given file after global files are read | (Supported in all NDB releases based on MySQL 8.0) |

| Format | Description | Added, Deprecated, or Removed |
|--|--|--|
| <code>--defaults-file=path</code> | Read default options from given file only | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-group-suffix=string</code> | Also read groups with concat(group, suffix) | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--help,</code> <code>-?</code> | Display help text and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--lock=#,</code> <code>-l</code> | Lock type | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--login-path=path</code> | Read given path from login file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-connectstring=connection-string,</code> <code>-c</code> | Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-mgmd-host=connection-string,</code> <code>-c</code> | Same as --ndb-connectstring | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-nodeid=#</code> | Set node ID for this node, overriding any ID set by --ndb-connectstring | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-optimized-node-selection</code> | Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--no-defaults</code> | Do not read default options from any option file other than login file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--parallelism=#,</code> <code>-p</code> | Degree of parallelism | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--print-defaults</code> | Print program argument list and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--usage,</code> <code>-?</code> | Display help text and exit; same as --help | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--version,</code> <code>-V</code> | Display version information and exit | (Supported in all NDB releases based on MySQL 8.0) |

- `--character-sets-dir`

| | |
|---------------------|--|
| Command-Line Format | <code>--character-sets-dir=path</code> |
|---------------------|--|

Directory containing character sets.

- `--connect-retries`

| | |
|---------------------|----------------------------------|
| Command-Line Format | <code>--connect-retries=#</code> |
| Type | Integer |
| Default Value | 12 |
| Minimum Value | 0 |
| Maximum Value | 12 |

Number of times to retry connection before giving up.

- `--connect-retry-delay`

| | |
|---------------------|--------------------------------------|
| Command-Line Format | <code>--connect-retry-delay=#</code> |
| Type | Integer |
| Default Value | 5 |
| Minimum Value | 0 |
| Maximum Value | 5 |

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

| | |
|---------------------|---|
| Command-Line Format | <code>--connect-string=connection-string</code> |
| Type | String |
| Default Value | [none] |

Same as `--ndb-connectstring`.

- `--core-file`

| | |
|---------------------|--------------------------|
| Command-Line Format | <code>--core-file</code> |
|---------------------|--------------------------|

Write core file on error; used in debugging.

- `--defaults-file`

| | |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--defaults-file=path</code> |
| Type | String |
| Default Value | [none] |

Read default options from given file only.

- `--defaults-extra-file`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-extra-file=path</code> |
| Type | String |
| Default Value | [none] |

Read given file after global files are read.

- `--defaults-group-suffix`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-group-suffix=string</code> |
| Type | String |
| Default Value | [none] |

Also read groups with `concat(group, suffix)`.

- `--login-path`

| | |
|---------------------|--------------------------------|
| Command-Line Format | <code>--login-path=path</code> |
| Type | String |
| Default Value | [none] |

Read given path from login file.

- `--help`

| | |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
|---------------------|---------------------|

Display help text and exit.

- `--ndb-connectstring`

| | |
|---------------------|--|
| Command-Line Format | <code>--ndb-connectstring=connection-string</code> |
| Type | String |
| Default Value | [none] |

Set connect string for connecting to `ndb_mgmd`. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in `NDB_CONNECTSTRING` and `my.cnf`.

- `--ndb-mgmd-host`

| | |
|---------------------|--|
| Command-Line Format | <code>--ndb-mgmd-host=connection-string</code> |
| Type | String |
| Default Value | [none] |

Same as `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

| | |
|---------------------|---|
| Command-Line Format | <code>--ndb-optimized-node-selection</code> |
|---------------------|---|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--ndb-nodeid`

| | |
|---------------------|-----------------------------|
| Command-Line Format | <code>--ndb-nodeid=#</code> |
|---------------------|-----------------------------|

| | |
|---------------|---------|
| Type | Integer |
| Default Value | [none] |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--no-defaults`

| | |
|---------------------|----------------------------|
| Command-Line Format | <code>--no-defaults</code> |
|---------------------|----------------------------|

Do not read default options from any option file other than login file.

- `--print-defaults`

| | |
|---------------------|-------------------------------|
| Command-Line Format | <code>--print-defaults</code> |
|---------------------|-------------------------------|

Print program argument list and exit.

- `--usage`

| | |
|---------------------|----------------------|
| Command-Line Format | <code>--usage</code> |
|---------------------|----------------------|

Display help text and exit; same as `--help`.

- `--version`

| | |
|---------------------|------------------------|
| Command-Line Format | <code>--version</code> |
|---------------------|------------------------|

Display version information and exit.

You can obtain row counts from multiple tables in the same database by listing the table names separated by spaces when invoking this command, as shown under **Sample Output**.

Sample Output

```
shell> ./ndb_select_count -c localhost -d ctest1 fish dogs
6 records in table fish
4 records in table dogs

NDBT_ProgramExit: 0 - OK
```

23.5.26 ndb_setup.py — Start browser-based Auto-Installer for NDB Cluster (DEPRECATED)

Note

This feature is deprecated and should be avoided. It is subject to removal in a future version of NDB Cluster.

`ndb_setup.py` starts the NDB Cluster Auto-Installer and opens the installer's Start page in the default Web browser.

Important

This program is intended to be invoked as a normal user, and not with the `mysql`, system `root` or other administrative account.

This section describes usage of and program options for the command-line tool only. For information about using the Auto-Installer GUI that is spawned when `ndb_setup.py` is invoked, see [The NDB Cluster Auto-Installer \(NDB 7.5\) \(No longer supported\)](#).

Usage

All platforms:

```
ndb_setup.py [options]
```

Additionally, on Windows platforms only:

```
setup.bat [options]
```

The following table includes all options that are supported by the NDB Cluster installation and configuration program `ndb_setup.py`. Additional descriptions follow the table.

Table 23.46 Command-line options used with the program `ndb_setup.py`

| Format | Description | Added, Deprecated, or Removed |
|--|--|--|
| <code>--browser-start-page=filename,</code> <code>-s</code> | Page that web browser opens when starting | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ca-certs-file=filename,</code> <code>-a</code> | File containing list of client certificates allowed to connect to server | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--cert-file=filename,</code> <code>-c</code> | File containing X509 certificate identifying server | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--debug-level=level,</code> <code>-d</code> | Python logging module debug level; one of DEBUG, INFO, WARNING (default), ERROR, or CRITICAL | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--help,</code> <code>-h</code> | Print help message | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--key-file=file,</code> <code>-k</code> | Specify file containing private key (if not included in <code>--cert-file</code>) | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--no-browser,</code> <code>-n</code> | Do not open start page in browser, merely start tool | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--port=#,</code> <code>-p</code> | Specify port used by web server | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--server-log-file=file,</code> <code>-o</code> | Log requests to this file; use '-' to force logging to stderr instead | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--server-name=name,</code> | Name of server to connect to | (Supported in all NDB releases based on MySQL 8.0) |

| Format | Description | Added, Deprecated, or Removed |
|--------------------|---|--|
| -N --use-http, | Use unencrypted (HTTP) client/server connection | (Supported in all NDB releases based on MySQL 8.0) |
| -H --use-https, | Use encrypted (HTTPS) client/server connection | (Supported in all NDB releases based on MySQL 8.0) |
| -S | | |

- `--browser-start-page=file, -s`

| | |
|---------------------|--|
| Command-Line Format | <code>--browser-start-page=filename</code> |
| Type | String |
| Default Value | <code>index.html</code> |

Specify the file to open in the browser as the installation and configuration Start page. The default is `index.html`.

- `--ca-certs-file=file, -a`

| | |
|---------------------|---------------------------------------|
| Command-Line Format | <code>--ca-certs-file=filename</code> |
| Type | File name |
| Default Value | <code>[none]</code> |

Specify a file containing a list of client certificates which are allowed to connect to the server. The default is an empty string, which means that no client authentication is used.

- `--cert-file=file, -c`

| | |
|---------------------|---|
| Command-Line Format | <code>--cert-file=filename</code> |
| Type | File name |
| Default Value | <code>/usr/share/mysql/mcc/cfg.pem</code> |

Specify a file containing an X509 certificate which identifies the server. It is possible for the certificate to be self-signed. The default is `cfg.pem`.

- `--debug-level=level, -d`

| | |
|---------------------|--|
| Command-Line Format | <code>--debug-level=level</code> |
| Type | Enumeration |
| Default Value | <code>WARNING</code> |
| Valid Values | <code>WARNING</code> <code>DEBUG</code> <code>INFO</code> <code>ERROR</code> <code>CRITICAL</code> |

Set the Python logging module debug level. This is one of `DEBUG`, `INFO`, `WARNING`, `ERROR`, or `CRITICAL`. `WARNING` is the default.

- `--help, -h`

| | |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
|---------------------|---------------------|

Print a help message.

- `--key-file=file, -d`

| | |
|---------------------|------------------------------|
| Command-Line Format | <code>--key-file=file</code> |
| Type | File name |
| Default Value | [none] |

Specify a file containing the private key if this is not included in the X509 certificate file (`--cert-file`). The default is an empty string, which means that no such file is used.

- `--no-browser, -n`

| | |
|---------------------|---------------------------|
| Command-Line Format | <code>--no-browser</code> |
|---------------------|---------------------------|

Start the installation and configuration tool, but do not open the Start page in a browser.

- `--port=#, -p`

| | |
|---------------------|-----------------------|
| Command-Line Format | <code>--port=#</code> |
| Type | Numeric |
| Default Value | 8081 |
| Minimum Value | 1 |
| Maximum Value | 65535 |

Set the port used by the web server. The default is 8081.

- `--server-log-file=file, -o`

| | |
|---------------------|---|
| Command-Line Format | <code>--server-log-file=file</code> |
| Type | File name |
| Default Value | <code>ndb_setup.log</code> |
| Valid Values | <code>ndb_setup.log</code> - (Log to stderr) |

Log requests to this file. The default is `ndb_setup.log`. To specify logging to `stderr`, rather than to a file, use a - (dash character) for the file name.

- `--server-name=host, -N`

| | | |
|---------------------|---------------------------------|------|
| Command-Line Format | <code>--server-name=name</code> | 4493 |
| Type | String | |

| | |
|---------------|-----------|
| Default Value | localhost |
|---------------|-----------|

Specify the host name or IP address for the browser to use when connecting. The default is `localhost`.

- `--use-http, -H`

| | |
|---------------------|-------------------------|
| Command-Line Format | <code>--use-http</code> |
|---------------------|-------------------------|

Make the browser use HTTP to connect with the server. This means that the connection is unencrypted and not secured in any way.

- `--use-https, -S`

| | |
|---------------------|--------------------------|
| Command-Line Format | <code>--use-https</code> |
|---------------------|--------------------------|

Make the browser use a secure (HTTPS) connection with the server.

23.5.27 ndb_show_tables — Display List of NDB Tables

`ndb_show_tables` displays a list of all NDB database objects in the cluster. By default, this includes not only both user-created tables and NDB system tables, but NDB-specific indexes, internal triggers, and NDB Cluster Disk Data objects as well.

Options that can be used with `ndb_show_tables` are shown in the following table. Additional descriptions follow the table.

Table 23.47 Command-line options used with the program `ndb_show_tables`

| Format | Description | Added, Deprecated, or Removed |
|---|--|--|
| <code>--character-sets-dir=path</code> | Directory containing character sets | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-retries=#</code> | Number of times to retry connection before giving up | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-retry-delay=#</code> | Number of seconds to wait between attempts to contact management server | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-string=connection-string,</code> <code>-c</code> | Same as <code>--ndb-connectstring</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--core-file</code> | Write core file on error; used in debugging | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--database=string,</code> <code>-d</code> | Specifies database in which table is found; database name must be followed by table name | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-extra-file=path</code> | Read given file after global files are read | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-file=path</code> | Read default options from given file only | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-group-suffix=string</code> | Also read groups with <code>concat(group, suffix)</code> | (Supported in all NDB releases based on MySQL 8.0) |

| Format | Description | Added, Deprecated, or Removed |
|--|--|--|
| <code>--login-path=path</code> | Read given path from login file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--loops=#,</code> <code>-l</code> | Number of times to repeat output | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--help,</code> <code>-?</code> | Display help text and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-connectstring=connection-string,</code> <code>-c</code> | Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-mgmd-host=connection-string,</code> <code>-c</code> | Same as --ndb-connectstring | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-nodeid=#</code> | Set node ID for this node, overriding any ID set by --ndb-connectstring | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-optimized-node-selection</code> | Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--no-defaults</code> | Do not read default options from any option file other than login file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--parsable,</code> <code>-p</code> | Return output suitable for MySQL LOAD DATA statement | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--print-defaults</code> | Print program argument list and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--show-temp-status</code> | Show table temporary flag | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--type=#,</code> <code>-t</code> | Limit output to objects of this type | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--unqualified,</code> <code>-u</code> | Do not qualify table names | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--usage,</code> <code>-?</code> | Display help text and exit; same as --help | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--version,</code> | Display version information and exit | (Supported in all NDB releases based on MySQL 8.0) |

| Format | Description | Added, Deprecated, or Removed |
|-----------------|-------------|-------------------------------|
| <code>-V</code> | | |

Usage

```
ndb_show_tables [-c connection_string]
```

- `--character-sets-dir`

| | |
|---------------------|--|
| Command-Line Format | <code>--character-sets-dir=path</code> |
|---------------------|--|

Directory containing character sets.

- `--connect-retries`

| | |
|---------------------|----------------------------------|
| Command-Line Format | <code>--connect-retries=#</code> |
| Type | Integer |
| Default Value | 12 |
| Minimum Value | 0 |
| Maximum Value | 12 |

Number of times to retry connection before giving up.

- `--connect-retry-delay`

| | |
|---------------------|--------------------------------------|
| Command-Line Format | <code>--connect-retry-delay=#</code> |
| Type | Integer |
| Default Value | 5 |
| Minimum Value | 0 |
| Maximum Value | 5 |

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

| | |
|---------------------|---|
| Command-Line Format | <code>--connect-string=connection-string</code> |
| Type | String |
| Default Value | [none] |

Same as `--ndb-connectstring`.

- `--core-file`

| | |
|---------------------|--------------------------|
| Command-Line Format | <code>--core-file</code> |
|---------------------|--------------------------|

Write core file on error; used in debugging.

- `--database, -d`

Specifies the name of the database in which the desired table is found. If this option is given, the name of a table must follow the database name.

If this option has not been specified, and no tables are found in the `TEST_DB` database, `ndb_show_tables` issues a warning.

- `--defaults-extra-file`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-extra-file=path</code> |
| Type | String |
| Default Value | [none] |

Read given file after global files are read.

- `--defaults-file`

| | |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--defaults-file=path</code> |
| Type | String |
| Default Value | [none] |

Read default options from given file only.

- `--defaults-group-suffix`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-group-suffix=string</code> |
| Type | String |
| Default Value | [none] |

Also read groups with `concat(group, suffix)`.

- `--help`

| | |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
|---------------------|---------------------|

Display help text and exit.

- `--login-path`

| | |
|---------------------|--------------------------------|
| Command-Line Format | <code>--login-path=path</code> |
| Type | String |
| Default Value | [none] |

Read given path from login file.

- `--loops, -l`

Specifies the number of times the utility should execute. This is 1 when this option is not specified, but if you do use the option, you must supply an integer argument for it.

- `--ndb-connectstring`

| | |
|---------------------|--|
| Command-Line Format | <code>--ndb-connectstring=connection-string</code> |
| Type | String |
| Default Value | [none] |

Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf.

- `--ndb-mgmd-host`

| | |
|---------------------|--|
| Command-Line Format | <code>--ndb-mgmd-host=connection-string</code> |
| Type | String |
| Default Value | [none] |

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

| | |
|---------------------|-----------------------------|
| Command-Line Format | <code>--ndb-nodeid=#</code> |
| Type | Integer |
| Default Value | [none] |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

| | |
|---------------------|---|
| Command-Line Format | <code>--ndb-optimized-node-selection</code> |
|---------------------|---|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--no-defaults`

| | |
|---------------------|----------------------------|
| Command-Line Format | <code>--no-defaults</code> |
|---------------------|----------------------------|

Do not read default options from any option file other than login file.

- `--parsable, -p`

Using this option causes the output to be in a format suitable for use with `LOAD DATA`.

- `--print-defaults`

| | |
|---------------------|-------------------------------|
| Command-Line Format | <code>--print-defaults</code> |
|---------------------|-------------------------------|

Print program argument list and exit.

- `--show-temp-status`

If specified, this causes temporary tables to be displayed.

- `--type, -t`

Can be used to restrict the output to one type of object, specified by an integer type code as shown here:

- 1: System table
- 2: User-created table
- 3: Unique hash index

Any other value causes all [NDB](#) database objects to be listed (the default).

- `--unqualified, -u`

If specified, this causes unqualified object names to be displayed.

- `--usage`

| | |
|---------------------|----------------------|
| Command-Line Format | <code>--usage</code> |
|---------------------|----------------------|

Display help text and exit; same as `--help`.

- `--version`

| | |
|---------------------|------------------------|
| Command-Line Format | <code>--version</code> |
|---------------------|------------------------|

Display version information and exit.

Note

Only user-created NDB Cluster tables may be accessed from MySQL; system tables such as `SYSTAB_0` are not visible to `mysqld`. However, you can examine the contents of system tables using NDB API applications such as `ndb_select_all` (see [Section 23.5.24](#), “`ndb_select_all` — Print Rows from an NDB Table”).

Prior to NDB 8.0.20, this program printed `NDBT_ProgramExit - status` upon completion of its run, due to an unnecessary dependency on the `NDBT` testing library. This dependency has been removed, eliminating the extraneous output.

23.5.28 ndb_size.pl — NDBCLUSTER Size Requirement Estimator

This is a Perl script that can be used to estimate the amount of space that would be required by a MySQL database if it were converted to use the [NDBCLUSTER](#) storage engine. Unlike the other utilities discussed in this section, it does not require access to an NDB Cluster (in fact, there is no reason for it to do so). However, it does need to access the MySQL server on which the database to be tested resides.

Requirements

- A running MySQL server. The server instance does not have to provide support for NDB Cluster.
- A working installation of Perl.
- The `DBI` module, which can be obtained from CPAN if it is not already part of your Perl installation. (Many Linux and other operating system distributions provide their own packages for this library.)
- A MySQL user account having the necessary privileges. If you do not wish to use an existing account, then creating one using `GRANT USAGE ON db_name.*`—where `db_name` is the name of the database to be examined—is sufficient for this purpose.

`ndb_size.pl` can also be found in the MySQL sources in `storage/ndb/tools`.

Options that can be used with `ndb_size.pl` are shown in the following table. Additional descriptions follow the table.

Table 23.48 Command-line options used with the program ndb_size.pl

| Format | Description | Added, Deprecated, or Removed |
|---------------------------------------|--|--|
| <code>--database=dbname</code> | Database or databases to examine; a comma-delimited list; default is ALL (use all databases found on server) | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--hostname[:port]</code> | Specify host and optional port as host[:port] | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--socket=file_name</code> | Specify socket to connect to | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--user=string</code> | Specify MySQL user name | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--password=string</code> | Specify MySQL user password | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--format=string</code> | Set output format (text or HTML) | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--excludetables=tbl_list</code> | Skip any tables in comma-separated list | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--excludedbs=db_list</code> | Skip any databases in comma-separated list | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--savequeries=file</code> | Saves all queries on database into file specified | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--loadqueries=file</code> | Loads all queries from file specified; does not connect to database | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--real_table_name=table</code> | Designates table to handle unique index size calculations | (Supported in all NDB releases based on MySQL 8.0) |

Usage

```
perl ndb_size.pl [--database={db_name|ALL}] [--hostname=host[:port]] [--socket=socket] \
  [--user=user] [--password=password] \
  [--help|-h] [--format={html|text}] \
  [--loadqueries=file_name] [--savequeries=file_name]
```

By default, this utility attempts to analyze all databases on the server. You can specify a single database using the `--database` option; the default behavior can be made explicit by using `ALL` for the name of the database. You can also exclude one or more databases by using the `--excludedbs` option with a comma-separated list of the names of the databases to be skipped. Similarly, you can cause specific tables to be skipped by listing their names, separated by commas, following the optional `--excludetables` option. A host name can be specified using `--hostname`; the default is `localhost`. You can specify a port in addition to the host using `host:port` format for the value of `--hostname`. The default port number is 3306. If necessary, you can also specify a socket; the default is `/var/lib/mysql.sock`. A MySQL user name and password can be specified the corresponding options shown. It also possible to control the format of the output using the `--format` option; this can take either of the values `html` or `text`, with `text` being the default. An example of the text output is shown here:

```
shell> ndb_size.pl --database=test --socket=/tmp/mysql.sock
ndb_size.pl report for database: 'test' (1 tables)
-----
Connected to: DBI:mysql:host=localhost;mysql_socket=/tmp/mysql.sock
```

```

Including information for versions: 4.1, 5.0, 5.1

test.tl

  NoOfUniqueHashIndexes  64         0         0         0
  NoOfAttributes   1000        3         3         3
  NoOfTriggers     768         5         5         5

```

For debugging purposes, the Perl arrays containing the queries run by this script can be read from the file specified using `--savequeries`; a file containing such arrays to be read during script execution can be specified using `--loadqueries`. Neither of these options has a default value.

To produce output in HTML format, use the `--format` option and redirect the output to a file, as shown here:

```
shell> ndb_size.pl --database=test --socket=/tmp/mysql.sock --format=html > ndb_size.html
```

(Without the redirection, the output is sent to `stdout`.)

The output from this script includes the following information:

- Minimum values for the `DataMemory`, `IndexMemory`, `MaxNoOfTables`, `MaxNoOfAttributes`, `MaxNoOfOrderedIndexes`, and `MaxNoOfTriggers` configuration parameters required to accommodate the tables analyzed.
- Memory requirements for all of the tables, attributes, ordered indexes, and unique hash indexes defined in the database.
- The `IndexMemory` and `DataMemory` required per table and table row.

23.5.29 ndb_top — View CPU usage information for NDB threads

`ndb_top` displays running information in the terminal about CPU usage by NDB threads on an NDB Cluster data node. Each thread is represented by two rows in the output, the first showing system statistics, the second showing the measured statistics for the thread.

`ndb_top` is available beginning with MySQL NDB Cluster 7.6.3.

Usage

```
ndb_top [-h hostname] [-t port] [-u user] [-p pass] [-n node_id]
```

`ndb_top` connects to a MySQL Server running as an SQL node of the cluster. By default, it attempts to connect to a `mysqld` running on `localhost` and port 3306, as the MySQL `root` user with no password specified. You can override the default host and port using, respectively, `--host` (`-h`) and `--port` (`-t`). To specify a MySQL user and password, use the `--user` (`-u`) and `--passwd` (`-p`) options. This user must be able to read tables in the `ndbinfo` database (`ndb_top` uses information from `ndbinfo.cpusstat` and related tables).

For more information about MySQL user accounts and passwords, see [Section 6.2, “Access Control and Account Management”](#).

Output is available as plain text or an ASCII graph; you can specify this using the `--text` (`-x`) and `--graph` (`-g`) options, respectively. These two display modes provide the same information; they can be used concurrently. At least one display mode must be in use.

Color display of the graph is supported and enabled by default (`--color` or `-c` option). With color support enabled, the graph display shows OS user time in blue, OS system time in green, and idle time as blank. For measured load, blue is used for execution time, yellow for send time, red for time spent in send buffer full waits, and blank spaces for idle time. The percentage shown in the graph display is the sum of percentages for all threads which are not idle. Colors are not currently configurable; you can use grayscale instead by using `--skip-color`.

The sorted view (`--sort`, `-r`) is based on the maximum of the measured load and the load reported by the OS. Display of these can be enabled and disabled using the `--measured-load` (`-m`) and `--os-load` (`-o`) options. Display of at least one of these loads must be enabled.

The program tries to obtain statistics from a data node having the node ID given by the `--node-id` (`-n`) option; if unspecified, this is 1. `ndb_top` cannot provide information about other types of nodes.

The view adjusts itself to the height and width of the terminal window; the minimum supported width is 76 characters.

Once started, `ndb_top` runs continuously until forced to exit; you can quit the program using `Ctrl-C`. The display updates once per second; to set a different delay interval, use `--sleep-time (-s)`.

Note

`ndb_top` is available on macOS, Linux, and Solaris. It is not currently supported on Windows platforms.

The following table includes all options that are specific to the NDB Cluster program `ndb_top`. Additional descriptions follow the table.

Table 23.49 Command-line options used with the program `ndb_top`

| Format | Description | Added, Deprecated, or Removed |
|--|--|--|
| <code>--color,</code> <code>-c</code> | Show ASCII graphs in color; use <code>--skip-colors</code> to disable | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-extra-file=path</code> | Read given file after global files are read | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-file=path</code> | Read default options from given file only | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-group-suffix=string</code> | Also read groups with <code>concat(group, suffix)</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--graph,</code> <code>-g</code> | Display data using graphs; use <code>--skip-graphs</code> to disable | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--help</code> | Show program usage information | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--host[=name],</code> <code>-h</code> | Host name or IP address of MySQL Server to connect to | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--login-path=path</code> | Read given path from login file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--measured-load,</code> <code>-m</code> | Show measured load by thread | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--no-defaults</code> | Do not read default options from any option file other than login file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--node-id[=#],</code> <code>-n</code> | Watch node having this node ID | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--os-load,</code> <code>-o</code> | Show load measured by operating system | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--password[=password],</code> <code>-p</code> | Connect using this password | (Supported in all NDB releases based on MySQL 8.0) |

| Format | Description | Added, Deprecated, or Removed |
|--|--|--|
| <code>--port[=#],</code> <code>-P (>=7.6.6)</code> | Port number to use when connecting to MySQL Server | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--print-defaults</code> | Print program argument list and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--sleep-time[=seconds],</code> <code>-s</code> | Time to wait between display refreshes, in seconds | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--socket,</code> <code>-S</code> | Socket file to use for connection | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--sort,</code> <code>-r</code> | Sort threads by usage; use <code>--skip-sort</code> to disable | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--text,</code> <code>-t (>=7.6.6)</code> | Display data using text | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--usage</code> | Show program usage information; same as <code>--help</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--user[=name],</code> <code>-u</code> | Connect as this MySQL user | (Supported in all NDB releases based on MySQL 8.0) |

Additional Options

- `--color, -c`

| | |
|---------------------|----------------------|
| Command-Line Format | <code>--color</code> |
| Type | Boolean |
| Default Value | <code>TRUE</code> |

Show ASCII graphs in color; use `--skip-colors` to disable.

- `--defaults-extra-file`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-extra-file=path</code> |
| Type | String |
| Default Value | <code>[none]</code> |

Read given file after global files are read.

- `--defaults-file`

| | |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--defaults-file=path</code> |
| Type | String |
| Default Value | <code>[none]</code> |

Read default options from given file only.

- `--defaults-group-suffix`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-group-suffix=string</code> |
| Type | String |
| Default Value | [none] |

Also read groups with `concat(group, suffix)`.

- `--graph, -g`

| | |
|---------------------|----------------------|
| Command-Line Format | <code>--graph</code> |
| Type | Boolean |
| Default Value | TRUE |

Display data using graphs; use `--skip-graphs` to disable. This option or `--text` must be true; both options may be true.

- `--help, -?`

| | |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
| Type | Boolean |
| Default Value | TRUE |

Show program usage information.

- `--host[=name], -h`

| | |
|---------------------|----------------------------|
| Command-Line Format | <code>--host[=name]</code> |
| Type | String |
| Default Value | localhost |

Host name or IP address of MySQL Server to connect to.

- `--login-path`

| | |
|---------------------|--------------------------------|
| Command-Line Format | <code>--login-path=path</code> |
| Type | String |
| Default Value | [none] |

Read given path from login file.

- `--measured-load, -m`

| | |
|---------------------|------------------------------|
| Command-Line Format | <code>--measured-load</code> |
| Type | Boolean |
| Default Value | FALSE |

Show measured load by thread. This option or `--os-load` must be true; both options may be true.

- `--no-defaults`

| | |
|---------------------|----------------------------|
| Command-Line Format | <code>--no-defaults</code> |
|---------------------|----------------------------|

Do not read default options from any option file other than login file.

- `--node-id[=#], -n`

| | |
|---------------------|----------------------------|
| Command-Line Format | <code>--node-id[=#]</code> |
| Type | Integer |
| Default Value | 1 |

Watch the data node having this node ID.

- `--os-load, -o`

| | |
|---------------------|------------------------|
| Command-Line Format | <code>--os-load</code> |
| Type | Boolean |
| Default Value | TRUE |

Show load measured by operating system. This option or `--measured-load` must be true; both options may be true.

- `--password[=password], -p`

| | |
|---------------------|------------------------------------|
| Command-Line Format | <code>--password[=password]</code> |
| Type | Boolean |
| Default Value | NULL |

Connect to a MySQL Server using this password and the MySQL user specified by `--user`.

This password is associated with a MySQL user account only, and is not related in any way to the password used with encrypted NDB backups.

- `--port[=#], -P`

| | |
|---------------------|-------------------------|
| Command-Line Format | <code>--port[=#]</code> |
| Type | Integer |
| Default Value | 3306 |

Port number to use when connecting to MySQL Server.

(Formerly, the short form for this option was `-t`, which was repurposed as the short form of `--text`.)

- `--print-defaults`

| | |
|---------------------|-------------------------------|
| Command-Line Format | <code>--print-defaults</code> |
|---------------------|-------------------------------|

- `--sleep-time[=seconds], -s`

| | |
|---------------------|--|
| Command-Line Format | <code>--sleep-time[=<i>seconds</i>]</code> |
| Type | Integer |
| Default Value | 1 |

Time to wait between display refreshes, in seconds.

- `--socket=path/to/file, -S`

| | |
|---------------------|-----------------------|
| Command-Line Format | <code>--socket</code> |
| Type | Path name |
| Default Value | [none] |

Use the specified socket file for the connection.

- `--sort, -r`

| | |
|---------------------|---------------------|
| Command-Line Format | <code>--sort</code> |
| Type | Boolean |
| Default Value | TRUE |

Sort threads by usage; use `--skip-sort` to disable.

- `--text, -t`

| | |
|---------------------|---------------------|
| Command-Line Format | <code>--text</code> |
| Type | Boolean |
| Default Value | FALSE |

Display data using text. This option or `--graph` must be true; both options may be true.

(The short form for this option was `-x` in previous versions of NDB Cluster, but this is no longer supported.)

- `--usage`

| | |
|---------------------|----------------------|
| Command-Line Format | <code>--usage</code> |
| Type | Boolean |
| Default Value | TRUE |

Display help text and exit; same as `--help`.

- `--user[=name], -u`

| | |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--user[=<i>name</i>]</code> |
| Type | String |
| Default Value | root |

Connect as this MySQL user. Normally requires a password supplied by the `--password` option.

Sample Output. The next figure shows `ndb_top` running in a terminal window on a Linux system with an `ndbmysqld` data node under a moderate load. Here, the program has been invoked using `ndb_top -n8 -x` to provide both text and graph output:

Figure 23.26 `ndb_top` Running in Terminal

Beginning with NDB 8.0.20, `ndb_top` also shows spin times for threads, displayed in green.

23.5.30 `ndb_waiter` — Wait for NDB Cluster to Reach a Given Status

`ndb_waiter` repeatedly (each 100 milliseconds) prints out the status of all cluster data nodes until either the cluster reaches a given status or the `--timeout` limit is exceeded, then exits. By default, it waits for the cluster to achieve `STARTED` status, in which all nodes have started and connected to the cluster. This can be overridden using the `--no-contact` and `--not-started` options.

The node states reported by this utility are as follows:

- `NO_CONTACT`: The node cannot be contacted.
- `UNKNOWN`: The node can be contacted, but its status is not yet known. Usually, this means that the node has received a `START` or `RESTART` command from the management server, but has not yet acted on it.
- `NOT_STARTED`: The node has stopped, but remains in contact with the cluster. This is seen when restarting the node using the management client's `RESTART` command.
- `STARTING`: The node's `ndbd` process has started, but the node has not yet joined the cluster.
- `STARTED`: The node is operational, and has joined the cluster.
- `SHUTTING_DOWN`: The node is shutting down.
- `SINGLE USER MODE`: This is shown for all cluster data nodes when the cluster is in single user mode.

Options that can be used with `ndb_waiter` are shown in the following table. Additional descriptions follow the table.

Table 23.50 Command-line options used with the program ndb_waiter

| Format | Description | Added, Deprecated, or Removed |
|--|--|--|
| <code>--character-sets-dir=path</code> | Directory containing character sets | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-retries=#</code> | Number of times to retry connection before giving up | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-retry-delay=#</code> | Number of seconds to wait between attempts to contact management server | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--connect-string=connection-string,</code> <code>-c</code> | Same as <code>--ndb-connectstring</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--core-file</code> | Write core file on error; used in debugging | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-extra-file=path</code> | Read given file after global files are read | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-file=path</code> | Read default options from given file only | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-group-suffix=string</code> | Also read groups with <code>concat(group, suffix)</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--help,</code> <code>-?</code> | Display help text and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--login-path=path</code> | Read given path from login file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-connectstring=connection-string,</code> <code>-c</code> | Set connect string for connecting to <code>ndb_mgmd</code> . Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in <code>NDB_CONNECTSTRING</code> and <code>my.cnf</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-mgmd-host=connection-string,</code> <code>-c</code> | Same as <code>--ndb-connectstring</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-nodeid=#</code> | Set node ID for this node, overriding any ID set by <code>--ndb-connectstring</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--ndb-optimized-node-selection</code> | Enable optimizations for selection of nodes for transactions. Enabled by default; use <code>--skip-ndb-optimized-node-selection</code> to disable | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--no-contact,</code> | Wait for cluster to reach NO CONTACT state | (Supported in all NDB releases based on MySQL 8.0) |

| Format | Description | Added, Deprecated, or Removed |
|----------------------------------|--|--|
| <code>-n</code> | | |
| <code>--no-defaults</code> | Do not read default options from any option file other than login file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--not-started</code> | Wait for cluster to reach NOT STARTED state | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--nowait-nodes=list</code> | List of nodes not to be waited for | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--print-defaults</code> | Print program argument list and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--single-user</code> | Wait for cluster to enter single user mode | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--timeout=#,</code> | Wait this many seconds, then exit whether or not cluster has reached desired state | (Supported in all NDB releases based on MySQL 8.0) |
| <code>-t</code> | | |
| <code>--usage,</code> | Display help text and exit; same as <code>--help</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>-?</code> | | |
| <code>--version,</code> | Display version information and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>-V</code> | | |
| <code>--wait-nodes=list,</code> | List of nodes to be waited for | (Supported in all NDB releases based on MySQL 8.0) |
| <code>-w</code> | | |

Usage

```
ndb_waiter [-c connection_string]
```

Additional Options

- `--character-sets-dir`

| | |
|---------------------|--|
| Command-Line Format | <code>--character-sets-dir=path</code> |
|---------------------|--|

Directory containing character sets.

- `--connect-retries`

| | |
|---------------------|----------------------------------|
| Command-Line Format | <code>--connect-retries=#</code> |
| Type | Integer |
| Default Value | 12 |
| Minimum Value | 0 |
| Maximum Value | 12 |

Number of times to retry connection before giving up.

- `--connect-retry-delay`

| | |
|---------------------|--------------------------------------|
| Command-Line Format | <code>--connect-retry-delay=#</code> |
| Type | Integer |
| Default Value | 5 |
| Minimum Value | 0 |
| Maximum Value | 5 |

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

| | |
|---------------------|---|
| Command-Line Format | <code>--connect-string=connection-string</code> |
| Type | String |
| Default Value | [none] |

Same as `--ndb-connectstring`.

- `--core-file`

| | |
|---------------------|--------------------------|
| Command-Line Format | <code>--core-file</code> |
|---------------------|--------------------------|

Write core file on error; used in debugging.

- `--defaults-extra-file`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-extra-file=path</code> |
| Type | String |
| Default Value | [none] |

Read given file after global files are read.

- `--defaults-file`

| | |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--defaults-file=path</code> |
| Type | String |
| Default Value | [none] |

Read default options from given file only.

- `--defaults-group-suffix`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-group-suffix=string</code> |
| Type | String |
| Default Value | [none] |

Also read groups with `concat(group, suffix)`.

- `--login-path`

| | |
|---------------------|--------------------------------|
| Command-Line Format | <code>--login-path=path</code> |
|---------------------|--------------------------------|

| | |
|---------------|--------|
| Type | String |
| Default Value | [none] |

Read given path from login file.

- `--help`

| | |
|---------------------|---------------------|
| Command-Line Format | <code>--help</code> |
|---------------------|---------------------|

Display help text and exit.

- `--ndb-connectstring`

| | |
|---------------------|--|
| Command-Line Format | <code>--ndb-connectstring=connection-string</code> |
| Type | String |
| Default Value | [none] |

Set connect string for connecting to `ndb_mgmd`. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in `NDB_CONNECTSTRING` and `my.cnf`.

- `--ndb-mgmd-host`

| | |
|---------------------|--|
| Command-Line Format | <code>--ndb-mgmd-host=connection-string</code> |
| Type | String |
| Default Value | [none] |

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

| | |
|---------------------|-----------------------------|
| Command-Line Format | <code>--ndb-nodeid=#</code> |
| Type | Integer |
| Default Value | [none] |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

| | |
|---------------------|---|
| Command-Line Format | <code>--ndb-optimized-node-selection</code> |
|---------------------|---|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--no-contact, -n`

Instead of waiting for the `STARTED` state, `ndb_waiter` continues running until the cluster reaches `NO_CONTACT` status before exiting.

- `--no-defaults`

| | |
|---------------------|----------------------------|
| Command-Line Format | <code>--no-defaults</code> |
|---------------------|----------------------------|

Do not read default options from any option file other than login file.

- `--not-started`

Instead of waiting for the `STARTED` state, `ndb_waiter` continues running until the cluster reaches `NOT_STARTED` status before exiting.

- `--nowait-nodes=list`

When this option is used, `ndb_waiter` does not wait for the nodes whose IDs are listed. The list is comma-delimited; ranges can be indicated by dashes, as shown here:

```
shell> ndb_waiter --nowait-nodes=1,3,7-9
```

Important

Do *not* use this option together with the `--wait-nodes` option.

- `--print-defaults`

| | |
|---------------------|-------------------------------|
| Command-Line Format | <code>--print-defaults</code> |
|---------------------|-------------------------------|

Print program argument list and exit.

- `--timeout=seconds, -t seconds`

Time to wait. The program exits if the desired state is not achieved within this number of seconds. The default is 120 seconds (1200 reporting cycles).

- `--single-user`

The program waits for the cluster to enter single user mode.

- `--usage`

| | |
|---------------------|----------------------|
| Command-Line Format | <code>--usage</code> |
|---------------------|----------------------|

Display help text and exit; same as `--help`.

- `--version`

| | |
|---------------------|------------------------|
| Command-Line Format | <code>--version</code> |
|---------------------|------------------------|

Display version information and exit.

- `--wait-nodes=list, -w list`

When this option is used, `ndb_waiter` waits only for the nodes whose IDs are listed. The list is comma-delimited; ranges can be indicated by dashes, as shown here:

```
shell> ndb_waiter --wait-nodes=2,4-6,10
```

Important

Do *not* use this option together with the `--nowait-nodes` option.

Sample Output. Shown here is the output from `ndb_waiter` when run against a 4-node cluster in which two nodes have been shut down and then started again manually. Duplicate reports (indicated by `...`) are omitted.

```
shell> ./ndb_waiter -c localhost

Connecting to mgmsrv at (localhost)
State node 1 STARTED
State node 2 NO_CONTACT
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 UNKNOWN
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 UNKNOWN
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 STARTING
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTED
State node 3 STARTED
State node 4 STARTING
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTED
State node 3 STARTED
State node 4 STARTED
Waiting for cluster enter state STARTED
```

**Note**

If no connection string is specified, then `ndb_waiter` tries to connect to a management on `localhost`, and reports `Connecting to mgmsrv at (null)`.

Prior to NDB 8.0.20, this program printed `NDBT_ProgramExit - status` upon completion of its run, due to an unnecessary dependency on the NDBT testing library. This dependency has been removed, eliminating the extraneous output.

23.5.31 ndbxfm — Compress, Decompress, Encrypt, and Decrypt Files Created by NDB Cluster

The `ndbxfm` utility, introduced in NDB 8.0.22, can be used to decompress, decrypt, and output information about files created by NDB Cluster that are compressed, encrypted, or both. It can also be used to compress or encrypt files.

Table 23.51 Command-line options used with the program `ndbxfm`

| Format | Description | Added, Deprecated, or Removed |
|---|--|--|
| <code>--compress,</code> <code>-c</code> | Compress file | ADDED: NDB 8.0.22 |
| <code>--decrypt-password=string</code> | Use this password to decrypt file | ADDED: NDB 8.0.22 |
| <code>--decrypt-password-from-stdin[=value]</code> | Get decryption password in a secure fashion from STDIN | ADDED: NDB 8.0.24 |
| <code>--defaults-extra-file=path</code> | Read given file after global files are read | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-group-suffix=string</code> | Also read groups with <code>concat(group, suffix)</code> | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--defaults-file=path</code> | Read default options from given file only | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--encrypt-kdf-iter-count=#,</code> <code>-k</code> | Number of iterations used in key definition | ADDED: NDB 8.0.22 |
| <code>--encrypt-password=string</code> | Use this password to encrypt file | ADDED: NDB 8.0.22 |
| <code>--encrypt-password-from-stdin[=value]</code> | Get encryption password in a secure fashion from STDIN | ADDED: NDB 8.0.24 |
| <code>--help,</code> <code>-?</code> | Print usage information | ADDED: NDB 8.0.22 |
| <code>--info,</code> <code>-i</code> | Print file information | ADDED: NDB 8.0.22 |
| <code>--login-path=path</code> | Read given path from login file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--no-defaults</code> | Do not read default options from any option file other than login file | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--print-defaults</code> | Print program argument list and exit | (Supported in all NDB releases based on MySQL 8.0) |
| <code>--usage,</code> <code>-?</code> | Prints usage information; synonym for <code>--help</code> | ADDED: NDB 8.0.22 |
| <code>--version,</code> <code>-V</code> | Output version information | ADDED: NDB 8.0.22 |

Usage

```
ndbxfrm --info file[ file ...]
ndbxfrm --compress input_file output_file
ndbxfrm --decrypt-password=password input_file output_file
ndbxfrm [--encrypt-ldf-iter-count=#] --encrypt-password=password input_file output_file
```

input_file and *output_file* cannot be the same file.

Options

- `--compress, -c`

Compresses the input file, using the same compression method as is used for compressing NDB Cluster backups, and writes the output to an output file. To decompress a compressed NDB backup file that is not encrypted, it is necessary only to invoke `ndbxfrm` using the names of the compressed file and an output file (with no options required).

- `--decrypt-password=password`

Decrypts a file encrypted by NDB using the password supplied.

- `--decrypt-password-from-stdin[=TRUE|FALSE]`

Decrypts a file encrypted by NDB, using a password supplied from standard input. This is similar to entering a password after invoking `mysql --password` with no password following the option.

- `--defaults-extra-file`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-extra-file=path</code> |
| Type | String |
| Default Value | [none] |

Read given file after global files are read.

- `--defaults-file`

| | |
|---------------------|-----------------------------------|
| Command-Line Format | <code>--defaults-file=path</code> |
| Type | String |
| Default Value | [none] |

Read default options from given file only.

- `--defaults-group-suffix`

| | |
|---------------------|---|
| Command-Line Format | <code>--defaults-group-suffix=string</code> |
| Type | String |
| Default Value | [none] |

Also read groups with `concat(group, suffix)`.

- `--encrypt-kdf-iter-count=#, -k #`

When encrypting a file, specifies the number of iterations to use for the encryption key. Requires the `--encrypt-password` option.

- `--encrypt-password=password`

Encrypts the backup file using the password supplied by the option. The password must meet the requirements listed here:

- Uses any of the printable ASCII characters except `!`, `'`, `"`, `$`, `%`, `\`, and `^`
- Is no more than 256 characters in length
- Is enclosed by single or double quotation marks

It is possible but not recommended to use an empty password (`'` or `"`).

- `--encrypt-password-from-stdin[=TRUE|FALSE]`

Encrypts a file using a password supplied from standard input. This is similar to entering a password is entered after invoking `mysql --password` with no password following the option.

- `--help, -?`

Prints usage information for the program.

- `--info, -i`

Prints the following information about one or more input files:

- The name of the file
- Whether the file is compressed (`compression=yes` or `compression=no`)
- Whether the file is encrypted (`encryption=yes` or `encryption=no`)

Example:

```
shell> ndbxfrm -i BACKUP-10-0.5.Data BACKUP-10.5.ct1 BACKUP-10.5.log
File=BACKUP-10-0.5.Data, compression=no, encryption=yes
File=BACKUP-10.5.ct1, compression=no, encryption=yes
File=BACKUP-10.5.log, compression=no, encryption=yes
```

- `--login-path`

| | |
|---------------------|--------------------------------|
| Command-Line Format | <code>--login-path=path</code> |
| Type | String |
| Default Value | [none] |

Read given path from login file.

- `--no-defaults`

| | |
|---------------------|----------------------------|
| Command-Line Format | <code>--no-defaults</code> |
|---------------------|----------------------------|

Do not read default options from any option file other than login file.

- `--print-defaults`

| | |
|---------------------|-------------------------------|
| Command-Line Format | <code>--print-defaults</code> |
|---------------------|-------------------------------|

Print program argument list and exit.

- `--usage, -?`

Synonym for `--help`.

- `--version, -V`

Prints out version information.

`ndbxfrm` can encrypt backups created by any version of NDB Cluster. The `.Data`, `.ctl`, and `.log` files comprising the backup must be encrypted separately, and these files must be encrypted separately for each data node. Once encrypted, such backups can be decrypted only by `ndbxfrm`, `ndb_restore`, or `ndb_print_backup` from NDB Cluster 8.0.22 or later.

An encrypted file can be re-encrypted with a new password using the `--encrypt-password` and `--decrypt-password` options together, like this:

```
ndbxfrm --decrypt-password=old --encrypt-password=new input_file output_file
```

In the example just shown, *old* and *new* are the old and new passwords, respectively; both of these must be quoted. The input file is decrypted and then encrypted as the output file. The input file itself is not changed; if you do not want it to be accessible using the old password, you must remove the input file manually.

23.6 Management of NDB Cluster

Managing an NDB Cluster involves a number of tasks, the first of which is to configure and start NDB Cluster. This is covered in [Section 23.4, “Configuration of NDB Cluster”](#), and [Section 23.5, “NDB Cluster Programs”](#).

The next few sections cover the management of a running NDB Cluster.

For information about security issues relating to management and deployment of an NDB Cluster, see [Section 23.6.17, “NDB Cluster Security Issues”](#).

There are essentially two methods of actively managing a running NDB Cluster. The first of these is through the use of commands entered into the management client whereby cluster status can be checked, log levels changed, backups started and stopped, and nodes stopped and started. The second method involves studying the contents of the cluster log `ndb_node_id_cluster.log`; this is usually found in the management server's `DataDir` directory, but this location can be overridden using the `LogDestination` option. (Recall that `node_id` represents the unique identifier of the node whose activity is being logged.) The cluster log contains event reports generated by `ndbd`. It is also possible to send cluster log entries to a Unix system log.

Some aspects of the cluster's operation can be also be monitored from an SQL node using the `SHOW ENGINE NDB STATUS` statement.

More detailed information about NDB Cluster operations is available in real time through an SQL interface using the `ndbinfo` database. For more information, see [Section 23.6.14, “ndbinfo: The NDB Cluster Information Database”](#).

NDB statistics counters provide improved monitoring using the `mysql` client. These counters, implemented in the NDB kernel, relate to operations performed by or affecting `Ndb` objects, such as starting, closing, and aborting transactions; primary key and unique key operations; table, range, and pruned scans; blocked

threads waiting for various operations to complete; and data and events sent and received by NDB Cluster. The counters are incremented by the NDB kernel whenever NDB API calls are made or data is sent to or received by the data nodes.

`mysqld` exposes the NDB API statistics counters as system status variables, which can be identified from the prefix common to all of their names (`Ndb_api_`). The values of these variables can be read in the `mysql` client from the output of a `SHOW STATUS` statement, or by querying either the Performance Schema `session_status` or `global_status` table. By comparing the values of the status variables before and after the execution of an SQL statement that acts on NDB tables, you can observe the actions taken on the NDB API level that correspond to this statement, which can be beneficial for monitoring and performance tuning of NDB Cluster.

MySQL Cluster Manager provides an advanced command-line interface that simplifies many otherwise complex NDB Cluster management tasks, such as starting, stopping, or restarting an NDB Cluster with a large number of nodes. The MySQL Cluster Manager client also supports commands for getting and setting the values of most node configuration parameters as well as `mysqld` server options and variables relating to NDB Cluster. MySQL Cluster Manager version 1.4.8 provides experimental support for NDB 8.0. See [MySQL Cluster Manager 1.4.8 User Manual](#), for more information.

23.6.1 Commands in the NDB Cluster Management Client

In addition to the central configuration file, a cluster may also be controlled through a command-line interface available through the management client `ndb_mgm`. This is the primary administrative interface to a running cluster.

Commands for the event logs are given in [Section 23.6.3, “Event Reports Generated in NDB Cluster”](#); commands for creating backups and restoring from them are provided in [Section 23.6.8, “Online Backup of NDB Cluster”](#).

Using `ndb_mgm` with MySQL Cluster Manager. MySQL Cluster Manager 1.4.8 provides experimental support for NDB 8.0. MySQL Cluster Manager handles starting and stopping processes and tracks their states internally, so it is not necessary to use `ndb_mgm` for these tasks for an NDB Cluster that is under MySQL Cluster Manager control. It is recommended *not* to use the `ndb_mgm` command-line client that comes with the NDB Cluster distribution to perform operations that involve starting or stopping nodes. These include but are not limited to the `START`, `STOP`, `RESTART`, and `SHUTDOWN` commands. For more information, see [MySQL Cluster Manager Process Commands](#).

The management client has the following basic commands. In the listing that follows, `node_id` denotes either a data node ID or the keyword `ALL`, which indicates that the command should be applied to all of the cluster's data nodes.

- `CONNECT connection-string`

Connects to the management server indicated by the connection string. If the client is already connected to this server, the client reconnects.

- `CREATE NODEGROUP nodeid[, nodeid, ...]`

Creates a new NDB Cluster node group and causes data nodes to join it.

This command is used after adding new data nodes online to an NDB Cluster, and causes them to join a new node group and thus to begin participating fully in the cluster. The command takes as its sole parameter a comma-separated list of node IDs—these are the IDs of the nodes just added and started, and that are to join the new node group. The list must contain no duplicate IDs; beginning with NDB 8.0.26, the presence of any duplicates causes the command to return an error. The number of nodes in the list must be the same as the number of nodes in each node group that is already part of the cluster (each NDB Cluster node group must have the same number of nodes). In other words, if the NDB

Cluster consists of 2 node groups having 2 data nodes each, then the new node group must also have 2 data nodes.

The node group ID of the new node group created by this command is determined automatically, and always the next highest unused node group ID in the cluster; it is not possible to set it manually.

For more information, see [Section 23.6.7, “Adding NDB Cluster Data Nodes Online”](#).

- `DROP NODEGROUP nodegroup_id`

Drops the NDB Cluster node group with the given *nodegroup_id*.

This command can be used to drop a node group from an NDB Cluster. `DROP NODEGROUP` takes as its sole argument the node group ID of the node group to be dropped.

`DROP NODEGROUP` acts only to remove the data nodes in the effected node group from that node group. It does not stop data nodes, assign them to a different node group, or remove them from the cluster's configuration. A data node that does not belong to a node group is indicated in the output of the management client `SHOW` command with `no nodegroup` in place of the node group ID, like this (indicated using bold text):

```
id=3      @10.100.2.67  (8.0.27-ndb-8.0.27, no nodegroup)
```

`DROP NODEGROUP` works only when all data nodes in the node group to be dropped are completely empty of any table data and table definitions. Since there is currently no way using `ndb_mgm` or the `mysql` client to remove all data from a specific data node or node group, this means that the command succeeds only in the two following cases:

1. After issuing `CREATE NODEGROUP` in the `ndb_mgm` client, but before issuing any `ALTER TABLE ... REORGANIZE PARTITION` statements in the `mysql` client.
2. After dropping all `NDBCLUSTER` tables using `DROP TABLE`.

`TRUNCATE TABLE` does not work for this purpose because this removes only the table data; the data nodes continue to store an `NDBCLUSTER` table's definition until a `DROP TABLE` statement is issued that causes the table metadata to be dropped.

For more information about `DROP NODEGROUP`, see [Section 23.6.7, “Adding NDB Cluster Data Nodes Online”](#).

- `ENTER SINGLE USER MODE node_id`

Enters single user mode, whereby only the MySQL server identified by the node ID *node_id* is permitted to access the database.

The `ndb_mgm` client provides a clear acknowledgement that this command has been issued and has taken effect, as shown here:

```
ndb_mgm> ENTER SINGLE USER MODE 100
Single user mode entered
Access is granted for API node 100 only.
```

In addition, the API or SQL node having exclusive access when in single user mode is indicated in the output of the `SHOW` command, like this:

```
ndb_mgm> SHOW
Cluster Configuration
-----
[ndbd(NDB)]      2 node(s)
```

```

id=5   @127.0.0.1 (mysql-8.0.27 ndb-8.0.27, single user mode, Nodegroup: 0, *)
id=6   @127.0.0.1 (mysql-8.0.27 ndb-8.0.27, single user mode, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=50   @127.0.0.1 (mysql-8.0.27 ndb-8.0.27)

[mysqld(API)] 2 node(s)
id=100  @127.0.0.1 (mysql-8.0.27 ndb-8.0.27, allowed single user)
id=101  (not connected, accepting connect from any host)
    
```

- `EXIT SINGLE USER MODE`

Exits single user mode, enabling all SQL nodes (that is, all running `mysqld` processes) to access the database.

Note

It is possible to use `EXIT SINGLE USER MODE` even when not in single user mode, although the command has no effect in this case.

- `HELP`

Displays information on all available commands.

- `node_id NODELOG DEBUG {ON|OFF}`

Toggles debug logging in the node log, as though the effected data node or nodes had been started with the `--verbose` option. `NODELOG DEBUG ON` starts debug logging; `NODELOG DEBUG OFF` switches debug logging off.

- `PROMPT [prompt]`

Changes the prompt shown by `ndb_mgm` to the string literal `prompt`.

`prompt` should not be quoted (unless you want the prompt to include the quotation marks). Unlike the case with the `mysql` client, special character sequences and escapes are not recognized. If called without an argument, the command resets the prompt to the default value (`ndb_mgm>`).

Some examples are shown here:

```

ndb_mgm> PROMPT mgm#1:
mgm#1: SHOW
Cluster Configuration
...
mgm#1: PROMPT mymgm >
mymgm > PROMPT 'mymgm:'
'mymgm:' PROMPT mymgm:
mymgm: PROMPT
ndb_mgm> EXIT
shell>
    
```

Note that leading spaces and spaces within the `prompt` string are not trimmed. Trailing spaces are removed.

- `QUIT`, `EXIT`

Terminates the management client.

This command does not affect any nodes connected to the cluster.

- `node_id REPORT report-type`

Displays a report of type *report-type* for the data node identified by *node_id*, or for all data nodes using *ALL*.

Currently, there are three accepted values for *report-type*:

- *BackupStatus* provides a status report on a cluster backup in progress
- *MemoryUsage* displays how much data memory and index memory is being used by each data node as shown in this example:

```
ndb_mgm> ALL REPORT MEMORY

Node 1: Data usage is 5%(177 32K pages of total 3200)
Node 1: Index usage is 0%(108 8K pages of total 12832)
Node 2: Data usage is 5%(177 32K pages of total 3200)
Node 2: Index usage is 0%(108 8K pages of total 12832)
```

This information is also available from the `ndbinfo.memoryusage` table.

- *EventLog* reports events from the event log buffers of one or more data nodes.

report-type is case-insensitive and “fuzzy”; for *MemoryUsage*, you can use *MEMORY* (as shown in the prior example), *memory*, or even simply *MEM* (or *mem*). You can abbreviate *BackupStatus* in a similar fashion.

- *node_id RESTART [-n] [-i] [-a] [-f]*

Restarts the data node identified by *node_id* (or all data nodes).

Using the *-i* option with *RESTART* causes the data node to perform an initial restart; that is, the node's file system is deleted and recreated. The effect is the same as that obtained from stopping the data node process and then starting it again using `ndbd --initial` from the system shell.

Note

Backup files and Disk Data files are not removed when this option is used.

Using the *-n* option causes the data node process to be restarted, but the data node is not actually brought online until the appropriate *START* command is issued. The effect of this option is the same as that obtained from stopping the data node and then starting it again using `ndbd --nostart` or `ndbd -n` from the system shell.

Using the *-a* causes all current transactions relying on this node to be aborted. No GCP check is done when the node rejoins the cluster.

Normally, *RESTART* fails if taking the node offline would result in an incomplete cluster. The *-f* option forces the node to restart without checking for this. If this option is used and the result is an incomplete cluster, the entire cluster is restarted.

- *SHOW*

Displays basic information about the cluster and cluster nodes. For all nodes, the output includes the node's ID, type, and *NDB* software version. If the node is connected, its IP address is also shown;

otherwise the output shows `not connected`, accepting connect from `ip_address`, with any `host` used for nodes that are permitted to connect from any address.

In addition, for data nodes, the output includes `starting` if the node has not yet started, and shows the node group of which the node is a member. If the data node is acting as the master node, this is indicated with an asterisk (*).

Consider a cluster whose configuration file includes the information shown here (possible additional settings are omitted for clarity):

```
[ndbd default]
DataMemory= 128G
NoOfReplicas= 2

[ndb_mgmd]
NodeId=50
HostName=198.51.100.150

[ndbd]
NodeId=5
HostName=198.51.100.10
DataDir=/var/lib/mysql-cluster

[ndbd]
NodeId=6
HostName=198.51.100.20
DataDir=/var/lib/mysql-cluster

[ndbd]
NodeId=7
HostName=198.51.100.30
DataDir=/var/lib/mysql-cluster

[ndbd]
NodeId=8
HostName=198.51.100.40
DataDir=/var/lib/mysql-cluster

[mysqld]
NodeId=100
HostName=198.51.100.100

[api]
NodeId=101
```

After this cluster (including one SQL node) has been started, `SHOW` displays the following output:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
-----
[ndbd(NDB)] 4 node(s)
id=5 @198.51.100.10 (mysql-8.0.27 ndb-8.0.27, Nodegroup: 0, *)
id=6 @198.51.100.20 (mysql-8.0.27 ndb-8.0.27, Nodegroup: 0)
id=7 @198.51.100.30 (mysql-8.0.27 ndb-8.0.27, Nodegroup: 1)
id=8 @198.51.100.40 (mysql-8.0.27 ndb-8.0.27, Nodegroup: 1)

[ndb_mgmd(MGM)] 1 node(s)
id=50 @198.51.100.150 (mysql-8.0.27 ndb-8.0.27)

[mysqld(API)] 2 node(s)
id=100 @198.51.100.100 (mysql-8.0.27 ndb-8.0.27)
```

```
id=101 (not connected, accepting connect from any host)
```

The output from this command also indicates when the cluster is in single user mode (see the description of the `ENTER SINGLE USER MODE` command, as well as [Section 23.6.6, “NDB Cluster Single User Mode”](#)). In NDB 8.0, it also indicates which API or SQL node has exclusive access when this mode is in effect; this works only when all data nodes and management nodes connected to the cluster are running NDB 8.0.

- `SHUTDOWN`

Shuts down all cluster data nodes and management nodes. To exit the management client after this has been done, use `EXIT` or `QUIT`.

This command does *not* shut down any SQL nodes or API nodes that are connected to the cluster.

- `node_id START`

Brings online the data node identified by `node_id` (or all data nodes).

`ALL START` works on all data nodes only, and does not affect management nodes.

Important

To use this command to bring a data node online, the data node must have been started using `--nostart` or `-n`.

- `node_id STATUS`

Displays status information for the data node identified by `node_id` (or for all data nodes).

Possible node status values include `UNKNOWN`, `NO_CONTACT`, `NOT_STARTED`, `STARTING`, `STARTED`, `SHUTTING_DOWN`, and `RESTARTING`.

The output from this command also indicates when the cluster is in single user mode.

- `node_id STOP [-a] [-f]`

Stops the data or management node identified by `node_id`.

Note

`ALL STOP` works to stop all data nodes only, and does not affect management nodes.

A node affected by this command disconnects from the cluster, and its associated `ndbd` or `ndb_mgmd` process terminates.

The `-a` option causes the node to be stopped immediately, without waiting for the completion of any pending transactions.

Normally, `STOP` fails if the result would cause an incomplete cluster. The `-f` option forces the node to shut down without checking for this. If this option is used and the result is an incomplete cluster, the cluster immediately shuts down.

Warning

Use of the `-a` option also disables the safety check otherwise performed when `STOP` is invoked to insure that stopping the node does not cause an incomplete

cluster. In other words, you should exercise extreme care when using the `-a` option with the `STOP` command, due to the fact that this option makes it possible for the cluster to undergo a forced shutdown because it no longer has a complete copy of all data stored in `NDB`.

Additional commands. A number of other commands available in the `ndb_mgm` client are described elsewhere, as shown in the following list:

- `START BACKUP` is used to perform an online backup in the `ndb_mgm` client; the `ABORT BACKUP` command is used to cancel a backup already in progress. For more information, see [Section 23.6.8, “Online Backup of NDB Cluster”](#).
- The `CLUSTERLOG` command is used to perform various logging functions. See [Section 23.6.3, “Event Reports Generated in NDB Cluster”](#), for more information and examples. `NODELOG DEBUG` activates or deactivates debug printouts in node logs, as described previously in this section.
- For testing and diagnostics work, the client supports a `DUMP` command which can be used to execute internal commands on the cluster. It should never be used in a production setting unless directed to do so by MySQL Support. For more information, see [NDB Cluster Management Client DUMP Commands](#).

23.6.2 NDB Cluster Log Messages

This section contains information about the messages written to the cluster log in response to different cluster log events. It provides additional, more specific information on `NDB` transporter errors.

23.6.2.1 NDB Cluster: Messages in the Cluster Log

The following table lists the most common `NDB` cluster log messages. For information about the cluster log, log events, and event types, see [Section 23.6.3, “Event Reports Generated in NDB Cluster”](#). These log messages also correspond to log event types in the MGM API; see [The Ndb_logevent_type Type](#), for related information of interest to Cluster API developers.

Table 23.52 Common NDB cluster log messages

| Log Message | Description | Event Name | Event Type | Priority | Severity |
|---|--|---------------|------------|----------|----------|
| Node <i>mgm_node_id</i> : Node <i>data_node_id</i> Connected | The data node having node ID <i>node_id</i> has connected to the management server (node <i>mgm_node_id</i>). | Connected | Connection | 8 | INFO |
| Node <i>mgm_node_id</i> : Node <i>data_node_id</i> Disconnected | The data node having node ID <i>data_node_id</i> has disconnected from the management server (node <i>mgm_node_id</i>). | Disconnected | Connection | 8 | ALERT |
| Node <i>data_node_id</i> : Communication to Node | The API node or SQL node having node ID <i>api_node_id</i> is no longer | Communication | Closed | 8 | INFO |

NDB Cluster Log Messages

| Log Message | Description | Event Name | Event Type | Priority | Severity |
|---|--|------------------|------------|----------|----------|
| <code>api_node_id</code> closed | communicating with data node <code>data_node_id</code> . | | | | |
| Node <code>data_node_id</code> : Communication to Node <code>api_node_id</code> opened | The API node or SQL node having node ID <code>api_node_id</code> is now communicating with data node <code>data_node_id</code> . | Communication | Opened | 8 | INFO |
| Node <code>mgm_node_id</code> : Node <code>api_node_id</code> : API version | The API node having node ID <code>api_node_id</code> has connected to management node <code>mgm_node_id</code> using NDB API version <code>version</code> (generally the same as the MySQL version number). | Connected | ApiVersion | 8 | INFO |
| Node <code>node_id</code> : Global checkpoint <code>gci</code> started | A global checkpoint with the ID <code>gci</code> has been started; node <code>node_id</code> is the master responsible for this global checkpoint. | GlobalCheckpoint | Started | 9 | INFO |
| Node <code>node_id</code> : Global checkpoint <code>gci</code> completed | The global checkpoint having the ID <code>gci</code> has been completed; node <code>node_id</code> was the master responsible for this global checkpoint. | GlobalCheckpoint | Completed | 10 | INFO |
| Node <code>node_id</code> : Local checkpoint <code>lcp</code> started. Keep GCI = | The local checkpoint having sequence ID <code>lcp</code> has been started on node | LocalCheckpoint | Started | 7 | INFO |

| Log Message | Description | Event Name | Event Type | Priority | Severity |
|---|--|--------------------------|------------|----------|----------|
| <code>current_gci</code> <code>oldest</code> <code>restorable</code> <code>GCI =</code> <code>old_gci</code> | <code>node_id</code> . The most recent GCI that can be used has the index <code>current_gci</code> , and the oldest GCI from which the cluster can be restored has the index <code>old_gci</code> . | | | | |
| Node <code>node_id</code> : Local checkpoint <code>lcp</code> completed | The local checkpoint having sequence ID <code>lcp</code> on node <code>node_id</code> has been completed. | LocalCheckpointCompleted | Checkpoint | 8 | INFO |
| Node <code>node_id</code> : Local Checkpoint stopped in <code>CALCULATED_KEEP_GCI</code> | The node was unable to determine the most recent usable GCI. | LCPStoppedInCheckpoint | Checkpoint | 0 | ALERT |
| Node <code>node_id</code> : Table ID = <code>table_id</code> , fragment ID = <code>fragment_id</code> has completed LCP on Node <code>node_id</code> <code>maxGciStarted</code> <code>started_gci</code> <code>maxGciCompleted</code> <code>completed_gci</code> | A table fragment has been checkpointed to disk on node <code>node_id</code> . The GCI in progress has the index <code>started_gci</code> , and the most recent GCI to have been completed has the index <code>completed_gci</code> . | LCPFragmentCompleted | Checkpoint | 11 | INFO |
| Node <code>node_id</code> : ACC Blocked <code>num_1</code> and TUP Blocked <code>num_2</code> times last second | Undo logging is blocked because the log buffer is close to overflowing. | UndoLogBlocked | Checkpoint | 7 | INFO |
| Node <code>node_id</code> : Start | Data node <code>node_id</code> , running NDB version | NDBStart | Startup | 1 | INFO |

NDB Cluster Log Messages

| Log Message | Description | Event Name | Event Type | Priority | Severity |
|---|--|-----------------|------------|----------|----------|
| <code>initiated version</code> | <code>version</code> , is beginning its startup process. | | | | |
| Node <code>node_id:</code> Started <code>version</code> | Data node <code>node_id</code> , running NDB version <code>version</code> , has started successfully. | NDBStartCompl | StartUp | 1 | INFO |
| Node <code>node_id:</code> STTORRY received after restart finished | The node has received a signal indicating that a cluster restart has completed. | STTORRYReciev | StartUp | 15 | INFO |
| Node <code>node_id:</code> Start phase <code>phase</code> completed (<code>type</code>) | The node has completed start phase <code>phase</code> of a <code>type</code> start. For a listing of start phases, see Section 23.6.4, "Summary of NDB Cluster Start Phases" . (<code>type</code> is one of <code>initial</code> , <code>system</code> , <code>node</code> , <code>initial node</code> , or <code><Unknown></code> .) | StartPhaseCompl | StartUp | 4 | INFO |
| Node <code>node_id:</code> CM_REGCONF president = <code>president_id</code> , own Node = <code>own_id</code> , our dynamic id = <code>dynamic_id</code> | Node <code>president_id</code> has been selected as "president". <code>own_id</code> and <code>dynamic_id</code> should always be the same as the ID (<code>node_id</code>) of the reporting node. | CM_REGCONF | StartUp | 3 | INFO |
| Node <code>node_id:</code> CM_REGREF | The reporting node (ID <code>node_id</code>) | CM_REGREF | StartUp | 8 | INFO |

| Log Message | Description | Event Name | Event Type | Priority | Severity |
|--|--|------------------|------------|----------|----------|
| from Node <i>president_id</i> to our Node <i>node_id</i> . Cause = <i>cause</i> | was unable to accept node <i>president_id</i> as president. The <i>cause</i> of the problem is given as one of <i>Busy</i> , <i>Election with wait = false</i> , <i>Not president</i> , <i>Election without selecting new candidate</i> , or <i>No such cause</i> . | | | | |
| Node <i>node_id</i> : We are Node <i>own_id</i> with dynamic ID <i>dynamic_id</i> , our left neighbor is Node <i>id_1</i> , our right is Node <i>id_2</i> | The node has discovered its neighboring nodes in the cluster (node <i>id_1</i> and node <i>id_2</i>). <i>node_id</i> , <i>own_id</i> , and <i>dynamic_id</i> should always be the same; if they are not, this indicates a serious misconfiguration of the cluster nodes. | FIND_NEIGHBOURS | StartUp | 8 | INFO |
| Node <i>node_id</i> : <i>type</i> shutdown initiated | The node has received a shutdown signal. The <i>type</i> of shutdown is either <i>Cluster</i> or <i>Node</i> . | NDBStopStarted | StartUp | 1 | INFO |
| Node <i>node_id</i> : Node shutdown completed [<i>, action</i>] [Initiated | The node has been shut down. This report may include an <i>action</i> , which if present is one of <i>restarting</i> , | NDBStopCompleted | StartUp | 1 | INFO |

NDB Cluster Log Messages

| Log Message | Description | Event Name | Event Type | Priority | Severity |
|--|--|---------------|------------|----------|----------|
| by signal signal.] | no start, or initial. The report may also include a reference to an NDB Protocol signal; for possible signals, refer to Operations and Signals. | | | | |
| Node node_id: Forced node shutdown completed [, action]. [Occurred during startphase start_phase.] [Initiated by signal.] [Caused by error error_code: 'error_message' error_status' [(extra info extra_code)]] | The node has been forcibly shut down. The action (one of restarting, no start, or initial) subsequently being taken, if any, is also reported. If the shutdown occurred while the node was starting, the report includes the start_phase during which the node failed. If this was a result of a signal sent to the node, this information is also provided (see Operations and Signals, for more information). If the error causing the failure is known, this is also included; for more information about NDB error messages and classifications, see NDB Cluster API Errors. | NDBStopForced | StartUp | 1 | ALERT |

NDB Cluster Log Messages

| Log Message | Description | Event Name | Event Type | Priority | Severity |
|--|--|----------------|-------------|----------|----------|
| Node <i>node_id</i> : Node shutdown aborted | The node shutdown process was aborted by the user. | NDBStopAborted | StartUp | 1 | INFO |
| Node <i>node_id</i> : StartLog: [GCI Keep: <i>keep_pos</i> LastCompleted <i>last_pos</i> NewestRestore <i>keep_pos</i> <i>restore_pos</i>] | This reports global checkpoints referenced during a node start. The redo log prior to <i>keep_pos</i> is dropped. <i>last_pos</i> is the last global checkpoint in which data node the participated; <i>restore_pos</i> is the global checkpoint which is actually used to restore all data nodes. | StartREDOLog | StartUp | 4 | INFO |
| <i>startup_message</i> [Listed separately; see below.] | There are a number of possible startup messages that can be logged under different circumstances. These are listed separately; see Section 23.6.2.2, "NDB Cluster Log Startup Messages" . | StartReport | StartUp | 4 | INFO |
| Node <i>node_id</i> : Node restart completed copy of dictionary information | Copying of data dictionary information to the restarted node has been completed. | NR_CopyDict | NodeRestart | 8 | INFO |
| Node <i>node_id</i> : Node restart completed copy of | Copying of data distribution information to the restarted | NR_CopyDistr | NodeRestart | 8 | INFO |

NDB Cluster Log Messages

| Log Message | Description | Event Name | Event Type | Priority | Severity |
|--|---|----------------|-------------|----------|----------|
| distribution information | node has been completed. | | | | |
| Node <i>node_id</i> : Node restart starting to copy the fragments to Node <i>node_id</i> | Copy of fragments to starting data node <i>node_id</i> has begun | NR_CopyFraggsS | NodeRestart | 8 | INFO |
| Node <i>node_id</i> : Table ID = <i>table_id</i> , fragment ID = <i>fragment_id</i> have been copied to Node <i>node_id</i> | Fragment <i>fragment_id</i> from table <i>table_id</i> has been copied to data node <i>node_id</i> | NR_CopyFragDo | NodeRestart | 10 | INFO |
| Node <i>node_id</i> : Node restart completed copying the fragments to Node <i>node_id</i> | Copying of all table fragments to restarting data node <i>node_id</i> has been completed | NR_CopyFraggsC | NodeRestart | 8 | INFO |

23.6.2.2 NDB Cluster Log Startup Messages

Possible startup messages with descriptions are provided in the following list:

- Initial start, waiting for %s to connect, nodes [all: %s connected: %s no-wait: %s]
- Waiting until nodes: %s connects, nodes [all: %s connected: %s no-wait: %s]
- Waiting %u sec for nodes %s to connect, nodes [all: %s connected: %s no-wait: %s]

- `Waiting for non partitioned start, nodes [all: %s connected: %s missing: %s no-wait: %s]`
- `Waiting %u sec for non partitioned start, nodes [all: %s connected: %s missing: %s no-wait: %s]`
- `Initial start with nodes %s [missing: %s no-wait: %s]`
- `Start with all nodes %s`
- `Start with nodes %s [missing: %s no-wait: %s]`
- `Start potentially partitioned with nodes %s [missing: %s no-wait: %s]`
- `Unknown startreport: 0x%x [%s %s %s %s]`

23.6.2.3 Event Buffer Reporting in the Cluster Log

NDB uses one or more memory buffers for events received from the data nodes. There is one such buffer for each Ndb object subscribing to table events, which means that there are usually two buffers for each mysqld performing binary logging (one buffer for schema events, and one for data events). Each buffer contains epochs made up of events. These events consist of operation types (insert, update, delete) and row data (before and after images plus metadata).

NDB generates messages in the cluster log to describe the state of these buffers. Although these reports appear in the cluster log, they refer to buffers on API nodes (unlike most other cluster log messages, which are generated by data nodes).

Event buffer logging reports in the cluster log use the format shown here:

```
Node node_id: Event buffer status (object_id):
used=bytes_used (percent_used% of alloc)
alloc=bytes_allocated (percent_alloc% of max) max=bytes_available
latest_consumed_epoch=latest_consumed_epoch
latest_buffered_epoch=latest_buffered_epoch
report_reason=report_reason
```

The fields making up this report are listed here, with descriptions:

- *node_id*: ID of the node where the report originated.
- *object_id*: ID of the Ndb object where the report originated.
- *bytes_used*: Number of bytes used by the buffer.
- *percent_used*: Percentage of allocated bytes used.
- *bytes_allocated*: Number of bytes allocated to this buffer.
- *percent_alloc*: Percentage of available bytes used; not printed if `ndb_eventbuffer_max_alloc` is equal to 0 (unlimited).
- *bytes_available*: Number of bytes available; this is 0 if `ndb_eventbuffer_max_alloc` is 0 (unlimited).
- *latest_consumed_epoch*: The epoch most recently consumed to completion. (In NDB API applications, this is done by calling `nextEvent()`.)
- *latest_buffered_epoch*: The epoch most recently buffered (completely) in the event buffer.

- `report_reason`: The reason for making the report. Possible reasons are shown later in this section.

Possible reasons for reporting are described in the following list:

- `ENOUGH_FREE_EVENTBUFFER`: The event buffer has sufficient space.

`LOW_FREE_EVENTBUFFER`: The event buffer is running low on free space.

The threshold free percentage level triggering these reports can be adjusted by setting the `ndb_report_thresh_binlog_mem_usage` server variable.

- `BUFFERED_EPOCHS_OVER_THRESHOLD`: Whether the number of buffered epochs has exceeded the configured threshold. This number is the difference between the latest epoch that has been received in its entirety and the epoch that has most recently been consumed (in NDB API applications, this is done by calling `nextEvent()` or `nextEvent2()`). The report is generated every second until the number of buffered epochs goes below the threshold, which can be adjusted by setting the `ndb_report_thresh_binlog_epoch_slip` server variable. You can also adjust the threshold in NDB API applications by calling `setEventBufferQueueEmptyEpoch()`.
- `PARTIALLY_DISCARDING`: Event buffer memory is exhausted—that is, 100% of `ndb_eventbuffer_max_alloc` has been used. Any partially buffered epoch is buffered to completion even if usage exceeds 100%, but any new epochs received are discarded. This means that a gap has occurred in the event stream.
- `COMPLETELY_DISCARDING`: No epochs are buffered.
- `PARTIALLY_BUFFERING`: The buffer free percentage following the gap has risen to the threshold, which can be set in the `mysql` client using the `ndb_eventbuffer_free_percent` server system variable or in NDB API applications by calling `set_eventbuffer_free_percent()`. New epochs are buffered. Epochs that could not be completed due to the gap are discarded.
- `COMPLETELY_BUFFERING`: All epochs received are being buffered, which means that there is sufficient event buffer memory. The gap in the event stream has been closed.

23.6.2.4 NDB Cluster: NDB Transporter Errors

This section lists error codes, names, and messages that are written to the cluster log in the event of transporter errors.

| | | |
|------|---|---|
| 0x00 | <code>TE_NO_ERROR</code> | No error |
| 0x01 | <code>TE_ERROR_CLOSING_SOCKET</code> | Error found during closing of socket |
| 0x02 | <code>TE_ERROR_IN_SELECT_BEFORE_ACCEPT</code> | Error found before accept. The transporter will retry |
| 0x03 | <code>TE_INVALID_MESSAGE_LENGTH</code> | Error found in message (invalid message length) |
| 0x04 | <code>TE_INVALID_CHECKSUM</code> | Error found in message (checksum) |

NDB Cluster Log Messages

| | |
|------|---|
| 0x05 | TE_COULD_NOT_CREATE_SOCKET Error found while creating socket(can't create socket) |
| 0x06 | TE_COULD_NOT_BIND_SOCKET Error found while binding server socket |
| 0x07 | TE_LISTEN_FAILED Error found while listening to server socket |
| 0x08 | TE_ACCEPT_RETURN_ERROR Error found during accept(accept return error) |
| 0x0b | TE_SHM_DISCONNECT The remote node has disconnected |
| 0x0c | TE_SHM_IPC_STAT Unable to check shm segment |
| 0x0d | TE_SHM_UNABLE_TO_CREATE_SEGMENT Unable to create shm segment |
| 0x0e | TE_SHM_UNABLE_TO_ATTACH_SEGMENT Unable to attach shm segment |
| 0x0f | TE_SHM_UNABLE_TO_REMOVE_SEGMENT Unable to remove shm segment |
| 0x10 | TE_TOO_SMALL_SIGID Sig ID too small |
| 0x11 | TE_TOO_LARGE_SIGID Sig ID too large |
| 0x12 | TE_WAIT_STACK_FULL Wait stack was full |
| 0x13 | TE_RECEIVE_BUFFER_FULL Receive buffer was full |
| 0x14 | TE_SIGNAL_LOST_SEND_BUFFER_FULL Send buffer was full,and trying to force send fails |
| 0x15 | TE_SIGNAL_LOST Send failed for unknown reason(signal lost) |

| | | |
|------|-----------------------------|---|
| 0x16 | TE_SEND_BUFFER_FULL | The send buffer was full, but sleeping for a while solved |
| 0x21 | TE_SHM_IPC_PERMANENT | Shm ipc Permanent error |

**Note**

Transporter error codes 0x17 through 0x20 and 0x22 are reserved for SCI connections, which are not supported in this version of NDB Cluster, and so are not included here.

23.6.3 Event Reports Generated in NDB Cluster

In this section, we discuss the types of event logs provided by NDB Cluster, and the types of events that are logged.

NDB Cluster provides two types of event log:

- The *cluster log*, which includes events generated by all cluster nodes. The cluster log is the log recommended for most uses because it provides logging information for an entire cluster in a single location.

By default, the cluster log is saved to a file named `ndb_node_id_cluster.log`, (where *node_id* is the node ID of the management server) in the management server's *DataDir*.

Cluster logging information can also be sent to `stdout` or a `syslog` facility in addition to or instead of being saved to a file, as determined by the values set for the `DataDir` and `LogDestination` configuration parameters. See [Section 23.4.3.5, “Defining an NDB Cluster Management Server”](#), for more information about these parameters.

- *Node logs* are local to each node.

Output generated by node event logging is written to the file `ndb_node_id_out.log` (where *node_id* is the node's node ID) in the node's *DataDir*. Node event logs are generated for both management nodes and data nodes.

Node logs are intended to be used only during application development, or for debugging application code.

Both types of event logs can be set to log different subsets of events.

Each reportable event can be distinguished according to three different criteria:

- *Category*: This can be any one of the following values: `STARTUP`, `SHUTDOWN`, `STATISTICS`, `CHECKPOINT`, `NODERESTART`, `CONNECTION`, `ERROR`, or `INFO`.
- *Priority*: This is represented by one of the numbers from 0 to 15 inclusive, where 0 indicates “most important” and 15 “least important.”
- *Severity Level*: This can be any one of the following values: `ON`, `DEBUG`, `INFO`, `WARNING`, `ERROR`, `CRITICAL`, `ALERT`, or `ALL`. (This is also sometimes referred to as the log level.)

Both the cluster log and the node log can be filtered on these properties.

The format used in a log message generated by NDB Cluster (as of NDB 8.0.26) is as shown here:

```
timestamp [node_type] level -- Node node_id: message
```

Each line in the log, or log message, contains the following information:

- A *timestamp* in `YYYY-MM-DD HH:MM:SS` format. The timestamp value currently resolves to whole seconds only; fractional seconds are not supported.
- The *node_type*, or type of node or application which is performing the logging. In the cluster log, this is always `[MgmtSrvr]`; in the data node log, it is always `[ndbd]`. `[NdbApi]` and other values are possible in logs generated by NDB API applications and tools.
- The *level* of the event, sometimes also referred to as its severity level or log level. See earlier in this section, as well as [Section 23.6.3.1, “NDB Cluster Logging Management Commands”](#), for more information about severity levels.
- The ID of the node reporting the event (*node_id*).
- A *message* containing a description of the event. The most common types of events to appear in the log are connections and disconnections between different nodes in the cluster, and when checkpoints occur. In some cases, the description may contain status or other information.

A sample from an actual cluster log is shown here:

```
2021-06-10 10:01:07 [MgmtSrvr] INFO -- Node 5: Start phase 5 completed (system restart)

```

For additional information, see [Section 23.6.3.2, “NDB Cluster Log Events”](#).

23.6.3.1 NDB Cluster Logging Management Commands

`ndb_mgm` supports a number of management commands related to the cluster log and node logs. In the listing that follows, *node_id* denotes either a storage node ID or the keyword `ALL`, which indicates that the command should be applied to all of the cluster's data nodes.

- `CLUSTERLOG ON`
Turns the cluster log on.
- `CLUSTERLOG OFF`
Turns the cluster log off.
- `CLUSTERLOG INFO`
Provides information about cluster log settings.
- `node_id CLUSTERLOG category=threshold`
Logs *category* events with priority less than or equal to *threshold* in the cluster log.
- `CLUSTERLOG FILTER severity_level`
Toggles cluster logging of events of the specified *severity_level*.

The following table describes the default setting (for all data nodes) of the cluster log category threshold. If an event has a priority with a value lower than or equal to the priority threshold, it is reported in the cluster log.

Note

Events are reported per data node, and that the threshold can be set to different values on different nodes.

Table 23.53 Cluster log categories, with default threshold setting

| Category | Default threshold (All data nodes) |
|-------------|------------------------------------|
| STARTUP | 7 |
| SHUTDOWN | 7 |
| STATISTICS | 7 |
| CHECKPOINT | 7 |
| NODERESTART | 7 |
| CONNECTION | 7 |
| ERROR | 15 |
| INFO | 7 |

The `STATISTICS` category can provide a great deal of useful data. See [Section 23.6.3.3, “Using CLUSTERLOG STATISTICS in the NDB Cluster Management Client”](#), for more information.

Thresholds are used to filter events within each category. For example, a `STARTUP` event with a priority of 3 is not logged unless the threshold for `STARTUP` is set to 3 or higher. Only events with priority 3 or lower are sent if the threshold is 3.

The following table shows the event severity levels.

Note

These correspond to Unix `syslog` levels, except for `LOG_EMERG` and `LOG_NOTICE`, which are not used or mapped.

Table 23.54 Event severity levels

| Severity Level Value | Severity | Description |
|----------------------|----------|---|
| 1 | ALERT | A condition that should be corrected immediately, such as a corrupted system database |
| 2 | CRITICAL | Critical conditions, such as device errors or insufficient resources |
| 3 | ERROR | Conditions that should be corrected, such as configuration errors |
| 4 | WARNING | Conditions that are not errors, but that might require special handling |
| 5 | INFO | Informational messages |
| 6 | DEBUG | Debugging messages used for NDBCLUSTER development |

Event severity levels can be turned on or off (using `CLUSTERLOG FILTER`—see above). If a severity level is turned on, then all events with a priority less than or equal to the category thresholds are logged. If the severity level is turned off then no events belonging to that severity level are logged.

Important

Cluster log levels are set on a per `ndb_mgmd`, per subscriber basis. This means that, in an NDB Cluster with multiple management servers, using a `CLUSTERLOG` command in an instance of `ndb_mgm` connected to one management server affects only logs generated by that management server but not by any of the others. This also means that, should one of the management servers be restarted, only logs generated by that management server are affected by the resetting of log levels caused by the restart.

23.6.3.2 NDB Cluster Log Events

An event report reported in the event logs has the following format:

```
datetime [string] severity -- message
```

For example:

```
09:19:30 2005-07-24 [NDB] INFO -- Node 4 Start phase 4 completed
```

This section discusses all reportable events, ordered by category and severity level within each category.

In the event descriptions, GCP and LCP mean “Global Checkpoint” and “Local Checkpoint”, respectively.

CONNECTION Events

These events are associated with connections between Cluster nodes.

Table 23.55 Events associated with connections between cluster nodes

| Event | Priority | Severity Level | Description |
|--------------|----------|----------------|-------------------------|
| Connected | 8 | INFO | Data nodes connected |
| Disconnected | 8 | ALERT | Data nodes disconnected |

| Event | Priority | Severity Level | Description |
|---------------------|----------|----------------|---|
| CommunicationClosed | 8 | INFO | SQL node or data node connection closed |
| CommunicationOpened | 8 | INFO | SQL node or data node connection open |
| ConnectedApiVersion | 8 | INFO | Connection using API version |

CHECKPOINT Events

The logging messages shown here are associated with checkpoints.

Table 23.56 Events associated with checkpoints

| Event | Priority | Severity Level | Description |
|---------------------------|----------|----------------|--|
| GlobalCheckpointStarted | 9 | INFO | Start of GCP: REDO log is written to disk |
| GlobalCheckpointCompleted | 10 | INFO | GCP finished |
| LocalCheckpointStarted | 7 | INFO | Start of LCP: data written to disk |
| LocalCheckpointCompleted | 7 | INFO | LCP completed normally |
| LCPStoppedInCalcKeepCci | 0 | ALERT | LCP stopped |
| LCPFragmentCompleted | 11 | INFO | LCP on a fragment has been completed |
| UndoLogBlocked | 7 | INFO | UNDO logging blocked; buffer near overflow |
| RedoStatus | 7 | INFO | Redo status |

STARTUP Events

The following events are generated in response to the startup of a node or of the cluster and of its success or failure. They also provide information relating to the progress of the startup process, including information concerning logging activities.

Table 23.57 Events relating to the startup of a node or cluster

| Event | Priority | Severity Level | Description |
|---------------------|----------|----------------|---|
| NDBStartStarted | 1 | INFO | Data node start phases initiated (all nodes starting) |
| NDBStartCompleted | 1 | INFO | Start phases completed, all data nodes |
| STTORYRecieved | 15 | INFO | Blocks received after completion of restart |
| StartPhaseCompleted | 4 | INFO | Data node start phase <i>x</i> completed |
| CM_REGCONF | 3 | INFO | Node has been successfully included into the cluster; shows the |

| Event | Priority | Severity Level | Description |
|-----------------------|----------|----------------|---|
| | | | node, managing node, and dynamic ID |
| CM_REGREF | 8 | INFO | Node has been refused for inclusion in the cluster; cannot be included in cluster due to misconfiguration, inability to establish communication, or other problem |
| FIND_NEIGHBOURS | 8 | INFO | Shows neighboring data nodes |
| NDBStopStarted | 1 | INFO | Data node shutdown initiated |
| NDBStopCompleted | 1 | INFO | Data node shutdown complete |
| NDBStopForced | 1 | ALERT | Forced shutdown of data node |
| NDBStopAborted | 1 | INFO | Unable to shut down data node normally |
| StartREDOLog | 4 | INFO | New redo log started; GCI keep <i>X</i> , newest restorable GCI <i>Y</i> |
| StartLog | 10 | INFO | New log started; log part <i>X</i> , start MB <i>Y</i> , stop MB <i>Z</i> |
| UNDORecordsExecuted | 15 | INFO | Undo records executed |
| StartReport | 4 | INFO | Report started |
| LogFileInitStatus | 7 | INFO | Log file initialization status |
| LogFileInitCompStatus | 7 | INFO | Log file completion status |
| StartReadLCP | 10 | INFO | Start read for local checkpoint |
| ReadLCPComplete | 10 | INFO | Read for local checkpoint completed |
| RunRedo | 8 | INFO | Running the redo log |
| RebuildIndex | 10 | INFO | Rebuilding indexes |

NODERESTART Events

The following events are generated when restarting a node and relate to the success or failure of the node restart process.

Table 23.58 Events relating to restarting a node

| Event | Priority | Severity Level | Description |
|-------------|----------|----------------|---|
| NR_CopyDict | 7 | INFO | Completed copying of dictionary information |

Event Reports Generated in NDB Cluster

| Event | Priority | Severity Level | Description |
|----------------------|----------|----------------|---|
| NR_CopyDistr | 7 | INFO | Completed copying distribution information |
| NR_CopyFragStarted | 7 | INFO | Starting to copy fragments |
| NR_CopyFragDone | 10 | INFO | Completed copying a fragment |
| NR_CopyFragCompleted | 7 | INFO | Completed copying all fragments |
| NodeFailCompleted | 8 | ALERT | Node failure phase completed |
| NODE_FAILREP | 8 | ALERT | Reports that a node has failed |
| ArbitState | 6 | INFO | <p>Report whether an arbitrator is found or not; there are seven different possible outcomes when seeking an arbitrator, listed here:</p> <ul style="list-style-type: none"> • Management server restarts arbitration thread [state=<i>x</i>] • Prepare arbitrator node <i>x</i> [ticket=<i>Y</i>] • Receive arbitrator node <i>x</i> [ticket=<i>Y</i>] • Started arbitrator node <i>x</i> [ticket=<i>Y</i>] • Lost arbitrator node <i>x</i> - process failure [state=<i>Y</i>] • Lost arbitrator node <i>x</i> - process exit [state=<i>Y</i>] • Lost arbitrator node <i>x</i> <error msg> [state=<i>Y</i>] |
| ArbitResult | 2 | ALERT | <p>Report arbitrator results; there are eight different possible results for arbitration attempts, listed here:</p> <ul style="list-style-type: none"> • Arbitration check failed: less than 1/2 nodes left |

| Event | Priority | Severity Level | Description |
|-----------------------|----------|----------------|---|
| | | | <ul style="list-style-type: none"> • Arbitration check succeeded: node group majority • Arbitration check failed: missing node group • Network partitioning: arbitration required • Arbitration succeeded: affirmative response from node <i>x</i> • Arbitration failed: negative response from node <i>x</i> • Network partitioning: no arbitrator available • Network partitioning: no arbitrator configured |
| GCP_TakeoverStarted | 7 | INFO | GCP takeover started |
| GCP_TakeoverCompleted | 7 | INFO | GCP takeover complete |
| LCP_TakeoverStarted | 7 | INFO | LCP takeover started |
| LCP_TakeoverCompleted | 7 | INFO | LCP takeover complete (state = <i>x</i>) |
| ConnectCheckStarted | 6 | INFO | Connection check started |
| ConnectCheckCompleted | 6 | INFO | Connection check completed |
| NodeFailRejected | 6 | ALERT | Node failure phase failed |

STATISTICS Events

The following events are of a statistical nature. They provide information such as numbers of transactions and other operations, amount of data sent or received by individual nodes, and memory usage.

Table 23.59 Events of a statistical nature

| Event | Priority | Severity Level | Description |
|-------------------------|----------|----------------|--|
| TransReportCounters | 8 | INFO | Report transaction statistics, including numbers of transactions, commits, reads, simple reads, writes, concurrent operations, attribute information, and aborts |
| OperationReportCounters | 8 | INFO | Number of operations |
| TableCreated | 7 | INFO | Report number of tables created |

| Event | Priority | Severity Level | Description |
|-----------------------|----------|----------------|--|
| JobStatistic | 9 | INFO | Mean internal job scheduling statistics |
| ThreadConfigLoop | 9 | INFO | Number of thread configuration loops |
| SendBytesStatistic | 9 | INFO | Mean number of bytes sent to node <i>x</i> |
| ReceiveBytesStatistic | 9 | INFO | Mean number of bytes received from node <i>x</i> |
| MemoryUsage | 5 | INFO | Data and index memory usage (80%, 90%, and 100%) |
| MTSignalStatistics | 9 | INFO | Multithreaded signals |

SCHEMA Events

These events relate to NDB Cluster schema operations.

Table 23.60 Events relating to NDB Cluster schema operations

| Event | Priority | Severity Level | Description |
|--------------------|----------|----------------|-----------------------|
| CreateSchemaObject | 8 | INFO | Schema object created |
| AlterSchemaObject | 8 | INFO | Schema object updated |
| DropSchemaObject | 8 | INFO | Schema object dropped |

ERROR Events

These events relate to Cluster errors and warnings. The presence of one or more of these generally indicates that a major malfunction or failure has occurred.

Table 23.61 Events relating to cluster errors and warnings

| Event | Priority | Severity Level | Description |
|--------------------|----------|----------------|---|
| TransporterError | 2 | ERROR | Transporter error |
| TransporterWarning | 8 | WARNING | Transporter warning |
| MissedHeartbeat | 8 | WARNING | Node <i>x</i> missed heartbeat number <i>y</i> |
| DeadDueToHeartbeat | 8 | ALERT | Node <i>x</i> declared “dead” due to missed heartbeat |
| WarningEvent | 2 | WARNING | General warning event |
| SubscriptionStatus | 4 | WARNING | Change in subscription status |

INFO Events

These events provide general information about the state of the cluster and activities associated with Cluster maintenance, such as logging and heartbeat transmission.

Table 23.62 Information events

| Event | Priority | Severity Level | Description |
|---------------------------------|----------|----------------|--|
| <code>SentHeartbeat</code> | 12 | INFO | Sent heartbeat |
| <code>CreateLogBytes</code> | 11 | INFO | Create log: Log part, log file, size in MB |
| <code>InfoEvent</code> | 2 | INFO | General informational event |
| <code>EventBufferStatus</code> | 7 | INFO | Event buffer status |
| <code>EventBufferStatus2</code> | 7 | INFO | Improved event buffer status information |

**Note**

`SentHeartbeat` events are available only if NDB Cluster was compiled with `VM_TRACE` enabled.

SINGLEUSER Events

These events are associated with entering and exiting single user mode.

Table 23.63 Events relating to single user mode

| Event | Priority | Severity Level | Description |
|-------------------------|----------|----------------|--------------------------------------|
| <code>SingleUser</code> | 7 | INFO | Entering or exiting single user mode |

BACKUP Events

These events provide information about backups being created or restored.

Table 23.64 Backup events

| Event | Priority | Severity Level | Description |
|----------------------------------|----------|----------------|---------------------------------|
| <code>BackupStarted</code> | 7 | INFO | Backup started |
| <code>BackupStatus</code> | 7 | INFO | Backup status |
| <code>BackupCompleted</code> | 7 | INFO | Backup completed |
| <code>BackupFailedToStart</code> | 7 | ALERT | Backup failed to start |
| <code>BackupAborted</code> | 7 | ALERT | Backup aborted by user |
| <code>RestoreStarted</code> | 7 | INFO | Started restoring from backup |
| <code>RestoreMetaData</code> | 7 | INFO | Restoring metadata |
| <code>RestoreData</code> | 7 | INFO | Restoring data |
| <code>RestoreLog</code> | 7 | INFO | Restoring log files |
| <code>RestoreCompleted</code> | 7 | INFO | Completed restoring from backup |
| <code>SavedEvent</code> | 7 | INFO | Event saved |

23.6.3.3 Using CLUSTERLOG STATISTICS in the NDB Cluster Management Client

The NDB management client's `CLUSTERLOG STATISTICS` command can provide a number of useful statistics in its output. Counters providing information about the state of the cluster are updated at 5-second reporting intervals by the transaction coordinator (TC) and the local query handler (LQH), and written to the cluster log.

Transaction coordinator statistics. Each transaction has one transaction coordinator, which is chosen by one of the following methods:

- In a round-robin fashion
- By communication proximity
- By supplying a data placement hint when the transaction is started

Note

You can determine which TC selection method is used for transactions started from a given SQL node using the `ndb_optimized_node_selection` system variable.

All operations within the same transaction use the same transaction coordinator, which reports the following statistics:

- **Trans count.** This is the number transactions started in the last interval using this TC as the transaction coordinator. Any of these transactions may have committed, have been aborted, or remain uncommitted at the end of the reporting interval.

Note

Transactions do not migrate between TCs.

- **Commit count.** This is the number of transactions using this TC as the transaction coordinator that were committed in the last reporting interval. Because some transactions committed in this reporting interval may have started in a previous reporting interval, it is possible for `Commit count` to be greater than `Trans count`.
- **Read count.** This is the number of primary key read operations using this TC as the transaction coordinator that were started in the last reporting interval, including simple reads. This count also includes reads performed as part of unique index operations. A unique index read operation generates 2 primary key read operations—1 for the hidden unique index table, and 1 for the table on which the read takes place.
- **Simple read count.** This is the number of simple read operations using this TC as the transaction coordinator that were started in the last reporting interval.
- **Write count.** This is the number of primary key write operations using this TC as the transaction coordinator that were started in the last reporting interval. This includes all inserts, updates, writes and deletes, as well as writes performed as part of unique index operations.

Note

A unique index update operation can generate multiple PK read and write operations on the index table and on the base table.

- **AttrInfoCount.** This is the number of 32-bit data words received in the last reporting interval for primary key operations using this TC as the transaction coordinator. For reads, this is proportional to the number of columns requested. For inserts and updates, this is proportional to the number of columns written, and the size of their data. For delete operations, this is usually zero.

Unique index operations generate multiple PK operations and so increase this count. However, data words sent to describe the PK operation itself, and the key information sent, are *not* counted here. Attribute information sent to describe columns to read for scans, or to describe ScanFilters, is also not counted in `AttrInfoCount`.

- **Concurrent Operations.** This is the number of primary key or scan operations using this TC as the transaction coordinator that were started during the last reporting interval but that were not completed. Operations increment this counter when they are started and decrement it when they are completed; this occurs after the transaction commits. Dirty reads and writes—as well as failed operations—decrement this counter.

The maximum value that `Concurrent Operations` can have is the maximum number of operations that a TC block can support; currently, this is $(2 * \text{MaxNoOfConcurrentOperations}) + 16 + \text{MaxNoOfConcurrentTransactions}$. (For more information about these configuration parameters, see the *Transaction Parameters* section of [Section 23.4.3.6, “Defining NDB Cluster Data Nodes”](#).)

- **Abort count.** This is the number of transactions using this TC as the transaction coordinator that were aborted during the last reporting interval. Because some transactions that were aborted in the last reporting interval may have started in a previous reporting interval, `Abort count` can sometimes be greater than `Trans count`.
- **Scans.** This is the number of table scans using this TC as the transaction coordinator that were started during the last reporting interval. This does not include range scans (that is, ordered index scans).
- **Range scans.** This is the number of ordered index scans using this TC as the transaction coordinator that were started in the last reporting interval.
- **Local reads.** This is the number of primary-key read operations performed using a transaction coordinator on a node that also holds the primary fragment replica of the record. This count can also be obtained from the `LOCAL_READS` counter in the `ndbinfo.counters` table.
- **Local writes.** This contains the number of primary-key read operations that were performed using a transaction coordinator on a node that also holds the primary fragment replica of the record. This count can also be obtained from the `LOCAL_WRITES` counter in the `ndbinfo.counters` table.

Local query handler statistics (Operations). There is 1 cluster event per local query handler block (that is, 1 per data node process). Operations are recorded in the LQH where the data they are operating on resides.

Note

A single transaction may operate on data stored in multiple LQH blocks.

The `Operations` statistic provides the number of local operations performed by this LQH block in the last reporting interval, and includes all types of read and write operations (insert, update, write, and delete operations). This also includes operations used to replicate writes. For example, in a cluster with two fragment replicas, the write to the primary fragment replica is recorded in the primary LQH, and the write to the backup is recorded in the backup LQH. Unique key operations may result in multiple local operations; however, this does *not* include local operations generated as a result of a table scan or ordered index scan, which are not counted.

Process scheduler statistics. In addition to the statistics reported by the transaction coordinator and local query handler, each `ndbd` process has a scheduler which also provides useful metrics relating to the performance of an NDB Cluster. This scheduler runs in an infinite loop; during each loop the scheduler performs the following tasks:

1. Read any incoming messages from sockets into a job buffer.
2. Check whether there are any timed messages to be executed; if so, put these into the job buffer as well.
3. Execute (in a loop) any messages in the job buffer.
4. Send any distributed messages that were generated by executing the messages in the job buffer.
5. Wait for any new incoming messages.

Process scheduler statistics include the following:

- **Mean Loop Counter.** This is the number of loops executed in the third step from the preceding list. This statistic increases in size as the utilization of the TCP/IP buffer improves. You can use this to monitor changes in performance as you add new data node processes.
- **Mean send size and Mean receive size.** These statistics enable you to gauge the efficiency of, respectively writes and reads between nodes. The values are given in bytes. Higher values mean a lower cost per byte sent or received; the maximum value is 64K.

To cause all cluster log statistics to be logged, you can use the following command in the [NDB](#) management client:

```
ndb_mgm> ALL CLUSTERLOG STATISTICS=15
```

Note

Setting the threshold for `STATISTICS` to 15 causes the cluster log to become very verbose, and to grow quite rapidly in size, in direct proportion to the number of cluster nodes and the amount of activity in the NDB Cluster.

For more information about NDB Cluster management client commands relating to logging and reporting, see [Section 23.6.3.1, “NDB Cluster Logging Management Commands”](#).

23.6.4 Summary of NDB Cluster Start Phases

This section provides a simplified outline of the steps involved when NDB Cluster data nodes are started. More complete information can be found in [NDB Cluster Start Phases](#), in the *NDB Internals Guide*.

These phases are the same as those reported in the output from the `node_id STATUS` command in the management client (see [Section 23.6.1, “Commands in the NDB Cluster Management Client”](#)). These start phases are also reported in the `start_phase` column of the `ndbinfo.nodes` table.

Start types. There are several different startup types and modes, as shown in the following list:

- **Initial start.** The cluster starts with a clean file system on all data nodes. This occurs either when the cluster started for the very first time, or when all data nodes are restarted using the `--initial` option.

Note

Disk Data files are not removed when restarting a node using `--initial`.

- **System restart.** The cluster starts and reads data stored in the data nodes. This occurs when the cluster has been shut down after having been in use, when it is desired for the cluster to resume operations from the point where it left off.

- **Node restart.** This is the online restart of a cluster node while the cluster itself is running.
- **Initial node restart.** This is the same as a node restart, except that the node is reinitialized and started with a clean file system.

Setup and initialization (phase -1). Prior to startup, each data node (`ndbd` process) must be initialized. Initialization consists of the following steps:

1. Obtain a node ID
2. Fetch configuration data
3. Allocate ports to be used for inter-node communications
4. Allocate memory according to settings obtained from the configuration file

When a data node or SQL node first connects to the management node, it reserves a cluster node ID. To make sure that no other node allocates the same node ID, this ID is retained until the node has managed to connect to the cluster and at least one `ndbd` reports that this node is connected. This retention of the node ID is guarded by the connection between the node in question and `ndb_mgmd`.

After each data node has been initialized, the cluster startup process can proceed. The stages which the cluster goes through during this process are listed here:

- **Phase 0.** The `NDBFS` and `NDBCNTR` blocks start. Data node file systems are cleared on those data nodes that were started with `--initial` option.
- **Phase 1.** In this stage, all remaining `NDB` kernel blocks are started. NDB Cluster connections are set up, inter-block communications are established, and heartbeats are started. In the case of a node restart, API node connections are also checked.

Note

When one or more nodes hang in Phase 1 while the remaining node or nodes hang in Phase 2, this often indicates network problems. One possible cause of such issues is one or more cluster hosts having multiple network interfaces. Another common source of problems causing this condition is the blocking of TCP/IP ports needed for communications between cluster nodes. In the latter case, this is often due to a misconfigured firewall.

- **Phase 2.** The `NDBCNTR` kernel block checks the states of all existing nodes. The master node is chosen, and the cluster schema file is initialized.
- **Phase 3.** The `DBLQH` and `DBTC` kernel blocks set up communications between them. The startup type is determined; if this is a restart, the `DBDIH` block obtains permission to perform the restart.
- **Phase 4.** For an initial start or initial node restart, the redo log files are created. The number of these files is equal to `NoOfFragmentLogFiles`.

For a system restart:

- Read schema or schemas.
- Read data from the local checkpoint.
- Apply all redo information until the latest restorable global checkpoint has been reached.

For a node restart, find the tail of the redo log.

- **Phase 5.** Most of the database-related portion of a data node start is performed during this phase. For an initial start or system restart, a local checkpoint is executed, followed by a global checkpoint. Periodic checks of memory usage begin during this phase, and any required node takeovers are performed.
- **Phase 6.** In this phase, node groups are defined and set up.
- **Phase 7.** The arbitrator node is selected and begins to function. The next backup ID is set, as is the backup disk write speed. Nodes reaching this start phase are marked as `Started`. It is now possible for API nodes (including SQL nodes) to connect to the cluster.
- **Phase 8.** If this is a system restart, all indexes are rebuilt (by `DBDIH`).
- **Phase 9.** The node internal startup variables are reset.
- **Phase 100 (OBSOLETE).** Formerly, it was at this point during a node restart or initial node restart that API nodes could connect to the node and begin to receive events. Currently, this phase is empty.
- **Phase 101.** At this point in a node restart or initial node restart, event delivery is handed over to the node joining the cluster. The newly-joined node takes over responsibility for delivering its primary data to subscribers. This phase is also referred to as *SUMA handover phase*.

After this process is completed for an initial start or system restart, transaction handling is enabled. For a node restart or initial node restart, completion of the startup process means that the node may now act as a transaction coordinator.

23.6.5 Performing a Rolling Restart of an NDB Cluster

This section discusses how to perform a *rolling restart* of an NDB Cluster installation, so called because it involves stopping and starting (or restarting) each node in turn, so that the cluster itself remains operational. This is often done as part of a *rolling upgrade* or *rolling downgrade*, where high availability of the cluster is mandatory and no downtime of the cluster as a whole is permissible. Where we refer to upgrades, the information provided here also generally applies to downgrades as well.

There are a number of reasons why a rolling restart might be desirable. These are described in the next few paragraphs.

Configuration change.

To make a change in the cluster's configuration, such as adding an SQL node to the cluster, or setting a configuration parameter to a new value.

NDB Cluster software upgrade or downgrade. To upgrade the cluster to a newer version of the NDB Cluster software (or to downgrade it to an older version). This is usually referred to as a "rolling upgrade" (or "rolling downgrade", when reverting to an older version of NDB Cluster).

Change on node host. To make changes in the hardware or operating system on which one or more NDB Cluster node processes are running.

System reset (cluster reset).

To reset the cluster because it has reached an undesirable state. In such cases it is often desirable to reload the data and metadata of one or more data nodes. This can be done in any of three ways:

- Start each data node process (`ndbd` or possibly `ndbmttd`) with the `--initial` option, which forces the data node to clear its file system and to reload all NDB Cluster data and metadata from the other data nodes.

Beginning with NDB 8.0.21, this also forces the removal of all Disk Data objects and files associated with those objects.

- Create a backup using the `ndb_mgm` client `START BACKUP` command prior to performing the restart. Following the upgrade, restore the node or nodes using `ndb_restore`.

See [Section 23.6.8, “Online Backup of NDB Cluster”](#), and [Section 23.5.23, “ndb_restore — Restore an NDB Cluster Backup”](#), for more information.

- Use `mysqldump` to create a backup prior to the upgrade; afterward, restore the dump using `LOAD DATA`.

Resource Recovery.

To free memory previously allocated to a table by successive `INSERT` and `DELETE` operations, for re-use by other NDB Cluster tables.

The process for performing a rolling restart may be generalized as follows:

1. Stop all cluster management nodes (`ndb_mgmd` processes), reconfigure them, then restart them. (See [Rolling restarts with multiple management servers](#).)
2. Stop, reconfigure, then restart each cluster data node (`ndbd` process) in turn.

Some node configuration parameters can be updated by issuing `RESTART` for each of the data nodes in the `ndb_mgm` client following the previous step. Other parameters require that the data node be stopped completely using the management client `STOP` command, then started again from a system shell by invoking the `ndbd` or `ndbmttd` executable as appropriate. (A shell command such as `kill` can also be used on most Unix systems to stop a data node process, but the `STOP` command is preferred and usually simpler.)

Note

On Windows, you can also use `SC STOP` and `SC START` commands, `NET STOP` and `NET START` commands, or the Windows Service Manager to stop and start nodes which have been installed as Windows services (see [Section 23.3.2.4, “Installing NDB Cluster Processes as Windows Services”](#)).

The type of restart required is indicated in the documentation for each node configuration parameter. See [Section 23.4.3, “NDB Cluster Configuration Files”](#).

3. Stop, reconfigure, then restart each cluster SQL node (`mysqld` process) in turn.

NDB Cluster supports a somewhat flexible order for upgrading nodes. When upgrading an NDB Cluster, you may upgrade API nodes (including SQL nodes) before upgrading the management nodes, data nodes, or both. In other words, you are permitted to upgrade the API and SQL nodes in any order. This is subject to the following provisions:

- This functionality is intended for use as part of an online upgrade only. A mix of node binaries from different NDB Cluster releases is neither intended nor supported for continuous, long-term use in a production setting.
- All management nodes must be upgraded before any data nodes are upgraded. This remains true regardless of the order in which you upgrade the cluster's API and SQL nodes.
- Features specific to the “new” version must not be used until all management nodes and data nodes have been upgraded.

This also applies to any MySQL Server version change that may apply, in addition to the NDB engine version change, so do not forget to take this into account when planning the upgrade. (This is true for online upgrades of NDB Cluster in general.)

It is not possible for any API node to perform schema operations (such as data definition statements) during a node restart. Due in part to this limitation, schema operations are also not supported during an online upgrade or downgrade.

Rolling restarts with multiple management servers. When performing a rolling restart of an NDB Cluster with multiple management nodes, you should keep in mind that `ndb_mgmd` checks to see if any other management node is running, and, if so, tries to use that node's configuration data. To keep this from occurring, and to force `ndb_mgmd` to re-read its configuration file, perform the following steps:

1. Stop all NDB Cluster `ndb_mgmd` processes.
2. Update all `config.ini` files.
3. Start a single `ndb_mgmd` with `--reload`, `--initial`, or both options as desired.
4. If you started the first `ndb_mgmd` with the `--initial` option, you must also start any remaining `ndb_mgmd` processes using `--initial`.

Regardless of any other options used when starting the first `ndb_mgmd`, you should not start any remaining `ndb_mgmd` processes after the first one using `--reload`.

5. Complete the rolling restarts of the data nodes and API nodes as normal.

When performing a rolling restart to update the cluster's configuration, you can use the `config_generation` column of the `ndbinfo.nodes` table to keep track of which data nodes have been successfully restarted with the new configuration. See [Section 23.6.14.38, "The ndbinfo nodes Table"](#).

23.6.6 NDB Cluster Single User Mode

Single user mode enables the database administrator to restrict access to the database system to a single API node, such as a MySQL server (SQL node) or an instance of `ndb_restore`. When entering single user mode, connections to all other API nodes are closed gracefully and all running transactions are aborted. No new transactions are permitted to start.

Once the cluster has entered single user mode, only the designated API node is granted access to the database.

You can use the `ALL STATUS` command in the `ndb_mgm` client to see when the cluster has entered single user mode. You can also check the `status` column of the `ndbinfo.nodes` table (see [Section 23.6.14.38, "The ndbinfo nodes Table"](#), for more information).

Example:

```
ndb_mgm> ENTER SINGLE USER MODE 5
```

After this command has executed and the cluster has entered single user mode, the API node whose node ID is 5 becomes the cluster's only permitted user.

The node specified in the preceding command must be an API node; attempting to specify any other type of node is rejected.

Note

When the preceding command is invoked, all transactions running on the designated node are aborted, the connection is closed, and the server must be restarted.

The command `EXIT SINGLE USER MODE` changes the state of the cluster's data nodes from single user mode to normal mode. API nodes—such as MySQL Servers—waiting for a connection (that is, waiting for the cluster to become ready and available), are again permitted to connect. The API node denoted as the single-user node continues to run (if still connected) during and after the state change.

Example:

```
ndb_mgm> EXIT SINGLE USER MODE
```

There are two recommended ways to handle a node failure when running in single user mode:

- Method 1:
 1. Finish all single user mode transactions
 2. Issue the `EXIT SINGLE USER MODE` command
 3. Restart the cluster's data nodes

- Method 2:

Restart storage nodes prior to entering single user mode.

23.6.7 Adding NDB Cluster Data Nodes Online

This section describes how to add NDB Cluster data nodes “online”—that is, without needing to shut down the cluster completely and restart it as part of the process.

Important

Currently, you must add new data nodes to an NDB Cluster as part of a new node group. In addition, it is not possible to change the number of fragment replicas (or the number of nodes per node group) online.

23.6.7.1 Adding NDB Cluster Data Nodes Online: General Issues

This section provides general information about the behavior of and current limitations in adding NDB Cluster nodes online.

Redistribution of Data. The ability to add new nodes online includes a means to reorganize `NDBCLUSTER` table data and indexes so that they are distributed across all data nodes, including the new ones, by means of the `ALTER TABLE ... REORGANIZE PARTITION` statement. Table reorganization of both in-memory and Disk Data tables is supported. This redistribution does not currently include unique indexes (only ordered indexes are redistributed).

The redistribution for `NDBCLUSTER` tables already existing before the new data nodes were added is not automatic, but can be accomplished using simple SQL statements in `mysql` or another MySQL client application. However, all data and indexes added to tables created after a new node group has been added are distributed automatically among all cluster data nodes, including those added as part of the new node group.

Partial starts. It is possible to add a new node group without all of the new data nodes being started. It is also possible to add a new node group to a degraded cluster—that is, a cluster that is only partially started, or where one or more data nodes are not running. In the latter case, the cluster must have enough nodes running to be viable before the new node group can be added.

Effects on ongoing operations. Normal DML operations using NDB Cluster data are not prevented by the creation or addition of a new node group, or by table reorganization. However, it is not possible to perform DDL concurrently with table reorganization—that is, no other DDL statements can be issued while an `ALTER TABLE ... REORGANIZE PARTITION` statement is executing. In addition, during the execution of `ALTER TABLE ... REORGANIZE PARTITION` (or the execution of any other DDL statement), it is not possible to restart cluster data nodes.

Failure handling. Failures of data nodes during node group creation and table reorganization are handled as shown in the following table:

Table 23.65 Data node failure handling during node group creation and table reorganization

| Failure during | Failure in “Old” data node | Failure in “New” data node | System Failure |
|----------------------|---|---|---|
| Node group creation | <ul style="list-style-type: none"> • If a node other than the master fails: The creation of the node group is always rolled forward. • If the master fails: <ul style="list-style-type: none"> • If the internal commit point has been reached: The creation of the node group is rolled forward. • If the internal commit point has not yet been reached. The creation of the node group is rolled back | <ul style="list-style-type: none"> • If a node other than the master fails: The creation of the node group is always rolled forward. • If the master fails: <ul style="list-style-type: none"> • If the internal commit point has been reached: The creation of the node group is rolled forward. • If the internal commit point has not yet been reached. The creation of the node group is rolled back | <ul style="list-style-type: none"> • If the execution of CREATE NODEGROUP has reached the internal commit point: When restarted, the cluster includes the new node group. Otherwise it without. • If the execution of CREATE NODEGROUP has not yet reached the internal commit point: When restarted, the cluster does not include the new node group. |
| Table reorganization | <ul style="list-style-type: none"> • If a node other than the master fails: The table reorganization is always rolled forward. • If the master fails: <ul style="list-style-type: none"> • If the internal commit point has been reached: The table reorganization is rolled forward. • If the internal commit point has not yet been reached. The | <ul style="list-style-type: none"> • If a node other than the master fails: The table reorganization is always rolled forward. • If the master fails: <ul style="list-style-type: none"> • If the internal commit point has been reached: The table reorganization is rolled forward. • If the internal commit point has not yet been reached. The | <ul style="list-style-type: none"> • If the execution of an ALTER TABLE ... REORGANIZE PARTITION statement has reached the internal commit point: When the cluster is restarted, the data and indexes belonging to <i>table</i> are distributed using the “new” data nodes. • If the execution of an ALTER TABLE ... REORGANIZE PARTITION statement has not yet reached |

| Failure during | Failure in “Old” data node | Failure in “New” data node | System Failure |
|----------------|--------------------------------------|--------------------------------------|--|
| | table reorganization is rolled back. | table reorganization is rolled back. | the internal commit point: When the cluster is restarted, the data and indexes belonging to <i>table</i> are distributed using only the “old” data nodes. |

Dropping node groups. The `ndb_mgm` client supports a `DROP NODEGROUP` command, but it is possible to drop a node group only when no data nodes in the node group contain any data. Since there is currently no way to “empty” a specific data node or node group, this command works only the following two cases:

1. After issuing `CREATE NODEGROUP` in the `ndb_mgm` client, but before issuing any `ALTER TABLE ... REORGANIZE PARTITION` statements in the `mysql` client.
2. After dropping all `NDBCLUSTER` tables using `DROP TABLE`.

`TRUNCATE TABLE` does not work for this purpose because the data nodes continue to store the table definitions.

23.6.7.2 Adding NDB Cluster Data Nodes Online: Basic procedure

In this section, we list the basic steps required to add new data nodes to an NDB Cluster. This procedure applies whether you are using `ndbd` or `ndbmtid` binaries for the data node processes. For a more detailed example, see [Section 23.6.7.3, “Adding NDB Cluster Data Nodes Online: Detailed Example”](#).

Assuming that you already have a running NDB Cluster, adding data nodes online requires the following steps:

1. Edit the cluster configuration `config.ini` file, adding new `[ndbd]` sections corresponding to the nodes to be added. In the case where the cluster uses multiple management servers, these changes need to be made to all `config.ini` files used by the management servers.

You must be careful that node IDs for any new data nodes added in the `config.ini` file do not overlap node IDs used by existing nodes. In the event that you have API nodes using dynamically allocated node IDs and these IDs match node IDs that you want to use for new data nodes, it is possible to force any such API nodes to “migrate”, as described later in this procedure.

2. Perform a rolling restart of all NDB Cluster management servers.

Important

All management servers must be restarted with the `--reload` or `--initial` option to force the reading of the new configuration.

3. Perform a rolling restart of all existing NDB Cluster data nodes. It is not necessary (or usually even desirable) to use `--initial` when restarting the existing data nodes.

If you are using API nodes with dynamically allocated IDs matching any node IDs that you wish to assign to new data nodes, you must restart all API nodes (including SQL nodes) before restarting any of the data nodes processes in this step. This causes any API nodes with node IDs that were previously not explicitly assigned to relinquish those node IDs and acquire new ones.

4. Perform a rolling restart of any SQL or API nodes connected to the NDB Cluster.
5. Start the new data nodes.

The new data nodes may be started in any order. They can also be started concurrently, as long as they are started after the rolling restarts of all existing data nodes have been completed, and before proceeding to the next step.

6. Execute one or more `CREATE NODEGROUP` commands in the NDB Cluster management client to create the new node group or node groups to which the new data nodes belong.
7. Redistribute the cluster's data among all data nodes, including the new ones. Normally this is done by issuing an `ALTER TABLE ... ALGORITHM=INPLACE, REORGANIZE PARTITION` statement in the `mysql` client for each `NDBCLUSTER` table.

Exception: For tables created using the `MAX_ROWS` option, this statement does not work; instead, use `ALTER TABLE ... ALGORITHM=INPLACE MAX_ROWS=...` to reorganize such tables. You should also bear in mind that using `MAX_ROWS` to set the number of partitions in this fashion is deprecated, and you should use `PARTITION_BALANCE` instead; see [Section 13.1.20.11, “Setting NDB_TABLE Options”](#), for more information.

Note

This needs to be done only for tables already existing at the time the new node group is added. Data in tables created after the new node group is added is distributed automatically; however, data added to any given table `tbl` that existed before the new nodes were added is not distributed using the new nodes until that table has been reorganized.

8. `ALTER TABLE ... REORGANIZE PARTITION ALGORITHM=INPLACE` reorganizes partitions but does not reclaim the space freed on the “old” nodes. You can do this by issuing, for each `NDBCLUSTER` table, an `OPTIMIZE TABLE` statement in the `mysql` client.

This works for space used by variable-width columns of in-memory `NDB` tables. `OPTIMIZE TABLE` is not supported for fixed-width columns of in-memory tables; it is also not supported for Disk Data tables.

You can add all the nodes desired, then issue several `CREATE NODEGROUP` commands in succession to add the new node groups to the cluster.

23.6.7.3 Adding NDB Cluster Data Nodes Online: Detailed Example

In this section we provide a detailed example illustrating how to add new NDB Cluster data nodes online, starting with an NDB Cluster having 2 data nodes in a single node group and concluding with a cluster having 4 data nodes in 2 node groups.

Starting configuration. For purposes of illustration, we assume a minimal configuration, and that the cluster uses a `config.ini` file containing only the following information:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 198.51.100.1
```

```
[ndbd]
Id = 2
HostName = 198.51.100.2

[mgm]
HostName = 198.51.100.10
Id = 10

[api]
Id=20
HostName = 198.51.100.20

[api]
Id=21
HostName = 198.51.100.21
```

Note

We have left a gap in the sequence between data node IDs and other nodes. This makes it easier later to assign node IDs that are not already in use to data nodes which are newly added.

We also assume that you have already started the cluster using the appropriate command line or `my.cnf` options, and that running `SHOW` in the management client produces output similar to what is shown here:

```
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: 198.51.100.10:1186
Cluster Configuration
-----
[ndbd(NDB)]      2 node(s)
id=1   @198.51.100.1  (8.0.27-ndb-8.0.27, Nodegroup: 0, *)
id=2   @198.51.100.2  (8.0.27-ndb-8.0.27, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=10  @198.51.100.10  (8.0.27-ndb-8.0.27)

[mysqld(API)]   2 node(s)
id=20  @198.51.100.20  (8.0.27-ndb-8.0.27)
id=21  @198.51.100.21  (8.0.27-ndb-8.0.27)
```

Finally, we assume that the cluster contains a single `NDBCLUSTER` table created as shown here:

```
USE n;

CREATE TABLE ips (
  id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  country_code CHAR(2) NOT NULL,
  type CHAR(4) NOT NULL,
  ip_address VARCHAR(15) NOT NULL,
  addresses BIGINT UNSIGNED DEFAULT NULL,
  date BIGINT UNSIGNED DEFAULT NULL
) ENGINE NDBCLUSTER;
```

The memory usage and related information shown later in this section was generated after inserting approximately 50000 rows into this table.

Note

In this example, we show the single-threaded `ndbd` being used for the data node processes. You can also apply this example, if you are using the multithreaded `ndbmt` by substituting `ndbmt` for `ndbd` wherever it appears in the steps that follow.

Step 1: Update configuration file. Open the cluster global configuration file in a text editor and add `[ndbd]` sections corresponding to the 2 new data nodes. (We give these data nodes IDs 3 and 4, and assume that they are to be run on host machines at addresses 198.51.100.3 and 198.51.100.4, respectively.) After you have added the new sections, the contents of the `config.ini` file should look like what is shown here, where the additions to the file are shown in bold type:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 198.51.100.1

[ndbd]
Id = 2
HostName = 198.51.100.2

[ndbd]
Id = 3
HostName = 198.51.100.3

[ndbd]
Id = 4
HostName = 198.51.100.4

[mgm]
HostName = 198.51.100.10
Id = 10

[api]
Id=20
HostName = 198.51.100.20

[api]
Id=21
HostName = 198.51.100.21
```

Once you have made the necessary changes, save the file.

Step 2: Restart the management server. Restarting the cluster management server requires that you issue separate commands to stop the management server and then to start it again, as follows:

1. Stop the management server using the management client `STOP` command, as shown here:

```
ndb_mgm> 10 STOP
Node 10 has shut down.
Disconnecting to allow Management Server to shutdown

shell>
```

2. Because shutting down the management server causes the management client to terminate, you must start the management server from the system shell. For simplicity, we assume that `config.ini` is in the same directory as the management server binary, but in practice, you must supply the correct path to the configuration file. You must also supply the `--reload` or `--initial` option so that the management server reads the new configuration from the file rather than its configuration cache. If your shell's current directory is also the same as the directory where the management server binary is located, then you can invoke the management server as shown here:

```
shell> ndb_mgmd -f config.ini --reload
2008-12-08 17:29:23 [MgmSrvr] INFO -- NDB Cluster Management Server. 8.0.27-ndb-8.0.27
```

```
2008-12-08 17:29:23 [MgmSrvr] INFO -- Reading cluster configuration from 'config.ini'
```

If you check the output of `SHOW` in the management client after restarting the `ndb_mgm` process, you should now see something like this:

```
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: 198.51.100.10:1186
Cluster Configuration
-----
[ndbd(NDB)]      2 node(s)
id=1      @198.51.100.1  (8.0.27-ndb-8.0.27, Nodegroup: 0, *)
id=2      @198.51.100.2  (8.0.27-ndb-8.0.27, Nodegroup: 0)
id=3 (not connected, accepting connect from 198.51.100.3)
id=4 (not connected, accepting connect from 198.51.100.4)

[ndb_mgmd(MGM)] 1 node(s)
id=10     @198.51.100.10  (8.0.27-ndb-8.0.27)

[mysqld(API)]   2 node(s)
id=20     @198.51.100.20  (8.0.27-ndb-8.0.27)
id=21     @198.51.100.21  (8.0.27-ndb-8.0.27)
```

Step 3: Perform a rolling restart of the existing data nodes. This step can be accomplished entirely within the cluster management client using the `RESTART` command, as shown here:

```
ndb_mgm> 1 RESTART
Node 1: Node shutdown initiated
Node 1: Node shutdown completed, restarting, no start.
Node 1 is being restarted

ndb_mgm> Node 1: Start initiated (version 8.0.27)
Node 1: Started (version 8.0.27)

ndb_mgm> 2 RESTART
Node 2: Node shutdown initiated
Node 2: Node shutdown completed, restarting, no start.
Node 2 is being restarted

ndb_mgm> Node 2: Start initiated (version 8.0.27)
ndb_mgm> Node 2: Started (version 8.0.27)
```

Important

After issuing each `X RESTART` command, wait until the management client reports `Node X: Started (version ...)` before proceeding any further.

You can verify that all existing data nodes were restarted using the updated configuration by checking the `ndbinfo.nodes` table in the `mysql` client.

Step 4: Perform a rolling restart of all cluster API nodes. Shut down and restart each MySQL server acting as an SQL node in the cluster using `mysqladmin shutdown` followed by `mysqld_safe` (or another startup script). This should be similar to what is shown here, where `password` is the MySQL `root` password for a given MySQL server instance:

```
shell> mysqladmin -uroot -ppassword shutdown
081208 20:19:56 mysqld_safe mysqld from pid file
/usr/local/mysql/var/tonfisk.pid ended
shell> mysqld_safe --ndbcluster --ndb-connectstring=198.51.100.10 &
081208 20:20:06 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
081208 20:20:06 mysqld_safe Starting mysqld daemon with databases
from /usr/local/mysql/var
```

Of course, the exact input and output depend on how and where MySQL is installed on the system, as well as which options you choose to start it (and whether or not some or all of these options are specified in a `my.cnf` file).

Step 5: Perform an initial start of the new data nodes. From a system shell on each of the hosts for the new data nodes, start the data nodes as shown here, using the `--initial` option:

```
shell> ndbd -c 198.51.100.10 --initial
```

Note

Unlike the case with restarting the existing data nodes, you can start the new data nodes concurrently; you do not need to wait for one to finish starting before starting the other.

Wait until both of the new data nodes have started before proceeding with the next step. Once the new data nodes have started, you can see in the output of the management client `SHOW` command that they do not yet belong to any node group (as indicated with bold type here):

```
ndb_mgm> SHOW
Connected to Management Server at: 198.51.100.10:1186
Cluster Configuration
-----
[ndbd(NDB)] 2 node(s)
id=1 @198.51.100.1 (8.0.27-ndb-8.0.27, Nodegroup: 0, *)
id=2 @198.51.100.2 (8.0.27-ndb-8.0.27, Nodegroup: 0)
id=3 @198.51.100.3 (8.0.27-ndb-8.0.27, no nodegroup)
id=4 @198.51.100.4 (8.0.27-ndb-8.0.27, no nodegroup)

[ndb_mgmd(MGM)] 1 node(s)
id=10 @198.51.100.10 (8.0.27-ndb-8.0.27)

[mysqld(API)] 2 node(s)
id=20 @198.51.100.20 (8.0.27-ndb-8.0.27)
id=21 @198.51.100.21 (8.0.27-ndb-8.0.27)
```

Step 6: Create a new node group. You can do this by issuing a `CREATE NODEGROUP` command in the cluster management client. This command takes as its argument a comma-separated list of the node IDs of the data nodes to be included in the new node group, as shown here:

```
ndb_mgm> CREATE NODEGROUP 3,4
Nodegroup 1 created
```

By issuing `SHOW` again, you can verify that data nodes 3 and 4 have joined the new node group (again indicated in bold type):

```
ndb_mgm> SHOW
Connected to Management Server at: 198.51.100.10:1186
Cluster Configuration
-----
[ndbd(NDB)] 2 node(s)
id=1 @198.51.100.1 (8.0.27-ndb-8.0.27, Nodegroup: 0, *)
id=2 @198.51.100.2 (8.0.27-ndb-8.0.27, Nodegroup: 0)
id=3 @198.51.100.3 (8.0.27-ndb-8.0.27, Nodegroup: 1)
id=4 @198.51.100.4 (8.0.27-ndb-8.0.27, Nodegroup: 1)

[ndb_mgmd(MGM)] 1 node(s)
id=10 @198.51.100.10 (8.0.27-ndb-8.0.27)

[mysqld(API)] 2 node(s)
id=20 @198.51.100.20 (8.0.27-ndb-8.0.27)
id=21 @198.51.100.21 (8.0.27-ndb-8.0.27)
```

Step 7: Redistribute cluster data. When a node group is created, existing data and indexes are not automatically distributed to the new node group's data nodes, as you can see by issuing the appropriate `REPORT` command in the management client:

```
ndb_mgm> ALL REPORT MEMORY

Node 1: Data usage is 5%(177 32K pages of total 3200)
Node 1: Index usage is 0%(108 8K pages of total 12832)
Node 2: Data usage is 5%(177 32K pages of total 3200)
Node 2: Index usage is 0%(108 8K pages of total 12832)
Node 3: Data usage is 0%(0 32K pages of total 3200)
Node 3: Index usage is 0%(0 8K pages of total 12832)
Node 4: Data usage is 0%(0 32K pages of total 3200)
Node 4: Index usage is 0%(0 8K pages of total 12832)
```

By using `ndb_desc` with the `-p` option, which causes the output to include partitioning information, you can see that the table still uses only 2 partitions (in the `Per partition info` section of the output, shown here in bold text):

```
shell> ndb_desc -c 198.51.100.10 -d n ips -p
-- ips --
Version: 1
Fragment type: 9
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 6
Number of primary keys: 1
Length of frm data: 340
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
FragmentCount: 2
TableStatus: Retrieved
-- Attributes --
id Bigint PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
country_code Char(2;latin1_swedish_ci) NOT NULL AT=FIXED ST=MEMORY
type Char(4;latin1_swedish_ci) NOT NULL AT=FIXED ST=MEMORY
ip_address Varchar(15;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
addresses Bigunsigned NULL AT=FIXED ST=MEMORY
date Bigunsigned NULL AT=FIXED ST=MEMORY

-- Indexes --
PRIMARY KEY(id) - UniqueHashIndex
PRIMARY(id) - OrderedIndex

-- Per partition info --
Partition  Row count  Commit count  Frag fixed memory  Frag varsized memory
0          26086      26086         1572864             557056
1          26329      26329         1605632             557056

NDBT_ProgramExit: 0 - OK
```

You can cause the data to be redistributed among all of the data nodes by performing, for each NDB table, an `ALTER TABLE ... ALGORITHM=INPLACE, REORGANIZE PARTITION` statement in the `mysql` client.

Important

`ALTER TABLE ... ALGORITHM=INPLACE, REORGANIZE PARTITION` does not work on tables that were created with the `MAX_ROWS` option. Instead, use `ALTER TABLE ... ALGORITHM=INPLACE, MAX_ROWS=...` to reorganize such tables.

Keep in mind that using `MAX_ROWS` to set the number of partitions per table is deprecated, and you should use `PARTITION_BALANCE` instead; see [Section 13.1.20.11, “Setting NDB_TABLE Options”](#), for more information.

After issuing the statement `ALTER TABLE ips ALGORITHM=INPLACE, REORGANIZE PARTITION`, you can see using `ndb_desc` that the data for this table is now stored using 4 partitions, as shown here (with the relevant portions of the output in bold type):

```
shell> ndb_desc -c 198.51.100.10 -d n ips -p
-- ips --
Version: 16777217
Fragment type: 9
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 6
Number of primary keys: 1
Length of frm data: 341
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
FragmentCount: 4
TableStatus: Retrieved
-- Attributes --
id Bigint PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR

ip_address Varchar(15;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
addresses Bigunsigned NULL AT=FIXED ST=MEMORY
date Bigunsigned NULL AT=FIXED ST=MEMORY

-- Indexes --
PRIMARY KEY(id) - UniqueHashIndex
PRIMARY(id) - OrderedIndex

-- Per partition info --
Partition  Row count  Commit count  Frag fixed memory  Frag var sized memory
0          12981         52296         1572864             557056
1          13236         52515         1605632             557056
2          13105         13105         819200              294912
3          13093         13093         819200              294912

NDBT_ProgramExit: 0 - OK
```

Note

Normally, `ALTER TABLE table_name [ALGORITHM=INPLACE,] REORGANIZE PARTITION` is used with a list of partition identifiers and a set of partition definitions to create a new partitioning scheme for a table that has already been explicitly partitioned. Its use here to redistribute data onto a new NDB Cluster node group is an exception in this regard; when used in this way, no other keywords or identifiers follow `REORGANIZE PARTITION`.

For more information, see [Section 13.1.9, “ALTER TABLE Statement”](#).

In addition, for each table, the `ALTER TABLE` statement should be followed by an `OPTIMIZE TABLE` to reclaim wasted space. You can obtain a list of all `NDBCLUSTER` tables using the following query against the `INFORMATION_SCHEMA.TABLES` table:

```
SELECT TABLE_SCHEMA, TABLE_NAME
```

```
FROM INFORMATION_SCHEMA.TABLES
WHERE ENGINE = 'NDBCLUSTER';
```

**Note**

The `INFORMATION_SCHEMA.TABLES.ENGINE` value for an NDB Cluster table is always `NDBCLUSTER`, regardless of whether the `CREATE TABLE` statement used to create the table (or `ALTER TABLE` statement used to convert an existing table from a different storage engine) used `NDB` or `NDBCLUSTER` in its `ENGINE` option.

You can see after performing these statements in the output of `ALL REPORT MEMORY` that the data and indexes are now redistributed between all cluster data nodes, as shown here:

```
ndb_mgm> ALL REPORT MEMORY

Node 1: Data usage is 5%(176 32K pages of total 3200)
Node 1: Index usage is 0%(76 8K pages of total 12832)
Node 2: Data usage is 5%(176 32K pages of total 3200)
Node 2: Index usage is 0%(76 8K pages of total 12832)
Node 3: Data usage is 2%(80 32K pages of total 3200)
Node 3: Index usage is 0%(51 8K pages of total 12832)
Node 4: Data usage is 2%(80 32K pages of total 3200)
Node 4: Index usage is 0%(50 8K pages of total 12832)
```

**Note**

Since only one DDL operation on `NDBCLUSTER` tables can be executed at a time, you must wait for each `ALTER TABLE ... REORGANIZE PARTITION` statement to finish before issuing the next one.

It is not necessary to issue `ALTER TABLE ... REORGANIZE PARTITION` statements for `NDBCLUSTER` tables created *after* the new data nodes have been added; data added to such tables is distributed among all data nodes automatically. However, in `NDBCLUSTER` tables that existed *prior* to the addition of the new nodes, neither existing nor new data is distributed using the new nodes until these tables have been reorganized using `ALTER TABLE ... REORGANIZE PARTITION`.

Alternative procedure, without rolling restart. It is possible to avoid the need for a rolling restart by configuring the extra data nodes, but not starting them, when first starting the cluster. We assume, as before, that you wish to start with two data nodes—nodes 1 and 2—in one node group and later to expand the cluster to four data nodes, by adding a second node group consisting of nodes 3 and 4:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 198.51.100.1

[ndbd]
Id = 2
HostName = 198.51.100.2

[ndbd]
Id = 3
HostName = 198.51.100.3
Nodegroup = 65536

[ndbd]
Id = 4
HostName = 198.51.100.4
```

```

Nodegroup = 65536

[mgm]
HostName = 198.51.100.10
Id = 10

[api]
Id=20
HostName = 198.51.100.20

[api]
Id=21
HostName = 198.51.100.21

```

The data nodes to be brought online at a later time (nodes 3 and 4) can be configured with `NodeGroup = 65536`, in which case nodes 1 and 2 can each be started as shown here:

```
shell> ndbd -c 198.51.100.10 --initial
```

The data nodes configured with `NodeGroup = 65536` are treated by the management server as though you had started nodes 1 and 2 using `--nowait-nodes=3,4` after waiting for a period of time determined by the setting for the `StartNoNodeGroupTimeout` data node configuration parameter. By default, this is 15 seconds (15000 milliseconds).

Note

`StartNoNodegroupTimeout` must be the same for all data nodes in the cluster; for this reason, you should always set it in the `[ndbd default]` section of the `config.ini` file, rather than for individual data nodes.

When you are ready to add the second node group, you need only perform the following additional steps:

1. Start data nodes 3 and 4, invoking the data node process once for each new node:

```
shell> ndbd -c 198.51.100.10 --initial
```

2. Issue the appropriate `CREATE NODEGROUP` command in the management client:

```
ndb_mgm> CREATE NODEGROUP 3,4
```

3. In the `mysql` client, issue `ALTER TABLE ... REORGANIZE PARTITION` and `OPTIMIZE TABLE` statements for each existing `NDBCLUSTER` table. (As noted elsewhere in this section, existing NDB Cluster tables cannot use the new nodes for data distribution until this has been done.)

23.6.8 Online Backup of NDB Cluster

The next few sections describe how to prepare for and then to create an NDB Cluster backup using the functionality for this purpose found in the `ndb_mgm` management client. To distinguish this type of backup from a backup made using `mysqldump`, we sometimes refer to it as a “native” NDB Cluster backup. (For information about the creation of backups with `mysqldump`, see [Section 4.5.4, “mysqldump — A Database Backup Program”](#).) Restoration of NDB Cluster backups is done using the `ndb_restore` utility provided with the NDB Cluster distribution; for information about `ndb_restore` and its use in restoring NDB Cluster backups, see [Section 23.5.23, “ndb_restore — Restore an NDB Cluster Backup”](#).

NDB 8.0 makes it possible to create backups using multiple LDMS to achieve parallelism on the data nodes. See [Section 23.6.8.5, “Taking an NDB Backup with Parallel Data Nodes”](#).

23.6.8.1 NDB Cluster Backup Concepts

A backup is a snapshot of the database at a given time. The backup consists of three main parts:

- **Metadata.** The names and definitions of all database tables
- **Table records.** The data actually stored in the database tables at the time that the backup was made
- **Transaction log.** A sequential record telling how and when data was stored in the database

Each of these parts is saved on all nodes participating in the backup. During backup, each node saves these three parts into three files on disk:

- `BACKUP-backup_id.node_id.ctl`

A control file containing control information and metadata. Each node saves the same table definitions (for all tables in the cluster) to its own version of this file.

- `BACKUP-backup_id-0.node_id.data`

A data file containing the table records, which are saved on a per-fragment basis. That is, different nodes save different fragments during the backup. The file saved by each node starts with a header that states the tables to which the records belong. Following the list of records there is a footer containing a checksum for all records.

- `BACKUP-backup_id.node_id.log`

A log file containing records of committed transactions. Only transactions on tables stored in the backup are stored in the log. Nodes involved in the backup save different records because different nodes host different database fragments.

In the listing just shown, `backup_id` stands for the backup identifier and `node_id` is the unique identifier for the node creating the file.

The location of the backup files is determined by the `BackupDataDir` parameter.

23.6.8.2 Using The NDB Cluster Management Client to Create a Backup

Before starting a backup, make sure that the cluster is properly configured for performing one. (See [Section 23.6.8.3, “Configuration for NDB Cluster Backups”](#).)

The `START BACKUP` command is used to create a backup:

```
START BACKUP [backup_id]
  [encryption_option]
  [wait_option]
  [snapshot_option]

encryption_option:
ENCRYPT [PASSWORD=password]

password:
{'password_string' | "password_string" }

wait_option:
WAIT {STARTED | COMPLETED} | NOWAIT

snapshot_option:
SNAPSHOTSTART | SNAPSHOTEND
```

Successive backups are automatically identified sequentially, so the `backup_id`, an integer greater than or equal to 1, is optional; if it is omitted, the next available value is used. If an existing `backup_id` value is used, the backup fails with the error `Backup failed: file already exists`. If used, the `backup_id` must follow `START BACKUP` immediately, before any other options are used.

NDB 8.0.22 and later supports the creation of encrypted backups using `ENCRYPT PASSWORD=password`; the `password` must meet all of the following requirements:

- Uses any of the printable ASCII characters except `!`, `'`, `"`, `$`, `%`, `\`, and `^`
- Is no more than 256 characters in length
- Is enclosed by single or double quotation marks

Starting with NDB 8.0.24, the `PASSWORD` clause can be omitted from `encryption_option`. In this case, the management client prompts the user for a password.

It is possible using `PASSWORD` to set an empty password (`' '` or `" "`), but this is not recommended.

An encrypted backup can be decrypted using any of the following commands:

- `ndb_restore --decrypt --backup-password=password`
- `ndbxfrm --decrypt-password=password input_file output_file`
- `ndb_print_backup_file -P password file_name`

NDB 8.0.24 and later supports the additional commands listed here:

- `ndb_restore --decrypt --backup-password-from-stdin`
- `ndbxfrm --decrypt-password-from-stdin input_file output_file`
- `ndb_print_backup_file --backup-password=password file_name`
- `ndb_print_backup_file --backup-password-from-stdin file_name`
- `ndb_mgm --backup-password-from-stdin --execute "START BACKUP ..."`

See the descriptions of these programs for more information, such as additional options that may be required.

The `wait_option` can be used to determine when control is returned to the management client after a `START BACKUP` command is issued, as shown in the following list:

- If `NOWAIT` is specified, the management client displays a prompt immediately, as seen here:

```
ndb_mgm> START BACKUP NOWAIT
ndb_mgm>
```

In this case, the management client can be used even while it prints progress information from the backup process.

- With `WAIT STARTED` the management client waits until the backup has started before returning control to the user, as shown here:

```
ndb_mgm> START BACKUP WAIT STARTED
Waiting for started, this may take several minutes
Node 2: Backup 3 started from node 1
ndb_mgm>
```

- `WAIT COMPLETED` causes the management client to wait until the backup process is complete before returning control to the user.

`WAIT COMPLETED` is the default.

A *snapshot_option* can be used to determine whether the backup matches the state of the cluster when `START BACKUP` was issued, or when it was completed. `SNAPSHOTSTART` causes the backup to match the state of the cluster when the backup began; `SNAPSHOTEND` causes the backup to reflect the state of the cluster when the backup was finished. `SNAPSHOTEND` is the default, and matches the behavior found in previous NDB Cluster releases.

Note

If you use the `SNAPSHOTSTART` option with `START BACKUP`, and the `CompressedBackup` parameter is enabled, only the data and control files are compressed—the log file is not compressed.

If both a *wait_option* and a *snapshot_option* are used, they may be specified in either order. For example, all of the following commands are valid, assuming that there is no existing backup having 4 as its ID:

```
START BACKUP WAIT STARTED SNAPSHOTSTART
START BACKUP SNAPSHOTSTART WAIT STARTED
START BACKUP 4 WAIT COMPLETED SNAPSHOTSTART
START BACKUP SNAPSHOTEND WAIT COMPLETED
START BACKUP 4 NOWAIT SNAPSHOTSTART
```

The procedure for creating a backup consists of the following steps:

1. Start the management client (`ndb_mgm`), if it not running already.
2. Execute the `START BACKUP` command. This produces several lines of output indicating the progress of the backup, as shown here:

```
ndb_mgm> START BACKUP
Waiting for completed, this may take several minutes
Node 2: Backup 1 started from node 1
Node 2: Backup 1 started from node 1 completed
StartGCP: 177 StopGCP: 180
#Records: 7362 #LogRecords: 0
Data: 453648 bytes Log: 0 bytes
ndb_mgm>
```

3. When the backup has started the management client displays this message:

```
Backup backup_id started from node node_id
```

backup_id is the unique identifier for this particular backup. This identifier is saved in the cluster log, if it has not been configured otherwise. *node_id* is the identifier of the management server that is coordinating the backup with the data nodes. At this point in the backup process the cluster has received and processed the backup request. It does not mean that the backup has finished. An example of this statement is shown here:

```
Node 2: Backup 1 started from node 1
```

4. The management client indicates with a message like this one that the backup has started:

```
Backup backup_id started from node node_id completed
```

As is the case for the notification that the backup has started, *backup_id* is the unique identifier for this particular backup, and *node_id* is the node ID of the management server that is coordinating the backup with the data nodes. This output is accompanied by additional information including relevant global checkpoints, the number of records backed up, and the size of the data, as shown here:

```
Node 2: Backup 1 started from node 1 completed
StartGCP: 177 StopGCP: 180
```

```
#Records: 7362 #LogRecords: 0
Data: 453648 bytes Log: 0 bytes
```

It is also possible to perform a backup from the system shell by invoking `ndb_mgm` with the `-e` or `--execute` option, as shown in this example:

```
shell> ndb_mgm -e "START BACKUP 6 WAIT COMPLETED SNAPSHOTSTART"
```

When using `START BACKUP` in this way, you must specify the backup ID.

Cluster backups are created by default in the `BACKUP` subdirectory of the `DataDir` on each data node. This can be overridden for one or more data nodes individually, or for all cluster data nodes in the `config.ini` file using the `BackupDataDir` configuration parameter. The backup files created for a backup with a given `backup_id` are stored in a subdirectory named `BACKUP-backup_id` in the backup directory.

Cancelling backups. To cancel or abort a backup that is already in progress, perform the following steps:

1. Start the management client.
2. Execute this command:

```
ndb_mgm> ABORT BACKUP backup_id
```

The number `backup_id` is the identifier of the backup that was included in the response of the management client when the backup was started (in the message `Backup backup_id started from node management_node_id`).

3. The management client acknowledges the abort request with `Abort of backup backup_id ordered.`

Note

At this point, the management client has not yet received a response from the cluster data nodes to this request, and the backup has not yet actually been aborted.

4. After the backup has been aborted, the management client reports this fact in a manner similar to what is shown here:

```
Node 1: Backup 3 started from 5 has been aborted.
Error: 1321 - Backup aborted by user request: Permanent error: User defined error
Node 3: Backup 3 started from 5 has been aborted.
Error: 1323 - 1323: Permanent error: Internal error
Node 2: Backup 3 started from 5 has been aborted.
Error: 1323 - 1323: Permanent error: Internal error
Node 4: Backup 3 started from 5 has been aborted.
Error: 1323 - 1323: Permanent error: Internal error
```

In this example, we have shown sample output for a cluster with 4 data nodes, where the sequence number of the backup to be aborted is 3, and the management node to which the cluster management client is connected has the node ID 5. The first node to complete its part in aborting the backup reports that the reason for the abort was due to a request by the user. (The remaining nodes report that the backup was aborted due to an unspecified internal error.)

Note

There is no guarantee that the cluster nodes respond to an `ABORT BACKUP` command in any particular order.

The Backup `backup_id` started from node `management_node_id` has been aborted messages mean that the backup has been terminated and that all files relating to this backup have been removed from the cluster file system.

It is also possible to abort a backup in progress from a system shell using this command:

```
shell> ndb_mgm -e "ABORT BACKUP backup_id"
```

Note

If there is no backup having the ID `backup_id` running when an `ABORT BACKUP` is issued, the management client makes no response, nor is it indicated in the cluster log that an invalid abort command was sent.

23.6.8.3 Configuration for NDB Cluster Backups

Five configuration parameters are essential for backup:

- `BackupDataBufferSize`

The amount of memory used to buffer data before it is written to disk.

- `BackupLogBufferSize`

The amount of memory used to buffer log records before these are written to disk.

- `BackupMemory`

The total memory allocated in a data node for backups. This should be the sum of the memory allocated for the backup data buffer and the backup log buffer.

- `BackupWriteSize`

The default size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.

- `BackupMaxWriteSize`

The maximum size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.

In addition, `CompressedBackup` causes `NDB` to use compression when creating and writing to backup files.

More detailed information about these parameters can be found in [Backup Parameters](#).

You can also set a location for the backup files using the `BackupDataDir` configuration parameter. The default is `FileSystemPath/BACKUP/BACKUP-backup_id`.

In `NDB 8.0.22` and later, you can enforce encryption of backup files by enabling `RequireEncryptedBackup`. When this parameter is set to 1, backups cannot be created without specifying `ENCRYPT PASSWORD=password` as part of a `START BACKUP` command.

23.6.8.4 NDB Cluster Backup Troubleshooting

If an error code is returned when issuing a backup request, the most likely cause is insufficient memory or disk space. You should check that there is enough memory allocated for the backup.

**Important**

If you have set `BackupDataBufferSize` and `BackupLogBufferSize` and their sum is greater than 4MB, then you must also set `BackupMemory` as well.

You should also make sure that there is sufficient space on the hard drive partition of the backup target.

NDB does not support repeatable reads, which can cause problems with the restoration process. Although the backup process is “hot”, restoring an NDB Cluster from backup is not a 100% “hot” process. This is due to the fact that, for the duration of the restore process, running transactions get nonrepeatable reads from the restored data. This means that the state of the data is inconsistent while the restore is in progress.

23.6.8.5 Taking an NDB Backup with Parallel Data Nodes

It is possible in NDB 8.0 to take a backup with multiple local data managers (LDMs) acting in parallel on the data nodes. For this to work, all data nodes in the cluster must use multiple LDMs, and each data node must use the same number of LDMs. This means that all data nodes must run `ndbmttd` (`ndbd` is single-threaded and thus always has only one LDM) and they must be configured to use multiple LDMs before taking the backup; `ndbmttd` by default runs in single-threaded mode. You can cause them to use multiple LDMs by choosing an appropriate setting for one of the multi-threaded data node configuration parameters `MaxNoOfExecutionThreads` or `ThreadConfig`. Keep in mind that changing these parameters requires a restart of the cluster; this can be a rolling restart. In addition, the `EnableMultithreadedBackup` parameter must be set to 1 for each data node (this is the default).

Depending on the number of LDMs and other factors, you may also need to increase `NoOfFragmentLogParts`. If you are using large Disk Data tables, you may also need to increase `DiskPageBufferMemory`. As with single-threaded backups, you may also want or need to make adjustments to settings for `BackupDataBufferSize`, `BackupMemory`, and other configuration parameters relating to backups (see [Backup parameters](#)).

Once all data nodes are using multiple LDMs, you can take the parallel backup using the `START BACKUP` command in the NDB management client just as you would if the data nodes were running `ndbd` (or `ndbmttd` in single-threaded mode); no additional or special syntax is required, and you can specify a backup ID, wait option, or snapshot option in any combination as needed or desired.

Backups using multiple LDMs create subdirectories, one per LDM, under the directory `BACKUP/BACKUP-backup_id/` (which in turn resides under the `BackupDataDir`) on each data node; these subdirectories are named `BACKUP-backup_id-PART-1-OF-N/`, `BACKUP-backup_id-PART-2-OF-N/`, and so on, up to `BACKUP-backup_id-PART-N-OF-N/`, where `backup_id` is the backup ID used for this backup and `N` is the number of LDMs per data node. Each of these subdirectories contains the usual backup files `BACKUP-backup_id-0.node_id.Data`, `BACKUP-backup_id.node_id.ctl`, and `BACKUP-backup_id.node_id.log`, where `node_id` is the node ID of this data node.

`ndb_restore` automatically checks for the presence of the subdirectories just described; if it finds them, it attempts to restore the backup in parallel. For information about restoring backups taken with multiple LDMs, see [Section 23.5.23.3, “Restoring from a backup taken in parallel”](#).

To force creation of a single-threaded backup that can easily be imported by `ndb_restore` from an NDB release prior to 8.0, you can set `EnableMultithreadedBackup = 0` for all data nodes (you can do this by setting the parameter in the `[ndbd default]` section of the `config.ini` global configuration file). It is also possible to restore a parallel backup to a cluster running an older version of NDB. See [Restoring an NDB backup to a previous version of NDB Cluster](#), for more information.

23.6.9 MySQL Server Usage for NDB Cluster

`mysqld` is the traditional MySQL server process. To be used with NDB Cluster, `mysqld` needs to be built with support for the NDB storage engine, as it is in the precompiled binaries available from

<https://dev.mysql.com/downloads/>. If you build MySQL from source, you must invoke `CMake` with the `-DWITH_NDBCLUSTER=1` option to include support for NDB.

For more information about compiling NDB Cluster from source, see [Section 23.3.1.4, “Building NDB Cluster from Source on Linux”](#), and [Section 23.3.2.2, “Compiling and Installing NDB Cluster from Source on Windows”](#).

(For information about `mysqld` options and variables, in addition to those discussed in this section, which are relevant to NDB Cluster, see [Section 23.4.3.9, “MySQL Server Options and Variables for NDB Cluster”](#).)

If the `mysqld` binary has been built with Cluster support, the `NDBCLUSTER` storage engine is still disabled by default. You can use either of two possible options to enable this engine:

- Use `--ndbcluster` as a startup option on the command line when starting `mysqld`.
- Insert a line containing `ndbcluster` in the `[mysqld]` section of your `my.cnf` file.

An easy way to verify that your server is running with the `NDBCLUSTER` storage engine enabled is to issue the `SHOW ENGINES` statement in the MySQL Monitor (`mysql`). You should see the value `YES` as the `Support` value in the row for `NDBCLUSTER`. If you see `NO` in this row or if there is no such row displayed in the output, you are not running an NDB-enabled version of MySQL. If you see `DISABLED` in this row, you need to enable it in either one of the two ways just described.

To read cluster configuration data, the MySQL server requires at a minimum three pieces of information:

- The MySQL server's own cluster node ID
- The host name or IP address for the management server
- The number of the TCP/IP port on which it can connect to the management server

Node IDs can be allocated dynamically, so it is not strictly necessary to specify them explicitly.

The `mysqld` parameter `ndb-connectstring` is used to specify the connection string either on the command line when starting `mysqld` or in `my.cnf`. The connection string contains the host name or IP address where the management server can be found, as well as the TCP/IP port it uses.

In the following example, `ndb_mgmd.mysql.com` is the host where the management server resides, and the management server listens for cluster messages on port 1186:

```
shell> mysqld --ndbcluster --ndb-connectstring=ndb_mgmd.mysql.com:1186
```

See [Section 23.4.3.3, “NDB Cluster Connection Strings”](#), for more information on connection strings.

Given this information, the MySQL server can act as a full participant in the cluster. (We often refer to a `mysqld` process running in this manner as an SQL node.) It is fully aware of all cluster data nodes as well as their status, and establishes connections to all data nodes. In this case, it is able to use any data node as a transaction coordinator and to read and update node data.

You can see in the `mysql` client whether a MySQL server is connected to the cluster using `SHOW PROCESSLIST`. If the MySQL server is connected to the cluster, and you have the `PROCESS` privilege, then the first row of the output is as shown here:

```
mysql> SHOW PROCESSLIST \G
***** 1. row *****
  Id: 1
  User: system user
  Host:
  db:
  Command: Daemon
```

```
Time: 1
State: Waiting for event from ndbcluster
Info: NULL
```

Important

To participate in an NDB Cluster, the `mysqld` process must be started with *both* the options `--ndbcluster` and `--ndb-connectstring` (or their equivalents in `my.cnf`). If `mysqld` is started with only the `--ndbcluster` option, or if it is unable to contact the cluster, it is not possible to work with NDB tables, *nor is it possible to create any new tables regardless of storage engine*. The latter restriction is a safety measure intended to prevent the creation of tables having the same names as NDB tables while the SQL node is not connected to the cluster. If you wish to create tables using a different storage engine while the `mysqld` process is not participating in an NDB Cluster, you must restart the server *without* the `--ndbcluster` option.

23.6.10 NDB Cluster Disk Data Tables

NDB Cluster supports storing nonindexed columns of NDB tables on disk, rather than in RAM. Column data and logging metadata are kept in data files and undo log files, conceptualized as tablespaces and log file groups, as described in the next section—see [Section 23.6.10.1, “NDB Cluster Disk Data Objects”](#).

NDB Cluster Disk Data performance can be influenced by a number of configuration parameters. For information about these parameters and their effects, see [Disk Data Configuration Parameters](#), and [Disk Data and GCP Stop errors](#).

You should also set the `DiskDataUsingSameDisk` data node configuration parameter to `false` when using separate disks for Disk Data files.

See also [Disk Data file system parameters](#).

NDB 8.0 provides improved support when using Disk Data tables with solid-state drives, in particular those using NVMe. See the following documentation for more information:

- [Disk Data latency parameters](#)
- [Section 23.6.14.28, “The ndbinfo diskstat Table”](#)
- [Section 23.6.14.29, “The ndbinfo diskstats_1sec Table”](#)
- [Section 23.6.14.40, “The ndbinfo pgman_time_track_stats Table”](#)

23.6.10.1 NDB Cluster Disk Data Objects

NDB Cluster Disk Data storage is implemented using the following objects:

- *Tablespace*: Acts as containers for other Disk Data objects. A tablespace contains one or more data files and one or more undo log file groups.
- *Data file*: Stores column data. A data file is assigned directly to a tablespace.
- *Undo log file*: Contains undo information required for rolling back transactions. Assigned to an undo log file group.
- *log file group*: Contains one or more undo log files. Assigned to a tablespace.

Undo log files and data files are actual files in the file system of each data node; by default they are placed in `ndb_node_id_fs` in the `DataDir` specified in the NDB Cluster `config.ini` file, and where `node_id` is the data node's node ID. It is possible to place these elsewhere by specifying either an absolute or

relative path as part of the filename when creating the undo log or data file. Statements that create these files are shown later in this section.

Undo log files are used only by Disk Data tables, and are not needed or used by NDB tables that are stored in memory only.

NDB Cluster tablespaces and log file groups are not implemented as files.

Although not all Disk Data objects are implemented as files, they all share the same namespace. This means that *each Disk Data object* must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a log file group both named `ddl`.

Assuming that you have already set up an NDB Cluster with all nodes (including management and SQL nodes), the basic steps for creating an NDB Cluster table on disk are as follows:

1. Create a log file group, and assign one or more undo log files to it (an undo log file is also sometimes referred to as an *undofile*).
2. Create a tablespace; assign the log file group, as well as one or more data files, to the tablespace.
3. Create a Disk Data table that uses this tablespace for data storage.

Each of these tasks can be accomplished using SQL statements in the `mysql` client or other MySQL client application, as shown in the example that follows.

1. We create a log file group named `lg_1` using `CREATE LOGFILE GROUP`. This log file group is to be made up of two undo log files, which we name `undo_1.log` and `undo_2.log`, whose initial sizes are 16 MB and 12 MB, respectively. (The default initial size for an undo log file is 128 MB.) Optionally, you can also specify a size for the log file group's undo buffer, or permit it to assume the default value of 8 MB. In this example, we set the UNDO buffer's size at 2 MB. A log file group must be created with an undo log file; so we add `undo_1.log` to `lg_1` in this `CREATE LOGFILE GROUP` statement:

```
CREATE LOGFILE GROUP lg_1
  ADD UNDOFILE 'undo_1.log'
  INITIAL_SIZE 16M
  UNDO_BUFFER_SIZE 2M
  ENGINE NDBCLUSTER;
```

To add `undo_2.log` to the log file group, use the following `ALTER LOGFILE GROUP` statement:

```
ALTER LOGFILE GROUP lg_1
  ADD UNDOFILE 'undo_2.log'
  INITIAL_SIZE 12M
  ENGINE NDBCLUSTER;
```

Some items of note:

- The `.log` file extension used here is not required. We employ it merely to make the log files easily recognizable.
- Every `CREATE LOGFILE GROUP` and `ALTER LOGFILE GROUP` statement must include an `ENGINE` option. The only permitted values for this option are `NDBCLUSTER` and `NDB`.

Important

There can exist at most one log file group in the same NDB Cluster at any given time.

- When you add an undo log file to a log file group using `ADD UNDOFILE 'filename'`, a file with the name `filename` is created in the `ndb_node_id_fs` directory within the `DataDir` of each data

node in the cluster, where `node_id` is the node ID of the data node. Each undo log file is of the size specified in the SQL statement. For example, if an NDB Cluster has 4 data nodes, then the `ALTER LOGFILE GROUP` statement just shown creates 4 undo log files, 1 each on in the data directory of each of the 4 data nodes; each of these files is named `undo_2.log` and each file is 12 MB in size.

- `UNDO_BUFFER_SIZE` is limited by the amount of system memory available.
 - See [Section 13.1.16, “CREATE LOGFILE GROUP Statement”](#), and [Section 13.1.6, “ALTER LOGFILE GROUP Statement”](#), for more information about these statements.
2. Now we can create a tablespace—an abstract container for files used by Disk Data tables to store data. A tablespace is associated with a particular log file group; when creating a new tablespace, you must specify the log file group it uses for undo logging. You must also specify at least one data file; you can add more data files to the tablespace after the tablespace is created. It is also possible to drop data files from a tablespace (see example later in this section).

Assume that we wish to create a tablespace named `ts_1` which uses `lg_1` as its log file group. We want the tablespace to contain two data files, named `data_1.dat` and `data_2.dat`, whose initial sizes are 32 MB and 48 MB, respectively. (The default value for `INITIAL_SIZE` is 128 MB.) We can do this using two SQL statements, as shown here:

```
CREATE TABLESPACE ts_1
  ADD DATAFILE 'data_1.dat'
  USE LOGFILE GROUP lg_1
  INITIAL_SIZE 32M
  ENGINE NDBCLUSTER;

ALTER TABLESPACE ts_1
  ADD DATAFILE 'data_2.dat'
  INITIAL_SIZE 48M;
```

The `CREATE TABLESPACE` statement creates a tablespace `ts_1` with the data file `data_1.dat`, and associates `ts_1` with log file group `lg_1`. The `ALTER TABLESPACE` adds the second data file (`data_2.dat`).

Some items of note:

- As is the case with the `.log` file extension used in this example for undo log files, there is no special significance for the `.dat` file extension; it is used merely for easy recognition.
- When you add a data file to a tablespace using `ADD DATAFILE 'filename'`, a file with the name `filename` is created in the `ndb_node_id_fs` directory within the `DataDir` of each data node in the cluster, where `node_id` is the node ID of the data node. Each data file is of the size specified in the SQL statement. For example, if an NDB Cluster has 4 data nodes, then the `ALTER TABLESPACE` statement just shown creates 4 data files, 1 each in the data directory of each of the 4 data nodes; each of these files is named `data_2.dat` and each file is 48 MB in size.
- NDB reserves 4% of each tablespace for use during data node restarts. This space is not available for storing data.
- `CREATE TABLESPACE` statements must contain an `ENGINE` clause; only tables using the same storage engine as the tablespace can be created in the tablespace. For `ALTER TABLESPACE`, an `ENGINE` clause is accepted but is deprecated and subject to removal in a future release. For NDB tablespaces, the only permitted values for this option are `NDBCLUSTER` and `NDB`.
- In NDB 8.0.20 and later, allocation of extents is performed in round-robin fashion among all data files used by a given tablespace.

- For more information about the [CREATE TABLESPACE](#) and [ALTER TABLESPACE](#) statements, see [Section 13.1.21, “CREATE TABLESPACE Statement”](#), and [Section 13.1.10, “ALTER TABLESPACE Statement”](#).
3. Now it is possible to create a table whose unindexed columns are stored on disk using files in tablespace `ts_1`:

```
CREATE TABLE dt_1 (
  member_id INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
  last_name VARCHAR(50) NOT NULL,
  first_name VARCHAR(50) NOT NULL,
  dob DATE NOT NULL,
  joined DATE NOT NULL,
  INDEX(last_name, first_name)
)
TABLESPACE ts_1 STORAGE DISK
ENGINE NDBCLUSTER;
```

`TABLESPACE ts_1 STORAGE DISK` tells the NDB storage engine to use tablespace `ts_1` for data storage on disk.

Once table `ts_1` has been created as shown, you can perform `INSERT`, `SELECT`, `UPDATE`, and `DELETE` statements on it just as you would with any other MySQL table.

It is also possible to specify whether an individual column is stored on disk or in memory by using a `STORAGE` clause as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement. `STORAGE DISK` causes the column to be stored on disk, and `STORAGE MEMORY` causes in-memory storage to be used. See [Section 13.1.20, “CREATE TABLE Statement”](#), for more information.

You can obtain information about the NDB disk data files and undo log files just created by querying the `FILES` table in the `INFORMATION_SCHEMA` database, as shown here:

```
mysql> SELECT
      FILE_NAME AS File, FILE_TYPE AS Type,
      TABLESPACE_NAME AS Tablespace, TABLE_NAME AS Name,
      LOGFILE_GROUP_NAME AS 'File group',
      FREE_EXTENTS AS Free, TOTAL_EXTENTS AS Total
      FROM INFORMATION_SCHEMA.FILES
      WHERE ENGINE='ndbcluster';
```

| File | Type | Tablespace | Name | File group | Free | Total |
|--------------|----------|------------|------|------------|------|---------|
| ./undo_1.log | UNDO LOG | lg_1 | NULL | lg_1 | 0 | 4194304 |
| ./undo_2.log | UNDO LOG | lg_1 | NULL | lg_1 | 0 | 3145728 |
| ./data_1.dat | DATAFILE | ts_1 | NULL | lg_1 | 32 | 32 |
| ./data_2.dat | DATAFILE | ts_1 | NULL | lg_1 | 48 | 48 |

```
4 rows in set (0.00 sec)
```

For more information and examples, see [Section 26.3.15, “The INFORMATION_SCHEMA FILES Table”](#).

Indexing of columns implicitly stored on disk. For table `dt_1` as defined in the example just shown, only the `dob` and `joined` columns are stored on disk. This is because there are indexes on the `id`, `last_name`, and `first_name` columns, and so data belonging to these columns is stored in RAM. Only nonindexed columns can be held on disk; indexes and indexed column data continue to be stored in memory. This tradeoff between the use of indexes and conservation of RAM is something you must keep in mind as you design Disk Data tables.

You cannot add an index to a column that has been explicitly declared `STORAGE DISK`, without first changing its storage type to `MEMORY`; any attempt to do so fails with an error. A column which *implicitly*

uses disk storage can be indexed; when this is done, the column's storage type is changed to `MEMORY` automatically. By “implicitly”, we mean a column whose storage type is not declared, but which is which inherited from the parent table. In the following `CREATE TABLE` statement (using the tablespace `ts_1` defined previously), columns `c2` and `c3` use disk storage implicitly:

```
mysql> CREATE TABLE ti (
->   c1 INT PRIMARY KEY,
->   c2 INT,
->   c3 INT,
->   c4 INT
-> )
->   STORAGE DISK
->   TABLESPACE ts_1
->   ENGINE NDBCLUSTER;
Query OK, 0 rows affected (1.31 sec)
```

Because `c2`, `c3`, and `c4` are themselves not declared with `STORAGE DISK`, it is possible to index them. Here, we add indexes to `c2` and `c3`, using, respectively, `CREATE INDEX` and `ALTER TABLE`:

```
mysql> CREATE INDEX i1 ON ti(c2);
Query OK, 0 rows affected (2.72 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql> ALTER TABLE ti ADD INDEX i2(c3);
Query OK, 0 rows affected (0.92 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

`SHOW CREATE TABLE` confirms that the indexes were added.

```
mysql> SHOW CREATE TABLE ti\G
***** 1. row *****
      Table: ti
Create Table: CREATE TABLE `ti` (
  `c1` int(11) NOT NULL,
  `c2` int(11) DEFAULT NULL,
  `c3` int(11) DEFAULT NULL,
  `c4` int(11) DEFAULT NULL,
  PRIMARY KEY (`c1`),
  KEY `i1` (`c2`),
  KEY `i2` (`c3`)
) /*!50100 TABLESPACE `ts_1` STORAGE DISK */ ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

You can see using `ndb_desc` that the indexed columns (emphasized text) now use in-memory rather than on-disk storage:

```
shell> ./ndb_desc -d test t1
-- t1 --
Version: 33554433
Fragment type: HashMapPartition
K Value: 6

NDBT_ProgramExit: 0 - OK

```

Performance note. The performance of a cluster using Disk Data storage is greatly improved if Disk Data files are kept on a separate physical disk from the data node file system. This must be done for each data node in the cluster to derive any noticeable benefit.

You can use absolute and relative file system paths with `ADD UNDOFILE` and `ADD DATAFILE`; relative paths are calculated with respect to the data node's data directory.

A log file group, a tablespace, and any Disk Data tables using these must be created in a particular order. This is also true for dropping these objects, subject to the following constraints:

- A log file group cannot be dropped as long as any tablespaces use it.
- A tablespace cannot be dropped as long as it contains any data files.
- You cannot drop any data files from a tablespace as long as there remain any tables which are using the tablespace.
- It is not possible to drop files created in association with a different tablespace other than the one with which the files were created.

For example, to drop all the objects created so far in this section, you can use the following statements:

```

mysql> DROP TABLE dt_1;

mysql> ALTER TABLESPACE ts_1
-> DROP DATAFILE 'data_2.dat'
-> ENGINE NDBCLUSTER;

mysql> ALTER TABLESPACE ts_1
-> DROP DATAFILE 'data_1.dat'
-> ENGINE NDBCLUSTER;

mysql> DROP TABLESPACE ts_1
-> ENGINE NDBCLUSTER;

mysql> DROP LOGFILE GROUP lg_1
-> ENGINE NDBCLUSTER;

```

These statements must be performed in the order shown, except that the two `ALTER TABLESPACE ... DROP DATAFILE` statements may be executed in either order.

23.6.10.2 NDB Cluster Disk Data Storage Requirements

The following items apply to Disk Data storage requirements:

- Variable-length columns of Disk Data tables take up a fixed amount of space. For each row, this is equal to the space required to store the largest possible value for that column.

For general information about calculating these values, see [Section 11.7, “Data Type Storage Requirements”](#).

You can obtain an estimate the amount of space available in data files and undo log files by querying the `INFORMATION_SCHEMA.FILES` table. For more information and examples, see [Section 26.3.15, “The INFORMATION_SCHEMA FILES Table”](#).

Note

The `OPTIMIZE TABLE` statement does not have any effect on Disk Data tables.

- In a Disk Data table, the first 256 bytes of a `TEXT` or `BLOB` column are stored in memory; only the remainder is stored on disk.
- Each row in a Disk Data table uses 8 bytes in memory to point to the data stored on disk. This means that, in some cases, converting an in-memory column to the disk-based format can actually result in greater memory usage. For example, converting a `CHAR(4)` column from memory-based to disk-based format increases the amount of `DataMemory` used per row from 4 to 8 bytes.

Important

Starting the cluster with the `--initial` option does *not* remove Disk Data files. You must remove these manually prior to performing an initial restart of the cluster.

Performance of Disk Data tables can be improved by minimizing the number of disk seeks by making sure that `DiskPageBufferMemory` is of sufficient size. You can query the `diskpagebuffer` table to help determine whether the value for this parameter needs to be increased.

23.6.11 Online Operations with ALTER TABLE in NDB Cluster

MySQL NDB Cluster 8.0 supports online table schema changes using the standard `ALTER TABLE` syntax employed by the MySQL Server (`ALGORITHM=DEFAULT | INPLACE | COPY`), and described elsewhere.

Note

Some older releases of NDB Cluster used a syntax specific to `NDB` for online `ALTER TABLE` operations. That syntax has since been removed.

Operations that add and drop indexes on variable-width columns of `NDB` tables occur online. Online operations are noncopying; that is, they do not require that indexes be re-created. They do not lock the table being altered from access by other API nodes in an NDB Cluster (but see [Limitations of NDB online operations](#), later in this section). Such operations do not require single user mode for `NDB` table alterations made in an NDB cluster with multiple API nodes; transactions can continue uninterrupted during online DDL operations.

`ALGORITHM=INPLACE` can be used to perform online `ADD COLUMN`, `ADD INDEX` (including `CREATE INDEX` statements), and `DROP INDEX` operations on `NDB` tables. Online renaming of `NDB` tables is also supported.

Previously, columns of `NDB` tables could not be renamed online; this limitation is removed in NDB 8.0.

Currently you cannot add disk-based columns to `NDB` tables online. This means that, if you wish to add an in-memory column to an `NDB` table that uses a table-level `STORAGE DISK` option, you must declare the

new column as using memory-based storage explicitly. For example—assuming that you have already created tablespace `ts1`—suppose that you create table `t1` as follows:

```
mysql> CREATE TABLE t1 (
>   c1 INT NOT NULL PRIMARY KEY,
>   c2 VARCHAR(30)
> )
> TABLESPACE ts1 STORAGE DISK
> ENGINE NDB;
Query OK, 0 rows affected (1.73 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

You can add a new in-memory column to this table online as shown here:

```
mysql> ALTER TABLE t1
>   ADD COLUMN c3 INT COLUMN_FORMAT DYNAMIC STORAGE MEMORY,
>   ALGORITHM=INPLACE;
Query OK, 0 rows affected (1.25 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

This statement fails if the `STORAGE MEMORY` option is omitted:

```
mysql> ALTER TABLE t1
>   ADD COLUMN c4 INT COLUMN_FORMAT DYNAMIC,
>   ALGORITHM=INPLACE;
ERROR 1846 (0A000): ALGORITHM=INPLACE is not supported. Reason:
Adding column(s) or add/reorganize partition not supported online. Try
ALGORITHM=COPY.
```

If you omit the `COLUMN_FORMAT DYNAMIC` option, the dynamic column format is employed automatically, but a warning is issued, as shown here:

```
mysql> ALTER ONLINE TABLE t1 ADD COLUMN c4 INT STORAGE MEMORY;
Query OK, 0 rows affected, 1 warning (1.17 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 1478
Message: DYNAMIC column c4 with STORAGE DISK is not supported, column will
become FIXED

mysql> SHOW CREATE TABLE t1\G
***** 1. row *****
Table: t1
Create Table: CREATE TABLE `t1` (
  `c1` int(11) NOT NULL,
  `c2` varchar(30) DEFAULT NULL,
  `c3` int(11) /*!50606 STORAGE MEMORY */ /*!50606 COLUMN_FORMAT DYNAMIC */ DEFAULT NULL,
  `c4` int(11) /*!50606 STORAGE MEMORY */ DEFAULT NULL,
  PRIMARY KEY (`c1`)
) /*!50606 TABLESPACE ts_1 STORAGE DISK */ ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.03 sec)
```

Note

The `STORAGE` and `COLUMN_FORMAT` keywords are supported only in NDB Cluster; in any other version of MySQL, attempting to use either of these keywords in a `CREATE TABLE` or `ALTER TABLE` statement results in an error.

It is also possible to use the statement `ALTER TABLE ... REORGANIZE PARTITION, ALGORITHM=INPLACE` with no `partition_names INTO (partition_definitions)` option on NDB tables. This can be used to redistribute NDB Cluster data among new data nodes that have been added

to the cluster online. This does *not* perform any defragmentation, which requires an `OPTIMIZE TABLE` or null `ALTER TABLE` statement. For more information, see [Section 23.6.7, “Adding NDB Cluster Data Nodes Online”](#).

Limitations of NDB online operations

Online `DROP COLUMN` operations are not supported.

Online `ALTER TABLE`, `CREATE INDEX`, or `DROP INDEX` statements that add columns or add or drop indexes are subject to the following limitations:

- A given online `ALTER TABLE` can use only one of `ADD COLUMN`, `ADD INDEX`, or `DROP INDEX`. One or more columns can be added online in a single statement; only one index may be created or dropped online in a single statement.
- The table being altered is not locked with respect to API nodes other than the one on which an online `ALTER TABLE ADD COLUMN`, `ADD INDEX`, or `DROP INDEX` operation (or `CREATE INDEX` or `DROP INDEX` statement) is run. However, the table is locked against any other operations originating on the *same* API node while the online operation is being executed.
- The table to be altered must have an explicit primary key; the hidden primary key created by the NDB storage engine is not sufficient for this purpose.
- The storage engine used by the table cannot be changed online.
- The tablespace used by the table cannot be changed online. Beginning with NDB 8.0.21, a statement such as `ALTER TABLE ndb_table ... ALGORITHM=INPLACE, TABLESPACE=new_tablespace` is specifically disallowed. (Bug #99269, Bug #31180526)
- When used with NDB Cluster Disk Data tables, it is not possible to change the storage type (`DISK` or `MEMORY`) of a column online. This means, that when you add or drop an index in such a way that the operation would be performed online, and you want the storage type of the column or columns to be changed, you must use `ALGORITHM=COPY` in the statement that adds or drops the index.

Columns to be added online cannot use the `BLOB` or `TEXT` type, and must meet the following criteria:

- The columns must be dynamic; that is, it must be possible to create them using `COLUMN_FORMAT DYNAMIC`. If you omit the `COLUMN_FORMAT DYNAMIC` option, the dynamic column format is employed automatically.
- The columns must permit `NULL` values and not have any explicit default value other than `NULL`. Columns added online are automatically created as `DEFAULT NULL`, as can be seen here:

```
mysql> CREATE TABLE t2 (
>     c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY
> ) ENGINE=NDB;
Query OK, 0 rows affected (1.44 sec)

mysql> ALTER TABLE t2
>     ADD COLUMN c2 INT,
>     ADD COLUMN c3 INT,
>     ALGORITHM=INPLACE;
Query OK, 0 rows affected, 2 warnings (0.93 sec)

mysql> SHOW CREATE TABLE t1\G
***** 1. row *****
Table: t1
Create Table: CREATE TABLE `t2` (
  `c1` int(11) NOT NULL AUTO_INCREMENT,
  `c2` int(11) DEFAULT NULL,
  `c3` int(11) DEFAULT NULL,
```

```
PRIMARY KEY (`c1`)
) ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

- The columns must be added following any existing columns. If you attempt to add a column online before any existing columns or using the `FIRST` keyword, the statement fails with an error.
- Existing table columns cannot be reordered online.

For online `ALTER TABLE` operations on `NDB` tables, fixed-format columns are converted to dynamic when they are added online, or when indexes are created or dropped online, as shown here (repeating the `CREATE TABLE` and `ALTER TABLE` statements just shown for the sake of clarity):

```
mysql> CREATE TABLE t2 (
>   c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY
> ) ENGINE=NDB;
Query OK, 0 rows affected (1.44 sec)

mysql> ALTER TABLE t2
>   ADD COLUMN c2 INT,
>   ADD COLUMN c3 INT,
>   ALGORITHM=INPLACE;
Query OK, 0 rows affected, 2 warnings (0.93 sec)

mysql> SHOW WARNINGS;
***** 1. row *****
Level: Warning
Code: 1478
Message: Converted FIXED field 'c2' to DYNAMIC to enable online ADD COLUMN
***** 2. row *****
Level: Warning
Code: 1478
Message: Converted FIXED field 'c3' to DYNAMIC to enable online ADD COLUMN
2 rows in set (0.00 sec)
```

Only the column or columns to be added online must be dynamic. Existing columns need not be; this includes the table's primary key, which may also be `FIXED`, as shown here:

```
mysql> CREATE TABLE t3 (
>   c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY COLUMN_FORMAT FIXED
> ) ENGINE=NDB;
Query OK, 0 rows affected (2.10 sec)

mysql> ALTER TABLE t3 ADD COLUMN c2 INT, ALGORITHM=INPLACE;
Query OK, 0 rows affected, 1 warning (0.78 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql> SHOW WARNINGS;
***** 1. row *****
Level: Warning
Code: 1478
Message: Converted FIXED field 'c2' to DYNAMIC to enable online ADD COLUMN
1 row in set (0.00 sec)
```

Columns are not converted from `FIXED` to `DYNAMIC` column format by renaming operations. For more information about `COLUMN_FORMAT`, see [Section 13.1.20, "CREATE TABLE Statement"](#).

The `KEY`, `CONSTRAINT`, and `IGNORE` keywords are supported in `ALTER TABLE` statements using `ALGORITHM=INPLACE`.

Setting `MAX_ROWS` to 0 using an online `ALTER TABLE` statement is disallowed. You must use a copying `ALTER TABLE` to perform this operation. (Bug #21960004)

23.6.12 Distributed MySQL Privileges with NDB_STORED_USER

NDB 8.0 introduces a new mechanism for sharing and synchronizing users, roles, and privileges between SQL nodes connected to an NDB Cluster. This can be enabled by granting the `NDB_STORED_USER` privilege. See the description of the privilege for usage information.

`NDB_STORED_USER` is printed in the output of `SHOW GRANTS` as with any other privilege. To verify that privileges are shared, use the `ndb_select_all` utility supplied with the NDB Cluster distribution, as shown here (some output wrapped to preserve formatting):

```
shell> ndb_select_all -d mysql ndb_sql_metadata
type  name      seq  note  sql_ddl_text
11    "'jon'@'localhost'"  0    4    "CREATE USER 'jon'@'localhost'
IDENTIFIED WITH 'caching_sha2_password' AS
'$A$005${B};3!?!tI\".EFy\ZA5K5DQHrWiBvuRNYTIme00YeBlPpZotFRPjvTYzTA5b0' REQUIRE
NONE PASSWORD EXPIRE DEFAULT ACCOUNT UNLOCK PASSWORD HISTORY DEFAULT PASSWORD
REUSE INTERVAL DEFAULT PASSWORD REQUIRE CURRENT DEFAULT"
12    "'jon'@'localhost'"  0    [NULL] "GRANT USAGE ON *.* TO `jon`@`localhost`"
12    "'jon'@'localhost'"  3    [NULL] "GRANT ALL PRIVILEGES ON `test`.* TO `jon`@`localhost`"
12    "'jon'@'localhost'"  2    [NULL] "GRANT ALL PRIVILEGES ON `mydb`.* TO `jon`@`localhost`"
12    "'jon'@'localhost'"  1    [NULL] "GRANT NDB_STORED_USER ON *.* TO `jon`@`localhost`"
5 rows returned
```

`ndb_sql_metadata` is a special NDB table that is not visible using the `mysql` or other MySQL client.

A statement granting the `NDB_STORED_USER` privilege, such as `GRANT NDB_STORED_USER ON *.* TO 'cluster_app_user'@'localhost'`, works by directing NDB to create a snapshot using the queries `SHOW CREATE USER cluster_app_user@localhost` and `SHOW GRANTS FOR cluster_app_user@localhost`, then storing the results in `ndb_sql_metadata`. Any other SQL nodes are then requested to read and apply the snapshot. Whenever a MySQL server starts up and joins the cluster as an SQL node it executes these stored `CREATE USER` and `GRANT` statements as part of the cluster schema synchronization process.

Whenever an SQL statement is executed on an SQL node other than the one where it originated, the statement is run in a utility thread of the `NDBCLUSTER` storage engine; this is done within a security environment equivalent to that of the MySQL replication replica applier thread.

Beginning with NDB 8.0.27, an SQL node performing a change to user privileges takes a global lock before doing so, which prevents deadlocks by concurrent ACL operations on different SQL nodes. Prior to NDB 8.0.27, changes to users with `NDB_STORED_USER` were distributed completely asynchronously, without any locks being taken.

You should keep in mind that, because distributed schema change operations are performed synchronously, the next distributed schema change following a change to any distributed user or users serves as a synchronization point. Any pending user changes run to completion before the schema change distribution can begin; after this the schema change itself runs synchronously. For example, if a `DROP DATABASE` statement follows a `DROP USER` of a distributed user, the drop of the database cannot take place until the drop of the user has completed on all SQL nodes.

In the event that multiple `GRANT`, `REVOKE`, or other user administration statements from multiple SQL nodes cause privileges for a given user to diverge on different SQL nodes, you can fix this problem by issuing `GRANT NDB_STORED_USER` for this user on an SQL node where the privileges are known to be correct; this causes a new snapshot of the privileges to be taken and synchronized to the other SQL nodes.

NDB Cluster 8.0 does not support distribution of MySQL users and privileges across SQL nodes in an NDB Cluster by converting the MySQL privilege tables to use the NDB storage engine, as implemented in NDB 7.6 and earlier releases (see [Distributed Privileges Using Shared Grant Tables](#)). For information about the impact of this change on upgrades to NDB 8.0 from a previous release, see [Section 23.3.7, "Upgrading and Downgrading NDB Cluster"](#).

23.6.13 NDB API Statistics Counters and Variables

A number of types of statistical counters relating to actions performed by or affecting `Ndb` objects are available. Such actions include starting and closing (or aborting) transactions; primary key and unique key operations; table, range, and pruned scans; threads blocked while waiting for the completion of various operations; and data and events sent and received by `NDBCLUSTER`. The counters are incremented inside the NDB kernel whenever NDB API calls are made or data is sent to or received by the data nodes. `mysqld` exposes these counters as system status variables; their values can be read in the output of `SHOW STATUS`, or by querying the Performance Schema `session_status` or `global_status` table. By comparing the values before and after statements operating on NDB tables, you can observe the corresponding actions taken on the API level, and thus the cost of performing the statement.

You can list all of these status variables using the following `SHOW STATUS` statement:

```
mysql> SHOW STATUS LIKE 'ndb_api%';
```

| Variable_name | Value |
|--|----------|
| Ndb_api_wait_exec_complete_count_session | 0 |
| Ndb_api_wait_scan_result_count_session | 0 |
| Ndb_api_wait_meta_request_count_session | 0 |
| Ndb_api_wait_nanos_count_session | 0 |
| Ndb_api_bytes_sent_count_session | 0 |
| Ndb_api_bytes_received_count_session | 0 |
| Ndb_api_trans_start_count_session | 0 |
| Ndb_api_trans_commit_count_session | 0 |
| Ndb_api_trans_abort_count_session | 0 |
| Ndb_api_trans_close_count_session | 0 |
| Ndb_api_pk_op_count_session | 0 |
| Ndb_api_uk_op_count_session | 0 |
| Ndb_api_table_scan_count_session | 0 |
| Ndb_api_range_scan_count_session | 0 |
| Ndb_api_pruned_scan_count_session | 0 |
| Ndb_api_scan_batch_count_session | 0 |
| Ndb_api_read_row_count_session | 0 |
| Ndb_api_trans_local_read_row_count_session | 0 |
| Ndb_api_event_data_count_injector | 0 |
| Ndb_api_event_nodata_count_injector | 0 |
| Ndb_api_event_bytes_count_injector | 0 |
| Ndb_api_wait_exec_complete_count_slave | 0 |
| Ndb_api_wait_scan_result_count_slave | 0 |
| Ndb_api_wait_meta_request_count_slave | 0 |
| Ndb_api_wait_nanos_count_slave | 0 |
| Ndb_api_bytes_sent_count_slave | 0 |
| Ndb_api_bytes_received_count_slave | 0 |
| Ndb_api_trans_start_count_slave | 0 |
| Ndb_api_trans_commit_count_slave | 0 |
| Ndb_api_trans_abort_count_slave | 0 |
| Ndb_api_trans_close_count_slave | 0 |
| Ndb_api_pk_op_count_slave | 0 |

-----+-----+-----
60 rows in set (0.00 sec)

Each `Ndb` object has its own counters. NDB API applications can read the values of the counters for use in optimization or monitoring. For multithreaded clients which use more than one `Ndb` object concurrently, it is also possible to obtain a summed view of counters from all `Ndb` objects belonging to a given `Ndb_cluster_connection`.

Four sets of these counters are exposed. One set applies to the current session only; the other 3 are global. *This is in spite of the fact that their values can be obtained as either session or global status variables in the `mysql` client.* This means that specifying the `SESSION` or `GLOBAL` keyword with `SHOW STATUS` has no effect on the values reported for NDB API statistics status variables, and the value for each of these variables is the same whether the value is obtained from the equivalent column of the `session_status` or the `global_status` table.

- *Session counters (session specific)*

Session counters relate to the `Ndb` objects in use by (only) the current session. Use of such objects by other MySQL clients does not influence these counts.

In order to minimize confusion with standard MySQL session variables, we refer to the variables that correspond to these NDB API session counters as “`_session` variables”, with a leading underscore.

- *Replica counters (global)*

This set of counters relates to the `Ndb` objects used by the replica SQL thread, if any. If this `mysqld` does not act as a replica, or does not use NDB tables, then all of these counts are 0.

We refer to the related status variables as “`_slave` variables” (with a leading underscore).

- *Injector counters (global)*

Injector counters relate to the `Ndb` object used to listen to cluster events by the binary log injector thread. Even when not writing a binary log, `mysqld` processes attached to an NDB Cluster continue to listen for some events, such as schema changes.

We refer to the status variables that correspond to NDB API injector counters as “`_injector` variables” (with a leading underscore).

- *Server (Global) counters (global)*

This set of counters relates to all `Ndb` objects currently used by this `mysqld`. This includes all MySQL client applications, the replica SQL thread (if any), the binary log injector, and the `NDB` utility thread.

We refer to the status variables that correspond to these counters as “global variables” or “`mysqld`-level variables”.

You can obtain values for a particular set of variables by additionally filtering for the substring `session`, `slave`, or `injector` in the variable name (along with the common prefix `Ndb_api`). For `_session` variables, this can be done as shown here:

```
mysql> SHOW STATUS LIKE 'ndb_api%session';
```

| Variable_name | Value |
|--|---------|
| Ndb_api_wait_exec_complete_count_session | 2 |
| Ndb_api_wait_scan_result_count_session | 0 |
| Ndb_api_wait_meta_request_count_session | 1 |
| Ndb_api_wait_nanos_count_session | 8144375 |
| Ndb_api_bytes_sent_count_session | 68 |
| Ndb_api_bytes_received_count_session | 84 |
| Ndb_api_trans_start_count_session | 1 |
| Ndb_api_trans_commit_count_session | 1 |
| Ndb_api_trans_abort_count_session | 0 |
| Ndb_api_trans_close_count_session | 1 |
| Ndb_api_pk_op_count_session | 1 |
| Ndb_api_uk_op_count_session | 0 |
| Ndb_api_table_scan_count_session | 0 |
| Ndb_api_range_scan_count_session | 0 |
| Ndb_api_pruned_scan_count_session | 0 |
| Ndb_api_scan_batch_count_session | 0 |
| Ndb_api_read_row_count_session | 1 |
| Ndb_api_trans_local_read_row_count_session | 1 |

```
18 rows in set (0.50 sec)
```

To obtain a listing of the NDB API `mysqld`-level status variables, filter for variable names beginning with `ndb_api` and ending in `_count`, like this:

```
mysql> SELECT * FROM performance_schema.session_status
-> WHERE VARIABLE_NAME LIKE 'ndb_api%count';
```

| VARIABLE_NAME | VARIABLE_VALUE |
|------------------------------------|----------------|
| NDB_API_WAIT_EXEC_COMPLETE_COUNT | 4 |
| NDB_API_WAIT_SCAN_RESULT_COUNT | 3 |
| NDB_API_WAIT_META_REQUEST_COUNT | 28 |
| NDB_API_WAIT_NANOS_COUNT | 53756398 |
| NDB_API_BYTES_SENT_COUNT | 1060 |
| NDB_API_BYTES_RECEIVED_COUNT | 9724 |
| NDB_API_TRANS_START_COUNT | 3 |
| NDB_API_TRANS_COMMIT_COUNT | 2 |
| NDB_API_TRANS_ABORT_COUNT | 0 |
| NDB_API_TRANS_CLOSE_COUNT | 3 |
| NDB_API_PK_OP_COUNT | 2 |
| NDB_API_UK_OP_COUNT | 0 |
| NDB_API_TABLE_SCAN_COUNT | 1 |
| NDB_API_RANGE_SCAN_COUNT | 0 |
| NDB_API_PRUNED_SCAN_COUNT | 0 |
| NDB_API_SCAN_BATCH_COUNT | 0 |
| NDB_API_READ_ROW_COUNT | 2 |
| NDB_API_TRANS_LOCAL_READ_ROW_COUNT | 2 |
| NDB_API_EVENT_DATA_COUNT | 0 |
| NDB_API_EVENT_NONDATA_COUNT | 0 |
| NDB_API_EVENT_BYTES_COUNT | 0 |

```
+-----+
21 rows in set (0.09 sec)
```

Not all counters are reflected in all 4 sets of status variables. For the event counters `DataEventsRecvdCount`, `NondataEventsRecvdCount`, and `EventBytesRecvdCount`, only `_injector` and `mysql`-level NDB API status variables are available:

```
mysql> SHOW STATUS LIKE 'ndb_api%event%';
+-----+
| Variable_name          | Value |
+-----+
| Ndb_api_event_data_count_injector | 0     |
| Ndb_api_event_nondata_count_injector | 0     |
| Ndb_api_event_bytes_count_injector | 0     |
| Ndb_api_event_data_count          | 0     |
| Ndb_api_event_nondata_count       | 0     |
| Ndb_api_event_bytes_count         | 0     |
+-----+
6 rows in set (0.00 sec)
```

`_injector` status variables are not implemented for any other NDB API counters, as shown here:

```
mysql> SHOW STATUS LIKE 'ndb_api%injector%';
+-----+
| Variable_name          | Value |
+-----+
| Ndb_api_event_data_count_injector | 0     |
| Ndb_api_event_nondata_count_injector | 0     |
| Ndb_api_event_bytes_count_injector | 0     |
+-----+
3 rows in set (0.00 sec)
```

The names of the status variables can easily be associated with the names of the corresponding counters. Each NDB API statistics counter is listed in the following table with a description as well as the names of any MySQL server status variables corresponding to this counter.

Table 23.66 NDB API statistics counters

| Counter Name | Description | Status Variables (by statistic type): |
|------------------------------------|--|---|
| | | <ul style="list-style-type: none"> • Session • Slave (replica) • Injector • Server |
| <code>WaitExecCompleteCount</code> | Number of times thread has been blocked while waiting for execution of an operation to complete. Includes all <code>execute()</code> calls as well as implicit executes for blob operations and auto-increment not visible to clients. | <ul style="list-style-type: none"> • <code>Ndb_api_wait_exec_complete_count_...</code> • <code>Ndb_api_wait_exec_complete_count_...</code> • [none] • <code>Ndb_api_wait_exec_complete_count</code> |
| <code>WaitScanResultCount</code> | Number of times thread has been blocked while waiting for a scan-based signal, such waiting for | <ul style="list-style-type: none"> • <code>Ndb_api_wait_scan_result_count_se...</code> • <code>Ndb_api_wait_scan_result_count_sl...</code> |

| Counter Name | Description | Status Variables (by statistic type): |
|----------------------|--|---|
| | additional results, or for a scan to close. | <ul style="list-style-type: none"> • [none] |
| WaitMetaRequestCount | Number of times thread has been blocked waiting for a metadata-based signal; this can occur when waiting for a DDL operation or for an epoch to be started (or ended). | <ul style="list-style-type: none"> • Ndb_api_wait_scan_result_count • Ndb_api_wait_meta_request_count • Ndb_api_wait_meta_request_count • [none] • Ndb_api_wait_meta_request_count |
| WaitNanosCount | Total time (in nanoseconds) spent waiting for some type of signal from the data nodes. | <ul style="list-style-type: none"> • Ndb_api_wait_nanos_count_session • Ndb_api_wait_nanos_count_slave • [none] • Ndb_api_wait_nanos_count |
| BytesSentCount | Amount of data (in bytes) sent to the data nodes | <ul style="list-style-type: none"> • Ndb_api_bytes_sent_count_session • Ndb_api_bytes_sent_count_slave • [none] • Ndb_api_bytes_sent_count |
| BytesRecvdCount | Amount of data (in bytes) received from the data nodes | <ul style="list-style-type: none"> • Ndb_api_bytes_received_count_session • Ndb_api_bytes_received_count_slave • [none] • Ndb_api_bytes_received_count |
| TransStartCount | Number of transactions started. | <ul style="list-style-type: none"> • Ndb_api_trans_start_count_session • Ndb_api_trans_start_count_slave • [none] • Ndb_api_trans_start_count |
| TransCommitCount | Number of transactions committed. | <ul style="list-style-type: none"> • Ndb_api_trans_commit_count_session • Ndb_api_trans_commit_count_slave • [none] • Ndb_api_trans_commit_count |

| Counter Name | Description | Status Variables (by statistic type): |
|-----------------|---|---|
| TransAbortCount | Number of transactions aborted. | <ul style="list-style-type: none"> • Session • Slave (replica) • Injector • Server |
| TransCloseCount | Number of transactions aborted. (This value may be greater than the sum of TransCommitCount and TransAbortCount.) | <ul style="list-style-type: none"> • Ndb_api_trans_abort_count_session • Ndb_api_trans_abort_count_slave • [none] • Ndb_api_trans_abort_count |
| PkOpCount | Number of operations based on or using primary keys. This count includes blob-part table operations, implicit unlocking operations, and auto-increment operations, as well as primary key operations normally visible to MySQL clients. | <ul style="list-style-type: none"> • Ndb_api_pk_op_count_session • Ndb_api_pk_op_count_slave • [none] • Ndb_api_pk_op_count |
| UkOpCount | Number of operations based on or using unique keys. | <ul style="list-style-type: none"> • Ndb_api_uk_op_count_session • Ndb_api_uk_op_count_slave • [none] • Ndb_api_uk_op_count |
| TableScanCount | Number of table scans that have been started. This includes scans of internal tables. | <ul style="list-style-type: none"> • Ndb_api_table_scan_count_session • Ndb_api_table_scan_count_slave • [none] • Ndb_api_table_scan_count |
| RangeScanCount | Number of range scans that have been started. | <ul style="list-style-type: none"> • Ndb_api_range_scan_count_session • Ndb_api_range_scan_count_slave • [none] • Ndb_api_range_scan_count |

| Counter Name | Description | Status Variables (by statistic type): |
|-------------------------|---|--|
| PrunedScanCount | Number of scans that have been pruned to a single partition. | <ul style="list-style-type: none"> • Session • Slave (replica) • Injector • Server |
| ScanBatchCount | Number of batches of rows received. (A <i>batch</i> in this context is a set of scan results from a single fragment.) | <ul style="list-style-type: none"> • Ndb_api_pruned_scan_count_session • Ndb_api_pruned_scan_count_slave • [none] • Ndb_api_pruned_scan_count |
| ReadRowCount | Total number of rows that have been read. Includes rows read using primary key, unique key, and scan operations. | <ul style="list-style-type: none"> • Ndb_api_scan_batch_count_session • Ndb_api_scan_batch_count_slave • [none] • Ndb_api_scan_batch_count |
| TransLocalReadRowCount | Number of rows read from the data same node on which the transaction was being run. | <ul style="list-style-type: none"> • Ndb_api_read_row_count_session • Ndb_api_read_row_count_slave • [none] • Ndb_api_read_row_count |
| DataEventsRecvdCount | Number of row change events received. | <ul style="list-style-type: none"> • Ndb_api_trans_local_read_row_count • Ndb_api_trans_local_read_row_count • [none] • Ndb_api_trans_local_read_row_count |
| NondataEventsRecvdCount | Number of events received, other than row change events. | <ul style="list-style-type: none"> • [none] • [none] • Ndb_api_event_data_count_injector • Ndb_api_event_data_count |
| EventBytesRecvdCount | Number of bytes of events received. | <ul style="list-style-type: none"> • [none] • [none] • Ndb_api_event_nondata_count_injector • Ndb_api_event_nondata_count |

| Counter Name | Description | Status Variables (by statistic type): |
|--------------|-------------|---|
| | | <ul style="list-style-type: none"> • Session • Slave (replica) • Injector • Server |
| | | <ul style="list-style-type: none"> • <code>Ndb_api_event_bytes_count_injector</code> • <code>Ndb_api_event_bytes_count</code> |

To see all counts of committed transactions—that is, all `TransCommitCount` counter status variables—you can filter the results of `SHOW STATUS` for the substring `trans_commit_count`, like this:

```
mysql> SHOW STATUS LIKE '%trans_commit_count%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ndb_api_trans_commit_count_session | 1 |
| Ndb_api_trans_commit_count_slave | 0 |
| Ndb_api_trans_commit_count | 2 |
+-----+-----+
3 rows in set (0.00 sec)
```

From this you can determine that 1 transaction has been committed in the current `mysql` client session, and 2 transactions have been committed on this `mysqld` since it was last restarted.

You can see how various NDB API counters are incremented by a given SQL statement by comparing the values of the corresponding `_session` status variables immediately before and after performing the statement. In this example, after getting the initial values from `SHOW STATUS`, we create in the `test` database an NDB table, named `t`, that has a single column:

```
mysql> SHOW STATUS LIKE 'ndb_api%session%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ndb_api_wait_exec_complete_count_session | 2 |
| Ndb_api_wait_scan_result_count_session | 0 |
| Ndb_api_wait_meta_request_count_session | 3 |
| Ndb_api_wait_nanos_count_session | 820705 |
| Ndb_api_bytes_sent_count_session | 132 |
| Ndb_api_bytes_received_count_session | 372 |
| Ndb_api_trans_start_count_session | 1 |
| Ndb_api_trans_commit_count_session | 1 |
| Ndb_api_trans_abort_count_session | 0 |
| Ndb_api_trans_close_count_session | 1 |
| Ndb_api_pk_op_count_session | 1 |
| Ndb_api_uk_op_count_session | 0 |
| Ndb_api_table_scan_count_session | 0 |
| Ndb_api_range_scan_count_session | 0 |
| Ndb_api_pruned_scan_count_session | 0 |
| Ndb_api_scan_batch_count_session | 0 |
| Ndb_api_read_row_count_session | 1 |
| Ndb_api_trans_local_read_row_count_session | 1 |
+-----+-----+
18 rows in set (0.00 sec)

mysql> USE test;
Database changed
```

```
mysql> CREATE TABLE t (c INT) ENGINE NDBCLUSTER;
Query OK, 0 rows affected (0.85 sec)
```

Now you can execute a new `SHOW STATUS` statement and observe the changes, as shown here (with the changed rows highlighted in the output):

```
mysql> SHOW STATUS LIKE 'ndb_api%session%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ndb_api_wait_exec_complete_count_session | 8 |
| Ndb_api_wait_scan_result_count_session | 0 |
| Ndb_api_wait_meta_request_count_session | 17 |
| Ndb_api_wait_nanos_count_session | 706871709 |
| Ndb_api_bytes_sent_count_session | 2376 |
| Ndb_api_bytes_received_count_session | 3844 |
| Ndb_api_trans_start_count_session | 4 |
| Ndb_api_trans_commit_count_session | 4 |
| Ndb_api_trans_abort_count_session | 0 |
| Ndb_api_trans_close_count_session | 4 |
| Ndb_api_pk_op_count_session | 6 |
| Ndb_api_uk_op_count_session | 0 |
| Ndb_api_table_scan_count_session | 0 |
| Ndb_api_range_scan_count_session | 0 |
| Ndb_api_pruned_scan_count_session | 0 |
| Ndb_api_scan_batch_count_session | 0 |
| Ndb_api_read_row_count_session | 2 |
| Ndb_api_trans_local_read_row_count_session | 1 |
+-----+-----+
18 rows in set (0.00 sec)
```

Similarly, you can see the changes in the NDB API statistics counters caused by inserting a row into `t`: Insert the row, then run the same `SHOW STATUS` statement used in the previous example, as shown here:

```
mysql> INSERT INTO t VALUES (100);
Query OK, 1 row affected (0.00 sec)

mysql> SHOW STATUS LIKE 'ndb_api%session%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ndb_api_wait_exec_complete_count_session | 11 |
| Ndb_api_wait_scan_result_count_session | 6 |
| Ndb_api_wait_meta_request_count_session | 20 |
| Ndb_api_wait_nanos_count_session | 707370418 |
| Ndb_api_bytes_sent_count_session | 2724 |
| Ndb_api_bytes_received_count_session | 4116 |
| Ndb_api_trans_start_count_session | 7 |
| Ndb_api_trans_commit_count_session | 6 |
| Ndb_api_trans_abort_count_session | 0 |
| Ndb_api_trans_close_count_session | 7 |
| Ndb_api_pk_op_count_session | 8 |
| Ndb_api_uk_op_count_session | 0 |
| Ndb_api_table_scan_count_session | 1 |
| Ndb_api_range_scan_count_session | 0 |
| Ndb_api_pruned_scan_count_session | 0 |
| Ndb_api_scan_batch_count_session | 0 |
| Ndb_api_read_row_count_session | 3 |
| Ndb_api_trans_local_read_row_count_session | 2 |
+-----+-----+
18 rows in set (0.00 sec)
```

We can make a number of observations from these results:

- Although we created `t` with no explicit primary key, 5 primary key operations were performed in doing so (the difference in the “before” and “after” values of `Ndb_api_pk_op_count_session`, or 6 minus 1).

This reflects the creation of the hidden primary key that is a feature of all tables using the [NDB](#) storage engine.

- By comparing successive values for `Ndb_api_wait_nanos_count_session`, we can see that the NDB API operations implementing the `CREATE TABLE` statement waited much longer ($706871709 - 820705 = 706051004$ nanoseconds, or approximately 0.7 second) for responses from the data nodes than those executed by the `INSERT` ($707370418 - 706871709 = 498709$ ns or roughly .0005 second). The execution times reported for these statements in the `mysql` client correlate roughly with these figures.

On platforms without sufficient (nanosecond) time resolution, small changes in the value of the `WaitNanosCount` NDB API counter due to SQL statements that execute very quickly may not always be visible in the values of `Ndb_api_wait_nanos_count_session`, `Ndb_api_wait_nanos_count_slave`, or `Ndb_api_wait_nanos_count`.

- The `INSERT` statement incremented both the `ReadRowCount` and `TransLocalReadRowCount` NDB API statistics counters, as reflected by the increased values of `Ndb_api_read_row_count_session` and `Ndb_api_trans_local_read_row_count_session`.

23.6.14 ndbinfo: The NDB Cluster Information Database

`ndbinfo` is a database containing information specific to NDB Cluster.

This database contains a number of tables, each providing a different sort of data about NDB Cluster node status, resource usage, and operations. You can find more detailed information about each of these tables in the next several sections.

`ndbinfo` is included with NDB Cluster support in the MySQL Server; no special compilation or configuration steps are required; the tables are created by the MySQL Server when it connects to the cluster. You can verify that `ndbinfo` support is active in a given MySQL Server instance using `SHOW PLUGINS`; if `ndbinfo` support is enabled, you should see a row containing `ndbinfo` in the `Name` column and `ACTIVE` in the `Status` column, as shown here (emphasized text):

```
mysql> SHOW PLUGINS;
```

| Name | Status | Type | Library | License |

+-----+-----+-----+-----+-----+
46 rows in set (0.00 sec)

```

You can also do this by checking the output of `SHOW ENGINES` for a line including `ndbinfo` in the `Engine` column and `YES` in the `Support` column, as shown here (emphasized text):

```

mysql> SHOW ENGINES\G
***** 1. row *****
  Engine: ndbcluster
  Support: YES
  Comment: Clustered, fault-tolerant tables
Transactions: YES
  XA: NO

    Savepoints: NO
10 rows in set (0.00 sec)

```

If `ndbinfo` support is enabled, then you can access `ndbinfo` using SQL statements in `mysql` or another MySQL client. For example, you can see `ndbinfo` listed in the output of `SHOW DATABASES`, as shown here (emphasized text):

```

mysql> SHOW DATABASES;
+-----+
| Database |
+-----+
| information_schema |
| mysql |
| ndbinfo |
| performance_schema |
| sys |
+-----+
5 rows in set (0.04 sec)

```

If the `mysqld` process was not started with the `--ndbcluster` option, `ndbinfo` is not available and is not displayed by `SHOW DATABASES`. If `mysqld` was formerly connected to an NDB Cluster but the cluster becomes unavailable (due to events such as cluster shutdown, loss of network connectivity, and so forth), `ndbinfo` and its tables remain visible, but an attempt to access any tables (other than `blocks` or `config_params`) fails with `Got error 157 'Connection to NDB failed' from NDBINFO`.

With the exception of the `blocks` and `config_params` tables, what we refer to as `ndbinfo` “tables” are actually views generated from internal NDB tables not normally visible to the MySQL Server.

All `ndbinfo` tables are read-only, and are generated on demand when queried. Because many of them are generated in parallel by the data nodes while other are specific to a given SQL node, they are not guaranteed to provide a consistent snapshot.

In addition, pushing down of joins is not supported on `ndbinfo` tables; so joining large `ndbinfo` tables can require transfer of a large amount of data to the requesting API node, even when the query makes use of a `WHERE` clause.

`ndbinfo` tables are not included in the query cache. (Bug #59831)

You can select the `ndbinfo` database with a `USE` statement, and then issue a `SHOW TABLES` statement to obtain a list of tables, just as for any other database, like this:

```
mysql> USE ndbinfo;
Database changed

mysql> SHOW TABLES;
+-----+
| Tables_in_ndbinfo |
+-----+
| arbitrator_validity_detail |
| arbitrator_validity_summary |
| blocks |
| cluster_locks |
| cluster_operations |
| cluster_transactions |
| config_nodes |
| config_params |
| config_values |
| counters |
| cpustat |
| cpustat_lsec |
| cpustat_20sec |
| cpustat_50ms |
| dict_obj_info |
| dict_obj_types |
| disk_write_speed_aggregate |
| disk_write_speed_aggregate_node |
| disk_write_speed_base |
| diskpagebuffer |
| error_messages |
| locks_per_fragment |
| logbuffers |
| logspaces |
| membership |
| memory_per_fragment |
| memoryusage |
| nodes |
| operations_per_fragment |
| processes |
| resources |
| restart_info |
| server_locks |
| server_operations |
| server_transactions |
| table_distribution_status |
| table_fragments |
| table_info |
| table_replicas |
| tc_time_track_stats |
| threadblocks |
| threads |
| threadstat |
| transporters |
+-----+
44 rows in set (0.00 sec)
```

In NDB 8.0, all `ndbinfo` tables use the `NDB` storage engine; however, an `ndbinfo` entry still appears in the output of `SHOW ENGINES` and `SHOW PLUGINS` as described previously.

You can execute `SELECT` statements against these tables, just as you would normally expect:

```
mysql> SELECT * FROM memoryusage;
+-----+-----+-----+-----+-----+-----+
| node_id | memory_type | used | used_pages | total | total_pages |
+-----+-----+-----+-----+-----+-----+
| 5 | Data memory | 753664 | 23 | 1073741824 | 32768 |
| 5 | Index memory | 163840 | 20 | 1074003968 | 131104 |
| 5 | Long message buffer | 2304 | 9 | 67108864 | 262144 |
| 6 | Data memory | 753664 | 23 | 1073741824 | 32768 |
| 6 | Index memory | 163840 | 20 | 1074003968 | 131104 |
| 6 | Long message buffer | 2304 | 9 | 67108864 | 262144 |
+-----+-----+-----+-----+-----+-----+
6 rows in set (0.02 sec)
```

More complex queries, such as the two following `SELECT` statements using the `memoryusage` table, are possible:

```
mysql> SELECT SUM(used) as 'Data Memory Used, All Nodes'
> FROM memoryusage
> WHERE memory_type = 'Data memory';
+-----+-----+
| Data Memory Used, All Nodes |
+-----+-----+
| 6460 |
+-----+-----+
1 row in set (0.37 sec)

mysql> SELECT SUM(max) as 'Total IndexMemory Available'
> FROM memoryusage
> WHERE memory_type = 'Index memory';
+-----+-----+
| Total IndexMemory Available |
+-----+-----+
| 25664 |
+-----+-----+
1 row in set (0.33 sec)
```

`ndbinfo` table and column names are case-sensitive (as is the name of the `ndbinfo` database itself). These identifiers are in lowercase. Trying to use the wrong lettercase results in an error, as shown in this example:

```
mysql> SELECT * FROM nodes;
+-----+-----+-----+-----+
| node_id | uptime | status | start_phase |
+-----+-----+-----+-----+
| 1 | 13602 | STARTED | 0 |
| 2 | 16 | STARTED | 0 |
+-----+-----+-----+-----+
2 rows in set (0.04 sec)

mysql> SELECT * FROM Nodes;
ERROR 1146 (42S02): Table 'ndbinfo.Nodes' doesn't exist
```

`mysqldump` ignores the `ndbinfo` database entirely, and excludes it from any output. This is true even when using the `--databases` or `--all-databases` option.

NDB Cluster also maintains tables in the `INFORMATION_SCHEMA` information database, including the `FILES` table which contains information about files used for NDB Cluster Disk Data storage, and the `ndb_transid_mysql_connection_map` table, which shows the relationships between transactions, transaction coordinators, and NDB Cluster API nodes. For more information, see the descriptions of the tables or [Section 23.6.15, "INFORMATION_SCHEMA Tables for NDB Cluster"](#).

23.6.14.1 The ndbinfo arbitrator_validity_detail Table

The `arbitrator_validity_detail` table shows the view that each data node in the cluster has of the arbitrator. It is a subset of the `membership` table.

The `arbitrator_validity_detail` table contains the following columns:

- `node_id`
This node's node ID
- `arbitrator`
Node ID of arbitrator
- `arb_ticket`
Internal identifier used to track arbitration
- `arb_connected`
Whether this node is connected to the arbitrator; either of `Yes` or `No`
- `arb_state`
Arbitration state

Notes

The node ID is the same as that reported by `ndb_mgm -e "SHOW"`.

All nodes should show the same `arbitrator` and `arb_ticket` values as well as the same `arb_state` value. Possible `arb_state` values are `ARBIT_NULL`, `ARBIT_INIT`, `ARBIT_FIND`, `ARBIT_PREP1`, `ARBIT_PREP2`, `ARBIT_START`, `ARBIT_RUN`, `ARBIT_CHOOSE`, `ARBIT_CRASH`, and `UNKNOWN`.

`arb_connected` shows whether the current node is connected to the `arbitrator`.

23.6.14.2 The ndbinfo arbitrator_validity_summary Table

The `arbitrator_validity_summary` table provides a composite view of the arbitrator with regard to the cluster's data nodes.

The `arbitrator_validity_summary` table contains the following columns:

- `arbitrator`
Node ID of arbitrator
- `arb_ticket`
Internal identifier used to track arbitration
- `arb_connected`
Whether this arbitrator is connected to the cluster
- `consensus_count`
Number of data nodes that see this node as arbitrator; either of `Yes` or `No`

Notes

In normal operations, this table should have only 1 row for any appreciable length of time. If it has more than 1 row for longer than a few moments, then either not all nodes are connected to the arbitrator, or all nodes are connected, but do not agree on the same arbitrator.

The `arbitrator` column shows the arbitrator's node ID.

`arb_ticket` is the internal identifier used by this arbitrator.

`arb_connected` shows whether this node is connected to the cluster as an arbitrator.

23.6.14.3 The `ndbinfo backup_id` Table

This table provides a way to find the ID of the backup started most recently for this cluster.

The `backup_id` table contains a single column `id`, which corresponds to a backup ID taken using the `ndb_mgm` client `START BACKUP` command. This table contains a single row.

Example: Assume the following sequence of `START BACKUP` commands issued in the NDB management client, with no other backups taken since the cluster was first started:

```
ndb_mgm> START BACKUP
Waiting for completed, this may take several minutes
Node 5: Backup 1 started from node 50
Node 5: Backup 1 started from node 50 completed
  StartGCP: 27894 StopGCP: 27897
  #Records: 2057 #LogRecords: 0
  Data: 51580 bytes Log: 0 bytes
ndb_mgm> START BACKUP 5
Waiting for completed, this may take several minutes
Node 5: Backup 5 started from node 50
Node 5: Backup 5 started from node 50 completed
  StartGCP: 27905 StopGCP: 27908
  #Records: 2057 #LogRecords: 0
  Data: 51580 bytes Log: 0 bytes
ndb_mgm> START BACKUP
Waiting for completed, this may take several minutes
Node 5: Backup 6 started from node 50
Node 5: Backup 6 started from node 50 completed
  StartGCP: 27912 StopGCP: 27915
  #Records: 2057 #LogRecords: 0
  Data: 51580 bytes Log: 0 bytes
ndb_mgm> START BACKUP 3
Connected to Management Server at: localhost:1186
Waiting for completed, this may take several minutes
Node 5: Backup 3 started from node 50
Node 5: Backup 3 started from node 50 completed
  StartGCP: 28149 StopGCP: 28152
  #Records: 2057 #LogRecords: 0
  Data: 51580 bytes Log: 0 bytes
ndb_mgm>
```

After this, the `backup_id` table contains the single row shown here, using the `mysql` client:

```
mysql> USE ndbinfo;
Database changed
mysql> SELECT * FROM backup_id;
+-----+
| id   |
+-----+
|    3 |
+-----+
```

```
1 row in set (0.00 sec)
```

If no backups can be found, the table contains a single row with 0 as the `id` value.

The `backup_id` table was added in NDB 8.0.24.

23.6.14.4 The `ndbinfo` `blocks` Table

The `blocks` table is a static table which simply contains the names and internal IDs of all NDB kernel blocks (see [NDB Kernel Blocks](#)). It is for use by the other `ndbinfo` tables (most of which are actually views) in mapping block numbers to block names for producing human-readable output.

The `blocks` table contains the following columns:

- `block_number`
Block number
- `block_name`
Block name

Notes

To obtain a list of all block names, simply execute `SELECT block_name FROM ndbinfo.blocks`. Although this is a static table, its content can vary between different NDB Cluster releases.

23.6.14.5 The `ndbinfo` `cluster_locks` Table

The `cluster_locks` table provides information about current lock requests holding and waiting for locks on NDB tables in an NDB Cluster, and is intended as a companion table to `cluster_operations`. Information obtain from the `cluster_locks` table may be useful in investigating stalls and deadlocks.

The `cluster_locks` table contains the following columns:

- `node_id`
ID of reporting node
- `block_instance`
ID of reporting LDM instance
- `tableid`
ID of table containing this row
- `fragmentid`
ID of fragment containing locked row
- `rowid`
ID of locked row
- `transid`
Transaction ID
- `mode`

Lock request mode

- `state`

Lock state

- `detail`

Whether this is first holding lock in row lock queue

- `op`

Operation type

- `duration_millis`

Milliseconds spent waiting or holding lock

- `lock_num`

ID of lock object

- `waiting_for`

Waiting for lock with this ID

Notes

The table ID (`tableid` column) is assigned internally, and is the same as that used in other `ndbinfo` tables. It is also shown in the output of `ndb_show_tables`.

The transaction ID (`transid` column) is the identifier generated by the NDB API for the transaction requesting or holding the current lock.

The `mode` column shows the lock mode; this is always one of `S` (indicating a shared lock) or `X` (an exclusive lock). If a transaction holds an exclusive lock on a given row, all other locks on that row have the same transaction ID.

The `state` column shows the lock state. Its value is always one of `H` (holding) or `W` (waiting). A waiting lock request waits for a lock held by a different transaction.

When the `detail` column contains a `*` (asterisk character), this means that this lock is the first holding lock in the affected row's lock queue; otherwise, this column is empty. This information can be used to help identify the unique entries in a list of lock requests.

The `op` column shows the type of operation requesting the lock. This is always one of the values `READ`, `INSERT`, `UPDATE`, `DELETE`, `SCAN`, or `REFRESH`.

The `duration_millis` column shows the number of milliseconds for which this lock request has been waiting or holding the lock. This is reset to 0 when a lock is granted for a waiting request.

The lock ID (`lockid` column) is unique to this node and block instance.

The lock state is shown in the `lock_state` column; if this is `W`, the lock is waiting to be granted, and the `waiting_for` column shows the lock ID of the lock object this request is waiting for. Otherwise, the `waiting_for` column is empty. `waiting_for` can refer only to locks on the same row, as identified by `node_id`, `block_instance`, `tableid`, `fragmentid`, and `rowid`.

23.6.14.6 The `ndbinfo cluster_operations` Table

The `cluster_operations` table provides a per-operation (stateful primary key op) view of all activity in the NDB Cluster from the point of view of the local data management (LQH) blocks (see [The DBLQH Block](#)).

The `cluster_operations` table contains the following columns:

- `node_id`
Node ID of reporting LQH block
- `block_instance`
LQH block instance
- `transid`
Transaction ID
- `operation_type`
Operation type (see text for possible values)
- `state`
Operation state (see text for possible values)
- `tableid`
Table ID
- `fragmentid`
Fragment ID
- `client_node_id`
Client node ID
- `client_block_ref`
Client block reference
- `tc_node_id`
Transaction coordinator node ID
- `tc_block_no`
Transaction coordinator block number
- `tc_block_instance`
Transaction coordinator block instance

Notes

The transaction ID is a unique 64-bit number which can be obtained using the NDB API's `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The `operation_type` column can take any one of the values `READ`, `READ-SH`, `READ-EX`, `INSERT`, `UPDATE`, `DELETE`, `WRITE`, `UNLOCK`, `REFRESH`, `SCAN`, `SCAN-SH`, `SCAN-EX`, or `<unknown>`.

The `state` column can have any one of the values `ABORT_QUEUED`, `ABORT_STOPPED`, `COMMITTED`, `COMMIT_QUEUED`, `COMMIT_STOPPED`, `COPY_CLOSE_STOPPED`, `COPY_FIRST_STOPPED`, `COPY_STOPPED`, `COPY_TUPKEY`, `IDLE`, `LOG_ABORT_QUEUED`, `LOG_COMMIT_QUEUED`, `LOG_COMMIT_QUEUED_WAIT_SIGNAL`, `LOG_COMMIT_WRITTEN`, `LOG_COMMIT_WRITTEN_WAIT_SIGNAL`, `LOG_QUEUED`, `PREPARED`, `PREPARED_RECEIVED_COMMIT`, `SCAN_CHECK_STOPPED`, `SCAN_CLOSE_STOPPED`, `SCAN_FIRST_STOPPED`, `SCAN_RELEASE_STOPPED`, `SCAN_STATE_USED`, `SCAN_STOPPED`, `SCAN_TUPKEY`, `STOPPED`, `TC_NOT_CONNECTED`, `WAIT_ACC`, `WAIT_ACC_ABORT`, `WAIT_AI_AFTER_ABORT`, `WAIT_ATTR`, `WAIT_SCAN_AI`, `WAIT_TUP`, `WAIT_TUPKEYINFO`, `WAIT_TUP_COMMIT`, or `WAIT_TUP_TO_ABORT`. (If the MySQL Server is running with `ndbinfo_show_hidden` enabled, you can view this list of states by selecting from the `ndb $dbldqh_tcconnect_state` table, which is normally hidden.)

You can obtain the name of an NDB table from its table ID by checking the output of `ndb_show_tables`.

The `fragid` is the same as the partition number seen in the output of `ndb_desc --extra-partition-info` (short form `-p`).

In `client_node_id` and `client_block_ref`, `client` refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

The `block_instance` and `tc_block_instance` column provide, respectively, the `DBLQH` and `DBTC` block instance numbers. You can use these along with the block names to obtain information about specific threads from the `threadblocks` table.

23.6.14.7 The `ndbinfo cluster_transactions` Table

The `cluster_transactions` table shows information about all ongoing transactions in an NDB Cluster.

The `cluster_transactions` table contains the following columns:

- `node_id`
Node ID of transaction coordinator
- `block_instance`
TC block instance
- `transid`
Transaction ID
- `state`
Operation state (see text for possible values)
- `count_operations`
Number of stateful primary key operations in transaction (includes reads with locks, as well as DML operations)
- `outstanding_operations`
Operations still being executed in local data management blocks
- `inactive_seconds`

Time spent waiting for API

- `client_node_id`

Client node ID

- `client_block_ref`

Client block reference

Notes

The transaction ID is a unique 64-bit number which can be obtained using the NDB API's `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

`block_instance` refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the `threadblocks` table.

The `state` column can have any one of the values `CS_ABORTING`, `CS_COMMITTING`, `CS_COMMIT_SENT`, `CS_COMPLETE_SENT`, `CS_COMPLETING`, `CS_CONNECTED`, `CS_DISCONNECTED`, `CS_FAIL_ABORTED`, `CS_FAIL_ABORTING`, `CS_FAIL_COMMITTED`, `CS_FAIL_COMMITTING`, `CS_FAIL_COMPLETED`, `CS_FAIL_PREPARED`, `CS_PREPARE_TO_COMMIT`, `CS_RECEIVING`, `CS_REC_COMMITTING`, `CS_RESTART`, `CS_SEND_FIRE_TRIG_REQ`, `CS_STARTED`, `CS_START_COMMITTING`, `CS_START_SCAN`, `CS_WAIT_ABORT_CONF`, `CS_WAIT_COMMIT_CONF`, `CS_WAIT_COMPLETE_CONF`, `CS_WAIT_FIRE_TRIG_REQ`. (If the MySQL Server is running with `ndbinfo_show_hidden` enabled, you can view this list of states by selecting from the `ndb$dbtc_apiconnect_state` table, which is normally hidden.)

In `client_node_id` and `client_block_ref`, `client` refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

The `tc_block_instance` column provides the `DBTC` block instance number. You can use this along with the block name to obtain information about specific threads from the `threadblocks` table.

23.6.14.8 The `ndbinfo config_nodes` Table

The `config_nodes` table shows nodes configured in an NDB Cluster `config.ini` file. For each node, the table displays a row containing the node ID, the type of node (management node, data node, or API node), and the name or IP address of the host on which the node is configured to run.

This table does not indicate whether a given node is actually running, or whether it is currently connected to the cluster. Information about nodes connected to an NDB Cluster can be obtained from the `nodes` and `processes` table.

The `config_nodes` table contains the following columns:

- `node_id`

The node's ID

- `node_type`

The type of node

- `node_hostname`

The name or IP address of the host on which the node resides

Notes

The `node_id` column shows the node ID used in the `config.ini` file for this node; if none is specified, the node ID that would be assigned automatically to this node is displayed.

The `node_type` column displays one of the following three values:

- `MGM`: Management node.
- `NDB`: Data node.
- `API`: API node; this includes SQL nodes.

The `node_hostname` column shows the node host as specified in the `config.ini` file. This can be empty for an API node, if `HostName` has not been set in the cluster configuration file. If `HostName` has not been set for a data node in the configuration file, `localhost` is used here. `localhost` is also used if `HostName` has not been specified for a management node.

23.6.14.9 The `ndbinfo config_params` Table

The `config_params` table is a static table which provides the names and internal ID numbers of and other information about NDB Cluster configuration parameters. This table can also be used in conjunction with the `config_values` table for obtaining realtime information about node configuration parameters.

The `config_params` table contains the following columns:

- `param_number`
The parameter's internal ID number
- `param_name`
The name of the parameter
- `param_description`
A brief description of the parameter
- `param_type`
The parameter's data type
- `param_default`
The parameter's default value, if any
- `param_min`
The parameter's maximum value, if any
- `param_max`
The parameter's minimum value, if any
- `param_mandatory`
This is 1 if the parameter is required, otherwise 0
- `param_status`

Currently unused

Notes

This table is read-only.

Although this is a static table, its content can vary between NDB Cluster installations, since supported parameters can vary due to differences between software releases, cluster hardware configurations, and other factors.

23.6.14.10 The ndbinfo config_values Table

The `config_values` table provides information about the current state of node configuration parameter values. Each row in the table corresponds to the current value of a parameter on a given node.

The `config_values` table contains the following columns:

- `node_id`
ID of the node in the cluster
- `config_param`
The parameter's internal ID number
- `config_value`
Current value of the parameter

Notes

This table's `config_param` column and the `config_params` table's `param_number` column use the same parameter identifiers. By joining the two tables on these columns, you can obtain detailed information about desired node configuration parameters. The query shown here provides the current values for all parameters on each data node in the cluster, ordered by node ID and parameter name:

```
SELECT  v.node_id AS 'Node Id',
        p.param_name AS 'Parameter',
        v.config_value AS 'Value'
FROM    config_values v
JOIN    config_params p
ON      v.config_param=p.param_number
WHERE   p.param_name NOT LIKE '\_ \_%'
ORDER BY v.node_id, p.param_name;
```

Partial output from the previous query when run on a small example cluster used for simple testing:

| Node Id | Parameter | Value |
|---------|-------------------------------------|----------------|
| 2 | Arbitration | 1 |
| 2 | ArbitrationTimeout | 7500 |
| 2 | BackupDataBufferSize | 16777216 |
| 2 | BackupDataDir | /home/jon/data |
| 2 | BackupDiskWriteSpeedPct | 50 |
| 2 | BackupLogBufferSize | 16777216 |
| ... | | |
| 3 | TotalSendBufferMemory | 0 |
| 3 | TransactionBufferMemory | 1048576 |
| 3 | TransactionDeadlockDetectionTimeout | 1200 |

| | | |
|---|-------------------------------|------------|
| 3 | TransactionInactiveTimeout | 4294967039 |
| 3 | TwoPassInitialNodeRestartCopy | 0 |
| 3 | UndoDataBuffer | 16777216 |
| 3 | UndoIndexBuffer | 2097152 |

248 rows in set (0.02 sec)

The **WHERE** clause filters out parameters whose names begin with a double underscore (**__**); these parameters are reserved for testing and other internal uses by the NDB developers, and are not intended for use in a production NDB Cluster.

You can obtain output that is more specific, more detailed, or both by issuing the proper queries. This example provides all types of available information about the **NodeId**, **NoOfReplicas**, **HostName**, **DataMemory**, **IndexMemory**, and **TotalSendBufferMemory** parameters as currently set for all data nodes in the cluster:

```
SELECT  p.param_name AS Name,
        v.node_id AS Node,
        p.param_type AS Type,
        p.param_default AS 'Default',
        p.param_min AS Minimum,
        p.param_max AS Maximum,
        CASE p.param_mandatory WHEN 1 THEN 'Y' ELSE 'N' END AS 'Required',
        v.config_value AS Current
FROM    config_params p
JOIN    config_values v
ON      p.param_number = v.config_param
WHERE   p.param_name
        IN ('NodeId', 'NoOfReplicas', 'HostName',
            'DataMemory', 'IndexMemory', 'TotalSendBufferMemory')\G
```

The output from this query when run on a small NDB Cluster with 2 data nodes used for simple testing is shown here:

```

23.6.14.11 The ndbinfo counters Table

The `counters` table provides running totals of events such as reads and writes for specific kernel blocks and data nodes. Counts are kept from the most recent node start or restart; a node start or restart resets all counters on that node. Not all kernel blocks have all types of counters.

The `counters` table contains the following columns:

- `node_id`

The data node ID

- `block_name`

Name of the associated NDB kernel block (see [NDB Kernel Blocks](#)).

- `block_instance`

Block instance

- `counter_id`

The counter's internal ID number; normally an integer between 1 and 10, inclusive.

- `counter_name`

The name of the counter. See text for names of individual counters and the NDB kernel block with which each counter is associated.

- `val`

The counter's value

Notes

Each counter is associated with a particular NDB kernel block.

The `OPERATIONS` counter is associated with the `DBLQH` (local query handler) kernel block. A primary-key read counts as one operation, as does a primary-key update. For reads, there is one operation in `DBLQH` per operation in `DBTC`. For writes, there is one operation counted per fragment replica.

The `ATTRINFO`, `TRANSACTIONS`, `COMMITTS`, `READS`, `LOCAL_READS`, `SIMPLE_READS`, `WRITES`, `LOCAL_WRITES`, `ABORTS`, `TABLE_SCANS`, and `RANGE_SCANS` counters are associated with the `DBTC` (transaction co-ordinator) kernel block.

`LOCAL_WRITES` and `LOCAL_READS` are primary-key operations using a transaction coordinator in a node that also holds the primary fragment replica of the record.

The `READS` counter includes all reads. `LOCAL_READS` includes only those reads of the primary fragment replica on the same node as this transaction coordinator. `SIMPLE_READS` includes only those reads in which the read operation is the beginning and ending operation for a given transaction. Simple reads do not hold locks but are part of a transaction, in that they observe uncommitted changes made by the transaction containing them but not of any other uncommitted transactions. Such reads are “simple” from the point of view of the TC block; since they hold no locks they are not durable, and once `DBTC` has routed them to the relevant LQH block, it holds no state for them.

`ATTRINFO` keeps a count of the number of times an interpreted program is sent to the data node. See [NDB Protocol Messages](#), for more information about `ATTRINFO` messages in the NDB kernel.

The `LOCAL_TABLE_SCANS_SENT`, `READS_RECEIVED`, `PRUNED_RANGE_SCANS_RECEIVED`, `RANGE_SCANS_RECEIVED`, `LOCAL_READS_SENT`, `CONST_PRUNED_RANGE_SCANS_RECEIVED`, `LOCAL_RANGE_SCANS_SENT`, `REMOTE_READS_SENT`, `REMOTE_RANGE_SCANS_SENT`, `READS_NOT_FOUND`, `SCAN_BATCHES_RETURNED`, `TABLE_SCANS_RECEIVED`, and `SCAN_ROWS_RETURNED` counters are associated with the `DBSPJ` (select push-down join) kernel block.

The `block_name` and `block_instance` columns provide, respectively, the applicable NDB kernel block name and instance number. You can use these to obtain information about specific threads from the `threadblocks` table.

A number of counters provide information about transporter overload and send buffer sizing when troubleshooting such issues. For each LQH instance, there is one instance of each counter in the following list:

- `LQHKEY_OVERLOAD`: Number of primary key requests rejected at the LQH block instance due to transporter overload
- `LQHKEY_OVERLOAD_TC`: Count of instances of `LQHKEY_OVERLOAD` where the TC node transporter was overloaded
- `LQHKEY_OVERLOAD_READER`: Count of instances of `LQHKEY_OVERLOAD` where the API reader (reads only) node was overloaded.
- `LQHKEY_OVERLOAD_NODE_PEER`: Count of instances of `LQHKEY_OVERLOAD` where the next backup data node (writes only) was overloaded
- `LQHKEY_OVERLOAD_SUBSCRIBER`: Count of instances of `LQHKEY_OVERLOAD` where a event subscriber (writes only) was overloaded.
- `LQHSCAN_SLOWDOWNS`: Count of instances where a fragment scan batch size was reduced due to scanning API transporter overload.

23.6.14.12 The `ndbinfo cpudata` Table

The `cpudata` table provides data about CPU usage during the last second.

The `cpustat` table contains the following columns:

- `node_id`
Node ID
- `cpu_no`
CPU ID
- `cpu_online`
1 if the CPU is currently online, otherwise 0
- `cpu_userspace_time`
CPU time spent in userspace
- `cpu_idle_time`
CPU time spent idle
- `cpu_system_time`
CPU time spent in system time
- `cpu_interrupt_time`
CPU time spent handling interrupts (hardware and software)

- `cpu_exec_vm_time`

CPU time spent in virtual machine execution

Notes

The `cpudata` table is available only on Linux and Solaris operating systems.

This table was added in NDB 8.0.23.

23.6.14.13 The `ndbinfo cpudata_1sec` Table

The `cpudata_1sec` table provides data about CPU usage per second over the last 20 seconds.

The `cpustat` table contains the following columns:

- `node_id`

Node ID

- `measurement_id`

Measurement sequence ID; later measurements have lower IDs

- `cpu_no`

CPU ID

- `cpu_online`

1 if the CPU is currently online, otherwise 0

- `cpu_userspace_time`

CPU time spent in userspace

- `cpu_idle_time`

CPU time spent idle

- `cpu_system_time`

CPU time spent in system time

- `cpu_interrupt_time`

CPU time spent handling interrupts (hardware and software)

- `cpu_exec_vm_time`

CPU time spent in virtual machine execution

- `elapsed_time`

Time in microseconds used for this measurement

Notes

The `cpudata_1sec` table is available only on Linux and Solaris operating systems.

This table was added in NDB 8.0.23.

23.6.14.14 The `ndbinfo cpudata_20sec` Table

The `cpudata_20sec` table provides data about CPU usage per 20-second interval over the last 400 seconds.

The `cpustat` table contains the following columns:

- `node_id`
Node ID
- `measurement_id`
Measurement sequence ID; later measurements have lower IDs
- `cpu_no`
CPU ID
- `cpu_online`
1 if the CPU is currently online, otherwise 0
- `cpu_userspace_time`
CPU time spent in userspace
- `cpu_idle_time`
CPU time spent idle
- `cpu_system_time`
CPU time spent in system time
- `cpu_interrupt_time`
CPU time spent handling interrupts (hardware and software)
- `cpu_exec_vm_time`
CPU time spent in virtual machine execution
- `elapsed_time`
Time in microseconds used for this measurement

Notes

The `cpudata_20sec` table is available only on Linux and Solaris operating systems.

This table was added in NDB 8.0.23.

23.6.14.15 The `ndbinfo cpudata_50ms` Table

The `cpudata_50ms` table provides data about CPU usage per 50-millisecond interval over the last second.

The `cpustat` table contains the following columns:

- `node_id`
Node ID
- `measurement_id`
Measurement sequence ID; later measurements have lower IDs
- `cpu_no`
CPU ID
- `cpu_online`
1 if the CPU is currently online, otherwise 0
- `cpu_userspace_time`
CPU time spent in userspace
- `cpu_idle_time`
CPU time spent idle
- `cpu_system_time`
CPU time spent in system time
- `cpu_interrupt_time`
CPU time spent handling interrupts (hardware and software)
- `cpu_exec_vm_time`
CPU time spent in virtual machine execution
- `elapsed_time`
Time in microseconds used for this measurement

Notes

The `cpudata_50ms` table is available only on Linux and Solaris operating systems.

This table was added in NDB 8.0.23.

23.6.14.16 The `ndbinfo` `cpuinfo` Table

The `cpuinfo` table provides information about the CPU on which a given data node executes.

The `cpuinfo` table contains the following columns:

- `node_id`
Node ID
- `cpu_no`

CPU ID

- `cpu_online`
1 if the CPU is online, otherwise 0
- `core_id`
CPU core ID
- `socket_id`
CPU socket ID

Notes

The `cpuinfo` table is available on all operating systems supported by NDB, with the exception of MacOS and FreeBSD.

This table was added in NDB 8.0.23.

23.6.14.17 The ndbinfo cpustat Table

The `cpustat` table provides per-thread CPU statistics gathered each second, for each thread running in the NDB kernel.

The `cpustat` table contains the following columns:

- `node_id`
ID of the node where the thread is running
- `thr_no`
Thread ID (specific to this node)
- `OS_user`
OS user time
- `OS_system`
OS system time
- `OS_idle`
OS idle time
- `thread_exec`
Thread execution time
- `thread_sleeping`
Thread sleep time
- `thread_spinning`
Thread spin time

- `thread_send`
Thread send time
- `thread_buffer_full`
Thread buffer full time
- `elapsed_time`
Elapsed time

23.6.14.18 The `ndbinfo cpustat_50ms` Table

The `cpustat_50ms` table provides raw, per-thread CPU data obtained each 50 milliseconds for each thread running in the `NDB` kernel.

Like `cpustat_1sec` and `cpustat_20sec`, this table shows 20 measurement sets per thread, each referencing a period of the named duration. Thus, `cpustat_50ms` provides 1 second of history.

The `cpustat_50ms` table contains the following columns:

- `node_id`
ID of the node where the thread is running
- `thr_no`
Thread ID (specific to this node)
- `OS_user_time`
OS user time
- `OS_system_time`
OS system time
- `OS_idle_time`
OS idle time
- `exec_time`
Thread execution time
- `sleep_time`
Thread sleep time
- `spin_time`
Thread spin time
- `send_time`
Thread send time
- `buffer_full_time`

Thread buffer full time

- `elapsed_time`

Elapsed time

23.6.14.19 The `ndbinfo cpustat_1sec` Table

The `cpustat_1sec` table provides raw, per-thread CPU data obtained each second for each thread running in the NDB kernel.

Like `cpustat_50ms` and `cpustat_20sec`, this table shows 20 measurement sets per thread, each referencing a period of the named duration. Thus, `cpustat_1sec` provides 20 seconds of history.

The `cpustat_1sec` table contains the following columns:

- `node_id`

ID of the node where the thread is running

- `thr_no`

Thread ID (specific to this node)

- `OS_user_time`

OS user time

- `OS_system_time`

OS system time

- `OS_idle_time`

OS idle time

- `exec_time`

Thread execution time

- `sleep_time`

Thread sleep time

- `spin_time`

Thread spin time

- `send_time`

Thread send time

- `buffer_full_time`

Thread buffer full time

- `elapsed_time`

Elapsed time

23.6.14.20 The ndbinfo cpustat_20sec Table

The `cpustat_20sec` table provides raw, per-thread CPU data obtained each 20 seconds, for each thread running in the NDB kernel.

Like `cpustat_50ms` and `cpustat_1sec`, this table shows 20 measurement sets per thread, each referencing a period of the named duration. Thus, `cpustat_20sec` provides 400 seconds of history.

The `cpustat_20sec` table contains the following columns:

- `node_id`
ID of the node where the thread is running
- `thr_no`
Thread ID (specific to this node)
- `OS_user_time`
OS user time
- `OS_system_time`
OS system time
- `OS_idle_time`
OS idle time
- `exec_time`
Thread execution time
- `sleep_time`
Thread sleep time
- `spin_time`
Thread spin time
- `send_time`
Thread send time
- `buffer_full_time`
Thread buffer full time
- `elapsed_time`
Elapsed time

23.6.14.21 The ndbinfo dict_obj_info Table

The `dict_obj_info` table provides information about NDB data dictionary (DICT) objects such as tables and indexes. (The `dict_obj_types` table can be queried for a list of all the types.) This information includes the object's type, state, parent object (if any), and fully qualified name.

The `dict_obj_info` table contains the following columns:

- `type`
Type of `DICT` object; join on `dict_obj_types` to obtain the name
- `id`
Object identifier; for Disk Data undo log files and data files, this is the same as the value shown in the `LOGFILE_GROUP_NUMBER` column of the `INFORMATION_SCHEMA.FILES` table; for undo log files, it also the same as the value shown for the `log_id` column in the `ndbinfo logbuffers` and `logspaces` tables
- `version`
Object version
- `state`
Object state
- `parent_obj_type`
Parent object's type (a `dict_obj_types` type ID); 0 indicates that the object has no parent
- `parent_obj_id`
Parent object ID (such as a base table); 0 indicates that the object has no parent
- `fq_name`
Fully qualified object name; for a table, this has the form `database_name/def/table_name`, for a primary key, the form is `sys/def/table_id/PRIMARY`, and for a unique key it is `sys/def/table_id/uk_name$unique`

23.6.14.22 The `ndbinfo dict_obj_tree` Table

The `dict_obj_tree` table provides a tree-based view of table information from the `dict_obj_info` table. This is intended primarily for use in testing, but can be useful in visualizing hierarchies of `NDB` database objects.

The `dict_obj_tree` table contains the following columns:

- `type`
Type of `DICT` object; join on `dict_obj_types` to obtain the name of the object type
- `id`
Object identifier; same as the `id` column in `dict_obj_info`

For Disk Data undo log files and data files, this is the same as the value shown in the `LOGFILE_GROUP_NUMBER` column of the `INFORMATION_SCHEMA.FILES` table; for undo log files, it also the same as the value shown for the `log_id` column in the `ndbinfo logbuffers` and `logspaces` tables
- `name`
The fully qualified name of the object; the same as the `fq_name` column in `dict_obj_info`

For a table, this is `database_name/def/table_name` (the same as its `parent_name`); for an index of any type, this takes the form `NDB$INDEX_index_id_CUSTOM`

- `parent_type`

The `DICT` object type of this object's parent object; join on `dict_obj_types` to obtain the name of the object type

- `parent_id`

Identifier for this object's parent object; the same as the `dict_obj_info` table's `id` column

- `parent_name`

Fully qualified name of this object's parent object; the same as the `dict_obj_info` table's `fq_name` column

For a table, this has the form `database_name/def/table_name`. For an index, the name is `sys/def/table_id/index_name`. For a primary key, it is `sys/def/table_id/PRIMARY`, and for a unique key it is `sys/def/table_id/uk_name$unique`

- `root_type`

The `DICT` object type of the root object; join on `dict_obj_types` to obtain the name of the object type

- `root_id`

Identifier for the root object; the same as the `dict_obj_info` table's `id` column

- `root_name`

Fully qualified name of the root object; the same as the `dict_obj_info` table's `fq_name` column

- `level`

Level of the object in the hierarchy

- `path`

Complete path to the object in the `NDB` object hierarchy; objects are separated by a right arrow (represented as `->`), starting with the root object on the left

- `indented_name`

The `name` prefixed with a right arrow (represented as `->`) with a number of spaces preceding it that correspond to the object's depth in the hierarchy

The `path` column is useful for obtaining a complete path to a given `NDB` database object in a single line, whereas the `indented_name` column can be used to obtain a tree-like layout of complete hierarchy information for a desired object.

Example: Assuming the existence of a `test` database and no existing table named `t1` in this database, execute the following SQL statement:

```
CREATE TABLE test.t1 (
  a INT PRIMARY KEY,
  b INT,
  UNIQUE KEY(b)
```

```
) ENGINE = NDB;
```

You can obtain the path to the table just created using the query shown here:

```
mysql> SELECT path FROM ndbinfo.dict_obj_tree
      -> WHERE name LIKE 'test%t1';
+-----+
| path          |
+-----+
| test/def/t1  |
+-----+
1 row in set (0.14 sec)
```

You can see the paths to all dependent objects of this table using the path to the table as the root name in a query like this one:

```
mysql> SELECT path FROM ndbinfo.dict_obj_tree
      -> WHERE root_name = 'test/def/t1';
+-----+
| path          |
+-----+
| test/def/t1   |
| test/def/t1 -> sys/def/13/b |
| test/def/t1 -> sys/def/13/b -> NDB$INDEX_15_CUSTOM |
| test/def/t1 -> sys/def/13/b$unique |
| test/def/t1 -> sys/def/13/b$unique -> NDB$INDEX_16_UI |
| test/def/t1 -> sys/def/13/PRIMARY |
| test/def/t1 -> sys/def/13/PRIMARY -> NDB$INDEX_14_CUSTOM |
+-----+
```

7 rows in set (0.16 sec)

To obtain a hierarchical view of the `t1` table with all its dependent objects, execute a query similar to this one which selects the indented name of each object having `test/def/t1` as the name of its root object:

```
mysql> SELECT indented_name FROM ndbinfo.dict_obj_tree
      -> WHERE root_name = 'test/def/t1';
+-----+
| indented_name |
+-----+
| test/def/t1   |
|   -> sys/def/13/b |
|     -> NDB$INDEX_15_CUSTOM |
|     -> sys/def/13/b$unique |
|       -> NDB$INDEX_16_UI |
|     -> sys/def/13/PRIMARY |
|       -> NDB$INDEX_14_CUSTOM |
+-----+
```

7 rows in set (0.15 sec)

When working with Disk Data tables, note that, in this context, a tablespace or log file group is considered a root object. This means that you must know the name of any tablespace or log file group associated with a given table, or obtain this information from `SHOW CREATE TABLE` and then querying `INFORMATION_SCHEMA.FILES`, or similar means as shown here:

```
mysql> SHOW CREATE TABLE test.dt_1\G
***** 1. row *****
      Table: dt_1
Create Table: CREATE TABLE `dt_1` (
  `member_id` int unsigned NOT NULL AUTO_INCREMENT,
  `last_name` varchar(50) NOT NULL,
  `first_name` varchar(50) NOT NULL,
  `dob` date NOT NULL,
  `joined` date NOT NULL,
  PRIMARY KEY (`member_id`),
  KEY `last_name` (`last_name`,`first_name`)
```

```
) /*!50100 TABLESPACE `ts_1` STORAGE DISK */ ENGINE=ndbcluster DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai
1 row in set (0.00 sec)

mysql> SELECT DISTINCT TABLESPACE_NAME, LOGFILE_GROUP_NAME
-> FROM INFORMATION_SCHEMA.FILES WHERE TABLESPACE_NAME='ts_1';
+-----+-----+
| TABLESPACE_NAME | LOGFILE_GROUP_NAME |
+-----+-----+
| ts_1             | lg_1               |
+-----+-----+
1 row in set (0.00 sec)
```

Now you can obtain hierarchical information for the table, tablespace, and log file group like this:

```
mysql> SELECT indented_name FROM ndbinfo.dict_obj_tree
-> WHERE root_name = 'test/def/dt_1';
+-----+
| indented_name |
+-----+
| test/def/dt_1 |
|   -> sys/def/23/last_name |
|   -> NDB$INDEX_25_CUSTOM |
|   -> sys/def/23/PRIMARY |
|   -> NDB$INDEX_24_CUSTOM |
+-----+
5 rows in set (0.15 sec)

mysql> SELECT indented_name FROM ndbinfo.dict_obj_tree
-> WHERE root_name = 'ts_1';
+-----+
| indented_name |
+-----+
| ts_1          |
|   -> data_1.dat |
|   -> data_2.dat |
+-----+
3 rows in set (0.17 sec)

mysql> SELECT indented_name FROM ndbinfo.dict_obj_tree
-> WHERE root_name LIKE 'lg_1';
+-----+
| indented_name |
+-----+
| lg_1          |
|   -> undo_1.log |
|   -> undo_2.log |
+-----+
3 rows in set (0.16 sec)
```

The `dict_obj_tree` table was added in NDB 8.0.24.

23.6.14.23 The `ndbinfo dict_obj_types` Table

The `dict_obj_types` table is a static table listing possible dictionary object types used in the NDB kernel. These are the same types defined by `Object::Type` in the NDB API.

The `dict_obj_types` table contains the following columns:

- `type_id`

The type ID for this type

- `type_name`

The name of this type

23.6.14.24 The ndbinfo disk_write_speed_base Table

The `disk_write_speed_base` table provides base information about the speed of disk writes during LCP, backup, and restore operations.

The `disk_write_speed_base` table contains the following columns:

- `node_id`
Node ID of this node
- `thr_no`
Thread ID of this LDM thread
- `millis_ago`
Milliseconds since this reporting period ended
- `millis_passed`
Milliseconds elapsed in this reporting period
- `backup_lcp_bytes_written`
Number of bytes written to disk by local checkpoints and backup processes during this period
- `redo_bytes_written`
Number of bytes written to REDO log during this period
- `target_disk_write_speed`
Actual speed of disk writes per LDM thread (base data)

23.6.14.25 The ndbinfo disk_write_speed_aggregate Table

The `disk_write_speed_aggregate` table provides aggregated information about the speed of disk writes during LCP, backup, and restore operations.

The `disk_write_speed_aggregate` table contains the following columns:

- `node_id`
Node ID of this node
- `thr_no`
Thread ID of this LDM thread
- `backup_lcp_speed_last_sec`
Number of bytes written to disk by backup and LCP processes in the last second
- `redo_speed_last_sec`
Number of bytes written to REDO log in the last second
- `backup_lcp_speed_last_10sec`

Number of bytes written to disk by backup and LCP processes per second, averaged over the last 10 seconds

- [redo_speed_last_10sec](#)

Number of bytes written to REDO log per second, averaged over the last 10 seconds

- [std_dev_backup_lcp_speed_last_10sec](#)

Standard deviation in number of bytes written to disk by backup and LCP processes per second, averaged over the last 10 seconds

- [std_dev_redo_speed_last_10sec](#)

Standard deviation in number of bytes written to REDO log per second, averaged over the last 10 seconds

- [backup_lcp_speed_last_60sec](#)

Number of bytes written to disk by backup and LCP processes per second, averaged over the last 60 seconds

- [redo_speed_last_60sec](#)

Number of bytes written to REDO log per second, averaged over the last 10 seconds

- [std_dev_backup_lcp_speed_last_60sec](#)

Standard deviation in number of bytes written to disk by backup and LCP processes per second, averaged over the last 60 seconds

- [std_dev_redo_speed_last_60sec](#)

Standard deviation in number of bytes written to REDO log per second, averaged over the last 60 seconds

- [slowdowns_due_to_io_lag](#)

Number of seconds since last node start that disk writes were slowed due to REDO log I/O lag

- [slowdowns_due_to_high_cpu](#)

Number of seconds since last node start that disk writes were slowed due to high CPU usage

- [disk_write_speed_set_to_min](#)

Number of seconds since last node start that disk write speed was set to minimum

- [current_target_disk_write_speed](#)

Actual speed of disk writes per LDM thread (aggregated)

23.6.14.26 The `ndbinfo disk_write_speed_aggregate_node` Table

The `disk_write_speed_aggregate_node` table provides aggregated information per node about the speed of disk writes during LCP, backup, and restore operations.

The `disk_write_speed_aggregate_node` table contains the following columns:

- `node_id`
Node ID of this node
- `backup_lcp_speed_last_sec`
Number of bytes written to disk by backup and LCP processes in the last second
- `redo_speed_last_sec`
Number of bytes written to REDO log in the last second
- `backup_lcp_speed_last_10sec`
Number of bytes written to disk by backup and LCP processes per second, averaged over the last 10 seconds
- `redo_speed_last_10sec`
Number of bytes written to REDO log per second, averaged over the last 10 seconds
- `backup_lcp_speed_last_60sec`
Number of bytes written to disk by backup and LCP processes per second, averaged over the last 60 seconds
- `redo_speed_last_60sec`
Number of bytes written to disk by backup and LCP processes per second, averaged over the last 60 seconds

23.6.14.27 The `ndbinfo diskpagebuffer` Table

The `diskpagebuffer` table provides statistics about disk page buffer usage by NDB Cluster Disk Data tables.

The `diskpagebuffer` table contains the following columns:

- `node_id`
The data node ID
- `block_instance`
Block instance
- `pages_written`
Number of pages written to disk.
- `pages_written_lcp`
Number of pages written by local checkpoints.
- `pages_read`
Number of pages read from disk
- `log_waits`

Number of page writes waiting for log to be written to disk

- [page_requests_direct_return](#)

Number of requests for pages that were available in buffer

- [page_requests_wait_queue](#)

Number of requests that had to wait for pages to become available in buffer

- [page_requests_wait_io](#)

Number of requests that had to be read from pages on disk (pages were unavailable in buffer)

Notes

You can use this table with NDB Cluster Disk Data tables to determine whether [DiskPageBufferMemory](#) is sufficiently large to allow data to be read from the buffer rather from disk; minimizing disk seeks can help improve performance of such tables.

You can determine the proportion of reads from [DiskPageBufferMemory](#) to the total number of reads using a query such as this one, which obtains this ratio as a percentage:

```
SELECT
  node_id,
  100 * page_requests_direct_return /
    (page_requests_direct_return + page_requests_wait_io)
    AS hit_ratio
FROM ndbinfo.diskpagebuffer;
```

The result from this query should be similar to what is shown here, with one row for each data node in the cluster (in this example, the cluster has 4 data nodes):

```
+-----+-----+
| node_id | hit_ratio |
+-----+-----+
|      5 | 97.6744 |
|      6 | 97.6879 |
|      7 | 98.1776 |
|      8 | 98.1343 |
+-----+-----+
4 rows in set (0.00 sec)
```

[hit_ratio](#) values approaching 100% indicate that only a very small number of reads are being made from disk rather than from the buffer, which means that Disk Data read performance is approaching an optimum level. If any of these values are less than 95%, this is a strong indicator that the setting for [DiskPageBufferMemory](#) needs to be increased in the [config.ini](#) file.

Note

A change in [DiskPageBufferMemory](#) requires a rolling restart of all of the cluster's data nodes before it takes effect.

[block_instance](#) refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the [threadblocks](#) table. Using this information, you can obtain information about disk page buffer metrics relating to individual threads; an example query using [LIMIT 1](#) to limit the output to a single thread is shown here:

```
mysql> SELECT
>   node_id, thr_no, block_name, thread_name, pages_written,
```

```

> pages_written_lcp, pages_read, log_waits,
> page_requests_direct_return, page_requests_wait_queue,
> page_requests_wait_io
> FROM ndbinfo.diskpagebuffer
> INNER JOIN ndbinfo.threadblocks USING (node_id, block_instance)
> INNER JOIN ndbinfo.threads USING (node_id, thr_no)
> WHERE block_name = 'PGMAN' LIMIT 1\G
***** 1. row *****
      node_id: 1
      thr_no: 1
      block_name: PGMAN
      thread_name: rep
      pages_written: 0
      pages_written_lcp: 0
      pages_read: 1
      log_waits: 0
page_requests_direct_return: 4
      page_requests_wait_queue: 0
      page_requests_wait_io: 1
1 row in set (0.01 sec)

```

23.6.14.28 The ndbinfo diskstat Table

The `diskstat` table provides information about writes to Disk Data tablespaces during the past 1 second.

The `diskstat` table contains the following columns:

- `node_id`
Node ID of this node
- `block_instance`
ID of reporting instance of `PGMAN`
- `pages_made_dirty`
Number of pages made dirty during the past second
- `reads_issued`
Reads issued during the past second
- `reads_completed`
Reads completed during the past second
- `writes_issued`
Writes issued during the past second
- `writes_completed`
Writes completed during the past second
- `log_writes_issued`
Number of times a page write has required a log write during the past second
- `log_writes_completed`
Number of log writes completed during the last second

- `get_page_calls_issued`
Number of `get_page()` calls issued during the past second
- `get_page_reqs_issued`
Number of times that a `get_page()` call has resulted in a wait for I/O or completion of I/O already begun during the past second
- `get_page_reqs_completed`
Number of `get_page()` calls waiting for I/O or I/O completion that have completed during the past second

Notes

Each row in this table corresponds to an instance of `PGMAN`; there is one such instance per LDM thread plus an additional instance for each data node.

23.6.14.29 The `ndbinfo diskstats_1sec` Table

The `diskstats_1sec` table provides information about writes to Disk Data tablespaces over the past 20 seconds.

The `diskstat` table contains the following columns:

- `node_id`
Node ID of this node
- `block_instance`
ID of reporting instance of `PGMAN`
- `pages_made_dirty`
Pages made dirty during the designated 1-second interval
- `reads_issued`
Reads issued during the designated 1-second interval
- `reads_completed`
Reads completed during the designated 1-second interval
- `writes_issued`
Writes issued during the designated 1-second interval
- `writes_completed`
Writes completed during the designated 1-second interval
- `log_writes_issued`
Number of times a page write has required a log write during the designated 1-second interval
- `log_writes_completed`

Number of log writes completed during the designated 1-second interval

- `get_page_calls_issued`

Number of `get_page()` calls issued during the designated 1-second interval

- `get_page_reqs_issued`

Number of times that a `get_page()` call has resulted in a wait for I/O or completion of I/O already begun during the designated 1-second interval

- `get_page_reqs_completed`

Number of `get_page()` calls waiting for I/O or I/O completion that have completed during the designated 1-second interval

- `seconds_ago`

Number of 1-second intervals in the past of the interval to which this row applies

Notes

Each row in this table corresponds to an instance of `PGMAN` during a 1-second interval occurring from 0 to 19 seconds ago; there is one such instance per LDM thread plus an additional instance for each data node.

23.6.14.30 The `ndbinfo error_messages` Table

The `error_messages` table provides information about

The `error_messages` table contains the following columns:

- `error_code`

Numeric error code

- `error_description`

Description of error

- `error_status`

Error status code

- `error_classification`

Error classification code

Notes

`error_code` is a numeric NDB error code. This is the same error code that can be supplied to `ndb_perror`.

`error_description` provides a basic description of the condition causing the error.

The `error_status` column provides status information relating to the error. Possible values for this column are listed here:

- `No error`

- `Illegal connect string`
- `Illegal server handle`
- `Illegal reply from server`
- `Illegal number of nodes`
- `Illegal node status`
- `Out of memory`
- `Management server not connected`
- `Could not connect to socket`
- `Start failed`
- `Stop failed`
- `Restart failed`
- `Could not start backup`
- `Could not abort backup`
- `Could not enter single user mode`
- `Could not exit single user mode`
- `Failed to complete configuration change`
- `Failed to get configuration`
- `Usage error`
- `Success`
- `Permanent error`
- `Temporary error`
- `Unknown result`
- `Temporary error, restart node`
- `Permanent error, external action needed`
- `Ndbd file system error, restart node initial`
- `Unknown`

The `error_classification` column shows the error classification. See [NDB Error Classifications](#), for information about classification codes and their meanings.

23.6.14.31 The `ndbinfo hwinfo` Table

The `hwinfo` table provides information about the hardware on which a given data node executes.

The `hwinfo` table contains the following columns:

- `node_id`
Node ID
- `cpu_cnt_max`
Number of processors on this host
- `cpu_cnt`
Number of processors available to this node
- `num_cpu_cores`
Number of CPU cores on this host
- `num_cpu_sockets`
Number of CPU sockets on this host
- `HW_memory_size`
Amount of memory available on this host
- `model_name`
CPU model name

Notes

The `hwinfo` table is available on all operating systems supported by NDB.

This table was added in NDB 8.0.23.

23.6.14.32 The `ndbinfo locks_per_fragment` Table

The `locks_per_fragment` table provides information about counts of lock claim requests, and the outcomes of these requests on a per-fragment basis, serving as a companion table to `operations_per_fragment` and `memory_per_fragment`. This table also shows the total time spent waiting for locks successfully and unsuccessfully since fragment or table creation, or since the most recent restart.

The `locks_per_fragment` table contains the following columns:

- `fq_name`
Fully qualified table name
- `parent_fq_name`
Fully qualified name of parent object
- `type`
Table type; see text for possible values
- `table_id`
Table ID

- `node_id`
Reporting node ID
- `block_instance`
LDM instance ID
- `fragment_num`
Fragment identifier
- `ex_req`
Exclusive lock requests started
- `ex_imm_ok`
Exclusive lock requests immediately granted
- `ex_wait_ok`
Exclusive lock requests granted following wait
- `ex_wait_fail`
Exclusive lock requests not granted
- `sh_req`
Shared lock requests started
- `sh_imm_ok`
Shared lock requests immediately granted
- `sh_wait_ok`
Shared lock requests granted following wait
- `sh_wait_fail`
Shared lock requests not granted
- `wait_ok_millis`
Time spent waiting for lock requests that were granted, in milliseconds
- `wait_fail_millis`
Time spent waiting for lock requests that failed, in milliseconds

Notes

`block_instance` refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the `threadblocks` table.

`fq_name` is a fully qualified database object name in `database/schema/name` format, such as `test/def/t1` or `sys/def/10/b$unique`.

`parent_fq_name` is the fully qualified name of this object's parent object (table).

`table_id` is the table's internal ID generated by NDB. This is the same internal table ID shown in other ndbinfo tables; it is also visible in the output of `ndb_show_tables`.

The `type` column shows the type of table. This is always one of `System table`, `User table`, `Unique hash index`, `Hash index`, `Unique ordered index`, `Ordered index`, `Hash index trigger`, `Subscription trigger`, `Read only constraint`, `Index trigger`, `Reorganize trigger`, `Tablespace`, `Log file group`, `Data file`, `Undo file`, `Hash map`, `Foreign key definition`, `Foreign key parent trigger`, `Foreign key child trigger`, or `Schema transaction`.

The values shown in all of the columns `ex_req`, `ex_req_imm_ok`, `ex_wait_ok`, `ex_wait_fail`, `sh_req`, `sh_req_imm_ok`, `sh_wait_ok`, and `sh_wait_fail` represent cumulative numbers of requests since the table or fragment was created, or since the last restart of this node, whichever of these occurred later. This is also true for the time values shown in the `wait_ok_millis` and `wait_fail_millis` columns.

Every lock request is considered either to be in progress, or to have completed in some way (that is, to have succeeded or failed). This means that the following relationships are true:

```
ex_req >= (ex_req_imm_ok + ex_wait_ok + ex_wait_fail)
sh_req >= (sh_req_imm_ok + sh_wait_ok + sh_wait_fail)
```

The number of requests currently in progress is the current number of incomplete requests, which can be found as shown here:

```
[exclusive lock requests in progress] =
  ex_req - (ex_req_imm_ok + ex_wait_ok + ex_wait_fail)
[shared lock requests in progress] =
  sh_req - (sh_req_imm_ok + sh_wait_ok + sh_wait_fail)
```

A failed wait indicates an aborted transaction, but the abort may or may not be caused by a lock wait timeout. You can obtain the total number of aborts while waiting for locks as shown here:

```
[aborts while waiting for locks] = ex_wait_fail + sh_wait_fail
```

23.6.14.33 The ndbinfo logbuffers Table

The `logbuffer` table provides information on NDB Cluster log buffer usage.

The `logbuffers` table contains the following columns:

- `node_id`

The ID of this data node.

- `log_type`

Type of log. One of: `REDO`, `DD-UNDO`, `BACKUP-DATA`, or `BACKUP-LOG`.

- `log_id`

The log ID; for Disk Data undo log files, this is the same as the value shown in the `LOGFILE_GROUP_NUMBER` column of the `INFORMATION_SCHEMA.FILES` table as well as the value shown for the `log_id` column of the `ndbinfo logspaces` table

- `log_part`

The log part number

- `total`

Total space available for this log

- `used`

Space used by this log

Notes

`logbuffers` table rows reflecting two additional log types are available when performing an NDB backup. One of these rows has the log type `BACKUP-DATA`, which shows the amount of data buffer used during backup to copy fragments to backup files. The other row has the log type `BACKUP-LOG`, which displays the amount of log buffer used during the backup to record changes made after the backup has started. One each of these `log_type` rows is shown in the `logbuffers` table for each data node in the cluster. These rows are not present unless an NDB backup is currently being performed.

23.6.14.34 The `ndbinfo logspaces` Table

This table provides information about NDB Cluster log space usage.

The `logspaces` table contains the following columns:

- `node_id`

The ID of this data node.

- `log_type`

Type of log; one of: `REDO` or `DD-UNDO`.

- `node_id`

The log ID; for Disk Data undo log files, this is the same as the value shown in the `LOGFILE_GROUP_NUMBER` column of the `INFORMATION_SCHEMA.FILES` table, as well as the value shown for the `log_id` column of the `ndbinfo logbuffers` table

- `log_part`

The log part number.

- `total`

Total space available for this log.

- `used`

Space used by this log.

23.6.14.35 The `ndbinfo membership` Table

The `membership` table describes the view that each data node has of all the others in the cluster, including node group membership, president node, arbitrator, arbitrator successor, arbitrator connection states, and other information.

The `membership` table contains the following columns:

- `node_id`
This node's node ID
- `group_id`
Node group to which this node belongs
- `left_node`
Node ID of the previous node
- `right_node`
Node ID of the next node
- `president`
President's node ID
- `successor`
Node ID of successor to president
- `succession_order`
Order in which this node succeeds to presidency
- `Conf_HB_order`
-
- `arbitrator`
Node ID of arbitrator
- `arb_ticket`
Internal identifier used to track arbitration
- `arb_state`
Arbitration state
- `arb_connected`
Whether this node is connected to the arbitrator; either of `Yes` or `No`
- `connected_rank1_arbs`
Connected arbitrators of rank 1
- `connected_rank2_arbs`
Connected arbitrators of rank 1

Notes

The node ID and node group ID are the same as reported by `ndb_mgm -e "SHOW"`.

`left_node` and `right_node` are defined in terms of a model that connects all data nodes in a circle, in order of their node IDs, similar to the ordering of the numbers on a clock dial, as shown here:

Figure 23.27 Circular Arrangement of NDB Cluster Nodes

In this example, we have 8 data nodes, numbered 5, 6, 7, 8, 12, 13, 14, and 15, ordered clockwise in a circle. We determine “left” and “right” from the interior of the circle. The node to the left of node 5 is node 15, and the node to the right of node 5 is node 6. You can see all these relationships by running the following query and observing the output:

```
mysql> SELECT node_id, left_node, right_node
-> FROM ndbinfo.membership;
```

| node_id | left_node | right_node |
|---------|-----------|------------|
| 5 | 15 | 6 |
| 6 | 5 | 7 |
| 7 | 6 | 8 |
| 8 | 7 | 12 |
| 12 | 8 | 13 |
| 13 | 12 | 14 |
| 14 | 13 | 15 |
| 15 | 14 | 5 |

```
8 rows in set (0.00 sec)
```

The designations “left” and “right” are used in the event log in the same way.

The `president` node is the node viewed by the current node as responsible for setting an arbitrator (see [NDB Cluster Start Phases](#)). If the president fails or becomes disconnected, the current node expects the node whose ID is shown in the `successor` column to become the new president. The `succession_order` column shows the place in the succession queue that the current node views itself as having.

In a normal NDB Cluster, all data nodes should see the same node as `president`, and the same node (other than the president) as its `successor`. In addition, the current president should see itself as `1` in the order of succession, the `successor` node should see itself as `2`, and so on.

All nodes should show the same `arb_ticket` values as well as the same `arb_state` values. Possible `arb_state` values are `ARBIT_NULL`, `ARBIT_INIT`, `ARBIT_FIND`, `ARBIT_PREP1`, `ARBIT_PREP2`, `ARBIT_START`, `ARBIT_RUN`, `ARBIT_CHOOSE`, `ARBIT_CRASH`, and `UNKNOWN`.

`arb_connected` shows whether this node is connected to the node shown as this node's `arbitorator`.

The `connected_rank1_arbs` and `connected_rank2_arbs` columns each display a list of 0 or more arbitrators having an `ArbitrationRank` equal to 1, or to 2, respectively.

**Note**

Both management nodes and API nodes are eligible to become arbitrators.

23.6.14.36 The ndbinfo memoryusage Table

Querying this table provides information similar to that provided by the `ALL REPORT MemoryUsage` command in the `ndb_mgm` client, or logged by `ALL DUMP 1000`.

The `memoryusage` table contains the following columns:

- `node_id`

The node ID of this data node.

- `memory_type`

One of `Data memory`, `Index memory`, or `Long message buffer`.

- `used`

Number of bytes currently used for data memory or index memory by this data node.

- `used_pages`

Number of pages currently used for data memory or index memory by this data node; see text.

- `total`

Total number of bytes of data memory or index memory available for this data node; see text.

- `total_pages`

Total number of memory pages available for data memory or index memory on this data node; see text.

Notes

The `total` column represents the total amount of memory in bytes available for the given resource (data memory or index memory) on a particular data node. This number should be approximately equal to the setting of the corresponding configuration parameter in the `config.ini` file.

Suppose that the cluster has 2 data nodes having node IDs 5 and 6, and the `config.ini` file contains the following:

```
[ndbd default]
DataMemory = 1G
IndexMemory = 1G
```

Suppose also that the value of the `LongMessageBuffer` configuration parameter is allowed to assume its default (64 MB).

The following query shows approximately the same values:

```
mysql> SELECT node_id, memory_type, total
> FROM ndbinfo.memoryusage;
+-----+-----+-----+
| node_id | memory_type | total |
+-----+-----+-----+
| 5 | Data memory | 1073741824 |
| 5 | Index memory | 1074003968 |
```

| | | |
|---|---------------------|------------|
| 5 | Long message buffer | 67108864 |
| 6 | Data memory | 1073741824 |
| 6 | Index memory | 1074003968 |
| 6 | Long message buffer | 67108864 |

6 rows in set (0.00 sec)

In this case, the `total` column values for index memory are slightly higher than the value set of `IndexMemory` due to internal rounding.

For the `used_pages` and `total_pages` columns, resources are measured in pages, which are 32K in size for `DataMemory` and 8K for `IndexMemory`. For long message buffer memory, the page size is 256 bytes.

23.6.14.37 The `ndbinfo memory_per_fragment` Table

The `memory_per_fragment` table provides information about the usage of memory by individual fragments.

The `memory_per_fragment` table contains the following columns:

- `fq_name`
Name of this fragment
- `parent_fq_name`
Name of this fragment's parent
- `type`
Type of object; see text for possible values
- `table_id`
Table ID for this table
- `node_id`
Node ID for this node
- `block_instance`
Kernel block instance ID
- `fragment_num`
Fragment ID (number)
- `fixed_elem_alloc_bytes`
Number of bytes allocated for fixed-sized elements
- `fixed_elem_free_bytes`
Free bytes remaining in pages allocated to fixed-size elements
- `fixed_elem_size_bytes`
Length of each fixed-size element in bytes

- `fixed_elem_count`
Number of fixed-size elements
- `fixed_elem_free_count`
Number of free rows for fixed-size elements
- `var_elem_alloc_bytes`
Number of bytes allocated for variable-size elements
- `var_elem_free_bytes`
Free bytes remaining in pages allocated to variable-size elements
- `var_elem_count`
Number of variable-size elements
- `hash_index_alloc_bytes`
Number of bytes allocated to hash indexes

Notes

The `type` column from this table shows the dictionary object type used for this fragment (`Object::Type`, in the NDB API), and can take any one of the values shown in the following list:

- System table
- User table
- Unique hash index
- Hash index
- Unique ordered index
- Ordered index
- Hash index trigger
- Subscription trigger
- Read only constraint
- Index trigger
- Reorganize trigger
- Tablespace
- Log file group
- Data file
- Undo file
- Hash map

- Foreign key definition
- Foreign key parent trigger
- Foreign key child trigger
- Schema transaction

You can also obtain this list by executing `SELECT * FROM ndbinfo.dict_obj_types` in the `mysql` client.

The `block_instance` column provides the NDB kernel block instance number. You can use this to obtain information about specific threads from the `threadblocks` table.

23.6.14.38 The ndbinfo nodes Table

This table contains information on the status of data nodes. For each data node that is running in the cluster, a corresponding row in this table provides the node's node ID, status, and uptime. For nodes that are starting, it also shows the current start phase.

The `nodes` table contains the following columns:

- `node_id`

The data node's unique node ID in the cluster.

- `uptime`

Time since the node was last started, in seconds.

- `status`

Current status of the data node; see text for possible values.

- `start_phase`

If the data node is starting, the current start phase.

- `config_generation`

The version of the cluster configuration file in use on this data node.

Notes

The `uptime` column shows the time in seconds that this node has been running since it was last started or restarted. This is a `BIGINT` value. This figure includes the time actually needed to start the node; in other words, this counter starts running the moment that `ndbd` or `ndbmta` is first invoked; thus, even for a node that has not yet finished starting, `uptime` may show a nonzero value.

The `status` column shows the node's current status. This is one of: `NOTHING`, `CMVMI`, `STARTING`, `STARTED`, `SINGLEUSER`, `STOPPING_1`, `STOPPING_2`, `STOPPING_3`, or `STOPPING_4`. When the status is `STARTING`, you can see the current start phase in the `start_phase` column (see later in this section). `SINGLEUSER` is displayed in the `status` column for all data nodes when the cluster is in single user mode (see [Section 23.6.6, "NDB Cluster Single User Mode"](#)). Seeing one of the `STOPPING` states does not necessarily mean that the node is shutting down but can mean rather that it is entering a new state. For example, if you put the cluster in single user mode, you can sometimes see data nodes report their state briefly as `STOPPING_2` before the status changes to `SINGLEUSER`.

The `start_phase` column uses the same range of values as those used in the output of the `ndb_mgm` client `node_id STATUS` command (see [Section 23.6.1, “Commands in the NDB Cluster Management Client”](#)). If the node is not currently starting, then this column shows `0`. For a listing of NDB Cluster start phases with descriptions, see [Section 23.6.4, “Summary of NDB Cluster Start Phases”](#).

The `config_generation` column shows which version of the cluster configuration is in effect on each data node. This can be useful when performing a rolling restart of the cluster in order to make changes in configuration parameters. For example, from the output of the following `SELECT` statement, you can see that node 3 is not yet using the latest version of the cluster configuration (`6`) although nodes 1, 2, and 4 are doing so:

```
mysql> USE ndbinfo;
Database changed
mysql> SELECT * FROM nodes;
+-----+-----+-----+-----+-----+
| node_id | uptime | status | start_phase | config_generation |
+-----+-----+-----+-----+-----+
|      1 | 10462 | STARTED |          0 |          6 |
|      2 | 10460 | STARTED |          0 |          6 |
|      3 | 10457 | STARTED |          0 |          5 |
|      4 | 10455 | STARTED |          0 |          6 |
+-----+-----+-----+-----+-----+
2 rows in set (0.04 sec)
```

Therefore, for the case just shown, you should restart node 3 to complete the rolling restart of the cluster.

Nodes that are stopped are not accounted for in this table. Suppose that you have an NDB Cluster with 4 data nodes (node IDs 1, 2, 3 and 4), and all nodes are running normally, then this table contains 4 rows, 1 for each data node:

```
mysql> USE ndbinfo;
Database changed
mysql> SELECT * FROM nodes;
+-----+-----+-----+-----+-----+
| node_id | uptime | status | start_phase | config_generation |
+-----+-----+-----+-----+-----+
|      1 | 11776 | STARTED |          0 |          6 |
|      2 | 11774 | STARTED |          0 |          6 |
|      3 | 11771 | STARTED |          0 |          6 |
|      4 | 11769 | STARTED |          0 |          6 |
+-----+-----+-----+-----+-----+
4 rows in set (0.04 sec)
```

If you shut down one of the nodes, only the nodes that are still running are represented in the output of this `SELECT` statement, as shown here:

```
ndb_mgm> 2 STOP
Node 2: Node shutdown initiated
Node 2: Node shutdown completed.
Node 2 has shutdown.

mysql> SELECT * FROM nodes;
+-----+-----+-----+-----+-----+
| node_id | uptime | status | start_phase | config_generation |
+-----+-----+-----+-----+-----+
|      1 | 11807 | STARTED |          0 |          6 |
|      3 | 11802 | STARTED |          0 |          6 |
|      4 | 11800 | STARTED |          0 |          6 |
+-----+-----+-----+-----+-----+
3 rows in set (0.02 sec)
```

23.6.14.39 The `ndbinfo` `operations_per_fragment` Table

The `operations_per_fragment` table provides information about the operations performed on individual fragments and fragment replicas, as well as about some of the results from these operations.

The `operations_per_fragment` table contains the following columns:

- `fq_name`
Name of this fragment
- `parent_fq_name`
Name of this fragment's parent
- `type`
Type of object; see text for possible values
- `table_id`
Table ID for this table
- `node_id`
Node ID for this node
- `block_instance`
Kernel block instance ID
- `fragment_num`
Fragment ID (number)
- `tot_key_reads`
Total number of key reads for this fragment replica
- `tot_key_inserts`
Total number of key inserts for this fragment replica
- `tot_key_updates`
total number of key updates for this fragment replica
- `tot_key_writes`
Total number of key writes for this fragment replica
- `tot_key_deletes`
Total number of key deletes for this fragment replica
- `tot_key_refs`
Number of key operations refused
- `tot_key_attrinfo_bytes`
Total size of all `attrinfo` attributes

- `tot_key_keyinfo_bytes`
Total size of all `keyinfo` attributes
- `tot_key_prog_bytes`
Total size of all interpreted programs carried by `attrinfo` attributes
- `tot_key_inst_exec`
Total number of instructions executed by interpreted programs for key operations
- `tot_key_bytes_returned`
Total size of all data and metadata returned from key read operations
- `tot_frag_scans`
Total number of scans performed on this fragment replica
- `tot_scan_rows_examined`
Total number of rows examined by scans
- `tot_scan_rows_returned`
Total number of rows returned to client
- `tot_scan_bytes_returned`
Total size of data and metadata returned to the client
- `tot_scan_prog_bytes`
Total size of interpreted programs for scan operations
- `tot_scan_bound_bytes`
Total size of all bounds used in ordered index scans
- `tot_scan_inst_exec`
Total number of instructions executed for scans
- `tot_qd_frag_scans`
Number of times that scans of this fragment replica have been queued
- `conc_frag_scans`
Number of scans currently active on this fragment replica (excluding queued scans)
- `conc_qd_frag_scans`
Number of scans currently queued for this fragment replica
- `tot_commits`
Total number of row changes committed to this fragment replica

Notes

The `fq_name` contains the fully qualified name of the schema object to which this fragment replica belongs. This currently has the following formats:

- Base table: `DbName/def/TblName`
- BLOB table: `DbName/def/NDB$BLOB_BaseTblId_ColNo`
- Ordered index: `sys/def/BaseTblId/IndexName`
- Unique index: `sys/def/BaseTblId/IndexName$unique`

The `$unique` suffix shown for unique indexes is added by `mysql`; for an index created by a different NDB API client application, this may differ, or not be present.

The syntax just shown for fully qualified object names is an internal interface which is subject to change in future releases.

Consider a table `t1` created and modified by the following SQL statements:

```
CREATE DATABASE mydb;

USE mydb;

CREATE TABLE t1 (
  a INT NOT NULL,
  b INT NOT NULL,
  t TEXT NOT NULL,
  PRIMARY KEY (b)
) ENGINE=ndbcluster;

CREATE UNIQUE INDEX ix1 ON t1(b) USING HASH;
```

If `t1` is assigned table ID 11, this yields the `fq_name` values shown here:

- Base table: `mydb/def/t1`
- BLOB table: `mydb/def/NDB$BLOB_11_2`
- Ordered index (primary key): `sys/def/11/PRIMARY`
- Unique index: `sys/def/11/ix1$unique`

For indexes or BLOB tables, the `parent_fq_name` column contains the `fq_name` of the corresponding base table. For base tables, this column is always `NULL`.

The `type` column shows the schema object type used for this fragment, which can take any one of the values `System table`, `User table`, `Unique hash index`, or `Ordered index`. BLOB tables are shown as `User table`.

The `table_id` column value is unique at any given time, but can be reused if the corresponding object has been deleted. The same ID can be seen using the `ndb_show_tables` utility.

The `block_instance` column shows which LDM instance this fragment replica belongs to. You can use this to obtain information about specific threads from the `threadblocks` table. The first such instance is always numbered 0.

Since there are typically two fragment replicas, and assuming that this is so, each `fragment_num` value should appear twice in the table, on two different data nodes from the same node group.

Since *NDB* does not use single-key access for ordered indexes, the counts for `tot_key_reads`, `tot_key_inserts`, `tot_key_updates`, `tot_key_writes`, and `tot_key_deletes` are not incremented by ordered index operations.

Note

When using `tot_key_writes`, you should keep in mind that a write operation in this context updates the row if the key exists, and inserts a new row otherwise. (One use of this is in the *NDB* implementation of the `REPLACE` SQL statement.)

The `tot_key_refs` column shows the number of key operations refused by the LDM. Generally, such a refusal is due to duplicate keys (inserts), `Key not found` errors (updates, deletes, and reads), or the operation was rejected by an interpreted program used as a predicate on the row matching the key.

The `attrinfo` and `keyinfo` attributes counted by the `tot_key_attrinfo_bytes` and `tot_key_keyinfo_bytes` columns are attributes of an `LQHKEYREQ` signal (see [The NDB Communication Protocol](#)) used to initiate a key operation by the LDM. An `attrinfo` typically contains tuple field values (inserts and updates) or projection specifications (for reads); `keyinfo` contains the primary or unique key needed to locate a given tuple in this schema object.

The value shown by `tot_frag_scans` includes both full scans (that examine every row) and scans of subsets. Unique indexes and `BLOB` tables are never scanned, so this value, like other scan-related counts, is 0 for fragment replicas of these.

`tot_scan_rows_examined` may display less than the total number of rows in a given fragment replica, since ordered index scans can be limited by bounds. In addition, a client may choose to end a scan before all potentially matching rows have been examined; this occurs when using an SQL statement containing a `LIMIT` or `EXISTS` clause, for example. `tot_scan_rows_returned` is always less than or equal to `tot_scan_rows_examined`.

`tot_scan_bytes_returned` includes, in the case of pushed joins, projections returned to the `DBSPJ` block in the *NDB* kernel.

`tot_qd_frag_scans` can be affected by the setting for the `MaxParallelScansPerFragment` data node configuration parameter, which limits the number of scans that may execute concurrently on a single fragment replica.

23.6.14.40 The `ndbinfo pgman_time_track_stats` Table

This table provides information regarding the latency of disk operations for *NDB* Cluster Disk Data tablespaces.

The `pgman_time_track_stats` table contains the following columns:

- `node_id`
Unique node ID of this node in the cluster
- `block_number`
Block number (from `blocks` table)
- `block_instance`
Block instance number
- `upper_bound`

Upper bound

- [page_reads](#)

Page read latency (ms)

- [page_writes](#)

Page write latency (ms)

- [log_waits](#)

Log wait latency (ms)

- [get_page](#)

Latency of `get_page()` calls (ms)

Notes

The read latency ([page_reads](#) column) measures the time from when the read request is sent to the file system thread until the read is complete and has been reported back to the execution thread. The write latency ([page_writes](#)) is calculated in a similar fashion. The size of the page read to or written from a Disk Data tablespace is always 32 KB.

Log wait latency ([log_waits](#) column) is the length of time a page write must wait for the undo log to be flushed, which must be done prior to each page write.

23.6.14.41 The `ndbinfo` processes Table

This table contains information about NDB Cluster node processes; each node is represented by the row in the table. Only nodes that are connected to the cluster are shown in this table. You can obtain information about nodes that are configured but not connected to the cluster from the [nodes](#) and [config_nodes](#) tables.

The `processes` table contains the following columns:

- [node_id](#)

The node's unique node ID in the cluster

- [node_type](#)

Type of node (management, data, or API node; see text)

- [node_version](#)

Version of the NDB software program running on this node.

- [process_id](#)

This node's process ID

- [angel_process_id](#)

Process ID of this node's angel process

- [process_name](#)

Name of the executable

- `service_URI`

Service URI of this node (see text)

Notes

`node_id` is the ID assigned to this node in the cluster.

The `node_type` column displays one of the following three values:

- **MGM**: Management node.
- **NDB**: Data node.
- **API**: API or SQL node.

For an executable shipped with the NDB Cluster distribution, `node_version` shows the software Cluster version string, such as `8.0.27-ndb-8.0.27`.

`process_id` is the node executable's process ID as shown by the host operating system using a process display application such as `top` on Linux, or the Task Manager on Windows platforms.

`angel_process_id` is the system process ID for the node's angel process, which ensures that a data node or SQL is automatically restarted in cases of failures. For management nodes and API nodes other than SQL nodes, the value of this column is `NULL`.

The `process_name` column shows the name of the running executable. For management nodes, this is `ndb_mgmd`. For data nodes, this is `ndbd` (single-threaded) or `ndbmtd` (multithreaded). For SQL nodes, this is `mysqld`. For other types of API nodes, it is the name of the executable program connected to the cluster; NDB API applications can set a custom value for this using `Ndb_cluster_connection::set_name()`.

`service_URI` shows the service network address. For management nodes and data nodes, the scheme used is `ndb://`. For SQL nodes, this is `mysql://`. By default, API nodes other than SQL nodes use `ndb://` for the scheme; NDB API applications can set this to a custom value using `Ndb_cluster_connection::set_service_uri()`. regardless of the node type, the scheme is followed by the IP address used by the NDB transporter for the node in question. For management nodes and SQL nodes, this address includes the port number (usually 1186 for management nodes and 3306 for SQL nodes). If the SQL node was started with the `bind_address` system variable set, this address is used instead of the transporter address, unless the bind address is set to `*`, `0.0.0.0`, or `::`.

Additional path information may be included in the `service_URI` value for an SQL node reflecting various configuration options. For example, `mysql://198.51.100.3/tmp/mysql.sock` indicates that the SQL node was started with the `skip_networking` system variable enabled, and `mysql://198.51.100.3:3306/?server-id=1` shows that replication is enabled for this SQL node.

23.6.14.42 The ndbinfo resources Table

This table provides information about data node resource availability and usage.

These resources are sometimes known as *super-pools*.

The `resources` table contains the following columns:

- `node_id`

The unique node ID of this data node.

- `resource_name`

Name of the resource; see text.

- `reserved`

The amount reserved for this resource.

- `used`

The amount actually used by this resource.

- `max`

The maximum amount of this resource used, since the node was last started.

Notes

The `resource_name` can be any one of the names shown in the following table:

- **RESERVED:** Reserved by the system; cannot be overridden.
- **DISK_OPERATIONS:** If a log file group is allocated, the size of the undo log buffer is used to set the size of this resource. This resource is used only to allocate the undo log buffer for an undo log file group; there can only be one such group. Overallocation occurs as needed by `CREATE LOGFILE GROUP`.
- **DISK_RECORDS:** Records allocated for Disk Data operations.
- **DATA_MEMORY:** Used for main memory tuples, indexes, and hash indexes. Sum of DataMemory and IndexMemory, plus 8 pages of 32 KB each if IndexMemory has been set. Cannot be overallocated.
- **JOBBUFFER:** Used for allocating job buffers by the NDB scheduler; cannot be overallocated. This is approximately 2 MB per thread plus a 1 MB buffer in both directions for all threads that can communicate. For large configurations this consume several GB.
- **FILE_BUFFERS:** Used by the redo log handler in the `DBLQH` kernel block; cannot be overallocated. Size is `NoOfFragmentLogParts * RedoBuffer`, plus 1 MB per log file part.
- **TRANSPORTER_BUFFERS:** Used for send buffers by `ndbmt`; the sum of `TotalSendBufferMemory` and `ExtraSendBufferMemory`. This resource that can be overallocated by up to 25 percent. `TotalSendBufferMemory` is calculated by summing the send buffer memory per node, the default value of which is 2 MB. Thus, in a system having four data nodes and eight API nodes, the data nodes have $12 * 2$ MB send buffer memory. `ExtraSendBufferMemory` is used by `ndbmt` and amounts to 2 MB extra memory per thread. Thus, with 4 LDM threads, 2 TC threads, 1 main thread, 1 replication thread, and 2 receive threads, `ExtraSendBufferMemory` is $10 * 2$ MB. Overallocation of this resource can be performed by setting the `SharedGlobalMemory` data node configuration parameter.
- **DISK_PAGE_BUFFER:** Used for the disk page buffer; determined by the `DiskPageBufferMemory` configuration parameter. Cannot be overallocated.
- **QUERY_MEMORY:** Used by the `DBSPJ` kernel block.
- **SCHEMA_TRANS_MEMORY:** Minimum is 2 MB; can be overallocated to use any remaining available memory.

23.6.14.43 The ndbinfo restart_info Table

The `restart_info` table contains information about node restart operations. Each entry in the table corresponds to a node restart status report in real time from a data node with the given node ID. Only the most recent report for any given node is shown.

The `restart_info` table contains the following columns:

- `node_id`
Node ID in the cluster
- `node_restart_status`
Node status; see text for values. Each of these corresponds to a possible value of `node_restart_status_int`.
- `node_restart_status_int`
Node status code; see text for values.
- `secs_to_complete_node_failure`
Time in seconds to complete node failure handling
- `secs_to_allocate_node_id`
Time in seconds from node failure completion to allocation of node ID
- `secs_to_include_in_heartbeat_protocol`
Time in seconds from allocation of node ID to inclusion in heartbeat protocol
- `secs_until_wait_for_ndbcntr_master`
Time in seconds from being included in heartbeat protocol until waiting for `NDBCNTR` master began
- `secs_wait_for_ndbcntr_master`
Time in seconds spent waiting to be accepted by `NDBCNTR` master for starting
- `secs_to_get_start_permitted`
Time in seconds elapsed from receiving of permission for start from master until all nodes have accepted start of this node
- `secs_to_wait_for_lcp_for_copy_meta_data`
Time in seconds spent waiting for LCP completion before copying metadata
- `secs_to_copy_meta_data`
Time in seconds required to copy metadata from master to newly starting node
- `secs_to_include_node`
Time in seconds waited for GCP and inclusion of all nodes into protocols
- `secs_starting_node_to_request_local_recovery`
Time in seconds that the node just starting spent waiting to request local recovery

- `secs_for_local_recovery`
Time in seconds required for local recovery by node just starting
- `secs_restore_fragments`
Time in seconds required to restore fragments from LCP files
- `secs_undo_disk_data`
Time in seconds required to execute undo log on disk data part of records
- `secs_exec_redo_log`
Time in seconds required to execute redo log on all restored fragments
- `secs_index_rebuild`
Time in seconds required to rebuild indexes on restored fragments
- `secs_to_synchronize_starting_node`
Time in seconds required to synchronize starting node from live nodes
- `secs_wait_lcp_for_restart`
Time in seconds required for LCP start and completion before restart was completed
- `secs_wait_subscription_handover`
Time in seconds spent waiting for handover of replication subscriptions
- `total_restart_secs`
Total number of seconds from node failure until node is started again

Notes

The following list contains values defined for the `node_restart_status_int` column with their internal status names (in parentheses), and the corresponding messages shown in the `node_restart_status` column:

- 0 (ALLOCATED_NODE_ID)
`Allocated node id`
- 1 (INCLUDED_IN_HB_PROTOCOL)
`Included in heartbeat protocol`
- 2 (NDBCNTR_START_WAIT)
`Wait for NDBCNTR master to permit us to start`
- 3 (NDBCNTR_STARTED)
`NDBCNTR master permitted us to start`
- 4 (START_PERMITTED)

All nodes permitted us to start

- 5 (WAIT_LCP_TO_COPY_DICT)

Wait for LCP completion to start copying metadata

- 6 (COPY_DICT_TO_STARTING_NODE)

Copying metadata to starting node

- 7 (INCLUDE_NODE_IN_LCP_AND_GCP)

Include node in LCP and GCP protocols

- 8 (LOCAL_RECOVERY_STARTED)

Restore fragments ongoing

- 9 (COPY_FRAGMENTS_STARTED)

Synchronizing starting node with live nodes

- 10 (WAIT_LCP_FOR_RESTART)

Wait for LCP to ensure durability

- 11 (WAIT_SUMA_HANOVER)

Wait for handover of subscriptions

- 12 (RESTART_COMPLETED)

Restart completed

- 13 (NODE_FAILED)

Node failed, failure handling in progress

- 14 (NODE_FAILURE_COMPLETED)

Node failure handling completed

- 15 (NODE_GETTING_PERMIT)

All nodes permitted us to start

- 16 (NODE_GETTING_INCLUDED)

Include node in LCP and GCP protocols

- 17 (NODE_GETTING_SYNCED)

Synchronizing starting node with live nodes

- 18 (NODE_GETTING_LCP_WAITED)

[none]

- 19 (NODE_ACTIVE)

Restart completed

- 20 (NOT_DEFINED_IN_CLUSTER)

[none]

- 21 (NODE_NOT_RESTARTED_YET)

Initial state

Status numbers 0 through 12 apply on master nodes only; the remainder of those shown in the table apply to all restarting data nodes. Status numbers 13 and 14 define node failure states; 20 and 21 occur when no information about the restart of a given node is available.

See also [Section 23.6.4, “Summary of NDB Cluster Start Phases”](#).

23.6.14.44 The ndbinfo server_locks Table

The `server_locks` table is similar in structure to the `cluster_locks` table, and provides a subset of the information found in the latter table, but which is specific to the SQL node (MySQL server) where it resides. (The `cluster_locks` table provides information about all locks in the cluster.) More precisely, `server_locks` contains information about locks requested by threads belonging to the current `mysqld` instance, and serves as a companion table to `server_operations`. This may be useful for correlating locking patterns with specific MySQL user sessions, queries, or use cases.

The `server_locks` table contains the following columns:

- `mysql_connection_id`
MySQL connection ID
- `node_id`
ID of reporting node
- `block_instance`
ID of reporting LDM instance
- `tableid`
ID of table containing this row
- `fragmentid`
ID of fragment containing locked row
- `rowid`
ID of locked row
- `transid`
Transaction ID
- `mode`
Lock request mode

- `state`
Lock state
- `detail`
Whether this is first holding lock in row lock queue
- `op`
Operation type
- `duration_millis`
Milliseconds spent waiting or holding lock
- `lock_num`
ID of lock object
- `waiting_for`
Waiting for lock with this ID

Notes

The `mysql_connection_id` column shows the MySQL connection or thread ID as shown by `SHOW PROCESSLIST`.

`block_instance` refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the `threadblocks` table.

The `tableid` is assigned to the table by `NDB`; the same ID is used for this table in other `ndbinfo` tables, as well as in the output of `ndb_show_tables`.

The transaction ID shown in the `transid` column is the identifier generated by the NDB API for the transaction requesting or holding the current lock.

The `mode` column shows the lock mode, which is always one of `S` (shared lock) or `X` (exclusive lock). If a transaction has an exclusive lock on a given row, all other locks on that row have the same transaction ID.

The `state` column shows the lock state. Its value is always one of `H` (holding) or `W` (waiting). A waiting lock request waits for a lock held by a different transaction.

The `detail` column indicates whether this lock is the first holding lock in the affected row's lock queue, in which case it contains a `*` (asterisk character); otherwise, this column is empty. This information can be used to help identify the unique entries in a list of lock requests.

The `op` column shows the type of operation requesting the lock. This is always one of the values `READ`, `INSERT`, `UPDATE`, `DELETE`, `SCAN`, or `REFRESH`.

The `duration_millis` column shows the number of milliseconds for which this lock request has been waiting or holding the lock. This is reset to 0 when a lock is granted for a waiting request.

The lock ID (`lockid` column) is unique to this node and block instance.

If the `lock_state` column's value is `W`, this lock is waiting to be granted, and the `waiting_for` column shows the lock ID of the lock object this request is waiting for. Otherwise, `waiting_for` is empty. `waiting_for` can refer only to locks on the same row (as identified by `node_id`, `block_instance`, `tableid`, `fragmentid`, and `rowid`).

23.6.14.45 The `ndbinfo server_operations` Table

The `server_operations` table contains entries for all ongoing `NDB` operations that the current SQL node (MySQL Server) is currently involved in. It effectively is a subset of the `cluster_operations` table, in which operations for other SQL and API nodes are not shown.

The `server_operations` table contains the following columns:

- `mysql_connection_id`
MySQL Server connection ID
- `node_id`
Node ID
- `block_instance`
Block instance
- `transid`
Transaction ID
- `operation_type`
Operation type (see text for possible values)
- `state`
Operation state (see text for possible values)
- `tableid`
Table ID
- `fragmentid`
Fragment ID
- `client_node_id`
Client node ID
- `client_block_ref`
Client block reference
- `tc_node_id`
Transaction coordinator node ID
- `tc_block_no`
Transaction coordinator block number
- `tc_block_instance`
Transaction coordinator block instance

Notes

The `mysql_connection_id` is the same as the connection or session ID shown in the output of `SHOW PROCESSLIST`. It is obtained from the `INFORMATION_SCHEMA` table `NDB_TRANSID_MYSQL_CONNECTION_MAP`.

`block_instance` refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the `threadblocks` table.

The transaction ID (`transid`) is a unique 64-bit number which can be obtained using the NDB API's `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The `operation_type` column can take any one of the values `READ`, `READ-SH`, `READ-EX`, `INSERT`, `UPDATE`, `DELETE`, `WRITE`, `UNLOCK`, `REFRESH`, `SCAN`, `SCAN-SH`, `SCAN-EX`, or `<unknown>`.

The `state` column can have any one of the values `ABORT_QUEUED`, `ABORT_STOPPED`, `COMMITTED`, `COMMIT_QUEUED`, `COMMIT_STOPPED`, `COPY_CLOSE_STOPPED`, `COPY_FIRST_STOPPED`, `COPY_STOPPED`, `COPY_TUPKEY`, `IDLE`, `LOG_ABORT_QUEUED`, `LOG_COMMIT_QUEUED`, `LOG_COMMIT_QUEUED_WAIT_SIGNAL`, `LOG_COMMIT_WRITTEN`, `LOG_COMMIT_WRITTEN_WAIT_SIGNAL`, `LOG_QUEUED`, `PREPARED`, `PREPARED_RECEIVED_COMMIT`, `SCAN_CHECK_STOPPED`, `SCAN_CLOSE_STOPPED`, `SCAN_FIRST_STOPPED`, `SCAN_RELEASE_STOPPED`, `SCAN_STATE_USED`, `SCAN_STOPPED`, `SCAN_TUPKEY`, `STOPPED`, `TC_NOT_CONNECTED`, `WAIT_ACC`, `WAIT_ACC_ABORT`, `WAIT_AI_AFTER_ABORT`, `WAIT_ATTR`, `WAIT_SCAN_AI`, `WAIT_TUP`, `WAIT_TUPKEYINFO`, `WAIT_TUP_COMMIT`, or `WAIT_TUP_TO_ABORT`. (If the MySQL Server is running with `ndbinfo_show_hidden` enabled, you can view this list of states by selecting from the `ndb $dbldqh_tcconnect_state` table, which is normally hidden.)

You can obtain the name of an NDB table from its table ID by checking the output of `ndb_show_tables`.

The `fragid` is the same as the partition number seen in the output of `ndb_desc --extra-partition-info` (short form `-p`).

In `client_node_id` and `client_block_ref`, `client` refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

The `block_instance` and `tc_block_instance` column provide NDB kernel block instance numbers. You can use these to obtain information about specific threads from the `threadblocks` table.

23.6.14.46 The `ndbinfo server_transactions` Table

The `server_transactions` table is subset of the `cluster_transactions` table, but includes only those transactions in which the current SQL node (MySQL Server) is a participant, while including the relevant connection IDs.

The `server_transactions` table contains the following columns:

- `mysql_connection_id`
MySQL Server connection ID
- `node_id`
Transaction coordinator node ID
- `block_instance`
Transaction coordinator block instance

- `transid`
Transaction ID
- `state`
Operation state (see text for possible values)
- `count_operations`
Number of stateful operations in the transaction
- `outstanding_operations`
Operations still being executed by local data management layer (LQH blocks)
- `inactive_seconds`
Time spent waiting for API
- `client_node_id`
Client node ID
- `client_block_ref`
Client block reference

Notes

The `mysql_connection_id` is the same as the connection or session ID shown in the output of `SHOW PROCESSLIST`. It is obtained from the `INFORMATION_SCHEMA` table `NDB_TRANSID_MYSQL_CONNECTION_MAP`.

`block_instance` refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the `threadblocks` table.

The transaction ID (`transid`) is a unique 64-bit number which can be obtained using the NDB API's `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The `state` column can have any one of the values `CS_ABORTING`, `CS_COMMITTING`, `CS_COMMIT_SENT`, `CS_COMPLETE_SENT`, `CS_COMPLETING`, `CS_CONNECTED`, `CS_DISCONNECTED`, `CS_FAIL_ABORTED`, `CS_FAIL_ABORTING`, `CS_FAIL_COMMITTED`, `CS_FAIL_COMMITTING`, `CS_FAIL_COMPLETED`, `CS_FAIL_PREPARED`, `CS_PREPARE_TO_COMMIT`, `CS_RECEIVING`, `CS_REC_COMMITTING`, `CS_RESTART`, `CS_SEND_FIRE_TRIG_REQ`, `CS_STARTED`, `CS_START_COMMITTING`, `CS_START_SCAN`, `CS_WAIT_ABORT_CONF`, `CS_WAIT_COMMIT_CONF`, `CS_WAIT_COMPLETE_CONF`, `CS_WAIT_FIRE_TRIG_REQ`. (If the MySQL Server is running with `ndbinfo_show_hidden` enabled, you can view this list of states by selecting from the `ndb$dbtc_apiconnect_state` table, which is normally hidden.)

In `client_node_id` and `client_block_ref`, `client` refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

The `block_instance` column provides the `DBTC` kernel block instance number. You can use this to obtain information about specific threads from the `threadblocks` table.

23.6.14.47 The `ndbinfo` `table_distribution_status` Table

The `table_distribution_status` table provides information about the progress of table distribution for NDB tables.

The `table_distribution_status` table contains the following columns:

- `node_id`

Node id

- `table_id`

Table ID

- `tab_copy_status`

Status of copying of table distribution data to disk; one of `IDLE`, `SR_PHASE1_READ_PAGES`, `SR_PHASE2_READ_TABLE`, `SR_PHASE3_COPY_TABLE`, `REMOVE_NODE`, `LCP_READ_TABLE`, `COPY_TAB_REQ`, `COPY_NODE_STATE`, `ADD_TABLE_COORDINATOR` (*prior to NDB 8.0.23: ADD_TABLE_MASTER*), `ADD_TABLE_PARTICIPANT` (*prior to NDB 8.0.23: ADD_TABLE_SLAVE*), `INVALIDATE_NODE_LCP`, `ALTER_TABLE`, `COPY_TO_SAVE`, or `GET_TABINFO`

- `tab_update_status`

Status of updating of table distribution data; one of `IDLE`, `LOCAL_CHECKPOINT`, `LOCAL_CHECKPOINT_QUEUED`, `REMOVE_NODE`, `COPY_TAB_REQ`, `ADD_TABLE_MASTER`, `ADD_TABLE_SLAVE`, `INVALIDATE_NODE_LCP`, or `CALLBACK`

- `tab_lcp_status`

Status of table LCP; one of `ACTIVE` (waiting for local checkpoint to be performed), `WRITING_TO_FILE` (checkpoint performed but not yet written to disk), or `COMPLETED` (checkpoint performed and persisted to disk)

- `tab_status`

Table internal status; one of `ACTIVE` (table exists), `CREATING` (table is being created), or `DROPPING` (table is being dropped)

- `tab_storage`

Table recoverability; one of `NORMAL` (fully recoverable with redo logging and checkpointing), `NOLOGGING` (recoverable from node crash, empty following cluster crash), or `TEMPORARY` (not recoverable)

- `tab_partitions`

Number of partitions in table

- `tab_fragments`

Number of fragments in table; normally same as `tab_partitions`; for fully replicated tables equal to `tab_partitions * [number of node groups]`

- `current_scan_count`

Current number of active scans

- `scan_count_wait`

Current number of scans waiting to be performed before `ALTER TABLE` can complete.

- `is_reorg_ongoing`

Whether the table is currently being reorganized (1 if true)

23.6.14.48 The `ndbinfo table_fragments` Table

The `table_fragments` table provides information about the fragmentation, partitioning, distribution, and (internal) replication of NDB tables.

The `table_fragments` table contains the following columns:

- `node_id`
Node ID (DIH master)
- `table_id`
Table ID
- `partition_id`
Partition ID
- `fragment_id`
Fragment ID (same as partition ID unless table is fully replicated)
- `partition_order`
Order of fragment in partition
- `log_part_id`
Log part ID of fragment
- `no_of_replicas`
Number of fragment replicas
- `current_primary`
Current primary node ID
- `preferred_primary`
Preferred primary node ID
- `current_first_backup`
Current first backup node ID
- `current_second_backup`
Current second backup node ID
- `current_third_backup`
Current third backup node ID
- `num_alive_replicas`

Current number of live fragment replicas

- `num_dead_replicas`

Current number of dead fragment replicas

- `num_lcp_replicas`

Number of fragment replicas remaining to be checkpointed

23.6.14.49 The `ndbinfo table_info` Table

The `table_info` table provides information about logging, checkpointing, distribution, and storage options in effect for individual `NDB` tables.

The `table_info` table contains the following columns:

- `table_id`

Table ID

- `logged_table`

Whether table is logged (1) or not (0)

- `row_contains_gci`

Whether table rows contain GCI (1 true, 0 false)

- `row_contains_checksum`

Whether table rows contain checksum (1 true, 0 false)

- `read_backup`

If backup fragment replicas are read this is 1, otherwise 0

- `fully_replicated`

If table is fully replicated this is 1, otherwise 0

- `storage_type`

Table storage type; one of `MEMORY` or `DISK`

- `hashmap_id`

Hashmap ID

- `partition_balance`

Partition balance (fragment count type) used for table; one of `FOR_RP_BY_NODE`, `FOR_RA_BY_NODE`, `FOR_RP_BY_LDM`, or `FOR_RA_BY_LDM`

- `create_gci`

GCI in which table was created

23.6.14.50 The `ndbinfo table_replicas` Table

The `table_replicas` table provides information about the copying, distribution, and checkpointing of NDB table fragments and fragment replicas.

The `table_replicas` table contains the following columns:

- `node_id`
ID of the node from which data is fetched (DIH master)
- `table_id`
Table ID
- `fragment_id`
Fragment ID
- `initial_gci`
Initial GCI for table
- `replica_node_id`
ID of node where fragment replica is stored
- `is_lcp_ongoing`
Is 1 if LCP is ongoing on this fragment, 0 otherwise
- `num_crashed_replicas`
Number of crashed fragment replica instances
- `last_max_gci_started`
Highest GCI started in most recent LCP
- `last_max_gci_completed`
Highest GCI completed in most recent LCP
- `last_lcp_id`
ID of most recent LCP
- `prev_lcp_id`
ID of previous LCP
- `prev_max_gci_started`
Highest GCI started in previous LCP
- `prev_max_gci_completed`
Highest GCI completed in previous LCP
- `last_create_gci`
Last Create GCI of last crashed fragment replica instance

- `last_replica_gci`
Last GCI of last crashed fragment replica instance
- `is_replica_alive`
1 if this fragment replica is alive, 0 otherwise

23.6.14.51 The `ndbinfo tc_time_track_stats` Table

The `tc_time_track_stats` table provides time-tracking information obtained from the `DBTC` block (TC) instances in the data nodes, through API nodes access `NDB`. Each TC instance tracks latencies for a set of activities it undertakes on behalf of API nodes or other data nodes; these activities include transactions, transaction errors, key reads, key writes, unique index operations, failed key operations of any type, scans, failed scans, fragment scans, and failed fragment scans.

A set of counters is maintained for each activity, each counter covering a range of latencies less than or equal to an upper bound. At the conclusion of each activity, its latency is determined and the appropriate counter incremented. `tc_time_track_stats` presents this information as rows, with a row for each instance of the following:

- Data node, using its ID
- TC block instance
- Other communicating data node or API node, using its ID
- Upper bound value

Each row contains a value for each activity type. This is the number of times that this activity occurred with a latency within the range specified by the row (that is, where the latency does not exceed the upper bound).

The `tc_time_track_stats` table contains the following columns:

- `node_id`
Requesting node ID
- `block_number`
TC block number
- `block_instance`
TC block instance number
- `comm_node_id`
Node ID of communicating API or data node
- `upper_bound`
Upper bound of interval (in microseconds)
- `scans`
Based on duration of successful scans from opening to closing, tracked against the API or data nodes requesting them.

- `scan_errors`

Based on duration of failed scans from opening to closing, tracked against the API or data nodes requesting them.

- `scan_fragments`

Based on duration of successful fragment scans from opening to closing, tracked against the data nodes executing them

- `scan_fragment_errors`

Based on duration of failed fragment scans from opening to closing, tracked against the data nodes executing them

- `transactions`

Based on duration of successful transactions from beginning until sending of commit `ACK`, tracked against the API or data nodes requesting them. Stateless transactions are not included.

- `transaction_errors`

Based on duration of failing transactions from start to point of failure, tracked against the API or data nodes requesting them.

- `read_key_ops`

Based on duration of successful primary key reads with locks. Tracked against both the API or data node requesting them and the data node executing them.

- `write_key_ops`

Based on duration of successful primary key writes, tracked against both the API or data node requesting them and the data node executing them.

- `index_key_ops`

Based on duration of successful unique index key operations, tracked against both the API or data node requesting them and the data node executing reads of base tables.

- `key_op_errors`

Based on duration of all unsuccessful key read or write operations, tracked against both the API or data node requesting them and the data node executing them.

Notes

The `block_instance` column provides the `DBTC` kernel block instance number. You can use this together with the block name to obtain information about specific threads from the `threadblocks` table.

23.6.14.52 The `ndbinfo threadblocks` Table

The `threadblocks` table associates data nodes, threads, and instances of `NDB` kernel blocks.

The `threadblocks` table contains the following columns:

- `node_id`

Node ID

- `thr_no`

Thread ID

- `block_name`

Block name

- `block_instance`

Block instance number

Notes

The value of the `block_name` in this table is one of the values found in the `block_name` column when selecting from the `ndbinfo.blocks` table. Although the list of possible values is static for a given NDB Cluster release, the list may vary between releases.

The `block_instance` column provides the kernel block instance number.

23.6.14.53 The `ndbinfo threads` Table

The `threads` table provides information about threads running in the NDB kernel.

The `threads` table contains the following columns:

- `node_id`

ID of the node where the thread is running

- `thr_no`

Thread ID (specific to this node)

- `thread_name`

Thread name (type of thread)

- `thread_description`

Thread (type) description

Notes

Sample output from a 2-node example cluster, including thread descriptions, is shown here:

```
mysql> SELECT * FROM threads;
+-----+-----+-----+-----+
| node_id | thr_no | thread_name | thread_description |
+-----+-----+-----+-----+
| 5 | 0 | main | main thread, schema and distribution handling |
| 5 | 1 | rep | rep thread, asynch replication and proxy block handling |
| 5 | 2 | ldm | ldm thread, handling a set of data partitions |
| 5 | 3 | recv | receive thread, performing receive and polling for new receives |
| 6 | 0 | main | main thread, schema and distribution handling |
| 6 | 1 | rep | rep thread, asynch replication and proxy block handling |
| 6 | 2 | ldm | ldm thread, handling a set of data partitions |
+-----+-----+-----+-----+
```

```
|      6 |      3 | recv      | receive thread, performing receive and polling for new receives |
+-----+-----+-----+-----+
8 rows in set (0.01 sec)
```

NDB 8.0.23 introduces the possibility to set either of the `ThreadConfig` arguments `main` or `rep` to 0 while keeping the other at 1, in which case the thread name is `main_rep` and its description is `main and rep thread, schema, distribution, proxy block and asynch replication handling`. It is also possible beginning with NDB 8.0.23 to set both `main` and `rep` to 0, in which case the name of the resulting thread is shown in this table as `main_rep_recv`, and its description is `main, rep and recv thread, schema, distribution, proxy block and asynch replication handling and handling receive and polling for new receives`.

23.6.14.54 The ndbinfo threadstat Table

The `threadstat` table provides a rough snapshot of statistics for threads running in the NDB kernel.

The `threadstat` table contains the following columns:

- `node_id`
Node ID
- `thr_no`
Thread ID
- `thr_nm`
Thread name
- `c_loop`
Number of loops in main loop
- `c_exec`
Number of signals executed
- `c_wait`
Number of times waiting for additional input
- `c_l_sent_prioa`
Number of priority A signals sent to own node
- `c_l_sent_priob`
Number of priority B signals sent to own node
- `c_r_sent_prioa`
Number of priority A signals sent to remote node
- `c_r_sent_priob`
Number of priority B signals sent to remote node
- `os_tid`

OS thread ID

- `os_now`

OS time (ms)

- `os_ru_utime`

OS user CPU time (μ s)

- `os_ru_stime`

OS system CPU time (μ s)

- `os_ru_minflt`

OS page reclaims (soft page faults)

- `os_ru_majflt`

OS page faults (hard page faults)

- `os_ru_nvcs`

OS voluntary context switches

- `os_ru_nivcs`

OS involuntary context switches

Notes

`os_time` uses the system `gettimeofday()` call.

The values of the `os_ru_utime`, `os_ru_stime`, `os_ru_minflt`, `os_ru_majflt`, `os_ru_nvcs`, and `os_ru_nivcs` columns are obtained using the system `getrusage()` call, or the equivalent.

Since this table contains counts taken at a given point in time, for best results it is necessary to query this table periodically and store the results in an intermediate table or tables. The MySQL Server's Event Scheduler can be employed to automate such monitoring. For more information, see [Section 25.4, "Using the Event Scheduler"](#).

23.6.14.55 The `ndbinfo transporters` Table

This table contains information about NDB transporters.

The `transporters` table contains the following columns:

- `node_id`

This data node's unique node ID in the cluster

- `remote_node_id`

The remote data node's node ID

- `status`

Status of the connection

- `remote_address`

Name or IP address of the remote host

- `bytes_sent`

Number of bytes sent using this connection

- `bytes_received`

Number of bytes received using this connection

- `connect_count`

Number of times connection established on this transporter

- `overloaded`

1 if this transporter is currently overloaded, otherwise 0

- `overload_count`

Number of times this transporter has entered overload state since connecting

- `slowdown`

1 if this transporter is in slowdown state, otherwise 0

- `slowdown_count`

Number of times this transporter has entered slowdown state since connecting

Notes

For each running data node in the cluster, the `transporters` table displays a row showing the status of each of that node's connections with all nodes in the cluster, *including itself*. This information is shown in the table's `status` column, which can have any one of the following values: `CONNECTING`, `CONNECTED`, `DISCONNECTING`, or `DISCONNECTED`.

Connections to API and management nodes which are configured but not currently connected to the cluster are shown with status `DISCONNECTED`. Rows where the `node_id` is that of a data node which is not currently connected are not shown in this table. (This is similar omission of disconnected nodes in the `ndbinfo.nodes` table.)

The `remote_address` is the host name or address for the node whose ID is shown in the `remote_node_id` column. The `bytes_sent` from this node and `bytes_received` by this node are the numbers, respectively, of bytes sent and received by the node using this connection since it was established. For nodes whose status is `CONNECTING` or `DISCONNECTED`, these columns always display 0.

Assume you have a 5-node cluster consisting of 2 data nodes, 2 SQL nodes, and 1 management node, as shown in the output of the `SHOW` command in the `ndb_mgm` client:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
-----
[ndbd(NDB)]      2 node(s)
```

```
id=1    @10.100.10.1  (8.0.27-ndb-8.0.27, Nodegroup: 0, *)
id=2    @10.100.10.2  (8.0.27-ndb-8.0.27, Nodegroup: 0)
```

```
[ndb_mgmd(MGM)] 1 node(s)
id=10    @10.100.10.10  (8.0.27-ndb-8.0.27)
```

```
[mysqld(API)] 2 node(s)
id=20    @10.100.10.20  (8.0.27-ndb-8.0.27)
id=21    @10.100.10.21  (8.0.27-ndb-8.0.27)
```

There are 10 rows in the `transporters` table—5 for the first data node, and 5 for the second—assuming that all data nodes are running, as shown here:

```
mysql> SELECT node_id, remote_node_id, status
-> FROM ndbinfo.transporters;
```

| node_id | remote_node_id | status |
|---------|----------------|--------------|
| 1 | 1 | DISCONNECTED |
| 1 | 2 | CONNECTED |
| 1 | 10 | CONNECTED |
| 1 | 20 | CONNECTED |
| 1 | 21 | CONNECTED |
| 2 | 1 | CONNECTED |
| 2 | 2 | DISCONNECTED |
| 2 | 10 | CONNECTED |
| 2 | 20 | CONNECTED |
| 2 | 21 | CONNECTED |

```
10 rows in set (0.04 sec)
```

If you shut down one of the data nodes in this cluster using the command `2 STOP` in the `ndb_mgm` client, then repeat the previous query (again using the `mysql` client), this table now shows only 5 rows—1 row for each connection from the remaining management node to another node, including both itself and the data node that is currently offline—and displays `CONNECTING` for the status of each remaining connection to the data node that is currently offline, as shown here:

```
mysql> SELECT node_id, remote_node_id, status
-> FROM ndbinfo.transporters;
```

| node_id | remote_node_id | status |
|---------|----------------|--------------|
| 1 | 1 | DISCONNECTED |
| 1 | 2 | CONNECTING |
| 1 | 10 | CONNECTED |
| 1 | 20 | CONNECTED |
| 1 | 21 | CONNECTED |

```
5 rows in set (0.02 sec)
```

The `connect_count`, `overloaded`, `overload_count`, `slowdown`, and `slowdown_count` counters are reset on connection, and retain their values after the remote node disconnects. The `bytes_sent` and `bytes_received` counters are also reset on connection, and so retain their values following disconnection (until the next connection resets them).

The *overload* state referred to by the `overloaded` and `overload_count` columns occurs when this transporter's send buffer contains more than `OVERloadLimit` bytes (default is 80% of `SendBufferMemory`, that is, $0.8 * 2097152 = 1677721$ bytes). When a given transporter is in a state of overload, any new transaction that tries to use this transporter fails with Error 1218 (`Send Buffers overloaded in NDB kernel`). This affects both scans and primary key operations.

The *slowdown* state referenced by the `slowdown` and `slowdown_count` columns of this table occurs when the transporter's send buffer contains more than 60% of the overload limit (equal to $0.6 * 2097152 =$

1258291 bytes by default). In this state, any new scan using this transporter has its batch size reduced to minimize the load on the transporter.

Common causes of send buffer slowdown or overloading include the following:

- Data size, in particular the quantity of data stored in `TEXT` columns or `BLOB` columns (or both types of columns)
- Having a data node (ndbd or ndbmtd) on the same host as an SQL node that is engaged in binary logging
- Large number of rows per transaction or transaction batch
- Configuration issues such as insufficient `SendBufferMemory`
- Hardware issues such as insufficient RAM or poor network connectivity

See also [Section 23.4.3.14, “Configuring NDB Cluster Send Buffer Parameters”](#).

23.6.15 INFORMATION_SCHEMA Tables for NDB Cluster

Two `INFORMATION_SCHEMA` tables provide information that is of particular use when managing an NDB Cluster. The `FILES` table provides information about NDB Cluster Disk Data files (see [Section 23.6.10.1, “NDB Cluster Disk Data Objects”](#)). The `ndb_transid_mysql_connection_map` table provides a mapping between transactions, transaction coordinators, and API nodes.

Additional statistical and other data about NDB Cluster transactions, operations, threads, blocks, and other aspects of performance can be obtained from the tables in the `ndbinfo` database. For information about these tables, see [Section 23.6.14, “ndbinfo: The NDB Cluster Information Database”](#).

23.6.16 Quick Reference: NDB Cluster SQL Statements

This section discusses several SQL statements that can prove useful in managing and monitoring a MySQL server that is connected to an NDB Cluster, and in some cases provide information about the cluster itself.

- `SHOW ENGINE NDB STATUS, SHOW ENGINE NDBCLUSTER STATUS`

The output of this statement contains information about the server's connection to the cluster, creation and usage of NDB Cluster objects, and binary logging for NDB Cluster replication.

See [Section 13.7.7.15, “SHOW ENGINE Statement”](#), for a usage example and more detailed information.

- `SHOW ENGINES`

This statement can be used to determine whether or not clustering support is enabled in the MySQL server, and if so, whether it is active.

See [Section 13.7.7.16, “SHOW ENGINES Statement”](#), for more detailed information.

Note

This statement does not support a `LIKE` clause. However, you can use `LIKE` to filter queries against the `INFORMATION_SCHEMA.ENGINES` table, as discussed in the next item.

- `SELECT * FROM INFORMATION_SCHEMA.ENGINES [WHERE ENGINE LIKE 'NDB%']`

This is the equivalent of `SHOW ENGINES`, but uses the `ENGINES` table of the `INFORMATION_SCHEMA` database. Unlike the case with the `SHOW ENGINES` statement, it is possible to filter the results using a `LIKE` clause, and to select specific columns to obtain information that may be of use in scripts. For example, the following query shows whether the server was built with `NDB` support and, if so, whether it is enabled:

```
mysql> SELECT ENGINE, SUPPORT FROM INFORMATION_SCHEMA.ENGINES
-> WHERE ENGINE LIKE 'NDB%';
+-----+-----+
| ENGINE      | SUPPORT |
+-----+-----+
| ndbcluster  | YES     |
| ndbinfo     | YES     |
+-----+-----+
```

If `NDB` support is not enabled, the preceding query returns an empty set. See [Section 26.3.13, “The INFORMATION_SCHEMA ENGINES Table”](#), for more information.

- `SHOW VARIABLES LIKE 'NDB%'`

This statement provides a list of most server system variables relating to the `NDB` storage engine, and their values, as shown here:

```
mysql> SHOW VARIABLES LIKE 'NDB%';
+-----+-----+
| Variable_name                                     | Value                                     |
+-----+-----+
| ndb_allow_copying_alter_table                     | ON                                       |
| ndb_autoincrement_prefetch_sz                     | 512                                       |
| ndb_batch_size                                     | 32768                                    |
| ndb_blob_read_batch_bytes                          | 65536                                    |
| ndb_blob_write_batch_bytes                        | 65536                                    |
| ndb_clear_apply_status                            | ON                                       |
| ndb_cluster_connection_pool                       | 1                                       |

See [Section 5.1.8, “Server System Variables”](#), for more information.

- `SELECT * FROM performance_schema.global_variables WHERE VARIABLE_NAME LIKE 'NDB%'`

This statement is the equivalent of the `SHOW VARIABLES` statement described in the previous item, and provides almost identical output, as shown here:

```
mysql> SELECT * FROM performance_schema.global_variables
-> WHERE VARIABLE_NAME LIKE 'NDB%';
```

| VARIABLE_NAME | VARIABLE_VALUE |
|-------------------------------------|----------------|
| ndb_allow_copying_alter_table | ON |

| ndbinfo_offline | OFF |
| ndbinfo_show_hidden | OFF |
| ndbinfo_table_prefix | ndb\$ |
| ndbinfo_version | 524308 |

Unlike the case with the `SHOW VARIABLES` statement, it is possible to select individual columns. For example:

```
mysql> SELECT VARIABLE_VALUE
-> FROM performance_schema.global_variables
-> WHERE VARIABLE_NAME = 'ndb_force_send';
+-----+
| VARIABLE_VALUE |
+-----+
| ON              |
```

A more useful query is shown here:

```
mysql> SELECT VARIABLE_NAME AS Name, VARIABLE_VALUE AS Value
> FROM performance_schema.global_variables
> WHERE VARIABLE_NAME
> IN ('version', 'ndb_version',
>     'ndb_version_string', 'ndbinfo_version');
```

| Name | Value |
|--------------------|----------------|
| ndb_version | 524308 |
| ndb_version_string | ndb-8.0.20 |
| ndbinfo_version | 524308 |
| version | 8.0.20-cluster |

4 rows in set (0.00 sec)

For more information, see [Section 27.12.15, “Performance Schema Status Variable Tables”](#), and [Section 5.1.8, “Server System Variables”](#).

- `SHOW STATUS LIKE 'NDB%'`

This statement shows at a glance whether or not the MySQL server is acting as a cluster SQL node, and if so, it provides the MySQL server's cluster node ID, the host name and port for the cluster management server to which it is connected, and the number of data nodes in the cluster, as shown here:

```
mysql> SHOW STATUS LIKE 'NDB%';
```
