break_on_hyphens [bool, optional] If True, wrapping will occur preferably on whitespace and right after hyphens in compound words, as it is customary in English. If false, only whitespaces will be considered as potentially good places for line breaks, but you need to set `break_long_words` to false if you want truly insecable words (default: True).

Returns

Series or Index

Notes

Internally, this method uses a `textwrap.TextWrapper` instance with default settings. To achieve behavior matching R's `stringr` library `str_wrap` function, use the arguments:

- `expand_tabs = False`
- `replace_whitespace = True`
- `drop_whitespace = True`
- `break_long_words = False`
- `break_on_hyphens = False`

Examples

```
>>> s = pd.Series(['line to be wrapped', 'another line to be wrapped'])
>>> s.str.wrap(12)
0          line to be\nwrapped
1  another line\nto be\nwrapped
dtype: object
```

`pandas.Series.str.zfill`

`Series.str.zfill(self, width)`

Pad strings in the Series/Index by prepending '0' characters.

Strings in the Series/Index are padded with '0' characters on the left of the string to reach a total string length *width*. Strings in the Series/Index with length greater or equal to *width* are unchanged.

Parameters

width [int] Minimum length of resulting string; strings with length less than *width* be prepended with '0' characters.

Returns

Series/Index of objects

See also:

Series.str.rjust Fills the left side of strings with an arbitrary character.

Series.str.ljust Fills the right side of strings with an arbitrary character.

Series.str.pad Fills the specified sides of strings with an arbitrary character.

Series.str.center Fills boths sides of strings with an arbitrary character.

Notes

Differs from `str.zfill()` which has special handling for '+'/'-' in the string.

Examples

```
>>> s = pd.Series(['-1', '1', '1000', 10, np.nan])
>>> s
0      -1
1       1
2     1000
3       10
4      NaN
dtype: object
```

Note that 10 and NaN are not strings, therefore they are converted to NaN. The minus sign in '-1' is treated as a regular character and the zero is added to the left of it (`str.zfill()` would have moved it to the left). 1000 remains unchanged as it is longer than *width*.

```
>>> s.str.zfill(3)
0     0-1
1     001
2    1000
3     NaN
4     NaN
dtype: object
```

pandas.Series.str.isalnum

Series.str.isalnum(*self*)

Check whether all characters in each string are alphanumeric.

This is equivalent to running the Python string method `str.isalnum()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

Returns

Series or Index of bool Series or Index of boolean values with the same length as the original Series/Index.

See also:

Series.str.isalpha Check whether all characters are alphabetic.

Series.str.isnumeric Check whether all characters are numeric.

Series.str.isalnum Check whether all characters are alphanumeric.

Series.str.isdigit Check whether all characters are digits.

Series.str.isdecimal Check whether all characters are decimal.

Series.str.isspace Check whether all characters are whitespace.

Series.str.islower Check whether all characters are lowercase.

Series.str.isupper Check whether all characters are uppercase.

Series.str.istitle Check whether all characters are titlecase.

Examples

Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0    True
1   False
2   False
3   False
dtype: bool
```

```
>>> s1.str.isnumeric()
0   False
1   False
2    True
3   False
dtype: bool
```

```
>>> s1.str.isalnum()
0    True
1    True
2    True
3   False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0    False
1    False
2    False
dtype: bool
```

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '³', ' ', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0     True
1    False
2    False
3    False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0     True
1     True
2    False
3    False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0     True
1     True
2     True
3    False
dtype: bool
```

Checks for Whitespace

```
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0     True
1     True
2    False
dtype: bool
```

Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```
>>> s5.str.islower()
0    True
1    False
2    False
3    False
dtype: bool
```

```
>>> s5.str.isupper()
0    False
1    False
2     True
3    False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0    False
1     True
2    False
3    False
dtype: bool
```

pandas.Series.str.isalpha

Series.str.isalpha(*self*)

Check whether all characters in each string are alphabetic.

This is equivalent to running the Python string method `str.isalpha()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

Returns

Series or Index of bool Series or Index of boolean values with the same length as the original Series/Index.

See also:

Series.str.isalpha Check whether all characters are alphabetic.

Series.str.isnumeric Check whether all characters are numeric.

Series.str.isalnum Check whether all characters are alphanumeric.

Series.str.isdigit Check whether all characters are digits.

Series.str.isdecimal Check whether all characters are decimal.

Series.str.isspace Check whether all characters are whitespace.

Series.str.islower Check whether all characters are lowercase.

Series.str.isupper Check whether all characters are uppercase.

Series.str.istitle Check whether all characters are titlecase.

Examples

Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0    True
1   False
2   False
3   False
dtype: bool
```

```
>>> s1.str.isnumeric()
0   False
1   False
2    True
3   False
dtype: bool
```

```
>>> s1.str.isalnum()
0    True
1    True
2    True
3   False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0   False
1   False
2   False
dtype: bool
```

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '3', '', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0    True
1   False
2   False
3   False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0    True
1    True
2   False
3   False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0    True
1    True
2    True
3   False
dtype: bool
```

Checks for Whitespace

```
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0    True
1    True
2   False
dtype: bool
```

Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```
>>> s5.str.islower()
0    True
1   False
2   False
3   False
dtype: bool
```

```
>>> s5.str.isupper()
0   False
1   False
2    True
3   False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0   False
1    True
2   False
```

(continues on next page)

(continued from previous page)

```
3    False
dtype: bool
```

pandas.Series.str.isdigit**Series.str.isdigit(*self*)**

Check whether all characters in each string are digits.

This is equivalent to running the Python string method `str.isdigit()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

Returns

Series or Index of bool Series or Index of boolean values with the same length as the original Series/Index.

See also:

Series.str.isalpha Check whether all characters are alphabetic.

Series.str.isnumeric Check whether all characters are numeric.

Series.str.isalnum Check whether all characters are alphanumeric.

Series.str.isdigit Check whether all characters are digits.

Series.str.isdecimal Check whether all characters are decimal.

Series.str.isspace Check whether all characters are whitespace.

Series.str.islower Check whether all characters are lowercase.

Series.str.isupper Check whether all characters are uppercase.

Series.str.istitle Check whether all characters are titlecase.

Examples**Checks for Alphabetic and Numeric Characters**

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
```

```
0    True
1    False
2    False
3    False
dtype: bool
```

```
>>> s1.str.isnumeric()
```

```
0    False
1    False
2     True
3    False
dtype: bool
```

```
>>> s1.str.isalnum()
0    True
1    True
2    True
3    False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0    False
1    False
2    False
dtype: bool
```

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '3', ' ', ' '])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0    True
1    False
2    False
3    False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0    True
1    True
2    False
3    False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0    True
1    True
2    True
3    False
dtype: bool
```

Checks for Whitespace

```
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0    True
1    True
2    False
dtype: bool
```

Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```
>>> s5.str.islower()
0    True
1    False
2    False
3    False
dtype: bool
```

```
>>> s5.str.isupper()
0    False
1    False
2    True
3    False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0    False
1    True
2    False
3    False
dtype: bool
```

pandas.Series.str.isspace

Series.str.isspace(*self*)

Check whether all characters in each string are whitespace.

This is equivalent to running the Python string method `str.isspace()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

Returns

Series or Index of bool Series or Index of boolean values with the same length as the original Series/Index.

See also:

Series.str.isalpha Check whether all characters are alphabetic.

Series.str.isnumeric Check whether all characters are numeric.

Series.str.isalnum Check whether all characters are alphanumeric.

Series.str.isdigit Check whether all characters are digits.

Series.str.isspace Check whether all characters are whitespace.

Series.str.islower Check whether all characters are lowercase.

Series.str.isupper Check whether all characters are uppercase.

Series.str.istitle Check whether all characters are titlecase.

Examples

Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0    True
1   False
2   False
3   False
dtype: bool
```

```
>>> s1.str.isnumeric()
0   False
1   False
2    True
3   False
dtype: bool
```

```
>>> s1.str.isalnum()
0    True
1    True
2    True
3   False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0   False
1   False
2   False
dtype: bool
```

```

```
>>> s5.str.islower()
0    True
1   False
2   False
3   False
dtype: bool
```

```
>>> s5.str.isupper()
0   False
```

(continues on next page)

(continued from previous page)

```
1    False
2     True
3    False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0    False
1     True
2    False
3    False
dtype: bool
```

pandas.Series.str.islower

`Series.str.islower(self)`

Check whether all characters in each string are lowercase.

This is equivalent to running the Python string method `str.islower()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

Returns

Series or Index of bool Series or Index of boolean values with the same length as the original Series/Index.

See also:

Series.str.isalpha Check whether all characters are alphabetic.

Series.str.isnumeric Check whether all characters are numeric.

Series.str.isalnum Check whether all characters are alphanumeric.

Series.str.isdigit Check whether all characters are digits.

Series.str.isdecimal Check whether all characters are decimal.

Series.str.isspace Check whether all characters are whitespace.

Series.str.islower Check whether all characters are lowercase.

Series.str.isupper Check whether all characters are uppercase.

Series.str.istitle Check whether all characters are titlecase.

Examples

Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0    True
1    False
2    False
3    False
dtype: bool
```

```
>>> s1.str.isnumeric()
0    False
1    False
2     True
3    False
dtype: bool
```

```
>>> s1.str.isalnum()
0     True
1     True
2     True
3    False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0    False
1    False
2    False
dtype: bool
```

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '³', '²', '¹'])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0     True
1    False
2    False
3    False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0     True
1     True
2    False

Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```
>>> s5.str.islower()
0    True
1    False
2    False
3    False
dtype: bool
```

```
>>> s5.str.isupper()
0    False
1    False
2     True
3    False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0    False
1     True
2    False
3    False
dtype: bool
```

pandas.Series.str.istitle

`Series.str.istitle(self)`

Check whether all characters in each string are titlecase.

This is equivalent to running the Python string method `str.istitle()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

Returns

Series or Index of bool Series or Index of boolean values with the same length as the original Series/Index.

See also:

Series.str.isalpha Check whether all characters are alphabetic.

Series.str.isnumeric Check whether all characters are numeric.

Series.str.isalnum Check whether all characters are alphanumeric.

`Series.str.isdigit` Check whether all characters are digits.

`Series.str.isdecimal` Check whether all characters are decimal.

`Series.str.isspace` Check whether all characters are whitespace.

`Series.str.islower` Check whether all characters are lowercase.

`Series.str.isupper` Check whether all characters are uppercase.

`Series.str.istitle` Check whether all characters are titlecase.

Examples

Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0    True
1   False
2   False
3   False
dtype: bool
```

```
>>> s1.str.isnumeric()
0    False
1    False
2     True
3    False
dtype: bool
```

```
>>> s1.str.isalnum()
0     True
1     True
2     True
3    False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0    False
1    False
2    False
dtype: bool
```

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '3', ' ', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0    True
1    False
2    False
3    False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0    True
1    True
2    False
3    False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0    True
1    True
2    True
3    False
dtype: bool
```

Checks for Whitespace

```
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0    True
1    True
2    False
dtype: bool
```

Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```
>>> s5.str.islower()
0    True
1    False
2    False
3    False
dtype: bool
```

```
>>> s5.str.isupper()
0    False
1    False
2    True
3    False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0    False
1     True
2    False
3    False
dtype: bool
```

pandas.Series.str.isnumeric

`Series.str.isnumeric(self)`

Check whether all characters in each string are numeric.

This is equivalent to running the Python string method `str.isnumeric()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

Returns

Series or Index of bool Series or Index of boolean values with the same length as the original Series/Index.

See also:

`Series.str.isalpha` Check whether all characters are alphabetic.

`Series.str.isnumeric` Check whether all characters are numeric.

`Series.str.isalnum` Check whether all characters are alphanumeric.

`Series.str.isdigit` Check whether all characters are digits.

`Series.str.isdecimal` Check whether all characters are decimal.

`Series.str.isspace` Check whether all characters are whitespace.

`Series.str.islower` Check whether all characters are lowercase.

`Series.str.isupper` Check whether all characters are uppercase.

`Series.str.istitle` Check whether all characters are titlecase.

Examples

Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0     True
1    False
2    False
3    False
dtype: bool
```

```
>>> s1.str.isnumeric()
0    False
1    False
2     True
3    False
dtype: bool
```

```
>>> s1.str.isalnum()
0     True
1     True
2     True
3    False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0    False
1    False
2    False
dtype: bool
```

More Detailed Checks for Numeric Characters

```
>>> s3 = pd.Series(['23', '3', ' ', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0     True
1    False
2    False
3    False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0     True
1     True
2    False
3    False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0     True
```

(continues on next page)

(continued from previous page)

```
1    True
2    True
3   False
dtype: bool
```

Checks for Whitespace

```
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0    True
1    True
2   False
dtype: bool
```

Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```
>>> s5.str.islower()
0    True
1   False
2   False
3   False
dtype: bool
```

```
>>> s5.str.isupper()
0   False
1   False
2    True
3   False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0   False
1    True
2   False
3   False
dtype: bool
```

pandas.Series.str.isdecimal

Series.str.isdecimal(*self*)

Check whether all characters in each string are decimal.

This is equivalent to running the Python string method `str.isdecimal()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

Returns

Series or Index of bool Series or Index of boolean values with the same length as the original Series/Index.

See also:

Series.str.isalpha Check whether all characters are alphabetic.

Series.str.isnumeric Check whether all characters are numeric.

Series.str.isalnum Check whether all characters are alphanumeric.

Series.str.isdigit Check whether all characters are digits.

Series.str.isdecimal Check whether all characters are decimal.

Series.str.isspace Check whether all characters are whitespace.

Series.str.islower Check whether all characters are lowercase.

Series.str.isupper Check whether all characters are uppercase.

Series.str.istitle Check whether all characters are titlecase.

Examples

Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0    True
1   False
2   False
3   False
dtype: bool
```

```
>>> s1.str.isnumeric()
0   False
1   False
2    True
3   False
dtype: bool
```

```
>>> s1.str.isalnum()
0    True
1    True
2    True
3   False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0   False
```

(continues on next page)

(continued from previous page)

```
1    False
2    False
dtype: bool
```

More Detailed Checks for Numeric Characters

```
>>> s3 = pd.Series(['23', '3', ' ', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0     True
1     False
2     False
3     False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0     True
1     True
2     False
3     False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0     True
1     True
2     True
3     False
dtype: bool
```

Checks for Whitespace

```
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0     True
1     True
2     False
dtype: bool
```

Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```
>>> s5.str.islower()
0    True
1    False
2    False
3    False
dtype: bool
```

```
>>> s5.str.isupper()
0    False
1    False
2     True
3    False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0    False
1     True
2    False
3    False
dtype: bool
```

pandas.Series.str.get_dummies

`Series.str.get_dummies(self, sep='/')`

Split each string in the Series by `sep` and return a DataFrame of dummy/indicator variables.

Parameters

sep [str, default “|”] String to split on.

Returns

DataFrame Dummy variables corresponding to values of the Series.

See also:

`get_dummies` Convert categorical variable into dummy/indicator variables.

Examples

```
>>> pd.Series(['a|b', 'a', 'a|c']).str.get_dummies()
   a  b  c
0  1  1  0
1  1  0  0
2  1  0  1
```

```
>>> pd.Series(['a|b', np.nan, 'a|c']).str.get_dummies()
   a  b  c
```

1	0	0	0
2	1	0	1

Categorical accessor

Categorical-dtype specific methods and attributes are available under the `Series.cat` accessor.

<code>Series.cat.categories</code>	The categories of this categorical.
<code>Series.cat.ordered</code>	Whether the categories have an ordered relationship.
<code>Series.cat.codes</code>	Return Series of codes as well as the index.

pandas.Series.cat.categories

Series.cat.categories

The categories of this categorical.

Setting assigns new values to each category (effectively a rename of each individual category).

The assigned value has to be a list-like object. All items must be unique and the number of items in the new categories must be the same as the number of items in the old categories.

Assigning to `categories` is a inplace operation!

Raises

ValueError If the new categories do not validate as categories or if the number of new categories is unequal the number of old categories

See also:

`rename_categories`

`reorder_categories`

`add_categories`

`remove_categories`

`remove_unused_categories`

`set_categories`

pandas.Series.cat.ordered

Series.cat.ordered

Whether the categories have an ordered relationship.

pandas.Series.cat.codes

Series.cat.codes

Return Series of codes as well as the index.

<code>Series.cat.rename_categories(self, *args, ...)</code>	Rename categories.
<code>Series.cat.reorder_categories(self, *args, ...)</code>	Reorder categories as specified in <code>new_categories</code> .
<code>Series.cat.add_categories(self, *args, ...)</code>	Add new categories.
<code>Series.cat.remove_categories(self, *args, ...)</code>	Remove the specified categories.
<code>Series.cat.remove_unused_categories(self, ...)</code>	Remove categories which are not used.
<code>Series.cat.set_categories(self, *args, ...)</code>	Set the categories to the specified <code>new_categories</code> .
<code>Series.cat.as_ordered(self, *args, **kwargs)</code>	Set the Categorical to be ordered.
<code>Series.cat.as_unordered(self, *args, **kwargs)</code>	Set the Categorical to be unordered.

pandas.Series.cat.rename_categories

`Series.cat.rename_categories(self, *args, **kwargs)`
 Rename categories.

Parameters

new_categories [list-like, dict-like or callable]

- list-like: all items must be unique and the number of items in the new categories must match the existing number of categories.
- dict-like: specifies a mapping from old categories to new. Categories not contained in the mapping are passed through and extra categories in the mapping are ignored.

New in version 0.21.0.

- callable : a callable that is called on all items in the old categories and whose return values comprise the new categories.

New in version 0.23.0.

inplace [bool, default False] Whether or not to rename the categories inplace or return a copy of this categorical with renamed categories.

Returns

cat [Categorical or None] With `inplace=False`, the new categorical is returned. With `inplace=True`, there is no return value.

Raises

ValueError If new categories are list-like and do not have the same number of items than the current categories or do not validate as categories

See also:

`reorder_categories`

`add_categories`

`remove_categories`

`remove_unused_categories`

`set_categories`

Examples

```
>>> c = pd.Categorical(['a', 'a', 'b'])
>>> c.rename_categories([0, 1])
[0, 0, 1]
Categories (2, int64): [0, 1]
```

For dict-like `new_categories`, extra keys are ignored and categories not in the dictionary are passed through

```
>>> c.rename_categories({'a': 'A', 'c': 'C'})
[A, A, b]
Categories (2, object): [A, b]
```

You may also provide a callable to create the new categories

```
>>> c.rename_categories(lambda x: x.upper())
[A, A, B]
Categories (2, object): [A, B]
```

pandas.Series.cat.reorder_categories

`Series.cat.reorder_categories(self, *args, **kwargs)`

Reorder categories as specified in `new_categories`.

`new_categories` need to include all old categories and no new category items.

Parameters

new_categories [Index-like] The categories in new order.

ordered [bool, optional] Whether or not the categorical is treated as a ordered categorical. If not given, do not change the ordered information.

inplace [bool, default False] Whether or not to reorder the categories inplace or return a copy of this categorical with reordered categories.

Returns

cat [Categorical with reordered categories or None if inplace.]

Raises

ValueError If the new categories do not contain all old category items or any new ones

See also:

`rename_categories`

`add_categories`

`remove_categories`

`remove_unused_categories`

`set_categories`

pandas.Series.cat.add_categories**Series.cat.add_categories**(*self*, **args*, ***kwargs*)

Add new categories.

new_categories will be included at the last/highest place in the categories and will be unused directly after this call.**Parameters****new_categories** [category or list-like of category] The new categories to be included.**inplace** [bool, default False] Whether or not to add the categories inplace or return a copy of this categorical with added categories.**Returns****cat** [Categorical with new categories added or None if inplace.]**Raises****ValueError** If the new categories include old categories or do not validate as categories**See also:***rename_categories**reorder_categories**remove_categories**remove_unused_categories**set_categories***pandas.Series.cat.remove_categories****Series.cat.remove_categories**(*self*, **args*, ***kwargs*)

Remove the specified categories.

removals must be included in the old categories. Values which were in the removed categories will be set to NaN**Parameters****removals** [category or list of categories] The categories which should be removed.**inplace** [bool, default False] Whether or not to remove the categories inplace or return a copy of this categorical with removed categories.**Returns****cat** [Categorical with removed categories or None if inplace.]**Raises****ValueError** If the removals are not contained in the categories**See also:***rename_categories**reorder_categories*

`add_categories`

`remove_unused_categories`

`set_categories`

`pandas.Series.cat.remove_unused_categories`

`Series.cat.remove_unused_categories(self, *args, **kwargs)`

Remove categories which are not used.

Parameters

inplace [bool, default False] Whether or not to drop unused categories inplace or return a copy of this categorical with unused categories dropped.

Returns

`cat` [Categorical with unused categories dropped or None if inplace.]

See also:

`rename_categories`

`reorder_categories`

`add_categories`

`remove_categories`

`set_categories`

`pandas.Series.cat.set_categories`

`Series.cat.set_categories(self, *args, **kwargs)`

Set the categories to the specified `new_categories`.

`new_categories` can include new categories (which will result in unused categories) or remove old categories (which results in values set to NaN). If `rename==True`, the categories will simply be renamed (less or more items than in old categories will result in values set to NaN or in unused categories respectively).

This method can be used to perform more than one action of adding, removing, and reordering simultaneously and is therefore faster than performing the individual steps via the more specialised methods.

On the other hand this methods does not do checks (e.g., whether the old categories are included in the new categories on a reorder), which can result in surprising changes, for example when using special string dtypes on python3, which does not considers a S1 string equal to a single char python string.

Parameters

new_categories [Index-like] The categories in new order.

ordered [bool, default False] Whether or not the categorical is treated as a ordered categorical. If not given, do not change the ordered information.

rename [bool, default False] Whether or not the `new_categories` should be considered as a rename of the old categories or as reordered categories.

inplace [bool, default False] Whether or not to reorder the categories in-place or return a copy of this categorical with reordered categories.

Returns

Categorical with reordered categories or None if inplace.

Raises

ValueError If `new_categories` does not validate as categories

See also:

`rename_categories`

`reorder_categories`

`add_categories`

`remove_categories`

`remove_unused_categories`

pandas.Series.cat.as_ordered

`Series.cat.as_ordered(self, *args, **kwargs)`

Set the Categorical to be ordered.

Parameters

inplace [bool, default False] Whether or not to set the ordered attribute in-place or return a copy of this categorical with ordered set to True.

Returns

Categorical Ordered Categorical.

pandas.Series.cat.as_unordered

`Series.cat.as_unordered(self, *args, **kwargs)`

Set the Categorical to be unordered.

Parameters

inplace [bool, default False] Whether or not to set the ordered attribute in-place or return a copy of this categorical with ordered set to False.

Returns

Categorical Unordered Categorical.

Sparse accessor

Sparse-dtype specific methods and attributes are provided under the `Series.sparse` accessor.

<code>Series.sparse.npoints</code>	The number of non- <code>fill_value</code> points.
<code>Series.sparse.density</code>	The percent of non- <code>fill_value</code> points, as decimal.
<code>Series.sparse.fill_value</code>	Elements in <code>data</code> that are <code>fill_value</code> are not stored.

Continued on next page

Table 48 – continued from previous page

<code>Series.sparse.sp_values</code>	An ndarray containing the non- <code>fill_value</code> values.
--------------------------------------	--

`pandas.Series.sparse.npoints`

`Series.sparse.npoints`

The number of non- `fill_value` points.

Examples

```
>>> s = SparseArray([0, 0, 1, 1, 1], fill_value=0)
>>> s.npoints
3
```

`pandas.Series.sparse.density`

`Series.sparse.density`

The percent of non- `fill_value` points, as decimal.

Examples

```
>>> s = SparseArray([0, 0, 1, 1, 1], fill_value=0)
>>> s.density
0.6
```

`pandas.Series.sparse.fill_value`

`Series.sparse.fill_value`

Elements in *data* that are *fill_value* are not stored.

For memory savings, this should be the most common value in the array.

`pandas.Series.sparse.sp_values`

`Series.sparse.sp_values`

An ndarray containing the non- `fill_value` values.

Examples

```
>>> s = SparseArray([0, 0, 1, 0, 2], fill_value=0)
>>> s.sp_values
array([1, 2])
```

<code>Series.sparse.from_coo(A[, dense_index])</code>	Create a SparseSeries from a scipy.sparse.coo_matrix.
<code>Series.sparse.to_coo(self[, row_levels, ...])</code>	Create a scipy.sparse.coo_matrix from a SparseSeries with MultiIndex.

pandas.Series.sparse.from_coo

classmethod `sparse.from_coo(A, dense_index=False)`
 Create a SparseSeries from a scipy.sparse.coo_matrix.

Parameters

A [scipy.sparse.coo_matrix]

dense_index [bool, default False] If False (default), the SparseSeries index consists of only the coords of the non-null entries of the original coo_matrix. If True, the SparseSeries index consists of the full sorted (row, col) coordinates of the coo_matrix.

Returns

s [SparseSeries]

Examples

```
>>> from scipy import sparse
>>> A = sparse.coo_matrix(([3.0, 1.0, 2.0], ([1, 0, 0], [0, 2, 3])),
                        shape=(3, 4))
>>> A
<3x4 sparse matrix of type '<class 'numpy.float64''>'
  with 3 stored elements in COOrdinate format>
>>> A.todense()
matrix([[ 0.,  0.,  1.,  2.],
        [ 3.,  0.,  0.,  0.],
        [ 0.,  0.,  0.,  0.]])
>>> ss = pd.SparseSeries.from_coo(A)
>>> ss
0 2 1
 3 2
1 0 3
dtype: float64
BlockIndex
Block locations: array([0], dtype=int32)
Block lengths: array([3], dtype=int32)
```

pandas.Series.sparse.to_coo

sparse.to_coo(self, row_levels=(0,), column_levels=(1,), sort_labels=False)
 Create a scipy.sparse.coo_matrix from a SparseSeries with MultiIndex.

Use `row_levels` and `column_levels` to determine the row and column coordinates respectively. `row_levels` and `column_levels` are the names (labels) or numbers of the levels. `{row_levels, column_levels}` must be a partition of the MultiIndex level names (or numbers).

Parameters

row_levels [tuple/list]

column_levels [tuple/list]

sort_labels [bool, default False] Sort the row and column labels before forming the sparse matrix.

Returns

y [scipy.sparse.coo_matrix]

rows [list (row labels)]

columns [list (column labels)]

Examples

```
>>> s = pd.Series([3.0, np.nan, 1.0, 3.0, np.nan, np.nan])
>>> s.index = pd.MultiIndex.from_tuples([(1, 2, 'a', 0),
                                         (1, 2, 'a', 1),
                                         (1, 1, 'b', 0),
                                         (1, 1, 'b', 1),
                                         (2, 1, 'b', 0),
                                         (2, 1, 'b', 1)],
                                         names=['A', 'B', 'C', 'D'])

>>> ss = s.to_sparse()
>>> A, rows, columns = ss.to_coo(row_levels=['A', 'B'],
                                column_levels=['C', 'D'],
                                sort_labels=True)

>>> A
<3x4 sparse matrix of type '<class 'numpy.float64'>'
  with 3 stored elements in COOrdinate format>
>>> A.todense()
matrix([[ 0.,  0.,  1.,  3.],
        [ 3.,  0.,  0.,  0.],
        [ 0.,  0.,  0.,  0.]])
>>> rows
[(1, 1), (1, 2), (2, 1)]
>>> columns
[( 'a', 0), ( 'a', 1), ( 'b', 0), ( 'b', 1)]
```

6.3.14 Plotting

`Series.plot` is both a callable method and a namespace attribute for specific plotting methods of the form `Series.plot.<kind>`.

`Series.plot([kind, ax, figsize, ...])`

Series plotting accessor and method

<code>Series.plot.area(self[, x, y])</code>	Draw a stacked area plot.
<code>Series.plot.bar(self[, x, y])</code>	Vertical bar plot.
<code>Series.plot.barh(self[, x, y])</code>	Make a horizontal bar plot.
<code>Series.plot.box(self[, by])</code>	Make a box plot of the DataFrame columns.
<code>Series.plot.density(self[, bw_method, ind])</code>	Generate Kernel Density Estimate plot using Gaussian kernels.
<code>Series.plot.hist(self[, by, bins])</code>	Draw one histogram of the DataFrame's columns.
<code>Series.plot.kde(self[, bw_method, ind])</code>	Generate Kernel Density Estimate plot using Gaussian kernels.
<code>Series.plot.line(self[, x, y])</code>	Plot Series or DataFrame as lines.
<code>Series.plot.pie(self, <code>**kwargs</code>)</code>	Generate a pie plot.

pandas.Series.plot.area

`Series.plot.area(self, x=None, y=None, **kwargs)`

Draw a stacked area plot.

An area plot displays quantitative data visually. This function wraps the matplotlib area function.

Parameters

- x** [label or position, optional] Coordinates for the X axis. By default uses the index.
- y** [label or position, optional] Column to plot. By default uses all columns.
- stacked** [bool, default True] Area plots are stacked by default. Set to False to create a unstacked plot.
- `**kwargs`** [optional] Additional keyword arguments are documented in `DataFrame.plot()`.

Returns

matplotlib.axes.Axes or numpy.ndarray Area plot, or array of area plots if subplots is True.

See also:

`DataFrame.plot` Make plots of DataFrame using matplotlib / pylab.

Examples

Draw an area plot based on basic business metrics:

```
>>> df = pd.DataFrame({
...     'sales': [3, 2, 3, 9, 10, 6],
...     'signups': [5, 5, 6, 12, 14, 13],
...     'visits': [20, 42, 28, 62, 81, 50],
... }, index=pd.date_range(start='2018/01/01', end='2018/07/01',
...                          freq='M'))
>>> ax = df.plot.area()
```

Area plots are stacked by default. To produce an unstacked plot, pass `stacked=False`:

```
>>> ax = df.plot.area(stacked=False)
```

Draw an area plot for a single column:

```
>>> ax = df.plot.area(y='sales')
```

Draw with a different *x*:

```
>>> df = pd.DataFrame({
...     'sales': [3, 2, 3],
...     'visits': [20, 42, 28],
...     'day': [1, 2, 3],
... })
>>> ax = df.plot.area(x='day')
```

pandas.Series.plot.bar

`Series.plot.bar`(*self*, *x=None*, *y=None*, ***kwargs*)

Vertical bar plot.

A bar plot is a plot that presents categorical data with rectangular bars with lengths proportional to the values that they represent. A bar plot shows comparisons among discrete categories. One axis of the plot shows the specific categories being compared, and the other axis represents a measured value.

Parameters

x [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.

y [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.

****kwargs** Additional keyword arguments are documented in `DataFrame.plot()`.

Returns

matplotlib.axes.Axes or np.ndarray of them An ndarray is returned with one `matplotlib.axes.Axes` per column when `subplots=True`.

See also:

`DataFrame.plot.barh` Horizontal bar plot.

`DataFrame.plot` Make plots of a DataFrame.

`matplotlib.pyplot.bar` Make a bar plot with matplotlib.

Examples

Basic plot.

```
>>> df = pd.DataFrame({'lab':['A', 'B', 'C'], 'val':[10, 30, 20]})
>>> ax = df.plot.bar(x='lab', y='val', rot=0)
```

Plot a whole dataframe to a bar plot. Each column is assigned a distinct color, and each row is nested in a group along the horizontal axis.

```
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
...         'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...                   'lifespan': lifespan}, index=index)
>>> ax = df.plot.bar(rot=0)
```

Instead of nesting, the figure can be split by column with `subplots=True`. In this case, a `numpy.ndarray` of `matplotlib.axes.Axes` are returned.

```
>>> axes = df.plot.bar(rot=0, subplots=True)
>>> axes[1].legend(loc=2) # doctest: +SKIP
```

Plot a single column.

```
>>> ax = df.plot.bar(y='speed', rot=0)
```

Plot only selected categories for the DataFrame.

```
>>> ax = df.plot.bar(x='lifespan', rot=0)
```

pandas.Series.plot.barh

`Series.plot.barh`(*self*, *x=None*, *y=None*, ***kwargs*)

Make a horizontal bar plot.

A horizontal bar plot is a plot that presents quantitative data with rectangular bars with lengths proportional to the values that they represent. A bar plot shows comparisons among discrete categories. One axis of the plot shows the specific categories being compared, and the other axis represents a measured value.

Parameters

x [label or position, default `DataFrame.index`] Column to be used for categories.

y [label or position, default All numeric columns in dataframe] Columns to be plotted from the DataFrame.

****kwargs** Keyword arguments to pass on to `DataFrame.plot()`.

Returns

`matplotlib.axes.Axes` or `numpy.ndarray` of them

See also:

`DataFrame.plot.bar` Vertical bar plot.

`DataFrame.plot` Make plots of DataFrame using matplotlib.

`matplotlib.axes.Axes.bar` Plot a vertical bar plot using matplotlib.

Examples

Basic example

```
>>> df = pd.DataFrame({'lab':['A', 'B', 'C'], 'val':[10, 30, 20]})
>>> ax = df.plot.barh(x='lab', y='val')
```

Plot a whole DataFrame to a horizontal bar plot

```
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
...         'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...                   'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh()
```

Plot a column of the DataFrame to a horizontal bar plot

```
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
...         'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...                   'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh(y='speed')
```

Plot DataFrame versus the desired column

```
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
...         'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...                   'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh(x='lifespan')
```

pandas.Series.plot.box

`Series.plot.box(self, by=None, **kwargs)`

Make a box plot of the DataFrame columns.

A box plot is a method for graphically depicting groups of numerical data through their quartiles. The box extends from the Q1 to Q3 quartile values of the data, with a line at the median (Q2). The whiskers extend from the edges of box to show the range of the data. The position of the whiskers is set by default to $1.5 \cdot \text{IQR}$ ($\text{IQR} = \text{Q3} - \text{Q1}$) from the edges of the box. Outlier points are those past the end of the whiskers.

For further details see Wikipedia's entry for [boxplot](#).

A consideration when using this chart is that the box and the whiskers can overlap, which is very common when plotting small sets of data.

Parameters

by [string or sequence] Column in the DataFrame to group by.

****kwds** [optional] Additional keywords are documented in `DataFrame.plot()`.

Returns

`matplotlib.axes.Axes` or `numpy.ndarray` of them

See also:

`DataFrame.boxplot` Another method to draw a box plot.

`Series.plot.box` Draw a box plot from a Series object.

`matplotlib.pyplot.boxplot` Draw a box plot in matplotlib.

Examples

Draw a box plot from a DataFrame with four columns of randomly generated data.

```
>>> data = np.random.randn(25, 4)
>>> df = pd.DataFrame(data, columns=list('ABCD'))
>>> ax = df.plot.box()
```

pandas.Series.plot.density

`Series.plot.density(self, bw_method=None, ind=None, **kwargs)`

Generate Kernel Density Estimate plot using Gaussian kernels.

In statistics, [kernel density estimation](#) (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

Parameters

bw_method [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be 'scott', 'silverman', a scalar constant or a callable. If None (default), 'scott' is used. See `scipy.stats.gaussian_kde` for more information.

ind [NumPy array or integer, optional] Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If *ind* is a NumPy array, the KDE is evaluated at the points passed. If *ind* is an integer, *ind* number of equally spaced points are used.

****kwargs** [optional] Additional keyword arguments are documented in `pandas.%(this-datatype)s.plot()`.

Returns

`matplotlib.axes.Axes` or `numpy.ndarray` of them

See also:

`scipy.stats.gaussian_kde` Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.

Examples

Given a Series of points randomly sampled from an unknown distribution, estimate its PDF using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```
>>> s = pd.Series([1, 2, 2.5, 3, 3.5, 4, 5])
>>> ax = s.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```
>>> ax = s.plot.kde(bw_method=0.3)
```

```
>>> ax = s.plot.kde(bw_method=3)
```

Finally, the *ind* parameter determines the evaluation points for the plot of the estimated PDF:

```
>>> ax = s.plot.kde(ind=[1, 2, 3, 4, 5])
```

For DataFrame, it works in the same way:

```
>>> df = pd.DataFrame({
...     'x': [1, 2, 2.5, 3, 3.5, 4, 5],
...     'y': [4, 4, 4.5, 5, 5.5, 6, 6],
... })
>>> ax = df.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```
>>> ax = df.plot.kde(bw_method=0.3)
```

```
>>> ax = df.plot.kde(bw_method=3)
```

Finally, the *ind* parameter determines the evaluation points for the plot of the estimated PDF:

```
>>> ax = df.plot.kde(ind=[1, 2, 3, 4, 5, 6])
```

pandas.Series.plot.hist

`Series.plot.hist(self, by=None, bins=10, **kwargs)`

Draw one histogram of the DataFrame's columns.

A histogram is a representation of the distribution of data. This function groups the values of all given Series in the DataFrame into bins and draws all bins in one `matplotlib.axes.Axes`. This is useful when the DataFrame's Series are in a similar scale.

Parameters

by [str or sequence, optional] Column in the DataFrame to group by.

bins [int, default 10] Number of histogram bins to be used.

****kwargs** Additional keyword arguments are documented in `DataFrame.plot()`.

Returns

class:matplotlib.AxesSubplot Return a histogram plot.

See also:

`DataFrame.hist` Draw histograms per DataFrame's Series.

`Series.hist` Draw a histogram with Series' data.

Examples

When we draw a dice 6000 times, we expect to get each value around 1000 times. But when we draw two dices and sum the result, the distribution is going to be quite different. A histogram illustrates those distributions.

```
>>> df = pd.DataFrame(
...     np.random.randint(1, 7, 6000),
...     columns = ['one'])
>>> df['two'] = df['one'] + np.random.randint(1, 7, 6000)
>>> ax = df.plot.hist(bins=12, alpha=0.5)
```

pandas.Series.plot.kde

`Series.plot.kde`(*self*, *bw_method=None*, *ind=None*, ***kwargs*)

Generate Kernel Density Estimate plot using Gaussian kernels.

In statistics, [kernel density estimation](#) (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

Parameters

bw_method [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be 'scott', 'silverman', a scalar constant or a callable. If None (default), 'scott' is used. See `scipy.stats.gaussian_kde` for more information.

ind [NumPy array or integer, optional] Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If *ind* is a NumPy array, the KDE is evaluated at the points passed. If *ind* is an integer, *ind* number of equally spaced points are used.

****kwargs** [optional] Additional keyword arguments are documented in `pandas.%(this-datatype)s.plot()`.

Returns

`matplotlib.axes.Axes` or `numpy.ndarray` of them

See also:

`scipy.stats.gaussian_kde` Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.

Examples

Given a Series of points randomly sampled from an unknown distribution, estimate its PDF using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```
>>> s = pd.Series([1, 2, 2.5, 3, 3.5, 4, 5])
>>> ax = s.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```
>>> ax = s.plot.kde(bw_method=0.3)
```

```
>>> ax = s.plot.kde(bw_method=3)
```

Finally, the *ind* parameter determines the evaluation points for the plot of the estimated PDF:

```
>>> ax = s.plot.kde(ind=[1, 2, 3, 4, 5])
```

For DataFrame, it works in the same way:

```
>>> df = pd.DataFrame({
...     'x': [1, 2, 2.5, 3, 3.5, 4, 5],
...     'y': [4, 4, 4.5, 5, 5.5, 6, 6],
... })
>>> ax = df.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```
>>> ax = df.plot.kde(bw_method=0.3)
```

```
>>> ax = df.plot.kde(bw_method=3)
```

Finally, the *ind* parameter determines the evaluation points for the plot of the estimated PDF:

```
>>> ax = df.plot.kde(ind=[1, 2, 3, 4, 5, 6])
```

pandas.Series.plot.line

`Series.plot.line(self, x=None, y=None, **kwargs)`

Plot Series or DataFrame as lines.

This function is useful to plot lines using DataFrame's values as coordinates.

Parameters

x [int or str, optional] Columns to use for the horizontal axis. Either the location or the label of the columns to be used. By default, it will use the DataFrame indices.

y [int, str, or list of them, optional] The values to be plotted. Either the location or the label of the columns to be used. By default, it will use the remaining DataFrame numeric columns.

****kwargs** Keyword arguments to pass on to `DataFrame.plot()`.

Returns

`matplotlib.axes.Axes` or `numpy.ndarray` Return an ndarray when `subplots=True`.

See also:

`matplotlib.pyplot.plot` Plot y versus x as lines and/or markers.

Examples

```
>>> s = pd.Series([1, 3, 2])
>>> s.plot.line()
```

The following example shows the populations for some animals over the years.

```
>>> df = pd.DataFrame({
...     'pig': [20, 18, 489, 675, 1776],
...     'horse': [4, 25, 281, 600, 1900]
...     }, index=[1990, 1997, 2003, 2009, 2014])
>>> lines = df.plot.line()
```

An example with subplots, so an array of axes is returned.

```
>>> axes = df.plot.line(subplots=True)
>>> type(axes)
<class 'numpy.ndarray'>
```

The following example shows the relationship between both populations.

```
>>> lines = df.plot.line(x='pig', y='horse')
```

pandas.Series.plot.pie

`Series.plot.pie(self, **kwargs)`

Generate a pie plot.

A pie plot is a proportional representation of the numerical data in a column. This function wraps `matplotlib.pyplot.pie()` for the specified column. If no column reference is passed and `subplots=True` a pie plot is drawn for each numerical column independently.

Parameters

y [int or label, optional] Label or position of the column to plot. If not provided, `subplots=True` argument must be passed.

****kwargs** Keyword arguments to pass on to `DataFrame.plot()`.

Returns

matplotlib.axes.Axes or np.ndarray of them A NumPy array is returned when `subplots` is True.

See also:

`Series.plot.pie` Generate a pie plot for a Series.

`DataFrame.plot` Make plots of a DataFrame.

Examples

In the example below we have a DataFrame with the information about planet's mass and radius. We pass the the 'mass' column to the pie function to get a pie plot.

```
>>> df = pd.DataFrame({'mass': [0.330, 4.87, 5.97],
...                    'radius': [2439.7, 6051.8, 6378.1]},
...                    index=['Mercury', 'Venus', 'Earth'])
>>> plot = df.plot.pie(y='mass', figsize=(5, 5))
```

```
>>> plot = df.plot.pie(subplots=True, figsize=(6, 3))
```

<i>Series.hist</i> (self[, by, ax, grid, ...])	Draw histogram of the input series using matplotlib.
--	--

6.3.15 Serialization / IO / conversion

<i>Series.to_pickle</i> (self, path[, compression, ...])	Pickle (serialize) object to file.
<i>Series.to_csv</i> (self, <i>*args</i> , <i>**kwargs</i>)	Write object to a comma-separated values (csv) file.
<i>Series.to_dict</i> (self[, into])	Convert Series to {label -> value} dict or dict-like object.
<i>Series.to_excel</i> (self, excel_writer[, ...])	Write object to an Excel sheet.
<i>Series.to_frame</i> (self[, name])	Convert Series to DataFrame.
<i>Series.to_xarray</i> (self)	Return an xarray object from the pandas object.
<i>Series.to_hdf</i> (self, path_or_buf, key, <i>**kwargs</i>)	Write the contained data to an HDF5 file using HDFStore.
<i>Series.to_sql</i> (self, name, con[, schema, ...])	Write records stored in a DataFrame to a SQL database.
<i>Series.to_msgpack</i> (self[, path_or_buf, encoding])	(DEPRECATED) Serialize object to input file path using msgpack format.
<i>Series.to_json</i> (self[, path_or_buf, orient, ...])	Convert the object to a JSON string.
<i>Series.to_sparse</i> (self[, kind, fill_value])	(DEPRECATED) Convert Series to SparseSeries.
<i>Series.to_dense</i> (self)	(DEPRECATED) Return dense representation of Series/DataFrame (as opposed to sparse).
<i>Series.to_string</i> (self[, buf, na_rep, ...])	Render a string representation of the Series.
<i>Series.to_clipboard</i> (self[, excel, sep])	Copy object to the system clipboard.
<i>Series.to_latex</i> (self[, buf, columns, ...])	Render an object to a LaTeX tabular environment table.

6.3.16 Sparse

<i>SparseSeries.to_coo</i> (self[, row_levels, ...])	Create a <code>scipy.sparse.coo_matrix</code> from a SparseSeries with MultiIndex.
<i>SparseSeries.from_coo</i> (A[, dense_index])	Create a SparseSeries from a <code>scipy.sparse.coo_matrix</code> .

pandas.SparseSeries.to_coo

`SparseSeries.to_coo`(self, row_levels=(0,), column_levels=(1,), sort_labels=False)
 Create a `scipy.sparse.coo_matrix` from a SparseSeries with MultiIndex.

Use `row_levels` and `column_levels` to determine the row and column coordinates respectively. `row_levels` and `column_levels` are the names (labels) or numbers of the levels. {`row_levels`, `column_levels`} must be a partition of the MultiIndex level names (or numbers).

Parameters**row_levels** [tuple/list]**column_levels** [tuple/list]**sort_labels** [bool, default False] Sort the row and column labels before forming the sparse matrix.**Returns****y** [scipy.sparse.coo_matrix]**rows** [list (row labels)]**columns** [list (column labels)]**Examples**

```

>>> s = pd.Series([3.0, np.nan, 1.0, 3.0, np.nan, np.nan])
>>> s.index = pd.MultiIndex.from_tuples([(1, 2, 'a', 0),
                                         (1, 2, 'a', 1),
                                         (1, 1, 'b', 0),
                                         (1, 1, 'b', 1),
                                         (2, 1, 'b', 0),
                                         (2, 1, 'b', 1)],
                                         names=['A', 'B', 'C', 'D'])

>>> ss = s.to_sparse()
>>> A, rows, columns = ss.to_coo(row_levels=['A', 'B'],
                                 column_levels=['C', 'D'],
                                 sort_labels=True)

>>> A
<3x4 sparse matrix of type '<class 'numpy.float64'>'
  with 3 stored elements in COOrdinate format>
>>> A.todense()
matrix([[ 0.,  0.,  1.,  3.],
 [ 3.,  0.,  0.,  0.],
 [ 0.,  0.,  0.,  0.]])
>>> rows
[(1, 1), (1, 2), (2, 1)]
>>> columns
[(('a', 0), ('a', 1), ('b', 0), ('b', 1))]

```

pandas.SparseSeries.from_coo**classmethod** SparseSeries.from_coo(*A*, *dense_index=False*)

Create a SparseSeries from a scipy.sparse.coo_matrix.

Parameters**A** [scipy.sparse.coo_matrix]**dense_index** [bool, default False] If False (default), the SparseSeries index consists of only the coords of the non-null entries of the original coo_matrix. If True, the SparseSeries index consists of the full sorted (row, col) coordinates of the coo_matrix.

Returns

s [SparseSeries]

Examples

```
>>> from scipy import sparse
>>> A = sparse.coo_matrix(([3.0, 1.0, 2.0], ([1, 0, 0], [0, 2, 3])),
                        shape=(3, 4))
>>> A
<3x4 sparse matrix of type '<class 'numpy.float64'>'
  with 3 stored elements in COOrdinate format>
>>> A.todense()
matrix([[ 0.,  0.,  1.,  2.],
        [ 3.,  0.,  0.,  0.],
        [ 0.,  0.,  0.,  0.]])
>>> ss = pd.SparseSeries.from_coo(A)
>>> ss
0 2 1
 3 2
1 0 3
dtype: float64
BlockIndex
Block locations: array([0], dtype=int32)
Block lengths: array([3], dtype=int32)
```

{{ header }}

6.4 DataFrame

6.4.1 Constructor

<code>DataFrame</code> ([data, index, columns, dtype, copy])	Two-dimensional size-mutable, potentially heterogeneous tabular data structure with labeled axes (rows and columns).
--	--

pandas.DataFrame

`class pandas.DataFrame`(*data=None, index=None, columns=None, dtype=None, copy=False*)

Two-dimensional size-mutable, potentially heterogeneous tabular data structure with labeled axes (rows and columns). Arithmetic operations align on both row and column labels. Can be thought of as a dict-like container for Series objects. The primary pandas data structure.

Parameters

data [ndarray (structured or homogeneous), Iterable, dict, or DataFrame] Dict can contain Series, arrays, constants, or list-like objects

Changed in version 0.23.0: If data is a dict, column order follows insertion-order for Python 3.6 and later.

Changed in version 0.25.0: If data is a list of dicts, column order follows insertion-

order for Python 3.6 and later.

index [Index or array-like] Index to use for resulting frame. Will default to RangeIndex if no indexing information part of input data and no index provided

columns [Index or array-like] Column labels to use for resulting frame. Will default to RangeIndex (0, 1, 2, ..., n) if no column labels are provided

dtype [dtype, default None] Data type to force. Only a single dtype is allowed. If None, infer

copy [boolean, default False] Copy data from inputs. Only affects DataFrame / 2d ndarray input

See also:

DataFrame.from_records Constructor from tuples, also record arrays.

DataFrame.from_dict From dicts of Series, arrays, or dicts.

DataFrame.from_items From sequence of (key, value) pairs `read_csv`, `pandas.read_table`, `pandas.read_clipboard`.

Examples

Constructing DataFrame from a dictionary.

```
>>> d = {'col1': [1, 2], 'col2': [3, 4]}
>>> df = pd.DataFrame(data=d)
>>> df
   col1  col2
0     1     3
1     2     4
```

Notice that the inferred dtype is int64.

```
>>> df.dtypes
col1    int64
col2    int64
dtype: object
```

To enforce a single dtype:

```
>>> df = pd.DataFrame(data=d, dtype=np.int8)
>>> df.dtypes
col1    int8
col2    int8
dtype: object
```

Constructing DataFrame from numpy ndarray:

```
>>> df2 = pd.DataFrame(np.array([[1, 2, 3], [4, 5, 6], [7, 8, 9]]),
...                      columns=['a', 'b', 'c'])
>>> df2
   a  b  c
0  1  2  3
```

(continues on next page)

(continued from previous page)

1	4	5	6
2	7	8	9

Attributes

<i>T</i>	Transpose index and columns.
<i>at</i>	Access a single value for a row/column label pair.
<i>axes</i>	Return a list representing the axes of the DataFrame.
<i>blocks</i>	(DEPRECATED) Internal property, property synonym for <code>as_blocks()</code> .
<i>columns</i>	The column labels of the DataFrame.
<i>dtypes</i>	Return the dtypes in the DataFrame.
<i>empty</i>	Indicator whether DataFrame is empty.
<i>ftypes</i>	(DEPRECATED) Return the ftypes (indication of sparse/dense and dtype) in DataFrame.
<i>iat</i>	Access a single value for a row/column pair by integer position.
<i>iloc</i>	Purely integer-location based indexing for selection by position.
<i>index</i>	The index (row labels) of the DataFrame.
<i>is_copy</i>	Return the copy.
<i>ix</i>	A primarily label-location based indexer, with integer position fallback.
<i>loc</i>	Access a group of rows and columns by label(s) or a boolean array.
<i>ndim</i>	Return an int representing the number of axes / array dimensions.
<i>shape</i>	Return a tuple representing the dimensionality of the DataFrame.
<i>size</i>	Return an int representing the number of elements in this object.
<i>style</i>	Property returning a Styler object containing methods for building a styled HTML representation fo the DataFrame.
<i>values</i>	Return a Numpy representation of the DataFrame.

pandas.DataFrame.T**DataFrame.T**

Transpose index and columns.

Reflect the DataFrame over its main diagonal by writing rows as columns and vice-versa. The property *T* is an accessor to the method `transpose()`.

Parameters

copy [bool, default False] If True, the underlying data is copied. Otherwise (default), no copy is made if possible.

***args, **kwargs** Additional keywords have no effect but might be accepted for compatibility with numpy.

Returns

DataFrame The transposed DataFrame.

See also:

`numpy.transpose` Permute the dimensions of a given array.

Notes

Transposing a DataFrame with mixed dtypes will result in a homogeneous DataFrame with the *object* dtype. In such a case, a copy of the data is always made.

Examples

Square DataFrame with homogeneous dtype

```
>>> d1 = {'col1': [1, 2], 'col2': [3, 4]}
>>> df1 = pd.DataFrame(data=d1)
>>> df1
   col1  col2
0     1     3
1     2     4
```

```
>>> df1_transposed = df1.T # or df1.transpose()
>>> df1_transposed
   0  1
col1 1  2
col2 3  4
```

When the dtype is homogeneous in the original DataFrame, we get a transposed DataFrame with the same dtype:

```
>>> df1.dtypes
col1    int64
col2    int64
dtype: object
>>> df1_transposed.dtypes
0    int64
1    int64
dtype: object
```

Non-square DataFrame with mixed dtypes

```
>>> d2 = {'name': ['Alice', 'Bob'],
...       'score': [9.5, 8],
...       'employed': [False, True],
...       'kids': [0, 0]}
>>> df2 = pd.DataFrame(data=d2)
>>> df2
```

(continues on next page)

(continued from previous page)

	name	score	employed	kids
0	Alice	9.5	False	0
1	Bob	8.0	True	0

```
>>> df2_transposed = df2.T # or df2.transpose()
>>> df2_transposed
      0    1
name  Alice  Bob
score    9.5    8
employed False  True
kids      0    0
```

When the DataFrame has mixed dtypes, we get a transposed DataFrame with the *object* dtype:

```
>>> df2.dtypes
name      object
score    float64
employed    bool
kids      int64
dtype: object
>>> df2_transposed.dtypes
0      object
1      object
dtype: object
```

pandas.DataFrame.at

DataFrame.at

Access a single value for a row/column label pair.

Similar to `loc`, in that both provide label-based lookups. Use `at` if you only need to get or set a single value in a DataFrame or Series.

Raises

KeyError When label does not exist in DataFrame

See also:

DataFrame.iat Access a single value for a row/column pair by integer position.

DataFrame.loc Access a group of rows and columns by label(s).

Series.at Access a single value using a label.

Examples

```
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
...                    index=[4, 5, 6], columns=['A', 'B', 'C'])
>>> df
   A  B  C
4  0  2  3
```

(continues on next page)

(continued from previous page)

```
5  0  4  1
6 10 20 30
```

Get value at specified row/column pair

```
>>> df.at[4, 'B']
2
```

Set value at specified row/column pair

```
>>> df.at[4, 'B'] = 10
>>> df.at[4, 'B']
10
```

Get value within a Series

```
>>> df.loc[5].at['B']
4
```

pandas.DataFrame.axes

DataFrame.axes

Return a list representing the axes of the DataFrame.

It has the row axis labels and column axis labels as the only members. They are returned in that order.

Examples

```
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.axes
[RangeIndex(start=0, stop=2, step=1), Index(['col1', 'col2'],
dtype='object')]
```

pandas.DataFrame.blocks

DataFrame.blocks

Internal property, property synonym for `as_blocks()`.

Deprecated since version 0.21.0.

pandas.DataFrame.columns

DataFrame.columns

The column labels of the DataFrame.

pandas.DataFrame.dtypes

DataFrame.dtypes

Return the dtypes in the DataFrame.

This returns a Series with the data type of each column. The result's index is the original DataFrame's columns. Columns with mixed types are stored with the `object` dtype. See *the User Guide* for more.

Returns

pandas.Series The data type of each column.

See also:

DataFrame.ftypes Dtype and sparsity information.

Examples

```
>>> df = pd.DataFrame({'float': [1.0],
...                    'int': [1],
...                    'datetime': [pd.Timestamp('20180310')],
...                    'string': ['foo']})
>>> df.dtypes
float                float64
int                  int64
datetime            datetime64[ns]
string              object
dtype: object
```

pandas.DataFrame.empty

DataFrame.empty

Indicator whether DataFrame is empty.

True if DataFrame is entirely empty (no items), meaning any of the axes are of length 0.

Returns

bool If DataFrame is empty, return True, if not return False.

See also:

Series.dropna

DataFrame.dropna

Notes

If DataFrame contains only NaNs, it is still not considered empty. See the example below.

Examples

An example of an actual empty DataFrame. Notice the index is empty:

```

>>> df_empty = pd.DataFrame({'A' : []})
>>> df_empty
Empty DataFrame
Columns: [A]
Index: []
>>> df_empty.empty
True

```

If we only have NaNs in our DataFrame, it is not considered empty! We will need to drop the NaNs to make the DataFrame empty:

```

>>> df = pd.DataFrame({'A' : [np.nan]})
>>> df
   A
0 NaN
>>> df.empty
False
>>> df.dropna().empty
True

```

pandas.DataFrame.ftypes

DataFrame.ftypes

Return the ftypes (indication of sparse/dense and dtype) in DataFrame.

Deprecated since version 0.25.0: Use `dtypes()` instead.

This returns a Series with the data type of each column. The result's index is the original DataFrame's columns. Columns with mixed types are stored with the `object` dtype. See *the User Guide* for more.

Returns

pandas.Series The data type and indication of sparse/dense of each column.

See also:

DataFrame.dtypes Series with just dtype information.

SparseDataFrame Container for sparse tabular data.

Notes

Sparse data should have the same dtypes as its dense representation.

Examples

```
>>> arr = np.random.RandomState(0).randn(100, 4)
>>> arr[arr < .8] = np.nan
>>> pd.DataFrame(arr).ftypes
0    float64:dense
1    float64:dense
2    float64:dense
3    float64:dense
dtype: object
```

```
>>> pd.SparseDataFrame(arr).ftypes # doctest: +SKIP
0    float64:sparse
1    float64:sparse
2    float64:sparse
3    float64:sparse
dtype: object
```

pandas.DataFrame.iat

DataFrame.iat

Access a single value for a row/column pair by integer position.

Similar to `iloc`, in that both provide integer-based lookups. Use `iat` if you only need to get or set a single value in a DataFrame or Series.

Raises

IndexError When integer position is out of bounds

See also:

DataFrame.at Access a single value for a row/column label pair.

DataFrame.loc Access a group of rows and columns by label(s).

DataFrame.iloc Access a group of rows and columns by integer position(s).

Examples

```
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
...                    columns=['A', 'B', 'C'])
>>> df
   A  B  C
0  0  2  3
1  0  4  1
2 10 20 30
```

Get value at specified row/column pair

```
>>> df.iat[1, 2]
1
```

Set value at specified row/column pair

```
>>> df.iat[1, 2] = 10
>>> df.iat[1, 2]
10
```

Get value within a series

```
>>> df.loc[0].iat[1]
2
```

pandas.DataFrame.iat

DataFrame.iat

Purely integer-location based indexing for selection by position.

`.iat[]` is primarily integer position based (from 0 to `length-1` of the axis), but may also be used with a boolean array.

Allowed inputs are:

- An integer, e.g. 5.
- A list or array of integers, e.g. [4, 3, 0].
- A slice object with ints, e.g. 1:7.
- A boolean array.
- A callable function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above). This is useful in method chains, when you don't have a reference to the calling object, but would like to base your selection on some value.

`.iat` will raise `IndexError` if a requested indexer is out-of-bounds, except *slice* indexers which allow out-of-bounds indexing (this conforms with python/numpy *slice* semantics).

See more at *Selection by Position*.

See also:

DataFrame.iat Fast integer location scalar accessor.

DataFrame.loc Purely label-location based indexer for selection by label.

Series.iat Purely integer-location based indexing for selection by position.

Examples

```
>>> mydict = [{'a': 1, 'b': 2, 'c': 3, 'd': 4},
...          {'a': 100, 'b': 200, 'c': 300, 'd': 400},
...          {'a': 1000, 'b': 2000, 'c': 3000, 'd': 4000 }]
>>> df = pd.DataFrame(mydict)
>>> df
   a    b    c    d
0   1    2    3    4
1 100  200  300  400
2 1000 2000 3000 4000
```

Indexing just the rows

With a scalar integer.

```
>>> type(df.iloc[0])
<class 'pandas.core.series.Series'>
>>> df.iloc[0]
a    1
b    2
c    3
d    4
Name: 0, dtype: int64
```

With a list of integers.

```
>>> df.iloc[[0]]
   a  b  c  d
0  1  2  3  4
>>> type(df.iloc[[0]])
<class 'pandas.core.frame.DataFrame'>
```

```
>>> df.iloc[[0, 1]]
   a  b  c  d
0  1  2  3  4
1 100 200 300 400
```

With a *slice* object.

```
>>> df.iloc[:3]
   a  b  c  d
0  1  2  3  4
1 100 200 300 400
2 1000 2000 3000 4000
```

With a boolean mask the same length as the index.

```
>>> df.iloc[[True, False, True]]
   a  b  c  d
0  1  2  3  4
2 1000 2000 3000 4000
```

With a callable, useful in method chains. The *x* passed to the `lambda` is the DataFrame being sliced. This selects the rows whose index label even.

```
>>> df.iloc[lambda x: x.index % 2 == 0]
   a  b  c  d
0  1  2  3  4
2 1000 2000 3000 4000
```

Indexing both axes

You can mix the indexer types for the index and columns. Use `:` to select the entire axis.

With scalar integers.

```
>>> df.iloc[0, 1]
2
```

With lists of integers.

```
>>> df.iloc[[0, 2], [1, 3]]
      b     d
0     2     4
2  2000  4000
```

With *slice* objects.

```
>>> df.iloc[1:3, 0:3]
      a     b     c
1   100   200   300
2  1000  2000  3000
```

With a boolean array whose length matches the columns.

```
>>> df.iloc[:, [True, False, True, False]]
      a     c
0     1     3
1   100   300
2  1000  3000
```

With a callable function that expects the Series or DataFrame.

```
>>> df.iloc[:, lambda df: [0, 2]]
      a     c
0     1     3
1   100   300
2  1000  3000
```

pandas.DataFrame.index

DataFrame.index

The index (row labels) of the DataFrame.

pandas.DataFrame.is_copy

DataFrame.is_copy

Return the copy.

pandas.DataFrame.ix

DataFrame.ix

A primarily label-location based indexer, with integer position fallback.

Warning: Starting in 0.20.0, the `.ix` indexer is deprecated, in favor of the more strict `.iloc` and `.loc` indexers.

`.ix[]` supports mixed integer and label based access. It is primarily label based, but will fall back to integer positional access unless the corresponding axis is of integer type.

`.ix` is the most general indexer and will support any of the inputs in `.loc` and `.iloc`. `.ix` also supports floating point label schemes. `.ix` is exceptionally useful when dealing with mixed positional and label based hierarchical indexes.

However, when an axis is integer based, ONLY label based access and not positional access is supported. Thus, in such cases, it's usually better to be explicit and use `.iloc` or `.loc`.

See more at *Advanced Indexing*.

pandas.DataFrame.loc

DataFrame.loc

Access a group of rows and columns by label(s) or a boolean array.

`.loc[]` is primarily label based, but may also be used with a boolean array.

Allowed inputs are:

- A single label, e.g. 5 or 'a', (note that 5 is interpreted as a *label* of the index, and **never** as an integer position along the index).
- A list or array of labels, e.g. ['a', 'b', 'c'].
- A slice object with labels, e.g. 'a':'f'.

Warning: Note that contrary to usual python slices, **both** the start and the stop are included

- A boolean array of the same length as the axis being sliced, e.g. [True, False, True].
- A callable function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above)

See more at *Selection by Label*

Raises

KeyError: when any items are not found

See also:

DataFrame.at Access a single value for a row/column label pair.

DataFrame.iloc Access group of rows and columns by integer position(s).

DataFrame.xs Returns a cross-section (row(s) or column(s)) from the Series/DataFrame.

Series.loc Access group of values using labels.

Examples

Getting values

```
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
...                    index=['cobra', 'viper', 'sidewinder'],
...                    columns=['max_speed', 'shield'])
>>> df
```

	max_speed	shield
cobra	1	2
viper	4	5
sidewinder	7	8

Single label. Note this returns the row as a Series.

```
>>> df.loc['viper']
max_speed    4
shield       5
Name: viper, dtype: int64
```

List of labels. Note using [[]] returns a DataFrame.

```
>>> df.loc[['viper', 'sidewinder']]
```

	max_speed	shield
viper	4	5
sidewinder	7	8

Single label for row and column

```
>>> df.loc['cobra', 'shield']
2
```

Slice with labels for row and single label for column. As mentioned above, note that both the start and stop of the slice are included.

```
>>> df.loc['cobra':'viper', 'max_speed']
cobra    1
viper    4
Name: max_speed, dtype: int64
```

Boolean list with the same length as the row axis

```
>>> df.loc[[False, False, True]]
```

	max_speed	shield
sidewinder	7	8

Conditional that returns a boolean Series

```
>>> df.loc[df['shield'] > 6]
```

	max_speed	shield
sidewinder	7	8

Conditional that returns a boolean Series with column labels specified

```
>>> df.loc[df['shield'] > 6, ['max_speed']]
```

	max_speed
sidewinder	7

Callable that returns a boolean Series

```
>>> df.loc[lambda df: df['shield'] == 8]
           max_speed  shield
sidewinder           7       8
```

Setting values

Set value for all items matching the list of labels

```
>>> df.loc[['viper', 'sidewinder'], ['shield']] = 50
>>> df
           max_speed  shield
cobra                1       2
viper                4      50
sidewinder           7      50
```

Set value for an entire row

```
>>> df.loc['cobra'] = 10
>>> df
           max_speed  shield
cobra            10      10
viper            4       50
sidewinder       7       50
```

Set value for an entire column

```
>>> df.loc[:, 'max_speed'] = 30
>>> df
           max_speed  shield
cobra             30      10
viper             30      50
sidewinder        30      50
```

Set value for rows matching callable condition

```
>>> df.loc[df['shield'] > 35] = 0
>>> df
           max_speed  shield
cobra             30      10
viper              0       0
sidewinder         0       0
```

Getting values on a DataFrame with an index that has integer labels

Another example using integers for the index

```
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
...                   index=[7, 8, 9], columns=['max_speed', 'shield'])
>>> df
           max_speed  shield
7             1       2
8             4       5
9             7       8
```

Slice with integer labels for rows. As mentioned above, note that both the start and stop of the slice are included.

```
>>> df.loc[7:9]
   max_speed  shield
7          1       2
8          4       5
9          7       8
```

Getting values with a MultiIndex

A number of examples using a DataFrame with a MultiIndex

```
>>> tuples = [
...     ('cobra', 'mark i'), ('cobra', 'mark ii'),
...     ('sidewinder', 'mark i'), ('sidewinder', 'mark ii'),
...     ('viper', 'mark ii'), ('viper', 'mark iii')
... ]
>>> index = pd.MultiIndex.from_tuples(tuples)
>>> values = [[12, 2], [0, 4], [10, 20],
...           [1, 4], [7, 1], [16, 36]]
>>> df = pd.DataFrame(values, columns=['max_speed', 'shield'], index=index)
>>> df
           max_speed  shield
cobra  mark i         12       2
       mark ii          0       4
sidewinder mark i         10      20
          mark ii          1       4
viper    mark ii          7       1
          mark iii         16      36
```

Single label. Note this returns a DataFrame with a single index.

```
>>> df.loc['cobra']
   max_speed  shield
mark i         12       2
mark ii          0       4
```

Single index tuple. Note this returns a Series.

```
>>> df.loc[('cobra', 'mark ii')]
max_speed    0
shield        4
Name: (cobra, mark ii), dtype: int64
```

Single label for row and column. Similar to passing in a tuple, this returns a Series.

```
>>> df.loc['cobra', 'mark i']
max_speed    12
shield         2
Name: (cobra, mark i), dtype: int64
```

Single tuple. Note using [[]] returns a DataFrame.

```
>>> df.loc[['cobra', 'mark ii']]
           max_speed  shield
cobra mark ii          0       4
```

Single tuple for the index with a single label for the column

```
>>> df.loc[('cobra', 'mark i'), 'shield']
2
```

Slice from index tuple to single label

```
>>> df.loc[('cobra', 'mark i'): 'viper']
      max_speed  shield
cobra  mark i      12     2
      mark ii     0     4
sidewinder mark i    10    20
      mark ii     1     4
viper  mark ii     7     1
      mark iii    16    36
```

Slice from index tuple to index tuple

```
>>> df.loc[('cobra', 'mark i'): ('viper', 'mark ii')]
      max_speed  shield
cobra  mark i      12     2
      mark ii     0     4
sidewinder mark i    10    20
      mark ii     1     4
viper  mark ii     7     1
```

pandas.DataFrame.ndim

DataFrame.ndim

Return an int representing the number of axes / array dimensions.

Return 1 if Series. Otherwise return 2 if DataFrame.

See also:

`ndarray.ndim` Number of array dimensions.

Examples

```
>>> s = pd.Series({'a': 1, 'b': 2, 'c': 3})
>>> s.ndim
1
```

```
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.ndim
2
```

pandas.DataFrame.shape

DataFrame.shape

Return a tuple representing the dimensionality of the DataFrame.

See also:

`ndarray.shape`

Examples

```
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.shape
(2, 2)
```

```
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4],
...                    'col3': [5, 6]})
>>> df.shape
(2, 3)
```

pandas.DataFrame.size

DataFrame.size

Return an int representing the number of elements in this object.

Return the number of rows if Series. Otherwise return the number of rows times number of columns if DataFrame.

See also:

`ndarray.size` Number of elements in the array.

Examples

```
>>> s = pd.Series({'a': 1, 'b': 2, 'c': 3})
>>> s.size
3
```

```
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.size
4
```

pandas.DataFrame.style

DataFrame.style

Property returning a Styler object containing methods for building a styled HTML representation for the DataFrame.

See also:

`io.formats.style.Styler`

pandas.DataFrame.values

DataFrame.values

Return a Numpy representation of the DataFrame.

Warning: We recommend using `DataFrame.to_numpy()` instead.

Only the values in the DataFrame will be returned, the axes labels will be removed.

Returns

numpy.ndarray The values of the DataFrame.

See also:

DataFrame.to_numpy Recommended alternative to this method.

DataFrame.index Retrieve the index labels.

DataFrame.columns Retrieving the column names.

Notes

The dtype will be a lower-common-denominator dtype (implicit upcasting); that is to say if the dtypes (even of numeric types) are mixed, the one that accommodates all will be chosen. Use this with care if you are not dealing with the blocks.

e.g. If the dtypes are float16 and float32, dtype will be upcast to float32. If dtypes are int32 and uint8, dtype will be upcast to int32. By `numpy.find_common_type()` convention, mixing int64 and uint64 will result in a float64 dtype.

Examples

A DataFrame where all columns are the same type (e.g., int64) results in an array of the same type.

```
>>> df = pd.DataFrame({'age':    [ 3, 29],
...                   'height': [94, 170],
...                   'weight': [31, 115]})
>>> df
   age  height  weight
0    3     94     31
1   29    170    115
>>> df.dtypes
age          int64
height       int64
weight       int64
dtype: object
>>> df.values
array([[ 3, 94, 31],
       [29, 170, 115]], dtype=int64)
```

A DataFrame with mixed type columns(e.g., str/object, int64, float32) results in an ndarray of the broadest type that accommodates these mixed types (e.g., object).

```

>>> df2 = pd.DataFrame([('parrot', 24.0, 'second'),
...                     ('lion', 80.5, 1),
...                     ('monkey', np.nan, None)],
...                     columns=('name', 'max_speed', 'rank'))
>>> df2.dtypes
name          object
max_speed    float64
rank         object
dtype: object
>>> df2.values
array([[ 'parrot', 24.0, 'second'],
       [ 'lion', 80.5, 1],
       [ 'monkey', nan, None]], dtype=object)

```

Methods

<code>abs(self)</code>	Return a Series/DataFrame with absolute numeric value of each element.
<code>add(self, other[, axis, level, fill_value])</code>	Get Addition of dataframe and other, element-wise (binary operator <i>add</i>).
<code>add_prefix(self, prefix)</code>	Prefix labels with string <i>prefix</i> .
<code>add_suffix(self, suffix)</code>	Suffix labels with string <i>suffix</i> .
<code>agg(self, func[, axis])</code>	Aggregate using one or more operations over the specified axis.
<code>aggregate(self, func[, axis])</code>	Aggregate using one or more operations over the specified axis.
<code>align(self, other[, join, axis, level, ...])</code>	Align two objects on their axes with the specified join method for each axis Index.
<code>all(self[, axis, bool_only, skipna, level])</code>	Return whether all elements are True, potentially over an axis.
<code>any(self[, axis, bool_only, skipna, level])</code>	Return whether any element is True, potentially over an axis.
<code>append(self, other[, ignore_index, ...])</code>	Append rows of <i>other</i> to the end of caller, returning a new object.
<code>apply(self, func[, axis, broadcast, raw, ...])</code>	Apply a function along an axis of the DataFrame.
<code>applymap(self, func)</code>	Apply a function to a Dataframe elementwise.
<code>as_blocks(self[, copy])</code>	(DEPRECATED) Convert the frame to a dict of dtype -> Constructor Types that each has a homogeneous dtype.
<code>as_matrix(self[, columns])</code>	(DEPRECATED) Convert the frame to its Numpy-array representation.
<code>asfreq(self, freq[, method, how, normalize, ...])</code>	Convert TimeSeries to specified frequency.
<code>asof(self, where[, subset])</code>	Return the last row(s) without any NaNs before <i>where</i> .
<code>assign(self, <i>kwargs</i>)</code>	Assign new columns to a DataFrame.
<code>astype(self, dtype[, copy, errors])</code>	Cast a pandas object to a specified dtype <i>dtype</i> .
<code>at_time(self, time[, asof, axis])</code>	Select values at particular time of day (e.g.
<code>between_time(self, start_time, end_time[, ...])</code>	Select values between particular times of the day (e.g., 9:00-9:30 AM).

Continued on next page

Table 57 – continued from previous page

<code>bfill(self[, axis, inplace, limit, downcast])</code>	Synonym for <code>DataFrame.fillna()</code> with <code>method='bfill'</code> .
<code>bool(self)</code>	Return the bool of a single element PandasObject.
<code>boxplot(self[, column, by, ax, fontsize, ...])</code>	Make a box plot from DataFrame columns.
<code>clip(self[, lower, upper, axis, inplace])</code>	Trim values at input threshold(s).
<code>clip_lower(self, threshold[, axis, inplace])</code>	(DEPRECATED) Trim values below a given threshold.
<code>clip_upper(self, threshold[, axis, inplace])</code>	(DEPRECATED) Trim values above a given threshold.
<code>combine(self, other, func[, fill_value, ...])</code>	Perform column-wise combine with another DataFrame.
<code>combine_first(self, other)</code>	Update null elements with value in the same location in <i>other</i> .
<code>compound(self[, axis, skipna, level])</code>	(DEPRECATED) Return the compound percentage of the values for the requested axis.
<code>copy(self[, deep])</code>	Make a copy of this object's indices and data.
<code>corr(self[, method, min_periods])</code>	Compute pairwise correlation of columns, excluding NA/null values.
<code>corrwith(self, other[, axis, drop, method])</code>	Compute pairwise correlation between rows or columns of DataFrame with rows or columns of Series or DataFrame.
<code>count(self[, axis, level, numeric_only])</code>	Count non-NA cells for each column or row.
<code>cov(self[, min_periods])</code>	Compute pairwise covariance of columns, excluding NA/null values.
<code>cummax(self[, axis, skipna])</code>	Return cumulative maximum over a DataFrame or Series axis.
<code>cummin(self[, axis, skipna])</code>	Return cumulative minimum over a DataFrame or Series axis.
<code>cumprod(self[, axis, skipna])</code>	Return cumulative product over a DataFrame or Series axis.
<code>cumsum(self[, axis, skipna])</code>	Return cumulative sum over a DataFrame or Series axis.
<code>describe(self[, percentiles, include, exclude])</code>	Generate descriptive statistics that summarize the central tendency, dispersion and shape of a dataset's distribution, excluding NaN values.
<code>diff(self[, periods, axis])</code>	First discrete difference of element.
<code>div(self, other[, axis, level, fill_value])</code>	Get Floating division of dataframe and other, element-wise (binary operator <i>truediv</i>).
<code>divide(self, other[, axis, level, fill_value])</code>	Get Floating division of dataframe and other, element-wise (binary operator <i>truediv</i>).
<code>dot(self, other)</code>	Compute the matrix multiplication between the DataFrame and other.
<code>drop(self[, labels, axis, index, columns, ...])</code>	Drop specified labels from rows or columns.
<code>drop_duplicates(self[, subset, keep, inplace])</code>	Return DataFrame with duplicate rows removed, optionally only considering certain columns.
<code>droplevel(self, level[, axis])</code>	Return DataFrame with requested index / column level(s) removed.
<code>dropna(self[, axis, how, thresh, subset, ...])</code>	Remove missing values.
<code>duplicated(self[, subset, keep])</code>	Return boolean Series denoting duplicate rows, optionally only considering certain columns.

Table 57 – continued from previous page

<code>eq(self, other[, axis, level])</code>	Get Equal to of dataframe and other, element-wise (binary operator <i>eq</i>).
<code>equals(self, other)</code>	Test whether two objects contain the same elements.
<code>eval(self, expr[, inplace])</code>	Evaluate a string describing operations on DataFrame columns.
<code>ewm(self[, com, span, halflife, alpha, ...])</code>	Provide exponential weighted functions.
<code>expanding(self[, min_periods, center, axis])</code>	Provide expanding transformations.
<code>explode(self, column, Tuple)</code>	Transform each element of a list-like to a row, replicating the index values.
<code>ffill(self[, axis, inplace, limit, downcast])</code>	Synonym for <code>DataFrame.fillna()</code> with <code>method='ffill'</code> .
<code>fillna(self[, value, method, axis, inplace, ...])</code>	Fill NA/NaN values using the specified method.
<code>filter(self[, items, like, regex, axis])</code>	Subset rows or columns of dataframe according to labels in the specified index.
<code>first(self, offset)</code>	Convenience method for subsetting initial periods of time series data based on a date offset.
<code>first_valid_index(self)</code>	Return index for first non-NA/null value.
<code>floordiv(self, other[, axis, level, fill_value])</code>	Get Integer division of dataframe and other, element-wise (binary operator <i>floordiv</i>).
<code>from_dict(data[, orient, dtype, columns])</code>	Construct DataFrame from dict of array-like or dicts.
<code>from_items(items[, columns, orient])</code>	(DEPRECATED) Construct a DataFrame from a list of tuples.
<code>from_records(data[, index, exclude, ...])</code>	Convert structured or record ndarray to DataFrame.
<code>ge(self, other[, axis, level])</code>	Get Greater than or equal to of dataframe and other, element-wise (binary operator <i>ge</i>).
<code>get(self, key[, default])</code>	Get item from object for given key (ex: DataFrame column).
<code>get_dtype_counts(self)</code>	(DEPRECATED) Return counts of unique dtypes in this object.
<code>get_fctype_counts(self)</code>	(DEPRECATED) Return counts of unique ftypes in this object.
<code>get_value(self, index, col[, takeable])</code>	(DEPRECATED) Quickly retrieve single value at passed column and index.
<code>get_values(self)</code>	(DEPRECATED) Return an ndarray after converting sparse values to dense.
<code>groupby(self[, by, axis, level, as_index, ...])</code>	Group DataFrame or Series using a mapper or by a Series of columns.
<code>gt(self, other[, axis, level])</code>	Get Greater than of dataframe and other, element-wise (binary operator <i>gt</i>).
<code>head(self[, n])</code>	Return the first <i>n</i> rows.
<code>hist(data[, column, by, grid, xlabelsize, ...])</code>	Make a histogram of the DataFrame's.
<code>idxmax(self[, axis, skipna])</code>	Return index of first occurrence of maximum over requested axis.
<code>idxmin(self[, axis, skipna])</code>	Return index of first occurrence of minimum over requested axis.
<code>infer_objects(self)</code>	Attempt to infer better dtypes for object columns.
<code>info(self[, verbose, buf, max_cols, ...])</code>	Print a concise summary of a DataFrame.

Table 57 – continued from previous page

<i>insert</i> (self, loc, column, value[, ...])	Insert column into DataFrame at specified location.
<i>interpolate</i> (self[, method, axis, limit, ...])	Interpolate values according to different methods.
<i>isin</i> (self, values)	Whether each element in the DataFrame is contained in values.
<i>isna</i> (self)	Detect missing values.
<i>isnull</i> (self)	Detect missing values.
<i>items</i> (self)	Iterator over (column name, Series) pairs.
<i>iteritems</i> (self)	Iterator over (column name, Series) pairs.
<i>iterrows</i> (self)	Iterate over DataFrame rows as (index, Series) pairs.
<i>itertuples</i> (self[, index, name])	Iterate over DataFrame rows as namedtuples.
<i>join</i> (self, other[, on, how, lsuffix, ...])	Join columns of another DataFrame.
<i>keys</i> (self)	Get the ‘info axis’ (see Indexing for more)
<i>kurt</i> (self[, axis, skipna, level, numeric_only])	Return unbiased kurtosis over requested axis using Fisher’s definition of kurtosis (kurtosis of normal == 0.0).
<i>kurtosis</i> (self[, axis, skipna, level, ...])	Return unbiased kurtosis over requested axis using Fisher’s definition of kurtosis (kurtosis of normal == 0.0).
<i>last</i> (self, offset)	Convenience method for subsetting final periods of time series data based on a date offset.
<i>last_valid_index</i> (self)	Return index for last non-NA/null value.
<i>le</i> (self, other[, axis, level])	Get Less than or equal to of dataframe and other, element-wise (binary operator <i>le</i>).
<i>lookup</i> (self, row_labels, col_labels)	Label-based “fancy indexing” function for DataFrame.
<i>lt</i> (self, other[, axis, level])	Get Less than of dataframe and other, element-wise (binary operator <i>lt</i>).
<i>mad</i> (self[, axis, skipna, level])	Return the mean absolute deviation of the values for the requested axis.
<i>mask</i> (self, cond[, other, inplace, axis, ...])	Replace values where the condition is True.
<i>max</i> (self[, axis, skipna, level, numeric_only])	Return the maximum of the values for the requested axis.
<i>mean</i> (self[, axis, skipna, level, numeric_only])	Return the mean of the values for the requested axis.
<i>median</i> (self[, axis, skipna, level, numeric_only])	Return the median of the values for the requested axis.
<i>melt</i> (self[, id_vars, value_vars, var_name, ...])	Unpivot a DataFrame from wide format to long format, optionally leaving identifier variables set.
<i>memory_usage</i> (self[, index, deep])	Return the memory usage of each column in bytes.
<i>merge</i> (self, right[, how, on, left_on, ...])	Merge DataFrame or named Series objects with a database-style join.
<i>min</i> (self[, axis, skipna, level, numeric_only])	Return the minimum of the values for the requested axis.
<i>mod</i> (self, other[, axis, level, fill_value])	Get Modulo of dataframe and other, element-wise (binary operator <i>mod</i>).
<i>mode</i> (self[, axis, numeric_only, dropna])	Get the mode(s) of each element along the selected axis.

Continued on next page

Table 57 – continued from previous page

<code>mul(self, other[, axis, level, fill_value])</code>	Get Multiplication of dataframe and other, element-wise (binary operator <code>mul</code>).
<code>multiply(self, other[, axis, level, fill_value])</code>	Get Multiplication of dataframe and other, element-wise (binary operator <code>mul</code>).
<code>ne(self, other[, axis, level])</code>	Get Not equal to of dataframe and other, element-wise (binary operator <code>ne</code>).
<code>nlargest(self, n, columns[, keep])</code>	Return the first <code>n</code> rows ordered by <code>columns</code> in descending order.
<code>notna(self)</code>	Detect existing (non-missing) values.
<code>notnull(self)</code>	Detect existing (non-missing) values.
<code>nsmallest(self, n, columns[, keep])</code>	Return the first <code>n</code> rows ordered by <code>columns</code> in ascending order.
<code>nunique(self[, axis, dropna])</code>	Count distinct observations over requested axis.
<code>pct_change(self[, periods, fill_method, ...])</code>	Percentage change between the current and a prior element.
<code>pipe(self, func, <code>\</code>*args, <code>\</code>***kwargs)</code>	Apply <code>func(self, *args, **kwargs)</code> .
<code>pivot(self[, index, columns, values])</code>	Return reshaped DataFrame organized by given index / column values.
<code>pivot_table(self[, values, index, columns, ...])</code>	Create a spreadsheet-style pivot table as a DataFrame.
<code>plot</code>	alias of <code>pandas.plotting._core.PlotAccessor</code>
<code>pop(self, item)</code>	Return item and drop from frame.
<code>pow(self, other[, axis, level, fill_value])</code>	Get Exponential power of dataframe and other, element-wise (binary operator <code>pow</code>).
<code>prod(self[, axis, skipna, level, ...])</code>	Return the product of the values for the requested axis.
<code>product(self[, axis, skipna, level, ...])</code>	Return the product of the values for the requested axis.
<code>quantile(self[, q, axis, numeric_only, ...])</code>	Return values at the given quantile over requested axis.
<code>query(self, expr[, inplace])</code>	Query the columns of a DataFrame with a boolean expression.
<code>radd(self, other[, axis, level, fill_value])</code>	Get Addition of dataframe and other, element-wise (binary operator <code>radd</code>).
<code>rank(self[, axis, method, numeric_only, ...])</code>	Compute numerical data ranks (1 through n) along axis.
<code>rdiv(self, other[, axis, level, fill_value])</code>	Get Floating division of dataframe and other, element-wise (binary operator <code>rtruediv</code>).
<code>reindex(self[, labels, index, columns, ...])</code>	Conform DataFrame to new index with optional filling logic, placing NA/NaN in locations having no value in the previous index.
<code>reindex_like(self, other[, method, copy, ...])</code>	Return an object with matching indices as other object.
<code>rename(self[, mapper, index, columns, axis, ...])</code>	Alter axes labels.
<code>rename_axis(self[, mapper, index, columns, ...])</code>	Set the name of the axis for the index or columns.
<code>reorder_levels(self, order[, axis])</code>	Rearrange index levels using input order.
<code>replace(self[, to_replace, value, inplace, ...])</code>	Replace values given in <code>to_replace</code> with <code>value</code> .
<code>resample(self, rule[, how, axis, ...])</code>	Resample time-series data.
<code>reset_index(self[, level, drop, inplace, ...])</code>	Reset the index, or a level of it.

Continued on next page

Table 57 – continued from previous page

<code>rfloordiv</code> (self, other[, axis, level, fill_value])	Get Integer division of dataframe and other, element-wise (binary operator <code>rfloordiv</code>).
<code>rmod</code> (self, other[, axis, level, fill_value])	Get Modulo of dataframe and other, element-wise (binary operator <code>rmod</code>).
<code>rmul</code> (self, other[, axis, level, fill_value])	Get Multiplication of dataframe and other, element-wise (binary operator <code>rmul</code>).
<code>rolling</code> (self, window[, min_periods, center, ...])	Provide rolling window calculations.
<code>round</code> (self[, decimals])	Round a DataFrame to a variable number of decimal places.
<code>rpow</code> (self, other[, axis, level, fill_value])	Get Exponential power of dataframe and other, element-wise (binary operator <code>rpow</code>).
<code>rsub</code> (self, other[, axis, level, fill_value])	Get Subtraction of dataframe and other, element-wise (binary operator <code>rsub</code>).
<code>rtruediv</code> (self, other[, axis, level, fill_value])	Get Floating division of dataframe and other, element-wise (binary operator <code>rtruediv</code>).
<code>sample</code> (self[, n, frac, replace, weights, ...])	Return a random sample of items from an axis of object.
<code>select_dtypes</code> (self[, include, exclude])	Return a subset of the DataFrame's columns based on the column dtypes.
<code>sem</code> (self[, axis, skipna, level, ddof, ...])	Return unbiased standard error of the mean over requested axis.
<code>set_axis</code> (self, labels[, axis, inplace])	Assign desired index to given axis.
<code>set_index</code> (self, keys[, drop, append, ...])	Set the DataFrame index using existing columns.
<code>set_value</code> (self, index, col, value[, takeable])	(DEPRECATED) Put single value at passed column and index.
<code>shift</code> (self[, periods, freq, axis, fill_value])	Shift index by desired number of periods with an optional time <code>freq</code> .
<code>skew</code> (self[, axis, skipna, level, numeric_only])	Return unbiased skew over requested axis Normalized by N-1.
<code>slice_shift</code> (self[, periods, axis])	Equivalent to <code>shift</code> without copying data.
<code>sort_index</code> (self[, axis, level, ascending, ...])	Sort object by labels (along an axis).
<code>sort_values</code> (self, by[, axis, ascending, ...])	Sort by the values along either axis.
<code>sparse</code>	alias of <code>pandas.core.arrays.sparse.SparseFrameAccessor</code>
<code>squeeze</code> (self[, axis])	Squeeze 1 dimensional axis objects into scalars.
<code>stack</code> (self[, level, dropna])	Stack the prescribed level(s) from columns to index.
<code>std</code> (self[, axis, skipna, level, ddof, ...])	Return sample standard deviation over requested axis.
<code>sub</code> (self, other[, axis, level, fill_value])	Get Subtraction of dataframe and other, element-wise (binary operator <code>sub</code>).
<code>subtract</code> (self, other[, axis, level, fill_value])	Get Subtraction of dataframe and other, element-wise (binary operator <code>sub</code>).
<code>sum</code> (self[, axis, skipna, level, ...])	Return the sum of the values for the requested axis.
<code>swapaxes</code> (self, axis1, axis2[, copy])	Interchange axes and swap values axes appropriately.
<code>swaplevel</code> (self[, i, j, axis])	Swap levels i and j in a MultiIndex on a particular axis.
<code>tail</code> (self[, n])	Return the last <code>n</code> rows.

Continued on next page

Table 57 – continued from previous page

<code>take(self, indices[, axis, is_copy])</code>	Return the elements in the given <i>positional</i> indices along an axis.
<code>to_clipboard(self[, excel, sep])</code>	Copy object to the system clipboard.
<code>to_csv(self[, path_or_buf, sep, na_rep, ...])</code>	Write object to a comma-separated values (csv) file.
<code>to_dense(self)</code>	(DEPRECATED) Return dense representation of Series/DataFrame (as opposed to sparse).
<code>to_dict(self[, orient, into])</code>	Convert the DataFrame to a dictionary.
<code>to_excel(self, excel_writer[, sheet_name, ...])</code>	Write object to an Excel sheet.
<code>to_feather(self, fname)</code>	Write out the binary feather-format for DataFrames.
<code>to_gbq(self, destination_table[, ...])</code>	Write a DataFrame to a Google BigQuery table.
<code>to_hdf(self, path_or_buf, key, <i>***</i>kwargs)</code>	Write the contained data to an HDF5 file using HDFStore.
<code>to_html(self[, buf, columns, col_space, ...])</code>	Render a DataFrame as an HTML table.
<code>to_json(self[, path_or_buf, orient, ...])</code>	Convert the object to a JSON string.
<code>to_latex(self[, buf, columns, col_space, ...])</code>	Render an object to a LaTeX tabular environment table.
<code>to_msgpack(self[, path_or_buf, encoding])</code>	(DEPRECATED) Serialize object to input file path using msgpack format.
<code>to_numpy(self[, dtype, copy])</code>	Convert the DataFrame to a NumPy array.
<code>to_parquet(self, fname[, engine, ...])</code>	Write a DataFrame to the binary parquet format.
<code>to_period(self[, freq, axis, copy])</code>	Convert DataFrame from DatetimeIndex to PeriodIndex with desired frequency (inferred from index if not passed).
<code>to_pickle(self, path[, compression, protocol])</code>	Pickle (serialize) object to file.
<code>to_records(self[, index, ...])</code>	Convert DataFrame to a NumPy record array.
<code>to_sparse(self[, fill_value, kind])</code>	(DEPRECATED) Convert to SparseDataFrame.
<code>to_sql(self, name, con[, schema, if_exists, ...])</code>	Write records stored in a DataFrame to a SQL database.
<code>to_stata(self, fname[, convert_dates, ...])</code>	Export DataFrame object to Stata dta format.
<code>to_string(self[, buf, columns, col_space, ...])</code>	Render a DataFrame to a console-friendly tabular output.
<code>to_timestamp(self[, freq, how, axis, copy])</code>	Cast to DatetimeIndex of timestamps, at <i>beginning</i> of period.
<code>to_xarray(self)</code>	Return an xarray object from the pandas object.
<code>transform(self, func[, axis])</code>	Call <code>func</code> on self producing a DataFrame with transformed values and that has the same axis length as self.
<code>transpose(self, <i>**args</i>, <i>****kwargs</i>)</code>	Transpose index and columns.
<code>truediv(self, other[, axis, level, fill_value])</code>	Get Floating division of dataframe and other, element-wise (binary operator <i>truediv</i>).
<code>truncate(self[, before, after, axis, copy])</code>	Truncate a Series or DataFrame before and after some index value.
<code>tshift(self[, periods, freq, axis])</code>	Shift the time index, using the index's frequency if available.
<code>tz_convert(self, tz[, axis, level, copy])</code>	Convert tz-aware axis to target time zone.
<code>tz_localize(self, tz[, axis, level, copy, ...])</code>	Localize tz-naive index of a Series or DataFrame to target time zone.

Continued on next page

Table 57 – continued from previous page

<code>unstack(self[, level, fill_value])</code>	Pivot a level of the (necessarily hierarchical) index labels, returning a DataFrame having a new level of column labels whose inner-most level consists of the pivoted index labels.
<code>update(self, other[, join, overwrite, ...])</code>	Modify in place using non-NA values from another DataFrame.
<code>var(self[, axis, skipna, level, ddof, ...])</code>	Return unbiased variance over requested axis.
<code>where(self, cond[, other, inplace, axis, ...])</code>	Replace values where the condition is False.
<code>xs(self, key[, axis, level, drop_level])</code>	Return cross-section from the Series/DataFrame.

pandas.DataFrame.abs**DataFrame.abs(self)**

Return a Series/DataFrame with absolute numeric value of each element.

This function only applies to elements that are all numeric.

Returns

abs Series/DataFrame containing the absolute value of each element.

See also:

`numpy.absolute` Calculate the absolute value element-wise.

Notes

For complex inputs, $1.2 + 1j$, the absolute value is $\sqrt{a^2 + b^2}$.

Examples

Absolute numeric values in a Series.

```
>>> s = pd.Series([-1.10, 2, -3.33, 4])
>>> s.abs()
0    1.10
1    2.00
2    3.33
3    4.00
dtype: float64
```

Absolute numeric values in a Series with complex numbers.

```
>>> s = pd.Series([1.2 + 1j])
>>> s.abs()
0    1.56205
dtype: float64
```

Absolute numeric values in a Series with a Timedelta element.

```
>>> s = pd.Series([pd.Timedelta('1 days')])
>>> s.abs()
0    1 days
dtype: timedelta64[ns]
```

Select rows with data closest to certain value using `argsort` (from [StackOverflow](#)).

```
>>> df = pd.DataFrame({
...     'a': [4, 5, 6, 7],
...     'b': [10, 20, 30, 40],
...     'c': [100, 50, -30, -50]
... })
>>> df
   a  b  c
0  4 10 100
1  5 20  50
2  6 30 -30
3  7 40 -50
>>> df.loc[(df.c - 43).abs().argsort()]
   a  b  c
1  5 20  50
0  4 10 100
2  6 30 -30
3  7 40 -50
```

pandas.DataFrame.add

DataFrame.add(*self*, *other*, *axis*='columns', *level*=None, *fill_value*=None)

Get Addition of dataframe and other, element-wise (binary operator *add*).

Equivalent to `dataframe + other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *radd*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.

DataFrame.sub Subtract DataFrames.

DataFrame.mul Multiply DataFrames.

DataFrame.div Divide DataFrames (float division).

DataFrame.truediv Divide DataFrames (float division).

DataFrame.floordiv Divide DataFrames (integer division).

DataFrame.mod Calculate modulo (remainder after division).

DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

	angles	degrees
circle	0	360
triangle	3	180
rectangle	4	360

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

```
>>> df.add(1)
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

Divide by constant with reverse version.

```
>>> df.div(10)
```

	angles	degrees
circle	0.0	36.0
triangle	0.3	18.0
rectangle	0.4	36.0

```
>>> df.rdiv(10)
      angles  degrees
circle      inf  0.027778
triangle  3.333333  0.055556
rectangle  2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
      angles  degrees
circle      -1    358
triangle     2    178
rectangle     3    358
```

```
>>> df.sub([1, 2], axis='columns')
      angles  degrees
circle      -1    358
triangle     2    178
rectangle     3    358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
      angles  degrees
circle      -1    359
triangle     2    179
rectangle     3    359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
      angles
circle     0
triangle   3
rectangle  4
```

```
>>> df * other
      angles  degrees
circle     0     NaN
triangle    9     NaN
rectangle  16     NaN
```

```
>>> df.mul(other, fill_value=0)
      angles  degrees
circle     0     0.0
triangle    9     0.0
rectangle  16     0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                               index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                       ['circle', 'triangle', 'rectangle',
...                                       'square', 'pentagon', 'hexagon']])
>>> df_multindex
```

	angles	degrees
A circle	0	360
triangle	3	180
rectangle	4	360
B square	4	360
pentagon	5	540
hexagon	6	720

```
>>> df.div(df_multindex, level=1, fill_value=0)
```

	angles	degrees
A circle	NaN	1.0
triangle	1.0	1.0
rectangle	1.0	1.0
B square	0.0	0.0
pentagon	0.0	0.0
hexagon	0.0	0.0

pandas.DataFrame.add_prefix

`DataFrame.add_prefix(self, prefix)`
Prefix labels with string *prefix*.

For Series, the row labels are prefixed. For DataFrame, the column labels are prefixed.

Parameters

prefix [str] The string to add before each label.

Returns

Series or DataFrame New Series or DataFrame with updated labels.

See also:

Series.add_suffix Suffix row labels with string *suffix*.

DataFrame.add_suffix Suffix column labels with string *suffix*.

Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s
```

0	1
1	2
2	3
3	4

```
dtype: int64
```

```
>>> s.add_prefix('item_')
item_0    1
item_1    2
item_2    3
item_3    4
dtype: int64
```

```
>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
>>> df
   A  B
0  1  3
1  2  4
2  3  5
3  4  6
```

```
>>> df.add_prefix('col_')
   col_A  col_B
0      1     3
1      2     4
2      3     5
3      4     6
```

pandas.DataFrame.add_suffix

`DataFrame.add_suffix(self, suffix)`
 Suffix labels with string *suffix*.

For Series, the row labels are suffixed. For DataFrame, the column labels are suffixed.

Parameters

suffix [str] The string to add after each label.

Returns

Series or DataFrame New Series or DataFrame with updated labels.

See also:

Series.add_prefix Prefix row labels with string *prefix*.

DataFrame.add_prefix Prefix column labels with string *prefix*.

Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64
```

```
>>> s.add_suffix('_item')
0_item    1
1_item    2
2_item    3
3_item    4
dtype: int64
```

```
>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
>>> df
   A  B
0  1  3
1  2  4
2  3  5
3  4  6
```

```
>>> df.add_suffix('_col')
   A_col  B_col
0      1      3
1      2      4
2      3      5
3      4      6
```

pandas.DataFrame.agg

`DataFrame.agg(self, func, axis=0, *args, **kwargs)`

Aggregate using one or more operations over the specified axis.

New in version 0.20.0.

Parameters

func [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. `[np.sum, 'mean']`
- dict of axis labels -> functions, function names or list of such.

axis [{0 or 'index', 1 or 'columns'}, default 0] If 0 or 'index': apply function to each column. If 1 or 'columns': apply function to each row.

***args** Positional arguments to pass to *func*.

****kwargs** Keyword arguments to pass to *func*.

Returns

scalar, Series or DataFrame The return can be:

- scalar : when Series.agg is called with single function
- Series : when DataFrame.agg is called with a single function

- `DataFrame` : when `DataFrame.agg` is called with several functions

Return scalar, Series or DataFrame.

The aggregation operations are always performed over an axis, either the

index (default) or the column axis. This behavior is different from

numpy aggregation functions (*mean*, *median*, *prod*, *sum*, *std*,

var), where the default is to compute the aggregation of the flattened

array, e.g., `numpy.mean(arr_2d)` as opposed to

`numpy.mean(arr_2d, axis=0)`.

agg is an alias for *aggregate*. Use the alias.

See also:

`DataFrame.apply` Perform any type of operations.

`DataFrame.transform` Perform transformation type operations.

`core.groupby.GroupBy` Perform operations over groups.

`core.resample.Resampler` Perform operations over resampled bins.

`core.window.Rolling` Perform operations over rolling window.

`core.window.Expanding` Perform operations over expanding window.

`core.window.EWM` Perform operation over exponential weighted window.

Notes

agg is an alias for *aggregate*. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```
>>> df = pd.DataFrame([[1, 2, 3],
...                    [4, 5, 6],
...                    [7, 8, 9],
...                    [np.nan, np.nan, np.nan]],
...                   columns=['A', 'B', 'C'])
```

Aggregate these functions over the rows.

```
>>> df.agg(['sum', 'min'])
      A    B    C
sum  12.0  15.0  18.0
min   1.0   2.0   3.0
```

Different aggregations per column.

```
>>> df.agg({'A' : ['sum', 'min'], 'B' : ['min', 'max']})
      A    B
max  NaN  8.0
min   1.0  2.0
sum  12.0 NaN
```

Aggregate over the columns.

```
>>> df.agg("mean", axis="columns")
0    2.0
1    5.0
2    8.0
3    NaN
dtype: float64
```

pandas.DataFrame.aggregate

`DataFrame.aggregate(self, func, axis=0, *args, **kwargs)`

Aggregate using one or more operations over the specified axis.

New in version 0.20.0.

Parameters

func [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. `[np.sum, 'mean']`
- dict of axis labels -> functions, function names or list of such.

axis [{0 or 'index', 1 or 'columns'}, default 0] If 0 or 'index': apply function to each column. If 1 or 'columns': apply function to each row.

***args** Positional arguments to pass to *func*.

****kwargs** Keyword arguments to pass to *func*.

Returns

scalar, Series or DataFrame The return can be:

- scalar : when Series.agg is called with single function
- Series : when DataFrame.agg is called with a single function
- DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

The aggregation operations are always performed over an axis, either the

index (default) or the column axis. This behavior is different from

numpy aggregation functions (*mean*, *median*, *prod*, *sum*, *std*, *var*), where the default is to compute the aggregation of the flattened

array, e.g., `numpy.mean(arr_2d)` as opposed to `numpy.mean(arr_2d, axis=0)`.

agg is an alias for *aggregate*. Use the alias.

See also:

`DataFrame.apply` Perform any type of operations.

`DataFrame.transform` Perform transformation type operations.

`core.groupby.GroupBy` Perform operations over groups.

`core.resample.Resampler` Perform operations over resampled bins.

`core.window.Rolling` Perform operations over rolling window.

`core.window.Expanding` Perform operations over expanding window.

`core.window.EWM` Perform operation over exponential weighted window.

Notes

agg is an alias for *aggregate*. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```
>>> df = pd.DataFrame([[1, 2, 3],
...                    [4, 5, 6],
...                    [7, 8, 9],
...                    [np.nan, np.nan, np.nan]],
...                   columns=['A', 'B', 'C'])
```

Aggregate these functions over the rows.

```
>>> df.agg(['sum', 'min'])
      A    B    C
sum  12.0  15.0  18.0
min   1.0   2.0   3.0
```

Different aggregations per column.

```
>>> df.agg({'A' : ['sum', 'min'], 'B' : ['min', 'max']})
      A    B
max  NaN  8.0
min   1.0  2.0
sum  12.0 NaN
```

Aggregate over the columns.

```

>>> df.agg("mean", axis="columns")
0    2.0
1    5.0
2    8.0
3    NaN
dtype: float64

```

pandas.DataFrame.align

```

DataFrame.align(self, other, join='outer', axis=None, level=None, copy=True,
                fill_value=None, method=None, limit=None, fill_axis=0, broad-
                cast_axis=None)

```

Align two objects on their axes with the specified join method for each axis Index.

Parameters

other [DataFrame or Series]

join [{'outer', 'inner', 'left', 'right'}, default 'outer']

axis [allowed axis of the other object, default None] Align on index (0), columns (1), or both (None)

level [int or level name, default None] Broadcast across a level, matching Index values on the passed MultiIndex level

copy [boolean, default True] Always returns new objects. If copy=False and no reindexing is required then original objects are returned.

fill_value [scalar, default np.NaN] Value to use for missing values. Defaults to NaN, but can be any “compatible” value

method [{'backfill', 'bfill', 'pad', 'ffill', None}, default None] Method to use for filling holes in reindexed Series pad / ffill: propagate last valid observation forward to next valid backfill / bfill: use NEXT valid observation to fill gap

limit [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

fill_axis [{0 or 'index', 1 or 'columns'}, default 0] Filling axis, method and limit

broadcast_axis [{0 or 'index', 1 or 'columns'}, default None] Broadcast values along this axis, if aligning two objects of different dimensions

Returns

(left, right) [(DataFrame, type of other)] Aligned objects.

pandas.DataFrame.all

```

DataFrame.all(self, axis=0, bool_only=None, skipna=True, level=None, **kwargs)

```

Return whether all elements are True, potentially over an axis.

Returns True unless there at least one element within a series or along a Dataframe axis that is False or equivalent (e.g. zero or empty).

Parameters

axis [{0 or 'index', 1 or 'columns', None}, default 0] Indicate which axis or axes should be reduced.

- 0 / 'index' : reduce the index, return a Series whose index is the original column labels.
- 1 / 'columns' : reduce the columns, return a Series whose index is the original index.
- None : reduce all axes, return a scalar.

bool_only [bool, default None] Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.

skipna [bool, default True] Exclude NA/null values. If the entire row/column is NA and skipna is True, then the result will be True, as for an empty row/column. If skipna is False, then NA are treated as True, because these are not equal to zero.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

****kwargs** [any, default None] Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

Series or DataFrame If level is specified, then, DataFrame is returned; otherwise, Series is returned.

See also:

Series.all Return True if all elements are True.

DataFrame.any Return True if one (or more) elements are True.

Examples

Series

```
>>> pd.Series([True, True]).all()
True
>>> pd.Series([True, False]).all()
False
>>> pd.Series([]).all()
True
>>> pd.Series([np.nan]).all()
True
>>> pd.Series([np.nan]).all(skipna=False)
True
```

DataFrames

Create a dataframe from a dictionary.

```
>>> df = pd.DataFrame({'col1': [True, True], 'col2': [True, False]})
>>> df
   col1  col2
0  True  True
1  True False
```

Default behaviour checks if column-wise values all return True.

```
>>> df.all()
col1    True
col2   False
dtype: bool
```

Specify `axis='columns'` to check if row-wise values all return True.

```
>>> df.all(axis='columns')
0     True
1    False
dtype: bool
```

Or `axis=None` for whether every value is True.

```
>>> df.all(axis=None)
False
```

pandas.DataFrame.any

`DataFrame.any(self, axis=0, bool_only=None, skipna=True, level=None, **kwargs)`

Return whether any element is True, potentially over an axis.

Returns False unless there at least one element within a series or along a Dataframe axis that is True or equivalent (e.g. non-zero or non-empty).

Parameters

axis [{0 or 'index', 1 or 'columns', None}, default 0] Indicate which axis or axes should be reduced.

- 0 / 'index' : reduce the index, return a Series whose index is the original column labels.
- 1 / 'columns' : reduce the columns, return a Series whose index is the original index.
- None : reduce all axes, return a scalar.

bool_only [bool, default None] Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.

skipna [bool, default True] Exclude NA/null values. If the entire row/column is NA and skipna is True, then the result will be False, as for an empty row/column. If skipna is False, then NA are treated as True, because these are not equal to zero.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

****kwargs** [any, default None] Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

Series or DataFrame If level is specified, then, DataFrame is returned; otherwise, Series is returned.

See also:

`numpy.any` Numpy version of this method.

Series.any Return whether any element is True.

Series.all Return whether all elements are True.

DataFrame.any Return whether any element is True over requested axis.

DataFrame.all Return whether all elements are True over requested axis.

Examples

Series

For Series input, the output is a scalar indicating whether any element is True.

```
>>> pd.Series([False, False]).any()
False
>>> pd.Series([True, False]).any()
True
>>> pd.Series([]).any()
False
>>> pd.Series([np.nan]).any()
False
>>> pd.Series([np.nan]).any(skipna=False)
True
```

DataFrame

Whether each column contains at least one True element (the default).

```
>>> df = pd.DataFrame({"A": [1, 2], "B": [0, 2], "C": [0, 0]})
>>> df
   A  B  C
0  1  0  0
1  2  2  0
```

```
>>> df.any()
A    True
B    True
C    False
dtype: bool
```

Aggregating over the columns.

```
>>> df = pd.DataFrame({"A": [True, False], "B": [1, 2]})
>>> df
```

(continues on next page)

(continued from previous page)

```

      A  B
0  True  1
1  False 2

```

```

>>> df.any(axis='columns')
0    True
1    True
dtype: bool

```

```

>>> df = pd.DataFrame({"A": [True, False], "B": [1, 0]})
>>> df
      A  B
0  True  1
1  False 0

```

```

>>> df.any(axis='columns')
0    True
1   False
dtype: bool

```

Aggregating over the entire DataFrame with `axis=None`.

```

>>> df.any(axis=None)
True

```

`any` for an empty DataFrame is an empty Series.

```

>>> pd.DataFrame([]).any()
Series([], dtype: bool)

```

pandas.DataFrame.append

`DataFrame.append(self, other, ignore_index=False, verify_integrity=False, sort=None)`

Append rows of *other* to the end of caller, returning a new object.

Columns in *other* that are not in the caller are added as new columns.

Parameters

other [DataFrame or Series/dict-like object, or list of these] The data to append.

ignore_index [boolean, default False] If True, do not use the index labels.

verify_integrity [boolean, default False] If True, raise `ValueError` on creating index with duplicates.

sort [boolean, default None] Sort columns if the columns of *self* and *other* are not aligned. The default sorting is deprecated and will change to not-sorting in a future version of pandas. Explicitly pass `sort=True` to silence the warning and sort. Explicitly pass `sort=False` to silence the warning and not sort.

New in version 0.23.0.

Returns

DataFrame

See also:

concat General function to concatenate DataFrame or Series objects.

Notes

If a list of dict/series is passed and the keys are all contained in the DataFrame's index, the order of the columns in the resulting DataFrame will be unchanged.

Iteratively appending rows to a DataFrame can be more computationally intensive than a single concatenate. A better solution is to append those rows to a list and then concatenate the list with the original DataFrame all at once.

Examples

```

>>> df = pd.DataFrame([[1, 2], [3, 4]], columns=list('AB'))
>>> df
   A  B
0  1  2
1  3  4
>>> df2 = pd.DataFrame([[5, 6], [7, 8]], columns=list('AB'))
>>> df.append(df2)
   A  B
0  1  2
1  3  4
0  5  6
1  7  8

```

With *ignore_index* set to True:

```

>>> df.append(df2, ignore_index=True)
   A  B
0  1  2
1  3  4
2  5  6
3  7  8

```

The following, while not recommended methods for generating DataFrames, show two ways to generate a DataFrame from multiple data sources.

Less efficient:

```

>>> df = pd.DataFrame(columns=['A'])
>>> for i in range(5):
...     df = df.append({'A': i}, ignore_index=True)
>>> df
   A
0  0
1  1
2  2
3  3
4  4

```

More efficient:

```
>>> pd.concat([pd.DataFrame([i], columns=['A']) for i in range(5)],
...            ignore_index=True)
   A
0  0
1  1
2  2
3  3
4  4
```

pandas.DataFrame.apply

```
DataFrame.apply(self, func, axis=0, broadcast=None, raw=False, reduce=None, result_type=None, args=(), **kwargs)
```

Apply a function along an axis of the DataFrame.

Objects passed to the function are Series objects whose index is either the DataFrame's index (`axis=0`) or the DataFrame's columns (`axis=1`). By default (`result_type=None`), the final return type is inferred from the return type of the applied function. Otherwise, it depends on the `result_type` argument.

Parameters

func [function] Function to apply to each column or row.

axis [{0 or 'index', 1 or 'columns'}, default 0] Axis along which the function is applied:

- 0 or 'index': apply function to each column.
- 1 or 'columns': apply function to each row.

broadcast [bool, optional] Only relevant for aggregation functions:

- **False** or **None** : returns a Series whose length is the length of the index or the number of columns (based on the `axis` parameter)
- **True** : results will be broadcast to the original shape of the frame, the original index and columns will be retained.

Deprecated since version 0.23.0: This argument will be removed in a future version, replaced by `result_type='broadcast'`.

raw [bool, default False]

- **False** : passes each row or column as a Series to the function.
- **True** : the passed function will receive ndarray objects instead. If you are just applying a NumPy reduction function this will achieve much better performance.

reduce [bool or None, default None] Try to apply reduction procedures. If the DataFrame is empty, `apply` will use `reduce` to determine whether the result should be a Series or a DataFrame. If `reduce=None` (the default), `apply`'s return value will be guessed by calling `func` on an empty Series (note: while guessing, exceptions raised by `func` will be ignored). If `reduce=True` a Series will always be returned, and if `reduce=False` a DataFrame will always be returned.

Deprecated since version 0.23.0: This argument will be removed in a future version, replaced by `result_type='reduce'`.

result_type [{‘expand’, ‘reduce’, ‘broadcast’, None}, default None] These only act when `axis=1` (columns):

- ‘expand’ : list-like results will be turned into columns.
- ‘reduce’ : returns a Series if possible rather than expanding list-like results. This is the opposite of ‘expand’.
- ‘broadcast’ : results will be broadcast to the original shape of the DataFrame, the original index and columns will be retained.

The default behaviour (None) depends on the return value of the applied function: list-like results will be returned as a Series of those. However if the apply function returns a Series these are expanded to columns.

New in version 0.23.0.

args [tuple] Positional arguments to pass to *func* in addition to the array/series.

****kwargs** Additional keyword arguments to pass as keywords arguments to *func*.

Returns

Series or DataFrame Result of applying *func* along the given axis of the DataFrame.

See also:

DataFrame.applymap For elementwise operations.

DataFrame.agg Only perform aggregating type operations.

DataFrame.transform Only perform transforming type operations.

Notes

In the current implementation `apply` calls *func* twice on the first column/row to decide whether it can take a fast or slow code path. This can lead to unexpected behavior if *func* has side-effects, as they will take effect twice for the first column/row.

Examples

```
>>> df = pd.DataFrame([[4, 9]] * 3, columns=['A', 'B'])
>>> df
   A  B
0  4  9
1  4  9
2  4  9
```

Using a numpy universal function (in this case the same as `np.sqrt(df)`):

```
>>> df.apply(np.sqrt)
   A    B
0  2.0  3.0
1  2.0  3.0
2  2.0  3.0
```

Using a reducing function on either axis

```
>>> df.apply(np.sum, axis=0)
A    12
B    27
dtype: int64
```

```
>>> df.apply(np.sum, axis=1)
0    13
1    13
2    13
dtype: int64
```

Returning a list-like will result in a Series

```
>>> df.apply(lambda x: [1, 2], axis=1)
0    [1, 2]
1    [1, 2]
2    [1, 2]
dtype: object
```

Passing `result_type='expand'` will expand list-like results to columns of a Dataframe

```
>>> df.apply(lambda x: [1, 2], axis=1, result_type='expand')
   0  1
0  1  2
1  1  2
2  1  2
```

Returning a Series inside the function is similar to passing `result_type='expand'`. The resulting column names will be the Series index.

```
>>> df.apply(lambda x: pd.Series([1, 2], index=['foo', 'bar']), axis=1)
   foo bar
0    1  2
1    1  2
2    1  2
```

Passing `result_type='broadcast'` will ensure the same shape result, whether list-like or scalar is returned by the function, and broadcast it along the axis. The resulting column names will be the originals.

```
>>> df.apply(lambda x: [1, 2], axis=1, result_type='broadcast')
   A  B
0  1  2
1  1  2
2  1  2
```

pandas.DataFrame.applymap

`DataFrame.applymap(self, func)`

Apply a function to a Dataframe elementwise.

This method applies a function that accepts and returns a scalar to every element of a DataFrame.

Parameters

func [callable] Python function, returns a single value from a single value.

Returns

DataFrame Transformed DataFrame.

See also:

DataFrame.apply Apply a function along input axis of DataFrame.

Notes

In the current implementation `applymap` calls *func* twice on the first column/row to decide whether it can take a fast or slow code path. This can lead to unexpected behavior if *func* has side-effects, as they will take effect twice for the first column/row.

Examples

```
>>> df = pd.DataFrame([[1, 2.12], [3.356, 4.567]])
>>> df
   0      1
0  1.000  2.120
1  3.356  4.567
```

```
>>> df.applymap(lambda x: len(str(x)))
   0  1
0  3  4
1  5  5
```

Note that a vectorized version of *func* often exists, which will be much faster. You could square each number elementwise.

```
>>> df.applymap(lambda x: x**2)
   0      1
0  1.000000  4.494400
1  11.262736  20.857489
```

But it's better to avoid `applymap` in that case.

```
>>> df ** 2
   0      1
0  1.000000  4.494400
1  11.262736  20.857489
```

pandas.DataFrame.as_blocks

DataFrame.as_blocks(*self*, *copy=True*)

Convert the frame to a dict of dtype -> Constructor Types that each has a homogeneous dtype.

Deprecated since version 0.21.0.

NOTE: the dtypes of the blocks **WILL BE PRESERVED HERE** (unlike in `as_matrix`)

Parameters

copy [boolean, default True]

Returns

values [a dict of dtype -> Constructor Types]

pandas.DataFrame.as_matrix

`DataFrame.as_matrix(self, columns=None)`

Convert the frame to its Numpy-array representation.

Deprecated since version 0.23.0: Use `DataFrame.values()` instead.

Parameters

columns [list, optional, default:None] If None, return all columns, otherwise, returns specified columns.

Returns

values [ndarray] If the caller is heterogeneous and contains booleans or objects, the result will be of dtype=object. See Notes.

See also:

`DataFrame.values`

Notes

Return is NOT a Numpy-matrix, rather, a Numpy-array.

The dtype will be a lower-common-denominator dtype (implicit upcasting); that is to say if the dtypes (even of numeric types) are mixed, the one that accommodates all will be chosen. Use this with care if you are not dealing with the blocks.

e.g. If the dtypes are float16 and float32, dtype will be upcast to float32. If dtypes are int32 and uint8, dtype will be upcase to int32. By `numpy.find_common_type` convention, mixing int64 and uint64 will result in a float64 dtype.

This method is provided for backwards compatibility. Generally, it is recommended to use ‘values’.

pandas.DataFrame.asfreq

`DataFrame.asfreq(self, freq, method=None, how=None, normalize=False, fill_value=None)`

Convert TimeSeries to specified frequency.

Optionally provide filling method to pad/backfill missing values.

Returns the original data conformed to a new index with the specified frequency. `resample` is more appropriate if an operation, such as summarization, is necessary to represent the data at the new frequency.

Parameters

freq [DateOffset object, or string]

method [{‘backfill’/’bfill’, ‘pad’/’ffill’}, default None] Method to use for filling holes in reindexed Series (note this does not fill NaNs that already were present):

- ‘pad’ / ‘ffill’: propagate last valid observation forward to next valid
- ‘backfill’ / ‘bfill’: use NEXT valid observation to fill

how [{‘start’, ‘end’}, default end] For PeriodIndex only, see PeriodIndex.asfreq

normalize [bool, default False] Whether to reset output index to midnight

fill_value [scalar, optional] Value to use for missing values, applied during up-sampling (note this does not fill NaNs that already were present).

New in version 0.20.0.

Returns

converted [same type as caller]

See also:

reindex

Notes

To learn more about the frequency strings, please see [this link](#).

Examples

Start by creating a series with 4 one minute timestamps.

```
>>> index = pd.date_range('1/1/2000', periods=4, freq='T')
>>> series = pd.Series([0.0, None, 2.0, 3.0], index=index)
>>> df = pd.DataFrame({'s':series})
>>> df
```

	s
2000-01-01 00:00:00	0.0
2000-01-01 00:01:00	NaN
2000-01-01 00:02:00	2.0
2000-01-01 00:03:00	3.0

Upsample the series into 30 second bins.

```
>>> df.asfreq(freq='30S')
```

	s
2000-01-01 00:00:00	0.0
2000-01-01 00:00:30	NaN
2000-01-01 00:01:00	NaN
2000-01-01 00:01:30	NaN
2000-01-01 00:02:00	2.0
2000-01-01 00:02:30	NaN
2000-01-01 00:03:00	3.0

Upsample again, providing a fill value.

```
>>> df.asfreq(freq='30S', fill_value=9.0)
      s
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30    9.0
2000-01-01 00:01:00   NaN
2000-01-01 00:01:30    9.0
2000-01-01 00:02:00    2.0
2000-01-01 00:02:30    9.0
2000-01-01 00:03:00    3.0
```

Upsample again, providing a method.

```
>>> df.asfreq(freq='30S', method='bfill')
      s
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30   NaN
2000-01-01 00:01:00   NaN
2000-01-01 00:01:30    2.0
2000-01-01 00:02:00    2.0
2000-01-01 00:02:30    3.0
2000-01-01 00:03:00    3.0
```

pandas.DataFrame.asof

DataFrame.asof(*self*, *where*, *subset=None*)

Return the last row(s) without any NaNs before *where*.

The last row (for each element in *where*, if list) without any NaN is taken. In case of a *DataFrame*, the last row without NaN considering only the subset of columns (if not *None*)

New in version 0.19.0: For DataFrame

If there is no good value, NaN is returned for a Series or a Series of NaN values for a DataFrame

Parameters

where [date or array-like of dates] Date(s) before which the last row(s) are returned.

subset [str or array-like of str, default *None*] For DataFrame, if not *None*, only use these columns to check for NaNs.

Returns

scalar, Series, or DataFrame The return can be:

- scalar : when *self* is a Series and *where* is a scalar
- Series: when *self* is a Series and *where* is an array-like, or when *self* is a DataFrame and *where* is a scalar
- DataFrame : when *self* is a DataFrame and *where* is an array-like

Return scalar, Series, or DataFrame.

See also:

merge_asof Perform an asof merge. Similar to left join.

Notes

Dates are assumed to be sorted. Raises if this is not the case.

Examples

A Series and a scalar *where*.

```
>>> s = pd.Series([1, 2, np.nan, 4], index=[10, 20, 30, 40])
>>> s
10    1.0
20    2.0
30    NaN
40    4.0
dtype: float64
```

```
>>> s.asof(20)
2.0
```

For a sequence *where*, a Series is returned. The first value is NaN, because the first element of *where* is before the first index value.

```
>>> s.asof([5, 20])
5      NaN
20     2.0
dtype: float64
```

Missing values are not considered. The following is 2.0, not NaN, even though NaN is at the index location for 30.

```
>>> s.asof(30)
2.0
```

Take all columns into consideration

```
>>> df = pd.DataFrame({'a': [10, 20, 30, 40, 50],
...                    'b': [None, None, None, None, 500]},
...                    index=pd.DatetimeIndex(['2018-02-27 09:01:00',
...                                             '2018-02-27 09:02:00',
...                                             '2018-02-27 09:03:00',
...                                             '2018-02-27 09:04:00',
...                                             '2018-02-27 09:05:00']))
>>> df.asof(pd.DatetimeIndex(['2018-02-27 09:03:30',
...                           '2018-02-27 09:04:30']))
...
           a  b
2018-02-27 09:03:30  NaN  NaN
2018-02-27 09:04:30  NaN  NaN
```

Take a single column into consideration

```
>>> df.asof(pd.DatetimeIndex(['2018-02-27 09:03:30',
...                           '2018-02-27 09:04:30']),
...         subset=['a'])
```

(continues on next page)

(continued from previous page)

	a	b
2018-02-27 09:03:30	30.0	NaN
2018-02-27 09:04:30	40.0	NaN

pandas.DataFrame.assign

`DataFrame.assign(self, **kwargs)`

Assign new columns to a DataFrame.

Returns a new object with all original columns in addition to new ones. Existing columns that are re-assigned will be overwritten.

Parameters

****kwargs** [dict of {str: callable or Series}] The column names are keywords. If the values are callable, they are computed on the DataFrame and assigned to the new columns. The callable must not change input DataFrame (though pandas doesn't check it). If the values are not callable, (e.g. a Series, scalar, or array), they are simply assigned.

Returns

DataFrame A new DataFrame with the new columns in addition to all the existing columns.

Notes

Assigning multiple columns within the same `assign` is possible. For Python 3.6 and above, later items in `**kwargs` may refer to newly created or modified columns in `'df'`; items are computed and assigned into `'df'` in order. For Python 3.5 and below, the order of keyword arguments is not specified, you cannot refer to newly created or modified columns. All items are computed first, and then assigned in alphabetical order.

Changed in version 0.23.0: Keyword argument order is maintained for Python 3.6 and later.

Examples

```
>>> df = pd.DataFrame({'temp_c': [17.0, 25.0]},
...                   index=['Portland', 'Berkeley'])
>>> df
      temp_c
Portland  17.0
Berkeley  25.0
```

Where the value is a callable, evaluated on `df`:

```
>>> df.assign(temp_f=lambda x: x.temp_c * 9 / 5 + 32)
      temp_c  temp_f
Portland   17.0   62.6
Berkeley   25.0   77.0
```

Alternatively, the same behavior can be achieved by directly referencing an existing Series or sequence:

```
>>> df.assign(temp_f=df['temp_c'] * 9 / 5 + 32)
      temp_c  temp_f
Portland   17.0   62.6
Berkeley   25.0   77.0
```

In Python 3.6+, you can create multiple columns within the same assign where one of the columns depends on another one defined within the same assign:

```
>>> df.assign(temp_f=lambda x: x['temp_c'] * 9 / 5 + 32,
...           temp_k=lambda x: (x['temp_f'] + 459.67) * 5 / 9)
      temp_c  temp_f  temp_k
Portland   17.0   62.6  290.15
Berkeley   25.0   77.0  298.15
```

pandas.DataFrame.astype

`DataFrame.astype(self, dtype, copy=True, errors='raise', **kwargs)`

Cast a pandas object to a specified dtype `dtype`.

Parameters

dtype [data type, or dict of column name -> data type] Use a `numpy.dtype` or Python type to cast entire pandas object to the same type. Alternatively, use `{col: dtype, ...}`, where `col` is a column label and `dtype` is a `numpy.dtype` or Python type to cast one or more of the DataFrame's columns to column-specific types.

copy [bool, default True] Return a copy when `copy=True` (be very careful setting `copy=False` as changes to values then may propagate to other pandas objects).

errors [{'raise', 'ignore'}, default 'raise'] Control raising of exceptions on invalid data for provided dtype.

- **raise** : allow exceptions to be raised
- **ignore** : suppress exceptions. On error return original object

New in version 0.20.0.

kwargs [keyword arguments to pass on to the constructor]

Returns

casted [same type as caller]

See also:

`to_datetime` Convert argument to datetime.

`to_timedelta` Convert argument to timedelta.

`to_numeric` Convert argument to a numeric type.

`numpy.ndarray.astype` Cast a numpy array to a specified type.

Examples

Create a DataFrame:

```
>>> d = {'col1': [1, 2], 'col2': [3, 4]}
>>> df = pd.DataFrame(data=d)
>>> df.dtypes
col1    int64
col2    int64
dtype: object
```

Cast all columns to int32:

```
>>> df.astype('int32').dtypes
col1    int32
col2    int32
dtype: object
```

Cast col1 to int32 using a dictionary:

```
>>> df.astype({'col1': 'int32'}).dtypes
col1    int32
col2    int64
dtype: object
```

Create a series:

```
>>> ser = pd.Series([1, 2], dtype='int32')
>>> ser
0    1
1    2
dtype: int32
>>> ser.astype('int64')
0    1
1    2
dtype: int64
```

Convert to categorical type:

```
>>> ser.astype('category')
0    1
1    2
dtype: category
Categories (2, int64): [1, 2]
```

Convert to ordered categorical type with custom ordering:

```
>>> cat_dtype = pd.api.types.CategoricalDtype(
...             categories=[2, 1], ordered=True)
>>> ser.astype(cat_dtype)
0    1
1    2
dtype: category
Categories (2, int64): [2 < 1]
```

Note that using `copy=False` and changing data on a new pandas object may propagate changes:

```

>>> s1 = pd.Series([1,2])
>>> s2 = s1.astype('int64', copy=False)
>>> s2[0] = 10
>>> s1 # note that s1[0] has changed too
0    10
1     2
dtype: int64

```

pandas.DataFrame.at_time

`DataFrame.at_time(self, time, asof=False, axis=None)`

Select values at particular time of day (e.g. 9:30AM).

Parameters

time [datetime.time or str]

axis [{0 or 'index', 1 or 'columns'}, default 0] New in version 0.24.0.

Returns

Series or DataFrame

Raises

TypeError If the index is not a *DatetimeIndex*

See also:

between_time Select values between particular times of the day.

first Select initial periods of time series based on a date offset.

last Select final periods of time series based on a date offset.

DatetimeIndex.indexer_at_time Get just the index locations for values at particular time of the day.

Examples

```

>>> i = pd.date_range('2018-04-09', periods=4, freq='12H')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts

```

	A
2018-04-09 00:00:00	1
2018-04-09 12:00:00	2
2018-04-10 00:00:00	3
2018-04-10 12:00:00	4

```

>>> ts.at_time('12:00')

```

	A
2018-04-09 12:00:00	2
2018-04-10 12:00:00	4

pandas.DataFrame.between_time

`DataFrame.between_time(self, start_time, end_time, include_start=True, include_end=True, axis=None)`

Select values between particular times of the day (e.g., 9:00-9:30 AM).

By setting `start_time` to be later than `end_time`, you can get the times that are *not* between the two times.

Parameters

`start_time` [datetime.time or str]

`end_time` [datetime.time or str]

`include_start` [bool, default True]

`include_end` [bool, default True]

`axis` [{0 or 'index', 1 or 'columns'}, default 0] New in version 0.24.0.

Returns

Series or DataFrame

Raises

TypeError If the index is not a *DatetimeIndex*

See also:

at_time Select values at a particular time of the day.

first Select initial periods of time series based on a date offset.

last Select final periods of time series based on a date offset.

DatetimeIndex.indexer_between_time Get just the index locations for values between particular times of the day.

Examples

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='1D20min')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
              A
2018-04-09 00:00:00  1
2018-04-10 00:20:00  2
2018-04-11 00:40:00  3
2018-04-12 01:00:00  4
```

```
>>> ts.between_time('0:15', '0:45')
              A
2018-04-10 00:20:00  2
2018-04-11 00:40:00  3
```

You get the times that are *not* between two times by setting `start_time` later than `end_time`:

```
>>> ts.between_time('0:45', '0:15')
      A
2018-04-09 00:00:00  1
2018-04-12 01:00:00  4
```

pandas.DataFrame.bfill

`DataFrame.bfill(self, axis=None, inplace=False, limit=None, downcast=None)`

Synonym for `DataFrame.fillna()` with `method='bfill'`.

Returns

`%(klass)s` Object with missing values filled.

pandas.DataFrame.bool

`DataFrame.bool(self)`

Return the bool of a single element PandasObject.

This must be a boolean scalar value, either True or False. Raise a `ValueError` if the PandasObject does not have exactly 1 element, or that element is not boolean

Returns

`bool` Same single boolean value converted to bool type.

pandas.DataFrame.boxplot

`DataFrame.boxplot(self, column=None, by=None, ax=None, fontsize=None, rot=0, grid=True, figsize=None, layout=None, return_type=None, **kwargs)`

Make a box plot from DataFrame columns.

Make a box-and-whisker plot from DataFrame columns, optionally grouped by some other columns. A box plot is a method for graphically depicting groups of numerical data through their quartiles. The box extends from the Q1 to Q3 quartile values of the data, with a line at the median (Q2). The whiskers extend from the edges of box to show the range of the data. The position of the whiskers is set by default to $1.5 * IQR$ ($IQR = Q3 - Q1$) from the edges of the box. Outlier points are those past the end of the whiskers.

For further details see Wikipedia's entry for [boxplot](#).

Parameters

column [str or list of str, optional] Column name or list of names, or vector. Can be any valid input to `pandas.DataFrame.groupby()`.

by [str or array-like, optional] Column in the DataFrame to `pandas.DataFrame.groupby()`. One box-plot will be done per value of columns in `by`.

ax [object of class `matplotlib.axes.Axes`, optional] The matplotlib axes to be used by boxplot.

fontsize [float or str] Tick label font size in points or as a string (e.g., `large`).

rot [int or float, default 0] The rotation angle of labels (in degrees) with respect to the screen coordinate system.

grid [bool, default True] Setting this to True will show the grid.

figsize [A tuple (width, height) in inches] The size of the figure to create in matplotlib.

layout [tuple (rows, columns), optional] For example, (3, 5) will display the subplots using 3 columns and 5 rows, starting from the top-left.

return_type [{‘axes’, ‘dict’, ‘both’} or None, default ‘axes’] The kind of object to return. The default is `axes`.

- ‘axes’ returns the matplotlib axes the boxplot is drawn on.
- ‘dict’ returns a dictionary whose values are the matplotlib Lines of the boxplot.
- ‘both’ returns a namedtuple with the axes and dict.
- when grouping with `by`, a Series mapping columns to `return_type` is returned.

If `return_type` is `None`, a NumPy array of axes with the same shape as `layout` is returned.

****kwds** All other plotting keyword arguments to be passed to `matplotlib.pyplot.boxplot()`.

Returns

result See Notes.

See also:

`Series.plot.hist` Make a histogram.

`matplotlib.pyplot.boxplot` Matplotlib equivalent plot.

Notes

The return type depends on the `return_type` parameter:

- ‘axes’ : object of class `matplotlib.axes.Axes`
- ‘dict’ : dict of `matplotlib.lines.Line2D` objects
- ‘both’ : a namedtuple with structure (ax, lines)

For data grouped with `by`, return a Series of the above or a numpy array:

- *Series*
- array (for `return_type = None`)

Use `return_type='dict'` when you want to tweak the appearance of the lines after plotting. In this case a dict containing the Lines making up the boxes, caps, fliers, medians, and whiskers is returned.

Examples

Boxplots can be created for every column in the dataframe by `df.boxplot()` or indicating the columns to be used:

```
>>> np.random.seed(1234)
>>> df = pd.DataFrame(np.random.randn(10,4),
...                    columns=['Col1', 'Col2', 'Col3', 'Col4'])
>>> boxplot = df.boxplot(column=['Col1', 'Col2', 'Col3'])
```

Boxplots of variables distributions grouped by the values of a third variable can be created using the option `by`. For instance:

```
>>> df = pd.DataFrame(np.random.randn(10, 2),
...                    columns=['Col1', 'Col2'])
>>> df['X'] = pd.Series(['A', 'A', 'A', 'A', 'A',
...                     'B', 'B', 'B', 'B', 'B'])
>>> boxplot = df.boxplot(by='X')
```

A list of strings (i.e. `['X', 'Y']`) can be passed to `boxplot` in order to group the data by combination of the variables in the x-axis:

```
>>> df = pd.DataFrame(np.random.randn(10,3),
...                    columns=['Col1', 'Col2', 'Col3'])
>>> df['X'] = pd.Series(['A', 'A', 'A', 'A', 'A',
...                     'B', 'B', 'B', 'B', 'B'])
>>> df['Y'] = pd.Series(['A', 'B', 'A', 'B', 'A',
...                     'B', 'A', 'B', 'A', 'B'])
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by=['X', 'Y'])
```

The layout of boxplot can be adjusted giving a tuple to `layout`:

```
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
...                       layout=(2, 1))
```

Additional formatting can be done to the boxplot, like suppressing the grid (`grid=False`), rotating the labels in the x-axis (i.e. `rot=45`) or changing the fontsize (i.e. `fontsize=15`):

```
>>> boxplot = df.boxplot(grid=False, rot=45, fontsize=15)
```

The parameter `return_type` can be used to select the type of element returned by `boxplot`. When `return_type='axes'` is selected, the matplotlib axes on which the boxplot is drawn are returned:

```
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], return_type='axes')
>>> type(boxplot)
<class 'matplotlib.axes._subplots.AxesSubplot'>
```

When grouping with `by`, a Series mapping columns to `return_type` is returned:

```
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
...                       return_type='axes')
>>> type(boxplot)
<class 'pandas.core.series.Series'>
```

If `return_type` is `None`, a NumPy array of axes with the same shape as `layout` is returned:

```
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
...                       return_type=None)
>>> type(boxplot)
<class 'numpy.ndarray'>
```

pandas.DataFrame.clip

`DataFrame.clip(self, lower=None, upper=None, axis=None, inplace=False, *args, **kwargs)`
Trim values at input threshold(s).

Assigns values outside boundary to boundary values. Thresholds can be singular values or array like, and in the latter case the clipping is performed element-wise in the specified axis.

Parameters

lower [float or array_like, default None] Minimum threshold value. All values below this threshold will be set to it.

upper [float or array_like, default None] Maximum threshold value. All values above this threshold will be set to it.

axis [int or str axis name, optional] Align object with lower and upper along the given axis.

inplace [bool, default False] Whether to perform the operation in place on the data.

New in version 0.21.0.

***args, **kwargs** Additional keywords have no effect but might be accepted for compatibility with numpy.

Returns

Series or DataFrame Same type as calling object with the values outside the clip boundaries replaced.

Examples

```
>>> data = {'col_0': [9, -3, 0, -1, 5], 'col_1': [-2, -7, 6, 8, -5]}
>>> df = pd.DataFrame(data)
>>> df
   col_0  col_1
0      9     -2
1     -3     -7
2      0      6
3     -1      8
4      5     -5
```

Clips per column using lower and upper thresholds:

```
>>> df.clip(-4, 6)
   col_0  col_1
0      6     -2
1     -3     -4
2      0      6
3     -1      6
4      5     -4
```

Clips using specific lower and upper thresholds per column element:

```
>>> t = pd.Series([2, -4, -1, 6, 3])
>>> t
0    2
1   -4
2   -1
3    6
4    3
dtype: int64
```

```
>>> df.clip(t, t + 4, axis=0)
   col_0  col_1
0      6      2
1     -3     -4
2      0      3
3      6      8
4      5      3
```

pandas.DataFrame.clip_lower

`DataFrame.clip_lower(self, threshold, axis=None, inplace=False)`

Trim values below a given threshold.

Deprecated since version 0.24.0: Use `clip(lower=threshold)` instead.

Elements below the *threshold* will be changed to match the *threshold* value(s). Threshold can be a single value or an array, in the latter case it performs the truncation element-wise.

Parameters

threshold [numeric or array-like] Minimum value allowed. All values below threshold will be set to this value.

- float : every value is compared to *threshold*.
- array-like : The shape of *threshold* should match the object it's compared to. When *self* is a Series, *threshold* should be the length. When *self* is a DataFrame, *threshold* should 2-D and the same shape as *self* for `axis=None`, or 1-D and the same length as the axis being compared.

axis [{0 or 'index', 1 or 'columns'}, default 0] Align *self* with *threshold* along the given axis.

inplace [bool, default False] Whether to perform the operation in place on the data.

New in version 0.21.0.

Returns

Series or DataFrame Original data with values trimmed.

See also:

Series.clip General purpose method to trim Series values to given threshold(s).

DataFrame.clip General purpose method to trim DataFrame values to given threshold(s).

Examples

Series single threshold clipping:

```
>>> s = pd.Series([5, 6, 7, 8, 9])
>>> s.clip(lower=8)
0    8
1    8
2    8
3    8
4    9
dtype: int64
```

Series clipping element-wise using an array of thresholds. *threshold* should be the same length as the Series.

```
>>> elemwise_thresholds = [4, 8, 7, 2, 5]
>>> s.clip(lower=elemwise_thresholds)
0    5
1    8
2    7
3    8
4    9
dtype: int64
```

DataFrames can be compared to a scalar.

```
>>> df = pd.DataFrame({"A": [1, 3, 5], "B": [2, 4, 6]})
>>> df
   A  B
0  1  2
1  3  4
2  5  6
```

```
>>> df.clip(lower=3)
   A  B
0  3  3
1  3  4
2  5  6
```

Or to an array of values. By default, *threshold* should be the same shape as the DataFrame.

```
>>> df.clip(lower=np.array([[3, 4], [2, 2], [6, 2]]))
   A  B
0  3  4
1  3  4
2  6  6
```

Control how *threshold* is broadcast with *axis*. In this case *threshold* should be the same length as the axis specified by *axis*.

```
>>> df.clip(lower=[3, 3, 5], axis='index')
   A  B
0  3  3
```

(continues on next page)

(continued from previous page)

```
1 3 4
2 5 6
```

```
>>> df.clip(lower=[4, 5], axis='columns')
   A  B
0  4  5
1  4  5
2  5  6
```

pandas.DataFrame.clip_upper

`DataFrame.clip_upper(self, threshold, axis=None, inplace=False)`

Trim values above a given threshold.

Deprecated since version 0.24.0: Use `clip(upper=threshold)` instead.

Elements above the *threshold* will be changed to match the *threshold* value(s). Threshold can be a single value or an array, in the latter case it performs the truncation element-wise.

Parameters

threshold [numeric or array-like] Maximum value allowed. All values above threshold will be set to this value.

- float : every value is compared to *threshold*.
- array-like : The shape of *threshold* should match the object it's compared to. When *self* is a Series, *threshold* should be the length. When *self* is a DataFrame, *threshold* should 2-D and the same shape as *self* for `axis=None`, or 1-D and the same length as the axis being compared.

axis [{0 or 'index', 1 or 'columns'}, default 0] Align object with *threshold* along the given axis.

inplace [bool, default False] Whether to perform the operation in place on the data.

New in version 0.21.0.

Returns

Series or DataFrame Original data with values trimmed.

See also:

Series.clip General purpose method to trim Series values to given threshold(s).

DataFrame.clip General purpose method to trim DataFrame values to given threshold(s).

Examples

```
>>> s = pd.Series([1, 2, 3, 4, 5])
>>> s
0    1
1    2
```

(continues on next page)

(continued from previous page)

```
2    3
3    4
4    5
dtype: int64
```

```
>>> s.clip(upper=3)
0    1
1    2
2    3
3    3
4    3
dtype: int64
```

```
>>> elemwise_thresholds = [5, 4, 3, 2, 1]
>>> elemwise_thresholds
[5, 4, 3, 2, 1]
```

```
>>> s.clip(upper=elemwise_thresholds)
0    1
1    2
2    3
3    2
4    1
dtype: int64
```

pandas.DataFrame.combine

`DataFrame.combine(self, other, func, fill_value=None, overwrite=True)`

Perform column-wise combine with another DataFrame.

Combines a DataFrame with *other* DataFrame using *func* to element-wise combine columns. The row and column indexes of the resulting DataFrame will be the union of the two.

Parameters

other [DataFrame] The DataFrame to merge column-wise.

func [function] Function that takes two series as inputs and return a Series or a scalar. Used to merge the two dataframes column by columns.

fill_value [scalar value, default None] The value to fill NaNs with prior to passing any column to the merge func.

overwrite [bool, default True] If True, columns in *self* that do not exist in *other* will be overwritten with NaNs.

Returns

DataFrame Combination of the provided DataFrames.

See also:

`DataFrame.combine_first` Combine two DataFrame objects and default to non-null values in frame calling the method.

Examples

Combine using a simple function that chooses the smaller column.

```
>>> df1 = pd.DataFrame({'A': [0, 0], 'B': [4, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [3, 3]})
>>> take_smaller = lambda s1, s2: s1 if s1.sum() < s2.sum() else s2
>>> df1.combine(df2, take_smaller)
   A  B
0  0  3
1  0  3
```

Example using a true element-wise combine function.

```
>>> df1 = pd.DataFrame({'A': [5, 0], 'B': [2, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [3, 3]})
>>> df1.combine(df2, np.minimum)
   A  B
0  1  2
1  0  3
```

Using `fill_value` fills Nones prior to passing the column to the merge function.

```
>>> df1 = pd.DataFrame({'A': [0, 0], 'B': [None, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [3, 3]})
>>> df1.combine(df2, take_smaller, fill_value=-5)
   A  B
0  0 -5.0
1  0  4.0
```

However, if the same element in both dataframes is None, that None is preserved

```
>>> df1 = pd.DataFrame({'A': [0, 0], 'B': [None, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [None, 3]})
>>> df1.combine(df2, take_smaller, fill_value=-5)
   A  B
0  0 -5.0
1  0  3.0
```

Example that demonstrates the use of `overwrite` and behavior when the axis differ between the dataframes.

```
>>> df1 = pd.DataFrame({'A': [0, 0], 'B': [4, 4]})
>>> df2 = pd.DataFrame({'B': [3, 3], 'C': [-10, 1], }, index=[1, 2])
>>> df1.combine(df2, take_smaller)
   A  B  C
0  NaN NaN NaN
1  NaN 3.0 -10.0
2  NaN 3.0  1.0
```

```
>>> df1.combine(df2, take_smaller, overwrite=False)
   A  B  C
0  0.0 NaN NaN
```

(continues on next page)

(continued from previous page)

```
1  0.0  3.0 -10.0
2  NaN  3.0   1.0
```

Demonstrating the preference of the passed in dataframe.

```
>>> df2 = pd.DataFrame({'B': [3, 3], 'C': [1, 1], }, index=[1, 2])
>>> df2.combine(df1, take_smaller)
   A    B    C
0  0.0  NaN NaN
1  0.0  3.0 NaN
2  NaN  3.0 NaN
```

```
>>> df2.combine(df1, take_smaller, overwrite=False)
   A    B    C
0  0.0  NaN NaN
1  0.0  3.0 1.0
2  NaN  3.0 1.0
```

pandas.DataFrame.combine_first

`DataFrame.combine_first(self, other)`

Update null elements with value in the same location in *other*.

Combine two DataFrame objects by filling null values in one DataFrame with non-null values from other DataFrame. The row and column indexes of the resulting DataFrame will be the union of the two.

Parameters

other [DataFrame] Provided DataFrame to use to fill null values.

Returns

DataFrame

See also:

DataFrame.combine Perform series-wise operation on two DataFrames using a given function.

Examples

```
>>> df1 = pd.DataFrame({'A': [None, 0], 'B': [None, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [3, 3]})
>>> df1.combine_first(df2)
   A    B
0  1.0  3.0
1  0.0  4.0
```

Null values still persist if the location of that null value does not exist in *other*

```
>>> df1 = pd.DataFrame({'A': [None, 0], 'B': [4, None]})
>>> df2 = pd.DataFrame({'B': [3, 3], 'C': [1, 1]}, index=[1, 2])
```

(continues on next page)

(continued from previous page)

```
>>> df1.combine_first(df2)
   A    B    C
0 NaN  4.0 NaN
1  0.0  3.0  1.0
2  NaN  3.0  1.0
```

pandas.DataFrame.compound

`DataFrame.compound(self, axis=None, skipna=None, level=None)`

Return the compound percentage of the values for the requested axis.

Deprecated since version 0.25.0.

Parameters

axis [{index (0), columns (1)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

pandas.DataFrame.copy

`DataFrame.copy(self, deep=True)`

Make a copy of this object's indices and data.

When **deep=True** (default), a new object will be created with a copy of the calling object's data and indices. Modifications to the data or indices of the copy will not be reflected in the original object (see notes below).

When **deep=False**, a new object will be created without copying the calling object's data or index (only references to the data and index are copied). Any changes to the data of the original will be reflected in the shallow copy (and vice versa).

Parameters

deep [bool, default True] Make a deep copy, including a copy of the data and the indices. With **deep=False** neither the indices nor the data are copied.

Returns

copy [Series or DataFrame] Object type matches caller.

Notes

When `deep=True`, data is copied but actual Python objects will not be copied recursively, only the reference to the object. This is in contrast to `copy.deepcopy` in the Standard Library, which recursively copies object data (see examples below).

While `Index` objects are copied when `deep=True`, the underlying numpy array is not copied for performance reasons. Since `Index` is immutable, the underlying data can be safely shared and a copy is not needed.

Examples

```
>>> s = pd.Series([1, 2], index=["a", "b"])
>>> s
a    1
b    2
dtype: int64
```

```
>>> s_copy = s.copy()
>>> s_copy
a    1
b    2
dtype: int64
```

Shallow copy versus default (deep) copy:

```
>>> s = pd.Series([1, 2], index=["a", "b"])
>>> deep = s.copy()
>>> shallow = s.copy(deep=False)
```

Shallow copy shares data and index with original.

```
>>> s is shallow
False
>>> s.values is shallow.values and s.index is shallow.index
True
```

Deep copy has own copy of data and index.

```
>>> s is deep
False
>>> s.values is deep.values or s.index is deep.index
False
```

Updates to the data shared by shallow copy and original is reflected in both; deep copy remains unchanged.

```
>>> s[0] = 3
>>> shallow[1] = 4
>>> s
a    3
b    4
dtype: int64
```

(continues on next page)

(continued from previous page)

```

>>> shallow
a    3
b    4
dtype: int64
>>> deep
a    1
b    2
dtype: int64

```

Note that when copying an object containing Python objects, a deep copy will copy the data, but will not do so recursively. Updating a nested data object will be reflected in the deep copy.

```

>>> s = pd.Series([[1, 2], [3, 4]])
>>> deep = s.copy()
>>> s[0][0] = 10
>>> s
0    [10, 2]
1     [3, 4]
dtype: object
>>> deep
0    [10, 2]
1     [3, 4]
dtype: object

```

pandas.DataFrame.corr

`DataFrame.corr` (*self*, *method='pearson'*, *min_periods=1*)

Compute pairwise correlation of columns, excluding NA/null values.

Parameters

method [{‘pearson’, ‘kendall’, ‘spearman’} or callable]

- **pearson** : standard correlation coefficient
- **kendall** : Kendall Tau correlation coefficient
- **spearman** : Spearman rank correlation
- **callable**: callable with input two 1d ndarrays and returning a float. Note that the returned matrix from `corr` will have 1 along the diagonals and will be symmetric regardless of the callable’s behavior .. version-added:: 0.24.0

min_periods [int, optional] Minimum number of observations required per pair of columns to have a valid result. Currently only available for Pearson and Spearman correlation.

Returns

DataFrame Correlation matrix.

See also:

`DataFrame.corrwith`

`Series.corr`

Examples

```

>>> def histogram_intersection(a, b):
...     v = np.minimum(a, b).sum().round(decimals=1)
...     return v
>>> df = pd.DataFrame([(0.2, 0.3), (0.0, 0.6), (0.6, 0.0), (0.2, 0.1)],
...                   columns=['dogs', 'cats'])
>>> df.corr(method=histogram_intersection)
      dogs  cats
dogs  1.0   0.3
cats  0.3   1.0

```

pandas.DataFrame.corrwith

`DataFrame.corrwith(self, other, axis=0, drop=False, method='pearson')`

Compute pairwise correlation between rows or columns of DataFrame with rows or columns of Series or DataFrame. DataFrames are first aligned along both axes before computing the correlations.

Parameters

other [DataFrame, Series] Object with which to compute correlations.

axis [{0 or 'index', 1 or 'columns'}, default 0] 0 or 'index' to compute column-wise, 1 or 'columns' for row-wise.

drop [bool, default False] Drop missing indices from result.

method [{'pearson', 'kendall', 'spearman'} or callable]

- **pearson** : standard correlation coefficient
 - **kendall** : Kendall Tau correlation coefficient
 - **spearman** : Spearman rank correlation
 - **callable**: callable with input two 1d ndarrays and returning a float
- New in version 0.24.0.

Returns

Series Pairwise correlations.

See also:

`DataFrame.corr`

pandas.DataFrame.count

`DataFrame.count(self, axis=0, level=None, numeric_only=False)`

Count non-NA cells for each column or row.

The values `None`, `NaN`, `NaT`, and optionally `numpy.inf` (depending on `pandas.options.mode.use_inf_as_na`) are considered NA.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] If 0 or 'index' counts are generated for each column. If 1 or 'columns' counts are generated for each **row**.

level [int or str, optional] If the axis is a *MultiIndex* (hierarchical), count along a particular *level*, collapsing into a *DataFrame*. A *str* specifies the level name.

numeric_only [bool, default False] Include only *float*, *int* or *boolean* data.

Returns

Series or DataFrame For each column/row the number of non-NA/null entries. If *level* is specified returns a *DataFrame*.

See also:

Series.count Number of non-NA elements in a Series.

DataFrame.shape Number of DataFrame rows and columns (including NA elements).

DataFrame.isna Boolean same-sized DataFrame showing places of NA elements.

Examples

Constructing DataFrame from a dictionary:

```
>>> df = pd.DataFrame({"Person":
...                     ["John", "Myla", "Lewis", "John", "Myla"],
...                     "Age": [24., np.nan, 21., 33, 26],
...                     "Single": [False, True, True, True, False]})
>>> df
   Person  Age  Single
0   John  24.0  False
1   Myla   NaN   True
2  Lewis  21.0   True
3   John  33.0   True
4   Myla  26.0  False
```

Notice the uncounted NA values:

```
>>> df.count()
Person      5
Age         4
Single      5
dtype: int64
```

Counts for each **row**:

```
>>> df.count(axis='columns')
0      3
1      2
2      3
3      3
4      3
dtype: int64
```

Counts for one level of a *MultiIndex*:

```
>>> df.set_index(["Person", "Single"]).count(level="Person")
      Age
Person
John    2
Lewis   1
Myla    1
```

pandas.DataFrame.cov

`DataFrame.cov(self, min_periods=None)`

Compute pairwise covariance of columns, excluding NA/null values.

Compute the pairwise covariance among the series of a DataFrame. The returned data frame is the [covariance matrix](#) of the columns of the DataFrame.

Both NA and null values are automatically excluded from the calculation. (See the note below about bias from missing values.) A threshold can be set for the minimum number of observations for each value created. Comparisons with observations below this threshold will be returned as NaN.

This method is generally used for the analysis of time series data to understand the relationship between different measures across time.

Parameters

min_periods [int, optional] Minimum number of observations required per pair of columns to have a valid result.

Returns

DataFrame The covariance matrix of the series of the DataFrame.

See also:

Series.cov Compute covariance with another Series.

core.window.EWM.cov Exponential weighted sample covariance.

core.window.Expanding.cov Expanding sample covariance.

core.window.Rolling.cov Rolling sample covariance.

Notes

Returns the covariance matrix of the DataFrame's time series. The covariance is normalized by N-1.

For DataFrames that have Series that are missing data (assuming that data is [missing at random](#)) the returned covariance matrix will be an unbiased estimate of the variance and covariance between the member Series.

However, for many applications this estimate may not be acceptable because the estimate covariance matrix is not guaranteed to be positive semi-definite. This could lead to estimate correlations having absolute values which are greater than one, and/or a non-invertible covariance matrix. See [Estimation of covariance matrices](#) for more details.

Examples

```
>>> df = pd.DataFrame([(1, 2), (0, 3), (2, 0), (1, 1)],
...                    columns=['dogs', 'cats'])
>>> df.cov()
           dogs      cats
dogs  0.666667 -1.000000
cats -1.000000  1.666667
```

```
>>> np.random.seed(42)
>>> df = pd.DataFrame(np.random.randn(1000, 5),
...                    columns=['a', 'b', 'c', 'd', 'e'])
>>> df.cov()
           a          b          c          d          e
a  0.998438 -0.020161  0.059277 -0.008943  0.014144
b -0.020161  1.059352 -0.008543 -0.024738  0.009826
c  0.059277 -0.008543  1.010670 -0.001486 -0.000271
d -0.008943 -0.024738 -0.001486  0.921297 -0.013692
e  0.014144  0.009826 -0.000271 -0.013692  0.977795
```

Minimum number of periods

This method also supports an optional `min_periods` keyword that specifies the required minimum number of non-NA observations for each column pair in order to have a valid result:

```
>>> np.random.seed(42)
>>> df = pd.DataFrame(np.random.randn(20, 3),
...                    columns=['a', 'b', 'c'])
>>> df.loc[df.index[:5], 'a'] = np.nan
>>> df.loc[df.index[5:10], 'b'] = np.nan
>>> df.cov(min_periods=12)
           a          b          c
a  0.316741      NaN -0.150812
b      NaN  1.248003  0.191417
c -0.150812  0.191417  0.895202
```

pandas.DataFrame.cummax

`DataFrame.cummax(self, axis=None, skipna=True, *args, **kwargs)`

Return cumulative maximum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative maximum.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

skipna [boolean, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

***args, **kwargs** : Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

Series or DataFrame

See also:

`core.window.Expanding.max` Similar functionality but ignores NaN values.

`DataFrame.max` Return the maximum over DataFrame axis.

`DataFrame.cummax` Return cumulative maximum over DataFrame axis.

`DataFrame.cummin` Return cumulative minimum over DataFrame axis.

`DataFrame.cumsum` Return cumulative sum over DataFrame axis.

`DataFrame.cumprod` Return cumulative product over DataFrame axis.

Examples

Series

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cummax()
0    2.0
1    NaN
2    5.0
3    5.0
4    5.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cummax(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                    [3.0, np.nan],
...                    [1.0, 0.0]],
...                    columns=list('AB'))
>>> df
```

(continues on next page)

(continued from previous page)

```

      A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0

```

By default, iterates over rows and finds the maximum in each column. This is equivalent to `axis=None` or `axis='index'`.

```

>>> df.cummax()
      A    B
0  2.0  1.0
1  3.0  NaN
2  3.0  1.0

```

To iterate over columns and find the maximum in each row, use `axis=1`

```

>>> df.cummax(axis=1)
      A    B
0  2.0  2.0
1  3.0  NaN
2  1.0  1.0

```

pandas.DataFrame.cummin

`DataFrame.cummin(self, axis=None, skipna=True, *args, **kwargs)`

Return cumulative minimum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative minimum.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

skipna [boolean, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

***args, **kwargs** : Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

Series or DataFrame

See also:

`core.window.Expanding.min` Similar functionality but ignores NaN values.

`DataFrame.min` Return the minimum over DataFrame axis.

`DataFrame.cummax` Return cumulative maximum over DataFrame axis.

`DataFrame.cummin` Return cumulative minimum over DataFrame axis.

`DataFrame.cumsum` Return cumulative sum over DataFrame axis.

`DataFrame.cumprod` Return cumulative product over DataFrame axis.

Examples

Series

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cummin()
0    2.0
1    NaN
2    2.0
3   -1.0
4   -1.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cummin(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                   [3.0, np.nan],
...                   [1.0, 0.0]],
...                   columns=list('AB'))
>>> df
   A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the minimum in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cummin()
   A    B
0  2.0  1.0
1  2.0  NaN
2  1.0  0.0
```

To iterate over columns and find the minimum in each row, use `axis=1`

```
>>> df.cummin(axis=1)
   A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

pandas.DataFrame.cumprod

DataFrame.cumprod(*self*, *axis=None*, *skipna=True*, **args*, ***kwargs*)

Return cumulative product over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative product.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

skipna [boolean, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

***args, **kwargs** : Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

Series or DataFrame

See also:

core.window.Expanding.prod Similar functionality but ignores NaN values.

DataFrame.prod Return the product over DataFrame axis.

DataFrame.cummax Return cumulative maximum over DataFrame axis.

DataFrame.cummin Return cumulative minimum over DataFrame axis.

DataFrame.cumsum Return cumulative sum over DataFrame axis.

DataFrame.cumprod Return cumulative product over DataFrame axis.

Examples

Series

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cumprod()
0    2.0
1    NaN
2    10.0
3   -10.0
4    -0.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cumprod(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                    [3.0, np.nan],
...                    [1.0, 0.0]],
...                   columns=list('AB'))
>>> df
   A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the product in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cumprod()
   A    B
0  2.0  1.0
1  6.0  NaN
2  6.0  0.0
```

To iterate over columns and find the product in each row, use `axis=1`

```
>>> df.cumprod(axis=1)
   A    B
0  2.0  2.0
1  3.0  NaN
2  1.0  0.0
```

pandas.DataFrame.cumsum

`DataFrame.cumsum(self, axis=None, skipna=True, *args, **kwargs)`

Return cumulative sum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative sum.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

skipna [boolean, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

***args, **kwargs** : Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

Series or DataFrame

See also:

core.window.Expanding.sum Similar functionality but ignores NaN values.

DataFrame.sum Return the sum over DataFrame axis.

DataFrame.cummax Return cumulative maximum over DataFrame axis.

DataFrame.cummin Return cumulative minimum over DataFrame axis.

DataFrame.cumsum Return cumulative sum over DataFrame axis.

DataFrame.cumprod Return cumulative product over DataFrame axis.

Examples

Series

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cumsum()
0    2.0
1    NaN
2    7.0
3    6.0
4    6.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cumsum(skipna=False)
0    2.0
1    NaN
2    NaN
```

(continues on next page)

(continued from previous page)

```
3    NaN
4    NaN
dtype: float64
```

DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                    [3.0, np.nan],
...                    [1.0, 0.0]],
...                    columns=list('AB'))
>>> df
   A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the sum in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cumsum()
   A    B
0  2.0  1.0
1  5.0  NaN
2  6.0  1.0
```

To iterate over columns and find the sum in each row, use `axis=1`

```
>>> df.cumsum(axis=1)
   A    B
0  2.0  3.0
1  3.0  NaN
2  1.0  1.0
```

pandas.DataFrame.describe

DataFrame.describe(*self*, *percentiles=None*, *include=None*, *exclude=None*)

Generate descriptive statistics that summarize the central tendency, dispersion and shape of a dataset's distribution, excluding NaN values.

Analyzes both numeric and object series, as well as **DataFrame** column sets of mixed data types. The output will vary depending on what is provided. Refer to the notes below for more detail.

Parameters

percentiles [list-like of numbers, optional] The percentiles to include in the output. All should fall between 0 and 1. The default is `[.25, .5, .75]`, which returns the 25th, 50th, and 75th percentiles.

include ['all', list-like of dtypes or None (default), optional] A white list of data types to include in the result. Ignored for **Series**. Here are the options:

- 'all': All columns of the input will be included in the output.
- A list-like of dtypes: Limits the results to the provided data types. To limit the result to numeric types submit `numpy.number`. To limit it instead

to object columns submit the `numpy.object` data type. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(include=['O'])`). To select pandas categorical columns, use `'category'`

- None (default) : The result will include all numeric columns.

exclude [list-like of dtypes or None (default), optional,] A black list of data types to omit from the result. Ignored for **Series**. Here are the options:

- A list-like of dtypes : Excludes the provided data types from the result. To exclude numeric types submit `numpy.number`. To exclude object columns submit the data type `numpy.object`. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(include=['O'])`). To exclude pandas categorical columns, use `'category'`
- None (default) : The result will exclude nothing.

Returns

Series or DataFrame Summary statistics of the Series or Dataframe provided.

See also:

DataFrame.count Count number of non-NA/null observations.

DataFrame.max Maximum of the values in the object.

DataFrame.min Minimum of the values in the object.

DataFrame.mean Mean of the values.

DataFrame.std Standard deviation of the observations.

DataFrame.select_dtypes Subset of a DataFrame including/excluding columns based on their dtype.

Notes

For numeric data, the result's index will include `count`, `mean`, `std`, `min`, `max` as well as lower, 50 and upper percentiles. By default the lower percentile is 25 and the upper percentile is 75. The 50 percentile is the same as the median.

For object data (e.g. strings or timestamps), the result's index will include `count`, `unique`, `top`, and `freq`. The `top` is the most common value. The `freq` is the most common value's frequency. Timestamps also include the `first` and `last` items.

If multiple object values have the highest count, then the `count` and `top` results will be arbitrarily chosen from among those with the highest count.

For mixed data types provided via a **DataFrame**, the default is to return only an analysis of numeric columns. If the dataframe consists only of object and categorical data without any numeric columns, the default is to return an analysis of both the object and categorical columns. If `include='all'` is provided as an option, the result will include a union of attributes of each type.

The `include` and `exclude` parameters can be used to limit which columns in a **DataFrame** are analyzed for the output. The parameters are ignored when analyzing a **Series**.

Examples

Describing a numeric Series.

```
>>> s = pd.Series([1, 2, 3])
>>> s.describe()
count      3.0
mean       2.0
std        1.0
min        1.0
25%        1.5
50%        2.0
75%        2.5
max        3.0
dtype: float64
```

Describing a categorical Series.

```
>>> s = pd.Series(['a', 'a', 'b', 'c'])
>>> s.describe()
count      4
unique     3
top        a
freq       2
dtype: object
```

Describing a timestamp Series.

```
>>> s = pd.Series([
...     np.datetime64("2000-01-01"),
...     np.datetime64("2010-01-01"),
...     np.datetime64("2010-01-01")
... ])
>>> s.describe()
count                3
unique                2
top      2010-01-01 00:00:00
freq                2
first    2000-01-01 00:00:00
last     2010-01-01 00:00:00
dtype: object
```

Describing a DataFrame. By default only numeric fields are returned.

```
>>> df = pd.DataFrame({'categorical': pd.Categorical(['d', 'e', 'f']),
...                    'numeric': [1, 2, 3],
...                    'object': ['a', 'b', 'c']
...                    })
>>> df.describe()
           numeric
count          3.0
mean           2.0
std            1.0
min            1.0
```

(continues on next page)

(continued from previous page)

25%	1.5
50%	2.0
75%	2.5
max	3.0

Describing all columns of a `DataFrame` regardless of data type.

```
>>> df.describe(include='all')
      categorical  numeric  object
count           3        3.0      3
unique          3        NaN      3
top            f        NaN      c
freq           1        NaN      1
mean          NaN        2.0     NaN
std           NaN        1.0     NaN
min           NaN        1.0     NaN
25%           NaN        1.5     NaN
50%           NaN        2.0     NaN
75%           NaN        2.5     NaN
max           NaN        3.0     NaN
```

Describing a column from a `DataFrame` by accessing it as an attribute.

```
>>> df.numeric.describe()
count    3.0
mean     2.0
std      1.0
min      1.0
25%     1.5
50%     2.0
75%     2.5
max      3.0
Name: numeric, dtype: float64
```

Including only numeric columns in a `DataFrame` description.

```
>>> df.describe(include=[np.number])
      numeric
count      3.0
mean       2.0
std        1.0
min        1.0
25%       1.5
50%       2.0
75%       2.5
max       3.0
```

Including only string columns in a `DataFrame` description.

```
>>> df.describe(include=[np.object])
      object
count      3
unique      3
```

(continues on next page)

(continued from previous page)

top	c
freq	1

Including only categorical columns from a DataFrame description.

```
>>> df.describe(include=['category'])
      categorical
count          3
unique          3
top            f
freq           1
```

Excluding numeric columns from a DataFrame description.

```
>>> df.describe(exclude=[np.number])
      categorical object
count          3      3
unique          3      3
top            f      c
freq           1      1
```

Excluding object columns from a DataFrame description.

```
>>> df.describe(exclude=[np.object])
      categorical  numeric
count           3      3.0
unique          3      NaN
top             f      NaN
freq            1      NaN
mean            NaN      2.0
std             NaN      1.0
min             NaN      1.0
25%            NaN      1.5
50%            NaN      2.0
75%            NaN      2.5
max            NaN      3.0
```

pandas.DataFrame.diff

`DataFrame.diff(self, periods=1, axis=0)`

First discrete difference of element.

Calculates the difference of a DataFrame element compared with another element in the DataFrame (default is the element in the same column of the previous row).

Parameters

periods [int, default 1] Periods to shift for calculating difference, accepts negative values.

axis [{0 or 'index', 1 or 'columns'}, default 0] Take difference over rows (0) or columns (1).

New in version 0.16.1..

Returns

DataFrame

See also:

Series.diff First discrete difference for a Series.

DataFrame.pct_change Percent change over given number of periods.

DataFrame.shift Shift index by desired number of periods with an optional time freq.

Examples

Difference with previous row

```
>>> df = pd.DataFrame({'a': [1, 2, 3, 4, 5, 6],
...                    'b': [1, 1, 2, 3, 5, 8],
...                    'c': [1, 4, 9, 16, 25, 36]})
>>> df
   a  b  c
0  1  1  1
1  2  1  4
2  3  2  9
3  4  3 16
4  5  5 25
5  6  8 36
```

```
>>> df.diff()
   a  b  c
0 NaN NaN NaN
1 1.0 0.0 3.0
2 1.0 1.0 5.0
3 1.0 1.0 7.0
4 1.0 2.0 9.0
5 1.0 3.0 11.0
```

Difference with previous column

```
>>> df.diff(axis=1)
   a  b  c
0 NaN 0.0 0.0
1 NaN -1.0 3.0
2 NaN -1.0 7.0
3 NaN -1.0 13.0
4 NaN 0.0 20.0
5 NaN 2.0 28.0
```

Difference with 3rd previous row

```
>>> df.diff(periods=3)
   a  b  c
0 NaN NaN NaN
1 NaN NaN NaN
2 NaN NaN NaN
```

(continues on next page)

(continued from previous page)

```

3  3.0  2.0  15.0
4  3.0  4.0  21.0
5  3.0  6.0  27.0

```

Difference with following row

```

>>> df.diff( periods=-1)
      a    b    c
0 -1.0  0.0 -3.0
1 -1.0 -1.0 -5.0
2 -1.0 -1.0 -7.0
3 -1.0 -2.0 -9.0
4 -1.0 -3.0 -11.0
5  NaN  NaN  NaN

```

pandas.DataFrame.div

DataFrame.div(*self*, *other*, *axis='columns'*, *level=None*, *fill_value=None*)

Get Floating division of dataframe and other, element-wise (binary operator *truediv*).

Equivalent to `dataframe / other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *rtruediv*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

Parameters

- other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.
- level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.

DataFrame.sub Subtract DataFrames.

DataFrame.mul Multiply DataFrames.

DataFrame.div Divide DataFrames (float division).

DataFrame.truediv Divide DataFrames (float division).

DataFrame.floordiv Divide DataFrames (integer division).

DataFrame.mod Calculate modulo (remainder after division).

DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

	angles	degrees
circle	0	360
triangle	3	180
rectangle	4	360

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

```
>>> df.add(1)
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

Divide by constant with reverse version.

```
>>> df.div(10)
```

	angles	degrees
circle	0.0	36.0
triangle	0.3	18.0
rectangle	0.4	36.0

```
>>> df.rdiv(10)
```

	angles	degrees
circle	inf	0.027778
triangle	3.333333	0.055556
rectangle	2.500000	0.027778

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
```

	angles	degrees
circle	-1	358

(continues on next page)

(continued from previous page)

```
triangle    2    178
rectangle   3    358
```

```
>>> df.sub([1, 2], axis='columns')
      angles  degrees
circle     -1    358
triangle    2    178
rectangle   3    358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
      angles  degrees
circle     -1    359
triangle    2    179
rectangle   3    359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
      angles
circle      0
triangle     3
rectangle    4
```

```
>>> df * other
      angles  degrees
circle      0     NaN
triangle     9     NaN
rectangle   16     NaN
```

```
>>> df.mul(other, fill_value=0)
      angles  degrees
circle      0     0.0
triangle     9     0.0
rectangle   16     0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                              'degrees': [360, 180, 360, 360, 540, 720]},
...                              index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                      ['circle', 'triangle', 'rectangle',
...                                       'square', 'pentagon', 'hexagon']])
>>> df_multindex
      angles  degrees
A circle      0    360
  triangle    3    180
  rectangle    4    360
B square      4    360
```

(continues on next page)

(continued from previous page)

pentagon	5	540
hexagon	6	720

```
>>> df.div(df_multindex, level=1, fill_value=0)
          angles  degrees
A circle      NaN     1.0
  triangle    1.0     1.0
  rectangle    1.0     1.0
B square       0.0     0.0
  pentagon     0.0     0.0
  hexagon      0.0     0.0
```

pandas.DataFrame.divide

DataFrame.divide(*self*, *other*, *axis*='columns', *level*=None, *fill_value*=None)

Get Floating division of dataframe and other, element-wise (binary operator *truediv*).

Equivalent to `dataframe / other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *rtruediv*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.

DataFrame.sub Subtract DataFrames.

DataFrame.mul Multiply DataFrames.

DataFrame.div Divide DataFrames (float division).

DataFrame.truediv Divide DataFrames (float division).

DataFrame.floordiv Divide DataFrames (integer division).

DataFrame.mod Calculate modulo (remainder after division).

`DataFrame.pow` Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

	angles	degrees
circle	0	360
triangle	3	180
rectangle	4	360

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

```
>>> df.add(1)
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

Divide by constant with reverse version.

```
>>> df.div(10)
```

	angles	degrees
circle	0.0	36.0
triangle	0.3	18.0
rectangle	0.4	36.0

```
>>> df.rdiv(10)
```

	angles	degrees
circle	inf	0.027778
triangle	3.333333	0.055556
rectangle	2.500000	0.027778

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
```

	angles	degrees
circle	-1	358
triangle	2	178
rectangle	3	358

```
>>> df.sub([1, 2], axis='columns')
      angles  degrees
circle     -1    358
triangle    2    178
rectangle   3    358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
      angles  degrees
circle     -1    359
triangle    2    179
rectangle   3    359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
      angles
circle      0
triangle    3
rectangle   4
```

```
>>> df * other
      angles  degrees
circle      0     NaN
triangle     9     NaN
rectangle   16     NaN
```

```
>>> df.mul(other, fill_value=0)
      angles  degrees
circle      0     0.0
triangle     9     0.0
rectangle   16     0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                              'degrees': [360, 180, 360, 360, 540, 720]},
...                              index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                     ['circle', 'triangle', 'rectangle',
...                                      'square', 'pentagon', 'hexagon']])
>>> df_multindex
      angles  degrees
A circle      0    360
  triangle    3    180
  rectangle   4    360
B square      4    360
  pentagon    5    540
  hexagon     6    720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
      angles  degrees
A circle   NaN     1.0
  triangle  1.0     1.0
 rectangle  1.0     1.0
B square   0.0     0.0
  pentagon  0.0     0.0
  hexagon   0.0     0.0
```

pandas.DataFrame.dot

`DataFrame.dot(self, other)`

Compute the matrix multiplication between the DataFrame and other.

This method computes the matrix product between the DataFrame and the values of an other Series, DataFrame or a numpy array.

It can also be called using `self @ other` in Python ≥ 3.5 .

Parameters

other [Series, DataFrame or array-like] The other object to compute the matrix product with.

Returns

Series or DataFrame If other is a Series, return the matrix product between self and other as a Serie. If other is a DataFrame or a numpy.array, return the matrix product of self and other in a DataFrame of a np.array.

See also:

Series.dot Similar method for Series.

Notes

The dimensions of DataFrame and other must be compatible in order to compute the matrix multiplication. In addition, the column names of DataFrame and the index of other must contain the same values, as they will be aligned prior to the multiplication.

The dot method for Series computes the inner product, instead of the matrix product here.

Examples

Here we multiply a DataFrame with a Series.

```
>>> df = pd.DataFrame([[0, 1, -2, -1], [1, 1, 1, 1]])
>>> s = pd.Series([1, 1, 2, 1])
>>> df.dot(s)
0    -4
1     5
dtype: int64
```

Here we multiply a DataFrame with another DataFrame.

```
>>> other = pd.DataFrame([[0, 1], [1, 2], [-1, -1], [2, 0]])
>>> df.dot(other)
   0  1
0  1  4
1  2  2
```

Note that the dot method give the same result as @

```
>>> df @ other
   0  1
0  1  4
1  2  2
```

The dot method works also if other is an np.array.

```
>>> arr = np.array([[0, 1], [1, 2], [-1, -1], [2, 0]])
>>> df.dot(arr)
   0  1
0  1  4
1  2  2
```

Note how shuffling of the objects does not change the result.

```
>>> s2 = s.reindex([1, 0, 2, 3])
>>> df.dot(s2)
0    -4
1     5
dtype: int64
```

pandas.DataFrame.drop

`DataFrame.drop(self, labels=None, axis=0, index=None, columns=None, level=None, inplace=False, errors='raise')`

Drop specified labels from rows or columns.

Remove rows or columns by specifying label names and corresponding axis, or by specifying directly index or column names. When using a multi-index, labels on different levels can be removed by specifying the level.

Parameters

labels [single label or list-like] Index or column labels to drop.

axis [{0 or 'index', 1 or 'columns'}, default 0] Whether to drop labels from the index (0 or 'index') or columns (1 or 'columns').

index [single label or list-like] Alternative to specifying axis (**labels**, **axis=0** is equivalent to **index=labels**).

New in version 0.21.0.

columns [single label or list-like] Alternative to specifying axis (**labels**, **axis=1** is equivalent to **columns=labels**).

New in version 0.21.0.

level [int or level name, optional] For MultiIndex, level from which the labels will be removed.

inplace [bool, default False] If True, do operation inplace and return None.

errors [{'ignore', 'raise'}, default 'raise'] If 'ignore', suppress error and only existing labels are dropped.

Returns

DataFrame DataFrame without the removed index or column labels.

Raises

KeyError If any of the labels is not found in the selected axis.

See also:

DataFrame.loc Label-location based indexer for selection by label.

DataFrame.dropna Return DataFrame with labels on given axis omitted where (all or any) data are missing.

DataFrame.drop_duplicates Return DataFrame with duplicate rows removed, optionally only considering certain columns.

Series.drop Return Series with specified index labels removed.

Examples

```
>>> df = pd.DataFrame(np.arange(12).reshape(3, 4),
...                    columns=['A', 'B', 'C', 'D'])
>>> df
   A  B  C  D
0  0  1  2  3
1  4  5  6  7
2  8  9 10 11
```

Drop columns

```
>>> df.drop(['B', 'C'], axis=1)
   A  D
0  0  3
1  4  7
2  8 11
```

```
>>> df.drop(columns=['B', 'C'])
   A  D
0  0  3
1  4  7
2  8 11
```

Drop a row by index

```
>>> df.drop([0, 1])
   A  B  C  D
2  8  9 10 11
```

Drop columns and/or rows of MultiIndex DataFrame

```
>>> midx = pd.MultiIndex(levels=[['lama', 'cow', 'falcon'],
...                             ['speed', 'weight', 'length']],
...                       codes=[[0, 0, 0, 1, 1, 1, 2, 2, 2],
...                              [0, 1, 2, 0, 1, 2, 0, 1, 2]])
>>> df = pd.DataFrame(index=midx, columns=['big', 'small'],
...                    data=[[45, 30], [200, 100], [1.5, 1], [30, 20],
...                          [250, 150], [1.5, 0.8], [320, 250],
...                          [1, 0.8], [0.3, 0.2]])
>>> df
```

		big	small
lama	speed	45.0	30.0
	weight	200.0	100.0
	length	1.5	1.0
cow	speed	30.0	20.0
	weight	250.0	150.0
	length	1.5	0.8
falcon	speed	320.0	250.0
	weight	1.0	0.8
	length	0.3	0.2

```
>>> df.drop(index='cow', columns='small')
```

		big
lama	speed	45.0
	weight	200.0
	length	1.5
falcon	speed	320.0
	weight	1.0
	length	0.3

```
>>> df.drop(index='length', level=1)
```

		big	small
lama	speed	45.0	30.0
	weight	200.0	100.0
cow	speed	30.0	20.0
	weight	250.0	150.0
falcon	speed	320.0	250.0
	weight	1.0	0.8

pandas.DataFrame.drop_duplicates

`DataFrame.drop_duplicates(self, subset=None, keep='first', inplace=False)`

Return DataFrame with duplicate rows removed, optionally only considering certain columns. Indexes, including time indexes are ignored.

Parameters

subset [column label or sequence of labels, optional] Only consider certain columns for identifying duplicates, by default use all of the columns

keep [{'first', 'last', False}, default 'first']

- **first** : Drop duplicates except for the first occurrence.

- `last` : Drop duplicates except for the last occurrence.
- `False` : Drop all duplicates.

inplace [boolean, default `False`] Whether to drop duplicates in place or to return a copy

Returns

DataFrame

pandas.DataFrame.droplevel

`DataFrame.droplevel(self, level, axis=0)`

Return DataFrame with requested index / column level(s) removed.

New in version 0.24.0.

Parameters

level [int, str, or list-like] If a string is given, must be the name of a level. If list-like, elements must be names or positional indexes of levels.

axis [{0 or 'index', 1 or 'columns'}, default 0]

Returns

DataFrame.droplevel()

Examples

```
>>> df = pd.DataFrame([
...     [1, 2, 3, 4],
...     [5, 6, 7, 8],
...     [9, 10, 11, 12]
... ]).set_index([0, 1]).rename_axis(['a', 'b'])
```

```
>>> df.columns = pd.MultiIndex.from_tuples([
...     ('c', 'e'), ('d', 'f')
... ], names=['level_1', 'level_2'])
```

```
>>> df
level_1  c  d
level_2  e  f
a b
1 2      3  4
5 6      7  8
9 10     11 12
```

```
>>> df.droplevel('a')
level_1  c  d
level_2  e  f
b
2      3  4
6      7  8
10     11 12
```

```
>>> df.droplevel('level2', axis=1)
level_1  c  d
a b
1 2      3  4
5 6      7  8
9 10     11 12
```

pandas.DataFrame.dropna

`DataFrame.dropna(self, axis=0, how='any', thresh=None, subset=None, inplace=False)`

Remove missing values.

See the *User Guide* for more on which values are considered missing, and how to work with missing data.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] Determine if rows or columns which contain missing values are removed.

- 0, or 'index': Drop rows which contain missing values.
- 1, or 'columns': Drop columns which contain missing value.

Deprecated since version 0.23.0: Pass tuple or list to drop on multiple axes. Only a single axis is allowed.

how [{'any', 'all'}, default 'any'] Determine if row or column is removed from DataFrame, when we have at least one NA or all NA.

- 'any': If any NA values are present, drop that row or column.
- 'all': If all values are NA, drop that row or column.

thresh [int, optional] Require that many non-NA values.

subset [array-like, optional] Labels along other axis to consider, e.g. if you are dropping rows these would be a list of columns to include.

inplace [bool, default False] If True, do operation inplace and return None.

Returns

DataFrame DataFrame with NA entries dropped from it.

See also:

`DataFrame.isna` Indicate missing values.

`DataFrame.notna` Indicate existing (non-missing) values.

`DataFrame.fillna` Replace missing values.

`Series.dropna` Drop missing values.

`Index.dropna` Drop missing indices.

Examples

```
>>> df = pd.DataFrame({"name": ['Alfred', 'Batman', 'Catwoman'],
...                    "toy": [np.nan, 'Batmobile', 'Bullwhip'],
...                    "born": [pd.NaT, pd.Timestamp("1940-04-25"),
...                             pd.NaT]})
>>> df
```

	name	toy	born
0	Alfred	NaN	NaT
1	Batman	Batmobile	1940-04-25
2	Catwoman	Bullwhip	NaT

Drop the rows where at least one element is missing.

```
>>> df.dropna()
```

	name	toy	born
1	Batman	Batmobile	1940-04-25

Drop the columns where at least one element is missing.

```
>>> df.dropna(axis='columns')
```

	name
0	Alfred
1	Batman
2	Catwoman

Drop the rows where all elements are missing.

```
>>> df.dropna(how='all')
```

	name	toy	born
0	Alfred	NaN	NaT
1	Batman	Batmobile	1940-04-25
2	Catwoman	Bullwhip	NaT

Keep only the rows with at least 2 non-NA values.

```
>>> df.dropna(thresh=2)
```

	name	toy	born
1	Batman	Batmobile	1940-04-25
2	Catwoman	Bullwhip	NaT

Define in which columns to look for missing values.

```
>>> df.dropna(subset=['name', 'born'])
```

	name	toy	born
1	Batman	Batmobile	1940-04-25

Keep the DataFrame with valid entries in the same variable.

```
>>> df.dropna(inplace=True)
>>> df
```

	name	toy	born
1	Batman	Batmobile	1940-04-25

pandas.DataFrame.duplicated**DataFrame.duplicated**(*self*, *subset=None*, *keep='first'*)

Return boolean Series denoting duplicate rows, optionally only considering certain columns.

Parameters**subset** [column label or sequence of labels, optional] Only consider certain columns for identifying duplicates, by default use all of the columns**keep** [{'first', 'last', False}, default 'first']

- **first** : Mark duplicates as **True** except for the first occurrence.
- **last** : Mark duplicates as **True** except for the last occurrence.
- **False** : Mark all duplicates as **True**.

Returns**Series****pandas.DataFrame.eq****DataFrame.eq**(*self*, *other*, *axis='columns'*, *level=None*)Get Equal to of dataframe and other, element-wise (binary operator *eq*).Among flexible wrappers (*eq*, *ne*, *le*, *lt*, *ge*, *gt*) to comparison operators.Equivalent to `==`, `!=`, `<=`, `<`, `>=`, `>` with support to choose axis (rows or columns) and level for comparison.**Parameters****other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.**axis** [{0 or 'index', 1 or 'columns'}], default 'columns'] Whether to compare by the index (0 or 'index') or columns (1 or 'columns').**level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.**Returns****DataFrame of bool** Result of the comparison.**See also:****DataFrame.eq** Compare DataFrames for equality elementwise.**DataFrame.ne** Compare DataFrames for inequality elementwise.**DataFrame.le** Compare DataFrames for less than inequality or equality elementwise.**DataFrame.lt** Compare DataFrames for strictly less than inequality elementwise.**DataFrame.ge** Compare DataFrames for greater than inequality or equality elementwise.**DataFrame.gt** Compare DataFrames for strictly greater than inequality elementwise.

Notes

Mismatched indices will be unioned together. *NaN* values are considered different (i.e. *NaN* != *NaN*).

Examples

```
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                    'revenue': [100, 250, 300]},
...                    index=['A', 'B', 'C'])
>>> df
   cost  revenue
A   250     100
B   150     250
C   100     300
```

Comparison with a scalar, using either the operator or method:

```
>>> df == 100
   cost  revenue
A  False     True
B  False     False
C   True     False
```

```
>>> df.eq(100)
   cost  revenue
A  False     True
B  False     False
C   True     False
```

When *other* is a *Series*, the columns of a DataFrame are aligned with the index of *other* and broadcast:

```
>>> df != pd.Series([100, 250], index=["cost", "revenue"])
   cost  revenue
A   True     True
B   True     False
C  False     True
```

Use the method to control the broadcast axis:

```
>>> df.ne(pd.Series([100, 300], index=["A", "D"]), axis='index')
   cost  revenue
A   True     False
B   True     True
C   True     True
D   True     True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in *other*:

```
>>> df == [250, 100]
   cost  revenue
```

(continues on next page)

(continued from previous page)

```
A True True
B False False
C False False
```

Use the method to control the axis:

```
>>> df.eq([250, 250, 100], axis='index')
      cost revenue
A  True  False
B  False  True
C  True  False
```

Compare to a DataFrame of different shape.

```
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
...                       index=['A', 'B', 'C', 'D'])
>>> other
      revenue
A         300
B         250
C         100
D         150
```

```
>>> df.gt(other)
      cost revenue
A  False  False
B  False  False
C  False  True
D  False  False
```

Compare to a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
...                               'revenue': [100, 250, 300, 200, 175, 225]},
...                              index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
...                                     ['A', 'B', 'C', 'A', 'B', 'C']])
>>> df_multindex
      cost revenue
Q1 A   250     100
   B   150     250
   C   100     300
Q2 A   150     200
   B   300     175
   C   220     225
```

```
>>> df.le(df_multindex, level=1)
      cost revenue
Q1 A  True  True
   B  True  True
   C  True  True
Q2 A  False True
   B  True  False
```

(continues on next page)

(continued from previous page)

C	True	False
---	------	-------

pandas.DataFrame.equals**DataFrame.equals**(*self*, *other*)

Test whether two objects contain the same elements.

This function allows two Series or DataFrames to be compared against each other to see if they have the same shape and elements. NaNs in the same location are considered equal. The column headers do not need to have the same type, but the elements within the columns must be the same dtype.

Parameters

other [Series or DataFrame] The other Series or DataFrame to be compared with the first.

Returns

bool True if all elements are the same in both objects, False otherwise.

See also:

Series.eq Compare two Series objects of the same length and return a Series where each element is True if the element in each Series is equal, False otherwise.

DataFrame.eq Compare two DataFrame objects of the same shape and return a DataFrame where each element is True if the respective element in each DataFrame is equal, False otherwise.

assert_series_equal Return True if left and right Series are equal, False otherwise.

assert_frame_equal Return True if left and right DataFrames are equal, False otherwise.

numpy.array_equal Return True if two arrays have the same shape and elements, False otherwise.

Notes

This function requires that the elements have the same dtype as their respective elements in the other Series or DataFrame. However, the column labels do not need to have the same type, as long as they are still considered equal.

Examples

```
>>> df = pd.DataFrame({'1': [10], '2': [20]})
>>> df
   1  2
0 10 20
```

DataFrames `df` and `df` have the same types and values for their elements and column labels, which will return True.

```

>>> exactly_equal = pd.DataFrame({'1': [10], '2': [20]})
>>> exactly_equal
   1  2
0 10 20
>>> df.equals(exactly_equal)
True

```

DataFrames `df` and `different_column_type` have the same element types and values, but have different types for the column labels, which will still return `True`.

```

>>> different_column_type = pd.DataFrame({'1.0': [10], '2.0': [20]})
>>> different_column_type
   1.0  2.0
0  10  20
>>> df.equals(different_column_type)
True

```

DataFrames `df` and `different_data_type` have different types for the same values for their elements, and will return `False` even though their column labels are the same values and types.

```

>>> different_data_type = pd.DataFrame({'1': [10.0], '2': [20.0]})
>>> different_data_type
   1    2
0 10.0 20.0
>>> df.equals(different_data_type)
False

```

pandas.DataFrame.eval

`DataFrame.eval(self, expr, inplace=False, **kwargs)`

Evaluate a string describing operations on DataFrame columns.

Operates on columns only, not specific rows or elements. This allows `eval` to run arbitrary code, which can make you vulnerable to code injection if you pass user input to this function.

Parameters

expr [str] The expression string to evaluate.

inplace [bool, default False] If the expression contains an assignment, whether to perform the operation inplace and mutate the existing DataFrame. Otherwise, a new DataFrame is returned.

New in version 0.18.0..

kwargs [dict] See the documentation for `eval()` for complete details on the keyword arguments accepted by `query()`.

Returns

ndarray, scalar, or pandas object The result of the evaluation.

See also:

`DataFrame.query` Evaluates a boolean expression to query the columns of a frame.

`DataFrame.assign` Can evaluate an expression or function to create new values for a column.

`eval` Evaluate a Python expression as a string using various backends.

Notes

For more details see the API documentation for `eval()`. For detailed examples see *enhancing performance with eval*.

Examples

```
>>> df = pd.DataFrame({'A': range(1, 6), 'B': range(10, 0, -2)})
>>> df
   A  B
0  1 10
1  2  8
2  3  6
3  4  4
4  5  2
>>> df.eval('A + B')
0    11
1    10
2     9
3     8
4     7
dtype: int64
```

Assignment is allowed though by default the original DataFrame is not modified.

```
>>> df.eval('C = A + B')
   A  B  C
0  1 10 11
1  2  8 10
2  3  6  9
3  4  4  8
4  5  2  7
>>> df
   A  B
0  1 10
1  2  8
2  3  6
3  4  4
4  5  2
```

Use `inplace=True` to modify the original DataFrame.

```
>>> df.eval('C = A + B', inplace=True)
>>> df
   A  B  C
0  1 10 11
1  2  8 10
2  3  6  9
3  4  4  8
4  5  2  7
```

pandas.DataFrame.ewm

`DataFrame.ewm(self, com=None, span=None, halflife=None, alpha=None, min_periods=0, adjust=True, ignore_na=False, axis=0)`

Provide exponential weighted functions.

New in version 0.18.0.

Parameters

com [float, optional] Specify decay in terms of center of mass, $\alpha = 1/(1 + com)$, for $com \geq 0$.

span [float, optional] Specify decay in terms of span, $\alpha = 2/(span+1)$, for $span \geq 1$.

halflife [float, optional] Specify decay in terms of half-life, $\alpha = 1 - \exp(\log(0.5)/halflife)$, for $halflife > 0$.

alpha [float, optional] Specify smoothing factor α directly, $0 < \alpha \leq 1$.

New in version 0.18.0.

min_periods [int, default 0] Minimum number of observations in window required to have a value (otherwise result is NA).

adjust [bool, default True] Divide by decaying adjustment factor in beginning periods to account for imbalance in relative weightings (viewing EWMA as a moving average).

ignore_na [bool, default False] Ignore missing values when calculating weights; specify True to reproduce pre-0.15.0 behavior.

axis [{0 or 'index', 1 or 'columns'}, default 0] The axis to use. The value 0 identifies the rows, and 1 identifies the columns.

Returns

DataFrame A Window sub-classed for the particular operation.

See also:

rolling Provides rolling window calculations.

expanding Provides expanding transformations.

Notes

Exactly one of center of mass, span, half-life, and alpha must be provided. Allowed values and relationship between the parameters are specified in the parameter descriptions above; see the link at the end of this section for a detailed explanation.

When `adjust` is True (default), weighted averages are calculated using weights $(1-\alpha)^{(n-1)}$, $(1-\alpha)^{(n-2)}$, ..., $1-\alpha$, 1.

When `adjust` is False, weighted averages are calculated recursively as:

$$\text{weighted_average}[0] = \text{arg}[0]; \text{weighted_average}[i] = (1-\alpha)*\text{weighted_average}[i-1] + \alpha*\text{arg}[i].$$

When `ignore_na` is False (default), weights are based on absolute positions. For example, the weights of `x` and `y` used in calculating the final weighted average of `[x, None, y]` are $(1-\alpha)^{**2}$ and 1 (if `adjust` is True), and $(1-\alpha)^{**2}$ and α (if `adjust` is False).

When `ignore_na` is `True` (reproducing pre-0.15.0 behavior), weights are based on relative positions. For example, the weights of `x` and `y` used in calculating the final weighted average of `[x, None, y]` are `1-alpha` and `1` (if `adjust` is `True`), and `1-alpha` and `alpha` (if `adjust` is `False`).

More details can be found at http://pandas.pydata.org/pandas-docs/stable/user_guide/computation.html#exponentially-weighted-windows

Examples

```
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
>>> df
   B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0
```

```
>>> df.ewm(com=0.5).mean()
   B
0  0.000000
1  0.750000
2  1.615385
3  1.615385
4  3.670213
```

`pandas.DataFrame.expanding`

`DataFrame.expanding(self, min_periods=1, center=False, axis=0)`

Provide expanding transformations.

New in version 0.18.0.

Parameters

min_periods [int, default 1] Minimum number of observations in window required to have a value (otherwise result is NA).

center [bool, default False] Set the labels at the center of the window.

axis [int or str, default 0]

Returns

a **Window** sub-classed for the particular operation

See also:

rolling Provides rolling window calculations.

ewm Provides exponential weighted functions.

Notes

By default, the result is set to the right edge of the window. This can be changed to the center of the window by setting `center=True`.

Examples

```
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
      B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0
```

```
>>> df.expanding(2).sum()
      B
0  NaN
1  1.0
2  3.0
3  3.0
4  7.0
```

pandas.DataFrame.explode

`DataFrame.explode(self, column: Union[str, Tuple])` → 'DataFrame'

Transform each element of a list-like to a row, replicating the index values.

New in version 0.25.0.

Parameters

column [str or tuple]

Returns

DataFrame Exploded lists to rows of the subset columns; index will be duplicated for these rows.

Raises

ValueError : if columns of the frame are not unique.

See also:

`DataFrame.unstack` Pivot a level of the (necessarily hierarchical) index labels

`DataFrame.melt` Unpivot a DataFrame from wide format to long format

`Series.explode` Explode a DataFrame from list-like columns to long format.

Notes

This routine will explode list-likes including lists, tuples, Series, and np.ndarray. The result dtype of the subset rows will be object. Scalars will be returned unchanged. Empty list-likes will result in a np.nan for that row.

Examples

```
>>> df = pd.DataFrame({'A': [[1, 2, 3], 'foo', [], [3, 4]], 'B': 1})
>>> df
```

	A	B
0	[1, 2, 3]	1
1	foo	1
2	[]	1
3	[3, 4]	1

```
>>> df.explode('A')
```

	A	B
0	1	1
0	2	1
0	3	1
1	foo	1
2	NaN	1
3	3	1
3	4	1

pandas.DataFrame.ffill

`DataFrame.ffill(self, axis=None, inplace=False, limit=None, downcast=None)`
 Synonym for `DataFrame.fillna()` with `method='ffill'`.

Returns

`%(klass)s` Object with missing values filled.

pandas.DataFrame.fillna

`DataFrame.fillna(self, value=None, method=None, axis=None, inplace=False, limit=None, downcast=None, **kwargs)`
 Fill NA/NaN values using the specified method.

Parameters

value [scalar, dict, Series, or DataFrame] Value to use to fill holes (e.g. 0), alternately a dict/Series/DataFrame of values specifying which value to use for each index (for a Series) or column (for a DataFrame). Values not in the dict/Series/DataFrame will not be filled. This value cannot be a list.

method [{‘backfill’, ‘bfill’, ‘pad’, ‘ffill’, None}, default None] Method to use for filling holes in reindexed Series `pad` / `ffill`: propagate last valid observation forward to next valid `backfill` / `bfill`: use next valid observation to fill gap.

axis [{0 or ‘index’, 1 or ‘columns’}] Axis along which to fill missing values.

inplace [bool, default False] If True, fill in-place. Note: this will modify any other views on this object (e.g., a no-copy slice for a column in a DataFrame).

limit [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially

filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

downcast [dict, default is None] A dict of item->dtype of what to downcast if possible, or the string 'infer' which will try to downcast to an appropriate equal type (e.g. float64 to int64 if possible).

Returns

DataFrame Object with missing values filled.

See also:

interpolate Fill NaN values using interpolation.

reindex Conform object to new index.

asfreq Convert TimeSeries to specified frequency.

Examples

```
>>> df = pd.DataFrame([[np.nan, 2, np.nan, 0],
...                    [3, 4, np.nan, 1],
...                    [np.nan, np.nan, np.nan, 5],
...                    [np.nan, 3, np.nan, 4]],
...                   columns=list('ABCD'))
>>> df
   A    B    C    D
0 NaN  2.0 NaN  0
1 3.0  4.0 NaN  1
2 NaN  NaN NaN  5
3 NaN  3.0 NaN  4
```

Replace all NaN elements with 0s.

```
>>> df.fillna(0)
   A    B    C    D
0  0.0  2.0  0.0  0
1  3.0  4.0  0.0  1
2  0.0  0.0  0.0  5
3  0.0  3.0  0.0  4
```

We can also propagate non-null values forward or backward.

```
>>> df.fillna(method='ffill')
   A    B    C    D
0 NaN  2.0 NaN  0
1  3.0  4.0 NaN  1
2  3.0  4.0 NaN  5
3  3.0  3.0 NaN  4
```

Replace all NaN elements in column 'A', 'B', 'C', and 'D', with 0, 1, 2, and 3 respectively.

```
>>> values = {'A': 0, 'B': 1, 'C': 2, 'D': 3}
>>> df.fillna(value=values)
   A    B    C    D
```

(continues on next page)

(continued from previous page)

```

0  0.0 2.0 2.0 0
1  3.0 4.0 2.0 1
2  0.0 1.0 2.0 5
3  0.0 3.0 2.0 4

```

Only replace the first NaN element.

```

>>> df.fillna(value=values, limit=1)
   A  B  C  D
0  0.0 2.0 2.0 0
1  3.0 4.0 NaN 1
2  NaN 1.0 NaN 5
3  NaN 3.0 NaN 4

```

pandas.DataFrame.filter

DataFrame.filter(*self*, *items=None*, *like=None*, *regex=None*, *axis=None*)

Subset rows or columns of dataframe according to labels in the specified index.

Note that this routine does not filter a dataframe on its contents. The filter is applied to the labels of the index.

Parameters

items [list-like] Keep labels from axis which are in items.

like [string] Keep labels from axis for which “like in label == True”.

regex [string (regular expression)] Keep labels from axis for which `re.search(regex, label) == True`.

axis [int or string axis name] The axis to filter on. By default this is the info axis, ‘index’ for Series, ‘columns’ for DataFrame.

Returns

same type as input object

See also:

DataFrame.loc

Notes

The `items`, `like`, and `regex` parameters are enforced to be mutually exclusive.

`axis` defaults to the info axis that is used when indexing with `[]`.

Examples

```

>>> df = pd.DataFrame(np.array([[1, 2, 3], [4, 5, 6]]),
...                   index=['mouse', 'rabbit'],
...                   columns=['one', 'two', 'three'])

```

```
>>> # select columns by name
>>> df.filter(items=['one', 'three'])
```

	one	three
mouse	1	3
rabbit	4	6

```
>>> # select columns by regular expression
>>> df.filter(regex='e$', axis=1)
```

	one	three
mouse	1	3
rabbit	4	6

```
>>> # select rows containing 'bbi'
>>> df.filter(like='bbi', axis=0)
```

	one	two	three
rabbit	4	5	6

pandas.DataFrame.first

`DataFrame.first(self, offset)`

Convenience method for subsetting initial periods of time series data based on a date offset.

Parameters

offset [string, DateOffset, dateutil.relativedelta]

Returns

subset [same type as caller]

Raises

TypeError If the index is not a *DatetimeIndex*

See also:

last Select final periods of time series based on a date offset.

at_time Select values at a particular time of the day.

between_time Select values between particular times of the day.

Examples

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1,2,3,4]}, index=i)
>>> ts
```

	A
2018-04-09	1
2018-04-11	2
2018-04-13	3
2018-04-15	4

Get the rows for the first 3 days:

```
>>> ts.first('3D')
           A
2018-04-09  1
2018-04-11  2
```

Notice the data for 3 first calendar days were returned, not the first 3 days observed in the dataset, and therefore data for 2018-04-13 was not returned.

pandas.DataFrame.first_valid_index

`DataFrame.first_valid_index(self)`
Return index for first non-NA/null value.

Returns

scalar [type of index]

Notes

If all elements are non-NA/null, returns None. Also returns None for empty Series/DataFrame.

pandas.DataFrame.floordiv

`DataFrame.floordiv(self, other, axis='columns', level=None, fill_value=None)`
Get Integer division of dataframe and other, element-wise (binary operator *floordiv*).

Equivalent to `dataframe // other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *rfloordiv*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

`DataFrame.add` Add DataFrames.

`DataFrame.sub` Subtract DataFrames.

DataFrame.mul Multiply DataFrames.

DataFrame.div Divide DataFrames (float division).

DataFrame.truediv Divide DataFrames (float division).

DataFrame.floordiv Divide DataFrames (integer division).

DataFrame.mod Calculate modulo (remainder after division).

DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

	angles	degrees
circle	0	360
triangle	3	180
rectangle	4	360

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

```
>>> df.add(1)
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

Divide by constant with reverse version.

```
>>> df.div(10)
```

	angles	degrees
circle	0.0	36.0
triangle	0.3	18.0
rectangle	0.4	36.0

```
>>> df.rdiv(10)
```

	angles	degrees
circle	inf	0.027778
triangle	3.333333	0.055556
rectangle	2.500000	0.027778

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
      angles  degrees
circle     -1     358
triangle    2     178
rectangle  3     358
```

```
>>> df.sub([1, 2], axis='columns')
      angles  degrees
circle     -1     358
triangle    2     178
rectangle  3     358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
      angles  degrees
circle     -1     359
triangle    2     179
rectangle  3     359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
      angles
circle      0
triangle    3
rectangle   4
```

```
>>> df * other
      angles  degrees
circle      0     NaN
triangle    9     NaN
rectangle  16     NaN
```

```
>>> df.mul(other, fill_value=0)
      angles  degrees
circle      0     0.0
triangle    9     0.0
rectangle  16     0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                              'degrees': [360, 180, 360, 360, 540, 720]},
...                              index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                    ['circle', 'triangle', 'rectangle',
...                                    'square', 'pentagon', 'hexagon']])
>>> df_multindex
      angles  degrees
A circle      0     360
```

(continues on next page)

(continued from previous page)

triangle	3	180
rectangle	4	360
B square	4	360
pentagon	5	540
hexagon	6	720

```
>>> df.div(df_multindex, level=1, fill_value=0)
          angles  degrees
A circle      NaN     1.0
  triangle     1.0     1.0
  rectangle     1.0     1.0
B square       0.0     0.0
  pentagon     0.0     0.0
  hexagon      0.0     0.0
```

pandas.DataFrame.from_dict

classmethod `DataFrame.from_dict(data, orient='columns', dtype=None, columns=None)`

Construct DataFrame from dict of array-like or dicts.

Creates DataFrame object from dictionary by columns or by index allowing dtype specification.

Parameters

data [dict] Of the form {field : array-like} or {field : dict}.

orient [{‘columns’, ‘index’}, default ‘columns’] The “orientation” of the data. If the keys of the passed dict should be the columns of the resulting DataFrame, pass ‘columns’ (default). Otherwise if the keys should be rows, pass ‘index’.

dtype [dtype, default None] Data type to force, otherwise infer.

columns [list, default None] Column labels to use when `orient='index'`. Raises a `ValueError` if used with `orient='columns'`.

New in version 0.23.0.

Returns

DataFrame

See also:

DataFrame.from_records DataFrame from ndarray (structured dtype), list of tuples, dict, or DataFrame.

DataFrame DataFrame object creation using constructor.

Examples

By default the keys of the dict become the DataFrame columns:

```
>>> data = {'col_1': [3, 2, 1, 0], 'col_2': ['a', 'b', 'c', 'd']}
>>> pd.DataFrame.from_dict(data)
   col_1 col_2
```

(continues on next page)

(continued from previous page)

0	3	a
1	2	b
2	1	c
3	0	d

Specify `orient='index'` to create the DataFrame using dictionary keys as rows:

```
>>> data = {'row_1': [3, 2, 1, 0], 'row_2': ['a', 'b', 'c', 'd']}
>>> pd.DataFrame.from_dict(data, orient='index')
      0  1  2  3
row_1 3  2  1  0
row_2 a  b  c  d
```

When using the 'index' orientation, the column names can be specified manually:

```
>>> pd.DataFrame.from_dict(data, orient='index',
...                          columns=['A', 'B', 'C', 'D'])
      A  B  C  D
row_1 3  2  1  0
row_2 a  b  c  d
```

pandas.DataFrame.from_items

classmethod `DataFrame.from_items(items, columns=None, orient='columns')`

Construct a DataFrame from a list of tuples.

Deprecated since version 0.23.0: `from_items` is deprecated and will be removed in a future version. Use `DataFrame.from_dict(dict(items))` instead. `DataFrame.from_dict(OrderedDict(items))` may be used to preserve the key order.

Convert (key, value) pairs to DataFrame. The keys will be the axis index (usually the columns, but depends on the specified orientation). The values should be arrays or Series.

Parameters

items [sequence of (key, value) pairs] Values should be arrays or Series.

columns [sequence of column labels, optional] Must be passed if `orient='index'`.

orient [{‘columns’, ‘index’}, default ‘columns’] The “orientation” of the data. If the keys of the input correspond to column labels, pass ‘columns’ (default). Otherwise if the keys correspond to the index, pass ‘index’.

Returns

DataFrame

pandas.DataFrame.from_records

classmethod `DataFrame.from_records(data, index=None, exclude=None, columns=None, coerce_float=False, nrow=None)`

Convert structured or record ndarray to DataFrame.

Parameters

data [ndarray (structured dtype), list of tuples, dict, or DataFrame]

index [string, list of fields, array-like] Field of array to use as the index, alternately a specific set of input labels to use

exclude [sequence, default None] Columns or fields to exclude

columns [sequence, default None] Column names to use. If the passed data do not have names associated with them, this argument provides names for the columns. Otherwise this argument indicates the order of the columns in the result (any names not found in the data will become all-NA columns)

coerce_float [boolean, default False] Attempt to convert values of non-string, non-numeric objects (like decimal.Decimal) to floating point, useful for SQL result sets

nrows [int, default None] Number of rows to read if data is an iterator

Returns

DataFrame

pandas.DataFrame.ge

`DataFrame.ge(self, other, axis='columns', level=None)`

Get Greater than or equal to of dataframe and other, element-wise (binary operator *ge*).

Among flexible wrappers (*eq*, *ne*, *le*, *lt*, *ge*, *gt*) to comparison operators.

Equivalent to `==`, `!=`, `<=`, `<`, `>=`, `>` with support to choose axis (rows or columns) and level for comparison.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}, default 'columns'] Whether to compare by the index (0 or 'index') or columns (1 or 'columns').

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

DataFrame of bool Result of the comparison.

See also:

DataFrame.eq Compare DataFrames for equality elementwise.

DataFrame.ne Compare DataFrames for inequality elementwise.

DataFrame.le Compare DataFrames for less than inequality or equality elementwise.

DataFrame.lt Compare DataFrames for strictly less than inequality elementwise.

DataFrame.ge Compare DataFrames for greater than inequality or equality elementwise.

DataFrame.gt Compare DataFrames for strictly greater than inequality elementwise.

Notes

Mismatched indices will be unioned together. *NaN* values are considered different (i.e. *NaN* != *NaN*).

Examples

```
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                    'revenue': [100, 250, 300]},
...                    index=['A', 'B', 'C'])
>>> df
   cost  revenue
A   250     100
B   150     250
C   100     300
```

Comparison with a scalar, using either the operator or method:

```
>>> df == 100
   cost  revenue
A  False     True
B  False    False
C   True    False
```

```
>>> df.eq(100)
   cost  revenue
A  False     True
B  False    False
C   True    False
```

When *other* is a *Series*, the columns of a DataFrame are aligned with the index of *other* and broadcast:

```
>>> df != pd.Series([100, 250], index=["cost", "revenue"])
   cost  revenue
A   True     True
B   True    False
C  False     True
```

Use the method to control the broadcast axis:

```
>>> df.ne(pd.Series([100, 300], index=["A", "D"]), axis='index')
   cost  revenue
A   True    False
B   True     True
C   True     True
D   True     True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in *other*:

```
>>> df == [250, 100]
   cost  revenue
```

(continues on next page)

(continued from previous page)

```
A  True    True
B  False   False
C  False   False
```

Use the method to control the axis:

```
>>> df.eq([250, 250, 100], axis='index')
      cost  revenue
A  True    False
B  False    True
C  True    False
```

Compare to a DataFrame of different shape.

```
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
...                       index=['A', 'B', 'C', 'D'])
>>> other
      revenue
A         300
B         250
C         100
D         150
```

```
>>> df.gt(other)
      cost  revenue
A  False   False
B  False   False
C  False    True
D  False   False
```

Compare to a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
...                              'revenue': [100, 250, 300, 200, 175, 225]},
...                              index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
...                                      ['A', 'B', 'C', 'A', 'B', 'C']])
>>> df_multindex
      cost  revenue
Q1 A   250     100
   B   150     250
   C   100     300
Q2 A   150     200
   B   300     175
   C   220     225
```

```
>>> df.le(df_multindex, level=1)
      cost  revenue
Q1 A  True    True
   B  True    True
   C  True    True
Q2 A  False   True
   B  True    False
```

(continues on next page)

(continued from previous page)

C	True	False
---	------	-------

pandas.DataFrame.get

`DataFrame.get(self, key, default=None)`

Get item from object for given key (ex: DataFrame column).

Returns default value if not found.

Parameters

key [object]

Returns

value [same type as items contained in object]

pandas.DataFrame.get_dtype_counts

`DataFrame.get_dtype_counts(self)`

Return counts of unique dtypes in this object.

Deprecated since version 0.25.0.

Use `.dtypes.value_counts()` instead.

Returns

dtype [Series] Series with the count of columns with each dtype.

See also:

dtypes Return the dtypes in this object.

Examples

```
>>> a = [['a', 1, 1.0], ['b', 2, 2.0], ['c', 3, 3.0]]
>>> df = pd.DataFrame(a, columns=['str', 'int', 'float'])
>>> df
   str  int  float
0   a    1    1.0
1   b    2    2.0
2   c    3    3.0
```

```
>>> df.get_dtype_counts()
float64    1
int64      1
object     1
dtype: int64
```

pandas.DataFrame.get_ftype_counts**DataFrame.get_ftype_counts**(*self*)

Return counts of unique ftypes in this object.

Deprecated since version 0.23.0.

This is useful for SparseDataFrame or for DataFrames containing sparse arrays.

Returns**dtype** [Series] Series with the count of columns with each type and sparsity (dense/sparse).**See also:****ftypes** Return ftypes (indication of sparse/dense and dtype) in this object.**Examples**

```
>>> a = [['a', 1, 1.0], ['b', 2, 2.0], ['c', 3, 3.0]]
>>> df = pd.DataFrame(a, columns=['str', 'int', 'float'])
>>> df
   str  int  float
0   a    1    1.0
1   b    2    2.0
2   c    3    3.0
```

```
>>> df.get_ftype_counts() # doctest: +SKIP
float64:dense    1
int64:dense      1
object:dense     1
dtype: int64
```

pandas.DataFrame.get_value**DataFrame.get_value**(*self*, *index*, *col*, *takeable=False*)

Quickly retrieve single value at passed column and index.

Deprecated since version 0.21.0: Use `.at[]` or `.iat[]` accessors instead.**Parameters****index** [row label]**col** [column label]**takeable** [interpret the index/col as indexers, default False]**Returns****scalar**

pandas.DataFrame.get_values`DataFrame.get_values(self)`

Return an ndarray after converting sparse values to dense.

Deprecated since version 0.25.0: Use `np.asarray(...)` or `DataFrame.values()` instead.This is the same as `.values` for non-sparse data. For sparse data contained in a `SparseArray`, the data are first converted to a dense representation.**Returns****numpy.ndarray** Numpy representation of DataFrame.**See also:****values** Numpy representation of DataFrame.**SparseArray** Container for sparse data.**Examples**

```
>>> df = pd.DataFrame({'a': [1, 2], 'b': [True, False],
...                    'c': [1.0, 2.0]})
>>> df
   a    b    c
0  1  True  1.0
1  2 False  2.0
```

```
>>> df.get_values()
array([[1, True, 1.0], [2, False, 2.0]], dtype=object)
```

```
>>> df = pd.DataFrame({"a": pd.SparseArray([1, None, None]),
...                    "c": [1.0, 2.0, 3.0]})
>>> df
   a    c
0  1.0  1.0
1  NaN  2.0
2  NaN  3.0
```

```
>>> df.get_values()
array([[ 1.,  1.],
       [nan,  2.],
       [nan,  3.]])
```

pandas.DataFrame.groupby`DataFrame.groupby(self, by=None, axis=0, level=None, as_index=True, sort=True, group_keys=True, squeeze=False, observed=False, **kwargs)`

Group DataFrame or Series using a mapper or by a Series of columns.

A groupby operation involves some combination of splitting the object, applying a function, and combining the results. This can be used to group large amounts of data and compute operations on these groups.

Parameters

by [mapping, function, label, or list of labels] Used to determine the groups for the groupby. If **by** is a function, it's called on each value of the object's index. If a dict or Series is passed, the Series or dict VALUES will be used to determine the groups (the Series' values are first aligned; see `.align()` method). If an ndarray is passed, the values are used as-is determine the groups. A label or list of labels may be passed to group by the columns in **self**. Notice that a tuple is interpreted as a (single) key.

axis [{0 or 'index', 1 or 'columns'}, default 0] Split along rows (0) or columns (1).

level [int, level name, or sequence of such, default None] If the axis is a MultiIndex (hierarchical), group by a particular level or levels.

as_index [bool, default True] For aggregated output, return object with group labels as the index. Only relevant for DataFrame input. `as_index=False` is effectively "SQL-style" grouped output.

sort [bool, default True] Sort group keys. Get better performance by turning this off. Note this does not influence the order of observations within each group. Groupby preserves the order of rows within each group.

group_keys [bool, default True] When calling `apply`, add group keys to index to identify pieces.

squeeze [bool, default False] Reduce the dimensionality of the return type if possible, otherwise return a consistent type.

observed [bool, default False] This only applies if any of the groupers are Categoricals. If True: only show observed values for categorical groupers. If False: show all values for categorical groupers.

New in version 0.23.0.

****kwargs** Optional, only accepts keyword argument 'mutated' and is passed to `groupby`.

Returns

DataFrameGroupBy or **SeriesGroupBy** Depends on the calling object and returns `groupby` object that contains information about the groups.

See also:

resample Convenience method for frequency conversion and resampling of time series.

Notes

See the [user guide](#) for more.

Examples

```
>>> df = pd.DataFrame({'Animal': ['Falcon', 'Falcon',
...                               'Parrot', 'Parrot'],
...                   'Max Speed': [380., 370., 24., 26.]})
>>> df
   Animal  Max Speed
```

(continues on next page)

(continued from previous page)

```

0 Falcon      380.0
1 Falcon      370.0
2 Parrot       24.0
3 Parrot       26.0
>>> df.groupby(['Animal']).mean()
      Max Speed
Animal
Falcon      375.0
Parrot       25.0

```

Hierarchical Indexes

We can groupby different levels of a hierarchical index using the *level* parameter:

```

>>> arrays = [['Falcon', 'Falcon', 'Parrot', 'Parrot'],
...           ['Captive', 'Wild', 'Captive', 'Wild']]
>>> index = pd.MultiIndex.from_arrays(arrays, names=('Animal', 'Type'))
>>> df = pd.DataFrame({'Max Speed': [390., 350., 30., 20.]},
...                   index=index)
>>> df
      Max Speed
Animal Type
Falcon Captive    390.0
        Wild      350.0
Parrot Captive     30.0
        Wild       20.0
>>> df.groupby(level=0).mean()
      Max Speed
Animal
Falcon      370.0
Parrot       25.0
>>> df.groupby(level=1).mean()
      Max Speed
Type
Captive     210.0
Wild       185.0

```

pandas.DataFrame.gt

DataFrame.gt(*self*, *other*, *axis='columns'*, *level=None*)

Get Greater than of dataframe and other, element-wise (binary operator *gt*).

Among flexible wrappers (*eq*, *ne*, *le*, *lt*, *ge*, *gt*) to comparison operators.

Equivalent to `==`, `!=`, `<=`, `<`, `>=`, `>` with support to choose axis (rows or columns) and level for comparison.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}, default 'columns'] Whether to compare by the index (0 or 'index') or columns (1 or 'columns').

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

DataFrame of bool Result of the comparison.

See also:

DataFrame.eq Compare DataFrames for equality elementwise.

DataFrame.ne Compare DataFrames for inequality elementwise.

DataFrame.le Compare DataFrames for less than inequality or equality elementwise.

DataFrame.lt Compare DataFrames for strictly less than inequality elementwise.

DataFrame.ge Compare DataFrames for greater than inequality or equality elementwise.

DataFrame.gt Compare DataFrames for strictly greater than inequality elementwise.

Notes

Mismatched indices will be unioned together. *NaN* values are considered different (i.e. *NaN* != *NaN*).

Examples

```
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                    'revenue': [100, 250, 300]},
...                   index=['A', 'B', 'C'])
>>> df
   cost  revenue
A   250     100
B   150     250
C   100     300
```

Comparison with a scalar, using either the operator or method:

```
>>> df == 100
   cost  revenue
A  False     True
B  False     False
C   True     False
```

```
>>> df.eq(100)
   cost  revenue
A  False     True
B  False     False
C   True     False
```

When *other* is a *Series*, the columns of a DataFrame are aligned with the index of *other* and broadcast:

```
>>> df != pd.Series([100, 250], index=["cost", "revenue"])
      cost  revenue
A   True    True
B   True   False
C  False    True
```

Use the method to control the broadcast axis:

```
>>> df.ne(pd.Series([100, 300], index=["A", "D"]), axis='index')
      cost  revenue
A   True   False
B   True    True
C   True    True
D   True    True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in *other*:

```
>>> df == [250, 100]
      cost  revenue
A   True    True
B  False   False
C  False   False
```

Use the method to control the axis:

```
>>> df.eq([250, 250, 100], axis='index')
      cost  revenue
A   True   False
B  False    True
C   True   False
```

Compare to a DataFrame of different shape.

```
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
...                       index=['A', 'B', 'C', 'D'])
>>> other
      revenue
A         300
B         250
C         100
D         150
```

```
>>> df.gt(other)
      cost  revenue
A  False   False
B  False   False
C  False    True
D  False   False
```

Compare to a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
...                               'revenue': [100, 250, 300, 200, 175, 225]},
...                               index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
...                                       ['A', 'B', 'C', 'A', 'B', 'C']])
>>> df_multindex
   cost  revenue
Q1 A    250     100
   B    150     250
   C    100     300
Q2 A    150     200
   B    300     175
   C    220     225
```

```
>>> df.le(df_multindex, level=1)
   cost  revenue
Q1 A   True     True
   B   True     True
   C   True     True
Q2 A  False     True
   B   True     False
   C   True     False
```

pandas.DataFrame.head

`DataFrame.head(self, n=5)`

Return the first n rows.

This function returns the first n rows for the object based on position. It is useful for quickly testing if your object has the right type of data in it.

Parameters

n [int, default 5] Number of rows to select.

Returns

obj_head [same type as caller] The first n rows of the caller object.

See also:

`DataFrame.tail` Returns the last n rows.

Examples

```
>>> df = pd.DataFrame({'animal': ['alligator', 'bee', 'falcon', 'lion',
...                               'monkey', 'parrot', 'shark', 'whale', 'zebra']})
>>> df
   animal
0 alligator
1      bee
2   falcon
3      lion
4   monkey
```

(continues on next page)

(continued from previous page)

```

5   parrot
6   shark
7   whale
8   zebra

```

Viewing the first 5 lines

```

>>> df.head()
      animal
0  alligator
1       bee
2    falcon
3       lion
4    monkey

```

Viewing the first n lines (three in this case)

```

>>> df.head(3)
      animal
0  alligator
1       bee
2    falcon

```

pandas.DataFrame.hist

`DataFrame.hist`(*data*, *column=None*, *by=None*, *grid=True*, *xlabelsize=None*, *xrot=None*, *ylabelsize=None*, *yrot=None*, *ax=None*, *sharex=False*, *sharey=False*, *figsize=None*, *layout=None*, *bins=10*, ***kws*)

Make a histogram of the DataFrame's.

A [histogram](#) is a representation of the distribution of data. This function calls `matplotlib.pyplot.hist()`, on each series in the DataFrame, resulting in one histogram per column.

Parameters

data [DataFrame] The pandas object holding the data.

column [string or sequence] If passed, will be used to limit data to a subset of columns.

by [object, optional] If passed, then used to form histograms for separate groups.

grid [bool, default True] Whether to show axis grid lines.

xlabelsize [int, default None] If specified changes the x-axis label size.

xrot [float, default None] Rotation of x axis labels. For example, a value of 90 displays the x labels rotated 90 degrees clockwise.

ylabelsize [int, default None] If specified changes the y-axis label size.

yrot [float, default None] Rotation of y axis labels. For example, a value of 90 displays the y labels rotated 90 degrees clockwise.

ax [Matplotlib axes object, default None] The axes to plot the histogram on.

sharex [bool, default True if ax is None else False] In case subplots=True, share x axis and set some x axis labels to invisible; defaults to True if ax is None

otherwise False if an `ax` is passed in. Note that passing in both an `ax` and `sharex=True` will alter all x axis labels for all subplots in a figure.

sharey [bool, default False] In case `subplots=True`, share y axis and set some y axis labels to invisible.

figsize [tuple] The size in inches of the figure to create. Uses the value in `matplotlib.rcParams` by default.

layout [tuple, optional] Tuple of (rows, columns) for the layout of the histograms.

bins [integer or sequence, default 10] Number of histogram bins to be used. If an integer is given, `bins + 1` bin edges are calculated and returned. If `bins` is a sequence, gives bin edges, including left edge of first bin and right edge of last bin. In this case, `bins` is returned unmodified.

****kwargs** All other plotting keyword arguments to be passed to `matplotlib.pyplot.hist()`.

Returns

`matplotlib.AxesSubplot` or `numpy.ndarray` of them

See also:

`matplotlib.pyplot.hist` Plot a histogram using matplotlib.

Examples

This example draws a histogram based on the length and width of some animals, displayed in three bins

```
>>> df = pd.DataFrame({
...     'length': [1.5, 0.5, 1.2, 0.9, 3],
...     'width': [0.7, 0.2, 0.15, 0.2, 1.1]
...     }, index= ['pig', 'rabbit', 'duck', 'chicken', 'horse'])
>>> hist = df.hist(bins=3)
```

pandas.DataFrame.idxmax

`DataFrame.idxmax(self, axis=0, skipna=True)`

Return index of first occurrence of maximum over requested axis. NA/null values are excluded.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] 0 or 'index' for row-wise, 1 or 'columns' for column-wise

skipna [boolean, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

Returns

Series Indexes of maxima along the specified axis.

Raises

ValueError

- If the row/column is empty

See also:

Series.idxmax

Notes

This method is the DataFrame version of `ndarray.argmax`.

pandas.DataFrame.idxmin

`DataFrame.idxmin(self, axis=0, skipna=True)`

Return index of first occurrence of minimum over requested axis. NA/null values are excluded.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] 0 or 'index' for row-wise, 1 or 'columns' for column-wise

skipna [boolean, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

Returns

Series Indexes of minima along the specified axis.

Raises

ValueError

- If the row/column is empty

See also:

Series.idxmin

Notes

This method is the DataFrame version of `ndarray.argmin`.

pandas.DataFrame.infer_objects

`DataFrame.infer_objects(self)`

Attempt to infer better dtypes for object columns.

Attempts soft conversion of object-dtyped columns, leaving non-object and unconvertible columns unchanged. The inference rules are the same as during normal Series/DataFrame construction.

New in version 0.21.0.

Returns

converted [same type as input object]

See also:

to_datetime Convert argument to datetime.

to_timedelta Convert argument to timedelta.

`to_numeric` Convert argument to numeric type.

Examples

```
>>> df = pd.DataFrame({"A": ["a", 1, 2, 3]})
>>> df = df.iloc[1:]
>>> df
   A
1  1
2  2
3  3
```

```
>>> df.dtypes
A    object
dtype: object
```

```
>>> df.infer_objects().dtypes
A    int64
dtype: object
```

pandas.DataFrame.info

`DataFrame.info(self, verbose=None, buf=None, max_cols=None, memory_usage=None, null_counts=None)`

Print a concise summary of a DataFrame.

This method prints information about a DataFrame including the index dtype and column dtypes, non-null values and memory usage.

Parameters

verbose [bool, optional] Whether to print the full summary. By default, the setting in `pandas.options.display.max_info_columns` is followed.

buf [writable buffer, defaults to `sys.stdout`] Where to send the output. By default, the output is printed to `sys.stdout`. Pass a writable buffer if you need to further process the output.

max_cols [int, optional] When to switch from the verbose to the truncated output. If the DataFrame has more than `max_cols` columns, the truncated output is used. By default, the setting in `pandas.options.display.max_info_columns` is used.

memory_usage [bool, str, optional] Specifies whether total memory usage of the DataFrame elements (including the index) should be displayed. By default, this follows the `pandas.options.display.memory_usage` setting.

True always show memory usage. False never shows memory usage. A value of 'deep' is equivalent to "True with deep introspection". Memory usage is shown in human-readable units (base-2 representation). Without deep introspection a memory estimation is made based in column dtype and number of rows assuming values consume the same memory amount for corresponding dtypes. With deep memory introspection, a real memory usage calculation is performed at the cost of computational resources.

null_counts [bool, optional] Whether to show the non-null counts. By default, this is shown only if the frame is smaller than `pandas.options.display.max_info_rows` and `pandas.options.display.max_info_columns`. A value of True always shows the counts, and False never shows the counts.

Returns

None This method prints a summary of a DataFrame and returns None.

See also:

DataFrame.describe Generate descriptive statistics of DataFrame columns.

DataFrame.memory_usage Memory usage of DataFrame columns.

Examples

```
>>> int_values = [1, 2, 3, 4, 5]
>>> text_values = ['alpha', 'beta', 'gamma', 'delta', 'epsilon']
>>> float_values = [0.0, 0.25, 0.5, 0.75, 1.0]
>>> df = pd.DataFrame({"int_col": int_values, "text_col": text_values,
...                    "float_col": float_values})
>>> df
   int_col text_col  float_col
0         1   alpha         0.00
1         2   beta         0.25
2         3  gamma         0.50
3         4  delta         0.75
4         5 epsilon         1.00
```

Prints information of all columns:

```
>>> df.info(verbose=True)
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5 entries, 0 to 4
Data columns (total 3 columns):
int_col      5 non-null int64
text_col     5 non-null object
float_col    5 non-null float64
dtypes: float64(1), int64(1), object(1)
memory usage: 248.0+ bytes
```

Prints a summary of columns count and its dtypes but not per column information:

```
>>> df.info(verbose=False)
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5 entries, 0 to 4
Columns: 3 entries, int_col to float_col
dtypes: float64(1), int64(1), object(1)
memory usage: 248.0+ bytes
```

Pipe output of `DataFrame.info` to buffer instead of `sys.stdout`, get buffer content and writes to a text file:

```

>>> import io
>>> buffer = io.StringIO()
>>> df.info(buf=buffer)
>>> s = buffer.getvalue()
>>> with open("df_info.txt", "w",
...           encoding="utf-8") as f: # doctest: +SKIP
...     f.write(s)
260

```

The `memory_usage` parameter allows deep introspection mode, specially useful for big DataFrames and fine-tune memory optimization:

```

>>> random_strings_array = np.random.choice(['a', 'b', 'c'], 10 ** 6)
>>> df = pd.DataFrame({
...     'column_1': np.random.choice(['a', 'b', 'c'], 10 ** 6),
...     'column_2': np.random.choice(['a', 'b', 'c'], 10 ** 6),
...     'column_3': np.random.choice(['a', 'b', 'c'], 10 ** 6)
... })
>>> df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 1000000 entries, 0 to 999999
Data columns (total 3 columns):
column_1    1000000 non-null object
column_2    1000000 non-null object
column_3    1000000 non-null object
dtypes: object(3)
memory usage: 22.9+ MB

```

```

>>> df.info(memory_usage='deep')
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 1000000 entries, 0 to 999999
Data columns (total 3 columns):
column_1    1000000 non-null object
column_2    1000000 non-null object
column_3    1000000 non-null object
dtypes: object(3)
memory usage: 188.8 MB

```

pandas.DataFrame.insert

`DataFrame.insert`(*self*, *loc*, *column*, *value*, *allow_duplicates=False*)

Insert column into DataFrame at specified location.

Raises a `ValueError` if *column* is already contained in the DataFrame, unless *allow_duplicates* is set to `True`.

Parameters

loc [int] Insertion index. Must verify $0 \leq \text{loc} \leq \text{len}(\text{columns})$

column [string, number, or hashable object] label of the inserted column

value [int, Series, or array-like]

allow_duplicates [bool, optional]

pandas.DataFrame.interpolate

```
DataFrame.interpolate(self, method='linear', axis=0, limit=None, inplace=False,
                       limit_direction='forward', limit_area=None, downcast=None,
                       **kwargs)
```

Interpolate values according to different methods.

Please note that only `method='linear'` is supported for DataFrame/Series with a MultiIndex.

Parameters

method [str, default 'linear'] Interpolation technique to use. One of:

- 'linear': Ignore the index and treat the values as equally spaced. This is the only method supported on MultiIndexes.
- 'time': Works on daily and higher resolution data to interpolate given length of interval.
- 'index', 'values': use the actual numerical values of the index.
- 'pad': Fill in NaNs using existing values.
- 'nearest', 'zero', 'slinear', 'quadratic', 'cubic', 'spline', 'barycentric', 'polynomial': Passed to `scipy.interpolate.interp1d`. These methods use the numerical values of the index. Both 'polynomial' and 'spline' require that you also specify an `order` (int), e.g. `df.interpolate(method='polynomial', order=5)`.
- 'krogh', 'piecewise_polynomial', 'spline', 'pchip', 'akima': Wrappers around the SciPy interpolation methods of similar names. See *Notes*.
- 'from_derivatives': Refers to `scipy.interpolate.BPoly.from_derivatives` which replaces 'piecewise_polynomial' interpolation method in scipy 0.18.

New in version 0.18.1: Added support for the 'akima' method. Added interpolate method 'from_derivatives' which replaces 'piecewise_polynomial' in SciPy 0.18; backwards-compatible with SciPy < 0.18

axis [{0 or 'index', 1 or 'columns', None}, default None] Axis to interpolate along.

limit [int, optional] Maximum number of consecutive NaNs to fill. Must be greater than 0.

inplace [bool, default False] Update the data in place if possible.

limit_direction [{'forward', 'backward', 'both'}, default 'forward'] If limit is specified, consecutive NaNs will be filled in this direction.

limit_area [{None, 'inside', 'outside'}, default None] If limit is specified, consecutive NaNs will be filled with this restriction.

- None: No fill restriction.
- 'inside': Only fill NaNs surrounded by valid values (interpolate).
- 'outside': Only fill NaNs outside valid values (extrapolate).

New in version 0.23.0.

downcast [optional, 'infer' or None, defaults to None] Downcast dtypes if possible.

****kwargs** Keyword arguments to pass on to the interpolating function.

Returns

Series or DataFrame Returns the same object type as the caller, interpolated at some or all NaN values.

See also:

fillna Fill missing values using different methods.

`scipy.interpolate.Akima1DInterpolator` Piecewise cubic polynomials (Akima interpolator).

`scipy.interpolate.BPoly.from_derivatives` Piecewise polynomial in the Bernstein basis.

`scipy.interpolate.interp1d` Interpolate a 1-D function.

`scipy.interpolate.KroghInterpolator` Interpolate polynomial (Krogh interpolator).

`scipy.interpolate.PchipInterpolator` PCHIP 1-d monotonic cubic interpolation.

`scipy.interpolate.CubicSpline` Cubic spline data interpolator.

Notes

The ‘krogh’, ‘piecewise_polynomial’, ‘spline’, ‘pchip’ and ‘akima’ methods are wrappers around the respective SciPy implementations of similar names. These use the actual numerical values of the index. For more information on their behavior, see the [SciPy documentation](#) and [SciPy tutorial](#).

Examples

Filling in NaN in a *Series* via linear interpolation.

```
>>> s = pd.Series([0, 1, np.nan, 3])
>>> s
0    0.0
1    1.0
2    NaN
3    3.0
dtype: float64
>>> s.interpolate()
0    0.0
1    1.0
2    2.0
3    3.0
dtype: float64
```

Filling in NaN in a Series by padding, but filling at most two consecutive NaN at a time.

```
>>> s = pd.Series([np.nan, "single_one", np.nan,
...               "fill_two_more", np.nan, np.nan, np.nan,
...               4.71, np.nan])
>>> s
0         NaN
1    single_one
2         NaN
3    fill_two_more
4         NaN
5         NaN
```

(continues on next page)

(continued from previous page)

```

6          NaN
7          4.71
8          NaN
dtype: object
>>> s.interpolate(method='pad', limit=2)
0          NaN
1    single_one
2    single_one
3  fill_two_more
4  fill_two_more
5  fill_two_more
6          NaN
7          4.71
8          4.71
dtype: object

```

Filling in NaN in a Series via polynomial interpolation or splines: Both 'polynomial' and 'spline' methods require that you also specify an `order` (int).

```

>>> s = pd.Series([0, 2, np.nan, 8])
>>> s.interpolate(method='polynomial', order=2)
0    0.000000
1    2.000000
2    4.666667
3    8.000000
dtype: float64

```

Fill the DataFrame forward (that is, going down) along each column using linear interpolation.

Note how the last entry in column 'a' is interpolated differently, because there is no entry after it to use for interpolation. Note how the first entry in column 'b' remains NaN, because there is no entry before it to use for interpolation.

```

>>> df = pd.DataFrame([(0.0, np.nan, -1.0, 1.0),
...                    (np.nan, 2.0, np.nan, np.nan),
...                    (2.0, 3.0, np.nan, 9.0),
...                    (np.nan, 4.0, -4.0, 16.0)],
...                    columns=list('abcd'))
>>> df
   a    b    c    d
0  0.0 NaN -1.0  1.0
1  NaN  2.0 NaN  NaN
2  2.0  3.0 NaN  9.0
3  NaN  4.0 -4.0 16.0
>>> df.interpolate(method='linear', limit_direction='forward', axis=0)
   a    b    c    d
0  0.0 NaN -1.0  1.0
1  1.0  2.0 -2.0  5.0
2  2.0  3.0 -3.0  9.0
3  2.0  4.0 -4.0 16.0

```

Using polynomial interpolation.

```
>>> df['d'].interpolate(method='polynomial', order=2)
0    1.0
1    4.0
2    9.0
3   16.0
Name: d, dtype: float64
```

pandas.DataFrame.isin

`DataFrame.isin(self, values)`

Whether each element in the DataFrame is contained in values.

Parameters

values [iterable, Series, DataFrame or dict] The result will only be true at a location if all the labels match. If *values* is a Series, that's the index. If *values* is a dict, the keys must be the column names, which must match. If *values* is a DataFrame, then both the index and column labels must match.

Returns

DataFrame DataFrame of booleans showing whether each element in the DataFrame is contained in values.

See also:

DataFrame.eq Equality test for DataFrame.

Series.isin Equivalent method on Series.

Series.str.contains Test if pattern or regex is contained within a string of a Series or Index.

Examples

```
>>> df = pd.DataFrame({'num_legs': [2, 4], 'num_wings': [2, 0]},
...                   index=['falcon', 'dog'])
>>> df
   num_legs  num_wings
falcon      2         2
dog         4         0
```

When *values* is a list check whether every value in the DataFrame is present in the list (which animals have 0 or 2 legs or wings)

```
>>> df.isin([0, 2])
   num_legs  num_wings
falcon    True     True
dog       False     True
```

When *values* is a dict, we can pass values to check for each column separately:

```
>>> df.isin({'num_wings': [0, 3]})
   num_legs  num_wings
```

(continues on next page)

(continued from previous page)

falcon	False	False
dog	False	True

When `values` is a Series or DataFrame the index and column must match. Note that 'falcon' does not match based on the number of legs in `df2`.

```
>>> other = pd.DataFrame({'num_legs': [8, 2], 'num_wings': [0, 2]},
...                       index=['spider', 'falcon'])
>>> df.isin(other)
      num_legs  num_wings
falcon      True         True
dog         False        False
```

pandas.DataFrame.isna

`DataFrame.isna(self)`

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as `None` or `numpy.NaN`, gets mapped to `True` values. Everything else gets mapped to `False` values. Characters such as empty strings `' '` or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`).

Returns

DataFrame Mask of bool values for each element in DataFrame that indicates whether an element is not an NA value.

See also:

`DataFrame.isnull` Alias of `isna`.

`DataFrame.notna` Boolean inverse of `isna`.

`DataFrame.dropna` Omit axes labels with missing values.

`isna` Top-level `isna`.

Examples

Show which entries in a DataFrame are NA.

```
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
...                   'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                             pd.Timestamp('1940-04-25')],
...                   'name': ['Alfred', 'Batman', ''],
...                   'toy': [None, 'Batmobile', 'Joker']})
>>> df
   age      born      name      toy
0  5.0      NaT  Alfred     None
1  6.0  1939-05-27  Batman  Batmobile
2  NaN  1940-04-25           Joker
```

```
>>> df.isna()
   age  born  name  toy
0  False  True  False  True
1  False  False  False  False
2   True  False  False  False
```

Show which entries in a Series are NA.

```
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2    NaN
dtype: float64
```

```
>>> ser.isna()
0    False
1    False
2     True
dtype: bool
```

pandas.DataFrame.isnull

`DataFrame.isnull(self)`

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as `None` or `numpy.NaN`, gets mapped to `True` values. Everything else gets mapped to `False` values. Characters such as empty strings `''` or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`).

Returns

DataFrame Mask of bool values for each element in `DataFrame` that indicates whether an element is not an NA value.

See also:

`DataFrame.isnull` Alias of `isna`.

`DataFrame.notna` Boolean inverse of `isna`.

`DataFrame.dropna` Omit axes labels with missing values.

`isna` Top-level `isna`.

Examples

Show which entries in a `DataFrame` are NA.

```
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
...                    'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                             pd.Timestamp('1940-04-25')],
...                    'name': ['Alfred', 'Batman', ''],
...                    })
```

(continues on next page)

(continued from previous page)

```
...          'toy': [None, 'Batmobile', 'Joker']})
>>> df
   age      born  name      toy
0  5.0      NaT  Alfred  None
1  6.0 1939-05-27  Batman  Batmobile
2  NaN 1940-04-25         Joker
```

```
>>> df.isna()
   age  born  name  toy
0  False  True  False  True
1  False  False  False  False
2   True  False  False  False
```

Show which entries in a Series are NA.

```
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2    NaN
dtype: float64
```

```
>>> ser.isna()
0    False
1    False
2     True
dtype: bool
```

pandas.DataFrame.items

`DataFrame.items(self)`

Iterator over (column name, Series) pairs.

Iterates over the DataFrame columns, returning a tuple with the column name and the content as a Series.

Yields

label [object] The column names for the DataFrame being iterated over.

content [Series] The column entries belonging to each label, as a Series.

See also:

DataFrame.iterrows Iterate over DataFrame rows as (index, Series) pairs.

DataFrame.itertuples Iterate over DataFrame rows as namedtuples of the values.

Examples

```

>>> df = pd.DataFrame({'species': ['bear', 'bear', 'marsupial'],
...                     'population': [1864, 22000, 80000]},
...                     index=['panda', 'polar', 'koala'])
>>> df
   species  population
panda  bear         1864
polar  bear        22000
koala  marsupial    80000
>>> for label, content in df.items():
...     print('label:', label)
...     print('content:', content, sep='\n')
...
label: species
content:
panda      bear
polar      bear
koala      marsupial
Name: species, dtype: object
label: population
content:
panda      1864
polar      22000
koala      80000
Name: population, dtype: int64

```

pandas.DataFrame.iteritems

`DataFrame.iteritems(self)`

Iterator over (column name, Series) pairs.

Iterates over the DataFrame columns, returning a tuple with the column name and the content as a Series.

Returns

label [object] The column names for the DataFrame being iterated over.

content [Series] The column entries belonging to each label, as a Series.

See also:

DataFrame.iterrows Iterate over DataFrame rows as (index, Series) pairs.

DataFrame.itertuples Iterate over DataFrame rows as namedtuples of the values.

Examples

```

>>> df = pd.DataFrame({'species': ['bear', 'bear', 'marsupial'],
...                     'population': [1864, 22000, 80000]},
...                     index=['panda', 'polar', 'koala'])
>>> df
   species  population
panda  bear         1864

```

(continues on next page)

(continued from previous page)

```

polar    bear      22000
koala    marsupial 80000
>>> for label, content in df.items():
...     print('label:', label)
...     print('content:', content, sep='\n')
...
label: species
content:
panda      bear
polar      bear
koala      marsupial
Name: species, dtype: object
label: population
content:
panda      1864
polar      22000
koala      80000
Name: population, dtype: int64

```

pandas.DataFrame.iterrows

DataFrame.iterrows(*self*)

Iterate over DataFrame rows as (index, Series) pairs.

Yields

index [label or tuple of label] The index of the row. A tuple for a *MultiIndex*.

data [Series] The data of the row as a Series.

it [generator] A generator that iterates over the rows of the frame.

See also:

itertuples Iterate over DataFrame rows as namedtuples of the values.

items Iterate over (column name, Series) pairs.

Notes

1. Because `iterrows` returns a Series for each row, it does **not** preserve dtypes across the rows (dtypes are preserved across columns for DataFrames). For example,

```

>>> df = pd.DataFrame([[1, 1.5]], columns=['int', 'float'])
>>> row = next(df.iterrows())[1]
>>> row
int      1.0
float    1.5
Name: 0, dtype: float64
>>> print(row['int'].dtype)
float64
>>> print(df['int'].dtype)
int64

```

To preserve dtypes while iterating over the rows, it is better to use `itertuples()` which returns namedtuples of the values and which is generally faster than `iterrows`.

2. You should **never modify** something you are iterating over. This is not guaranteed to work in all cases. Depending on the data types, the iterator returns a copy and not a view, and writing to it will have no effect.

pandas.DataFrame.itertuples

`DataFrame.itertuples(self, index=True, name='Pandas')`

Iterate over DataFrame rows as namedtuples.

Parameters

index [bool, default True] If True, return the index as the first element of the tuple.

name [str or None, default "Pandas"] The name of the returned namedtuples or None to return regular tuples.

Returns

iterator An object to iterate over namedtuples for each row in the DataFrame with the first field possibly being the index and following fields being the column values.

See also:

`DataFrame.iterrows` Iterate over DataFrame rows as (index, Series) pairs.

`DataFrame.items` Iterate over (column name, Series) pairs.

Notes

The column names will be renamed to positional names if they are invalid Python identifiers, repeated, or start with an underscore. With a large number of columns (>255), regular tuples are returned.

Examples

```
>>> df = pd.DataFrame({'num_legs': [4, 2], 'num_wings': [0, 2]},
...                   index=['dog', 'hawk'])
>>> df
   num_legs  num_wings
dog         4         0
hawk        2         2
>>> for row in df.itertuples():
...     print(row)
...
Pandas(Index='dog', num_legs=4, num_wings=0)
Pandas(Index='hawk', num_legs=2, num_wings=2)
```

By setting the `index` parameter to False we can remove the index as the first element of the tuple:

```
>>> for row in df.itertuples(index=False):
...     print(row)
...
Pandas(num_legs=4, num_wings=0)
Pandas(num_legs=2, num_wings=2)
```

With the *name* parameter set we set a custom name for the yielded namedtuples:

```
>>> for row in df.itertuples(name='Animal'):
...     print(row)
...
Animal(Index='dog', num_legs=4, num_wings=0)
Animal(Index='hawk', num_legs=2, num_wings=2)
```

pandas.DataFrame.join

`DataFrame.join(self, other, on=None, how='left', lsuffix="", rsuffix="", sort=False)`

Join columns of another DataFrame.

Join columns with *other* DataFrame either on index or on a key column. Efficiently join multiple DataFrame objects by index at once by passing a list.

Parameters

other [DataFrame, Series, or list of DataFrame] Index should be similar to one of the columns in this one. If a Series is passed, its name attribute must be set, and that will be used as the column name in the resulting joined DataFrame.

on [str, list of str, or array-like, optional] Column or index level name(s) in the caller to join on the index in *other*, otherwise joins index-on-index. If multiple values given, the *other* DataFrame must have a MultiIndex. Can pass an array as the join key if it is not already contained in the calling DataFrame. Like an Excel VLOOKUP operation.

how [{'left', 'right', 'outer', 'inner'}, default 'left'] How to handle the operation of the two objects.

- left: use calling frame's index (or column if on is specified)
- right: use *other*'s index.
- outer: form union of calling frame's index (or column if on is specified) with *other*'s index, and sort it. lexicographically.
- inner: form intersection of calling frame's index (or column if on is specified) with *other*'s index, preserving the order of the calling's one.

lsuffix [str, default ''] Suffix to use from left frame's overlapping columns.

rsuffix [str, default ''] Suffix to use from right frame's overlapping columns.

sort [bool, default False] Order result DataFrame lexicographically by the join key. If False, the order of the join key depends on the join type (how keyword).

Returns

DataFrame A dataframe containing columns from both the caller and *other*.

See also:

`DataFrame.merge` For column(s)-on-columns(s) operations.

Notes

Parameters `on`, `lsuffix`, and `rsuffix` are not supported when passing a list of `DataFrame` objects. Support for specifying index levels as the `on` parameter was added in version 0.23.0.

Examples

```
>>> df = pd.DataFrame({'key': ['K0', 'K1', 'K2', 'K3', 'K4', 'K5'],
...                    'A': ['A0', 'A1', 'A2', 'A3', 'A4', 'A5']})
```

```
>>> df
   key  A
0  K0  A0
1  K1  A1
2  K2  A2
3  K3  A3
4  K4  A4
5  K5  A5
```

```
>>> other = pd.DataFrame({'key': ['K0', 'K1', 'K2'],
...                       'B': ['B0', 'B1', 'B2']})
```

```
>>> other
   key  B
0  K0  B0
1  K1  B1
2  K2  B2
```

Join DataFrames using their indexes.

```
>>> df.join(other, lsuffix='_caller', rsuffix='_other')
   key_caller  A key_other  B
0          K0  A0         K0  B0
1          K1  A1         K1  B1
2          K2  A2         K2  B2
3          K3  A3         NaN NaN
4          K4  A4         NaN NaN
5          K5  A5         NaN NaN
```

If we want to join using the key columns, we need to set `key` to be the index in both `df` and `other`. The joined DataFrame will have `key` as its index.

```
>>> df.set_index('key').join(other.set_index('key'))
   A  B
key
K0  A0  B0
K1  A1  B1
K2  A2  B2
```

(continues on next page)

(continued from previous page)

K3	A3	NaN
K4	A4	NaN
K5	A5	NaN

Another option to join using the key columns is to use the *on* parameter. `DataFrame.join` always uses *other*'s index but we can use any column in *df*. This method preserves the original `DataFrame`'s index in the result.

```
>>> df.join(other.set_index('key'), on='key')
   key  A  B
0  K0  A0  B0
1  K1  A1  B1
2  K2  A2  B2
3  K3  A3  NaN
4  K4  A4  NaN
5  K5  A5  NaN
```

pandas.DataFrame.keys

`DataFrame.keys(self)`

Get the 'info axis' (see Indexing for more)

This is index for Series, columns for DataFrame.

Returns

Index Info axis.

pandas.DataFrame.kurt

`DataFrame.kurt(self, axis=None, skipna=None, level=None, numeric_only=None, **kwargs)`

Return unbiased kurtosis over requested axis using Fisher's definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1.

Parameters

axis [{index (0), columns (1)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

pandas.DataFrame.kurtosis

`DataFrame.kurtosis(self, axis=None, skipna=None, level=None, numeric_only=None, **kwargs)`

Return unbiased kurtosis over requested axis using Fisher's definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1.

Parameters

axis [{index (0), columns (1)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

pandas.DataFrame.last

`DataFrame.last(self, offset)`

Convenience method for subsetting final periods of time series data based on a date offset.

Parameters

offset [string, DateOffset, dateutil.relativedelta]

Returns

subset [same type as caller]

Raises

TypeError If the index is not a *DatetimeIndex*

See also:

first Select initial periods of time series based on a date offset.

at_time Select values at a particular time of the day.

between_time Select values between particular times of the day.

Examples

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1,2,3,4]}, index=i)
>>> ts
           A
2018-04-09  1
2018-04-11  2
```

(continues on next page)

(continued from previous page)

```
2018-04-13  3
2018-04-15  4
```

Get the rows for the last 3 days:

```
>>> ts.last('3D')
           A
2018-04-13  3
2018-04-15  4
```

Notice the data for 3 last calendar days were returned, not the last 3 observed days in the dataset, and therefore data for 2018-04-11 was not returned.

pandas.DataFrame.last_valid_index

`DataFrame.last_valid_index(self)`

Return index for last non-NA/null value.

Returns

scalar [type of index]

Notes

If all elements are non-NA/null, returns None. Also returns None for empty Series/DataFrame.

pandas.DataFrame.le

`DataFrame.le(self, other, axis='columns', level=None)`

Get Less than or equal to of dataframe and other, element-wise (binary operator *le*).

Among flexible wrappers (*eq*, *ne*, *le*, *lt*, *ge*, *gt*) to comparison operators.

Equivalent to `==`, `!=`, `<=`, `<`, `>=`, `>` with support to choose axis (rows or columns) and level for comparison.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}], default 'columns' Whether to compare by the index (0 or 'index') or columns (1 or 'columns').

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

DataFrame of bool Result of the comparison.

See also:

DataFrame.eq Compare DataFrames for equality elementwise.

DataFrame.ne Compare DataFrames for inequality elementwise.

DataFrame.le Compare DataFrames for less than inequality or equality elementwise.

DataFrame.lt Compare DataFrames for strictly less than inequality elementwise.

DataFrame.ge Compare DataFrames for greater than inequality or equality elementwise.

DataFrame.gt Compare DataFrames for strictly greater than inequality elementwise.

Notes

Mismatched indices will be unioned together. *NaN* values are considered different (i.e. *NaN* != *NaN*).

Examples

```
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                    'revenue': [100, 250, 300]},
...                    index=['A', 'B', 'C'])
>>> df
   cost  revenue
A   250     100
B   150     250
C   100     300
```

Comparison with a scalar, using either the operator or method:

```
>>> df == 100
   cost  revenue
A  False     True
B  False     False
C   True     False
```

```
>>> df.eq(100)
   cost  revenue
A  False     True
B  False     False
C   True     False
```

When *other* is a *Series*, the columns of a *DataFrame* are aligned with the index of *other* and broadcast:

```
>>> df != pd.Series([100, 250], index=["cost", "revenue"])
   cost  revenue
A   True     True
B   True     False
C  False     True
```

Use the method to control the broadcast axis:

```
>>> df.ne(pd.Series([100, 300], index=["A", "D"]), axis='index')
   cost  revenue
A   True     False
B   True     True
```

(continues on next page)

(continued from previous page)

```
C True    True
D True    True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in *other*:

```
>>> df == [250, 100]
      cost revenue
A    True     True
B   False    False
C   False    False
```

Use the method to control the axis:

```
>>> df.eq([250, 250, 100], axis='index')
      cost revenue
A    True     False
B   False     True
C    True     False
```

Compare to a DataFrame of different shape.

```
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
...                       index=['A', 'B', 'C', 'D'])
>>> other
      revenue
A         300
B         250
C         100
D         150
```

```
>>> df.gt(other)
      cost revenue
A   False    False
B   False    False
C   False     True
D   False    False
```

Compare to a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
...                              'revenue': [100, 250, 300, 200, 175, 225]},
...                              index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
...                                      ['A', 'B', 'C', 'A', 'B', 'C']])
>>> df_multindex
      cost revenue
Q1 A    250     100
   B    150     250
   C    100     300
Q2 A    150     200
   B    300     175
   C    220     225
```

```
>>> df.le(df_multindex, level=1)
      cost  revenue
Q1 A   True    True
   B   True    True
   C   True    True
Q2 A  False    True
   B   True   False
   C   True   False
```

pandas.DataFrame.lookup

`DataFrame.lookup(self, row_labels, col_labels)`

Label-based “fancy indexing” function for DataFrame.

Given equal-length arrays of row and column labels, return an array of the values corresponding to each (row, col) pair.

Parameters

row_labels [sequence] The row labels to use for lookup

col_labels [sequence] The column labels to use for lookup

Returns

`numpy.ndarray`

Notes

Akin to:

```
result = [df.get_value(row, col)
          for row, col in zip(row_labels, col_labels)]
```

Examples

values [ndarray] The found values

pandas.DataFrame.lt

`DataFrame.lt(self, other, axis='columns', level=None)`

Get Less than of dataframe and other, element-wise (binary operator *lt*).

Among flexible wrappers (*eq*, *ne*, *le*, *lt*, *ge*, *gt*) to comparison operators.

Equivalent to `==`, `!=`, `<=`, `<`, `>=`, `>` with support to choose axis (rows or columns) and level for comparison.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}, default 'columns'] Whether to compare by the index (0 or 'index') or columns (1 or 'columns').

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

DataFrame of bool Result of the comparison.

See also:

DataFrame.eq Compare DataFrames for equality elementwise.

DataFrame.ne Compare DataFrames for inequality elementwise.

DataFrame.le Compare DataFrames for less than inequality or equality elementwise.

DataFrame.lt Compare DataFrames for strictly less than inequality elementwise.

DataFrame.ge Compare DataFrames for greater than inequality or equality elementwise.

DataFrame.gt Compare DataFrames for strictly greater than inequality elementwise.

Notes

Mismatched indices will be unioned together. *NaN* values are considered different (i.e. *NaN* != *NaN*).

Examples

```
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                    'revenue': [100, 250, 300]},
...                    index=['A', 'B', 'C'])
>>> df
   cost  revenue
A   250     100
B   150     250
C   100     300
```

Comparison with a scalar, using either the operator or method:

```
>>> df == 100
   cost  revenue
A  False     True
B  False     False
C   True     False
```

```
>>> df.eq(100)
   cost  revenue
A  False     True
B  False     False
C   True     False
```

When *other* is a *Series*, the columns of a DataFrame are aligned with the index of *other* and broadcast:

```
>>> df != pd.Series([100, 250], index=["cost", "revenue"])
      cost  revenue
A   True    True
B   True   False
C  False    True
```

Use the method to control the broadcast axis:

```
>>> df.ne(pd.Series([100, 300], index=["A", "D"]), axis='index')
      cost  revenue
A   True   False
B   True    True
C   True    True
D   True    True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in *other*:

```
>>> df == [250, 100]
      cost  revenue
A   True    True
B  False   False
C  False   False
```

Use the method to control the axis:

```
>>> df.eq([250, 250, 100], axis='index')
      cost  revenue
A   True   False
B  False    True
C   True   False
```

Compare to a DataFrame of different shape.

```
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
...                       index=['A', 'B', 'C', 'D'])
>>> other
      revenue
A         300
B         250
C         100
D         150
```

```
>>> df.gt(other)
      cost  revenue
A  False   False
B  False   False
C  False    True
D  False   False
```

Compare to a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
...                               'revenue': [100, 250, 300, 200, 175, 225]},
...                               index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
...                                       ['A', 'B', 'C', 'A', 'B', 'C']])
>>> df_multindex
   cost  revenue
Q1 A    250     100
   B    150     250
   C    100     300
Q2 A    150     200
   B    300     175
   C    220     225
```

```
>>> df.le(df_multindex, level=1)
   cost  revenue
Q1 A   True     True
   B   True     True
   C   True     True
Q2 A  False     True
   B   True    False
   C   True    False
```

pandas.DataFrame.mad

`DataFrame.mad(self, axis=None, skipna=None, level=None)`

Return the mean absolute deviation of the values for the requested axis.

Parameters

axis [{index (0), columns (1)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

pandas.DataFrame.mask

`DataFrame.mask(self, cond, other=nan, inplace=False, axis=None, level=None, errors='raise', try_cast=False)`

Replace values where the condition is True.

Parameters

cond [boolean Series/DataFrame, array-like, or callable] Where *cond* is False, keep the original value. Where True, replace with corresponding value from *other*.

If *cond* is callable, it is computed on the Series/DataFrame and should return boolean Series/DataFrame or array. The callable must not change input Series/DataFrame (though pandas doesn't check it).

New in version 0.18.1: A callable can be used as *cond*.

other [scalar, Series/DataFrame, or callable] Entries where *cond* is True are replaced with corresponding value from *other*. If *other* is callable, it is computed on the Series/DataFrame and should return scalar or Series/DataFrame. The callable must not change input Series/DataFrame (though pandas doesn't check it).

New in version 0.18.1: A callable can be used as *other*.

inplace [bool, default False] Whether to perform the operation in place on the data.

axis [int, default None] Alignment axis if needed.

level [int, default None] Alignment level if needed.

errors [str, {'raise', 'ignore'}, default 'raise'] Note that currently this parameter won't affect the results and will always coerce to a suitable dtype.

- 'raise' : allow exceptions to be raised.
- 'ignore' : suppress exceptions. On error return original object.

try_cast [bool, default False] Try to cast the result back to the input type (if possible).

Returns

Same type as caller

See also:

DataFrame.where() Return an object of same shape as self.

Notes

The mask method is an application of the if-then idiom. For each element in the calling DataFrame, if *cond* is *False* the element is used; otherwise the corresponding element from the DataFrame *other* is used.

The signature for *DataFrame.where()* differs from *numpy.where()*. Roughly *df1.where(m, df2)* is equivalent to *np.where(m, df1, df2)*.

For further details and examples see the *mask* documentation in *indexing*.

Examples

```
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0    NaN
1    1.0
2    2.0
3    3.0
```

(continues on next page)

(continued from previous page)

```
4    4.0
dtype: float64
```

```
>>> s.mask(s > 0)
0    0.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

```
>>> s.where(s > 1, 10)
0    10
1    10
2     2
3     3
4     4
dtype: int64
```

```
>>> df = pd.DataFrame(np.arange(10).reshape(-1, 2), columns=['A', 'B'])
>>> df
   A  B
0  0  1
1  2  3
2  4  5
3  6  7
4  8  9
>>> m = df % 3 == 0
>>> df.where(m, -df)
   A  B
0  0 -1
1 -2  3
2 -4 -5
3  6 -7
4 -8  9
>>> df.where(m, -df) == np.where(m, df, -df)
   A      B
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True
>>> df.where(m, -df) == df.mask(~m, -df)
   A      B
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True
```

pandas.DataFrame.max

`DataFrame.max(self, axis=None, skipna=None, level=None, numeric_only=None, **kwargs)`

Return the maximum of the values for the requested axis.

If you want the *index* of the maximum, use `idxmax`. This is the equivalent of the `numpy.ndarray` method `argmax`.

Parameters

axis [{index (0), columns (1)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

See also:

Series.sum Return the sum.

Series.min Return the minimum.

Series.max Return the maximum.

Series.idxmin Return the index of the minimum.

Series.idxmax Return the index of the maximum.

DataFrame.sum Return the sum over the requested axis.

DataFrame.min Return the minimum over the requested axis.

DataFrame.max Return the maximum over the requested axis.

DataFrame.idxmin Return the index of the minimum over the requested axis.

DataFrame.idxmax Return the index of the maximum over the requested axis.

Examples

```
>>> idx = pd.MultiIndex.from_arrays([
...     ['warm', 'warm', 'cold', 'cold'],
...     ['dog', 'falcon', 'fish', 'spider']],
...     names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded  animal
warm     dog      4
         falcon   2
```

(continues on next page)

(continued from previous page)

```
cold    fish    0
        spider  8
Name: legs, dtype: int64
```

```
>>> s.max()
8
```

Max using level names, as well as indices.

```
>>> s.max(level='blooded')
blooded
warm    4
cold    8
Name: legs, dtype: int64
```

```
>>> s.max(level=0)
blooded
warm    4
cold    8
Name: legs, dtype: int64
```

pandas.DataFrame.mean

`DataFrame.mean(self, axis=None, skipna=None, level=None, numeric_only=None, **kwargs)`
Return the mean of the values for the requested axis.

Parameters

- axis** [{index (0), columns (1)}] Axis for the function to be applied on.
- skipna** [bool, default True] Exclude NA/null values when computing the result.
- level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
- numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- **kwargs** Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

pandas.DataFrame.median

`DataFrame.median(self, axis=None, skipna=None, level=None, numeric_only=None, **kwargs)`
Return the median of the values for the requested axis.

Parameters

- axis** [{index (0), columns (1)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

pandas.DataFrame.melt

```
DataFrame.melt(self, id_vars=None, value_vars=None, var_name=None,
                value_name='value', col_level=None)
```

Unpivot a DataFrame from wide format to long format, optionally leaving identifier variables set.

This function is useful to massage a DataFrame into a format where one or more columns are identifier variables (*id_vars*), while all other columns, considered measured variables (*value_vars*), are “unpivoted” to the row axis, leaving just two non-identifier columns, ‘variable’ and ‘value’. .. versionadded:: 0.20.0

Parameters

frame [DataFrame]

id_vars [tuple, list, or ndarray, optional] Column(s) to use as identifier variables.

value_vars [tuple, list, or ndarray, optional] Column(s) to unpivot. If not specified, uses all columns that are not set as *id_vars*.

var_name [scalar] Name to use for the ‘variable’ column. If None it uses `frame.columns.name` or ‘variable’.

value_name [scalar, default ‘value’] Name to use for the ‘value’ column.

col_level [int or string, optional] If columns are a MultiIndex then use this level to melt.

Returns

DataFrame Unpivoted DataFrame.

See also:

`melt`

`pivot_table`

`DataFrame.pivot`

`Series.explode`

Examples

```
>>> df = pd.DataFrame({'A': {0: 'a', 1: 'b', 2: 'c'},
...                    'B': {0: 1, 1: 3, 2: 5},
...                    'C': {0: 2, 1: 4, 2: 6}})
>>> df
   A  B  C
0  a  1  2
1  b  3  4
2  c  5  6
```

```
>>> df.melt(id_vars=['A'], value_vars=['B'])
   A variable  value
0  a         B      1
1  b         B      3
2  c         B      5
```

```
>>> df.melt(id_vars=['A'], value_vars=['B', 'C'])
   A variable  value
0  a         B      1
1  b         B      3
2  c         B      5
3  a         C      2
4  b         C      4
5  c         C      6
```

The names of 'variable' and 'value' columns can be customized:

```
>>> df.melt(id_vars=['A'], value_vars=['B'],
...         var_name='myVarname', value_name='myValname')
   A myVarname myValname
0  a         B          1
1  b         B          3
2  c         B          5
```

If you have multi-index columns:

```
>>> df.columns = [list('ABC'), list('DEF')]
>>> df
   A B C
   D E F
0  a 1 2
1  b 3 4
2  c 5 6
```

```
>>> df.melt(col_level=0, id_vars=['A'], value_vars=['B'])
   A variable  value
0  a         B      1
1  b         B      3
2  c         B      5
```

```
>>> df.melt(id_vars=[('A', 'D')], value_vars=[('B', 'E')])
   (A, D) variable_0 variable_1  value
0      a           B           E      1
```

(continues on next page)

(continued from previous page)

1	b	B	E	3
2	c	B	E	5

pandas.DataFrame.memory_usage**DataFrame.memory_usage**(*self*, *index=True*, *deep=False*)

Return the memory usage of each column in bytes.

The memory usage can optionally include the contribution of the index and elements of *object* dtype.This value is displayed in *DataFrame.info* by default. This can be suppressed by setting `pandas.options.display.memory_usage` to `False`.**Parameters****index** [bool, default True] Specifies whether to include the memory usage of the DataFrame's index in returned Series. If `index=True`, the memory usage of the index is the first item in the output.**deep** [bool, default False] If True, introspect the data deeply by interrogating *object* dtypes for system-level memory consumption, and include it in the returned values.**Returns****Series** A Series whose index is the original column names and whose values is the memory usage of each column in bytes.**See also:**`numpy.ndarray.nbytes` Total bytes consumed by the elements of an ndarray.`Series.memory_usage` Bytes consumed by a Series.`Categorical` Memory-efficient array for string values with many repeated values.`DataFrame.info` Concise summary of a DataFrame.**Examples**

```
>>> dtypes = ['int64', 'float64', 'complex128', 'object', 'bool']
>>> data = dict([(t, np.ones(shape=5000).astype(t))
...             for t in dtypes])
>>> df = pd.DataFrame(data)
>>> df.head()
   int64  float64      complex128  object  bool
0      1      1.0  1.000000+0.000000j      1  True
1      1      1.0  1.000000+0.000000j      1  True
2      1      1.0  1.000000+0.000000j      1  True
3      1      1.0  1.000000+0.000000j      1  True
4      1      1.0  1.000000+0.000000j      1  True
```

```
>>> df.memory_usage()
Index          128
int64          40000
float64        40000
complex128     80000
object         40000
bool           5000
dtype: int64
```

```
>>> df.memory_usage(index=False)
int64          40000
float64        40000
complex128     80000
object         40000
bool           5000
dtype: int64
```

The memory footprint of *object* dtype columns is ignored by default:

```
>>> df.memory_usage(deep=True)
Index          128
int64          40000
float64        40000
complex128     80000
object        160000
bool           5000
dtype: int64
```

Use a Categorical for efficient storage of an object-dtype column with many repeated values.

```
>>> df['object'].astype('category').memory_usage(deep=True)
5216
```

pandas.DataFrame.merge

```
DataFrame.merge(self, right, how='inner', on=None, left_on=None, right_on=None,
                 left_index=False, right_index=False, sort=False, suffixes=('_x', '_y'),
                 copy=True, indicator=False, validate=None)
```

Merge DataFrame or named Series objects with a database-style join.

The join is done on columns or indexes. If joining columns on columns, the DataFrame indexes *will be ignored*. Otherwise if joining indexes on indexes or indexes on a column or columns, the index will be passed on.

Parameters

right [DataFrame or named Series] Object to merge with.

how [{'left', 'right', 'outer', 'inner'}, default 'inner'] Type of merge to be performed.

- left: use only keys from left frame, similar to a SQL left outer join; preserve key order.

- **right**: use only keys from right frame, similar to a SQL right outer join; preserve key order.
- **outer**: use union of keys from both frames, similar to a SQL full outer join; sort keys lexicographically.
- **inner**: use intersection of keys from both frames, similar to a SQL inner join; preserve the order of the left keys.

on [label or list] Column or index level names to join on. These must be found in both DataFrames. If *on* is None and not merging on indexes then this defaults to the intersection of the columns in both DataFrames.

left_on [label or list, or array-like] Column or index level names to join on in the left DataFrame. Can also be an array or list of arrays of the length of the left DataFrame. These arrays are treated as if they are columns.

right_on [label or list, or array-like] Column or index level names to join on in the right DataFrame. Can also be an array or list of arrays of the length of the right DataFrame. These arrays are treated as if they are columns.

left_index [bool, default False] Use the index from the left DataFrame as the join key(s). If it is a MultiIndex, the number of keys in the other DataFrame (either the index or a number of columns) must match the number of levels.

right_index [bool, default False] Use the index from the right DataFrame as the join key. Same caveats as `left_index`.

sort [bool, default False] Sort the join keys lexicographically in the result DataFrame. If False, the order of the join keys depends on the join type (how keyword).

suffixes [tuple of (str, str), default ('_x', '_y')] Suffix to apply to overlapping column names in the left and right side, respectively. To raise an exception on overlapping columns use (False, False).

copy [bool, default True] If False, avoid copy if possible.

indicator [bool or str, default False] If True, adds a column to output DataFrame called “_merge” with information on the source of each row. If string, column with information on source of each row will be added to output DataFrame, and column will be named value of string. Information column is Categorical-type and takes on a value of “left_only” for observations whose merge key only appears in ‘left’ DataFrame, “right_only” for observations whose merge key only appears in ‘right’ DataFrame, and “both” if the observation’s merge key is found in both.

validate [str, optional] If specified, checks if merge is of specified type.

- “one_to_one” or “1:1”: check if merge keys are unique in both left and right datasets.
- “one_to_many” or “1:m”: check if merge keys are unique in left dataset.
- “many_to_one” or “m:1”: check if merge keys are unique in right dataset.
- “many_to_many” or “m:m”: allowed, but does not result in checks.

New in version 0.21.0.

Returns

DataFrame A DataFrame of the two merged objects.

See also:

`merge_ordered` Merge with optional filling/interpolation.

`merge_asof` Merge on nearest keys.

`DataFrame.join` Similar method using indices.

Notes

Support for specifying index levels as the `on`, `left_on`, and `right_on` parameters was added in version 0.23.0 Support for merging named Series objects was added in version 0.24.0

Examples

```
>>> df1 = pd.DataFrame({'lkey': ['foo', 'bar', 'baz', 'foo'],
...                     'value': [1, 2, 3, 5]})
>>> df2 = pd.DataFrame({'rkey': ['foo', 'bar', 'baz', 'foo'],
...                     'value': [5, 6, 7, 8]})
>>> df1
   lkey  value
0  foo     1
1  bar     2
2  baz     3
3  foo     5
>>> df2
   rkey  value
0  foo     5
1  bar     6
2  baz     7
3  foo     8
```

Merge `df1` and `df2` on the `lkey` and `rkey` columns. The value columns have the default suffixes, `_x` and `_y`, appended.

```
>>> df1.merge(df2, left_on='lkey', right_on='rkey')
   lkey  value_x  rkey  value_y
0  foo         1  foo         5
1  foo         1  foo         8
2  foo         5  foo         5
3  foo         5  foo         8
4  bar         2  bar         6
5  baz         3  baz         7
```

Merge DataFrames `df1` and `df2` with specified left and right suffixes appended to any overlapping columns.

```
>>> df1.merge(df2, left_on='lkey', right_on='rkey',
...           suffixes=('_left', '_right'))
   lkey  value_left  rkey  value_right
0  foo           1  foo           5
1  foo           1  foo           8
2  foo           5  foo           5
```

(continues on next page)

(continued from previous page)

3	foo	5	foo	8
4	bar	2	bar	6
5	baz	3	baz	7

Merge DataFrames `df1` and `df2`, but raise an exception if the DataFrames have any overlapping columns.

```
>>> df1.merge(df2, left_on='lkey', right_on='rkey', suffixes=(False, False))
Traceback (most recent call last):
...
ValueError: columns overlap but no suffix specified:
      Index(['value'], dtype='object')
```

pandas.DataFrame.min

`DataFrame.min(self, axis=None, skipna=None, level=None, numeric_only=None, **kwargs)`

Return the minimum of the values for the requested axis.

If you want the *index* of the minimum, use `idxmin`. This is the equivalent of the `numpy.ndarray` method `argmin`.

Parameters

axis [{index (0), columns (1)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

See also:

`Series.sum` Return the sum.

`Series.min` Return the minimum.

`Series.max` Return the maximum.

`Series.idxmin` Return the index of the minimum.

`Series.idxmax` Return the index of the maximum.

`DataFrame.sum` Return the sum over the requested axis.

`DataFrame.min` Return the minimum over the requested axis.

`DataFrame.max` Return the maximum over the requested axis.

`DataFrame.idxmin` Return the index of the minimum over the requested axis.

`DataFrame.idxmax` Return the index of the maximum over the requested axis.

Examples

```
>>> idx = pd.MultiIndex.from_arrays([
...     ['warm', 'warm', 'cold', 'cold'],
...     ['dog', 'falcon', 'fish', 'spider']],
...     names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded  animal
warm     dog      4
         falcon   2
cold     fish     0
         spider   8
Name: legs, dtype: int64
```

```
>>> s.min()
0
```

Min using level names, as well as indices.

```
>>> s.min(level='blooded')
blooded
warm     2
cold     0
Name: legs, dtype: int64
```

```
>>> s.min(level=0)
blooded
warm     2
cold     0
Name: legs, dtype: int64
```

pandas.DataFrame.mod

`DataFrame.mod(self, other, axis='columns', level=None, fill_value=None)`

Get Modulo of dataframe and other, element-wise (binary operator `mod`).

Equivalent to `dataframe % other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, `rmod`.

Among flexible wrappers (`add`, `sub`, `mul`, `div`, `mod`, `pow`) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.

DataFrame.sub Subtract DataFrames.

DataFrame.mul Multiply DataFrames.

DataFrame.div Divide DataFrames (float division).

DataFrame.truediv Divide DataFrames (float division).

DataFrame.floordiv Divide DataFrames (integer division).

DataFrame.mod Calculate modulo (remainder after division).

DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

	angles	degrees
circle	0	360
triangle	3	180
rectangle	4	360

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

```
>>> df.add(1)
```

	angles	degrees
circle	1	361

(continues on next page)

(continued from previous page)

triangle	4	181
rectangle	5	361

Divide by constant with reverse version.

```
>>> df.div(10)
      angles  degrees
circle    0.0    36.0
triangle  0.3    18.0
rectangle 0.4    36.0
```

```
>>> df.rdiv(10)
      angles  degrees
circle    inf  0.027778
triangle  3.333333  0.055556
rectangle 2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
      angles  degrees
circle    -1    358
triangle  2     178
rectangle 3     358
```

```
>>> df.sub([1, 2], axis='columns')
      angles  degrees
circle    -1    358
triangle  2     178
rectangle 3     358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
      angles  degrees
circle    -1    359
triangle  2     179
rectangle 3     359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
      angles
circle    0
triangle  3
rectangle 4
```

```
>>> df * other
      angles  degrees
circle    0     NaN
```

(continues on next page)

(continued from previous page)

triangle	9	NaN
rectangle	16	NaN

```
>>> df.mul(other, fill_value=0)
      angles  degrees
circle      0    0.0
triangle    9    0.0
rectangle   16    0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                               index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                       ['circle', 'triangle', 'rectangle',
...                                        'square', 'pentagon', 'hexagon']])
>>> df_multindex
      angles  degrees
A circle      0    360
  triangle    3    180
  rectangle    4    360
B square      4    360
  pentagon    5    540
  hexagon     6    720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
      angles  degrees
A circle   NaN     1.0
  triangle  1.0     1.0
  rectangle 1.0     1.0
B square   0.0     0.0
  pentagon 0.0     0.0
  hexagon  0.0     0.0
```

pandas.DataFrame.mode

`DataFrame.mode(self, axis=0, numeric_only=False, dropna=True)`

Get the mode(s) of each element along the selected axis.

The mode of a set of values is the value that appears most often. It can be multiple values.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] The axis to iterate over while searching for the mode:

- 0 or 'index' : get mode of each column
- 1 or 'columns' : get mode of each row

numeric_only [bool, default False] If True, only apply to numeric columns.

dropna [bool, default True] Don't consider counts of NaN/NaT.

New in version 0.24.0.

Returns

DataFrame The modes of each column or row.

See also:

Series.mode Return the highest frequency value in a Series.

Series.value_counts Return the counts of values in a Series.

Examples

```
>>> df = pd.DataFrame([('bird', 2, 2),
...                    ('mammal', 4, np.nan),
...                    ('arthropod', 8, 0),
...                    ('bird', 2, np.nan)],
...                    index=('falcon', 'horse', 'spider', 'ostrich'),
...                    columns=('species', 'legs', 'wings'))
>>> df
```

	species	legs	wings
falcon	bird	2	2.0
horse	mammal	4	NaN
spider	arthropod	8	0.0
ostrich	bird	2	NaN

By default, missing values are not considered, and the mode of wings are both 0 and 2. The second row of species and legs contains NaN, because they have only one mode, but the DataFrame has two rows.

```
>>> df.mode()
   species  legs  wings
0   bird    2.0   0.0
1   NaN    NaN   2.0
```

Setting `dropna=False` NaN values are considered and they can be the mode (like for wings).

```
>>> df.mode(dropna=False)
   species  legs  wings
0   bird    2   NaN
```

Setting `numeric_only=True`, only the mode of numeric columns is computed, and columns of other types are ignored.

```
>>> df.mode(numeric_only=True)
   legs  wings
0   2.0   0.0
1   NaN   2.0
```

To compute the mode over columns and not rows, use the `axis` parameter:

```
>>> df.mode(axis='columns', numeric_only=True)
           0    1
falcon    2.0  NaN
horse     4.0  NaN
```

(continues on next page)

(continued from previous page)

spider	0.0	8.0
ostrich	2.0	NaN

pandas.DataFrame.mul**DataFrame.mul**(*self*, *other*, *axis*='columns', *level*=None, *fill_value*=None)Get Multiplication of dataframe and other, element-wise (binary operator *mul*).Equivalent to `dataframe * other`, but with support to substitute a *fill_value* for missing data in one of the inputs. With reverse version, *rmul*.Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: *+*, *-*, ***, */*, *//*, *%*, ****.**Parameters****other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.**axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.**level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.**fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.**Returns****DataFrame** Result of the arithmetic operation.**See also:****DataFrame.add** Add DataFrames.**DataFrame.sub** Subtract DataFrames.**DataFrame.mul** Multiply DataFrames.**DataFrame.div** Divide DataFrames (float division).**DataFrame.truediv** Divide DataFrames (float division).**DataFrame.floordiv** Divide DataFrames (integer division).**DataFrame.mod** Calculate modulo (remainder after division).**DataFrame.pow** Calculate exponential power.**Notes**

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

	angles	degrees
circle	0	360
triangle	3	180
rectangle	4	360

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

```
>>> df.add(1)
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

Divide by constant with reverse version.

```
>>> df.div(10)
```

	angles	degrees
circle	0.0	36.0
triangle	0.3	18.0
rectangle	0.4	36.0

```
>>> df.rdiv(10)
```

	angles	degrees
circle	inf	0.027778
triangle	3.333333	0.055556
rectangle	2.500000	0.027778

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
```

	angles	degrees
circle	-1	358
triangle	2	178
rectangle	3	358

```
>>> df.sub([1, 2], axis='columns')
```

	angles	degrees
circle	-1	358
triangle	2	178
rectangle	3	358

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...         axis='index')
           angles  degrees
circle         -1     359
triangle        2     179
rectangle        3     359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
           angles
circle          0
triangle         3
rectangle        4
```

```
>>> df * other
           angles  degrees
circle          0     NaN
triangle         9     NaN
rectangle       16     NaN
```

```
>>> df.mul(other, fill_value=0)
           angles  degrees
circle          0     0.0
triangle         9     0.0
rectangle       16     0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                               index=[[ 'A', 'A', 'A', 'B', 'B', 'B'],
...                                       ['circle', 'triangle', 'rectangle',
...                                        'square', 'pentagon', 'hexagon']])
>>> df_multindex
           angles  degrees
A circle          0     360
  triangle         3     180
  rectangle         4     360
B square          4     360
  pentagon         5     540
  hexagon          6     720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
           angles  degrees
A circle        NaN     1.0
  triangle        1.0     1.0
  rectangle        1.0     1.0
B square         0.0     0.0
  pentagon         0.0     0.0
  hexagon         0.0     0.0
```

pandas.DataFrame.multiply

`DataFrame.multiply(self, other, axis='columns', level=None, fill_value=None)`

Get Multiplication of dataframe and other, element-wise (binary operator *mul*).

Equivalent to `dataframe * other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *rmul*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

`DataFrame.add` Add DataFrames.

`DataFrame.sub` Subtract DataFrames.

`DataFrame.mul` Multiply DataFrames.

`DataFrame.div` Divide DataFrames (float division).

`DataFrame.truediv` Divide DataFrames (float division).

`DataFrame.floordiv` Divide DataFrames (integer division).

`DataFrame.mod` Calculate modulo (remainder after division).

`DataFrame.pow` Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
```

	angles	degrees
A circle	NaN	1.0
triangle	1.0	1.0
rectangle	1.0	1.0
B square	0.0	0.0
pentagon	0.0	0.0
hexagon	0.0	0.0

pandas.DataFrame.ne**DataFrame.ne**(*self*, *other*, *axis*='columns', *level*=None)Get Not equal to of dataframe and other, element-wise (binary operator *ne*).Among flexible wrappers (*eq*, *ne*, *le*, *lt*, *ge*, *gt*) to comparison operators.Equivalent to `==`, `!=`, `<=`, `<`, `>=`, `>` with support to choose axis (rows or columns) and level for comparison.**Parameters****other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.**axis** [{0 or 'index', 1 or 'columns'}], default 'columns' Whether to compare by the index (0 or 'index') or columns (1 or 'columns').**level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.**Returns****DataFrame of bool** Result of the comparison.**See also:****DataFrame.eq** Compare DataFrames for equality elementwise.**DataFrame.ne** Compare DataFrames for inequality elementwise.**DataFrame.le** Compare DataFrames for less than inequality or equality elementwise.**DataFrame.lt** Compare DataFrames for strictly less than inequality elementwise.**DataFrame.ge** Compare DataFrames for greater than inequality or equality elementwise.**DataFrame.gt** Compare DataFrames for strictly greater than inequality elementwise.**Notes**Mismatched indices will be unioned together. *NaN* values are considered different (i.e. *NaN* != *NaN*).**Examples**

```

>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                    'revenue': [100, 250, 300]},
...                    index=['A', 'B', 'C'])
>>> df
   cost  revenue
A   250     100
B   150     250
C   100     300

```

Comparison with a scalar, using either the operator or method:

```
>>> df == 100
      cost  revenue
A  False    True
B  False   False
C   True   False
```

```
>>> df.eq(100)
      cost  revenue
A  False    True
B  False   False
C   True   False
```

When *other* is a *Series*, the columns of a DataFrame are aligned with the index of *other* and broadcast:

```
>>> df != pd.Series([100, 250], index=["cost", "revenue"])
      cost  revenue
A   True    True
B   True   False
C  False    True
```

Use the method to control the broadcast axis:

```
>>> df.ne(pd.Series([100, 300], index=["A", "D"]), axis='index')
      cost  revenue
A   True   False
B   True    True
C   True    True
D   True    True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in *other*:

```
>>> df == [250, 100]
      cost  revenue
A   True    True
B  False   False
C  False   False
```

Use the method to control the axis:

```
>>> df.eq([250, 250, 100], axis='index')
      cost  revenue
A   True   False
B  False    True
C   True   False
```

Compare to a DataFrame of different shape.

```
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
...                       index=['A', 'B', 'C', 'D'])
>>> other
      revenue
```

(continues on next page)

(continued from previous page)

A	300
B	250
C	100
D	150

```
>>> df.gt(other)
      cost  revenue
A  False   False
B  False   False
C  False    True
D  False   False
```

Compare to a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
...                               'revenue': [100, 250, 300, 200, 175, 225]},
...                               index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
...                                       ['A', 'B', 'C', 'A', 'B', 'C']])
>>> df_multindex
      cost  revenue
Q1 A   250     100
   B   150     250
   C   100     300
Q2 A   150     200
   B   300     175
   C   220     225
```

```
>>> df.le(df_multindex, level=1)
      cost  revenue
Q1 A   True    True
   B   True    True
   C   True    True
Q2 A  False    True
   B   True   False
   C   True   False
```

pandas.DataFrame.nlargest

DataFrame.nlargest(*self*, *n*, *columns*, *keep*='first')

Return the first *n* rows ordered by *columns* in descending order.

Return the first *n* rows with the largest values in *columns*, in descending order. The columns that are not specified are returned as well, but not used for ordering.

This method is equivalent to `df.sort_values(columns, ascending=False).head(n)`, but more performant.

Parameters

n [int] Number of rows to return.

columns [label or list of labels] Column label(s) to order by.

keep [{'first', 'last', 'all'}, default 'first'] Where there are duplicate values:

- *first* : prioritize the first occurrence(s)
- *last* : prioritize the last occurrence(s)
- **all** [do not drop any duplicates, even it means] selecting more than *n* items.

New in version 0.24.0.

Returns

DataFrame The first *n* rows ordered by the given columns in descending order.

See also:

DataFrame.nsmallest Return the first *n* rows ordered by *columns* in ascending order.

DataFrame.sort_values Sort DataFrame by the values.

DataFrame.head Return the first *n* rows without re-ordering.

Notes

This function cannot be used with all column types. For example, when specifying columns with *object* or *category* dtypes, `TypeError` is raised.

Examples

```
>>> df = pd.DataFrame({'population': [59000000, 65000000, 434000,
...                                  434000, 434000, 337000, 11300,
...                                  11300, 11300],
...                    'GDP': [1937894, 2583560, 12011, 4520, 12128,
...                              17036, 182, 38, 311],
...                    'alpha-2': ["IT", "FR", "MT", "MV", "BN",
...                                  "IS", "NR", "TV", "AI"]},
...                    index=["Italy", "France", "Malta",
...                              "Maldives", "Brunei", "Iceland",
...                              "Nauru", "Tuvalu", "Anguilla"])
>>> df
```

	population	GDP	alpha-2
Italy	59000000	1937894	IT
France	65000000	2583560	FR
Malta	434000	12011	MT
Maldives	434000	4520	MV
Brunei	434000	12128	BN
Iceland	337000	17036	IS
Nauru	11300	182	NR
Tuvalu	11300	38	TV
Anguilla	11300	311	AI

In the following example, we will use `nlargest` to select the three rows having the largest values in column “population”.

```
>>> df.nlargest(3, 'population')
```

	population	GDP	alpha-2
France	65000000	2583560	FR

(continues on next page)

(continued from previous page)

Italy	59000000	1937894	IT
Malta	434000	12011	MT

When using `keep='last'`, ties are resolved in reverse order:

```
>>> df.nlargest(3, 'population', keep='last')
      population      GDP alpha-2
France  65000000  2583560      FR
Italy   59000000  1937894      IT
Brunei   434000    12128      BN
```

When using `keep='all'`, all duplicate items are maintained:

```
>>> df.nlargest(3, 'population', keep='all')
      population      GDP alpha-2
France  65000000  2583560      FR
Italy   59000000  1937894      IT
Malta   434000    12011      MT
Maldives 434000    4520      MV
Brunei  434000    12128      BN
```

To order by the largest values in column “population” and then “GDP”, we can specify multiple columns like in the next example.

```
>>> df.nlargest(3, ['population', 'GDP'])
      population      GDP alpha-2
France  65000000  2583560      FR
Italy   59000000  1937894      IT
Brunei   434000    12128      BN
```

pandas.DataFrame.notna

`DataFrame.notna(self)`

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`). NA values, such as None or `numpy.NaN`, get mapped to False values.

Returns

DataFrame Mask of bool values for each element in DataFrame that indicates whether an element is not an NA value.

See also:

`DataFrame.notnull` Alias of `notna`.

`DataFrame.isna` Boolean inverse of `notna`.

`DataFrame.dropna` Omit axes labels with missing values.

`notna` Top-level `notna`.

Examples

Show which entries in a DataFrame are not NA.

```
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
...                    'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                             pd.Timestamp('1940-04-25')],
...                    'name': ['Alfred', 'Batman', ''],
...                    'toy': [None, 'Batmobile', 'Joker']})
>>> df
   age      born  name      toy
0  5.0      NaT  Alfred  None
1  6.0 1939-05-27  Batman  Batmobile
2  NaN 1940-04-25           Joker
```

```
>>> df.notna()
   age  born  name  toy
0  True False  True False
1  True  True  True  True
2  False  True  True  True
```

Show which entries in a Series are not NA.

```
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2    NaN
dtype: float64
```

```
>>> ser.notna()
0     True
1     True
2    False
dtype: bool
```

pandas.DataFrame.notnull

`DataFrame.notnull(self)`

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`). NA values, such as `None` or `numpy.NaN`, get mapped to False values.

Returns

DataFrame Mask of bool values for each element in DataFrame that indicates whether an element is not an NA value.

See also:

`DataFrame.notnull` Alias of `notna`.

DataFrame.isna Boolean inverse of notna.

DataFrame.dropna Omit axes labels with missing values.

notna Top-level notna.

Examples

Show which entries in a DataFrame are not NA.

```
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
...                    'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                             pd.Timestamp('1940-04-25')],
...                    'name': ['Alfred', 'Batman', ''],
...                    'toy': [None, 'Batmobile', 'Joker']})
>>> df
   age      born  name      toy
0  5.0      NaT  Alfred    None
1  6.0  1939-05-27  Batman  Batmobile
2  NaN  1940-04-25         Joker
```

```
>>> df.notna()
   age  born  name  toy
0  True False  True False
1  True  True  True  True
2  False  True  True  True
```

Show which entries in a Series are not NA.

```
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2    NaN
dtype: float64
```

```
>>> ser.notna()
0    True
1    True
2    False
dtype: bool
```

pandas.DataFrame.nsmallest

DataFrame.nsmallest(*self*, *n*, *columns*, *keep*='first')

Return the first *n* rows ordered by *columns* in ascending order.

Return the first *n* rows with the smallest values in *columns*, in ascending order. The columns that are not specified are returned as well, but not used for ordering.

This method is equivalent to `df.sort_values(columns, ascending=True).head(n)`, but more performant.

Parameters

n [int] Number of items to retrieve.

columns [list or str] Column name or names to order by.

keep [{'first', 'last', 'all'}, default 'first'] Where there are duplicate values:

- **first** : take the first occurrence.
- **last** : take the last occurrence.
- **all** : do not drop any duplicates, even it means selecting more than *n* items.

New in version 0.24.0.

Returns

DataFrame

See also:

DataFrame.nlargest Return the first *n* rows ordered by *columns* in descending order.

DataFrame.sort_values Sort DataFrame by the values.

DataFrame.head Return the first *n* rows without re-ordering.

Examples

```
>>> df = pd.DataFrame({'population': [59000000, 65000000, 434000,
...                                  434000, 434000, 337000, 11300,
...                                  11300, 11300],
...                    'GDP': [1937894, 2583560, 12011, 4520, 12128,
...                             17036, 182, 38, 311],
...                    'alpha-2': ["IT", "FR", "MT", "MV", "BN",
...                                  "IS", "NR", "TV", "AI"]},
...                    index=["Italy", "France", "Malta",
...                             "Maldives", "Brunei", "Iceland",
...                             "Nauru", "Tuvalu", "Anguilla"])
>>> df
```

	population	GDP	alpha-2
Italy	59000000	1937894	IT
France	65000000	2583560	FR
Malta	434000	12011	MT
Maldives	434000	4520	MV
Brunei	434000	12128	BN
Iceland	337000	17036	IS
Nauru	11300	182	NR
Tuvalu	11300	38	TV
Anguilla	11300	311	AI

In the following example, we will use **nsmallest** to select the three rows having the smallest values in column “a”.

```
>>> df.nsmallest(3, 'population')
```

	population	GDP	alpha-2
Nauru	11300	182	NR
Tuvalu	11300	38	TV
Anguilla	11300	311	AI

When using `keep='last'`, ties are resolved in reverse order:

```
>>> df.nsmallest(3, 'population', keep='last')
      population  GDP alpha-2
Anguilla      11300   311      AI
Tuvalu        11300    38      TV
Nauru         11300   182      NR
```

When using `keep='all'`, all duplicate items are maintained:

```
>>> df.nsmallest(3, 'population', keep='all')
      population  GDP alpha-2
Nauru         11300   182      NR
Tuvalu        11300    38      TV
Anguilla      11300   311      AI
```

To order by the largest values in column “a” and then “c”, we can specify multiple columns like in the next example.

```
>>> df.nsmallest(3, ['population', 'GDP'])
      population  GDP alpha-2
Tuvalu        11300    38      TV
Nauru         11300   182      NR
Anguilla      11300   311      AI
```

pandas.DataFrame.nunique

`DataFrame.nunique(self, axis=0, dropna=True)`

Count distinct observations over requested axis.

Return Series with number of distinct observations. Can ignore NaN values.

New in version 0.20.0.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] The axis to use. 0 or 'index' for row-wise, 1 or 'columns' for column-wise.

dropna [bool, default True] Don't include NaN in the counts.

Returns

Series

See also:

`Series.nunique` Method `nunique` for Series.

`DataFrame.count` Count non-NA cells for each column or row.

Examples

```
>>> df = pd.DataFrame({'A': [1, 2, 3], 'B': [1, 1, 1]})
>>> df.nunique()
A      3
```

(continues on next page)

(continued from previous page)

```
B    1
dtype: int64
```

```
>>> df.nunique(axis=1)
0    1
1    2
2    2
dtype: int64
```

pandas.DataFrame.pct_change

`DataFrame.pct_change(self, periods=1, fill_method='pad', limit=None, freq=None, **kwargs)`
 Percentage change between the current and a prior element.

Computes the percentage change from the immediately previous row by default. This is useful in comparing the percentage of change in a time series of elements.

Parameters

periods [int, default 1] Periods to shift for forming percent change.

fill_method [str, default 'pad'] How to handle NAs before computing percent changes.

limit [int, default None] The number of consecutive NAs to fill before stopping.

freq [DateOffset, timedelta, or offset alias string, optional] Increment to use from time series API (e.g. 'M' or BDay()).

****kwargs** Additional keyword arguments are passed into `DataFrame.shift` or `Series.shift`.

Returns

chg [Series or DataFrame] The same type as the calling object.

See also:

`Series.diff` Compute the difference of two elements in a Series.

`DataFrame.diff` Compute the difference of two elements in a DataFrame.

`Series.shift` Shift the index by some number of periods.

`DataFrame.shift` Shift the index by some number of periods.

Examples

Series

```
>>> s = pd.Series([90, 91, 85])
>>> s
0    90
1    91
2    85
dtype: int64
```

```
>>> s.pct_change()
0      NaN
1    0.011111
2   -0.065934
dtype: float64
```

```
>>> s.pct_change( periods=2)
0      NaN
1      NaN
2   -0.055556
dtype: float64
```

See the percentage change in a Series where filling NAs with last valid observation forward to next valid.

```
>>> s = pd.Series([90, 91, None, 85])
>>> s
0    90.0
1    91.0
2     NaN
3    85.0
dtype: float64
```

```
>>> s.pct_change(fill_method='ffill')
0      NaN
1    0.011111
2    0.000000
3   -0.065934
dtype: float64
```

DataFrame

Percentage change in French franc, Deutsche Mark, and Italian lira from 1980-01-01 to 1980-03-01.

```
>>> df = pd.DataFrame({
...     'FR': [4.0405, 4.0963, 4.3149],
...     'GR': [1.7246, 1.7482, 1.8519],
...     'IT': [804.74, 810.01, 860.13]},
...     index=['1980-01-01', '1980-02-01', '1980-03-01'])
>>> df
              FR      GR      IT
1980-01-01  4.0405  1.7246  804.74
1980-02-01  4.0963  1.7482  810.01
1980-03-01  4.3149  1.8519  860.13
```

```
>>> df.pct_change()
              FR      GR      IT
1980-01-01     NaN     NaN     NaN
1980-02-01  0.013810  0.013684  0.006549
1980-03-01  0.053365  0.059318  0.061876
```

Percentage of change in GOOG and APPL stock volume. Shows computing the percentage change between columns.

```
>>> df = pd.DataFrame({
...     '2016': [1769950, 30586265],
...     '2015': [1500923, 40912316],
...     '2014': [1371819, 41403351]},
...     index=['GOOG', 'APPL'])
>>> df
```

	2016	2015	2014
GOOG	1769950	1500923	1371819
APPL	30586265	40912316	41403351

```
>>> df.pct_change(axis='columns')
```

	2016	2015	2014
GOOG	NaN	-0.151997	-0.086016
APPL	NaN	0.337604	0.012002

pandas.DataFrame.pipe

`DataFrame.pipe(self, func, *args, **kwargs)`
Apply `func`(`self`, `*args`, `**kwargs`).

Parameters

func [function] function to apply to the Series/DataFrame. `args`, and `kwargs` are passed into `func`. Alternatively a (`callable`, `data_keyword`) tuple where `data_keyword` is a string indicating the keyword of `callable` that expects the Series/DataFrame.

args [iterable, optional] positional arguments passed into `func`.

kwargs [mapping, optional] a dictionary of keyword arguments passed into `func`.

Returns

object [the return type of `func`.]

See also:

`DataFrame.apply`

`DataFrame.applymap`

`Series.map`

Notes

Use `.pipe` when chaining together functions that expect Series, DataFrames or GroupBy objects. Instead of writing

```
>>> f(g(h(df), arg1=a), arg2=b, arg3=c)
```

You can write

```
>>> (df.pipe(h)
...   .pipe(g, arg1=a)
```

(continues on next page)

(continued from previous page)

```
...     .pipe(f, arg2=b, arg3=c)
... )
```

If you have a function that takes the data as (say) the second argument, pass a tuple indicating which keyword expects the data. For example, suppose `f` takes its data as `arg2`:

```
>>> (df.pipe(h)
...     .pipe(g, arg1=a)
...     .pipe((f, 'arg2'), arg1=a, arg3=c)
... )
```

pandas.DataFrame.pivot

`DataFrame.pivot`(*self*, *index=None*, *columns=None*, *values=None*)

Return reshaped DataFrame organized by given index / column values.

Reshape data (produce a “pivot” table) based on column values. Uses unique values from specified *index* / *columns* to form axes of the resulting DataFrame. This function does not support data aggregation, multiple values will result in a MultiIndex in the columns. See the *User Guide* for more on reshaping.

Parameters

index [string or object, optional] Column to use to make new frame’s index. If None, uses existing index.

columns [string or object] Column to use to make new frame’s columns.

values [string, object or a list of the previous, optional] Column(s) to use for populating new frame’s values. If not specified, all remaining columns will be used and the result will have hierarchically indexed columns.

Changed in version 0.23.0: Also accept list of column names.

Returns

DataFrame Returns reshaped DataFrame.

Raises

ValueError: When there are any *index*, *columns* combinations with multiple values. *DataFrame.pivot_table* when you need to aggregate.

See also:

DataFrame.pivot_table Generalization of pivot that can handle duplicate values for one index/column pair.

DataFrame.unstack Pivot based on the index values instead of a column.

Notes

For finer-tuned control, see hierarchical indexing documentation along with the related `stack/unstack` methods.

Examples

```
>>> df = pd.DataFrame({'foo': ['one', 'one', 'one', 'two', 'two',
...                             'two'],
...                    'bar': ['A', 'B', 'C', 'A', 'B', 'C'],
...                    'baz': [1, 2, 3, 4, 5, 6],
...                    'zoo': ['x', 'y', 'z', 'q', 'w', 't']})
>>> df
   foo  bar  baz  zoo
0  one   A    1    x
1  one   B    2    y
2  one   C    3    z
3  two   A    4    q
4  two   B    5    w
5  two   C    6    t
```

```
>>> df.pivot(index='foo', columns='bar', values='baz')
bar  A  B  C
foo
one  1  2  3
two  4  5  6
```

```
>>> df.pivot(index='foo', columns='bar')['baz']
bar  A  B  C
foo
one  1  2  3
two  4  5  6
```

```
>>> df.pivot(index='foo', columns='bar', values=['baz', 'zoo'])
      baz      zoo
bar  A B C  A B C
foo
one  1 2 3  x y z
two  4 5 6  q w t
```

A `ValueError` is raised if there are any duplicates.

```
>>> df = pd.DataFrame({"foo": ['one', 'one', 'two', 'two'],
...                    "bar": ['A', 'A', 'B', 'C'],
...                    "baz": [1, 2, 3, 4]})
>>> df
   foo bar  baz
0  one  A    1
1  one  A    2
2  two  B    3
3  two  C    4
```

Notice that the first two rows are the same for our *index* and *columns* arguments.

```
>>> df.pivot(index='foo', columns='bar', values='baz')
Traceback (most recent call last):
...
ValueError: Index contains duplicate entries, cannot reshape
```

pandas.DataFrame.pivot_table

```
DataFrame.pivot_table(self, values=None, index=None, columns=None, agg-
func='mean', fill_value=None, margins=False, dropna=True,
margins_name='All', observed=False)
```

Create a spreadsheet-style pivot table as a DataFrame. The levels in the pivot table will be stored in MultiIndex objects (hierarchical indexes) on the index and columns of the result DataFrame.

Parameters

values [column to aggregate, optional]

index [column, Grouper, array, or list of the previous] If an array is passed, it must be the same length as the data. The list can contain any of the other types (except list). Keys to group by on the pivot table index. If an array is passed, it is being used as the same manner as column values.

columns [column, Grouper, array, or list of the previous] If an array is passed, it must be the same length as the data. The list can contain any of the other types (except list). Keys to group by on the pivot table column. If an array is passed, it is being used as the same manner as column values.

aggfunc [function, list of functions, dict, default numpy.mean] If list of functions passed, the resulting pivot table will have hierarchical columns whose top level are the function names (inferred from the function objects themselves) If dict is passed, the key is column to aggregate and value is function or list of functions

fill_value [scalar, default None] Value to replace missing values with

margins [boolean, default False] Add all row / columns (e.g. for subtotal / grand totals)

dropna [boolean, default True] Do not include columns whose entries are all NaN

margins_name [string, default 'All'] Name of the row / column that will contain the totals when margins is True.

observed [boolean, default False] This only applies if any of the groupers are Categoricals. If True: only show observed values for categorical groupers. If False: show all values for categorical groupers.

Changed in version 0.25.0.

Returns

DataFrame

See also:

DataFrame.pivot Pivot without aggregation that can handle non-numeric data.

Examples

```
>>> df = pd.DataFrame({"A": ["foo", "foo", "foo", "foo", "foo",
...                          "bar", "bar", "bar", "bar"],
...                   "B": ["one", "one", "one", "two", "two",
...                          "one", "one", "two", "two"],
...                   "C": ["small", "large", "large", "small",
...                          "small", "large", "small", "small"]})
```

(continues on next page)

(continued from previous page)

```

...         "large"],
...         "D": [1, 2, 2, 3, 3, 4, 5, 6, 7],
...         "E": [2, 4, 5, 5, 6, 6, 8, 9, 9])
>>> df
   A  B    C  D  E
0  foo one small 1  2
1  foo one large 2  4
2  foo one large 2  5
3  foo two small 3  5
4  foo two small 3  6
5  bar one large 4  6
6  bar one small 5  8
7  bar two small 6  9
8  bar two large 7  9

```

This first example aggregates values by taking the sum.

```

>>> table = pd.pivot_table(df, values='D', index=['A', 'B'],
...                          columns=['C'], aggfunc=np.sum)
>>> table
C      large  small
A  B
bar one    4.0    5.0
   two    7.0    6.0
foo one    4.0    1.0
   two    NaN    6.0

```

We can also fill missing values using the *fill_value* parameter.

```

>>> table = pd.pivot_table(df, values='D', index=['A', 'B'],
...                          columns=['C'], aggfunc=np.sum, fill_value=0)
>>> table
C      large  small
A  B
bar one     4     5
   two     7     6
foo one     4     1
   two     0     6

```

The next example aggregates by taking the mean across multiple columns.

```

>>> table = pd.pivot_table(df, values=['D', 'E'], index=['A', 'C'],
...                          aggfunc={'D': np.mean,
...                                    'E': np.mean})
>>> table
   A  C      D      E
bar large  5.500000  7.500000
   small  5.500000  8.500000
foo large  2.000000  4.500000
   small  2.333333  4.333333

```

We can also calculate multiple types of aggregations for any given value column.

```

>>> table = pd.pivot_table(df, values=['D', 'E'], index=['A', 'C'],
...                          aggfunc={'D': np.mean,
...                                    'E': [min, max, np.mean]})
>>> table

```

		D		E	
		mean	max	mean	min
A	C				
bar	large	5.500000	9.0	7.500000	6.0
	small	5.500000	9.0	8.500000	8.0
foo	large	2.000000	5.0	4.500000	4.0
	small	2.333333	6.0	4.333333	2.0

pandas.DataFrame.plot

`DataFrame.plot(self, *args, **kwargs)`
 Call self as a function.

pandas.DataFrame.pop

`DataFrame.pop(self, item)`
 Return item and drop from frame. Raise `KeyError` if not found.

Parameters

`item` [str] Label of column to be popped.

Returns

Series

Examples

```

>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
...                    ('parrot', 'bird', 24.0),
...                    ('lion', 'mammal', 80.5),
...                    ('monkey', 'mammal', np.nan)],
...                    columns=('name', 'class', 'max_speed'))
>>> df

```

	name	class	max_speed
0	falcon	bird	389.0
1	parrot	bird	24.0
2	lion	mammal	80.5
3	monkey	mammal	NaN

```

>>> df.pop('class')
0    bird
1    bird
2    mammal
3    mammal
Name: class, dtype: object

```

```
>>> df
   name  max_speed
0  falcon    389.0
1  parrot    24.0
2   lion    80.5
3  monkey     NaN
```

pandas.DataFrame.pow

DataFrame.pow(*self*, *other*, *axis*='columns', *level*=None, *fill_value*=None)

Get Exponential power of dataframe and other, element-wise (binary operator *pow*).

Equivalent to `dataframe ** other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, `rpow`.

Among flexible wrappers (`add`, `sub`, `mul`, `div`, `mod`, `pow`) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.

DataFrame.sub Subtract DataFrames.

DataFrame.mul Multiply DataFrames.

DataFrame.div Divide DataFrames (float division).

DataFrame.truediv Divide DataFrames (float division).

DataFrame.floordiv Divide DataFrames (integer division).

DataFrame.mod Calculate modulo (remainder after division).

DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

	angles	degrees
circle	0	360
triangle	3	180
rectangle	4	360

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

```
>>> df.add(1)
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

Divide by constant with reverse version.

```
>>> df.div(10)
```

	angles	degrees
circle	0.0	36.0
triangle	0.3	18.0
rectangle	0.4	36.0

```
>>> df.rdiv(10)
```

	angles	degrees
circle	inf	0.027778
triangle	3.333333	0.055556
rectangle	2.500000	0.027778

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
```

	angles	degrees
circle	-1	358
triangle	2	178
rectangle	3	358

```
>>> df.sub([1, 2], axis='columns')
```

	angles	degrees
circle	-1	358
triangle	2	178
rectangle	3	358

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...         axis='index')
           angles  degrees
circle         -1     359
triangle        2     179
rectangle        3     359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
           angles
circle          0
triangle         3
rectangle        4
```

```
>>> df * other
           angles  degrees
circle          0     NaN
triangle         9     NaN
rectangle       16     NaN
```

```
>>> df.mul(other, fill_value=0)
           angles  degrees
circle          0     0.0
triangle         9     0.0
rectangle       16     0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                              index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                     ['circle', 'triangle', 'rectangle',
...                                      'square', 'pentagon', 'hexagon']])
>>> df_multindex
           angles  degrees
A circle          0     360
  triangle         3     180
  rectangle        4     360
B square          4     360
  pentagon         5     540
  hexagon          6     720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
           angles  degrees
A circle        NaN     1.0
  triangle        1.0     1.0
  rectangle        1.0     1.0
B square         0.0     0.0
  pentagon         0.0     0.0
  hexagon         0.0     0.0
```

pandas.DataFrame.prod

```
DataFrame.prod(self, axis=None, skipna=None, level=None, numeric_only=None,
               min_count=0, **kwargs)
```

Return the product of the values for the requested axis.

Parameters

axis [{index (0), columns (1)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

min_count [int, default 0] The required number of valid values to perform the operation. If fewer than **min_count** non-NA values are present the result will be NA.

New in version 0.22.0: Added with the default being 0. This means the sum of an all-NA or empty Series is 0, and the product of an all-NA or empty Series is 1.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

Examples

By default, the product of an empty or all-NA Series is 1

```
>>> pd.Series([]).prod()
1.0
```

This can be controlled with the **min_count** parameter

```
>>> pd.Series([]).prod(min_count=1)
nan
```

Thanks to the **skipna** parameter, **min_count** handles all-NA and empty series identically.

```
>>> pd.Series([np.nan]).prod()
1.0
```

```
>>> pd.Series([np.nan]).prod(min_count=1)
nan
```

pandas.DataFrame.product

`DataFrame.product(self, axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs)`

Return the product of the values for the requested axis.

Parameters

axis [{index (0), columns (1)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

min_count [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

New in version 0.22.0: Added with the default being 0. This means the sum of an all-NA or empty Series is 0, and the product of an all-NA or empty Series is 1.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

Examples

By default, the product of an empty or all-NA Series is 1

```
>>> pd.Series([]).prod()
1.0
```

This can be controlled with the `min_count` parameter

```
>>> pd.Series([]).prod(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```
>>> pd.Series([np.nan]).prod()
1.0
```

```
>>> pd.Series([np.nan]).prod(min_count=1)
nan
```

pandas.DataFrame.quantile

`DataFrame.quantile(self, q=0.5, axis=0, numeric_only=True, interpolation='linear')`

Return values at the given quantile over requested axis.

Parameters

q [float or array-like, default 0.5 (50% quantile)] Value between $0 \leq q \leq 1$, the quantile(s) to compute.

axis [{0, 1, 'index', 'columns'} (default 0)] Equals 0 or 'index' for row-wise, 1 or 'columns' for column-wise.

numeric_only [bool, default True] If False, the quantile of datetime and timedelta data will be computed as well.

interpolation [{'linear', 'lower', 'higher', 'midpoint', 'nearest'}] This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points i and j :

- linear: $i + (j - i) * fraction$, where *fraction* is the fractional part of the index surrounded by i and j .
- lower: i .
- higher: j .
- nearest: i or j whichever is nearest.
- midpoint: $(i + j) / 2$.

New in version 0.18.0.

Returns

Series or DataFrame

If **q** is an array, a **DataFrame** will be returned where the index is **q**, the columns are the columns of self, and the values are the quantiles.

If **q** is a float, a **Series** will be returned where the index is the columns of self and the values are the quantiles.

See also:

`core.window.Rolling.quantile` Rolling quantile.

`numpy.percentile` Numpy function to compute the percentile.

Examples

```
>>> df = pd.DataFrame(np.array([[1, 1], [2, 10], [3, 100], [4, 100]]),
...                   columns=['a', 'b'])
>>> df.quantile(.1)
a    1.3
b    3.7
Name: 0.1, dtype: float64
>>> df.quantile([.1, .5])
      a    b
0.1  1.3  3.7
0.5  2.5 55.0
```

Specifying `numeric_only=False` will also compute the quantile of datetime and timedelta data.

```

>>> df = pd.DataFrame({'A': [1, 2],
...                     'B': [pd.Timestamp('2010'),
...                             pd.Timestamp('2011')],
...                     'C': [pd.Timedelta('1 days'),
...                             pd.Timedelta('2 days')]})
>>> df.quantile(0.5, numeric_only=False)
A          1.5
B    2010-07-02 12:00:00
C          1 days 12:00:00
Name: 0.5, dtype: object

```

pandas.DataFrame.query

`DataFrame.query(self, expr, inplace=False, **kwargs)`

Query the columns of a DataFrame with a boolean expression.

Parameters

expr [str] The query string to evaluate. You can refer to variables in the environment by prefixing them with an '@' character like @a + b.

New in version 0.25.0.

You can refer to column names that contain spaces by surrounding them in backticks.

For example, if one of your columns is called a a and you want to sum it with b, your query should be `a a` + b.

inplace [bool] Whether the query should modify the data in place or return a modified copy.

****kwargs** See the documentation for `eval()` for complete details on the keyword arguments accepted by `DataFrame.query()`.

New in version 0.18.0.

Returns

DataFrame DataFrame resulting from the provided query expression.

See also:

eval Evaluate a string describing operations on DataFrame columns.

DataFrame.eval Evaluate a string describing operations on DataFrame columns.

Notes

The result of the evaluation of this expression is first passed to `DataFrame.loc` and if that fails because of a multidimensional key (e.g., a DataFrame) then the result will be passed to `DataFrame.__getitem__()`.

This method uses the top-level `eval()` function to evaluate the passed query.

The `query()` method uses a slightly modified Python syntax by default. For example, the `&` and `|` (bitwise) operators have the precedence of their boolean cousins, `and` and `or`. This *is* syntactically valid Python, however the semantics are different.

You can change the semantics of the expression by passing the keyword argument `parser='python'`. This enforces the same semantics as evaluation in Python space. Likewise, you can pass `engine='python'` to evaluate an expression using Python itself as a backend. This is not recommended as it is inefficient compared to using `numexpr` as the engine.

The `DataFrame.index` and `DataFrame.columns` attributes of the `DataFrame` instance are placed in the query namespace by default, which allows you to treat both the index and columns of the frame as a column in the frame. The identifier `index` is used for the frame index; you can also use the name of the index to identify it in a query. Please note that Python keywords may not be used as identifiers.

For further details and examples see the [query](#) documentation in *indexing*.

Examples

```
>>> df = pd.DataFrame({'A': range(1, 6),
...                   'B': range(10, 0, -2),
...                   'C C': range(10, 5, -1)})
>>> df
   A  B  C C
0  1 10  10
1  2  8   9
2  3  6   8
3  4  4   7
4  5  2   6
>>> df.query('A > B')
   A  B  C C
4  5  2   6
```

The previous expression is equivalent to

```
>>> df[df.A > df.B]
   A  B  C C
4  5  2   6
```

For columns with spaces in their name, you can use backtick quoting.

```
>>> df.query('B == `C C`')
   A  B  C C
0  1 10  10
```

The previous expression is equivalent to

```
>>> df[df.B == df['C C']]
   A  B  C C
0  1 10  10
```

pandas.DataFrame.radd

`DataFrame.radd(self, other, axis='columns', level=None, fill_value=None)`

Get Addition of dataframe and other, element-wise (binary operator *radd*).

Equivalent to `other + dataframe`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *add*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: $+$, $-$, $*$, $/$, $//$, $\%$, $**$.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.

DataFrame.sub Subtract DataFrames.

DataFrame.mul Multiply DataFrames.

DataFrame.div Divide DataFrames (float division).

DataFrame.truediv Divide DataFrames (float division).

DataFrame.floordiv Divide DataFrames (integer division).

DataFrame.mod Calculate modulo (remainder after division).

DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
      angles  degrees
circle      0     360
triangle    3     180
rectangle   4     360
```

Add a scalar with operator version which return the same results.

```
>>> df + 1
      angles  degrees
circle      1     361
triangle    4     181
rectangle   5     361
```

```
>>> df.add(1)
      angles  degrees
circle      1     361
triangle    4     181
rectangle   5     361
```

Divide by constant with reverse version.

```
>>> df.div(10)
      angles  degrees
circle    0.0     36.0
triangle  0.3     18.0
rectangle 0.4     36.0
```

```
>>> df.rdiv(10)
      angles  degrees
circle      inf  0.027778
triangle  3.333333  0.055556
rectangle  2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
      angles  degrees
circle     -1     358
triangle    2     178
rectangle   3     358
```

```
>>> df.sub([1, 2], axis='columns')
      angles  degrees
circle     -1     358
triangle    2     178
rectangle   3     358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
      angles  degrees
circle     -1     359
triangle    2     179
rectangle   3     359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
```

(continues on next page)

(continued from previous page)

```

           angles
circle      0
triangle    3
rectangle   4

```

```

>>> df * other
           angles  degrees
circle      0      NaN
triangle    9      NaN
rectangle  16      NaN

```

```

>>> df.mul(other, fill_value=0)
           angles  degrees
circle      0      0.0
triangle    9      0.0
rectangle  16      0.0

```

Divide by a MultiIndex by level.

```

>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                               index=[[ 'A', 'A', 'A', 'B', 'B', 'B'],
...                                       ['circle', 'triangle', 'rectangle',
...                                       'square', 'pentagon', 'hexagon']])
>>> df_multindex
           angles  degrees
A circle      0      360
  triangle    3      180
  rectangle    4      360
B square      4      360
  pentagon    5      540
  hexagon     6      720

```

```

>>> df.div(df_multindex, level=1, fill_value=0)
           angles  degrees
A circle      NaN      1.0
  triangle    1.0      1.0
  rectangle    1.0      1.0
B square      0.0      0.0
  pentagon    0.0      0.0
  hexagon     0.0      0.0

```

pandas.DataFrame.rank

`DataFrame.rank`(*self*, *axis*=0, *method*='average', *numeric_only*=None, *na_option*='keep', *ascending*=True, *pct*=False)

Compute numerical data ranks (1 through n) along axis.

By default, equal values are assigned a rank that is the average of the ranks of those values.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] Index to direct ranking.

method [{‘average’, ‘min’, ‘max’, ‘first’, ‘dense’}, default ‘average’] How to rank the group of records that have the same value (i.e. ties):

- average: average rank of the group
- min: lowest rank in the group
- max: highest rank in the group
- first: ranks assigned in order they appear in the array
- dense: like ‘min’, but rank always increases by 1 between groups

numeric_only [bool, optional] For DataFrame objects, rank only numeric columns if set to True.

na_option [{‘keep’, ‘top’, ‘bottom’}, default ‘keep’] How to rank NaN values:

- keep: assign NaN rank to NaN values
- top: assign smallest rank to NaN values if ascending
- bottom: assign highest rank to NaN values if ascending

ascending [bool, default True] Whether or not the elements should be ranked in ascending order.

pct [bool, default False] Whether or not to display the returned rankings in percentile form.

Returns

same type as caller Return a Series or DataFrame with data ranks as values.

See also:

core.groupby.GroupBy.rank Rank of values within each group.

Examples

```
>>> df = pd.DataFrame(data={'Animal': ['cat', 'penguin', 'dog',
...                                   'spider', 'snake'],
...                       'Number_legs': [4, 2, 4, 8, np.nan]})
>>> df
   Animal  Number_legs
0     cat             4.0
1  penguin             2.0
2     dog             4.0
3  spider             8.0
4   snake             NaN
```

The following example shows how the method behaves with the above parameters:

- `default_rank`: this is the default behaviour obtained without using any parameter.
- `max_rank`: setting `method = 'max'` the records that have the same values are ranked using the highest rank (e.g.: since ‘cat’ and ‘dog’ are both in the 2nd and 3rd position, rank 3 is assigned.)

- `NA_bottom`: choosing `na_option = 'bottom'`, if there are records with NaN values they are placed at the bottom of the ranking.
- `pct_rank`: when setting `pct = True`, the ranking is expressed as percentile rank.

```
>>> df['default_rank'] = df['Number_legs'].rank()
>>> df['max_rank'] = df['Number_legs'].rank(method='max')
>>> df['NA_bottom'] = df['Number_legs'].rank(na_option='bottom')
>>> df['pct_rank'] = df['Number_legs'].rank(pct=True)
>>> df
```

	Animal	Number_legs	default_rank	max_rank	NA_bottom	pct_rank
0	cat	4.0	2.5	3.0	2.5	0.625
1	penguin	2.0	1.0	1.0	1.0	0.250
2	dog	4.0	2.5	3.0	2.5	0.625
3	spider	8.0	4.0	4.0	4.0	1.000
4	snake	NaN	NaN	NaN	5.0	NaN

pandas.DataFrame.rdiv

`DataFrame.rdiv(self, other, axis='columns', level=None, fill_value=None)`

Get Floating division of dataframe and other, element-wise (binary operator *rtruediv*).

Equivalent to `other / dataframe`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *truediv*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.

DataFrame.sub Subtract DataFrames.

DataFrame.mul Multiply DataFrames.

DataFrame.div Divide DataFrames (float division).

DataFrame.truediv Divide DataFrames (float division).

DataFrame.floordiv Divide DataFrames (integer division).

`DataFrame.mod` Calculate modulo (remainder after division).

`DataFrame.pow` Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

	angles	degrees
circle	0	360
triangle	3	180
rectangle	4	360

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

```
>>> df.add(1)
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

Divide by constant with reverse version.

```
>>> df.div(10)
```

	angles	degrees
circle	0.0	36.0
triangle	0.3	18.0
rectangle	0.4	36.0

```
>>> df.rdiv(10)
```

	angles	degrees
circle	inf	0.027778
triangle	3.333333	0.055556
rectangle	2.500000	0.027778

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
```

	angles	degrees
circle	-1	358

(continues on next page)

(continued from previous page)

```
triangle    2    178
rectangle   3    358
```

```
>>> df.sub([1, 2], axis='columns')
      angles  degrees
circle     -1    358
triangle    2    178
rectangle   3    358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
      angles  degrees
circle     -1    359
triangle    2    179
rectangle   3    359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
      angles
circle      0
triangle    3
rectangle   4
```

```
>>> df * other
      angles  degrees
circle      0     NaN
triangle     9     NaN
rectangle   16     NaN
```

```
>>> df.mul(other, fill_value=0)
      angles  degrees
circle      0     0.0
triangle     9     0.0
rectangle   16     0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                              index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                      ['circle', 'triangle', 'rectangle',
...                                       'square', 'pentagon', 'hexagon']])
>>> df_multindex
      angles  degrees
A circle      0    360
  triangle    3    180
  rectangle    4    360
B square      4    360
```

(continues on next page)

(continued from previous page)

pentagon	5	540
hexagon	6	720

```
>>> df.div(df_multindex, level=1, fill_value=0)
      angles  degrees
A circle   NaN     1.0
  triangle   1.0     1.0
 rectangle   1.0     1.0
B square    0.0     0.0
  pentagon   0.0     0.0
  hexagon    0.0     0.0
```

pandas.DataFrame.reindex

`DataFrame.reindex(self, labels=None, index=None, columns=None, axis=None, method=None, copy=True, level=None, fill_value=nan, limit=None, tolerance=None)`

Conform DataFrame to new index with optional filling logic, placing NA/NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and `copy=False`.

Parameters

labels [array-like, optional] New labels / index to conform the axis specified by 'axis' to.

index, columns [array-like, optional] New labels / index to conform to, should be specified using keywords. Preferably an Index object to avoid duplicating data

axis [int or str, optional] Axis to target. Can be either the axis name ('index', 'columns') or number (0, 1).

method [{None, 'backfill'/'bfill', 'pad'/'ffill', 'nearest'}] Method to use for filling holes in reindexed DataFrame. Please note: this is only applicable to DataFrames/Series with a monotonically increasing/decreasing index.

- None (default): don't fill gaps
- pad / ffill: propagate last valid observation forward to next valid
- backfill / bfill: use next valid observation to fill gap
- nearest: use nearest valid observations to fill gap

copy [bool, default True] Return a new object, even if the passed indexes are the same.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [scalar, default np.NaN] Value to use for missing values. Defaults to NaN, but can be any "compatible" value.

limit [int, default None] Maximum number of consecutive elements to forward or backward fill.

tolerance [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations most satisfy the equation $\text{abs}(\text{index}[\text{indexer}] - \text{target}) \leq \text{tolerance}$.

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index's type.

New in version 0.21.0: (list-like tolerance)

Returns

DataFrame with changed index.

See also:

`DataFrame.set_index` Set row labels.

`DataFrame.reset_index` Remove row labels or move them to new columns.

`DataFrame.reindex_like` Change to same indices as other DataFrame.

Examples

`DataFrame.reindex` supports two calling conventions

- `(index=index_labels, columns=column_labels, ...)`
- `(labels, axis={'index', 'columns'}, ...)`

We *highly* recommend using keyword arguments to clarify your intent.

Create a dataframe with some fictional data.

```
>>> index = ['Firefox', 'Chrome', 'Safari', 'IE10', 'Konqueror']
>>> df = pd.DataFrame({
...     'http_status': [200,200,404,404,301],
...     'response_time': [0.04, 0.02, 0.07, 0.08, 1.0]},
...     index=index)
>>> df
```

	http_status	response_time
Firefox	200	0.04
Chrome	200	0.02
Safari	404	0.07
IE10	404	0.08
Konqueror	301	1.00

Create a new index and reindex the dataframe. By default values in the new index that do not have corresponding records in the dataframe are assigned NaN.

```
>>> new_index= ['Safari', 'Iceweasel', 'Comodo Dragon', 'IE10',
...             'Chrome']
>>> df.reindex(new_index)
```

	http_status	response_time
Safari	404.0	0.07
Iceweasel	NaN	NaN
Comodo Dragon	NaN	NaN

(continues on next page)

(continued from previous page)

IE10	404.0	0.08
Chrome	200.0	0.02

We can fill in the missing values by passing a value to the keyword `fill_value`. Because the index is not monotonically increasing or decreasing, we cannot use arguments to the keyword `method` to fill the NaN values.

```
>>> df.reindex(new_index, fill_value=0)
           http_status  response_time
Safari              404              0.07
Iceweasel            0              0.00
Comodo Dragon        0              0.00
IE10                 404              0.08
Chrome               200              0.02
```

```
>>> df.reindex(new_index, fill_value='missing')
           http_status  response_time
Safari              404              0.07
Iceweasel           missing           missing
Comodo Dragon       missing           missing
IE10                 404              0.08
Chrome               200              0.02
```

We can also reindex the columns.

```
>>> df.reindex(columns=['http_status', 'user_agent'])
           http_status  user_agent
Firefox              200          NaN
Chrome               200          NaN
Safari               404          NaN
IE10                 404          NaN
Konqueror            301          NaN
```

Or we can use “axis-style” keyword arguments

```
>>> df.reindex(['http_status', 'user_agent'], axis="columns")
           http_status  user_agent
Firefox              200          NaN
Chrome               200          NaN
Safari               404          NaN
IE10                 404          NaN
Konqueror            301          NaN
```

To further illustrate the filling functionality in `reindex`, we will create a dataframe with a monotonically increasing index (for example, a sequence of dates).

```
>>> date_index = pd.date_range('1/1/2010', periods=6, freq='D')
>>> df2 = pd.DataFrame({"prices": [100, 101, np.nan, 100, 89, 88]},
...                    index=date_index)
>>> df2
           prices
2010-01-01  100.0
```

(continues on next page)

(continued from previous page)

2010-01-02	101.0
2010-01-03	NaN
2010-01-04	100.0
2010-01-05	89.0
2010-01-06	88.0

Suppose we decide to expand the dataframe to cover a wider date range.

```
>>> date_index2 = pd.date_range('12/29/2009', periods=10, freq='D')
>>> df2.reindex(date_index2)
```

	prices
2009-12-29	NaN
2009-12-30	NaN
2009-12-31	NaN
2010-01-01	100.0
2010-01-02	101.0
2010-01-03	NaN
2010-01-04	100.0
2010-01-05	89.0
2010-01-06	88.0
2010-01-07	NaN

The index entries that did not have a value in the original data frame (for example, '2009-12-29') are by default filled with NaN. If desired, we can fill in the missing values using one of several options.

For example, to back-propagate the last valid value to fill the NaN values, pass `bfill` as an argument to the `method` keyword.

```
>>> df2.reindex(date_index2, method='bfill')
```

	prices
2009-12-29	100.0
2009-12-30	100.0
2009-12-31	100.0
2010-01-01	100.0
2010-01-02	101.0
2010-01-03	NaN
2010-01-04	100.0
2010-01-05	89.0
2010-01-06	88.0
2010-01-07	NaN

Please note that the NaN value present in the original dataframe (at index value 2010-01-03) will not be filled by any of the value propagation schemes. This is because filling while reindexing does not look at dataframe values, but only compares the original and desired indexes. If you do want to fill in the NaN values present in the original dataframe, use the `fillna()` method.

See the *user guide* for more.

pandas.DataFrame.reindex_like

`DataFrame.reindex_like(self, other, method=None, copy=True, limit=None, tolerance=None)`
Return an object with matching indices as other object.

Conform the object to the same index on all axes. Optional filling logic, placing NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and `copy=False`.

Parameters

other [Object of the same data type] Its row and column indices are used to define the new indices of this object.

method [{None, 'backfill'/'bfill', 'pad'/'ffill', 'nearest'}] Method to use for filling holes in reindexed DataFrame. Please note: this is only applicable to DataFrames/Series with a monotonically increasing/decreasing index.

- None (default): don't fill gaps
- pad / ffill: propagate last valid observation forward to next valid
- backfill / bfill: use next valid observation to fill gap
- nearest: use nearest valid observations to fill gap

copy [bool, default True] Return a new object, even if the passed indexes are the same.

limit [int, default None] Maximum number of consecutive labels to fill for inexact matches.

tolerance [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations most satisfy the equation `abs(index[indexer] - target) <= tolerance`.

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index's type.

New in version 0.21.0: (list-like tolerance)

Returns

Series or DataFrame Same type as caller, but with changed indices on each axis.

See also:

`DataFrame.set_index` Set row labels.

`DataFrame.reset_index` Remove row labels or move them to new columns.

`DataFrame.reindex` Change to new indices or expand indices.

Notes

Same as calling `.reindex(index=other.index, columns=other.columns, ...)`.

Examples

```
>>> df1 = pd.DataFrame([[24.3, 75.7, 'high'],
...                     [31, 87.8, 'high'],
...                     [22, 71.6, 'medium'],
...                     [35, 95, 'medium']],
...                     columns=['temp_celsius', 'temp_fahrenheit', 'windspeed'],
...                     index=pd.date_range(start='2014-02-12',
...                                         end='2014-02-15', freq='D'))
```

```
>>> df1
           temp_celsius  temp_fahrenheit  windspeed
2014-02-12           24.3             75.7         high
2014-02-13           31.0             87.8         high
2014-02-14           22.0             71.6         medium
2014-02-15           35.0             95.0         medium
```

```
>>> df2 = pd.DataFrame([[28, 'low'],
...                     [30, 'low'],
...                     [35.1, 'medium']],
...                     columns=['temp_celsius', 'windspeed'],
...                     index=pd.DatetimeIndex(['2014-02-12', '2014-02-13',
...                                             '2014-02-15']))
```

```
>>> df2
           temp_celsius  windspeed
2014-02-12           28.0         low
2014-02-13           30.0         low
2014-02-15           35.1         medium
```

```
>>> df2.reindex_like(df1)
           temp_celsius  temp_fahrenheit  windspeed
2014-02-12           28.0                NaN         low
2014-02-13           30.0                NaN         low
2014-02-14                NaN                NaN         NaN
2014-02-15           35.1                NaN         medium
```

pandas.DataFrame.rename

`DataFrame.rename`(*self*, *mapper=None*, *index=None*, *columns=None*, *axis=None*, *copy=True*, *inplace=False*, *level=None*, *errors='ignore'*)

Alter axes labels.

Function / dict values must be unique (1-to-1). Labels not contained in a dict / Series will be left as-is. Extra labels listed don't throw an error.

See the [user guide](#) for more.

Parameters

mapper [dict-like or function] Dict-like or functions transformations to apply to that axis' values. Use either `mapper` and `axis` to specify the axis to target with `mapper`, or `index` and `columns`.

index [dict-like or function] Alternative to specifying axis (`mapper`, `axis=0` is equivalent to `index=mapper`).

columns [dict-like or function] Alternative to specifying axis (`mapper`, `axis=1` is equivalent to `columns=mapper`).

axis [int or str] Axis to target with `mapper`. Can be either the axis name ('index', 'columns') or number (0, 1). The default is 'index'.

copy [bool, default True] Also copy underlying data.

inplace [bool, default False] Whether to return a new DataFrame. If True then value of copy is ignored.

level [int or level name, default None] In case of a MultiIndex, only rename labels in the specified level.

errors [{'ignore', 'raise'}, default 'ignore'] If 'raise', raise a *KeyError* when a dict-like *mapper*, *index*, or *columns* contains labels that are not present in the Index being transformed. If 'ignore', existing keys will be renamed and extra keys will be ignored.

Returns

DataFrame DataFrame with the renamed axis labels.

Raises

KeyError If any of the labels is not found in the selected axis and "errors='raise'".

See also:

DataFrame.rename_axis Set the name of the axis.

Examples

`DataFrame.rename` supports two calling conventions

- (`index=index_mapper`, `columns=columns_mapper`, ...)
- (`mapper`, `axis={'index', 'columns'}`, ...)

We *highly* recommend using keyword arguments to clarify your intent.

Rename columns using a mapping:

```
>>> df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6]})
>>> df.rename(columns={"A": "a", "B": "c"})
   a  c
0  1  4
1  2  5
2  3  6
```

Rename index using a mapping:

```
>>> df.rename(index={0: "x", 1: "y", 2: "z"})
   A  B
x  1  4
y  2  5
z  3  6
```

Cast index labels to a different type:

```
>>> df.index
RangeIndex(start=0, stop=3, step=1)
>>> df.rename(index=str).index
Index(['0', '1', '2'], dtype='object')
```

```
>>> df.rename(columns={"A": "a", "B": "b", "C": "c"}, errors="raise")
Traceback (most recent call last):
KeyError: ['C'] not found in axis
```

Using axis-style parameters

```
>>> df.rename(str.lower, axis='columns')
   a  b
0  1  4
1  2  5
2  3  6
```

```
>>> df.rename({1: 2, 2: 4}, axis='index')
   A  B
0  1  4
2  2  5
4  3  6
```

pandas.DataFrame.rename_axis

`DataFrame.rename_axis(self, mapper=None, index=None, columns=None, axis=None, copy=True, inplace=False)`

Set the name of the axis for the index or columns.

Parameters

mapper [scalar, list-like, optional] Value to set the axis name attribute.

index, columns [scalar, list-like, dict-like or function, optional] A scalar, list-like, dict-like or functions transformations to apply to that axis' values.

Use either **mapper** and **axis** to specify the axis to target with **mapper**, or **index** and/or **columns**.

Changed in version 0.24.0.

axis [{0 or 'index', 1 or 'columns'}, default 0] The axis to rename.

copy [bool, default True] Also copy underlying data.

inplace [bool, default False] Modifies the object directly, instead of creating a new Series or DataFrame.

Returns

Series, DataFrame, or None The same type as the caller or None if *inplace* is True.

See also:

Series.rename Alter Series index labels or name.

DataFrame.rename Alter DataFrame index labels or name.

Index.rename Set new names on index.

Notes

DataFrame.rename_axis supports two calling conventions

- (index=index_mapper, columns=columns_mapper, ...)
- (mapper, axis={'index', 'columns'}, ...)

The first calling convention will only modify the names of the index and/or the names of the Index object that is the columns. In this case, the parameter `copy` is ignored.

The second calling convention will modify the names of the the corresponding index if mapper is a list or a scalar. However, if mapper is dict-like or a function, it will use the deprecated behavior of modifying the axis *labels*.

We *highly* recommend using keyword arguments to clarify your intent.

Examples

Series

```
>>> s = pd.Series(["dog", "cat", "monkey"])
>>> s
0      dog
1      cat
2  monkey
dtype: object
>>> s.rename_axis("animal")
animal
0      dog
1      cat
2  monkey
dtype: object
```

DataFrame

```
>>> df = pd.DataFrame({"num_legs": [4, 4, 2],
...                    "num_arms": [0, 0, 2]},
...                    ["dog", "cat", "monkey"])
>>> df
   num_legs  num_arms
dog         4         0
cat         4         0
monkey      2         2
>>> df = df.rename_axis("animal")
>>> df
   num_legs  num_arms
animal
dog         4         0
cat         4         0
monkey      2         2
>>> df = df.rename_axis("limbs", axis="columns")
>>> df
```

(continues on next page)

(continued from previous page)

limbs	num_legs	num_arms
animal		
dog	4	0
cat	4	0
monkey	2	2

MultiIndex

```
>>> df.index = pd.MultiIndex.from_product(['mammal'],
...                                       ['dog', 'cat', 'monkey']],
...                                       names=['type', 'name'])
>>> df
```

limbs		num_legs	num_arms
type	name		
mammal	dog	4	0
	cat	4	0
	monkey	2	2

```
>>> df.rename_axis(index={'type': 'class'})
```

limbs		num_legs	num_arms
class	name		
mammal	dog	4	0
	cat	4	0
	monkey	2	2

```
>>> df.rename_axis(columns=str.upper)
```

LIMBS		num_legs	num_arms
type	name		
mammal	dog	4	0
	cat	4	0
	monkey	2	2

pandas.DataFrame.reorder_levels**DataFrame.reorder_levels**(*self*, *order*, *axis=0*)

Rearrange index levels using input order. May not drop or duplicate levels.

Parameters**order** [list of int or list of str] List representing new level order. Reference level by number (position) or by key (label).**axis** [int] Where to reorder levels.**Returns****type of caller (new object)****pandas.DataFrame.replace****DataFrame.replace**(*self*, *to_replace=None*, *value=None*, *inplace=False*, *limit=None*, *regex=False*, *method='pad'*)Replace values given in *to_replace* with *value*.

Values of the DataFrame are replaced with other values dynamically. This differs from updating with `.loc` or `.iloc`, which require you to specify a location to update with some value.

Parameters

to_replace [str, regex, list, dict, Series, int, float, or None] How to find the values that will be replaced.

- numeric, str or regex:
 - numeric: numeric values equal to `to_replace` will be replaced with `value`
 - str: string exactly matching `to_replace` will be replaced with `value`
 - regex: regexs matching `to_replace` will be replaced with `value`
- list of str, regex, or numeric:
 - First, if `to_replace` and `value` are both lists, they **must** be the same length.
 - Second, if `regex=True` then all of the strings in **both** lists will be interpreted as regexs otherwise they will match directly. This doesn't matter much for `value` since there are only a few possible substitution regexes you can use.
 - str, regex and numeric rules apply as above.
- dict:
 - Dicts can be used to specify different replacement values for different existing values. For example, `{'a': 'b', 'y': 'z'}` replaces the value 'a' with 'b' and 'y' with 'z'. To use a dict in this way the `value` parameter should be `None`.
 - For a DataFrame a dict can specify that different values should be replaced in different columns. For example, `{'a': 1, 'b': 'z'}` looks for the value 1 in column 'a' and the value 'z' in column 'b' and replaces these values with whatever is specified in `value`. The `value` parameter should not be `None` in this case. You can treat this as a special case of passing two lists except that you are specifying the column to search in.
 - For a DataFrame nested dictionaries, e.g., `{'a': {'b': np.nan}}`, are read as follows: look in column 'a' for the value 'b' and replace it with NaN. The `value` parameter should be `None` to use a nested dict in this way. You can nest regular expressions as well. Note that column names (the top-level dictionary keys in a nested dictionary) **cannot** be regular expressions.
- None:
 - This means that the `regex` argument must be a string, compiled regular expression, or list, dict, ndarray or Series of such elements. If `value` is also `None` then this **must** be a nested dictionary or Series.

See the examples section for examples of each of these.

value [scalar, dict, list, str, regex, default None] Value to replace any values matching `to_replace` with. For a DataFrame a dict of values can be used to specify which value to use for each column (columns not in the dict will not be filled). Regular expressions, strings and lists or dicts of such objects are also allowed.

inplace [bool, default False] If True, in place. Note: this will modify any other views on this object (e.g. a column from a DataFrame). Returns the caller if this is True.

limit [int, default None] Maximum size gap to forward or backward fill.

regex [bool or same types as *to_replace*, default False] Whether to interpret *to_replace* and/or *value* as regular expressions. If this is True then *to_replace* must be a string. Alternatively, this could be a regular expression or a list, dict, or array of regular expressions in which case *to_replace* must be None.

method [{‘pad’, ‘ffill’, ‘bfill’, None}] The method to use when for replacement, when *to_replace* is a scalar, list or tuple and *value* is None.

Changed in version 0.23.0: Added to DataFrame.

Returns

DataFrame Object after replacement.

Raises

AssertionError

- If *regex* is not a bool and *to_replace* is not None.

TypeError

- If *to_replace* is a dict and *value* is not a list, dict, ndarray, or Series
- If *to_replace* is None and *regex* is not compilable into a regular expression or is a list, dict, ndarray, or Series.
- When replacing multiple bool or datetime64 objects and the arguments to *to_replace* does not match the type of the value being replaced

ValueError

- If a list or an ndarray is passed to *to_replace* and *value* but they are not the same length.

See also:

DataFrame.fillna Fill NA values.

DataFrame.where Replace values based on boolean condition.

Series.str.replace Simple string replacement.

Notes

- Regex substitution is performed under the hood with `re.sub`. The rules for substitution for `re.sub` are the same.
- Regular expressions will only substitute on strings, meaning you cannot provide, for example, a regular expression matching floating point numbers and expect the columns in your frame that have a numeric dtype to be matched. However, if those floating point numbers are strings, then you can do this.
- This method has a lot of options. You are encouraged to experiment and play with this method to gain intuition about how it works.
- When dict is used as the *to_replace* value, it is like key(s) in the dict are the *to_replace* part and value(s) in the dict are the *value* parameter.

Examples

Scalar 'to_replace' and 'value'

```
>>> s = pd.Series([0, 1, 2, 3, 4])
>>> s.replace(0, 5)
0    5
1    1
2    2
3    3
4    4
dtype: int64
```

```
>>> df = pd.DataFrame({'A': [0, 1, 2, 3, 4],
...                   'B': [5, 6, 7, 8, 9],
...                   'C': ['a', 'b', 'c', 'd', 'e']})
>>> df.replace(0, 5)
   A  B  C
0  5  5  a
1  1  6  b
2  2  7  c
3  3  8  d
4  4  9  e
```

List-like 'to_replace'

```
>>> df.replace([0, 1, 2, 3], 4)
   A  B  C
0  4  5  a
1  4  6  b
2  4  7  c
3  4  8  d
4  4  9  e
```

```
>>> df.replace([0, 1, 2, 3], [4, 3, 2, 1])
   A  B  C
0  4  5  a
1  3  6  b
2  2  7  c
3  1  8  d
4  4  9  e
```

```
>>> s.replace([1, 2], method='bfill')
0    0
1    3
2    3
3    3
4    4
dtype: int64
```

dict-like 'to_replace'

```
>>> df.replace({0: 10, 1: 100})
   A  B  C
0  10  5  a
1 100  6  b
2   2  7  c
3   3  8  d
4   4  9  e
```

```
>>> df.replace({'A': 0, 'B': 5}, 100)
   A  B  C
0 100 100 a
1   1   6  b
2   2   7  c
3   3   8  d
4   4   9  e
```

```
>>> df.replace({'A': {0: 100, 4: 400}})
   A  B  C
0 100  5  a
1   1  6  b
2   2  7  c
3   3  8  d
4 400  9  e
```

Regular expression 'to_replace'

```
>>> df = pd.DataFrame({'A': ['bat', 'foo', 'bait'],
...                    'B': ['abc', 'bar', 'xyz']})
>>> df.replace(to_replace=r'^ba.$', value='new', regex=True)
   A  B
0  new abc
1  foo new
2  bait xyz
```

```
>>> df.replace({'A': r'^ba.$'}, {'A': 'new'}, regex=True)
   A  B
0  new abc
1  foo bar
2  bait xyz
```

```
>>> df.replace(regex=r'^ba.$', value='new')
   A  B
0  new abc
1  foo new
2  bait xyz
```

```
>>> df.replace(regex={r'^ba.$': 'new', 'foo': 'xyz'})
   A  B
0  new abc
1  xyz new
2  bait xyz
```

```
>>> df.replace(regex=[r'^ba.$', 'foo'], value='new')
   A   B
0  new abc
1  new new
2  bait xyz
```

Note that when replacing multiple `bool` or `datetime64` objects, the data types in the `to_replace` parameter must match the data type of the value being replaced:

```
>>> df = pd.DataFrame({'A': [True, False, True],
...                   'B': [False, True, False]})
>>> df.replace({'a string': 'new value', True: False}) # raises
Traceback (most recent call last):
...
TypeError: Cannot compare types 'ndarray(dtype=bool)' and 'str'
```

This raises a `TypeError` because one of the dict keys is not of the correct type for replacement.

Compare the behavior of `s.replace({'a': None})` and `s.replace('a', None)` to understand the peculiarities of the `to_replace` parameter:

```
>>> s = pd.Series([10, 'a', 'a', 'b', 'a'])
```

When one uses a dict as the `to_replace` value, it is like the value(s) in the dict are equal to the `value` parameter. `s.replace({'a': None})` is equivalent to `s.replace(to_replace={'a': None}, value=None, method=None)`:

```
>>> s.replace({'a': None})
0    10
1    None
2    None
3     b
4    None
dtype: object
```

When `value=None` and `to_replace` is a scalar, list or tuple, `replace` uses the `method` parameter (default 'pad') to do the replacement. So this is why the 'a' values are being replaced by 10 in rows 1 and 2 and 'b' in row 4 in this case. The command `s.replace('a', None)` is actually equivalent to `s.replace(to_replace='a', value=None, method='pad')`:

```
>>> s.replace('a', None)
0    10
1    10
2    10
3     b
4     b
dtype: object
```

pandas.DataFrame.resample

```
DataFrame.resample(self, rule, how=None, axis=0, fill_method=None, closed=None, label=None, convention='start', kind=None, loffset=None, limit=None, base=0, on=None, level=None)
```

Resample time-series data.

Convenience method for frequency conversion and resampling of time series. Object must have a datetime-like index (*DatetimeIndex*, *PeriodIndex*, or *TimedeltaIndex*), or pass datetime-like values to the *on* or *level* keyword.

Parameters

- rule** [DateOffset, Timedelta or str] The offset string or object representing target conversion.
- how** [str] Method for down/re-sampling, default to 'mean' for downsampling.
Deprecated since version 0.18.0: The new syntax is `.resample(...).mean()`, or `.resample(...).apply(<func>)`
- axis** [{0 or 'index', 1 or 'columns'}, default 0] Which axis to use for up- or down-sampling. For *Series* this will default to 0, i.e. along the rows. Must be *DatetimeIndex*, *TimedeltaIndex* or *PeriodIndex*.
- fill_method** [str, default None] Filling method for upsampling.
Deprecated since version 0.18.0: The new syntax is `.resample(...).<func>()`, e.g. `.resample(...).pad()`
- closed** [{'right', 'left'}, default None] Which side of bin interval is closed. The default is 'left' for all frequency offsets except for 'M', 'A', 'Q', 'BM', 'BA', 'BQ', and 'W' which all have a default of 'right'.
- label** [{'right', 'left'}, default None] Which bin edge label to label bucket with. The default is 'left' for all frequency offsets except for 'M', 'A', 'Q', 'BM', 'BA', 'BQ', and 'W' which all have a default of 'right'.
- convention** [{'start', 'end', 's', 'e'}, default 'start'] For *PeriodIndex* only, controls whether to use the start or end of *rule*.
- kind** [{'timestamp', 'period'}, optional, default None] Pass 'timestamp' to convert the resulting index to a *DateTimeIndex* or 'period' to convert it to a *PeriodIndex*. By default the input representation is retained.
- loffset** [timedelta, default None] Adjust the resampled time labels.
- limit** [int, default None] Maximum size gap when reindexing with *fill_method*.
Deprecated since version 0.18.0.
- base** [int, default 0] For frequencies that evenly subdivide 1 day, the "origin" of the aggregated intervals. For example, for '5min' frequency, base could range from 0 through 4. Defaults to 0.
- on** [str, optional] For a DataFrame, column to use instead of index for resampling. Column must be datetime-like.
New in version 0.19.0.
- level** [str or int, optional] For a MultiIndex, level (name or number) to use for resampling. *level* must be datetime-like.
New in version 0.19.0.

Returns

Resampler object

See also:

groupby Group by mapping, function, label, or list of labels.

Series.resample Resample a Series.

DataFrame.resample Resample a DataFrame.

Notes

See the [user guide](#) for more.

To learn more about the offset strings, please see [this link](#).

Examples

Start by creating a series with 9 one minute timestamps.

```
>>> index = pd.date_range('1/1/2000', periods=9, freq='T')
>>> series = pd.Series(range(9), index=index)
>>> series
2000-01-01 00:00:00    0
2000-01-01 00:01:00    1
2000-01-01 00:02:00    2
2000-01-01 00:03:00    3
2000-01-01 00:04:00    4
2000-01-01 00:05:00    5
2000-01-01 00:06:00    6
2000-01-01 00:07:00    7
2000-01-01 00:08:00    8
Freq: T, dtype: int64
```

Downsample the series into 3 minute bins and sum the values of the timestamps falling into a bin.

```
>>> series.resample('3T').sum()
2000-01-01 00:00:00    3
2000-01-01 00:03:00   12
2000-01-01 00:06:00   21
Freq: 3T, dtype: int64
```

Downsample the series into 3 minute bins as above, but label each bin using the right edge instead of the left. Please note that the value in the bucket used as the label is not included in the bucket, which it labels. For example, in the original series the bucket 2000-01-01 00:03:00 contains the value 3, but the summed value in the resampled bucket with the label 2000-01-01 00:03:00 does not include 3 (if it did, the summed value would be 6, not 3). To include this value close the right side of the bin interval as illustrated in the example below this one.

```
>>> series.resample('3T', label='right').sum()
2000-01-01 00:03:00    3
2000-01-01 00:06:00   12
2000-01-01 00:09:00   21
Freq: 3T, dtype: int64
```

Downsample the series into 3 minute bins as above, but close the right side of the bin interval.

```
>>> series.resample('3T', label='right', closed='right').sum()
2000-01-01 00:00:00    0
2000-01-01 00:03:00    6
2000-01-01 00:06:00   15
2000-01-01 00:09:00   15
Freq: 3T, dtype: int64
```

Upsample the series into 30 second bins.

```
>>> series.resample('30S').asfreq()[0:5]    # Select first 5 rows
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30   NaN
2000-01-01 00:01:00    1.0
2000-01-01 00:01:30   NaN
2000-01-01 00:02:00    2.0
Freq: 30S, dtype: float64
```

Upsample the series into 30 second bins and fill the NaN values using the `pad` method.

```
>>> series.resample('30S').pad()[0:5]
2000-01-01 00:00:00    0
2000-01-01 00:00:30    0
2000-01-01 00:01:00    1
2000-01-01 00:01:30    1
2000-01-01 00:02:00    2
Freq: 30S, dtype: int64
```

Upsample the series into 30 second bins and fill the NaN values using the `bfill` method.

```
>>> series.resample('30S').bfill()[0:5]
2000-01-01 00:00:00    0
2000-01-01 00:00:30    1
2000-01-01 00:01:00    1
2000-01-01 00:01:30    2
2000-01-01 00:02:00    2
Freq: 30S, dtype: int64
```

Pass a custom function via `apply`

```
>>> def custom_resampler(array_like):
...     return np.sum(array_like) + 5
...
>>> series.resample('3T').apply(custom_resampler)
2000-01-01 00:00:00    8
2000-01-01 00:03:00   17
2000-01-01 00:06:00   26
Freq: 3T, dtype: int64
```

For a Series with a PeriodIndex, the keyword *convention* can be used to control whether to use the start or end of *rule*.

Resample a year by quarter using 'start' *convention*. Values are assigned to the first quarter of the period.

```

>>> s = pd.Series([1, 2], index=pd.period_range('2012-01-01',
...                                           freq='A',
...                                           periods=2))
>>> s
2012    1
2013    2
Freq: A-DEC, dtype: int64
>>> s.resample('Q', convention='start').asfreq()
2012Q1    1.0
2012Q2     NaN
2012Q3     NaN
2012Q4     NaN
2013Q1    2.0
2013Q2     NaN
2013Q3     NaN
2013Q4     NaN
Freq: Q-DEC, dtype: float64

```

Resample quarters by month using 'end' *convention*. Values are assigned to the last month of the period.

```

>>> q = pd.Series([1, 2, 3, 4], index=pd.period_range('2018-01-01',
...                                           freq='Q',
...                                           periods=4))
>>> q
2018Q1    1
2018Q2    2
2018Q3    3
2018Q4    4
Freq: Q-DEC, dtype: int64
>>> q.resample('M', convention='end').asfreq()
2018-03    1.0
2018-04     NaN
2018-05     NaN
2018-06    2.0
2018-07     NaN
2018-08     NaN
2018-09    3.0
2018-10     NaN
2018-11     NaN
2018-12    4.0
Freq: M, dtype: float64

```

For DataFrame objects, the keyword *on* can be used to specify the column instead of the index for resampling.

```

>>> d = dict({'price': [10, 11, 9, 13, 14, 18, 17, 19],
...          'volume': [50, 60, 40, 100, 50, 100, 40, 50]})
>>> df = pd.DataFrame(d)
>>> df['week_starting'] = pd.date_range('01/01/2018',
...                                     periods=8,
...                                     freq='W')
>>> df

```

(continues on next page)

(continued from previous page)

```

price  volume  week_starting
0      10      50    2018-01-07
1      11      60    2018-01-14
2       9      40    2018-01-21
3      13     100    2018-01-28
4      14      50    2018-02-04
5      18     100    2018-02-11
6      17      40    2018-02-18
7      19      50    2018-02-25
>>> df.resample('M', on='week_starting').mean()
           price  volume
week_starting
2018-01-31    10.75    62.5
2018-02-28    17.00    60.0

```

For a DataFrame with MultiIndex, the keyword *level* can be used to specify on which level the resampling needs to take place.

```

>>> days = pd.date_range('1/1/2000', periods=4, freq='D')
>>> d2 = dict({'price': [10, 11, 9, 13, 14, 18, 17, 19],
...          'volume': [50, 60, 40, 100, 50, 100, 40, 50]})
>>> df2 = pd.DataFrame(d2,
...                    index=pd.MultiIndex.from_product([days,
...                                                       ['morning',
...                                                       'afternoon']])
>>> df2
           price  volume
2000-01-01 morning    10     50
           afternoon    11     60
2000-01-02 morning     9     40
           afternoon    13    100
2000-01-03 morning    14     50
           afternoon    18    100
2000-01-04 morning    17     40
           afternoon    19     50
>>> df2.resample('D', level=0).sum()
           price  volume
2000-01-01     21    110
2000-01-02     22    140
2000-01-03     32    150
2000-01-04     36     90

```

pandas.DataFrame.reset_index

`DataFrame.reset_index(self, level=None, drop=False, inplace=False, col_level=0, col_fill="")`

Reset the index, or a level of it.

Reset the index of the DataFrame, and use the default one instead. If the DataFrame has a MultiIndex, this method can remove one or more levels.

Parameters

level [int, str, tuple, or list, default None] Only remove the given levels from the index. Removes all levels by default.

drop [bool, default False] Do not try to insert index into dataframe columns. This resets the index to the default integer index.

inplace [bool, default False] Modify the DataFrame in place (do not create a new object).

col_level [int or str, default 0] If the columns have multiple levels, determines which level the labels are inserted into. By default it is inserted into the first level.

col_fill [object, default “”] If the columns have multiple levels, determines how the other levels are named. If None then the index name is repeated.

Returns

DataFrame DataFrame with the new index.

See also:

DataFrame.set_index Opposite of reset_index.

DataFrame.reindex Change to new indices or expand indices.

DataFrame.reindex_like Change to same indices as other DataFrame.

Examples

```
>>> df = pd.DataFrame([('bird', 389.0),
...                    ('bird', 24.0),
...                    ('mammal', 80.5),
...                    ('mammal', np.nan)],
...                    index=['falcon', 'parrot', 'lion', 'monkey'],
...                    columns=('class', 'max_speed'))
>>> df
```

	class	max_speed
falcon	bird	389.0
parrot	bird	24.0
lion	mammal	80.5
monkey	mammal	NaN

When we reset the index, the old index is added as a column, and a new sequential index is used:

```
>>> df.reset_index()
   index  class  max_speed
0  falcon  bird    389.0
1  parrot  bird    24.0
2    lion  mammal    80.5
3  monkey  mammal     NaN
```

We can use the *drop* parameter to avoid the old index being added as a column:

```
>>> df.reset_index(drop=True)
   class  max_speed
0    bird    389.0
```

(continues on next page)

(continued from previous page)

1	bird	24.0
2	mammal	80.5
3	mammal	NaN

You can also use `reset_index` with `MultiIndex`.

```
>>> index = pd.MultiIndex.from_tuples([('bird', 'falcon'),
...                                   ('bird', 'parrot'),
...                                   ('mammal', 'lion'),
...                                   ('mammal', 'monkey')],
...                                   names=['class', 'name'])
>>> columns = pd.MultiIndex.from_tuples([('speed', 'max'),
...                                      ('species', 'type')])
>>> df = pd.DataFrame([(389.0, 'fly'),
...                    ( 24.0, 'fly'),
...                    ( 80.5, 'run'),
...                    (np.nan, 'jump')],
...                    index=index,
...                    columns=columns)
>>> df
```

		speed	species
		max	type
class	name		
bird	falcon	389.0	fly
	parrot	24.0	fly
mammal	lion	80.5	run
	monkey	NaN	jump

If the index has multiple levels, we can reset a subset of them:

```
>>> df.reset_index(level='class')
      class  speed species
      max    type
name
falcon  bird  389.0    fly
parrot  bird   24.0    fly
lion    mammal 80.5    run
monkey  mammal  NaN    jump
```

If we are not dropping the index, by default, it is placed in the top level. We can place it in another level:

```
>>> df.reset_index(level='class', col_level=1)
      class  speed species
      max    type
name
falcon  bird  389.0    fly
parrot  bird   24.0    fly
lion    mammal 80.5    run
monkey  mammal  NaN    jump
```

When the index is inserted under another level, we can specify under which one with the parameter `col_fill`:

```
>>> df.reset_index(level='class', col_level=1, col_fill='species')
      species  speed species
name      class    max   type
falcon    bird  389.0    fly
parrot    bird   24.0    fly
lion     mammal   80.5    run
monkey   mammal    NaN    jump
```

If we specify a nonexistent level for `col_fill`, it is created:

```
>>> df.reset_index(level='class', col_level=1, col_fill='genus')
      genus  speed species
name      class    max   type
falcon    bird  389.0    fly
parrot    bird   24.0    fly
lion     mammal   80.5    run
monkey   mammal    NaN    jump
```

pandas.DataFrame.rfloordiv

DataFrame.rfloordiv(*self*, *other*, *axis*='columns', *level*=None, *fill_value*=None)

Get Integer division of dataframe and other, element-wise (binary operator *rfloordiv*).

Equivalent to `other // dataframe`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *floordiv*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.

DataFrame.sub Subtract DataFrames.

DataFrame.mul Multiply DataFrames.

`DataFrame.div` Divide DataFrames (float division).

`DataFrame.truediv` Divide DataFrames (float division).

`DataFrame.floordiv` Divide DataFrames (integer division).

`DataFrame.mod` Calculate modulo (remainder after division).

`DataFrame.pow` Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

	angles	degrees
circle	0	360
triangle	3	180
rectangle	4	360

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

```
>>> df.add(1)
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

Divide by constant with reverse version.

```
>>> df.div(10)
```

	angles	degrees
circle	0.0	36.0
triangle	0.3	18.0
rectangle	0.4	36.0

```
>>> df.rdiv(10)
```

	angles	degrees
circle	inf	0.027778
triangle	3.333333	0.055556
rectangle	2.500000	0.027778

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
      angles  degrees
circle      -1     358
triangle     2     178
rectangle    3     358
```

```
>>> df.sub([1, 2], axis='columns')
      angles  degrees
circle      -1     358
triangle     2     178
rectangle    3     358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
      angles  degrees
circle      -1     359
triangle     2     179
rectangle    3     359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
      angles
circle      0
triangle     3
rectangle    4
```

```
>>> df * other
      angles  degrees
circle      0     NaN
triangle     9     NaN
rectangle   16     NaN
```

```
>>> df.mul(other, fill_value=0)
      angles  degrees
circle      0     0.0
triangle     9     0.0
rectangle   16     0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                              'degrees': [360, 180, 360, 360, 540, 720]},
...                              index=[[ 'A', 'A', 'A', 'B', 'B', 'B'],
...                                     ['circle', 'triangle', 'rectangle',
...                                      'square', 'pentagon', 'hexagon']])
>>> df_multindex
      angles  degrees
A circle      0     360
  triangle     3     180
```

(continues on next page)

(continued from previous page)

rectangle	4	360
B square	4	360
pentagon	5	540
hexagon	6	720

```
>>> df.div(df_multindex, level=1, fill_value=0)
          angles  degrees
A circle      NaN      1.0
  triangle    1.0      1.0
  rectangle    1.0      1.0
B square      0.0      0.0
  pentagon    0.0      0.0
  hexagon     0.0      0.0
```

pandas.DataFrame.rmod

DataFrame.rmod(*self*, *other*, *axis*='columns', *level*=None, *fill_value*=None)

Get Modulo of dataframe and other, element-wise (binary operator *rmod*).

Equivalent to `other % dataframe`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *mod*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                   'degrees': [360, 180, 360]},
...                   index=['circle', 'triangle', 'rectangle'])
>>> df
```

	angles	degrees
circle	0	360
triangle	3	180
rectangle	4	360

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

```
>>> df.add(1)
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

Divide by constant with reverse version.

```
>>> df.div(10)
```

	angles	degrees
circle	0.0	36.0
triangle	0.3	18.0
rectangle	0.4	36.0

```
>>> df.rdiv(10)
```

	angles	degrees
circle	inf	0.027778
triangle	3.333333	0.055556
rectangle	2.500000	0.027778

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
```

	angles	degrees
circle	-1	358

(continues on next page)

(continued from previous page)

```
triangle    2    178
rectangle   3    358
```

```

...        axis='index')
      angles  degrees
circle     -1    359
triangle    2    179
rectangle   3    359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
      angles
circle      0
triangle    3
rectangle   4
```

```
>>> df * other
      angles  degrees
circle      0     NaN
triangle     9     NaN
rectangle   16     NaN
```

```
>>> df.mul(other, fill_value=0)
      angles  degrees
circle      0     0.0
triangle     9     0.0
rectangle   16     0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                              index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                      ['circle', 'triangle', 'rectangle',
...                                       'square', 'pentagon', 'hexagon']])
>>> df_multindex
      angles  degrees
A circle      0    360
  triangle    3    180
  rectangle    4    360
B square      4    360
```

(continues on next page)

(continued from previous page)

pentagon	5	540
hexagon	6	720

```
>>> df.div(df_multindex, level=1, fill_value=0)
          angles  degrees
A circle      NaN      1.0
  triangle      1.0      1.0
 rectangle      1.0      1.0
B square       0.0      0.0
  pentagon      0.0      0.0
  hexagon      0.0      0.0
```

pandas.DataFrame.rmul

DataFrame.rmul(self, other, axis='columns', level=None, fill_value=None)

Get Multiplication of dataframe and other, element-wise (binary operator *rmul*).

Equivalent to `other * dataframe`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *mul*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

`DataFrame.pow` Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

	angles	degrees
circle	0	360
triangle	3	180
rectangle	4	360

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

```
>>> df.add(1)
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

Divide by constant with reverse version.

```
>>> df.div(10)
```

	angles	degrees
circle	0.0	36.0
triangle	0.3	18.0
rectangle	0.4	36.0

```

```

	angles	degrees
circle	inf	0.027778
triangle	3.333333	0.055556
rectangle	2.500000	0.027778

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
```

	angles	degrees
circle	-1	358
triangle	2	178
rectangle	3	358

```
>>> df.sub([1, 2], axis='columns')
      angles  degrees
circle      -1     358
triangle     2     178
rectangle    3     358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
      angles  degrees
circle      -1     359
triangle     2     179
rectangle    3     359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
      angles
circle      0
triangle     3
rectangle    4
```

```
>>> df * other
      angles  degrees
circle      0     NaN
triangle     9     NaN
rectangle   16     NaN
```

```
>>> df.mul(other, fill_value=0)
      angles  degrees
circle      0     0.0
triangle     9     0.0
rectangle   16     0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                              'degrees': [360, 180, 360, 360, 540, 720]},
...                              index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                     ['circle', 'triangle', 'rectangle',
...                                      'square', 'pentagon', 'hexagon']])
>>> df_multindex
      angles  degrees
A circle      0     360
  triangle     3     180
  rectangle    4     360

      angles  degrees
A circle   NaN     1.0
  triangle  1.0     1.0
 rectangle  1.0     1.0
B square    0.0     0.0
  pentagon  0.0     0.0
  hexagon   0.0     0.0
```

pandas.DataFrame.rolling

`DataFrame.rolling(self, window, min_periods=None, center=False, win_type=None, on=None, axis=0, closed=None)`

Provide rolling window calculations.

New in version 0.18.0.

Parameters

window [int, or offset] Size of the moving window. This is the number of observations used for calculating the statistic. Each window will be a fixed size.

If its an offset then this will be the time period of each window. Each window will be a variable sized based on the observations included in the time-period. This is only valid for datetimelike indexes. This is new in 0.19.0

min_periods [int, default None] Minimum number of observations in window required to have a value (otherwise result is NA). For a window that is specified by an offset, *min_periods* will default to 1. Otherwise, *min_periods* will default to the size of the window.

center [bool, default False] Set the labels at the center of the window.

win_type [str, default None] Provide a window type. If `None`, all points are evenly weighted. See the notes below for further information.

on [str, optional] For a DataFrame, a datetime-like column on which to calculate the rolling window, rather than the DataFrame's index. Provided integer column is ignored and excluded from result since an integer index is not used to calculate the rolling window.

axis [int or str, default 0]

closed [str, default None] Make the interval closed on the 'right', 'left', 'both' or 'neither' endpoints. For offset-based windows, it defaults to 'right'. For fixed windows, defaults to 'both'. Remaining cases not implemented for fixed windows.

New in version 0.20.0.

Returns

a **Window or Rolling** sub-classed for the particular operation

See also:

expanding Provides expanding transformations.

ewm Provides exponential weighted functions.

Notes

By default, the result is set to the right edge of the window. This can be changed to the center of the window by setting `center=True`.

To learn more about the offsets & frequency strings, please see [this link](#).

The recognized `win_types` are:

- `boxcar`
- `triang`
- `blackman`
- `hamming`
- `bartlett`
- `parzen`
- `bohman`
- `blackmanharris`
- `nutttall`
- `barthann`
- `kaiser` (needs beta)
- `gaussian` (needs std)
- `general_gaussian` (needs power, width)
- `slepian` (needs width)
- `exponential` (needs tau), center is set to `None`.

If `win_type=None` all points are evenly weighted. To learn more about different window types see [scipy.signal window functions](#).

Examples

```
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
>>> df
   B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0
```

Rolling sum with a window length of 2, using the 'triang' window type.

```
>>> df.rolling(2, win_type='triang').sum()
   B
0  NaN
1  0.5
2  1.5
3  NaN
4  NaN
```

Rolling sum with a window length of 2, `min_periods` defaults to the window length.

```
>>> df.rolling(2).sum()
      B
0  NaN
1  1.0
2  3.0
3  NaN
4  NaN
```

Same as above, but explicitly set the `min_periods`

```
>>> df.rolling(2, min_periods=1).sum()
      B
0  0.0
1  1.0
2  3.0
3  2.0
4  4.0
```

A ragged (meaning not-a-regular frequency), time-indexed DataFrame

```
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]},
...                   index = [pd.Timestamp('20130101 09:00:00'),
...                             pd.Timestamp('20130101 09:00:02'),
...                             pd.Timestamp('20130101 09:00:03'),
...                             pd.Timestamp('20130101 09:00:05'),
...                             pd.Timestamp('20130101 09:00:06')])
```

```
>>> df
                B
2013-01-01 09:00:00  0.0
2013-01-01 09:00:02  1.0
2013-01-01 09:00:03  2.0
2013-01-01 09:00:05  NaN
2013-01-01 09:00:06  4.0
```

Contrasting to an integer rolling window, this will roll a variable length window corresponding to the time period. The default for `min_periods` is 1.

```
>>> df.rolling('2s').sum()
                B
2013-01-01 09:00:00  0.0
2013-01-01 09:00:02  1.0
2013-01-01 09:00:03  3.0
2013-01-01 09:00:05  NaN
2013-01-01 09:00:06  4.0
```

pandas.DataFrame.round

`DataFrame.round(self, decimals=0, *args, **kwargs)`

Round a DataFrame to a variable number of decimal places.

Parameters

decimals [int, dict, Series] Number of decimal places to round each column to. If an int is given, round each column to the same number of places. Otherwise dict and Series round to variable numbers of places. Column names should be in the keys if *decimals* is a dict-like, or in the index if *decimals* is a Series. Any columns not included in *decimals* will be left as is. Elements of *decimals* which are not columns of the input will be ignored.

***args** Additional keywords have no effect but might be accepted for compatibility with numpy.

****kwargs** Additional keywords have no effect but might be accepted for compatibility with numpy.

Returns

DataFrame A DataFrame with the affected columns rounded to the specified number of decimal places.

See also:

numpy.around Round a numpy array to the given number of decimals.

Series.round Round a Series to the given number of decimals.

Examples

```
>>> df = pd.DataFrame([(.21, .32), (.01, .67), (.66, .03), (.21, .18)],
...                    columns=['dogs', 'cats'])
>>> df
   dogs  cats
0  0.21  0.32
1  0.01  0.67
2  0.66  0.03
3  0.21  0.18
```

By providing an integer each column is rounded to the same number of decimal places

```
>>> df.round(1)
   dogs  cats
0   0.2  0.3
1   0.0  0.7
2   0.7  0.0
3   0.2  0.2
```

With a dict, the number of places for specific columns can be specified with the column names as key and the number of decimal places as value

```
>>> df.round({'dogs': 1, 'cats': 0})
   dogs  cats
0   0.2  0.0
1   0.0  1.0
2   0.7  0.0
3   0.2  0.0
```

Using a Series, the number of places for specific columns can be specified with the column names as index and the number of decimal places as value

```

>>> decimals = pd.Series([0, 1], index=['cats', 'dogs'])
>>> df.round(decimals)
   dogs  cats
0    0.2  0.0
1    0.0  1.0
2    0.7  0.0
3    0.2  0.0

```

pandas.DataFrame.rpow

DataFrame.rpow(*self*, *other*, *axis='columns'*, *level=None*, *fill_value=None*)

Get Exponential power of dataframe and other, element-wise (binary operator *rpow*).

Equivalent to `other ** dataframe`, but with support to substitute a *fill_value* for missing data in one of the inputs. With reverse version, *pow*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: *+*, *-*, ***, */*, *//*, *%*, ****.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.

DataFrame.sub Subtract DataFrames.

DataFrame.mul Multiply DataFrames.

DataFrame.div Divide DataFrames (float division).

DataFrame.truediv Divide DataFrames (float division).

DataFrame.floordiv Divide DataFrames (integer division).

DataFrame.mod Calculate modulo (remainder after division).

DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

	angles	degrees
circle	0	360
triangle	3	180
rectangle	4	360

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

```
>>> df.add(1)
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

Divide by constant with reverse version.

```
>>> df.div(10)
```

	angles	degrees
circle	0.0	36.0
triangle	0.3	18.0
rectangle	0.4	36.0

```
>>> df.rdiv(10)
```

	angles	degrees
circle	inf	0.027778
triangle	3.333333	0.055556
rectangle	2.500000	0.027778

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
```

	angles	degrees
circle	-1	358
triangle	2	178
rectangle	3	358

```
>>> df.sub([1, 2], axis='columns')
```

	angles	degrees
circle	-1	358
triangle	2	178
rectangle	3	358

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...         axis='index')
           angles  degrees
circle         -1     359
triangle        2     179
rectangle       3     359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
           angles
circle          0
triangle         3
rectangle        4
```

```
>>> df * other
           angles  degrees
circle          0     NaN
triangle         9     NaN
rectangle       16     NaN
```

```
>>> df.mul(other, fill_value=0)
           angles  degrees
circle          0     0.0
triangle         9     0.0
rectangle       16     0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                               index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                       ['circle', 'triangle', 'rectangle',
...                                        'square', 'pentagon', 'hexagon']])
>>> df_multindex
           angles  degrees
A circle          0     360
  triangle         3     180
  rectangle        4     360
B square          4     360
  pentagon         5     540
  hexagon          6     720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
           angles  degrees
A circle        NaN     1.0
  triangle        1.0     1.0
  rectangle        1.0     1.0
B square         0.0     0.0
  pentagon         0.0     0.0
  hexagon         0.0     0.0
```

pandas.DataFrame.rsub

`DataFrame.rsub(self, other, axis='columns', level=None, fill_value=None)`

Get Subtraction of dataframe and other, element-wise (binary operator *rsub*).

Equivalent to `other - dataframe`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *sub*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

hexagon	0.0	0.0

pandas.DataFrame.rtruediv

`DataFrame.rtruediv(self, other, axis='columns', level=None, fill_value=None)`

Get Floating division of dataframe and other, element-wise (binary operator *rtruediv*).

Equivalent to `other / dataframe`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *truediv*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

pentagon	5	540
hexagon	6	720

```
>>> df.div(df_multindex, level=1, fill_value=0)
```

	angles	degrees
A circle	NaN	1.0
triangle	1.0	1.0
rectangle	1.0	1.0
B square	0.0	0.0
pentagon	0.0	0.0
hexagon	0.0	0.0

pandas.DataFrame.sample

```
DataFrame.sample(self, n=None, frac=None, replace=False, weights=None, random_state=None, axis=None)
```

Return a random sample of items from an axis of object.

You can use `random_state` for reproducibility.

Parameters

n [int, optional] Number of items from axis to return. Cannot be used with `frac`. Default = 1 if `frac` = None.

frac [float, optional] Fraction of axis items to return. Cannot be used with `n`.

replace [bool, default False] Sample with or without replacement.

weights [str or ndarray-like, optional] Default 'None' results in equal probability weighting. If passed a Series, will align with target object on index. Index values in weights not found in sampled object will be ignored and index values in sampled object not in weights will be assigned weights of zero. If called on a DataFrame, will accept the name of a column when `axis = 0`. Unless weights are a Series, weights must be same length as axis being sampled. If weights do not sum to 1, they will be normalized to sum to 1. Missing values in the weights column will be treated as zero. Infinite values not allowed.

random_state [int or numpy.random.RandomState, optional] Seed for the random number generator (if int), or numpy RandomState object.

axis [int or string, optional] Axis to sample. Accepts axis number or name. Default is stat axis for given data type (0 for Series and DataFrames).

Returns

Series or DataFrame A new object of same type as caller containing `n` items randomly sampled from the caller object.

See also:

`numpy.random.choice` Generates a random sample from a given 1-D numpy array.

Examples

```
>>> df = pd.DataFrame({'num_legs': [2, 4, 8, 0],
...                    'num_wings': [2, 0, 0, 0],
...                    'num_specimen_seen': [10, 2, 1, 8]},
...                   index=['falcon', 'dog', 'spider', 'fish'])
>>> df
```

	num_legs	num_wings	num_specimen_seen
falcon	2	2	10
dog	4	0	2
spider	8	0	1
fish	0	0	8

Extract 3 random elements from the Series `df['num_legs']`: Note that we use `random_state` to ensure the reproducibility of the examples.

```
>>> df['num_legs'].sample(n=3, random_state=1)
fish      0
spider    8
falcon    2
Name: num_legs, dtype: int64
```

A random 50% sample of the DataFrame with replacement:

```
>>> df.sample(frac=0.5, replace=True, random_state=1)
   num_legs  num_wings  num_specimen_seen
dog         4         0                 2
fish        0         0                 8
```

Using a DataFrame column as weights. Rows with larger value in the *num_specimen_seen* column are more likely to be sampled.

```
>>> df.sample(n=2, weights='num_specimen_seen', random_state=1)
   num_legs  num_wings  num_specimen_seen
falcon     2         2                 10
fish       0         0                 8
```

pandas.DataFrame.select_dtypes

`DataFrame.select_dtypes(self, include=None, exclude=None)`

Return a subset of the DataFrame's columns based on the column dtypes.

Parameters

include, exclude [scalar or list-like] A selection of dtypes or strings to be included/excluded. At least one of these parameters must be supplied.

Returns

DataFrame The subset of the frame including the dtypes in **include** and excluding the dtypes in **exclude**.

Raises

ValueError

- If both of **include** and **exclude** are empty
- If **include** and **exclude** have overlapping elements
- If any kind of string dtype is passed in.

Notes

- To select all *numeric* types, use `np.number` or `'number'`
- To select strings you must use the `object` dtype, but note that this will return *all* object dtype columns
- See the [numpy dtype hierarchy](#)
- To select datetimes, use `np.datetime64`, `'datetime'` or `'datetime64'`
- To select timedeltas, use `np.timedelta64`, `'timedelta'` or `'timedelta64'`

- To select Pandas categorical dtypes, use 'category'
- To select Pandas datetimetz dtypes, use 'datetimetz' (new in 0.20.0) or 'datetime64[ns, tz]'

Examples

```
>>> df = pd.DataFrame({'a': [1, 2] * 3,
...                    'b': [True, False] * 3,
...                    'c': [1.0, 2.0] * 3})
>>> df
```

	a	b	c
0	1	True	1.0
1	2	False	2.0
2	1	True	1.0
3	2	False	2.0
4	1	True	1.0
5	2	False	2.0

```
>>> df.select_dtypes(include='bool')
b
0 True
1 False
2 True
3 False
4 True
5 False
```

```
>>> df.select_dtypes(include=['float64'])
c
0 1.0
1 2.0
2 1.0
3 2.0
4 1.0
5 2.0
```

```
>>> df.select_dtypes(exclude=['int'])
b c
0 True 1.0
1 False 2.0
2 True 1.0
3 False 2.0
4 True 1.0
5 False 2.0
```

pandas.DataFrame.sem

`DataFrame.sem(self, axis=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs)`

Return unbiased standard error of the mean over requested axis.

Normalized by N-1 by default. This can be changed using the `ddof` argument

Parameters

- axis** [{index (0), columns (1)}]
- skipna** [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA
- level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series
- ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is $N - \text{ddof}$, where N represents the number of elements.
- numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns

Series or DataFrame (if level specified)

pandas.DataFrame.set_axis

`DataFrame.set_axis(self, labels, axis=0, inplace=None)`

Assign desired index to given axis.

Indexes for column or row labels can be changed by assigning a list-like or Index.

Changed in version 0.21.0: The signature is now `labels` and `axis`, consistent with the rest of pandas API. Previously, the `axis` and `labels` arguments were respectively the first and second positional arguments.

Parameters

- labels** [list-like, Index] The values for the new index.
- axis** [{0 or 'index', 1 or 'columns'}, default 0] The axis to update. The value 0 identifies the rows, and 1 identifies the columns.
- inplace** [bool, default None] Whether to return a new `%(klass)s` instance.

Warning: `inplace=None` currently falls back to `True`, but in a future version, will default to `False`. Use `inplace=True` explicitly rather than relying on the default.

Returns

- renamed** [%(klass)s or None] An object of same type as caller if `inplace=False`, None otherwise.

See also:

`DataFrame.rename_axis` Alter the name of the index or columns.

Examples

Series

```
>>> s = pd.Series([1, 2, 3])
>>> s
0    1
1    2
2    3
dtype: int64
```

```
>>> s.set_axis(['a', 'b', 'c'], axis=0, inplace=False)
a    1
b    2
c    3
dtype: int64
```

The original object is not modified.

```
>>> s
0    1
1    2
2    3
dtype: int64
```

DataFrame

```
>>> df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6]})
```

Change the row labels.

```
>>> df.set_axis(['a', 'b', 'c'], axis='index', inplace=False)
   A  B
a  1  4
b  2  5
c  3  6
```

Change the column labels.

```
>>> df.set_axis(['I', 'II'], axis='columns', inplace=False)
   I  II
0  1  4
1  2  5
2  3  6
```

Now, update the labels inplace.

```
>>> df.set_axis(['i', 'ii'], axis='columns', inplace=True)
>>> df
   i  ii
0  1  4
1  2  5
2  3  6
```

pandas.DataFrame.set_index

```
DataFrame.set_index(self, keys, drop=True, append=False, inplace=False, verify_integrity=False)
```

Set the DataFrame index using existing columns.

Set the DataFrame index (row labels) using one or more existing columns or arrays (of the correct length). The index can replace the existing index or expand on it.

Parameters

keys [label or array-like or list of labels/arrays] This parameter can be either a single column key, a single array of the same length as the calling DataFrame, or a list containing an arbitrary combination of column keys and arrays. Here, “array” encompasses *Series*, *Index*, *np.ndarray*, and instances of *Iterator*.

drop [bool, default True] Delete columns to be used as the new index.

append [bool, default False] Whether to append columns to existing index.

inplace [bool, default False] Modify the DataFrame in place (do not create a new object).

verify_integrity [bool, default False] Check the new index for duplicates. Otherwise defer the check until necessary. Setting to False will improve the performance of this method.

Returns

DataFrame Changed row labels.

See also:

DataFrame.reset_index Opposite of `set_index`.

DataFrame.reindex Change to new indices or expand indices.

DataFrame.reindex_like Change to same indices as other DataFrame.

Examples

```
>>> df = pd.DataFrame({'month': [1, 4, 7, 10],
...                    'year': [2012, 2014, 2013, 2014],
...                    'sale': [55, 40, 84, 31]})
>>> df
   month  year  sale
0      1  2012    55
1      4  2014    40
2      7  2013    84
3     10  2014    31
```

Set the index to become the ‘month’ column:

```
>>> df.set_index('month')
   year  sale
month
1     2012    55
4     2014    40
```

(continues on next page)

(continued from previous page)

7	2013	84
10	2014	31

Create a MultiIndex using columns 'year' and 'month':

```
>>> df.set_index(['year', 'month'])
      sale
year month
2012  1    55
2014  4    40
2013  7    84
2014 10    31
```

Create a MultiIndex using an Index and a column:

```
>>> df.set_index([pd.Index([1, 2, 3, 4]), 'year'])
      month sale
year
1 2012  1    55
2 2014  4    40
3 2013  7    84
4 2014 10    31
```

Create a MultiIndex using two Series:

```
>>> s = pd.Series([1, 2, 3, 4])
>>> df.set_index([s, s**2])
      month year sale
1 1      1 2012  55
2 4      4 2014  40
3 9      7 2013  84
4 16     10 2014  31
```

pandas.DataFrame.set_value

`DataFrame.set_value(self, index, col, value, takeable=False)`

Put single value at passed column and index.

Deprecated since version 0.21.0: Use `.at[]` or `.iat[]` accessors instead.

Parameters

index [row label]

col [column label]

value [scalar]

takeable [interpret the index/col as indexers, default False]

Returns

DataFrame If label pair is contained, will be reference to calling DataFrame, otherwise a new object.

pandas.DataFrame.shift

`DataFrame.shift(self, periods=1, freq=None, axis=0, fill_value=None)`

Shift index by desired number of periods with an optional time *freq*.

When *freq* is not passed, shift the index without realigning the data. If *freq* is passed (in this case, the index must be date or datetime, or it will raise a *NotImplementedError*), the index will be increased using the periods and the *freq*.

Parameters

periods [int] Number of periods to shift. Can be positive or negative.

freq [DateOffset, tseries.offsets, timedelta, or str, optional] Offset to use from the tseries module or time rule (e.g. 'EOM'). If *freq* is specified then the index values are shifted but the data is not realigned. That is, use *freq* if you would like to extend the index when shifting and preserve the original data.

axis [{0 or 'index', 1 or 'columns', None}, default None] Shift direction.

fill_value [object, optional] The scalar value to use for newly introduced missing values. the default depends on the dtype of *self*. For numeric data, `np.nan` is used. For datetime, timedelta, or period data, etc. `NaT` is used. For extension dtypes, `self.dtype.na_value` is used.

Changed in version 0.24.0.

Returns

DataFrame Copy of input object, shifted.

See also:

Index.shift Shift values of Index.

DatetimeIndex.shift Shift values of DatetimeIndex.

PeriodIndex.shift Shift values of PeriodIndex.

tshift Shift the time index, using the index's frequency if available.

Examples

```
>>> df = pd.DataFrame({'Col1': [10, 20, 15, 30, 45],
...                    'Col2': [13, 23, 18, 33, 48],
...                    'Col3': [17, 27, 22, 37, 52]})
```

```
>>> df.shift(periods=3)
   Col1  Col2  Col3
0   NaN   NaN   NaN
1   NaN   NaN   NaN
2   NaN   NaN   NaN
3  10.0  13.0  17.0
4  20.0  23.0  27.0
```

```
>>> df.shift(periods=1, axis='columns')
   Col1  Col2  Col3
0   NaN  10.0  13.0
```

(continues on next page)

(continued from previous page)

1	NaN	20.0	23.0
2	NaN	15.0	18.0
3	NaN	30.0	33.0
4	NaN	45.0	48.0

```
>>> df.shift(periods=3, fill_value=0)
   Col1  Col2  Col3
0      0     0     0
1      0     0     0
2      0     0     0
3     10    13    17
4     20    23    27
```

pandas.DataFrame.skew

`DataFrame.skew(self, axis=None, skipna=None, level=None, numeric_only=None, **kwargs)`
Return unbiased skew over requested axis Normalized by N-1.

Parameters

axis [{index (0), columns (1)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

pandas.DataFrame.slice_shift

`DataFrame.slice_shift(self, periods=1, axis=0)`

Equivalent to *shift* without copying data. The shifted data will not include the dropped periods and the shifted axis will be smaller than the original.

Parameters

periods [int] Number of periods to move, can be positive or negative

Returns

shifted [same type as caller]

Notes

While the *slice_shift* is faster than *shift*, you may pay for it later during alignment.

pandas.DataFrame.sort_index

`DataFrame.sort_index(self, axis=0, level=None, ascending=True, inplace=False, kind='quicksort', na_position='last', sort_remaining=True, by=None)`
Sort object by labels (along an axis).

Parameters

- axis** [{0 or 'index', 1 or 'columns'}, default 0] The axis along which to sort. The value 0 identifies the rows, and 1 identifies the columns.
- level** [int or level name or list of ints or list of level names] If not None, sort on values in specified index level(s).
- ascending** [bool, default True] Sort ascending vs. descending.
- inplace** [bool, default False] If True, perform operation in-place.
- kind** [{'quicksort', 'mergesort', 'heapsort'}, default 'quicksort'] Choice of sorting algorithm. See also `ndarray.sort` for more information. *mergesort* is the only stable algorithm. For DataFrames, this option is only applied when sorting on a single column or label.
- na_position** [{'first', 'last'}, default 'last'] Puts NaNs at the beginning if *first*; *last* puts NaNs at the end. Not implemented for MultiIndex.
- sort_remaining** [bool, default True] If True and sorting by level and index is multilevel, sort by other levels too (in order) after sorting by specified level.

Returns

- sorted_obj** [DataFrame or None] DataFrame with sorted index if `inplace=False`, None otherwise.

pandas.DataFrame.sort_values

`DataFrame.sort_values(self, by, axis=0, ascending=True, inplace=False, kind='quicksort', na_position='last')`
Sort by the values along either axis.

Parameters

- by** [str or list of str] Name or list of names to sort by.
- if *axis* is 0 or *'index'* then *by* may contain index levels and/or column labels
 - if *axis* is 1 or *'columns'* then *by* may contain column levels and/or index labels
- Changed in version 0.23.0: Allow specifying index or column level names.
- axis** [{0 or 'index', 1 or 'columns'}, default 0] Axis to be sorted.
- ascending** [bool or list of bool, default True] Sort ascending vs. descending. Specify list for multiple sort orders. If this is a list of bools, must match the length of the *by*.
- inplace** [bool, default False] If True, perform operation in-place.
- kind** [{'quicksort', 'mergesort', 'heapsort'}, default 'quicksort'] Choice of sorting algorithm. See also `ndarray.sort` for more information. *mergesort* is the only

stable algorithm. For DataFrames, this option is only applied when sorting on a single column or label.

na_position [{'first', 'last'}, default 'last'] Puts NaNs at the beginning if *first*; *last* puts NaNs at the end.

Returns

sorted_obj [DataFrame or None] DataFrame with sorted values if inplace=False, None otherwise.

Examples

```
>>> df = pd.DataFrame({
...     'col1': ['A', 'A', 'B', np.nan, 'D', 'C'],
...     'col2': [2, 1, 9, 8, 7, 4],
...     'col3': [0, 1, 9, 4, 2, 3],
... })
>>> df
   col1 col2 col3
0    A     2     0
1    A     1     1
2    B     9     9
3  NaN     8     4
4    D     7     2
5    C     4     3
```

Sort by col1

```
>>> df.sort_values(by=['col1'])
   col1 col2 col3
0    A     2     0
1    A     1     1
2    B     9     9
5    C     4     3
4    D     7     2
3  NaN     8     4
```

Sort by multiple columns

```
>>> df.sort_values(by=['col1', 'col2'])
   col1 col2 col3
1    A     1     1
0    A     2     0
2    B     9     9
5    C     4     3
4    D     7     2
3  NaN     8     4
```

Sort Descending

```
>>> df.sort_values(by='col1', ascending=False)
   col1 col2 col3
4    D     7     2
```

(continues on next page)

(continued from previous page)

5	C	4	3
2	B	9	9
0	A	2	0
1	A	1	1
3	NaN	8	4

Putting NAs first

```
>>> df.sort_values(by='col1', ascending=False, na_position='first')
   col1 col2 col3
3  NaN   8    4
4   D    7    2
5   C    4    3
2   B    9    9
0   A    2    0
1   A    1    1
```

pandas.DataFrame.sparse

DataFrame.sparse()

DataFrame accessor for sparse data.

New in version 0.25.0.

pandas.DataFrame.squeeze

DataFrame.squeeze(self, axis=None)

Squeeze 1 dimensional axis objects into scalars.

Series or DataFrames with a single element are squeezed to a scalar. DataFrames with a single column or a single row are squeezed to a Series. Otherwise the object is unchanged.

This method is most useful when you don't know if your object is a Series or DataFrame, but you do know it has just a single column. In that case you can safely call *squeeze* to ensure you have a Series.

Parameters

axis [{0 or 'index', 1 or 'columns', None}, default None] A specific axis to squeeze. By default, all length-1 axes are squeezed.

New in version 0.20.0.

Returns

DataFrame, Series, or scalar The projection after squeezing *axis* or all the axes.**See also:****Series.iloc** Integer-location based indexing for selecting scalars.**DataFrame.iloc** Integer-location based indexing for selecting Series.**Series.to_frame** Inverse of DataFrame.squeeze for a single-column DataFrame.

Examples

```
>>> primes = pd.Series([2, 3, 5, 7])
```

Slicing might produce a Series with a single value:

```
>>> even_primes = primes[primes % 2 == 0]
>>> even_primes
0    2
dtype: int64
```

```
>>> even_primes.squeeze()
2
```

Squeezing objects with more than one value in every axis does nothing:

```
>>> odd_primes = primes[primes % 2 == 1]
>>> odd_primes
1    3
2    5
3    7
dtype: int64
```

```
>>> odd_primes.squeeze()
1    3
2    5
3    7
dtype: int64
```

Squeezing is even more effective when used with DataFrames.

```
>>> df = pd.DataFrame([[1, 2], [3, 4]], columns=['a', 'b'])
>>> df
   a  b
0  1  2
1  3  4
```

Slicing a single column will produce a DataFrame with the columns having only one value:

```
>>> df_a = df[['a']]
>>> df_a
   a
0  1
1  3
```

So the columns can be squeezed down, resulting in a Series:

```
>>> df_a.squeeze('columns')
0    1
1    3
Name: a, dtype: int64
```

Slicing a single row from a single column will produce a single scalar DataFrame:

```
>>> df_0a = df.loc[df.index < 1, ['a']]
>>> df_0a
   a
0  1
```

Squeezing the rows produces a single scalar Series:

```
>>> df_0a.squeeze('rows')
a    1
Name: 0, dtype: int64
```

Squeezing all axes will project directly into a scalar:

```
>>> df_0a.squeeze()
1
```

pandas.DataFrame.stack

DataFrame.stack(*self*, *level=-1*, *dropna=True*)

Stack the prescribed level(s) from columns to index.

Return a reshaped DataFrame or Series having a multi-level index with one or more new inner-most levels compared to the current DataFrame. The new inner-most levels are created by pivoting the columns of the current dataframe:

- if the columns have a single level, the output is a Series;
- if the columns have multiple levels, the new index level(s) is (are) taken from the prescribed level(s) and the output is a DataFrame.

The new index levels are sorted.

Parameters

level [int, str, list, default -1] Level(s) to stack from the column axis onto the index axis, defined as one index or label, or a list of indices or labels.

dropna [bool, default True] Whether to drop rows in the resulting Frame/Series with missing values. Stacking a column level onto the index axis can create combinations of index and column values that are missing from the original dataframe. See Examples section.

Returns

DataFrame or Series Stacked dataframe or series.

See also:

DataFrame.unstack Unstack prescribed level(s) from index axis onto column axis.

DataFrame.pivot Reshape dataframe from long format to wide format.

DataFrame.pivot_table Create a spreadsheet-style pivot table as a DataFrame.

Notes

The function is named by analogy with a collection of books being reorganized from being side by side on a horizontal position (the columns of the dataframe) to being stacked vertically on top of each other (in the index of the dataframe).

Examples

Single level columns

```
>>> df_single_level_cols = pd.DataFrame([[0, 1], [2, 3]],
...                                     index=['cat', 'dog'],
...                                     columns=['weight', 'height'])
```

Stacking a dataframe with a single level column axis returns a Series:

```
>>> df_single_level_cols
   weight height
cat      0      1
dog      2      3
>>> df_single_level_cols.stack()
cat weight      0
   height      1
dog weight      2
   height      3
dtype: int64
```

Multi level columns: simple case

```
>>> multicol1 = pd.MultiIndex.from_tuples([('weight', 'kg'),
...                                       ('weight', 'pounds')])
>>> df_multi_level_cols1 = pd.DataFrame([[1, 2], [2, 4]],
...                                     index=['cat', 'dog'],
...                                     columns=multicol1)
```

Stacking a dataframe with a multi-level column axis:

```
>>> df_multi_level_cols1
   weight
   kg    pounds
cat    1      2
dog    2      4
>>> df_multi_level_cols1.stack()
   weight
cat kg      1
   pounds  2
dog kg      2
   pounds  4
```

Missing values

```
>>> multicol2 = pd.MultiIndex.from_tuples([('weight', 'kg'),
...                                       ('height', 'm')])
```

(continues on next page)

(continued from previous page)

```
>>> df_multi_level_cols2 = pd.DataFrame([[1.0, 2.0], [3.0, 4.0]],
...                                     index=['cat', 'dog'],
...                                     columns=multicol2)
```

It is common to have missing values when stacking a dataframe with multi-level columns, as the stacked dataframe typically has more values than the original dataframe. Missing values are filled with NaNs:

```
>>> df_multi_level_cols2
      weight height
      kg      m
cat    1.0    2.0
dog    3.0    4.0
>>> df_multi_level_cols2.stack()
      height weight
cat kg    NaN    1.0
     m    2.0    NaN
dog kg    NaN    3.0
     m    4.0    NaN
```

Prescribing the level(s) to be stacked

The first parameter controls which level or levels are stacked:

```
>>> df_multi_level_cols2.stack(0)
      kg      m
cat height NaN  2.0
   weight 1.0 NaN
dog height NaN  4.0
   weight 3.0 NaN
>>> df_multi_level_cols2.stack([0, 1])
cat height m    2.0
   weight kg    1.0
dog height m    4.0
   weight kg    3.0
dtype: float64
```

Dropping missing values

```
>>> df_multi_level_cols3 = pd.DataFrame([[None, 1.0], [2.0, 3.0]],
...                                     index=['cat', 'dog'],
...                                     columns=multicol2)
```

Note that rows where all values are missing are dropped by default but this behaviour can be controlled via the `dropna` keyword parameter:

```
>>> df_multi_level_cols3
      weight height
      kg      m
cat    NaN    1.0
dog    2.0    3.0
>>> df_multi_level_cols3.stack(dropna=False)
      height weight
```

(continues on next page)

(continued from previous page)

```

cat kg    NaN    NaN
   m      1.0    NaN
dog kg    NaN    2.0
   m      3.0    NaN
>>> df_multi_level_cols3.stack(dropna=True)
      height  weight
cat m      1.0    NaN
dog kg     NaN    2.0
   m      3.0    NaN

```

pandas.DataFrame.std

`DataFrame.std(self, axis=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs)`

Return sample standard deviation over requested axis.

Normalized by N-1 by default. This can be changed using the `ddof` argument

Parameters

axis [{index (0), columns (1)}]

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is $N - \text{ddof}$, where N represents the number of elements.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns

Series or DataFrame (if level specified)

pandas.DataFrame.sub

`DataFrame.sub(self, other, axis='columns', level=None, fill_value=None)`

Get Subtraction of dataframe and other, element-wise (binary operator `sub`).

Equivalent to `dataframe - other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, `rsub`.

Among flexible wrappers (`add`, `sub`, `mul`, `div`, `mod`, `pow`) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.

DataFrame.sub Subtract DataFrames.

DataFrame.mul Multiply DataFrames.

DataFrame.div Divide DataFrames (float division).

DataFrame.truediv Divide DataFrames (float division).

DataFrame.floordiv Divide DataFrames (integer division).

DataFrame.mod Calculate modulo (remainder after division).

DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

	angles	degrees
circle	0	360
triangle	3	180
rectangle	4	360

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

```
>>> df.add(1)
```

	angles	degrees
circle	1	361

(continues on next page)

(continued from previous page)

triangle	4	181
rectangle	5	361

Divide by constant with reverse version.

```
>>> df.div(10)
      angles  degrees
circle    0.0    36.0
triangle  0.3    18.0
rectangle 0.4    36.0
```

```
>>> df.rdiv(10)
      angles  degrees
circle    inf  0.027778
triangle  3.333333  0.055556
rectangle 2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
      angles  degrees
circle    -1    358
triangle  2     178
rectangle 3     358
```

```
>>> df.sub([1, 2], axis='columns')
      angles  degrees
circle    -1    358
triangle  2     178
rectangle 3     358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
      angles  degrees
circle    -1    359
triangle  2     179
rectangle 3     359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
      angles
circle    0
triangle  3
rectangle 4
```

```
>>> df * other
      angles  degrees
circle    0     NaN
```

(continues on next page)

(continued from previous page)

triangle	9	NaN
rectangle	16	NaN

```
>>> df.mul(other, fill_value=0)
      angles  degrees
circle      0    0.0
triangle    9    0.0
rectangle   16    0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                               index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                       ['circle', 'triangle', 'rectangle',
...                                       'square', 'pentagon', 'hexagon']])
>>> df_multindex
      angles  degrees
A circle      0    360
  triangle    3    180
  rectangle    4    360
B square      4    360
  pentagon    5    540
  hexagon     6    720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
      angles  degrees
A circle   NaN     1.0
  triangle  1.0     1.0
  rectangle 1.0     1.0
B square   0.0     0.0
  pentagon 0.0     0.0
  hexagon  0.0     0.0
```

pandas.DataFrame.subtract

DataFrame.subtract(*self*, *other*, *axis*='columns', *level*=None, *fill_value*=None)

Get Subtraction of dataframe and other, element-wise (binary operator *sub*).

Equivalent to `dataframe - other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *rsub*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: *+*, *-*, ***, */*, *//*, *%*, ****.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

DataFrame.mul Multiply DataFrames.

DataFrame.div Divide DataFrames (float division).

DataFrame.truediv Divide DataFrames (float division).

DataFrame.floordiv Divide DataFrames (integer division).

DataFrame.mod Calculate modulo (remainder after division).

DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

	angles	degrees
circle	0	360
triangle	3	180
rectangle	4	360

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

```
>>> df.add(1)
```

	angles	degrees
circle	1	361

(continues on next page)

(continued from previous page)

triangle	4	181
rectangle	5	361

Divide by constant with reverse version.

```
>>> df.div(10)
      angles  degrees
circle    0.0    36.0
triangle  0.3    18.0
rectangle 0.4    36.0
```

```
>>> df.rdiv(10)
      angles  degrees
circle    inf  0.027778
triangle 3.333333 0.055556
rectangle 2.500000 0.027778
```

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
      angles  degrees
circle    -1    358
triangle     2    178
rectangle     3    358
```

```
>>> df.sub([1, 2], axis='columns')
      angles  degrees
circle    -1    358
triangle     2    178
rectangle     3    358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
      angles  degrees
circle    -1    359
triangle     2    179
rectangle     3    359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
      angles
circle     0
triangle    3
rectangle   4
```

```
>>> df * other
      angles  degrees
circle     0     NaN
```

(continues on next page)

(continued from previous page)

triangle	9	NaN
rectangle	16	NaN

```
>>> df.mul(other, fill_value=0)
           angles  degrees
circle         0     0.0
triangle        9     0.0
rectangle       16     0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                               index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                       ['circle', 'triangle', 'rectangle',
...                                       'square', 'pentagon', 'hexagon']])
>>> df_multindex
           angles  degrees
A circle         0     360
  triangle        3     180
  rectangle       4     360
B square         4     360
  pentagon        5     540
  hexagon         6     720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
           angles  degrees
A circle       NaN     1.0
  triangle     1.0     1.0
  rectangle     1.0     1.0
B square       0.0     0.0
  pentagon     0.0     0.0
  hexagon      0.0     0.0
```

pandas.DataFrame.sum

`DataFrame.sum(self, axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs)`

Return the sum of the values for the requested axis.

This is equivalent to the method `numpy.sum`.

Parameters

axis [{index (0), columns (1)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

min_count [int, default 0] The required number of valid values to perform the operation. If fewer than **min_count** non-NA values are present the result will be NA.

New in version 0.22.0: Added with the default being 0. This means the sum of an all-NA or empty Series is 0, and the product of an all-NA or empty Series is 1.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

See also:

Series.sum Return the sum.

Series.min Return the minimum.

Series.max Return the maximum.

Series.idxmin Return the index of the minimum.

Series.idxmax Return the index of the maximum.

DataFrame.sum Return the sum over the requested axis.

DataFrame.min Return the minimum over the requested axis.

DataFrame.max Return the maximum over the requested axis.

DataFrame.idxmin Return the index of the minimum over the requested axis.

DataFrame.idxmax Return the index of the maximum over the requested axis.

Examples

```
>>> idx = pd.MultiIndex.from_arrays([
...     ['warm', 'warm', 'cold', 'cold'],
...     ['dog', 'falcon', 'fish', 'spider']],
...     names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded  animal
warm     dog      4
         falcon   2
cold     fish     0
         spider   8
Name: legs, dtype: int64
```

```
>>> s.sum()
14
```

Sum using level names, as well as indices.

```
>>> s.sum(level='blooded')
blooded
warm    6
cold    8
Name: legs, dtype: int64
```

```
>>> s.sum(level=0)
blooded
warm    6
cold    8
Name: legs, dtype: int64
```

By default, the sum of an empty or all-NA Series is 0.

```
>>> pd.Series([]).sum() # min_count=0 is the default
0.0
```

This can be controlled with the `min_count` parameter. For example, if you'd like the sum of an empty series to be NaN, pass `min_count=1`.

```
>>> pd.Series([]).sum(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```
>>> pd.Series([np.nan]).sum()
0.0
```

```
>>> pd.Series([np.nan]).sum(min_count=1)
nan
```

pandas.DataFrame.swapaxes

`DataFrame.swapaxes(self, axis1, axis2, copy=True)`

Interchange axes and swap values axes appropriately.

Returns

`y` [same as input]

pandas.DataFrame.swaplevel

`DataFrame.swaplevel(self, i=-2, j=-1, axis=0)`

Swap levels `i` and `j` in a MultiIndex on a particular axis.

Parameters

`i, j` [int, string (can be mixed)] Level of index to be swapped. Can pass level name as string.

Returns

`DataFrame`

Changed in version 0.18.1: The indexes `i` and `j` are now optional, and default to the two innermost levels of the index.

`pandas.DataFrame.tail`

`DataFrame.tail(self, n=5)`

Return the last n rows.

This function returns last n rows from the object based on position. It is useful for quickly verifying data, for example, after sorting or appending rows.

Parameters

`n` [int, default 5] Number of rows to select.

Returns

type of caller The last n rows of the caller object.

See also:

`DataFrame.head` The first n rows of the caller object.

Examples

```
>>> df = pd.DataFrame({'animal':['alligator', 'bee', 'falcon', 'lion',
...                               'monkey', 'parrot', 'shark', 'whale', 'zebra']})
>>> df
   animal
0 alligator
1      bee
2   falcon
3     lion
4  monkey
5  parrot
6   shark
7   whale
8   zebra
```

Viewing the last 5 lines

```
>>> df.tail()
   animal
4  monkey
5  parrot
6   shark
7   whale
8   zebra
```

Viewing the last n lines (three in this case)

```
>>> df.tail(3)
   animal
6   shark
```

(continues on next page)

(continued from previous page)

```
7 whale
8 zebra
```

pandas.DataFrame.take**DataFrame.take**(*self*, *indices*, *axis=0*, *is_copy=True*, ***kwargs*)Return the elements in the given *positional* indices along an axis.

This means that we are not indexing according to actual values in the index attribute of the object. We are indexing according to the actual position of the element in the object.

Parameters**indices** [array-like] An array of ints indicating which positions to take.**axis** [{0 or 'index', 1 or 'columns', None}, default 0] The axis on which to select elements. 0 means that we are selecting rows, 1 means that we are selecting columns.**is_copy** [bool, default True] Whether to return a copy of the original object or not.****kwargs** For compatibility with `numpy.take()`. Has no effect on the output.**Returns****taken** [same type as caller] An array-like containing the elements taken from the object.**See also:****DataFrame.loc** Select a subset of a DataFrame by labels.**DataFrame.iloc** Select a subset of a DataFrame by positions.**numpy.take** Take elements from an array along an axis.**Examples**

```
>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
...                    ('parrot', 'bird', 24.0),
...                    ('lion', 'mammal', 80.5),
...                    ('monkey', 'mammal', np.nan)],
...                    columns=['name', 'class', 'max_speed'],
...                    index=[0, 2, 3, 1])
>>> df
   name  class  max_speed
0  falcon   bird    389.0
2  parrot   bird     24.0
3   lion  mammal    80.5
1  monkey  mammal     NaN
```

Take elements at positions 0 and 3 along the axis 0 (default).

Note how the actual indices selected (0 and 1) do not correspond to our selected indices 0 and 3. That's because we are selecting the 0th and 3rd rows, not rows whose indices equal 0 and 3.

```
>>> df.take([0, 3])
   name  class  max_speed
0  falcon  bird    389.0
1  monkey  mammal     NaN
```

Take elements at indices 1 and 2 along the axis 1 (column selection).

```
>>> df.take([1, 2], axis=1)
   class  max_speed
0  bird    389.0
2  bird    24.0
3  mammal    80.5
1  mammal     NaN
```

We may take elements using negative integers for positive indices, starting from the end of the object, just like with Python lists.

```
>>> df.take([-1, -2])
   name  class  max_speed
1  monkey  mammal     NaN
3  lion  mammal    80.5
```

pandas.DataFrame.to_clipboard

`DataFrame.to_clipboard(self, excel=True, sep=None, **kwargs)`

Copy object to the system clipboard.

Write a text representation of object to the system clipboard. This can be pasted into Excel, for example.

Parameters

`excel` [bool, default True]

- True, use the provided separator, writing in a csv format for allowing easy pasting into excel.
- False, write a string representation of the object to the clipboard.

`sep` [str, default '\t'] Field delimiter.

`**kwargs` These parameters will be passed to `DataFrame.to_csv`.

See also:

`DataFrame.to_csv` Write a DataFrame to a comma-separated values (csv) file.

`read_clipboard` Read text from clipboard and pass to `read_table`.

Notes

Requirements for your platform.

- Linux : `xclip`, or `xsel` (with `PyQt4` modules)
- Windows : none
- OS X : none

Examples

Copy the contents of a DataFrame to the clipboard.

```
>>> df = pd.DataFrame([[1, 2, 3], [4, 5, 6]], columns=['A', 'B', 'C'])
>>> df.to_clipboard(sep=',')
... # Wrote the following to the system clipboard:
... # ,A,B,C
... # 0,1,2,3
... # 1,4,5,6
```

We can omit the the index by passing the keyword *index* and setting it to false.

```
>>> df.to_clipboard(sep=',', index=False)
... # Wrote the following to the system clipboard:
... # A,B,C
... # 1,2,3
... # 4,5,6
```

pandas.DataFrame.to_csv

```
DataFrame.to_csv(self, path_or_buf=None, sep=',', na_rep="", float_format=None,
                  columns=None, header=True, index=True, index_label=None, mode='w',
                  encoding=None, compression='infer', quoting=None, quotechar='"',
                  line_terminator=None, chunksize=None, date_format=None, double-
                  quote=True, escapechar=None, decimal='.')
```

Write object to a comma-separated values (csv) file.

Changed in version 0.24.0: The order of arguments for Series was changed.

Parameters

path_or_buf [str or file handle, default None] File path or object, if None is provided the result is returned as a string. If a file object is passed it should be opened with *newline=''*, disabling universal newlines.

Changed in version 0.24.0: Was previously named “path” for Series.

sep [str, default ‘,’] String of length 1. Field delimiter for the output file.

na_rep [str, default ‘’] Missing data representation.

float_format [str, default None] Format string for floating point numbers.

columns [sequence, optional] Columns to write.

header [bool or list of str, default True] Write out the column names. If a list of strings is given it is assumed to be aliases for the column names.

Changed in version 0.24.0: Previously defaulted to False for Series.

index [bool, default True] Write row names (index).

index_label [str or sequence, or False, default None] Column label for index column(s) if desired. If None is given, and *header* and *index* are True, then the index names are used. A sequence should be given if the object uses MultiIndex. If False do not print fields for index names. Use *index_label=False* for easier importing in R.

mode [str] Python write mode, default 'w'.

encoding [str, optional] A string representing the encoding to use in the output file, defaults to 'utf-8'.

compression [str, default 'infer'] Compression mode among the following possible values: {'infer', 'gzip', 'bz2', 'zip', 'xz', None}. If 'infer' and *path_or_buf* is path-like, then detect compression from the following extensions: '.gz', '.bz2', '.zip' or '.xz'. (otherwise no compression).

Changed in version 0.24.0: 'infer' option added and set to default.

quoting [optional constant from csv module] Defaults to csv.QUOTE_MINIMAL. If you have set a *float_format* then floats are converted to strings and thus csv.QUOTE_NONNUMERIC will treat them as non-numeric.

quotechar [str, default '"'] String of length 1. Character used to quote fields.

line_terminator [str, optional] The newline character or character sequence to use in the output file. Defaults to *os.linesep*, which depends on the OS in which this method is called ('n' for linux, 'rn' for Windows, i.e.).

Changed in version 0.24.0.

chunksize [int or None] Rows to write at a time.

date_format [str, default None] Format string for datetime objects.

doublequote [bool, default True] Control quoting of *quotechar* inside a field.

escapechar [str, default None] String of length 1. Character used to escape *sep* and *quotechar* when appropriate.

decimal [str, default '.'] Character recognized as decimal separator. E.g. use ',' for European data.

Returns

None or str If *path_or_buf* is None, returns the resulting csv format as a string. Otherwise returns None.

See also:

read_csv Load a CSV file into a DataFrame.

to_excel Write DataFrame to an Excel file.

Examples

```
>>> df = pd.DataFrame({'name': ['Raphael', 'Donatello'],
...                   'mask': ['red', 'purple'],
...                   'weapon': ['sai', 'bo staff']})
>>> df.to_csv(index=False)
'name,mask,weapon\nRaphael,red,sai\nDonatello,purple,bo staff\n'
```

pandas.DataFrame.to_dense

DataFrame.to_dense(*self*)

Return dense representation of Series/DataFrame (as opposed to sparse).

Deprecated since version 0.25.0.

Returns

`%(klass)s` Dense `%(klass)s`.

pandas.DataFrame.to_dict

`DataFrame.to_dict(self, orient='dict', into=<class 'dict'>)`

Convert the DataFrame to a dictionary.

The type of the key-value pairs can be customized with the parameters (see below).

Parameters

orient [str {'dict', 'list', 'series', 'split', 'records', 'index'}] Determines the type of the values of the dictionary.

- 'dict' (default) : dict like {column -> {index -> value}}
- 'list' : dict like {column -> [values]}
- 'series' : dict like {column -> Series(values)}
- 'split' : dict like {'index' -> [index], 'columns' -> [columns], 'data' -> [values]}
- 'records' : list like [{column -> value}, ... , {column -> value}]
- 'index' : dict like {index -> {column -> value}}

Abbreviations are allowed. *s* indicates *series* and *sp* indicates *split*.

into [class, default dict] The collections.abc.Mapping subclass used for all Mappings in the return value. Can be the actual class or an empty instance of the mapping type you want. If you want a collections.defaultdict, you must pass it initialized.

New in version 0.21.0.

Returns

dict, list or collections.abc.Mapping Return a collections.abc.Mapping object representing the DataFrame. The resulting transformation depends on the *orient* parameter.

See also:

`DataFrame.from_dict` Create a DataFrame from a dictionary.

`DataFrame.to_json` Convert a DataFrame to JSON format.

Examples

```
>>> df = pd.DataFrame({'col1': [1, 2],
...                    'col2': [0.5, 0.75]},
...                    index=['row1', 'row2'])
>>> df
   col1  col2
row1    1  0.50
```

(continues on next page)

(continued from previous page)

```
row2    2  0.75
>>> df.to_dict()
{'col1': {'row1': 1, 'row2': 2}, 'col2': {'row1': 0.5, 'row2': 0.75}}
```

You can specify the return orientation.

```
>>> df.to_dict('series')
{'col1': row1    1
          row2    2
Name: col1, dtype: int64,
 'col2': row1    0.50
          row2    0.75
Name: col2, dtype: float64}
```

```
>>> df.to_dict('split')
{'index': ['row1', 'row2'], 'columns': ['col1', 'col2'],
 'data': [[1, 0.5], [2, 0.75]]}
```

```
>>> df.to_dict('records')
[{'col1': 1, 'col2': 0.5}, {'col1': 2, 'col2': 0.75}]
```

```
>>> df.to_dict('index')
{'row1': {'col1': 1, 'col2': 0.5}, 'row2': {'col1': 2, 'col2': 0.75}}
```

You can also specify the mapping type.

```
>>> from collections import OrderedDict, defaultdict
>>> df.to_dict(into=OrderedDict)
OrderedDict([('col1', OrderedDict([('row1', 1), ('row2', 2)])),
            ('col2', OrderedDict([('row1', 0.5), ('row2', 0.75)]))])
```

If you want a *defaultdict*, you need to initialize it:

```
>>> dd = defaultdict(list)
>>> df.to_dict('records', into=dd)
[defaultdict(<class 'list'>, {'col1': 1, 'col2': 0.5}),
 defaultdict(<class 'list'>, {'col1': 2, 'col2': 0.75})]
```

pandas.DataFrame.to_excel

```
DataFrame.to_excel(self, excel_writer, sheet_name='Sheet1', na_rep="", float_format=None,
                    columns=None, header=True, index=True, index_label=None,
                    startrow=0, startcol=0, engine=None, merge_cells=True, encoding=None,
                    inf_rep='inf', verbose=True, freeze_panes=None)
```

Write object to an Excel sheet.

To write a single object to an Excel .xlsx file it is only necessary to specify a target file name. To write to multiple sheets it is necessary to create an *ExcelWriter* object with a target file name, and specify a sheet in the file to write to.

Multiple sheets may be written to by specifying unique *sheet_name*. With all data written to the file it is necessary to save the changes. Note that creating an *ExcelWriter* object with a file

name that already exists will result in the contents of the existing file being erased.

Parameters

- excel_writer** [str or ExcelWriter object] File path or existing ExcelWriter.
- sheet_name** [str, default 'Sheet1'] Name of sheet which will contain DataFrame.
- na_rep** [str, default ''] Missing data representation.
- float_format** [str, optional] Format string for floating point numbers. For example `float_format="%.2f"` will format 0.1234 to 0.12.
- columns** [sequence or list of str, optional] Columns to write.
- header** [bool or list of str, default True] Write out the column names. If a list of string is given it is assumed to be aliases for the column names.
- index** [bool, default True] Write row names (index).
- index_label** [str or sequence, optional] Column label for index column(s) if desired. If not specified, and `header` and `index` are True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.
- startrow** [int, default 0] Upper left cell row to dump data frame.
- startcol** [int, default 0] Upper left cell column to dump data frame.
- engine** [str, optional] Write engine to use, 'openpyxl' or 'xlsxwriter'. You can also set this via the options `io.excel.xlsx.writer`, `io.excel.xls.writer`, and `io.excel.xlsm.writer`.
- merge_cells** [bool, default True] Write MultiIndex and Hierarchical Rows as merged cells.
- encoding** [str, optional] Encoding of the resulting excel file. Only necessary for xlwt, other writers support unicode natively.
- inf_rep** [str, default 'inf'] Representation for infinity (there is no native representation for infinity in Excel).
- verbose** [bool, default True] Display more information in the error logs.
- freeze_panes** [tuple of int (length 2), optional] Specifies the one-based bottom-most row and rightmost column that is to be frozen.
New in version 0.20.0..

See also:

- to_csv** Write DataFrame to a comma-separated values (csv) file.
- ExcelWriter** Class for writing DataFrame objects into excel sheets.
- read_excel** Read an Excel file into a pandas DataFrame.
- read_csv** Read a comma-separated values (csv) file into DataFrame.

Notes

For compatibility with `to_csv()`, `to_excel` serializes lists and dicts to strings before writing.

Once a workbook has been saved it is not possible write further data without rewriting the whole workbook.

Examples

Create, write to and save a workbook:

```
>>> df1 = pd.DataFrame([[ 'a', 'b'], [ 'c', 'd']],
...                     index=[ 'row 1', 'row 2'],
...                     columns=[ 'col 1', 'col 2'])
>>> df1.to_excel("output.xlsx") # doctest: +SKIP
```

To specify the sheet name:

```
>>> df1.to_excel("output.xlsx",
...              sheet_name='Sheet_name_1') # doctest: +SKIP
```

If you wish to write to more than one sheet in the workbook, it is necessary to specify an ExcelWriter object:

```
>>> df2 = df1.copy()
>>> with pd.ExcelWriter('output.xlsx') as writer: # doctest: +SKIP
...     df1.to_excel(writer, sheet_name='Sheet_name_1')
...     df2.to_excel(writer, sheet_name='Sheet_name_2')
```

To set the library that is used to write the Excel file, you can pass the *engine* keyword (the default engine is automatically chosen depending on the file extension):

```
>>> df1.to_excel('output1.xlsx', engine='xlsxwriter') # doctest: +SKIP
```

pandas.DataFrame.to_feather

`DataFrame.to_feather(self, fname)`

Write out the binary feather-format for DataFrames.

New in version 0.20.0.

Parameters

fname [str] string file path

pandas.DataFrame.to_gbq

`DataFrame.to_gbq(self, destination_table, project_id=None, chunksize=None, reauth=False, if_exists='fail', auth_local_webserver=False, table_schema=None, location=None, progress_bar=True, credentials=None, verbose=None, private_key=None)`

Write a DataFrame to a Google BigQuery table.

This function requires the `pandas-gbq` package.

See the [How to authenticate with Google BigQuery guide](#) for authentication instructions.

Parameters

destination_table [str] Name of table to be written, in the form `dataset.tablename`.

project_id [str, optional] Google BigQuery Account project ID. Optional when available from the environment.

chunksize [int, optional] Number of rows to be inserted in each chunk from the dataframe. Set to `None` to load the whole dataframe at once.

reauth [bool, default False] Force Google BigQuery to re-authenticate the user. This is useful if multiple accounts are used.

if_exists [str, default 'fail'] Behavior when the destination table exists. Value can be one of:

'fail' If table exists, do nothing.

'replace' If table exists, drop it, recreate it, and insert data.

'append' If table exists, insert data. Create if does not exist.

auth_local_webserver [bool, default False] Use the [local webserver flow](#) instead of the [console flow](#) when getting user credentials.

New in version 0.2.0 of pandas-gbq.

table_schema [list of dicts, optional] List of BigQuery table fields to which according DataFrame columns conform to, e.g. `[{'name': 'col1', 'type': 'STRING'}, ...]`. If schema is not provided, it will be generated according to dtypes of DataFrame columns. See BigQuery API documentation on available names of a field.

New in version 0.3.1 of pandas-gbq.

location [str, optional] Location where the load job should run. See the [BigQuery locations documentation](#) for a list of available locations. The location must match that of the target dataset.

New in version 0.5.0 of pandas-gbq.

progress_bar [bool, default True] Use the library *tqdm* to show the progress bar for the upload, chunk by chunk.

New in version 0.5.0 of pandas-gbq.

credentials [google.auth.credentials.Credentials, optional] Credentials for accessing Google APIs. Use this parameter to override default credentials, such as to use Compute Engine `google.auth.compute_engine.Credentials` or Service Account `google.oauth2.service_account.Credentials` directly.

New in version 0.8.0 of pandas-gbq.

New in version 0.24.0.

verbose [bool, deprecated] Deprecated in pandas-gbq version 0.4.0. Use the [logging module to adjust verbosity instead](#).

private_key [str, deprecated] Deprecated in pandas-gbq version 0.8.0. Use the `credentials` parameter and `google.oauth2.service_account.Credentials.from_service_account_info()` or `google.oauth2.service_account.Credentials.from_service_account_file()` instead.

Service account private key in JSON format. Can be file path or string contents. This is useful for remote server authentication (eg. Jupyter/IPython notebook on remote host).

See also:

`pandas_gbq.to_gbq` This function in the pandas-gbq library.

`read_gbq` Read a DataFrame from Google BigQuery.

`pandas.DataFrame.to_hdf`

`DataFrame.to_hdf(self, path_or_buf, key, **kwargs)`

Write the contained data to an HDF5 file using HDFStore.

Hierarchical Data Format (HDF) is self-describing, allowing an application to interpret the structure and contents of a file with no outside information. One HDF file can hold a mix of related objects which can be accessed as a group or as individual objects.

In order to add another DataFrame or Series to an existing HDF file please use append mode and a different a key.

For more information see the [user guide](#).

Parameters

path_or_buf [str or pandas.HDFStore] File path or HDFStore object.

key [str] Identifier for the group in the store.

mode [{‘a’, ‘w’, ‘r+’}, default ‘a’] Mode to open file:

- ‘w’: write, a new file is created (an existing file with the same name would be deleted).
- ‘a’: append, an existing file is opened for reading and writing, and if the file does not exist it is created.
- ‘r+’: similar to ‘a’, but the file must already exist.

format [{‘fixed’, ‘table’}, default ‘fixed’] Possible values:

- ‘fixed’: Fixed format. Fast writing/reading. Not-appendable, nor searchable.
- ‘table’: Table format. Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data.

append [bool, default False] For Table formats, append the input data to the existing.

data_columns [list of columns or True, optional] List of columns to create as indexed data columns for on-disk queries, or True to use all columns. By default only the axes of the object are indexed. See [Query via data columns](#). Applicable only to format=‘table’.

complevel [{0-9}, optional] Specifies a compression level for data. A value of 0 disables compression.

complib [{‘zlib’, ‘lzo’, ‘bzip2’, ‘blosc’}, default ‘zlib’] Specifies the compression library to be used. As of v0.20.2 these additional compressors for Blosc are supported (default if no compressor specified: ‘blosc:blosclz’): {‘blosc:blosclz’, ‘blosc:lz4’, ‘blosc:lz4hc’, ‘blosc:snappy’, ‘blosc:zlib’, ‘blosc:zstd’}. Specifying a compression library which is not available issues a ValueError.

fletcher32 [bool, default False] If applying compression use the fletcher32 checksum.

dropna [bool, default False] If true, ALL nan rows will not be written to store.

errors [str, default 'strict'] Specifies how encoding and decoding errors are to be handled. See the errors argument for `open()` for a full list of options.

See also:

`DataFrame.read_hdf` Read from HDF file.

`DataFrame.to_parquet` Write a DataFrame to the binary parquet format.

`DataFrame.to_sql` Write to a sql table.

`DataFrame.to_feather` Write out feather-format for DataFrames.

`DataFrame.to_csv` Write out to a csv file.

Examples

```
>>> df = pd.DataFrame({'A': [1, 2, 3], 'B': [4, 5, 6]},
...                    index=['a', 'b', 'c'])
>>> df.to_hdf('data.h5', key='df', mode='w')
```

We can add another object to the same file:

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s.to_hdf('data.h5', key='s')
```

Reading from HDF file:

```
>>> pd.read_hdf('data.h5', 'df')
A B
a 1 4
b 2 5
c 3 6
>>> pd.read_hdf('data.h5', 's')
0    1
1    2
2    3
3    4
dtype: int64
```

Deleting file with data:

```
>>> import os
>>> os.remove('data.h5')
```

pandas.DataFrame.to_html

`DataFrame.to_html(self, buf=None, columns=None, col_space=None, header=True, index=True, na_rep='NaN', formatters=None, float_format=None, sparsify=None, index_names=True, justify=None, max_rows=None, max_cols=None, show_dimensions=False, decimal='.', bold_rows=True, classes=None, escape=True, notebook=False, border=None, table_id=None, render_links=False)`

Render a DataFrame as an HTML table.

Parameters

- buf** [StringIO-like, optional] Buffer to write to.
- columns** [sequence, optional, default None] The subset of columns to write. Writes all columns by default.
- col_space** [str or int, optional] The minimum width of each column in CSS length units. An int is assumed to be px units.
New in version 0.25.0: Ability to use str.
- header** [bool, optional] Whether to print column labels, default True.
- index** [bool, optional, default True] Whether to print index (row) labels.
- na_rep** [str, optional, default 'NaN'] String representation of NAN to use.
- formatters** [list or dict of one-param. functions, optional] Formatter functions to apply to columns' elements by position or name. The result of each function must be a unicode string. List must be of length equal to the number of columns.
- float_format** [one-parameter function, optional, default None] Formatter function to apply to columns' elements if they are floats. The result of this function must be a unicode string.
- sparsify** [bool, optional, default True] Set to False for a DataFrame with a hierarchical index to print every multiindex key at each row.
- index_names** [bool, optional, default True] Prints the names of the indexes.
- justify** [str, default None] How to justify the column labels. If None uses the option from the print configuration (controlled by `set_option`), 'right' out of the box. Valid values are
- left
 - right
 - center
 - justify
 - justify-all
 - start
 - end
 - inherit
 - match-parent
 - initial
 - unset.
- max_rows** [int, optional] Maximum number of rows to display in the console.
- min_rows** [int, optional] The number of rows to display in the console in a truncated repr (when number of rows is above *max_rows*).
- max_cols** [int, optional] Maximum number of columns to display in the console.
- show_dimensions** [bool, default False] Display DataFrame dimensions (number of rows by number of columns).

decimal [str, default ‘.’] Character recognized as decimal separator, e.g. ‘,’ in Europe.

New in version 0.18.0.

bold_rows [bool, default True] Make the row labels bold in the output.

classes [str or list or tuple, default None] CSS class(es) to apply to the resulting html table.

escape [bool, default True] Convert the characters <, >, and & to HTML-safe sequences.

notebook [{True, False}, default False] Whether the generated HTML is for IPython Notebook.

border [int] A `border=border` attribute is included in the opening `<table>` tag. Default `pd.options.display.html.border`.

New in version 0.19.0.

table_id [str, optional] A css id is included in the opening `<table>` tag if specified.

New in version 0.23.0.

render_links [bool, default False] Convert URLs to HTML links.

New in version 0.24.0.

Returns

str (or unicode, depending on data and options) String representation of the dataframe.

See also:

to_string Convert DataFrame to a string.

pandas.DataFrame.to_json

```
DataFrame.to_json(self, path_or_buf=None, orient=None, date_format=None,
                  double_precision=10, force_ascii=True, date_unit='ms',
                  default_handler=None, lines=False, compression='infer', index=True)
```

Convert the object to a JSON string.

Note NaN's and None will be converted to null and datetime objects will be converted to UNIX timestamps.

Parameters

path_or_buf [string or file handle, optional] File path or object. If not specified, the result is returned as a string.

orient [string] Indication of expected JSON string format.

- Series
 - default is ‘index’
 - allowed values are: {‘split’, ‘records’, ‘index’, ‘table’}
- DataFrame
 - default is ‘columns’

- allowed values are: {'split', 'records', 'index', 'columns', 'values', 'table'}
- The format of the JSON string
 - 'split' : dict like {'index' -> [index], 'columns' -> [columns], 'data' -> [values]}
 - 'records' : list like [{column -> value}, ... , {column -> value}]
 - 'index' : dict like {index -> {column -> value}}
 - 'columns' : dict like {column -> {index -> value}}
 - 'values' : just the values array
 - 'table' : dict like {'schema': {schema}, 'data': {data}} describing the data, and the data component is like `orient='records'`.

Changed in version 0.20.0.

date_format [{None, 'epoch', 'iso'}] Type of date conversion. 'epoch' = epoch milliseconds, 'iso' = ISO8601. The default depends on the *orient*. For `orient='table'`, the default is 'iso'. For all other orients, the default is 'epoch'.

double_precision [int, default 10] The number of decimal places to use when encoding floating point values.

force_ascii [bool, default True] Force encoded string to be ASCII.

date_unit [string, default 'ms' (milliseconds)] The time unit to encode to, governs timestamp and ISO8601 precision. One of 's', 'ms', 'us', 'ns' for second, millisecond, microsecond, and nanosecond respectively.

default_handler [callable, default None] Handler to call if object cannot otherwise be converted to a suitable format for JSON. Should receive a single argument which is the object to convert and return a serialisable object.

lines [bool, default False] If 'orient' is 'records' write out line delimited json format. Will throw ValueError if incorrect 'orient' since others are not list like.

New in version 0.19.0.

compression [{'infer', 'gzip', 'bz2', 'zip', 'xz', None}] A string representing the compression to use in the output file, only used when the first argument is a filename. By default, the compression is inferred from the filename.

New in version 0.21.0.

Changed in version 0.24.0: 'infer' option added and set to default

index [bool, default True] Whether to include the index values in the JSON string. Not including the index (`index=False`) is only supported when orient is 'split' or 'table'.

New in version 0.23.0.

Returns

None or str If `path_or_buf` is None, returns the resulting json format as a string. Otherwise returns None.

See also:

`read_json`

Examples

```
>>> df = pd.DataFrame([[ 'a', 'b'], [ 'c', 'd']],
...                    index=['row 1', 'row 2'],
...                    columns=['col 1', 'col 2'])
>>> df.to_json(orient='split')
'{"columns":["col 1","col 2"],
  "index":["row 1","row 2"],
  "data":[["a","b"],["c","d"]}]'
```

Encoding/decoding a Dataframe using 'records' formatted JSON. Note that index labels are not preserved with this encoding.

```
>>> df.to_json(orient='records')
'[{"col 1":"a","col 2":"b"}, {"col 1":"c","col 2":"d"}]'
```

Encoding/decoding a Dataframe using 'index' formatted JSON:

```
>>> df.to_json(orient='index')
'{"row 1":{"col 1":"a","col 2":"b"},"row 2":{"col 1":"c","col 2":"d"}}'
```

Encoding/decoding a Dataframe using 'columns' formatted JSON:

```
>>> df.to_json(orient='columns')
'{"col 1":{"row 1":"a","row 2":"c"},"col 2":{"row 1":"b","row 2":"d"}}'
```

Encoding/decoding a Dataframe using 'values' formatted JSON:

```
>>> df.to_json(orient='values')
'[["a","b"],["c","d"]]
```

Encoding with Table Schema

```
>>> df.to_json(orient='table')
'{"schema": {"fields": [{"name": "index", "type": "string"},
                       {"name": "col 1", "type": "string"},
                       {"name": "col 2", "type": "string"}],
  "primaryKey": "index",
  "pandas_version": "0.20.0"},
  "data": [{"index": "row 1", "col 1": "a", "col 2": "b"},
           {"index": "row 2", "col 1": "c", "col 2": "d"}]}'
```

pandas.DataFrame.to_latex

`DataFrame.to_latex(self, buf=None, columns=None, col_space=None, header=True, index=True, na_rep='NaN', formatters=None, float_format=None, sparsify=None, index_names=True, bold_rows=False, column_format=None, longtable=None, escape=None, encoding=None, decimal='.', multicolumn=None, multicolumn_format=None, multirow=None)`

Render an object to a LaTeX tabular environment table.

Render an object to a tabular environment table. You can splice this into a LaTeX document. Requires `usepackage{booktabs}`.

Changed in version 0.20.2: Added to Series

Parameters

- buf** [file descriptor or None] Buffer to write to. If None, the output is returned as a string.
- columns** [list of label, optional] The subset of columns to write. Writes all columns by default.
- col_space** [int, optional] The minimum width of each column.
- header** [bool or list of str, default True] Write out the column names. If a list of strings is given, it is assumed to be aliases for the column names.
- index** [bool, default True] Write row names (index).
- na_rep** [str, default 'NaN'] Missing data representation.
- formatters** [list of functions or dict of {str: function}, optional] Formatter functions to apply to columns' elements by position or name. The result of each function must be a unicode string. List must be of length equal to the number of columns.
- float_format** [one-parameter function or str, optional, default None] Formatter for floating point numbers. For example `float_format="%.2f"` and `float_format="{:0.2f}".format` will both result in 0.1234 being formatted as 0.12.
- sparsify** [bool, optional] Set to False for a DataFrame with a hierarchical index to print every multiindex key at each row. By default, the value will be read from the config module.
- index_names** [bool, default True] Prints the names of the indexes.
- bold_rows** [bool, default False] Make the row labels bold in the output.
- column_format** [str, optional] The columns format as specified in [LaTeX table format](#) e.g. 'rcl' for 3 columns. By default, 'l' will be used for all columns except columns of numbers, which default to 'r'.
- longtable** [bool, optional] By default, the value will be read from the pandas config module. Use a longtable environment instead of tabular. Requires adding a `usepackage{longtable}` to your LaTeX preamble.
- escape** [bool, optional] By default, the value will be read from the pandas config module. When set to False prevents from escaping latex special characters in column names.
- encoding** [str, optional] A string representing the encoding to use in the output file, defaults to 'utf-8'.
- decimal** [str, default '.'] Character recognized as decimal separator, e.g. ',' in Europe.
New in version 0.18.0.
- multicolumn** [bool, default True] Use multicolumn to enhance MultiIndex columns. The default will be read from the config module.
New in version 0.20.0.
- multicolumn_format** [str, default 'l'] The alignment for multicolumns, similar to `column_format` The default will be read from the config module.

New in version 0.20.0.

multirow [bool, default False] Use multirow to enhance MultiIndex rows. Requires adding a usepackage{multirow} to your LaTeX preamble. Will print centered labels (instead of top-aligned) across the contained rows, separating groups via clines. The default will be read from the pandas config module.

New in version 0.20.0.

Returns

str or None If buf is None, returns the resulting LaTeX format as a string. Otherwise returns None.

See also:

DataFrame.to_string Render a DataFrame to a console-friendly tabular output.

DataFrame.to_html Render a DataFrame as an HTML table.

Examples

```
>>> df = pd.DataFrame({'name': ['Raphael', 'Donatello'],
...                    'mask': ['red', 'purple'],
...                    'weapon': ['sai', 'bo staff']})
>>> df.to_latex(index=False) # doctest: +NORMALIZE_WHITESPACE
'\\begin{tabular}{lll}\\n\\toprule\\n    name &    mask &    weapon
\\\\\\n\\midrule\\n    Raphael &    red &    sai \\\\\\n Donatello &
purple & bo staff \\\\\\n\\bottomrule\\n\\end{tabular}\\n'
```

pandas.DataFrame.to_msgpack

DataFrame.to_msgpack(self, path_or_buf=None, encoding='utf-8', **kwargs)

Serialize object to input file path using msgpack format.

Deprecated since version 0.25.0.

to_msgpack is deprecated and will be removed in a future version. It is recommended to use pyarrow for on-the-wire transmission of pandas objects.

Parameters

path [string File path, buffer-like, or None] if None, return generated bytes

append [bool whether to append to an existing msgpack] (default is False)

compress [type of compressor (zlib or blosc), default to None (no) compression]

Returns

None or bytes If path_or_buf is None, returns the resulting msgpack format as a byte string. Otherwise returns None.

pandas.DataFrame.to_numpy

DataFrame.to_numpy(self, dtype=None, copy=False)

Convert the DataFrame to a NumPy array.

New in version 0.24.0.

By default, the dtype of the returned array will be the common NumPy dtype of all types in the DataFrame. For example, if the dtypes are `float16` and `float32`, the results dtype will be `float32`. This may require copying data and coercing values, which may be expensive.

Parameters

dtype [str or numpy.dtype, optional] The dtype to pass to `numpy.asarray()`

copy [bool, default False] Whether to ensure that the returned value is a not a view on another array. Note that `copy=False` does not *ensure* that `to_numpy()` is no-copy. Rather, `copy=True` ensure that a copy is made, even if not strictly necessary.

Returns

`numpy.ndarray`

See also:

Series.to_numpy Similar method for Series.

Examples

```
>>> pd.DataFrame({"A": [1, 2], "B": [3, 4]}).to_numpy()
array([[1, 3],
       [2, 4]])
```

With heterogenous data, the lowest common type will have to be used.

```
>>> df = pd.DataFrame({"A": [1, 2], "B": [3.0, 4.5]})
>>> df.to_numpy()
array([[1. , 3. ],
       [2. , 4.5]])
```

For a mix of numeric and non-numeric types, the output array will have object dtype.

```
>>> df['C'] = pd.date_range('2000', periods=2)
>>> df.to_numpy()
array([[1, 3.0, Timestamp('2000-01-01 00:00:00')],
       [2, 4.5, Timestamp('2000-01-02 00:00:00')]], dtype=object)
```

`pandas.DataFrame.to_parquet`

`DataFrame.to_parquet`(*self*, *fname*, *engine='auto'*, *compression='snappy'*, *index=None*, *partition_cols=None*, ***kwargs*)

Write a DataFrame to the binary parquet format.

New in version 0.21.0.

This function writes the dataframe as a `parquet` file. You can choose different parquet backends, and have the option of compression. See *the user guide* for more details.

Parameters

fname [str] File path or Root Directory path. Will be used as Root Directory path while writing a partitioned dataset.

Changed in version 0.24.0.

engine [{'auto', 'pyarrow', 'fastparquet'}, default 'auto'] Parquet library to use. If 'auto', then the option `io.parquet.engine` is used. The default `io.parquet.engine` behavior is to try 'pyarrow', falling back to 'fastparquet' if 'pyarrow' is unavailable.

compression [{'snappy', 'gzip', 'brotli', None}, default 'snappy'] Name of the compression to use. Use `None` for no compression.

index [bool, default None] If `True`, include the dataframe's index(es) in the file output. If `False`, they will not be written to the file. If `None`, the behavior depends on the chosen engine.

New in version 0.24.0.

partition_cols [list, optional, default None] Column names by which to partition the dataset Columns are partitioned in the order they are given

New in version 0.24.0.

****kwargs** Additional arguments passed to the parquet library. See [pandas io](#) for more details.

See also:

`read_parquet` Read a parquet file.

`DataFrame.to_csv` Write a csv file.

`DataFrame.to_sql` Write to a sql table.

`DataFrame.to_hdf` Write to hdf.

Notes

This function requires either the `fastparquet` or `pyarrow` library.

Examples

```
>>> df = pd.DataFrame(data={'col1': [1, 2], 'col2': [3, 4]})
>>> df.to_parquet('df.parquet.gzip',
...               compression='gzip') # doctest: +SKIP
>>> pd.read_parquet('df.parquet.gzip') # doctest: +SKIP
   col1  col2
0     1     3
1     2     4
```

pandas.DataFrame.to_period

`DataFrame.to_period(self, freq=None, axis=0, copy=True)`

Convert `DataFrame` from `DatetimeIndex` to `PeriodIndex` with desired frequency (inferred from index if not passed).

Parameters

freq [str, default] Frequency of the PeriodIndex.

axis [{0 or 'index', 1 or 'columns'}, default 0] The axis to convert (the index by default).

copy [bool, default True] If False then underlying input data is not copied.

Returns

TimeSeries with PeriodIndex

pandas.DataFrame.to_pickle

`DataFrame.to_pickle(self, path, compression='infer', protocol=4)`

Pickle (serialize) object to file.

Parameters

path [str] File path where the pickled object will be stored.

compression [{'infer', 'gzip', 'bz2', 'zip', 'xz', None}, default 'infer'] A string representing the compression to use in the output file. By default, infers from the file extension in specified path.

New in version 0.20.0.

protocol [int] Int which indicates which protocol should be used by the pickler, default HIGHEST_PROTOCOL (see [?] paragraph 12.1.2). The possible values are 0, 1, 2, 3, 4. A negative value for the protocol parameter is equivalent to setting its value to HIGHEST_PROTOCOL.

New in version 0.21.0.

See also:

`read_pickle` Load pickled pandas object (or any object) from file.

`DataFrame.to_hdf` Write DataFrame to an HDF5 file.

`DataFrame.to_sql` Write DataFrame to a SQL database.

`DataFrame.to_parquet` Write a DataFrame to the binary parquet format.

Examples

```
>>> original_df = pd.DataFrame({"foo": range(5), "bar": range(5, 10)})
>>> original_df
   foo  bar
0    0    5
1    1    6
2    2    7
3    3    8
4    4    9
>>> original_df.to_pickle("./dummy.pkl")
```

```
>>> unpickled_df = pd.read_pickle("./dummy.pkl")
>>> unpickled_df
   foo  bar
0    0    5
1    1    6
2    2    7
3    3    8
4    4    9
```

```
>>> import os
>>> os.remove("./dummy.pkl")
```

pandas.DataFrame.to_records

`DataFrame.to_records(self, index=True, convert_datetime64=None, column_dtypes=None, index_dtypes=None)`

Convert DataFrame to a NumPy record array.

Index will be included as the first field of the record array if requested.

Parameters

index [bool, default True] Include index in resulting record array, stored in ‘index’ field or using the index label, if set.

convert_datetime64 [bool, default None] Deprecated since version 0.23.0.

Whether to convert the index to `datetime.datetime` if it is a `DatetimeIndex`.

column_dtypes [str, type, dict, default None] New in version 0.24.0.

If a string or type, the data type to store all columns. If a dictionary, a mapping of column names and indices (zero-indexed) to specific data types.

index_dtypes [str, type, dict, default None] New in version 0.24.0.

If a string or type, the data type to store all index levels. If a dictionary, a mapping of index level names and indices (zero-indexed) to specific data types.

This mapping is applied only if `index=True`.

Returns

numpy.recarray NumPy ndarray with the DataFrame labels as fields and each row of the DataFrame as entries.

See also:

`DataFrame.from_records` Convert structured or record ndarray to DataFrame.

`numpy.recarray` An ndarray that allows field access using attributes, analogous to typed columns in a spreadsheet.

Examples

```
>>> df = pd.DataFrame({'A': [1, 2], 'B': [0.5, 0.75]},
...                    index=['a', 'b'])
>>> df
   A    B
a  1  0.5
b  2  0.75
>>> df.to_records()
rec.array([(('a', 1, 0.5 ), ('b', 2, 0.75)],
          dtype=[('index', 'O'), ('A', '<i8'), ('B', '<f8')])
```

If the DataFrame index has no label then the recarray field name is set to 'index'. If the index has a label then this is used as the field name:

```
>>> df.index = df.index.rename("I")
>>> df.to_records()
rec.array([(('a', 1, 0.5 ), ('b', 2, 0.75)],
          dtype=[('I', 'O'), ('A', '<i8'), ('B', '<f8')])
```

The index can be excluded from the record array:

```
>>> df.to_records(index=False)
rec.array([(1, 0.5 ), (2, 0.75)],
          dtype=[('A', '<i8'), ('B', '<f8')])
```

Data types can be specified for the columns:

```
>>> df.to_records(column_dtypes={"A": "int32"})
rec.array([(('a', 1, 0.5 ), ('b', 2, 0.75)],
          dtype=[('I', 'O'), ('A', '<i4'), ('B', '<f8')])
```

As well as for the index:

```
>>> df.to_records(index_dtypes="<S2")
rec.array([(b'a', 1, 0.5 ), (b'b', 2, 0.75)],
          dtype=[('I', 'S2'), ('A', '<i8'), ('B', '<f8')])
```

```
>>> index_dtypes = "<S{}".format(df.index.str.len().max())
>>> df.to_records(index_dtypes=index_dtypes)
rec.array([(b'a', 1, 0.5 ), (b'b', 2, 0.75)],
          dtype=[('I', 'S1'), ('A', '<i8'), ('B', '<f8')])
```

pandas.DataFrame.to_sparse

`DataFrame.to_sparse(self, fill_value=None, kind='block')`

Convert to SparseDataFrame.

Deprecated since version 0.25.0.

Implement the sparse version of the DataFrame meaning that any data matching a specific value it's omitted in the representation. The sparse DataFrame allows for a more efficient storage.

Parameters

fill_value [float, default None] The specific value that should be omitted in the representation.

kind [{‘block’, ‘integer’}, default ‘block’] The kind of the SparseIndex tracking where data is not equal to the fill value:

- ‘block’ tracks only the locations and sizes of blocks of data.
- ‘integer’ keeps an array with all the locations of the data.

In most cases ‘block’ is recommended, since it’s more memory efficient.

Returns

SparseDataFrame The sparse representation of the DataFrame.

See also:

DataFrame.to_dense Converts the DataFrame back to the its dense form.

Examples

```
>>> df = pd.DataFrame([(np.nan, np.nan),
...                    (1., np.nan),
...                    (np.nan, 1.)])
>>> df
   0    1
0 NaN NaN
1 1.0 NaN
2 NaN 1.0
>>> type(df)
<class 'pandas.core.frame.DataFrame'>
```

```
>>> sdf = df.to_sparse() # doctest: +SKIP
>>> sdf # doctest: +SKIP
   0    1
0 NaN NaN
1 1.0 NaN
2 NaN 1.0
>>> type(sdf) # doctest: +SKIP
<class 'pandas.core.sparse.frame.SparseDataFrame'>
```

pandas.DataFrame.to_stata

DataFrame.to_stata(self, fname, convert_dates=None, write_index=True, encoding='latin-1', byteorder=None, time_stamp=None, data_label=None, variable_labels=None, version=114, convert_strl=None)

Export DataFrame object to Stata dta format.

Writes the DataFrame to a Stata dataset file. “dta” files contain a Stata dataset.

Parameters

fname [str, buffer or path object] String, path object (pathlib.Path or py._path.local.LocalPath) or object implementing a binary write() function. If using a buffer then the buffer will not be automatically closed after the file data has been written.

convert_dates [dict] Dictionary mapping columns containing datetime types to stata internal format to use when writing the dates. Options are 'tc', 'td', 'tm', 'tw', 'th', 'tq', 'ty'. Column can be either an integer or a name. Datetime columns that do not have a conversion type specified will be converted to 'tc'. Raises `NotImplementedError` if a datetime column has timezone information.

write_index [bool] Write the index to Stata dataset.

encoding [str] Default is latin-1. Unicode is not supported.

byteorder [str] Can be ">", "<", "little", or "big". default is *sys.byteorder*.

time_stamp [datetime] A datetime to use as file creation date. Default is the current time.

data_label [str, optional] A label for the data set. Must be 80 characters or smaller.

variable_labels [dict] Dictionary containing columns as keys and variable labels as values. Each label must be 80 characters or smaller.

New in version 0.19.0.

version [{114, 117}, default 114] Version to use in the output dta file. Version 114 can be used read by Stata 10 and later. Version 117 can be read by Stata 13 or later. Version 114 limits string variables to 244 characters or fewer while 117 allows strings with lengths up to 2,000,000 characters.

New in version 0.23.0.

convert_strl [list, optional] List of column names to convert to string columns to Stata StrL format. Only available if version is 117. Storing strings in the StrL format can produce smaller dta files if strings have more than 8 characters and values are repeated.

New in version 0.23.0.

Raises

NotImplementedError

- If datetimes contain timezone information
- Column dtype is not representable in Stata

ValueError

- Columns listed in `convert_dates` are neither `datetime64[ns]` or `datetime.datetime`
- Column listed in `convert_dates` is not in `DataFrame`
- Categorical label contains more than 32,000 characters

New in version 0.19.0.

See also:

`read_stata` Import Stata data files.

`io.stata.StataWriter` Low-level writer for Stata data files.

`io.stata.StataWriter117` Low-level writer for version 117 files.

Examples

```
>>> df = pd.DataFrame({'animal': ['falcon', 'parrot', 'falcon',
...                               'parrot'],
...                   'speed': [350, 18, 361, 15]})
>>> df.to_stata('animals.dta') # doctest: +SKIP
```

pandas.DataFrame.to_string

`DataFrame.to_string`(*self*, *buf=None*, *columns=None*, *col_space=None*, *header=True*, *index=True*, *na_rep='NaN'*, *formatters=None*, *float_format=None*, *sparsify=None*, *index_names=True*, *justify=None*, *max_rows=None*, *min_rows=None*, *max_cols=None*, *show_dimensions=False*, *decimal='.'*, *line_width=None*)

Render a DataFrame to a console-friendly tabular output.

Parameters

- buf** [StringIO-like, optional] Buffer to write to.
- columns** [sequence, optional, default None] The subset of columns to write. Writes all columns by default.
- col_space** [int, optional] The minimum width of each column.
- header** [bool, optional] Write out the column names. If a list of strings is given, it is assumed to be aliases for the column names.
- index** [bool, optional, default True] Whether to print index (row) labels.
- na_rep** [str, optional, default 'NaN'] String representation of NAN to use.
- formatters** [list or dict of one-param. functions, optional] Formatter functions to apply to columns' elements by position or name. The result of each function must be a unicode string. List must be of length equal to the number of columns.
- float_format** [one-parameter function, optional, default None] Formatter function to apply to columns' elements if they are floats. The result of this function must be a unicode string.
- sparsify** [bool, optional, default True] Set to False for a DataFrame with a hierarchical index to print every multiindex key at each row.
- index_names** [bool, optional, default True] Prints the names of the indexes.
- justify** [str, default None] How to justify the column labels. If None uses the option from the print configuration (controlled by `set_option`), 'right' out of the box. Valid values are
 - left
 - right
 - center
 - justify
 - justify-all
 - start

- end
- inherit
- match-parent
- initial
- unset.

max_rows [int, optional] Maximum number of rows to display in the console.

min_rows [int, optional] The number of rows to display in the console in a truncated repr (when number of rows is above *max_rows*).

max_cols [int, optional] Maximum number of columns to display in the console.

show_dimensions [bool, default False] Display DataFrame dimensions (number of rows by number of columns).

decimal [str, default ‘.’] Character recognized as decimal separator, e.g. ‘,’ in Europe.

New in version 0.18.0.

line_width [int, optional] Width to wrap a line in characters.

Returns

str (or unicode, depending on data and options) String representation of the dataframe.

See also:

to_html Convert DataFrame to HTML.

Examples

```
>>> d = {'col1': [1, 2, 3], 'col2': [4, 5, 6]}
>>> df = pd.DataFrame(d)
>>> print(df.to_string())
   col1  col2
0     1     4
1     2     5
2     3     6
```

pandas.DataFrame.to_timestamp

DataFrame.to_timestamp(*self*, *freq=None*, *how='start'*, *axis=0*, *copy=True*)

Cast to DatetimeIndex of timestamps, at *beginning* of period.

Parameters

freq [str, default frequency of PeriodIndex] Desired frequency.

how [{‘s’, ‘e’, ‘start’, ‘end’}] Convention for converting period to timestamp; start of period vs. end.

axis [{0 or ‘index’, 1 or ‘columns’}, default 0] The axis to convert (the index by default).

`copy` [bool, default True] If False then underlying input data is not copied.

Returns

DataFrame with DatetimeIndex

pandas.DataFrame.to_xarray

`DataFrame.to_xarray(self)`

Return an xarray object from the pandas object.

Returns

xarray.DataArray or xarray.Dataset Data in the pandas structure converted to Dataset if the object is a DataFrame, or a DataArray if the object is a Series.

See also:

`DataFrame.to_hdf` Write DataFrame to an HDF5 file.

`DataFrame.to_parquet` Write a DataFrame to the binary parquet format.

Notes

See the `xarray` docs

Examples

```
>>> df = pd.DataFrame([('falcon', 'bird', 389.0, 2),
...                    ('parrot', 'bird', 24.0, 2),
...                    ('lion', 'mammal', 80.5, 4),
...                    ('monkey', 'mammal', np.nan, 4)],
...                    columns=['name', 'class', 'max_speed',
...                             'num_legs'])
>>> df
```

	name	class	max_speed	num_legs
0	falcon	bird	389.0	2
1	parrot	bird	24.0	2
2	lion	mammal	80.5	4
3	monkey	mammal	NaN	4

```
>>> df.to_xarray()
<xarray.Dataset>
Dimensions:  (index: 4)
Coordinates:
  * index    (index) int64 0 1 2 3
Data variables:
  name      (index) object 'falcon' 'parrot' 'lion' 'monkey'
  class     (index) object 'bird' 'bird' 'mammal' 'mammal'
  max_speed (index) float64 389.0 24.0 80.5 nan
  num_legs  (index) int64 2 2 4 4
```

```
>>> df['max_speed'].to_xarray()
<xarray.DataArray 'max_speed' (index: 4)>
array([389. , 24. , 80.5, nan])
Coordinates:
  * index      (index) int64 0 1 2 3
```

```
>>> dates = pd.to_datetime(['2018-01-01', '2018-01-01',
...                          '2018-01-02', '2018-01-02'])
>>> df_multiindex = pd.DataFrame({'date': dates,
...                               'animal': ['falcon', 'parrot', 'falcon',
...                                         'parrot'],
...                               'speed': [350, 18, 361, 15]}).set_index(['date',
...                               'animal'])
>>> df_multiindex
           speed
date animal
2018-01-01 falcon    350
           parrot     18
2018-01-02 falcon    361
           parrot     15
```

```
>>> df_multiindex.to_xarray()
<xarray.Dataset>
Dimensions: (animal: 2, date: 2)
Coordinates:
  * date      (date) datetime64[ns] 2018-01-01 2018-01-02
  * animal    (animal) object 'falcon' 'parrot'
Data variables:
  speed      (date, animal) int64 350 18 361 15
```

pandas.DataFrame.transform

DataFrame.transform(*self*, *func*, *axis=0*, **args*, ***kwargs*)

Call *func* on self producing a DataFrame with transformed values and that has the same axis length as self.

New in version 0.20.0.

Parameters

func [function, str, list or dict] Function to use for transforming the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. [np.exp, 'sqrt']
- dict of axis labels -> functions, function names or list of such.

axis [{0 or 'index', 1 or 'columns'}, default 0] If 0 or 'index': apply function to each column. If 1 or 'columns': apply function to each row.

***args** Positional arguments to pass to *func*.

****kwargs** Keyword arguments to pass to *func*.

Returns

DataFrame A DataFrame that must have the same length as self.

Raises

ValueError [If the returned DataFrame has a different length than self.]

See also:

DataFrame.agg Only perform aggregating type operations.

DataFrame.apply Invoke function on a DataFrame.

Examples

```
>>> df = pd.DataFrame({'A': range(3), 'B': range(1, 4)})
>>> df
   A  B
0  0  1
1  1  2
2  2  3
>>> df.transform(lambda x: x + 1)
   A  B
0  1  2
1  2  3
2  3  4
```

Even though the resulting DataFrame must have the same length as the input DataFrame, it is possible to provide several input functions:

```
>>> s = pd.Series(range(3))
>>> s
0    0
1    1
2    2
dtype: int64
>>> s.transform([np.sqrt, np.exp])
      sqrt      exp
0  0.000000  1.000000
1  1.000000  2.718282
2  1.414214  7.389056
```

pandas.DataFrame.transpose

DataFrame.transpose(*self*, **args*, ***kwargs*)

Transpose index and columns.

Reflect the DataFrame over its main diagonal by writing rows as columns and vice-versa. The property *T* is an accessor to the method *transpose()*.

Parameters

copy [bool, default False] If True, the underlying data is copied. Otherwise (default), no copy is made if possible.

***args, **kwargs** Additional keywords have no effect but might be accepted for compatibility with numpy.

Returns

DataFrame The transposed DataFrame.

See also:

`numpy.transpose` Permute the dimensions of a given array.

Notes

Transposing a DataFrame with mixed dtypes will result in a homogeneous DataFrame with the *object* dtype. In such a case, a copy of the data is always made.

Examples

Square DataFrame with homogeneous dtype

```
>>> d1 = {'col1': [1, 2], 'col2': [3, 4]}
>>> df1 = pd.DataFrame(data=d1)
>>> df1
   col1  col2
0     1     3
1     2     4
```

```
>>> df1_transposed = df1.T # or df1.transpose()
>>> df1_transposed
   0  1
col1 1  2
col2 3  4
```

When the dtype is homogeneous in the original DataFrame, we get a transposed DataFrame with the same dtype:

```
>>> df1.dtypes
col1    int64
col2    int64
dtype: object
>>> df1_transposed.dtypes
0    int64
1    int64
dtype: object
```

Non-square DataFrame with mixed dtypes

```
>>> d2 = {'name': ['Alice', 'Bob'],
...       'score': [9.5, 8],
...       'employed': [False, True],
...       'kids': [0, 0]}
```

(continues on next page)

(continued from previous page)

```
>>> df2 = pd.DataFrame(data=d2)
>>> df2
   name  score  employed  kids
0  Alice   9.5     False    0
1   Bob    8.0      True    0
```

```
>>> df2_transposed = df2.T # or df2.transpose()
>>> df2_transposed
      0    1
name   Alice  Bob
score    9.5    8
employed False  True
kids      0    0
```

When the DataFrame has mixed dtypes, we get a transposed DataFrame with the *object* dtype:

```
>>> df2.dtypes
name      object
score    float64
employed    bool
kids      int64
dtype: object
>>> df2_transposed.dtypes
0      object
1      object
dtype: object
```

pandas.DataFrame.truediv

DataFrame.truediv(*self*, *other*, *axis='columns'*, *level=None*, *fill_value=None*)

Get Floating division of dataframe and other, element-wise (binary operator *truediv*).

Equivalent to `dataframe / other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *rtruediv*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.

DataFrame.sub Subtract DataFrames.

DataFrame.mul Multiply DataFrames.

DataFrame.div Divide DataFrames (float division).

DataFrame.truediv Divide DataFrames (float division).

DataFrame.floordiv Divide DataFrames (integer division).

DataFrame.mod Calculate modulo (remainder after division).

DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

	angles	degrees
circle	0	360
triangle	3	180
rectangle	4	360

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

```
>>> df.add(1)
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

Divide by constant with reverse version.

```
>>> df.div(10)
```

	angles	degrees
circle	0.0	36.0
triangle	0.3	18.0
rectangle	0.4	36.0

```
>>> df.rdiv(10)
      angles  degrees
circle      inf  0.027778
triangle  3.333333  0.055556
rectangle  2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
      angles  degrees
circle      -1    358
triangle     2    178
rectangle     3    358
```

```
>>> df.sub([1, 2], axis='columns')
      angles  degrees
circle      -1    358
triangle     2    178
rectangle     3    358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
      angles  degrees
circle      -1    359
triangle     2    179
rectangle     3    359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
      angles
circle      0
triangle     3
rectangle     4
```

```
>>> df * other
      angles  degrees
circle      0    NaN
triangle     9    NaN
rectangle   16    NaN
```

```
>>> df.mul(other, fill_value=0)
      angles  degrees
circle      0    0.0
triangle     9    0.0
rectangle   16    0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                               index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                       ['circle', 'triangle', 'rectangle',
...                                       'square', 'pentagon', 'hexagon']])
>>> df_multindex
```

	angles	degrees
A circle	0	360
triangle	3	180
rectangle	4	360
B square	4	360
pentagon	5	540
hexagon	6	720

```
>>> df.div(df_multindex, level=1, fill_value=0)
```

	angles	degrees
A circle	NaN	1.0
triangle	1.0	1.0
rectangle	1.0	1.0
B square	0.0	0.0
pentagon	0.0	0.0
hexagon	0.0	0.0

pandas.DataFrame.truncate

DataFrame.truncate(*self*, *before=None*, *after=None*, *axis=None*, *copy=True*)

Truncate a Series or DataFrame before and after some index value.

This is a useful shorthand for boolean indexing based on index values above or below certain thresholds.

Parameters

before [date, string, int] Truncate all rows before this index value.

after [date, string, int] Truncate all rows after this index value.

axis [{0 or 'index', 1 or 'columns'}, optional] Axis to truncate. Truncates the index (rows) by default.

copy [boolean, default is True,] Return a copy of the truncated section.

Returns

type of caller The truncated Series or DataFrame.

See also:

DataFrame.loc Select a subset of a DataFrame by label.

DataFrame.iloc Select a subset of a DataFrame by position.

Notes

If the index being truncated contains only datetime values, *before* and *after* may be specified as strings instead of Timestamps.

Examples

```
>>> df = pd.DataFrame({'A': ['a', 'b', 'c', 'd', 'e'],
...                    'B': ['f', 'g', 'h', 'i', 'j'],
...                    'C': ['k', 'l', 'm', 'n', 'o']},
...                    index=[1, 2, 3, 4, 5])
>>> df
   A B C
1  a f k
2  b g l
3  c h m
4  d i n
5  e j o
```

```
>>> df.truncate(before=2, after=4)
   A B C
2  b g l
3  c h m
4  d i n
```

The columns of a DataFrame can be truncated.

```
>>> df.truncate(before="A", after="B", axis="columns")
   A B
1  a f
2  b g
3  c h
4  d i
5  e j
```

For Series, only rows can be truncated.

```
>>> df['A'].truncate(before=2, after=4)
2    b
3    c
4    d
Name: A, dtype: object
```

The index values in truncate can be datetimes or string dates.

```
>>> dates = pd.date_range('2016-01-01', '2016-02-01', freq='s')
>>> df = pd.DataFrame(index=dates, data={'A': 1})
>>> df.tail()
                A
2016-01-31 23:59:56  1
2016-01-31 23:59:57  1
2016-01-31 23:59:58  1
2016-01-31 23:59:59  1
2016-02-01 00:00:00  1
```

```
>>> df.truncate(before=pd.Timestamp('2016-01-05'),
...             after=pd.Timestamp('2016-01-10')).tail()
                A
```

(continues on next page)

(continued from previous page)

```

2016-01-09 23:59:56 1
2016-01-09 23:59:57 1
2016-01-09 23:59:58 1
2016-01-09 23:59:59 1
2016-01-10 00:00:00 1

```

Because the index is a `DatetimeIndex` containing only dates, we can specify *before* and *after* as strings. They will be coerced to `Timestamps` before truncation.

```

>>> df.truncate('2016-01-05', '2016-01-10').tail()
           A
2016-01-09 23:59:56 1
2016-01-09 23:59:57 1
2016-01-09 23:59:58 1
2016-01-09 23:59:59 1
2016-01-10 00:00:00 1

```

Note that `truncate` assumes a 0 value for any unspecified time component (midnight). This differs from partial string slicing, which returns any partially matching dates.

```

>>> df.loc['2016-01-05':'2016-01-10', :].tail()
           A
2016-01-10 23:59:55 1
2016-01-10 23:59:56 1
2016-01-10 23:59:57 1
2016-01-10 23:59:58 1
2016-01-10 23:59:59 1

```

pandas.DataFrame.tshift

`DataFrame.tshift(self, periods=1, freq=None, axis=0)`

Shift the time index, using the index's frequency if available.

Parameters

periods [int] Number of periods to move, can be positive or negative

freq [DateOffset, timedelta, or time rule string, default None] Increment to use from the `tseries` module or time rule (e.g. 'EOM')

axis [int or basestring] Corresponds to the axis that contains the Index

Returns

shifted [Series/DataFrame]

Notes

If `freq` is not specified then tries to use the `freq` or `inferred_freq` attributes of the index. If neither of those attributes exist, a `ValueError` is thrown

pandas.DataFrame.tz_convert

`DataFrame.tz_convert(self, tz, axis=0, level=None, copy=True)`

Convert tz-aware axis to target time zone.

Parameters

tz [string or `pytz.timezone` object]

axis [the axis to convert]

level [int, str, default None] If axis is a MultiIndex, convert a specific level. Otherwise must be None

copy [boolean, default True] Also make a copy of the underlying data

Returns

`%(klass)s` Object with time zone converted axis.

Raises

TypeError If the axis is tz-naive.

pandas.DataFrame.tz_localize

`DataFrame.tz_localize(self, tz, axis=0, level=None, copy=True, ambiguous='raise', nonexistent='raise')`

Localize tz-naive index of a Series or DataFrame to target time zone.

This operation localizes the Index. To localize the values in a timezone-naive Series, use `Series.dt.tz_localize()`.

Parameters

tz [string or `pytz.timezone` object]

axis [the axis to localize]

level [int, str, default None] If axis is a MultiIndex, localize a specific level. Otherwise must be None

copy [boolean, default True] Also make a copy of the underlying data

ambiguous ['infer', bool-ndarray, 'NaT', default 'raise'] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the *ambiguous* parameter dictates how ambiguous times should be handled.

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an `AmbiguousTimeError` if there are ambiguous times

nonexistent [str, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST. Valid values are:

- ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
- ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
- ‘NaT’ will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- ‘raise’ will raise a NonExistentTimeError if there are nonexistent times

New in version 0.24.0.

Returns

Series or DataFrame Same type as the input.

Raises

TypeError If the TimeSeries is tz-aware and tz is not None.

Examples

Localize local times:

```
>>> s = pd.Series([1],
... index=pd.DatetimeIndex(['2018-09-15 01:30:00']))
>>> s.tz_localize('CET')
2018-09-15 01:30:00+02:00    1
dtype: int64
```

Be careful with DST changes. When there is sequential data, pandas can infer the DST time:

```
>>> s = pd.Series(range(7), index=pd.DatetimeIndex([
... '2018-10-28 01:30:00',
... '2018-10-28 02:00:00',
... '2018-10-28 02:30:00',
... '2018-10-28 02:00:00',
... '2018-10-28 02:30:00',
... '2018-10-28 03:00:00',
... '2018-10-28 03:30:00']))
>>> s.tz_localize('CET', ambiguous='infer')
2018-10-28 01:30:00+02:00    0
2018-10-28 02:00:00+02:00    1
2018-10-28 02:30:00+02:00    2
2018-10-28 02:00:00+01:00    3
2018-10-28 02:30:00+01:00    4
2018-10-28 03:00:00+01:00    5
2018-10-28 03:30:00+01:00    6
dtype: int64
```

In some cases, inferring the DST is impossible. In such cases, you can pass an ndarray to the ambiguous parameter to set the DST explicitly

```
>>> s = pd.Series(range(3), index=pd.DatetimeIndex([
... '2018-10-28 01:20:00',
```

(continues on next page)

(continued from previous page)

```

... '2018-10-28 02:36:00',
... '2018-10-28 03:46:00'])
>>> s.tz_localize('CET', ambiguous=np.array([True, True, False]))
2018-10-28 01:20:00+02:00    0
2018-10-28 02:36:00+02:00    1
2018-10-28 03:46:00+01:00    2
dtype: int64

```

If the DST transition causes nonexistent times, you can shift these dates forward or backwards with a `timedelta` object or `'shift_forward'` or `'shift_backwards'`. `>>> s = pd.Series(range(2), index=pd.DatetimeIndex(['... '2015-03-29 02:30:00', ... '2015-03-29 03:30:00']))`
`>>> s.tz_localize('Europe/Warsaw', nonexistent='shift_forward')` 2015-03-29 03:00:00+02:00
0 2015-03-29 03:30:00+02:00 1 dtype: int64 `>>> s.tz_localize('Europe/Warsaw', nonexistent='shift_backward')` 2015-03-29 01:59:59.999999999+01:00 0 2015-03-29 03:30:00+02:00 1
dtype: int64 `>>> s.tz_localize('Europe/Warsaw', nonexistent=pd.Timedelta('1H'))` 2015-03-29
03:30:00+02:00 0 2015-03-29 03:30:00+02:00 1 dtype: int64

pandas.DataFrame.unstack

`DataFrame.unstack(self, level=-1, fill_value=None)`

Pivot a level of the (necessarily hierarchical) index labels, returning a `DataFrame` having a new level of column labels whose inner-most level consists of the pivoted index labels.

If the index is not a `MultiIndex`, the output will be a `Series` (the analogue of `stack` when the columns are not a `MultiIndex`).

The level involved will automatically get sorted.

Parameters

level [int, string, or list of these, default -1 (last level)] Level(s) of index to unstack, can pass level name

fill_value [replace NaN with this value if the unstack produces] missing values

New in version 0.18.0.

Returns

Series or DataFrame

See also:

`DataFrame.pivot` Pivot a table based on column values.

`DataFrame.stack` Pivot a level of the column labels (inverse operation from `unstack`).

Examples

```

>>> index = pd.MultiIndex.from_tuples([('one', 'a'), ('one', 'b'),
...                                   ('two', 'a'), ('two', 'b')])
>>> s = pd.Series(np.arange(1.0, 5.0), index=index)
>>> s
one  a    1.0
     b    2.0

```

(continues on next page)

(continued from previous page)

```
two a    3.0
    b    4.0
dtype: float64
```

```
>>> s.unstack(level=-1)
    a    b
one  1.0  2.0
two  3.0  4.0
```

```
>>> s.unstack(level=0)
    one  two
a  1.0   3.0
b  2.0   4.0
```

```
>>> df = s.unstack(level=0)
>>> df.unstack()
one a    1.0
    b    2.0
two a    3.0
    b    4.0
dtype: float64
```

pandas.DataFrame.update

DataFrame.update(*self*, *other*, *join='left'*, *overwrite=True*, *filter_func=None*, *errors='ignore'*)
 Modify in place using non-NA values from another DataFrame.

Aligns on indices. There is no return value.

Parameters

other [DataFrame, or object coercible into a DataFrame] Should have at least one matching index/column label with the original DataFrame. If a Series is passed, its name attribute must be set, and that will be used as the column name to align with the original DataFrame.

join [{'left'}, default 'left'] Only left join is implemented, keeping the index and columns of the original object.

overwrite [bool, default True] How to handle non-NA values for overlapping keys:

- True: overwrite original DataFrame's values with values from *other*.
- False: only update values that are NA in the original DataFrame.

filter_func [callable(1d-array) -> bool 1d-array, optional] Can choose to replace values other than NA. Return True for values that should be updated.

errors [{'raise', 'ignore'}, default 'ignore'] If 'raise', will raise a ValueError if the DataFrame and *other* both contain non-NA data in the same place.

Changed in version 0.24.0: Changed from *raise_conflict=False/True* to *errors='ignore'/'raise'*.

Returns

None [method directly changes calling object]

Raises

ValueError

- When `errors='raise'` and there's overlapping non-NA data.
- When `errors` is not either `'ignore'` or `'raise'`

NotImplementedError

- If `join != 'left'`

See also:

`dict.update` Similar method for dictionaries.

`DataFrame.merge` For column(s)-on-columns(s) operations.

Examples

```
>>> df = pd.DataFrame({'A': [1, 2, 3],
...                    'B': [400, 500, 600]})
>>> new_df = pd.DataFrame({'B': [4, 5, 6],
...                        'C': [7, 8, 9]})
>>> df.update(new_df)
>>> df
   A  B
0  1  4
1  2  5
2  3  6
```

The DataFrame's length does not increase as a result of the update, only values at matching index/column labels are updated.

```
>>> df = pd.DataFrame({'A': ['a', 'b', 'c'],
...                    'B': ['x', 'y', 'z']})
>>> new_df = pd.DataFrame({'B': ['d', 'e', 'f', 'g', 'h', 'i']})
>>> df.update(new_df)
>>> df
   A  B
0  a  d
1  b  e
2  c  f
```

For Series, it's name attribute must be set.

```
>>> df = pd.DataFrame({'A': ['a', 'b', 'c'],
...                    'B': ['x', 'y', 'z']})
>>> new_column = pd.Series(['d', 'e'], name='B', index=[0, 2])
>>> df.update(new_column)
>>> df
   A  B
0  a  d
1  b  y
```

(continues on next page)

(continued from previous page)

```

2 c e
>>> df = pd.DataFrame({'A': ['a', 'b', 'c'],
...                    'B': ['x', 'y', 'z']})
>>> new_df = pd.DataFrame({'B': ['d', 'e']}, index=[1, 2])
>>> df.update(new_df)
>>> df
   A B
0  a x
1  b d
2  c e

```

If *other* contains NaNs the corresponding values are not updated in the original dataframe.

```

>>> df = pd.DataFrame({'A': [1, 2, 3],
...                    'B': [400, 500, 600]})
>>> new_df = pd.DataFrame({'B': [4, np.nan, 6]})
>>> df.update(new_df)
>>> df
   A    B
0  1  4.0
1  2 500.0
2  3  6.0

```

pandas.DataFrame.var

`DataFrame.var(self, axis=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs)`

Return unbiased variance over requested axis.

Normalized by N-1 by default. This can be changed using the `ddof` argument

Parameters

axis [{index (0), columns (1)}]

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is $N - \text{ddof}$, where N represents the number of elements.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns

Series or DataFrame (if level specified)

pandas.DataFrame.where

`DataFrame.where(self, cond, other=nan, inplace=False, axis=None, level=None, errors='raise', try_cast=False)`

Replace values where the condition is False.

Parameters

cond [boolean Series/DataFrame, array-like, or callable] Where *cond* is True, keep the original value. Where False, replace with corresponding value from *other*. If *cond* is callable, it is computed on the Series/DataFrame and should return boolean Series/DataFrame or array. The callable must not change input Series/DataFrame (though pandas doesn't check it).

New in version 0.18.1: A callable can be used as *cond*.

other [scalar, Series/DataFrame, or callable] Entries where *cond* is False are replaced with corresponding value from *other*. If *other* is callable, it is computed on the Series/DataFrame and should return scalar or Series/DataFrame. The callable must not change input Series/DataFrame (though pandas doesn't check it).

New in version 0.18.1: A callable can be used as *other*.

inplace [bool, default False] Whether to perform the operation in place on the data.

axis [int, default None] Alignment axis if needed.

level [int, default None] Alignment level if needed.

errors [str, {'raise', 'ignore'}, default 'raise'] Note that currently this parameter won't affect the results and will always coerce to a suitable dtype.

- 'raise' : allow exceptions to be raised.
- 'ignore' : suppress exceptions. On error return original object.

try_cast [bool, default False] Try to cast the result back to the input type (if possible).

Returns

Same type as caller

See also:

`DataFrame.mask()` Return an object of same shape as self.

Notes

The `where` method is an application of the if-then idiom. For each element in the calling DataFrame, if `cond` is True the element is used; otherwise the corresponding element from the DataFrame `other` is used.

The signature for `DataFrame.where()` differs from `numpy.where()`. Roughly `df1.where(m, df2)` is equivalent to `np.where(m, df1, df2)`.

For further details and examples see the `where` documentation in *indexing*.

Examples

```
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0    NaN
1    1.0
2    2.0
3    3.0
4    4.0
dtype: float64
```

```
>>> s.mask(s > 0)
0    0.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

```
>>> s.where(s > 1, 10)
0    10
1    10
2     2
3     3
4     4
dtype: int64
```

```
>>> df = pd.DataFrame(np.arange(10).reshape(-1, 2), columns=['A', 'B'])
>>> df
   A  B
0  0  1
1  2  3
2  4  5
3  6  7
4  8  9
>>> m = df % 3 == 0
>>> df.where(m, -df)
   A  B
0  0 -1
1 -2  3
2 -4 -5
3  6 -7
4 -8  9
>>> df.where(m, -df) == np.where(m, df, -df)
   A    B
0  True  True
1  True  True
2  True  True

pandas.DataFrame.xs**DataFrame.xs**(*self*, *key*, *axis=0*, *level=None*, *drop_level=True*)

Return cross-section from the Series/DataFrame.

This method takes a *key* argument to select data at a particular level of a MultiIndex.**Parameters****key** [label or tuple of label] Label contained in the index, or partially in a Multi-Index.**axis** [{0 or 'index', 1 or 'columns'}, default 0] Axis to retrieve cross-section on.**level** [object, defaults to first n levels (n=1 or len(key))] In case of a key partially contained in a MultiIndex, indicate which levels are used. Levels can be referred by label or position.**drop_level** [bool, default True] If False, returns object with same levels as self.**Returns****Series or DataFrame** Cross-section from the original Series or DataFrame corresponding to the selected index levels.**See also:****DataFrame.loc** Access a group of rows and columns by label(s) or a boolean array.**DataFrame.iloc** Purely integer-location based indexing for selection by position.**Notes***xs* can not be used to set values.MultiIndex Slicers is a generic way to get/set values on any level or levels. It is a superset of *xs* functionality, see *MultiIndex Slicers*.**Examples**

```

>>> d = {'num_legs': [4, 4, 2, 2],
...      'num_wings': [0, 0, 2, 2],
...      'class': ['mammal', 'mammal', 'mammal', 'bird'],
...      'animal': ['cat', 'dog', 'bat', 'penguin'],
...      'locomotion': ['walks', 'walks', 'flies', 'walks']}
>>> df = pd.DataFrame(data=d)
>>> df = df.set_index(['class', 'animal', 'locomotion'])
>>> df

```

(continues on next page)

(continued from previous page)

			num_legs	num_wings
class	animal	locomotion		
mammal	cat	walks	4	0
	dog	walks	4	0
	bat	flies	2	2
bird	penguin	walks	2	2

Get values at specified index

```
>>> df.xs('mammal')
           num_legs  num_wings
animal locomotion
cat     walks      4          0
dog     walks      4          0
bat     flies      2          2
```

Get values at several indexes

```
>>> df.xs(('mammal', 'dog'))
           num_legs  num_wings
locomotion
walks          4          0
```

Get values at specified index and level

```
>>> df.xs('cat', level=1)
           num_legs  num_wings
class locomotion
mammal walks      4          0
```

Get values at several indexes and levels

```
>>> df.xs(('bird', 'walks'),
...       level=[0, 'locomotion'])
           num_legs  num_wings
animal
penguin      2          2
```

Get values at specified column and axis

```
>>> df.xs('num_wings', axis=1)
class  animal  locomotion
mammal  cat    walks      0
         dog    walks      0
         bat    flies      2
bird    penguin walks      2
Name: num_wings, dtype: int64
```

6.4.2 Attributes and underlying data

Axes

<i>DataFrame.index</i>	The index (row labels) of the DataFrame.
<i>DataFrame.columns</i>	The column labels of the DataFrame.
<i>DataFrame.dtypes</i>	Return the dtypes in the DataFrame.
<i>DataFrame.ftypes</i>	(DEPRECATED) Return the ftypes (indication of sparse/dense and dtype) in DataFrame.
<i>DataFrame.get_dtype_counts</i> (self)	(DEPRECATED) Return counts of unique dtypes in this object.
<i>DataFrame.get_ftype_counts</i> (self)	(DEPRECATED) Return counts of unique ftypes in this object.
<i>DataFrame.select_dtypes</i> (self[, include, exclude])	Return a subset of the DataFrame's columns based on the column dtypes.
<i>DataFrame.values</i>	Return a Numpy representation of the DataFrame.
<i>DataFrame.get_values</i> (self)	(DEPRECATED) Return an ndarray after converting sparse values to dense.
<i>DataFrame.axes</i>	Return a list representing the axes of the DataFrame.
<i>DataFrame.ndim</i>	Return an int representing the number of axes / array dimensions.
<i>DataFrame.size</i>	Return an int representing the number of elements in this object.
<i>DataFrame.shape</i>	Return a tuple representing the dimensionality of the DataFrame.
<i>DataFrame.memory_usage</i> (self[, index, deep])	Return the memory usage of each column in bytes.
<i>DataFrame.empty</i>	Indicator whether DataFrame is empty.
<i>DataFrame.is_copy</i>	Return the copy.

6.4.3 Conversion

<i>DataFrame.astype</i> (self, dtype[, copy, errors])	Cast a pandas object to a specified dtype <i>dtype</i> .
<i>DataFrame.infer_objects</i> (self)	Attempt to infer better dtypes for object columns.
<i>DataFrame.copy</i> (self[, deep])	Make a copy of this object's indices and data.
<i>DataFrame.isna</i> (self)	Detect missing values.
<i>DataFrame.notna</i> (self)	Detect existing (non-missing) values.
<i>DataFrame.bool</i> (self)	Return the bool of a single element PandasObject.

6.4.4 Indexing, iteration

<i>DataFrame.head</i> (self[, n])	Return the first <i>n</i> rows.
<i>DataFrame.at</i>	Access a single value for a row/column label pair.
<i>DataFrame.iat</i>	Access a single value for a row/column pair by integer position.
<i>DataFrame.loc</i>	Access a group of rows and columns by label(s) or a boolean array.
<i>DataFrame.iloc</i>	Purely integer-location based indexing for selection by position.
<i>DataFrame.insert</i> (self, loc, column, value[, ...])	Insert column into DataFrame at specified location.

Continued on next page

Table 61 – continued from previous page

<code>DataFrame.__iter__(self)</code>	Iterate over info axis.
<code>DataFrame.items(self)</code>	Iterator over (column name, Series) pairs.
<code>DataFrame.iteritems(self)</code>	Iterator over (column name, Series) pairs.
<code>DataFrame.keys(self)</code>	Get the ‘info axis’ (see Indexing for more)
<code>DataFrame.iterrows(self)</code>	Iterate over DataFrame rows as (index, Series) pairs.
<code>DataFrame.itertuples(self[, index, name])</code>	Iterate over DataFrame rows as namedtuples.
<code>DataFrame.lookup(self, row_labels, col_labels)</code>	Label-based “fancy indexing” function for DataFrame.
<code>DataFrame.pop(self, item)</code>	Return item and drop from frame.
<code>DataFrame.tail(self[, n])</code>	Return the last <i>n</i> rows.
<code>DataFrame.xs(self, key[, axis, level, ...])</code>	Return cross-section from the Series/DataFrame.
<code>DataFrame.get(self, key[, default])</code>	Get item from object for given key (ex: DataFrame column).
<code>DataFrame.isin(self, values)</code>	Whether each element in the DataFrame is contained in values.
<code>DataFrame.where(self, cond[, other, ...])</code>	Replace values where the condition is False.
<code>DataFrame.mask(self, cond[, other, inplace, ...])</code>	Replace values where the condition is True.
<code>DataFrame.query(self, expr[, inplace])</code>	Query the columns of a DataFrame with a boolean expression.

pandas.DataFrame.__iter__

`DataFrame.__iter__(self)`
Iterate over info axis.

Returns

iterator Info axis as iterator.

For more information on `.at`, `.iat`, `.loc`, and `.iloc`, see the [indexing documentation](#).

6.4.5 Binary operator functions

<code>DataFrame.add(self, other[, axis, level, ...])</code>	Get Addition of dataframe and other, element-wise (binary operator <i>add</i>).
<code>DataFrame.sub(self, other[, axis, level, ...])</code>	Get Subtraction of dataframe and other, element-wise (binary operator <i>sub</i>).
<code>DataFrame.mul(self, other[, axis, level, ...])</code>	Get Multiplication of dataframe and other, element-wise (binary operator <i>mul</i>).
<code>DataFrame.div(self, other[, axis, level, ...])</code>	Get Floating division of dataframe and other, element-wise (binary operator <i>truediv</i>).
<code>DataFrame.truediv(self, other[, axis, ...])</code>	Get Floating division of dataframe and other, element-wise (binary operator <i>truediv</i>).
<code>DataFrame.floordiv(self, other[, axis, ...])</code>	Get Integer division of dataframe and other, element-wise (binary operator <i>floordiv</i>).
<code>DataFrame.mod(self, other[, axis, level, ...])</code>	Get Modulo of dataframe and other, element-wise (binary operator <i>mod</i>).
<code>DataFrame.pow(self, other[, axis, level, ...])</code>	Get Exponential power of dataframe and other, element-wise (binary operator <i>pow</i>).

Continued on next page

Table 62 – continued from previous page

<code>DataFrame.dot(self, other)</code>	Compute the matrix multiplication between the DataFrame and other.
<code>DataFrame.radd(self, other[, axis, level, ...])</code>	Get Addition of dataframe and other, element-wise (binary operator <i>radd</i>).
<code>DataFrame.rsub(self, other[, axis, level, ...])</code>	Get Subtraction of dataframe and other, element-wise (binary operator <i>rsub</i>).
<code>DataFrame.rmul(self, other[, axis, level, ...])</code>	Get Multiplication of dataframe and other, element-wise (binary operator <i>rmul</i>).
<code>DataFrame.rdiv(self, other[, axis, level, ...])</code>	Get Floating division of dataframe and other, element-wise (binary operator <i>rtruediv</i>).
<code>DataFrame.rtruediv(self, other[, axis, ...])</code>	Get Floating division of dataframe and other, element-wise (binary operator <i>rtruediv</i>).
<code>DataFrame.rfloordiv(self, other[, axis, ...])</code>	Get Integer division of dataframe and other, element-wise (binary operator <i>rfloordiv</i>).
<code>DataFrame.rmod(self, other[, axis, level, ...])</code>	Get Modulo of dataframe and other, element-wise (binary operator <i>rmod</i>).
<code>DataFrame.rpow(self, other[, axis, level, ...])</code>	Get Exponential power of dataframe and other, element-wise (binary operator <i>rpow</i>).
<code>DataFrame.lt(self, other[, axis, level])</code>	Get Less than of dataframe and other, element-wise (binary operator <i>lt</i>).
<code>DataFrame.gt(self, other[, axis, level])</code>	Get Greater than of dataframe and other, element-wise (binary operator <i>gt</i>).
<code>DataFrame.le(self, other[, axis, level])</code>	Get Less than or equal to of dataframe and other, element-wise (binary operator <i>le</i>).
<code>DataFrame.ge(self, other[, axis, level])</code>	Get Greater than or equal to of dataframe and other, element-wise (binary operator <i>ge</i>).
<code>DataFrame.ne(self, other[, axis, level])</code>	Get Not equal to of dataframe and other, element-wise (binary operator <i>ne</i>).
<code>DataFrame.eq(self, other[, axis, level])</code>	Get Equal to of dataframe and other, element-wise (binary operator <i>eq</i>).
<code>DataFrame.combine(self, other, func[, ...])</code>	Perform column-wise combine with another DataFrame.
<code>DataFrame.combine_first(self, other)</code>	Update null elements with value in the same location in <i>other</i> .

6.4.6 Function application, GroupBy & window

<code>DataFrame.apply(self, func[, axis, ...])</code>	Apply a function along an axis of the DataFrame.
<code>DataFrame.applymap(self, func)</code>	Apply a function to a Dataframe elementwise.
<code>DataFrame.pipe(self, func, <i>\</i>*args, <i>\</i>*<i>\</i>*kwargs)</code>	Apply <code>func(self, *args, **kwargs)</code> .
<code>DataFrame.agg(self, func[, axis])</code>	Aggregate using one or more operations over the specified axis.
<code>DataFrame.aggregate(self, func[, axis])</code>	Aggregate using one or more operations over the specified axis.
<code>DataFrame.transform(self, func[, axis])</code>	Call <code>func</code> on self producing a DataFrame with transformed values and that has the same axis length as self.
<code>DataFrame.groupby(self[, by, axis, level, ...])</code>	Group DataFrame or Series using a mapper or by a Series of columns.
<code>DataFrame.rolling(self, window[, ...])</code>	Provide rolling window calculations.

Continued on next page

Table 63 – continued from previous page

<code>DataFrame.expanding(self[, min_periods, ...])</code>	Provide expanding transformations.
<code>DataFrame.ewm(self[, com, span, halfife, ...])</code>	Provide exponential weighted functions.

6.4.7 Computations / descriptive stats

<code>DataFrame.abs(self)</code>	Return a Series/DataFrame with absolute numeric value of each element.
<code>DataFrame.all(self[, axis, bool_only, ...])</code>	Return whether all elements are True, potentially over an axis.
<code>DataFrame.any(self[, axis, bool_only, ...])</code>	Return whether any element is True, potentially over an axis.
<code>DataFrame.clip(self[, lower, upper, axis, ...])</code>	Trim values at input threshold(s).
<code>DataFrame.clip_lower(self, threshold[, ...])</code>	(DEPRECATED) Trim values below a given threshold.
<code>DataFrame.clip_upper(self, threshold[, ...])</code>	(DEPRECATED) Trim values above a given threshold.
<code>DataFrame.compound(self[, axis, skipna, level])</code>	(DEPRECATED) Return the compound percentage of the values for the requested axis.
<code>DataFrame.corr(self[, method, min_periods])</code>	Compute pairwise correlation of columns, excluding NA/null values.
<code>DataFrame.corrwith(self, other[, axis, ...])</code>	Compute pairwise correlation between rows or columns of DataFrame with rows or columns of Series or DataFrame.
<code>DataFrame.count(self[, axis, level, ...])</code>	Count non-NA cells for each column or row.
<code>DataFrame.cov(self[, min_periods])</code>	Compute pairwise covariance of columns, excluding NA/null values.
<code>DataFrame.cummax(self[, axis, skipna])</code>	Return cumulative maximum over a DataFrame or Series axis.
<code>DataFrame.cummin(self[, axis, skipna])</code>	Return cumulative minimum over a DataFrame or Series axis.
<code>DataFrame.cumprod(self[, axis, skipna])</code>	Return cumulative product over a DataFrame or Series axis.
<code>DataFrame.cumsum(self[, axis, skipna])</code>	Return cumulative sum over a DataFrame or Series axis.
<code>DataFrame.describe(self[, percentiles, ...])</code>	Generate descriptive statistics that summarize the central tendency, dispersion and shape of a dataset's distribution, excluding NaN values.
<code>DataFrame.diff(self[, periods, axis])</code>	First discrete difference of element.
<code>DataFrame.eval(self, expr[, inplace])</code>	Evaluate a string describing operations on DataFrame columns.
<code>DataFrame.kurt(self[, axis, skipna, level, ...])</code>	Return unbiased kurtosis over requested axis using Fisher's definition of kurtosis (kurtosis of normal == 0.0).
<code>DataFrame.kurtosis(self[, axis, skipna, ...])</code>	Return unbiased kurtosis over requested axis using Fisher's definition of kurtosis (kurtosis of normal == 0.0).
<code>DataFrame.mad(self[, axis, skipna, level])</code>	Return the mean absolute deviation of the values for the requested axis.
<code>DataFrame.max(self[, axis, skipna, level, ...])</code>	Return the maximum of the values for the requested axis.

Continued on next page

Table 64 – continued from previous page

<code>DataFrame.mean(self[, axis, skipna, level, ...])</code>	Return the mean of the values for the requested axis.
<code>DataFrame.median(self[, axis, skipna, ...])</code>	Return the median of the values for the requested axis.
<code>DataFrame.min(self[, axis, skipna, level, ...])</code>	Return the minimum of the values for the requested axis.
<code>DataFrame.mode(self[, axis, numeric_only, ...])</code>	Get the mode(s) of each element along the selected axis.
<code>DataFrame.pct_change(self[, periods, ...])</code>	Percentage change between the current and a prior element.
<code>DataFrame.prod(self[, axis, skipna, level, ...])</code>	Return the product of the values for the requested axis.
<code>DataFrame.product(self[, axis, skipna, ...])</code>	Return the product of the values for the requested axis.
<code>DataFrame.quantile(self[, q, axis, ...])</code>	Return values at the given quantile over requested axis.
<code>DataFrame.rank(self[, axis, method, ...])</code>	Compute numerical data ranks (1 through n) along axis.
<code>DataFrame.round(self[, decimals])</code>	Round a DataFrame to a variable number of decimal places.
<code>DataFrame.sem(self[, axis, skipna, level, ...])</code>	Return unbiased standard error of the mean over requested axis.
<code>DataFrame.skew(self[, axis, skipna, level, ...])</code>	Return unbiased skew over requested axis Normalized by N-1.
<code>DataFrame.sum(self[, axis, skipna, level, ...])</code>	Return the sum of the values for the requested axis.
<code>DataFrame.std(self[, axis, skipna, level, ...])</code>	Return sample standard deviation over requested axis.
<code>DataFrame.var(self[, axis, skipna, level, ...])</code>	Return unbiased variance over requested axis.
<code>DataFrame.unique(self[, axis, dropna])</code>	Count distinct observations over requested axis.

6.4.8 Reindexing / selection / label manipulation

<code>DataFrame.add_prefix(self, prefix)</code>	Prefix labels with string <i>prefix</i> .
<code>DataFrame.add_suffix(self, suffix)</code>	Suffix labels with string <i>suffix</i> .
<code>DataFrame.align(self, other[, join, axis, ...])</code>	Align two objects on their axes with the specified join method for each axis Index.
<code>DataFrame.at_time(self, time[, asof, axis])</code>	Select values at particular time of day (e.g.
<code>DataFrame.between_time(self, start_time, ...)</code>	Select values between particular times of the day (e.g., 9:00-9:30 AM).
<code>DataFrame.drop(self[, labels, axis, index, ...])</code>	Drop specified labels from rows or columns.
<code>DataFrame.drop_duplicates(self[, subset, ...])</code>	Return DataFrame with duplicate rows removed, optionally only considering certain columns.
<code>DataFrame.duplicated(self[, subset, keep])</code>	Return boolean Series denoting duplicate rows, optionally only considering certain columns.
<code>DataFrame.equals(self, other)</code>	Test whether two objects contain the same elements.
<code>DataFrame.filter(self[, items, like, regex, ...])</code>	Subset rows or columns of dataframe according to labels in the specified index.
<code>DataFrame.first(self, offset)</code>	Convenience method for subsetting initial periods of time series data based on a date offset.

Continued on next page

Table 65 – continued from previous page

<code>DataFrame.head(self[, n])</code>	Return the first n rows.
<code>DataFrame.idxmax(self[, axis, skipna])</code>	Return index of first occurrence of maximum over requested axis.
<code>DataFrame.idxmin(self[, axis, skipna])</code>	Return index of first occurrence of minimum over requested axis.
<code>DataFrame.last(self, offset)</code>	Convenience method for subsetting final periods of time series data based on a date offset.
<code>DataFrame.reindex(self[, labels, index, ...])</code>	Conform DataFrame to new index with optional filling logic, placing NA/NaN in locations having no value in the previous index.
<code>DataFrame.reindex_like(self, other[, ...])</code>	Return an object with matching indices as other object.
<code>DataFrame.rename(self[, mapper, index, ...])</code>	Alter axes labels.
<code>DataFrame.rename_axis(self[, mapper, index, ...])</code>	Set the name of the axis for the index or columns.
<code>DataFrame.reset_index(self[, level, drop, ...])</code>	Reset the index, or a level of it.
<code>DataFrame.sample(self[, n, frac, replace, ...])</code>	Return a random sample of items from an axis of object.
<code>DataFrame.set_axis(self, labels[, axis, inplace])</code>	Assign desired index to given axis.
<code>DataFrame.set_index(self, keys[, drop, ...])</code>	Set the DataFrame index using existing columns.
<code>DataFrame.tail(self[, n])</code>	Return the last n rows.
<code>DataFrame.take(self, indices[, axis, is_copy])</code>	Return the elements in the given <i>positional</i> indices along an axis.
<code>DataFrame.truncate(self[, before, after, ...])</code>	Truncate a Series or DataFrame before and after some index value.

6.4.9 Missing data handling

<code>DataFrame.dropna(self[, axis, how, thresh, ...])</code>	Remove missing values.
<code>DataFrame.fillna(self[, value, method, ...])</code>	Fill NA/NaN values using the specified method.
<code>DataFrame.replace(self[, to_replace, value, ...])</code>	Replace values given in <i>to_replace</i> with <i>value</i> .
<code>DataFrame.interpolate(self[, method, axis, ...])</code>	Interpolate values according to different methods.

6.4.10 Reshaping, sorting, transposing

<code>DataFrame.droplevel(self, level[, axis])</code>	Return DataFrame with requested index / column level(s) removed.
<code>DataFrame.pivot(self[, index, columns, values])</code>	Return reshaped DataFrame organized by given index / column values.
<code>DataFrame.pivot_table(self[, values, index, ...])</code>	Create a spreadsheet-style pivot table as a DataFrame.
<code>DataFrame.reorder_levels(self, order[, axis])</code>	Rearrange index levels using input order.
<code>DataFrame.sort_values(self, by[, axis, ...])</code>	Sort by the values along either axis.
<code>DataFrame.sort_index(self[, axis, level, ...])</code>	Sort object by labels (along an axis).
<code>DataFrame.nlargest(self, n, columns[, keep])</code>	Return the first n rows ordered by <i>columns</i> in descending order.
<code>DataFrame.nsmallest(self, n, columns[, keep])</code>	Return the first n rows ordered by <i>columns</i> in ascending order.
<code>DataFrame.swaplevel(self[, i, j, axis])</code>	Swap levels i and j in a MultiIndex on a particular axis.

Continued on next page

Table 67 – continued from previous page

<code>DataFrame.stack(self[, level, dropna])</code>	Stack the prescribed level(s) from columns to index.
<code>DataFrame.unstack(self[, level, fill_value])</code>	Pivot a level of the (necessarily hierarchical) index labels, returning a DataFrame having a new level of column labels whose inner-most level consists of the pivoted index labels.
<code>DataFrame.swapaxes(self, axis1, axis2[, copy])</code>	Interchange axes and swap values axes appropriately.
<code>DataFrame.melt(self[, id_vars, value_vars, ...])</code>	Unpivot a DataFrame from wide format to long format, optionally leaving identifier variables set.
<code>DataFrame.explode(self, column, Tuple)</code>	Transform each element of a list-like to a row, replicating the index values.
<code>DataFrame.squeeze(self[, axis])</code>	Squeeze 1 dimensional axis objects into scalars.
<code>DataFrame.to_xarray(self)</code>	Return an xarray object from the pandas object.
<code>DataFrame.T</code>	Transpose index and columns.
<code>DataFrame.transpose(self, *args, **kwargs)</code>	Transpose index and columns.

6.4.11 Combining / joining / merging

<code>DataFrame.append(self, other[, ...])</code>	Append rows of <i>other</i> to the end of caller, returning a new object.
<code>DataFrame.assign(self, **kwargs)</code>	Assign new columns to a DataFrame.
<code>DataFrame.join(self, other[, on, how, ...])</code>	Join columns of another DataFrame.
<code>DataFrame.merge(self, right[, how, on, ...])</code>	Merge DataFrame or named Series objects with a database-style join.
<code>DataFrame.update(self, other[, join, ...])</code>	Modify in place using non-NA values from another DataFrame.

6.4.12 Time series-related

<code>DataFrame.asfreq(self, freq[, method, how, ...])</code>	Convert TimeSeries to specified frequency.
<code>DataFrame.asof(self, where[, subset])</code>	Return the last row(s) without any NaNs before <i>where</i> .
<code>DataFrame.shift(self[, periods, freq, axis, ...])</code>	Shift index by desired number of periods with an optional time <i>freq</i> .
<code>DataFrame.slice_shift(self[, periods, axis])</code>	Equivalent to <i>shift</i> without copying data.
<code>DataFrame.tshift(self[, periods, freq, axis])</code>	Shift the time index, using the index's frequency if available.
<code>DataFrame.first_valid_index(self)</code>	Return index for first non-NA/null value.
<code>DataFrame.last_valid_index(self)</code>	Return index for last non-NA/null value.
<code>DataFrame.resample(self, rule[, how, axis, ...])</code>	Resample time-series data.
<code>DataFrame.to_period(self[, freq, axis, copy])</code>	Convert DataFrame from DatetimeIndex to PeriodIndex with desired frequency (inferred from index if not passed).
<code>DataFrame.to_timestamp(self[, freq, how, ...])</code>	Cast to DatetimeIndex of timestamps, at <i>beginning</i> of period.
<code>DataFrame.tz_convert(self, tz[, axis, ...])</code>	Convert tz-aware axis to target time zone.
<code>DataFrame.tz_localize(self, tz[, axis, ...])</code>	Localize tz-naive index of a Series or DataFrame to target time zone.

6.4.13 Plotting

`DataFrame.plot` is both a callable method and a namespace attribute for specific plotting methods of the form `DataFrame.plot.<kind>`.

<code>DataFrame.plot</code> ([x, y, kind, ax,])	DataFrame plotting accessor and method
<code>DataFrame.plot.area</code> (self[, x, y])	Draw a stacked area plot.
<code>DataFrame.plot.bar</code> (self[, x, y])	Vertical bar plot.
<code>DataFrame.plot.barh</code> (self[, x, y])	Make a horizontal bar plot.
<code>DataFrame.plot.box</code> (self[, by])	Make a box plot of the DataFrame columns.
<code>DataFrame.plot.density</code> (self[, bw_method, ind])	Generate Kernel Density Estimate plot using Gaussian kernels.
<code>DataFrame.plot.hexbin</code> (self, x, y[, C, ...])	Generate a hexagonal binning plot.
<code>DataFrame.plot.hist</code> (self[, by, bins])	Draw one histogram of the DataFrame's columns.
<code>DataFrame.plot.kde</code> (self[, bw_method, ind])	Generate Kernel Density Estimate plot using Gaussian kernels.
<code>DataFrame.plot.line</code> (self[, x, y])	Plot Series or DataFrame as lines.
<code>DataFrame.plot.pie</code> (self, <code>**kwargs</code>)	Generate a pie plot.
<code>DataFrame.plot.scatter</code> (self, x, y[, s, c])	Create a scatter plot with varying marker point size and color.

pandas.DataFrame.plot.area

`DataFrame.plot.area`(self, x=None, y=None, `**kwargs`)

Draw a stacked area plot.

An area plot displays quantitative data visually. This function wraps the matplotlib area function.

Parameters

- `x` [label or position, optional] Coordinates for the X axis. By default uses the index.
- `y` [label or position, optional] Column to plot. By default uses all columns.
- `stacked` [bool, default True] Area plots are stacked by default. Set to False to create a unstacked plot.
- `**kwds` [optional] Additional keyword arguments are documented in `DataFrame.plot()`.

Returns

- `matplotlib.axes.Axes` or `numpy.ndarray` Area plot, or array of area plots if subplots is True.

See also:

`DataFrame.plot` Make plots of DataFrame using matplotlib / pylab.

Examples

Draw an area plot based on basic business metrics:

```
>>> df = pd.DataFrame({
...     'sales': [3, 2, 3, 9, 10, 6],
...     'signups': [5, 5, 6, 12, 14, 13],
...     'visits': [20, 42, 28, 62, 81, 50],
... }, index=pd.date_range(start='2018/01/01', end='2018/07/01',
...                          freq='M'))
>>> ax = df.plot.area()
```

Area plots are stacked by default. To produce an unstacked plot, pass `stacked=False`:

```
>>> ax = df.plot.area(stacked=False)
```

Draw an area plot for a single column:

```
>>> ax = df.plot.area(y='sales')
```

Draw with a different *x*:

```
>>> df = pd.DataFrame({
...     'sales': [3, 2, 3],
...     'visits': [20, 42, 28],
...     'day': [1, 2, 3],
... })
>>> ax = df.plot.area(x='day')
```

pandas.DataFrame.plot.bar

`DataFrame.plot.bar`(*self*, *x=None*, *y=None*, ***kwargs*)

Vertical bar plot.

A bar plot is a plot that presents categorical data with rectangular bars with lengths proportional to the values that they represent. A bar plot shows comparisons among discrete categories. One axis of the plot shows the specific categories being compared, and the other axis represents a measured value.

Parameters

x [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.

y [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.

****kwargs** Additional keyword arguments are documented in `DataFrame.plot()`.

Returns

matplotlib.axes.Axes or np.ndarray of them An ndarray is returned with one `matplotlib.axes.Axes` per column when `subplots=True`.

See also:

`DataFrame.plot.barh` Horizontal bar plot.

`DataFrame.plot` Make plots of a DataFrame.

`matplotlib.pyplot.bar` Make a bar plot with matplotlib.

Examples

Basic plot.

```
>>> df = pd.DataFrame({'lab':['A', 'B', 'C'], 'val':[10, 30, 20]})
>>> ax = df.plot.bar(x='lab', y='val', rot=0)
```

Plot a whole dataframe to a bar plot. Each column is assigned a distinct color, and each row is nested in a group along the horizontal axis.

```
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
...         'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...                   'lifespan': lifespan}, index=index)
>>> ax = df.plot.bar(rot=0)
```

Instead of nesting, the figure can be split by column with `subplots=True`. In this case, a `numpy.ndarray` of `matplotlib.axes.Axes` are returned.

```
>>> axes = df.plot.bar(rot=0, subplots=True)
>>> axes[1].legend(loc=2) # doctest: +SKIP
```

Plot a single column.

```
>>> ax = df.plot.bar(y='speed', rot=0)
```

Plot only selected categories for the DataFrame.

```
>>> ax = df.plot.bar(x='lifespan', rot=0)
```

pandas.DataFrame.plot.barh

`DataFrame.plot.barh`(*self*, *x=None*, *y=None*, ***kwargs*)

Make a horizontal bar plot.

A horizontal bar plot is a plot that presents quantitative data with rectangular bars with lengths proportional to the values that they represent. A bar plot shows comparisons among discrete categories. One axis of the plot shows the specific categories being compared, and the other axis represents a measured value.

Parameters

- `x` [label or position, default `DataFrame.index`] Column to be used for categories.
- `y` [label or position, default All numeric columns in dataframe] Columns to be plotted from the DataFrame.
- `**kwargs` Keyword arguments to pass on to `DataFrame.plot()`.

Returns

`matplotlib.axes.Axes` or `numpy.ndarray` of them

See also:

`DataFrame.plot.bar` Vertical bar plot.

`DataFrame.plot` Make plots of DataFrame using matplotlib.

`matplotlib.axes.Axes.bar` Plot a vertical bar plot using matplotlib.

Examples

Basic example

```
>>> df = pd.DataFrame({'lab':['A', 'B', 'C'], 'val':[10, 30, 20]})
>>> ax = df.plot.barh(x='lab', y='val')
```

Plot a whole DataFrame to a horizontal bar plot

```
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
...         'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...                   'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh()
```

Plot a column of the DataFrame to a horizontal bar plot

```
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
...         'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...                   'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh(y='speed')
```

Plot DataFrame versus the desired column

```
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
...         'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...                   'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh(x='lifespan')
```

pandas.DataFrame.plot.box

`DataFrame.plot.box(self, by=None, **kwargs)`

Make a box plot of the DataFrame columns.

A box plot is a method for graphically depicting groups of numerical data through their quartiles. The box extends from the Q1 to Q3 quartile values of the data, with a line at the median (Q2). The whiskers extend from the edges of box to show the range of the data. The position of the whiskers is set by default to 1.5*IQR (IQR = Q3 - Q1) from the edges of the box. Outlier points are those past the end of the whiskers.

For further details see Wikipedia's entry for [boxplot](#).

A consideration when using this chart is that the box and the whiskers can overlap, which is very common when plotting small sets of data.

Parameters

by [string or sequence] Column in the DataFrame to group by.

****kwargs** [optional] Additional keywords are documented in `DataFrame.plot()`.

Returns

`matplotlib.axes.Axes` or `numpy.ndarray` of them

See also:

`DataFrame.boxplot` Another method to draw a box plot.

`Series.plot.box` Draw a box plot from a Series object.

`matplotlib.pyplot.boxplot` Draw a box plot in matplotlib.

Examples

Draw a box plot from a DataFrame with four columns of randomly generated data.

```
>>> data = np.random.randn(25, 4)
>>> df = pd.DataFrame(data, columns=list('ABCD'))
>>> ax = df.plot.box()
```

pandas.DataFrame.plot.density

`DataFrame.plot.density(self, bw_method=None, ind=None, **kwargs)`

Generate Kernel Density Estimate plot using Gaussian kernels.

In statistics, [kernel density estimation](#) (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

Parameters

bw_method [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be 'scott', 'silverman', a scalar constant or a callable. If None (default), 'scott' is used. See `scipy.stats.gaussian_kde` for more information.

ind [NumPy array or integer, optional] Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If *ind* is a NumPy array, the KDE is evaluated at the points passed. If *ind* is an integer, *ind* number of equally spaced points are used.

****kwargs** [optional] Additional keyword arguments are documented in `pandas.%(this-datatype)s.plot()`.

Returns

`matplotlib.axes.Axes` or `numpy.ndarray` of them

See also:

`scipy.stats.gaussian_kde` Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.

Examples

Given a Series of points randomly sampled from an unknown distribution, estimate its PDF using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```
>>> s = pd.Series([1, 2, 2.5, 3, 3.5, 4, 5])
>>> ax = s.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```
>>> ax = s.plot.kde(bw_method=0.3)
```

```
>>> ax = s.plot.kde(bw_method=3)
```

Finally, the *ind* parameter determines the evaluation points for the plot of the estimated PDF:

```
>>> ax = s.plot.kde(ind=[1, 2, 3, 4, 5])
```

For DataFrame, it works in the same way:

```
>>> df = pd.DataFrame({
...     'x': [1, 2, 2.5, 3, 3.5, 4, 5],
...     'y': [4, 4, 4.5, 5, 5.5, 6, 6],
... })
>>> ax = df.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```
>>> ax = df.plot.kde(bw_method=0.3)
```

```
>>> ax = df.plot.kde(bw_method=3)
```

Finally, the *ind* parameter determines the evaluation points for the plot of the estimated PDF:

```
>>> ax = df.plot.kde(ind=[1, 2, 3, 4, 5, 6])
```

pandas.DataFrame.plot.hexbin

`DataFrame.plot.hexbin(self, x, y, C=None, reduce_C_function=None, gridsize=None, **kwargs)`
Generate a hexagonal binning plot.

Generate a hexagonal binning plot of *x* versus *y*. If *C* is *None* (the default), this is a histogram of the number of occurrences of the observations at (*x*[*i*], *y*[*i*]).

If *C* is specified, specifies values at given coordinates (*x*[*i*], *y*[*i*]). These values are accumulated for each hexagonal bin and then reduced according to *reduce_C_function*, having as default the NumPy's mean function (`numpy.mean()`). (If *C* is specified, it must also be a 1-D sequence of the same length as *x* and *y*, or a column label.)

Parameters

x [int or str] The column label or position for x points.

y [int or str] The column label or position for y points.

C [int or str, optional] The column label or position for the value of (x, y) point.

reduce_C_function [callable, default `np.mean`] Function of one argument that reduces all the values in a bin to a single number (e.g. `np.mean`, `np.max`, `np.sum`, `np.std`).

gridsize [int or tuple of (int, int), default 100] The number of hexagons in the x-direction. The corresponding number of hexagons in the y-direction is chosen in a way that the hexagons are approximately regular. Alternatively, `gridsize` can be a tuple with two elements specifying the number of hexagons in the x-direction and the y-direction.

****kwargs** Additional keyword arguments are documented in `DataFrame.plot()`.

Returns

matplotlib.AxesSubplot The matplotlib Axes on which the hexbin is plotted.

See also:

`DataFrame.plot` Make plots of a DataFrame.

`matplotlib.pyplot.hexbin` Hexagonal binning plot using matplotlib, the matplotlib function that is used under the hood.

Examples

The following examples are generated with random data from a normal distribution.

```

>>> n = 10000
>>> df = pd.DataFrame({'x': np.random.randn(n),
...                   'y': np.random.randn(n)})
>>> ax = df.plot.hexbin(x='x', y='y', gridsize=20)

```

The next example uses `C` and `np.sum` as `reduce_C_function`. Note that `'observations'` values ranges from 1 to 5 but the result plot shows values up to more than 25. This is because of the `reduce_C_function`.

```

>>> n = 500
>>> df = pd.DataFrame({
...     'coord_x': np.random.uniform(-3, 3, size=n),
...     'coord_y': np.random.uniform(30, 50, size=n),
...     'observations': np.random.randint(1,5, size=n)
... })
>>> ax = df.plot.hexbin(x='coord_x',
...                     y='coord_y',
...                     C='observations',
...                     reduce_C_function=np.sum,
...                     gridsize=10,
...                     cmap="viridis")

```

pandas.DataFrame.plot.hist

`DataFrame.plot.hist(self, by=None, bins=10, **kwargs)`

Draw one histogram of the DataFrame's columns.

A histogram is a representation of the distribution of data. This function groups the values of all given Series in the DataFrame into bins and draws all bins in one `matplotlib.axes.Axes`. This is useful when the DataFrame's Series are in a similar scale.

Parameters

by [str or sequence, optional] Column in the DataFrame to group by.

bins [int, default 10] Number of histogram bins to be used.

****kwargs** Additional keyword arguments are documented in `DataFrame.plot()`.

Returns

class:matplotlib.AxesSubplot Return a histogram plot.

See also:

DataFrame.hist Draw histograms per DataFrame's Series.

Series.hist Draw a histogram with Series' data.

Examples

When we draw a dice 6000 times, we expect to get each value around 1000 times. But when we draw two dices and sum the result, the distribution is going to be quite different. A histogram illustrates those distributions.

```

>>> df = pd.DataFrame(
...     np.random.randint(1, 7, 6000),
...     columns = ['one'])
>>> df['two'] = df['one'] + np.random.randint(1, 7, 6000)
>>> ax = df.plot.hist(bins=12, alpha=0.5)

```

pandas.DataFrame.plot.kde

`DataFrame.plot.kde(self, bw_method=None, ind=None, **kwargs)`

Generate Kernel Density Estimate plot using Gaussian kernels.

In statistics, [kernel density estimation](#) (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

Parameters

bw_method [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be 'scott', 'silverman', a scalar constant or a callable. If None (default), 'scott' is used. See `scipy.stats.gaussian_kde` for more information.

ind [NumPy array or integer, optional] Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If *ind* is a NumPy array, the KDE is evaluated at the points passed. If *ind* is an integer, *ind* number of equally spaced points are used.

```
**kwargs [optional] Additional keyword arguments are documented in pandas.  
%(this-datatype)s.plot().
```

Returns

`matplotlib.axes.Axes` or `numpy.ndarray` of them

See also:

`scipy.stats.gaussian_kde` Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.

Examples

Given a Series of points randomly sampled from an unknown distribution, estimate its PDF using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```
>>> s = pd.Series([1, 2, 2.5, 3, 3.5, 4, 5])  
>>> ax = s.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```
>>> ax = s.plot.kde(bw_method=0.3)
```

```
>>> ax = s.plot.kde(bw_method=3)
```

Finally, the *ind* parameter determines the evaluation points for the plot of the estimated PDF:

```
>>> ax = s.plot.kde(ind=[1, 2, 3, 4, 5])
```

For DataFrame, it works in the same way:

```
>>> df = pd.DataFrame({  
...     'x': [1, 2, 2.5, 3, 3.5, 4, 5],  
...     'y': [4, 4, 4.5, 5, 5.5, 6, 6],  
... })  
>>> ax = df.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```
>>> ax = df.plot.kde(bw_method=0.3)
```

```
>>> ax = df.plot.kde(bw_method=3)
```

Finally, the *ind* parameter determines the evaluation points for the plot of the estimated PDF:

```
>>> ax = df.plot.kde(ind=[1, 2, 3, 4, 5, 6])
```

pandas.DataFrame.plot.line

`DataFrame.plot.line`(*self*, *x=None*, *y=None*, ***kwargs*)
Plot Series or DataFrame as lines.

This function is useful to plot lines using DataFrame's values as coordinates.

Parameters

x [int or str, optional] Columns to use for the horizontal axis. Either the location or the label of the columns to be used. By default, it will use the DataFrame indices.

y [int, str, or list of them, optional] The values to be plotted. Either the location or the label of the columns to be used. By default, it will use the remaining DataFrame numeric columns.

****kwargs** Keyword arguments to pass on to `DataFrame.plot()`.

Returns

`matplotlib.axes.Axes` or `numpy.ndarray` Return an ndarray when `subplots=True`.

See also:

`matplotlib.pyplot.plot` Plot y versus x as lines and/or markers.

Examples

```
>>> s = pd.Series([1, 3, 2])
>>> s.plot.line()
```

The following example shows the populations for some animals over the years.

```
>>> df = pd.DataFrame({
...     'pig': [20, 18, 489, 675, 1776],
...     'horse': [4, 25, 281, 600, 1900]
...     }, index=[1990, 1997, 2003, 2009, 2014])
>>> lines = df.plot.line()
```

An example with subplots, so an array of axes is returned.

```
>>> axes = df.plot.line(subplots=True)
>>> type(axes)
<class 'numpy.ndarray'>
```

The following example shows the relationship between both populations.

```
>>> lines = df.plot.line(x='pig', y='horse')
```

pandas.DataFrame.plot.pie

`DataFrame.plot.pie(self, **kwargs)`

Generate a pie plot.

A pie plot is a proportional representation of the numerical data in a column. This function wraps `matplotlib.pyplot.pie()` for the specified column. If no column reference is passed and `subplots=True` a pie plot is drawn for each numerical column independently.

Parameters

y [int or label, optional] Label or position of the column to plot. If not provided, `subplots=True` argument must be passed.

****kwargs** Keyword arguments to pass on to `DataFrame.plot()`.

Returns

matplotlib.axes.Axes or np.ndarray of them A NumPy array is returned when `subplots` is True.

See also:

`Series.plot.pie` Generate a pie plot for a Series.

`DataFrame.plot` Make plots of a DataFrame.

Examples

In the example below we have a DataFrame with the information about planet's mass and radius. We pass the the 'mass' column to the pie function to get a pie plot.

```
>>> df = pd.DataFrame({'mass': [0.330, 4.87 , 5.97],
...                    'radius': [2439.7, 6051.8, 6378.1]},
...                    index=['Mercury', 'Venus', 'Earth'])
>>> plot = df.plot.pie(y='mass', figsize=(5, 5))
```

```
>>> plot = df.plot.pie(subplots=True, figsize=(6, 3))
```

pandas.DataFrame.plot.scatter

`DataFrame.plot.scatter(self, x, y, s=None, c=None, **kwargs)`

Create a scatter plot with varying marker point size and color.

The coordinates of each point are defined by two dataframe columns and filled circles are used to represent each point. This kind of plot is useful to see complex correlations between two variables. Points could be for instance natural 2D coordinates like longitude and latitude in a map or, in general, any pair of metrics that can be plotted against each other.

Parameters

x [int or str] The column name or column position to be used as horizontal coordinates for each point.

y [int or str] The column name or column position to be used as vertical coordinates for each point.

s [scalar or array_like, optional] The size of each point. Possible values are:

- A single scalar so all points have the same size.
- A sequence of scalars, which will be used for each point's size recursively. For instance, when passing [2,14] all points size will be either 2 or 14, alternatively.

c [str, int or array_like, optional] The color of each point. Possible values are:

- A single color string referred to by name, RGB or RGBA code, for instance 'red' or '#a98d19'.

- A sequence of color strings referred to by name, RGB or RGBA code, which will be used for each point's color recursively. For instance ['green','yellow'] all points will be filled in green or yellow, alternatively.
- A column name or position whose values will be used to color the marker points according to a colormap.

****kwargs** Keyword arguments to pass on to `DataFrame.plot()`.

Returns

`matplotlib.axes.Axes` or `numpy.ndarray` of them

See also:

`matplotlib.pyplot.scatter` Scatter plot using multiple input data formats.

Examples

Let's see how to draw a scatter plot using coordinates from the values in a DataFrame's columns.

```
>>> df = pd.DataFrame([[5.1, 3.5, 0], [4.9, 3.0, 0], [7.0, 3.2, 1],
...                   [6.4, 3.2, 1], [5.9, 3.0, 2]],
...                   columns=['length', 'width', 'species'])
>>> ax1 = df.plot.scatter(x='length',
...                       y='width',
...                       c='DarkBlue')
```

And now with the color determined by a column as well.

```
>>> ax2 = df.plot.scatter(x='length',
...                       y='width',
...                       c='species',
...                       colormap='viridis')
```

<code>DataFrame.boxplot(self[, column, by, ax, ...])</code>	Make a box plot from DataFrame columns.
<code>DataFrame.hist(data[, column, by, grid, ...])</code>	Make a histogram of the DataFrame's.

6.4.14 Sparse accessor

Sparse-dtype specific methods and attributes are provided under the `DataFrame.sparse` accessor.

<code>DataFrame.sparse.density</code>	Ratio of non-sparse points to total (dense) data points represented in the DataFrame.
---------------------------------------	---

`pandas.DataFrame.sparse.density`

`DataFrame.sparse.density`

Ratio of non-sparse points to total (dense) data points represented in the DataFrame.

<code>DataFrame.sparse.from_spmatrix(data[, ...])</code>	Create a new DataFrame from a scipy sparse matrix.
<code>DataFrame.sparse.to_coo(self)</code>	Return the contents of the frame as a sparse SciPy COO matrix.
<code>DataFrame.sparse.to_dense(self)</code>	Convert a DataFrame with sparse values to dense.

`pandas.DataFrame.sparse.from_spmatrix`

classmethod `sparse.from_spmatrix(data, index=None, columns=None)`

Create a new DataFrame from a scipy sparse matrix.

New in version 0.25.0.

Parameters

data [`scipy.sparse.spmatrix`] Must be convertible to csc format.

index, columns [`Index`, optional] Row and column labels to use for the resulting DataFrame. Defaults to a `RangeIndex`.

Returns

DataFrame Each column of the DataFrame is stored as a `SparseArray`.

Examples

```
>>> import scipy.sparse
>>> mat = scipy.sparse.eye(3)
>>> pd.DataFrame.sparse.from_spmatrix(mat)
   0  1  2
0  1.0 0.0 0.0
1  0.0 1.0 0.0
2  0.0 0.0 1.0
```

`pandas.DataFrame.sparse.to_coo`

`sparse.to_coo(self)`

Return the contents of the frame as a sparse SciPy COO matrix.

New in version 0.25.0.

Returns

coo_matrix [`scipy.sparse.spmatrix`] If the caller is heterogeneous and contains booleans or objects, the result will be of `dtype=object`. See Notes.

Notes

The dtype will be the lowest-common-denominator type (implicit upcasting); that is to say if the dtypes (even of numeric types) are mixed, the one that accommodates all will be chosen.

e.g. If the dtypes are `float16` and `float32`, dtype will be upcast to `float32`. By `numpy.find_common_type` convention, mixing `int64` and `uint64` will result in a `float64` dtype.

pandas.DataFrame.sparse.to_dense`sparse.to_dense(self)`

Convert a DataFrame with sparse values to dense.

New in version 0.25.0.

Returns**DataFrame** A DataFrame with the same values stored as dense arrays.**Examples**

```

>>> df = pd.DataFrame({"A": pd.SparseArray([0, 1, 0])})
>>> df.sparse.to_dense()
   A
0  0
1  1
2  0

```

6.4.15 Serialization / IO / conversion

<code>DataFrame.from_dict(data[, orient, dtype, ...])</code>	Construct DataFrame from dict of array-like or dicts.
<code>DataFrame.from_items(items[, columns, orient])</code>	(DEPRECATED) Construct a DataFrame from a list of tuples.
<code>DataFrame.from_records(data[, index, ...])</code>	Convert structured or record ndarray to DataFrame.
<code>DataFrame.info(self[, verbose, buf, ...])</code>	Print a concise summary of a DataFrame.
<code>DataFrame.to_parquet(self, fname[, engine, ...])</code>	Write a DataFrame to the binary parquet format.
<code>DataFrame.to_pickle(self, path[, ...])</code>	Pickle (serialize) object to file.
<code>DataFrame.to_csv(self[, path_or_buf, sep, ...])</code>	Write object to a comma-separated values (csv) file.
<code>DataFrame.to_hdf(self, path_or_buf, key, ...)</code>	Write the contained data to an HDF5 file using HDFStore.
<code>DataFrame.to_sql(self, name, con[, schema, ...])</code>	Write records stored in a DataFrame to a SQL database.
<code>DataFrame.to_dict(self[, orient, into])</code>	Convert the DataFrame to a dictionary.
<code>DataFrame.to_excel(self, excel_writer[, ...])</code>	Write object to an Excel sheet.
<code>DataFrame.to_json(self[, path_or_buf, ...])</code>	Convert the object to a JSON string.
<code>DataFrame.to_html(self[, buf, columns, ...])</code>	Render a DataFrame as an HTML table.
<code>DataFrame.to_feather(self, fname)</code>	Write out the binary feather-format for DataFrames.
<code>DataFrame.to_latex(self[, buf, columns, ...])</code>	Render an object to a LaTeX tabular environment table.
<code>DataFrame.to_stata(self, fname[, ...])</code>	Export DataFrame object to Stata dta format.
<code>DataFrame.to_msgpack(self[, path_or_buf, ...])</code>	(DEPRECATED) Serialize object to input file path using msgpack format.
<code>DataFrame.to_gbq(self, destination_table[, ...])</code>	Write a DataFrame to a Google BigQuery table.
<code>DataFrame.to_records(self[, index, ...])</code>	Convert DataFrame to a NumPy record array.
<code>DataFrame.to_sparse(self[, fill_value, kind])</code>	(DEPRECATED) Convert to SparseDataFrame.

Continued on next page

Table 75 – continued from previous page

<code>DataFrame.to_dense(self)</code>	(DEPRECATED) Return dense representation of Series/DataFrame (as opposed to sparse).
<code>DataFrame.to_string(self[, buf, columns, ...])</code>	Render a DataFrame to a console-friendly tabular output.
<code>DataFrame.to_clipboard(self[, excel, sep])</code>	Copy object to the system clipboard.
<code>DataFrame.style</code>	Property returning a Styler object containing methods for building a styled HTML representation for the DataFrame.

6.4.16 Sparse

<code>SparseDataFrame.to_coo(self)</code>	Return the contents of the frame as a sparse SciPy COO matrix.
---	--

pandas.SparseDataFrame.to_coo

`SparseDataFrame.to_coo(self)`

Return the contents of the frame as a sparse SciPy COO matrix.

New in version 0.25.0.

Returns

coo_matrix [`scipy.sparse.spmatrix`] If the caller is heterogeneous and contains booleans or objects, the result will be of `dtype=object`. See Notes.

Notes

The dtype will be the lowest-common-denominator type (implicit upcasting); that is to say if the dtypes (even of numeric types) are mixed, the one that accommodates all will be chosen.

e.g. If the dtypes are float16 and float32, dtype will be upcast to float32. By `numpy.find_common_type` convention, mixing int64 and uint64 will result in a float64 dtype.

{{ header }}

6.5 Pandas arrays

For most data types, pandas uses NumPy arrays as the concrete objects contained with a *Index*, *Series*, or *DataFrame*.

For some data types, pandas extends NumPy's type system.

Kind of Data	Pandas Data Type	Scalar	Array
TZ-aware datetime	<i>DatetimeTZDtype</i>	<i>Timestamp</i>	<i>Datetime data</i>
Timedeltas	(none)	<i>Timedelta</i>	<i>Timedelta data</i>
Period (time spans)	<i>PeriodDtype</i>	<i>Period</i>	<i>Timespan data</i>
Intervals	<i>IntervalDtype</i>	<i>Interval</i>	<i>Interval data</i>
Nullable Integer	<i>Int64Dtype, ...</i>	(none)	<i>Nullable integer</i>
Categorical	<i>CategoricalDtype</i>	(none)	<i>Categorical data</i>
Sparse	<i>SparseDtype</i>	(none)	<i>Sparse data</i>

Pandas and third-party libraries can extend NumPy's type system (see *Extension types*). The top-level `array()` method can be used to create a new array, which may be stored in a *Series*, *Index*, or as a column in a *DataFrame*.

`array(data, dtype, numpy.dtype, ...)` Create an array.

6.5.1 pandas.array

`pandas.array(data: Sequence[object], dtype: Union[str, numpy.dtype, pandas.core.dtypes.base.ExtensionDtype, NoneType] = None, copy: bool = True) → pandas.core.dtypes.generic.ABCExtensionArray`

Create an array.

New in version 0.24.0.

Parameters

data [Sequence of objects] The scalars inside *data* should be instances of the scalar type for *dtype*. It's expected that *data* represents a 1-dimensional array of data.

When *data* is an *Index* or *Series*, the underlying array will be extracted from *data*.

dtype [str, np.dtype, or ExtensionDtype, optional] The dtype to use for the array. This may be a NumPy dtype or an extension type registered with pandas using `pandas.api.extensions.register_extension_dtype()`.

If not specified, there are two possibilities:

1. When *data* is a *Series*, *Index*, or *ExtensionArray*, the *dtype* will be taken from the data.
2. Otherwise, pandas will attempt to infer the *dtype* from the data.

Note that when *data* is a NumPy array, `data.dtype` is *not* used for inferring the array type. This is because NumPy cannot represent all the types of data that can be held in extension arrays.

Currently, pandas will infer an extension dtype for sequences of

Scalar Type	Array Type
<code>pandas.Interval</code>	<code>pandas.arrays.IntervalArray</code>
<code>pandas.Period</code>	<code>pandas.arrays.PeriodArray</code>
<code>datetime.datetime</code>	<code>pandas.arrays.DatetimeArray</code>
<code>datetime.timedelta</code>	<code>pandas.arrays.TimedeltaArray</code>

For all other cases, NumPy's usual inference rules will be used.

copy [bool, default True] Whether to copy the data, even if not necessary. Depending on the type of *data*, creating the new array may require copying data, even if `copy=False`.

Returns

ExtensionArray The newly created array.

Raises

ValueError When *data* is not 1-dimensional.

See also:

`numpy.array` Construct a NumPy array.

`Series` Construct a pandas Series.

`Index` Construct a pandas Index.

`arrays.PandasArray` ExtensionArray wrapping a NumPy array.

`Series.array` Extract the array stored within a Series.

Notes

Omitting the `dtype` argument means pandas will attempt to infer the best array type from the values in the data. As new array types are added by pandas and 3rd party libraries, the “best” array type may change. We recommend specifying `dtype` to ensure that

1. the correct array type for the data is returned
2. the returned array type doesn’t change as new extension types are added by pandas and third-party libraries

Additionally, if the underlying memory representation of the returned array matters, we recommend specifying the `dtype` as a concrete object rather than a string alias or allowing it to be inferred. For example, a future version of pandas or a 3rd-party library may include a dedicated ExtensionArray for string data. In this event, the following would no longer return a `arrays.PandasArray` backed by a NumPy array.

```
>>> pd.array(['a', 'b'], dtype=str)
<PandasArray>
['a', 'b']
Length: 2, dtype: str32
```

This would instead return the new ExtensionArray dedicated for string data. If you really need the new array to be backed by a NumPy array, specify that in the `dtype`.

```
>>> pd.array(['a', 'b'], dtype=np.dtype("<U1"))
<PandasArray>
['a', 'b']
Length: 2, dtype: str32
```

Or use the dedicated constructor for the array you’re expecting, and wrap that in a `PandasArray`

```
>>> pd.array(np.array(['a', 'b'], dtype='<U1'))
<PandasArray>
['a', 'b']
Length: 2, dtype: str32
```

Finally, Pandas has arrays that mostly overlap with NumPy

- `arrays.DatetimeArray`
- `arrays.TimedeltaArray`

When data with a `datetime64[ns]` or `timedelta64[ns]` dtype is passed, pandas will always return a `DatetimeArray` or `TimedeltaArray` rather than a `PandasArray`. This is for symmetry with the case of timezone-aware data, which NumPy does not natively support.

```
>>> pd.array(['2015', '2016'], dtype='datetime64[ns]')
<DatetimeArray>
['2015-01-01 00:00:00', '2016-01-01 00:00:00']
Length: 2, dtype: datetime64[ns]
```

```
>>> pd.array(["1H", "2H"], dtype='timedelta64[ns]')
<TimedeltaArray>
['01:00:00', '02:00:00']
Length: 2, dtype: timedelta64[ns]
```

Examples

If a dtype is not specified, *data* is passed through to `numpy.array()`, and a `pandas.arrays.PandasArray` is returned.

```
>>> pd.array([1, 2])
<PandasArray>
[1, 2]
Length: 2, dtype: int64
```

Or the NumPy dtype can be specified

```
>>> pd.array([1, 2], dtype=np.dtype("int32"))
<PandasArray>
[1, 2]
Length: 2, dtype: int32
```

You can use the string alias for *dtype*

```
>>> pd.array(['a', 'b', 'a'], dtype='category')
[a, b, a]
Categories (2, object): [a, b]
```

Or specify the actual dtype

```
>>> pd.array(['a', 'b', 'a'],
...          dtype=pd.CategoricalDtype(['a', 'b', 'c'], ordered=True))
[a, b, a]
Categories (3, object): [a < b < c]
```

Because omitting the *dtype* passes the data through to NumPy, a mixture of valid integers and NA will return a floating-point NumPy array.

```
>>> pd.array([1, 2, np.nan])
<PandasArray>
[1.0, 2.0, nan]
Length: 3, dtype: float64
```

To use pandas' nullable `pandas.arrays.IntegerArray`, specify the dtype:

```
>>> pd.array([1, 2, np.nan], dtype='Int64')
<IntegerArray>
```

(continues on next page)

(continued from previous page)

```
[1, 2, NaN]
Length: 3, dtype: Int64
```

Pandas will infer an ExtensionArray for some types of data:

```
>>> pd.array([pd.Period('2000', freq="D"), pd.Period("2000", freq="D")])
<PeriodArray>
['2000-01-01', '2000-01-01']
Length: 2, dtype: period[D]
```

data must be 1-dimensional. A `ValueError` is raised when the input has the wrong dimensionality.

```
>>> pd.array(1)
Traceback (most recent call last):
...
ValueError: Cannot pass scalar '1' to 'pandas.array'.
```

6.5.2 Datetime data

NumPy cannot natively represent timezone-aware datetimes. Pandas supports this with the *arrays*. *DatetimeArray* extension array, which can hold timezone-naive or timezone-aware values.

Timestamp, a subclass of `datetime.datetime`, is pandas' scalar type for timezone-naive or timezone-aware datetime data.

Timestamp

Pandas replacement for python `datetime.datetime` object.

pandas.Timestamp

`class pandas.Timestamp`

Pandas replacement for python `datetime.datetime` object.

`Timestamp` is the pandas equivalent of python's `Datetime` and is interchangeable with it in most cases. It's the type used for the entries that make up a `DatetimeIndex`, and other timeseries oriented data structures in pandas.

Parameters

ts_input [datetime-like, str, int, float] Value to be converted to `Timestamp`.

freq [str, `DateOffset`] Offset which `Timestamp` will have.

tz [str, `pytz.timezone`, `dateutil.tz.tzfile` or `None`] Time zone for time which `Timestamp` will have.

unit [str] Unit used for conversion if `ts_input` is of type `int` or `float`. The valid values are 'D', 'h', 'm', 's', 'ms', 'us', and 'ns'. For example, 's' means seconds and 'ms' means milliseconds.

year, month, day [int] New in version 0.19.0.

hour, minute, second, microsecond [int, optional, default 0] New in version 0.19.0.

nanosecond [int, optional, default 0] New in version 0.23.0.

tzinfo [datetime.tzinfo, optional, default None] New in version 0.19.0.

Notes

There are essentially three calling conventions for the constructor. The primary form accepts four parameters. They can be passed by position or keyword.

The other two forms mimic the parameters from `datetime.datetime`. They can be passed by either position or keyword, but not both mixed together.

Examples

Using the primary calling convention:

This converts a datetime-like string

```
>>> pd.Timestamp('2017-01-01T12')
Timestamp('2017-01-01 12:00:00')
```

This converts a float representing a Unix epoch in units of seconds

```
>>> pd.Timestamp(1513393355.5, unit='s')
Timestamp('2017-12-16 03:02:35.500000')
```

This converts an int representing a Unix-epoch in units of seconds and for a particular timezone

```
>>> pd.Timestamp(1513393355, unit='s', tz='US/Pacific')
Timestamp('2017-12-15 19:02:35-0800', tz='US/Pacific')
```

Using the other two forms that mimic the API for `datetime.datetime`:

```
>>> pd.Timestamp(2017, 1, 1, 12)
Timestamp('2017-01-01 12:00:00')
```

```
>>> pd.Timestamp(year=2017, month=1, day=1, hour=12)
Timestamp('2017-01-01 12:00:00')
```

Attributes

<i>asm8</i>	Return numpy datetime64 format in nanoseconds.
<i>dayofweek</i>	Return day of the week.
<i>dayofyear</i>	Return the day of the year.
<i>days_in_month</i>	Return the number of days in the month.
<i>daysinmonth</i>	Return the number of days in the month.
<i>freqstr</i>	Return the total number of days in the month.
<i>is_leap_year</i>	Return True if year is a leap year.
<i>is_month_end</i>	Return True if date is last day of month.
<i>is_month_start</i>	Return True if date is first day of month.

Continued on next page

Table 79 – continued from previous page

<i>is_quarter_end</i>	Return True if date is last day of the quarter.
<i>is_quarter_start</i>	Return True if date is first day of the quarter.
<i>is_year_end</i>	Return True if date is last day of the year.
<i>is_year_start</i>	Return True if date is first day of the year.
<i>quarter</i>	Return the quarter of the year.
<i>resolution</i>	Return resolution describing the smallest difference between two times that can be represented by Timestamp object <i>_state</i>
<i>tz</i>	Alias for <i>tzinfo</i>
<i>week</i>	Return the week number of the year.
<i>weekday_name</i>	(DEPRECATED) .. deprecated:: 0.23.0
<i>weekofyear</i>	Return the week number of the year.

pandas.Timestamp.asm8`Timestamp.asm8`

Return numpy datetime64 format in nanoseconds.

pandas.Timestamp.dayofweek`Timestamp.dayofweek`

Return day of the week.

pandas.Timestamp.dayofyear`Timestamp.dayofyear`

Return the day of the year.

pandas.Timestamp.days_in_month`Timestamp.days_in_month`

Return the number of days in the month.

pandas.Timestamp.daysinmonth`Timestamp.daysinmonth`

Return the number of days in the month.

pandas.Timestamp.freqstr`Timestamp.freqstr`

Return the total number of days in the month.

pandas.Timestamp.is_leap_year

`Timestamp.is_leap_year`

Return True if year is a leap year.

pandas.Timestamp.is_month_end

`Timestamp.is_month_end`

Return True if date is last day of month.

pandas.Timestamp.is_month_start

`Timestamp.is_month_start`

Return True if date is first day of month.

pandas.Timestamp.is_quarter_end

`Timestamp.is_quarter_end`

Return True if date is last day of the quarter.

pandas.Timestamp.is_quarter_start

`Timestamp.is_quarter_start`

Return True if date is first day of the quarter.

pandas.Timestamp.is_year_end

`Timestamp.is_year_end`

Return True if date is last day of the year.

pandas.Timestamp.is_year_start

`Timestamp.is_year_start`

Return True if date is first day of the year.

pandas.Timestamp.quarter

`Timestamp.quarter`

Return the quarter of the year.

pandas.Timestamp.resolution

`Timestamp.resolution`

Return resolution describing the smallest difference between two times that can be represented by Timestamp object `_state`

pandas.Timestamp.tz

`Timestamp.tz`
Alias for `tzinfo`

pandas.Timestamp.week

`Timestamp.week`
Return the week number of the year.

pandas.Timestamp.weekday_name

`Timestamp.weekday_name`
Deprecated since version 0.23.0: Use `Timestamp.day_name()` instead

pandas.Timestamp.weekofyear

`Timestamp.weekofyear`
Return the week number of the year.

year	

Methods

<code>astimezone(self, tz)</code>	Convert tz-aware Timestamp to another time zone.
<code>ceil(self, freq[, ambiguous, nonexistent])</code>	return a new Timestamp ceiled to this resolution
<code>combine(date, time)</code>	date, time -> datetime with same date and time fields
<code>ctime()</code>	Return <code>ctime()</code> style string.
<code>date()</code>	Return date object with same year, month and day.
<code>day_name(self[, locale])</code>	Return the day name of the Timestamp with specified locale.
<code>dst()</code>	Return <code>self.tzinfo.dst(self)</code> .

Continued on next page

Table 80 – continued from previous page

<i>floor</i> (self, freq[, ambiguous, nonexistent])	return a new Timestamp floored to this resolution
<i>fromisoformat</i> ()	string -> datetime from datetime.isoformat() output
<i>fromordinal</i> (ordinal[, freq, tz])	passed an ordinal, translate and convert to a ts note: by definition there cannot be any tz info on the ordinal itself
<i>fromtimestamp</i> (ts)	timestamp[, tz] -> tz's local time from POSIX timestamp.
<i>isocalendar</i> ()	Return a 3-tuple containing ISO year, week number, and weekday.
<i>isoweekday</i> ()	Return the day of the week represented by the date.
<i>month_name</i> (self[, locale])	Return the month name of the Timestamp with specified locale.
<i>normalize</i> (self)	Normalize Timestamp to midnight, preserving tz information.
<i>now</i> ([tz])	Return new Timestamp object representing current time local to tz.
<i>replace</i> (self[, year, month, day, hour, ...])	implements datetime.replace, handles nanoseconds
<i>round</i> (self, freq[, ambiguous, nonexistent])	Round the Timestamp to the specified resolution
<i>strftime</i> ()	format -> strftime() style string.
<i>strptime</i> (string, format)	Function is not implemented.
<i>time</i> ()	Return time object with same time but with tzinfo=None.
<i>timestamp</i> ()	Return POSIX timestamp as float.
<i>timetuple</i> ()	Return time tuple, compatible with time.localtime().
<i>timetz</i> ()	Return time object with same time and tzinfo.
<i>to_datetime64</i> ()	Return a numpy.datetime64 object with 'ns' precision.
<i>to_julian_date</i> (self)	Convert TimeStamp to a Julian Date.
<i>to_numpy</i> ()	Convert the Timestamp to a NumPy datetime64.
<i>to_period</i> (self[, freq])	Return an period of which this timestamp is an observation.
<i>to_pydatetime</i> ()	Convert a Timestamp object to a native Python datetime object.
<i>today</i> (cls[, tz])	Return the current time in the local timezone.
<i>toordinal</i> ()	Return proleptic Gregorian ordinal.
<i>tz_convert</i> (self, tz)	Convert tz-aware Timestamp to another time zone.
<i>tz_localize</i> (self, tz[, ambiguous, ...])	Convert naive Timestamp to local time zone, or remove timezone from tz-aware Timestamp.
<i>tzname</i> ()	Return self.tzinfo.tzname(self).
<i>utcfromtimestamp</i> (ts)	Construct a naive UTC datetime from a POSIX timestamp.
<i>utcnow</i> ()	Return a new Timestamp representing UTC day and time.
<i>utcoffset</i> ()	Return self.tzinfo.utcoffset(self).

Continued on next page

Table 80 – continued from previous page

<code>utctimetuple()</code>	Return UTC time tuple, compatible with <code>time.localtime()</code> .
<code>weekday()</code>	Return the day of the week represented by the date.

pandas.Timestamp.astimezone`Timestamp.astimezone(self, tz)`

Convert tz-aware Timestamp to another time zone.

Parameters

tz [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time which Timestamp will be converted to. None will remove timezone holding UTC time.

Returns

converted [Timestamp]

Raises

TypeError If Timestamp is tz-naive.

pandas.Timestamp.ceil`Timestamp.ceil(self, freq, ambiguous='raise', nonexistent='raise')`

return a new Timestamp ceiled to this resolution

Parameters

freq [a freq string indicating the ceiling resolution]

ambiguous [bool, 'NaT', default 'raise']

- bool contains flags to determine if time is dst or not (note that this flag is only applicable for ambiguous fall dst dates)
- 'NaT' will return NaT for an ambiguous time
- 'raise' will raise an AmbiguousTimeError for an ambiguous time

New in version 0.24.0.

nonexistent ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise']
A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift_forward' will shift the nonexistent time forward to the closest existing time
- 'shift_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise a NonExistentTimeError if there are nonexistent times

New in version 0.24.0.

Raises

ValueError if the freq cannot be converted

pandas.Timestamp.combine

`Timestamp.combine(date, time)`
 date, time -> datetime with same date and time fields

pandas.Timestamp.ctime

`Timestamp.ctime()`
 Return ctime() style string.

pandas.Timestamp.date

`Timestamp.date()`
 Return date object with same year, month and day.

pandas.Timestamp.day_name

`Timestamp.day_name(self, locale=None)`
 Return the day name of the Timestamp with specified locale.

Parameters

locale [string, default None (English locale)] locale determining the language in which to return the day name

Returns

day_name [string]
 New in version 0.23.0: ..

pandas.Timestamp.dst

`Timestamp.dst()`
 Return self.tzinfo.dst(self).

pandas.Timestamp.floor

`Timestamp.floor(self, freq, ambiguous='raise', nonexistent='raise')`
 return a new Timestamp floored to this resolution

Parameters

freq [a freq string indicating the flooring resolution]

ambiguous [bool, 'NaT', default 'raise']

- bool contains flags to determine if time is dst or not (note that this flag is only applicable for ambiguous fall dst dates)
- 'NaT' will return NaT for an ambiguous time

- ‘raise’ will raise an `AmbiguousTimeError` for an ambiguous time

New in version 0.24.0.

nonexistent [‘shift_forward’, ‘shift_backward’, ‘NaT’, `timedelta`, default ‘raise’]
A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
- ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
- ‘NaT’ will return `NaT` where there are nonexistent times
- `timedelta` objects will shift nonexistent times by the `timedelta`
- ‘raise’ will raise an `NonExistentTimeError` if there are nonexistent times

New in version 0.24.0.

Raises

ValueError if the `freq` cannot be converted

`pandas.Timestamp.fromisoformat`

`Timestamp.fromisoformat()`
string -> datetime from `datetime.isoformat()` output

`pandas.Timestamp.fromordinal`

classmethod `Timestamp.fromordinal(ordinal, freq=None, tz=None)`
passed an ordinal, translate and convert to a ts note: by definition there cannot be any tz info on the ordinal itself

Parameters

ordinal [int] date corresponding to a proleptic Gregorian ordinal

freq [str, `DateOffset`] Offset which `Timestamp` will have

tz [str, `pytz.timezone`, `dateutil.tz.tzfile` or `None`] Time zone for time which `Timestamp` will have.

`pandas.Timestamp.fromtimestamp`

classmethod `Timestamp.fromtimestamp(ts)`
`timestamp`, [tz] -> tz’s local time from POSIX timestamp.

`pandas.Timestamp.isocalendar`

`Timestamp.isocalendar()`
Return a 3-tuple containing ISO year, week number, and weekday.

pandas.Timestamp.isoweekday**Timestamp.isoweekday()**

Return the day of the week represented by the date. Monday == 1 ... Sunday == 7

pandas.Timestamp.month_name**Timestamp.month_name(self, locale=None)**

Return the month name of the Timestamp with specified locale.

Parameters**locale** [string, default None (English locale)] locale determining the language in which to return the month name**Returns****month_name** [string]

New in version 0.23.0: ..

pandas.Timestamp.normalize**Timestamp.normalize(self)**

Normalize Timestamp to midnight, preserving tz information.

pandas.Timestamp.now**classmethod Timestamp.now(tz=None)**

Return new Timestamp object representing current time local to tz.

Parameters**tz** [str or timezone object, default None] Timezone to localize to**pandas.Timestamp.replace****Timestamp.replace(self, year=None, month=None, day=None, hour=None, minute=None, second=None, microsecond=None, nanosecond=None, tzinfo=<class 'object'>, fold=0)**

implements datetime.replace, handles nanoseconds

Parameters**year** [int, optional]**month** [int, optional]**day** [int, optional]**hour** [int, optional]**minute** [int, optional]**second** [int, optional]**microsecond** [int, optional]

nanosecond [int, optional]
tzinfo [tz-convertible, optional]
fold [int, optional, default is 0]

Returns

Timestamp with fields replaced

pandas.Timestamp.round

`Timestamp.round(self, freq, ambiguous='raise', nonexistent='raise')`

Round the Timestamp to the specified resolution

Parameters

freq [a freq string indicating the rounding resolution]

ambiguous [bool, 'NaT', default 'raise']

- bool contains flags to determine if time is dst or not (note that this flag is only applicable for ambiguous fall dst dates)
- 'NaT' will return NaT for an ambiguous time
- 'raise' will raise an AmbiguousTimeError for an ambiguous time

New in version 0.24.0.

nonexistent ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise']

A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift_forward' will shift the nonexistent time forward to the closest existing time
- 'shift_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise an NonExistentTimeError if there are nonexistent times

New in version 0.24.0.

Returns

a new Timestamp rounded to the given resolution of *freq*

Raises

ValueError if the freq cannot be converted

pandas.Timestamp.strftime

`Timestamp.strftime()`

format -> strftime() style string.

pandas.Timestamp.strptime

`classmethod Timestamp.strptime(string, format)`
Function is not implemented. Use `pd.to_datetime()`.

pandas.Timestamp.time

`Timestamp.time()`
Return time object with same time but with `tzinfo=None`.

pandas.Timestamp.timestamp

`Timestamp.timestamp()`
Return POSIX timestamp as float.

pandas.Timestamp.timetuple

`Timestamp.timetuple()`
Return time tuple, compatible with `time.localtime()`.

pandas.Timestamp.timetz

`Timestamp.timetz()`
Return time object with same time and `tzinfo`.

pandas.Timestamp.to_datetime64

`Timestamp.to_datetime64()`
Return a `numpy.datetime64` object with 'ns' precision.

pandas.Timestamp.to_julian_date

`Timestamp.to_julian_date(self)`
Convert `TimeStamp` to a Julian Date. 0 Julian date is noon January 1, 4713 BC.

pandas.Timestamp.to_numpy

`Timestamp.to_numpy()`
Convert the `Timestamp` to a NumPy `datetime64`.

New in version 0.25.0.

This is an alias method for `Timestamp.to_datetime64()`. The `dtype` and `copy` parameters are available here only for compatibility. Their values will not affect the return value.

Returns

`numpy.datetime64`

See also:

`DatetimeIndex.to_numpy` Similar method for `DatetimeIndex`.

pandas.Timestamp.to_period

`Timestamp.to_period(self, freq=None)`

Return an period of which this timestamp is an observation.

pandas.Timestamp.to_pydatetime

`Timestamp.to_pydatetime()`

Convert a `Timestamp` object to a native Python datetime object.

If `warn=True`, issue a warning if nanoseconds is nonzero.

pandas.Timestamp.today

`classmethod Timestamp.today(cls, tz=None)`

Return the current time in the local timezone. This differs from `datetime.today()` in that it can be localized to a passed timezone.

Parameters

`tz` [str or timezone object, default None] Timezone to localize to

pandas.Timestamp.toordinal

`Timestamp.toordinal()`

Return proleptic Gregorian ordinal. January 1 of year 1 is day 1.

pandas.Timestamp.tz_convert

`Timestamp.tz_convert(self, tz)`

Convert tz-aware `Timestamp` to another time zone.

Parameters

`tz` [str, `pytz.timezone`, `dateutil.tz.tzfile` or None] Time zone for time which `Timestamp` will be converted to. None will remove timezone holding UTC time.

Returns

`converted` [`Timestamp`]

Raises

TypeError If `Timestamp` is tz-naive.

pandas.Timestamp.tz_localize

`Timestamp.tz_localize(self, tz, ambiguous='raise', nonexistent='raise', errors=None)`

Convert naive Timestamp to local time zone, or remove timezone from tz-aware Timestamp.

Parameters

tz [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time which Timestamp will be converted to. None will remove timezone holding local time.

ambiguous [bool, 'NaT', default 'raise'] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the *ambiguous* parameter dictates how ambiguous times should be handled.

- bool contains flags to determine if time is dst or not (note that this flag is only applicable for ambiguous fall dst dates)
- 'NaT' will return NaT for an ambiguous time
- 'raise' will raise an `AmbiguousTimeError` for an ambiguous time

nonexistent ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift_forward' will shift the nonexistent time forward to the closest existing time
- 'shift_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise an `NonExistentTimeError` if there are nonexistent times

New in version 0.24.0.

errors ['raise', 'coerce', default None]

- 'raise' will raise a `NonExistentTimeError` if a timestamp is not valid in the specified timezone (e.g. due to a transition from or to DST time). Use `nonexistent='raise'` instead.
- 'coerce' will return NaT if the timestamp can not be converted into the specified timezone. Use `nonexistent='NaT'` instead.

Deprecated since version 0.24.0.

Returns

localized [Timestamp]

Raises

TypeError If the Timestamp is tz-aware and tz is not None.

pandas.Timestamp.tzname

`Timestamp.tzname()`
Return `self.tzinfo.tzname(self)`.

pandas.Timestamp.utctimestamp

`classmethod Timestamp.utctimestamp(ts)`
Construct a naive UTC datetime from a POSIX timestamp.

pandas.Timestamp.utcnow

`classmethod Timestamp.utcnow()`
Return a new `Timestamp` representing UTC day and time.

pandas.Timestamp.utcoffset

`Timestamp.utcoffset()`
Return `self.tzinfo.utcoffset(self)`.

pandas.Timestamp.utctimetuple

`Timestamp.utctimetuple()`
Return UTC time tuple, compatible with `time.localtime()`.

pandas.Timestamp.weekday

`Timestamp.weekday()`
Return the day of the week represented by the date. Monday == 0 ... Sunday == 6

isoformat	
-----------	--

Properties

<i>Timestamp.asm8</i>	Return numpy datetime64 format in nanoseconds.
<i>Timestamp.day</i>	
<i>Timestamp.dayofweek</i>	Return day of the week.
<i>Timestamp.dayofyear</i>	Return the day of the year.
<i>Timestamp.days_in_month</i>	Return the number of days in the month.
<i>Timestamp.daysinmonth</i>	Return the number of days in the month.
<i>Timestamp.fold</i>	
<i>Timestamp.hour</i>	
<i>Timestamp.is_leap_year</i>	Return True if year is a leap year.
<i>Timestamp.is_month_end</i>	Return True if date is last day of month.
<i>Timestamp.is_month_start</i>	Return True if date is first day of month.

Continued on next page

Table 81 – continued from previous page

<i>Timestamp.is_quarter_end</i>	Return True if date is last day of the quarter.
<i>Timestamp.is_quarter_start</i>	Return True if date is first day of the quarter.
<i>Timestamp.is_year_end</i>	Return True if date is last day of the year.
<i>Timestamp.is_year_start</i>	Return True if date is first day of the year.
<i>Timestamp.max</i>	
<i>Timestamp.microsecond</i>	
<i>Timestamp.min</i>	
<i>Timestamp.minute</i>	
<i>Timestamp.month</i>	
<i>Timestamp.nanosecond</i>	
<i>Timestamp.quarter</i>	Return the quarter of the year.
<i>Timestamp.resolution</i>	Return resolution describing the smallest difference between two times that can be represented by Timestamp object_state
<i>Timestamp.second</i>	
<i>Timestamp.tz</i>	Alias for tzinfo
<i>Timestamp.tzinfo</i>	
<i>Timestamp.value</i>	
<i>Timestamp.week</i>	Return the week number of the year.
<i>Timestamp.weekofyear</i>	Return the week number of the year.
<i>Timestamp.year</i>	

pandas.Timestamp.day

Timestamp.day

pandas.Timestamp.fold

Timestamp.fold

pandas.Timestamp.hour

Timestamp.hour

pandas.Timestamp.max

Timestamp.max = Timestamp('2262-04-11 23:47:16.854775807')

pandas.Timestamp.microsecond

Timestamp.microsecond

pandas.Timestamp.min

Timestamp.min = Timestamp('1677-09-21 00:12:43.145225')

pandas.Timestamp.minute

Timestamp.minute

pandas.Timestamp.month

Timestamp.month

pandas.Timestamp.nanosecond

Timestamp.nanosecond

pandas.Timestamp.second

Timestamp.second

pandas.Timestamp.tzinfo

Timestamp.tzinfo

pandas.Timestamp.value

Timestamp.value

pandas.Timestamp.year

Timestamp.year

Methods

<i>Timestamp.astimezone</i> (self, tz)	Convert tz-aware Timestamp to another time zone.
<i>Timestamp.ceil</i> (self, freq[, ambiguous, ...])	return a new Timestamp ceiled to this resolution
<i>Timestamp.combine</i> (date, time)	date, time -> datetime with same date and time fields
<i>Timestamp.ctime</i> ()	Return ctime() style string.
<i>Timestamp.date</i> ()	Return date object with same year, month and day.
<i>Timestamp.day_name</i> (self[, locale])	Return the day name of the Timestamp with specified locale.
<i>Timestamp.dst</i> ()	Return self.tzinfo.dst(self).
<i>Timestamp.floor</i> (self, freq[, ambiguous, ...])	return a new Timestamp floored to this resolution
<i>Timestamp.freq</i>	
<i>Timestamp.freqstr</i>	Return the total number of days in the month.
<i>Timestamp.fromordinal</i> (ordinal[, freq, tz])	passed an ordinal, translate and convert to a ts note: by definition there cannot be any tz info on the ordinal itself

Continued on next page

Table 82 – continued from previous page

<i>Timestamp.fronttimestamp</i> (ts)	timestamp[, tz] -> tz's local time from POSIX timestamp.
<i>Timestamp.isocalendar</i> ()	Return a 3-tuple containing ISO year, week number, and weekday.
<i>Timestamp.isoformat</i> (self[, sep])	
<i>Timestamp.isoweekday</i> ()	Return the day of the week represented by the date.
<i>Timestamp.month_name</i> (self[, locale])	Return the month name of the Timestamp with specified locale.
<i>Timestamp.normalize</i> (self)	Normalize Timestamp to midnight, preserving tz information.
<i>Timestamp.now</i> ([tz])	Return new Timestamp object representing current time local to tz.
<i>Timestamp.replace</i> (self[, year, month, day, ...])	implements datetime.replace, handles nanoseconds
<i>Timestamp.round</i> (self, freq[, ambiguous, ...])	Round the Timestamp to the specified resolution
<i>Timestamp.strftime</i> ()	format -> strftime() style string.
<i>Timestamp.strptime</i> (string, format)	Function is not implemented.
<i>Timestamp.time</i> ()	Return time object with same time but with tzinfo=None.
<i>Timestamp.timestamp</i> ()	Return POSIX timestamp as float.
<i>Timestamp.timetuple</i> ()	Return time tuple, compatible with time.localtime().
<i>Timestamp.timetz</i> ()	Return time object with same time and tzinfo.
<i>Timestamp.to_datetime64</i> ()	Return a numpy.datetime64 object with 'ns' precision.
<i>Timestamp.to_numpy</i> ()	Convert the Timestamp to a NumPy datetime64.
<i>Timestamp.to_julian_date</i> (self)	Convert TimeStamp to a Julian Date.
<i>Timestamp.to_period</i> (self[, freq])	Return an period of which this timestamp is an observation.
<i>Timestamp.to_pydatetime</i> ()	Convert a Timestamp object to a native Python datetime object.
<i>Timestamp.today</i> (cls[, tz])	Return the current time in the local timezone.
<i>Timestamp.toordinal</i> ()	Return proleptic Gregorian ordinal.
<i>Timestamp.tz_convert</i> (self, tz)	Convert tz-aware Timestamp to another time zone.
<i>Timestamp.tz_localize</i> (self, tz[, ambiguous, ...])	Convert naive Timestamp to local time zone, or remove timezone from tz-aware Timestamp.
<i>Timestamp.tzname</i> ()	Return self.tzinfo.tzname(self).
<i>Timestamp.utcfrofromtimestamp</i> (ts)	Construct a naive UTC datetime from a POSIX timestamp.
<i>Timestamp.utcnow</i> ()	Return a new Timestamp representing UTC day and time.
<i>Timestamp.utcoffset</i> ()	Return self.tzinfo.utcoffset(self).
<i>Timestamp.utctimetuple</i> ()	Return UTC time tuple, compatible with time.localtime().
<i>Timestamp.weekday</i> ()	Return the day of the week represented by the date.

pandas.Timestamp.freq

Timestamp.freq

pandas.Timestamp.isoformat

`Timestamp.isoformat(self, sep='T')`

A collection of timestamps may be stored in a `arrays.DatetimeArray`. For timezone-aware data, the `.dtype` of a `DatetimeArray` is a `DatetimeTZDtype`. For timezone-naive data, `np.dtype("datetime64[ns]")` is used.

If the data are tz-aware, then every value in the array must have the same timezone.

`arrays.DatetimeArray(values[, dtype, freq, copy])` Pandas ExtensionArray for tz-naive or tz-aware datetime data.

pandas.arrays.DatetimeArray

`class pandas.arrays.DatetimeArray(values, dtype=dtype('<M8[ns]'), freq=None, copy=False)`
 Pandas ExtensionArray for tz-naive or tz-aware datetime data.

New in version 0.24.0.

Warning: `DatetimeArray` is currently experimental, and its API may change without warning. In particular, `DatetimeArray.dtype` is expected to change to always be an instance of an `ExtensionDtype` subclass.

Parameters

values [Series, Index, `DatetimeArray`, ndarray] The datetime data.

For `DatetimeArray values` (or a Series or Index boxing one), `dtype` and `freq` will be extracted from `values`, with precedence given to

dtype [numpy.dtype or `DatetimeTZDtype`] Note that the only NumPy dtype allowed is `'datetime64[ns]'`.

freq [str or Offset, optional]

copy [bool, default False] Whether to copy the underlying array of values.

Attributes

None	
------	--

Methods

None	
------	--

`DatetimeTZDtype([unit, tz])`

An `ExtensionDtype` for timezone-aware datetime data.

pandas.DatetimeTZDtype

`class pandas.DatetimeTZDtype(unit='ns', tz=None)`

An ExtensionDtype for timezone-aware datetime data.

This is not an actual numpy dtype, but a duck type.

Parameters

unit [str, default “ns”] The precision of the datetime data. Currently limited to “ns”.

tz [str, int, or datetime.tzinfo] The timezone.

Raises

pytz.UnknownTimeZoneError When the requested timezone cannot be found.

Examples

```
>>> pd.DatetimeTZDtype(tz='UTC')
datetime64[ns, UTC]
```

```
>>> pd.DatetimeTZDtype(tz='dateutil/US/Central')
datetime64[ns, tzfile('/usr/share/zoneinfo/US/Central')]
```

Attributes

<i>unit</i>	The precision of the datetime data.
<i>tz</i>	The timezone.

pandas.DatetimeTZDtype.unit

`DatetimeTZDtype.unit`
The precision of the datetime data.

pandas.DatetimeTZDtype.tz

`DatetimeTZDtype.tz`
The timezone.

Methods

None

6.5.3 Timedelta data

NumPy can natively represent timedeltas. Pandas provides *Timedelta* for symmetry with *Timestamp*.

Timedelta

Represents a duration, the difference between two dates or times.

pandas.Timedelta**class pandas.Timedelta**

Represents a duration, the difference between two dates or times.

Timedelta is the pandas equivalent of python's `datetime.timedelta` and is interchangeable with it in most cases.**Parameters****value** [Timedelta, timedelta, np.timedelta64, string, or integer]**unit** [str, optional] Denote the unit of the input, if input is an integer. Default 'ns'. Possible values: {'Y', 'M', 'W', 'D', 'days', 'day', 'hours', 'hour', 'hr', 'h', 'm', 'minute', 'min', 'minutes', 'T', 'S', 'seconds', 'sec', 'second', 'ms', 'milliseconds', 'millisecond', 'milli', 'millis', 'L', 'us', 'microseconds', 'microsecond', 'micro', 'micros', 'U', 'ns', 'nanoseconds', 'nano', 'nanos', 'nanosecond', 'N'}****kwargs** Available kwargs: {days, seconds, microseconds, milliseconds, minutes, hours, weeks}. Values for construction in compat with `datetime.timedelta`. Numpy ints and floats will be coerced to python ints and floats.**Notes**The `.value` attribute is always in ns.**Attributes**

<i>asm8</i>	Return a numpy timedelta64 array scalar view.
<i>components</i>	Return a components namedtuple-like.
<i>days</i>	Number of days.
<i>delta</i>	Return the timedelta in nanoseconds (ns), for internal compatibility.
<i>microseconds</i>	Number of microseconds (≥ 0 and less than 1 second).
<i>nanoseconds</i>	Return the number of nanoseconds (n), where $0 \leq n < 1$ microsecond.
<i>resolution</i>	Return a string representing the lowest timedelta resolution.
<i>resolution_string</i>	Return a string representing the lowest timedelta resolution.
<i>seconds</i>	Number of seconds (≥ 0 and less than 1 day).

pandas.Timedelta.asm8**Timedelta.asm8**

Return a numpy timedelta64 array scalar view.

Provides access to the array scalar view (i.e. a combination of the value and the units) associated

with the `numpy.timedelta64().view()`, including a 64-bit integer representation of the timedelta in nanoseconds (Python int compatible).

Returns

numpy timedelta64 array scalar view Array scalar view of the timedelta in nanoseconds.

Examples

```
>>> td = pd.Timedelta('1 days 2 min 3 us 42 ns')
>>> td.asm8
numpy.timedelta64(86520000003042, 'ns')
```

```
>>> td = pd.Timedelta('2 min 3 s')
>>> td.asm8
numpy.timedelta64(123000000000, 'ns')
```

```
>>> td = pd.Timedelta('3 ms 5 us')
>>> td.asm8
numpy.timedelta64(3005000, 'ns')
```

```
>>> td = pd.Timedelta(42, unit='ns')
>>> td.asm8
numpy.timedelta64(42, 'ns')
```

pandas.Timedelta.components

Timedelta.components

Return a components namedtuple-like.

pandas.Timedelta.days

Timedelta.days

Number of days.

pandas.Timedelta.delta

Timedelta.delta

Return the timedelta in nanoseconds (ns), for internal compatibility.

Returns

int Timedelta in nanoseconds.

Examples

```
>>> td = pd.Timedelta('1 days 42 ns')
>>> td.delta
86400000000042
```

```
>>> td = pd.Timedelta('3 s')
>>> td.delta
3000000000
```

```
>>> td = pd.Timedelta('3 ms 5 us')
>>> td.delta
3005000
```

```
>>> td = pd.Timedelta(42, unit='ns')
>>> td.delta
42
```

pandas.Timedelta.microseconds

Timedelta.microseconds

Number of microseconds (≥ 0 and less than 1 second).

pandas.Timedelta.nanoseconds

Timedelta.nanoseconds

Return the number of nanoseconds (n), where $0 \leq n < 1$ microsecond.

Returns

int Number of nanoseconds.

See also:

Timedelta.components Return all attributes with assigned values (i.e. days, hours, minutes, seconds, milliseconds, microseconds, nanoseconds).

Examples

Using string input

```
>>> td = pd.Timedelta('1 days 2 min 3 us 42 ns')
>>> td.nanoseconds
42
```

Using integer input

```
>>> td = pd.Timedelta(42, unit='ns')
>>> td.nanoseconds
42
```

pandas.Timedelta.resolution**Timedelta.resolution**

Return a string representing the lowest timedelta resolution.

Each timedelta has a defined resolution that represents the lowest OR most granular level of precision. Each level of resolution is represented by a short string as defined below:

Resolution: Return value

- Days: 'D'
- Hours: 'H'
- Minutes: 'T'
- Seconds: 'S'
- Milliseconds: 'L'
- Microseconds: 'U'
- Nanoseconds: 'N'

Returns

str Timedelta resolution.

Examples

```
>>> td = pd.Timedelta('1 days 2 min 3 us 42 ns')
>>> td.resolution
'N'
```

```
>>> td = pd.Timedelta('1 days 2 min 3 us')
>>> td.resolution
'U'
```

```
>>> td = pd.Timedelta('2 min 3 s')
>>> td.resolution
'S'
```

```
>>> td = pd.Timedelta(36, unit='us')
>>> td.resolution
'U'
```

pandas.Timedelta.resolution_string**Timedelta.resolution_string**

Return a string representing the lowest timedelta resolution.

Each timedelta has a defined resolution that represents the lowest OR most granular level of precision. Each level of resolution is represented by a short string as defined below:

Resolution: Return value

- Days: 'D'

- Hours: 'H'
- Minutes: 'T'
- Seconds: 'S'
- Milliseconds: 'L'
- Microseconds: 'U'
- Nanoseconds: 'N'

Returns

str Timedelta resolution.

Examples

```
>>> td = pd.Timedelta('1 days 2 min 3 us 42 ns')
>>> td.resolution
'N'
```

```
>>> td = pd.Timedelta('1 days 2 min 3 us')
>>> td.resolution
'U'
```

```
>>> td = pd.Timedelta('2 min 3 s')
>>> td.resolution
'S'
```

```
>>> td = pd.Timedelta(36, unit='us')
>>> td.resolution
'U'
```

pandas.Timedelta.seconds

Timedelta.seconds

Number of seconds (≥ 0 and less than 1 day).

freq	
is_populated	
value	

Methods

<i>ceil</i> (self, freq)	return a new Timedelta ceiled to this resolution
<i>floor</i> (self, freq)	return a new Timedelta floored to this resolution
<i>isoformat</i> ()	Format Timedelta as ISO 8601 Duration like P[n]Y[n]M[n]DT[n]H[n]M[n]S, where the [n] s are replaced by the values.

Continued on next page

Table 88 – continued from previous page

<code>round(self, freq)</code>	Round the Timedelta to the specified resolution
<code>to_numpy()</code>	Convert the Timestamp to a NumPy timedelta64.
<code>to_pytimedelta()</code>	Convert a pandas Timedelta object into a python timedelta object.
<code>to_timedelta64()</code>	Return a numpy.timedelta64 object with 'ns' precision.
<code>total_seconds()</code>	Total duration of timedelta in seconds (to ns precision).
<code>view()</code>	Array view compatibility.

pandas.Timedelta.ceil`Timedelta.ceil(self, freq)`

return a new Timedelta ceiled to this resolution

Parameters**freq** [a freq string indicating the ceiling resolution]**pandas.Timedelta.floor**`Timedelta.floor(self, freq)`

return a new Timedelta floored to this resolution

Parameters**freq** [a freq string indicating the flooring resolution]**pandas.Timedelta.isoformat**`Timedelta.isoformat()`Format Timedelta as ISO 8601 Duration like P[n]Y[n]M[n]DT[n]H[n]M[n]S, where the [n] s are replaced by the values. See https://en.wikipedia.org/wiki/ISO_8601#Durations

New in version 0.20.0.

Returns**formatted** [str]**See also:**`Timestamp.isoformat`**Notes**

The longest component is days, whose value may be larger than 365. Every component is always included, even if its value is 0. Pandas uses nanosecond precision, so up to 9 decimal places may be included in the seconds component. Trailing 0's are removed from the seconds component after the decimal. We do not 0 pad components, so it's ...*T5H...*, not ...*T05H...*

Examples

```
>>> td = pd.Timedelta(days=6, minutes=50, seconds=3,
...                   milliseconds=10, microseconds=10, nanoseconds=12)
>>> td.isoformat()
'P6DTH50M3.010010012S'
>>> pd.Timedelta(hours=1, seconds=10).isoformat()
'PODTHOM10S'
>>> pd.Timedelta(hours=1, seconds=10).isoformat()
'PODTHOM10S'
>>> pd.Timedelta(days=500.5).isoformat()
'P500DT12HOMS'
```

pandas.Timedelta.round

`Timedelta.round(self, freq)`

Round the Timedelta to the specified resolution

Parameters

`freq` [a freq string indicating the rounding resolution]

Returns

a new `Timedelta` rounded to the given resolution of `freq`

Raises

`ValueError` if the `freq` cannot be converted

pandas.Timedelta.to_numpy

`Timedelta.to_numpy()`

Convert the Timestamp to a NumPy timedelta64.

New in version 0.25.0.

This is an alias method for `Timedelta.to_timedelta64()`. The `dtype` and `copy` parameters are available here only for compatibility. Their values will not affect the return value.

Returns

`numpy.timedelta64`

See also:

`Series.to_numpy` Similar method for Series.

pandas.Timedelta.to_pytimedelta

`Timedelta.to_pytimedelta()`

Convert a pandas Timedelta object into a python timedelta object.

Timedelta objects are internally saved as `numpy.datetime64[ns]` dtype. Use `to_pytimedelta()` to convert to object dtype.

Returns

`datetime.timedelta` or `numpy.array` of `datetime.timedelta`

See also:

`to_timedelta` Convert argument to Timedelta type.

Notes

Any nanosecond resolution will be lost.

`pandas.Timedelta.to_timedelta64`

`Timedelta.to_timedelta64()`

Return a `numpy.timedelta64` object with ‘ns’ precision.

`pandas.Timedelta.total_seconds`

`Timedelta.total_seconds()`

Total duration of timedelta in seconds (to ns precision).

`pandas.Timedelta.view`

`Timedelta.view()`

Array view compatibility.

Properties

<code>Timedelta.asm8</code>	Return a numpy timedelta64 array scalar view.
<code>Timedelta.components</code>	Return a components namedtuple-like.
<code>Timedelta.days</code>	Number of days.
<code>Timedelta.delta</code>	Return the timedelta in nanoseconds (ns), for internal compatibility.
<code>Timedelta.freq</code>	
<code>Timedelta.is_populated</code>	
<code>Timedelta.max</code>	
<code>Timedelta.microseconds</code>	Number of microseconds (≥ 0 and less than 1 second).
<code>Timedelta.min</code>	
<code>Timedelta.nanoseconds</code>	Return the number of nanoseconds (n), where $0 \leq n < 1$ microsecond.
<code>Timedelta.resolution</code>	Return a string representing the lowest timedelta resolution.
<code>Timedelta.seconds</code>	Number of seconds (≥ 0 and less than 1 day).
<code>Timedelta.value</code>	
<code>Timedelta.view()</code>	Array view compatibility.

pandas.Timedelta.freq`Timedelta.freq`**pandas.Timedelta.is_populated**`Timedelta.is_populated`**pandas.Timedelta.max**`Timedelta.max = Timedelta('106751 days 23:47:16.854775')`**pandas.Timedelta.min**`Timedelta.min = Timedelta('-106752 days +00:12:43.145224')`**pandas.Timedelta.value**`Timedelta.value`**Methods**

<code><i>Timedelta.ceil</i>(self, freq)</code>	return a new Timedelta ceiled to this resolution
<code><i>Timedelta.floor</i>(self, freq)</code>	return a new Timedelta floored to this resolution
<code><i>Timedelta.isoformat</i>()</code>	Format Timedelta as ISO 8601 Duration like P[n]Y[n]M[n]DT[n]H[n]M[n]S, where the [n] s are replaced by the values.
<code><i>Timedelta.round</i>(self, freq)</code>	Round the Timedelta to the specified resolution
<code><i>Timedelta.to_pytimedelta</i>()</code>	Convert a pandas Timedelta object into a python timedelta object.
<code><i>Timedelta.to_timedelta64</i>()</code>	Return a numpy.timedelta64 object with 'ns' precision.
<code><i>Timedelta.to_numpy</i>()</code>	Convert the Timestamp to a NumPy timedelta64.
<code><i>Timedelta.total_seconds</i>()</code>	Total duration of timedelta in seconds (to ns precision).

A collection of timedeltas may be stored in a `TimedeltaArray`.

<code><i>arrays.TimedeltaArray</i>(values[, dtype, freq, ...])</code>	Pandas ExtensionArray for timedelta data.
---	---

pandas.arrays.TimedeltaArray

```
class pandas.arrays.TimedeltaArray(values, dtype=dtype('<m8[ns]'), freq=None, copy=False)
    Pandas ExtensionArray for timedelta data.
```

New in version 0.24.0.

Warning: TimedeltaArray is currently experimental, and its API may change without warning. In particular, `TimedeltaArray.dtype` is expected to change to be an instance of an `ExtensionDtype` subclass.

Parameters

- values** [array-like] The timedelta data.
- dtype** [numpy.dtype] Currently, only `numpy.dtype("timedelta64[ns]")` is accepted.
- freq** [Offset, optional]
- copy** [bool, default False] Whether to copy the underlying array of data.

Attributes

None

Methods

None

6.5.4 Timespan data

Pandas represents spans of times as *Period* objects.

6.5.5 Period

<i>Period</i>	Represents a period of time
---------------	-----------------------------

pandas.Period

`class pandas.Period`
Represents a period of time

Parameters

- value** [Period or str, default None] The time period represented (e.g., '4Q2005')
- freq** [str, default None] One of pandas period strings or corresponding objects
- year** [int, default None]
- month** [int, default 1]
- quarter** [int, default None]
- day** [int, default 1]
- hour** [int, default 0]
- minute** [int, default 0]

`second` [int, default 0]

Attributes

<i>day</i>	Get day of the month that a Period falls on.
<i>dayofweek</i>	Day of the week the period lies in, with Monday=0 and Sunday=6.
<i>dayofyear</i>	Return the day of the year.
<i>days_in_month</i>	Get the total number of days in the month that this period falls on.
<i>daysinmonth</i>	Get the total number of days of the month that the Period falls in.
<i>hour</i>	Get the hour of the day component of the Period.
<i>minute</i>	Get minute of the hour component of the Period.
<i>qyear</i>	Fiscal year the Period lies in according to its starting-quarter.
<i>second</i>	Get the second component of the Period.
<i>start_time</i>	Get the Timestamp for the start of the period.
<i>week</i>	Get the week of the year on the given Period.
<i>weekday</i>	Day of the week the period lies in, with Monday=0 and Sunday=6.

pandas.Period.day

Period.day

Get day of the month that a Period falls on.

Returns

int

See also:

Period.dayofweek Get the day of the week.

Period.dayofyear Get the day of the year.

Examples

```
>>> p = pd.Period("2018-03-11", freq='H')
>>> p.day
11
```

pandas.Period.dayofweek

Period.dayofweek

Day of the week the period lies in, with Monday=0 and Sunday=6.

If the period frequency is lower than daily (e.g. hourly), and the period spans over multiple days, the day at the start of the period is used.

If the frequency is higher than daily (e.g. monthly), the last day of the period is used.

Returns

int Day of the week.

See also:

Period.dayofweek Day of the week the period lies in.

Period.weekday Alias of *Period.dayofweek*.

Period.day Day of the month.

Period.dayofyear Day of the year.

Examples

```
>>> per = pd.Period('2017-12-31 22:00', 'H')
>>> per.dayofweek
6
```

For periods that span over multiple days, the day at the beginning of the period is returned.

```
>>> per = pd.Period('2017-12-31 22:00', '4H')
>>> per.dayofweek
6
>>> per.start_time.dayofweek
6
```

For periods with a frequency higher than days, the last day of the period is returned.

```
>>> per = pd.Period('2018-01', 'M')
>>> per.dayofweek
2
>>> per.end_time.dayofweek
2
```

pandas.Period.dayofyear

Period.dayofyear

Return the day of the year.

This attribute returns the day of the year on which the particular date occurs. The return value ranges between 1 to 365 for regular years and 1 to 366 for leap years.

Returns

int The day of year.

See also:

Period.day Return the day of the month.

Period.dayofweek Return the day of week.

PeriodIndex.dayofyear Return the day of year of all indexes.

Examples

```
>>> period = pd.Period("2015-10-23", freq='H')
>>> period.dayofyear
296
>>> period = pd.Period("2012-12-31", freq='D')
>>> period.dayofyear
366
>>> period = pd.Period("2013-01-01", freq='D')
>>> period.dayofyear
1
```

pandas.Period.days_in_month

Period.days_in_month

Get the total number of days in the month that this period falls on.

Returns

int

See also:

Period.daysinmonth Gets the number of days in the month.

DatetimeIndex.daysinmonth Gets the number of days in the month.

calendar.monthrange Returns a tuple containing weekday (0-6 ~ Mon-Sun) and number of days (28-31).

Examples

```
>>> p = pd.Period('2018-2-17')
>>> p.days_in_month
28
```

```
>>> pd.Period('2018-03-01').days_in_month
31
```

Handles the leap year case as well:

```
>>> p = pd.Period('2016-2-17')
>>> p.days_in_month
29
```

pandas.Period.daysinmonth

Period.daysinmonth

Get the total number of days of the month that the Period falls in.

Returns

int

See also:

Period.days_in_month Return the days of the month.

Period.dayofyear Return the day of the year.

Examples

```
>>> p = pd.Period("2018-03-11", freq='H')
>>> p.daysinmonth
31
```

pandas.Period.hour

Period.hour

Get the hour of the day component of the Period.

Returns

int The hour as an integer, between 0 and 23.

See also:

Period.second Get the second component of the Period.

Period.minute Get the minute component of the Period.

Examples

```
>>> p = pd.Period("2018-03-11 13:03:12.050000")
>>> p.hour
13
```

Period longer than a day

```
>>> p = pd.Period("2018-03-11", freq="M")
>>> p.hour
0
```

pandas.Period.minute

Period.minute

Get minute of the hour component of the Period.

Returns

int The minute as an integer, between 0 and 59.

See also:

Period.hour Get the hour component of the Period.

Period.second Get the second component of the Period.

Examples

```
>>> p = pd.Period("2018-03-11 13:03:12.050000")
>>> p.minute
3
```

pandas.Period.qyear

Period.qyear

Fiscal year the Period lies in according to its starting-quarter.

The *year* and the *qyear* of the period will be the same if the fiscal and calendar years are the same. When they are not, the fiscal year can be different from the calendar year of the period.

Returns

int The fiscal year of the period.

See also:

Period.year Return the calendar year of the period.

Examples

If the natural and fiscal year are the same, *qyear* and *year* will be the same.

```
>>> per = pd.Period('2018Q1', freq='Q')
>>> per.qyear
2018
>>> per.year
2018
```

If the fiscal year starts in April (*Q-MAR*), the first quarter of 2018 will start in April 2017. *year* will then be 2018, but *qyear* will be the fiscal year, 2018.

```
>>> per = pd.Period('2018Q1', freq='Q-MAR')
>>> per.start_time
Timestamp('2017-04-01 00:00:00')
>>> per.qyear
2018
>>> per.year
2017
```

pandas.Period.second

Period.second

Get the second component of the Period.

Returns

int The second of the Period (ranges from 0 to 59).

See also:

Period.hour Get the hour component of the Period.

Period.minute Get the minute component of the Period.

Examples

```
>>> p = pd.Period("2018-03-11 13:03:12.050000")
>>> p.second
12
```

pandas.Period.start_time

Period.start_time

Get the Timestamp for the start of the period.

Returns

Timestamp

See also:

Period.end_time Return the end Timestamp.

Period.dayofyear Return the day of year.

Period.daysinmonth Return the days in that month.

Period.dayofweek Return the day of the week.

Examples

```
>>> period = pd.Period('2012-1-1', freq='D')
>>> period
Period('2012-01-01', 'D')
```

```
>>> period.start_time
Timestamp('2012-01-01 00:00:00')
```

```
>>> period.end_time
Timestamp('2012-01-01 23:59:59.999999999')
```

pandas.Period.week

Period.week

Get the week of the year on the given Period.

Returns

int

See also:

Period.dayofweek Get the day component of the Period.

Period.weekday Get the day component of the Period.

Examples

```
>>> p = pd.Period("2018-03-11", "H")
>>> p.week
10
```

```
>>> p = pd.Period("2018-02-01", "D")
>>> p.week
5
```

```
>>> p = pd.Period("2018-01-06", "D")
>>> p.week
1
```

pandas.Period.weekday

Period.weekday

Day of the week the period lies in, with Monday=0 and Sunday=6.

If the period frequency is lower than daily (e.g. hourly), and the period spans over multiple days, the day at the start of the period is used.

If the frequency is higher than daily (e.g. monthly), the last day of the period is used.

Returns

int Day of the week.

See also:

Period.dayofweek Day of the week the period lies in.

Period.weekday Alias of *Period.dayofweek*.

Period.day Day of the month.

Period.dayofyear Day of the year.

Examples

```
>>> per = pd.Period('2017-12-31 22:00', 'H')
>>> per.dayofweek
6
```

For periods that span over multiple days, the day at the beginning of the period is returned.

```
>>> per = pd.Period('2017-12-31 22:00', '4H')
>>> per.dayofweek
6
>>> per.start_time.dayofweek
6
```

For periods with a frequency higher than days, the last day of the period is returned.

```
>>> per = pd.Period('2018-01', 'M')
>>> per.dayofweek
2
>>> per.end_time.dayofweek
2
```

end_time	
freq	
freqstr	
is_leap_year	
month	
ordinal	
quarter	
weekofyear	
year	

Methods

<i>asfreq()</i>	Convert Period to desired frequency, either at the start or end of the interval
<i>strftime()</i>	Returns the string representation of the <i>Period</i> , depending on the selected <i>fmt</i> .
<i>to_timestamp()</i>	Return the Timestamp representation of the Period at the target frequency at the specified end (how) of the Period

pandas.Period.asfreq

Period.asfreq()

Convert Period to desired frequency, either at the start or end of the interval

Parameters

freq [string]

how [{'E', 'S', 'end', 'start'}, default 'end'] Start or end of the timespan

Returns

resampled [Period]

pandas.Period.strftime

Period.strftime()

Returns the string representation of the *Period*, depending on the selected *fmt*. *fmt* must be a string containing one or several directives. The method recognizes the same directives as the `time.strftime()` function of the standard Python distribution, as well as the specific additional directives `%f`, `%F`, `%q`. (formatting & docs originally from `scikits.timeries`)

Directive	Meaning	Notes
%a	Locale's abbreviated weekday name.	
%A	Locale's full weekday name.	
%b	Locale's abbreviated month name.	
%B	Locale's full month name.	
%c	Locale's appropriate date and time representation.	
%d	Day of the month as a decimal number [01,31].	
%f	'Fiscal' year without a century as a decimal number [00,99]	(1)
%F	'Fiscal' year with a century as a decimal number	(2)
%H	Hour (24-hour clock) as a decimal number [00,23].	
%I	Hour (12-hour clock) as a decimal number [01,12].	
%j	Day of the year as a decimal number [001,366].	
%m	Month as a decimal number [01,12].	
%M	Minute as a decimal number [00,59].	
%p	Locale's equivalent of either AM or PM.	(3)
%q	Quarter as a decimal number [01,04]	
%S	Second as a decimal number [00,61].	(4)
%U	Week number of the year (Sunday as the first day of the week) as a decimal number [00,53]. All days in a new year preceding the first Sunday are considered to be in week 0.	(5)
%w	Weekday as a decimal number [0(Sunday),6].	
%W	Week number of the year (Monday as the first day of the week) as a decimal number [00,53]. All days in a new year preceding the first Monday are considered to be in week 0.	(5)
%x	Locale's appropriate date representation.	
%X	Locale's appropriate time representation.	
%y	Year without century as a decimal number [00,99].	
%Y	Year with century as a decimal number.	
%Z	Time zone name (no characters if no time zone exists).	
%%	A literal '%' character.	

Notes

- (1) The %f directive is the same as %y if the frequency is not quarterly. Otherwise, it corresponds to the 'fiscal' year, as defined by the *qyear* attribute.
- (2) The %F directive is the same as %Y if the frequency is not quarterly. Otherwise, it corresponds to the 'fiscal' year, as defined by the *qyear* attribute.
- (3) The %p directive only affects the output hour field if the %I directive is used to parse the hour.
- (4) The range really is 0 to 61; this accounts for leap seconds and the (very rare) double leap seconds.
- (5) The %U and %W directives are only used in calculations when the day of the week and the year are specified.

Examples

```

>>> a = Period(freq='Q-JUL', year=2006, quarter=1)
>>> a.strftime('%F-Q%q')
'2006-Q1'
>>> # Output the last month in the quarter of this date
>>> a.strftime('%b-%Y')
'Oct-2005'
>>>
>>> a = Period(freq='D', year=2001, month=1, day=1)
>>> a.strftime('%d-%b-%Y')
'01-Jan-2006'
>>> a.strftime('%b. %d, %Y was a %A')
'Jan. 01, 2001 was a Monday'

```

pandas.Period.to_timestamp

Period.to_timestamp()

Return the Timestamp representation of the Period at the target frequency at the specified end (how) of the Period

Parameters

freq [string or DateOffset] Target frequency. Default is 'D' if self.freq is week or longer and 'S' otherwise

how [str, default 'S' (start)] 'S', 'E'. Can be aliased as case insensitive 'Start', 'Finish', 'Begin', 'End'

Returns

Timestamp

now	
-----	--

Properties

<i>Period.day</i>	Get day of the month that a Period falls on.
<i>Period.dayofweek</i>	Day of the week the period lies in, with Monday=0 and Sunday=6.
<i>Period.dayofyear</i>	Return the day of the year.
<i>Period.days_in_month</i>	Get the total number of days in the month that this period falls on.
<i>Period.daysinmonth</i>	Get the total number of days of the month that the Period falls in.
<i>Period.end_time</i>	
<i>Period.freq</i>	
<i>Period.freqstr</i>	
<i>Period.hour</i>	Get the hour of the day component of the Period.
<i>Period.is_leap_year</i>	
<i>Period.minute</i>	Get minute of the hour component of the Period.

Methods

<code>Period.asfreq()</code>	Convert Period to desired frequency, either at the start or end of the interval
<code>Period.now()</code>	
<code>Period.strftime()</code>	Returns the string representation of the <i>Period</i> , depending on the selected fmt .
<code>Period.to_timestamp()</code>	Return the Timestamp representation of the Period at the target frequency at the specified end (how) of the Period

pandas.Period.now

Period.now()

A collection of timedeltas may be stored in a `arrays.PeriodArray`. Every period in a `PeriodArray` must have the same `freq`.

<code>arrays.PeriodArray(values[, freq, dtype, copy])</code>	Pandas ExtensionArray for storing Period data.
--	--

pandas.arrays.PeriodArray

`class pandas.arrays.PeriodArray(values, freq=None, dtype=None, copy=False)`

Pandas ExtensionArray for storing Period data.

Users should use `period_array()` to create new instances.

Parameters

values [Union[PeriodArray, Series[period], ndarray[int], PeriodIndex]] The data to store. These should be arrays that can be directly converted to ordinals without inference or copy (PeriodArray, ndarray[int64]), or a box around such an array (Series[period], PeriodIndex).

freq [str or DateOffset] The *freq* to use for the array. Mostly applicable when *values* is an ndarray of integers, when *freq* is required. When *values* is a PeriodArray (or box around), it's checked that `values.freq` matches *freq*.

dtype [PeriodDtype, optional] A PeriodDtype instance from which to extract a *freq*. If both *freq* and *dtype* are specified, then the frequencies must match.

copy [bool, default False] Whether to copy the ordinals before storing.

See also:

`period_array` Create a new PeriodArray.

`PeriodIndex` Immutable Index for period data.

Notes

There are two components to a PeriodArray

- ordinals : integer ndarray
- freq : pd.tseries.offsets.Offset

The values are physically stored as a 1-D ndarray of integers. These are called “ordinals” and represent some kind of offset from a base.

The *freq* indicates the span covered by each element of the array. All elements in the PeriodArray have the same *freq*.

Attributes

None	
------	--

Methods

None	
------	--

PeriodDtype

An ExtensionDtype for Period data.

pandas.PeriodDtype

class pandas.PeriodDtype

An ExtensionDtype for Period data.

This is not an actual numpy dtype, but a duck type.

Parameters

freq [str or DateOffset] The frequency of this PeriodDtype

Examples

```
>>> pd.PeriodDtype(freq='D')
period[D]
```

```
>>> pd.PeriodDtype(freq=pd.offsets.MonthEnd())
period[M]
```

Attributes

freq

The frequency object of this PeriodDtype.

pandas.PeriodDtype.freq**PeriodDtype.freq**

The frequency object of this PeriodDtype.

Methods

None	
------	--

6.5.6 Interval data

Arbitrary intervals can be represented as *Interval* objects.

<i>Interval</i>	Immutable object implementing an Interval, a bounded slice-like interval.
-----------------	---

pandas.Interval**class pandas.Interval**

Immutable object implementing an Interval, a bounded slice-like interval.

New in version 0.20.0.

Parameters

left [orderable scalar] Left bound for the interval.

right [orderable scalar] Right bound for the interval.

closed [{'right', 'left', 'both', 'neither'}, default 'right'] Whether the interval is closed on the left-side, right-side, both or neither. See the Notes for more detailed explanation.

See also:

IntervalIndex An Index of Interval objects that are all closed on the same side.

cut Convert continuous data into discrete bins (Categorical of Interval objects).

qcut Convert continuous data into bins (Categorical of Interval objects) based on quantiles.

Period Represents a period of time.

Notes

The parameters *left* and *right* must be from the same type, you must be able to compare them and they must satisfy $left \leq right$.

A closed interval (in mathematics denoted by square brackets) contains its endpoints, i.e. the closed interval $[0, 5]$ is characterized by the conditions $0 \leq x \leq 5$. This is what `closed='both'` stands for. An open interval (in mathematics denoted by parentheses) does not contain its endpoints, i.e. the open interval $(0, 5)$ is characterized by the conditions $0 < x < 5$. This is what `closed='neither'` stands for. Intervals can also be half-open or half-closed, i.e. $[0, 5)$ is described by $0 \leq x < 5$ (`closed='left'`) and $(0, 5]$ is described by $0 < x \leq 5$ (`closed='right'`).

Examples

It is possible to build Intervals of different types, like numeric ones:

```
>>> iv = pd.Interval(left=0, right=5)
>>> iv
Interval(0, 5, closed='right')
```

You can check if an element belongs to it

```
>>> 2.5 in iv
True
```

You can test the bounds (closed='right', so $0 < x \leq 5$):

```
>>> 0 in iv
False
>>> 5 in iv
True
>>> 0.0001 in iv
True
```

Calculate its length

```
>>> iv.length
5
```

You can operate with $+$ and $*$ over an Interval and the operation is applied to each of its bounds, so the result depends on the type of the bound elements

```
>>> shifted_iv = iv + 3
>>> shifted_iv
Interval(3, 8, closed='right')
>>> extended_iv = iv * 10.0
>>> extended_iv
Interval(0.0, 50.0, closed='right')
```

To create a time interval you can use Timestamps as the bounds

```
>>> year_2017 = pd.Interval(pd.Timestamp('2017-01-01 00:00:00'),
...                         pd.Timestamp('2018-01-01 00:00:00'),
...                         closed='left')
>>> pd.Timestamp('2017-01-01 00:00:00') in year_2017
True
>>> year_2017.length
Timedelta('365 days 00:00:00')
```

And also you can create string intervals

```
>>> volume_1 = pd.Interval('Ant', 'Dog', closed='both')
>>> 'Bee' in volume_1
True
```

Attributes

<i>closed</i>	Whether the interval is closed on the left-side, right-side, both or neither
<i>closed_left</i>	Check if the interval is closed on the left side.
<i>closed_right</i>	Check if the interval is closed on the right side.
<i>is_empty</i>	Indicates if an interval is empty, meaning it contains no points.
<i>left</i>	Left bound for the interval
<i>length</i>	Return the length of the Interval
<i>mid</i>	Return the midpoint of the Interval
<i>open_left</i>	Check if the interval is open on the left side.
<i>open_right</i>	Check if the interval is open on the right side.
<i>right</i>	Right bound for the interval

pandas.Interval.closed**Interval.closed**

Whether the interval is closed on the left-side, right-side, both or neither

pandas.Interval.closed_left**Interval.closed_left**

Check if the interval is closed on the left side.

For the meaning of *closed* and *open* see *Interval*.

Returns

bool True if the Interval is closed on the left-side, else False.

pandas.Interval.closed_right**Interval.closed_right**

Check if the interval is closed on the right side.

For the meaning of *closed* and *open* see *Interval*.

Returns

bool True if the Interval is closed on the left-side, else False.

pandas.Interval.is_empty**Interval.is_empty**

Indicates if an interval is empty, meaning it contains no points.

New in version 0.25.0.

Returns

bool or ndarray A boolean indicating if a scalar *Interval* is empty, or a boolean ndarray positionally indicating if an *Interval* in an *IntervalArray* or *IntervalIndex* is empty.

Examples

An *Interval* that contains points is not empty:

```
>>> pd.Interval(0, 1, closed='right').is_empty
False
```

An *Interval* that does not contain any points is empty:

```
>>> pd.Interval(0, 0, closed='right').is_empty
True
>>> pd.Interval(0, 0, closed='left').is_empty
True
>>> pd.Interval(0, 0, closed='neither').is_empty
True
```

An *Interval* that contains a single point is not empty:

```
>>> pd.Interval(0, 0, closed='both').is_empty
False
```

An *IntervalArray* or *IntervalIndex* returns a boolean ndarray positionally indicating if an *Interval* is empty:

```
>>> ivs = [pd.Interval(0, 0, closed='neither'),
...        pd.Interval(1, 2, closed='neither')]
>>> pd.arrays.IntervalArray(ivs).is_empty
array([ True, False])
```

Missing values are not considered empty:

```
>>> ivs = [pd.Interval(0, 0, closed='neither'), np.nan]
>>> pd.IntervalIndex(ivs).is_empty
array([ True, False])
```

pandas.Interval.left

`Interval.left`

Left bound for the interval

pandas.Interval.length

`Interval.length`

Return the length of the Interval

pandas.Interval.mid

`Interval.mid`

Return the midpoint of the Interval

pandas.Interval.open_left**Interval.open_left**

Check if the interval is open on the left side.

For the meaning of *closed* and *open* see *Interval*.

Returns

bool True if the Interval is closed on the left-side, else False.

pandas.Interval.open_right**Interval.open_right**

Check if the interval is open on the right side.

For the meaning of *closed* and *open* see *Interval*.

Returns

bool True if the Interval is closed on the left-side, else False.

pandas.Interval.right**Interval.right**

Right bound for the interval

Methods

<i>overlaps()</i>	Check whether two Interval objects overlap.
-------------------	---

pandas.Interval.overlaps**Interval.overlaps()**

Check whether two Interval objects overlap.

Two intervals overlap if they share a common point, including closed endpoints. Intervals that only have an open endpoint in common do not overlap.

New in version 0.24.0.

Parameters

other [Interval] The interval to check against for an overlap.

Returns

bool True if the two intervals overlap, else False.

See also:

IntervalArray.overlaps The corresponding method for IntervalArray.

IntervalIndex.overlaps The corresponding method for IntervalIndex.

Examples

```
>>> i1 = pd.Interval(0, 2)
>>> i2 = pd.Interval(1, 3)
>>> i1.overlaps(i2)
True
>>> i3 = pd.Interval(4, 5)
>>> i1.overlaps(i3)
False
```

Intervals that share closed endpoints overlap:

```
>>> i4 = pd.Interval(0, 1, closed='both')
>>> i5 = pd.Interval(1, 2, closed='both')
>>> i4.overlaps(i5)
True
```

Intervals that only have an open endpoint in common do not overlap:

```
>>> i6 = pd.Interval(1, 2, closed='neither')
>>> i4.overlaps(i6)
False
```

Properties

<i>Interval.closed</i>	Whether the interval is closed on the left-side, right-side, both or neither
<i>Interval.closed_left</i>	Check if the interval is closed on the left side.
<i>Interval.closed_right</i>	Check if the interval is closed on the right side.
<i>Interval.is_empty</i>	Indicates if an interval is empty, meaning it contains no points.
<i>Interval.left</i>	Left bound for the interval
<i>Interval.length</i>	Return the length of the Interval
<i>Interval.mid</i>	Return the midpoint of the Interval
<i>Interval.open_left</i>	Check if the interval is open on the left side.
<i>Interval.open_right</i>	Check if the interval is open on the right side.
<i>Interval.overlaps()</i>	Check whether two Interval objects overlap.
<i>Interval.right</i>	Right bound for the interval

A collection of intervals may be stored in an *arrays.IntervalArray*.

<i>arrays.IntervalArray</i>	Pandas array for interval data that are closed on the same side.
-----------------------------	--

pandas.arrays.IntervalArray

```
class pandas.arrays.IntervalArray
```

Pandas array for interval data that are closed on the same side.

New in version 0.24.0.

Parameters

data [array-like (1-dimensional)] Array-like containing Interval objects from which to build the IntervalArray.

closed [{‘left’, ‘right’, ‘both’, ‘neither’}, default ‘right’] Whether the intervals are closed on the left-side, right-side, both or neither.

dtype [dtype or None, default None] If None, dtype will be inferred.

New in version 0.23.0.

copy [bool, default False] Copy the input data.

verify_integrity [bool, default True] Verify that the IntervalArray is valid.

See also:

Index The base pandas Index type.

Interval A bounded slice-like interval; the elements of an IntervalArray.

interval_range Function to create a fixed frequency IntervalIndex.

cut Bin values into discrete Intervals.

qcut Bin values into equal-sized Intervals based on rank or sample quantiles.

Notes

See the [user guide](#) for more.

Examples

A new IntervalArray can be constructed directly from an array-like of Interval objects:

```
>>> pd.arrays.IntervalArray([pd.Interval(0, 1), pd.Interval(1, 5)])
IntervalArray([(0, 1], (1, 5]],
              closed='right',
              dtype='interval[int64]')
```

It may also be constructed using one of the constructor methods: *IntervalArray.from_arrays()*, *IntervalArray.from_breaks()*, and *IntervalArray.from_tuples()*.

Attributes

<i>left</i>	Return the left endpoints of each Interval in the IntervalArray as an Index
<i>right</i>	Return the right endpoints of each Interval in the IntervalArray as an Index
<i>closed</i>	Whether the intervals are closed on the left-side, right-side, both or neither
<i>mid</i>	Return the midpoint of each Interval in the IntervalArray as an Index
<i>length</i>	Return an Index with entries denoting the length of each Interval in the IntervalArray

Continued on next page

Table 105 – continued from previous page

<i>is_empty</i>	Indicates if an interval is empty, meaning it contains no points.
<i>is_non_overlapping_monotonic</i>	Return True if the IntervalArray is non-overlapping (no Intervals share points) and is either monotonic increasing or monotonic decreasing, else False

pandas.arrays.IntervalArray.left**IntervalArray.left**

Return the left endpoints of each Interval in the IntervalArray as an Index

pandas.arrays.IntervalArray.right**IntervalArray.right**

Return the right endpoints of each Interval in the IntervalArray as an Index

pandas.arrays.IntervalArray.closed**IntervalArray.closed**

Whether the intervals are closed on the left-side, right-side, both or neither

pandas.arrays.IntervalArray.mid**IntervalArray.mid**

Return the midpoint of each Interval in the IntervalArray as an Index

pandas.arrays.IntervalArray.length**IntervalArray.length**

Return an Index with entries denoting the length of each Interval in the IntervalArray

pandas.arrays.IntervalArray.is_empty**IntervalArray.is_empty**

Indicates if an interval is empty, meaning it contains no points.

New in version 0.25.0.

Returns

bool or ndarray A boolean indicating if a scalar `Interval` is empty, or a boolean `ndarray` positionally indicating if an `Interval` in an `IntervalArray` or `IntervalIndex` is empty.

Examples

An Interval that contains points is not empty:

```
>>> pd.Interval(0, 1, closed='right').is_empty
False
```

An Interval that does not contain any points is empty:

```
>>> pd.Interval(0, 0, closed='right').is_empty
True
>>> pd.Interval(0, 0, closed='left').is_empty
True
>>> pd.Interval(0, 0, closed='neither').is_empty
True
```

An Interval that contains a single point is not empty:

```
>>> pd.Interval(0, 0, closed='both').is_empty
False
```

An IntervalArray or IntervalIndex returns a boolean ndarray positionally indicating if an Interval is empty:

```
>>> ivs = [pd.Interval(0, 0, closed='neither'),
...        pd.Interval(1, 2, closed='neither')]
>>> pd.arrays.IntervalArray(ivs).is_empty
array([ True, False])
```

Missing values are not considered empty:

```
>>> ivs = [pd.Interval(0, 0, closed='neither'), np.nan]
>>> pd.IntervalIndex(ivs).is_empty
array([ True, False])
```

pandas.arrays.IntervalArray.is_non_overlapping_monotonic

IntervalArray.is_non_overlapping_monotonic

Return True if the IntervalArray is non-overlapping (no Intervals share points) and is either monotonic increasing or monotonic decreasing, else False

Methods

<i>from_arrays</i> (left, right[, closed, copy, dtype])	Construct from two arrays defining the left and right bounds.
<i>from_tuples</i> (data[, closed, copy, dtype])	Construct an IntervalArray from an array-like of tuples
<i>from_breaks</i> (breaks[, closed, copy, dtype])	Construct an IntervalArray from an array of splits.
<i>contains</i> (self, other)	Check elementwise if the Intervals contain the value.

Continued on next page

Table 106 – continued from previous page

<code>overlaps(self, other)</code>	Check elementwise if an Interval overlaps the values in the IntervalArray.
<code>set_closed(self, closed)</code>	Return an IntervalArray identical to the current one, but closed on the specified side
<code>to_tuples(self[, na_tuple])</code>	Return an ndarray of tuples of the form (left, right)

pandas.arrays.IntervalArray.from_arrays

`classmethod IntervalArray.from_arrays(left, right, closed='right', copy=False, dtype=None)`

Construct from two arrays defining the left and right bounds.

Parameters

left [array-like (1-dimensional)] Left bounds for each interval.

right [array-like (1-dimensional)] Right bounds for each interval.

closed [{'left', 'right', 'both', 'neither'}, default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.

copy [boolean, default False] Copy the data.

dtype [dtype, optional] If None, dtype will be inferred.

New in version 0.23.0.

Returns

IntervalArray

Raises

ValueError When a value is missing in only one of *left* or *right*. When a value in *left* is greater than the corresponding value in *right*.

See also:

interval_range Function to create a fixed frequency IntervalIndex.

IntervalArray.from_breaks Construct an IntervalArray from an array of splits.

IntervalArray.from_tuples Construct an IntervalArray from an array-like of tuples.

Notes

Each element of *left* must be less than or equal to the *right* element at the same position. If an element is missing, it must be missing in both *left* and *right*. A `TypeError` is raised when using an unsupported type for *left* or *right*. At the moment, 'category', 'object', and 'string' subtypes are not supported.

Examples

```
>>> IntervalArray.from_arrays([0, 1, 2], [1, 2, 3])
IntervalArray([(0, 1], (1, 2], (2, 3]],
              closed='right',
              dtype='interval[int64]')
```

pandas.arrays.IntervalArray.from_tuples

classmethod `IntervalArray.from_tuples`(*data*, *closed='right'*, *copy=False*, *dtype=None*)

Construct an IntervalArray from an array-like of tuples

Parameters

data [array-like (1-dimensional)] Array of tuples

closed [{'left', 'right', 'both', 'neither'}, default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.

copy [boolean, default False] by-default copy the data, this is compat only and ignored

dtype [dtype or None, default None] If None, dtype will be inferred

..versionadded:: 0.23.0

Returns

IntervalArray

See also:

interval_range Function to create a fixed frequency IntervalIndex.

IntervalArray.from_arrays Construct an IntervalArray from a left and right array.

IntervalArray.from_breaks Construct an IntervalArray from an array of splits.

Examples

```
>>> pd.arrays.IntervalArray.from_tuples([(0, 1), (1, 2)])
IntervalArray([(0, 1], (1, 2]],
              closed='right', dtype='interval[int64]')
```

pandas.arrays.IntervalArray.from_breaks

classmethod `IntervalArray.from_breaks`(*breaks*, *closed='right'*, *copy=False*, *dtype=None*)

Construct an IntervalArray from an array of splits.

Parameters

breaks [array-like (1-dimensional)] Left and right bounds for each interval.

closed [{'left', 'right', 'both', 'neither'}, default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.

copy [boolean, default False] copy the data

dtype [dtype or None, default None] If None, dtype will be inferred

New in version 0.23.0.

Returns

IntervalArray

See also:

interval_range Function to create a fixed frequency IntervalIndex.

IntervalArray.from_arrays Construct from a left and right array.

IntervalArray.from_tuples Construct from a sequence of tuples.

Examples

```
>>> pd.arrays.IntervalArray.from_breaks([0, 1, 2, 3])
IntervalArray([(0, 1], (1, 2], (2, 3]],
              closed='right',
              dtype='interval[int64]')
```

pandas.arrays.IntervalArray.contains

IntervalArray.contains(*self*, *other*)

Check elementwise if the Intervals contain the value.

Return a boolean mask whether the value is contained in the Intervals of the IntervalArray.

New in version 0.25.0.

Parameters

other [scalar] The value to check whether it is contained in the Intervals.

Returns

boolean array

See also:

Interval.contains Check whether Interval object contains value.

IntervalArray.overlaps Check if an Interval overlaps the values in the IntervalArray.

Examples

```
>>> intervals = pd.arrays.IntervalArray.from_tuples([(0, 1), (1, 3), (2, 4)])
>>> intervals
IntervalArray([(0, 1], (1, 3], (2, 4]],
              closed='right',
              dtype='interval[int64]')
>>> intervals.contains(0.5)
array([ True, False, False])
```

pandas.arrays.IntervalArray.overlaps**IntervalArray.overlaps**(*self*, *other*)

Check elementwise if an Interval overlaps the values in the IntervalArray.

Two intervals overlap if they share a common point, including closed endpoints. Intervals that only have an open endpoint in common do not overlap.

New in version 0.24.0.

Parameters**other** [Interval] Interval to check against for an overlap.**Returns****ndarray** Boolean array positionally indicating where an overlap occurs.**See also:****Interval.overlaps** Check whether two Interval objects overlap.**Examples**

```
>>> intervals = pd.arrays.IntervalArray.from_tuples([(0, 1), (1, 3), (2, 4)])
>>> intervals
IntervalArray([(0, 1], (1, 3], (2, 4]],
              closed='right',
              dtype='interval[int64]')
>>> intervals.overlaps(pd.Interval(0.5, 1.5))
array([ True,  True, False])
```

Intervals that share closed endpoints overlap:

```
>>> intervals.overlaps(pd.Interval(1, 3, closed='left'))
array([ True,  True,  True])
```

Intervals that only have an open endpoint in common do not overlap:

```
>>> intervals.overlaps(pd.Interval(1, 2, closed='right'))
array([False,  True, False])
```

pandas.arrays.IntervalArray.set_closed**IntervalArray.set_closed**(*self*, *closed*)

Return an IntervalArray identical to the current one, but closed on the specified side

New in version 0.24.0.

Parameters**closed** [{'left', 'right', 'both', 'neither'}] Whether the intervals are closed on the left-side, right-side, both or neither.**Returns****new_index** [IntervalArray]

Examples

```
>>> index = pd.interval_range(0, 3)
>>> index
IntervalIndex([(0, 1], (1, 2], (2, 3]],
              closed='right',
              dtype='interval[int64]')
>>> index.set_closed('both')
IntervalIndex([[0, 1], [1, 2], [2, 3]],
              closed='both',
              dtype='interval[int64]')
```

`pandas.arrays.IntervalArray.to_tuples`

`IntervalArray.to_tuples(self, na_tuple=True)`

Return an ndarray of tuples of the form (left, right)

Parameters

na_tuple [boolean, default True] Returns NA as a tuple if True, (nan, nan), or just as the NA value itself if False, nan.

New in version 0.23.0.

Returns

tuples: ndarray

IntervalDtype

An ExtensionDtype for Interval data.

`pandas.IntervalDtype`

`class pandas.IntervalDtype`

An ExtensionDtype for Interval data.

This is not an actual numpy dtype, but a duck type.

Parameters

subtype [str, np.dtype] The dtype of the Interval bounds.

Examples

```
>>> pd.IntervalDtype(subtype='int64')
interval[int64]
```

Attributes

subtype

The dtype of the Interval bounds.

pandas.IntervalDtype.subtype`IntervalDtype.subtype`

The dtype of the Interval bounds.

Methods

None	
------	--

6.5.7 Nullable integer

`numpy.ndarray` cannot natively represent integer-data with missing values. Pandas provides this through `arrays.IntegerArray`.

`arrays.IntegerArray(values, mask[, copy])` Array of integer (optional missing) values.

pandas.arrays.IntegerArray`class pandas.arrays.IntegerArray(values, mask, copy=False)`

Array of integer (optional missing) values.

New in version 0.24.0.

Warning: `IntegerArray` is currently experimental, and its API or internal implementation may change without warning.

We represent an `IntegerArray` with 2 numpy arrays:

- `data`: contains a numpy integer array of the appropriate dtype
- `mask`: a boolean array holding a mask on the data, True is missing

To construct an `IntegerArray` from generic array-like input, use `pandas.array()` with one of the integer dtypes (see examples).See *Nullable integer data type* for more.**Parameters****values** [numpy.ndarray] A 1-d integer-dtype array.**mask** [numpy.ndarray] A 1-d boolean-dtype array indicating missing values.**copy** [bool, default False] Whether to copy the *values* and *mask*.**Returns**`IntegerArray`**Examples**Create an `IntegerArray` with `pandas.array()`.

```
>>> int_array = pd.array([1, None, 3], dtype=pd.Int32Dtype())
>>> int_array
<IntegerArray>
[1, NaN, 3]
Length: 3, dtype: Int32
```

String aliases for the dtypes are also available. They are capitalized.

```
>>> pd.array([1, None, 3], dtype='Int32')
<IntegerArray>
[1, NaN, 3]
Length: 3, dtype: Int32
```

```
>>> pd.array([1, None, 3], dtype='UInt16')
<IntegerArray>
[1, NaN, 3]
Length: 3, dtype: UInt16
```

6.5.8 Categorical data

Pandas defines a custom data type for representing data that can take only a limited, fixed set of values. The dtype of a `Categorical` can be described by a `pandas.api.types.CategoricalDtype`.

<i>CategoricalDtype</i> ([categories])	Type for categorical data with the categories and orderedness.
--	--

pandas.CategoricalDtype**class** pandas.CategoricalDtype(*categories=None, ordered: Union[None, bool, object] = <object object>*)

Type for categorical data with the categories and orderedness.

Changed in version 0.21.0.

Parameters**categories** [sequence, optional] Must be unique, and must not contain any nulls.**ordered** [bool, default False]**See also:***Categorical***Notes**

This class is useful for specifying the type of a `Categorical` independent of the values. See *CategoricalDtype* for more.

Examples

```

>>> t = pd.CategoricalDtype(categories=['b', 'a'], ordered=True)
>>> pd.Series(['a', 'b', 'a', 'c'], dtype=t)
0      a
1      b
2      a
3     NaN
dtype: category
Categories (2, object): [b < a]

```

Attributes

<i>categories</i>	An Index containing the unique categories allowed.
<i>ordered</i>	Whether the categories have an ordered relationship.

pandas.CategoricalDtype.categories

`CategoricalDtype.categories`
An Index containing the unique categories allowed.

pandas.CategoricalDtype.ordered

`CategoricalDtype.ordered`
Whether the categories have an ordered relationship.

Methods

None

<i>CategoricalDtype.categories</i>	An Index containing the unique categories allowed.
<i>CategoricalDtype.ordered</i>	Whether the categories have an ordered relationship.

Categorical data can be stored in a *pandas.Categorical*

<i>Categorical</i> (values[, categories, ordered, ...])	Represent a categorical variable in classic R / S-plus fashion.
---	---

pandas.Categorical

`class pandas.Categorical(values, categories=None, ordered=None, dtype=None, fastpath=False)`
Represent a categorical variable in classic R / S-plus fashion.

Categoricals can only take on only a limited, and usually fixed, number of possible values (*categories*). In contrast to statistical categorical variables, a *Categorical* might have an order, but numerical operations (additions, divisions, ...) are not possible.

All values of the *Categorical* are either in *categories* or *np.nan*. Assigning values outside of *categories* will raise a *ValueError*. Order is defined by the order of the *categories*, not lexical order of the values.

Parameters

values [list-like] The values of the categorical. If categories are given, values not in categories will be replaced with NaN.

categories [Index-like (unique), optional] The unique categories for this categorical. If not given, the categories are assumed to be the unique values of *values* (sorted, if possible, otherwise in the order in which they appear).

ordered [bool, default False] Whether or not this categorical is treated as a ordered categorical. If True, the resulting categorical will be ordered. An ordered categorical respects, when sorted, the order of its *categories* attribute (which in turn is the *categories* argument, if provided).

dtype [CategoricalDtype] An instance of `CategoricalDtype` to use for this categorical

New in version 0.21.0.

Raises

ValueError If the categories do not validate.

TypeError If an explicit `ordered=True` is given but no *categories* and the *values* are not sortable.

See also:

`api.types.CategoricalDtype` Type for categorical data.

CategoricalIndex An Index with an underlying *Categorical*.

Notes

See the [user guide](#) for more.

Examples

```
>>> pd.Categorical([1, 2, 3, 1, 2, 3])
[1, 2, 3, 1, 2, 3]
Categories (3, int64): [1, 2, 3]
```

```
>>> pd.Categorical(['a', 'b', 'c', 'a', 'b', 'c'])
[a, b, c, a, b, c]
Categories (3, object): [a, b, c]
```

Ordered *Categoricals* can be sorted according to the custom order of the categories and can have a min and max value.

```

>>> c = pd.Categorical(['a', 'b', 'c', 'a', 'b', 'c'], ordered=True,
...                    categories=['c', 'b', 'a'])
>>> c
[a, b, c, a, b, c]
Categories (3, object): [c < b < a]
>>> c.min()
'c'

```

Attributes

<i>categories</i>	The categories of this categorical.
<i>codes</i>	The category codes of this categorical.
<i>ordered</i>	Whether the categories have an ordered relationship.
<i>dtype</i>	The <code>CategoricalDtype</code> for this instance

`pandas.Categorical.categories`

`Categorical.categories`

The categories of this categorical.

`Setting` assigns new values to each category (effectively a rename of each individual category).

The assigned value has to be a list-like object. All items must be unique and the number of items in the new categories must be the same as the number of items in the old categories.

Assigning to `categories` is an inplace operation!

Raises

ValueError If the new categories do not validate as categories or if the number of new categories is unequal the number of old categories

See also:

- `rename_categories`
- `reorder_categories`
- `add_categories`
- `remove_categories`
- `remove_unused_categories`
- `set_categories`

`pandas.Categorical.codes`

`Categorical.codes`

The category codes of this categorical.

Level codes are an array of integer which are the positions of the real values in the categories array.

There is not setter, use the other categorical methods and the normal item setter to change values in the categorical.

pandas.Categorical.ordered

Categorical.ordered

Whether the categories have an ordered relationship.

pandas.Categorical.dtype

Categorical.dtype

The CategoricalDtype for this instance

Methods

<code>from_codes(codes[, categories, ordered, dtype])</code>	Make a Categorical type from codes and categories or dtype.
<code>__array__(self[, dtype])</code>	The numpy array interface.

pandas.Categorical.from_codes

classmethod `Categorical.from_codes(codes, categories=None, ordered=None, dtype=None)`

Make a Categorical type from codes and categories or dtype.

This constructor is useful if you already have codes and categories/dtype and so do not need the (computation intensive) factorization step, which is usually done on the constructor.

If your data does not follow this convention, please use the normal constructor.

Parameters

codes [array-like, integers] An integer array, where each integer points to a category in categories or dtype.categories, or else is -1 for NaN.

categories [index-like, optional] The categories for the categorical. Items need to be unique. If the categories are not given here, then they must be provided in *dtype*.

ordered [bool, optional] Whether or not this categorical is treated as an ordered categorical. If not given here or in *dtype*, the resulting categorical will be unordered.

dtype [CategoricalDtype or the string “category”, optional] If *CategoricalDtype*, cannot be used together with *categories* or *ordered*.

New in version 0.24.0: When *dtype* is provided, neither *categories* nor *ordered* should be provided.

Returns

Categorical

Examples

```
>>> dtype = pd.CategoricalDtype(['a', 'b'], ordered=True)
>>> pd.Categorical.from_codes(codes=[0, 1, 0, 1], dtype=dtype)
[a, b, a, b]
Categories (2, object): [a < b]
```

pandas.Categorical.__array__

`Categorical.__array__(self, dtype=None)`

The numpy array interface.

Returns

numpy.array A numpy array of either the specified dtype or, if dtype==None (default), the same dtype as categorical.categories.dtype.

The alternative `Categorical.from_codes()` constructor can be used when you have the categories and integer codes already:

<code>Categorical.from_codes(codes[, categories, ...])</code>	Make a Categorical type from codes and categories or dtype.
---	---

The dtype information is available on the `Categorical`

<code>Categorical.dtype</code>	The <code>CategoricalDtype</code> for this instance
<code>Categorical.categories</code>	The categories of this categorical.
<code>Categorical.ordered</code>	Whether the categories have an ordered relationship.
<code>Categorical.codes</code>	The category codes of this categorical.

`np.asarray(categorical)` works by implementing the array interface. Be aware, that this converts the `Categorical` back to a NumPy array, so categories and order information is not preserved!

<code>Categorical.__array__(self[, dtype])</code>	The numpy array interface.
---	----------------------------

A `Categorical` can be stored in a `Series` or `DataFrame`. To create a `Series` of dtype `category`, use `cat = s.astype(dtype)` or `Series(..., dtype=dtype)` where `dtype` is either

- the string 'category'
- an instance of `CategoricalDtype`.

If the `Series` is of dtype `CategoricalDtype`, `Series.cat` can be used to change the categorical data. See *Categorical accessor* for more.

6.5.9 Sparse data

Data where a single value is repeated many times (e.g. 0 or NaN) may be stored efficiently as a *SparseArray*.

<code>SparseArray(data[, sparse_index, index, ...])</code>	An <code>ExtensionArray</code> for storing sparse data.
--	---

pandas.SparseArray

```
class pandas.SparseArray(data, sparse_index=None, index=None, fill_value=None,
                        kind='integer', dtype=None, copy=False)
```

An ExtensionArray for storing sparse data.

Changed in version 0.24.0: Implements the ExtensionArray interface.

Parameters

data [array-like] A dense array of values to store in the SparseArray. This may contain *fill_value*.

sparse_index [SparseIndex, optional]

index [Index]

fill_value [scalar, optional] Elements in *data* that are *fill_value* are not stored in the SparseArray. For memory savings, this should be the most common value in *data*. By default, *fill_value* depends on the dtype of *data*:

data.dtype	na_value
float	np.nan
int	0
bool	False
datetime64	pd.NaT
timedelta64	pd.NaT

The fill value is potentially specified in three ways. In order of precedence, these are

1. The *fill_value* argument
2. `dtype.fill_value` if *fill_value* is None and *dtype* is a `SparseDtype`
3. `data.dtype.fill_value` if *fill_value* is None and *dtype* is not a `SparseDtype` and *data* is a `SparseArray`.

kind [{‘integer’, ‘block’}, default ‘integer’] The type of storage for sparse locations.

- ‘block’: Stores a *block* and *block_length* for each contiguous *span* of sparse values. This is best when sparse data tends to be clumped together, with large regions of *fill-value* values between sparse values.
- ‘integer’: uses an integer to store the location of each sparse value.

dtype [np.dtype or SparseDtype, optional] The dtype to use for the SparseArray. For numpy dtypes, this determines the dtype of `self.sp_values`. For SparseDtype, this determines `self.sp_values` and `self.fill_value`.

copy [bool, default False] Whether to explicitly copy the incoming *data* array.

Attributes

None

Methods

None	
------	--

SparseDtype(dtype, numpy.dtype, ...) Dtype for data stored in *SparseArray*.

pandas.SparseDtype

```
class pandas.SparseDtype(dtype: Union[str, numpy.dtype, pandas.core.dtypes.base.ExtensionDtype]
                          = <class 'numpy.float64'>, fill_value: Any = None)
```

Dtype for data stored in *SparseArray*.

This dtype implements the pandas *ExtensionDtype* interface.

New in version 0.24.0.

Parameters

dtype [str, *ExtensionDtype*, *numpy.dtype*, type, default *numpy.float64*] The dtype of the underlying array storing the non-fill value values.

fill_value [scalar, optional] The scalar value not stored in the *SparseArray*. By default, this depends on *dtype*.

dtype	na_value
float	<i>np.nan</i>
int	0
bool	<i>False</i>
datetime64	<i>pd.NaT</i>
timedelta64	<i>pd.NaT</i>

The default value may be overridden by specifying a *fill_value*.

Attributes

None	
------	--

Methods

None	
------	--

The *Series.sparse* accessor may be used to access sparse-specific attributes and methods if the *Series* contains sparse values. See *Sparse accessor* for more.

```

6.7 Index objects

6.7.1 Index

Many of these methods or variants thereof are available on the objects that contain an index (Series/DataFrame) and those should most likely be used before calling these methods directly.

<i>Index</i>	Immutable ndarray implementing an ordered, sliceable set.
--------------	---

pandas.Index

class pandas.Index

Immutable ndarray implementing an ordered, sliceable set. The basic object storing axis labels for all pandas objects.

Parameters

data [array-like (1-dimensional)]

dtype [NumPy dtype (default: object)] If dtype is None, we find the dtype that best fits the data. If an actual dtype is provided, we coerce to that dtype if it's safe. Otherwise, an error will be raised.

copy [bool] Make a copy of input ndarray

name [object] Name to be stored in the index

tupleize_cols [bool (default: True)] When True, attempt to create a MultiIndex if possible

See also:

RangeIndex Index implementing a monotonic integer range.

CategoricalIndex Index of *Categorical* s.

MultiIndex A multi-level, or hierarchical, Index.

IntervalIndex An Index of *Interval* s.

DatetimeIndex, *TimedeltaIndex*, *PeriodIndex*

Int64Index, *UInt64Index*, *Float64Index*

Notes

An Index instance can **only** contain hashable objects

Examples

```
>>> pd.Index([1, 2, 3])
Int64Index([1, 2, 3], dtype='int64')
```

```
>>> pd.Index(list('abc'))
Index(['a', 'b', 'c'], dtype='object')
```

Attributes

<i>T</i>	Return the transpose, which is by
<i>array</i>	The ExtensionArray of the data backing this Series or Index.
<i>asi8</i>	Integer representation of the values.
<i>base</i>	(DEPRECATED) Return the base object if the memory of the underlying data is shared.
<i>data</i>	(DEPRECATED) Return the data pointer of the underlying data.
<i>dtype</i>	Return the dtype object of the underlying data.
<i>dtype_str</i>	(DEPRECATED) Return the dtype str of the underlying data.
<i>flags</i>	(DEPRECATED)
<i>hasnans</i>	Return if I have any nans; enables various perf speedups.
<i>inferred_type</i>	Return a string of the type inferred from the values.
<i>is_monotonic</i>	Alias for <code>is_monotonic_increasing</code> .
<i>is_monotonic_decreasing</i>	Return if the index is monotonic decreasing (only equal or decreasing) values.
<i>is_monotonic_increasing</i>	Return if the index is monotonic increasing (only equal or increasing) values.
<i>is_unique</i>	Return if the index has unique values.
<i>itemsize</i>	(DEPRECATED) Return the size of the dtype of the item of the underlying data.
<i>nbytes</i>	Return the number of bytes in the underlying data.
<i>ndim</i>	Number of dimensions of the underlying data, by definition 1.
<i>nlevels</i>	Number of levels.
<i>shape</i>	Return a tuple of the shape of the underlying data.
<i>size</i>	Return the number of elements in the underlying data.
<i>strides</i>	(DEPRECATED) Return the strides of the underlying data.
<i>values</i>	Return an array representing the data in the Index.

pandas.Index.T

Index.T

Return the transpose, which is by definition self.

pandas.Index.array

Index.array

The ExtensionArray of the data backing this Series or Index.

New in version 0.24.0.

Returns

ExtensionArray An ExtensionArray of the values stored within. For extension types, this is the actual array. For NumPy native types, this is a thin (no copy) wrapper around `numpy.ndarray`.

`.array` differs `.values` which may require converting the data to a different form.

See also:

Index.to_numpy Similar method that always returns a NumPy array.

Series.to_numpy Similar method that always returns a NumPy array.

Notes

This table lays out the different array types for each extension dtype within pandas.

dtype	array type
category	Categorical
period	PeriodArray
interval	IntervalArray
IntegerNA	IntegerArray
datetime64[ns, tz]	DatetimeArray

For any 3rd-party extension types, the array type will be an ExtensionArray.

For all remaining dtypes `.array` will be a `arrays.NumpyExtensionArray` wrapping the actual ndarray stored within. If you absolutely need a NumPy array (possibly with copying / coercing data), then use `Series.to_numpy()` instead.

Examples

For regular NumPy types like int, and float, a PandasArray is returned.

```
>>> pd.Series([1, 2, 3]).array
<PandasArray>
[1, 2, 3]
Length: 3, dtype: int64
```

For extension types, like Categorical, the actual ExtensionArray is returned

```
>>> ser = pd.Series(pd.Categorical(['a', 'b', 'a']))
>>> ser.array
[a, b, a]
Categories (2, object): [a, b]
```

pandas.Index.asi8

Index.asi8

Integer representation of the values.

Returns

ndarray An ndarray with int64 dtype.

pandas.Index.base

Index.base

Return the base object if the memory of the underlying data is shared.

Deprecated since version 0.23.0.

pandas.Index.data

Index.data

Return the data pointer of the underlying data.

Deprecated since version 0.23.0.

pandas.Index.dtype

Index.dtype

Return the dtype object of the underlying data.

pandas.Index.dtype_str

Index.dtype_str

Return the dtype str of the underlying data.

Deprecated since version 0.25.0.

pandas.Index.flags

Index.flags

pandas.Index.hasnans

Index.hasnans

Return if I have any nans; enables various perf speedups.

pandas.Index.inferred_type**Index.inferred_type**

Return a string of the type inferred from the values.

pandas.Index.is_monotonic**Index.is_monotonic**

Alias for `is_monotonic_increasing`.

pandas.Index.is_monotonic_decreasing**Index.is_monotonic_decreasing**

Return if the index is monotonic decreasing (only equal or decreasing) values.

Examples

```
>>> Index([3, 2, 1]).is_monotonic_decreasing
True
>>> Index([3, 2, 2]).is_monotonic_decreasing
True
>>> Index([3, 1, 2]).is_monotonic_decreasing
False
```

pandas.Index.is_monotonic_increasing**Index.is_monotonic_increasing**

Return if the index is monotonic increasing (only equal or increasing) values.

Examples

```
>>> Index([1, 2, 3]).is_monotonic_increasing
True
>>> Index([1, 2, 2]).is_monotonic_increasing
True
>>> Index([1, 3, 2]).is_monotonic_increasing
False
```

pandas.Index.is_unique**Index.is_unique**

Return if the index has unique values.

pandas.Index.itemsize

Index.itemsize

Return the size of the dtype of the item of the underlying data.

Deprecated since version 0.23.0.

pandas.Index.nbytes

Index.nbytes

Return the number of bytes in the underlying data.

pandas.Index.ndim

Index.ndim

Number of dimensions of the underlying data, by definition 1.

pandas.Index.nlevels

Index.nlevels

Number of levels.

pandas.Index.shape

Index.shape

Return a tuple of the shape of the underlying data.

pandas.Index.size

Index.size

Return the number of elements in the underlying data.

pandas.Index.strides

Index.strides

Return the strides of the underlying data.

Deprecated since version 0.23.0.

pandas.Index.values

Index.values

Return an array representing the data in the Index.

Warning: We recommend using *Index.array* or *Index.to_numpy()*, depending on whether you need a reference to the underlying data or a NumPy array.

Returns

array: `numpy.ndarray` or `ExtensionArray`

See also:

`Index.array` Reference to the underlying data.

`Index.to_numpy` A NumPy array representing the underlying data.

<code>empty</code>	
<code>has_duplicates</code>	
<code>is_all_dates</code>	
<code>name</code>	
<code>names</code>	

Methods

<code>all(self, *args, **kwargs)</code>	Return whether all elements are True.
<code>any(self, *args, **kwargs)</code>	Return whether any element is True.
<code>append(self, other)</code>	Append a collection of Index options together.
<code>argmax(self[, axis, skipna])</code>	Return an ndarray of the maximum argument indexer.
<code>argmin(self[, axis, skipna])</code>	Return a ndarray of the minimum argument indexer.
<code>argsort(self, *args, **kwargs)</code>	Return the integer indices that would sort the index.
<code>asof(self, label)</code>	Return the label from the index, or, if not present, the previous one.
<code>asof_locs(self, where, mask)</code>	Find the locations (indices) of the labels from the index for every entry in the <i>where</i> argument.
<code>astype(self, dtype[, copy])</code>	Create an Index with values cast to dtypes.
<code>contains(self, key)</code>	(DEPRECATED) Return a boolean indicating whether the provided key is in the index.
<code>copy(self[, name, deep, dtype])</code>	Make a copy of this object.
<code>delete(self, loc)</code>	Make new Index with passed location(-s) deleted.
<code>difference(self, other[, sort])</code>	Return a new Index with elements from the index that are not in <i>other</i> .
<code>drop(self, labels[, errors])</code>	Make new Index with passed list of labels deleted.
<code>drop_duplicates(self[, keep])</code>	Return Index with duplicate values removed.
<code>droplevel(self[, level])</code>	Return index with requested level(s) removed.
<code>dropna(self[, how])</code>	Return Index without NA/NaN values
<code>duplicated(self[, keep])</code>	Indicate duplicate index values.
<code>equals(self, other)</code>	Determine if two Index objects contain the same elements.
<code>factorize(self[, sort, na_sentinel])</code>	Encode the object as an enumerated type or categorical variable.
<code>fillna(self[, value, downcast])</code>	Fill NA/NaN values with the specified value
<code>format(self[, name, formatter])</code>	Render a string representation of the Index.

Continued on next page

Table 124 – continued from previous page

<code>get_duplicates(self)</code>	(DEPRECATED) Extract duplicated index elements.
<code>get_indexer(self, target[, method, limit, ...])</code>	Compute indexer and mask for new index given the current index.
<code>get_indexer_for(self, target, **kwargs)</code>	Guaranteed return of an indexer even when non-unique.
<code>get_indexer_non_unique(self, target)</code>	Compute indexer and mask for new index given the current index.
<code>get_level_values(self, level)</code>	Return an Index of values for requested level.
<code>get_loc(self, key[, method, tolerance])</code>	Get integer location, slice or boolean mask for requested label.
<code>get_slice_bound(self, label, side, kind)</code>	Calculate slice bound that corresponds to given label.
<code>get_value(self, series, key)</code>	Fast lookup of value from 1-dimensional ndarray.
<code>get_values(self)</code>	(DEPRECATED) Return <i>Index</i> data as an <i>numpy.ndarray</i> .
<code>groupby(self, values)</code>	Group the index labels by a given array of values.
<code>holds_integer(self)</code>	Whether the type is an integer type.
<code>identical(self, other)</code>	Similar to <code>equals</code> , but check that other comparable attributes are also equal.
<code>insert(self, loc, item)</code>	Make new Index inserting new item at location.
<code>intersection(self, other[, sort])</code>	Form the intersection of two Index objects.
<code>is_(self, other)</code>	More flexible, faster check like <code>is</code> but that works through views.
<code>is_categorical(self)</code>	Check if the Index holds categorical data.
<code>is_type_compatible(self, kind)</code>	Whether the index type is compatible with the provided type.
<code>isin(self, values[, level])</code>	Return a boolean array where the index values are in <i>values</i> .
<code>isna(self)</code>	Detect missing values.
<code>isnull(self)</code>	Detect missing values.
<code>item(self)</code>	Return the first element of the underlying data as a python scalar.
<code>join(self, other[, how, level, ...])</code>	Compute <code>join_index</code> and <code>indexers</code> to conform data structures to the new index.
<code>map(self, mapper[, na_action])</code>	Map values using input correspondence (a dict, Series, or function).
<code>max(self[, axis, skipna])</code>	Return the maximum value of the Index.
<code>memory_usage(self[, deep])</code>	Memory usage of the values
<code>min(self[, axis, skipna])</code>	Return the minimum value of the Index.
<code>notna(self)</code>	Detect existing (non-missing) values.
<code>notnull(self)</code>	Detect existing (non-missing) values.
<code>nunique(self[, dropna])</code>	Return number of unique elements in the object.
<code>putmask(self, mask, value)</code>	Return a new Index of the values set with the mask.
<code>ravel(self[, order])</code>	Return an ndarray of the flattened values of the underlying data.
<code>reindex(self, target[, method, level, ...])</code>	Create index with target's values (move/add/delete values as necessary).
<code>rename(self, name[, inplace])</code>	Alter Index or MultiIndex name.
<code>repeat(self, repeats[, axis])</code>	Repeat elements of a Index.

Continued on next page

Table 124 – continued from previous page

<code>searchsorted(self, value[, side, sorter])</code>	Find indices where elements should be inserted to maintain order.
<code>set_names(self, names[, level, inplace])</code>	Set Index or MultiIndex name.
<code>set_value(self, arr, key, value)</code>	Fast lookup of value from 1-dimensional ndarray.
<code>shift(self[, periods, freq])</code>	Shift index by desired number of time frequency increments.
<code>slice_indexer(self[, start, end, step, kind])</code>	For an ordered or unique index, compute the slice indexer for input labels and step.
<code>slice_locs(self[, start, end, step, kind])</code>	Compute slice locations for input labels.
<code>sort(self, *args, **kwargs)</code>	Use <code>sort_values</code> instead.
<code>sort_values(self[, return_indexer, ascending])</code>	Return a sorted copy of the index.
<code>sortlevel(self[, level, ascending, ...])</code>	For internal compatibility with with the Index API.
<code>str</code>	alias of <code>pandas.core.strings.StringMethods</code>
<code>summary(self[, name])</code>	(DEPRECATED) Return a summarized representation.
<code>symmetric_difference(self, other[, ...])</code>	Compute the symmetric difference of two Index objects.
<code>take(self, indices[, axis, allow_fill, ...])</code>	Return a new Index of the values selected by the indices.
<code>to_flat_index(self)</code>	Identity method.
<code>to_frame(self[, index, name])</code>	Create a DataFrame with a column containing the Index.
<code>to_list(self)</code>	Return a list of the values.
<code>to_native_types(self[, slicer])</code>	Format specified values of <code>self</code> and return them.
<code>to_numpy(self[, dtype, copy])</code>	A NumPy ndarray representing the values in this Series or Index.
<code>to_series(self[, index, name])</code>	Create a Series with both index and values equal to the index keys useful with map for returning an indexer based on an index.
<code>tolist(self)</code>	Return a list of the values.
<code>transpose(self, *args, **kwargs)</code>	Return the transpose, which is by definition self.
<code>union(self, other[, sort])</code>	Form the union of two Index objects.
<code>unique(self[, level])</code>	Return unique values in the index.
<code>value_counts(self[, normalize, sort, ...])</code>	Return a Series containing counts of unique values.
<code>where(self, cond[, other])</code>	Return an Index of same shape as self and whose corresponding entries are from self where cond is True and otherwise are from other.

pandas.Index.all

`Index.all(self, *args, **kwargs)`

Return whether all elements are True.

Parameters

***args** These parameters will be passed to `numpy.all`.

****kwargs** These parameters will be passed to `numpy.all`.

Returns

`all` [bool or array_like (if axis is specified)] A single element array_like may be

converted to bool.

See also:

`Index.any` Return whether any element in an Index is True.

`Series.any` Return whether any element in a Series is True.

`Series.all` Return whether all elements in a Series are True.

Notes

Not a Number (NaN), positive infinity and negative infinity evaluate to True because these are not equal to zero.

Examples

all

True, because nonzero integers are considered True.

```
>>> pd.Index([1, 2, 3]).all()
True
```

False, because 0 is considered False.

```
>>> pd.Index([0, 1, 2]).all()
False
```

any

True, because 1 is considered True.

```
>>> pd.Index([0, 0, 1]).any()
True
```

False, because 0 is considered False.

```
>>> pd.Index([0, 0, 0]).any()
False
```

pandas.Index.any

`Index.any`(*self*, *args, **kwargs)

Return whether any element is True.

Parameters

***args** These parameters will be passed to `numpy.any`.

****kwargs** These parameters will be passed to `numpy.any`.

Returns

any [bool or array_like (if axis is specified)] A single element array_like may be converted to bool.

See also:

Index.all Return whether all elements are True.

Series.all Return whether all elements are True.

Notes

Not a Number (NaN), positive infinity and negative infinity evaluate to True because these are not equal to zero.

Examples

```
>>> index = pd.Index([0, 1, 2])
>>> index.any()
True
```

```
>>> index = pd.Index([0, 0, 0])
>>> index.any()
False
```

pandas.Index.append

Index.append(*self*, *other*)

Append a collection of Index options together.

Parameters

other [Index or list/tuple of indices]

Returns

appended [Index]

pandas.Index.argmax

Index.argmax(*self*, *axis=None*, *skipna=True*, **args*, ***kwargs*)

Return an ndarray of the maximum argument indexer.

Parameters

axis [{None}] Dummy argument for consistency with Series

skipna [bool, default True]

Returns

numpy.ndarray Indices of the maximum values.

See also:

[numpy.ndarray.argmax](#)

pandas.Index.argmax

`Index.argmax(self, axis=None, skipna=True, *args, **kwargs)`

Return a ndarray of the minimum argument indexer.

Parameters

`axis` [{None}] Dummy argument for consistency with Series

`skipna` [bool, default True]

Returns

`numpy.ndarray`

See also:

`numpy.ndarray.argmax`

pandas.Index.argsort

`Index.argsort(self, *args, **kwargs)`

Return the integer indices that would sort the index.

Parameters

`*args` Passed to `numpy.ndarray.argsort`.

`**kwargs` Passed to `numpy.ndarray.argsort`.

Returns

`numpy.ndarray` Integer indices that would sort the index if used as an indexer.

See also:

`numpy.argsort` Similar method for NumPy arrays.

`Index.sort_values` Return sorted copy of Index.

Examples

```
>>> idx = pd.Index(['b', 'a', 'd', 'c'])
>>> idx
Index(['b', 'a', 'd', 'c'], dtype='object')
```

```
>>> order = idx.argsort()
>>> order
array([1, 0, 3, 2])
```

```
>>> idx[order]
Index(['a', 'b', 'c', 'd'], dtype='object')
```

pandas.Index.asof**Index.asof**(*self*, *label*)

Return the label from the index, or, if not present, the previous one.

Assuming that the index is sorted, return the passed index label if it is in the index, or return the previous index label if the passed one is not in the index.

Parameters**label** [object] The label up to which the method returns the latest index label.**Returns****object** The passed label if it is in the index. The previous label if the passed label is not in the sorted index or *NaN* if there is no such label.**See also:****Series.asof** Return the latest value in a Series up to the passed index.**merge_asof** Perform an asof merge (similar to left join but it matches on nearest key rather than equal key).**Index.get_loc** An *asof* is a thin wrapper around *get_loc* with *method='pad'*.**Examples***Index.asof* returns the latest index label up to the passed label.

```
>>> idx = pd.Index(['2013-12-31', '2014-01-02', '2014-01-03'])
>>> idx.asof('2014-01-01')
'2013-12-31'
```

If the label is in the index, the method returns the passed label.

```
>>> idx.asof('2014-01-02')
'2014-01-02'
```

If all of the labels in the index are later than the passed label, NaN is returned.

```
>>> idx.asof('1999-01-02')
nan
```

If the index is not sorted, an error is raised.

```
>>> idx_not_sorted = pd.Index(['2013-12-31', '2015-01-02',
...                             '2014-01-03'])
>>> idx_not_sorted.asof('2013-12-31')
Traceback (most recent call last):
ValueError: index must be monotonic increasing or decreasing
```

pandas.Index.asof_locs**Index.asof_locs**(*self*, *where*, *mask*)Find the locations (indices) of the labels from the index for every entry in the *where* argument.

As in the *asof* function, if the label (a particular entry in *where*) is not in the index, the latest index label upto the passed label is chosen and its index returned.

If all of the labels in the index are later than a label in *where*, -1 is returned.

mask is used to ignore NA values in the index during calculation.

Parameters

where [Index] An Index consisting of an array of timestamps.

mask [array-like] Array of booleans denoting where values in the original data are not NA.

Returns

numpy.ndarray An array of locations (indices) of the labels from the Index which correspond to the return values of the *asof* function for every element in *where*.

pandas.Index.astype

`Index.astype(self, dtype, copy=True)`

Create an Index with values cast to dtypes. The class of a new Index is determined by dtype. When conversion is impossible, a ValueError exception is raised.

Parameters

dtype [numpy dtype or pandas type] Note that any signed integer *dtype* is treated as 'int64', and any unsigned integer *dtype* is treated as 'uint64', regardless of the size.

copy [bool, default True] By default, *astype* always returns a newly allocated object. If *copy* is set to False and internal requirements on dtype are satisfied, the original data is used to create a new Index or the original Index is returned.

New in version 0.19.0.

Returns

Index Index with values cast to specified dtype.

pandas.Index.contains

`Index.contains(self, key)`

Return a boolean indicating whether the provided key is in the index.

Deprecated since version 0.25.0: Use `key in index` instead of `index.contains(key)`.

Returns

bool

pandas.Index.copy

`Index.copy(self, name=None, deep=False, dtype=None, **kwargs)`

Make a copy of this object. Name and dtype sets those attributes on the new object.

Parameters

name [string, optional]

deep [boolean, default False]
dtype [numpy dtype or pandas type]

Returns

copy [Index]

Notes

In most cases, there should be no functional difference from using `deep`, but if `deep` is passed it will attempt to deepcopy.

pandas.Index.delete

`Index.delete(self, loc)`

Make new Index with passed location(-s) deleted.

Returns

new_index [Index]

pandas.Index.difference

`Index.difference(self, other, sort=None)`

Return a new Index with elements from the index that are not in *other*.

This is the set difference of two Index objects.

Parameters

other [Index or array-like]

sort [False or None, default None] Whether to sort the resulting index. By default, the values are attempted to be sorted, but any `TypeError` from incomparable elements is caught by pandas.

- None : Attempt to sort the result, but catch any `TypeError`s from comparing incomparable elements.
- False : Do not sort the result.

New in version 0.24.0.

Changed in version 0.24.1: Changed the default value from `True` to `None` (without change in behaviour).

Returns

difference [Index]

Examples

```
>>> idx1 = pd.Index([2, 1, 3, 4])
>>> idx2 = pd.Index([3, 4, 5, 6])
>>> idx1.difference(idx2)
Int64Index([1, 2], dtype='int64')
```

(continues on next page)

(continued from previous page)

```
>>> idx1.difference(idx2, sort=False)
Int64Index([2, 1], dtype='int64')
```

pandas.Index.drop

`Index.drop(self, labels, errors='raise')`

Make new Index with passed list of labels deleted.

Parameters

labels [array-like]

errors [{'ignore', 'raise'}, default 'raise'] If 'ignore', suppress error and existing labels are dropped.

Returns

dropped [Index]

Raises

KeyError If not all of the labels are found in the selected axis

pandas.Index.drop_duplicates

`Index.drop_duplicates(self, keep='first')`

Return Index with duplicate values removed.

Parameters

keep [{'first', 'last', False}, default 'first']

- 'first' : Drop duplicates except for the first occurrence.
- 'last' : Drop duplicates except for the last occurrence.
- False : Drop all duplicates.

Returns

deduplicated [Index]

See also:

Series.drop_duplicates Equivalent method on Series.

DataFrame.drop_duplicates Equivalent method on DataFrame.

Index.duplicated Related method on Index, indicating duplicate Index values.

Examples

Generate an pandas.Index with duplicate values.

```
>>> idx = pd.Index(['lama', 'cow', 'lama', 'beetle', 'lama', 'hippo'])
```

The *keep* parameter controls which duplicate values are removed. The value 'first' keeps the first occurrence for each set of duplicated entries. The default value of *keep* is 'first'.

```
>>> idx.drop_duplicates(keep='first')
Index(['lama', 'cow', 'beetle', 'hippo'], dtype='object')
```

The value 'last' keeps the last occurrence for each set of duplicated entries.

```
>>> idx.drop_duplicates(keep='last')
Index(['cow', 'beetle', 'lama', 'hippo'], dtype='object')
```

The value `False` discards all sets of duplicated entries.

```
>>> idx.drop_duplicates(keep=False)
Index(['cow', 'beetle', 'hippo'], dtype='object')
```

pandas.Index.droplevel

`Index.droplevel(self, level=0)`

Return index with requested level(s) removed.

If resulting index has only 1 level left, the result will be of `Index` type, not `MultiIndex`.

New in version 0.23.1: (support for non-`MultiIndex`)

Parameters

level [int, str, or list-like, default 0] If a string is given, must be the name of a level. If list-like, elements must be names or indexes of levels.

Returns

`Index` or `MultiIndex`

pandas.Index.dropna

`Index.dropna(self, how='any')`

Return `Index` without NA/NaN values

Parameters

how [{'any', 'all'}, default 'any'] If the `Index` is a `MultiIndex`, drop the value when any or all levels are NaN.

Returns

`valid` [`Index`]

pandas.Index.duplicated

`Index.duplicated(self, keep='first')`

Indicate duplicate index values.

Duplicated values are indicated as `True` values in the resulting array. Either all duplicates, all except the first, or all except the last occurrence of duplicates can be indicated.

Parameters

keep [{'first', 'last', `False`}, default 'first'] The value or values in a set of duplicates to mark as missing.

- ‘first’ : Mark duplicates as `True` except for the first occurrence.
- ‘last’ : Mark duplicates as `True` except for the last occurrence.
- `False` : Mark all duplicates as `True`.

Returns

`numpy.ndarray`

See also:

`Series.duplicated` Equivalent method on `pandas.Series`.

`DataFrame.duplicated` Equivalent method on `pandas.DataFrame`.

`Index.drop_duplicates` Remove duplicate values from `Index`.

Examples

By default, for each set of duplicated values, the first occurrence is set to `False` and all others to `True`:

```
>>> idx = pd.Index(['lama', 'cow', 'lama', 'beetle', 'lama'])
>>> idx.duplicated()
array([False, False,  True, False,  True])
```

which is equivalent to

```
>>> idx.duplicated(keep='first')
array([False, False,  True, False,  True])
```

By using ‘last’, the last occurrence of each set of duplicated values is set on `False` and all others on `True`:

```
>>> idx.duplicated(keep='last')
array([ True, False,  True, False, False])
```

By setting `keep` on `False`, all duplicates are `True`:

```
>>> idx.duplicated(keep=False)
array([ True, False,  True, False,  True])
```

`pandas.Index.equals`

`Index.equals(self, other)`

Determine if two `Index` objects contain the same elements.

Returns

bool `True` if “other” is an `Index` and it has the same elements as calling `index`;
`False` otherwise.

pandas.Index.factorize

`Index.factorize(self, sort=False, na_sentinel=-1)`

Encode the object as an enumerated type or categorical variable.

This method is useful for obtaining a numeric representation of an array when all that matters is identifying distinct values. `factorize` is available as both a top-level function `pandas.factorize()`, and as a method `Series.factorize()` and `Index.factorize()`.

Parameters

sort [boolean, default False] Sort *uniques* and shuffle *labels* to maintain the relationship.

na_sentinel [int, default -1] Value to mark “not found”.

Returns

labels [ndarray] An integer ndarray that’s an indexer into *uniques*. `uniques.take(labels)` will have the same values as *values*.

uniques [ndarray, Index, or Categorical] The unique valid values. When *values* is Categorical, *uniques* is a Categorical. When *values* is some other pandas object, an *Index* is returned. Otherwise, a 1-D ndarray is returned.

Note: Even if there’s a missing value in *values*, *uniques* will *not* contain an entry for it.

See also:

cut Discretize continuous-valued array.

unique Find the unique value in an array.

Examples

These examples all show `factorize` as a top-level method like `pd.factorize(values)`. The results are identical for methods like `Series.factorize()`.

```
>>> labels, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'])
>>> labels
array([0, 0, 1, 2, 0])
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

With `sort=True`, the *uniques* will be sorted, and *labels* will be shuffled so that the relationship is the maintained.

```
>>> labels, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'], sort=True)
>>> labels
array([1, 1, 0, 2, 1])
>>> uniques
array(['a', 'b', 'c'], dtype=object)
```

Missing values are indicated in *labels* with `na_sentinel` (-1 by default). Note that missing values are never included in *uniques*.

```
>>> labels, uniques = pd.factorize(['b', None, 'a', 'c', 'b'])
>>> labels
array([ 0, -1,  1,  2,  0])
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

Thus far, we've only factorized lists (which are internally coerced to NumPy arrays). When factorizing pandas objects, the type of *uniques* will differ. For Categoricals, a *Categorical* is returned.

```
>>> cat = pd.Categorical(['a', 'a', 'c'], categories=['a', 'b', 'c'])
>>> labels, uniques = pd.factorize(cat)
>>> labels
array([0, 0, 1])
>>> uniques
[a, c]
Categories (3, object): [a, b, c]
```

Notice that 'b' is in `uniques.categories`, despite not being present in `cat.values`.

For all other pandas objects, an Index of the appropriate type is returned.

```
>>> cat = pd.Series(['a', 'a', 'c'])
>>> labels, uniques = pd.factorize(cat)
>>> labels
array([0, 0, 1])
>>> uniques
Index(['a', 'c'], dtype='object')
```

pandas.Index.fillna

`Index.fillna(self, value=None, downcast=None)`

Fill NA/NaN values with the specified value

Parameters

value [scalar] Scalar value to use to fill holes (e.g. 0). This value cannot be a list-likes.

downcast [dict, default is None] a dict of item->dtype of what to downcast if possible, or the string 'infer' which will try to downcast to an appropriate equal type (e.g. float64 to int64 if possible)

Returns

filled [Index]

pandas.Index.format

`Index.format(self, name=False, formatter=None, **kwargs)`

Render a string representation of the Index.

pandas.Index.get_duplicates**Index.get_duplicates**(*self*)

Extract duplicated index elements.

Deprecated since version 0.23.0: Use `idx[idx.duplicated()].unique()` instead

Returns a sorted list of index elements which appear more than once in the index.

Returns**array-like** List of duplicated indexes.**See also:****Index.duplicated** Return boolean array denoting duplicates.**Index.drop_duplicates** Return Index with duplicates removed.**Examples**

Works on different Index of types.

```
>>> pd.Index([1, 2, 2, 3, 3, 3, 4]).get_duplicates() # doctest: +SKIP
[2, 3]
```

Note that for a DatetimeIndex, it does not return a list but a new DatetimeIndex:

```
>>> dates = pd.to_datetime(['2018-01-01', '2018-01-02', '2018-01-03',
...                          '2018-01-03', '2018-01-04', '2018-01-04'],
...                          format='%Y-%m-%d')
>>> pd.Index(dates).get_duplicates() # doctest: +SKIP
DatetimeIndex(['2018-01-03', '2018-01-04'],
              dtype='datetime64[ns]', freq=None)
```

Sorts duplicated elements even when indexes are unordered.

```
>>> pd.Index([1, 2, 3, 2, 3, 4, 3]).get_duplicates() # doctest: +SKIP
[2, 3]
```

Return empty array-like structure when all elements are unique.

```
>>> pd.Index([1, 2, 3, 4]).get_duplicates() # doctest: +SKIP
[]
>>> dates = pd.to_datetime(['2018-01-01', '2018-01-02', '2018-01-03'],
...                          format='%Y-%m-%d')
>>> pd.Index(dates).get_duplicates() # doctest: +SKIP
DatetimeIndex([], dtype='datetime64[ns]', freq=None)
```

pandas.Index.get_indexer**Index.get_indexer**(*self*, *target*, *method=None*, *limit=None*, *tolerance=None*)Compute indexer and mask for new index given the current index. The indexer should be then used as an input to `ndarray.take` to align the current data to the new index.**Parameters**

target [Index]

method [{None, 'pad'/'ffill', 'backfill'/'bfill', 'nearest'}, optional]

- default: exact matches only.
- pad / ffill: find the PREVIOUS index value if no exact match.
- backfill / bfill: use NEXT index value if no exact match
- nearest: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.

limit [int, optional] Maximum number of consecutive labels in **target** to match for inexact matches.

tolerance [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations most satisfy the equation $\text{abs}(\text{index}[\text{indexer}] - \text{target}) \leq \text{tolerance}$.

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index's type.

New in version 0.21.0: (list-like tolerance)

Returns

indexer [ndarray of int] Integers from 0 to n - 1 indicating that the index at these positions matches the corresponding target values. Missing values in the target are marked by -1.

Examples

```
>>> index = pd.Index(['c', 'a', 'b'])
>>> index.get_indexer(['a', 'b', 'x'])
array([ 1,  2, -1])
```

Notice that the return value is an array of locations in **index** and **x** is marked by -1, as it is not in **index**.

pandas.Index.get_indexer_for

`Index.get_indexer_for(self, target, **kwargs)`

Guaranteed return of an indexer even when non-unique.

This dispatches to `get_indexer` or `get_indexer_nonunique` as appropriate.

Returns

numpy.ndarray List of indices.

pandas.Index.get_indexer_non_unique

`Index.get_indexer_non_unique(self, target)`

Compute indexer and mask for new index given the current index. The indexer should be then used as an input to `ndarray.take` to align the current data to the new index.

Parameters**target** [Index]**Returns****indexer** [ndarray of int] Integers from 0 to n - 1 indicating that the index at these positions matches the corresponding target values. Missing values in the target are marked by -1.**missing** [ndarray of int] An indexer into the target of the values not found. These correspond to the -1 in the indexer array.**pandas.Index.get_level_values****Index.get_level_values**(*self*, *level*)

Return an Index of values for requested level.

This is primarily useful to get an individual level of values from a MultiIndex, but is provided on Index as well for compatibility.

Parameters**level** [int or str] It is either the integer position or the name of the level.**Returns****Index** Calling object, as there is only one level in the Index.**See also:****MultiIndex.get_level_values** Get values for a level of a MultiIndex.**Notes**

For Index, level should be 0, since there are no multiple levels.

Examples

```
>>> idx = pd.Index(list('abc'))
>>> idx
Index(['a', 'b', 'c'], dtype='object')
```

Get level values by supplying *level* as integer:

```
>>> idx.get_level_values(0)
Index(['a', 'b', 'c'], dtype='object')
```

pandas.Index.get_loc**Index.get_loc**(*self*, *key*, *method=None*, *tolerance=None*)

Get integer location, slice or boolean mask for requested label.

Parameters**key** [label]

method [{None, 'pad'/'ffill', 'backfill'/'bfill', 'nearest'}, optional]

- default: exact matches only.
- pad / ffill: find the PREVIOUS index value if no exact match.
- backfill / bfill: use NEXT index value if no exact match
- nearest: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.

tolerance [int or float, optional] Maximum distance from index value for inexact matches. The value of the index at the matching location most satisfy the equation $\text{abs}(\text{index}[\text{loc}] - \text{key}) \leq \text{tolerance}$.

New in version 0.21.0: (list-like tolerance)

Returns

loc [int if unique index, slice if monotonic index, else mask]

Examples

```
>>> unique_index = pd.Index(list('abc'))
>>> unique_index.get_loc('b')
1
```

```
>>> monotonic_index = pd.Index(list('abbc'))
>>> monotonic_index.get_loc('b')
slice(1, 3, None)
```

```
>>> non_monotonic_index = pd.Index(list('abcb'))
>>> non_monotonic_index.get_loc('b')
array([False,  True,  False,  True], dtype=bool)
```

pandas.Index.get_slice_bound

`Index.get_slice_bound(self, label, side, kind)`

Calculate slice bound that corresponds to given label.

Returns leftmost (one-past-the-rightmost if `side=='right'`) position of given label.

Parameters

- label** [object]
- side** [{'left', 'right'}]
- kind** [{'ix', 'loc', 'getitem'}]

Returns

int Index of label.

pandas.Index.get_value

`Index.get_value(self, series, key)`

Fast lookup of value from 1-dimensional ndarray. Only use this if you know what you're doing.

Returns

scalar A value in the Series with the index of the key value in self.

pandas.Index.get_values

`Index.get_values(self)`

Return *Index* data as an *numpy.ndarray*.

Deprecated since version 0.25.0: Use *Index.to_numpy()* or *Index.array* instead.

Returns

numpy.ndarray A one-dimensional numpy array of the *Index* values.

See also:

Index.values The attribute that *get_values* wraps.

Examples

Getting the *Index* values of a *DataFrame*:

```
>>> df = pd.DataFrame([[1, 2, 3], [4, 5, 6], [7, 8, 9]],
...                    index=['a', 'b', 'c'], columns=['A', 'B', 'C'])
>>> df
   A  B  C
a  1  2  3
b  4  5  6
c  7  8  9
>>> df.index.get_values()
array(['a', 'b', 'c'], dtype=object)
```

Standalone *Index* values:

```
>>> idx = pd.Index(['1', '2', '3'])
>>> idx.get_values()
array(['1', '2', '3'], dtype=object)
```

MultiIndex arrays also have only one dimension:

```
>>> midx = pd.MultiIndex.from_arrays([[1, 2, 3], ['a', 'b', 'c']],
...                                  names=('number', 'letter'))
>>> midx.get_values()
array([(1, 'a'), (2, 'b'), (3, 'c')], dtype=object)
>>> midx.get_values().ndim
1
```

pandas.Index.groupby

`Index.groupby(self, values)`

Group the index labels by a given array of values.

Parameters

values [array] Values used to determine the groups.

Returns

groups [dict] {group name -> group labels}

pandas.Index.holds_integer

`Index.holds_integer(self)`

Whether the type is an integer type.

pandas.Index.identical

`Index.identical(self, other)`

Similar to equals, but check that other comparable attributes are also equal.

Returns

bool If two Index objects have equal elements and same type True, otherwise False.

pandas.Index.insert

`Index.insert(self, loc, item)`

Make new Index inserting new item at location.

Follows Python list.append semantics for negative values.

Parameters

loc [int]

item [object]

Returns

new_index [Index]

pandas.Index.intersection

`Index.intersection(self, other, sort=False)`

Form the intersection of two Index objects.

This returns a new Index with elements common to the index and *other*.

Parameters

other [Index or array-like]

sort [False or None, default False] Whether to sort the resulting index.

- False : do not sort the result.
- None : sort the result, except when *self* and *other* are equal or when the values cannot be compared.

New in version 0.24.0.

Changed in version 0.24.1: Changed the default from `True` to `False`, to match the behaviour of 0.23.4 and earlier.

Returns

intersection [Index]

Examples

```
>>> idx1 = pd.Index([1, 2, 3, 4])
>>> idx2 = pd.Index([3, 4, 5, 6])
>>> idx1.intersection(idx2)
Int64Index([3, 4], dtype='int64')
```

pandas.Index.is_

`Index.is_(self, other)`

More flexible, faster check like `is` but that works through views.

Note: this is *not* the same as `Index.identical()`, which checks that metadata is also the same.

Parameters

other [object] other object to compare against.

Returns

True if both have same underlying data, False otherwise [bool]

pandas.Index.is_categorical

`Index.is_categorical(self)`

Check if the Index holds categorical data.

Returns

boolean True if the Index is categorical.

See also:

CategoricalIndex Index for categorical data.

Examples

```
>>> idx = pd.Index(["Watermelon", "Orange", "Apple",
...                 "Watermelon"]).astype("category")
>>> idx.is_categorical()
True
```

```
>>> idx = pd.Index([1, 3, 5, 7])
>>> idx.is_categorical()
False
```

```
>>> s = pd.Series(["Peter", "Victor", "Elisabeth", "Mar"])
>>> s
0      Peter
1      Victor
2  Elisabeth
3         Mar
dtype: object
>>> s.index.is_categorical()
False
```

pandas.Index.is_type_compatible

`Index.is_type_compatible(self, kind)`

Whether the index type is compatible with the provided type.

pandas.Index.isin

`Index.isin(self, values, level=None)`

Return a boolean array where the index values are in *values*.

Compute boolean array of whether each index value is found in the passed set of values. The length of the returned boolean array matches the length of the index.

Parameters

values [set or list-like] Sought values.

New in version 0.18.1: Support for values as a set.

level [str or int, optional] Name or position of the index level to use (if the index is a *MultiIndex*).

Returns

is_contained [ndarray] NumPy array of boolean values.

See also:

Series.isin Same for Series.

DataFrame.isin Same method for DataFrames.

Notes

In the case of *MultiIndex* you must either specify *values* as a list-like object containing tuples that are the same length as the number of levels, or specify *level*. Otherwise it will raise a **ValueError**.

If *level* is specified:

- if it is the name of one *and only one* index level, use that level;
- otherwise it should be a number indicating level position.

Examples

```
>>> idx = pd.Index([1,2,3])
>>> idx
Int64Index([1, 2, 3], dtype='int64')
```

Check whether each index value in a list of values. `>>> idx.isin([1, 4])` `array([True, False, False])`

```
>>> midx = pd.MultiIndex.from_arrays([[1,2,3],
...                                  ['red', 'blue', 'green']],
...                                  names=('number', 'color'))
>>> midx
MultiIndex(levels=[[1, 2, 3], ['blue', 'green', 'red']],
            codes=[[0, 1, 2], [2, 0, 1]],
            names=['number', 'color'])
```

Check whether the strings in the ‘color’ level of the MultiIndex are in a list of colors.

```
>>> midx.isin(['red', 'orange', 'yellow'], level='color')
array([ True, False, False])
```

To check across the levels of a MultiIndex, pass a list of tuples:

```
>>> midx.isin([(1, 'red'), (3, 'red')])
array([ True, False, False])
```

For a DatetimeIndex, string values in *values* are converted to Timestamps.

```
>>> dates = ['2000-03-11', '2000-03-12', '2000-03-13']
>>> dti = pd.to_datetime(dates)
>>> dti
DatetimeIndex(['2000-03-11', '2000-03-12', '2000-03-13'],
              dtype='datetime64[ns]', freq=None)
```

```
>>> dti.isin(['2000-03-11'])
array([ True, False, False])
```

pandas.Index.isna

Index.isna(*self*)

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as `None`, `numpy.NaN` or `pd.NaT`, get mapped to `True` values. Everything else get mapped to `False` values. Characters such as empty strings `''` or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`).

New in version 0.20.0.

Returns

`numpy.ndarray` A boolean array of whether my values are NA.

See also:

Index.notna Boolean inverse of `isna`.

Index.dropna Omit entries with missing values.

isna Top-level `isna`.

Series.isna Detect missing values in Series object.

Examples

Show which entries in a `pandas.Index` are NA. The result is an array.

```
>>> idx = pd.Index([5.2, 6.0, np.NaN])
>>> idx
Float64Index([5.2, 6.0, nan], dtype='float64')
>>> idx.isna()
array([False, False,  True], dtype=bool)
```

Empty strings are not considered NA values. `None` is considered an NA value.

```
>>> idx = pd.Index(['black', '', 'red', None])
>>> idx
Index(['black', '', 'red', None], dtype='object')
>>> idx.isna()
array([False, False, False,  True], dtype=bool)
```

For datetimes, `NaT` (Not a Time) is considered as an NA value.

```
>>> idx = pd.DatetimeIndex([pd.Timestamp('1940-04-25'),
...                          pd.Timestamp(''), None, pd.NaT])
>>> idx
DatetimeIndex(['1940-04-25', 'NaT', 'NaT', 'NaT'],
              dtype='datetime64[ns]', freq=None)
>>> idx.isna()
array([False,  True,  True,  True], dtype=bool)
```

`pandas.Index.isnull`

`Index.isnull(self)`

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as `None`, `numpy.NaN` or `pd.NaT`, get mapped to `True` values. Everything else get mapped to `False` values. Characters such as empty strings `''` or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`).

New in version 0.20.0.

Returns

numpy.ndarray A boolean array of whether my values are NA.

See also:

Index.notna Boolean inverse of `isna`.

Index.dropna Omit entries with missing values.

isna Top-level isna.

Series.isna Detect missing values in Series object.

Examples

Show which entries in a pandas.Index are NA. The result is an array.

```
>>> idx = pd.Index([5.2, 6.0, np.NaN])
>>> idx
Float64Index([5.2, 6.0, nan], dtype='float64')
>>> idx.isna()
array([False, False,  True], dtype=bool)
```

Empty strings are not considered NA values. None is considered an NA value.

```
>>> idx = pd.Index(['black', '', 'red', None])
>>> idx
Index(['black', '', 'red', None], dtype='object')
>>> idx.isna()
array([False, False, False,  True], dtype=bool)
```

For datetimes, *NaT* (Not a Time) is considered as an NA value.

```
>>> idx = pd.DatetimeIndex([pd.Timestamp('1940-04-25'),
...                          pd.Timestamp(''), None, pd.NaT])
>>> idx
DatetimeIndex(['1940-04-25', 'NaT', 'NaT', 'NaT'],
              dtype='datetime64[ns]', freq=None)
>>> idx.isna()
array([False,  True,  True,  True], dtype=bool)
```

pandas.Index.item

Index.item(*self*)

Return the first element of the underlying data as a python scalar.

Returns

scalar The first element of %(klass)s.

pandas.Index.join

Index.join(*self*, *other*, *how*='left', *level*=None, *return_indexers*=False, *sort*=False)

Compute *join_index* and *indexers* to conform data structures to the new index.

Parameters

other [Index]

how [{'left', 'right', 'inner', 'outer'}]

level [int or level name, default None]

return_indexers [boolean, default False]

sort [boolean, default False] Sort the join keys lexicographically in the result Index. If False, the order of the join keys depends on the join type (how keyword)

New in version 0.20.0.

Returns

join_index, (**left_indexer**, **right_indexer**)

pandas.Index.map

`Index.map(self, mapper, na_action=None)`

Map values using input correspondence (a dict, Series, or function).

Parameters

mapper [function, dict, or Series] Mapping correspondence.

na_action [{None, 'ignore'}] If 'ignore', propagate NA values, without passing them to the mapping correspondence.

Returns

applied [Union[Index, MultiIndex], inferred] The output of the mapping function applied to the index. If the function returns a tuple with more than one element a MultiIndex will be returned.

pandas.Index.max

`Index.max(self, axis=None, skipna=True, *args, **kwargs)`

Return the maximum value of the Index.

Parameters

axis [int, optional] For compatibility with NumPy. Only 0 or None are allowed.

skipna [bool, default True]

Returns

scalar Maximum value.

See also:

Index.min Return the minimum value in an Index.

Series.max Return the maximum value in a Series.

DataFrame.max Return the maximum values in a DataFrame.

Examples

```
>>> idx = pd.Index([3, 2, 1])
>>> idx.max()
3
```

```
>>> idx = pd.Index(['c', 'b', 'a'])
>>> idx.max()
'c'
```

For a MultiIndex, the maximum is determined lexicographically.

```
>>> idx = pd.MultiIndex.from_product(['a', 'b'], (2, 1))
>>> idx.max()
('b', 2)
```

pandas.Index.memory_usage

`Index.memory_usage(self, deep=False)`

Memory usage of the values

Parameters

deep [bool] Introspect the data deeply, interrogate *object* dtypes for system-level memory consumption

Returns

bytes used

See also:

[numpy.ndarray.nbytes](#)

Notes

Memory usage does not include memory consumed by elements that are not components of the array if `deep=False` or if used on PyPy

pandas.Index.min

`Index.min(self, axis=None, skipna=True, *args, **kwargs)`

Return the minimum value of the Index.

Parameters

axis [{None}] Dummy argument for consistency with Series

skipna [bool, default True]

Returns

scalar Minimum value.

See also:

Index.max Return the maximum value of the object.

Series.min Return the minimum value in a Series.

DataFrame.min Return the minimum values in a DataFrame.

Examples

```
>>> idx = pd.Index([3, 2, 1])
>>> idx.min()
1
```

```
>>> idx = pd.Index(['c', 'b', 'a'])
>>> idx.min()
'a'
```

For a MultiIndex, the minimum is determined lexicographically.

```
>>> idx = pd.MultiIndex.from_product(['a', 'b'], (2, 1))
>>> idx.min()
('a', 1)
```

pandas.Index.notna

Index.notna(*self*)

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to **True**. Characters such as empty strings '' or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`). NA values, such as `None` or `numpy.NaN`, get mapped to **False** values.

New in version 0.20.0.

Returns

numpy.ndarray Boolean array to indicate which entries are not NA.

See also:

Index.notnull Alias of `notna`.

Index.isna Inverse of `notna`.

notna Top-level `notna`.

Examples

Show which entries in an Index are not NA. The result is an array.

```
>>> idx = pd.Index([5.2, 6.0, np.NaN])
>>> idx
Float64Index([5.2, 6.0, nan], dtype='float64')
>>> idx.notna()
array([ True,  True, False])
```

Empty strings are not considered NA values. `None` is considered a NA value.

```
>>> idx = pd.Index(['black', '', 'red', None])
>>> idx
Index(['black', '', 'red', None], dtype='object')
>>> idx.notna()
array([ True,  True,  True, False])
```

pandas.Index.notnull

`Index.notnull(self)`

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to `True`. Characters such as empty strings `''` or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`). NA values, such as `None` or `numpy.NaN`, get mapped to `False` values.

New in version 0.20.0.

Returns

numpy.ndarray Boolean array to indicate which entries are not NA.

See also:

Index.notnull Alias of `notna`.

Index.isna Inverse of `notna`.

notna Top-level `notna`.

Examples

Show which entries in an `Index` are not NA. The result is an array.

```
>>> idx = pd.Index([5.2, 6.0, np.NaN])
>>> idx
Float64Index([5.2, 6.0, nan], dtype='float64')
>>> idx.notna()
array([ True,  True, False])
```

Empty strings are not considered NA values. `None` is considered a NA value.

```
>>> idx = pd.Index(['black', '', 'red', None])
>>> idx
Index(['black', '', 'red', None], dtype='object')
>>> idx.notna()
array([ True,  True,  True, False])
```

pandas.Index.nunique

`Index.nunique(self, dropna=True)`

Return number of unique elements in the object.

Excludes NA values by default.

Parameters

dropna [bool, default True] Don't include NaN in the count.

Returns

int

See also:

DataFrame.unique Method unique for DataFrame.

Series.count Count non-NA/null observations in the Series.

Examples

```
>>> s = pd.Series([1, 3, 5, 7, 7])
>>> s
0    1
1    3
2    5
3    7
4    7
dtype: int64
```

```
>>> s.nunique()
4
```

pandas.Index.putmask

Index.putmask(self, mask, value)

Return a new Index of the values set with the mask.

Returns

Index

See also:

`numpy.ndarray.putmask`

pandas.Index.ravel

Index.ravel(self, order='C')

Return an ndarray of the flattened values of the underlying data.

Returns

numpy.ndarray Flattened array.

See also:

`numpy.ndarray.ravel`

pandas.Index.reindex

`Index.reindex(self, target, method=None, level=None, limit=None, tolerance=None)`
 Create index with target's values (move/add/delete values as necessary).

Parameters

target [an iterable]

Returns

new_index [pd.Index] Resulting index.

indexer [np.ndarray or None] Indices of output values in original index.

pandas.Index.rename

`Index.rename(self, name, inplace=False)`
 Alter Index or MultiIndex name.

Able to set new names without level. Defaults to returning new index. Length of names must match number of levels in MultiIndex.

Parameters

name [label or list of labels] Name(s) to set.

inplace [boolean, default False] Modifies the object directly, instead of creating a new Index or MultiIndex.

Returns

Index The same type as the caller or None if inplace is True.

See also:

`Index.set_names` Able to set new names partially and by level.

Examples

```
>>> idx = pd.Index(['A', 'C', 'A', 'B'], name='score')
>>> idx.rename('grade')
Index(['A', 'C', 'A', 'B'], dtype='object', name='grade')
```

```
>>> idx = pd.MultiIndex.from_product([['python', 'cobra'],
...                                  [2018, 2019]],
...                                  names=['kind', 'year'])
>>> idx
MultiIndex([('python', 2018),
            ('python', 2019),
            ('cobra', 2018),
            ('cobra', 2019)],
           names=['kind', 'year'])
>>> idx.rename(['species', 'year'])
MultiIndex([('python', 2018),
            ('python', 2019),
```

(continues on next page)

(continued from previous page)

```

        ( 'cobra', 2018),
        ( 'cobra', 2019)],
        names=['species', 'year'])
>>> idx.rename('species')
Traceback (most recent call last):
TypeError: Must pass list-like as `names`.

```

pandas.Index.repeat

`Index.repeat(self, repeats, axis=None)`

Repeat elements of a Index.

Returns a new Index where each element of the current Index is repeated consecutively a given number of times.

Parameters

repeats [int or array of ints] The number of repetitions for each element. This should be a non-negative integer. Repeating 0 times will return an empty Index.

axis [None] Must be None. Has no effect but is accepted for compatibility with numpy.

Returns

repeated_index [Index] Newly created Index with repeated elements.

See also:

Series.repeat Equivalent function for Series.

numpy.repeat Similar method for `numpy.ndarray`.

Examples

```

>>> idx = pd.Index(['a', 'b', 'c'])
>>> idx
Index(['a', 'b', 'c'], dtype='object')
>>> idx.repeat(2)
Index(['a', 'a', 'b', 'b', 'c', 'c'], dtype='object')
>>> idx.repeat([1, 2, 3])
Index(['a', 'b', 'b', 'c', 'c', 'c'], dtype='object')

```

pandas.Index.searchsorted

`Index.searchsorted(self, value, side='left', sorter=None)`

Find indices where elements should be inserted to maintain order.

Find the indices into a sorted Index *self* such that, if the corresponding elements in *value* were inserted before the indices, the order of *self* would be preserved.

Parameters

value [array_like] Values to insert into *self*.

side [{'left', 'right'}, optional] If 'left', the index of the first suitable location found is given. If 'right', return the last such index. If there is no suitable index, return either 0 or N (where N is the length of *self*).

sorter [1-D array_like, optional] Optional array of integer indices that sort *self* into ascending order. They are typically the result of `np.argsort`.

Returns

int or array of int A scalar or array of insertion points with the same shape as *value*.

Changed in version 0.24.0: If *value* is a scalar, an int is now always returned. Previously, scalar inputs returned an 1-item array for *Series* and *Categorical*.

See also:

`numpy.searchsorted`

Notes

Binary search is used to find the required insertion points.

Examples

```
>>> x = pd.Series([1, 2, 3])
>>> x
0    1
1    2
2    3
dtype: int64
```

```
>>> x.searchsorted(4)
3
```

```
>>> x.searchsorted([0, 4])
array([0, 3])
```

```
>>> x.searchsorted([1, 3], side='left')
array([0, 2])
```

```
>>> x.searchsorted([1, 3], side='right')
array([1, 3])
```

```
>>> x = pd.Categorical(['apple', 'bread', 'bread',
                       'cheese', 'milk'], ordered=True)
[apple, bread, bread, cheese, milk]
Categories (4, object): [apple < bread < cheese < milk]
```

```
>>> x.searchsorted('bread')
1
```

```
>>> x.searchsorted(['bread'], side='right')
array([3])
```

pandas.Index.set_names

`Index.set_names(self, names, level=None, inplace=False)`
Set Index or MultiIndex name.

Able to set new names partially and by level.

Parameters

names [label or list of label] Name(s) to set.

level [int, label or list of int or label, optional] If the index is a MultiIndex, level(s) to set (None for all levels). Otherwise level must be None.

inplace [bool, default False] Modifies the object directly, instead of creating a new Index or MultiIndex.

Returns

Index The same type as the caller or None if inplace is True.

See also:

Index.rename Able to set new names without level.

Examples

```
>>> idx = pd.Index([1, 2, 3, 4])
>>> idx
Int64Index([1, 2, 3, 4], dtype='int64')
>>> idx.set_names('quarter')
Int64Index([1, 2, 3, 4], dtype='int64', name='quarter')
```

```
>>> idx = pd.MultiIndex.from_product(['python', 'cobra'],
...                                  [2018, 2019])
>>> idx
MultiIndex([('python', 2018),
            ('python', 2019),
            ('cobra', 2018),
            ('cobra', 2019)],
           )
>>> idx.set_names(['kind', 'year'], inplace=True)
>>> idx
MultiIndex([('python', 2018),
            ('python', 2019),
            ('cobra', 2018),
            ('cobra', 2019)],
           )
```

(continues on next page)

(continued from previous page)

```

        names=['kind', 'year'])
>>> idx.set_names('species', level=0)
MultiIndex([( 'python', 2018),
            ( 'python', 2019),
            ( 'cobra', 2018),
            ( 'cobra', 2019)],
           names=['species', 'year'])

```

pandas.Index.set_value**Index.set_value**(*self*, *arr*, *key*, *value*)

Fast lookup of value from 1-dimensional ndarray.

Notes

Only use this if you know what you're doing.

pandas.Index.shift**Index.shift**(*self*, *periods=1*, *freq=None*)

Shift index by desired number of time frequency increments.

This method is for shifting the values of datetime-like indexes by a specified time increment a given number of times.

Parameters**periods** [int, default 1] Number of periods (or increments) to shift by, can be positive or negative.**freq** [pandas.DateOffset, pandas.Timedelta or string, optional] Frequency increment to shift by. If None, the index is shifted by its own *freq* attribute. Offset aliases are valid strings, e.g., 'D', 'W', 'M' etc.**Returns****pandas.Index** Shifted index.**See also:****Series.shift** Shift values of Series.**Notes**

This method is only implemented for datetime-like index classes, i.e., DatetimeIndex, PeriodIndex and TimedeltaIndex.

Examples

Put the first 5 month starts of 2011 into an index.

```
>>> month_starts = pd.date_range('1/1/2011', periods=5, freq='MS')
>>> month_starts
DatetimeIndex(['2011-01-01', '2011-02-01', '2011-03-01', '2011-04-01',
              '2011-05-01'],
              dtype='datetime64[ns]', freq='MS')
```

Shift the index by 10 days.

```
>>> month_starts.shift(10, freq='D')
DatetimeIndex(['2011-01-11', '2011-02-11', '2011-03-11', '2011-04-11',
              '2011-05-11'],
              dtype='datetime64[ns]', freq=None)
```

The default value of *freq* is the *freq* attribute of the index, which is 'MS' (month start) in this example.

```
>>> month_starts.shift(10)
DatetimeIndex(['2011-11-01', '2011-12-01', '2012-01-01', '2012-02-01',
              '2012-03-01'],
              dtype='datetime64[ns]', freq='MS')
```

pandas.Index.slice_indexer

`Index.slice_indexer(self, start=None, end=None, step=None, kind=None)`

For an ordered or unique index, compute the slice indexer for input labels and step.

Parameters

- start** [label, default None] If None, defaults to the beginning
- end** [label, default None] If None, defaults to the end
- step** [int, default None]
- kind** [string, default None]

Returns

- indexer** [slice]

Raises

- KeyError** [If key does not exist, or key is not unique and index is] not ordered.

Notes

This function assumes that the data is sorted, so use at your own peril

Examples

This is a method on all index types. For example you can do:

```
>>> idx = pd.Index(list('abcd'))
>>> idx.slice_indexer(start='b', end='c')
slice(1, 3)
```

```
>>> idx = pd.MultiIndex.from_arrays([list('abcd'), list('efgh')])
>>> idx.slice_indexer(start='b', end=('c', 'g'))
slice(1, 3)
```

pandas.Index.slice_locs

Index.slice_locs(*self*, *start=None*, *end=None*, *step=None*, *kind=None*)
 Compute slice locations for input labels.

Parameters

start [label, default None] If None, defaults to the beginning
end [label, default None] If None, defaults to the end
step [int, defaults None] If None, defaults to 1
kind [{'ix', 'loc', 'getitem'} or None]

Returns

start, end [int]

See also:

Index.get_loc Get location for a single label.

Notes

This method only works if the index is monotonic or unique.

Examples

```
>>> idx = pd.Index(list('abcd'))
>>> idx.slice_locs(start='b', end='c')
(1, 3)
```

pandas.Index.sort

Index.sort(*self*, **args*, ***kwargs*)
 Use `sort_values` instead.

pandas.Index.sort_values

Index.sort_values(*self*, *return_indexer=False*, *ascending=True*)
 Return a sorted copy of the index.

Return a sorted copy of the index, and optionally return the indices that sorted the index itself.

Parameters

return_indexer [bool, default False] Should the indices that would sort the index be returned.

ascending [bool, default True] Should the index values be sorted in an ascending order.

Returns

sorted_index [pandas.Index] Sorted copy of the index.

indexer [numpy.ndarray, optional] The indices that the index itself was sorted by.

See also:

Series.sort_values Sort values of a Series.

DataFrame.sort_values Sort values in a DataFrame.

Examples

```
>>> idx = pd.Index([10, 100, 1, 1000])
>>> idx
Int64Index([10, 100, 1, 1000], dtype='int64')
```

Sort values in ascending order (default behavior).

```
>>> idx.sort_values()
Int64Index([1, 10, 100, 1000], dtype='int64')
```

Sort values in descending order, and also get the indices *idx* was sorted by.

```
>>> idx.sort_values(ascending=False, return_indexer=True)
(Int64Index([1000, 100, 10, 1], dtype='int64'), array([3, 1, 0, 2]))
```

pandas.Index.sortlevel

Index.sortlevel(*self*, *level=None*, *ascending=True*, *sort_remaining=None*)

For internal compatibility with with the Index API.

Sort the Index. This is for compat with MultiIndex

Parameters

ascending [boolean, default True] False to sort in descending order

level, **sort_remaining** are compat parameters

Returns

Index

pandas.Index.str

Index.str()

Vectorized string functions for Series and Index. NAs stay NA unless handled otherwise by a particular method. Patterned after Python's string methods, with some inspiration from R's stringr package.

Examples

```
>>> s.str.split('_')
>>> s.str.replace('_', '')
```

pandas.Index.summary

`Index.summary(self, name=None)`

Return a summarized representation.

Deprecated since version 0.23.0.

pandas.Index.symmetric_difference

`Index.symmetric_difference(self, other, result_name=None, sort=None)`

Compute the symmetric difference of two Index objects.

Parameters

other [Index or array-like]

result_name [str]

sort [False or None, default None] Whether to sort the resulting index. By default, the values are attempted to be sorted, but any `TypeError` from incomparable elements is caught by pandas.

- `None` : Attempt to sort the result, but catch any `TypeError`s from comparing incomparable elements.
- `False` : Do not sort the result.

New in version 0.24.0.

Changed in version 0.24.1: Changed the default value from `True` to `None` (without change in behaviour).

Returns

symmetric_difference [Index]

Notes

`symmetric_difference` contains elements that appear in either `idx1` or `idx2` but not both. Equivalent to the Index created by `idx1.difference(idx2) | idx2.difference(idx1)` with duplicates dropped.

Examples

```
>>> idx1 = pd.Index([1, 2, 3, 4])
>>> idx2 = pd.Index([2, 3, 4, 5])
>>> idx1.symmetric_difference(idx2)
Int64Index([1, 5], dtype='int64')
```

You can also use the `^` operator:

```
>>> idx1 ^ idx2
Int64Index([1, 5], dtype='int64')
```

pandas.Index.take

Index.take(*self*, *indices*, *axis=0*, *allow_fill=True*, *fill_value=None*, ***kwargs*)

Return a new Index of the values selected by the indices.

For internal compatibility with numpy arrays.

Parameters

indices [list] Indices to be taken

axis [int, optional] The axis over which to select values, always 0.

allow_fill [bool, default True]

fill_value [bool, default None] If `allow_fill=True` and `fill_value` is not None, indices specified by -1 is regarded as NA. If Index doesn't hold NA, raise `ValueError`

Returns

numpy.ndarray Elements of given indices.

See also:

`numpy.ndarray.take`

pandas.Index.to_flat_index

Index.to_flat_index(*self*)

Identity method.

New in version 0.24.0.

This is implemented for compatibility with subclass implementations when chaining.

Returns

pd.Index Caller.

See also:

`MultiIndex.to_flat_index` Subclass implementation.

pandas.Index.to_frame

Index.to_frame(*self*, *index=True*, *name=None*)

Create a DataFrame with a column containing the Index.

New in version 0.24.0.

Parameters

index [boolean, default True] Set the index of the returned DataFrame as the original Index.

name [object, default None] The passed name should substitute for the index name (if it has one).

Returns

DataFrame DataFrame containing the original Index data.

See also:

Index.to_series Convert an Index to a Series.

Series.to_frame Convert Series to DataFrame.

Examples

```
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')
>>> idx.to_frame()
      animal
animal
Ant      Ant
Bear     Bear
Cow      Cow
```

By default, the original Index is reused. To enforce a new Index:

```
>>> idx.to_frame(index=False)
      animal
0   Ant
1  Bear
2   Cow
```

To override the name of the resulting column, specify *name*:

```
>>> idx.to_frame(index=False, name='zoo')
      zoo
0   Ant
1  Bear
2   Cow
```

pandas.Index.to_list

Index.to_list(*self*)

Return a list of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

Returns

list

See also:

[numpy.ndarray.tolist](#)

pandas.Index.to_native_types

`Index.to_native_types(self, slicer=None, **kwargs)`

Format specified values of *self* and return them.

Parameters

slicer [int, array-like] An indexer into *self* that specifies which values are used in the formatting process.

kwargs [dict] Options for specifying how the values should be formatted. These options include the following:

- 1) **na_rep** [str] The value that serves as a placeholder for NULL values
- 2) **quoting** [bool or None] Whether or not there are quoted values in *self*
- 3) **date_format** [str] The format used to represent date-like values

Returns

`numpy.ndarray` Formatted values.

pandas.Index.to_numpy

`Index.to_numpy(self, dtype=None, copy=False)`

A NumPy ndarray representing the values in this Series or Index.

New in version 0.24.0.

Parameters

dtype [str or numpy.dtype, optional] The dtype to pass to `numpy.asarray()`

copy [bool, default False] Whether to ensure that the returned value is a not a view on another array. Note that `copy=False` does not *ensure* that `to_numpy()` is no-copy. Rather, `copy=True` ensure that a copy is made, even if not strictly necessary.

Returns

`numpy.ndarray`

See also:

Series.array Get the actual data stored within.

Index.array Get the actual data stored within.

DataFrame.to_numpy Similar method for DataFrame.

Notes

The returned array will be the same up to equality (values equal in *self* will be equal in the returned array; likewise for values that are not equal). When *self* contains an `ExtensionArray`, the dtype may be different. For example, for a category-dtype Series, `to_numpy()` will return a NumPy array and the categorical dtype will be lost.

For NumPy dtypes, this will be a reference to the actual data stored in this Series or Index (assuming `copy=False`). Modifying the result in place will modify the data stored in the Series or Index (not that we recommend doing that).

For extension types, `to_numpy()` *may* require copying data and coercing the result to a NumPy type (possibly object), which may be expensive. When you need a no-copy reference to the underlying data, `Series.array` should be used instead.

This table lays out the different dtypes and default return types of `to_numpy()` for various dtypes within pandas.

dtype	array type
category[T]	ndarray[T] (same dtype as input)
period	ndarray[object] (Periods)
interval	ndarray[object] (Intervals)
IntegerNA	ndarray[object]
datetime64[ns]	datetime64[ns]
datetime64[ns, tz]	ndarray[object] (Timestamps)

Examples

```
>>> ser = pd.Series(pd.Categorical(['a', 'b', 'a']))
>>> ser.to_numpy()
array(['a', 'b', 'a'], dtype=object)
```

Specify the *dtype* to control how datetime-aware data is represented. Use `dtype=object` to return an ndarray of pandas *Timestamp* objects, each with the correct *tz*.

```
>>> ser = pd.Series(pd.date_range('2000', periods=2, tz="CET"))
>>> ser.to_numpy(dtype=object)
array([Timestamp('2000-01-01 00:00:00+0100', tz='CET', freq='D'),
       Timestamp('2000-01-02 00:00:00+0100', tz='CET', freq='D')],
      dtype=object)
```

Or `dtype='datetime64[ns]'` to return an ndarray of native datetime64 values. The values are converted to UTC and the timezone info is dropped.

```
>>> ser.to_numpy(dtype="datetime64[ns]")
... # doctest: +ELLIPSIS
array(['1999-12-31T23:00:00.000000000', '2000-01-01T23:00:00...'],
      dtype='datetime64[ns]')
```

pandas.Index.to_series

`Index.to_series(self, index=None, name=None)`

Create a Series with both index and values equal to the index keys useful with `map` for returning an indexer based on an index.

Parameters

index [Index, optional] index of resulting Series. If None, defaults to original index

name [string, optional] name of resulting Series. If None, defaults to name of original index

Returns

Series [dtype will be based on the type of the Index values.]

pandas.Index.tolist

`Index.tolist(self)`

Return a list of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

Returns

list

See also:

`numpy.ndarray.tolist`

pandas.Index.transpose

`Index.transpose(self, *args, **kwargs)`

Return the transpose, which is by definition self.

Returns

%(klass)s

pandas.Index.union

`Index.union(self, other, sort=None)`

Form the union of two Index objects.

If the Index objects are incompatible, both Index objects will be cast to dtype('object') first.

Changed in version 0.25.0.

Parameters

other [Index or array-like]

sort [bool or None, default None] Whether to sort the resulting Index.

- None : Sort the result, except when
 1. *self* and *other* are equal.
 2. *self* or *other* has length 0.
 3. Some values in *self* or *other* cannot be compared. A RuntimeWarning is issued in this case.
- False : do not sort the result.

New in version 0.24.0.

Changed in version 0.24.1: Changed the default value from True to None (without change in behaviour).

Returns

union [Index]**Examples**

Union matching dtypes

```
>>> idx1 = pd.Index([1, 2, 3, 4])
>>> idx2 = pd.Index([3, 4, 5, 6])
>>> idx1.union(idx2)
Int64Index([1, 2, 3, 4, 5, 6], dtype='int64')
```

Union mismatched dtypes

```
>>> idx1 = pd.Index(['a', 'b', 'c', 'd'])
>>> idx2 = pd.Index([1, 2, 3, 4])
>>> idx1.union(idx2)
Index(['a', 'b', 'c', 'd', 1, 2, 3, 4], dtype='object')
```

pandas.Index.unique**Index.unique**(*self*, *level=None*)

Return unique values in the index. Uniques are returned in order of appearance, this does NOT sort.

Parameters

level [int or str, optional, default None] Only return values from specified level (for MultiIndex)

New in version 0.23.0.

Returns

Index without duplicates

See also:

unique

Series.unique

pandas.Index.value_counts

Index.value_counts(*self*, *normalize=False*, *sort=True*, *ascending=False*, *bins=None*, *dropna=True*)

Return a Series containing counts of unique values.

The resulting object will be in descending order so that the first element is the most frequently-occurring element. Excludes NA values by default.

Parameters

normalize [boolean, default False] If True then the object returned will contain the relative frequencies of the unique values.

sort [boolean, default True] Sort by frequencies.

ascending [boolean, default False] Sort in ascending order.

bins [integer, optional] Rather than count values, group them into half-open bins, a convenience for `pd.cut`, only works with numeric data.

dropna [boolean, default True] Don't include counts of NaN.

Returns

Series

See also:

Series.count Number of non-NA elements in a Series.

DataFrame.count Number of non-NA elements in a DataFrame.

Examples

```
>>> index = pd.Index([3, 1, 2, 3, 4, np.nan])
>>> index.value_counts()
3.0    2
4.0    1
2.0    1
1.0    1
dtype: int64
```

With *normalize* set to *True*, returns the relative frequency by dividing all values by the sum of values.

```
>>> s = pd.Series([3, 1, 2, 3, 4, np.nan])
>>> s.value_counts(normalize=True)
3.0    0.4
4.0    0.2
2.0    0.2
1.0    0.2
dtype: float64
```

bins

Bins can be useful for going from a continuous variable to a categorical variable; instead of counting unique apparitions of values, divide the index in the specified number of half-open bins.

```
>>> s.value_counts(bins=3)
(2.0, 3.0]    2
(0.996, 2.0]  2
(3.0, 4.0]    1
dtype: int64
```

dropna

With *dropna* set to *False* we can also see NaN index values.

```
>>> s.value_counts(dropna=False)
3.0    2
NaN    1
4.0    1
```

(continues on next page)

(continued from previous page)

```

2.0    1
1.0    1
dtype: int64

```

pandas.Index.where**Index.where**(*self*, *cond*, *other=None*)

Return an Index of same shape as self and whose corresponding entries are from self where cond is True and otherwise are from other.

New in version 0.19.0.

Parameters

cond [boolean array-like with the same length as self]

other [scalar, or array-like]

Returns

Index

is_boolean	
is_floating	
is_integer	
is_interval	
is_lexsorted_for_tuple	
is_mixed	
is_numeric	
is_object	
view	

Properties

<i>Index.values</i>	Return an array representing the data in the Index.
<i>Index.is_monotonic</i>	Alias for <code>is_monotonic_increasing</code> .
<i>Index.is_monotonic_increasing</i>	Return if the index is monotonic increasing (only equal or increasing) values.
<i>Index.is_monotonic_decreasing</i>	Return if the index is monotonic decreasing (only equal or decreasing) values.
<i>Index.is_unique</i>	Return if the index has unique values.
<i>Index.has_duplicates</i>	
<i>Index.hasnans</i>	Return if I have any nans; enables various perf speedups.
<i>Index.dtype</i>	Return the dtype object of the underlying data.
<i>Index.dtype_str</i>	(DEPRECATED) Return the dtype str of the underlying data.
<i>Index.inferred_type</i>	Return a string of the type inferred from the values.
<i>Index.is_all_dates</i>	
<i>Index.shape</i>	Return a tuple of the shape of the underlying data.

Continued on next page

Table 125 – continued from previous page

<i>Index.name</i>	
<i>Index.names</i>	
<i>Index.nbytes</i>	Return the number of bytes in the underlying data.
<i>Index.ndim</i>	Number of dimensions of the underlying data, by definition 1.
<i>Index.size</i>	Return the number of elements in the underlying data.
<i>Index.empty</i>	
<i>Index.strides</i>	(DEPRECATED) Return the strides of the underlying data.
<i>Index.itemsize</i>	(DEPRECATED) Return the size of the dtype of the item of the underlying data.
<i>Index.base</i>	(DEPRECATED) Return the base object if the memory of the underlying data is shared.
<i>Index.T</i>	Return the transpose, which is by
<i>Index.memory_usage</i> (self[, deep])	Memory usage of the values

pandas.Index.has_duplicates

Index.has_duplicates

pandas.Index.is_all_dates

Index.is_all_dates

pandas.Index.name

Index.name = None

pandas.Index.names

Index.names

pandas.Index.empty

Index.empty

Modifying and computations

<i>Index.all</i> (self, *args, **kwargs)	Return whether all elements are True.
<i>Index.any</i> (self, *args, **kwargs)	Return whether any element is True.
<i>Index.argmin</i> (self[, axis, skipna])	Return a ndarray of the minimum argument in-dexer.
<i>Index.argmax</i> (self[, axis, skipna])	Return an ndarray of the maximum argument in-dexer.

Continued on next page

Table 126 – continued from previous page

<i>Index.copy</i> (self[, name, deep, dtype])	Make a copy of this object.
<i>Index.delete</i> (self, loc)	Make new Index with passed location(-s) deleted.
<i>Index.drop</i> (self, labels[, errors])	Make new Index with passed list of labels deleted.
<i>Index.drop_duplicates</i> (self[, keep])	Return Index with duplicate values removed.
<i>Index.duplicated</i> (self[, keep])	Indicate duplicate index values.
<i>Index.equals</i> (self, other)	Determine if two Index objects contain the same elements.
<i>Index.factorize</i> (self[, sort, na_sentinel])	Encode the object as an enumerated type or categorical variable.
<i>Index.identical</i> (self, other)	Similar to equals, but check that other comparable attributes are also equal.
<i>Index.insert</i> (self, loc, item)	Make new Index inserting new item at location.
<i>Index.is_</i> (self, other)	More flexible, faster check like <code>is</code> but that works through views.
<i>Index.is_boolean</i> (self)	
<i>Index.is_categorical</i> (self)	Check if the Index holds categorical data.
<i>Index.is_floating</i> (self)	
<i>Index.is_integer</i> (self)	
<i>Index.is_interval</i> (self)	
<i>Index.is_mixed</i> (self)	
<i>Index.is_numeric</i> (self)	
<i>Index.is_object</i> (self)	
<i>Index.min</i> (self[, axis, skipna])	Return the minimum value of the Index.
<i>Index.max</i> (self[, axis, skipna])	Return the maximum value of the Index.
<i>Index.reindex</i> (self, target[, method, level, ...])	Create index with target's values (move/add/delete values as necessary).
<i>Index.rename</i> (self, name[, inplace])	Alter Index or MultiIndex name.
<i>Index.repeat</i> (self, repeats[, axis])	Repeat elements of a Index.
<i>Index.where</i> (self, cond[, other])	Return an Index of same shape as self and whose corresponding entries are from self where cond is True and otherwise are from other.
<i>Index.take</i> (self, indices[, axis, ...])	Return a new Index of the values selected by the indices.
<i>Index.putmask</i> (self, mask, value)	Return a new Index of the values set with the mask.
<i>Index.unique</i> (self[, level])	Return unique values in the index.
<i>Index.nunique</i> (self[, dropna])	Return number of unique elements in the object.
<i>Index.value_counts</i> (self[, normalize, sort, ...])	Return a Series containing counts of unique values.

pandas.Index.is_boolean`Index.is_boolean(self)`**pandas.Index.is_floating**`Index.is_floating(self)`**pandas.Index.is_integer**`Index.is_integer(self)`

pandas.Index.is_interval

`Index.is_interval(self)`

pandas.Index.is_mixed

`Index.is_mixed(self)`

pandas.Index.is_numeric

`Index.is_numeric(self)`

pandas.Index.is_object

`Index.is_object(self)`

Compatibility with MultiIndex

<code>Index.set_names(self, names[, level, inplace])</code>	Set Index or MultiIndex name.
<code>Index.is_lexsorted_for_tuple(self, tup)</code>	
<code>Index.droplevel(self[, level])</code>	Return index with requested level(s) removed.

pandas.Index.is_lexsorted_for_tuple

`Index.is_lexsorted_for_tuple(self, tup)`

Missing values

<code>Index.fillna(self[, value, downcast])</code>	Fill NA/NaN values with the specified value
<code>Index.dropna(self[, how])</code>	Return Index without NA/NaN values
<code>Index.isna(self)</code>	Detect missing values.
<code>Index.notna(self)</code>	Detect existing (non-missing) values.

Conversion

<code>Index.astype(self, dtype[, copy])</code>	Create an Index with values cast to dtypes.
<code>Index.item(self)</code>	Return the first element of the underlying data as a python scalar.
<code>Index.map(self, mapper[, na_action])</code>	Map values using input correspondence (a dict, Series, or function).
<code>Index.ravel(self[, order])</code>	Return an ndarray of the flattened values of the underlying data.
<code>Index.to_list(self)</code>	Return a list of the values.
<code>Index.to_native_types(self[, slicer])</code>	Format specified values of <i>self</i> and return them.

Continued on next page

Table 129 – continued from previous page

<i>Index.to_series</i> (self[, index, name])	Create a Series with both index and values equal to the index keys useful with map for returning an indexer based on an index.
<i>Index.to_frame</i> (self[, index, name])	Create a DataFrame with a column containing the Index.
<i>Index.view</i> (self[, cls])	

pandas.Index.view`Index.view(self, cls=None)`**Sorting**

<i>Index.argsort</i> (self, *args, **kwargs)	Return the integer indices that would sort the index.
<i>Index.searchsorted</i> (self, value[, side, sorter])	Find indices where elements should be inserted to maintain order.
<i>Index.sort_values</i> (self[, return_indexer, ...])	Return a sorted copy of the index.

Time-specific operations

<i>Index.shift</i> (self[, periods, freq])	Shift index by desired number of time frequency increments.
--	---

Combining / joining / set operations

<i>Index.append</i> (self, other)	Append a collection of Index options together.
<i>Index.join</i> (self, other[, how, level, ...])	Compute join_index and indexers to conform data structures to the new index.
<i>Index.intersection</i> (self, other[, sort])	Form the intersection of two Index objects.
<i>Index.union</i> (self, other[, sort])	Form the union of two Index objects.
<i>Index.difference</i> (self, other[, sort])	Return a new Index with elements from the index that are not in <i>other</i> .
<i>Index.symmetric_difference</i> (self, other[, ...])	Compute the symmetric difference of two Index objects.

Selecting

<i>Index.asof</i> (self, label)	Return the label from the index, or, if not present, the previous one.
<i>Index.asof_locs</i> (self, where, mask)	Find the locations (indices) of the labels from the index for every entry in the <i>where</i> argument.
<i>Index.contains</i> (self, key)	(DEPRECATED) Return a boolean indicating whether the provided key is in the index.
<i>Index.get_duplicates</i> (self)	(DEPRECATED) Extract duplicated index elements.

Continued on next page

Table 133 – continued from previous page

<code>Index.get_indexer(self, target[, method, ...])</code>	Compute indexer and mask for new index given the current index.
<code>Index.get_indexer_for(self, target, **kwargs)</code>	Guaranteed return of an indexer even when non-unique.
<code>Index.get_indexer_non_unique(self, target)</code>	Compute indexer and mask for new index given the current index.
<code>Index.get_level_values(self, level)</code>	Return an Index of values for requested level.
<code>Index.get_loc(self, key[, method, tolerance])</code>	Get integer location, slice or boolean mask for requested label.
<code>Index.get_slice_bound(self, label, side, kind)</code>	Calculate slice bound that corresponds to given label.
<code>Index.get_value(self, series, key)</code>	Fast lookup of value from 1-dimensional ndarray.
<code>Index.get_values(self)</code>	(DEPRECATED) Return <i>Index</i> data as an <i>numpy.ndarray</i> .
<code>Index.set_value(self, arr, key, value)</code>	Fast lookup of value from 1-dimensional ndarray.
<code>Index.isin(self, values[, level])</code>	Return a boolean array where the index values are in <i>values</i> .
<code>Index.slice_indexer(self[, start, end, ...])</code>	For an ordered or unique index, compute the slice indexer for input labels and step.
<code>Index.slice_locs(self[, start, end, step, kind])</code>	Compute slice locations for input labels.

6.7.2 Numeric Index

<i>RangeIndex</i>	Immutable Index implementing a monotonic integer range.
<i>Int64Index</i>	Immutable ndarray implementing an ordered, sliceable set.
<i>UInt64Index</i>	Immutable ndarray implementing an ordered, sliceable set.
<i>Float64Index</i>	Immutable ndarray implementing an ordered, sliceable set.

pandas.RangeIndex

class pandas.RangeIndex

Immutable Index implementing a monotonic integer range.

RangeIndex is a memory-saving special case of Int64Index limited to representing monotonic ranges. Using RangeIndex may in some instances improve computing speed.

This is the default index type used by DataFrame and Series when no explicit index is provided by the user.

Parameters

start [int (default: 0), or other RangeIndex instance] If int and “stop” is not given, interpreted as “stop” instead.

stop [int (default: 0)]

step [int (default: 1)]

name [object, optional] Name to be stored in the index

copy [bool, default False] Unused, accepted for homogeneity with other index types.

See also:

Index The base pandas Index type.

Int64Index Index of int64 data.

Attributes

<i>start</i>	The value of the <i>start</i> parameter (0 if this was not supplied)
<i>stop</i>	The value of the <i>stop</i> parameter
<i>step</i>	The value of the <i>step</i> parameter (1 if this was not supplied)

pandas.RangeIndex.start**RangeIndex.start**

The value of the *start* parameter (0 if this was not supplied)

pandas.RangeIndex.stop**RangeIndex.stop**

The value of the *stop* parameter

pandas.RangeIndex.step**RangeIndex.step**

The value of the *step* parameter (1 if this was not supplied)

Methods

<i>from_range</i> (data[, name, dtype])	Create RangeIndex from a range object.
---	--

pandas.RangeIndex.from_range

classmethod `RangeIndex.from_range(data, name=None, dtype=None)`

Create RangeIndex from a range object.

Returns

RangeIndex

pandas.Int64Index

class `pandas.Int64Index`

Immutable ndarray implementing an ordered, sliceable set. The basic object storing axis labels for all pandas objects. Int64Index is a special case of *Index* with purely integer labels.

Parameters

data [array-like (1-dimensional)]
dtype [NumPy dtype (default: int64)]
copy [bool] Make a copy of input ndarray
name [object] Name to be stored in the index

See also:

Index The base pandas Index type.

Notes

An Index instance can **only** contain hashable objects.

Attributes

None	
------	--

Methods

None	
------	--

pandas.UInt64Index

class pandas.UInt64Index

Immutable ndarray implementing an ordered, sliceable set. The basic object storing axis labels for all pandas objects. UInt64Index is a special case of *Index* with purely unsigned integer labels.

Parameters

data [array-like (1-dimensional)]
dtype [NumPy dtype (default: uint64)]
copy [bool] Make a copy of input ndarray
name [object] Name to be stored in the index

See also:

Index The base pandas Index type.

Notes

An Index instance can **only** contain hashable objects.

Attributes

None	
------	--

Methods

None	
------	--

pandas.Float64Index

class pandas.Float64Index

Immutable ndarray implementing an ordered, sliceable set. The basic object storing axis labels for all pandas objects. Float64Index is a special case of *Index* with purely float labels.

Parameters

data [array-like (1-dimensional)]

dtype [NumPy dtype (default: float64)]

copy [bool] Make a copy of input ndarray

name [object] Name to be stored in the index

See also:

Index The base pandas Index type.

Notes

An Index instance can **only** contain hashable objects.

Attributes

None	
------	--

Methods

None	
------	--

<i>RangeIndex.start</i>	The value of the <i>start</i> parameter (0 if this was not supplied)
<i>RangeIndex.stop</i>	The value of the <i>stop</i> parameter
<i>RangeIndex.step</i>	The value of the <i>step</i> parameter (1 if this was not supplied)
<i>RangeIndex.from_range</i> (data[, name, dtype])	Create RangeIndex from a range object.

6.7.3 CategoricalIndex

<i>CategoricalIndex</i>	Index based on an underlying <i>Categorical</i> .
-------------------------	---

pandas.CategoricalIndex

class pandas.CategoricalIndex

Index based on an underlying *Categorical*.

CategoricalIndex, like Categorical, can only take on a limited, and usually fixed, number of possible values (*categories*). Also, like Categorical, it might have an order, but numerical operations (additions, divisions, ...) are not possible.

Parameters

data [array-like (1-dimensional)] The values of the categorical. If *categories* are given, values not in *categories* will be replaced with NaN.

categories [index-like, optional] The categories for the categorical. Items need to be unique. If the categories are not given here (and also not in *dtype*), they will be inferred from the *data*.

ordered [bool, optional] Whether or not this categorical is treated as an ordered categorical. If not given here or in *dtype*, the resulting categorical will be unordered.

dtype [CategoricalDtype or the string “category”, optional] If *CategoricalDtype*, cannot be used together with *categories* or *ordered*.

New in version 0.21.0.

copy [bool, default False] Make a copy of input ndarray.

name [object, optional] Name to be stored in the index.

Raises

ValueError If the categories do not validate.

TypeError If an explicit *ordered=True* is given but no *categories* and the *values* are not sortable.

See also:

Index The base pandas Index type.

Categorical A categorical array.

CategoricalDtype Type for categorical data.

Notes

See the [user guide](#) for more.

Examples

```
>>> pd.CategoricalIndex(['a', 'b', 'c', 'a', 'b', 'c'])
CategoricalIndex(['a', 'b', 'c', 'a', 'b', 'c'], categories=['a', 'b', 'c'],
↳ ordered=False, dtype='category') # noqa
```

CategoricalIndex can also be instantiated from a Categorical:

```
>>> c = pd.Categorical(['a', 'b', 'c', 'a', 'b', 'c'])
>>> pd.CategoricalIndex(c)
CategoricalIndex(['a', 'b', 'c', 'a', 'b', 'c'], categories=['a', 'b', 'c'],
↳ordered=False, dtype='category') # noqa
```

Ordered `CategoricalIndex` can have a min and max value.

```
>>> ci = pd.CategoricalIndex(['a','b','c','a','b','c'], ordered=True,
...                           categories=['c', 'b', 'a'])
>>> ci
CategoricalIndex(['a', 'b', 'c', 'a', 'b', 'c'], categories=['c', 'b', 'a'],
↳ordered=True, dtype='category') # noqa
>>> ci.min()
'c'
```

Attributes

codes	
categories	
ordered	

Methods

<i>rename_categories</i> (self, *args, **kwargs)	Rename categories.
<i>reorder_categories</i> (self, *args, **kwargs)	Reorder categories as specified in <i>new_categories</i> .
<i>add_categories</i> (self, *args, **kwargs)	Add new categories.
<i>remove_categories</i> (self, *args, **kwargs)	Remove the specified categories.
<i>remove_unused_categories</i> (self, *args, ...)	Remove categories which are not used.
<i>set_categories</i> (self, *args, **kwargs)	Set the categories to the specified <i>new_categories</i> .
<i>as_ordered</i> (self, *args, **kwargs)	Set the Categorical to be ordered.
<i>as_unordered</i> (self, *args, **kwargs)	Set the Categorical to be unordered.
<i>map</i> (self, mapper)	Map values using input correspondence (a dict, Series, or function).

`pandas.CategoricalIndex.rename_categories`

```
CategoricalIndex.rename_categories(self, *args, **kwargs)
Rename categories.
```

Parameters

new_categories [list-like, dict-like or callable]

- list-like: all items must be unique and the number of items in the new categories must match the existing number of categories.
- dict-like: specifies a mapping from old categories to new. Categories not contained in the mapping are passed through and extra categories in the mapping are ignored.

New in version 0.21.0.

- `callable` : a callable that is called on all items in the old categories and whose return values comprise the new categories.

New in version 0.23.0.

inplace [bool, default False] Whether or not to rename the categories inplace or return a copy of this categorical with renamed categories.

Returns

cat [Categorical or None] With `inplace=False`, the new categorical is returned. With `inplace=True`, there is no return value.

Raises

ValueError If new categories are list-like and do not have the same number of items than the current categories or do not validate as categories

See also:

`reorder_categories`

`add_categories`

`remove_categories`

`remove_unused_categories`

`set_categories`

Examples

```
>>> c = pd.Categorical(['a', 'a', 'b'])
>>> c.rename_categories([0, 1])
[0, 0, 1]
Categories (2, int64): [0, 1]
```

For dict-like `new_categories`, extra keys are ignored and categories not in the dictionary are passed through

```
>>> c.rename_categories({'a': 'A', 'c': 'C'})
[A, A, b]
Categories (2, object): [A, b]
```

You may also provide a callable to create the new categories

```
>>> c.rename_categories(lambda x: x.upper())
[A, A, B]
Categories (2, object): [A, B]
```

pandas.CategoricalIndex.reorder_categories

`CategoricalIndex.reorder_categories(self, *args, **kwargs)`

Reorder categories as specified in `new_categories`.

`new_categories` need to include all old categories and no new category items.

Parameters

- new_categories** [Index-like] The categories in new order.
- ordered** [bool, optional] Whether or not the categorical is treated as a ordered categorical. If not given, do not change the ordered information.
- inplace** [bool, default False] Whether or not to reorder the categories inplace or return a copy of this categorical with reordered categories.

Returns

cat [Categorical with reordered categories or None if inplace.]

Raises

ValueError If the new categories do not contain all old category items or any new ones

See also:

rename_categories
add_categories
remove_categories
remove_unused_categories
set_categories

pandas.CategoricalIndex.add_categories

`CategoricalIndex.add_categories(self, *args, **kwargs)`

Add new categories.

new_categories will be included at the last/highest place in the categories and will be unused directly after this call.

Parameters

- new_categories** [category or list-like of category] The new categories to be included.
- inplace** [bool, default False] Whether or not to add the categories inplace or return a copy of this categorical with added categories.

Returns

cat [Categorical with new categories added or None if inplace.]

Raises

ValueError If the new categories include old categories or do not validate as categories

See also:

rename_categories
reorder_categories
remove_categories
remove_unused_categories

set_categories

pandas.CategoricalIndex.remove_categories

`CategoricalIndex.remove_categories(self, *args, **kwargs)`

Remove the specified categories.

removals must be included in the old categories. Values which were in the removed categories will be set to NaN

Parameters

removals [category or list of categories] The categories which should be removed.

inplace [bool, default False] Whether or not to remove the categories inplace or return a copy of this categorical with removed categories.

Returns

cat [Categorical with removed categories or None if inplace.]

Raises

ValueError If the removals are not contained in the categories

See also:

rename_categories

reorder_categories

add_categories

remove_unused_categories

set_categories

pandas.CategoricalIndex.remove_unused_categories

`CategoricalIndex.remove_unused_categories(self, *args, **kwargs)`

Remove categories which are not used.

Parameters

inplace [bool, default False] Whether or not to drop unused categories inplace or return a copy of this categorical with unused categories dropped.

Returns

cat [Categorical with unused categories dropped or None if inplace.]

See also:

rename_categories

reorder_categories

add_categories

remove_categories

set_categories

pandas.CategoricalIndex.set_categories

`CategoricalIndex.set_categories(self, *args, **kwargs)`

Set the categories to the specified `new_categories`.

`new_categories` can include new categories (which will result in unused categories) or remove old categories (which results in values set to NaN). If `rename==True`, the categories will simply be renamed (less or more items than in old categories will result in values set to NaN or in unused categories respectively).

This method can be used to perform more than one action of adding, removing, and reordering simultaneously and is therefore faster than performing the individual steps via the more specialised methods.

On the other hand this methods does not do checks (e.g., whether the old categories are included in the new categories on a reorder), which can result in surprising changes, for example when using special string dtypes on python3, which does not considers a S1 string equal to a single char python string.

Parameters

new_categories [Index-like] The categories in new order.

ordered [bool, default False] Whether or not the categorical is treated as a ordered categorical. If not given, do not change the ordered information.

rename [bool, default False] Whether or not the `new_categories` should be considered as a rename of the old categories or as reordered categories.

inplace [bool, default False] Whether or not to reorder the categories in-place or return a copy of this categorical with reordered categories.

Returns

Categorical with reordered categories or None if inplace.

Raises

ValueError If `new_categories` does not validate as categories

See also:

`rename_categories`

`reorder_categories`

`add_categories`

`remove_categories`

`remove_unused_categories`

pandas.CategoricalIndex.as_ordered

`CategoricalIndex.as_ordered(self, *args, **kwargs)`

Set the Categorical to be ordered.

Parameters

inplace [bool, default False] Whether or not to set the ordered attribute in-place or return a copy of this categorical with ordered set to True.

Returns

Categorical Ordered Categorical.

pandas.CategoricalIndex.as_unordered

`CategoricalIndex.as_unordered(self, *args, **kwargs)`

Set the Categorical to be unordered.

Parameters

inplace [bool, default False] Whether or not to set the ordered attribute in-place or return a copy of this categorical with ordered set to False.

Returns

Categorical Unordered Categorical.

pandas.CategoricalIndex.map

`CategoricalIndex.map(self, mapper)`

Map values using input correspondence (a dict, Series, or function).

Maps the values (their categories, not the codes) of the index to new categories. If the mapping correspondence is one-to-one the result is a *CategoricalIndex* which has the same order property as the original, otherwise an *Index* is returned.

If a *dict* or *Series* is used any unmapped category is mapped to *NaN*. Note that if this happens an *Index* will be returned.

Parameters

mapper [function, dict, or Series] Mapping correspondence.

Returns

pandas.CategoricalIndex or **pandas.Index** Mapped index.

See also:

Index.map Apply a mapping correspondence on an *Index*.

Series.map Apply a mapping correspondence on a *Series*.

Series.apply Apply more complex functions on a *Series*.

Examples

```
>>> idx = pd.CategoricalIndex(['a', 'b', 'c'])
>>> idx
CategoricalIndex(['a', 'b', 'c'], categories=['a', 'b', 'c'],
                 ordered=False, dtype='category')
>>> idx.map(lambda x: x.upper())
CategoricalIndex(['A', 'B', 'C'], categories=['A', 'B', 'C'],
                 ordered=False, dtype='category')
>>> idx.map({'a': 'first', 'b': 'second', 'c': 'third'})
CategoricalIndex(['first', 'second', 'third'], categories=['first',
                 'second', 'third'], ordered=False, dtype='category')
```

If the mapping is one-to-one the ordering of the categories is preserved:

```
>>> idx = pd.CategoricalIndex(['a', 'b', 'c'], ordered=True)
>>> idx
CategoricalIndex(['a', 'b', 'c'], categories=['a', 'b', 'c'],
                 ordered=True, dtype='category')
>>> idx.map({'a': 3, 'b': 2, 'c': 1})
CategoricalIndex([3, 2, 1], categories=[3, 2, 1], ordered=True,
                 dtype='category')
```

If the mapping is not one-to-one an *Index* is returned:

```
>>> idx.map({'a': 'first', 'b': 'second', 'c': 'first'})
Index(['first', 'second', 'first'], dtype='object')
```

If a *dict* is used, all unmapped categories are mapped to *NaN* and the result is an *Index*:

```
>>> idx.map({'a': 'first', 'b': 'second'})
Index(['first', 'second', nan], dtype='object')
```

Categorical components

CategoricalIndex.codes

CategoricalIndex.categories

CategoricalIndex.ordered

CategoricalIndex.rename_categories(self, ...) Rename categories.

CategoricalIndex.reorder_categories(self, ...) Reorder categories as specified in new_categories.

CategoricalIndex.add_categories(self, ...) Add new categories.

CategoricalIndex.remove_categories(self, ...) Remove the specified categories.

CategoricalIndex.remove_unused_categories(...) Remove categories which are not used.

CategoricalIndex.set_categories(self, ...) Set the categories to the specified new_categories.

CategoricalIndex.as_ordered(self, *args, ...) Set the Categorical to be ordered.

CategoricalIndex.as_unordered(self, *args, ...) Set the Categorical to be unordered.

CategoricalIndex.codes

pandas.CategoricalIndex.categories

CategoricalIndex.categories

pandas.CategoricalIndex.ordered

CategoricalIndex.ordered

Modifying and computations

<i>CategoricalIndex.map</i> (self, mapper)	Map values using input correspondence (a dict, Series, or function).
<i>CategoricalIndex.equals</i> (self, other)	Determine if two CategoricalIndex objects contain the same elements.

pandas.CategoricalIndex.equals

`CategoricalIndex.equals(self, other)`

Determine if two CategoricalIndex objects contain the same elements.

Returns

bool If two CategoricalIndex objects have equal elements True, otherwise False.

6.7.4 IntervalIndex

<i>IntervalIndex</i>	Immutable index of intervals that are closed on the same side.
----------------------	--

pandas.IntervalIndex

`class pandas.IntervalIndex`

Immutable index of intervals that are closed on the same side.

New in version 0.20.0.

Parameters

data [array-like (1-dimensional)] Array-like containing Interval objects from which to build the IntervalIndex.

closed [{'left', 'right', 'both', 'neither'}, default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.

dtype [dtype or None, default None] If None, dtype will be inferred.

New in version 0.23.0.

copy [bool, default False] Copy the input data.

name [object, optional] Name to be stored in the index.

verify_integrity [bool, default True] Verify that the IntervalIndex is valid.

See also:

Index The base pandas Index type.

Interval A bounded slice-like interval; the elements of an IntervalIndex.

interval_range Function to create a fixed frequency IntervalIndex.

cut Bin values into discrete Intervals.

qcut Bin values into equal-sized Intervals based on rank or sample quantiles.

Notes

See the [user guide](#) for more.

Examples

A new `IntervalIndex` is typically constructed using `interval_range()`:

```
>>> pd.interval_range(start=0, end=5)
IntervalIndex([(0, 1], (1, 2], (2, 3], (3, 4], (4, 5]],
              closed='right',
              dtype='interval[int64]')
```

It may also be constructed using one of the constructor methods: `IntervalIndex.from_arrays()`, `IntervalIndex.from_breaks()`, and `IntervalIndex.from_tuples()`.

See further examples in the doc strings of `interval_range` and the mentioned constructor methods.

Attributes

<code>left</code>	Return the left endpoints of each Interval in the IntervalIndex as an Index
<code>right</code>	Return the right endpoints of each Interval in the IntervalIndex as an Index
<code>closed</code>	Whether the intervals are closed on the left-side, right-side, both or neither
<code>mid</code>	Return the midpoint of each Interval in the IntervalIndex as an Index
<code>length</code>	Return an Index with entries denoting the length of each Interval in the IntervalIndex
<code>is_empty</code>	Indicates if an interval is empty, meaning it contains no points.
<code>is_non_overlapping_monotonic</code>	Return True if the IntervalIndex is non-overlapping (no Intervals share points) and is either monotonic increasing or monotonic decreasing, else False
<code>is_overlapping</code>	Return True if the IntervalIndex has overlapping intervals, else False.
<code>values</code>	Return the IntervalIndex's data as an IntervalArray.

`pandas.IntervalIndex.left`

`IntervalIndex.left`

Return the left endpoints of each Interval in the IntervalIndex as an Index

`pandas.IntervalIndex.right`

`IntervalIndex.right`

Return the right endpoints of each Interval in the IntervalIndex as an Index

pandas.IntervalIndex.closed**IntervalIndex.closed**

Whether the intervals are closed on the left-side, right-side, both or neither

pandas.IntervalIndex.mid**IntervalIndex.mid**

Return the midpoint of each Interval in the IntervalIndex as an Index

pandas.IntervalIndex.length**IntervalIndex.length**

Return an Index with entries denoting the length of each Interval in the IntervalIndex

pandas.IntervalIndex.is_empty**IntervalIndex.is_empty**

Indicates if an interval is empty, meaning it contains no points.

New in version 0.25.0.

Returns

bool or ndarray A boolean indicating if a scalar *Interval* is empty, or a boolean ndarray positionally indicating if an *Interval* in an *IntervalArray* or *IntervalIndex* is empty.

Examples

An *Interval* that contains points is not empty:

```
>>> pd.Interval(0, 1, closed='right').is_empty
False
```

An *Interval* that does not contain any points is empty:

```
>>> pd.Interval(0, 0, closed='right').is_empty
True
>>> pd.Interval(0, 0, closed='left').is_empty
True
>>> pd.Interval(0, 0, closed='neither').is_empty
True
```

An *Interval* that contains a single point is not empty:

```
>>> pd.Interval(0, 0, closed='both').is_empty
False
```

An *IntervalArray* or *IntervalIndex* returns a boolean ndarray positionally indicating if an *Interval* is empty:

```
>>> ivs = [pd.Interval(0, 0, closed='neither'),
...        pd.Interval(1, 2, closed='neither')]
>>> pd.arrays.IntervalArray(ivs).is_empty
array([ True, False])
```

Missing values are not considered empty:

```
>>> ivs = [pd.Interval(0, 0, closed='neither'), np.nan]
>>> pd.IntervalIndex(ivs).is_empty
array([ True, False])
```

pandas.IntervalIndex.is_non_overlapping_monotonic

IntervalIndex.is_non_overlapping_monotonic

Return True if the IntervalIndex is non-overlapping (no Intervals share points) and is either monotonic increasing or monotonic decreasing, else False

pandas.IntervalIndex.is_overlapping

IntervalIndex.is_overlapping

Return True if the IntervalIndex has overlapping intervals, else False.

Two intervals overlap if they share a common point, including closed endpoints. Intervals that only have an open endpoint in common do not overlap.

New in version 0.24.0.

Returns

bool Boolean indicating if the IntervalIndex has overlapping intervals.

See also:

Interval.overlaps Check whether two Interval objects overlap.

IntervalIndex.overlaps Check an IntervalIndex elementwise for overlaps.

Examples

```
>>> index = pd.IntervalIndex.from_tuples([(0, 2), (1, 3), (4, 5)])
>>> index
IntervalIndex([(0, 2], [1, 3], [4, 5]],
              closed='right',
              dtype='interval[int64]')
>>> index.is_overlapping
True
```

Intervals that share closed endpoints overlap:

```
>>> index = pd.interval_range(0, 3, closed='both')
>>> index
IntervalIndex([(0, 1], [1, 2], [2, 3]],
```

(continues on next page)

(continued from previous page)

```

        closed='both',
        dtype='interval[int64]')
>>> index.is_overlapping
True

```

Intervals that only have an open endpoint in common do not overlap:

```

>>> index = pd.interval_range(0, 3, closed='left')
>>> index
IntervalIndex([[0, 1), [1, 2), [2, 3)],
              closed='left',
              dtype='interval[int64]')
>>> index.is_overlapping
False

```

pandas.IntervalIndex.values

IntervalIndex.values

Return the IntervalIndex's data as an IntervalArray.

Methods

<i>from_arrays</i> (left, right[, closed, name, ...])	Construct from two arrays defining the left and right bounds.
<i>from_tuples</i> (data[, closed, name, copy, dtype])	Construct an IntervalIndex from an array-like of tuples
<i>from_breaks</i> (breaks[, closed, name, copy, dtype])	Construct an IntervalIndex from an array of splits.
<i>contains</i> (self, other)	Check elementwise if the Intervals contain the value.
<i>overlaps</i> (self, other)	Check elementwise if an Interval overlaps the values in the IntervalIndex.
<i>set_closed</i> (self, closed)	Return an IntervalIndex identical to the current one, but closed on the specified side
<i>to_tuples</i> (self[, na_tuple])	Return an Index of tuples of the form (left, right)

pandas.IntervalIndex.from_arrays

classmethod IntervalIndex.**from_arrays**(left, right, closed='right', name=None, copy=False, dtype=None)

Construct from two arrays defining the left and right bounds.

Parameters

- left** [array-like (1-dimensional)] Left bounds for each interval.
- right** [array-like (1-dimensional)] Right bounds for each interval.
- closed** [{'left', 'right', 'both', 'neither'}, default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.
- copy** [boolean, default False] Copy the data.

dtype [dtype, optional] If None, dtype will be inferred.

New in version 0.23.0.

Returns

IntervalIndex

Raises

ValueError When a value is missing in only one of *left* or *right*. When a value in *left* is greater than the corresponding value in *right*.

See also:

interval_range Function to create a fixed frequency IntervalIndex.

IntervalIndex.from_breaks Construct an IntervalIndex from an array of splits.

IntervalIndex.from_tuples Construct an IntervalIndex from an array-like of tuples.

Notes

Each element of *left* must be less than or equal to the *right* element at the same position. If an element is missing, it must be missing in both *left* and *right*. A `TypeError` is raised when using an unsupported type for *left* or *right*. At the moment, ‘category’, ‘object’, and ‘string’ subtypes are not supported.

Examples

```
>>> IntervalIndex.from_arrays([0, 1, 2], [1, 2, 3])
IntervalIndex([[0, 1], (1, 2], (2, 3]],
              closed='right',
              dtype='interval[int64]')
```

pandas.IntervalIndex.from_tuples

classmethod `IntervalIndex.from_tuples`(*data*, *closed*='right', *name*=None, *copy*=False, *dtype*=None)

Construct an IntervalIndex from an array-like of tuples

Parameters

data [array-like (1-dimensional)] Array of tuples

closed [{‘left’, ‘right’, ‘both’, ‘neither’}, default ‘right’] Whether the intervals are closed on the left-side, right-side, both or neither.

copy [boolean, default False] by-default copy the data, this is compat only and ignored

dtype [dtype or None, default None] If None, dtype will be inferred

..versionadded:: 0.23.0

Returns

IntervalIndex

See also:

interval_range Function to create a fixed frequency IntervalIndex.

IntervalIndex.from_arrays Construct an IntervalIndex from a left and right array.

IntervalIndex.from_breaks Construct an IntervalIndex from an array of splits.

Examples

```
>>> pd.IntervalIndex.from_tuples([(0, 1), (1, 2)])
IntervalIndex([(0, 1], (1, 2]],
              closed='right', dtype='interval[int64]')
```

pandas.IntervalIndex.from_breaks

classmethod `IntervalIndex.from_breaks(breaks, closed='right', name=None, copy=False, dtype=None)`

Construct an IntervalIndex from an array of splits.

Parameters

breaks [array-like (1-dimensional)] Left and right bounds for each interval.

closed [{'left', 'right', 'both', 'neither'}, default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.

copy [boolean, default False] copy the data

dtype [dtype or None, default None] If None, dtype will be inferred

New in version 0.23.0.

Returns

IntervalIndex

See also:

interval_range Function to create a fixed frequency IntervalIndex.

IntervalIndex.from_arrays Construct from a left and right array.

IntervalIndex.from_tuples Construct from a sequence of tuples.

Examples

```
>>> pd.IntervalIndex.from_breaks([0, 1, 2, 3])
IntervalIndex([(0, 1], (1, 2], (2, 3]],
              closed='right',
              dtype='interval[int64]')
```

pandas.IntervalIndex.contains**IntervalIndex.contains**(*self*, *other*)

Check elementwise if the Intervals contain the value.

Return a boolean mask whether the value is contained in the Intervals of the IntervalIndex.

New in version 0.25.0.

Parameters**other** [scalar] The value to check whether it is contained in the Intervals.**Returns****boolean array****See also:****Interval.contains** Check whether Interval object contains value.**IntervalIndex.overlaps** Check if an Interval overlaps the values in the IntervalIndex.**Examples**

```

>>> intervals = pd.IntervalIndex.from_tuples([(0, 1), (1, 3), (2, 4)])
>>> intervals
IntervalIndex([(0, 1], (1, 3], (2, 4]],
              closed='right',
              dtype='interval[int64]')
>>> intervals.contains(0.5)
array([ True, False, False])

```

pandas.IntervalIndex.overlaps**IntervalIndex.overlaps**(*self*, *other*)

Check elementwise if an Interval overlaps the values in the IntervalIndex.

Two intervals overlap if they share a common point, including closed endpoints. Intervals that only have an open endpoint in common do not overlap.

New in version 0.24.0.

Parameters**other** [Interval] Interval to check against for an overlap.**Returns****ndarray** Boolean array positionally indicating where an overlap occurs.**See also:****Interval.overlaps** Check whether two Interval objects overlap.

Examples

```
>>> intervals = pd.IntervalIndex.from_tuples([(0, 1), (1, 3), (2, 4)])
>>> intervals
IntervalIndex([(0, 1], (1, 3], (2, 4]],
              closed='right',
              dtype='interval[int64]')
>>> intervals.overlaps(pd.Interval(0.5, 1.5))
array([ True,  True, False])
```

Intervals that share closed endpoints overlap:

```
>>> intervals.overlaps(pd.Interval(1, 3, closed='left'))
array([ True,  True,  True])
```

Intervals that only have an open endpoint in common do not overlap:

```
>>> intervals.overlaps(pd.Interval(1, 2, closed='right'))
array([False,  True, False])
```

pandas.IntervalIndex.set_closed

`IntervalIndex.set_closed(self, closed)`

Return an IntervalIndex identical to the current one, but closed on the specified side

New in version 0.24.0.

Parameters

closed [{'left', 'right', 'both', 'neither'}] Whether the intervals are closed on the left-side, right-side, both or neither.

Returns

new_index [IntervalIndex]

Examples

```
>>> index = pd.interval_range(0, 3)
>>> index
IntervalIndex([(0, 1], (1, 2], (2, 3]],
              closed='right',
              dtype='interval[int64]')
>>> index.set_closed('both')
IntervalIndex([(0, 1], [1, 2], [2, 3]],
              closed='both',
              dtype='interval[int64]')
```

pandas.IntervalIndex.to_tuples

`IntervalIndex.to_tuples(self, na_tuple=True)`

Return an Index of tuples of the form (left, right)

Parameters

na_tuple [boolean, default True] Returns NA as a tuple if True, (nan, nan), or just as the NA value itself if False, nan.

New in version 0.23.0.

Returns

tuples: Index

Examples

```
>>> idx = pd.IntervalIndex.from_arrays([0, np.nan, 2], [1, np.nan, 3])
>>> idx.to_tuples()
Index([(0.0, 1.0), (nan, nan), (2.0, 3.0)], dtype='object')
>>> idx.to_tuples(na_tuple=False)
Index([(0.0, 1.0), nan, (2.0, 3.0)], dtype='object')
```

IntervalIndex components

<i>IntervalIndex.from_arrays</i> (left, right[, ...])	Construct from two arrays defining the left and right bounds.
<i>IntervalIndex.from_tuples</i> (data[, closed, ...])	Construct an IntervalIndex from an array-like of tuples
<i>IntervalIndex.from_breaks</i> (breaks[, closed, ...])	Construct an IntervalIndex from an array of splits.
<i>IntervalIndex.left</i>	Return the left endpoints of each Interval in the IntervalIndex as an Index
<i>IntervalIndex.right</i>	Return the right endpoints of each Interval in the IntervalIndex as an Index
<i>IntervalIndex.mid</i>	Return the midpoint of each Interval in the IntervalIndex as an Index
<i>IntervalIndex.closed</i>	Whether the intervals are closed on the left-side, right-side, both or neither
<i>IntervalIndex.length</i>	Return an Index with entries denoting the length of each Interval in the IntervalIndex
<i>IntervalIndex.values</i>	Return the IntervalIndex's data as an IntervalArray.
<i>IntervalIndex.is_empty</i>	Indicates if an interval is empty, meaning it contains no points.
<i>IntervalIndex.is_non_overlapping_monotonic</i>	Return True if the IntervalIndex is non-overlapping (no Intervals share points) and is either monotonic increasing or monotonic decreasing, else False
<i>IntervalIndex.is_overlapping</i>	Return True if the IntervalIndex has overlapping intervals, else False.
<i>IntervalIndex.get_loc</i> (self, key, method, ...)	Get integer location, slice or boolean mask for requested label.
<i>IntervalIndex.get_indexer</i> (self, target, ...)	Compute indexer and mask for new index given the current index.
<i>IntervalIndex.set_closed</i> (self, closed)	Return an IntervalIndex identical to the current one, but closed on the specified side

Continued on next page

Table 145 – continued from previous page

<code>IntervalIndex.contains(self, other)</code>	Check elementwise if the Intervals contain the value.
<code>IntervalIndex.overlaps(self, other)</code>	Check elementwise if an Interval overlaps the values in the IntervalIndex.
<code>IntervalIndex.to_tuples(self[, na_tuple])</code>	Return an Index of tuples of the form (left, right)

pandas.IntervalIndex.get_loc

`IntervalIndex.get_loc(self, key: Any, method: Union[str, NoneType] = None) → Union[int, slice, numpy.ndarray]`

Get integer location, slice or boolean mask for requested label.

Parameters

key [label]

method [{None}, optional]

- default: matches where the label is within an interval only.

Returns

loc [int if unique index, slice if monotonic index, else mask]

Examples

```
>>> i1, i2 = pd.Interval(0, 1), pd.Interval(1, 2)
>>> index = pd.IntervalIndex([i1, i2])
>>> index.get_loc(1)
0
```

You can also supply a point inside an interval.

```
>>> index.get_loc(1.5)
1
```

If a label is in several intervals, you get the locations of all the relevant intervals.

```
>>> i3 = pd.Interval(0, 2)
>>> overlapping_index = pd.IntervalIndex([i1, i2, i3])
>>> overlapping_index.get_loc(0.5)
array([ True, False,  True])
```

Only exact matches will be returned if an interval is provided.

```
>>> index.get_loc(pd.Interval(0, 1))
0
```

pandas.IntervalIndex.get_indexer

`IntervalIndex.get_indexer(self, target: ~AnyArrayLike, method: Union[str, NoneType] = None, limit: Union[int, NoneType] = None, tolerance: Union[Any, NoneType] = None) → numpy.ndarray`

Compute indexer and mask for new index given the current index. The indexer should be then used

as an input to `ndarray.take` to align the current data to the new index.

Parameters

target [IntervalIndex or list of Intervals]

method [{None, 'pad'/'ffill', 'backfill'/'bfill', 'nearest'}], optional

- default: exact matches only.
- pad / ffill: find the PREVIOUS index value if no exact match.
- backfill / bfill: use NEXT index value if no exact match
- nearest: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.

limit [int, optional] Maximum number of consecutive labels in **target** to match for inexact matches.

tolerance [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations most satisfy the equation `abs(index[indexer] - target) <= tolerance`.

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index's type.

New in version 0.21.0: (list-like tolerance)

Returns

indexer [ndarray of int] Integers from 0 to n - 1 indicating that the index at these positions matches the corresponding target values. Missing values in the target are marked by -1.

Raises

NotImplementedError If any method argument other than the default of None is specified as these are not yet implemented.

Examples

```
>>> index = pd.Index(['c', 'a', 'b'])
>>> index.get_indexer(['a', 'b', 'x'])
array([ 1,  2, -1])
```

Notice that the return value is an array of locations in `index` and `x` is marked by -1, as it is not in `index`.

6.7.5 MultiIndex

MultiIndex

A multi-level, or hierarchical, index object for pandas objects.

pandas.MultiIndex

class pandas.MultiIndex

A multi-level, or hierarchical, index object for pandas objects.

Parameters

levels [sequence of arrays] The unique labels for each level.

codes [sequence of arrays] Integers for each level designating which label at each location.

New in version 0.24.0.

labels [sequence of arrays] Integers for each level designating which label at each location.

Deprecated since version 0.24.0: Use **codes** instead

sortorder [optional int] Level of sortedness (must be lexicographically sorted by that level).

names [optional sequence of objects] Names for each of the index levels. (name is accepted for compat).

copy [bool, default False] Copy the meta-data.

verify_integrity [bool, default True] Check that the levels/codes are consistent and valid.

See also:

MultiIndex.from_arrays Convert list of arrays to MultiIndex.

MultiIndex.from_product Create a MultiIndex from the cartesian product of iterables.

MultiIndex.from_tuples Convert list of tuples to a MultiIndex.

MultiIndex.from_frame Make a MultiIndex from a DataFrame.

Index The base pandas Index type.

Notes

See the [user guide](#) for more.

Examples

A new MultiIndex is typically constructed using one of the helper methods *MultiIndex.from_arrays()*, *MultiIndex.from_product()* and *MultiIndex.from_tuples()*. For example (using *.from_arrays()*):

```
>>> arrays = [[1, 1, 2, 2], ['red', 'blue', 'red', 'blue']]
>>> pd.MultiIndex.from_arrays(arrays, names=('number', 'color'))
MultiIndex([(1, 'red'),
            (1, 'blue'),
            (2, 'red'),
            (2, 'blue')],
            names=['number', 'color'])
```

See further examples for how to construct a MultiIndex in the doc strings of the mentioned helper methods.

Attributes

<i>names</i>	Names of levels in MultiIndex
<i>nlevels</i>	Integer number of levels in this MultiIndex.
<i>levshape</i>	A tuple with the length of each level.

pandas.MultiIndex.names

`MultiIndex.names`
Names of levels in MultiIndex

pandas.MultiIndex.nlevels

`MultiIndex.nlevels`
Integer number of levels in this MultiIndex.

pandas.MultiIndex.levshape

`MultiIndex.levshape`
A tuple with the length of each level.

levels	
codes	

Methods

<i>from_arrays</i> (arrays[, sortorder, names])	Convert arrays to MultiIndex.
<i>from_tuples</i> (tuples[, sortorder, names])	Convert list of tuples to MultiIndex.
<i>from_product</i> (iterables[, sortorder, names])	Make a MultiIndex from the cartesian product of multiple iterables.
<i>from_frame</i> (df[, sortorder, names])	Make a MultiIndex from a DataFrame.
<i>set_levels</i> (self, levels[, level, inplace, ...])	Set new levels on MultiIndex.
<i>set_codes</i> (self, codes[, level, inplace, ...])	Set new codes on MultiIndex.
<i>to_frame</i> (self[, index, name])	Create a DataFrame with the levels of the MultiIndex as columns.
<i>to_flat_index</i> (self)	Convert a MultiIndex to an Index of Tuples containing the level values.
<i>is_lexsorted</i> (self)	Return True if the codes are lexicographically sorted
<i>sortlevel</i> (self[, level, ascending, ...])	Sort MultiIndex at the requested level.
<i>droplevel</i> (self[, level])	Return index with requested level(s) removed.
<i>swaplevel</i> (self[, i, j])	Swap level i with level j.
<i>reorder_levels</i> (self, order)	Rearrange levels using input order.

Continued on next page

Table 148 – continued from previous page

<code>remove_unused_levels(self)</code>	Create a new MultiIndex from the current that removes unused levels, meaning that they are not expressed in the labels.
---	---

pandas.MultiIndex.from_arrays

classmethod `MultiIndex.from_arrays(arrays, sortorder=None, names=None)`

Convert arrays to MultiIndex.

Parameters

arrays [list / sequence of array-likes] Each array-like gives one level's value for each data point. `len(arrays)` is the number of levels.

sortorder [int or None] Level of sortedness (must be lexicographically sorted by that level).

names [list / sequence of str, optional] Names for the levels in the index.

Returns

index [MultiIndex]

See also:

`MultiIndex.from_tuples` Convert list of tuples to MultiIndex.

`MultiIndex.from_product` Make a MultiIndex from cartesian product of iterables.

`MultiIndex.from_frame` Make a MultiIndex from a DataFrame.

Examples

```
>>> arrays = [[1, 1, 2, 2], ['red', 'blue', 'red', 'blue']]
>>> pd.MultiIndex.from_arrays(arrays, names=('number', 'color'))
MultiIndex([(1, 'red'),
            (1, 'blue'),
            (2, 'red'),
            (2, 'blue')],
            names=['number', 'color'])
```

pandas.MultiIndex.from_tuples

classmethod `MultiIndex.from_tuples(tuples, sortorder=None, names=None)`

Convert list of tuples to MultiIndex.

Parameters

tuples [list / sequence of tuple-likes] Each tuple is the index of one row/column.

sortorder [int or None] Level of sortedness (must be lexicographically sorted by that level).

names [list / sequence of str, optional] Names for the levels in the index.

Returns

index [MultiIndex]

See also:

MultiIndex.from_arrays Convert list of arrays to MultiIndex.

MultiIndex.from_product Make a MultiIndex from cartesian product of iterables.

MultiIndex.from_frame Make a MultiIndex from a DataFrame.

Examples

```
>>> tuples = [(1, 'red'), (1, 'blue'),
...           (2, 'red'), (2, 'blue')]
>>> pd.MultiIndex.from_tuples(tuples, names=('number', 'color'))
MultiIndex([(1, 'red'),
            (1, 'blue'),
            (2, 'red'),
            (2, 'blue')],
           names=['number', 'color'])
```

pandas.MultiIndex.from_product

classmethod `MultiIndex.from_product(iterables, sortorder=None, names=None)`

Make a MultiIndex from the cartesian product of multiple iterables.

Parameters

iterables [list / sequence of iterables] Each iterable has unique labels for each level of the index.

sortorder [int or None] Level of sortedness (must be lexicographically sorted by that level).

names [list / sequence of str, optional] Names for the levels in the index.

Returns

index [MultiIndex]

See also:

MultiIndex.from_arrays Convert list of arrays to MultiIndex.

MultiIndex.from_tuples Convert list of tuples to MultiIndex.

MultiIndex.from_frame Make a MultiIndex from a DataFrame.

Examples

```
>>> numbers = [0, 1, 2]
>>> colors = ['green', 'purple']
>>> pd.MultiIndex.from_product([numbers, colors],
...                             names=['number', 'color'])
MultiIndex([(0, 'green'),
            (0, 'purple'),
```

(continues on next page)

(continued from previous page)

```
(1, 'green'),
(1, 'purple'),
(2, 'green'),
(2, 'purple']],
names=['number', 'color'])
```

pandas.MultiIndex.from_frame**classmethod** `MultiIndex.from_frame(df, sortorder=None, names=None)`

Make a MultiIndex from a DataFrame.

New in version 0.24.0.

Parameters**df** [DataFrame] DataFrame to be converted to MultiIndex.**sortorder** [int, optional] Level of sortedness (must be lexicographically sorted by that level).**names** [list-like, optional] If no names are provided, use the column names, or tuple of column names if the columns is a MultiIndex. If a sequence, overwrite names with the given sequence.**Returns****MultiIndex** The MultiIndex representation of the given DataFrame.**See also:****MultiIndex.from_arrays** Convert list of arrays to MultiIndex.**MultiIndex.from_tuples** Convert list of tuples to MultiIndex.**MultiIndex.from_product** Make a MultiIndex from cartesian product of iterables.**Examples**

```
>>> df = pd.DataFrame([[('HI', 'Temp'), ('HI', 'Precip'),
...                    ('NJ', 'Temp'), ('NJ', 'Precip')],
...                   columns=['a', 'b'])
>>> df
   a      b
0  HI  Temp
1  HI  Precip
2  NJ  Temp
3  NJ  Precip
```

```
>>> pd.MultiIndex.from_frame(df)
MultiIndex([(('HI', 'Temp'),
             ('HI', 'Precip'),
             ('NJ', 'Temp'),
             ('NJ', 'Precip'))],
           names=['a', 'b'])
```

Using explicit names, instead of the column names

```
>>> pd.MultiIndex.from_frame(df, names=['state', 'observation'])
MultiIndex([(HI, 'Temp'),
            (HI, 'Precip'),
            (NJ, 'Temp'),
            (NJ, 'Precip')],
            names=['state', 'observation'])
```

pandas.MultiIndex.set_levels

`MultiIndex.set_levels(self, levels, level=None, inplace=False, verify_integrity=True)`

Set new levels on MultiIndex. Defaults to returning new index.

Parameters

levels [sequence or list of sequence] new level(s) to apply

level [int, level name, or sequence of int/level names (default None)] level(s) to set (None for all levels)

inplace [bool] if True, mutates in place

verify_integrity [bool (default True)] if True, checks that levels and codes are compatible

Returns

new index (of same type and class...etc)

Examples

```
>>> idx = pd.MultiIndex.from_tuples([(1, 'one'), (1, 'two'),
                                   (2, 'one'), (2, 'two')],
                                   names=['foo', 'bar'])
>>> idx.set_levels(['a', 'b'], [1, 2])
MultiIndex([('a', 1),
            ('a', 2),
            ('b', 1),
            ('b', 2)],
            names=['foo', 'bar'])
>>> idx.set_levels(['a', 'b'], level=0)
MultiIndex([('a', 'one'),
            ('a', 'two'),
            ('b', 'one'),
            ('b', 'two')],
            names=['foo', 'bar'])
>>> idx.set_levels(['a', 'b'], level='bar')
MultiIndex([(1, 'a'),
            (1, 'b'),
            (2, 'a'),
            (2, 'b')],
            names=['foo', 'bar'])
>>> idx.set_levels(['a', 'b'], [1, 2], level=[0, 1])
```

(continues on next page)

(continued from previous page)

```
MultiIndex([('a', 1),
           ('a', 2),
           ('b', 1),
           ('b', 2)],
          names=['foo', 'bar'])
```

pandas.MultiIndex.set_codes

`MultiIndex.set_codes(self, codes, level=None, inplace=False, verify_integrity=True)`
 Set new codes on MultiIndex. Defaults to returning new index.

New in version 0.24.0: New name for deprecated method `set_labels`.

Parameters

codes [sequence or list of sequence] new codes to apply

level [int, level name, or sequence of int/level names (default None)] level(s) to set (None for all levels)

inplace [bool] if True, mutates in place

verify_integrity [bool (default True)] if True, checks that levels and codes are compatible

Returns

new index (of same type and class...etc)

Examples

```
>>> idx = pd.MultiIndex.from_tuples([(1, 'one'),
                                   (1, 'two'),
                                   (2, 'one'),
                                   (2, 'two')],
                                   names=['foo', 'bar'])
>>> idx.set_codes([[1, 0, 1, 0], [0, 0, 1, 1]])
MultiIndex([(2, 'one'),
           (1, 'one'),
           (2, 'two'),
           (1, 'two')],
          names=['foo', 'bar'])
>>> idx.set_codes([1, 0, 1, 0], level=0)
MultiIndex([(2, 'one'),
           (1, 'two'),
           (2, 'one'),
           (1, 'two')],
          names=['foo', 'bar'])
>>> idx.set_codes([0, 0, 1, 1], level='bar')
MultiIndex([(1, 'one'),
           (1, 'one'),
           (2, 'two'),
           (2, 'two')],
```

(continues on next page)

(continued from previous page)

```

        names=['foo', 'bar'])
>>> idx.set_codes([[1, 0, 1, 0], [0, 0, 1, 1]], level=[0, 1])
MultiIndex([(2, 'one'),
            (1, 'one'),
            (2, 'two'),
            (1, 'two')],
            names=['foo', 'bar'])

```

pandas.MultiIndex.to_frame**MultiIndex.to_frame**(*self*, *index=True*, *name=None*)

Create a DataFrame with the levels of the MultiIndex as columns.

Column ordering is determined by the DataFrame constructor with data as a dict.

New in version 0.24.0.

Parameters**index** [boolean, default True] Set the index of the returned DataFrame as the original MultiIndex.**name** [list / sequence of strings, optional] The passed names should substitute index level names.**Returns****DataFrame** [a DataFrame containing the original MultiIndex data.]**See also:***DataFrame***pandas.MultiIndex.to_flat_index****MultiIndex.to_flat_index**(*self*)

Convert a MultiIndex to an Index of Tuples containing the level values.

New in version 0.24.0.

Returns**pd.Index** Index with the MultiIndex data represented in Tuples.**Notes**

This method will simply return the caller if called by anything other than a MultiIndex.

Examples

```
>>> index = pd.MultiIndex.from_product(
...     [['foo', 'bar'], ['baz', 'qux']],
...     names=['a', 'b'])
>>> index.to_flat_index()
Index([( 'foo', 'baz'), ( 'foo', 'qux'),
      ( 'bar', 'baz'), ( 'bar', 'qux')],
      dtype='object')
```

pandas.MultiIndex.is_lexsorted

`MultiIndex.is_lexsorted(self)`

Return True if the codes are lexicographically sorted

Returns

bool

pandas.MultiIndex.sortlevel

`MultiIndex.sortlevel(self, level=0, ascending=True, sort_remaining=True)`

Sort MultiIndex at the requested level. The result will respect the original ordering of the associated factor at that level.

Parameters

level [list-like, int or str, default 0] If a string is given, must be a name of the level
If list-like must be names or ints of levels.

ascending [boolean, default True] False to sort in descending order Can also be
a list to specify a directed ordering

sort_remaining [sort by the remaining levels after level]

Returns

sorted_index [pd.MultiIndex] Resulting index.

indexer [np.ndarray] Indices of output values in original index.

pandas.MultiIndex.droplevel

`MultiIndex.droplevel(self, level=0)`

Return index with requested level(s) removed.

If resulting index has only 1 level left, the result will be of Index type, not MultiIndex.

New in version 0.23.1: (support for non-MultiIndex)

Parameters

level [int, str, or list-like, default 0] If a string is given, must be the name of a
level If list-like, elements must be names or indexes of levels.

Returns

Index or MultiIndex

pandas.MultiIndex.swaplevel**MultiIndex.swaplevel**(*self*, *i=-2*, *j=-1*)Swap level *i* with level *j*.

Calling this method does not change the ordering of the values.

Parameters**i** [int, str, default -2] First level of index to be swapped. Can pass level name as string. Type of parameters can be mixed.**j** [int, str, default -1] Second level of index to be swapped. Can pass level name as string. Type of parameters can be mixed.**Returns****MultiIndex** A new MultiIndex.Changed in version 0.18.1: The indexes *i* and *j* are now optional, and default to the two innermost levels of the index.**See also:****Series.swaplevel** Swap levels *i* and *j* in a MultiIndex.**Dataframe.swaplevel** Swap levels *i* and *j* in a MultiIndex on a particular axis.**Examples**

```

>>> mi = pd.MultiIndex(levels=[['a', 'b'], ['bb', 'aa']],
...                     codes=[[0, 0, 1, 1], [0, 1, 0, 1]])
>>> mi
MultiIndex([(('a', 'bb'),
             ('a', 'aa'),
             ('b', 'bb'),
             ('b', 'aa'))],
           )
>>> mi.swaplevel(0, 1)
MultiIndex([(('bb', 'a'),
             ('aa', 'a'),
             ('bb', 'b'),
             ('aa', 'b'))],
           )

```

pandas.MultiIndex.reorder_levels**MultiIndex.reorder_levels**(*self*, *order*)

Rearrange levels using input order. May not drop or duplicate levels

Returns**MultiIndex**

pandas.MultiIndex.remove_unused_levels

`MultiIndex.remove_unused_levels(self)`

Create a new MultiIndex from the current that removes unused levels, meaning that they are not expressed in the labels.

The resulting MultiIndex will have the same outward appearance, meaning the same `.values` and ordering. It will also be `.equals()` to the original.

New in version 0.20.0.

Returns

MultiIndex

Examples

```
>>> mi = pd.MultiIndex.from_product([range(2), list('ab')])
>>> mi
MultiIndex([(0, 'a'),
            (0, 'b'),
            (1, 'a'),
            (1, 'b')],
           )
```

```
>>> mi[2:]
MultiIndex([(1, 'a'),
            (1, 'b')],
           )
```

The 0 from the first level is not represented and can be removed

```
>>> mi2 = mi[2:].remove_unused_levels()
>>> mi2.levels
FrozenList([[1], ['a', 'b']])
```

IndexSlice

Create an object to more easily perform multi-index slicing

pandas.IndexSlice

`pandas.IndexSlice = <pandas.core.indexing._IndexSlice object>`

Create an object to more easily perform multi-index slicing

See also:

MultiIndex.remove_unused_levels New MultiIndex with no unused levels.

Notes

See *Defined Levels* for further info on slicing a MultiIndex.

Examples

```
>>> midx = pd.MultiIndex.from_product(['A0', 'A1'], ['B0', 'B1', 'B2', 'B3'])
>>> columns = ['foo', 'bar']
>>> dfmi = pd.DataFrame(np.arange(16).reshape((len(midx), len(columns))),
                        index=midx, columns=columns)
```

Using the default slice command:

```
>>> dfmi.loc[(slice(None), slice('B0', 'B1')), :]
      foo  bar
A0 B0    0    1
   B1    2    3
A1 B0    8    9
   B1   10   11
```

Using the IndexSlice class for a more intuitive command:

```
>>> idx = pd.IndexSlice
>>> dfmi.loc[idx[:, 'B0':'B1'], :]
      foo  bar
A0 B0    0    1
   B1    2    3
A1 B0    8    9
   B1   10   11
```

MultiIndex constructors

<i>MultiIndex.from_arrays</i> (arrays[, sortorder, ...])	Convert arrays to MultiIndex.
<i>MultiIndex.from_tuples</i> (tuples[, sortorder, ...])	Convert list of tuples to MultiIndex.
<i>MultiIndex.from_product</i> (iterables[, ...])	Make a MultiIndex from the cartesian product of multiple iterables.
<i>MultiIndex.from_frame</i> (df[, sortorder, names])	Make a MultiIndex from a DataFrame.

MultiIndex properties

<i>MultiIndex.names</i>	Names of levels in MultiIndex
<i>MultiIndex.levels</i>	
<i>MultiIndex.codes</i>	
<i>MultiIndex.nlevels</i>	Integer number of levels in this MultiIndex.
<i>MultiIndex.levshape</i>	A tuple with the length of each level.

pandas.MultiIndex.levels

MultiIndex.levels

pandas.MultiIndex.codes

MultiIndex.codes

MultilIndex components

<code>MultiIndex.set_levels(self, levels[, level, ...])</code>	Set new levels on MultiIndex.
<code>MultiIndex.set_codes(self, codes[, level, ...])</code>	Set new codes on MultiIndex.
<code>MultiIndex.to_hierarchical(self, n_repeat[, ...])</code>	(DEPRECATED) Return a MultiIndex reshaped to conform to the shapes given by <code>n_repeat</code> and <code>n_shuffle</code> .
<code>MultiIndex.to_flat_index(self)</code>	Convert a MultiIndex to an Index of Tuples containing the level values.
<code>MultiIndex.to_frame(self[, index, name])</code>	Create a DataFrame with the levels of the MultiIndex as columns.
<code>MultiIndex.is_lexsorted(self)</code>	Return True if the codes are lexicographically sorted
<code>MultiIndex.sortlevel(self[, level, ...])</code>	Sort MultiIndex at the requested level.
<code>MultiIndex.droplevel(self[, level])</code>	Return index with requested level(s) removed.
<code>MultiIndex.swaplevel(self[, i, j])</code>	Swap level <code>i</code> with level <code>j</code> .
<code>MultiIndex.reorder_levels(self, order)</code>	Rearrange levels using input order.
<code>MultiIndex.remove_unused_levels(self)</code>	Create a new MultiIndex from the current that removes unused levels, meaning that they are not expressed in the labels.

pandas.MultiIndex.to_hierarchical

`MultiIndex.to_hierarchical(self, n_repeat, n_shuffle=1)`

Return a MultiIndex reshaped to conform to the shapes given by `n_repeat` and `n_shuffle`.

Deprecated since version 0.24.0.

Useful to replicate and rearrange a MultiIndex for combination with another Index with `n_repeat` items.

Parameters

n_repeat [int] Number of times to repeat the labels on self

n_shuffle [int] Controls the reordering of the labels. If the result is going to be an inner level in a MultiIndex, `n_shuffle` will need to be greater than one. The size of each label must divisible by `n_shuffle`.

Returns

MultiIndex

Examples

```
>>> idx = pd.MultiIndex.from_tuples([(1, 'one'), (1, 'two'),
                                     (2, 'one'), (2, 'two')])
>>> idx.to_hierarchical(3)
MultiIndex([(1, 'one'),
            (1, 'one'),
            (1, 'one'),
            (1, 'two'),
            (1, 'two'),
            (1, 'two')])
```

(continues on next page)

(continued from previous page)

```
(2, 'one'),
(2, 'one'),
(2, 'one'),
(2, 'two'),
(2, 'two'),
(2, 'two')],
)
```

MultiIndex selecting

<code>MultiIndex.get_loc(self, key[, method])</code>	Get location for a label or a tuple of labels as an integer, slice or boolean mask.
<code>MultiIndex.get_loc_level(self, key[, level, ...])</code>	Get both the location for the requested label(s) and the resulting sliced index.
<code>MultiIndex.get_indexer(self, target[, ...])</code>	Compute indexer and mask for new index given the current index.
<code>MultiIndex.get_level_values(self, level)</code>	Return vector of label values for requested level, equal to the length of the index.

pandas.MultiIndex.get_loc

`MultiIndex.get_loc(self, key, method=None)`

Get location for a label or a tuple of labels as an integer, slice or boolean mask.

Parameters

key [label or tuple of labels (one for each level)]

method [None]

Returns

loc [int, slice object or boolean mask] If the key is past the lexsort depth, the return may be a boolean mask array, otherwise it is always a slice or int.

See also:

`Index.get_loc` The `get_loc` method for (single-level) index.

`MultiIndex.slice_locs` Get slice location given start label(s) and end label(s).

`MultiIndex.get_locs` Get location for a label/slice/list/mask or a sequence of such.

Notes

The key cannot be a slice, list of same-level labels, a boolean mask, or a sequence of such. If you want to use those, use `MultiIndex.get_locs()` instead.

Examples

```
>>> mi = pd.MultiIndex.from_arrays([list('abb'), list('def')])
```

```
>>> mi.get_loc('b')
slice(1, 3, None)
```

```
>>> mi.get_loc(('b', 'e'))
1
```

pandas.MultiIndex.get_loc_level

`MultiIndex.get_loc_level(self, key, level=0, drop_level=True)`

Get both the location for the requested label(s) and the resulting sliced index.

Parameters

key [label or sequence of labels]

level [int/level name or list thereof, optional]

drop_level [bool, default True] if `False`, the resulting index will not drop any level.

Returns

loc [A 2-tuple where the elements are:] Element 0: int, slice object or boolean array
Element 1: The resulting sliced multiindex/index. If the key contains all levels, this will be `None`.

See also:

`MultiIndex.get_loc` Get location for a label or a tuple of labels.

`MultiIndex.get_locs` Get location for a label/slice/list/mask or a sequence of such.

Examples

```
>>> mi = pd.MultiIndex.from_arrays([list('abb'), list('def')],
...                               names=['A', 'B'])
```

```
>>> mi.get_loc_level('b')
(slice(1, 3, None), Index(['e', 'f'], dtype='object', name='B'))
```

```
>>> mi.get_loc_level('e', level='B')
(array([False,  True, False], dtype=bool),
 Index(['b'], dtype='object', name='A'))
```

```
>>> mi.get_loc_level(['b', 'e'])
(1, None)
```

pandas.MultiIndex.get_indexer

`MultiIndex.get_indexer(self, target, method=None, limit=None, tolerance=None)`

Compute indexer and mask for new index given the current index. The indexer should be then used as an input to `ndarray.take` to align the current data to the new index.

Parameters

target [MultiIndex or list of tuples]

method [{None, 'pad'/'ffill', 'backfill'/'bfill', 'nearest'}, optional]

- default: exact matches only.
- pad / ffill: find the PREVIOUS index value if no exact match.
- backfill / bfill: use NEXT index value if no exact match
- nearest: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.

limit [int, optional] Maximum number of consecutive labels in **target** to match for inexact matches.

tolerance [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations most satisfy the equation `abs(index[indexer] - target) <= tolerance`.

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index's type.

New in version 0.21.0: (list-like tolerance)

Returns

indexer [ndarray of int] Integers from 0 to n - 1 indicating that the index at these positions matches the corresponding target values. Missing values in the target are marked by -1.

Examples

```
>>> index = pd.Index(['c', 'a', 'b'])
>>> index.get_indexer(['a', 'b', 'x'])
array([ 1,  2, -1])
```

Notice that the return value is an array of locations in **index** and **x** is marked by -1, as it is not in **index**.

pandas.MultiIndex.get_level_values

`MultiIndex.get_level_values(self, level)`

Return vector of label values for requested level, equal to the length of the index.

Parameters

level [int or str] **level** is either the integer position of the level in the MultiIndex, or the name of the level.

Returns

values [Index] Values is a level of this MultiIndex converted to a single *Index* (or subclass thereof).

Examples

Create a MultiIndex:

```
>>> mi = pd.MultiIndex.from_arrays((list('abc'), list('def')))
>>> mi.names = ['level_1', 'level_2']
```

Get level values by supplying level as either integer or name:

```
>>> mi.get_level_values(0)
Index(['a', 'b', 'c'], dtype='object', name='level_1')
>>> mi.get_level_values('level_2')
Index(['d', 'e', 'f'], dtype='object', name='level_2')
```

6.7.6 DatetimeIndex

DatetimeIndex

Immutable ndarray of datetime64 data, represented internally as int64, and which can be boxed to Timestamp objects that are subclasses of datetime and carry metadata such as frequency information.

pandas.DatetimeIndex

class pandas.DatetimeIndex

Immutable ndarray of datetime64 data, represented internally as int64, and which can be boxed to Timestamp objects that are subclasses of datetime and carry metadata such as frequency information.

Parameters

data [array-like (1-dimensional), optional] Optional datetime-like data to construct index with

copy [bool] Make a copy of input ndarray

freq [string or pandas offset object, optional] One of pandas date offset strings or corresponding objects. The string 'infer' can be passed in order to set the frequency of the index as the inferred frequency upon creation

start [starting value, datetime-like, optional] If data is None, start is used as the start point in generating regular timestamp data.

Deprecated since version 0.24.0.

periods [int, optional, > 0] Number of periods to generate, if generating index. Takes precedence over end argument

Deprecated since version 0.24.0.

end [end time, datetime-like, optional] If periods is none, generated index will extend to first conforming time on or just past end argument

Deprecated since version 0.24.0.

closed [string or None, default None] Make the interval closed with respect to the given frequency to the 'left', 'right', or both sides (None)

Deprecated since version 0.24.: 0

tz [pytz.timezone or dateutil.tz.tzfile]

ambiguous ['infer', bool-ndarray, 'NaT', default 'raise'] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the *ambiguous* parameter dictates how ambiguous times should be handled.

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False signifies a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times

name [object] Name to be stored in the index

dayfirst [bool, default False] If True, parse dates in *data* with the day first order

yearfirst [bool, default False] If True parse dates in *data* with the year first order

See also:

Index The base pandas Index type.

TimedeltaIndex Index of timedelta64 data.

PeriodIndex Index of Period data.

to_datetime Convert argument to datetime.

date_range Create a fixed-frequency DatetimeIndex.

Notes

To learn more about the frequency strings, please see [this link](#).

Creating a DatetimeIndex based on *start*, *periods*, and *end* has been deprecated in favor of *date_range()*.

Attributes

<i>year</i>	The year of the datetime.
<i>month</i>	The month as January=1, December=12.
<i>day</i>	The days of the datetime.
<i>hour</i>	The hours of the datetime.
<i>minute</i>	The minutes of the datetime.
<i>second</i>	The seconds of the datetime.
<i>microsecond</i>	The microseconds of the datetime.
<i>nanosecond</i>	The nanoseconds of the datetime.
<i>date</i>	Returns numpy array of python datetime.date objects (namely, the date part of Timestamps without timezone information).
<i>time</i>	Returns numpy array of datetime.time.

Continued on next page

Table 155 – continued from previous page

<i>timetz</i>	Returns numpy array of datetime.time also containing timezone information.
<i>dayofyear</i>	The ordinal day of the year.
<i>weekofyear</i>	The week ordinal of the year.
<i>week</i>	The week ordinal of the year.
<i>dayofweek</i>	The day of the week with Monday=0, Sunday=6.
<i>weekday</i>	The day of the week with Monday=0, Sunday=6.
<i>quarter</i>	The quarter of the date.
<i>freq</i>	Return the frequency object if it is set, otherwise None.
<i>freqstr</i>	Return the frequency object as a string if it is set, otherwise None.
<i>is_month_start</i>	Indicates whether the date is the first day of the month.
<i>is_month_end</i>	Indicates whether the date is the last day of the month.
<i>is_quarter_start</i>	Indicator for whether the date is the first day of a quarter.
<i>is_quarter_end</i>	Indicator for whether the date is the last day of a quarter.
<i>is_year_start</i>	Indicate whether the date is the first day of a year.
<i>is_year_end</i>	Indicate whether the date is the last day of the year.
<i>is_leap_year</i>	Boolean indicator if the date belongs to a leap year.
<i>inferred_freq</i>	Tryies to return a string representing a frequency guess, generated by infer_freq.

pandas.DatetimeIndex.year

`DatetimeIndex.year`
The year of the datetime.

pandas.DatetimeIndex.month

`DatetimeIndex.month`
The month as January=1, December=12.

pandas.DatetimeIndex.day

`DatetimeIndex.day`
The days of the datetime.

pandas.DatetimeIndex.hour

`DatetimeIndex.hour`
The hours of the datetime.

pandas.DatetimeIndex.minute

`DatetimeIndex.minute`

The minutes of the datetime.

pandas.DatetimeIndex.second

`DatetimeIndex.second`

The seconds of the datetime.

pandas.DatetimeIndex.microsecond

`DatetimeIndex.microsecond`

The microseconds of the datetime.

pandas.DatetimeIndex.nanosecond

`DatetimeIndex.nanosecond`

The nanoseconds of the datetime.

pandas.DatetimeIndex.date

`DatetimeIndex.date`

Returns numpy array of python datetime.date objects (namely, the date part of Timestamps without timezone information).

pandas.DatetimeIndex.time

`DatetimeIndex.time`

Returns numpy array of datetime.time. The time part of the Timestamps.

pandas.DatetimeIndex.timetz

`DatetimeIndex.timetz`

Returns numpy array of datetime.time also containing timezone information. The time part of the Timestamps.

pandas.DatetimeIndex.dayofyear

`DatetimeIndex.dayofyear`

The ordinal day of the year.

pandas.DatetimeIndex.weekofyear

`DatetimeIndex.weekofyear`

The week ordinal of the year.

`pandas.DatetimeIndex.week`

`DatetimeIndex.week`

The week ordinal of the year.

`pandas.DatetimeIndex.dayofweek`

`DatetimeIndex.dayofweek`

The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the *dt* accessor) or `DatetimeIndex`.

Returns

Series or Index Containing integers indicating the day number.

See also:

`Series.dt.dayofweek` Alias.

`Series.dt.weekday` Alias.

`Series.dt.day_name` Returns the name of the day of the week.

Examples

```
>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31    5
2017-01-01    6
2017-01-02    0
2017-01-03    1
2017-01-04    2
2017-01-05    3
2017-01-06    4
2017-01-07    5
2017-01-08    6
Freq: D, dtype: int64
```

`pandas.DatetimeIndex.weekday`

`DatetimeIndex.weekday`

The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the *dt* accessor) or `DatetimeIndex`.

Returns

Series or Index Containing integers indicating the day number.

See also:

`Series.dt.dayofweek` Alias.

`Series.dt.weekday` Alias.

`Series.dt.day_name` Returns the name of the day of the week.

Examples

```
>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31    5
2017-01-01    6
2017-01-02    0
2017-01-03    1
2017-01-04    2
2017-01-05    3
2017-01-06    4
2017-01-07    5
2017-01-08    6
Freq: D, dtype: int64
```

`pandas.DatetimeIndex.quarter`

`DatetimeIndex.quarter`

The quarter of the date.

`pandas.DatetimeIndex.freq`

`DatetimeIndex.freq`

Return the frequency object if it is set, otherwise None.

`pandas.DatetimeIndex.freqstr`

`DatetimeIndex.freqstr`

Return the frequency object as a string if it is set, otherwise None.

`pandas.DatetimeIndex.is_month_start`

`DatetimeIndex.is_month_start`

Indicates whether the date is the first day of the month.

Returns

Series or array For Series, returns a Series with boolean values. For `DatetimeIndex`, returns a boolean array.

See also:

`is_month_start` Return a boolean indicating whether the date is the first day of the month.

`is_month_end` Return a boolean indicating whether the date is the last day of the month.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```
>>> s = pd.Series(pd.date_range("2018-02-27", periods=3))
>>> s
0    2018-02-27
1    2018-02-28
2    2018-03-01
dtype: datetime64[ns]
>>> s.dt.is_month_start
0    False
1    False
2     True
dtype: bool
>>> s.dt.is_month_end
0    False
1     True
2    False
dtype: bool
```

```
>>> idx = pd.date_range("2018-02-27", periods=3)
>>> idx.is_month_start
array([False, False,  True])
>>> idx.is_month_end
array([False,  True, False])
```

pandas.DatetimeIndex.is_month_end

DatetimeIndex.is_month_end

Indicates whether the date is the last day of the month.

Returns

Series or array For Series, returns a Series with boolean values. For DatetimeIndex, returns a boolean array.

See also:

`is_month_start` Return a boolean indicating whether the date is the first day of the month.

`is_month_end` Return a boolean indicating whether the date is the last day of the month.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```
>>> s = pd.Series(pd.date_range("2018-02-27", periods=3))
>>> s
0    2018-02-27
1    2018-02-28
```

(continues on next page)

(continued from previous page)

```

2    2018-03-01
dtype: datetime64[ns]
>>> s.dt.is_month_start
0    False
1    False
2     True
dtype: bool
>>> s.dt.is_month_end
0    False
1     True
2    False
dtype: bool

```

```

>>> idx = pd.date_range("2018-02-27", periods=3)
>>> idx.is_month_start
array([False, False,  True])
>>> idx.is_month_end
array([False,  True, False])

```

pandas.DatetimeIndex.is_quarter_start

DatetimeIndex.is_quarter_start

Indicator for whether the date is the first day of a quarter.

Returns

is_quarter_start [Series or DatetimeIndex] The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

quarter Return the quarter of the date.

is_quarter_end Similar property for indicating the quarter start.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```

>>> df = pd.DataFrame({'dates': pd.date_range("2017-03-30",
...                                           periods=4)})
>>> df.assign(quarter=df.dates.dt.quarter,
...           is_quarter_start=df.dates.dt.is_quarter_start)
   dates      quarter  is_quarter_start
0 2017-03-30         1             False
1 2017-03-31         1             False
2 2017-04-01         2              True
3 2017-04-02         2             False

```

```
>>> idx = pd.date_range('2017-03-30', periods=4)
>>> idx
DatetimeIndex(['2017-03-30', '2017-03-31', '2017-04-01', '2017-04-02'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_quarter_start
array([False, False,  True, False])
```

pandas.DatetimeIndex.is_quarter_end

DatetimeIndex.is_quarter_end

Indicator for whether the date is the last day of a quarter.

Returns

is_quarter_end [Series or DatetimeIndex] The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

quarter Return the quarter of the date.

is_quarter_start Similar property indicating the quarter start.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```
>>> df = pd.DataFrame({'dates': pd.date_range("2017-03-30",
...                                         periods=4)})
>>> df.assign(quarter=df.dates.dt.quarter,
...          is_quarter_end=df.dates.dt.is_quarter_end)
   dates  quarter  is_quarter_end
0 2017-03-30      1             False
1 2017-03-31      1              True
2 2017-04-01      2             False
3 2017-04-02      2             False
```

```
>>> idx = pd.date_range('2017-03-30', periods=4)
>>> idx
DatetimeIndex(['2017-03-30', '2017-03-31', '2017-04-01', '2017-04-02'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_quarter_end
array([False,  True, False, False])
```

pandas.DatetimeIndex.is_year_start

DatetimeIndex.is_year_start

Indicate whether the date is the first day of a year.

Returns

Series or DatetimeIndex The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

is_year_end Similar property indicating the last day of the year.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```
>>> dates = pd.Series(pd.date_range("2017-12-30", periods=3))
>>> dates
0    2017-12-30
1    2017-12-31
2    2018-01-01
dtype: datetime64[ns]
```

```
>>> dates.dt.is_year_start
0    False
1    False
2     True
dtype: bool
```

```
>>> idx = pd.date_range("2017-12-30", periods=3)
>>> idx
DatetimeIndex(['2017-12-30', '2017-12-31', '2018-01-01'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_year_start
array([False, False,  True])
```

pandas.DatetimeIndex.is_year_end

DatetimeIndex.is_year_end

Indicate whether the date is the last day of the year.

Returns

Series or DatetimeIndex The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

`is_year_start` Similar property indicating the start of the year.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```
>>> dates = pd.Series(pd.date_range("2017-12-30", periods=3))
>>> dates
0    2017-12-30
1    2017-12-31
2    2018-01-01
dtype: datetime64[ns]
```

```
>>> dates.dt.is_year_end
0    False
1     True
2    False
dtype: bool
```

```
>>> idx = pd.date_range("2017-12-30", periods=3)
>>> idx
DatetimeIndex(['2017-12-30', '2017-12-31', '2018-01-01'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_year_end
array([False,  True, False])
```

pandas.DatetimeIndex.is_leap_year

DatetimeIndex.is_leap_year

Boolean indicator if the date belongs to a leap year.

A leap year is a year, which has 366 days (instead of 365) including 29th of February as an intercalary day. Leap years are years which are multiples of four with the exception of years divisible by 100 but not by 400.

Returns

Series or ndarray Booleans indicating if dates belong to a leap year.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```
>>> idx = pd.date_range("2012-01-01", "2015-01-01", freq="Y")
>>> idx
DatetimeIndex(['2012-12-31', '2013-12-31', '2014-12-31'],
              dtype='datetime64[ns]', freq='A-DEC')
>>> idx.is_leap_year
array([ True, False, False], dtype=bool)
```

```

>>> dates = pd.Series(idx)
>>> dates_series
0    2012-12-31
1    2013-12-31
2    2014-12-31
dtype: datetime64[ns]
>>> dates_series.dt.is_leap_year
0     True
1    False
2    False
dtype: bool

```

pandas.DatetimeIndex.inferred_freq

DatetimeIndex.inferred_freq

Tryies to return a string representing a frequency guess, generated by `infer_freq`. Returns None if it can't autodetect the frequency.

tz	
----	--

Methods

<i>normalize</i> (self, *args, **kwargs)	Convert times to midnight.
<i>strftime</i> (self, *args, **kwargs)	Convert to Index using specified <code>date_format</code> .
<i>snap</i> (self[, freq])	Snap time stamps to nearest occurring frequency
<i>tz_convert</i> (self, *args, **kwargs)	Convert tz-aware Datetime Array/Index from one time zone to another.
<i>tz_localize</i> (self, *args, **kwargs)	Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index.
<i>round</i> (self, *args, **kwargs)	Perform round operation on the data to the specified <i>freq</i> .
<i>floor</i> (self, *args, **kwargs)	Perform floor operation on the data to the specified <i>freq</i> .
<i>ceil</i> (self, *args, **kwargs)	Perform ceil operation on the data to the specified <i>freq</i> .
<i>to_period</i> (self, *args, **kwargs)	Cast to PeriodArray/Index at a particular frequency.
<i>to_perioddelta</i> (self, *args, **kwargs)	Calculate TimedeltaArray of difference between index values and index converted to PeriodArray at specified freq.
<i>to_pydatetime</i> (self, *args, **kwargs)	Return Datetime Array/Index as object ndarray of <code>datetime.datetime</code> objects
<i>to_series</i> (self[, keep_tz, index, name])	Create a Series with both index and values equal to the index keys useful with <code>map</code> for returning an indexer based on an index
<i>to_frame</i> (self[, index, name])	Create a DataFrame with a column containing the Index.

Continued on next page

Table 156 – continued from previous page

<code>month_name(self, *args, **kwargs)</code>	Return the month names of the <code>DatetimeIndex</code> with specified locale.
<code>day_name(self, *args, **kwargs)</code>	Return the day names of the <code>DatetimeIndex</code> with specified locale.
<code>mean(self, *args, **kwargs)</code>	Return the mean value of the Array.

pandas.DatetimeIndex.normalize

`DatetimeIndex.normalize(self, *args, **kwargs)`

Convert times to midnight.

The time component of the date-time is converted to midnight i.e. 00:00:00. This is useful in cases, when the time does not matter. Length is unaltered. The timezones are unaffected.

This method is available on Series with datetime values under the `.dt` accessor, and directly on Datetime Array/Index.

Returns

DatetimeArray, DatetimeIndex or Series The same type as the original data. Series will have the same name and index. `DatetimeIndex` will have the same name.

See also:

floor Floor the datetimes to the specified freq.

ceil Ceil the datetimes to the specified freq.

round Round the datetimes to the specified freq.

Examples

```
>>> idx = pd.date_range(start='2014-08-01 10:00', freq='H',
...                       periods=3, tz='Asia/Calcutta')
>>> idx
DatetimeIndex(['2014-08-01 10:00:00+05:30',
               '2014-08-01 11:00:00+05:30',
               '2014-08-01 12:00:00+05:30'],
              dtype='datetime64[ns, Asia/Calcutta]', freq='H')
>>> idx.normalize()
DatetimeIndex(['2014-08-01 00:00:00+05:30',
               '2014-08-01 00:00:00+05:30',
               '2014-08-01 00:00:00+05:30'],
              dtype='datetime64[ns, Asia/Calcutta]', freq=None)
```

pandas.DatetimeIndex.strftime

`DatetimeIndex.strftime(self, *args, **kwargs)`

Convert to Index using specified `date_format`.

Return an Index of formatted strings specified by `date_format`, which supports the same string format as the python standard library. Details of the string format can be found in [python string format doc](#).

Parameters

date_format [str] Date format string (e.g. “%Y-%m-%d”).

Returns

Index Index of formatted strings.

See also:

to_datetime Convert the given argument to datetime.

DatetimeIndex.normalize Return DatetimeIndex with times to midnight.

DatetimeIndex.round Round the DatetimeIndex to the specified freq.

DatetimeIndex.floor Floor the DatetimeIndex to the specified freq.

Examples

```
>>> rng = pd.date_range(pd.Timestamp("2018-03-10 09:00"),
...                      periods=3, freq='s')
>>> rng.strftime('%B %d, %Y, %r')
Index(['March 10, 2018, 09:00:00 AM', 'March 10, 2018, 09:00:01 AM',
       'March 10, 2018, 09:00:02 AM'],
      dtype='object')
```

pandas.DatetimeIndex.snap

DatetimeIndex.snap(*self*, *freq='S'*)

Snap time stamps to nearest occurring frequency

Returns

DatetimeIndex

pandas.DatetimeIndex.tz_convert

DatetimeIndex.tz_convert(*self*, **args*, ***kwargs*)

Convert tz-aware Datetime Array/Index from one time zone to another.

Parameters

tz [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time. Corresponding timestamps would be converted to this time zone of the Datetime Array/Index. A *tz* of None will convert to UTC and remove the timezone information.

Returns

Array or Index

Raises

TypeError If Datetime Array/Index is tz-naive.

See also:

DatetimeIndex.tz A timezone that has a variable offset from UTC.

DatetimeIndex.tz_localize Localize tz-naive DatetimeIndex to a given time zone, or remove timezone from a tz-aware DatetimeIndex.

Examples

With the `tz` parameter, we can change the DatetimeIndex to other time zones:

```
>>> dti = pd.date_range(start='2014-08-01 09:00',
...                       freq='H', periods=3, tz='Europe/Berlin')
```

```
>>> dti
DatetimeIndex(['2014-08-01 09:00:00+02:00',
               '2014-08-01 10:00:00+02:00',
               '2014-08-01 11:00:00+02:00'],
              dtype='datetime64[ns, Europe/Berlin]', freq='H')
```

```
>>> dti.tz_convert('US/Central')
DatetimeIndex(['2014-08-01 02:00:00-05:00',
               '2014-08-01 03:00:00-05:00',
               '2014-08-01 04:00:00-05:00'],
              dtype='datetime64[ns, US/Central]', freq='H')
```

With the `tz=None`, we can remove the timezone (after converting to UTC if necessary):

```
>>> dti = pd.date_range(start='2014-08-01 09:00', freq='H',
...                       periods=3, tz='Europe/Berlin')
```

```
>>> dti
DatetimeIndex(['2014-08-01 09:00:00+02:00',
               '2014-08-01 10:00:00+02:00',
               '2014-08-01 11:00:00+02:00'],
              dtype='datetime64[ns, Europe/Berlin]', freq='H')
```

```
>>> dti.tz_convert(None)
DatetimeIndex(['2014-08-01 07:00:00',
               '2014-08-01 08:00:00',
               '2014-08-01 09:00:00'],
              dtype='datetime64[ns]', freq='H')
```

pandas.DatetimeIndex.tz_localize

DatetimeIndex.tz_localize(*self*, *args, **kwargs)

Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index.

This method takes a time zone (tz) naive Datetime Array/Index object and makes this time zone aware. It does not move the time to another time zone. Time zone localization helps to switch from time zone aware to time zone unaware objects.

Parameters

tz [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone to convert timestamps to. Passing `None` will remove the time zone information preserving local time.

ambiguous ['infer', 'NaT', bool array, default 'raise'] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the *ambiguous* parameter dictates how ambiguous times should be handled.

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False signifies a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an `AmbiguousTimeError` if there are ambiguous times

nonexistent ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift_forward' will shift the nonexistent time forward to the closest existing time
- 'shift_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise an `NonExistentTimeError` if there are nonexistent times

New in version 0.24.0.

errors [{'raise', 'coerce'}, default None]

- 'raise' will raise a `NonExistentTimeError` if a timestamp is not valid in the specified time zone (e.g. due to a transition from or to DST time). Use `nonexistent='raise'` instead.
- 'coerce' will return NaT if the timestamp can not be converted to the specified time zone. Use `nonexistent='NaT'` instead.

Deprecated since version 0.24.0.

Returns

Same type as self Array/Index converted to the specified time zone.

Raises

TypeError If the Datetime Array/Index is tz-aware and tz is not None.

See also:

DatetimeIndex.tz_convert Convert tz-aware `DatetimeIndex` from one time zone to another.

Examples

```
>>> tz_naive = pd.date_range('2018-03-01 09:00', periods=3)
>>> tz_naive
DatetimeIndex(['2018-03-01 09:00:00', '2018-03-02 09:00:00',
              '2018-03-03 09:00:00'],
              dtype='datetime64[ns]', freq='D')
```

Localize DatetimeIndex in US/Eastern time zone:

```
>>> tz_aware = tz_naive.tz_localize(tz='US/Eastern')
>>> tz_aware
DatetimeIndex(['2018-03-01 09:00:00-05:00',
              '2018-03-02 09:00:00-05:00',
              '2018-03-03 09:00:00-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq='D')
```

With the `tz=None`, we can remove the time zone information while keeping the local time (not converted to UTC):

```
>>> tz_aware.tz_localize(None)
DatetimeIndex(['2018-03-01 09:00:00', '2018-03-02 09:00:00',
              '2018-03-03 09:00:00'],
              dtype='datetime64[ns]', freq='D')
```

Be careful with DST changes. When there is sequential data, pandas can infer the DST time:

```
>>> s = pd.to_datetime(pd.Series(['2018-10-28 01:30:00', ... '2018-10-28 02:00:00', ... '2018-10-28 02:30:00', ... '2018-10-28 02:00:00', ... '2018-10-28 02:30:00', ... '2018-10-28 03:00:00', ... '2018-10-28 03:30:00']))
>>> s.dt.tz_localize('CET', ambiguous='infer')
0 2018-10-28 01:30:00+02:00
1 2018-10-28 02:00:00+02:00
2 2018-10-28 02:30:00+02:00
3 2018-10-28 02:00:00+01:00
4 2018-10-28 02:30:00+01:00
5 2018-10-28 03:00:00+01:00
6 2018-10-28 03:30:00+01:00
dtype: datetime64[ns, CET]
```

In some cases, inferring the DST is impossible. In such cases, you can pass an ndarray to the `ambiguous` parameter to set the DST explicitly

```
>>> s = pd.to_datetime(pd.Series(['2018-10-28 01:20:00',
...                               '2018-10-28 02:36:00',
...                               '2018-10-28 03:46:00']))
>>> s.dt.tz_localize('CET', ambiguous=np.array([True, True, False]))
0 2015-03-29 03:00:00+02:00
1 2015-03-29 03:30:00+02:00
dtype: datetime64[ns, Europe/Warsaw]
```

If the DST transition causes nonexistent times, you can shift these dates forward or backwards with a `timedelta` object or `'shift_forward'` or `'shift_backwards'`.

```
>>> s = pd.to_datetime(pd.Series(['2015-03-29 02:30:00', ... '2015-03-29 03:30:00']))
>>> s.dt.tz_localize('Europe/Warsaw', nonexistent='shift_forward')
0 2015-03-29 03:00:00+02:00
1 2015-03-29 03:30:00+02:00
dtype: datetime64[ns, 'Europe/Warsaw']
>>> s.dt.tz_localize('Europe/Warsaw', nonexistent='shift_backwards')
0 2015-03-29 01:59:59.999999999+01:00
1 2015-03-29 03:30:00+02:00
dtype: datetime64[ns, 'Europe/Warsaw']
>>> s.dt.tz_localize('Europe/Warsaw', nonexistent=pd.Timedelta('1H'))
0 2015-03-29 03:30:00+02:00
1 2015-03-29 03:30:00+02:00
dtype: datetime64[ns, 'Europe/Warsaw']
```

pandas.DatetimeIndex.round

`DatetimeIndex.round(self, *args, **kwargs)`

Perform round operation on the data to the specified *freq*.

Parameters

freq [str or Offset] The frequency level to round the index to. Must be a fixed frequency like 'S' (second) not 'ME' (month end). See *frequency aliases* for a list of possible *freq* values.

ambiguous ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for `DatetimeIndex`:

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an `AmbiguousTimeError` if there are ambiguous times

New in version 0.24.0.

nonexistent ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift_forward' will shift the nonexistent time forward to the closest existing time
- 'shift_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise a `NonExistentTimeError` if there are nonexistent times

New in version 0.24.0.

Returns

DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a `DatetimeIndex` or `TimedeltaIndex`, or a `Series` with the same index for a `Series`.

Raises

ValueError if the *freq* cannot be converted.

Examples**DatetimeIndex**

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
              '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.round('H')
```

(continued from previous page)

```
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
              '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Series

```
>>> pd.Series(rng).dt.round("H")
0    2018-01-01 12:00:00
1    2018-01-01 12:00:00
2    2018-01-01 12:00:00
dtype: datetime64[ns]
```

pandas.DatetimeIndex.floor`DatetimeIndex.floor(self, *args, **kwargs)`Perform floor operation on the data to the specified *freq*.**Parameters**

freq [str or Offset] The frequency level to floor the index to. Must be a fixed frequency like 'S' (second) not 'ME' (month end). See *frequency aliases* for a list of possible *freq* values.

ambiguous ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for `DatetimeIndex`:

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an `AmbiguousTimeError` if there are ambiguous times

New in version 0.24.0.

nonexistent ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift_forward' will shift the nonexistent time forward to the closest existing time
- 'shift_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise an `NonExistentTimeError` if there are nonexistent times

New in version 0.24.0.

Returns

DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a `DatetimeIndex` or `TimedeltaIndex`, or a `Series` with the same index for a `Series`.

Raises

ValueError if the *freq* cannot be converted.

Examples

DatetimeIndex

```

>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
              '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.floor('H')
DatetimeIndex(['2018-01-01 11:00:00', '2018-01-01 12:00:00',
              '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq=None)

```

Series

```

>>> pd.Series(rng).dt.floor("H")
0    2018-01-01 11:00:00
1    2018-01-01 12:00:00
2    2018-01-01 12:00:00
dtype: datetime64[ns]

```

pandas.DatetimeIndex.ceil

`DatetimeIndex.ceil(self, *args, **kwargs)`

Perform ceil operation on the data to the specified *freq*.

Parameters

freq [str or Offset] The frequency level to ceil the index to. Must be a fixed frequency like 'S' (second) not 'ME' (month end). See *frequency aliases* for a list of possible *freq* values.

ambiguous ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for `DatetimeIndex`:

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an `AmbiguousTimeError` if there are ambiguous times

New in version 0.24.0.

nonexistent ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift_forward' will shift the nonexistent time forward to the closest existing time

- ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
- ‘NaT’ will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- ‘raise’ will raise a NonExistentTimeError if there are nonexistent times

New in version 0.24.0.

Returns

DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

ValueError if the *freq* cannot be converted.

Examples

DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
              '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.ceil('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
              '2018-01-01 13:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Series

```
>>> pd.Series(rng).dt.ceil("H")
0    2018-01-01 12:00:00
1    2018-01-01 12:00:00
2    2018-01-01 13:00:00
dtype: datetime64[ns]
```

pandas.DatetimeIndex.to_period

DatetimeIndex.to_period(*self*, *args, **kwargs)

Cast to PeriodArray/Index at a particular frequency.

Converts DatetimeArray/Index to PeriodArray/Index.

Parameters

freq [str or Offset, optional] One of pandas’ *offset strings* or an Offset object. Will be inferred by default.

Returns

PeriodArray/Index

Raises

ValueError When converting a DatetimeArray/Index with non-regular values, so that a frequency cannot be inferred.

See also:

PeriodIndex Immutable ndarray holding ordinal values.

DatetimeIndex.to_pydatetime Return DatetimeIndex as object.

Examples

```
>>> df = pd.DataFrame({"y": [1, 2, 3]},
...                    index=pd.to_datetime(["2000-03-31 00:00:00",
...                                          "2000-05-31 00:00:00",
...                                          "2000-08-31 00:00:00"]))
>>> df.index.to_period("M")
PeriodIndex(['2000-03', '2000-05', '2000-08'],
            dtype='period[M]', freq='M')
```

Infer the daily frequency

```
>>> idx = pd.date_range("2017-01-01", periods=2)
>>> idx.to_period()
PeriodIndex(['2017-01-01', '2017-01-02'],
            dtype='period[D]', freq='D')
```

pandas.DatetimeIndex.to_perioddelta

DatetimeIndex.to_perioddelta(*self*, *args, **kwargs)

Calculate TimedeltaArray of difference between index values and index converted to PeriodArray at specified freq. Used for vectorized offsets

Parameters

freq [Period frequency]

Returns

TimedeltaArray/Index

pandas.DatetimeIndex.to_pydatetime

DatetimeIndex.to_pydatetime(*self*, *args, **kwargs)

Return Datetime Array/Index as object ndarray of datetime.datetime objects

Returns

datetimes [ndarray]

pandas.DatetimeIndex.to_series

DatetimeIndex.to_series(*self*, keep_tz=None, index=None, name=None)

Create a Series with both index and values equal to the index keys useful with map for returning an indexer based on an index

Parameters

keep_tz [optional, defaults False] Return the data keeping the timezone.

If `keep_tz` is True:

If the timezone is not set, the resulting Series will have a `datetime64[ns]` dtype.

Otherwise the Series will have an `datetime64[ns, tz]` dtype; the `tz` will be preserved.

If `keep_tz` is False:

Series will have a `datetime64[ns]` dtype. TZ aware objects will have the `tz` removed.

Changed in version 0.24: The default value will change to True in a future release. You can set `keep_tz=True` to already obtain the future behaviour and silence the warning.

index [Index, optional] index of resulting Series. If None, defaults to original index

name [string, optional] name of resulting Series. If None, defaults to name of original index

Returns

Series

pandas.DatetimeIndex.to_frame

`DatetimeIndex.to_frame(self, index=True, name=None)`

Create a DataFrame with a column containing the Index.

New in version 0.24.0.

Parameters

index [boolean, default True] Set the index of the returned DataFrame as the original Index.

name [object, default None] The passed name should substitute for the index name (if it has one).

Returns

DataFrame DataFrame containing the original Index data.

See also:

Index.to_series Convert an Index to a Series.

Series.to_frame Convert Series to DataFrame.

Examples

```
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')
>>> idx.to_frame()
      animal
animal
Ant      Ant
Bear    Bear
Cow     Cow
```

By default, the original Index is reused. To enforce a new Index:

```
>>> idx.to_frame(index=False)
      animal
0   Ant
1  Bear
2   Cow
```

To override the name of the resulting column, specify *name*:

```
>>> idx.to_frame(index=False, name='zoo')
      zoo
0   Ant
1  Bear
2   Cow
```

pandas.DatetimeIndex.month_name

`DatetimeIndex.month_name(self, *args, **kwargs)`

Return the month names of the `DatetimeIndex` with specified locale.

New in version 0.23.0.

Parameters

locale [str, optional] Locale determining the language in which to return the month name. Default is English locale.

Returns

Index Index of month names.

Examples

```
>>> idx = pd.date_range(start='2018-01', freq='M', periods=3)
>>> idx
DatetimeIndex(['2018-01-31', '2018-02-28', '2018-03-31'],
              dtype='datetime64[ns]', freq='M')
>>> idx.month_name()
Index(['January', 'February', 'March'], dtype='object')
```

pandas.DatetimeIndex.day_name

`DatetimeIndex.day_name(self, *args, **kwargs)`

Return the day names of the `DatetimeIndex` with specified locale.

New in version 0.23.0.

Parameters

locale [str, optional] Locale determining the language in which to return the day name. Default is English locale.

Returns

Index Index of day names.

Examples

```
>>> idx = pd.date_range(start='2018-01-01', freq='D', periods=3)
>>> idx
DatetimeIndex(['2018-01-01', '2018-01-02', '2018-01-03'],
              dtype='datetime64[ns]', freq='D')
>>> idx.day_name()
Index(['Monday', 'Tuesday', 'Wednesday'], dtype='object')
```

pandas.DatetimeIndex.mean

`DatetimeIndex.mean(self, *args, **kwargs)`

Return the mean value of the Array.

New in version 0.25.0.

Parameters

skipna [bool, default True] Whether to ignore any NaT elements

Returns

scalar (Timestamp or Timedelta)

See also:

[numpy.ndarray.mean](#)

Series.mean Return the mean value in a Series.

Notes

mean is only defined for Datetime and Timedelta dtypes, not for Period.

Time/Date components

<i>DatetimeIndex.year</i>	The year of the datetime.
<i>DatetimeIndex.month</i>	The month as January=1, December=12.
<i>DatetimeIndex.day</i>	The days of the datetime.
<i>DatetimeIndex.hour</i>	The hours of the datetime.
<i>DatetimeIndex.minute</i>	The minutes of the datetime.
<i>DatetimeIndex.second</i>	The seconds of the datetime.
<i>DatetimeIndex.microsecond</i>	The microseconds of the datetime.

Continued on next page

Table 157 – continued from previous page

<i>DatetimeIndex.nanosecond</i>	The nanoseconds of the datetime.
<i>DatetimeIndex.date</i>	Returns numpy array of python datetime.date objects (namely, the date part of Timestamps without timezone information).
<i>DatetimeIndex.time</i>	Returns numpy array of datetime.time.
<i>DatetimeIndex.timetz</i>	Returns numpy array of datetime.time also containing timezone information.
<i>DatetimeIndex.dayofyear</i>	The ordinal day of the year.
<i>DatetimeIndex.weekofyear</i>	The week ordinal of the year.
<i>DatetimeIndex.week</i>	The week ordinal of the year.
<i>DatetimeIndex.dayofweek</i>	The day of the week with Monday=0, Sunday=6.
<i>DatetimeIndex.weekday</i>	The day of the week with Monday=0, Sunday=6.
<i>DatetimeIndex.quarter</i>	The quarter of the date.
<i>DatetimeIndex.tz</i>	
<i>DatetimeIndex.freq</i>	Return the frequency object if it is set, otherwise None.
<i>DatetimeIndex.freqstr</i>	Return the frequency object as a string if it is set, otherwise None.
<i>DatetimeIndex.is_month_start</i>	Indicates whether the date is the first day of the month.
<i>DatetimeIndex.is_month_end</i>	Indicates whether the date is the last day of the month.
<i>DatetimeIndex.is_quarter_start</i>	Indicator for whether the date is the first day of a quarter.
<i>DatetimeIndex.is_quarter_end</i>	Indicator for whether the date is the last day of a quarter.
<i>DatetimeIndex.is_year_start</i>	Indicate whether the date is the first day of a year.
<i>DatetimeIndex.is_year_end</i>	Indicate whether the date is the last day of the year.
<i>DatetimeIndex.is_leap_year</i>	Boolean indicator if the date belongs to a leap year.
<i>DatetimeIndex.inferred_freq</i>	Tryies to return a string representing a frequency guess, generated by infer_freq.

pandas.DatetimeIndex.tz

DatetimeIndex.tz

Selecting

<i>DatetimeIndex.indexer_at_time</i> (self, time[, asof])	Return index locations of index values at particular time of day (e.g.
<i>DatetimeIndex.indexer_between_time</i> (self, ...)	Return index locations of values between particular times of day (e.g., 9:00-9:30AM).

pandas.DatetimeIndex.indexer_at_time

DatetimeIndex.indexer_at_time(self, time, asof=False)

Return index locations of index values at particular time of day (e.g. 9:30AM).

Parameters

time [datetime.time or string] datetime.time or string in appropriate format (“%H:%M”, “%H%M”, “%I:%M%p”, “%I%M%p”, “%H:%M:%S”, “%H%M%S”, “%I:%M:%S%p”, “%I%M%S%p”).

Returns

values_at_time [array of integers]

See also:

indexer_between_time, *DataFrame.at_time*

pandas.DatetimeIndex.indexer_between_time

`DatetimeIndex.indexer_between_time(self, start_time, end_time, include_start=True, include_end=True)`

Return index locations of values between particular times of day (e.g., 9:00-9:30AM).

Parameters

start_time, end_time [datetime.time, str] datetime.time or string in appropriate format (“%H:%M”, “%H%M”, “%I:%M%p”, “%I%M%p”, “%H:%M:%S”, “%H%M%S”, “%I:%M:%S%p”, “%I%M%S%p”).

include_start [boolean, default True]

include_end [boolean, default True]

Returns

values_between_time [array of integers]

See also:

indexer_at_time, *DataFrame.between_time*

Time-specific operations

<code>DatetimeIndex.normalize(self, **kwargs)</code>	<code>*args,</code>	Convert times to midnight.
<code>DatetimeIndex.strftime(self, **kwargs)</code>	<code>*args,</code>	Convert to Index using specified <code>date_format</code> .
<code>DatetimeIndex.snap(self[, freq])</code>		Snap time stamps to nearest occurring frequency
<code>DatetimeIndex.tz_convert(self, *args, ...)</code>		Convert tz-aware Datetime Array/Index from one time zone to another.
<code>DatetimeIndex.tz_localize(self, *args, ...)</code>		Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index.
<code>DatetimeIndex.round(self, *args, **kwargs)</code>		Perform round operation on the data to the specified <i>freq</i> .
<code>DatetimeIndex.floor(self, *args, **kwargs)</code>		Perform floor operation on the data to the specified <i>freq</i> .
<code>DatetimeIndex.ceil(self, *args, **kwargs)</code>		Perform ceil operation on the data to the specified <i>freq</i> .
<code>DatetimeIndex.month_name(self, *args, ...)</code>		Return the month names of the <code>DateTimeIndex</code> with specified locale.

Continued on next page

Table 159 – continued from previous page

<i>DatetimeIndex.day_name</i> (self, <code>**args, **kwargs</code>)	Return the day names of the <code>DateTimeIndex</code> with specified locale.
--	---

Conversion

<i>DatetimeIndex.to_period</i> (self, <code>**args, **kwargs</code>)	Cast to <code>PeriodArray/Index</code> at a particular frequency.
<i>DatetimeIndex.to_perioddelta</i> (self, <code>**args, ...</code>)	Calculate <code>TimedeltaArray</code> of difference between index values and index converted to <code>PeriodArray</code> at specified freq.
<i>DatetimeIndex.to_pydatetime</i> (self, <code>**args, ...</code>)	Return <code>Datetime Array/Index</code> as object ndarray of <code>datetime.datetime</code> objects
<i>DatetimeIndex.to_series</i> (self[, <code>keep_tz, ...</code>])	Create a <code>Series</code> with both index and values equal to the index keys useful with <code>map</code> for returning an indexer based on an index
<i>DatetimeIndex.to_frame</i> (self[, <code>index, name</code>])	Create a <code>DataFrame</code> with a column containing the <code>Index</code> .

Methods

<i>DatetimeIndex.mean</i> (self, <code>**args, **kwargs</code>)	Return the mean value of the <code>Array</code> .
--	---

6.7.7 TimedeltaIndex

<i>TimedeltaIndex</i>	Immutable ndarray of <code>timedelta64</code> data, represented internally as <code>int64</code> , and which can be boxed to <code>timedelta</code> objects
-----------------------	---

pandas.TimedeltaIndex

class pandas.TimedeltaIndex

Immutable ndarray of `timedelta64` data, represented internally as `int64`, and which can be boxed to `timedelta` objects

Parameters

data [array-like (1-dimensional), optional] Optional `timedelta`-like data to construct index with

unit [unit of the arg (D,h,m,s,ms,us,ns) denote the unit, optional] which is an integer/float number

freq [string or pandas offset object, optional] One of pandas date offset strings or corresponding objects. The string ‘infer’ can be passed in order to set the frequency of the index as the inferred frequency upon creation

copy [bool] Make a copy of input ndarray

start [starting value, `timedelta`-like, optional] If data is `None`, start is used as the start point in generating regular `timedelta` data.

Deprecated since version 0.24.0.

periods [int, optional, > 0] Number of periods to generate, if generating index. Takes precedence over end argument

Deprecated since version 0.24.0.

end [end time, timedelta-like, optional] If periods is none, generated index will extend to first conforming time on or just past end argument

Deprecated since version 0.24.: 0

closed [string or None, default None] Make the interval closed with respect to the given frequency to the 'left', 'right', or both sides (None)

Deprecated since version 0.24.: 0

name [object] Name to be stored in the index

See also:

Index The base pandas Index type.

Timedelta Represents a duration between two dates or times.

DatetimeIndex Index of datetime64 data.

PeriodIndex Index of Period data.

timedelta_range Create a fixed-frequency TimedeltaIndex.

Notes

To learn more about the frequency strings, please see [this link](#).

Creating a TimedeltaIndex based on *start*, *periods*, and *end* has been deprecated in favor of *timedelta_range()*.

Attributes

<i>days</i>	Number of days for each element.
<i>seconds</i>	Number of seconds (≥ 0 and less than 1 day) for each element.
<i>microseconds</i>	Number of microseconds (≥ 0 and less than 1 second) for each element.
<i>nanoseconds</i>	Number of nanoseconds (≥ 0 and less than 1 microsecond) for each element.
<i>components</i>	Return a dataframe of the components (days, hours, minutes, seconds, milliseconds, microseconds, nanoseconds) of the Timedeltas.
<i>inferred_freq</i>	Tryies to return a string representing a frequency guess, generated by <i>infer_freq</i> .

pandas.TimedeltaIndex.days

TimedeltaIndex.days

Number of days for each element.

pandas.TimedeltaIndex.seconds**TimedeltaIndex.seconds**

Number of seconds (≥ 0 and less than 1 day) for each element.

pandas.TimedeltaIndex.microseconds**TimedeltaIndex.microseconds**

Number of microseconds (≥ 0 and less than 1 second) for each element.

pandas.TimedeltaIndex.nanoseconds**TimedeltaIndex.nanoseconds**

Number of nanoseconds (≥ 0 and less than 1 microsecond) for each element.

pandas.TimedeltaIndex.components**TimedeltaIndex.components**

Return a dataframe of the components (days, hours, minutes, seconds, milliseconds, microseconds, nanoseconds) of the Timedeltas.

Returns

a **DataFrame**

pandas.TimedeltaIndex.inferred_freq**TimedeltaIndex.inferred_freq**

Tryies to return a string representing a frequency guess, generated by `infer_freq`. Returns None if it can't autodetect the frequency.

Methods

<code>to_pytimedelta(self, *args, **kwargs)</code>	Return Timedelta Array/Index as object ndarray of <code>datetime.timedelta</code> objects.
<code>to_series(self[, index, name])</code>	Create a Series with both index and values equal to the index keys useful with <code>map</code> for returning an indexer based on an index.
<code>round(self, freq[, ambiguous, nonexistent])</code>	Perform round operation on the data to the specified <i>freq</i> .
<code>floor(self, freq[, ambiguous, nonexistent])</code>	Perform floor operation on the data to the specified <i>freq</i> .
<code>ceil(self, freq[, ambiguous, nonexistent])</code>	Perform ceil operation on the data to the specified <i>freq</i> .
<code>to_frame(self[, index, name])</code>	Create a DataFrame with a column containing the Index.
<code>mean(self, *args, **kwargs)</code>	Return the mean value of the Array.

pandas.TimedeltaIndex.to_pytimedelta**TimedeltaIndex.to_pytimedelta**(*self*, **args*, ***kwargs*)

Return Timedelta Array/Index as object ndarray of datetime.timedelta objects.

Returns**datetimes** [ndarray]**pandas.TimedeltaIndex.to_series****TimedeltaIndex.to_series**(*self*, *index=None*, *name=None*)

Create a Series with both index and values equal to the index keys useful with map for returning an indexer based on an index.

Parameters**index** [Index, optional] index of resulting Series. If None, defaults to original index**name** [string, optional] name of resulting Series. If None, defaults to name of original index**Returns****Series** [dtype will be based on the type of the Index values.]**pandas.TimedeltaIndex.round****TimedeltaIndex.round**(*self*, *freq*, *ambiguous='raise'*, *nonexistent='raise'*)Perform round operation on the data to the specified *freq*.**Parameters****freq** [str or Offset] The frequency level to round the index to. Must be a fixed frequency like 'S' (second) not 'ME' (month end). See *frequency aliases* for a list of possible *freq* values.**ambiguous** ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for Date-timeIndex:

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times

New in version 0.24.0.

nonexistent ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise']

A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift_forward' will shift the nonexistent time forward to the closest existing time
- 'shift_backward' will shift the nonexistent time backward to the closest existing time

- ‘NaT’ will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- ‘raise’ will raise a NonExistentTimeError if there are nonexistent times

New in version 0.24.0.

Returns

DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

ValueError if the *freq* cannot be converted.

Examples

DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
              '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.round('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
              '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Series

```
>>> pd.Series(rng).dt.round("H")
0    2018-01-01 12:00:00
1    2018-01-01 12:00:00
2    2018-01-01 12:00:00
dtype: datetime64[ns]
```

pandas.TimedeltaIndex.floor

`TimedeltaIndex.floor(self, freq, ambiguous='raise', nonexistent='raise')`

Perform floor operation on the data to the specified *freq*.

Parameters

freq [str or Offset] The frequency level to floor the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See *frequency aliases* for a list of possible *freq* values.

ambiguous [‘infer’, bool-ndarray, ‘NaT’, default ‘raise’] Only relevant for DatetimeIndex:

- ‘infer’ will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- ‘NaT’ will return NaT where there are ambiguous times

- ‘raise’ will raise an `AmbiguousTimeError` if there are ambiguous times

New in version 0.24.0.

nonexistent [‘shift_forward’, ‘shift_backward’, ‘NaT’, `timedelta`, default ‘raise’]
A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
- ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
- ‘NaT’ will return `NaT` where there are nonexistent times
- `timedelta` objects will shift nonexistent times by the `timedelta`
- ‘raise’ will raise an `NonExistentTimeError` if there are nonexistent times

New in version 0.24.0.

Returns

DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a `DatetimeIndex` or `TimedeltaIndex`, or a `Series` with the same index for a `Series`.

Raises

ValueError if the *freq* cannot be converted.

Examples

DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
              '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.floor('H')
DatetimeIndex(['2018-01-01 11:00:00', '2018-01-01 12:00:00',
              '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Series

```
>>> pd.Series(rng).dt.floor("H")
0    2018-01-01 11:00:00
1    2018-01-01 12:00:00
2    2018-01-01 12:00:00
dtype: datetime64[ns]
```

pandas.TimedeltaIndex.ceil

`TimedeltaIndex.ceil(self, freq, ambiguous='raise', nonexistent='raise')`

Perform ceil operation on the data to the specified *freq*.

Parameters

freq [str or Offset] The frequency level to ceil the index to. Must be a fixed frequency like 'S' (second) not 'ME' (month end). See *frequency aliases* for a list of possible *freq* values.

ambiguous ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for DatetimeIndex:

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times

New in version 0.24.0.

nonexistent ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift_forward' will shift the nonexistent time forward to the closest existing time
- 'shift_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise a NonExistentTimeError if there are nonexistent times

New in version 0.24.0.

Returns

DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

ValueError if the *freq* cannot be converted.

Examples

DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
              '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.ceil('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
              '2018-01-01 13:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Series

```
>>> pd.Series(rng).dt.ceil("H")
0    2018-01-01 12:00:00
1    2018-01-01 12:00:00
2    2018-01-01 13:00:00
dtype: datetime64[ns]
```

pandas.TimedeltaIndex.to_frame

`TimedeltaIndex.to_frame(self, index=True, name=None)`

Create a DataFrame with a column containing the Index.

New in version 0.24.0.

Parameters

index [boolean, default True] Set the index of the returned DataFrame as the original Index.

name [object, default None] The passed name should substitute for the index name (if it has one).

Returns

DataFrame DataFrame containing the original Index data.

See also:

`Index.to_series` Convert an Index to a Series.

`Series.to_frame` Convert Series to DataFrame.

Examples

```
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')
>>> idx.to_frame()
      animal
animal
Ant      Ant
Bear    Bear
Cow     Cow
```

By default, the original Index is reused. To enforce a new Index:

```
>>> idx.to_frame(index=False)
      animal
0    Ant
1  Bear
2    Cow
```

To override the name of the resulting column, specify `name`:

```
>>> idx.to_frame(index=False, name='zoo')
      zoo
0    Ant
```

(continues on next page)

(continued from previous page)

1	Bear
2	Cow

pandas.TimedeltaIndex.mean**TimedeltaIndex.mean**(*self*, *args, **kwargs)

Return the mean value of the Array.

New in version 0.25.0.

Parameters**skipna** [bool, default True] Whether to ignore any NaT elements**Returns**scalar (**Timestamp** or **Timedelta**)**See also:**[numpy.ndarray.mean](#)**Series.mean** Return the mean value in a Series.**Notes**

mean is only defined for Datetime and Timedelta dtypes, not for Period.

Components

<i>TimedeltaIndex.days</i>	Number of days for each element.
<i>TimedeltaIndex.seconds</i>	Number of seconds (≥ 0 and less than 1 day) for each element.
<i>TimedeltaIndex.microseconds</i>	Number of microseconds (≥ 0 and less than 1 second) for each element.
<i>TimedeltaIndex.nanoseconds</i>	Number of nanoseconds (≥ 0 and less than 1 microsecond) for each element.
<i>TimedeltaIndex.components</i>	Return a dataframe of the components (days, hours, minutes, seconds, milliseconds, microseconds, nanoseconds) of the Timedeltas.
<i>TimedeltaIndex.inferred_freq</i>	Tryies to return a string representing a frequency guess, generated by infer_freq.

Conversion

<i>TimedeltaIndex.to_pytimedelta</i> (<i>self</i> , *args, ...)	Return Timedelta Array/Index as object ndarray of datetime.timedelta objects.
<i>TimedeltaIndex.to_series</i> (<i>self</i> [, index, name])	Create a Series with both index and values equal to the index keys useful with map for returning an indexer based on an index.

Continued on next page

Table 166 – continued from previous page

<code>TimedeltaIndex.round(self, freq[, ...])</code>	Perform round operation on the data to the specified <i>freq</i> .
<code>TimedeltaIndex.floor(self, freq[, ...])</code>	Perform floor operation on the data to the specified <i>freq</i> .
<code>TimedeltaIndex.ceil(self, freq[, ambiguous, ...])</code>	Perform ceil operation on the data to the specified <i>freq</i> .
<code>TimedeltaIndex.to_frame(self[, index, name])</code>	Create a DataFrame with a column containing the Index.

Methods

<code>TimedeltaIndex.mean(self, *args, **kwargs)</code>	Return the mean value of the Array.
--	-------------------------------------

6.7.8 PeriodIndex

<code>PeriodIndex</code>	Immutable ndarray holding ordinal values indicating regular periods in time such as particular years, quarters, months, etc.
--------------------------	--

pandas.PeriodIndex

class pandas.PeriodIndex

Immutable ndarray holding ordinal values indicating regular periods in time such as particular years, quarters, months, etc.

Index keys are boxed to Period objects which carries the metadata (eg, frequency information).

Parameters

data [array-like (1d integer np.ndarray or PeriodArray), optional] Optional period-like data to construct index with

copy [bool] Make a copy of input ndarray

freq [string or period object, optional] One of pandas period strings or corresponding objects

start [starting value, period-like, optional] If data is None, used as the start point in generating regular period data.

Deprecated since version 0.24.0.

periods [int, optional, > 0] Number of periods to generate, if generating index. Takes precedence over end argument

Deprecated since version 0.24.0.

end [end value, period-like, optional] If periods is none, generated index will extend to first conforming period on or just past end argument

Deprecated since version 0.24.0.

year [int, array, or Series, default None]

month [int, array, or Series, default None]

quarter [int, array, or Series, default None]

day [int, array, or Series, default None]
hour [int, array, or Series, default None]
minute [int, array, or Series, default None]
second [int, array, or Series, default None]
tz [object, default None] Timezone for converting datetime64 data to Periods
dtype [str or PeriodDtype, default None]

See also:

Index The base pandas Index type.

Period Represents a period of time.

DatetimeIndex Index with datetime64 data.

TimedeltaIndex Index of timedelta64 data.

period_range Create a fixed-frequency PeriodIndex.

Notes

Creating a PeriodIndex based on *start*, *periods*, and *end* has been deprecated in favor of *period_range()*.

Examples

```
>>> idx = pd.PeriodIndex(year=year_arr, quarter=q_arr)
```

Attributes

<i>day</i>	The days of the period
<i>dayofweek</i>	The day of the week with Monday=0, Sunday=6
<i>dayofyear</i>	The ordinal day of the year
<i>days_in_month</i>	The number of days in the month
<i>daysinmonth</i>	The number of days in the month
<i>freq</i>	Return the frequency object if it is set, otherwise None.
<i>freqstr</i>	Return the frequency object as a string if it is set, otherwise None.
<i>hour</i>	The hour of the period
<i>is_leap_year</i>	Logical indicating if the date belongs to a leap year
<i>minute</i>	The minute of the period
<i>month</i>	The month as January=1, December=12
<i>quarter</i>	The quarter of the date
<i>second</i>	The second of the period
<i>week</i>	The week ordinal of the year
<i>weekday</i>	The day of the week with Monday=0, Sunday=6
<i>weekofyear</i>	The week ordinal of the year

Continued on next page

Table 169 – continued from previous page

<i>year</i>	The year of the period
-------------	------------------------

pandas.PeriodIndex.day

`PeriodIndex.day`
The days of the period

pandas.PeriodIndex.dayofweek

`PeriodIndex.dayofweek`
The day of the week with Monday=0, Sunday=6

pandas.PeriodIndex.dayofyear

`PeriodIndex.dayofyear`
The ordinal day of the year

pandas.PeriodIndex.days_in_month

`PeriodIndex.days_in_month`
The number of days in the month

pandas.PeriodIndex.daysinmonth

`PeriodIndex.daysinmonth`
The number of days in the month

pandas.PeriodIndex.freq

`PeriodIndex.freq`
Return the frequency object if it is set, otherwise None.

pandas.PeriodIndex.freqstr

`PeriodIndex.freqstr`
Return the frequency object as a string if it is set, otherwise None.

pandas.PeriodIndex.hour

`PeriodIndex.hour`
The hour of the period

pandas.PeriodIndex.is_leap_year

`PeriodIndex.is_leap_year`

Logical indicating if the date belongs to a leap year

pandas.PeriodIndex.minute

`PeriodIndex.minute`

The minute of the period

pandas.PeriodIndex.month

`PeriodIndex.month`

The month as January=1, December=12

pandas.PeriodIndex.quarter

`PeriodIndex.quarter`

The quarter of the date

pandas.PeriodIndex.second

`PeriodIndex.second`

The second of the period

pandas.PeriodIndex.week

`PeriodIndex.week`

The week ordinal of the year

pandas.PeriodIndex.weekday

`PeriodIndex.weekday`

The day of the week with Monday=0, Sunday=6

pandas.PeriodIndex.weekofyear

`PeriodIndex.weekofyear`

The week ordinal of the year

pandas.PeriodIndex.year

`PeriodIndex.year`

The year of the period

end_time	
qyear	
start_time	

Methods

<code>asfreq(self, *args, **kwargs)</code>	Convert the Period Array/Index to the specified frequency <i>freq</i> .
<code>strftime(self, *args, **kwargs)</code>	Convert to Index using specified <code>date_format</code> .
<code>to_timestamp(self, *args, **kwargs)</code>	Cast to DatetimeArray/Index.

pandas.PeriodIndex.asfreq

`PeriodIndex.asfreq(self, *args, **kwargs)`
Convert the Period Array/Index to the specified frequency *freq*.

Parameters

freq [str] a frequency

how [str {'E', 'S'}] 'E', 'END', or 'FINISH' for end, 'S', 'START', or 'BEGIN' for start. Whether the elements should be aligned to the end or start within pa period. January 31st ('END') vs. January 1st ('START') for example.

Returns

new [Period Array/Index with the new frequency]

Examples

```
>>> pidx = pd.period_range('2010-01-01', '2015-01-01', freq='A')
>>> pidx
PeriodIndex(['2010', '2011', '2012', '2013', '2014', '2015'],
            dtype='period[A-DEC]', freq='A-DEC')
```

```
>>> pidx.asfreq('M')
PeriodIndex(['2010-12', '2011-12', '2012-12', '2013-12', '2014-12',
            '2015-12'], dtype='period[M]', freq='M')
```

```
>>> pidx.asfreq('M', how='S')
PeriodIndex(['2010-01', '2011-01', '2012-01', '2013-01', '2014-01',
            '2015-01'], dtype='period[M]', freq='M')
```

pandas.PeriodIndex.strftime

`PeriodIndex.strftime(self, *args, **kwargs)`
Convert to Index using specified `date_format`.

Return an Index of formatted strings specified by `date_format`, which supports the same string format as the python standard library. Details of the string format can be found in [python string format doc](#).

Parameters

date_format [str] Date format string (e.g. “%Y-%m-%d”).

Returns

Index Index of formatted strings.

See also:

to_datetime Convert the given argument to datetime.

DatetimeIndex.normalize Return DatetimeIndex with times to midnight.

DatetimeIndex.round Round the DatetimeIndex to the specified freq.

DatetimeIndex.floor Floor the DatetimeIndex to the specified freq.

Examples

```
>>> rng = pd.date_range(pd.Timestamp("2018-03-10 09:00"),
...                     periods=3, freq='s')
>>> rng.strftime('%B %d, %Y, %r')
Index(['March 10, 2018, 09:00:00 AM', 'March 10, 2018, 09:00:01 AM',
       'March 10, 2018, 09:00:02 AM'],
      dtype='object')
```

pandas.PeriodIndex.to_timestamp

PeriodIndex.to_timestamp(*self*, *args, **kwargs)
Cast to DatetimeArray/Index.

Parameters

freq [string or DateOffset, optional] Target frequency. The default is ‘D’ for week or longer, ‘S’ otherwise

how [{‘s’, ‘e’, ‘start’, ‘end’}]

Returns

DatetimeArray/Index

Properties

<i>PeriodIndex.day</i>	The days of the period
<i>PeriodIndex.dayofweek</i>	The day of the week with Monday=0, Sunday=6
<i>PeriodIndex.dayofyear</i>	The ordinal day of the year
<i>PeriodIndex.days_in_month</i>	The number of days in the month
<i>PeriodIndex.daysinmonth</i>	The number of days in the month
<i>PeriodIndex.end_time</i>	
<i>PeriodIndex.freq</i>	Return the frequency object if it is set, otherwise None.
<i>PeriodIndex.freqstr</i>	Return the frequency object as a string if it is set, otherwise None.

Continued on next page

Table 171 – continued from previous page

<i>PeriodIndex.hour</i>	The hour of the period
<i>PeriodIndex.is_leap_year</i>	Logical indicating if the date belongs to a leap year
<i>PeriodIndex.minute</i>	The minute of the period
<i>PeriodIndex.month</i>	The month as January=1, December=12
<i>PeriodIndex.quarter</i>	The quarter of the date
<i>PeriodIndex.qyear</i>	
<i>PeriodIndex.second</i>	The second of the period
<i>PeriodIndex.start_time</i>	
<i>PeriodIndex.week</i>	The week ordinal of the year
<i>PeriodIndex.weekday</i>	The day of the week with Monday=0, Sunday=6
<i>PeriodIndex.weekofyear</i>	The week ordinal of the year
<i>PeriodIndex.year</i>	The year of the period

pandas.PeriodIndex.end_time

PeriodIndex.end_time

pandas.PeriodIndex.qyear

PeriodIndex.qyear

pandas.PeriodIndex.start_time

PeriodIndex.start_time

Methods

<i>PeriodIndex.asfreq</i> (self, <i>*args</i> , <i>*kwargs</i>)	Convert the Period Array/Index to the specified frequency <i>freq</i> .
<i>PeriodIndex.strftime</i> (self, <i>*args</i> , <i>*kwargs</i>)	Convert to Index using specified <i>date_format</i> .
<i>PeriodIndex.to_timestamp</i> (self, <i>*args</i> , ...)	Cast to DatetimeArray/Index.

{{ header }}

6.8 Date offsets

6.8.1 DateOffset

DateOffset(*n*, *normalize*)

Standard kind of date increment used for a date range.

pandas.tseries.offsets.DateOffset

class pandas.tseries.offsets.DateOffset(*n=1*, *normalize=False*, ***kws*)

Standard kind of date increment used for a date range.

Works exactly like `relativedelta` in terms of the keyword args you pass in, use of the keyword `n` is discouraged— you would be better off specifying `n` in the keywords you use, but regardless it is there for you. `n` is needed for `DateOffset` subclasses.

`DateOffset` work as follows. Each offset specify a set of dates that conform to the `DateOffset`. For example, `Bday` defines this set to be the set of dates that are weekdays (M-F). To test if a date is in the set of a `DateOffset` `dateOffset` we can use the `onOffset` method: `dateOffset.onOffset(date)`.

If a date is not on a valid date, the `rollback` and `rollforward` methods can be used to roll the date to the nearest valid date before/after the date.

`DateOffsets` can be created to move dates forward a given number of valid dates. For example, `Bday(2)` can be added to a date to move it two business days forward. If the date does not start on a valid date, first it is moved to a valid date. Thus pseudo code is:

```
def __add__(date): date = rollback(date) # does nothing if date is valid return date + <n number of periods>
```

When a date offset is created for a negative number of periods, the date is first rolled forward. The pseudo code is:

```
def __add__(date): date = rollforward(date) # does nothing is date is valid return date + <n number of periods>
```

Zero presents a problem. Should it roll forward or back? We arbitrarily have it rollforward:

```
date + BDay(0) == BDay.rollforward(date)
```

Since 0 is a bit weird, we suggest avoiding its use.

Parameters

n [int, default 1] The number of time periods the offset represents.

normalize [bool, default False] Whether to round the result of a `DateOffset` addition down to the previous midnight.

****kwds** Temporal parameter that add to or replace the offset value.

Parameters that **add** to the offset (like `Timedelta`):

- years
- months
- weeks
- days
- hours
- minutes
- seconds
- microseconds
- nanoseconds

Parameters that **replace** the offset value:

- year
- month
- day
- weekday

- hour
- minute
- second
- microsecond
- nanosecond

See also:

`dateutil.relativedelta.relativedelta`

Examples

```
>>> ts = pd.Timestamp('2017-01-01 09:10:11')
>>> ts + DateOffset(months=3)
Timestamp('2017-04-01 09:10:11')
```

```
>>> ts = pd.Timestamp('2017-01-01 09:10:11')
>>> ts + DateOffset(month=3)
Timestamp('2017-03-01 09:10:11')
```

Attributes

<code>base</code>	Returns a copy of the calling offset object with <code>n=1</code> and all other attributes equal.
-------------------	---

`pandas.tseries.offsets.DateOffset.base`

`DateOffset.base`

Returns a copy of the calling offset object with `n=1` and all other attributes equal.

<code>freqstr</code>	
<code>kwds</code>	
<code>name</code>	
<code>nanos</code>	
<code>rule_code</code>	

Methods

<code>apply_index(self, other)</code>	Vectorized apply of <code>DateOffset</code> to <code>DatetimeIndex</code> , raises <code>NotImplementedError</code> for offsets without a vectorized implementation.
<code>rollback(self, dt)</code>	Roll provided date backward to next offset only if not on offset.
<code>rollforward(self, dt)</code>	Roll provided date forward to next offset only if not on offset.

pandas.tseries.offsets.DateOffset.apply_index`DateOffset.apply_index(self, other)`

Vectorized apply of DateOffset to DatetimeIndex, raises NotImplementedError for offsets without a vectorized implementation.

Parameters`i` [DatetimeIndex]**Returns**`y` [DatetimeIndex]**pandas.tseries.offsets.DateOffset.rollback**`DateOffset.rollback(self, dt)`

Roll provided date backward to next offset only if not on offset.

Returns**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.**pandas.tseries.offsets.DateOffset.rollforward**`DateOffset.rollforward(self, dt)`

Roll provided date forward to next offset only if not on offset.

Returns**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

pandas.tseries.offsets.BusinessHour.normalize

`BusinessHour.normalize = False`

pandas.tseries.offsets.BusinessHour.rule_code

`BusinessHour.rule_code`

Methods

BusinessHour.apply(self, other)

BusinessHour.copy(self)

BusinessHour.isAnchored(self)

BusinessHour.onOffset(self, dt)

pandas.tseries.offsets.BusinessHour.apply

`BusinessHour.apply(self, other)`

pandas.tseries.offsets.BusinessHour.copy

`BusinessHour.copy(self)`

pandas.tseries.offsets.BusinessHour.isAnchored

`BusinessHour.isAnchored(self)`

pandas.tseries.offsets.BusinessHour.onOffset

`BusinessHour.onOffset(self, dt)`

6.8.4 CustomBusinessDay

CustomBusinessDay([n, normalize, weekmask, ...]) DateOffset subclass representing possibly n custom business days, excluding holidays.

pandas.tseries.offsets.CustomBusinessDay

```
class pandas.tseries.offsets.CustomBusinessDay(n=1, normalize=False, weekmask='Mon
Tue Wed Thu Fri', holidays=None, calendar=None, offset=datetime.timedelta(0))
```

DateOffset subclass representing possibly n custom business days, excluding holidays.

Parameters

n [int, default 1]

normalize [bool, default False] Normalize start/end dates to midnight before generating date range

weekmask [str, Default 'Mon Tue Wed Thu Fri'] weekmask of valid business days, passed to `numpy.busdaycalendar`

holidays [list] list/array of dates to exclude from the set of valid business days, passed to `numpy.busdaycalendar`

calendar [pd.HolidayCalendar or np.busdaycalendar]

offset [timedelta, default timedelta(0)]

Attributes

<i>base</i>	Returns a copy of the calling offset object with n=1 and all other attributes equal.
<i>offset</i>	Alias for self._offset.

pandas.tseries.offsets.CustomBusinessDay.base

`CustomBusinessDay.base`

Returns a copy of the calling offset object with n=1 and all other attributes equal.

pandas.tseries.offsets.CustomBusinessDay.offset

`CustomBusinessDay.offset`

Alias for self._offset.

Methods

<i>apply_index</i> (self, i)	Vectorized apply of DateOffset to DatetimeIndex, raises NotImplementedError for offsets without a vectorized implementation.
<i>rollback</i> (self, dt)	Roll provided date backward to next offset only if not on offset.
<i>rollforward</i> (self, dt)	Roll provided date forward to next offset only if not on offset.

pandas.tseries.offsets.CustomBusinessDay.apply_index

`CustomBusinessDay.apply_index(self, i)`

Vectorized apply of DateOffset to DatetimeIndex, raises NotImplementedError for offsets without a vectorized implementation.

Parameters

i [DatetimeIndex]

Returns

y [DatetimeIndex]

pandas.tseries.offsets.CustomBusinessDay.rollback

`CustomBusinessDay.rollback(self, dt)`

Roll provided date backward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

pandas.tseries.offsets.CustomBusinessDay.rollforward

`CustomBusinessDay.rollforward(self, dt)`

Roll provided date forward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

6.8.5 CustomBusinessHour

CustomBusinessHour([n, normalize, weekmask, ...]) DateOffset subclass representing possibly n custom business days.

pandas.tseries.offsets.CustomBusinessHour

```
class pandas.tseries.offsets.CustomBusinessHour(n=1, normalize=False, weekmask='Mon Tue
Wed Thu Fri', holidays=None, calendar=None, start='09:00', end='17:00', offset=
datetime.timedelta(0))
```

DateOffset subclass representing possibly n custom business days.

New in version 0.18.1.

Attributes

<i>base</i>	Returns a copy of the calling offset object with n=1 and all other attributes equal.
<i>next_bday</i>	Used for moving to next business day.
<i>offset</i>	Alias for self._offset.

pandas.tseries.offsets.CustomBusinessHour.base

`CustomBusinessHour.base`

Returns a copy of the calling offset object with n=1 and all other attributes equal.

pandas.tseries.offsets.CustomBusinessHour.next_bday

`CustomBusinessHour.next_bday`

Used for moving to next business day.

pandas.tseries.offsets.CustomBusinessHour.offset

`CustomBusinessHour.offset`

Alias for self._offset.

6.8.17 WeekOfMonth

<code>WeekOfMonth(n, normalize, week, weekday)</code>	Describes monthly dates like “the Tuesday of the 2nd week of each month”.
---	---

pandas.tseries.offsets.WeekOfMonth

`class pandas.tseries.offsets.WeekOfMonth(n=1, normalize=False, week=0, weekday=0)`

Describes monthly dates like “the Tuesday of the 2nd week of each month”.

Parameters

n [int]

week [{0, 1, 2, 3, ...}, default 0] 0 is 1st week of month, 1 2nd week, etc.

weekday [{0, 1, ..., 6}, default 0] 0: Mondays 1: Tuesdays 2: Wednesdays 3: Thursdays 4: Fridays 5: Saturdays 6: Sundays

Attributes

<code>base</code>	Returns a copy of the calling offset object with n=1 and all other attributes equal.
-------------------	--

pandas.tseries.offsets.WeekOfMonth.base

`WeekOfMonth.base`

Returns a copy of the calling offset object with n=1 and all other attributes equal.

Methods

<i>apply_index</i> (self, other)	Vectorized apply of DateOffset to DatetimeIndex, raises NotImplementedError for offsets without a vectorized implementation.
<i>rollback</i> (self, dt)	Roll provided date backward to next offset only if not on offset.
<i>rollforward</i> (self, dt)	Roll provided date forward to next offset only if not on offset.

pandas.tseries.offsets.WeekOfMonth.apply_index

`WeekOfMonth.apply_index(self, other)`

Vectorized apply of DateOffset to DatetimeIndex, raises NotImplementedError for offsets without a vectorized implementation.

Parameters

i [DatetimeIndex]

Returns

y [DatetimeIndex]

pandas.tseries.offsets.WeekOfMonth.rollback

`WeekOfMonth.rollback(self, dt)`

Roll provided date backward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

pandas.tseries.offsets.WeekOfMonth.rollforward

`WeekOfMonth.rollforward(self, dt)`

Roll provided date forward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

6.8.29 FY5253

FY5253(*n*, *normalize*, *weekday*, ...)

Describes 52-53 week fiscal year.

pandas.tseries.offsets.FY5253

`class pandas.tseries.offsets.FY5253(n=1, normalize=False, weekday=0, startingMonth=1, variation='nearest')`

Describes 52-53 week fiscal year. This is also known as a 4-4-5 calendar.

It is used by companies that desire that their fiscal year always end on the same day of the week.

It is a method of managing accounting periods. It is a common calendar structure for some industries, such as retail, manufacturing and parking industry.

For more information see: http://en.wikipedia.org/wiki/4-4-5_calendar

The year may either: - end on the last X day of the Y month. - end on the last X day closest to the last day of the Y month.

X is a specific day of the week. Y is a certain month of the year

Parameters

n [int]

weekday [{0, 1, ..., 6}] 0: Mondays 1: Tuesdays 2: Wednesdays 3: Thursdays 4: Fridays 5: Saturdays 6: Sundays

startingMonth [The month in which fiscal years end. {1, 2, ... 12}]

variation [str] {"nearest", "last"} for "LastOfMonth" or "NearestEndMonth"

Attributes

<i>base</i>	Returns a copy of the calling offset object with n=1 and all other attributes equal.
-------------	--

pandas.tseries.offsets.FY5253.base

FY5253.base

Returns a copy of the calling offset object with n=1 and all other attributes equal.

Methods

<i>apply_index</i> (self, other)	Vectorized apply of DateOffset to DatetimeIndex, raises NotImplementedError for offsets without a vectorized implementation.
<i>rollback</i> (self, dt)	Roll provided date backward to next offset only if not on offset.
<i>rollforward</i> (self, dt)	Roll provided date forward to next offset only if not on offset.

pandas.tseries.offsets.FY5253.apply_index

FY5253.apply_index(self, other)

Vectorized apply of DateOffset to DatetimeIndex, raises NotImplementedError for offsets without a vectorized implementation.

Parameters

i [DatetimeIndex]

Returns

y [DatetimeIndex]

pandas.tseries.offsets.FY5253.rollback

`FY5253.rollback(self, dt)`

Roll provided date backward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

pandas.tseries.offsets.FY5253.rollforward

`FY5253.rollforward(self, dt)`

Roll provided date forward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

6.8.30 FY5253Quarter

FY5253Quarter([n, normalize, weekday, ...]) DateOffset increments between business quarter dates for 52-53 week fiscal year (also known as a 4-4-5 calendar).

pandas.tseries.offsets.FY5253Quarter

```
class pandas.tseries.offsets.FY5253Quarter(n=1, normalize=False, weekday=0, starting-
Month=1, qtr_with_extra_week=1, varia-
tion='nearest')
```

DateOffset increments between business quarter dates for 52-53 week fiscal year (also known as a 4-4-5 calendar).

It is used by companies that desire that their fiscal year always end on the same day of the week.

It is a method of managing accounting periods. It is a common calendar structure for some industries, such as retail, manufacturing and parking industry.

For more information see: http://en.wikipedia.org/wiki/4-4-5_calendar

The year may either: - end on the last X day of the Y month. - end on the last X day closest to the last day of the Y month.

X is a specific day of the week. Y is a certain month of the year

startingMonth = 1 corresponds to dates like 1/31/2007, 4/30/2007, ... startingMonth = 2 corresponds to dates like 2/28/2007, 5/31/2007, ... startingMonth = 3 corresponds to dates like 3/30/2007, 6/29/2007, ...

Parameters

n [int]

weekday [{0, 1, ..., 6}] 0: Mondays 1: Tuesdays 2: Wednesdays 3: Thursdays 4: Fridays 5: Saturdays 6: Sundays

startingMonth [The month in which fiscal years end. {1, 2, ... 12}]

qtr_with_extra_week [The quarter number that has the leap] or 14 week when needed. {1,2,3,4}

variation [str] {"nearest", "last"} for "LastOfMonth" or "NearestEndMonth"

Attributes

base Returns a copy of the calling offset object with n=1 and all other attributes equal.

pandas.tseries.offsets.FY5253Quarter.base

FY5253Quarter.base

Returns a copy of the calling offset object with n=1 and all other attributes equal.

```

6.8.31 Easter

<i>Easter</i>	DateOffset for the Easter holiday using logic defined in dateutil.
---------------	--

pandas.tseries.offsets.Easter

```
class pandas.tseries.offsets.Easter
    DateOffset for the Easter holiday using logic defined in dateutil.
    Right now uses the revised method which is valid in years 1583-4099.
```

Attributes

base Returns a copy of the calling offset object with n=1 and all other attributes equal.

pandas.tseries.offsets.Easter.base

Easter.base

Returns a copy of the calling offset object with n=1 and all other attributes equal.

freqstr	
kwds	
name	
nanos	
rule_code	

Methods

apply_index(self, other) Vectorized apply of DateOffset to DatetimeIndex, raises NotImplementedError for offsets without a vectorized implementation.

rollback(self, dt) Roll provided date backward to next offset only if not on offset.

rollforward(self, dt) Roll provided date forward to next offset only if not on offset.

pandas.tseries.offsets.Easter.apply_index

Easter.apply_index(self, other)

Vectorized apply of DateOffset to DatetimeIndex, raises NotImplementedError for offsets without a vectorized implementation.

Parameters

i [DatetimeIndex]

Returns

y [DatetimeIndex]

pandas.tseries.offsets.Easter.rollback

Easter.rollback(self, dt)

Roll provided date backward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

pandas.tseries.offsets.Easter.rollforward`Easter.rollforward(self, dt)`

Roll provided date forward to next offset only if not on offset.

Returns**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

`BDay.rollforward(self, dt)`

Roll provided date forward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

6.8.41 BMonthEnd

BMonthEnd alias of *pandas.tseries.offsets.BusinessMonthEnd*

pandas.tseries.offsets.BMonthEnd

`pandas.tseries.offsets.BMonthEnd`
alias of `pandas.tseries.offsets.BusinessMonthEnd`

Properties

BMonthEnd.base Returns a copy of the calling offset object with n=1 and all other attributes equal.

BMonthEnd.freqstr

BMonthEnd.kwds

BMonthEnd.name

BMonthEnd.nanos

BMonthEnd.normalize

BMonthEnd.rule_code

pandas.tseries.offsets.BMonthEnd.base**BMonthEnd.base**

Returns a copy of the calling offset object with n=1 and all other attributes equal.

Roll provided date backward to next offset only if not on offset.

BMonthEnd.rollforward(self, dt)

Roll provided date forward to next offset only if not on offset.

pandas.tseries.offsets.BMonthEnd.apply**BMonthEnd.apply**(self, other)

`pandas.tseries.offsets.BMonthEnd.apply_index`

`BMonthEnd.apply_index(self, other)`

`pandas.tseries.offsets.BMonthEnd.copy`

`BMonthEnd.copy(self)`

`pandas.tseries.offsets.BMonthEnd.isAnchored`

`BMonthEnd.isAnchored(self)`

`pandas.tseries.offsets.BMonthEnd.onOffset`

`BMonthEnd.onOffset(self, dt)`

`pandas.tseries.offsets.BMonthEnd.rollback`

`BMonthEnd.rollback(self, dt)`

Roll provided date backward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

`pandas.tseries.offsets.BMonthEnd.rollforward`

`BMonthEnd.rollforward(self, dt)`

Roll provided date forward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

6.8.42 BMonthBegin

BMonthBegin

alias of `pandas.tseries.offsets.
BusinessMonthBegin`

`pandas.tseries.offsets.BMonthBegin`

`pandas.tseries.offsets.BMonthBegin`

alias of `pandas.tseries.offsets.BusinessMonthBegin`

Properties

<i>BMonthBegin.base</i>	Returns a copy of the calling offset object with n=1 and all other attributes equal.

Returns**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.**6.8.43 CBMonthEnd**

<i>CBMonthEnd</i>	alias of <code>pandas.tseries.offsets.CustomBusinessMonthEnd</code>
-------------------	---

pandas.tseries.offsets.CBMonthEnd

`pandas.tseries.offsets.CBMonthEnd`
 alias of `pandas.tseries.offsets.CustomBusinessMonthEnd`

Properties

<i>CBMonthEnd.base</i>	Returns a copy of the calling offset object with n=1 and all other attributes equal.
<i>CBMonthEnd.cbdays_rol</i>	Define default roll function to be called in apply method.
<i>CBMonthEnd.freqstr</i>	
<i>CBMonthEnd.kwds</i>	
<i>CBMonthEnd.m_offset</i>	
<i>CBMonthEnd.month_rol</i>	Define default roll function to be called in apply method.
<i>CBMonthEnd.name</i>	
<i>CBMonthEnd.nanos</i>	
<i>CBMonthEnd.normalize</i>	
<i>CBMonthEnd.offset</i>	Alias for self._offset.
<i>CBMonthEnd.rule_code</i>	

pandas.tseries.offsets.CBMonthEnd.base

`CBMonthEnd.base`
 Returns a copy of the calling offset object with n=1 and all other attributes equal.

pandas.tseries.offsets.CBMonthEnd.cbdays_rol

`CBMonthEnd.cbdays_rol`
 Define default roll function to be called in apply method.

pandas.tseries.offsets.CBMonthEnd.freqstr

`CBMonthEnd.freqstr`

pandas.tseries.offsets.CBMonthEnd.kwds

`CBMonthEnd.kwds`

pandas.tseries.offsets.CBMonthEnd.m_offset

`CBMonthEnd.m_offset`

pandas.tseries.offsets.CBMonthEnd.month_roll

`CBMonthEnd.month_roll`

Define default roll function to be called in apply method.

pandas.tseries.offsets.CBMonthEnd.name

`CBMonthEnd.name`

pandas.tseries.offsets.CBMonthEnd.nanos

`CBMonthEnd.nanos`

pandas.tseries.offsets.CBMonthEnd.normalize

`CBMonthEnd.normalize = False`

pandas.tseries.offsets.CBMonthEnd.offset

`CBMonthEnd.offset`

Alias for `self._offset`.

pandas.tseries.offsets.CBMonthEnd.rule_code

`CBMonthEnd.rule_code`

Methods

<code>CBMonthEnd.apply(self, other)</code>	
<code>CBMonthEnd.apply_index(self, other)</code>	Vectorized apply of DateOffset to DatetimeIndex, raises NotImplementedError for offsets without a vectorized implementation.
<code>CBMonthEnd.copy(self)</code>	
<code>CBMonthEnd.isAnchored(self)</code>	
<code>CBMonthEnd.onOffset(self, dt)</code>	
<code>CBMonthEnd.rollback(self, dt)</code>	Roll provided date backward to next offset only if not on offset.
<code>CBMonthEnd.rollforward(self, dt)</code>	Roll provided date forward to next offset only if not on offset.

pandas.tseries.offsets.CBMonthEnd.apply

`CBMonthEnd.apply(self, other)`

pandas.tseries.offsets.CBMonthEnd.apply_index`CBMonthEnd.apply_index(self, other)`

Vectorized apply of DateOffset to DatetimeIndex, raises NotImplementedError for offsets without a vectorized implementation.

Parameters

`i` [DatetimeIndex]

Returns

`y` [DatetimeIndex]

pandas.tseries.offsets.CBMonthEnd.copy`CBMonthEnd.copy(self)`**pandas.tseries.offsets.CBMonthEnd.isAnchored**`CBMonthEnd.isAnchored(self)`**pandas.tseries.offsets.CBMonthEnd.onOffset**`CBMonthEnd.onOffset(self, dt)`**pandas.tseries.offsets.CBMonthEnd.rollback**`CBMonthEnd.rollback(self, dt)`

Roll provided date backward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

pandas.tseries.offsets.CBMonthEnd.rollforward`CBMonthEnd.rollforward(self, dt)`

Roll provided date forward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

6.8.44 CBMonthBegin

CBMonthBegin

alias of `pandas.tseries.offsets.CustomBusinessMonthBegin`

pandas.tseries.offsets.CBMonthBegin

pandas.tseries.offsets.CBMonthBegin

alias of *pandas.tseries.offsets.CustomBusinessMonthBegin*

Properties

<i>CBMonthBegin.base</i>	Returns a copy of the calling offset object with n=1 and all other attributes equal.
<i>CBMonthBegin.cbdays_rol</i>	Define default roll function to be called in apply method.
<i>CBMonthBegin.freqstr</i>	
<i>CBMonthBegin.kwds</i>	
<i>CBMonthBegin.m_offset</i>	
<i>CBMonthBegin.month_rol</i>	Define default roll function to be called in apply method.
<i>CBMonthBegin.name</i>	
<i>CBMonthBegin.nanos</i>	
<i>CBMonthBegin.normalize</i>	
<i>CBMonthBegin.offset</i>	Alias for self._offset.
<i>CBMonthBegin.rule_code</i>	

pandas.tseries.offsets.CBMonthBegin.base

CBMonthBegin.base

Returns a copy of the calling offset object with n=1 and all other attributes equal.

pandas.tseries.offsets.CBMonthBegin.cbdays_rol

CBMonthBegin.cbdays_rol

Define default roll function to be called in apply method.

pandas.tseries.offsets.CBMonthBegin.freqstr

CBMonthBegin.freqstr

pandas.tseries.offsets.CBMonthBegin.kwds

CBMonthBegin.kwds

pandas.tseries.offsets.CBMonthBegin.m_offset

CBMonthBegin.m_offset

pandas.tseries.offsets.CBMonthBegin.month_roll`CBMonthBegin.month_roll`

Define default roll function to be called in apply method.

pandas.tseries.offsets.CBMonthBegin.name`CBMonthBegin.name`**pandas.tseries.offsets.CBMonthBegin.nanos**`CBMonthBegin.nanos`**pandas.tseries.offsets.CBMonthBegin.normalize**`CBMonthBegin.normalize = False`**pandas.tseries.offsets.CBMonthBegin.offset**`CBMonthBegin.offset`Alias for `self._offset`.**pandas.tseries.offsets.CBMonthBegin.rule_code**`CBMonthBegin.rule_code`**Methods**

<code>CBMonthBegin.apply(self, other)</code>	
<code>CBMonthBegin.apply_index(self, other)</code>	Vectorized apply of DateOffset to DatetimeIndex, raises NotImplementedError for offsets without a vectorized implementation.
<code>CBMonthBegin.copy(self)</code>	
<code>CBMonthBegin.isAnchored(self)</code>	
<code>CBMonthBegin.onOffset(self, dt)</code>	
<code>CBMonthBegin.rollback(self, dt)</code>	Roll provided date backward to next offset only if not on offset.
<code>CBMonthBegin.rollforward(self, dt)</code>	Roll provided date forward to next offset only if not on offset.

pandas.tseries.offsets.CBMonthBegin.apply`CBMonthBegin.apply(self, other)`

pandas.tseries.offsets.CBMonthBegin.apply_index

`CBMonthBegin.apply_index(self, other)`

Vectorized apply of DateOffset to DatetimeIndex, raises NotImplementedError for offsets without a vectorized implementation.

Parameters

`i` [DatetimeIndex]

Returns

`y` [DatetimeIndex]

pandas.tseries.offsets.CBMonthBegin.copy

`CBMonthBegin.copy(self)`

pandas.tseries.offsets.CBMonthBegin.isAnchored

`CBMonthBegin.isAnchored(self)`

pandas.tseries.offsets.CBMonthBegin.onOffset

`CBMonthBegin.onOffset(self, dt)`

pandas.tseries.offsets.CBMonthBegin.rollback

`CBMonthBegin.rollback(self, dt)`

Roll provided date backward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

pandas.tseries.offsets.CBMonthBegin.rollforward

`CBMonthBegin.rollforward(self, dt)`

Roll provided date forward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

6.8.45 CDay

CDay

alias of `pandas.tseries.offsets.CustomBusinessDay`

pandas.tseries.offsets.CDay`pandas.tseries.offsets.CDay`alias of `pandas.tseries.offsets.CustomBusinessDay`**Properties**

<code>CDay.base</code>	Returns a copy of the calling offset object with n=1 and all other attributes equal.
<code>CDay.freqstr</code>	
<code>CDay.kwds</code>	
<code>CDay.name</code>	
<code>CDay.nanos</code>	
<code>CDay.normalize</code>	
<code>CDay.offset</code>	Alias for self.__offset.
<code>CDay.rule_code</code>	

pandas.tseries.offsets.CDay.base`CDay.base`

Returns a copy of the calling offset object with n=1 and all other attributes equal.

pandas.tseries.offsets.CDay.freqstr`CDay.freqstr`**pandas.tseries.offsets.CDay.kwds**`CDay.kwds`**pandas.tseries.offsets.CDay.name**`CDay.name`**pandas.tseries.offsets.CDay.nanos**`CDay.nanos`**pandas.tseries.offsets.CDay.normalize**`CDay.normalize = False`**pandas.tseries.offsets.CDay.offset**`CDay.offset`

Alias for self.__offset.

pandas.tseries.offsets.CDay.rule_code

CDay.rule_code

Methods

<i>CDay.apply</i> (self, other)	
<i>CDay.apply_index</i> (self, i)	Vectorized apply of DateOffset to DatetimeIndex, raises NotImplementedError for offsets without a vectorized implementation.
<i>CDay.copy</i> (self)	
<i>CDay.isAnchored</i> (self)	
<i>CDay.onOffset</i> (self, dt)	
<i>CDay.rollback</i> (self, dt)	Roll provided date backward to next offset only if not on offset.
<i>CDay.rollforward</i> (self, dt)	Roll provided date forward to next offset only if not on offset.

pandas.tseries.offsets.CDay.apply

CDay.apply(*self*, *other*)

pandas.tseries.offsets.CDay.apply_index

CDay.apply_index(*self*, *i*)

Vectorized apply of DateOffset to DatetimeIndex, raises NotImplementedError for offsets without a vectorized implementation.

Parameters

i [DatetimeIndex]

Returns

y [DatetimeIndex]

pandas.tseries.offsets.CDay.copy

CDay.copy(*self*)

pandas.tseries.offsets.CDay.isAnchored

CDay.isAnchored(*self*)

pandas.tseries.offsets.CDay.onOffset

CDay.onOffset(*self*, *dt*)

pandas.tseries.offsets.CDay.rollback`CDay.rollback(self, dt)`

Roll provided date backward to next offset only if not on offset.

Returns**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.**pandas.tseries.offsets.CDay.rollforward**`CDay.rollforward(self, dt)`

Roll provided date forward to next offset only if not on offset.

Returns**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

6.9 Frequencies

`to_offset(freq)`

Return DateOffset object from string or tuple representation or datetime.timedelta object

6.9.1 pandas.tseries.frequencies.to_offset

`pandas.tseries.frequencies.to_offset(freq)`

Return DateOffset object from string or tuple representation or datetime.timedelta object

Parameters**freq** [str, tuple, datetime.timedelta, DateOffset or None]**Returns****DateOffset** None if freq is None.**Raises****ValueError** If freq is an invalid frequency**See also:****DateOffset****Examples**

```
>>> to_offset('5min')
<5 * Minutes>
```

```
>>> to_offset('1D1H')
<25 * Hours>
```

```
>>> to_offset(('W', 2))
<2 * Weeks: weekday=6>
```

```
>>> to_offset((2, 'B'))
<2 * BusinessDays>
```

```
>>> to_offset(datetime.timedelta(days=1))
<Day>
```

```
>>> to_offset(Hour())
<Hour>
```

```
{{ header }}
```

6.10 Window

Rolling objects are returned by `.rolling` calls: `pandas.DataFrame.rolling()`, `pandas.Series.rolling()`, etc. Expanding objects are returned by `.expanding` calls: `pandas.DataFrame.expanding()`, `pandas.Series.expanding()`, etc. EWM objects are returned by `.ewm` calls: `pandas.DataFrame.ewm()`, `pandas.Series.ewm()`, etc.

6.10.1 Standard moving window functions

<code>Rolling.count(self)</code>	The rolling count of any non-NaN observations inside the window.
<code>Rolling.sum(self, *args, **kwargs)</code>	Calculate rolling sum of given DataFrame or Series.
<code>Rolling.mean(self, *args, **kwargs)</code>	Calculate the rolling mean of the values.
<code>Rolling.median(self, **kwargs)</code>	Calculate the rolling median.
<code>Rolling.var(self[, ddof])</code>	Calculate unbiased rolling variance.
<code>Rolling.std(self[, ddof])</code>	Calculate rolling standard deviation.
<code>Rolling.min(self, *args, **kwargs)</code>	Calculate the rolling minimum.
<code>Rolling.max(self, *args, **kwargs)</code>	Calculate the rolling maximum.
<code>Rolling.corr(self[, other, pairwise])</code>	Calculate rolling correlation.
<code>Rolling.cov(self[, other, pairwise, ddof])</code>	Calculate the rolling sample covariance.
<code>Rolling.skew(self, **kwargs)</code>	Unbiased rolling skewness.
<code>Rolling.kurt(self, **kwargs)</code>	Calculate unbiased rolling kurtosis.
<code>Rolling.apply(self, func[, raw, args, kwargs])</code>	The rolling function's apply function.
<code>Rolling.aggregate(self, arg, *args, **kwargs)</code>	Aggregate using one or more operations over the specified axis.
<code>Rolling.quantile(self, quantile[, interpolation])</code>	Calculate the rolling quantile.
<code>Window.mean(self, *args, **kwargs)</code>	Calculate the window mean of the values.
<code>Window.sum(self, *args, **kwargs)</code>	Calculate window sum of given DataFrame or Series.

pandas.core.window.Rolling.count

`Rolling.count(self)`

The rolling count of any non-NaN observations inside the window.

Returns

Series or DataFrame Returned object type is determined by the caller of the rolling calculation.

See also:

Series.rolling Calling object with Series data.

DataFrame.rolling Calling object with DataFrames.

DataFrame.count Count of the full DataFrame.

Examples

```

>>> s = pd.Series([2, 3, np.nan, 10])
>>> s.rolling(2).count()
0    1.0
1    2.0
2    1.0
3    1.0
dtype: float64
>>> s.rolling(3).count()
0    1.0
1    2.0
2    2.0
3    2.0
dtype: float64
>>> s.rolling(4).count()
0    1.0
1    2.0
2    2.0
3    3.0
dtype: float64

```

pandas.core.window.Rolling.sum

Rolling.sum(*self*, *args, **kwargs)

Calculate rolling sum of given DataFrame or Series.

Parameters

***args, **kwargs** For compatibility with other rolling methods. Has no effect on the computed value.

Returns

Series or DataFrame Same type as the input, with the same index, containing the rolling sum.

See also:

Series.sum Reducing sum for Series.

DataFrame.sum Reducing sum for DataFrame.

Examples

```
>>> s = pd.Series([1, 2, 3, 4, 5])
>>> s
0    1
1    2
2    3
3    4
4    5
dtype: int64
```

```
>>> s.rolling(3).sum()
0    NaN
1    NaN
2    6.0
3    9.0
4   12.0
dtype: float64
```

```
>>> s.expanding(3).sum()
0    NaN
1    NaN
2    6.0
3   10.0
4   15.0
dtype: float64
```

```
>>> s.rolling(3, center=True).sum()
0    NaN
1    6.0
2    9.0
3   12.0
4    NaN
dtype: float64
```

For DataFrame, each rolling sum is computed column-wise.

```
>>> df = pd.DataFrame({"A": s, "B": s ** 2})
>>> df
   A  B
0  1  1
1  2  4
2  3  9
3  4 16
4  5 25
```

```
>>> df.rolling(3).sum()
   A    B
0  NaN  NaN
1  NaN  NaN
2  6.0 14.0
3  9.0 29.0
```

(continues on next page)

(continued from previous page)

```
4  12.0  50.0
```

pandas.core.window.Rolling.mean**Rolling.mean**(*self*, **args*, ***kwargs*)

Calculate the rolling mean of the values.

Parameters***args** Under Review.****kwargs** Under Review.**Returns****Series or DataFrame** Returned object type is determined by the caller of the rolling calculation.**See also:****Series.rolling** Calling object with Series data.**DataFrame.rolling** Calling object with DataFrames.**Series.mean** Equivalent method for Series.**DataFrame.mean** Equivalent method for DataFrame.**Examples**

The below examples will show rolling mean calculations with window sizes of two and three, respectively.

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s.rolling(2).mean()
0    NaN
1    1.5
2    2.5
3    3.5
dtype: float64
```

```
>>> s.rolling(3).mean()
0    NaN
1    NaN
2    2.0
3    3.0
dtype: float64
```

pandas.core.window.Rolling.median**Rolling.median**(*self*, ***kwargs*)

Calculate the rolling median.

Parameters

****kwargs** For compatibility with other rolling methods. Has no effect on the computed median.

Returns

Series or DataFrame Returned type is the same as the original object.

See also:

Series.rolling Calling object with Series data.

DataFrame.rolling Calling object with DataFrames.

Series.median Equivalent method for Series.

DataFrame.median Equivalent method for DataFrame.

Examples

Compute the rolling median of a series with a window size of 3.

```
>>> s = pd.Series([0, 1, 2, 3, 4])
>>> s.rolling(3).median()
0    NaN
1    NaN
2    1.0
3    2.0
4    3.0
dtype: float64
```

pandas.core.window.Rolling.var

Rolling.var(*self*, *ddof*=1, **args*, ***kwargs*)

Calculate unbiased rolling variance.

Normalized by N-1 by default. This can be changed using the *ddof* argument.

Parameters

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is $N - \text{ddof}$, where N represents the number of elements.

***args, **kwargs** For NumPy compatibility. No additional arguments are used.

Returns

Series or DataFrame Returns the same object type as the caller of the rolling calculation.

See also:

Series.rolling Calling object with Series data.

DataFrame.rolling Calling object with DataFrames.

Series.var Equivalent method for Series.

DataFrame.var Equivalent method for DataFrame.

numpy.var Equivalent method for Numpy array.

Notes

The default *ddof* of 1 used in `Series.var()` is different than the default *ddof* of 0 in `numpy.var()`.

A minimum of 1 period is required for the rolling calculation.

Examples

```
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
>>> s.rolling(3).var()
0      NaN
1      NaN
2    0.333333
3    1.000000
4    1.000000
5    1.333333
6    0.000000
dtype: float64
```

```
>>> s.expanding(3).var()
0      NaN
1      NaN
2    0.333333
3    0.916667
4    0.800000
5    0.700000
6    0.619048
dtype: float64
```

pandas.core.window.Rolling.std

`Rolling.std(self, ddof=1, *args, **kwargs)`

Calculate rolling standard deviation.

Normalized by N-1 by default. This can be changed using the *ddof* argument.

Parameters

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is $N - \text{ddof}$, where N represents the number of elements.

***args, **kwargs** For NumPy compatibility. No additional arguments are used.

Returns

Series or DataFrame Returns the same object type as the caller of the rolling calculation.

See also:

Series.rolling Calling object with Series data.

DataFrame.rolling Calling object with DataFrames.

Series.std Equivalent method for Series.

DataFrame.std Equivalent method for DataFrame.

`numpy.std` Equivalent method for Numpy array.

Notes

The default *ddof* of 1 used in `Series.std` is different than the default *ddof* of 0 in `numpy.std`.

A minimum of one period is required for the rolling calculation.

Examples

```
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
>>> s.rolling(3).std()
0         NaN
1         NaN
2    0.577350
3    1.000000
4    1.000000
5    1.154701
6    0.000000
dtype: float64
```

```
>>> s.expanding(3).std()
0         NaN
1         NaN
2    0.577350
3    0.957427
4    0.894427
5    0.836660
6    0.786796
dtype: float64
```

`pandas.core.window.Rolling.min`

`Rolling.min(self, *args, **kwargs)`

Calculate the rolling minimum.

Parameters

****kwargs** Under Review.

Returns

Series or DataFrame Returned object type is determined by the caller of the rolling calculation.

See also:

Series.rolling Calling object with a Series.

DataFrame.rolling Calling object with a DataFrame.

Series.min Similar method for Series.

DataFrame.min Similar method for DataFrame.

Examples

Performing a rolling minimum with a window size of 3.

```

>>> s = pd.Series([4, 3, 5, 2, 6])
>>> s.rolling(3).min()
0    NaN
1    NaN
2    3.0
3    2.0
4    2.0
dtype: float64

```

pandas.core.window.Rolling.max

`Rolling.max(self, *args, **kwargs)`
Calculate the rolling maximum.

Parameters

***args, **kwargs** Arguments and keyword arguments to be passed into func.

Returns

Series or DataFrame Return type is determined by the caller.

See also:

Series.rolling Series rolling.

DataFrame.rolling DataFrame rolling.

pandas.core.window.Rolling.corr

`Rolling.corr(self, other=None, pairwise=None, **kwargs)`
Calculate rolling correlation.

Parameters

other [Series, DataFrame, or ndarray, optional] If not supplied then will default to self.

pairwise [bool, default None] Calculate pairwise combinations of columns within a DataFrame. If *other* is not specified, defaults to *True*, otherwise defaults to *False*. Not relevant for *Series*.

****kwargs** Unused.

Returns

Series or DataFrame Returned object type is determined by the caller of the rolling calculation.

See also:

Series.rolling Calling object with Series data.

DataFrame.rolling Calling object with DataFrames.

Series.corr Equivalent method for Series.

`DataFrame.corr` Equivalent method for DataFrame.

`rolling.cov` Similar method to calculate covariance.

`numpy.corrcoef` NumPy Pearson's correlation calculation.

Notes

This function uses Pearson's definition of correlation (https://en.wikipedia.org/wiki/Pearson_correlation_coefficient).

When *other* is not specified, the output will be self correlation (e.g. all 1's), except for *DataFrame* inputs with *pairwise* set to *True*.

Function will return NaN for correlations of equal valued sequences; this is the result of a 0/0 division error.

When *pairwise* is set to *False*, only matching columns between *self* and *other* will be used.

When *pairwise* is set to *True*, the output will be a MultiIndex DataFrame with the original index on the first level, and the *other* DataFrame columns on the second level.

In the case of missing elements, only complete pairwise observations will be used.

Examples

The below example shows a rolling calculation with a window size of four matching the equivalent function call using `numpy.corrcoef()`.

```
>>> v1 = [3, 3, 3, 5, 8]
>>> v2 = [3, 4, 4, 4, 8]
>>> fmt = "{0:.6f}" # limit the printed precision to 6 digits
>>> # numpy returns a 2X2 array, the correlation coefficient
>>> # is the number at entry [0][1]
>>> print(fmt.format(np.corrcoef(v1[:-1], v2[:-1])[0][1]))
0.333333
>>> print(fmt.format(np.corrcoef(v1[1:], v2[1:])[0][1]))
0.916949
>>> s1 = pd.Series(v1)
>>> s2 = pd.Series(v2)
>>> s1.rolling(4).corr(s2)
0      NaN
1      NaN
2      NaN
3    0.333333
4    0.916949
dtype: float64
```

The below example shows a similar rolling calculation on a DataFrame using the pairwise option.

```
>>> matrix = np.array([[51., 35.], [49., 30.], [47., 32.], [46., 31.], [50., 36.
↵]])
>>> print(np.corrcoef(matrix[:-1,0], matrix[:-1,1]).round(7))
[[1.         0.6263001]
 [0.6263001  1.         ]]
>>> print(np.corrcoef(matrix[1:,0], matrix[1:,1]).round(7))
```

(continues on next page)

(continued from previous page)

```

[[1.          0.5553681]
 [0.5553681  1.          ]]
>>> df = pd.DataFrame(matrix, columns=['X', 'Y'])
>>> df
   X     Y
0 51.0 35.0
1 49.0 30.0
2 47.0 32.0
3 46.0 31.0
4 50.0 36.0
>>> df.rolling(4).corr(pairwise=True)
   X     Y
0 X   NaN NaN
  Y   NaN NaN
1 X   NaN NaN
  Y   NaN NaN
2 X   NaN NaN
  Y   NaN NaN
3 X 1.000000 0.626300
  Y 0.626300 1.000000
4 X 1.000000 0.555368
  Y 0.555368 1.000000

```

pandas.core.window.Rolling.cov

`Rolling.cov(self, other=None, pairwise=None, ddof=1, **kwargs)`

Calculate the rolling sample covariance.

Parameters

other [Series, DataFrame, or ndarray, optional] If not supplied then will default to self and produce pairwise output.

pairwise [bool, default None] If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndexed DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is $N - \text{ddof}$, where N represents the number of elements.

****kwargs** Keyword arguments to be passed into func.

Returns

Series or DataFrame Return type is determined by the caller.

See also:

`Series.rolling` Series rolling.

`DataFrame.rolling` DataFrame rolling.

`pandas.core.window.Rolling.skew`

`Rolling.skew(self, **kwargs)`
Unbiased rolling skewness.

Parameters

****kwargs** Keyword arguments to be passed into func.

Returns

Series or DataFrame Return type is determined by the caller.

See also:

`Series.rolling` Series rolling.

`DataFrame.rolling` DataFrame rolling.

`pandas.core.window.Rolling.kurt`

`Rolling.kurt(self, **kwargs)`
Calculate unbiased rolling kurtosis.

This function uses Fisher's definition of kurtosis without bias.

Parameters

****kwargs** Under Review.

Returns

Series or DataFrame Returned object type is determined by the caller of the rolling calculation.

See also:

`Series.rolling` Calling object with Series data.

`DataFrame.rolling` Calling object with DataFrames.

`Series.kurt` Equivalent method for Series.

`DataFrame.kurt` Equivalent method for DataFrame.

`scipy.stats.skew` Third moment of a probability density.

`scipy.stats.kurtosis` Reference SciPy method.

Notes

A minimum of 4 periods is required for the rolling calculation.

Examples

The example below will show a rolling calculation with a window size of four matching the equivalent function call using `scipy.stats`.

```

>>> arr = [1, 2, 3, 4, 999]
>>> fmt = "{0:.6f}" # limit the printed precision to 6 digits
>>> import scipy.stats
>>> print(fmt.format(scipy.stats.kurtosis(arr[:-1], bias=False)))
-1.200000
>>> print(fmt.format(scipy.stats.kurtosis(arr[1:], bias=False)))
3.999946
>>> s = pd.Series(arr)
>>> s.rolling(4).kurt()
0         NaN
1         NaN
2         NaN
3    -1.200000
4     3.999946
dtype: float64

```

pandas.core.window.Rolling.apply

`Rolling.apply(self, func, raw=None, args=(), kwargs={})`

The rolling function's apply function.

Parameters

func [function] Must produce a single value from an ndarray input if `raw=True` or a single value from a Series if `raw=False`.

raw [bool, default None]

- **False** : passes each row or column as a Series to the function.
- **True** or **None** : the passed function will receive ndarray objects instead. If you are just applying a NumPy reduction function this will achieve much better performance.

The `raw` parameter is required and will show a FutureWarning if not passed. In the future `raw` will default to False.

New in version 0.23.0.

***args, **kwargs** Arguments and keyword arguments to be passed into func.

Returns

Series or DataFrame Return type is determined by the caller.

See also:

Series.rolling Series rolling.

DataFrame.rolling DataFrame rolling.

pandas.core.window.Rolling.aggregate

`Rolling.aggregate(self, arg, *args, **kwargs)`

Aggregate using one or more operations over the specified axis.

Parameters

func [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a Series/Dataframe or when passed to Series/Dataframe.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. `[np.sum, 'mean']`
- dict of axis labels -> functions, function names or list of such.

***args** Positional arguments to pass to *func*.

****kwargs** Keyword arguments to pass to *func*.

Returns

scalar, Series or DataFrame The return can be:

- scalar : when Series.agg is called with single function
- Series : when DataFrame.agg is called with a single function
- DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

See also:

`Series.rolling`

`DataFrame.rolling`

Notes

agg is an alias for *aggregate*. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```
>>> df = pd.DataFrame(np.random.randn(10, 3), columns=['A', 'B', 'C'])
>>> df
   A         B         C
0 -2.385977 -0.102758  0.438822
1 -1.004295  0.905829 -0.954544
2  0.735167 -0.165272 -1.619346
3 -0.702657 -1.340923 -0.706334
4 -0.246845  0.211596 -0.901819
5  2.463718  3.157577 -1.380906

9  0.212668  0.403198 -0.093924
```

```
>>> df.rolling(3).agg({'A': 'sum', 'B': 'min'})
      A         B
0     NaN      NaN
1     NaN      NaN
2 -2.655105 -0.165272
3 -0.971785 -1.340923
4 -0.214334 -1.340923
5  1.514216 -1.340923
6  1.074618  0.211596
7  2.718061 -1.647453
8 -0.289082 -1.647453
9  0.212668 -1.647453
```

pandas.core.window.Rolling.quantile

`Rolling.quantile(self, quantile, interpolation='linear', **kwargs)`

Calculate the rolling quantile.

Parameters

quantile [float] Quantile to compute. $0 \leq \text{quantile} \leq 1$.

interpolation [{{'linear', 'lower', 'higher', 'midpoint', 'nearest'}}] New in version 0.23.0.

This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points i and j :

- linear: $i + (j - i) * \text{fraction}$, where *fraction* is the fractional part of the index surrounded by i and j .
- lower: i .
- higher: j .
- nearest: i or j whichever is nearest.
- midpoint: $(i + j) / 2$.

****kwargs**: For compatibility with other rolling methods. Has no effect on the result.

Returns

Series or DataFrame Returned object type is determined by the caller of the rolling calculation.

See also:

Series.quantile Computes value at the given quantile over all data in Series.

DataFrame.quantile Computes values at the given quantile over requested axis in DataFrame.

Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s.rolling(2).quantile(.4, interpolation='lower')
0    NaN
1    1.0
2    2.0
3    3.0
dtype: float64
```

```
>>> s.rolling(2).quantile(.4, interpolation='midpoint')
0    NaN
1    1.5
2    2.5
3    3.5
dtype: float64
```

pandas.core.window.Window.mean

Window.mean(*self*, *args, **kwargs)

Calculate the window mean of the values.

Parameters

***args** Under Review.

****kwargs** Under Review.

Returns

Series or DataFrame Returned object type is determined by the caller of the window calculation.

See also:

Series.window Calling object with Series data.

DataFrame.window Calling object with DataFrames.

Series.mean Equivalent method for Series.

DataFrame.mean Equivalent method for DataFrame.

Examples

The below examples will show rolling mean calculations with window sizes of two and three, respectively.

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s.rolling(2).mean()
0    NaN
1    1.5
2    2.5
3    3.5
dtype: float64
```

```
>>> s.rolling(3).mean()
0    NaN
1    NaN
2    2.0
3    3.0
dtype: float64
```

pandas.core.window.Window.sum

`Window.sum(self, *args, **kwargs)`

Calculate window sum of given DataFrame or Series.

Parameters

***args, **kwargs** For compatibility with other window methods. Has no effect on the computed value.

Returns

Series or DataFrame Same type as the input, with the same index, containing the window sum.

See also:

Series.sum Reducing sum for Series.

DataFrame.sum Reducing sum for DataFrame.

Examples

```
>>> s = pd.Series([1, 2, 3, 4, 5])
>>> s
0    1
1    2
2    3
3    4
4    5
dtype: int64
```

```
>>> s.rolling(3).sum()
0    NaN
1    NaN
2    6.0
3    9.0
```

(continues on next page)

(continued from previous page)

```
4    12.0
dtype: float64
```

```
>>> s.expanding(3).sum()
0    NaN
1    NaN
2    6.0
3   10.0
4   15.0
dtype: float64
```

```
>>> s.rolling(3, center=True).sum()
0    NaN
1    6.0
2    9.0
3   12.0
4    NaN
dtype: float64
```

For DataFrame, each window sum is computed column-wise.

```
>>> df = pd.DataFrame({"A": s, "B": s ** 2})
>>> df
   A  B
0  1  1
1  2  4
2  3  9
3  4 16
4  5 25
```

```
>>> df.rolling(3).sum()
   A    B
0  NaN  NaN
1  NaN  NaN
2  6.0 14.0
3  9.0 29.0
4 12.0 50.0
```

6.10.2 Standard expanding window functions

<i>Expanding.count</i> (self, <i>**kwargs</i>)	The expanding count of any non-NaN observations inside the window.
<i>Expanding.sum</i> (self, <i>*args, **kwargs</i>)	Calculate expanding sum of given DataFrame or Series.
<i>Expanding.mean</i> (self, <i>*args, **kwargs</i>)	Calculate the expanding mean of the values.
<i>Expanding.median</i> (self, <i>**kwargs</i>)	Calculate the expanding median.
<i>Expanding.var</i> (self[, <i>ddof</i>])	Calculate unbiased expanding variance.
<i>Expanding.std</i> (self[, <i>ddof</i>])	Calculate expanding standard deviation.
<i>Expanding.min</i> (self, <i>*args, **kwargs</i>)	Calculate the expanding minimum.

Continued on next page

Table 388 – continued from previous page

<i>Expanding.max</i> (self, <i>*args</i> , <i>**kwargs</i>)	Calculate the expanding maximum.
<i>Expanding.corr</i> (self[, other, pairwise])	Calculate expanding correlation.
<i>Expanding.cov</i> (self[, other, pairwise, ddof])	Calculate the expanding sample covariance.
<i>Expanding.skew</i> (self, <i>**kwargs</i>)	Unbiased expanding skewness.
<i>Expanding.kurt</i> (self, <i>**kwargs</i>)	Calculate unbiased expanding kurtosis.
<i>Expanding.apply</i> (self, func[, raw, args, kwargs])	The expanding function's apply function.
<i>Expanding.aggregate</i> (self, arg, <i>*args</i> , ...)	Aggregate using one or more operations over the specified axis.
<i>Expanding.quantile</i> (self, quantile[, ...])	Calculate the expanding quantile.

pandas.core.window.Expanding.count

`Expanding.count(self, **kwargs)`

The expanding count of any non-NaN observations inside the window.

Returns

Series or DataFrame Returned object type is determined by the caller of the expanding calculation.

See also:

Series.expanding Calling object with Series data.

DataFrame.expanding Calling object with DataFrames.

DataFrame.count Count of the full DataFrame.

Examples

```
>>> s = pd.Series([2, 3, np.nan, 10])
>>> s.rolling(2).count()
0    1.0
1    2.0
2    1.0
3    1.0
dtype: float64
>>> s.rolling(3).count()
0    1.0
1    2.0
2    2.0
3    2.0
dtype: float64
>>> s.rolling(4).count()
0    1.0
1    2.0
2    2.0
3    3.0
dtype: float64
```

pandas.core.window.Expanding.sum`Expanding.sum(self, *args, **kwargs)`

Calculate expanding sum of given DataFrame or Series.

Parameters***args, **kwargs** For compatibility with other expanding methods. Has no effect on the computed value.**Returns****Series or DataFrame** Same type as the input, with the same index, containing the expanding sum.**See also:****Series.sum** Reducing sum for Series.**DataFrame.sum** Reducing sum for DataFrame.**Examples**

```
>>> s = pd.Series([1, 2, 3, 4, 5])
>>> s
0    1
1    2
2    3
3    4
4    5
dtype: int64
```

```
>>> s.rolling(3).sum()
0    NaN
1    NaN
2    6.0
3    9.0
4   12.0
dtype: float64
```

```
>>> s.expanding(3).sum()
0    NaN
1    NaN
2    6.0
3   10.0
4   15.0
dtype: float64
```

```
>>> s.rolling(3, center=True).sum()
0    NaN
1    6.0
2    9.0
3   12.0
4    NaN
dtype: float64
```

For DataFrame, each expanding sum is computed column-wise.

```
>>> df = pd.DataFrame({"A": s, "B": s ** 2})
>>> df
   A  B
0  1  1
1  2  4
2  3  9
3  4 16
4  5 25
```

```
>>> df.rolling(3).sum()
   A    B
0 NaN NaN
1 NaN NaN
2 6.0 14.0
3 9.0 29.0
4 12.0 50.0
```

pandas.core.window.Expanding.mean

`Expanding.mean(self, *args, **kwargs)`

Calculate the expanding mean of the values.

Parameters

***args** Under Review.

****kwargs** Under Review.

Returns

Series or DataFrame Returned object type is determined by the caller of the expanding calculation.

See also:

Series.expanding Calling object with Series data.

DataFrame.expanding Calling object with DataFrames.

Series.mean Equivalent method for Series.

DataFrame.mean Equivalent method for DataFrame.

Examples

The below examples will show rolling mean calculations with window sizes of two and three, respectively.

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s.rolling(2).mean()
0    NaN
1    1.5
2    2.5
```

(continues on next page)

(continued from previous page)

```
3    3.5
dtype: float64
```

```
>>> s.rolling(3).mean()
0    NaN
1    NaN
2    2.0
3    3.0
dtype: float64
```

pandas.core.window.Expanding.median

`Expanding.median(self, **kwargs)`

Calculate the expanding median.

Parameters

****kwargs** For compatibility with other expanding methods. Has no effect on the computed median.

Returns

Series or DataFrame Returned type is the same as the original object.

See also:

Series.expanding Calling object with Series data.

DataFrame.expanding Calling object with DataFrames.

Series.median Equivalent method for Series.

DataFrame.median Equivalent method for DataFrame.

Examples

Compute the rolling median of a series with a window size of 3.

```
>>> s = pd.Series([0, 1, 2, 3, 4])
>>> s.rolling(3).median()
0    NaN
1    NaN
2    1.0
3    2.0
4    3.0
dtype: float64
```

pandas.core.window.Expanding.var

`Expanding.var(self, ddof=1, *args, **kwargs)`

Calculate unbiased expanding variance.

Normalized by N-1 by default. This can be changed using the *ddof* argument.

Parameters

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is $N - \text{ddof}$, where N represents the number of elements.

***args, **kwargs** For NumPy compatibility. No additional arguments are used.

Returns

Series or DataFrame Returns the same object type as the caller of the expanding calculation.

See also:

Series.expanding Calling object with Series data.

DataFrame.expanding Calling object with DataFrames.

Series.var Equivalent method for Series.

DataFrame.var Equivalent method for DataFrame.

numpy.var Equivalent method for Numpy array.

Notes

The default *ddof* of 1 used in `Series.var()` is different than the default *ddof* of 0 in `numpy.var()`.

A minimum of 1 period is required for the rolling calculation.

Examples

```
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
>>> s.rolling(3).var()
0         NaN
1         NaN
2    0.333333
3    1.000000
4    1.000000
5    1.333333
6    0.000000
dtype: float64
```

```
>>> s.expanding(3).var()
0         NaN
1         NaN
2    0.333333
3    0.916667
4    0.800000
5    0.700000
6    0.619048
dtype: float64
```

pandas.core.window.Expanding.std

`Expanding.std(self, ddof=1, *args, **kwargs)`

Calculate expanding standard deviation.

Normalized by N-1 by default. This can be changed using the *ddof* argument.

Parameters

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is $N - \text{ddof}$, where N represents the number of elements.

***args, **kwargs** For NumPy compatibility. No additional arguments are used.

Returns

Series or DataFrame Returns the same object type as the caller of the expanding calculation.

See also:

Series.expanding Calling object with Series data.

DataFrame.expanding Calling object with DataFrames.

Series.std Equivalent method for Series.

DataFrame.std Equivalent method for DataFrame.

numpy.std Equivalent method for Numpy array.

Notes

The default *ddof* of 1 used in `Series.std` is different than the default *ddof* of 0 in `numpy.std`.

A minimum of one period is required for the rolling calculation.

Examples

```
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
>>> s.rolling(3).std()
0         NaN
1         NaN
2    0.577350
3    1.000000
4    1.000000
5    1.154701
6    0.000000
dtype: float64
```

```
>>> s.expanding(3).std()
0         NaN
1         NaN
2    0.577350
3    0.957427
4    0.894427
5    0.836660
```

(continues on next page)

(continued from previous page)

```
6    0.786796
dtype: float64
```

pandas.core.window.Expanding.min

`Expanding.min(self, *args, **kwargs)`

Calculate the expanding minimum.

Parameters

****kwargs** Under Review.

Returns

Series or DataFrame Returned object type is determined by the caller of the expanding calculation.

See also:

Series.expanding Calling object with a Series.

DataFrame.expanding Calling object with a DataFrame.

Series.min Similar method for Series.

DataFrame.min Similar method for DataFrame.

Examples

Performing a rolling minimum with a window size of 3.

```
>>> s = pd.Series([4, 3, 5, 2, 6])
>>> s.rolling(3).min()
0    NaN
1    NaN
2    3.0
3    2.0
4    2.0
dtype: float64
```

pandas.core.window.Expanding.max

`Expanding.max(self, *args, **kwargs)`

Calculate the expanding maximum.

Parameters

***args, **kwargs** Arguments and keyword arguments to be passed into func.

Returns

Series or DataFrame Return type is determined by the caller.

See also:

Series.expanding Series expanding.

`DataFrame.expanding` DataFrame expanding.

`pandas.core.window.Expanding.corr`

`Expanding.corr(self, other=None, pairwise=None, **kwargs)`
Calculate expanding correlation.

Parameters

other [Series, DataFrame, or ndarray, optional] If not supplied then will default to self.

pairwise [bool, default None] Calculate pairwise combinations of columns within a DataFrame. If *other* is not specified, defaults to *True*, otherwise defaults to *False*. Not relevant for *Series*.

****kwargs** Unused.

Returns

Series or DataFrame Returned object type is determined by the caller of the expanding calculation.

See also:

`Series.expanding` Calling object with Series data.

`DataFrame.expanding` Calling object with DataFrames.

`Series.corr` Equivalent method for Series.

`DataFrame.corr` Equivalent method for DataFrame.

`expanding.cov` Similar method to calculate covariance.

`numpy.corrcoef` NumPy Pearson's correlation calculation.

Notes

This function uses Pearson's definition of correlation (https://en.wikipedia.org/wiki/Pearson_correlation_coefficient).

When *other* is not specified, the output will be self correlation (e.g. all 1's), except for *DataFrame* inputs with *pairwise* set to *True*.

Function will return NaN for correlations of equal valued sequences; this is the result of a 0/0 division error.

When *pairwise* is set to *False*, only matching columns between *self* and *other* will be used.

When *pairwise* is set to *True*, the output will be a MultiIndex DataFrame with the original index on the first level, and the *other* DataFrame columns on the second level.

In the case of missing elements, only complete pairwise observations will be used.

Examples

The below example shows a rolling calculation with a window size of four matching the equivalent function call using `numpy.corrcoef()`.

```

>>> v1 = [3, 3, 3, 5, 8]
>>> v2 = [3, 4, 4, 4, 8]
>>> fmt = "{0:.6f}" # limit the printed precision to 6 digits
>>> # numpy returns a 2X2 array, the correlation coefficient
>>> # is the number at entry [0][1]
>>> print(fmt.format(np.corrcoef(v1[:-1], v2[:-1])[0][1]))
0.333333
>>> print(fmt.format(np.corrcoef(v1[1:], v2[1:])[0][1]))
0.916949
>>> s1 = pd.Series(v1)
>>> s2 = pd.Series(v2)
>>> s1.rolling(4).corr(s2)
0      NaN
1      NaN
2      NaN
3      0.333333
4      0.916949
dtype: float64

```

The below example shows a similar rolling calculation on a DataFrame using the pairwise option.

```

>>> matrix = np.array([[51., 35.], [49., 30.], [47., 32.], [46., 31.], [50., 36.
→]])
>>> print(np.corrcoef(matrix[:-1,0], matrix[:-1,1]).round(7))
[[1.         0.6263001]
 [0.6263001  1.         ]]
>>> print(np.corrcoef(matrix[1:,0], matrix[1:,1]).round(7))
[[1.         0.5553681]
 [0.5553681  1.         ]]
>>> df = pd.DataFrame(matrix, columns=['X', 'Y'])
>>> df
   X    Y
0 51.0 35.0
1 49.0 30.0
2 47.0 32.0
3 46.0 31.0
4 50.0 36.0
>>> df.rolling(4).corr(pairwise=True)
   X      Y
0 X   NaN  NaN
  Y   NaN  NaN
1 X   NaN  NaN
  Y   NaN  NaN
2 X   NaN  NaN
  Y   NaN  NaN
3 X  1.000000  0.626300
  Y  0.626300  1.000000
4 X  1.000000  0.555368
  Y  0.555368  1.000000

```

pandas.core.window.Expanding.cov

`Expanding.cov(self, other=None, pairwise=None, ddof=1, **kwargs)`
Calculate the expanding sample covariance.

Parameters

other [Series, DataFrame, or ndarray, optional] If not supplied then will default to self and produce pairwise output.

pairwise [bool, default None] If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndexed DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is $N - \text{ddof}$, where N represents the number of elements.

****kwargs** Keyword arguments to be passed into func.

Returns

Series or DataFrame Return type is determined by the caller.

See also:

`Series.expanding` Series expanding.

`DataFrame.expanding` DataFrame expanding.

pandas.core.window.Expanding.skew

`Expanding.skew(self, **kwargs)`
Unbiased expanding skewness.

Parameters

****kwargs** Keyword arguments to be passed into func.

Returns

Series or DataFrame Return type is determined by the caller.

See also:

`Series.expanding` Series expanding.

`DataFrame.expanding` DataFrame expanding.

pandas.core.window.Expanding.kurt

`Expanding.kurt(self, **kwargs)`
Calculate unbiased expanding kurtosis.

This function uses Fisher's definition of kurtosis without bias.

Parameters

****kwargs** Under Review.

Returns

Series or DataFrame Returned object type is determined by the caller of the expanding calculation.

See also:

Series.expanding Calling object with Series data.

DataFrame.expanding Calling object with DataFrames.

Series.kurt Equivalent method for Series.

DataFrame.kurt Equivalent method for DataFrame.

scipy.stats.skew Third moment of a probability density.

scipy.stats.kurtosis Reference SciPy method.

Notes

A minimum of 4 periods is required for the expanding calculation.

Examples

The example below will show an expanding calculation with a window size of four matching the equivalent function call using *scipy.stats*.

```
>>> arr = [1, 2, 3, 4, 999]
>>> import scipy.stats
>>> fmt = "{0:.6f}" # limit the printed precision to 6 digits
>>> print(fmt.format(scipy.stats.kurtosis(arr[:-1], bias=False)))
-1.200000
>>> print(fmt.format(scipy.stats.kurtosis(arr, bias=False)))
4.999874
>>> s = pd.Series(arr)
>>> s.expanding(4).kurt()
0      NaN
1      NaN
2      NaN
3    -1.200000
4     4.999874
dtype: float64
```

pandas.core.window.Expanding.apply

Expanding.apply(*self*, *func*, *raw=None*, *args=()*, *kwargs={}*)

The expanding function's apply function.

Parameters

func [function] Must produce a single value from an ndarray input if **raw=True** or a single value from a Series if **raw=False**.

raw [bool, default None]

- **False** : passes each row or column as a Series to the function.

- **True or None** : the passed function will receive ndarray objects instead. If you are just applying a NumPy reduction function this will achieve much better performance.

The *raw* parameter is required and will show a FutureWarning if not passed. In the future *raw* will default to False.

New in version 0.23.0.

***args, **kwargs** Arguments and keyword arguments to be passed into func.

Returns

Series or DataFrame Return type is determined by the caller.

See also:

Series.expanding Series expanding.

DataFrame.expanding DataFrame expanding.

pandas.core.window.Expanding.aggregate

Expanding.aggregate(*self*, *arg*, **args*, ***kwargs*)

Aggregate using one or more operations over the specified axis.

Parameters

func [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a Series/Dataframe or when passed to Series/Dataframe.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. [`np.sum`, 'mean']
- dict of axis labels -> functions, function names or list of such.

***args** Positional arguments to pass to *func*.

****kwargs** Keyword arguments to pass to *func*.

Returns

scalar, Series or DataFrame The return can be:

- scalar : when Series.agg is called with single function
- Series : when DataFrame.agg is called with a single function
- DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

See also:

DataFrame.expanding.aggregate

DataFrame.rolling.aggregate

DataFrame.aggregate

Notes

agg is an alias for *aggregate*. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```
>>> df = pd.DataFrame(np.random.randn(10, 3), columns=['A', 'B', 'C'])
>>> df
```

	A	B	C
0	-2.385977	-0.102758	0.438822
1	-1.004295	0.905829	-0.954544
2	0.735167	-0.165272	-1.619346
3	-0.702657	-1.340923	-0.706334
4	-0.246845	0.211596	-0.901819
5	2.463718	3.157577	-1.380906

5	1.076417	1.503943	-1.146293
6	-0.041654	1.925562	-0.588728
7	0.680292	0.132049	0.548693
8	0.067236	0.948257	0.163353
9	-0.286980	0.618493	-0.694496

pandas.core.window.Expanding.quantile

`Expanding.quantile(self, quantile, interpolation='linear', **kwargs)`

Calculate the expanding quantile.

Parameters

quantile [float] Quantile to compute. $0 \leq \text{quantile} \leq 1$.

interpolation [{'linear', 'lower', 'higher', 'midpoint', 'nearest'}] New in version 0.23.0.

This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points i and j :

- linear: $i + (j - i) * \text{fraction}$, where *fraction* is the fractional part of the index surrounded by i and j .
- lower: i .

- higher: j .
- nearest: i or j whichever is nearest.
- midpoint: $(i + j) / 2$.

****kwargs:** For compatibility with other expanding methods. Has no effect on the result.

Returns

Series or DataFrame Returned object type is determined by the caller of the expanding calculation.

See also:

Series.quantile Computes value at the given quantile over all data in Series.

DataFrame.quantile Computes values at the given quantile over requested axis in DataFrame.

Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s.rolling(2).quantile(.4, interpolation='lower')
0    NaN
1    1.0
2    2.0
3    3.0
dtype: float64
```

```
>>> s.rolling(2).quantile(.4, interpolation='midpoint')
0    NaN
1    1.5
2    2.5
3    3.5
dtype: float64
```

6.10.3 Exponentially-weighted moving window functions

<i>EWM.mean</i> (self, [*args, **kwargs])	Exponential weighted moving average.
<i>EWM.std</i> (self[, bias])	Exponential weighted moving stddev.
<i>EWM.var</i> (self[, bias])	Exponential weighted moving variance.
<i>EWM.corr</i> (self[, other, pairwise])	Exponential weighted sample correlation.
<i>EWM.cov</i> (self[, other, pairwise, bias])	Exponential weighted sample covariance.

pandas.core.window.EWM.mean

EWM.mean(self, *args, **kwargs)
Exponential weighted moving average.

Parameters

***args, **kwargs** Arguments and keyword arguments to be passed into func.

Returns

Series or DataFrame Return type is determined by the caller.

See also:

Series.ewm Series ewm.

DataFrame.ewm DataFrame ewm.

pandas.core.window.EWM.std

EWM.std(*self*, *bias=False*, *args, **kwargs)

Exponential weighted moving stddev.

Parameters

bias [bool, default False] Use a standard estimation bias correction.

***args, **kwargs** Arguments and keyword arguments to be passed into func.

Returns

Series or DataFrame Return type is determined by the caller.

See also:

Series.ewm Series ewm.

DataFrame.ewm DataFrame ewm.

pandas.core.window.EWM.var

EWM.var(*self*, *bias=False*, *args, **kwargs)

Exponential weighted moving variance.

Parameters

bias [bool, default False] Use a standard estimation bias correction.

***args, **kwargs** Arguments and keyword arguments to be passed into func.

Returns

Series or DataFrame Return type is determined by the caller.

See also:

Series.ewm Series ewm.

DataFrame.ewm DataFrame ewm.

pandas.core.window.EWM.corr

EWM.corr(*self*, *other=None*, *pairwise=None*, **kwargs)

Exponential weighted sample correlation.

Parameters

other [Series, DataFrame, or ndarray, optional] If not supplied then will default to self and produce pairwise output.

pairwise [bool, default None] If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndex DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.

bias [bool, default False] Use a standard estimation bias correction.

****kwargs** Keyword arguments to be passed into func.

Returns

Series or DataFrame Return type is determined by the caller.

See also:

Series.ewm Series ewm.

DataFrame.ewm DataFrame ewm.

pandas.core.window.EWM.cov

EWM.cov(*self*, *other=None*, *pairwise=None*, *bias=False*, ***kwargs*)

Exponential weighted sample covariance.

Parameters

other [Series, DataFrame, or ndarray, optional] If not supplied then will default to self and produce pairwise output.

pairwise [bool, default None] If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndex DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.

bias [bool, default False] Use a standard estimation bias correction.

****kwargs** Keyword arguments to be passed into func.

Returns

Series or DataFrame Return type is determined by the caller.

See also:

Series.ewm Series ewm.

DataFrame.ewm DataFrame ewm.

{{ header }}

6.11 GroupBy

GroupBy objects are returned by groupby calls: `pandas.DataFrame.groupby()`, `pandas.Series.groupby()`, etc.

6.11.1 Indexing, iteration

<code>GroupBy.__iter__(self)</code>	Groupby iterator.
<code>GroupBy.groups</code>	Dict {group name -> group labels}.
<code>GroupBy.indices</code>	Dict {group name -> group indices}.
<code>GroupBy.get_group(self, name[, obj])</code>	Construct DataFrame from group with provided name.

`pandas.core.groupby.GroupBy.__iter__`

`GroupBy.__iter__(self)`
Groupby iterator.

Returns

Generator yielding sequence of (name, subsetted object)
for each group

`pandas.core.groupby.GroupBy.groups`

`GroupBy.groups`
Dict {group name -> group labels}.

`pandas.core.groupby.GroupBy.indices`

`GroupBy.indices`
Dict {group name -> group indices}.

`pandas.core.groupby.GroupBy.get_group`

`GroupBy.get_group(self, name, obj=None)`
Construct DataFrame from group with provided name.

Parameters

name [object] the name of the group to get as a DataFrame

obj [DataFrame, default None] the DataFrame to take the DataFrame out of. If it is None, the object groupby was called on will be used

Returns

group [same type as obj]

`Grouper([key, level, freq, axis, sort])`

A Grouper allows the user to specify a groupby instruction for a target object

`pandas.Grouper`

`class pandas.Grouper(key=None, level=None, freq=None, axis=0, sort=False)`
A Grouper allows the user to specify a groupby instruction for a target object

This specification will select a column via the key parameter, or if the level and/or axis parameters

are given, a level of the index of the target object.

If *axis* and/or *level* are passed as keywords to both *Grouper* and *groupby*, the values passed to *Grouper* take precedence.

Parameters

key [string, defaults to None] groupby key, which selects the grouping column of the target

level [name/number, defaults to None] the level for the target index

freq [string / frequency object, defaults to None] This will groupby the specified frequency if the target selection (via key or level) is a datetime-like object. For full specification of available frequencies, please see [here](#).

axis [number/name of the axis, defaults to 0]

sort [boolean, default to False] whether to sort the resulting labels

closed [{'left' or 'right'}] Closed end of interval. Only when *freq* parameter is passed.

label [{'left' or 'right'}] Interval boundary to use for labeling. Only when *freq* parameter is passed.

convention [{'start', 'end', 'e', 's'}] If grouper is PeriodIndex and *freq* parameter is passed.

base [int, default 0] Only when *freq* parameter is passed.

loffset [string, DateOffset, timedelta object] Only when *freq* parameter is passed.

Returns

A specification for a groupby instruction

Examples

Syntactic sugar for `df.groupby('A')`

```
>>> df.groupby(Grouper(key='A'))
```

Specify a resample operation on the column 'date'

```
>>> df.groupby(Grouper(key='date', freq='60s'))
```

Specify a resample operation on the level 'date' on the columns axis with a frequency of 60s

```
>>> df.groupby(Grouper(level='date', freq='60s', axis=1))
```

Attributes

ax	
groups	

6.11.2 Function application

<code>GroupBy.apply(self, func, *args, **kwargs)</code>	Apply function <i>func</i> group-wise and combine the results together.
<code>GroupBy.agg(self, func, *args, **kwargs)</code>	
<code>GroupBy.aggregate(self, func, *args, **kwargs)</code>	
<code>GroupBy.transform(self, func, *args, **kwargs)</code>	
<code>GroupBy.pipe(self, func, *args, **kwargs)</code>	Apply a function <i>func</i> with arguments to this GroupBy object and return the function's result.

pandas.core.groupby.GroupBy.apply

`GroupBy.apply(self, func, *args, **kwargs)`

Apply function *func* group-wise and combine the results together.

The function passed to *apply* must take a dataframe as its first argument and return a DataFrame, Series or scalar. *apply* will then take care of combining the results back together into a single dataframe or series. *apply* is therefore a highly flexible grouping method.

While *apply* is a very flexible method, its downside is that using it can be quite a bit slower than using more specific methods like *agg* or *transform*. Pandas offers a wide range of method that will be much faster than using *apply* for their specific purposes, so try to use them before reaching for *apply*.

Parameters

func [callable] A callable that takes a dataframe as its first argument, and returns a dataframe, a series or a scalar. In addition the callable may take positional and keyword arguments.

args, kwargs [tuple and dict] Optional positional and keyword arguments to pass to *func*.

Returns

applied [Series or DataFrame]

See also:

pipe Apply function to the full GroupBy object instead of to each group.

aggregate Apply aggregate function to the GroupBy object.

transform Apply function column-by-column to the GroupBy object.

Series.apply Apply a function to a Series.

DataFrame.apply Apply a function to each row or column of a DataFrame.

pandas.core.groupby.GroupBy.agg

`GroupBy.agg(self, func, *args, **kwargs)`

pandas.core.groupby.GroupBy.aggregate

`GroupBy.aggregate(self, func, *args, **kwargs)`

pandas.core.groupby.GroupBy.transform

`GroupBy.transform(self, func, *args, **kwargs)`

pandas.core.groupby.GroupBy.pipe

`GroupBy.pipe(self, func, *args, **kwargs)`

Apply a function *func* with arguments to this GroupBy object and return the function's result.

New in version 0.21.0.

Use *.pipe* when you want to improve readability by chaining together functions that expect Series, DataFrames, GroupBy or Resampler objects. Instead of writing

```
>>> h(g(f(df.groupby('group')), arg1=a), arg2=b, arg3=c)
```

You can write

```
>>> (df.groupby('group')
...   .pipe(f)
...   .pipe(g, arg1=a)
...   .pipe(h, arg2=b, arg3=c))
```

which is much more readable.

Parameters

func [callable or tuple of (callable, string)] Function to apply to this GroupBy object or, alternatively, a (*callable, data_keyword*) tuple where *data_keyword* is a string indicating the keyword of *callable* that expects the GroupBy object.

args [iterable, optional] positional arguments passed into *func*.

kwargs [dict, optional] a dictionary of keyword arguments passed into *func*.

Returns

object [the return type of *func*.]

See also:

Series.pipe Apply a function with arguments to a series.

DataFrame.pipe Apply a function with arguments to a dataframe.

apply Apply function to each group instead of to the full GroupBy object.

Notes

See more [here](#)

Examples

```
>>> df = pd.DataFrame({'A': 'a b a b'.split(), 'B': [1, 2, 3, 4]})
>>> df
   A  B
```

(continues on next page)

(continued from previous page)

```

0 a 1
1 b 2
2 a 3
3 b 4

```

To get the difference between each groups maximum and minimum value in one pass, you can do

```

>>> df.groupby('A').pipe(lambda x: x.max() - x.min())
      B
A
a  2
b  2

```

6.11.3 Computations / descriptive stats

<i>GroupBy.all</i> (self[, skipna])	Return True if all values in the group are truthful, else False.
<i>GroupBy.any</i> (self[, skipna])	Return True if any value in the group is truthful, else False.
<i>GroupBy.bfill</i> (self[, limit])	Backward fill the values.
<i>GroupBy.count</i> (self)	Compute count of group, excluding missing values.
<i>GroupBy.cumcount</i> (self[, ascending])	Number each item in each group from 0 to the length of that group - 1.
<i>GroupBy.cummax</i> (self[, axis])	Cumulative max for each group.
<i>GroupBy.cummin</i> (self[, axis])	Cumulative min for each group.
<i>GroupBy.cumprod</i> (self[, axis])	Cumulative product for each group.
<i>GroupBy.cumsum</i> (self[, axis])	Cumulative sum for each group.
<i>GroupBy.ffill</i> (self[, limit])	Forward fill the values.
<i>GroupBy.first</i> (self, <i>**kwargs</i>)	Compute first of group values.
<i>GroupBy.head</i> (self[, n])	Return first n rows of each group.
<i>GroupBy.last</i> (self, <i>**kwargs</i>)	Compute last of group values.
<i>GroupBy.max</i> (self, <i>**kwargs</i>)	Compute max of group values.
<i>GroupBy.mean</i> (self, <i>*args</i> , <i>**kwargs</i>)	Compute mean of groups, excluding missing values.
<i>GroupBy.median</i> (self, <i>**kwargs</i>)	Compute median of groups, excluding missing values.
<i>GroupBy.min</i> (self, <i>**kwargs</i>)	Compute min of group values.
<i>GroupBy.ngroup</i> (self[, ascending])	Number each group from 0 to the number of groups - 1.
<i>GroupBy.nth</i> (self, n, List[int], dropna, ...)	Take the nth row from each group if n is an int, or a subset of rows if n is a list of ints.
<i>GroupBy.ohlc</i> (self)	Compute sum of values, excluding missing values.
<i>GroupBy.prod</i> (self, <i>**kwargs</i>)	Compute prod of group values.
<i>GroupBy.rank</i> (self[, method, ascending, ...])	Provide the rank of values within each group.
<i>GroupBy.pct_change</i> (self[, periods, ...])	Calculate pct_change of each value to previous entry in group.
<i>GroupBy.size</i> (self)	Compute group sizes.
<i>GroupBy.sem</i> (self[, ddof])	Compute standard error of the mean of groups, excluding missing values.

Continued on next page

Table 393 – continued from previous page

<code>GroupBy.std(self[, ddof])</code>	Compute standard deviation of groups, excluding missing values.
<code>GroupBy.sum(self, *\kwargs)</code>	Compute sum of group values.
<code>GroupBy.var(self[, ddof])</code>	Compute variance of groups, excluding missing values.
<code>GroupBy.tail(self[, n])</code>	Return last n rows of each group.

pandas.core.groupby.GroupBy.all

`GroupBy.all(self, skipna=True)`

Return True if all values in the group are truthful, else False.

Parameters

skipna [bool, default True] Flag to ignore nan values during truth testing

Returns

bool

See also:

`Series.groupby`

`DataFrame.groupby`

pandas.core.groupby.GroupBy.any

`GroupBy.any(self, skipna=True)`

Return True if any value in the group is truthful, else False.

Parameters

skipna [bool, default True] Flag to ignore nan values during truth testing

Returns

bool

See also:

`Series.groupby`

`DataFrame.groupby`

pandas.core.groupby.GroupBy.bfill

`GroupBy.bfill(self, limit=None)`

Backward fill the values.

Parameters

limit [integer, optional] limit of how many values to fill

Returns

Series or DataFrame Object with missing values filled.

See also:

Series.backfill
 DataFrame.backfill
 Series.fillna
 DataFrame.fillna

pandas.core.groupby.GroupBy.count

GroupBy.count(*self*)
 Compute count of group, excluding missing values.

Returns

Series or DataFrame Count of values within each group.

See also:

Series.groupby
 DataFrame.groupby

pandas.core.groupby.GroupBy.cumcount

GroupBy.cumcount(*self*, *ascending=True*)
 Number each item in each group from 0 to the length of that group - 1.

Essentially this is equivalent to

```
>>> self.apply(lambda x: pd.Series(np.arange(len(x)), x.index))
```

Parameters

ascending [bool, default True] If False, number in reverse, from length of group - 1 to 0.

Returns

Series Sequence number of each element within each group.

See also:

ngroup Number the groups themselves.

Examples

```
>>> df = pd.DataFrame([[ 'a' ], [ 'a' ], [ 'a' ], [ 'b' ], [ 'b' ], [ 'a' ]],
...                   columns=[ 'A' ])
>>> df
   A
0  a
1  a
2  a
3  b
4  b
```

(continues on next page)

(continued from previous page)

```
5 a
>>> df.groupby('A').cumcount()
0 0
1 1
2 2
3 0
4 1
5 3
dtype: int64
>>> df.groupby('A').cumcount(ascending=False)
0 3
1 2
2 1
3 1
4 0
5 0
dtype: int64
```

pandas.core.groupby.GroupBy.cummax

`GroupBy.cummax(self, axis=0, **kwargs)`
Cumulative max for each group.

Returns

Series or DataFrame

See also:

`Series.groupby`

`DataFrame.groupby`

pandas.core.groupby.GroupBy.cummin

`GroupBy.cummin(self, axis=0, **kwargs)`
Cumulative min for each group.

Returns

Series or DataFrame

See also:

`Series.groupby`

`DataFrame.groupby`

pandas.core.groupby.GroupBy.cumprod

`GroupBy.cumprod(self, axis=0, *args, **kwargs)`
Cumulative product for each group.

Returns

Series or DataFrame

See also:

`Series.groupby`

`DataFrame.groupby`

pandas.core.groupby.GroupBy.cumsum

`GroupBy.cumsum(self, axis=0, *args, **kwargs)`

Cumulative sum for each group.

Returns

Series or DataFrame

See also:

`Series.groupby`

`DataFrame.groupby`

pandas.core.groupby.GroupBy.ffill

`GroupBy.ffill(self, limit=None)`

Forward fill the values.

Parameters

limit [integer, optional] limit of how many values to fill

Returns

Series or DataFrame Object with missing values filled.

See also:

`Series.pad`

`DataFrame.pad`

`Series.fillna`

`DataFrame.fillna`

pandas.core.groupby.GroupBy.first

`GroupBy.first(self, **kwargs)`

Compute first of group values.

Returns

Series or DataFrame Computed first of values within each group.

pandas.core.groupby.GroupBy.head**GroupBy.head**(*self*, *n=5*)Return first *n* rows of each group.Essentially equivalent to `.apply(lambda x: x.head(n))`, except ignores `as_index` flag.**Returns****Series or DataFrame**

See also:

Series.groupby**DataFrame.groupby****Examples**

```
>>> df = pd.DataFrame([[1, 2], [1, 4], [5, 6]],
...                   columns=['A', 'B'])
>>> df.groupby('A', as_index=False).head(1)
   A  B
0  1  2
2  5  6
>>> df.groupby('A').head(1)
   A  B
0  1  2
2  5  6
```

pandas.core.groupby.GroupBy.last**GroupBy.last**(*self*, ***kwargs*)

Compute last of group values.

Returns**Series or DataFrame** Computed last of values within each group.**pandas.core.groupby.GroupBy.max****GroupBy.max**(*self*, ***kwargs*)

Compute max of group values.

Returns**Series or DataFrame** Computed max of values within each group.**pandas.core.groupby.GroupBy.mean****GroupBy.mean**(*self*, **args*, ***kwargs*)

Compute mean of groups, excluding missing values.

Returns**pandas.Series or pandas.DataFrame**

See also:

`Series.groupby`

`DataFrame.groupby`

Examples

```
>>> df = pd.DataFrame({'A': [1, 1, 2, 1, 2],
...                    'B': [np.nan, 2, 3, 4, 5],
...                    'C': [1, 2, 1, 1, 2]}, columns=['A', 'B', 'C'])
```

Groupby one column and return the mean of the remaining columns in each group.

```
>>> df.groupby('A').mean()
   B      C
A
1  3.0  1.333333
2  4.0  1.500000
```

Groupby two columns and return the mean of the remaining column.

```
>>> df.groupby(['A', 'B']).mean()
   C
A B
1  2.0  2
   4.0  1
2  3.0  1
   5.0  2
```

Groupby one column and return the mean of only particular column in the group.

```
>>> df.groupby('A')['B'].mean()
A
1    3.0
2    4.0
Name: B, dtype: float64
```

`pandas.core.groupby.GroupBy.median`

`GroupBy.median(self, **kwargs)`

Compute median of groups, excluding missing values.

For multiple groupings, the result index will be a `MultiIndex`

Returns

Series or DataFrame Median of values within each group.

See also:

`Series.groupby`

`DataFrame.groupby`

pandas.core.groupby.GroupBy.min

`GroupBy.min(self, **kwargs)`
Compute min of group values.

Returns

Series or DataFrame Computed min of values within each group.

pandas.core.groupby.GroupBy.ngroup

`GroupBy.ngroup(self, ascending=True)`
Number each group from 0 to the number of groups - 1.

This is the enumerative complement of `cumcount`. Note that the numbers given to the groups match the order in which the groups would be seen when iterating over the groupby object, not the order they are first observed.

New in version 0.20.2.

Parameters

ascending [bool, default True] If False, number in reverse, from number of group - 1 to 0.

Returns

Series Unique numbers for each group.

See also:

`cumcount` Number the rows in each group.

Examples

```
>>> df = pd.DataFrame({"A": list("aaabba")})
>>> df
   A
0  a
1  a
2  a
3  b
4  b
5  a
>>> df.groupby('A').ngroup()
0    0
1    0
2    0
3    1
4    1
5    0
dtype: int64
>>> df.groupby('A').ngroup(ascending=False)
0    1
1    1
2    1
```

(continues on next page)

(continued from previous page)

```

3    0
4    0
5    1
dtype: int64
>>> df.groupby(["A", [1,1,2,3,2,1]]).ngroup()
0    0
1    0
2    1
3    3
4    2
5    0
dtype: int64

```

pandas.core.groupby.GroupBy.nth

`GroupBy.nth(self, n: Union[int, List[int]], dropna: Union[str, NoneType] = None) → pandas.core.frame.DataFrame`

Take the *n*th row from each group if *n* is an int, or a subset of rows if *n* is a list of ints.

If *dropna*, will take the *n*th non-null row, *dropna* is either 'all' or 'any'; this is equivalent to calling `dropna(how=dropna)` before the groupby.

Parameters

n [int or list of ints] a single *n*th value for the row or a list of *n*th values

dropna [None or str, optional] apply the specified *dropna* operation before counting which row is the *n*th row. Needs to be None, 'any' or 'all'

Returns

Series or DataFrame *N*-th value within each group.

See also:

`Series.groupby`

`DataFrame.groupby`

Examples

```

>>> df = pd.DataFrame({'A': [1, 1, 2, 1, 2],
...                    'B': [np.nan, 2, 3, 4, 5]}, columns=['A', 'B'])
>>> g = df.groupby('A')
>>> g.nth(0)
   B
A
1 NaN
2 3.0
>>> g.nth(1)
   B
A
1 2.0
2 5.0

```

(continues on next page)

(continued from previous page)

```

>>> g.nth(-1)
      B
A
1  4.0
2  5.0
>>> g.nth([0, 1])
      B
A
1  NaN
1  2.0
2  3.0
2  5.0

```

Specifying *dropna* allows count ignoring NaN

```

>>> g.nth(0, dropna='any')
      B
A
1  2.0
2  3.0

```

NaNs denote group exhausted when using dropna

```

>>> g.nth(3, dropna='any')
      B
A
1  NaN
2  NaN

```

Specifying *as_index=False* in *groupby* keeps the original index.

```

>>> df.groupby('A', as_index=False).nth(1)
   A  B
1  1  2.0
4  2  5.0

```

pandas.core.groupby.GroupBy.ohlc

`GroupBy.ohlc(self)`

Compute sum of values, excluding missing values.

For multiple groupings, the result index will be a MultiIndex

Returns

DataFrame Open, high, low and close values within each group.

See also:

`Series.groupby`

`DataFrame.groupby`

pandas.core.groupby.GroupBy.prod

`GroupBy.prod(self, **kwargs)`
 Compute prod of group values.

Returns

Series or DataFrame Computed prod of values within each group.

pandas.core.groupby.GroupBy.rank

`GroupBy.rank(self, method='average', ascending=True, na_option='keep', pct=False, axis=0)`
 Provide the rank of values within each group.

Parameters

method [{‘average’, ‘min’, ‘max’, ‘first’, ‘dense’}, default ‘average’]

- average: average rank of group
- min: lowest rank in group
- max: highest rank in group
- first: ranks assigned in order they appear in the array
- dense: like ‘min’, but rank always increases by 1 between groups

ascending [boolean, default True] False for ranks by high (1) to low (N)

na_option [{‘keep’, ‘top’, ‘bottom’}, default ‘keep’]

- keep: leave NA values where they are
- top: smallest rank if ascending
- bottom: smallest rank if descending

pct [boolean, default False] Compute percentage rank of data within each group

axis [int, default 0] The axis of the object over which to compute the rank.

Returns

DataFrame with ranking of values within each group

See also:

`Series.groupby`

`DataFrame.groupby`

pandas.core.groupby.GroupBy.pct_change

`GroupBy.pct_change(self, periods=1, fill_method='pad', limit=None, freq=None, axis=0)`
 Calculate pct_change of each value to previous entry in group.

Returns

Series or DataFrame Percentage changes within each group.

See also:

`Series.groupby`

`DataFrame.groupby`

`pandas.core.groupby.GroupBy.size`

`GroupBy.size(self)`

Compute group sizes.

Returns

Series Number of rows in each group.

See also:

`Series.groupby`

`DataFrame.groupby`

`pandas.core.groupby.GroupBy.sem`

`GroupBy.sem(self, ddof=1)`

Compute standard error of the mean of groups, excluding missing values.

For multiple groupings, the result index will be a MultiIndex.

Parameters

ddof [integer, default 1] degrees of freedom

Returns

Series or DataFrame Standard error of the mean of values within each group.

See also:

`Series.groupby`

`DataFrame.groupby`

`pandas.core.groupby.GroupBy.std`

`GroupBy.std(self, ddof=1, *args, **kwargs)`

Compute standard deviation of groups, excluding missing values.

For multiple groupings, the result index will be a MultiIndex.

Parameters

ddof [integer, default 1] degrees of freedom

Returns

Series or DataFrame Standard deviation of values within each group.

See also:

`Series.groupby`

`DataFrame.groupby`

pandas.core.groupby.GroupBy.sum`GroupBy.sum(self, **kwargs)`

Compute sum of group values.

Returns**Series or DataFrame** Computed sum of values within each group.**pandas.core.groupby.GroupBy.var**`GroupBy.var(self, ddof=1, *args, **kwargs)`

Compute variance of groups, excluding missing values.

For multiple groupings, the result index will be a MultiIndex.

Parameters**ddof** [integer, default 1] degrees of freedom**Returns****Series or DataFrame** Variance of values within each group.

See also:

`Series.groupby``DataFrame.groupby`**pandas.core.groupby.GroupBy.tail**`GroupBy.tail(self, n=5)`

Return last n rows of each group.

Essentially equivalent to `.apply(lambda x: x.tail(n))`, except ignores `as_index` flag.**Returns****Series or DataFrame**

See also:

`Series.groupby``DataFrame.groupby`**Examples**

```

>>> df = pd.DataFrame([[ 'a', 1], [ 'a', 2], [ 'b', 1], [ 'b', 2]],
...                    columns=[ 'A', 'B'])
>>> df.groupby('A').tail(1)
   A  B
1  a  2
3  b  2
>>> df.groupby('A').head(1)
   A  B

```

(continues on next page)

(continued from previous page)

```

0 a 1
2 b 1

```

The following methods are available in both `SeriesGroupBy` and `DataFrameGroupBy` objects, but may differ slightly, usually in that the `DataFrameGroupBy` version usually permits the specification of an axis argument, and often an argument indicating whether to restrict application to columns of a specific data type.

<code>DataFrameGroupBy.all(self[, skipna])</code>	Return True if all values in the group are truthful, else False.
<code>DataFrameGroupBy.any(self[, skipna])</code>	Return True if any value in the group is truthful, else False.
<code>DataFrameGroupBy.bfill(self[, limit])</code>	Backward fill the values.
<code>DataFrameGroupBy.corr</code>	Compute pairwise correlation of columns, excluding NA/null values.
<code>DataFrameGroupBy.count(self)</code>	Compute count of group, excluding missing values.
<code>DataFrameGroupBy.cov</code>	Compute pairwise covariance of columns, excluding NA/null values.
<code>DataFrameGroupBy.cummax(self[, axis])</code>	Cumulative max for each group.
<code>DataFrameGroupBy.cummin(self[, axis])</code>	Cumulative min for each group.
<code>DataFrameGroupBy.cumprod(self[, axis])</code>	Cumulative product for each group.
<code>DataFrameGroupBy.cumsum(self[, axis])</code>	Cumulative sum for each group.
<code>DataFrameGroupBy.describe(self, *\kwargs)</code>	Generate descriptive statistics that summarize the central tendency, dispersion and shape of a dataset's distribution, excluding NaN values.
<code>DataFrameGroupBy.diff</code>	First discrete difference of element.
<code>DataFrameGroupBy.ffill(self[, limit])</code>	Forward fill the values.
<code>DataFrameGroupBy.fillna</code>	Fill NA/NaN values using the specified method.
<code>DataFrameGroupBy.filter(self, func[, dropna])</code>	Return a copy of a DataFrame excluding elements from groups that do not satisfy the boolean criterion specified by func.
<code>DataFrameGroupBy.hist</code>	Make a histogram of the DataFrame's.
<code>DataFrameGroupBy.idxmax</code>	Return index of first occurrence of maximum over requested axis.
<code>DataFrameGroupBy.idxmin</code>	Return index of first occurrence of minimum over requested axis.
<code>DataFrameGroupBy.mad</code>	Return the mean absolute deviation of the values for the requested axis.
<code>DataFrameGroupBy.nunique(self[, dropna])</code>	Return DataFrame with number of distinct observations per group for each column.
<code>DataFrameGroupBy.pct_change(self[, periods, ...])</code>	Calculate pct_change of each value to previous entry in group.
<code>DataFrameGroupBy.plot</code>	Class implementing the .plot attribute for groupby objects.
<code>DataFrameGroupBy.quantile(self[, q, ...])</code>	Return group values at the given quantile, a la numpy.percentile.
<code>DataFrameGroupBy.rank(self[, method, ...])</code>	Provide the rank of values within each group.
<code>DataFrameGroupBy.resample(self, rule, ...)</code>	Provide resampling when using a TimeGrouper.
<code>DataFrameGroupBy.shift(self[, periods, ...])</code>	Shift each group by periods observations.
<code>DataFrameGroupBy.size(self)</code>	Compute group sizes.

Continued on next page

Table 394 – continued from previous page

<code>DataFrameGroupBy.skew</code>	Return unbiased skew over requested axis Normalized by N-1.
<code>DataFrameGroupBy.take</code>	Return the elements in the given <i>positional</i> indices along an axis.
<code>DataFrameGroupBy.tshift</code>	Shift the time index, using the index's frequency if available.

pandas.core.groupby.DataFrameGroupBy.all`DataFrameGroupBy.all(self, skipna=True)`

Return True if all values in the group are truthful, else False.

Parameters**skipna** [bool, default True] Flag to ignore nan values during truth testing**Returns****bool**

See also:

`Series.groupby``DataFrame.groupby`**pandas.core.groupby.DataFrameGroupBy.any**`DataFrameGroupBy.any(self, skipna=True)`

Return True if any value in the group is truthful, else False.

Parameters**skipna** [bool, default True] Flag to ignore nan values during truth testing**Returns****bool**

See also:

`Series.groupby``DataFrame.groupby`**pandas.core.groupby.DataFrameGroupBy.bfill**`DataFrameGroupBy.bfill(self, limit=None)`

Backward fill the values.

Parameters**limit** [integer, optional] limit of how many values to fill**Returns****Series or DataFrame** Object with missing values filled.

See also:

`Series.backfill`

`DataFrame.backfill`

`Series.fillna`

`DataFrame.fillna`

`pandas.core.groupby.DataFrameGroupBy.corr`

`DataFrameGroupBy.corr`

Compute pairwise correlation of columns, excluding NA/null values.

Parameters

method [{‘pearson’, ‘kendall’, ‘spearman’} or callable]

- `pearson` : standard correlation coefficient
- `kendall` : Kendall Tau correlation coefficient
- `spearman` : Spearman rank correlation
- **callable: callable with input two 1d ndarrays** and returning a float.
Note that the returned matrix from `corr` will have 1 along the diagonals and will be symmetric regardless of the callable’s behavior .. versionadded:: 0.24.0

min_periods [int, optional] Minimum number of observations required per pair of columns to have a valid result. Currently only available for Pearson and Spearman correlation.

Returns

DataFrame Correlation matrix.

See also:

`DataFrame.corrwith`

`Series.corr`

Examples

```
>>> def histogram_intersection(a, b):
...     v = np.minimum(a, b).sum().round(decimals=1)
...     return v
>>> df = pd.DataFrame([(0.2, 0.3), (0.0, 0.6), (0.6, 0.0), (0.2, 0.1)],
...                    columns=['dogs', 'cats'])
>>> df.corr(method=histogram_intersection)
      dogs  cats
dogs    1.0  0.3
cats    0.3  1.0
```

`pandas.core.groupby.DataFrameGroupBy.count`

`DataFrameGroupBy.count(self)`

Compute count of group, excluding missing values.

Returns

DataFrame Count of values within each group.

pandas.core.groupby.DataFrameGroupBy.cov**DataFrameGroupBy.cov**

Compute pairwise covariance of columns, excluding NA/null values.

Compute the pairwise covariance among the series of a DataFrame. The returned data frame is the [covariance matrix](#) of the columns of the DataFrame.

Both NA and null values are automatically excluded from the calculation. (See the note below about bias from missing values.) A threshold can be set for the minimum number of observations for each value created. Comparisons with observations below this threshold will be returned as NaN.

This method is generally used for the analysis of time series data to understand the relationship between different measures across time.

Parameters

min_periods [int, optional] Minimum number of observations required per pair of columns to have a valid result.

Returns

DataFrame The covariance matrix of the series of the DataFrame.

See also:

Series.cov Compute covariance with another Series.

core.window.EWM.cov Exponential weighted sample covariance.

core.window.Expanding.cov Expanding sample covariance.

core.window.Rolling.cov Rolling sample covariance.

Notes

Returns the covariance matrix of the DataFrame's time series. The covariance is normalized by N-1.

For DataFrames that have Series that are missing data (assuming that data is [missing at random](#)) the returned covariance matrix will be an unbiased estimate of the variance and covariance between the member Series.

However, for many applications this estimate may not be acceptable because the estimate covariance matrix is not guaranteed to be positive semi-definite. This could lead to estimate correlations having absolute values which are greater than one, and/or a non-invertible covariance matrix. See [Estimation of covariance matrices](#) for more details.

Examples

```
>>> df = pd.DataFrame([(1, 2), (0, 3), (2, 0), (1, 1)],
...                   columns=['dogs', 'cats'])
>>> df.cov()
           dogs    cats
```

(continues on next page)

(continued from previous page)

```
dogs 0.666667 -1.000000
cats -1.000000  1.666667
```

```
>>> np.random.seed(42)
>>> df = pd.DataFrame(np.random.randn(1000, 5),
...                    columns=['a', 'b', 'c', 'd', 'e'])
>>> df.cov()
           a          b          c          d          e
a  0.998438 -0.020161  0.059277 -0.008943  0.014144
b -0.020161  1.059352 -0.008543 -0.024738  0.009826
c  0.059277 -0.008543  1.010670 -0.001486 -0.000271
d -0.008943 -0.024738 -0.001486  0.921297 -0.013692
e  0.014144  0.009826 -0.000271 -0.013692  0.977795
```

Minimum number of periods

This method also supports an optional `min_periods` keyword that specifies the required minimum number of non-NA observations for each column pair in order to have a valid result:

```
>>> np.random.seed(42)
>>> df = pd.DataFrame(np.random.randn(20, 3),
...                    columns=['a', 'b', 'c'])
>>> df.loc[df.index[:5], 'a'] = np.nan
>>> df.loc[df.index[5:10], 'b'] = np.nan
>>> df.cov(min_periods=12)
           a          b          c
a  0.316741      NaN -0.150812
b      NaN  1.248003  0.191417
c -0.150812  0.191417  0.895202
```

pandas.core.groupby.DataFrameGroupBy.cummax

`DataFrameGroupBy.cummax(self, axis=0, **kwargs)`
Cumulative max for each group.

Returns

Series or DataFrame

See also:

`Series.groupby`

`DataFrame.groupby`

pandas.core.groupby.DataFrameGroupBy.cummin

`DataFrameGroupBy.cummin(self, axis=0, **kwargs)`
Cumulative min for each group.

Returns

Series or DataFrame

See also:

`Series.groupby``DataFrame.groupby`**pandas.core.groupby.DataFrameGroupBy.cumprod**

`DataFrameGroupBy.cumprod(self, axis=0, *args, **kwargs)`
 Cumulative product for each group.

Returns**Series or DataFrame**

See also:

`Series.groupby``DataFrame.groupby`**pandas.core.groupby.DataFrameGroupBy.cumsum**

`DataFrameGroupBy.cumsum(self, axis=0, *args, **kwargs)`
 Cumulative sum for each group.

Returns**Series or DataFrame**

See also:

`Series.groupby``DataFrame.groupby`**pandas.core.groupby.DataFrameGroupBy.describe**

`DataFrameGroupBy.describe(self, **kwargs)`

Generate descriptive statistics that summarize the central tendency, dispersion and shape of a dataset's distribution, excluding NaN values.

Analyzes both numeric and object series, as well as `DataFrame` column sets of mixed data types. The output will vary depending on what is provided. Refer to the notes below for more detail.

Parameters

percentiles [list-like of numbers, optional] The percentiles to include in the output. All should fall between 0 and 1. The default is `[.25, .5, .75]`, which returns the 25th, 50th, and 75th percentiles.

include ['all', list-like of dtypes or None (default), optional] A white list of data types to include in the result. Ignored for `Series`. Here are the options:

- 'all' : All columns of the input will be included in the output.
- A list-like of dtypes : Limits the results to the provided data types. To limit the result to numeric types submit `numpy.number`. To limit it instead to object columns submit the `numpy.object` data type. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(include=['O'])`). To select pandas categorical columns, use `'category'`

- None (default) : The result will include all numeric columns.

exclude [list-like of dtypes or None (default), optional,] A black list of data types to omit from the result. Ignored for **Series**. Here are the options:

- A list-like of dtypes : Excludes the provided data types from the result. To exclude numeric types submit `numpy.number`. To exclude object columns submit the data type `numpy.object`. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(include=['O'])`). To exclude pandas categorical columns, use `'category'`
- None (default) : The result will exclude nothing.

Returns

Series or DataFrame Summary statistics of the Series or Dataframe provided.

See also:

DataFrame.count Count number of non-NA/null observations.

DataFrame.max Maximum of the values in the object.

DataFrame.min Minimum of the values in the object.

DataFrame.mean Mean of the values.

DataFrame.std Standard deviation of the observations.

DataFrame.select_dtypes Subset of a DataFrame including/excluding columns based on their dtype.

Notes

For numeric data, the result's index will include `count`, `mean`, `std`, `min`, `max` as well as lower, 50 and upper percentiles. By default the lower percentile is 25 and the upper percentile is 75. The 50 percentile is the same as the median.

For object data (e.g. strings or timestamps), the result's index will include `count`, `unique`, `top`, and `freq`. The `top` is the most common value. The `freq` is the most common value's frequency. Timestamps also include the `first` and `last` items.

If multiple object values have the highest count, then the `count` and `top` results will be arbitrarily chosen from among those with the highest count.

For mixed data types provided via a **DataFrame**, the default is to return only an analysis of numeric columns. If the dataframe consists only of object and categorical data without any numeric columns, the default is to return an analysis of both the object and categorical columns. If `include='all'` is provided as an option, the result will include a union of attributes of each type.

The `include` and `exclude` parameters can be used to limit which columns in a **DataFrame** are analyzed for the output. The parameters are ignored when analyzing a **Series**.

Examples

Describing a numeric **Series**.

```
>>> s = pd.Series([1, 2, 3])
>>> s.describe()
count      3.0
```

(continues on next page)

(continued from previous page)

```

mean      2.0
std       1.0
min       1.0
25%      1.5
50%      2.0
75%      2.5
max       3.0
dtype: float64

```

Describing a categorical Series.

```

>>> s = pd.Series(['a', 'a', 'b', 'c'])
>>> s.describe()
count      4
unique     3
top        a
freq       2
dtype: object

```

Describing a timestamp Series.

```

>>> s = pd.Series([
...     np.datetime64("2000-01-01"),
...     np.datetime64("2010-01-01"),
...     np.datetime64("2010-01-01")
... ])
>>> s.describe()
count                3
unique                2
top      2010-01-01 00:00:00
freq                2
first    2000-01-01 00:00:00
last     2010-01-01 00:00:00
dtype: object

```

Describing a DataFrame. By default only numeric fields are returned.

```

>>> df = pd.DataFrame({'categorical': pd.Categorical(['d', 'e', 'f']),
...                    'numeric': [1, 2, 3],
...                    'object': ['a', 'b', 'c']
...                    })
>>> df.describe()

pandas.core.groupby.DataFrameGroupBy.diff

DataFrameGroupBy.diff

First discrete difference of element.

Calculates the difference of a `DataFrame` element compared with another element in the `DataFrame` (default is the element in the same column of the previous row).

Parameters

periods [int, default 1] Periods to shift for calculating difference, accepts negative values.

axis [{0 or 'index', 1 or 'columns'}, default 0] Take difference over rows (0) or columns (1).

New in version 0.16.1..

Returns

DataFrame

See also:

Series.diff First discrete difference for a Series.

`DataFrame.pct_change` Percent change over given number of periods.

`DataFrame.shift` Shift index by desired number of periods with an optional time freq.

Examples

Difference with previous row

```
>>> df = pd.DataFrame({'a': [1, 2, 3, 4, 5, 6],
...                    'b': [1, 1, 2, 3, 5, 8],
...                    'c': [1, 4, 9, 16, 25, 36]})
>>> df
   a  b  c
0  1  1  1
1  2  1  4
2  3  2  9
3  4  3 16
4  5  5 25
5  6  8 36
```

```
>>> df.diff()
   a  b  c
0 NaN NaN NaN
1 1.0 0.0 3.0
2 1.0 1.0 5.0
3 1.0 1.0 7.0
4 1.0 2.0 9.0
5 1.0 3.0 11.0
```

Difference with previous column

```
>>> df.diff(axis=1)
   a  b  c
0 NaN 0.0 0.0
1 NaN -1.0 3.0
2 NaN -1.0 7.0
3 NaN -1.0 13.0
4 NaN 0.0 20.0
5 NaN 2.0 28.0
```

Difference with 3rd previous row

```
>>> df.diff(periods=3)
   a  b  c
0 NaN NaN NaN
1 NaN NaN NaN
2 NaN NaN NaN
3 3.0 2.0 15.0
4 3.0 4.0 21.0
5 3.0 6.0 27.0
```

Difference with following row

```
>>> df.diff( periods=-1)
      a    b    c
0 -1.0  0.0 -3.0
1 -1.0 -1.0 -5.0
2 -1.0 -1.0 -7.0
3 -1.0 -2.0 -9.0
4 -1.0 -3.0 -11.0
5  NaN  NaN  NaN
```

pandas.core.groupby.DataFrameGroupBy.ffill

`DataFrameGroupBy.ffiil(self, limit=None)`

Forward fill the values.

Parameters

limit [integer, optional] limit of how many values to fill

Returns

Series or DataFrame Object with missing values filled.

See also:

`Series.pad`

`DataFrame.pad`

`Series.fillna`

`DataFrame.fillna`

pandas.core.groupby.DataFrameGroupBy.fillna

`DataFrameGroupBy.fillna`

Fill NA/NaN values using the specified method.

Parameters

value [scalar, dict, Series, or DataFrame] Value to use to fill holes (e.g. 0), alternately a dict/Series/DataFrame of values specifying which value to use for each index (for a Series) or column (for a DataFrame). Values not in the dict/Series/DataFrame will not be filled. This value cannot be a list.

method [{'backfill', 'bfill', 'pad', 'ffill', None}, default None] Method to use for filling holes in reindexed Series pad / ffill: propagate last valid observation forward to next valid backfill / bfill: use next valid observation to fill gap.

axis [{0 or 'index', 1 or 'columns'}] Axis along which to fill missing values.

inplace [bool, default False] If True, fill in-place. Note: this will modify any other views on this object (e.g., a no-copy slice for a column in a DataFrame).

limit [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

downcast [dict, default is None] A dict of item->dtype of what to downcast if possible, or the string 'infer' which will try to downcast to an appropriate equal type (e.g. float64 to int64 if possible).

Returns

DataFrame Object with missing values filled.

See also:

interpolate Fill NaN values using interpolation.

reindex Conform object to new index.

asfreq Convert TimeSeries to specified frequency.

Examples

```
>>> df = pd.DataFrame([[np.nan, 2, np.nan, 0],
...                    [3, 4, np.nan, 1],
...                    [np.nan, np.nan, np.nan, 5],
...                    [np.nan, 3, np.nan, 4]],
...                   columns=list('ABCD'))
>>> df
   A    B    C    D
0 NaN  2.0 NaN  0
1  3.0  4.0 NaN  1
2 NaN  NaN NaN  5
3 NaN  3.0 NaN  4
```

Replace all NaN elements with 0s.

```
>>> df.fillna(0)
   A    B    C    D
0  0.0  2.0  0.0  0
1  3.0  4.0  0.0  1
2  0.0  0.0  0.0  5
3  0.0  3.0  0.0  4
```

We can also propagate non-null values forward or backward.

```
>>> df.fillna(method='ffill')
   A    B    C    D
0 NaN  2.0 NaN  0
1  3.0  4.0 NaN  1
2  3.0  4.0 NaN  5
3  3.0  3.0 NaN  4
```

Replace all NaN elements in column 'A', 'B', 'C', and 'D', with 0, 1, 2, and 3 respectively.

```
>>> values = {'A': 0, 'B': 1, 'C': 2, 'D': 3}
>>> df.fillna(value=values)
   A    B    C    D
0  0.0  2.0  2.0  0
1  3.0  4.0  2.0  1
```

(continues on next page)

(continued from previous page)

```
2  0.0 1.0 2.0 5
3  0.0 3.0 2.0 4
```

Only replace the first NaN element.

```
>>> df.fillna(value=values, limit=1)
   A  B  C  D
0  0.0 2.0 2.0 0
1  3.0 4.0 NaN 1
2  NaN 1.0 NaN 5
3  NaN 3.0 NaN 4
```

pandas.core.groupby.DataFrameGroupBy.filter

`DataFrameGroupBy.filter`(*self*, *func*, *dropna=True*, **args*, ***kwargs*)

Return a copy of a DataFrame excluding elements from groups that do not satisfy the boolean criterion specified by *func*.

Parameters

f [function] Function to apply to each subframe. Should return True or False.

dropna [Drop groups that do not pass the filter. True by default;] if False, groups that evaluate False are filled with NaNs.

Returns

filtered [DataFrame]

Notes

Each subframe is endowed the attribute ‘name’ in case you need to know which group you are working on.

Examples

```
>>> df = pd.DataFrame({'A' : ['foo', 'bar', 'foo', 'bar',
...                          'foo', 'bar'],
...                   'B' : [1, 2, 3, 4, 5, 6],
...                   'C' : [2.0, 5., 8., 1., 2., 9.]})
>>> grouped = df.groupby('A')
>>> grouped.filter(lambda x: x['B'].mean() > 3.)
   A  B  C
1  bar  2  5.0
3  bar  4  1.0
5  bar  6  9.0
```

pandas.core.groupby.DataFrameGroupBy.hist

`DataFrameGroupBy.hist`

Make a histogram of the DataFrame’s.

A `histogram` is a representation of the distribution of data. This function calls `matplotlib.pyplot.hist()`, on each series in the DataFrame, resulting in one histogram per column.

Parameters

- data** [DataFrame] The pandas object holding the data.
- column** [string or sequence] If passed, will be used to limit data to a subset of columns.
- by** [object, optional] If passed, then used to form histograms for separate groups.
- grid** [bool, default True] Whether to show axis grid lines.
- xlabelsize** [int, default None] If specified changes the x-axis label size.
- xrot** [float, default None] Rotation of x axis labels. For example, a value of 90 displays the x labels rotated 90 degrees clockwise.
- ylabelsize** [int, default None] If specified changes the y-axis label size.
- yrot** [float, default None] Rotation of y axis labels. For example, a value of 90 displays the y labels rotated 90 degrees clockwise.
- ax** [Matplotlib axes object, default None] The axes to plot the histogram on.
- sharex** [bool, default True if ax is None else False] In case subplots=True, share x axis and set some x axis labels to invisible; defaults to True if ax is None otherwise False if an ax is passed in. Note that passing in both an ax and sharex=True will alter all x axis labels for all subplots in a figure.
- sharey** [bool, default False] In case subplots=True, share y axis and set some y axis labels to invisible.
- figsize** [tuple] The size in inches of the figure to create. Uses the value in `matplotlib.rcParams` by default.
- layout** [tuple, optional] Tuple of (rows, columns) for the layout of the histograms.
- bins** [integer or sequence, default 10] Number of histogram bins to be used. If an integer is given, bins + 1 bin edges are calculated and returned. If bins is a sequence, gives bin edges, including left edge of first bin and right edge of last bin. In this case, bins is returned unmodified.
- **kwds** All other plotting keyword arguments to be passed to `matplotlib.pyplot.hist()`.

Returns

`matplotlib.AxesSubplot` or `numpy.ndarray` of them

See also:

`matplotlib.pyplot.hist` Plot a histogram using matplotlib.

Examples

This example draws a histogram based on the length and width of some animals, displayed in three bins

```
>>> df = pd.DataFrame({
...     'length': [1.5, 0.5, 1.2, 0.9, 3],
...     'width': [0.7, 0.2, 0.15, 0.2, 1.1]
```

(continues on next page)

(continued from previous page)

```
...     }, index= ['pig', 'rabbit', 'duck', 'chicken', 'horse'])
>>> hist = df.hist(bins=3)
```

pandas.core.groupby.DataFrameGroupBy.idxmax**DataFrameGroupBy.idxmax**

Return index of first occurrence of maximum over requested axis. NA/null values are excluded.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] 0 or 'index' for row-wise, 1 or 'columns' for column-wise

skipna [boolean, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

Returns

Series Indexes of maxima along the specified axis.

Raises**ValueError**

- If the row/column is empty

See also:

Series.idxmax

Notes

This method is the DataFrame version of `ndarray.argmax`.

pandas.core.groupby.DataFrameGroupBy.idxmin**DataFrameGroupBy.idxmin**

Return index of first occurrence of minimum over requested axis. NA/null values are excluded.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] 0 or 'index' for row-wise, 1 or 'columns' for column-wise

skipna [boolean, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

Returns

Series Indexes of minima along the specified axis.

Raises**ValueError**

- If the row/column is empty

See also:

`Series.idxmin`

Notes

This method is the DataFrame version of `ndarray.argmin`.

pandas.core.groupby.DataFrameGroupBy.mad

`DataFrameGroupBy.mad`

Return the mean absolute deviation of the values for the requested axis.

Parameters

axis [{index (0), columns (1)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

pandas.core.groupby.DataFrameGroupBy.nunique

`DataFrameGroupBy.nunique(self, dropna=True)`

Return DataFrame with number of distinct observations per group for each column.

New in version 0.20.0.

Parameters

dropna [boolean, default True] Don't include NaN in the counts.

Returns

nunique: DataFrame

Examples

```
>>> df = pd.DataFrame({'id': ['spam', 'egg', 'egg', 'spam',
...                           'ham', 'ham'],
...                   'value1': [1, 5, 5, 2, 5, 5],
...                   'value2': list('abbaxy')})
>>> df
   id  value1 value2
0  spam      1      a
1  egg      5      b
2  egg      5      b
```

(continues on next page)

(continued from previous page)

3	spam	2	a
4	ham	5	x
5	ham	5	y

```
>>> df.groupby('id').nunique()
      id  value1  value2
id
egg    1      1      1
ham    1      1      2
spam   1      2      1
```

Check for rows with the same id but conflicting values:

```
>>> df.groupby('id').filter(lambda g: (g.nunique() > 1).any())
      id  value1  value2
0  spam      1      a
3  spam      2      a
4  ham       5      x
5  ham       5      y
```

pandas.core.groupby.DataFrameGroupBy.pct_change

`DataFrameGroupBy.pct_change(self, periods=1, fill_method='pad', limit=None, freq=None, axis=0)`
 Calculate pct_change of each value to previous entry in group.

Returns

Series or DataFrame Percentage changes within each group.

See also:

`Series.groupby`

`DataFrame.groupby`

pandas.core.groupby.DataFrameGroupBy.plot

`DataFrameGroupBy.plot`
 Class implementing the .plot attribute for groupby objects.

pandas.core.groupby.DataFrameGroupBy.quantile

`DataFrameGroupBy.quantile(self, q=0.5, interpolation='linear')`
 Return group values at the given quantile, a la numpy.percentile.

Parameters

q [float or array-like, default 0.5 (50% quantile)] Value(s) between 0 and 1 providing the quantile(s) to compute.

interpolation [{'linear', 'lower', 'higher', 'midpoint', 'nearest'}] Method to use when the desired quantile falls between two points.

Returns

Series or **DataFrame** Return type determined by caller of GroupBy object.

See also:

Series.quantile Similar method for Series.

DataFrame.quantile Similar method for DataFrame.

numpy.percentile NumPy method to compute qth percentile.

Examples

```
>>> df = pd.DataFrame([
...     ['a', 1], ['a', 2], ['a', 3],
...     ['b', 1], ['b', 3], ['b', 5]
... ], columns=['key', 'val'])
>>> df.groupby('key').quantile()
      val
key
a      2.0
b      3.0
```

pandas.core.groupby.DataFrameGroupBy.rank

`DataFrameGroupBy.rank(self, method='average', ascending=True, na_option='keep', pct=False, axis=0)`

Provide the rank of values within each group.

Parameters

method [{‘average’, ‘min’, ‘max’, ‘first’, ‘dense’}, default ‘average’]

- average: average rank of group
- min: lowest rank in group
- max: highest rank in group
- first: ranks assigned in order they appear in the array
- dense: like ‘min’, but rank always increases by 1 between groups

ascending [boolean, default True] False for ranks by high (1) to low (N)

na_option [{‘keep’, ‘top’, ‘bottom’}, default ‘keep’]

- keep: leave NA values where they are
- top: smallest rank if ascending
- bottom: smallest rank if descending

pct [boolean, default False] Compute percentage rank of data within each group

axis [int, default 0] The axis of the object over which to compute the rank.

Returns

DataFrame with ranking of values within each group

See also:

`Series.groupby``DataFrame.groupby`**pandas.core.groupby.DataFrameGroupBy.resample**`DataFrameGroupBy.resample(self, rule, *args, **kwargs)`Provide resampling when using a `TimeGrouper`.

Given a grouper, the function resamples it according to a string “string” -> “frequency”.

See the *frequency aliases* documentation for more details.**Parameters****rule** [str or `DateOffset`] The offset string or object representing target grouper conversion.***args, **kwargs** Possible arguments are *how*, *fill_method*, *limit*, *kind* and *on*, and other arguments of `TimeGrouper`.**Returns****Grouper** Return a new grouper with our resampler appended.**See also:****Grouper** Specify a frequency to resample with when grouping by a key.**DatetimeIndex.resample** Frequency conversion and resampling of time series.**Examples**

```
>>> idx = pd.date_range('1/1/2000', periods=4, freq='T')
>>> df = pd.DataFrame(data=4 * [range(2)],
...                   index=idx,
...                   columns=['a', 'b'])
>>> df.iloc[2, 0] = 5
>>> df
```

	a	b
2000-01-01 00:00:00	0	1
2000-01-01 00:01:00	0	1
2000-01-01 00:02:00	5	1
2000-01-01 00:03:00	0	1

Downsample the `DataFrame` into 3 minute bins and sum the values of the timestamps falling into a bin.

```
>>> df.groupby('a').resample('3T').sum()
```

	a	b
a		
0	2000-01-01 00:00:00	0 2
	2000-01-01 00:03:00	0 1
5	2000-01-01 00:00:00	5 1

Upsample the series into 30 second bins.

```
>>> df.groupby('a').resample('30S').sum()
          a  b
a
0  2000-01-01 00:00:00  0  1
   2000-01-01 00:00:30  0  0
   2000-01-01 00:01:00  0  1
   2000-01-01 00:01:30  0  0
   2000-01-01 00:02:00  0  0
   2000-01-01 00:02:30  0  0
   2000-01-01 00:03:00  0  1
5  2000-01-01 00:02:00  5  1
```

Resample by month. Values are assigned to the month of the period.

```
>>> df.groupby('a').resample('M').sum()
          a  b
a
0  2000-01-31  0  3
5  2000-01-31  5  1
```

Downsample the series into 3 minute bins as above, but close the right side of the bin interval.

```
>>> df.groupby('a').resample('3T', closed='right').sum()
          a  b
a
0  1999-12-31 23:57:00  0  1
   2000-01-01 00:00:00  0  2
5  2000-01-01 00:00:00  5  1
```

Downsample the series into 3 minute bins and close the right side of the bin interval, but label each bin using the right edge instead of the left.

```
>>> df.groupby('a').resample('3T', closed='right', label='right').sum()
          a  b
a
0  2000-01-01 00:00:00  0  1
   2000-01-01 00:03:00  0  2
5  2000-01-01 00:03:00  5  1
```

Add an offset of twenty seconds.

```
>>> df.groupby('a').resample('3T', loffset='20s').sum()
          a  b
a
0  2000-01-01 00:00:20  0  2
   2000-01-01 00:03:20  0  1
5  2000-01-01 00:00:20  5  1
```

pandas.core.groupby.DataFrameGroupBy.shift

`DataFrameGroupBy.shift(self, periods=1, freq=None, axis=0, fill_value=None)`

Shift each group by periods observations.

Parameters

periods [integer, default 1] number of periods to shift

freq [frequency string]

axis [axis to shift, default 0]

fill_value [optional] New in version 0.24.0.

Returns

Series or DataFrame Object shifted within each group.

See also:

`Series.groupby`

`DataFrame.groupby`

`pandas.core.groupby.DataFrameGroupBy.size`

`DataFrameGroupBy.size(self)`

Compute group sizes.

Returns

Series Number of rows in each group.

See also:

`Series.groupby`

`DataFrame.groupby`

`pandas.core.groupby.DataFrameGroupBy.skew`

`DataFrameGroupBy.skew`

Return unbiased skew over requested axis Normalized by N-1.

Parameters

axis [{index (0), columns (1)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

pandas.core.groupby.DataFrameGroupBy.take**DataFrameGroupBy.take**

Return the elements in the given *positional* indices along an axis.

This means that we are not indexing according to actual values in the index attribute of the object. We are indexing according to the actual position of the element in the object.

Parameters

indices [array-like] An array of ints indicating which positions to take.

axis [{0 or 'index', 1 or 'columns', None}, default 0] The axis on which to select elements. 0 means that we are selecting rows, 1 means that we are selecting columns.

is_copy [bool, default True] Whether to return a copy of the original object or not.

****kwargs** For compatibility with `numpy.take()`. Has no effect on the output.

Returns

taken [same type as caller] An array-like containing the elements taken from the object.

See also:

DataFrame.loc Select a subset of a DataFrame by labels.

DataFrame.iloc Select a subset of a DataFrame by positions.

numpy.take Take elements from an array along an axis.

Examples

```
>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
...                    ('parrot', 'bird', 24.0),
...                    ('lion', 'mammal', 80.5),
...                    ('monkey', 'mammal', np.nan)],
...                    columns=['name', 'class', 'max_speed'],
...                    index=[0, 2, 3, 1])
>>> df
   name  class  max_speed
0  falcon   bird    389.0
2  parrot   bird     24.0
3   lion  mammal     80.5
1  monkey  mammal      NaN
```

Take elements at positions 0 and 3 along the axis 0 (default).

Note how the actual indices selected (0 and 1) do not correspond to our selected indices 0 and 3. That's because we are selecting the 0th and 3rd rows, not rows whose indices equal 0 and 3.

```
>>> df.take([0, 3])
   name  class  max_speed
0  falcon   bird    389.0
1  monkey  mammal      NaN
```

Take elements at indices 1 and 2 along the axis 1 (column selection).

```
>>> df.take([1, 2], axis=1)
      class  max_speed
0     bird     389.0
2     bird     24.0
3  mammal     80.5
1  mammal      NaN
```

We may take elements using negative integers for positive indices, starting from the end of the object, just like with Python lists.

```
>>> df.take([-1, -2])
      name  class  max_speed
1  monkey  mammal      NaN
3     lion  mammal     80.5
```

pandas.core.groupby.DataFrameGroupBy.tshift

DataFrameGroupBy.tshift

Shift the time index, using the index's frequency if available.

Parameters

- periods** [int] Number of periods to move, can be positive or negative
- freq** [DateOffset, timedelta, or time rule string, default None] Increment to use from the tseries module or time rule (e.g. 'EOM')
- axis** [int or basestring] Corresponds to the axis that contains the Index

Returns

- shifted** [Series/DataFrame]

Notes

If freq is not specified then tries to use the freq or inferred_freq attributes of the index. If neither of those attributes exist, a ValueError is thrown

The following methods are available only for SeriesGroupBy objects.

<i>SeriesGroupBy.nlargest</i>	Return the largest <i>n</i> elements.
<i>SeriesGroupBy.nsmallest</i>	Return the smallest <i>n</i> elements.
<i>SeriesGroupBy.nunique</i> (self[, dropna])	Return number of unique elements in the group.
<i>SeriesGroupBy.unique</i>	Return unique values of Series object.
<i>SeriesGroupBy.value_counts</i> (self[, ...])	
<i>SeriesGroupBy.is_monotonic_increasing</i>	Return boolean if values in the object are monotonic_increasing.
<i>SeriesGroupBy.is_monotonic_decreasing</i>	Return boolean if values in the object are monotonic_decreasing.

pandas.core.groupby.SeriesGroupBy.nlargest

SeriesGroupBy.nlargest

Return the largest *n* elements.

Parameters

n [int, default 5] Return this many descending sorted values.

keep [{‘first’, ‘last’, ‘all’}, default ‘first’] When there are duplicate values that cannot all fit in a Series of *n* elements:

- **first** [return the first *n* occurrences in order] of appearance.
- **last** [return the last *n* occurrences in reverse] order of appearance.
- **all** [keep all occurrences. This can result in a Series of] size larger than *n*.

Returns

Series The *n* largest values in the Series, sorted in decreasing order.

See also:

Series.nsmallest Get the *n* smallest elements.

Series.sort_values Sort Series by values.

Series.head Return the first *n* rows.

Notes

Faster than `.sort_values(ascending=False).head(n)` for small *n* relative to the size of the Series object.

Examples

```
>>> countries_population = {"Italy": 59000000, "France": 65000000,
...                          "Malta": 434000, "Maldives": 434000,
...                          "Brunei": 434000, "Iceland": 337000,
...                          "Nauru": 11300, "Tuvalu": 11300,
...                          "Anguilla": 11300, "Monserat": 5200}
>>> s = pd.Series(countries_population)
>>> s
Italy          59000000
France         65000000
Malta           434000
Maldives       434000
Brunei         434000
Iceland        337000
Nauru           11300
Tuvalu         11300
Anguilla       11300
Monserat        5200
dtype: int64
```

The *n* largest elements where *n*=5 by default.

```
>>> s.nlargest()
France         65000000
Italy          59000000
Malta           434000
```

(continues on next page)

(continued from previous page)

```
Maldives    434000
Brunei      434000
dtype: int64
```

The n largest elements where $n=3$. Default *keep* value is 'first' so Malta will be kept.

```
>>> s.nlargest(3)
France    65000000
Italy     59000000
Malta     434000
dtype: int64
```

The n largest elements where $n=3$ and keeping the last duplicates. Brunei will be kept since it is the last with value 434000 based on the index order.

```
>>> s.nlargest(3, keep='last')
France    65000000
Italy     59000000
Brunei    434000
dtype: int64
```

The n largest elements where $n=3$ with all duplicates kept. Note that the returned Series has five elements due to the three duplicates.

```
>>> s.nlargest(3, keep='all')
France    65000000
Italy     59000000
Malta     434000
Maldives  434000
Brunei    434000
dtype: int64
```

pandas.core.groupby.SeriesGroupBy.nsmallest

SeriesGroupBy.nsmallest

Return the smallest n elements.

Parameters

n [int, default 5] Return this many ascending sorted values.

keep [{‘first’, ‘last’, ‘all’}, default ‘first’] When there are duplicate values that cannot all fit in a Series of n elements:

- **first** [return the first n occurrences in order] of appearance.
- **last** [return the last n occurrences in reverse] order of appearance.
- **all** [keep all occurrences. This can result in a Series of] size larger than n .

Returns

Series The n smallest values in the Series, sorted in increasing order.

See also:

Series.nlargest Get the n largest elements.

`Series.sort_values` Sort Series by values.

`Series.head` Return the first n rows.

Notes

Faster than `.sort_values().head(n)` for small n relative to the size of the Series object.

Examples

```
>>> countries_population = {"Italy": 59000000, "France": 65000000,
...                          "Brunei": 434000, "Malta": 434000,
...                          "Maldives": 434000, "Iceland": 337000,
...                          "Nauru": 11300, "Tuvalu": 11300,
...                          "Anguilla": 11300, "Monserat": 5200}
>>> s = pd.Series(countries_population)
>>> s
Italy          59000000
France         65000000
Brunei          434000
Malta           434000
Maldives        434000
Iceland         337000
Nauru           11300
Tuvalu          11300
Anguilla        11300
Monserat         5200
dtype: int64
```

The n smallest elements where $n=5$ by default.

```
>>> s.nsmallest()
Monserat         5200
Nauru            11300
Tuvalu           11300
Anguilla         11300
Iceland          337000
dtype: int64
```

The n smallest elements where $n=3$. Default `keep` value is 'first' so Nauru and Tuvalu will be kept.

```
>>> s.nsmallest(3)
Monserat         5200
Nauru            11300
Tuvalu           11300
dtype: int64
```

The n smallest elements where $n=3$ and keeping the last duplicates. Anguilla and Tuvalu will be kept since they are the last with value 11300 based on the index order.

```
>>> s.nsmallest(3, keep='last')
Monserat         5200
```

(continues on next page)

(continued from previous page)

```

Anguilla    11300
Tuvalu     11300
dtype: int64

```

The n smallest elements where $n=3$ with all duplicates kept. Note that the returned Series has four elements due to the three duplicates.

```

>>> s.nsmallest(3, keep='all')
Monserat    5200
Nauru       11300
Tuvalu     11300
Anguilla    11300
dtype: int64

```

pandas.core.groupby.SeriesGroupBy.nunique

`SeriesGroupBy.nunique(self, dropna=True)`

Return number of unique elements in the group.

Returns

Series Number of unique values within each group.

pandas.core.groupby.SeriesGroupBy.unique

`SeriesGroupBy.unique`

Return unique values of Series object.

Uniques are returned in order of appearance. Hash table-based unique, therefore does NOT sort.

Returns

ndarray or ExtensionArray The unique values returned as a NumPy array. See Notes.

See also:

unique Top-level unique method for any 1-d array-like object.

Index.unique Return Index with unique values from an Index object.

Notes

Returns the unique values as a NumPy array. In case of an extension-array backed Series, a new `ExtensionArray` of that type with just the unique values is returned. This includes

- Categorical
- Period
- Datetime with Timezone
- Interval
- Sparse
- IntegerNA

See Examples section.

Examples

```
>>> pd.Series([2, 1, 3, 3], name='A').unique()
array([2, 1, 3])
```

```
>>> pd.Series([pd.Timestamp('2016-01-01') for _ in range(3)]).unique()
array(['2016-01-01T00:00:00.000000000'], dtype='datetime64[ns]')
```

```
>>> pd.Series([pd.Timestamp('2016-01-01', tz='US/Eastern')
...           for _ in range(3)]).unique()
<DatetimeArray>
['2016-01-01 00:00:00-05:00']
Length: 1, dtype: datetime64[ns, US/Eastern]
```

An unordered Categorical will return categories in the order of appearance.

```
>>> pd.Series(pd.Categorical(list('baabc'))).unique()
[b, a, c]
Categories (3, object): [b, a, c]
```

An ordered Categorical preserves the category ordering.

```
>>> pd.Series(pd.Categorical(list('baabc'), categories=list('abc'),
...                           ordered=True)).unique()
[b, a, c]
Categories (3, object): [a < b < c]
```

pandas.core.groupby.SeriesGroupBy.value_counts

`SeriesGroupBy.value_counts`(*self*, *normalize=False*, *sort=True*, *ascending=False*, *bins=None*, *dropna=True*)

pandas.core.groupby.SeriesGroupBy.is_monotonic_increasing

`SeriesGroupBy.is_monotonic_increasing`

Return boolean if values in the object are `monotonic_increasing`.

New in version 0.19.0.

Returns

bool

pandas.core.groupby.SeriesGroupBy.is_monotonic_decreasing

`SeriesGroupBy.is_monotonic_decreasing`

Return boolean if values in the object are `monotonic_decreasing`.

New in version 0.19.0.

Returns

bool

The following methods are available only for `DataFrameGroupBy` objects.

<code>DataFrameGroupBy.corrwith</code>	Compute pairwise correlation between rows or columns of <code>DataFrame</code> with rows or columns of <code>Series</code> or <code>DataFrame</code> .
<code>DataFrameGroupBy.boxplot(grouped[, ...])</code>	Make box plots from <code>DataFrameGroupBy</code> data.

pandas.core.groupby.DataFrameGroupBy.corrwith**DataFrameGroupBy.corrwith**

Compute pairwise correlation between rows or columns of `DataFrame` with rows or columns of `Series` or `DataFrame`. `DataFrames` are first aligned along both axes before computing the correlations.

Parameters

other [`DataFrame`, `Series`] Object with which to compute correlations.

axis [{0 or 'index', 1 or 'columns'}, default 0] 0 or 'index' to compute column-wise, 1 or 'columns' for row-wise.

drop [bool, default False] Drop missing indices from result.

method [{'pearson', 'kendall', 'spearman'} or callable]

- `pearson` : standard correlation coefficient
- `kendall` : Kendall Tau correlation coefficient
- `spearman` : Spearman rank correlation
- **callable**: callable with input two 1d ndarrays and returning a float

New in version 0.24.0.

Returns

Series Pairwise correlations.

See also:

`DataFrame.corr`

pandas.core.groupby.DataFrameGroupBy.boxplot

`DataFrameGroupBy.boxplot(grouped, subplots=True, column=None, fontsize=None, rot=0, grid=True, ax=None, figsize=None, layout=None, sharex=False, sharey=True, **kwargs)`

Make box plots from `DataFrameGroupBy` data.

Parameters

grouped [Grouped `DataFrame`]

subplots [bool]

- `False` - no subplots will be used
- `True` - create a subplot for each group

column [column name or list of names, or vector] Can be any valid input to `groupby`

fontsize [int or string]

rot [label rotation angle]

grid [Setting this to True will show the grid]

ax [Matplotlib axis object, default None]

figsize [A tuple (width, height) in inches]

layout [tuple (optional)] (rows, columns) for the layout of the plot

sharex [bool, default False] Whether x-axes will be shared among subplots

New in version 0.23.1.

sharey [bool, default True] Whether y-axes will be shared among subplots

New in version 0.23.1.

****kwargs** [Keyword Arguments] All other plotting keyword arguments to be passed to matplotlib's boxplot function

Returns

dict of key/value = group key/DataFrame.boxplot return value
or DataFrame.boxplot return value in case subplots=figures=False

Examples

```
>>> import itertools
>>> tuples = [t for t in itertools.product(range(1000), range(4))]
>>> index = pd.MultiIndex.from_tuples(tuples, names=['lv10', 'lv11'])
>>> data = np.random.randn(len(index), 4)
>>> df = pd.DataFrame(data, columns=list('ABCD'), index=index)
>>>
>>> grouped = df.groupby(level='lv11')
>>> boxplot_frame_groupby(grouped)
>>>
>>> grouped = df.unstack(level='lv11').groupby(level=0, axis=1)
>>> boxplot_frame_groupby(grouped, subplots=False)
```

{{ header }}

6.12 Resampling

Resampler objects are returned by `resample` calls: `pandas.DataFrame.resample()`, `pandas.Series.resample()`.

6.12.1 Indexing, iteration

<code>Resampler.__iter__(self)</code>	Resampler iterator.
<code>Resampler.groups</code>	Dict {group name -> group labels}.
<code>Resampler.indices</code>	Dict {group name -> group indices}.

Continued on next page

Table 397 – continued from previous page

<code>Resampler.get_group(self, name[, obj])</code>	Construct DataFrame from group with provided name.
---	--

pandas.core.resample.Resampler.__iter__

`Resampler.__iter__(self)`
Resampler iterator.

Returns

Generator yielding sequence of (name, subsetted object)
for each group.

See also:

`GroupBy.__iter__`

pandas.core.resample.Resampler.groups

`Resampler.groups`
Dict {group name -> group labels}.

pandas.core.resample.Resampler.indices

`Resampler.indices`
Dict {group name -> group indices}.

pandas.core.resample.Resampler.get_group

`Resampler.get_group(self, name, obj=None)`
Construct DataFrame from group with provided name.

Parameters

name [object] the name of the group to get as a DataFrame

obj [DataFrame, default None] the DataFrame to take the DataFrame out of. If it is None, the object groupby was called on will be used

Returns

group [same type as obj]

6.12.2 Function application

<code>Resampler.apply(self, func, *args, **kwargs)</code>	Aggregate using one or more operations over the specified axis.
<code>Resampler.aggregate(self, func, *args, ...)</code>	Aggregate using one or more operations over the specified axis.

Continued on next page

Table 398 – continued from previous page

<code>Resampler.transform(self, arg, *args, ...)</code>	Call function producing a like-indexed Series on each group and return a Series with the transformed values.
<code>Resampler.pipe(self, func, *args, **kwargs)</code>	Apply a function <i>func</i> with arguments to this Resampler object and return the function's result.

pandas.core.resample.Resampler.apply

`Resampler.apply(self, func, *args, **kwargs)`

Aggregate using one or more operations over the specified axis.

Parameters

func [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. `[np.sum, 'mean']`
- dict of axis labels -> functions, function names or list of such.

***args** Positional arguments to pass to *func*.

****kwargs** Keyword arguments to pass to *func*.

Returns

scalar, Series or DataFrame The return can be:

- scalar : when Series.agg is called with single function
- Series : when DataFrame.agg is called with a single function
- DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

See also:

`DataFrame.groupby.aggregate`

`DataFrame.resample.transform`

`DataFrame.aggregate`

Notes

agg is an alias for *aggregate*. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```
>>> s = pd.Series([1,2,3,4,5],
                  index=pd.date_range('20130101', periods=5,freq='s'))
2013-01-01 00:00:00    1
2013-01-01 00:00:01    2
2013-01-01 00:00:02    3
2013-01-01 00:00:03    4
2013-01-01 00:00:04    5
Freq: S, dtype: int64
```

```
>>> r = s.resample('2s')
DatetimeIndexResampler [freq=<2 * Seconds>, axis=0, closed=left,
                        label=left, convention=start, base=0]
```

```
>>> r.agg(np.sum)
2013-01-01 00:00:00    3
2013-01-01 00:00:02    7
2013-01-01 00:00:04    5
Freq: 2S, dtype: int64
```

```
>>> r.agg(['sum', 'mean', 'max'])
                sum  mean  max
2013-01-01 00:00:00    3   1.5   2
2013-01-01 00:00:02    7   3.5   4
2013-01-01 00:00:04    5   5.0   5
```

```
>>> r.agg({'result' : lambda x: x.mean() / x.std(),
          'total' : np.sum})
                total  result
2013-01-01 00:00:00    3  2.121320
2013-01-01 00:00:02    7  4.949747
2013-01-01 00:00:04    5         NaN
```

pandas.core.resample.Resampler.aggregate

`Resampler.aggregate(self, func, *args, **kwargs)`

Aggregate using one or more operations over the specified axis.

Parameters

func [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. `[np.sum, 'mean']`
- dict of axis labels -> functions, function names or list of such.

***args** Positional arguments to pass to *func*.

****kwargs** Keyword arguments to pass to *func*.

Returns

scalar, Series or DataFrame The return can be:

- scalar : when Series.agg is called with single function
- Series : when DataFrame.agg is called with a single function
- DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

See also:

`DataFrame.groupby.aggregate`

`DataFrame.resample.transform`

`DataFrame.aggregate`

Notes

`agg` is an alias for `aggregate`. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```
>>> s = pd.Series([1,2,3,4,5],
                  index=pd.date_range('20130101', periods=5,freq='s'))
2013-01-01 00:00:00    1
2013-01-01 00:00:01    2
2013-01-01 00:00:02    3
2013-01-01 00:00:03    4
2013-01-01 00:00:04    5
Freq: S, dtype: int64
```

```
>>> r = s.resample('2s')
DatetimeIndexResampler [freq=<2 * Seconds>, axis=0, closed=left,
                        label=left, convention=start, base=0]
```

```
>>> r.agg(np.sum)
2013-01-01 00:00:00    3
2013-01-01 00:00:02    7
2013-01-01 00:00:04    5
Freq: 2S, dtype: int64
```

```
>>> r.agg(['sum', 'mean', 'max'])
                sum  mean  max
2013-01-01 00:00:00    3   1.5   2
2013-01-01 00:00:02    7   3.5   4
2013-01-01 00:00:04    5   5.0   5
```

```
>>> r.agg({'result' : lambda x: x.mean() / x.std(),
         'total' : np.sum})
         total  result
2013-01-01 00:00:00    3  2.121320
2013-01-01 00:00:02    7  4.949747

```

pandas.core.resample.Resampler.transform

`Resampler.transform(self, arg, *args, **kwargs)`

Call function producing a like-indexed Series on each group and return a Series with the transformed values.

Parameters

arg [function] To apply to each group. Should return a Series with the same index.

Returns

transformed [Series]

Examples

```
>>> resampled.transform(lambda x: (x - x.mean()) / x.std())
```

pandas.core.resample.Resampler.pipe

`Resampler.pipe(self, func, *args, **kwargs)`

Apply a function *func* with arguments to this Resampler object and return the function's result.

New in version 0.23.0.

Use *.pipe* when you want to improve readability by chaining together functions that expect Series, DataFrames, GroupBy or Resampler objects. Instead of writing

```
>>> h(g(f(df.groupby('group')), arg1=a), arg2=b, arg3=c)
```

You can write

```
>>> (df.groupby('group')
...   .pipe(f)
...   .pipe(g, arg1=a)
...   .pipe(h, arg2=b, arg3=c))
```

which is much more readable.

Parameters

func [callable or tuple of (callable, string)] Function to apply to this Resampler object or, alternatively, a (*callable*, *data_keyword*) tuple where *data_keyword* is a string indicating the keyword of *callable* that expects the Resampler object.

args [iterable, optional] positional arguments passed into *func*.

kwargs [dict, optional] a dictionary of keyword arguments passed into *func*.

Returns

object [the return type of *func*.]

See also:

Series.pipe Apply a function with arguments to a series.

DataFrame.pipe Apply a function with arguments to a dataframe.

apply Apply function to each group instead of to the full Resampler object.

Notes

See more [here](#)

Examples

```

>>> df = pd.DataFrame({'A': [1, 2, 3, 4]},
...                    index=pd.date_range('2012-08-02', periods=4))
>>> df

```

	A
2012-08-02	1
2012-08-03	2
2012-08-04	3
2012-08-05	4

To get the difference between each 2-day period's maximum and minimum value in one pass, you can do

```

>>> df.resample('2D').pipe(lambda x: x.max() - x.min())

```

	A
2012-08-02	1
2012-08-04	1

6.12.3 Upsampling

<i>Resampler.fill</i> (self[, limit])	Forward fill the values.
<i>Resampler.backfill</i> (self[, limit])	Backward fill the new missing values in the resampled data.
<i>Resampler.bfill</i> (self[, limit])	Backward fill the new missing values in the resampled data.
<i>Resampler.pad</i> (self[, limit])	Forward fill the values.
<i>Resampler.nearest</i> (self[, limit])	Resample by using the nearest value.
<i>Resampler.fillna</i> (self, method[, limit])	Fill missing values introduced by upsampling.
<i>Resampler.asfreq</i> (self[, fill_value])	Return the values at the new freq, essentially a reindex.
<i>Resampler.interpolate</i> (self[, method, axis, ...])	Interpolate values according to different methods.

pandas.core.resample.Resampler.ffill`Resampler.ffill(self, limit=None)`

Forward fill the values.

Parameters**limit** [integer, optional] limit of how many values to fill**Returns****An upsampled Series.****See also:**`Series.fillna``DataFrame.fillna`**pandas.core.resample.Resampler.backfill**`Resampler.backfill(self, limit=None)`

Backward fill the new missing values in the resampled data.

In statistics, imputation is the process of replacing missing data with substituted values [?]. When resampling data, missing values may appear (e.g., when the resampling frequency is higher than the original frequency). The backward fill will replace NaN values that appeared in the resampled data with the next value in the original sequence. Missing values that existed in the original data will not be modified.

Parameters**limit** [integer, optional] Limit of how many values to fill.**Returns****Series, DataFrame** An upsampled Series or DataFrame with backward filled NaN values.**See also:*****bfill*** Alias of backfill.***fillna*** Fill NaN values using the specified method, which can be ‘backfill’.***nearest*** Fill NaN values with nearest neighbor starting from center.***pad*** Forward fill NaN values.**`Series.fillna`** Fill NaN values in the Series using the specified method, which can be ‘backfill’.**`DataFrame.fillna`** Fill NaN values in the DataFrame using the specified method, which can be ‘backfill’.**References**

Examples

Resampling a Series:

```
>>> s = pd.Series([1, 2, 3],
...               index=pd.date_range('20180101', periods=3, freq='h'))
>>> s
2018-01-01 00:00:00    1
2018-01-01 01:00:00    2
2018-01-01 02:00:00    3
Freq: H, dtype: int64
```

```
>>> s.resample('30min').backfill()
2018-01-01 00:00:00    1
2018-01-01 00:30:00    2
2018-01-01 01:00:00    2
2018-01-01 01:30:00    3
2018-01-01 02:00:00    3
Freq: 30T, dtype: int64
```

```
>>> s.resample('15min').backfill(limit=2)
2018-01-01 00:00:00    1.0
2018-01-01 00:15:00    NaN
2018-01-01 00:30:00    2.0
2018-01-01 00:45:00    2.0
2018-01-01 01:00:00    2.0
2018-01-01 01:15:00    NaN
2018-01-01 01:30:00    3.0
2018-01-01 01:45:00    3.0
2018-01-01 02:00:00    3.0
Freq: 15T, dtype: float64
```

Resampling a DataFrame that has missing values:

```
>>> df = pd.DataFrame({'a': [2, np.nan, 6], 'b': [1, 3, 5]},
...                   index=pd.date_range('20180101', periods=3,
...                                       freq='h'))
>>> df
              a  b
2018-01-01 00:00:00  2.0  1
2018-01-01 01:00:00  NaN  3
2018-01-01 02:00:00  6.0  5
```

```
>>> df.resample('30min').backfill()
              a  b
2018-01-01 00:00:00  2.0  1
2018-01-01 00:30:00  NaN  3
2018-01-01 01:00:00  NaN  3
2018-01-01 01:30:00  6.0  5
2018-01-01 02:00:00  6.0  5
```

```
>>> df.resample('15min').backfill(limit=2)
```

pandas.core.resample.Resampler.pad`Resampler.pad(self, limit=None)`

Forward fill the values.

Parameters**limit** [integer, optional] limit of how many values to fill**Returns****An upsampled Series.****See also:**`Series.fillna``DataFrame.fillna`**pandas.core.resample.Resampler.nearest**`Resampler.nearest(self, limit=None)`

Resample by using the nearest value.

When resampling data, missing values may appear (e.g., when the resampling frequency is higher than the original frequency). The *nearest* method will replace NaN values that appeared in the resampled data with the value from the nearest member of the sequence, based on the index value. Missing values that existed in the original data will not be modified. If *limit* is given, fill only this many values in each direction for each of the original values.

Parameters**limit** [int, optional] Limit of how many values to fill.

New in version 0.21.0.

Returns**Series or DataFrame** An upsampled Series or DataFrame with NaN values filled with their nearest value.**See also:****backfill** Backward fill the new missing values in the resampled data.**pad** Forward fill NaN values.

Examples

```
>>> s = pd.Series([1, 2],
...               index=pd.date_range('20180101',
...                                   periods=2,
...                                   freq='1h'))
>>> s
2018-01-01 00:00:00    1
2018-01-01 01:00:00    2
Freq: H, dtype: int64
```

```
>>> s.resample('15min').nearest()
2018-01-01 00:00:00    1
2018-01-01 00:15:00    1
2018-01-01 00:30:00    2
2018-01-01 00:45:00    2
2018-01-01 01:00:00    2
Freq: 15T, dtype: int64
```

Limit the number of upsampled values imputed by the nearest:

```
>>> s.resample('15min').nearest(limit=1)
2018-01-01 00:00:00    1.0
2018-01-01 00:15:00    1.0
2018-01-01 00:30:00    NaN
2018-01-01 00:45:00    2.0
2018-01-01 01:00:00    2.0
Freq: 15T, dtype: float64
```

pandas.core.resample.Resampler.fillna

`Resampler.fillna(self, method, limit=None)`

Fill missing values introduced by upsampling.

In statistics, imputation is the process of replacing missing data with substituted values [?]. When resampling data, missing values may appear (e.g., when the resampling frequency is higher than the original frequency).

Missing values that existed in the original data will not be modified.

Parameters

method [{'pad', 'backfill', 'ffill', 'bfill', 'nearest'}] Method to use for filling holes in resampled data

- 'pad' or 'ffill': use previous valid observation to fill gap (forward fill).
- 'backfill' or 'bfill': use next valid observation to fill gap.
- 'nearest': use nearest valid observation to fill gap.

limit [integer, optional] Limit of how many consecutive missing values to fill.

Returns

Series or DataFrame An upsampled Series or DataFrame with missing values filled.

See also:

backfill Backward fill NaN values in the resampled data.

pad Forward fill NaN values in the resampled data.

nearest Fill NaN values in the resampled data with nearest neighbor starting from center.

interpolate Fill NaN values using interpolation.

Series.fillna Fill NaN values in the Series using the specified method, which can be 'bfill' and 'ffill'.

DataFrame.fillna Fill NaN values in the DataFrame using the specified method, which can be 'bfill' and 'ffill'.

Examples

Resampling a Series:

```
>>> s = pd.Series([1, 2, 3],
...               index=pd.date_range('20180101', periods=3, freq='h'))
>>> s
2018-01-01 00:00:00    1
2018-01-01 01:00:00    2
2018-01-01 02:00:00    3
Freq: H, dtype: int64
```

Without filling the missing values you get:

```
>>> s.resample("30min").asfreq()
2018-01-01 00:00:00    1.0
2018-01-01 00:30:00    NaN
2018-01-01 01:00:00    2.0
2018-01-01 01:30:00    NaN
2018-01-01 02:00:00    3.0
Freq: 30T, dtype: float64
```

```
>>> s.resample('30min').fillna("backfill")

2018-01-01 02:00:00  6.0  5
```

pandas.core.resample.Resampler.asfreq

`Resampler.asfreq(self, fill_value=None)`

Return the values at the new freq, essentially a reindex.

Parameters

fill_value [scalar, optional] Value to use for missing values, applied during upsampling (note this does not fill NaNs that already were present).

New in version 0.20.0.

Returns

DataFrame or Series Values at the specified freq.

`DataFrame.asfreq`

pandas.core.resample.Resampler.interpolate

`Resampler.interpolate(self, method='linear', axis=0, limit=None, inplace=False, limit_direction='forward', limit_area=None, downcast=None, **kwargs)`

Interpolate values according to different methods.

New in version 0.18.1.

Please note that only `method='linear'` is supported for DataFrame/Series with a MultiIndex.

Parameters

method [str, default 'linear'] Interpolation technique to use. One of:

- 'linear': Ignore the index and treat the values as equally spaced. This is the only method supported on MultiIndexes.
- 'time': Works on daily and higher resolution data to interpolate given length of interval.
- 'index', 'values': use the actual numerical values of the index.
- 'pad': Fill in NaNs using existing values.
- 'nearest', 'zero', 'slinear', 'quadratic', 'cubic', 'spline', 'barycentric', 'polynomial': Passed to `scipy.interpolate.interp1d`. These methods use the numerical values of the index. Both 'polynomial' and 'spline' require that you also specify an *order* (int), e.g. `df.interpolate(method='polynomial', order=5)`.
- 'krogh', 'piecewise_polynomial', 'spline', 'pchip', 'akima': Wrappers around the SciPy interpolation methods of similar names. See *Notes*.
- 'from_derivatives': Refers to `scipy.interpolate.BPoly.from_derivatives` which replaces 'piecewise_polynomial' interpolation method in scipy 0.18.

New in version 0.18.1: Added support for the 'akima' method. Added interpolate method 'from_derivatives' which replaces 'piecewise_polynomial' in SciPy 0.18; backwards-compatible with SciPy < 0.18

axis [{0 or 'index', 1 or 'columns', None}, default None] Axis to interpolate along.

limit [int, optional] Maximum number of consecutive NaNs to fill. Must be greater than 0.

inplace [bool, default False] Update the data in place if possible.

limit_direction [{'forward', 'backward', 'both'}, default 'forward'] If limit is specified, consecutive NaNs will be filled in this direction.

limit_area [{None, 'inside', 'outside'}, default None] If limit is specified, consecutive NaNs will be filled with this restriction.

- **None**: No fill restriction.
- 'inside': Only fill NaNs surrounded by valid values (interpolate).
- 'outside': Only fill NaNs outside valid values (extrapolate).

New in version 0.23.0.

downcast [optional, 'infer' or None, defaults to None] Downcast dtypes if possible.

****kwargs** Keyword arguments to pass on to the interpolating function.

Returns

Series or DataFrame Returns the same object type as the caller, interpolated at some or all NaN values.

See also:

fillna Fill missing values using different methods.

scipy.interpolate.Akima1DInterpolator Piecewise cubic polynomials (Akima interpolator).

scipy.interpolate.BPoly.from_derivatives Piecewise polynomial in the Bernstein basis.

scipy.interpolate.interp1d Interpolate a 1-D function.

`scipy.interpolate.KroghInterpolator` Interpolate polynomial (Krogh interpolator).

`scipy.interpolate.PchipInterpolator` PCHIP 1-d monotonic cubic interpolation.

`scipy.interpolate.CubicSpline` Cubic spline data interpolator.

Notes

The ‘krogh’, ‘piecewise_polynomial’, ‘spline’, ‘pchip’ and ‘akima’ methods are wrappers around the respective SciPy implementations of similar names. These use the actual numerical values of the index. For more information on their behavior, see the [SciPy documentation](#) and [SciPy tutorial](#).

Examples

Filling in NaN in a *Series* via linear interpolation.

```
>>> s = pd.Series([0, 1, np.nan, 3])
>>> s
0    0.0
1    1.0
2    NaN
3    3.0
dtype: float64
>>> s.interpolate()
0    0.0
1    1.0
2    2.0
3    3.0
dtype: float64
```

Filling in NaN in a Series by padding, but filling at most two consecutive NaN at a time.

```
>>> s = pd.Series([np.nan, "single_one", np.nan,
...               "fill_two_more", np.nan, np.nan, np.nan,
...               4.71, np.nan])
>>> s
0         NaN
1    single_one
2         NaN
3    fill_two_more
4         NaN
5         NaN
6         NaN
7         4.71
8         NaN
dtype: object
>>> s.interpolate(method='pad', limit=2)
0         NaN
1    single_one
2    single_one
3    fill_two_more
4    fill_two_more
5    fill_two_more
```

(continues on next page)

(continued from previous page)

```

6          NaN
7          4.71
8          4.71
dtype: object

```

Filling in NaN in a Series via polynomial interpolation or splines: Both ‘polynomial’ and ‘spline’ methods require that you also specify an `order` (int).

```

>>> s = pd.Series([0, 2, np.nan, 8])
>>> s.interpolate(method='polynomial', order=2)
0    0.000000
1    2.000000
2    4.666667
3    8.000000
dtype: float64

```

Fill the DataFrame forward (that is, going down) along each column using linear interpolation.

Note how the last entry in column ‘a’ is interpolated differently, because there is no entry after it to use for interpolation. Note how the first entry in column ‘b’ remains NaN, because there is no entry before it to use for interpolation.

```

>>> df = pd.DataFrame([(0.0, np.nan, -1.0, 1.0),
...                    (np.nan, 2.0, np.nan, np.nan),
...                    (2.0, 3.0, np.nan, 9.0),
...                    (np.nan, 4.0, -4.0, 16.0)],
...                    columns=list('abcd'))
>>> df
   a    b    c    d
0  0.0 NaN -1.0  1.0
1  NaN  2.0 NaN  NaN
2  2.0  3.0 NaN  9.0
3  NaN  4.0 -4.0 16.0
>>> df.interpolate(method='linear', limit_direction='forward', axis=0)
   a    b    c    d
0  0.0 NaN -1.0  1.0
1  1.0  2.0 -2.0  5.0
2  2.0  3.0 -3.0  9.0
3  2.0  4.0 -4.0 16.0

```

Using polynomial interpolation.

```

>>> df['d'].interpolate(method='polynomial', order=2)
0    1.0
1    4.0
2    9.0
3   16.0
Name: d, dtype: float64

```

6.12.4 Computations / descriptive stats

<code>Resampler.count(self[, _method])</code>	Compute count of group, excluding missing values.
<code>Resampler.nunique(self[, _method])</code>	Return number of unique elements in the group.
<code>Resampler.first(self[, _method])</code>	Compute first of group values.
<code>Resampler.last(self[, _method])</code>	Compute last of group values.
<code>Resampler.max(self[, _method])</code>	Compute max of group values.
<code>Resampler.mean(self[, _method])</code>	Compute mean of groups, excluding missing values.
<code>Resampler.median(self[, _method])</code>	Compute median of groups, excluding missing values.
<code>Resampler.min(self[, _method])</code>	Compute min of group values.
<code>Resampler.ohlc(self[, _method])</code>	Compute sum of values, excluding missing values.
<code>Resampler.prod(self[, _method, min_count])</code>	Compute prod of group values.
<code>Resampler.size(self)</code>	Compute group sizes.
<code>Resampler.sem(self[, _method])</code>	Compute standard error of the mean of groups, excluding missing values.
<code>Resampler.std(self[, ddof])</code>	Compute standard deviation of groups, excluding missing values.
<code>Resampler.sum(self[, _method, min_count])</code>	Compute sum of group values.
<code>Resampler.var(self[, ddof])</code>	Compute variance of groups, excluding missing values.
<code>Resampler.quantile(self[, q])</code>	Return value at the given quantile.

pandas.core.resample.Resampler.count

`Resampler.count(self, _method='count')`
 Compute count of group, excluding missing values.

Returns

Series or DataFrame Count of values within each group.

See also:

`Series.groupby`

`DataFrame.groupby`

pandas.core.resample.Resampler.nunique

`Resampler.nunique(self, _method='nunique')`
 Return number of unique elements in the group.

Returns

Series Number of unique values within each group.

pandas.core.resample.Resampler.first

`Resampler.first(self, _method='first', *args, **kwargs)`
 Compute first of group values.

Returns

Series or DataFrame Computed first of values within each group.

pandas.core.resample.Resampler.last

`Resampler.last(self, _method='last', *args, **kwargs)`
Compute last of group values.

Returns

Series or DataFrame Computed last of values within each group.

pandas.core.resample.Resampler.max

`Resampler.max(self, _method='max', *args, **kwargs)`
Compute max of group values.

Returns

Series or DataFrame Computed max of values within each group.

pandas.core.resample.Resampler.mean

`Resampler.mean(self, _method='mean', *args, **kwargs)`
Compute mean of groups, excluding missing values.

Returns

pandas.Series or pandas.DataFrame

See also:

`Series.groupby`

`DataFrame.groupby`

Examples

```
>>> df = pd.DataFrame({'A': [1, 1, 2, 1, 2],
...                   'B': [np.nan, 2, 3, 4, 5],
...                   'C': [1, 2, 1, 1, 2]}, columns=['A', 'B', 'C'])
```

Groupby one column and return the mean of the remaining columns in each group.

```
>>> df.groupby('A').mean()
   B      C
A
1  3.0  1.333333
2  4.0  1.500000
```

Groupby two columns and return the mean of the remaining column.

```
>>> df.groupby(['A', 'B']).mean()
   C
A B
1  2.0  2
   4.0  1
2  3.0  1
   5.0  2
```

Groupby one column and return the mean of only particular column in the group.

```
>>> df.groupby('A')['B'].mean()
A
1    3.0
2    4.0
Name: B, dtype: float64
```

pandas.core.resample.Resampler.median

`Resampler.median(self, _method='median', *args, **kwargs)`

Compute median of groups, excluding missing values.

For multiple groupings, the result index will be a MultiIndex

Returns

Series or DataFrame Median of values within each group.

See also:

`Series.groupby`

`DataFrame.groupby`

pandas.core.resample.Resampler.min

`Resampler.min(self, _method='min', *args, **kwargs)`

Compute min of group values.

Returns

Series or DataFrame Computed min of values within each group.

pandas.core.resample.Resampler.ohlc

`Resampler.ohlc(self, _method='ohlc', *args, **kwargs)`

Compute sum of values, excluding missing values.

For multiple groupings, the result index will be a MultiIndex

Returns

DataFrame Open, high, low and close values within each group.

See also:

`Series.groupby`

`DataFrame.groupby`

pandas.core.resample.Resampler.prod

`Resampler.prod(self, _method='prod', min_count=0, *args, **kwargs)`

Compute prod of group values.

Returns

Series or DataFrame Computed prod of values within each group.

pandas.core.resample.Resampler.size

`Resampler.size(self)`

Compute group sizes.

Returns

Series Number of rows in each group.

See also:

`Series.groupby`

`DataFrame.groupby`

pandas.core.resample.Resampler.sem

`Resampler.sem(self, _method='sem', *args, **kwargs)`

Compute standard error of the mean of groups, excluding missing values.

For multiple groupings, the result index will be a MultiIndex.

Parameters

ddof [integer, default 1] degrees of freedom

Returns

Series or DataFrame Standard error of the mean of values within each group.

See also:

`Series.groupby`

`DataFrame.groupby`

pandas.core.resample.Resampler.std

`Resampler.std(self, ddof=1, *args, **kwargs)`

Compute standard deviation of groups, excluding missing values.

Parameters

ddof [integer, default 1] Degrees of freedom.

Returns

DataFrame or Series Standard deviation of values within each group.

pandas.core.resample.Resampler.sum

`Resampler.sum(self, _method='sum', min_count=0, *args, **kwargs)`

Compute sum of group values.

Returns

Series or DataFrame Computed sum of values within each group.

pandas.core.resample.Resampler.var**Resampler.var**(*self*, *ddof*=1, **args*, ***kwargs*)

Compute variance of groups, excluding missing values.

Parameters**ddof** [integer, default 1] degrees of freedom**Returns****DataFrame or Series** Variance of values within each group.**pandas.core.resample.Resampler.quantile****Resampler.quantile**(*self*, *q*=0.5, ***kwargs*)

Return value at the given quantile.

New in version 0.24.0.

Parameters**q** [float or array-like, default 0.5 (50% quantile)]**Returns****DataFrame or Series** Quantile of values within each group.**See also:****Series.quantile****DataFrame.quantile****DataFrameGroupBy.quantile**`{{ header }}`

6.13 Style

Styler objects are returned by `pandas.DataFrame.style`.

6.13.1 Styler constructor

<code>Styler</code> (<i>data</i> [, <i>precision</i> , <i>table_styles</i> , ...])	Helps style a DataFrame or Series according to the data with HTML and CSS.
<code>Styler.from_custom_template</code> (<i>searchpath</i> , <i>name</i>)	Factory function for creating a subclass of <code>Styler</code> with a custom template and Jinja environment.

pandas.io.formats.style.Styler

```
class pandas.io.formats.style.Styler(data, precision=None, table_styles=None, uuid=None,
                                     caption=None, table_attributes=None, cell_ids=True)
```

Helps style a DataFrame or Series according to the data with HTML and CSS.

Parameters

data [Series or DataFrame]

precision [int] precision to round floats to, defaults to `pd.options.display.precision`

table_styles [list-like, default None] list of {selector: (attr, value)} dicts; see Notes

uuid [str, default None] a unique identifier to avoid CSS collisions; generated automatically

caption [str, default None] caption to attach to the table

cell_ids [bool, default True] If True, each cell will have an `id` attribute in their HTML tag. The `id` takes the form `T_<uuid>_row<num_row>_col<num_col>` where `<uuid>` is the unique identifier, `<num_row>` is the row number and `<num_col>` is the column number.

See also:

`DataFrame.style`

Notes

Most styling will be done by passing style functions into `Styler.apply` or `Styler.applymap`. Style functions should return values with strings containing CSS `'attr: value'` that will be applied to the indicated cells.

If using in the Jupyter notebook, `Styler` has defined a `_repr_html_` to automatically render itself. Otherwise call `Styler.render` to get the generated HTML.

CSS classes are attached to the generated HTML

- Index and Column names include `index_name` and `level<k>` where `k` is its level in a `MultiIndex`
- Index label cells include
 - `row_heading`
 - `row<n>` where `n` is the numeric position of the row
 - `level<k>` where `k` is the level in a `MultiIndex`
- Column label cells include `* col_heading * col<n>` where `n` is the numeric position of the column `* level<k>` where `k` is the level in a `MultiIndex`
- Blank cells include `blank`
- Data cells include `data`

Attributes

env	(<code>Jinja2 Jinja2.Environment</code>)
template	(<code>Jinja2 Template</code>)
loader	(<code>Jinja2 Loader</code>)

Methods

<code>apply(self, func[, axis, subset])</code>	Apply a function column-wise, row-wise, or table-wise, updating the HTML representation with the result.
<code>applymap(self, func[, subset])</code>	Apply a function elementwise, updating the HTML representation with the result.
<code>background_gradient(self[, cmap, low, high, ...])</code>	Color the background in a gradient according to the data in each column (optionally row).
<code>bar(self[, subset, axis, color, width, ...])</code>	Draw bar chart in the cell backgrounds.
<code>clear(self)</code>	Reset the styler, removing any previously applied styles.
<code>export(self)</code>	Export the styles to applied to the current Styler.
<code>format(self, formatter[, subset])</code>	Format the text display value of cells.
<code>from_custom_template(searchpath, name)</code>	Factory function for creating a subclass of Styler with a custom template and Jinja environment.
<code>hide_columns(self, subset)</code>	Hide columns from rendering.
<code>hide_index(self)</code>	Hide any indices from rendering.
<code>highlight_max(self[, subset, color, axis])</code>	Highlight the maximum by shading the background.
<code>highlight_min(self[, subset, color, axis])</code>	Highlight the minimum by shading the background.
<code>highlight_null(self[, null_color])</code>	Shade the background <code>null_color</code> for missing values.
<code>pipe(self, func, <i>*</i>args, <i>*</i>kwargs)</code>	Apply <code>func(self, *args, **kwargs)</code> , and return the result.
<code>render(self, <i>*</i>kwargs)</code>	Render the built up styles to HTML.
<code>set_caption(self, caption)</code>	Set the caption on a Styler
<code>set_precision(self, precision)</code>	Set the precision used to render.
<code>set_properties(self[, subset])</code>	Convenience method for setting one or more non-data dependent properties or each cell.
<code>set_table_attributes(self, attributes)</code>	Set the table attributes.
<code>set_table_styles(self, table_styles)</code>	Set the table styles on a Styler.
<code>set_uuid(self, uuid)</code>	Set the uuid for a Styler.
<code>to_excel(self, excel_writer[, sheet_name, ...])</code>	Write Styler to an Excel sheet.
<code>use(self, styles)</code>	Set the styles on the current Styler, possibly using styles from Styler.export .
<code>where(self, cond, value[, other, subset])</code>	Apply a function elementwise, updating the HTML representation with a style which is selected in accordance with the return value of a function.

pandas.io.formats.style.Styler.apply

Styler.apply(*self*, *func*, *axis=0*, *subset=None*, ***kwargs*)

Apply a function column-wise, row-wise, or table-wise, updating the HTML representation with the result.

Parameters

func [function] **func** should take a Series or DataFrame (depending on **axis**), and return an object with the same shape. Must return a DataFrame with identical index and column labels when **axis=None**

axis [{0 or 'index', 1 or 'columns', None}, default 0] apply to each column (**axis**=0 or 'index'), to each row (**axis**=1 or 'columns'), or to the entire DataFrame at once with **axis**=None.

subset [IndexSlice] a valid indexer to limit data to *before* applying the function. Consider using a pandas.IndexSlice

kwargs [dict] pass along to **func**

Returns

self [Styler]

Notes

The output shape of **func** should match the input, i.e. if **x** is the input row, column, or table (depending on **axis**), then **func(x).shape == x.shape** should be true.

This is similar to **DataFrame.apply**, except that **axis=None** applies the function to the entire DataFrame at once, rather than column-wise or row-wise.

Examples

```
>>> def highlight_max(x):
...     return ['background-color: yellow' if v == x.max() else ''
...            for v in x]
...
>>> df = pd.DataFrame(np.random.randn(5, 2))
>>> df.style.apply(highlight_max)
```

pandas.io.formats.style.Styler.applymap

Styler.applymap(*self*, *func*, *subset=None*, ***kwargs*)

Apply a function elementwise, updating the HTML representation with the result.

Parameters

func [function] **func** should take a scalar and return a scalar

subset [IndexSlice] a valid indexer to limit data to *before* applying the function. Consider using a pandas.IndexSlice

kwargs [dict] pass along to **func**

Returns

self [Styler]

See also:

Styler.where

pandas.io.formats.style.Styler.background_gradient

`Styler.background_gradient`(*self*, *cmap*='PuBu', *low*=0, *high*=0, *axis*=0, *subset*=None, *text_color_threshold*=0.408)

Color the background in a gradient according to the data in each column (optionally row).

Requires matplotlib.

Parameters

cmap [str or colormap] matplotlib colormap

low, high [float] compress the range by these values.

axis [{0 or 'index', 1 or 'columns', None}, default 0] apply to each column (**axis**=0 or 'index'), to each row (**axis**=1 or 'columns'), or to the entire DataFrame at once with **axis**=None.

subset [IndexSlice] a valid slice for **data** to limit the style application to.

text_color_threshold [float or int] luminance threshold for determining text color. Facilitates text visibility across varying background colors. From 0 to 1. 0 = all text is dark colored, 1 = all text is light colored.

New in version 0.24.0.

Returns

self [Styler]

Raises

ValueError If **text_color_threshold** is not a value from 0 to 1.

Notes

Set **text_color_threshold** or tune **low** and **high** to keep the text legible by not using the entire range of the color map. The range of the data is extended by $\text{low} * (\text{x.max}() - \text{x.min}())$ and $\text{high} * (\text{x.max}() - \text{x.min}())$ before normalizing.

pandas.io.formats.style.Styler.bar

`Styler.bar`(*self*, *subset*=None, *axis*=0, *color*='#d65f5f', *width*=100, *align*='left', *vmin*=None, *vmax*=None)

Draw bar chart in the cell backgrounds.

Parameters

subset [IndexSlice, optional] A valid slice for **data** to limit the style application to.

axis [{0 or 'index', 1 or 'columns', None}, default 0] apply to each column (**axis**=0 or 'index'), to each row (**axis**=1 or 'columns'), or to the entire DataFrame at once with **axis**=None.

color [str or 2-tuple/list] If a str is passed, the color is the same for both negative and positive numbers. If 2-tuple/list is used, the first element is the **color_negative** and the second is the **color_positive** (eg: ['#d65f5f', '#5fba7d']).

width [float, default 100] A number between 0 or 100. The largest value will cover *width* percent of the cell's width.

align [{'left', 'zero', 'mid'}], default 'left' How to align the bars with the cells.

- 'left' : the min value starts at the left of the cell.
- 'zero' : a value of zero is located at the center of the cell.
- 'mid' : the center of the cell is at $(\max - \min) / 2$, or if values are all negative (positive) the zero is aligned at the right (left) of the cell.

New in version 0.20.0.

vmin [float, optional] Minimum bar value, defining the left hand limit of the bar drawing range, lower values are clipped to *vmin*. When None (default): the minimum value of the data will be used.

New in version 0.24.0.

vmax [float, optional] Maximum bar value, defining the right hand limit of the bar drawing range, higher values are clipped to *vmax*. When None (default): the maximum value of the data will be used.

New in version 0.24.0.

Returns

self [Styler]

pandas.io.formats.style.Styler.clear

Styler.clear(*self*)

Reset the styler, removing any previously applied styles. Returns None.

pandas.io.formats.style.Styler.export

Styler.export(*self*)

Export the styles to applied to the current Styler.

Can be applied to a second style with **Styler.use**.

Returns

styles [list]

See also:

Styler.use

pandas.io.formats.style.Styler.format

Styler.format(*self*, *formatter*, *subset=None*)

Format the text display value of cells.

New in version 0.18.0.

Parameters

formatter [str, callable, or dict]

subset [IndexSlice] An argument to `DataFrame.loc` that restricts which elements `formatter` is applied to.

Returns

`self` [Styler]

Notes

`formatter` is either an `a` or a dict `{column name: a}` where `a` is one of

- `str`: this will be wrapped in: `a.format(x)`
- callable: called with the value of an individual cell

The default display value for numeric values is the “general” (g) format with `pd.options.display.precision` precision.

Examples

```
>>> df = pd.DataFrame(np.random.randn(4, 2), columns=['a', 'b'])
>>> df.style.format("{:.2%}")
>>> df['c'] = ['a', 'b', 'c', 'd']
>>> df.style.format({'c': str.upper})
```

pandas.io.formats.style.Styler.from_custom_template

classmethod `Styler.from_custom_template(searchpath, name)`

Factory function for creating a subclass of `Styler` with a custom template and Jinja environment.

Parameters

searchpath [str or list] Path or paths of directories containing the templates

name [str] Name of your custom template to use for rendering

Returns

MyStyler [subclass of `Styler`] Has the correct `env` and `template` class attributes set.

pandas.io.formats.style.Styler.hide_columns

Styler.hide_columns(self, subset)

Hide columns from rendering.

New in version 0.23.0.

Parameters

subset [IndexSlice] An argument to `DataFrame.loc` that identifies which columns are hidden.

Returns

`self` [Styler]

`pandas.io.formats.style.Styler.hide_index`

`Styler.hide_index(self)`

Hide any indices from rendering.

New in version 0.23.0.

Returns

`self` [`Styler`]

`pandas.io.formats.style.Styler.highlight_max`

`Styler.highlight_max(self, subset=None, color='yellow', axis=0)`

Highlight the maximum by shading the background.

Parameters

subset [`IndexSlice`, default `None`] a valid slice for `data` to limit the style application to.

color [`str`, default `'yellow'`]

axis [{0 or `'index'`, 1 or `'columns'`, `None`}, default 0] apply to each column (`axis=0` or `'index'`), to each row (`axis=1` or `'columns'`), or to the entire `DataFrame` at once with `axis=None`.

Returns

`self` [`Styler`]

`pandas.io.formats.style.Styler.highlight_min`

`Styler.highlight_min(self, subset=None, color='yellow', axis=0)`

Highlight the minimum by shading the background.

Parameters

subset [`IndexSlice`, default `None`] a valid slice for `data` to limit the style application to.

color [`str`, default `'yellow'`]

axis [{0 or `'index'`, 1 or `'columns'`, `None`}, default 0] apply to each column (`axis=0` or `'index'`), to each row (`axis=1` or `'columns'`), or to the entire `DataFrame` at once with `axis=None`.

Returns

`self` [`Styler`]

`pandas.io.formats.style.Styler.highlight_null`

`Styler.highlight_null(self, null_color='red')`

Shade the background `null_color` for missing values.

Parameters

null_color [`str`]

Returns`self` [Styler]**pandas.io.formats.style.Styler.pipe**`Styler.pipe(self, func, *args, **kwargs)`Apply `func(self, *args, **kwargs)`, and return the result.

New in version 0.24.0.

Parameters**func** [function] Function to apply to the Styler. Alternatively, a (callable, keyword) tuple where **keyword** is a string indicating the keyword of callable that expects the Styler.***args, **kwargs** : Arguments passed to *func*.**Returns****object** : The value returned by *func*.**See also:****DataFrame.pipe** Analogous method for DataFrame.**Styler.apply** Apply a function row-wise, column-wise, or table-wise to modify the dataframe's styling.**Notes**Like `DataFrame.pipe()`, this method can simplify the application of several user-defined functions to a styler. Instead of writing:

```
f(g(df.style.set_precision(3), arg1=a), arg2=b, arg3=c)
```

users can write:

```
(df.style.set_precision(3)
 .pipe(g, arg1=a)
 .pipe(f, arg2=b, arg3=c))
```

In particular, this allows users to define functions that take a styler object, along with other parameters, and return the styler after making styling changes (such as calling `Styler.apply()` or `Styler.set_properties()`). Using `.pipe`, these user-defined style “transformations” can be interleaved with calls to the built-in Styler interface.**Examples**

```
>>> def format_conversion(styler):
...     return (styler.set_properties(**{'text-align': 'right'})
...             .format({'conversion': '{:.1%}'))
```

The user-defined `format_conversion` function above can be called within a sequence of other style modifications:

```
>>> df = pd.DataFrame({'trial': list(range(5)),
...                    'conversion': [0.75, 0.85, np.nan, 0.7, 0.72]})
>>> (df.style
...   .highlight_min(subset=['conversion'], color='yellow')
...   .pipe(format_conversion)
...   .set_caption("Results with minimum conversion highlighted."))
```

pandas.io.formats.style.Styler.render

`Styler.render(self, **kwargs)`

Render the built up styles to HTML.

Parameters

****kwargs** Any additional keyword arguments are passed through to `self.template.render`. This is useful when you need to provide additional variables for a custom template.

New in version 0.20.

Returns

rendered [str] The rendered HTML.

Notes

`Styler` objects have defined the `_repr_html_` method which automatically calls `self.render()` when it's the last item in a Notebook cell. When calling `Styler.render()` directly, wrap the result in `IPython.display.HTML` to view the rendered HTML in the notebook.

Pandas uses the following keys in `render`. Arguments passed in ****kwargs** take precedence, so think carefully if you want to override them:

- head
- cellstyle
- body
- uuid
- precision
- table_styles
- caption
- table_attributes

pandas.io.formats.style.Styler.set_caption

`Styler.set_caption(self, caption)`

Set the caption on a `Styler`

Parameters

caption [str]

Returns

`self` [Styler]

`pandas.io.formats.style.Styler.set_precision`

`Styler.set_precision(self, precision)`

Set the precision used to render.

Parameters

`precision` [int]

Returns

`self` [Styler]

`pandas.io.formats.style.Styler.set_properties`

`Styler.set_properties(self, subset=None, **kwargs)`

Convenience method for setting one or more non-data dependent properties or each cell.

Parameters

`subset` [IndexSlice] a valid slice for `data` to limit the style application to

`kwargs` [dict] property: value pairs to be set for each cell

Returns

`self` [Styler]

Examples

```
>>> df = pd.DataFrame(np.random.randn(10, 4))
>>> df.style.set_properties(color="white", align="right")
>>> df.style.set_properties(**{'background-color': 'yellow'})
```

`pandas.io.formats.style.Styler.set_table_attributes`

`Styler.set_table_attributes(self, attributes)`

Set the table attributes.

These are the items that show up in the opening `<table>` tag in addition to to automatic (by default) id.

Parameters

`attributes` [string]

Returns

`self` [Styler]

Examples

```
>>> df = pd.DataFrame(np.random.randn(10, 4))
>>> df.style.set_table_attributes('class="pure-table"')
# ... <table class="pure-table"> ...
```

pandas.io.formats.style.Styler.set_table_styles

`Styler.set_table_styles(self, table_styles)`

Set the table styles on a Styler.

These are placed in a `<style>` tag before the generated HTML table.

Parameters

table_styles [list] Each individual `table_style` should be a dictionary with `selector` and `props` keys. `selector` should be a CSS selector that the style will be applied to (automatically prefixed by the table's UUID) and `props` should be a list of tuples with (`attribute`, `value`).

Returns

`self` [Styler]

Examples

```
>>> df = pd.DataFrame(np.random.randn(10, 4))
>>> df.style.set_table_styles(
...     [{'selector': 'tr:hover',
...       'props': [('background-color', 'yellow')]}]
... )
```

pandas.io.formats.style.Styler.set_uuid

`Styler.set_uuid(self, uuid)`

Set the uuid for a Styler.

Parameters

uuid [str]

Returns

`self` [Styler]

pandas.io.formats.style.Styler.to_excel

`Styler.to_excel(self, excel_writer, sheet_name='Sheet1', na_rep="", float_format=None, columns=None, header=True, index=True, index_label=None, startrow=0, startcol=0, engine=None, merge_cells=True, encoding=None, inf_rep='inf', verbose=True, freeze_panes=None)`

Write Styler to an Excel sheet.

To write a single Styler to an Excel `.xlsx` file it is only necessary to specify a target file name. To write to multiple sheets it is necessary to create an `ExcelWriter` object with a target file name, and specify a sheet in the file to write to.

Multiple sheets may be written to by specifying unique *sheet_name*. With all data written to the file it is necessary to save the changes. Note that creating an *ExcelWriter* object with a file name that already exists will result in the contents of the existing file being erased.

Parameters

- excel_writer** [str or ExcelWriter object] File path or existing ExcelWriter.
- sheet_name** [str, default 'Sheet1'] Name of sheet which will contain DataFrame.
- na_rep** [str, default ''] Missing data representation.
- float_format** [str, optional] Format string for floating point numbers. For example `float_format="%.2f"` will format 0.1234 to 0.12.
- columns** [sequence or list of str, optional] Columns to write.
- header** [bool or list of str, default True] Write out the column names. If a list of string is given it is assumed to be aliases for the column names.
- index** [bool, default True] Write row names (index).
- index_label** [str or sequence, optional] Column label for index column(s) if desired. If not specified, and *header* and *index* are True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.
- startrow** [int, default 0] Upper left cell row to dump data frame.
- startcol** [int, default 0] Upper left cell column to dump data frame.
- engine** [str, optional] Write engine to use, 'openpyxl' or 'xlsxwriter'. You can also set this via the options `io.excel.xlsx.writer`, `io.excel.xls.writer`, and `io.excel.xlsm.writer`.
- merge_cells** [bool, default True] Write MultiIndex and Hierarchical Rows as merged cells.
- encoding** [str, optional] Encoding of the resulting excel file. Only necessary for xlwt, other writers support unicode natively.
- inf_rep** [str, default 'inf'] Representation for infinity (there is no native representation for infinity in Excel).
- verbose** [bool, default True] Display more information in the error logs.
- freeze_panes** [tuple of int (length 2), optional] Specifies the one-based bottom-most row and rightmost column that is to be frozen.
New in version 0.20.0..

See also:

- to_csv** Write DataFrame to a comma-separated values (csv) file.
- ExcelWriter** Class for writing DataFrame objects into excel sheets.
- read_excel** Read an Excel file into a pandas DataFrame.
- read_csv** Read a comma-separated values (csv) file into DataFrame.

Notes

For compatibility with `to_csv()`, `to_excel` serializes lists and dicts to strings before writing.

Once a workbook has been saved it is not possible write further data without rewriting the whole workbook.

Examples

Create, write to and save a workbook:

```
>>> df1 = pd.DataFrame([[ 'a', 'b'], [ 'c', 'd']],
...                     index=[ 'row 1', 'row 2'],
...                     columns=[ 'col 1', 'col 2'])
>>> df1.to_excel("output.xlsx") # doctest: +SKIP
```

To specify the sheet name:

```
>>> df1.to_excel("output.xlsx",
...              sheet_name='Sheet_name_1') # doctest: +SKIP
```

If you wish to write to more than one sheet in the workbook, it is necessary to specify an `ExcelWriter` object:

```
>>> df2 = df1.copy()
>>> with pd.ExcelWriter('output.xlsx') as writer: # doctest: +SKIP
...     df1.to_excel(writer, sheet_name='Sheet_name_1')
...     df2.to_excel(writer, sheet_name='Sheet_name_2')
```

To set the library that is used to write the Excel file, you can pass the `engine` keyword (the default engine is automatically chosen depending on the file extension):

```
>>> df1.to_excel('output1.xlsx', engine='xlsxwriter') # doctest: +SKIP
```

pandas.io.formats.style.Styler.use

`Styler.use(self, styles)`

Set the styles on the current `Styler`, possibly using styles from `Styler.export`.

Parameters

`styles` [list] list of style functions

Returns

`self` [`Styler`]

See also:

`Styler.export`

pandas.io.formats.style.Styler.where

`Styler.where(self, cond, value, other=None, subset=None, **kwargs)`

Apply a function elementwise, updating the HTML representation with a style which is selected in accordance with the return value of a function.

New in version 0.21.0.

Parameters

- cond** [callable] `cond` should take a scalar and return a boolean
- value** [str] applied when `cond` returns true
- other** [str] applied when `cond` returns false
- subset** [IndexSlice] a valid indexer to limit `data` to *before* applying the function.
Consider using a `pandas.IndexSlice`
- kwargs** [dict] pass along to `cond`

Returns

`self` [Styler]

See also:

`Styler.applymap`

6.13.2 Styler properties

`Styler.env`

`Styler.template`

`Styler.loader`

pandas.io.formats.style.Styler.env

`Styler.env` = < `jinjia2.environment.Environment` object >

pandas.io.formats.style.Styler.template

`Styler.template` = < `Template` 'html.tpl' >

pandas.io.formats.style.Styler.loader

`Styler.loader` = < `jinjia2.loaders.PackageLoader` object >

6.13.3 Style application

<code>Styler.apply(self, func[, axis, subset])</code>	Apply a function column-wise, row-wise, or table-wise, updating the HTML representation with the result.
<code>Styler.applymap(self, func[, subset])</code>	Apply a function elementwise, updating the HTML representation with the result.
<code>Styler.where(self, cond, value[, other, subset])</code>	Apply a function elementwise, updating the HTML representation with a style which is selected in accordance with the return value of a function.
<code>Styler.format(self, formatter[, subset])</code>	Format the text display value of cells.
<code>Styler.set_precision(self, precision)</code>	Set the precision used to render.
<code>Styler.set_table_styles(self, table_styles)</code>	Set the table styles on a Styler.

Continued on next page

Table 404 – continued from previous page

<code>Styler.set_table_attributes(self, attributes)</code>	Set the table attributes.
<code>Styler.set_caption(self, caption)</code>	Set the caption on a Styler
<code>Styler.set_properties(self[, subset])</code>	Convenience method for setting one or more non-data dependent properties or each cell.
<code>Styler.set_uuid(self, uuid)</code>	Set the uuid for a Styler.
<code>Styler.clear(self)</code>	Reset the styler, removing any previously applied styles.
<code>Styler.pipe(self, func, <i>*</i>args, <i>*</i>kwargs)</code>	Apply <code>func(self, *args, **kwargs)</code> , and return the result.

6.13.4 Builtin styles

<code>Styler.highlight_max(self[, subset, color, axis])</code>	Highlight the maximum by shading the background.
<code>Styler.highlight_min(self[, subset, color, axis])</code>	Highlight the minimum by shading the background.
<code>Styler.highlight_null(self[, null_color])</code>	Shade the background <code>null_color</code> for missing values.
<code>Styler.background_gradient(self[, cmap, ...])</code>	Color the background in a gradient according to the data in each column (optionally row).
<code>Styler.bar(self[, subset, axis, color, ...])</code>	Draw bar chart in the cell backgrounds.

6.13.5 Style export and import

<code>Styler.render(self, <i>*</i>kwargs)</code>	Render the built up styles to HTML.
<code>Styler.export(self)</code>	Export the styles to applied to the current Styler.
<code>Styler.use(self, styles)</code>	Set the styles on the current Styler, possibly using styles from <code>Styler.export</code> .
<code>Styler.to_excel(self, excel_writer[, ...])</code>	Write Styler to an Excel sheet.

{{ header }}

6.14 Plotting

The following functions are contained in the `pandas.plotting` module.

<code>andrews_curves(frame, class_column[, ax, ...])</code>	Generate a matplotlib plot of Andrews curves, for visualising clusters of multivariate data.
<code>bootstrap_plot(series[, fig, size, samples])</code>	Bootstrap plot on mean, median and mid-range statistics.
<code>deregister_matplotlib_converters()</code>	Remove pandas' formatters and converters
<code>lag_plot(series[, lag, ax])</code>	Lag plot for time series.
<code>parallel_coordinates(frame, class_column[, ...])</code>	Parallel coordinates plotting.
<code>radviz(frame, class_column[, ax, color, ...])</code>	Plot a multidimensional dataset in 2D.
<code>register_matplotlib_converters([explicit])</code>	Register Pandas Formatters and Converters with matplotlib
<code>scatter_matrix(frame[, alpha, figsize, ax, ...])</code>	Draw a matrix of scatter plots.

6.14.1 pandas.plotting.andrews_curves

`pandas.plotting.andrews_curves`(*frame*, *class_column*, *ax=None*, *samples=200*, *color=None*, *colormap=None*, ***kwargs*)

Generate a matplotlib plot of Andrews curves, for visualising clusters of multivariate data.

Andrews curves have the functional form:

$$f(t) = x_1/\sqrt{2} + x_2 \sin(t) + x_3 \cos(t) + x_4 \sin(2t) + x_5 \cos(2t) + \dots$$

Where *x* coefficients correspond to the values of each dimension and *t* is linearly spaced between $-\pi$ and $+\pi$. Each row of *frame* then corresponds to a single curve.

Parameters

frame [DataFrame] Data to be plotted, preferably normalized to (0.0, 1.0)

class_column [Name of the column containing class names]

ax [matplotlib axes object, default None]

samples [Number of points to plot in each curve]

color [list or tuple, optional] Colors to use for the different classes

colormap [str or matplotlib colormap object, default None] Colormap to select colors from. If string, load colormap with that name from matplotlib.

kwargs [keywords] Options to pass to matplotlib plotting method

Returns

class:*matplotlib.axis.Axes*

6.14.2 pandas.plotting.bootstrap_plot

`pandas.plotting.bootstrap_plot`(*series*, *fig=None*, *size=50*, *samples=500*, ***kwargs*)

Bootstrap plot on mean, median and mid-range statistics.

The bootstrap plot is used to estimate the uncertainty of a statistic by relying on random sampling with replacement [?]. This function will generate bootstrapping plots for mean, median and mid-range statistics for the given number of samples of the given size.

Parameters

series [pandas.Series] Pandas Series from where to get the samplings for the bootstrapping.

fig [matplotlib.figure.Figure, default None] If given, it will use the *fig* reference for plotting instead of creating a new one with default parameters.

size [int, default 50] Number of data points to consider during each sampling. It must be greater or equal than the length of the *series*.

samples [int, default 500] Number of times the bootstrap procedure is performed.

****kwargs** : Options to pass to matplotlib plotting method.

Returns

matplotlib.figure.Figure Matplotlib figure.

See also:

DataFrame.plot Basic plotting for DataFrame objects.

`Series.plot` Basic plotting for Series objects.

Examples

```
>>> s = pd.Series(np.random.uniform(size=100))
>>> fig = pd.plotting.bootstrap_plot(s) # doctest: +SKIP
```

6.14.3 pandas.plotting.deregister_matplotlib_converters

`pandas.plotting.deregister_matplotlib_converters()`

Remove pandas' formatters and converters

Removes the custom converters added by `register()`. This attempts to set the state of the registry back to the state before pandas registered its own units. Converters for pandas' own types like `Timestamp` and `Period` are removed completely. Converters for types pandas overwrites, like `datetime.datetime`, are restored to their original value.

See also:

`deregister_matplotlib_converters`

6.14.4 pandas.plotting.lag_plot

`pandas.plotting.lag_plot(series, lag=1, ax=None, **kwargs)`

Lag plot for time series.

Parameters

`series` [Time series]

`lag` [lag of the scatter plot, default 1]

`ax` [Matplotlib axis object, optional]

`kwargs` [Matplotlib scatter method keyword arguments, optional]

Returns

class:`matplotlib.axis.Axes`

6.14.5 pandas.plotting.parallel_coordinates

`pandas.plotting.parallel_coordinates(frame, class_column, cols=None, ax=None, color=None, use_columns=False, xticks=None, colormap=None, axvlines=True, axvlines_kwargs=None, sort_labels=False, **kwargs)`

Parallel coordinates plotting.

Parameters

`frame` [DataFrame]

`class_column` [str] Column name containing class names

`cols` [list, optional] A list of column names to use

`ax` [matplotlib.axis, optional] matplotlib axis object

color [list or tuple, optional] Colors to use for the different classes

use_columns [bool, optional] If true, columns will be used as xticks

xticks [list or tuple, optional] A list of values to use for xticks

colormap [str or matplotlib colormap, default None] Colormap to use for line colors.

axvlines [bool, optional] If true, vertical lines will be added at each xtick

axvlines_kwds [keywords, optional] Options to be passed to axvline method for vertical lines

sort_labels [bool, False] Sort class_column labels, useful when assigning colors

New in version 0.20.0.

kwds [keywords] Options to pass to matplotlib plotting method

Returns

class: *matplotlib.axis.Axes*

Examples

```
>>> from matplotlib import pyplot as plt
>>> df = pd.read_csv('https://raw.githubusercontent.com/pandas-dev/pandas/master/
                    /pandas/tests/data/iris.csv')
>>> pd.plotting.parallel_coordinates(
    df, 'Name',
    color=('556270', '4ECDC4', 'C7F464'))
>>> plt.show()
```

6.14.6 pandas.plotting.radviz

`pandas.plotting.radviz(frame, class_column, ax=None, color=None, colormap=None, **kwds)`
Plot a multidimensional dataset in 2D.

Each Series in the DataFrame is represented as a evenly distributed slice on a circle. Each data point is rendered in the circle according to the value on each Series. Highly correlated *Series* in the *DataFrame* are placed closer on the unit circle.

RadViz allow to project a N-dimensional data set into a 2D space where the influence of each dimension can be interpreted as a balance between the influence of all dimensions.

More info available at the [original article](#) describing RadViz.

Parameters

frame [*DataFrame*] Pandas object holding the data.

class_column [str] Column name containing the name of the data point category.

ax [*matplotlib.axes.Axes*, optional] A plot instance to which to add the information.

color [list[str] or tuple[str], optional] Assign a color to each category. Example: ['blue', 'green'].

colormap [str or *matplotlib.colors.Colormap*, default None] Colormap to select colors from. If string, load colormap with that name from matplotlib.

kwds [optional] Options to pass to matplotlib scatter plotting method.

Returns

class:*matplotlib.axes.Axes*

See also:

`plotting.andrews_curves` Plot clustering visualization.

Examples

```
>>> df = pd.DataFrame({
...     'SepalLength': [6.5, 7.7, 5.1, 5.8, 7.6, 5.0, 5.4, 4.6,
...                    6.7, 4.6],
...     'SepalWidth': [3.0, 3.8, 3.8, 2.7, 3.0, 2.3, 3.0, 3.2,
...                   3.3, 3.6],
...     'PetalLength': [5.5, 6.7, 1.9, 5.1, 6.6, 3.3, 4.5, 1.4,
...                    5.7, 1.0],
...     'PetalWidth': [1.8, 2.2, 0.4, 1.9, 2.1, 1.0, 1.5, 0.2,
...                   2.1, 0.2],
...     'Category': ['virginica', 'virginica', 'setosa',
...                  'virginica', 'virginica', 'versicolor',
...                  'versicolor', 'setosa', 'virginica',
...                  'setosa']
... })
>>> rad_viz = pd.plotting.radviz(df, 'Category') # doctest: +SKIP
```

6.14.7 pandas.plotting.register_matplotlib_converters

`pandas.plotting.register_matplotlib_converters`(*explicit=True*)

Register Pandas Formatters and Converters with matplotlib

This function modifies the global `matplotlib.units.registry` dictionary. Pandas adds custom converters for

- `pd.Timestamp`
- `pd.Period`
- `np.datetime64`
- `datetime.datetime`
- `datetime.date`
- `datetime.time`

See also:

`deregister_matplotlib_converter`

6.14.8 pandas.plotting.scatter_matrix

`pandas.plotting.scatter_matrix`(*frame*, *alpha*=0.5, *figsize*=None, *ax*=None, *grid*=False, *diagonal*='hist', *marker*='.', *density_kwds*=None, *hist_kwds*=None, *range_padding*=0.05, ***kwds*)

Draw a matrix of scatter plots.

Parameters

- frame** [DataFrame]
- alpha** [float, optional] amount of transparency applied
- figsize** [(float,float), optional] a tuple (width, height) in inches
- ax** [Matplotlib axis object, optional]
- grid** [bool, optional] setting this to True will show the grid
- diagonal** [{'hist', 'kde'}] pick between 'kde' and 'hist' for either Kernel Density Estimation or Histogram plot in the diagonal
- marker** [str, optional] Matplotlib marker type, default '.'
- hist_kwds** [other plotting keyword arguments] To be passed to hist function
- density_kwds** [other plotting keyword arguments] To be passed to kernel density estimate plot
- range_padding** [float, optional] relative extension of axis range in x and y with respect to (x_max - x_min) or (y_max - y_min), default 0.05
- kwds** [other plotting keyword arguments] To be passed to scatter function

Returns

numpy.ndarray A matrix of scatter plots.

Examples

```
>>> df = pd.DataFrame(np.random.randn(1000, 4), columns=['A', 'B', 'C', 'D'])
>>> scatter_matrix(df, alpha=0.2)
```

{{ header }}

6.15 General utility functions

6.15.1 Working with options

<code>describe_option(pat[, _print_desc])</code>	Prints the description for one or more registered options.
<code>reset_option(pat)</code>	Reset one or more options to their default value.
<code>get_option(pat)</code>	Retrieves the value of the specified option.
<code>set_option(pat, value)</code>	Sets the value of the specified option.
<code>option_context(*args)</code>	Context manager to temporarily set options in the <i>with</i> statement context.

pandas.describe_option

`pandas.describe_option(pat, _print_desc=False)` = `<pandas._config.config.CallableDynamicDoc object>`

Prints the description for one or more registered options.

Call with not arguments to get a listing for all registered options.

Available options:

- `compute`.`[use_bottleneck, use_numexpr]`
- `display`.`[chop_threshold, colheader_justify, column_space, date_dayfirst, date_yearfirst, encoding, expand_frame_repr, float_format]`
- `display.html`.`[border, table_schema, use_mathjax]`
- `display`.`[large_repr]`
- `display.latex`.`[escape, longtable, multicolumn, multicolumn_format, multirow, repr]`
- `display`.`[max_categories, max_columns, max_colwidth, max_info_columns, max_info_rows, max_rows, max_seq_items, memory_usage, min_rows, multi_sparse, notebook_repr_html, pprint_nest_depth, precision, show_dimensions]`
- `display.unicode`.`[ambiguous_as_wide, east_asian_width]`
- `display`.`[width]`
- `io.excel.ods`.`[reader]`
- `io.excel.xls`.`[reader, writer]`
- `io.excel.xlsm`.`[reader, writer]`
- `io.excel.xlsx`.`[reader, writer]`
- `io.hdf`.`[default_format, dropna_table]`
- `io.parquet`.`[engine]`
- `mode`.`[chained_assignment, sim_interactive, use_inf_as_na, use_inf_as_null]`
- `plotting`.`[backend]`
- `plotting.matplotlib`.`[register_converters]`

Parameters

pat [str] Regexp pattern. All matching keys will have their description displayed.

__print_desc [bool, default True] If True (default) the description(s) will be printed to stdout. Otherwise, the description(s) will be returned as a unicode string (for testing).

Returns

None by default, the description(s) as a unicode string if `__print_desc` is False

Notes

The available options with its descriptions:

compute.use_bottleneck [bool] Use the bottleneck library to accelerate if it is installed, the default is True Valid values: False,True [default: True] [currently: True]
compute.use_numexpr : bool Use the numexpr library to accelerate computation if it is installed, the default is True Valid values: False,True [default: True] [currently: True]
display.chop_threshold : float or None if set to a float value, all float values smaller then the given threshold will be displayed as exactly 0 by repr and friends. [default: None] [currently: None]
display.colheader_justify : 'left'/'right' Controls the justification of column headers. used by DataFrameFormatter. [default: right] [currently: right]
display.column_space No description available. [default: 12] [currently: 12]
display.date_dayfirst : boolean When True, prints and parses dates with the day first, eg 20/01/2005 [default: False] [currently: False]
display.date_yearfirst : boolean When True, prints and parses dates with the year first, eg 2005/01/20 [default: False] [currently: False]
display.encoding : str/unicode Defaults to the detected encoding of the console. Specifies the encoding to be used for strings returned by to_string, these are generally strings meant to be displayed on the console. [default: UTF-8] [currently: UTF-8]
display.expand_frame_repr : boolean Whether to print out the full DataFrame repr for wide DataFrames across multiple lines, *max_columns* is still respected, but the output will wrap-around across multiple “pages” if its width exceeds *display.width*. [default: True] [currently: True]
display.float_format : callable The callable should accept a floating point number and return a string with the desired format of the number. This is used in some places like SeriesFormatter. See formats.format.EngFormatter for an example. [default: None] [currently: None]
display.html.border : int A `border=value` attribute is inserted in the `<table>` tag for the DataFrame HTML repr. [default: 1] [currently: 1]
display.html.table_schema : boolean Whether to publish a Table Schema representation for frontends that support it. (default: False) [default: False] [currently: False]
display.html.use_mathjax : boolean When True, Jupyter notebook will process table contents using MathJax, rendering mathematical expressions enclosed by the dollar symbol. (default: True) [default: True] [currently: True]
display.large_repr : 'truncate'/'info' For DataFrames exceeding *max_rows*/*max_cols*, the repr (and HTML repr) can show a truncated table (the default from 0.13), or switch to the view from `df.info()` (the behaviour in earlier versions of pandas). [default: truncate] [currently: truncate]
display.latex.escape : bool This specifies if the `to_latex` method of a Dataframe uses escapes special characters. Valid values: False,True [default: True] [currently: True]
display.latex.longtable :bool This specifies if the `to_latex` method of a Dataframe uses the longtable format. Valid values: False,True [default: False] [currently: False]
display.latex.multicolumn : bool This specifies if the `to_latex` method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: True] [currently: True]
display.latex.multicolumn_format : bool This specifies if the `to_latex` method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: 1] [currently: 1]
display.latex.mulirow : bool This specifies if the `to_latex` method of a Dataframe uses multirows to pretty-print MultiIndex rows. Valid values: False,True [default: False] [currently: False]
display.latex.repr : boolean Whether to produce a latex DataFrame representation for jupyter environments that support it. (default: False) [default: False] [currently: False]
display.max_categories : int This sets the maximum number of categories pandas should output when printing out a *Categorical* or a Series of dtype “category”. [default: 8] [currently: 8]
display.max_columns : int If *max_cols* is exceeded, switch to truncate view. Depending on *large_repr*, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and *large_repr* equals ‘truncate’ this can be set to 0 and pandas will auto-detect the width of the terminal and print a truncated object which fits the screen width. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 0] [currently: 0]
display.max_colwidth : int The maximum width in characters of a column in the repr of a pandas data structure. When the column overflows, a “...” placeholder is embedded in the output. [default: 50] [currently: 50]
display.max_info_columns : int *max_info_columns* is used in DataFrame.info method to decide if per column information will be printed. [default: 100]

[currently: 100]display.max_info_rows : int or None df.info() will usually show null-counts for each column. For large frames this can be quite slow. max_info_rows and max_info_cols limit this null check only to frames with smaller dimensions than specified. [default: 1690785] [currently: 1690785]display.max_rows : int If max_rows is exceeded, switch to truncate view. Depending on large_repr, objects are either centrally truncated or printed as a summary view. 'None' value means unlimited.

In case python/IPython is running in a terminal and large_repr equals 'truncate' this can be set to 0 and pandas will auto-detect the height of the terminal and print a truncated object which fits the screen height. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 60] [currently: 60]display.max_seq_items : int or None when pretty-printing a long sequence, no more than max_seq_items will be printed. If items are omitted, they will be denoted by the addition of "..." to the resulting string.

If set to None, the number of items to be printed is unlimited. [default: 100] [currently: 100]display.memory_usage : bool, string or None This specifies if the memory usage of a DataFrame should be displayed when df.info() is called. Valid values True,False,'deep' [default: True] [currently: True]display.min_rows : int The numbers of rows to show in a truncated view (when max_rows is exceeded). Ignored when max_rows is set to None or 0. When set to None, follows the value of max_rows. [default: 10] [currently: 10]display.multi_sparse : boolean "sparsify" MultiIndex display (don't display repeated elements in outer levels within groups) [default: True] [currently: True]display.notebook_repr_html : boolean When True, IPython notebook will use html representation for pandas objects (if it is available). [default: True] [currently: True]display.pprint_nest_depth : int Controls the number of nested levels to process when pretty-printing [default: 3] [currently: 3]display.precision : int Floating point output precision (number of significant digits). This is only a suggestion [default: 6] [currently: 6]display.show_dimensions : boolean or 'truncate' Whether to print out dimensions at the end of DataFrame repr. If 'truncate' is specified, only print out the dimensions if the frame is truncated (e.g. not display all rows and/or columns) [default: truncate] [currently: truncate]display.unicode.ambiguous_as_wide : boolean Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]display.unicode.east_asian_width : boolean Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]display.width : int Width of the display in characters. In case python/IPython is running in a terminal this can be set to None and pandas will correctly auto-detect the width. Note that the IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to correctly detect the width. [default: 80] [currently: 80]io.excel.ods.reader : string The default Excel reader engine for 'ods' files. Available options: auto, odf. [default: auto] [currently: auto]io.excel.xls.reader : string The default Excel reader engine for 'xls' files. Available options: auto, xlrd. [default: auto] [currently: auto]io.excel.xls.writer : string The default Excel writer engine for 'xls' files. Available options: auto, xlwt. [default: auto] [currently: auto]io.excel.xlsm.reader : string The default Excel reader engine for 'xlsm' files. Available options: auto, xlrd, openpyxl. [default: auto] [currently: auto]io.excel.xlsm.writer : string The default Excel writer engine for 'xlsm' files. Available options: auto, openpyxl. [default: auto] [currently: auto]io.excel.xlsx.reader : string The default Excel reader engine for 'xlsx' files. Available options: auto, xlrd, openpyxl. [default: auto] [currently: auto]io.excel.xlsx.writer : string The default Excel writer engine for 'xlsx' files. Available options: auto, openpyxl, xlsxwriter. [default: auto] [currently: auto]io.hdf.default_format : format default format writing format, if None, then put will default to 'fixed' and append will default to 'table' [default: None] [currently: None]io.hdf.dropna_table : boolean drop ALL nan rows when appending to a table [default: False] [currently: False]io.parquet.engine : string The default parquet reader/writer engine. Available options: 'auto', 'pyarrow', 'fastparquet', the default is 'auto' [default: auto] [currently: auto]mode.chained_assignment : string Raise an exception, warn, or no action if trying to use

chained assignment, The default is warn [default: warn] [currently: warn]mode.sim_interactive : boolean Whether to simulate interactive mode for purposes of testing [default: False] [currently: False]mode.use_inf_as_na : boolean True means treat None, NaN, INF, -INF as NA (old way), False means None and NaN are null, but INF, -INF are not NA (new way). [default: False] [currently: False]mode.use_inf_as_null : boolean use_inf_as_null had been deprecated and will be removed in a future version. Use *use_inf_as_na* instead. [default: False] [currently: False] (Deprecated, use *mode.use_inf_as_na* instead.)plotting.backend : str The plotting backend to use. The default value is “matplotlib”, the backend provided with pandas. Other backends can be specified by providing the name of the module that implements the backend. [default: matplotlib] [currently: matplotlib]plotting.matplotlib.register_converters : bool Whether to register converters with matplotlib’s units registry for dates, times, datetimes, and Periods. Toggling to False will remove the converters, restoring any converters that pandas overwrote. [default: True] [currently: True]

pandas.reset_option

`pandas.reset_option(pat) = <pandas._config.config.CallableDynamicDoc object>`

Reset one or more options to their default value.

Pass “all” as argument to reset all options.

Available options:

- compute.[use_bottleneck, use_numexpr]
- display.[chop_threshold, colheader_justify, column_space, date_dayfirst, date_yearfirst, encoding, expand_frame_repr, float_format]
- display.html.[border, table_schema, use_mathjax]
- display.[large_repr]
- display.latex.[escape, longtable, multicolumn, multicolumn_format, multirow, repr]
- display.[max_categories, max_columns, max_colwidth, max_info_columns, max_info_rows, max_rows, max_seq_items, memory_usage, min_rows, multi_sparse, notebook_repr_html, pprint_nest_depth, precision, show_dimensions]
- display.unicode.[ambiguous_as_wide, east_asian_width]
- display.[width]
- io.excel.ods.[reader]
- io.excel.xls.[reader, writer]
- io.excel.xlsm.[reader, writer]
- io.excel.xlsx.[reader, writer]
- io.hdf.[default_format, dropna_table]
- io.parquet.[engine]
- mode.[chained_assignment, sim_interactive, use_inf_as_na, use_inf_as_null]
- plotting.[backend]
- plotting.matplotlib.[register_converters]

Parameters

pat [str/regex] If specified only options matching *prefix** will be reset. Note: partial matches are supported for convenience, but unless you use the full option name (e.g. x.y.z.option_name), your code may break in future versions if new options with similar names are introduced.

Returns

None

Notes

The available options with its descriptions:

compute.use_bottleneck [bool] Use the bottleneck library to accelerate if it is installed, the default is True Valid values: False,True [default: True] [currently: True]
compute.use_numexpr : bool Use the numexpr library to accelerate computation if it is installed, the default is True Valid values: False,True [default: True] [currently: True]
display.chop_threshold : float or None if set to a float value, all float values smaller then the given threshold will be displayed as exactly 0 by repr and friends. [default: None] [currently: None]
display.colheader_justify : 'left'/'right' Controls the justification of column headers. used by DataFrameFormatter. [default: right] [currently: right]
display.column_space No description available. [default: 12] [currently: 12]
display.date_dayfirst : boolean When True, prints and parses dates with the day first, eg 20/01/2005 [default: False] [currently: False]
display.date_yearfirst : boolean When True, prints and parses dates with the year first, eg 2005/01/20 [default: False] [currently: False]
display.encoding : str/unicode Defaults to the detected encoding of the console. Specifies the encoding to be used for strings returned by to_string, these are generally strings meant to be displayed on the console. [default: UTF-8] [currently: UTF-8]
display.expand_frame_repr : boolean Whether to print out the full DataFrame repr for wide DataFrames across multiple lines, *max_columns* is still respected, but the output will wrap-around across multiple “pages” if its width exceeds *display.width*. [default: True] [currently: True]
display.float_format : callable The callable should accept a floating point number and return a string with the desired format of the number. This is used in some places like SeriesFormatter. See formats.format.EngFormatter for an example. [default: None] [currently: None]
display.html.border : int A **border=value** attribute is inserted in the <table> tag for the DataFrame HTML repr. [default: 1] [currently: 1]
display.html.table_schema : boolean Whether to publish a Table Schema representation for frontends that support it. (default: False) [default: False] [currently: False]
display.html.use_mathjax : boolean When True, Jupyter notebook will process table contents using MathJax, rendering mathematical expressions enclosed by the dollar symbol. (default: True) [default: True] [currently: True]
display.large_repr : 'truncate'/'info' For DataFrames exceeding *max_rows*/*max_cols*, the repr (and HTML repr) can show a truncated table (the default from 0.13), or switch to the view from df.info() (the behaviour in earlier versions of pandas). [default: truncate] [currently: truncate]
display.latex.escape : bool This specifies if the to_latex method of a Dataframe uses escapes special characters. Valid values: False,True [default: True] [currently: True]
display.latex.longtable :bool This specifies if the to_latex method of a Dataframe uses the longtable format. Valid values: False,True [default: False] [currently: False]
display.latex.multicolumn : bool This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: True] [currently: True]
display.latex.multicolumn_format : bool This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: 1] [currently: 1]
display.latex.multirow : bool This specifies if the to_latex method of a Dataframe uses multirows to pretty-print MultiIndex rows. Valid values: False,True [default: False] [currently: False]
display.latex.repr : boolean Whether to produce a latex DataFrame representation for jupyter environments that support it. (default: False) [default: False] [currently: False]
display.max_categories : int This sets the maximum number of categories pandas should output when printing out a *Categorical* or a Series of dtype “category”. [default: 8] [currently:

`display.max_columns` : int If `max_cols` is exceeded, switch to truncate view. Depending on `large_repr`, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and `large_repr` equals ‘truncate’ this can be set to 0 and pandas will auto-detect the width of the terminal and print a truncated object which fits the screen width. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 0] [currently: 0]
`display.max_colwidth` : int The maximum width in characters of a column in the repr of a pandas data structure. When the column overflows, a “...” placeholder is embedded in the output. [default: 50] [currently: 50]
`display.max_info_columns` : int `max_info_columns` is used in `DataFrame.info` method to decide if per column information will be printed. [default: 100] [currently: 100]
`display.max_info_rows` : int or None `df.info()` will usually show null-counts for each column. For large frames this can be quite slow. `max_info_rows` and `max_info_cols` limit this null check only to frames with smaller dimensions than specified. [default: 1690785] [currently: 1690785]
`display.max_rows` : int If `max_rows` is exceeded, switch to truncate view. Depending on `large_repr`, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and `large_repr` equals ‘truncate’ this can be set to 0 and pandas will auto-detect the height of the terminal and print a truncated object which fits the screen height. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 60] [currently: 60]
`display.max_seq_items` : int or None when pretty-printing a long sequence, no more than `max_seq_items` will be printed. If items are omitted, they will be denoted by the addition of “...” to the resulting string.

If set to None, the number of items to be printed is unlimited. [default: 100] [currently: 100]
`display.memory_usage` : bool, string or None This specifies if the memory usage of a `DataFrame` should be displayed when `df.info()` is called. Valid values `True, False, 'deep'` [default: `True`] [currently: `True`]
`display.min_rows` : int The numbers of rows to show in a truncated view (when `max_rows` is exceeded). Ignored when `max_rows` is set to None or 0. When set to None, follows the value of `max_rows`. [default: 10] [currently: 10]
`display.multi_sparse` : boolean “sparsify” `MultiIndex` display (don’t display repeated elements in outer levels within groups) [default: `True`] [currently: `True`]
`display.notebook_repr_html` : boolean When `True`, IPython notebook will use html representation for pandas objects (if it is available). [default: `True`] [currently: `True`]
`display.pprint_nest_depth` : int Controls the number of nested levels to process when pretty-printing [default: 3] [currently: 3]
`display.precision` : int Floating point output precision (number of significant digits). This is only a suggestion [default: 6] [currently: 6]
`display.show_dimensions` : boolean or ‘truncate’ Whether to print out dimensions at the end of `DataFrame` repr. If ‘truncate’ is specified, only print out the dimensions if the frame is truncated (e.g. not display all rows and/or columns) [default: `truncate`] [currently: `truncate`]
`display.unicode.ambiguous_as_wide` : boolean Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: `False`) [default: `False`] [currently: `False`]
`display.unicode.east_asian_width` : boolean Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: `False`) [default: `False`] [currently: `False`]
`display.width` : int Width of the display in characters. In case python/IPython is running in a terminal this can be set to None and pandas will correctly auto-detect the width. Note that the IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to correctly detect the width. [default: 80] [currently: 80]
`io.excel.ods.reader` : string The default Excel reader engine for ‘ods’ files. Available options: `auto, odf`. [default: `auto`] [currently: `auto`]
`io.excel.xls.reader` : string The default Excel reader engine for ‘xls’ files. Available options: `auto, xlrd`. [default: `auto`] [currently: `auto`]
`io.excel.xls.writer` : string The default Excel writer engine for ‘xls’ files. Available options: `auto, xlwt`. [default: `auto`] [currently:

`auto]io.excel.xlsm.reader` : string The default Excel reader engine for ‘xlsm’ files. Available options: auto, xlrd, openpyxl. [default: auto] [currently: auto]
`io.excel.xlsm.writer` : string The default Excel writer engine for ‘xlsm’ files. Available options: auto, openpyxl. [default: auto] [currently: auto]
`io.excel.xlsx.reader` : string The default Excel reader engine for ‘xlsx’ files. Available options: auto, xlrd, openpyxl. [default: auto] [currently: auto]
`io.excel.xlsx.writer` : string The default Excel writer engine for ‘xlsx’ files. Available options: auto, openpyxl, xlsxwriter. [default: auto] [currently: auto]
`io.hdf.default_format` : format default format writing format, if None, then put will default to ‘fixed’ and append will default to ‘table’ [default: None] [currently: None]
`io.hdf.dropna_table` : boolean drop ALL nan rows when appending to a table [default: False] [currently: False]
`io.parquet.engine` : string The default parquet reader/writer engine. Available options: ‘auto’, ‘pyarrow’, ‘fastparquet’, the default is ‘auto’ [default: auto] [currently: auto]
`mode.chained_assignment` : string Raise an exception, warn, or no action if trying to use chained assignment, The default is warn [default: warn] [currently: warn]
`mode.sim_interactive` : boolean Whether to simulate interactive mode for purposes of testing [default: False] [currently: False]
`mode.use_inf_as_na` : boolean True means treat None, NaN, INF, -INF as NA (old way), False means None and NaN are null, but INF, -INF are not NA (new way). [default: False] [currently: False]
`mode.use_inf_as_null` : boolean use_inf_as_null had been deprecated and will be removed in a future version. Use `use_inf_as_na` instead. [default: False] [currently: False] (Deprecated, use `mode.use_inf_as_na` instead.)
`plotting.backend` : str The plotting backend to use. The default value is “matplotlib”, the backend provided with pandas. Other backends can be specified by providing the name of the module that implements the backend. [default: matplotlib] [currently: matplotlib]
`plotting.matplotlib.register_converters` : bool Whether to register converters with matplotlib’s units registry for dates, times, datetimes, and Periods. Toggling to False will remove the converters, restoring any converters that pandas overwrote. [default: True] [currently: True]

pandas.get_option

`pandas.get_option(pat) = <pandas._config.config.CallableDynamicDoc object>`

Retrieves the value of the specified option.

Available options:

- `compute.[use_bottleneck, use_numexpr]`
- `display.[chop_threshold, colheader_justify, column_space, date_dayfirst, date_yearfirst, encoding, expand_frame_repr, float_format]`
- `display.html.[border, table_schema, use_mathjax]`
- `display.[large_repr]`
- `display.latex.[escape, longtable, multicolumn, multicolumn_format, multirow, repr]`
- `display.[max_categories, max_columns, max_colwidth, max_info_columns, max_info_rows, max_rows, max_seq_items, memory_usage, min_rows, multi_sparse, notebook_repr_html, pprint_nest_depth, precision, show_dimensions]`
- `display.unicode.[ambiguous_as_wide, east_asian_width]`
- `display.[width]`
- `io.excel.ods.[reader]`
- `io.excel.xls.[reader, writer]`
- `io.excel.xlsm.[reader, writer]`
- `io.excel.xlsx.[reader, writer]`

- `io.hdf.[default_format, dropna_table]`
- `io.parquet.[engine]`
- `mode.[chained_assignment, sim_interactive, use_inf_as_na, use_inf_as_null]`
- `plotting.[backend]`
- `plotting.matplotlib.[register_converters]`

Parameters

pat [str] Regexp which should match a single option. Note: partial matches are supported for convenience, but unless you use the full option name (e.g. `x.y.z.option_name`), your code may break in future versions if new options with similar names are introduced.

Returns

result [the value of the option]

Raises

OptionError [if no such option exists]

Notes

The available options with its descriptions:

compute.use_bottleneck [bool] Use the bottleneck library to accelerate if it is installed, the default is True Valid values: False,True [default: True] [currently: True]
compute.use_numexpr : bool Use the numexpr library to accelerate computation if it is installed, the default is True Valid values: False,True [default: True] [currently: True]
display.chop_threshold : float or None if set to a float value, all float values smaller then the given threshold will be displayed as exactly 0 by repr and friends. [default: None] [currently: None]
display.colheader_justify : 'left'/'right' Controls the justification of column headers. used by DataFrameFormatter. [default: right] [currently: right]
display.column_space No description available. [default: 12] [currently: 12]
display.date_dayfirst : boolean When True, prints and parses dates with the day first, eg 20/01/2005 [default: False] [currently: False]
display.date_yearfirst : boolean When True, prints and parses dates with the year first, eg 2005/01/20 [default: False] [currently: False]
display.encoding : str/unicode Defaults to the detected encoding of the console. Specifies the encoding to be used for strings returned by `to_string`, these are generally strings meant to be displayed on the console. [default: UTF-8] [currently: UTF-8]
display.expand_frame_repr : boolean Whether to print out the full DataFrame repr for wide DataFrames across multiple lines, `max_columns` is still respected, but the output will wrap-around across multiple "pages" if its width exceeds `display.width`. [default: True] [currently: True]
display.float_format : callable The callable should accept a floating point number and return a string with the desired format of the number. This is used in some places like SeriesFormatter. See `formats.format.EngFormatter` for an example. [default: None] [currently: None]
display.html.border : int A `border=value` attribute is inserted in the `<table>` tag for the DataFrame HTML repr. [default: 1] [currently: 1]
display.html.table_schema : boolean Whether to publish a Table Schema representation for frontends that support it. (default: False) [default: False] [currently: False]
display.html.use_mathjax : boolean When True, Jupyter notebook will process table contents using MathJax, rendering mathematical expressions enclosed by the dollar symbol. (default: True) [default: True] [currently: True]
display.large_repr : 'truncate'/'info' For DataFrames exceeding `max_rows`/`max_cols`, the repr (and HTML repr) can show a truncated table (the default from 0.13), or switch to the view from `df.info()` (the behaviour in earlier versions of pandas). [default: truncate] [currently: truncate]
display.latex.escape : bool This specifies if

the `to_latex` method of a DataFrame uses escapes special characters. Valid values: `False, True` [default: `True`] [currently: `True`]`display.latex.longtable` : bool This specifies if the `to_latex` method of a DataFrame uses the `longtable` format. Valid values: `False, True` [default: `False`] [currently: `False`]`display.latex.multicolumn` : bool This specifies if the `to_latex` method of a DataFrame uses `multicolumns` to pretty-print `MultiIndex` columns. Valid values: `False, True` [default: `True`] [currently: `True`]`display.latex.multicolumn_format` : bool This specifies if the `to_latex` method of a DataFrame uses `multicolumns` to pretty-print `MultiIndex` columns. Valid values: `False, True` [default: `1`] [currently: `1`]`display.latex.multirow` : bool This specifies if the `to_latex` method of a DataFrame uses `multirows` to pretty-print `MultiIndex` rows. Valid values: `False, True` [default: `False`] [currently: `False`]`display.latex.repr` : boolean Whether to produce a latex DataFrame representation for jupyter environments that support it. (default: `False`) [default: `False`] [currently: `False`]`display.max_categories` : int This sets the maximum number of categories pandas should output when printing out a *Categorical* or a Series of dtype “category”. [default: `8`] [currently: `8`]`display.max_columns` : int If `max_cols` is exceeded, switch to truncate view. Depending on *large_repr*, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and *large_repr* equals ‘truncate’ this can be set to 0 and pandas will auto-detect the width of the terminal and print a truncated object which fits the screen width. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: `0`] [currently: `0`]`display.max_colwidth` : int The maximum width in characters of a column in the repr of a pandas data structure. When the column overflows, a “...” placeholder is embedded in the output. [default: `50`] [currently: `50`]`display.max_info_columns` : int `max_info_columns` is used in `DataFrame.info` method to decide if per column information will be printed. [default: `100`] [currently: `100`]`display.max_info_rows` : int or None `df.info()` will usually show null-counts for each column. For large frames this can be quite slow. `max_info_rows` and `max_info_cols` limit this null check only to frames with smaller dimensions than specified. [default: `1690785`] [currently: `1690785`]`display.max_rows` : int If `max_rows` is exceeded, switch to truncate view. Depending on *large_repr*, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and *large_repr* equals ‘truncate’ this can be set to 0 and pandas will auto-detect the height of the terminal and print a truncated object which fits the screen height. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: `60`] [currently: `60`]`display.max_seq_items` : int or None when pretty-printing a long sequence, no more than *max_seq_items* will be printed. If items are omitted, they will be denoted by the addition of “...” to the resulting string.

If set to None, the number of items to be printed is unlimited. [default: `100`] [currently: `100`]`display.memory_usage` : bool, string or None This specifies if the memory usage of a DataFrame should be displayed when `df.info()` is called. Valid values `True, False, 'deep'` [default: `True`] [currently: `True`]`display.min_rows` : int The numbers of rows to show in a truncated view (when *max_rows* is exceeded). Ignored when *max_rows* is set to None or 0. When set to None, follows the value of *max_rows*. [default: `10`] [currently: `10`]`display.multi_sparse` : boolean “sparsify” `MultiIndex` display (don’t display repeated elements in outer levels within groups) [default: `True`] [currently: `True`]`display.notebook_repr_html` : boolean When True, IPython notebook will use html representation for pandas objects (if it is available). [default: `True`] [currently: `True`]`display.pprint_nest_depth` : int Controls the number of nested levels to process when pretty-printing [default: `3`] [currently: `3`]`display.precision` : int Floating point output precision (number of significant digits). This is only a suggestion [default: `6`] [currently: `6`]`display.show_dimensions` : boolean or ‘truncate’ Whether to print out dimensions at the end of DataFrame repr. If ‘truncate’ is specified, only print out the dimensions if the frame is truncated (e.g. not display all rows and/or columns) [default: `truncate`] [currently: `trun-`

`display.unicode.ambiguous_as_wide` : boolean Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]
`display.unicode.east_asian_width` : boolean Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]
`display.width` : int Width of the display in characters. In case python/IPython is running in a terminal this can be set to None and pandas will correctly auto-detect the width. Note that the IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to correctly detect the width. [default: 80] [currently: 80]
`io.excel.ods.reader` : string The default Excel reader engine for ‘ods’ files. Available options: auto, odf. [default: auto] [currently: auto]
`io.excel.xls.reader` : string The default Excel reader engine for ‘xls’ files. Available options: auto, xlrd. [default: auto] [currently: auto]
`io.excel.xls.writer` : string The default Excel writer engine for ‘xls’ files. Available options: auto, xlwt. [default: auto] [currently: auto]
`io.excel.xlsm.reader` : string The default Excel reader engine for ‘xlsm’ files. Available options: auto, xlrd, openpyxl. [default: auto] [currently: auto]
`io.excel.xlsm.writer` : string The default Excel writer engine for ‘xlsm’ files. Available options: auto, openpyxl. [default: auto] [currently: auto]
`io.excel.xlsx.reader` : string The default Excel reader engine for ‘xlsx’ files. Available options: auto, xlrd, openpyxl. [default: auto] [currently: auto]
`io.excel.xlsx.writer` : string The default Excel writer engine for ‘xlsx’ files. Available options: auto, openpyxl, xlsxwriter. [default: auto] [currently: auto]
`io.hdf.default_format` : format default format writing format, if None, then put will default to ‘fixed’ and append will default to ‘table’ [default: None] [currently: None]
`io.hdf.dropna_table` : boolean drop ALL nan rows when appending to a table [default: False] [currently: False]
`io.parquet.engine` : string The default parquet reader/writer engine. Available options: ‘auto’, ‘pyarrow’, ‘fastparquet’, the default is ‘auto’ [default: auto] [currently: auto]
`mode.chained_assignment` : string Raise an exception, warn, or no action if trying to use chained assignment, The default is warn [default: warn] [currently: warn]
`mode.sim_interactive` : boolean Whether to simulate interactive mode for purposes of testing [default: False] [currently: False]
`mode.use_inf_as_na` : boolean True means treat None, NaN, INF, -INF as NA (old way), False means None and NaN are null, but INF, -INF are not NA (new way). [default: False] [currently: False]
`mode.use_inf_as_null` : boolean use_inf_as_null had been deprecated and will be removed in a future version. Use `use_inf_as_na` instead. [default: False] [currently: False] (Deprecated, use `mode.use_inf_as_na` instead.)
`plotting.backend` : str The plotting backend to use. The default value is “matplotlib”, the backend provided with pandas. Other backends can be specified by providing the name of the module that implements the backend. [default: matplotlib] [currently: matplotlib]
`plotting.matplotlib.register_converters` : bool Whether to register converters with matplotlib’s units registry for dates, times, datetimes, and Periods. Toggling to False will remove the converters, restoring any converters that pandas overwrote. [default: True] [currently: True]

pandas.set_option

`pandas.set_option(pat, value) = <pandas._config.config.CallableDynamicDoc object>`

Sets the value of the specified option.

Available options:

- `compute.[use_bottleneck, use_numexpr]`
- `display.[chop_threshold, colheader_justify, column_space, date_dayfirst, date_yearfirst, encoding, expand_frame_repr, float_format]`
- `display.html.[border, table_schema, use_mathjax]`
- `display.[large_repr]`
- `display.latex.[escape, longtable, multicolumn, multicolumn_format, multirow, repr]`

- `display.[max_categories, max_columns, max_colwidth, max_info_columns, max_info_rows, max_rows, max_seq_items, memory_usage, min_rows, multi_sparse, notebook_repr_html, pprint_nest_depth, precision, show_dimensions]`
- `display.unicode.[ambiguous_as_wide, east_asian_width]`
- `display.[width]`
- `io.excel.ods.[reader]`
- `io.excel.xls.[reader, writer]`
- `io.excel.xlsm.[reader, writer]`
- `io.excel.xlsx.[reader, writer]`
- `io.hdf.[default_format, dropna_table]`
- `io.parquet.[engine]`
- `mode.[chained_assignment, sim_interactive, use_inf_as_na, use_inf_as_null]`
- `plotting.[backend]`
- `plotting.matplotlib.[register_converters]`

Parameters

pat [str] Regexp which should match a single option. Note: partial matches are supported for convenience, but unless you use the full option name (e.g. `x.y.z.option_name`), your code may break in future versions if new options with similar names are introduced.

value [object] New value of option.

Returns

None

Raises

OptionError if no such option exists

Notes

The available options with its descriptions:

compute.use_bottleneck [bool] Use the bottleneck library to accelerate if it is installed, the default is True Valid values: False,True [default: True] [currently: True]
compute.use_numexpr : bool Use the numexpr library to accelerate computation if it is installed, the default is True Valid values: False,True [default: True] [currently: True]
display.chop_threshold : float or None if set to a float value, all float values smaller then the given threshold will be displayed as exactly 0 by repr and friends. [default: None] [currently: None]
display.colheader_justify : 'left'/'right' Controls the justification of column headers. used by DataFrameFormatter. [default: right] [currently: right]
display.column_space No description available. [default: 12] [currently: 12]
display.date_dayfirst : boolean When True, prints and parses dates with the day first, eg 20/01/2005 [default: False] [currently: False]
display.date_yearfirst : boolean When True, prints and parses dates with the year first, eg 2005/01/20 [default: False] [currently: False]
display.encoding : str/unicode Defaults to the detected encoding of the console. Specifies the encoding to be used for strings returned by `to_string`, these are generally strings meant to be displayed on the console. [default: UTF-8] [currently: UTF-8]
display.expand_frame_repr

: boolean Whether to print out the full DataFrame repr for wide DataFrames across multiple lines, *max_columns* is still respected, but the output will wrap-around across multiple “pages” if its width exceeds *display.width*. [default: True] [currently: True]*display.float_format*: callable The callable should accept a floating point number and return a string with the desired format of the number. This is used in some places like SeriesFormatter. See `formats.format.EngFormatter` for an example. [default: None] [currently: None]*display.html.border*: int A `border=value` attribute is inserted in the `<table>` tag for the DataFrame HTML repr. [default: 1] [currently: 1]*display.html.table_schema*: boolean Whether to publish a Table Schema representation for frontends that support it. (default: False) [default: False] [currently: False]*display.html.use_mathjax*: boolean When True, Jupyter notebook will process table contents using MathJax, rendering mathematical expressions enclosed by the dollar symbol. (default: True) [default: True] [currently: True]*display.large_repr*: ‘truncate’/’info’ For DataFrames exceeding *max_rows*/*max_cols*, the repr (and HTML repr) can show a truncated table (the default from 0.13), or switch to the view from `df.info()` (the behaviour in earlier versions of pandas). [default: truncate] [currently: truncate]*display.latex.escape*: bool This specifies if the `to_latex` method of a Dataframe uses escapes special characters. Valid values: False, True [default: True] [currently: True]*display.latex.longtable*: bool This specifies if the `to_latex` method of a Dataframe uses the `longtable` format. Valid values: False, True [default: False] [currently: False]*display.latex.multicolumn*: bool This specifies if the `to_latex` method of a Dataframe uses `multicolumns` to pretty-print MultiIndex columns. Valid values: False, True [default: True] [currently: True]*display.latex.multicolumn_format*: bool This specifies if the `to_latex` method of a Dataframe uses `multicolumns` to pretty-print MultiIndex columns. Valid values: False, True [default: 1] [currently: 1]*display.latex.multirow*: bool This specifies if the `to_latex` method of a Dataframe uses `multirows` to pretty-print MultiIndex rows. Valid values: False, True [default: False] [currently: False]*display.latex.repr*: boolean Whether to produce a latex DataFrame representation for jupyter environments that support it. (default: False) [default: False] [currently: False]*display.max_categories*: int This sets the maximum number of categories pandas should output when printing out a *Categorical* or a Series of dtype “category”. [default: 8] [currently: 8]*display.max_columns*: int If *max_cols* is exceeded, switch to truncate view. Depending on *large_repr*, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and *large_repr* equals ‘truncate’ this can be set to 0 and pandas will auto-detect the width of the terminal and print a truncated object which fits the screen width. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 0] [currently: 0]*display.max_colwidth*: int The maximum width in characters of a column in the repr of a pandas data structure. When the column overflows, a “...” placeholder is embedded in the output. [default: 50] [currently: 50]*display.max_info_columns*: int *max_info_columns* is used in `DataFrame.info` method to decide if per column information will be printed. [default: 100] [currently: 100]*display.max_info_rows*: int or None `df.info()` will usually show null-counts for each column. For large frames this can be quite slow. *max_info_rows* and *max_info_cols* limit this null check only to frames with smaller dimensions than specified. [default: 1690785] [currently: 1690785]*display.max_rows*: int If *max_rows* is exceeded, switch to truncate view. Depending on *large_repr*, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and *large_repr* equals ‘truncate’ this can be set to 0 and pandas will auto-detect the height of the terminal and print a truncated object which fits the screen height. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 60] [currently: 60]*display.max_seq_items*: int or None when pretty-printing a long sequence, no more than *max_seq_items* will be printed. If items are omitted, they will be denoted by the addition of “...” to the resulting string.

If set to None, the number of items to be printed is unlimited. [default: 100] [currently: 100]

`display.memory_usage` : bool, string or None This specifies if the memory usage of a DataFrame should be displayed when `df.info()` is called. Valid values True, False, 'deep' [default: True] [currently: True]

`display.min_rows` : int The numbers of rows to show in a truncated view (when `max_rows` is exceeded). Ignored when `max_rows` is set to None or 0. When set to None, follows the value of `max_rows`. [default: 10] [currently: 10]

`display.multi_sparse` : boolean “sparsify” MultiIndex display (don’t display repeated elements in outer levels within groups) [default: True] [currently: True]

`display.notebook_repr_html` : boolean When True, IPython notebook will use html representation for pandas objects (if it is available). [default: True] [currently: True]

`display.pprint_nest_depth` : int Controls the number of nested levels to process when pretty-printing [default: 3] [currently: 3]

`display.precision` : int Floating point output precision (number of significant digits). This is only a suggestion [default: 6] [currently: 6]

`display.show_dimensions` : boolean or ‘truncate’ Whether to print out dimensions at the end of DataFrame repr. If ‘truncate’ is specified, only print out the dimensions if the frame is truncated (e.g. not display all rows and/or columns) [default: truncate] [currently: truncate]

`display.unicode.ambiguous_as_wide` : boolean Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]

`display.unicode.east_asian_width` : boolean Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]

`display.width` : int Width of the display in characters. In case python/IPython is running in a terminal this can be set to None and pandas will correctly auto-detect the width. Note that the IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to correctly detect the width. [default: 80] [currently: 80]

`io.excel.ods.reader` : string The default Excel reader engine for ‘ods’ files. Available options: auto, odf. [default: auto] [currently: auto]

`io.excel.xls.reader` : string The default Excel reader engine for ‘xls’ files. Available options: auto, xlrd. [default: auto] [currently: auto]

`io.excel.xls.writer` : string The default Excel writer engine for ‘xls’ files. Available options: auto, xlwt. [default: auto] [currently: auto]

`io.excel.xlsm.reader` : string The default Excel reader engine for ‘xlsm’ files. Available options: auto, xlrd, openpyxl. [default: auto] [currently: auto]

`io.excel.xlsm.writer` : string The default Excel writer engine for ‘xlsm’ files. Available options: auto, openpyxl. [default: auto] [currently: auto]

`io.excel.xlsx.reader` : string The default Excel reader engine for ‘xlsx’ files. Available options: auto, xlrd, openpyxl. [default: auto] [currently: auto]

`io.excel.xlsx.writer` : string The default Excel writer engine for ‘xlsx’ files. Available options: auto, openpyxl, xlsxwriter. [default: auto] [currently: auto]

`io.hdf.default_format` : format default format writing format, if None, then put will default to ‘fixed’ and append will default to ‘table’ [default: None] [currently: None]

`io.hdf.dropna_table` : boolean drop ALL nan rows when appending to a table [default: False] [currently: False]

`io.parquet.engine` : string The default parquet reader/writer engine. Available options: ‘auto’, ‘pyarrow’, ‘fastparquet’, the default is ‘auto’ [default: auto] [currently: auto]

`mode.chained_assignment` : string Raise an exception, warn, or no action if trying to use chained assignment, The default is warn [default: warn] [currently: warn]

`mode.sim_interactive` : boolean Whether to simulate interactive mode for purposes of testing [default: False] [currently: False]

`mode.use_inf_as_na` : boolean True means treat None, NaN, INF, -INF as NA (old way), False means None and NaN are null, but INF, -INF are not NA (new way). [default: False] [currently: False]

`mode.use_inf_as_null` : boolean `use_inf_as_null` had been deprecated and will be removed in a future version. Use `use_inf_as_na` instead. [default: False] [currently: False] (Deprecated, use `mode.use_inf_as_na` instead.)

`plotting.backend` : str The plotting backend to use. The default value is “matplotlib”, the backend provided with pandas. Other backends can be specified by providing the name of the module that implements the backend. [default: matplotlib] [currently: matplotlib]

`plotting.matplotlib.register_converters` : bool Whether to register converters with matplotlib’s units registry for dates, times, datetimes, and Periods. Toggling to False will remove the converters, restoring any converters that pandas overwrote. [default: True] [currently: True]

pandas.option_context

```
class pandas.option_context(*args)
```

Context manager to temporarily set options in the *with* statement context.

You need to invoke as `option_context(pat, val, [(pat, val), ...])`.

Examples

```
>>> with option_context('display.max_rows', 10, 'display.max_columns', 5):
...     ...
```

6.15.2 Testing functions

<code>testing.assert_frame_equal(left, right[, ...])</code>	Check that left and right DataFrame are equal.
<code>testing.assert_series_equal(left, right[, ...])</code>	Check that left and right Series are equal.
<code>testing.assert_index_equal(left, right, ...)</code>	Check that left and right Index are equal.

pandas.testing.assert_frame_equal

```
pandas.testing.assert_frame_equal(left, right, check_dtype=True, check_index_type='equiv',
                                  check_column_type='equiv', check_frame_type=True,
                                  check_less_precise=False, check_names=True,
                                  by_blocks=False, check_exact=False,
                                  check_datetimelike_compat=False, check_categorical=True,
                                  check_like=False, obj='DataFrame')
```

Check that left and right DataFrame are equal.

This function is intended to compare two DataFrames and output any differences. Is is mostly intended for use in unit tests. Additional parameters allow varying the strictness of the equality checks performed.

Parameters

left [DataFrame] First DataFrame to compare.

right [DataFrame] Second DataFrame to compare.

check_dtype [bool, default True] Whether to check the DataFrame dtype is identical.

check_index_type [bool / string {'equiv'}, default 'equiv'] Whether to check the Index class, dtype and `inferred_type` are identical.

check_column_type [bool / string {'equiv'}, default 'equiv'] Whether to check the columns class, dtype and `inferred_type` are identical. Is passed as the `exact` argument of `assert_index_equal()`.

check_frame_type [bool, default True] Whether to check the DataFrame class is identical.

check_less_precise [bool or int, default False] Specify comparison precision. Only used when `check_exact` is False. 5 digits (False) or 3 digits (True) after decimal points are compared. If int, then specify the digits to compare.

When comparing two numbers, if the first number has magnitude less than $1e-5$, we compare the two numbers directly and check whether they are equivalent within the specified precision. Otherwise, we compare the **ratio** of the second number to the first number and check whether it is equivalent to 1 within the specified precision.

check_names [bool, default True] Whether to check that the *names* attribute for both the *index* and *column* attributes of the DataFrame is identical, i.e.

- `left.index.names == right.index.names`
- `left.columns.names == right.columns.names`

by_blocks [bool, default False] Specify how to compare internal data. If False, compare by columns. If True, compare by blocks.

check_exact [bool, default False] Whether to compare number exactly.

check_datetimelike_compat [bool, default False] Compare datetime-like which is comparable ignoring dtype.

check_categorical [bool, default True] Whether to compare internal Categorical exactly.

check_like [bool, default False] If True, ignore the order of index & columns. Note: index labels must match their respective rows (same as in columns) - same labels must be with the same data.

obj [str, default 'DataFrame'] Specify object name being compared, internally used to show appropriate assertion message.

See also:

assert_series_equal Equivalent method for asserting Series equality.

DataFrame.equals Check DataFrame equality.

Examples

This example shows comparing two DataFrames that are equal but with columns of differing dtypes.

```
>>> from pandas.util.testing import assert_frame_equal
>>> df1 = pd.DataFrame({'a': [1, 2], 'b': [3, 4]})
>>> df2 = pd.DataFrame({'a': [1, 2], 'b': [3.0, 4.0]})
```

df1 equals itself.

```
>>> assert_frame_equal(df1, df1)
```

df1 differs from df2 as column 'b' is of a different type.

```
>>> assert_frame_equal(df1, df2)
Traceback (most recent call last):
AssertionError: Attributes are different
...
Attribute "dtype" are different
[left]: int64
[right]: float64
```

Ignore differing dtypes in columns with `check_dtype`.

```
>>> assert_frame_equal(df1, df2, check_dtype=False)
```

pandas.testing.assert_series_equal

```
pandas.testing.assert_series_equal(left, right, check_dtype=True, check_index_type='equiv',
                                   check_series_type=True, check_less_precise=False,
                                   check_names=True, check_exact=False,
                                   check_datetimelike_compat=False,
                                   check_categorical=True, obj='Series')
```

Check that left and right Series are equal.

Parameters

left [Series]

right [Series]

check_dtype [bool, default True] Whether to check the Series dtype is identical.

check_index_type [bool / string {'equiv'}, default 'equiv'] Whether to check the Index class, dtype and `inferred_type` are identical.

check_series_type [bool, default True] Whether to check the Series class is identical.

check_less_precise [bool or int, default False] Specify comparison precision. Only used when `check_exact` is False. 5 digits (False) or 3 digits (True) after decimal points are compared. If int, then specify the digits to compare.

When comparing two numbers, if the first number has magnitude less than $1e-5$, we compare the two numbers directly and check whether they are equivalent within the specified precision. Otherwise, we compare the **ratio** of the second number to the first number and check whether it is equivalent to 1 within the specified precision.

check_names [bool, default True] Whether to check the Series and Index names attribute.

check_exact [bool, default False] Whether to compare number exactly.

check_datetimelike_compat [bool, default False] Compare datetime-like which is comparable ignoring dtype.

check_categorical [bool, default True] Whether to compare internal Categorical exactly.

obj [str, default 'Series'] Specify object name being compared, internally used to show appropriate assertion message.

pandas.testing.assert_index_equal

```
pandas.testing.assert_index_equal(left: pandas.core.indexes.base.Index, right: pandas.core.indexes.base.Index, exact: Union[bool, str] = 'equiv',
                                   check_names: bool = True, check_less_precise: Union[bool, int] = False, check_exact: bool = True, check_categorical: bool = True, obj: str = 'Index') → None
```

Check that left and right Index are equal.

Parameters

left [Index]

right [Index]

exact [bool / string {'equiv'}, default 'equiv'] Whether to check the Index class, dtype and `inferred_type` are identical. If 'equiv', then `RangeIndex` can be substituted for `Int64Index` as well.

check_names [bool, default True] Whether to check the names attribute.

check_less_precise [bool or int, default False] Specify comparison precision. Only used when `check_exact` is False. 5 digits (False) or 3 digits (True) after decimal points are compared. If int, then specify the digits to compare

check_exact [bool, default True] Whether to compare number exactly.

check_categorical [bool, default True] Whether to compare internal Categorical exactly.

obj [str, default 'Index'] Specify object name being compared, internally used to show appropriate assertion message

6.15.3 Exceptions and warnings

<code>errors.DtypeWarning</code>	Warning raised when reading different dtypes in a column from a file.
<code>errors.EmptyDataError</code>	Exception that is thrown in <code>pd.read_csv</code> (by both the C and Python engines) when empty data or header is encountered.
<code>errors.OutOfBoundsDatetime</code>	
<code>errors.ParserError</code>	Exception that is raised by an error encountered in parsing file contents.
<code>errors.ParserWarning</code>	Warning raised when reading a file that doesn't use the default 'c' parser.
<code>errors.PerformanceWarning</code>	Warning raised when there is a possible performance impact.
<code>errors.UnsortedIndexError</code>	Error raised when attempting to get a slice of a <code>MultiIndex</code> , and the index has not been lexsorted.
<code>errors.UnsupportedFunctionCall</code>	Exception raised when attempting to call a numpy function on a pandas object, but that function is not supported by the object e.g.

pandas.errors.DtypeWarning

exception `pandas.errors.DtypeWarning`

Warning raised when reading different dtypes in a column from a file.

Raised for a dtype incompatibility. This can happen whenever `read_csv` or `read_table` encounter non-uniform dtypes in a column(s) of a given CSV file.

See also:

`read_csv` Read CSV (comma-separated) file into a `DataFrame`.

`read_table` Read general delimited file into a `DataFrame`.

Notes

This warning is issued when dealing with larger files because the dtype checking happens per chunk read.

Despite the warning, the CSV file is read with mixed types in a single column which will be an object type. See the examples below to better understand this issue.

Examples

This example creates and reads a large CSV file with a column that contains *int* and *str*.

```
>>> df = pd.DataFrame({'a': ([ '1' ] * 100000 + [ 'X' ] * 100000 +
...                          [ '1' ] * 100000),
...                    'b': [ 'b' ] * 300000})
>>> df.to_csv('test.csv', index=False)
>>> df2 = pd.read_csv('test.csv')
... # DtypeWarning: Columns (0) have mixed types
```

Important to notice that `df2` will contain both *str* and *int* for the same input, '1'.

```
>>> df2.iloc[262140, 0]
'1'
>>> type(df2.iloc[262140, 0])
<class 'str'>
>>> df2.iloc[262150, 0]
1
>>> type(df2.iloc[262150, 0])
<class 'int'>
```

One way to solve this issue is using the *dtype* parameter in the `read_csv` and `read_table` functions to explicit the conversion:

```
>>> df2 = pd.read_csv('test.csv', sep=',', dtype={'a': str})
```

No warning was issued.

```
>>> import os
>>> os.remove('test.csv')
```

pandas.errors.EmptyDataError

exception pandas.errors.EmptyDataError

Exception that is thrown in `pd.read_csv` (by both the C and Python engines) when empty data or header is encountered.

pandas.errors.OutOfBoundsDatetime

exception pandas.errors.OutOfBoundsDatetime

pandas.errors.ParserError

exception pandas.errors.ParserError

Exception that is raised by an error encountered in parsing file contents.

This is a generic error raised for errors encountered when functions like `read_csv` or `read_html` are parsing contents of a file.

See also:

`read_csv` Read CSV (comma-separated) file into a DataFrame.

`read_html` Read HTML table into a DataFrame.

pandas.errors.ParserWarning

exception pandas.errors.ParserWarning

Warning raised when reading a file that doesn't use the default 'c' parser.

Raised by `pd.read_csv` and `pd.read_table` when it is necessary to change parsers, generally from the default 'c' parser to 'python'.

It happens due to a lack of support or functionality for parsing a particular attribute of a CSV file with the requested engine.

Currently, 'c' unsupported options include the following parameters:

1. `sep` other than a single character (e.g. regex separators)
2. `skipfooter` higher than 0
3. `sep=None` with `delim_whitespace=False`

The warning can be avoided by adding `engine='python'` as a parameter in `pd.read_csv` and `pd.read_table` methods.

See also:

`pd.read_csv` Read CSV (comma-separated) file into DataFrame.

`pd.read_table` Read general delimited file into DataFrame.

Examples

Using a `sep` in `pd.read_csv` other than a single character:

```
>>> import io
>>> csv = '''a;b;c
...      1;1,8
...      1;2,1'''
>>> df = pd.read_csv(io.StringIO(csv), sep='[;,]') # doctest: +SKIP
... # ParserWarning: Falling back to the 'python' engine...
```

Adding `engine='python'` to `pd.read_csv` removes the Warning:

```
>>> df = pd.read_csv(io.StringIO(csv), sep='[;,]', engine='python')
```

pandas.errors.PerformanceWarning**exception pandas.errors.PerformanceWarning**

Warning raised when there is a possible performance impact.

pandas.errors.UnsortedIndexError**exception pandas.errors.UnsortedIndexError**

Error raised when attempting to get a slice of a MultiIndex, and the index has not been lexsorted. Subclass of *KeyError*.

New in version 0.20.0.

pandas.errors.UnsupportedFunctionCall**exception pandas.errors.UnsupportedFunctionCall**

Exception raised when attempting to call a numpy function on a pandas object, but that function is not supported by the object e.g. `np.cumsum(groupby_object)`.

6.15.4 Data types related functionality

<code>api.types.union_categoricals(to_union[, ...])</code>	Combine list-like of Categorical-like, unioning categories.
<code>api.types.infer_dtype()</code>	Efficiently infer the type of a passed val, or list-like array of values.
<code>api.types.pandas_dtype(dtype)</code>	Convert input into a pandas only dtype object or a numpy dtype object.

pandas.api.types.union_categoricals**pandas.api.types.union_categoricals(to_union, sort_categories=False, ignore_order=False)**

Combine list-like of Categorical-like, unioning categories. All categories must have the same dtype.

New in version 0.19.0.

Parameters

to_union [list-like of Categorical, CategoricalIndex,] or Series with dtype='category'

sort_categories [boolean, default False] If true, resulting categories will be lexsorted, otherwise they will be ordered as they appear in the data.

ignore_order [boolean, default False] If true, the ordered attribute of the Categoricals will be ignored. Results in an unordered categorical.

New in version 0.20.0.

Returns

result [Categorical]

Raises**TypeError**

- all inputs do not have the same dtype

- all inputs do not have the same ordered property
- all inputs are ordered and their categories are not identical
- `sort_categories=True` and `Categoricals` are ordered

ValueError Empty list of categoricals passed

Notes

To learn more about categories, see [link](#)

Examples

```
>>> from pandas.api.types import union_categoricals
```

If you want to combine categoricals that do not necessarily have the same categories, `union_categoricals` will combine a list-like of categoricals. The new categories will be the union of the categories being combined.

```
>>> a = pd.Categorical(["b", "c"])
>>> b = pd.Categorical(["a", "b"])
>>> union_categoricals([a, b])
[b, c, a, b]
Categories (3, object): [b, c, a]
```

By default, the resulting categories will be ordered as they appear in the `categories` of the data. If you want the categories to be lexsorted, use `sort_categories=True` argument.

```
>>> union_categoricals([a, b], sort_categories=True)
[b, c, a, b]
Categories (3, object): [a, b, c]
```

`union_categoricals` also works with the case of combining two categoricals of the same categories and order information (e.g. what you could also `append` for).

```
>>> a = pd.Categorical(["a", "b"], ordered=True)
>>> b = pd.Categorical(["a", "b", "a"], ordered=True)
>>> union_categoricals([a, b])
[a, b, a, b, a]
Categories (2, object): [a < b]
```

Raises `TypeError` because the categories are ordered and not identical.

```
>>> a = pd.Categorical(["a", "b"], ordered=True)
>>> b = pd.Categorical(["a", "b", "c"], ordered=True)
>>> union_categoricals([a, b])
TypeError: to union ordered Categoricals, all categories must be the same
```

New in version 0.20.0

Ordered categoricals with different categories or orderings can be combined by using the `ignore_ordered=True` argument.

```
>>> a = pd.Categorical(["a", "b", "c"], ordered=True)
>>> b = pd.Categorical(["c", "b", "a"], ordered=True)
>>> union_categoricals([a, b], ignore_order=True)
[a, b, c, c, b, a]
Categories (3, object): [a, b, c]
```

`union_categoricals` also works with a *CategoricalIndex*, or *Series* containing categorical data, but note that the resulting array will always be a plain *Categorical*

```
>>> a = pd.Series(["b", "c"], dtype='category')
>>> b = pd.Series(["a", "b"], dtype='category')
>>> union_categoricals([a, b])
[b, c, a, b]
Categories (3, object): [b, c, a]
```

pandas.api.types.infer_dtype

`pandas.api.types.infer_dtype()`

Efficiently infer the type of a passed val, or list-like array of values. Return a string describing the type.

Parameters

value [scalar, list, ndarray, or pandas type]

skipna [bool, default False] Ignore NaN values when inferring the type.

New in version 0.21.0.

Returns

string describing the common type of the input data.

Results can include:

- string
- unicode
- bytes
- floating
- integer
- mixed-integer
- mixed-integer-float
- decimal
- complex
- categorical
- boolean
- datetime64
- datetime
- date

- `timedelta64`
- `timedelta`
- `time`
- `period`
- `mixed`

Raises

`TypeError` if ndarray-like but cannot infer the dtype

Notes

- ‘mixed’ is the catchall for anything that is not otherwise specialized
- ‘mixed-integer-float’ are floats and integers
- ‘mixed-integer’ are integers mixed with non-integers

Examples

```
>>> infer_dtype(['foo', 'bar'])  
'string'
```

```
>>> infer_dtype(['a', np.nan, 'b'], skipna=True)  
'string'
```

```
>>> infer_dtype(['a', np.nan, 'b'], skipna=False)  
'mixed'
```

```
>>> infer_dtype([b'foo', b'bar'])  
'bytes'
```

```
>>> infer_dtype([1, 2, 3])  
'integer'
```

```
>>> infer_dtype([1, 2, 3.5])  
'mixed-integer-float'
```

```
>>> infer_dtype([1.0, 2.0, 3.5])  
'floating'
```

```
>>> infer_dtype(['a', 1])  
'mixed-integer'
```

```
>>> infer_dtype([Decimal(1), Decimal(2.0)])  
'decimal'
```

```
>>> infer_dtype([True, False])  
'boolean'
```

```
>>> infer_dtype([True, False, np.nan])
'mixed'
```

```
>>> infer_dtype([pd.Timestamp('20130101')])
'datetime'
```

```
>>> infer_dtype([datetime.date(2013, 1, 1)])
'date'
```

```
>>> infer_dtype([np.datetime64('2013-01-01')])
'datetime64'
```

```
>>> infer_dtype([datetime.timedelta(0, 1, 1)])
'timedelta'
```

```
>>> infer_dtype(pd.Series(list('abc')).astype('category'))
'categorical'
```

pandas.api.types.pandas_dtype

`pandas.api.types.pandas_dtype(dtype)`

Convert input into a pandas only dtype object or a numpy dtype object.

Parameters

dtype [object to be converted]

Returns

np.dtype or a pandas dtype

Raises

TypeError if not a dtype

Dtype introspection

<code>api.types.is_bool_dtype(arr_or_dtype)</code>	Check whether the provided array or dtype is of a boolean dtype.
<code>api.types.is_categorical_dtype(arr_or_dtype)</code>	Check whether an array-like or dtype is of the Categorical dtype.
<code>api.types.is_complex_dtype(arr_or_dtype)</code>	Check whether the provided array or dtype is of a complex dtype.
<code>api.types.is_datetime64_any_dtype(arr_or_dtype)</code>	Check whether the provided array or dtype is of the datetime64 dtype.
<code>api.types.is_datetime64_dtype(arr_or_dtype)</code>	Check whether an array-like or dtype is of the datetime64 dtype.
<code>api.types.is_datetime64_ns_dtype(arr_or_dtype)</code>	Check whether the provided array or dtype is of the datetime64[ns] dtype.
<code>api.types.is_datetime64tz_dtype(arr_or_dtype)</code>	Check whether an array-like or dtype is of a DatetimeTZDtype dtype.

Continued on next page

Table 412 – continued from previous page

<code>api.types.is_extension_type(arr)</code>	Check whether an array-like is of a pandas extension class instance.
<code>api.types.is_extension_array_dtype(arr_or_dtype)</code>	Check if an object is a pandas extension array type.
<code>api.types.is_float_dtype(arr_or_dtype)</code>	Check whether the provided array or dtype is of a float dtype.
<code>api.types.is_int64_dtype(arr_or_dtype)</code>	Check whether the provided array or dtype is of the int64 dtype.
<code>api.types.is_integer_dtype(arr_or_dtype)</code>	Check whether the provided array or dtype is of an integer dtype.
<code>api.types.is_interval_dtype(arr_or_dtype)</code>	Check whether an array-like or dtype is of the Interval dtype.
<code>api.types.is_numeric_dtype(arr_or_dtype)</code>	Check whether the provided array or dtype is of a numeric dtype.
<code>api.types.is_object_dtype(arr_or_dtype)</code>	Check whether an array-like or dtype is of the object dtype.
<code>api.types.is_period_dtype(arr_or_dtype)</code>	Check whether an array-like or dtype is of the Period dtype.
<code>api.types.is_signed_integer_dtype(arr_or_dtype)</code>	Check whether the provided array or dtype is of a signed integer dtype.
<code>api.types.is_string_dtype(arr_or_dtype)</code>	Check whether the provided array or dtype is of the string dtype.
<code>api.types.is_timedelta64_dtype(arr_or_dtype)</code>	Check whether an array-like or dtype is of the timedelta64 dtype.
<code>api.types.is_timedelta64_ns_dtype(arr_or_dtype)</code>	Check whether the provided array or dtype is of the timedelta64[ns] dtype.
<code>api.types.is_unsigned_integer_dtype(arr_or_dtype)</code>	Check whether the provided array or dtype is of an unsigned integer dtype.
<code>api.types.is_sparse(arr)</code>	Check whether an array-like is a 1-D pandas sparse array.

pandas.api.types.is_bool_dtype`pandas.api.types.is_bool_dtype(arr_or_dtype)`

Check whether the provided array or dtype is of a boolean dtype.

Parameters**arr_or_dtype** [array-like] The array or dtype to check.**Returns****boolean** Whether or not the array or dtype is of a boolean dtype.**Notes**An ExtensionArray is considered boolean when the `_is_boolean` attribute is set to `True`.**Examples**

```
>>> is_bool_dtype(str)
False
```

(continues on next page)

(continued from previous page)

```
>>> is_bool_dtype(int)
False
>>> is_bool_dtype(bool)
True
>>> is_bool_dtype(np.bool)
True
>>> is_bool_dtype(np.array(['a', 'b']))
False
>>> is_bool_dtype(pd.Series([1, 2]))
False
>>> is_bool_dtype(np.array([True, False]))
True
>>> is_bool_dtype(pd.Categorical([True, False]))
True
>>> is_bool_dtype(pd.SparseArray([True, False]))
True
```

pandas.api.types.is_categorical_dtype

`pandas.api.types.is_categorical_dtype(arr_or_dtype)`

Check whether an array-like or dtype is of the Categorical dtype.

Parameters

arr_or_dtype [array-like] The array-like or dtype to check.

Returns

boolean Whether or not the array-like or dtype is of the Categorical dtype.

Examples

```
>>> is_categorical_dtype(object)
False
>>> is_categorical_dtype(CategoricalDtype())
True
>>> is_categorical_dtype([1, 2, 3])
False
>>> is_categorical_dtype(pd.Categorical([1, 2, 3]))
True
>>> is_categorical_dtype(pd.CategoricalIndex([1, 2, 3]))
True
```

pandas.api.types.is_complex_dtype

`pandas.api.types.is_complex_dtype(arr_or_dtype)`

Check whether the provided array or dtype is of a complex dtype.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of a complex dtype.

Examples

```
>>> is_complex_dtype(str)
False
>>> is_complex_dtype(int)
False
>>> is_complex_dtype(np.complex)
True
>>> is_complex_dtype(np.array(['a', 'b']))
False
>>> is_complex_dtype(pd.Series([1, 2]))
False
>>> is_complex_dtype(np.array([1 + 1j, 5]))
True
```

pandas.api.types.is_datetime64_any_dtype

`pandas.api.types.is_datetime64_any_dtype(arr_or_dtype)`

Check whether the provided array or dtype is of the datetime64 dtype.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of the datetime64 dtype.

Examples

```
>>> is_datetime64_any_dtype(str)
False
>>> is_datetime64_any_dtype(int)
False
>>> is_datetime64_any_dtype(np.datetime64) # can be tz-naive
True
>>> is_datetime64_any_dtype(DatetimeTZDtype("ns", "US/Eastern"))
True
>>> is_datetime64_any_dtype(np.array(['a', 'b']))
False
>>> is_datetime64_any_dtype(np.array([1, 2]))
False
>>> is_datetime64_any_dtype(np.array([], dtype=np.datetime64))
True
>>> is_datetime64_any_dtype(pd.DatetimeIndex([1, 2, 3],
                                             dtype=np.datetime64))
True
```

pandas.api.types.is_datetime64_dtype`pandas.api.types.is_datetime64_dtype(arr_or_dtype)`

Check whether an array-like or dtype is of the datetime64 dtype.

Parameters**arr_or_dtype** [array-like] The array-like or dtype to check.**Returns****boolean** Whether or not the array-like or dtype is of the datetime64 dtype.**Examples**

```

>>> is_datetime64_dtype(object)
False
>>> is_datetime64_dtype(np.datetime64)
True
>>> is_datetime64_dtype(np.array([], dtype=int))
False
>>> is_datetime64_dtype(np.array([], dtype=np.datetime64))
True
>>> is_datetime64_dtype([1, 2, 3])
False

```

pandas.api.types.is_datetime64_ns_dtype`pandas.api.types.is_datetime64_ns_dtype(arr_or_dtype)`

Check whether the provided array or dtype is of the datetime64[ns] dtype.

Parameters**arr_or_dtype** [array-like] The array or dtype to check.**Returns****boolean** Whether or not the array or dtype is of the datetime64[ns] dtype.**Examples**

```

>>> is_datetime64_ns_dtype(str)
False
>>> is_datetime64_ns_dtype(int)
False
>>> is_datetime64_ns_dtype(np.datetime64) # no unit
False
>>> is_datetime64_ns_dtype(DatetimeTZDtype("ns", "US/Eastern"))
True
>>> is_datetime64_ns_dtype(np.array(['a', 'b']))
False
>>> is_datetime64_ns_dtype(np.array([1, 2]))
False

```

(continues on next page)

(continued from previous page)

```

>>> is_datetime64_ns_dtype(np.array([], dtype=np.datetime64)) # no unit
False
>>> is_datetime64_ns_dtype(np.array([],
                                dtype="datetime64[ps]")) # wrong unit
False
>>> is_datetime64_ns_dtype(pd.DatetimeIndex([1, 2, 3],
                                             dtype=np.datetime64)) # has 'ns' unit
True

```

pandas.api.types.is_datetime64tz_dtype

pandas.api.types.is_datetime64tz_dtype(arr_or_dtype)

Check whether an array-like or dtype is of a DatetimeTZDtype dtype.

Parameters

arr_or_dtype [array-like] The array-like or dtype to check.

Returns

boolean Whether or not the array-like or dtype is of a DatetimeTZDtype dtype.

Examples

```

>>> is_datetime64tz_dtype(object)
False
>>> is_datetime64tz_dtype([1, 2, 3])
False
>>> is_datetime64tz_dtype(pd.DatetimeIndex([1, 2, 3])) # tz-naive
False
>>> is_datetime64tz_dtype(pd.DatetimeIndex([1, 2, 3], tz="US/Eastern"))
True

```

```

>>> dtype = DatetimeTZDtype("ns", tz="US/Eastern")
>>> s = pd.Series([], dtype=dtype)
>>> is_datetime64tz_dtype(dtype)
True
>>> is_datetime64tz_dtype(s)
True

```

pandas.api.types.is_extension_type

pandas.api.types.is_extension_type(arr)

Check whether an array-like is of a pandas extension class instance.

Extension classes include categoricals, pandas sparse objects (i.e. classes represented within the pandas library and not ones external to it like scipy sparse matrices), and datetime-like arrays.

Parameters

arr [array-like] The array-like to check.

Returns

boolean Whether or not the array-like is of a pandas extension class instance.

Examples

```

>>> is_extension_type([1, 2, 3])
False
>>> is_extension_type(np.array([1, 2, 3]))
False
>>>
>>> cat = pd.Categorical([1, 2, 3])
>>>
>>> is_extension_type(cat)
True
>>> is_extension_type(pd.Series(cat))
True
>>> is_extension_type(pd.SparseArray([1, 2, 3]))
True
>>> is_extension_type(pd.SparseSeries([1, 2, 3]))
True
>>>
>>> from scipy.sparse import bsr_matrix
>>> is_extension_type(bsr_matrix([1, 2, 3]))
False
>>> is_extension_type(pd.DatetimeIndex([1, 2, 3]))
False
>>> is_extension_type(pd.DatetimeIndex([1, 2, 3], tz="US/Eastern"))
True
>>>
>>> dtype = DatetimeTZDtype("ns", tz="US/Eastern")
>>> s = pd.Series([], dtype=dtype)
>>> is_extension_type(s)
True

```

pandas.api.types.is_extension_array_dtype

`pandas.api.types.is_extension_array_dtype(arr_or_dtype)`

Check if an object is a pandas extension array type.

See the *Use Guide* for more.

Parameters

arr_or_dtype [object] For array-like input, the `.dtype` attribute will be extracted.

Returns

bool Whether the `arr_or_dtype` is an extension array type.

Notes

This checks whether an object implements the pandas extension array interface. In pandas, this includes:

- Categorical
- Sparse
- Interval
- Period
- DatetimeArray
- TimedeltaArray

Third-party libraries may implement arrays or types satisfying this interface as well.

Examples

```
>>> from pandas.api.types import is_extension_array_dtype
>>> arr = pd.Categorical(['a', 'b'])
>>> is_extension_array_dtype(arr)
True
>>> is_extension_array_dtype(arr.dtype)
True
```

```
>>> arr = np.array(['a', 'b'])
>>> is_extension_array_dtype(arr.dtype)
False
```

pandas.api.types.is_float_dtype

`pandas.api.types.is_float_dtype(arr_or_dtype)`

Check whether the provided array or dtype is of a float dtype.

This function is internal and should not be exposed in the public API.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of a float dtype.

Examples

```
>>> is_float_dtype(str)
False
>>> is_float_dtype(int)
False
>>> is_float_dtype(float)
True
>>> is_float_dtype(np.array(['a', 'b']))
False
>>> is_float_dtype(pd.Series([1, 2]))
False
```

(continues on next page)

(continued from previous page)

```
>>> is_float_dtype(pd.Index([1, 2.]))
True
```

pandas.api.types.is_int64_dtype

`pandas.api.types.is_int64_dtype(arr_or_dtype)`

Check whether the provided array or dtype is of the int64 dtype.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of the int64 dtype.

Notes

Depending on system architecture, the return value of `is_int64_dtype(int)` will be True if the OS uses 64-bit integers and False if the OS uses 32-bit integers.

Examples

```
>>> is_int64_dtype(str)
False
>>> is_int64_dtype(np.int32)
False
>>> is_int64_dtype(np.int64)
True
>>> is_int64_dtype('int8')
False
>>> is_int64_dtype('Int8')
False
>>> is_int64_dtype(pd.Int64Dtype)
True
>>> is_int64_dtype(float)
False
>>> is_int64_dtype(np.uint64) # unsigned
False
>>> is_int64_dtype(np.array(['a', 'b']))
False
>>> is_int64_dtype(np.array([1, 2], dtype=np.int64))
True
>>> is_int64_dtype(pd.Index([1, 2.])) # float
False
>>> is_int64_dtype(np.array([1, 2], dtype=np.uint32)) # unsigned
False
```

pandas.api.types.is_integer_dtype

`pandas.api.types.is_integer_dtype(arr_or_dtype)`

Check whether the provided array or dtype is of an integer dtype.

Unlike in `in_any_int_dtype`, `timedelta64` instances will return `False`.

Changed in version 0.24.0: The nullable Integer dtypes (e.g. `pandas.Int64Dtype`) are also considered as integer by this function.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of an integer dtype and not an instance of `timedelta64`.

Examples

```
>>> is_integer_dtype(str)
False
>>> is_integer_dtype(int)
True
>>> is_integer_dtype(float)
False
>>> is_integer_dtype(np.uint64)
True
>>> is_integer_dtype('int8')
True
>>> is_integer_dtype('Int8')
True
>>> is_integer_dtype(pd.Int8Dtype)
True
>>> is_integer_dtype(np.datetime64)
False
>>> is_integer_dtype(np.timedelta64)
False
>>> is_integer_dtype(np.array(['a', 'b']))
False
>>> is_integer_dtype(pd.Series([1, 2]))
True
>>> is_integer_dtype(np.array([], dtype=np.timedelta64))
False
>>> is_integer_dtype(pd.Index([1, 2])) # float
False
```

pandas.api.types.is_interval_dtype

`pandas.api.types.is_interval_dtype(arr_or_dtype)`

Check whether an array-like or dtype is of the Interval dtype.

Parameters

arr_or_dtype [array-like] The array-like or dtype to check.

Returns

boolean Whether or not the array-like or dtype is of the Interval dtype.

Examples

```
>>> is_interval_dtype(object)
False
>>> is_interval_dtype(IntervalDtype())
True
>>> is_interval_dtype([1, 2, 3])
False
>>>
>>> interval = pd.Interval(1, 2, closed="right")
>>> is_interval_dtype(interval)
False
>>> is_interval_dtype(pd.IntervalIndex([interval]))
True
```

pandas.api.types.is_numeric_dtype

`pandas.api.types.is_numeric_dtype(arr_or_dtype)`

Check whether the provided array or dtype is of a numeric dtype.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of a numeric dtype.

Examples

```
>>> is_numeric_dtype(str)
False
>>> is_numeric_dtype(int)
True
>>> is_numeric_dtype(float)
True
>>> is_numeric_dtype(np.uint64)
True
>>> is_numeric_dtype(np.datetime64)
False
>>> is_numeric_dtype(np.timedelta64)
False
>>> is_numeric_dtype(np.array(['a', 'b']))
False
>>> is_numeric_dtype(pd.Series([1, 2]))
True
>>> is_numeric_dtype(pd.Index([1, 2.]))
```

(continues on next page)

(continued from previous page)

```
True
>>> is_numeric_dtype(np.array([], dtype=np.timedelta64))
False
```

pandas.api.types.is_object_dtype

`pandas.api.types.is_object_dtype(arr_or_dtype)`

Check whether an array-like or dtype is of the object dtype.

Parameters

arr_or_dtype [array-like] The array-like or dtype to check.

Returns

boolean Whether or not the array-like or dtype is of the object dtype.

Examples

```
>>> is_object_dtype(object)
True
>>> is_object_dtype(int)
False
>>> is_object_dtype(np.array([], dtype=object))
True
>>> is_object_dtype(np.array([], dtype=int))
False
>>> is_object_dtype([1, 2, 3])
False
```

pandas.api.types.is_period_dtype

`pandas.api.types.is_period_dtype(arr_or_dtype)`

Check whether an array-like or dtype is of the Period dtype.

Parameters

arr_or_dtype [array-like] The array-like or dtype to check.

Returns

boolean Whether or not the array-like or dtype is of the Period dtype.

Examples

```
>>> is_period_dtype(object)
False
>>> is_period_dtype(PeriodDtype(freq="D"))
True
>>> is_period_dtype([1, 2, 3])
False
```

(continues on next page)

(continued from previous page)

```

>>> is_period_dtype(pd.Period("2017-01-01"))
False
>>> is_period_dtype(pd.PeriodIndex([], freq="A"))
True

```

pandas.api.types.is_signed_integer_dtype

`pandas.api.types.is_signed_integer_dtype(arr_or_dtype)`

Check whether the provided array or dtype is of a signed integer dtype.

Unlike in *in_any_int_dtype*, `timedelta64` instances will return `False`.

Changed in version 0.24.0: The nullable Integer dtypes (e.g. `pandas.Int64Dtype`) are also considered as integer by this function.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of a signed integer dtype and not an instance of `timedelta64`.

Examples

```

>>> is_signed_integer_dtype(str)
False
>>> is_signed_integer_dtype(int)
True
>>> is_signed_integer_dtype(float)
False
>>> is_signed_integer_dtype(np.uint64) # unsigned
False
>>> is_signed_integer_dtype('int8')
True
>>> is_signed_integer_dtype('Int8')
True
>>> is_signed_dtype(pd.Int8Dtype)
True
>>> is_signed_integer_dtype(np.datetime64)
False
>>> is_signed_integer_dtype(np.timedelta64)
False
>>> is_signed_integer_dtype(np.array(['a', 'b']))
False
>>> is_signed_integer_dtype(pd.Series([1, 2]))
True
>>> is_signed_integer_dtype(np.array([], dtype=np.timedelta64))
False
>>> is_signed_integer_dtype(pd.Index([1, 2.])) # float
False

```

(continues on next page)

(continued from previous page)

```
>>> is_signed_integer_dtype(np.array([1, 2], dtype=np.uint32)) # unsigned
False
```

pandas.api.types.is_string_dtype

`pandas.api.types.is_string_dtype(arr_or_dtype)`

Check whether the provided array or dtype is of the string dtype.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of the string dtype.

Examples

```
>>> is_string_dtype(str)
True
>>> is_string_dtype(object)
True
>>> is_string_dtype(int)
False
>>>
>>> is_string_dtype(np.array(['a', 'b']))
True
>>> is_string_dtype(pd.Series([1, 2]))
False
```

pandas.api.types.is_timedelta64_dtype

`pandas.api.types.is_timedelta64_dtype(arr_or_dtype)`

Check whether an array-like or dtype is of the timedelta64 dtype.

Parameters

arr_or_dtype [array-like] The array-like or dtype to check.

Returns

boolean Whether or not the array-like or dtype is of the timedelta64 dtype.

Examples

```
>>> is_timedelta64_dtype(object)
False
>>> is_timedelta64_dtype(np.timedelta64)
True
>>> is_timedelta64_dtype([1, 2, 3])
False
```

(continues on next page)

(continued from previous page)

```
>>> is_timedelta64_dtype(pd.Series([], dtype="timedelta64[ns]"))
True
>>> is_timedelta64_dtype('0 days')
False
```

pandas.api.types.is_timedelta64_ns_dtype`pandas.api.types.is_timedelta64_ns_dtype(arr_or_dtype)`

Check whether the provided array or dtype is of the timedelta64[ns] dtype.

This is a very specific dtype, so generic ones like `np.timedelta64` will return False if passed into this function.**Parameters****arr_or_dtype** [array-like] The array or dtype to check.**Returns****boolean** Whether or not the array or dtype is of the timedelta64[ns] dtype.**Examples**

```
>>> is_timedelta64_ns_dtype(np.dtype('m8[ns]'))
True
>>> is_timedelta64_ns_dtype(np.dtype('m8[ps]')) # Wrong frequency
False
>>> is_timedelta64_ns_dtype(np.array([1, 2], dtype='m8[ns]'))
True
>>> is_timedelta64_ns_dtype(np.array([1, 2], dtype=np.timedelta64))
False
```

pandas.api.types.is_unsigned_integer_dtype`pandas.api.types.is_unsigned_integer_dtype(arr_or_dtype)`

Check whether the provided array or dtype is of an unsigned integer dtype.

Changed in version 0.24.0: The nullable Integer dtypes (e.g. `pandas.UInt64Dtype`) are also considered as integer by this function.**Parameters****arr_or_dtype** [array-like] The array or dtype to check.**Returns****boolean** Whether or not the array or dtype is of an unsigned integer dtype.**Examples**

```

>>> is_unsigned_integer_dtype(str)
False
>>> is_unsigned_integer_dtype(int) # signed
False
>>> is_unsigned_integer_dtype(float)
False
>>> is_unsigned_integer_dtype(np.uint64)
True
>>> is_unsigned_integer_dtype('uint8')
True
>>> is_unsigned_integer_dtype('UInt8')
True
>>> is_unsigned_integer_dtype(pd.UInt8Dtype)
True
>>> is_unsigned_integer_dtype(np.array(['a', 'b']))
False
>>> is_unsigned_integer_dtype(pd.Series([1, 2])) # signed
False
>>> is_unsigned_integer_dtype(pd.Index([1, 2.])) # float
False
>>> is_unsigned_integer_dtype(np.array([1, 2], dtype=np.uint32))
True

```

pandas.api.types.is_sparse

`pandas.api.types.is_sparse(arr)`

Check whether an array-like is a 1-D pandas sparse array.

Check that the one-dimensional array-like is a pandas sparse array. Returns True if it is a pandas sparse array, not another type of sparse array.

Parameters

arr [array-like] Array-like to check.

Returns

bool Whether or not the array-like is a pandas sparse array.

See also:

DataFrame.to_sparse Convert DataFrame to a SparseDataFrame.

Series.to_sparse Convert Series to SparseSeries.

Series.to_dense Return dense representation of a Series.

Examples

Returns *True* if the parameter is a 1-D pandas sparse array.

```

>>> is_sparse(pd.SparseArray([0, 0, 1, 0]))
True
>>> is_sparse(pd.SparseSeries([0, 0, 1, 0]))
True

```

Returns *False* if the parameter is not sparse.

```
>>> is_sparse(np.array([0, 0, 1, 0]))
False
>>> is_sparse(pd.Series([0, 1, 0, 0]))
False
```

Returns *False* if the parameter is not a pandas sparse array.

```
>>> from scipy.sparse import bsr_matrix
>>> is_sparse(bsr_matrix([0, 1, 0, 0]))
False
```

Returns *False* if the parameter has more than one dimension.

```
>>> df = pd.SparseDataFrame([389., 24., 80.5, np.nan],
                           columns=['max_speed'],
                           index=['falcon', 'parrot', 'lion', 'monkey'])
>>> is_sparse(df)
False
>>> is_sparse(df.max_speed)
True
```

Iterable introspection

<code>api.types.is_dict_like(obj)</code>	Check if the object is dict-like.
<code>api.types.is_file_like(obj)</code>	Check if the object is a file-like object.
<code>api.types.is_list_like()</code>	Check if the object is list-like.
<code>api.types.is_named_tuple(obj)</code>	Check if the object is a named tuple.
<code>api.types.is_iterator(obj)</code>	Check if the object is an iterator.

pandas.api.types.is_dict_like

`pandas.api.types.is_dict_like(obj)`

Check if the object is dict-like.

Parameters

obj [The object to check]

Returns

is_dict_like [bool] Whether *obj* has dict-like properties.

Examples

```
>>> is_dict_like({1: 2})
True
>>> is_dict_like([1, 2, 3])
False
>>> is_dict_like(dict)
False
```

(continues on next page)

(continued from previous page)

```
>>> is_dict_like(dict())
True
```

pandas.api.types.is_file_like

`pandas.api.types.is_file_like(obj)`

Check if the object is a file-like object.

For objects to be considered file-like, they must be an iterator AND have either a *read* and/or *write* method as an attribute.

Note: file-like objects must be iterable, but iterable objects need not be file-like.

New in version 0.20.0.

Parameters

obj [The object to check]

Returns

is_file_like [bool] Whether *obj* has file-like properties.

Examples

```
>>> buffer(StringIO("data"))
>>> is_file_like(buffer)
True
>>> is_file_like([1, 2, 3])
False
```

pandas.api.types.is_list_like

`pandas.api.types.is_list_like()`

Check if the object is list-like.

Objects that are considered list-like are for example Python lists, tuples, sets, NumPy arrays, and Pandas Series.

Strings and datetime objects, however, are not considered list-like.

Parameters

obj [The object to check]

allow_sets [boolean, default True] If this parameter is False, sets will not be considered list-like

New in version 0.24.0.

Returns

is_list_like [bool] Whether *obj* has list-like properties.

Examples

```

>>> is_list_like([1, 2, 3])
True
>>> is_list_like({1, 2, 3})
True
>>> is_list_like(datetime(2017, 1, 1))
False
>>> is_list_like("foo")
False
>>> is_list_like(1)
False
>>> is_list_like(np.array([2]))
True
>>> is_list_like(np.array(2))
False

```

pandas.api.types.is_named_tuple

`pandas.api.types.is_named_tuple(obj)`
Check if the object is a named tuple.

Parameters

obj [The object to check]

Returns

is_named_tuple [bool] Whether *obj* is a named tuple.

Examples

```

>>> Point = namedtuple("Point", ["x", "y"])
>>> p = Point(1, 2)
>>>
>>> is_named_tuple(p)
True
>>> is_named_tuple((1, 2))
False

```

pandas.api.types.is_iterator

`pandas.api.types.is_iterator(obj)`
Check if the object is an iterator.

For example, lists are considered iterators but not strings or datetime objects.

Parameters

obj [The object to check]

Returns

is_iter [bool] Whether *obj* is an iterator.

Examples

```

>>> is_iterator([1, 2, 3])
True
>>> is_iterator(datetime(2017, 1, 1))
False
>>> is_iterator("foo")
False
>>> is_iterator(1)
False

```

Scalar introspection

<i>api.types.is_bool()</i>	
<i>api.types.is_categorical</i> (arr)	Check whether an array-like is a Categorical instance.
<i>api.types.is_complex()</i>	
<i>api.types.is_datetimetz</i> (arr)	(DEPRECATED) Check whether an array-like is a datetime array-like with a timezone component in its dtype.
<i>api.types.is_float()</i>	
<i>api.types.is_hashable</i> (obj)	Return True if hash(obj) will succeed, False otherwise.
<i>api.types.is_integer()</i>	
<i>api.types.is_interval()</i>	
<i>api.types.is_number</i> (obj)	Check if the object is a number.
<i>api.types.is_period</i> (arr)	(DEPRECATED) Check whether an array-like is a periodical index.
<i>api.types.is_re</i> (obj)	Check if the object is a regex pattern instance.
<i>api.types.is_re_compilable</i> (obj)	Check if the object can be compiled into a regex pattern instance.
<i>api.types.is_scalar()</i>	Return True if given value is scalar.

pandas.api.types.is_bool

pandas.api.types.is_bool()

pandas.api.types.is_categorical

pandas.api.types.is_categorical(arr)
Check whether an array-like is a Categorical instance.

Parameters

arr [array-like] The array-like to check.

Returns

boolean Whether or not the array-like is of a Categorical instance.

Examples

```
>>> is_categorical([1, 2, 3])
False
```

Categoricals, Series Categoricals, and CategoricalIndex will return True.

```
>>> cat = pd.Categorical([1, 2, 3])
>>> is_categorical(cat)
True
>>> is_categorical(pd.Series(cat))
True
>>> is_categorical(pd.CategoricalIndex([1, 2, 3]))
True
```

pandas.api.types.is_complex

pandas.api.types.is_complex()

pandas.api.types.is_datetimetz

pandas.api.types.is_datetimetz(*arr*)

Check whether an array-like is a datetime array-like with a timezone component in its dtype.

Deprecated since version 0.24.0.

Parameters

arr [array-like] The array-like to check.

Returns

boolean Whether or not the array-like is a datetime array-like with a timezone component in its dtype.

Examples

```
>>> is_datetimetz([1, 2, 3])
False
```

Although the following examples are both DatetimeIndex objects, the first one returns False because it has no timezone component unlike the second one, which returns True.

```
>>> is_datetimetz(pd.DatetimeIndex([1, 2, 3]))
False
>>> is_datetimetz(pd.DatetimeIndex([1, 2, 3], tz="US/Eastern"))
True
```

The object need not be a DatetimeIndex object. It just needs to have a dtype which has a timezone component.

```
>>> dtype = DatetimeTZDtype("ns", tz="US/Eastern")
>>> s = pd.Series([], dtype=dtype)
>>> is_datetimetz(s)
True
```

pandas.api.types.is_float

`pandas.api.types.is_float()`

pandas.api.types.is_hashable

`pandas.api.types.is_hashable(obj)`

Return True if `hash(obj)` will succeed, False otherwise.

Some types will pass a test against `collections.abc.Hashable` but fail when they are actually hashed with `hash()`.

Distinguish between these and other types by trying the call to `hash()` and seeing if they raise `TypeError`.

Returns

bool

Examples

```
>>> a = ([],)
>>> isinstance(a, collections.abc.Hashable)
True
>>> is_hashable(a)
False
```

pandas.api.types.is_integer

`pandas.api.types.is_integer()`

pandas.api.types.is_interval

`pandas.api.types.is_interval()`

pandas.api.types.is_number

`pandas.api.types.is_number(obj)`

Check if the object is a number.

Returns True when the object is a number, and False if is not.

Parameters

obj [any type] The object to check if is a number.

Returns

is_number [bool] Whether *obj* is a number or not.

See also:

api.types.is_integer Checks a subgroup of numbers.

Examples

```
>>> pd.api.types.is_number(1)
True
>>> pd.api.types.is_number(7.15)
True
```

Booleans are valid because they are int subclass.

```
>>> pd.api.types.is_number(False)
True
```

```
>>> pd.api.types.is_number("foo")
False
>>> pd.api.types.is_number("5")
False
```

pandas.api.types.is_period

pandas.api.types.is_period(*arr*)

Check whether an array-like is a periodical index.

Deprecated since version 0.24.0.

Parameters

arr [array-like] The array-like to check.

Returns

boolean Whether or not the array-like is a periodical index.

Examples

```
>>> is_period([1, 2, 3])
False
>>> is_period(pd.Index([1, 2, 3]))
False
>>> is_period(pd.PeriodIndex(["2017-01-01"], freq="D"))
True
```

pandas.api.types.is_re

pandas.api.types.is_re(*obj*)

Check if the object is a regex pattern instance.

Parameters

obj [The object to check]

Returns

is_regex [bool] Whether *obj* is a regex pattern.

Examples

```
>>> is_re(re.compile(".*"))
True
>>> is_re("foo")
False
```

pandas.api.types.is_re_compilable

`pandas.api.types.is_re_compilable(obj)`

Check if the object can be compiled into a regex pattern instance.

Parameters

obj [The object to check]

Returns

is_regex_compilable [bool] Whether *obj* can be compiled as a regex pattern.

Examples

```
>>> is_re_compilable(".*")
True
>>> is_re_compilable(1)
False
```

pandas.api.types.is_scalar

`pandas.api.types.is_scalar()`

Return True if given value is scalar.

Parameters

val [object] This includes:

- numpy array scalar (e.g. np.int64)
- Python builtin numerics
- Python builtin byte arrays and strings
- None
- datetime.datetime
- datetime.timedelta
- Period

- decimal.Decimal
- Interval
- DateOffset
- Fraction
- Number

Returns

bool Return True if given object is scalar, False otherwise

Examples

```
>>> dt = pd.datetime.datetime(2018, 10, 3)
>>> pd.is_scalar(dt)
True
```

```
>>> pd.api.types.is_scalar([2, 3])
False
```

```
>>> pd.api.types.is_scalar({0: 1, 2: 3})
False
```

```
>>> pd.api.types.is_scalar((0, 2))
False
```

pandas supports PEP 3141 numbers:

```
>>> from fractions import Fraction
>>> pd.api.types.is_scalar(Fraction(3, 5))
True
```

{{ header }}

6.16 Extensions

These are primarily intended for library authors looking to extend pandas objects.

<code>api.extensions.register_extension_dtype(cls)</code>	Register an ExtensionType with pandas as class decorator.
<code>api.extensions.register_dataframe_accessor(name)</code>	Register a custom accessor on DataFrame objects.
<code>api.extensions.register_series_accessor(name)</code>	Register a custom accessor on Series objects.
<code>api.extensions.register_index_accessor(name)</code>	Register a custom accessor on Index objects.
<code>api.extensions.ExtensionDtype</code>	A custom data type, to be paired with an ExtensionArray.

6.16.1 pandas.api.extensions.register_extension_dtype

`pandas.api.extensions.register_extension_dtype`(*cls*: `Type[pandas.core.dtypes.base.ExtensionDtype]`)
→ `Type[pandas.core.dtypes.base.ExtensionDtype]`

Register an ExtensionType with pandas as class decorator.

New in version 0.24.0.

This enables operations like `.astype(name)` for the name of the ExtensionDtype.

Returns

callable A class decorator.

Examples

```
>>> from pandas.api.extensions import register_extension_dtype
>>> from pandas.api.extensions import ExtensionDtype
>>> @register_extension_dtype
... class MyExtensionDtype(ExtensionDtype):
...     pass
```

6.16.2 pandas.api.extensions.register_dataframe_accessor

`pandas.api.extensions.register_dataframe_accessor`(*name*)

Register a custom accessor on DataFrame objects.

Parameters

name [str] Name under which the accessor should be registered. A warning is issued if this name conflicts with a preexisting attribute.

Returns

callable A class decorator.

See also:

`register_series_accessor`, `register_index_accessor`

Notes

When accessed, your accessor will be initialized with the pandas object the user is interacting with. So the signature must be

```
def __init__(self, pandas_object): # noqa: E999
    ...
```

For consistency with pandas methods, you should raise an `AttributeError` if the data passed to your accessor has an incorrect dtype.

```
>>> pd.Series(['a', 'b']).dt
Traceback (most recent call last):
...
AttributeError: Can only use .dt accessor with datetimelike values
```

Examples

In your library code:

```
import pandas as pd

@pd.api.extensions.register_dataframe_accessor("geo")
class GeoAccessor:
    def __init__(self, pandas_obj):
        self._obj = pandas_obj

    @property
    def center(self):
        # return the geographic center point of this DataFrame
        lat = self._obj.latitude
        lon = self._obj.longitude
        return (float(lon.mean()), float(lat.mean()))

    def plot(self):
        # plot this array's data on a map, e.g., using Cartopy
        pass
```

Back in an interactive IPython session:

```
>>> ds = pd.DataFrame({'longitude': np.linspace(0, 10),
...                    'latitude': np.linspace(0, 20)})
>>> ds.geo.center
(5.0, 10.0)
>>> ds.geo.plot()
# plots data on a map
```

6.16.3 pandas.api.extensions.register_series_accessor

`pandas.api.extensions.register_series_accessor(name)`

Register a custom accessor on Series objects.

Parameters

name [str] Name under which the accessor should be registered. A warning is issued if this name conflicts with a preexisting attribute.

Returns

callable A class decorator.

See also:

`register_dataframe_accessor`, `register_index_accessor`

Notes

When accessed, your accessor will be initialized with the pandas object the user is interacting with. So the signature must be

```
def __init__(self, pandas_object): # noqa: E999
    ...
```

For consistency with pandas methods, you should raise an `AttributeError` if the data passed to your accessor has an incorrect dtype.

```
>>> pd.Series(['a', 'b']).dt
Traceback (most recent call last):
...
AttributeError: Can only use .dt accessor with datetimelike values
```

Examples

In your library code:

```
import pandas as pd

@pd.api.extensions.register_dataframe_accessor("geo")
class GeoAccessor:
    def __init__(self, pandas_obj):
        self._obj = pandas_obj

    @property
    def center(self):
        # return the geographic center point of this DataFrame
        lat = self._obj.latitude
        lon = self._obj.longitude
        return (float(lon.mean()), float(lat.mean()))

    def plot(self):
        # plot this array's data on a map, e.g., using Cartopy
        pass
```

Back in an interactive IPython session:

```
>>> ds = pd.DataFrame({'longitude': np.linspace(0, 10),
...                    'latitude': np.linspace(0, 20)})
>>> ds.geo.center
(5.0, 10.0)
>>> ds.geo.plot()
# plots data on a map
```

6.16.4 pandas.api.extensions.register_index_accessor

`pandas.api.extensions.register_index_accessor(name)`

Register a custom accessor on Index objects.

Parameters

name [str] Name under which the accessor should be registered. A warning is issued if this name conflicts with a preexisting attribute.

Returns

callable A class decorator.

See also:

`register_dataframe_accessor`, `register_series_accessor`

Notes

When accessed, your accessor will be initialized with the pandas object the user is interacting with. So the signature must be

```
def __init__(self, pandas_object): # noqa: E999
    ...
```

For consistency with pandas methods, you should raise an `AttributeError` if the data passed to your accessor has an incorrect dtype.

```
>>> pd.Series(['a', 'b']).dt
Traceback (most recent call last):
...
AttributeError: Can only use .dt accessor with datetimelike values
```

Examples

In your library code:

```
import pandas as pd

@pd.api.extensions.register_dataframe_accessor("geo")
class GeoAccessor:
    def __init__(self, pandas_obj):
        self._obj = pandas_obj

    @property
    def center(self):
        # return the geographic center point of this DataFrame
        lat = self._obj.latitude
        lon = self._obj.longitude
        return (float(lon.mean()), float(lat.mean()))

    def plot(self):
        # plot this array's data on a map, e.g., using Cartopy
        pass
```

Back in an interactive IPython session:

```
>>> ds = pd.DataFrame({'longitude': np.linspace(0, 10),
...                    'latitude': np.linspace(0, 20)})
>>> ds.geo.center
(5.0, 10.0)
>>> ds.geo.plot()
# plots data on a map
```

6.16.5 pandas.api.extensions.ExtensionDtype

`class pandas.api.extensions.ExtensionDtype`

A custom data type, to be paired with an `ExtensionArray`.

New in version 0.23.0.

See also:

`extensions.register_extension_dtype`

`extensions.ExtensionArray`

Notes

The interface includes the following abstract methods that must be implemented by subclasses:

- `type`
- `name`
- `construct_from_string`

The following attributes influence the behavior of the dtype in pandas operations

- `_is_numeric`
- `_is_boolean`

Optionally one can override `construct_array_type` for construction with the name of this dtype via the Registry. See `extensions.register_extension_dtype()`.

- `construct_array_type`

The `na_value` class attribute can be used to set the default NA value for this type. `numpy.nan` is used by default.

`ExtensionDtypes` are required to be hashable. The base class provides a default implementation, which relies on the `_metadata` class attribute. `_metadata` should be a tuple containing the strings that define your data type. For example, with `PeriodDtype` that's the `freq` attribute.

If you have a parametrized dtype you should set the “`_metadata`” class property.

Ideally, the attributes in `_metadata` will match the parameters to your `ExtensionDtype.__init__` (if any). If any of the attributes in `_metadata` don't implement the standard `__eq__` or `__hash__`, the default implementations here will not work.

Changed in version 0.24.0: Added `_metadata`, `__hash__`, and changed the default definition of `__eq__`.

This class does not inherit from `'abc.ABCMeta'` for performance reasons. Methods and properties required by the interface raise `pandas.errors.AbstractMethodError` and no `register` method is provided for registering virtual subclasses.

Attributes

<i>kind</i>	A character code (one of 'biufcmMOSUV'), default 'O'
<i>na_value</i>	Default NA value to use for this type.
<i>name</i>	A string identifying the data type.

Continued on next page

Table 416 – continued from previous page

<i>names</i>	Ordered list of field names, or None if there are no fields.
<i>type</i>	The scalar type for the array, e.g.

pandas.api.extensions.ExtensionDtype.kind**ExtensionDtype.kind**

A character code (one of ‘biufcmMOSUV’), default ‘O’

This should match the NumPy dtype used when the array is converted to an ndarray, which is probably ‘O’ for object if the extension type cannot be represented as a built-in NumPy type.

See also:

`numpy.dtype.kind`

pandas.api.extensions.ExtensionDtype.na_value**ExtensionDtype.na_value**

Default NA value to use for this type.

This is used in e.g. `ExtensionArray.take`. This should be the user-facing “boxed” version of the NA value, not the physical NA value for storage. e.g. for `JSONArray`, this is an empty dictionary.

pandas.api.extensions.ExtensionDtype.name**ExtensionDtype.name**

A string identifying the data type.

Will be used for display in, e.g. `Series.dtype`

pandas.api.extensions.ExtensionDtype.names**ExtensionDtype.names**

Ordered list of field names, or None if there are no fields.

This is for compatibility with NumPy arrays, and may be removed in the future.

pandas.api.extensions.ExtensionDtype.type**ExtensionDtype.type**

The scalar type for the array, e.g. `int`

It’s expected `ExtensionArray[item]` returns an instance of `ExtensionDtype.type` for scalar `item`, assuming that value is valid (not NA). NA values do not need to be instances of `type`.

Methods

<code>construct_array_type()</code>	Return the array type associated with this dtype
<code>construct_from_string(string)</code>	Construct this type from a string.
<code>is_dtype(dtype)</code>	Check if we match ‘dtype’.

pandas.api.extensions.ExtensionDtype.construct_array_type

classmethod `ExtensionDtype.construct_array_type()`
Return the array type associated with this dtype

Returns

`type`

pandas.api.extensions.ExtensionDtype.construct_from_string

classmethod `ExtensionDtype.construct_from_string(string: str)`
Construct this type from a string.

This is useful mainly for data types that accept parameters. For example, a period dtype accepts a frequency parameter that can be set as `period[H]` (where H means hourly frequency).

By default, in the abstract class, just the name of the type is expected. But subclasses can overwrite this method to accept parameters.

Parameters

string [str] The name of the type, for example `category`.

Returns

ExtensionDtype Instance of the dtype.

Raises

TypeError If a class cannot be constructed from this 'string'.

Examples

For extension dtypes with arguments the following may be an adequate implementation.

```
>>> @classmethod
... def construct_from_string(cls, string):
...     pattern = re.compile(r"^my_type\[((?P<arg_name>.+)\]$")
...     match = pattern.match(string)
...     if match:
...         return cls(**match.groupdict())
...     else:
...         raise TypeError("Cannot construct a '{}' from "
...                          "'{}'".format(cls.__name__, string))
```

pandas.api.extensions.ExtensionDtype.is_dtype

classmethod `ExtensionDtype.is_dtype(dtype) → bool`
Check if we match 'dtype'.

Parameters

dtype [object] The object to check.

Returns

is_dtype [bool]

Notes

The default implementation is True if

1. `cls.construct_from_string(dtype)` is an instance of `cls`.
2. `dtype` is an object and is an instance of `cls`
3. `dtype` has a `dtype` attribute, and any of the above conditions is true for `dtype.dtype`.

<i>api.extensions.ExtensionArray</i>	Abstract base class for custom 1-D array types.
<i>arrays.PandasArray(values[, copy])</i>	A pandas ExtensionArray for NumPy data.

6.16.6 pandas.api.extensions.ExtensionArray

class `pandas.api.extensions.ExtensionArray`

Abstract base class for custom 1-D array types.

pandas will recognize instances of this class as proper arrays with a custom type and will not attempt to coerce them to objects. They may be stored directly inside a `DataFrame` or `Series`.

New in version 0.23.0.

Notes

The interface includes the following abstract methods that must be implemented by subclasses:

- `_from_sequence`
- `_from_factorized`
- `__getitem__`
- `__len__`
- `dtype`
- `nbytes`
- `isna`
- `take`
- `copy`
- `_concat_same_type`

A default repr displaying the type, (truncated) data, length, and dtype is provided. It can be customized or replaced by by overriding:

- `__repr__` : A default repr for the ExtensionArray.
- `_formatter` : Print scalars inside a Series or DataFrame.

Some methods require casting the ExtensionArray to an ndarray of Python objects with `self.astype(object)`, which may be expensive. When performance is a concern, we highly recommend overriding the following methods:

- `fillna`
- `dropna`
- `unique`

- `factorize / _values_for_factorize`
- `argsort / _values_for_argsort`
- `searchsorted`

The remaining methods implemented on this class should be performant, as they only compose abstract methods. Still, a more efficient implementation may be available, and these methods can be overridden.

One can implement methods to handle array reductions.

- `_reduce`

One can implement methods to handle parsing from strings that will be used in methods such as `pandas.io.parsers.read_csv`.

- `_from_sequence_of_strings`

This class does not inherit from `'abc.ABCMeta'` for performance reasons. Methods and properties required by the interface raise `pandas.errors.AbstractMethodError` and no `register` method is provided for registering virtual subclasses.

ExtensionArrays are limited to 1 dimension.

They may be backed by none, one, or many NumPy arrays. For example, `pandas.Categorical` is an extension array backed by two arrays, one for codes and one for categories. An array of IPv6 address may be backed by a NumPy structured array with two fields, one for the lower 64 bits and one for the upper 64 bits. Or they may be backed by some other storage type, like Python lists. Pandas makes no assumptions on how the data are stored, just that it can be converted to a NumPy array. The `ExtensionArray` interface does not impose any rules on how this data is stored. However, currently, the backing data cannot be stored in attributes called `.values` or `._values` to ensure full compatibility with pandas internals. But other names as `.data`, `._data`, `._items`, ... can be freely used.

If implementing NumPy's `__array_ufunc__` interface, pandas expects that

1. You defer by raising `NotImplemented` when any Series are present in `inputs`. Pandas will extract the arrays and call the ufunc again.
2. You define a `_HANDLED_TYPES` tuple as an attribute on the class. Pandas inspect this to determine whether the ufunc is valid for the types present.

See *NumPy Universal Functions* for more.

Attributes

<i>dtype</i>	An instance of 'ExtensionDtype'.
<i>nbytes</i>	The number of bytes needed to store this object in memory.
<i>ndim</i>	Extension Arrays are only allowed to be 1-dimensional.
<i>shape</i>	Return a tuple of the array dimensions.

`pandas.api.extensions.ExtensionArray.dtype`

`ExtensionArray.dtype`

An instance of 'ExtensionDtype'.

pandas.api.extensions.ExtensionArray.nbytes**ExtensionArray.nbytes**

The number of bytes needed to store this object in memory.

pandas.api.extensions.ExtensionArray.ndim**ExtensionArray.ndim**

Extension Arrays are only allowed to be 1-dimensional.

pandas.api.extensions.ExtensionArray.shape**ExtensionArray.shape**

Return a tuple of the array dimensions.

Methods

<i>argsort</i> (self[, ascending, kind])	Return the indices that would sort this array.
<i>astype</i> (self, dtype[, copy])	Cast to a NumPy array with 'dtype'.
<i>copy</i> (self)	Return a copy of the array.
<i>dropna</i> (self)	Return ExtensionArray without NA values
<i>factorize</i> (self, na_sentinel)	Encode the extension array as an enumerated type.
<i>fillna</i> (self[, value, method, limit])	Fill NA/NaN values using the specified method.
<i>isna</i> (self)	A 1-D array indicating if each value is missing.
<i>ravel</i> (self[, order])	Return a flattened view on this array.
<i>repeat</i> (self, repeats[, axis])	Repeat elements of a ExtensionArray.
<i>searchsorted</i> (self, value[, side, sorter])	Find indices where elements should be inserted to maintain order.
<i>shift</i> (self, periods, fill_value)	Shift values by desired number.
<i>take</i> (self, indices, allow_fill, fill_value)	Take elements from an array.
<i>unique</i> (self)	Compute the ExtensionArray of unique values.
<i>_concat_same_type</i> (to_concat)	Concatenate multiple array
<i>_formatter</i> (self, boxed)	Formatting function for scalar values.
<i>_formatting_values</i> (self)	(DEPRECATED) An array of values to be printed in, e.g.
<i>_from_factorized</i> (values, original)	Reconstruct an ExtensionArray after factorization.
<i>_from_sequence</i> (scalars[, dtype, copy])	Construct a new ExtensionArray from a sequence of scalars.
<i>_from_sequence_of_strings</i> (strings[, dtype, copy])	Construct a new ExtensionArray from a sequence of strings.
<i>_ndarray_values</i>	Internal pandas method for lossy conversion to a NumPy ndarray.
<i>_reduce</i> (self, name[, skipna])	Return a scalar result of performing the reduction operation.
<i>_values_for_argsort</i> (self)	Return values for sorting.
<i>_values_for_factorize</i> (self)	Return an array and missing value suitable for factorization.

pandas.api.extensions.ExtensionArray.argsort

`ExtensionArray.argsort(self, ascending=True, kind='quicksort', *args, **kwargs)`

Return the indices that would sort this array.

Parameters

ascending [bool, default True] Whether the indices should result in an ascending or descending sort.

kind [{'quicksort', 'mergesort', 'heapsort'}, optional] Sorting algorithm.

***args, **kwargs:** passed through to `numpy.argsort()`.

Returns

index_array [ndarray] Array of indices that sort `self`. If NaN values are contained, NaN values are placed at the end.

See also:

`numpy.argsort` Sorting implementation used internally.

pandas.api.extensions.ExtensionArray.astype

`ExtensionArray.astype(self, dtype, copy=True)`

Cast to a NumPy array with 'dtype'.

Parameters

dtype [str or dtype] Typecode or data-type to which the array is cast.

copy [bool, default True] Whether to copy the data, even if not necessary. If False, a copy is made only if the old dtype does not match the new dtype.

Returns

array [ndarray] NumPy ndarray with 'dtype' for its dtype.

pandas.api.extensions.ExtensionArray.copy

`ExtensionArray.copy(self) → pandas.core.dtypes.generic.ABCExtensionArray`

Return a copy of the array.

Returns

ExtensionArray

pandas.api.extensions.ExtensionArray.dropna

`ExtensionArray.dropna(self)`

Return ExtensionArray without NA values

Returns

valid [ExtensionArray]

pandas.api.extensions.ExtensionArray.factorize

`ExtensionArray.factorize(self, na_sentinel: int = -1) → Tuple[numpy.ndarray, pandas.core.dtypes.generic.ABCExtensionArray]`

Encode the extension array as an enumerated type.

Parameters

na_sentinel [int, default -1] Value to use in the *labels* array to indicate missing values.

Returns

labels [ndarray] An integer NumPy array that's an indexer into the original ExtensionArray.

uniques [ExtensionArray] An ExtensionArray containing the unique values of *self*.

Note: *uniques* will *not* contain an entry for the NA value of the ExtensionArray if there are any missing values present in *self*.

See also:

factorize Top-level factorize method that dispatches here.

Notes

`pandas.factorize()` offers a *sort* keyword as well.

pandas.api.extensions.ExtensionArray.fillna

`ExtensionArray.fillna(self, value=None, method=None, limit=None)`

Fill NA/NaN values using the specified method.

Parameters

value [scalar, array-like] If a scalar value is passed it is used to fill all missing values. Alternatively, an array-like 'value' can be given. It's expected that the array-like have the same length as 'self'.

method [{'backfill', 'bfill', 'pad', 'ffill', None}, default None] Method to use for filling holes in reindexed Series pad / ffill: propagate last valid observation forward to next valid backfill / bfill: use NEXT valid observation to fill gap

limit [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled.

Returns

filled [ExtensionArray with NA/NaN filled]

pandas.api.extensions.ExtensionArray.isna**ExtensionArray.isna**(*self*) → ~ArrayLike

A 1-D array indicating if each value is missing.

Returns**na_values** [Union[np.ndarray, ExtensionArray]] In most cases, this should return a NumPy ndarray. For exceptional cases like `SparseArray`, where returning an ndarray would be expensive, an `ExtensionArray` may be returned.**Notes**If returning an `ExtensionArray`, then

- `na_values._is_boolean` should be `True`
- `na_values` should implement `ExtensionArray._reduce()`
- `na_values.any` and `na_values.all` should be implemented

pandas.api.extensions.ExtensionArray.ravel**ExtensionArray.ravel**(*self*, *order*='C') → pandas.core.dtypes.generic.ABCExtensionArray

Return a flattened view on this array.

Parameters**order** [{None, 'C', 'F', 'A', 'K'}, default 'C']**Returns****ExtensionArray****Notes**

- Because `ExtensionArrays` are 1D-only, this is a no-op.
- The “order” argument is ignored, is for compatibility with NumPy.

pandas.api.extensions.ExtensionArray.repeat**ExtensionArray.repeat**(*self*, *repeats*, *axis*=None)Repeat elements of a `ExtensionArray`.Returns a new `ExtensionArray` where each element of the current `ExtensionArray` is repeated consecutively a given number of times.**Parameters****repeats** [int or array of ints] The number of repetitions for each element. This should be a non-negative integer. Repeating 0 times will return an empty `ExtensionArray`.**axis** [None] Must be `None`. Has no effect but is accepted for compatibility with `numpy`.**Returns**

repeated_array [ExtensionArray] Newly created ExtensionArray with repeated elements.

See also:

Series.repeat Equivalent function for Series.

Index.repeat Equivalent function for Index.

numpy.repeat Similar method for `numpy.ndarray`.

ExtensionArray.take Take arbitrary positions.

Examples

```
>>> cat = pd.Categorical(['a', 'b', 'c'])
>>> cat
[a, b, c]
Categories (3, object): [a, b, c]
>>> cat.repeat(2)
[a, a, b, b, c, c]
Categories (3, object): [a, b, c]
>>> cat.repeat([1, 2, 3])
[a, b, b, c, c, c]
Categories (3, object): [a, b, c]
```

pandas.api.extensions.ExtensionArray.searchsorted

ExtensionArray.searchsorted(*self*, *value*, *side*='left', *sorter*=None)

Find indices where elements should be inserted to maintain order.

New in version 0.24.0.

Find the indices into a sorted array *self* (a) such that, if the corresponding elements in *value* were inserted before the indices, the order of *self* would be preserved.

Assuming that *self* is sorted:

<i>side</i>	returned index <i>i</i> satisfies
left	<code>self[i-1] < value <= self[i]</code>
right	<code>self[i-1] <= value < self[i]</code>

Parameters

value [array_like] Values to insert into *self*.

side [{'left', 'right'}, optional] If 'left', the index of the first suitable location found is given. If 'right', return the last such index. If there is no suitable index, return either 0 or N (where N is the length of *self*).

sorter [1-D array_like, optional] Optional array of integer indices that sort array a into ascending order. They are typically the result of `argsort`.

Returns

array of ints Array of insertion points with the same shape as *value*.

See also:

`numpy.searchsorted` Similar method from NumPy.

pandas.api.extensions.ExtensionArray.shift

`ExtensionArray.shift(self, periods: int = 1, fill_value: object = None) → pandas.core.dtypes.generic.ABCExtensionArray`

Shift values by desired number.

Newly introduced missing values are filled with `self.dtype.na_value`.

New in version 0.24.0.

Parameters

periods [int, default 1] The number of periods to shift. Negative values are allowed for shifting backwards.

fill_value [object, optional] The scalar value to use for newly introduced missing values. The default is `self.dtype.na_value`

New in version 0.24.0.

Returns

shifted [ExtensionArray]

Notes

If `self` is empty or `periods` is 0, a copy of `self` is returned.

If `periods > len(self)`, then an array of size `len(self)` is returned, with all values filled with `self.dtype.na_value`.

pandas.api.extensions.ExtensionArray.take

`ExtensionArray.take(self, indices: Sequence[int], allow_fill: bool = False, fill_value: Any = None) → pandas.core.dtypes.generic.ABCExtensionArray`

Take elements from an array.

Parameters

indices [sequence of integers] Indices to be taken.

allow_fill [bool, default False] How to handle negative values in *indices*.

- False: negative values in *indices* indicate positional indices from the right (the default). This is similar to `numpy.take()`.
- True: negative values in *indices* indicate missing values. These values are set to *fill_value*. Any other other negative values raise a `ValueError`.

fill_value [any, optional] Fill value to use for NA-indices when *allow_fill* is True. This may be `None`, in which case the default NA value for the type, `self.dtype.na_value`, is used.

For many ExtensionArrays, there will be two representations of *fill_value*: a user-facing “boxed” scalar, and a low-level physical NA value. *fill_value* should

be the user-facing version, and the implementation should handle translating that to the physical version for processing the take if necessary.

Returns

ExtensionArray

Raises

IndexError When the indices are out of bounds for the array.

ValueError When *indices* contains negative values other than -1 and *allow_fill* is True.

See also:

`numpy.take`

`api.extensions.take`

Notes

`ExtensionArray.take` is called by `Series.__getitem__`, `.loc`, `iloc`, when *indices* is a sequence of values. Additionally, it's called by `Series.reindex()`, or any other method that causes realignment, with a *fill_value*.

Examples

Here's an example implementation, which relies on casting the extension array to object dtype. This uses the helper method `pandas.api.extensions.take()`.

```
def take(self, indices, allow_fill=False, fill_value=None):
    from pandas.core.algorithms import take

    # If the ExtensionArray is backed by an ndarray, then
    # just pass that here instead of coercing to object.
    data = self.astype(object)

    if allow_fill and fill_value is None:
        fill_value = self.dtype.na_value

    # fill value should always be translated from the scalar
    # type for the array, to the physical storage type for
    # the data, before passing to take.

    result = take(data, indices, fill_value=fill_value,
                  allow_fill=allow_fill)
    return self._from_sequence(result, dtype=self.dtype)
```

`pandas.api.extensions.ExtensionArray.unique`

`ExtensionArray.unique(self)`

Compute the `ExtensionArray` of unique values.

Returns

uniques [ExtensionArray]

pandas.api.extensions.ExtensionArray._concat_same_type

classmethod `ExtensionArray._concat_same_type`(*to_concat*: Sequence[pandas.core.dtypes.generic.ABCExtensionArray])
→ pandas.core.dtypes.generic.ABCExtensionArray

Concatenate multiple array

Parameters

to_concat [sequence of this type]

Returns

ExtensionArray

pandas.api.extensions.ExtensionArray._formatter

`ExtensionArray._formatter`(*self*, *boxed*: bool = False) → Callable[[Any], Union[str, NoneType]]

Formatting function for scalar values.

This is used in the default ‘`__repr__`’. The returned formatting function receives instances of your scalar type.

Parameters

boxed [bool, default False] An indicated for whether or not your array is being printed within a Series, DataFrame, or Index (True), or just by itself (False). This may be useful if you want scalar values to appear differently within a Series versus on its own (e.g. quoted or not).

Returns

Callable[[Any], str] A callable that gets instances of the scalar type and returns a string. By default, `repr()` is used when `boxed=False` and `str()` is used when `boxed=True`.

pandas.api.extensions.ExtensionArray._formatting_values

`ExtensionArray._formatting_values`(*self*) → numpy.ndarray

An array of values to be printed in, e.g. the Series repr

Deprecated since version 0.24.0: Use `ExtensionArray._formatter()` instead.

Returns

array [ndarray]

pandas.api.extensions.ExtensionArray._from_factorized

classmethod `ExtensionArray._from_factorized`(*values*, *original*)

Reconstruct an ExtensionArray after factorization.

Parameters

values [ndarray] An integer ndarray with the factorized values.

original [ExtensionArray] The original ExtensionArray that factorize was called on.

See also:

factorize

ExtensionArray.factorize

pandas.api.extensions.ExtensionArray._from_sequence

classmethod `ExtensionArray._from_sequence(scalars, dtype=None, copy=False)`

Construct a new ExtensionArray from a sequence of scalars.

Parameters

scalars [Sequence] Each element will be an instance of the scalar type for this array, `cls.dtype.type`.

dtype [dtype, optional] Construct for this particular dtype. This should be a Dtype compatible with the ExtensionArray.

copy [boolean, default False] If True, copy the underlying data.

Returns

ExtensionArray

pandas.api.extensions.ExtensionArray._from_sequence_of_strings

classmethod `ExtensionArray._from_sequence_of_strings(strings, dtype=None, copy=False)`

Construct a new ExtensionArray from a sequence of strings.

New in version 0.24.0.

Parameters

strings [Sequence] Each element will be an instance of the scalar type for this array, `cls.dtype.type`.

dtype [dtype, optional] Construct for this particular dtype. This should be a Dtype compatible with the ExtensionArray.

copy [boolean, default False] If True, copy the underlying data.

Returns

ExtensionArray

pandas.api.extensions.ExtensionArray._ndarray_values

ExtensionArray._ndarray_values

Internal pandas method for lossy conversion to a NumPy ndarray.

This method is not part of the pandas interface.

The expectation is that this is cheap to compute, and is primarily used for interacting with our indexers.

Returns

`array` [ndarray]

`pandas.api.extensions.ExtensionArray._reduce`

`ExtensionArray._reduce(self, name, skipna=True, **kwargs)`

Return a scalar result of performing the reduction operation.

Parameters

name [str] Name of the function, supported values are: { any, all, min, max, sum, mean, median, prod, std, var, sem, kurt, skew }.

skipna [bool, default True] If True, skip NaN values.

****kwargs** Additional keyword arguments passed to the reduction function. Currently, *ddof* is the only supported kwarg.

Returns

scalar

Raises

TypeError [subclass does not define reductions]

`pandas.api.extensions.ExtensionArray._values_for_argsort`

`ExtensionArray._values_for_argsort(self) → numpy.ndarray`

Return values for sorting.

Returns

ndarray The transformed values should maintain the ordering between values within the array.

See also:

`ExtensionArray.argsort`

`pandas.api.extensions.ExtensionArray._values_for_factorize`

`ExtensionArray._values_for_factorize(self) → Tuple[numpy.ndarray, Any]`

Return an array and missing value suitable for factorization.

Returns

values [ndarray] An array suitable for factorization. This should maintain order and be a supported dtype (Float64, Int64, UInt64, String, Object). By default, the extension array is cast to object dtype.

na_value [object] The value in *values* to consider missing. This will be treated as NA in the factorization routines, so it will be coded as *na_sentinal* and not included in *uniques*. By default, `np.nan` is used.

Notes

The values returned by this method are also used in `pandas.util.hash_pandas_object()`.

6.16.7 pandas.arrays.PandasArray

`class pandas.arrays.PandasArray(values, copy=False)`

A pandas ExtensionArray for NumPy data.

New in version 0.24.0.

This is mostly for internal compatibility, and is not especially useful on its own.

Parameters

values [ndarray] The NumPy ndarray to wrap. Must be 1-dimensional.

copy [bool, default False] Whether to copy *values*.

7.1.1 Where to start?

All contributions, bug reports, bug fixes, documentation improvements, enhancements, and ideas are welcome.

If you are brand new to pandas or open-source development, we recommend going through the [GitHub “issues” tab](#) to find issues that interest you. There are a number of issues listed under [Docs](#) and [good first issue](#) where you could start out. Once you’ve found an interesting issue, you can return here to get your development environment setup.

Feel free to ask questions on the [mailing list](#) or on [Gitter](#).

7.1.2 Bug reports and enhancement requests

Bug reports are an important part of making *pandas* more stable. Having a complete bug report will allow others to reproduce the bug and provide insight into fixing. See [this stackoverflow article](#) and [this blogpost](#) for tips on writing a good bug report.

Trying the bug-producing code out on the *master* branch is often a worthwhile exercise to confirm the bug still exists. It is also worth searching existing bug reports and pull requests to see if the issue has already been reported and/or fixed.

Bug reports must:

1. Include a short, self-contained Python snippet reproducing the problem. You can format the code nicely by using [GitHub Flavored Markdown](#):

```
```python
>>> from pandas import DataFrame
>>> df = DataFrame(...)
...
```
```

2. Include the full version string of *pandas* and its dependencies. You can use the built-in function:

```
>>> import pandas as pd
>>> pd.show_versions()
```

3. Explain why the current behavior is wrong/not desired and what you expect instead.

The issue will then show up to the *pandas* community and be open to comments/ideas from others.

7.1.3 Working with the code

Now that you have an issue you want to fix, enhancement to add, or documentation to improve, you need to learn how to work with GitHub and the *pandas* code base.

Version control, Git, and GitHub

To the new user, working with Git is one of the more daunting aspects of contributing to *pandas*. It can very quickly become overwhelming, but sticking to the guidelines below will help keep the process straightforward and mostly trouble free. As always, if you are having difficulties please feel free to ask for help.

The code is hosted on [GitHub](#). To contribute you will need to sign up for a [free GitHub account](#). We use [Git](#) for version control to allow many people to work together on the project.

Some great resources for learning Git:

- the [GitHub help pages](#).
- the [NumPy's documentation](#).
- [Matthew Brett's Pydagogue](#).

Getting started with Git

[GitHub has instructions](#) for installing git, setting up your SSH key, and configuring git. All these steps need to be completed before you can work seamlessly between your local repository and GitHub.

Forking

You will need your own fork to work on the code. Go to the [pandas project page](#) and hit the **Fork** button. You will want to clone your fork to your machine:

```
git clone https://github.com/your-user-name/pandas.git pandas-yourname
cd pandas-yourname
git remote add upstream https://github.com/pandas-dev/pandas.git
```

This creates the directory *pandas-yourname* and connects your repository to the upstream (main project) *pandas* repository.

Creating a development environment

To test out code changes, you'll need to build pandas from source, which requires a C compiler and Python environment. If you're making documentation changes, you can skip to *Contributing to the documentation* but you won't be able to build the documentation locally before pushing your changes.

Installing a C compiler

Pandas uses C extensions (mostly written using Cython) to speed up certain operations. To install pandas from source, you need to compile these C extensions, which means you need a C compiler. This process depends on which platform you're using. Follow the [Cython contributing guide](#) for getting a compiler installed. You don't need to do any of the `./configure` or `make` steps; you only need to install the compiler.

For Windows developers, when using Python 3.5 and later, it is sufficient to install [Visual Studio 2017](#) with the **Python development workload** and the **Python native development tools** option. Otherwise, the following links may be helpful.

- <https://blogs.msdn.microsoft.com/pythonengineering/2017/03/07/python-support-in-vs2017/>
- <https://blogs.msdn.microsoft.com/pythonengineering/2016/04/11/unable-to-find-vcvarsall-bat/>
- <https://github.com/conda/conda-recipes/wiki/Building-from-Source-on-Windows-32-bit-and-64-bit>
- <https://cowboyprogrammer.org/building-python-wheels-for-windows/>
- <https://blog.ionelmc.ro/2014/12/21/compiling-python-extensions-on-windows/>
- <https://support.enthought.com/hc/en-us/articles/204469260-Building-Python-extensions-with-Canopy>

Let us know if you have any difficulties by opening an issue or reaching out on [Gitter](#).

Creating a Python environment

Now that you have a C compiler, create an isolated pandas development environment:

- Install either [Anaconda](#) or [miniconda](#)
- Make sure your conda is up to date (`conda update conda`)
- Make sure that you have *cloned the repository*
- `cd` to the *pandas* source directory

We'll now kick off a three-step process:

1. Install the build dependencies
2. Build and install pandas
3. Install the optional dependencies

```
# Create and activate the build environment
conda env create -f environment.yml
conda activate pandas-dev

# or with older versions of Anaconda:
```

(continues on next page)

(continued from previous page)

```
source activate pandas-dev

# Build and install pandas
python setup.py build_ext --inplace -j 4
python -m pip install -e .
```

At this point you should be able to import pandas from your locally built version:

```
$ python # start an interpreter
>>> import pandas
>>> print(pandas.__version__)
0.22.0.dev0+29.g4ad6d4d74
```

This will create the new environment, and not touch any of your existing environments, nor any existing Python installation.

To view your environments:

```
conda info -e
```

To return to your root environment:

```
conda deactivate
```

See the full conda docs [here](#).

Creating a Python environment (pip)

If you aren't using conda for your development environment, follow these instructions. You'll need to have at least python3.5 installed on your system.

```
# Create a virtual environment
# Use an ENV_DIR of your choice. We'll use ~/virtualenvs/pandas-dev
# Any parent directories should already exist
python3 -m venv ~/virtualenvs/pandas-dev
# Activate the virtualenv
. ~/virtualenvs/pandas-dev/bin/activate

# Install the build dependencies
python -m pip install -r requirements-dev.txt

# Build and install pandas
python setup.py build_ext --inplace -j 4
python -m pip install -e .
```

Creating a branch

You want your master branch to reflect only production-ready code, so create a feature branch for making your changes. For example:

```
git branch shiny-new-feature
git checkout shiny-new-feature
```

The above can be simplified to:

```
git checkout -b shiny-new-feature
```

This changes your working directory to the shiny-new-feature branch. Keep any changes in this branch specific to one bug or feature so it is clear what the branch brings to *pandas*. You can have many shiny-new-features and switch in between them using the git checkout command.

When creating this branch, make sure your master branch is up to date with the latest upstream master version. To update your local master branch, you can do:

```
git checkout master
git pull upstream master --ff-only
```

When you want to update the feature branch with changes in master after you created the branch, check the section on *updating a PR*.

7.1.4 Contributing to the documentation

Contributing to the documentation benefits everyone who uses *pandas*. We encourage you to help us improve the documentation, and you don't have to be an expert on *pandas* to do so! In fact, there are sections of the docs that are worse off after being written by experts. If something in the docs doesn't make sense to you, updating the relevant section after you figure it out is a great way to ensure it will help the next person.

Documentation:

- *About the pandas documentation*
- *Updating a pandas docstring*
- *How to build the pandas documentation*
 - *Requirements*
 - *Building the documentation*
 - *Building master branch documentation*

About the *pandas* documentation

The documentation is written in **reStructuredText**, which is almost like writing in plain English, and built using **Sphinx**. The Sphinx Documentation has an excellent [introduction to reST](#). Review the Sphinx docs to perform more complex changes to the documentation as well.

Some other important things to know about the docs:

- The *pandas* documentation consists of two parts: the docstrings in the code itself and the docs in this folder `doc/`.

The docstrings provide a clear explanation of the usage of the individual functions, while the documentation in this folder consists of tutorial-like overviews per topic together with some other information (what's new, installation, etc).

- The docstrings follow a pandas convention, based on the **Numpy Docstring Standard**. Follow the *pandas docstring guide* for detailed instructions on how to write a correct docstring. `{{ header }}`

pandas docstring guide

About docstrings and standards

A Python docstring is a string used to document a Python module, class, function or method, so programmers can understand what it does without having to read the details of the implementation.

Also, it is a common practice to generate online (html) documentation automatically from docstrings. Sphinx serves this purpose.

Next example gives an idea on how a docstring looks like:

```
def add(num1, num2):
    """
    Add up two integer numbers.

    This function simply wraps the `+` operator, and does not
    do anything interesting, except for illustrating what is
    the docstring of a very simple function.

    Parameters
    -----
    num1 : int
        First number to add
    num2 : int
        Second number to add

    Returns
    -----
    int
        The sum of `num1` and `num2`

    See Also
    -----
    subtract : Subtract one integer from another

    Examples
    -----
    >>> add(2, 2)
    4
    >>> add(25, 0)
    25
    >>> add(10, -10)
    0
    """
    return num1 + num2
```

Some standards exist about docstrings, so they are easier to read, and they can be exported to other formats such as html or pdf.

The first conventions every Python docstring should follow are defined in PEP-257.

As PEP-257 is quite open, and some other standards exist on top of it. In the case of pandas, the numpy docstring convention is followed. The conventions is explained in this document:

- [numpydoc docstring guide](#) (which is based in the original [Guide to NumPy/SciPy documentation](#))

numpydoc is a Sphinx extension to support the numpy docstring convention.

The standard uses reStructuredText (reST). reStructuredText is a markup language that allows encoding styles in plain text files. Documentation about reStructuredText can be found in:

- [Sphinx reStructuredText primer](#)
- [Quick reStructuredText reference](#)
- [Full reStructuredText specification](#)

Pandas has some helpers for sharing docstrings between related classes, see *Sharing docstrings*.

The rest of this document will summarize all the above guides, and will provide additional convention specific to the pandas project.

Writing a docstring

General rules

Docstrings must be defined with three double-quotes. No blank lines should be left before or after the docstring. The text starts in the next line after the opening quotes. The closing quotes have their own line (meaning that they are not at the end of the last sentence).

In rare occasions reST styles like bold text or italics will be used in docstrings, but it is common to have inline code, which is presented between backticks. It is considered inline code:

- The name of a parameter
- Python code, a module, function, built-in, type, literal... (e.g. `os`, `list`, `numpy.abs`, `datetime.date`, `True`)
- A pandas class (in the form `:class:~pandas.Series``)
- A pandas method (in the form `:meth:~pandas.Series.sum``)
- A pandas function (in the form `:func:~pandas.to_datetime``)

Note: To display only the last component of the linked class, method or function, prefix it with `~`. For example, `:class:~pandas.Series`` will link to `pandas.Series` but only display the last part, `Series` as the link text. See [Sphinx cross-referencing syntax](#) for details.

Good:

```
def add_values(arr):
    """
    Add the values in `arr`.

    This is equivalent to Python `sum` of :meth:~pandas.Series.sum`.

    Some sections are omitted here for simplicity.
    """
    return sum(arr)
```

Bad:

```
def func():
    """Some function.

    With several mistakes in the docstring.

    It has a blank line after the signature `def func():`.

    The text 'Some function' should go in the line after the
    opening quotes of the docstring, not in the same line.

    There is a blank line between the docstring and the first line
    of code `foo = 1`.

    The closing quotes should be in the next line, not in this one."""

    foo = 1
    bar = 2
    return foo + bar
```

Section 1: Short summary

The short summary is a single sentence that expresses what the function does in a concise way.

The short summary must start with a capital letter, end with a dot, and fit in a single line. It needs to express what the object does without providing details. For functions and methods, the short summary must start with an infinitive verb.

Good:

```
def astype(dtype):
    """
    Cast Series type.

    This section will provide further details.
    """
    pass
```

Bad:

```
def astype(dtype):
    """
    Casts Series type.

    Verb in third-person of the present simple, should be infinitive.
    """
    pass
```

```
def astype(dtype):
    """
    Method to cast Series type.
```

(continues on next page)

(continued from previous page)

```
Does not start with verb.
"""
pass
```

```
def astype(dtype):
    """
    Cast Series type

    Missing dot at the end.
    """
    pass
```

```
def astype(dtype):
    """
    Cast Series type from its current type to the new type defined in
    the parameter dtype.

    Summary is too verbose and doesn't fit in a single line.
    """
    pass
```

Section 2: Extended summary

The extended summary provides details on what the function does. It should not go into the details of the parameters, or discuss implementation notes, which go in other sections.

A blank line is left between the short summary and the extended summary. And every paragraph in the extended summary is finished by a dot.

The extended summary should provide details on why the function is useful and their use cases, if it is not too generic.

```
def unstack():
    """
    Pivot a row index to columns.

    When using a MultiIndex, a level can be pivoted so each value in
    the index becomes a column. This is especially useful when a subindex
    is repeated for the main index, and data is easier to visualize as a
    pivot table.

    The index level will be automatically removed from the index when added
    as columns.
    """
    pass
```

Section 3: Parameters

The details of the parameters will be added in this section. This section has the title “Parameters”, followed by a line with a hyphen under each letter of the word “Parameters”. A blank line is left before

the section title, but not after, and not between the line with the word “Parameters” and the one with the hyphens.

After the title, each parameter in the signature must be documented, including **args* and ***kwargs*, but not *self*.

The parameters are defined by their name, followed by a space, a colon, another space, and the type (or types). Note that the space between the name and the colon is important. Types are not defined for **args* and ***kwargs*, but must be defined for all other parameters. After the parameter definition, it is required to have a line with the parameter description, which is indented, and can have multiple lines. The description must start with a capital letter, and finish with a dot.

For keyword arguments with a default value, the default will be listed after a comma at the end of the type. The exact form of the type in this case will be “int, default 0”. In some cases it may be useful to explain what the default argument means, which can be added after a comma “int, default -1, meaning all cpus”.

In cases where the default value is *None*, meaning that the value will not be used. Instead of “str, default None”, it is preferred to write “str, optional”. When *None* is a value being used, we will keep the form “str, default None”. For example, in `df.to_csv(compression=None)`, *None* is not a value being used, but means that compression is optional, and no compression is being used if not provided. In this case we will use *str, optional*. Only in cases like `func(value=None)` and *None* is being used in the same way as *0* or *foo* would be used, then we will specify “str, int or None, default None”.

Good:

```
class Series:
    def plot(self, kind, color='blue', **kwargs):
        """
        Generate a plot.

        Render the data in the Series as a matplotlib plot of the
        specified kind.

        Parameters
        -----
        kind : str
            Kind of matplotlib plot.
        color : str, default 'blue'
            Color name or rgb code.
        **kwargs
            These parameters will be passed to the matplotlib plotting
            function.
        """
        pass
```

Bad:

```
class Series:
    def plot(self, kind, **kwargs):
        """
        Generate a plot.

        Render the data in the Series as a matplotlib plot of the
        specified kind.
```

(continues on next page)

(continued from previous page)

Note the blank line between the parameters title and the first parameter. Also, note that after the name of the parameter `kind` and before the colon, a space is missing.

Also, note that the parameter descriptions do not start with a capital letter, and do not finish with a dot.

*Finally, the `**kwargs` parameter is missing.*

Parameters

```
kind: str
    kind of matplotlib plot
"""
pass
```

Parameter types

When specifying the parameter types, Python built-in data types can be used directly (the Python type is preferred to the more verbose string, integer, boolean, etc):

- int
- float
- str
- bool

For complex types, define the subtypes. For *dict* and *tuple*, as more than one type is present, we use the brackets to help read the type (curly brackets for *dict* and normal brackets for *tuple*):

- list of int
- dict of {str : int}
- tuple of (str, int, int)
- tuple of (str,)
- set of str

In case where there are just a set of values allowed, list them in curly brackets and separated by commas (followed by a space). If the values are ordinal and they have an order, list them in this order. Otherwise, list the default value first, if there is one:

- {0, 10, 25}
- {'simple', 'advanced'}
- {'low', 'medium', 'high'}
- {'cat', 'dog', 'bird'}

If the type is defined in a Python module, the module must be specified:

- datetime.date
- datetime.datetime

- decimal.Decimal

If the type is in a package, the module must be also specified:

- numpy.ndarray
- scipy.sparse.coo_matrix

If the type is a pandas type, also specify pandas except for Series and DataFrame:

- Series
- DataFrame
- pandas.Index
- pandas.Categorical
- pandas.SparseArray

If the exact type is not relevant, but must be compatible with a numpy array, array-like can be specified.

If Any type that can be iterated is accepted, iterable can be used:

- array-like
- iterable

If more than one type is accepted, separate them by commas, except the last two types, that need to be separated by the word ‘or’:

- int or float
- float, decimal.Decimal or None
- str or list of str

If `None` is one of the accepted values, it always needs to be the last in the list.

For axis, the convention is to use something like:

- axis : {0 or ‘index’, 1 or ‘columns’, None}, default None

Section 4: Returns or Yields

If the method returns a value, it will be documented in this section. Also if the method yields its output.

The title of the section will be defined in the same way as the “Parameters”. With the names “Returns” or “Yields” followed by a line with as many hyphens as the letters in the preceding word.

The documentation of the return is also similar to the parameters. But in this case, no name will be provided, unless the method returns or yields more than one value (a tuple of values).

The types for “Returns” and “Yields” are the same as the ones for the “Parameters”. Also, the description must finish with a dot.

For example, with a single value:

```
def sample():
    """
    Generate and return a random number.

    The value is sampled from a continuous uniform distribution between
    0 and 1.
```

(continues on next page)

(continued from previous page)

```

Returns
-----
float
    Random number generated.
"""
return np.random.random()

```

With more than one value:

```

import string

def random_letters():
    """
    Generate and return a sequence of random letters.

    The length of the returned string is also random, and is also
    returned.

    Returns
    -----
    length : int
        Length of the returned string.
    letters : str
        String of random letters.
    """
    length = np.random.randint(1, 10)
    letters = ''.join(np.random.choice(string.ascii_lowercase)
                      for i in range(length))
    return length, letters

```

If the method yields its value:

```

def sample_values():
    """
    Generate an infinite sequence of random numbers.

    The values are sampled from a continuous uniform distribution between
    0 and 1.

    Yields
    -----
    float
        Random number generated.
    """
    while True:
        yield np.random.random()

```

Section 5: See Also

This section is used to let users know about pandas functionality related to the one being documented. In rare cases, if no related methods or functions can be found at all, this section can be skipped.

An obvious example would be the `head()` and `tail()` methods. As `tail()` does the equivalent as `head()` but at the end of the `Series` or `DataFrame` instead of at the beginning, it is good to let the users know about it.

To give an intuition on what can be considered related, here there are some examples:

- `loc` and `iloc`, as they do the same, but in one case providing indices and in the other positions
- `max` and `min`, as they do the opposite
- `iterrows`, `itertuples` and `items`, as it is easy that a user looking for the method to iterate over columns ends up in the method to iterate over rows, and vice-versa
- `fillna` and `dropna`, as both methods are used to handle missing values
- `read_csv` and `to_csv`, as they are complementary
- `merge` and `join`, as one is a generalization of the other
- `astype` and `pandas.to_datetime`, as users may be reading the documentation of `astype` to know how to cast as a date, and the way to do it is with `pandas.to_datetime`
- `where` is related to `numpy.where`, as its functionality is based on it

When deciding what is related, you should mainly use your common sense and think about what can be useful for the users reading the documentation, especially the less experienced ones.

When relating to other libraries (mainly `numpy`), use the name of the module first (not an alias like `np`). If the function is in a module which is not the main one, like `scipy.sparse`, list the full module (e.g. `scipy.sparse.coo_matrix`).

This section, as the previous, also has a header, “See Also” (note the capital S and A). Also followed by the line with hyphens, and preceded by a blank line.

After the header, we will add a line for each related method or function, followed by a space, a colon, another space, and a short description that illustrated what this method or function does, why is it relevant in this context, and what are the key differences between the documented function and the one referencing. The description must also finish with a dot.

Note that in “Returns” and “Yields”, the description is located in the following line than the type. But in this section it is located in the same line, with a colon in between. If the description does not fit in the same line, it can continue in the next ones, but it has to be indented in them.

For example:

```
class Series:
    def head(self):
        """
        Return the first 5 elements of the Series.

        This function is mainly useful to preview the values of the
        Series without displaying the whole of it.

        Returns
        -----
        Series
            Subset of the original series with the 5 first values.

        See Also
        -----
        Series.tail : Return the last 5 elements of the Series.
```

(continues on next page)

(continued from previous page)

```

Series.iloc : Return a slice of the elements in the Series,
    which can also be used to return the first or last n.
    """
    return self.iloc[:5]

```

Section 6: Notes

This is an optional section used for notes about the implementation of the algorithm. Or to document technical aspects of the function behavior.

Feel free to skip it, unless you are familiar with the implementation of the algorithm, or you discover some counter-intuitive behavior while writing the examples for the function.

This section follows the same format as the extended summary section.

Section 7: Examples

This is one of the most important sections of a docstring, even if it is placed in the last position. As often, people understand concepts better with examples, than with accurate explanations.

Examples in docstrings, besides illustrating the usage of the function or method, must be valid Python code, that in a deterministic way returns the presented output, and that can be copied and run by users.

They are presented as a session in the Python terminal. `>>>` is used to present code. `...` is used for code continuing from the previous line. Output is presented immediately after the last line of code generating the output (no blank lines in between). Comments describing the examples can be added with blank lines before and after them.

The way to present examples is as follows:

1. Import required libraries (except `numpy` and `pandas`)
2. Create the data required for the example
3. Show a very basic example that gives an idea of the most common use case
4. Add examples with explanations that illustrate how the parameters can be used for extended functionality

A simple example could be:

```

class Series:

    def head(self, n=5):
        """
        Return the first elements of the Series.

        This function is mainly useful to preview the values of the
        Series without displaying the whole of it.

        Parameters
        -----
        n : int

```

(continues on next page)

(continued from previous page)

```

    Number of values to return.

Return
-----
pandas.Series
    Subset of the original series with the n first values.

See Also
-----
tail : Return the last n elements of the Series.

Examples
-----
>>> s = pd.Series(['Ant', 'Bear', 'Cow', 'Dog', 'Falcon',
...                'Lion', 'Monkey', 'Rabbit', 'Zebra'])
>>> s.head()
0    Ant
1    Bear
2    Cow
3    Dog
4    Falcon
dtype: object

With the `n` parameter, we can change the number of returned rows:

>>> s.head(n=3)
0    Ant
1    Bear
2    Cow
dtype: object
"""
return self.iloc[:n]

```

The examples should be as concise as possible. In cases where the complexity of the function requires long examples, is recommended to use blocks with headers in bold. Use double star ****** to make a text bold, like in ****this example****.

Conventions for the examples

Code in examples is assumed to always start with these two lines which are not shown:

```

import numpy as np
import pandas as pd

```

Any other module used in the examples must be explicitly imported, one per line (as recommended in [PEP 8#imports](#)) and avoiding aliases. Avoid excessive imports, but if needed, imports from the standard library go first, followed by third-party libraries (like matplotlib).

When illustrating examples with a single `Series` use the name `s`, and if illustrating with a single `DataFrame` use the name `df`. For indices, `idx` is the preferred name. If a set of homogeneous `Series` or `DataFrame` is used, name them `s1`, `s2`, `s3...` or `df1`, `df2`, `df3...` If the data is not homogeneous, and more than one structure is needed, name them with something meaningful, for example `df_main` and

`df_to_join`.

Data used in the example should be as compact as possible. The number of rows is recommended to be around 4, but make it a number that makes sense for the specific example. For example in the `head` method, it requires to be higher than 5, to show the example with the default values. If doing the `mean`, we could use something like `[1, 2, 3]`, so it is easy to see that the value returned is the mean.

For more complex examples (grouping for example), avoid using data without interpretation, like a matrix of random numbers with columns A, B, C, D... And instead use a meaningful example, which makes it easier to understand the concept. Unless required by the example, use names of animals, to keep examples consistent. And numerical properties of them.

When calling the method, keywords arguments `head(n=3)` are preferred to positional arguments `head(3)`.

Good:

```
class Series:

    def mean(self):
        """
        Compute the mean of the input.

        Examples
        -----
        >>> s = pd.Series([1, 2, 3])
        >>> s.mean()
        2
        """
        pass

    def fillna(self, value):
        """
        Replace missing values by `value`.

        Examples
        -----
        >>> s = pd.Series([1, np.nan, 3])
        >>> s.fillna(0)
        [1, 0, 3]
        """
        pass

    def groupby_mean(self):
        """
        Group by index and return mean.

        Examples
        -----
        >>> s = pd.Series([380., 370., 24., 26],
        ...               name='max_speed',
        ...               index=['falcon', 'falcon', 'parrot', 'parrot'])
        >>> s.groupby_mean()
        index
```

(continues on next page)

(continued from previous page)

```

falcon    375.0
parrot    25.0
Name: max_speed, dtype: float64
"""
pass

def contains(self, pattern, case_sensitive=True, na=numpy.nan):
    """
    Return whether each value contains `pattern`.

    In this case, we are illustrating how to use sections, even
    if the example is simple enough and does not require them.

    Examples
    -----
    >>> s = pd.Series('Antelope', 'Lion', 'Zebra', np.nan)
    >>> s.contains(pattern='a')
    0    False
    1    False
    2     True
    3     NaN
    dtype: bool

    **Case sensitivity**

    With `case_sensitive` set to `False` we can match `a` with both
    `a` and `A`:

    >>> s.contains(pattern='a', case_sensitive=False)
    0     True
    1    False
    2     True
    3     NaN
    dtype: bool

    **Missing values**

    We can fill missing values in the output using the `na` parameter:

    >>> s.contains(pattern='a', na=False)
    0    False
    1    False
    2     True
    3    False
    dtype: bool
    """
    pass

```

Bad:

```

def method(foo=None, bar=None):
    """

```

(continues on next page)

(continued from previous page)

A sample DataFrame method.

Do not import numpy and pandas.

Try to use meaningful data, when it makes the example easier to understand.

Try to avoid positional arguments like in `df.method(1)`. They can be all right if previously defined with a meaningful name, like in `present_value(interest_rate)`, but avoid them otherwise.

When presenting the behavior with different parameters, do not place all the calls one next to the other. Instead, add a short sentence explaining what the example shows.

Examples

```
>>> import numpy as np
>>> import pandas as pd
>>> df = pd.DataFrame(np.random.randn(3, 3),
...                   columns=('a', 'b', 'c'))
>>> df.method(1)
21
>>> df.method(bar=14)
123
"""
pass
```

Tips for getting your examples pass the doctests

Getting the examples pass the doctests in the validation script can sometimes be tricky. Here are some attention points:

- Import all needed libraries (except for pandas and numpy, those are already imported as `import pandas as pd` and `import numpy as np`) and define all variables you use in the example.
- Try to avoid using random data. However random data might be OK in some cases, like if the function you are documenting deals with probability distributions, or if the amount of data needed to make the function result meaningful is too much, such that creating it manually is very cumbersome. In those cases, always use a fixed random seed to make the generated examples predictable. Example:

```
>>> np.random.seed(42)
>>> df = pd.DataFrame({'normal': np.random.normal(100, 5, 20)})
```

- If you have a code snippet that wraps multiple lines, you need to use `'...'` on the continued lines:

```
>>> df = pd.DataFrame([[1, 2, 3], [4, 5, 6]], index=['a', 'b', 'c'],
...                   columns=['A', 'B'])
```

- If you want to show a case where an exception is raised, you can do:

```
>>> pd.to_datetime(["712-01-01"])
Traceback (most recent call last):
OutOfBoundsDatetime: Out of bounds nanosecond timestamp: 712-01-01 00:00:00
```

It is essential to include the “Traceback (most recent call last):”, but for the actual error only the error name is sufficient.

- If there is a small part of the result that can vary (e.g. a hash in an object representation), you can use ... to represent this part.

If you want to show that `s.plot()` returns a matplotlib `AxesSubplot` object, this will fail the doctest

```
>>> s.plot()
<matplotlib.axes._subplots.AxesSubplot at 0x7efd0c0b0690>
```

However, you can do (notice the comment that needs to be added)

```
>>> s.plot()
<matplotlib.axes._subplots.AxesSubplot at ...>
```

Plots in examples

There are some methods in pandas returning plots. To render the plots generated by the examples in the documentation, the `.. plot::` directive exists.

To use it, place the next code after the “Examples” header as shown below. The plot will be generated automatically when building the documentation.

```
class Series:
    def plot(self):
        """
        Generate a plot with the `Series` data.

        Examples
        -----

        .. plot::
           :context: close-figs

           >>> s = pd.Series([1, 2, 3])
           >>> s.plot()

        """
        pass
```

Sharing docstrings

Pandas has a system for sharing docstrings, with slight variations, between classes. This helps us keep docstrings consistent, while keeping things clear for the user reading. It comes at the cost of some complexity when writing.

Each shared docstring will have a base template with variables, like `%(class)s`. The variables filled in later on using the `Substitution` decorator. Finally, docstrings can be appended to with the `Appender`

decorator.

In this example, we'll create a parent docstring normally (this is like `pandas.core.generic.NDFrame`). Then we'll have two children (like `pandas.core.series.Series` and `pandas.core.frame.DataFrame`). We'll substitute the children's class names in this docstring.

```
class Parent:
    def my_function(self):
        """Apply my function to %(klass)s."""
        ...

class ChildA(Parent):
    @Substitution(klass="ChildA")
    @Appender(Parent.my_function.__doc__)
    def my_function(self):
        ...

class ChildB(Parent):
    @Substitution(klass="ChildB")
    @Appender(Parent.my_function.__doc__)
    def my_function(self):
        ...
```

The resulting docstrings are

```
>>> print(Parent.my_function.__doc__)
Apply my function to %(klass)s.
>>> print(ChildA.my_function.__doc__)
Apply my function to ChildA.
>>> print(ChildB.my_function.__doc__)
Apply my function to ChildB.
```

Notice two things:

1. We “append” the parent docstring to the children docstrings, which are initially empty.
2. Python decorators are applied inside out. So the order is Append then Substitution, even though Substitution comes first in the file.

Our files will often contain a module-level `_shared_doc_kwargs` with some common substitution values (things like `klass`, `axes`, etc).

You can substitute and append in one shot with something like

```
@Appender(template % _shared_doc_kwargs)
def my_function(self):
    ...
```

where `template` may come from a module-level `_shared_docs` dictionary mapping function names to docstrings. Wherever possible, we prefer using `Appender` and `Substitution`, since the docstring-writing processes is slightly closer to normal.

See `pandas.core.generic.NDFrame.fillna` for an example template, and `pandas.core.series.Series.fillna` and `pandas.core.generic.frame.fillna` for the filled versions.

- The tutorials make heavy use of the `ipython directive` sphinx extension. This directive lets you put code in the documentation which will be run during the doc build. For example:

```
.. ipython:: python

    x = 2
    x**3
```

will be rendered as:

```
In [1]: x = 2

In [2]: x**3
Out[2]: 8
```

Almost all code examples in the docs are run (and the output saved) during the doc build. This approach means that code examples will always be up to date, but it does make the doc building a bit more complex.

- Our API documentation in `doc/source/api.rst` houses the auto-generated documentation from the docstrings. For classes, there are a few subtleties around controlling which methods and attributes have pages auto-generated.

We have two autosummary templates for classes.

1. `_templates/autosummary/class.rst`. Use this when you want to automatically generate a page for every public method and attribute on the class. The `Attributes` and `Methods` sections will be automatically added to the class' rendered documentation by `numpydoc`. See `DataFrame` for an example.
2. `_templates/autosummary/class_without_autosummary`. Use this when you want to pick a subset of methods / attributes to auto-generate pages for. When using this template, you should include an `Attributes` and `Methods` section in the class docstring. See `CategoricalIndex` for an example.

Every method should be included in a `toctree` in `api.rst`, else Sphinx will emit a warning.

Note: The `.rst` files are used to automatically generate Markdown and HTML versions of the docs. For this reason, please do not edit `CONTRIBUTING.md` directly, but instead make any changes to `doc/source/development/contributing.rst`. Then, to generate `CONTRIBUTING.md`, use `pandoc` with the following command:

```
pandoc doc/source/development/contributing.rst -t markdown_github > CONTRIBUTING.md
```

The utility script `scripts/validate_docstrings.py` can be used to get a csv summary of the API documentation. And also validate common errors in the docstring of a specific class, function or method. The summary also compares the list of methods documented in `doc/source/api.rst` (which is used to generate the [API Reference](#) page) and the actual public methods. This will identify methods documented in `doc/source/api.rst` that are not actually class methods, and existing methods that are not documented in `doc/source/api.rst`.

Updating a *pandas* docstring

When improving a single function or method's docstring, it is not necessarily needed to build the full documentation (see next section). However, there is a script that checks a docstring (for example for the

DataFrame.mean method):

```
python scripts/validate_docstrings.py pandas.DataFrame.mean
```

This script will indicate some formatting errors if present, and will also run and test the examples included in the docstring. Check the *pandas docstring guide* for a detailed guide on how to format the docstring.

The examples in the docstring (‘doctests’) must be valid Python code, that in a deterministic way returns the presented output, and that can be copied and run by users. This can be checked with the script above, and is also tested on Travis. A failing doctest will be a blocker for merging a PR. Check the *examples* section in the docstring guide for some tips and tricks to get the doctests passing.

When doing a PR with a docstring update, it is good to post the output of the validation script in a comment on github.

How to build the *pandas* documentation

Requirements

First, you need to have a development environment to be able to build pandas (see the docs on *creating a development environment* above).

Building the documentation

So how do you build the docs? Navigate to your local `doc/` directory in the console and run:

```
python make.py html
```

Then you can find the HTML output in the folder `doc/build/html/`.

The first time you build the docs, it will take quite a while because it has to run all the code examples and build all the generated docstring pages. In subsequent evocations, sphinx will try to only build the pages that have been modified.

If you want to do a full clean build, do:

```
python make.py clean
python make.py html
```

You can tell `make.py` to compile only a single section of the docs, greatly reducing the turn-around time for checking your changes.

```
# omit autosummary and API section
python make.py clean
python make.py --no-api

# compile the docs with only a single section, relative to the "source" folder.
# For example, compiling only this guide (docs/source/development/contributing.rst)
python make.py clean
python make.py --single development/contributing.rst

# compile the reference docs for a single function
python make.py clean
python make.py --single pandas.DataFrame.join
```

For comparison, a full documentation build may take 15 minutes, but a single section may take 15 seconds. Subsequent builds, which only process portions you have changed, will be faster.

You can also specify to use multiple cores to speed up the documentation build:

```
python make.py html --num-jobs 4
```

Open the following file in a web browser to see the full documentation you just built:

```
doc/build/html/index.html
```

And you'll have the satisfaction of seeing your new and improved documentation!

Building master branch documentation

When pull requests are merged into the *pandas* master branch, the main parts of the documentation are also built by Travis-CI. These docs are then hosted [here](#), see also the *Continuous Integration* section.

7.1.5 Contributing to the code base

Code Base:

- *Code standards*
- *Optional dependencies*
 - *C (cpplint)*
 - *Python (PEP8 / black)*
 - *Import formatting*
 - *Backwards compatibility*
- *Testing with continuous integration*
- *Test-driven development/code writing*
 - *Writing tests*
 - *Transitioning to `pytest`*
 - *Using `pytest`*
 - *Using `hypothesis`*
 - *Testing warnings*
- *Running the test suite*
- *Running the performance test suite*
- *Documenting your code*

Code standards

Writing good code is not just about what you write. It is also about *how* you write it. During *Continuous Integration* testing, several tools will be run to check your code for stylistic errors. Generating any warnings

will cause the test to fail. Thus, good style is a requirement for submitting code to *pandas*.

There is a tool in pandas to help contributors verify their changes before contributing them to the project:

```
./ci/code_checks.sh
```

The script verifies the linting of code files, it looks for common mistake patterns (like missing spaces around sphinx directives that make the documentation not being rendered properly) and it also validates the doctests. It is possible to run the checks independently by using the parameters `lint`, `patterns` and `doctests` (e.g. `./ci/code_checks.sh lint`).

In addition, because a lot of people use our library, it is important that we do not make sudden changes to the code that could have the potential to break a lot of user code as a result, that is, we need it to be as *backwards compatible* as possible to avoid mass breakages.

Additional standards are outlined on the [code style wiki page](#).

Optional dependencies

Optional dependencies (e.g. `matplotlib`) should be imported with the private helper `pandas.compat._optional.import_optional_dependency`. This ensures a consistent error message when the dependency is not met.

All methods using an optional dependency should include a test asserting that an `ImportError` is raised when the optional dependency is not found. This test should be skipped if the library is present.

All optional dependencies should be documented in *Optional dependencies* and the minimum required version should be set in the `pandas.compat._optional.VERSIONS` dict.

C (cpplint)

pandas uses the [Google](#) standard. Google provides an open source style checker called `cpplint`, but we use a fork of it that can be found [here](#). Here are *some* of the more common `cpplint` issues:

- we restrict line-length to 80 characters to promote readability
- every header file must include a header guard to avoid name collisions if re-included

Continuous Integration will run the `cpplint` tool and report any stylistic errors in your code. Therefore, it is helpful before submitting code to run the check yourself:

```
cpplint --extensions=c,h --headers=h --filter=--readability/casting,-runtime/int,-build/  
↪include_subdir modified-c-file
```

You can also run this command on an entire directory if necessary:

```
cpplint --extensions=c,h --headers=h --filter=--readability/casting,-runtime/int,-build/  
↪include_subdir --recursive modified-c-directory
```

To make your commits compliant with this standard, you can install the [ClangFormat](#) tool, which can be downloaded [here](#). To configure, in your home directory, run the following command:

```
clang-format style=google -dump-config > .clang-format
```

Then modify the file to ensure that any indentation width parameters are at least four. Once configured, you can run the tool as follows:

```
clang-format modified-c-file
```

This will output what your file will look like if the changes are made, and to apply them, run the following command:

```
clang-format -i modified-c-file
```

To run the tool on an entire directory, you can run the following analogous commands:

```
clang-format modified-c-directory/*.c modified-c-directory/*.h
clang-format -i modified-c-directory/*.c modified-c-directory/*.h
```

Do note that this tool is best-effort, meaning that it will try to correct as many errors as possible, but it may not correct *all* of them. Thus, it is recommended that you run `cpplint` to double check and make any other style fixes manually.

Python (PEP8 / black)

`pandas` follows the [PEP8](#) standard and uses `Black` and `Flake8` to ensure a consistent code format throughout the project.

Continuous Integration will run those tools and report any stylistic errors in your code. Therefore, it is helpful before submitting code to run the check yourself:

```
black pandas
git diff upstream/master -u -- "*.py" | flake8 --diff
```

to auto-format your code. Additionally, many editors have plugins that will apply `black` as you edit files.

Optionally, you may wish to setup [pre-commit hooks](#) to automatically run `black` and `flake8` when you make a git commit. This can be done by installing `pre-commit`:

```
pip install pre-commit
```

and then running:

```
pre-commit install
```

from the root of the `pandas` repository. Now `black` and `flake8` will be run each time you commit changes. You can skip these checks with `git commit --no-verify`.

This command will catch any stylistic errors in your changes specifically, but be beware it may not catch all of them. For example, if you delete the only usage of an imported function, it is stylistically incorrect to import an unused function. However, style-checking the diff will not catch this because the actual import is not part of the diff. Thus, for completeness, you should run this command, though it will take longer:

```
git diff upstream/master --name-only -- "*.py" | xargs -r flake8
```

Note that on OSX, the `-r` flag is not available, so you have to omit it and run this slightly modified command:

```
git diff upstream/master --name-only -- "*.py" | xargs flake8
```

Windows does not support the `xargs` command (unless installed for example via the [MinGW](#) toolchain), but one can imitate the behaviour as follows:

```
for /f %i in ('git diff upstream/master --name-only -- "*.py"') do flake8 %i
```

This will get all the files being changed by the PR (and ending with `.py`), and run `flake8` on them, one after the other.

Import formatting

pandas uses `isort` to standardise import formatting across the codebase.

A guide to import layout as per pep8 can be found [here](#).

A summary of our current import sections (in order):

- Future
- Python Standard Library
- Third Party
- `pandas._libs`, `pandas.compat`, `pandas.util.*`, `pandas.errors` (largely not dependent on `pandas.core`)
- `pandas.core.dtypes` (largely not dependent on the rest of `pandas.core`)
- Rest of `pandas.core.*`
- Non-core `pandas.io`, `pandas.plotting`, `pandas.tseries`
- Local application/library specific imports

Imports are alphabetically sorted within these sections.

As part of *Continuous Integration* checks we run:

```
isort --recursive --check-only pandas
```

to check that imports are correctly formatted as per the `setup.cfg`.

If you see output like the below in *Continuous Integration* checks:

```
Check import format using isort
ERROR: /home/travis/build/pandas-dev/pandas/pandas/io/pytables.py Imports are
↪incorrectly sorted
Check import format using isort DONE
The command "ci/code_checks.sh" exited with 1
```

You should run:

```
isort pandas/io/pytables.py
```

to automatically format imports correctly. This will modify your local copy of the files.

The `-recursive` flag can be passed to sort all files in a directory.

You can then verify the changes look ok, then `git commit` and `push`.

Backwards compatibility

Please try to maintain backward compatibility. *pandas* has lots of users with lots of existing code, so don't break it if at all possible. If you think breakage is required, clearly state why as part of the pull request. Also, be careful when changing method signatures and add deprecation warnings where needed. Also, add the deprecated sphinx directive to the deprecated functions or methods.

If a function with the same arguments as the one being deprecated exist, you can use the `pandas.util._decorators.deprecate`:

```
from pandas.util._decorators import deprecate

deprecate('old_func', 'new_func', '0.21.0')
```

Otherwise, you need to do it manually:

```
import warnings

def old_func():
    """Summary of the function.

    .. deprecated:: 0.21.0
       Use new_func instead.
    """
    warnings.warn('Use new_func instead.', FutureWarning, stacklevel=2)
    new_func()

def new_func():
    pass
```

You'll also need to

1. Write a new test that asserts a warning is issued when calling with the deprecated argument
2. Update all of pandas existing tests and code to use the new argument

See *Testing warnings* for more.

Testing with continuous integration

The *pandas* test suite will run automatically on [Travis-CI](#) and [Azure Pipelines](#) continuous integration services, once your pull request is submitted. However, if you wish to run the test suite on a branch prior to submitting the pull request, then the continuous integration services need to be hooked to your GitHub repository. Instructions are here for [Travis-CI](#) and [Azure Pipelines](#).

A pull-request will be considered for merging when you have an all 'green' build. If any tests are failing, then you will get a red 'X', where you can click through to see the individual failed tests. This is an example of a green build.

All checks have passed

2 successful checks

[Hide all checks](#)

continuous-integration/travis-ci/pr — The Travis CI build passed

pandas-dev.pandas Successful in 36m — Build #20190109.23 succeeded

This branch has no conflicts with the base branch

Merging can be performed automatically.

Squash and merge

or view [command line instructions](#).

Note: Each time you push to *your* fork, a *new* run of the tests will be triggered on the CI. You can enable the auto-cancel feature, which removes any non-currently-running tests for that same pull-request, for [Travis-CI here](#).

Test-driven development/code writing

pandas is serious about testing and strongly encourages contributors to embrace [test-driven development \(TDD\)](#). This development process “relies on the repetition of a very short development cycle: first the developer writes an (initially failing) automated test case that defines a desired improvement or new function, then produces the minimum amount of code to pass that test.” So, before actually writing any code, you should write your tests. Often the test can be taken from the original GitHub issue. However, it is always worth considering additional use cases and writing corresponding tests.

Adding tests is one of the most common requests after code is pushed to *pandas*. Therefore, it is worth getting in the habit of writing tests ahead of time so this is never an issue.

Like many packages, *pandas* uses `pytest` and the convenient extensions in `numpy.testing`.

Note: The earliest supported `pytest` version is 4.0.2.

Writing tests

All tests should go into the `tests` subdirectory of the specific package. This folder contains many current examples of tests, and we suggest looking to these for inspiration. If your test requires working with files or network connectivity, there is more information on the [testing page](#) of the wiki.

The `pandas.util.testing` module has many special `assert` functions that make it easier to make statements about whether Series or DataFrame objects are equivalent. The easiest way to verify that your code is correct is to explicitly construct the result you expect, then compare the actual result to the expected correct result:

```

def test_pivot(self):
    data = {
        'index' : ['A', 'B', 'C', 'C', 'B', 'A'],
        'columns' : ['One', 'One', 'One', 'Two', 'Two', 'Two'],
        'values' : [1., 2., 3., 3., 2., 1.]
    }

    frame = DataFrame(data)
    pivoted = frame.pivot(index='index', columns='columns', values='values')

    expected = DataFrame({
        'One' : {'A' : 1., 'B' : 2., 'C' : 3.},
        'Two' : {'A' : 1., 'B' : 2., 'C' : 3.}
    })

    assert_frame_equal(pivoted, expected)

```

Transitioning to pytest

pandas existing test structure is *mostly* classed based, meaning that you will typically find tests wrapped in a class.

```

class TestReallyCoolFeature:
    pass

```

Going forward, we are moving to a more *functional* style using the `pytest` framework, which offers a richer testing framework that will facilitate testing and developing. Thus, instead of writing test classes, we will write test functions like this:

```

def test_really_cool_feature():
    pass

```

Using pytest

Here is an example of a self-contained set of tests that illustrate multiple features that we like to use.

- functional style: tests are like `test_*` and *only* take arguments that are either fixtures or parameters
- `pytest.mark` can be used to set metadata on test functions, e.g. `skip` or `xfail`.
- using `parametrize`: allow testing of multiple cases
- to set a mark on a parameter, `pytest.param(..., marks=...)` syntax should be used
- `fixture`, code for object construction, on a per-test basis
- using bare `assert` for scalars and truth-testing
- `tm.assert_series_equal` (and its counter part `tm.assert_frame_equal`), for pandas object comparisons.
- the typical pattern of constructing an `expected` and comparing versus the `result`

We would name this file `test_cool_feature.py` and put in an appropriate place in the `pandas/tests/` structure.

```

import pytest
import numpy as np
import pandas as pd

@pytest.mark.parametrize('dtype', ['int8', 'int16', 'int32', 'int64'])
def test_dtypes(dtype):
    assert str(np.dtype(dtype)) == dtype

@pytest.mark.parametrize(
    'dtype', ['float32', pytest.param('int16', marks=pytest.mark.skip),
           pytest.param('int32', marks=pytest.mark.xfail(
               reason='to show how it works'))])
def test_mark(dtype):
    assert str(np.dtype(dtype)) == 'float32'

@pytest.fixture
def series():
    return pd.Series([1, 2, 3])

@pytest.fixture(params=['int8', 'int16', 'int32', 'int64'])
def dtype(request):
    return request.param

def test_series(series, dtype):
    result = series.astype(dtype)
    assert result.dtype == dtype

    expected = pd.Series([1, 2, 3], dtype=dtype)
    tm.assert_series_equal(result, expected)

```

A test run of this yields

```

((pandas) bash-3.2$ pytest test_cool_feature.py -v
===== test session starts =====
platform darwin -- Python 3.6.2, pytest-3.6.0, py-1.4.31, pluggy-0.4.0
collected 11 items

tester.py::test_dtypes[int8] PASSED
tester.py::test_dtypes[int16] PASSED
tester.py::test_dtypes[int32] PASSED
tester.py::test_dtypes[int64] PASSED
tester.py::test_mark[float32] PASSED
tester.py::test_mark[int16] SKIPPED
tester.py::test_mark[int32] xfail
tester.py::test_series[int8] PASSED
tester.py::test_series[int16] PASSED
tester.py::test_series[int32] PASSED
tester.py::test_series[int64] PASSED

```

Tests that we have parametrized are now accessible via the test name, for example we could run these with `-k int8` to sub-select *only* those tests which match `int8`.

```
((pandas) bash-3.2$ pytest test_cool_feature.py -v -k int8
===== test session starts =====
platform darwin -- Python 3.6.2, pytest-3.6.0, py-1.4.31, pluggy-0.4.0
collected 11 items

test_cool_feature.py::test_dtypes[int8] PASSED
test_cool_feature.py::test_series[int8] PASSED
```

Using hypothesis

Hypothesis is a library for property-based testing. Instead of explicitly parametrizing a test, you can describe *all* valid inputs and let Hypothesis try to find a failing input. Even better, no matter how many random examples it tries, Hypothesis always reports a single minimal counterexample to your assertions - often an example that you would never have thought to test.

See [Getting Started with Hypothesis](#) for more of an introduction, then refer to the [Hypothesis documentation](#) for details.

```
import json
from hypothesis import given, strategies as st

any_json_value = st.deferred(lambda: st.one_of(
    st.none(), st.booleans(), st.floats(allow_nan=False), st.text(),
    st.lists(any_json_value), st.dictionaries(st.text(), any_json_value)
))

@given(value=any_json_value)
def test_json_roundtrip(value):
    result = json.loads(json.dumps(value))
    assert value == result
```

This test shows off several useful features of Hypothesis, as well as demonstrating a good use-case: checking properties that should hold over a large or complicated domain of inputs.

To keep the Pandas test suite running quickly, parametrized tests are preferred if the inputs or logic are simple, with Hypothesis tests reserved for cases with complex logic or where there are too many combinations of options or subtle interactions to test (or think of!) all of them.

Testing warnings

By default, one of pandas CI workers will fail if any unhandled warnings are emitted.

If your change involves checking that a warning is actually emitted, use `tm.assert_produces_warning(ExpectedWarning)`.

```
import pandas.util.testing as tm

df = pd.DataFrame()
```

(continues on next page)

(continued from previous page)

```
with tm.assert_produces_warning(FutureWarning):
    df.some_operation()
```

We prefer this to the `pytest.warns` context manager because ours checks that the warning's stacklevel is set correctly. The stacklevel is what ensure the *user's* file name and line number is printed in the warning, rather than something internal to pandas. It represents the number of function calls from user code (e.g. `df.some_operation()`) to the function that actually emits the warning. Our linter will fail the build if you use `pytest.warns` in a test.

If you have a test that would emit a warning, but you aren't actually testing the warning itself (say because it's going to be removed in the future, or because we're matching a 3rd-party library's behavior), then use `pytest.mark.filterwarnings` to ignore the error.

```
@pytest.mark.filterwarnings("ignore:msg:category")
def test_thing(self):
    ...
```

If the test generates a warning of class `category` whose message starts with `msg`, the warning will be ignored and the test will pass.

If you need finer-grained control, you can use Python's usual `warnings` module to control whether a warning is ignored / raised at different places within a single test.

```
with warnings.catch_warnings():
    warnings.simplefilter("ignore", FutureWarning)
    # Or use warnings.filterwarnings(...)
```

Alternatively, consider breaking up the unit test.

Running the test suite

The tests can then be run directly inside your Git clone (without having to install *pandas*) by typing:

```
pytest pandas
```

The tests suite is exhaustive and takes around 20 minutes to run. Often it is worth running only a subset of tests first around your changes before running the entire suite.

The easiest way to do this is with:

```
pytest pandas/path/to/test.py -k regex_matching_test_name
```

Or with one of the following constructs:

```
pytest pandas/tests/[test-module].py
pytest pandas/tests/[test-module].py::[TestClass]
pytest pandas/tests/[test-module].py::[TestClass]::[test_method]
```

Using `pytest-xdist`, one can speed up local testing on multicore machines. To use this feature, you will need to install *pytest-xdist* via:

```
pip install pytest-xdist
```

Two scripts are provided to assist with this. These scripts distribute testing across 4 threads.

On Unix variants, one can type:

```
test_fast.sh
```

On Windows, one can type:

```
test_fast.bat
```

This can significantly reduce the time it takes to locally run tests before submitting a pull request.

For more, see the [pytest](#) documentation.

New in version 0.20.0.

Furthermore one can run

```
pd.test()
```

with an imported pandas to run tests similarly.

Running the performance test suite

Performance matters and it is worth considering whether your code has introduced performance regressions. *pandas* is in the process of migrating to [asv benchmarks](#) to enable easy monitoring of the performance of critical *pandas* operations. These benchmarks are all found in the `pandas/asv_bench` directory. *asv* supports both python2 and python3.

To use all features of *asv*, you will need either `conda` or `virtualenv`. For more details please check the [asv installation webpage](#).

To install *asv*:

```
pip install git+https://github.com/spacetelescope/asv
```

If you need to run a benchmark, change your directory to `asv_bench/` and run:

```
asv continuous -f 1.1 upstream/master HEAD
```

You can replace `HEAD` with the name of the branch you are working on, and report benchmarks that changed by more than 10%. The command uses `conda` by default for creating the benchmark environments. If you want to use `virtualenv` instead, write:

```
asv continuous -f 1.1 -E virtualenv upstream/master HEAD
```

The `-E virtualenv` option should be added to all *asv* commands that run benchmarks. The default value is defined in `asv.conf.json`.

Running the full test suite can take up to one hour and use up to 3GB of RAM. Usually it is sufficient to paste only a subset of the results into the pull request to show that the committed changes do not cause unexpected performance regressions. You can run specific benchmarks using the `-b` flag, which takes a regular expression. For example, this will only run tests from a `pandas/asv_bench/benchmarks/groupby.py` file:

```
asv continuous -f 1.1 upstream/master HEAD -b ^groupby
```

If you want to only run a specific group of tests from a file, you can do it using `.` as a separator. For example:

```
asv continuous -f 1.1 upstream/master HEAD -b groupby.GroupByMethods
```

will only run the `GroupByMethods` benchmark defined in `groupby.py`.

You can also run the benchmark suite using the version of `pandas` already installed in your current Python environment. This can be useful if you do not have `virtualenv` or `conda`, or are using the `setup.py develop` approach discussed above; for the in-place build you need to set `PYTHONPATH`, e.g. `PYTHONPATH="$PWD/.."` `asv [remaining arguments]`. You can run benchmarks using an existing Python environment by:

```
asv run -e -E existing
```

or, to use a specific Python interpreter,:

```
asv run -e -E existing:python3.5
```

This will display `stderr` from the benchmarks, and use your local `python` that comes from your `$PATH`.

Information on how to write a benchmark and how to use `asv` can be found in the [asv documentation](#).

Documenting your code

Changes should be reflected in the release notes located in `doc/source/whatsnew/vx.y.z.rst`. This file contains an ongoing change log for each release. Add an entry to this file to document your fix, enhancement or (unavoidable) breaking change. Make sure to include the GitHub issue number when adding your entry (using `:issue:`1234`` where `1234` is the issue/pull request number).

If your code is an enhancement, it is most likely necessary to add usage examples to the existing documentation. This can be done following the section regarding documentation *above*. Further, to let users know when this feature was added, the `versionadded` directive is used. The sphinx syntax for that is:

```
.. versionadded:: 0.21.0
```

This will put the text *New in version 0.21.0* wherever you put the sphinx directive. This should also be put in the docstring when adding a new function or method ([example](#)) or a new keyword argument ([example](#)).

7.1.6 Contributing your changes to *pandas*

Committing your code

Keep style fixes to a separate commit to make your pull request more readable.

Once you've made changes, you can see them by typing:

```
git status
```

If you have created a new file, it is not being tracked by `git`. Add it by typing:

```
git add path/to/file-to-be-added.py
```

Doing 'git status' again should give something like:

```
# On branch shiny-new-feature
#
#       modified:   /relative/path/to/file-you-added.py
#
```

Finally, commit your changes to your local repository with an explanatory message. *Pandas* uses a convention for commit message prefixes and layout. Here are some common prefixes along with general guidelines for when to use them:

- ENH: Enhancement, new functionality
- BUG: Bug fix
- DOC: Additions/updates to documentation
- TST: Additions/updates to tests
- BLD: Updates to the build process/scripts
- PERF: Performance improvement
- CLN: Code cleanup

The following defines how a commit message should be structured. Please reference the relevant GitHub issues in your commit message using GH1234 or #1234. Either style is fine, but the former is generally preferred:

- a subject line with < 80 chars.
- One blank line.
- Optionally, a commit message body.

Now you can commit your changes in your local repository:

```
git commit -m
```

Pushing your changes

When you want your changes to appear publicly on your GitHub page, push your forked feature branch's commits:

```
git push origin shiny-new-feature
```

Here `origin` is the default name given to your remote repository on GitHub. You can see the remote repositories:

```
git remote -v
```

If you added the upstream repository as described above you will see something like:

```
origin  git@github.com:yourname/pandas.git (fetch)
origin  git@github.com:yourname/pandas.git (push)
upstream      git://github.com/pandas-dev/pandas.git (fetch)
upstream      git://github.com/pandas-dev/pandas.git (push)
```

Now your code is on GitHub, but it is not yet a part of the *pandas* project. For that to happen, a pull request needs to be submitted on GitHub.

Review your code

When you're ready to ask for a code review, file a pull request. Before you do, once again make sure that you have followed all the guidelines outlined in this document regarding code style, tests, performance tests, and documentation. You should also double check your branch changes against the branch it was based on:

1. Navigate to your repository on GitHub – <https://github.com/your-user-name/pandas>
2. Click on **Branches**
3. Click on the **Compare** button for your feature branch
4. Select the **base** and **compare** branches, if necessary. This will be **master** and **shiny-new-feature**, respectively.

Finally, make the pull request

If everything looks good, you are ready to make a pull request. A pull request is how code from a local repository becomes available to the GitHub community and can be looked at and eventually merged into the master version. This pull request and its associated changes will eventually be committed to the master branch and available in the next release. To submit a pull request:

1. Navigate to your repository on GitHub
2. Click on the **Pull Request** button
3. You can then click on **Commits** and **Files Changed** to make sure everything looks okay one last time
4. Write a description of your changes in the **Preview Discussion** tab
5. Click **Send Pull Request**.

This request then goes to the repository maintainers, and they will review the code.

Updating your pull request

Based on the review you get on your pull request, you will probably need to make some changes to the code. In that case, you can make them in your branch, add a new commit to that branch, push it to GitHub, and the pull request will be automatically updated. Pushing them to GitHub again is done by:

```
git push origin shiny-new-feature
```

This will automatically update your pull request with the latest code and restart the *Continuous Integration* tests.

Another reason you might need to update your pull request is to solve conflicts with changes that have been merged into the master branch since you opened your pull request.

To do this, you need to “merge upstream master” in your branch:

```
git checkout shiny-new-feature
git fetch upstream
git merge upstream/master
```

If there are no conflicts (or they could be fixed automatically), a file with a default commit message will open, and you can simply save and quit this file.

If there are merge conflicts, you need to solve those conflicts. See for example at <https://help.github.com/articles/resolving-a-merge-conflict-using-the-command-line/> for an explanation on how to do this. Once the conflicts are merged and the files where the conflicts were solved are added, you can run `git commit` to save those fixes.

If you have uncommitted changes at the moment you want to update the branch with master, you will need to **stash** them prior to updating (see the [stash docs](#)). This will effectively store your changes and they can be reapplied after updating.

After the feature branch has been update locally, you can now update your pull request by pushing to the branch on GitHub:

```
git push origin shiny-new-feature
```

Delete your merged branch (optional)

Once your feature branch is accepted into upstream, you'll probably want to get rid of the branch. First, merge upstream master into your branch so git knows it is safe to delete your branch:

```
git fetch upstream
git checkout master
git merge upstream/master
```

Then you can do:

```
git branch -d shiny-new-feature
```

Make sure you use a lower-case `-d`, or else git won't warn you if your feature branch has not actually been merged.

The branch will still exist on GitHub, so to delete it there do:

```
git push origin --delete shiny-new-feature
```

```
{{ header }}
```

7.2 Internals

This section will provide a look into some of pandas internals. It's primarily intended for developers of pandas itself.

7.2.1 Indexing

In pandas there are a few objects implemented which can serve as valid containers for the axis labels:

- **Index**: the generic “ordered set” object, an ndarray of object dtype assuming nothing about its contents. The labels must be hashable (and likely immutable) and unique. Populates a dict of label to location in Cython to do $O(1)$ lookups.
- **Int64Index**: a version of **Index** highly optimized for 64-bit integer data, such as time stamps
- **Float64Index**: a version of **Index** highly optimized for 64-bit float data
- **MultiIndex**: the standard hierarchical index object
- **DatetimeIndex**: An **Index** object with **Timestamp** boxed elements (impl are the int64 values)
- **TimedeltaIndex**: An **Index** object with **Timedelta** boxed elements (impl are the in64 values)
- **PeriodIndex**: An **Index** object with **Period** elements

There are functions that make the creation of a regular index easy:

- **date_range**: fixed frequency date range generated from a time rule or **DateOffset**. An ndarray of Python datetime objects

- `period_range`: fixed frequency date range generated from a time rule or `DateOffset`. An ndarray of `Period` objects, representing timespans

The motivation for having an `Index` class in the first place was to enable different implementations of indexing. This means that it's possible for you, the user, to implement a custom `Index` subclass that may be better suited to a particular application than the ones provided in pandas.

From an internal implementation point of view, the relevant methods that an `Index` must define are one or more of the following (depending on how incompatible the new object internals are with the `Index` functions):

- `get_loc`: returns an “indexer” (an integer, or in some cases a slice object) for a label
- `slice_locs`: returns the “range” to slice between two labels
- `get_indexer`: Computes the indexing vector for reindexing / data alignment purposes. See the source / docstrings for more on this
- `get_indexer_non_unique`: Computes the indexing vector for reindexing / data alignment purposes when the index is non-unique. See the source / docstrings for more on this
- `reindex`: Does any pre-conversion of the input index then calls `get_indexer`
- `union`, `intersection`: computes the union or intersection of two `Index` objects
- `insert`: Inserts a new label into an `Index`, yielding a new object
- `delete`: Delete a label, yielding a new object
- `drop`: Deletes a set of labels
- `take`: Analogous to `ndarray.take`

MultiIndex

Internally, the `MultiIndex` consists of a few things: the **levels**, the integer **codes** (until version 0.24 named *labels*), and the level **names**:

```
In [1]: index = pd.MultiIndex.from_product([range(3), ['one', 'two']],
...:                                     names=['first', 'second'])
...:
```

```
-----
NameError                                Traceback (most recent call last)
<ipython-input-1-325313b74147> in <module>
----> 1 index = pd.MultiIndex.from_product([range(3), ['one', 'two']],
      2                                     names=['first', 'second'])
```

NameError: name 'pd' is not defined

```
In [2]: index
```

```
-----
NameError                                Traceback (most recent call last)
<ipython-input-2-c17665332d8f> in <module>
----> 1 index
```

NameError: name 'index' is not defined

```
In [3]: index.levels
```

```
-----
NameError                                Traceback (most recent call last)
<ipython-input-3-caa84382af6f> in <module>
```

```
----> 1 index.levels
```

```
NameError: name 'index' is not defined
```

```
In [4]: index.codes
```

```
-----
NameError                                Traceback (most recent call last)
<ipython-input-4-9caf1b7e70ce> in <module>
----> 1 index.codes
```

```
NameError: name 'index' is not defined
```

```
In [5]: index.names
```

```
-----
NameError                                Traceback (most recent call last)
<ipython-input-5-f95ab7546e25> in <module>
----> 1 index.names
```

```
NameError: name 'index' is not defined
```

You can probably guess that the codes determine which unique element is identified with that location at each layer of the index. It's important to note that sortedness is determined **solely** from the integer codes and does not check (or care) whether the levels themselves are sorted. Fortunately, the constructors `from_tuples` and `from_arrays` ensure that this is true, but if you compute the levels and codes yourself, please be careful.

Values

Pandas extends NumPy's type system with custom types, like `Categorical` or datetimes with a timezone, so we have multiple notions of “values”. For 1-D containers (`Index` classes and `Series`) we have the following convention:

- `cls._ndarray_values` is *always* a NumPy `ndarray`. Ideally, `_ndarray_values` is cheap to compute. For example, for a `Categorical`, this returns the codes, not the array of objects.
- `cls._values` refers to the “best possible” array. This could be an `ndarray`, `ExtensionArray`, or in `Index` subclass (note: we're in the process of removing the index subclasses here so that it's always an `ndarray` or `ExtensionArray`).

So, for example, `Series[category]._values` is a `Categorical`, while `Series[category]._ndarray_values` is the underlying codes.

7.2.2 Subclassing pandas data structures

This section has been moved to *Subclassing pandas data structures*. `{{ header }}`

7.3 Extending pandas

While pandas provides a rich set of methods, containers, and data types, your needs may not be fully satisfied. Pandas offers a few options for extending pandas.

7.3.1 Registering custom accessors

Libraries can use the decorators `pandas.api.extensions.register_dataframe_accessor()`, `pandas.api.extensions.register_series_accessor()`, and `pandas.api.extensions.register_index_accessor()`, to add additional “namespaces” to pandas objects. All of these follow a similar convention: you decorate a class, providing the name of attribute to add. The class’s `__init__` method gets the object being decorated. For example:

```
@pd.api.extensions.register_dataframe_accessor("geo")
class GeoAccessor:
    def __init__(self, pandas_obj):
        self._validate(pandas_obj)
        self._obj = pandas_obj

    @staticmethod
    def _validate(obj):
        # verify there is a column latitude and a column longitude
        if 'latitude' not in obj.columns or 'longitude' not in obj.columns:
            raise AttributeError("Must have 'latitude' and 'longitude'.")

    @property
    def center(self):
        # return the geographic center point of this DataFrame
        lat = self._obj.latitude
        lon = self._obj.longitude
        return (float(lon.mean()), float(lat.mean()))

    def plot(self):
        # plot this array's data on a map, e.g., using Cartopy
        pass
```

Now users can access your methods using the `geo` namespace:

```
>>> ds = pd.DataFrame({'longitude': np.linspace(0, 10),
...                    'latitude': np.linspace(0, 20)})
>>> ds.geo.center
(5.0, 10.0)
>>> ds.geo.plot()
# plots data on a map
```

This can be a convenient way to extend pandas objects without subclassing them. If you write a custom accessor, make a pull request adding it to our ecosystem page.

We highly recommend validating the data in your accessor’s `__init__`. In our `GeoAccessor`, we validate that the data contains the expected columns, raising an `AttributeError` when the validation fails. For a `Series` accessor, you should validate the `dtype` if the accessor applies only to certain dtypes.

7.3.2 Extension types

New in version 0.23.0.

Warning: The `pandas.api.extensions.ExtensionDtype` and `pandas.api.extensions.ExtensionArray` APIs are new and experimental. They may change between versions without warning.

Pandas defines an interface for implementing data types and arrays that *extend* NumPy's type system. Pandas itself uses the extension system for some types that aren't built into NumPy (categorical, period, interval, datetime with timezone).

Libraries can define a custom array and data type. When pandas encounters these objects, they will be handled properly (i.e. not converted to an ndarray of objects). Many methods like `pandas.isna()` will dispatch to the extension type's implementation.

If you're building a library that implements the interface, please publicize it on *Extension data types*.

The interface consists of two classes.

ExtensionDtype

A `pandas.api.extensions.ExtensionDtype` is similar to a `numpy.dtype` object. It describes the data type. Implementors are responsible for a few unique items like the name.

One particularly important item is the `type` property. This should be the class that is the scalar type for your data. For example, if you were writing an extension array for IP Address data, this might be `ipaddress.IPv4Address`.

See the [extension dtype source](#) for interface definition.

New in version 0.24.0.

`pandas.api.extension.ExtensionDtype` can be registered to pandas to allow creation via a string dtype name. This allows one to instantiate `Series` and `.astype()` with a registered string name, for example `'category'` is a registered string accessor for the `CategoricalDtype`.

See the [extension dtype dtypes](#) for more on how to register dtypes.

ExtensionArray

This class provides all the array-like functionality. ExtensionArrays are limited to 1 dimension. An ExtensionArray is linked to an ExtensionDtype via the `dtype` attribute.

Pandas makes no restrictions on how an extension array is created via its `__new__` or `__init__`, and puts no restrictions on how you store your data. We do require that your array be convertible to a NumPy array, even if this is relatively expensive (as it is for `Categorical`).

They may be backed by none, one, or many NumPy arrays. For example, `pandas.Categorical` is an extension array backed by two arrays, one for codes and one for categories. An array of IPv6 addresses may be backed by a NumPy structured array with two fields, one for the lower 64 bits and one for the upper 64 bits. Or they may be backed by some other storage type, like Python lists.

See the [extension array source](#) for the interface definition. The docstrings and comments contain guidance for properly implementing the interface.

ExtensionArray Operator Support

New in version 0.24.0.

By default, there are no operators defined for the class `ExtensionArray`. There are two approaches for providing operator support for your `ExtensionArray`:

1. Define each of the operators on your `ExtensionArray` subclass.
2. Use an operator implementation from pandas that depends on operators that are already defined on the underlying elements (scalars) of the `ExtensionArray`.

Note: Regardless of the approach, you may want to set `__array_priority__` if you want your implementation to be called when involved in binary operations with NumPy arrays.

For the first approach, you define selected operators, e.g., `__add__`, `__le__`, etc. that you want your `ExtensionArray` subclass to support.

The second approach assumes that the underlying elements (i.e., scalar type) of the `ExtensionArray` have the individual operators already defined. In other words, if your `ExtensionArray` named `MyExtensionArray` is implemented so that each element is an instance of the class `MyExtensionElement`, then if the operators are defined for `MyExtensionElement`, the second approach will automatically define the operators for `MyExtensionArray`.

A mixin class, `ExtensionScalarOpsMixin` supports this second approach. If developing an `ExtensionArray` subclass, for example `MyExtensionArray`, can simply include `ExtensionScalarOpsMixin` as a parent class of `MyExtensionArray`, and then call the methods `_add_arithmetic_ops()` and/or `_add_comparison_ops()` to hook the operators into your `MyExtensionArray` class, as follows:

```
from pandas.api.extensions import ExtensionArray, ExtensionScalarOpsMixin

class MyExtensionArray(ExtensionArray, ExtensionScalarOpsMixin):
    pass

MyExtensionArray._add_arithmetic_ops()
MyExtensionArray._add_comparison_ops()
```

Note: Since pandas automatically calls the underlying operator on each element one-by-one, this might not be as performant as implementing your own version of the associated operators directly on the `ExtensionArray`.

For arithmetic operations, this implementation will try to reconstruct a new `ExtensionArray` with the result of the element-wise operation. Whether or not that succeeds depends on whether the operation returns a result that's valid for the `ExtensionArray`. If an `ExtensionArray` cannot be reconstructed, an `ndarray` containing the scalars returned instead.

For ease of implementation and consistency with operations between pandas and NumPy `ndarrays`, we recommend *not* handling `Series` and `Indexes` in your binary ops. Instead, you should detect these cases and return `NotImplemented`. When pandas encounters an operation like `op(Series, ExtensionArray)`, pandas will

1. unbox the array from the `Series` (`Series.array`)
2. call `result = op(values, ExtensionArray)`
3. re-box the result in a `Series`

NumPy Universal Functions

`Series` implements `__array_ufunc__`. As part of the implementation, pandas unboxes the `ExtensionArray` from the `Series`, applies the ufunc, and re-boxes it if necessary.

If applicable, we highly recommend that you implement `__array_ufunc__` in your extension array to avoid coercion to an ndarray. See [the numpy documentation](#) for an example.

As part of your implementation, we require that you defer to pandas when a pandas container (`Series`, `DataFrame`, `Index`) is detected in `inputs`. If any of those is present, you should return `NotImplemented`. Pandas will take care of unboxing the array from the container and re-calling the ufunc with the unwrapped input.

Testing extension arrays

We provide a test suite for ensuring that your extension arrays satisfy the expected behavior. To use the test suite, you must provide several pytest fixtures and inherit from the base test class. The required fixtures are found in <https://github.com/pandas-dev/pandas/blob/master/pandas/tests/extension/conftest.py>.

To use a test, subclass it:

```
from pandas.tests.extension import base

class TestConstructors(base.BaseConstructorsTests):
    pass
```

See https://github.com/pandas-dev/pandas/blob/master/pandas/tests/extension/base/__init__.py for a list of all the tests available.

7.3.3 Subclassing pandas data structures

Warning: There are some easier alternatives before considering subclassing pandas data structures.

1. Extensible method chains with *pipe*
2. Use *composition*. See [here](#).
3. Extending by *registering an accessor*
4. Extending by *extension type*

This section describes how to subclass pandas data structures to meet more specific needs. There are two points that need attention:

1. Override constructor properties.
2. Define original properties

Note: You can find a nice example in [geopandas](#) project.

Override constructor properties

Each data structure has several *constructor properties* for returning a new data structure as the result of an operation. By overriding these properties, you can retain subclasses through pandas data manipulations.

There are 3 constructor properties to be defined:

- `_constructor`: Used when a manipulation result has the same dimensions as the original.
- `_constructor_sliced`: Used when a manipulation result has one lower dimension(s) as the original, such as `DataFrame` single columns slicing.
- `_constructor_expanddim`: Used when a manipulation result has one higher dimension as the original, such as `Series.to_frame()`.

Following table shows how pandas data structures define constructor properties by default.

| Property Attributes | Series | DataFrame |
|-------------------------------------|---------------------|---------------------|
| <code>_constructor</code> | Series | DataFrame |
| <code>_constructor_sliced</code> | NotImplementedError | Series |
| <code>_constructor_expanddim</code> | DataFrame | NotImplementedError |

Below example shows how to define `SubclassedSeries` and `SubclassedDataFrame` overriding constructor properties.

```
class SubclassedSeries(pd.Series):

    @property
    def _constructor(self):
        return SubclassedSeries

    @property
    def _constructor_expanddim(self):
        return SubclassedDataFrame

class SubclassedDataFrame(pd.DataFrame):

    @property
    def _constructor(self):
        return SubclassedDataFrame

    @property
    def _constructor_sliced(self):
        return SubclassedSeries
```

```
>>> s = SubclassedSeries([1, 2, 3])
>>> type(s)
<class '__main__.SubclassedSeries'>

>>> to_framed = s.to_frame()
>>> type(to_framed)
<class '__main__.SubclassedDataFrame'>

>>> df = SubclassedDataFrame({'A': [1, 2, 3], 'B': [4, 5, 6], 'C': [7, 8, 9]})
```

(continues on next page)

(continued from previous page)

```

>>> df
   A  B  C
0  1  4  7
1  2  5  8
2  3  6  9

>>> type(df)
<class '__main__.SubclassedDataFrame'>

>>> sliced1 = df[['A', 'B']]
>>> sliced1
   A  B
0  1  4
1  2  5
2  3  6

>>> type(sliced1)
<class '__main__.SubclassedDataFrame'>

>>> sliced2 = df['A']
>>> sliced2
0    1
1    2
2    3
Name: A, dtype: int64

>>> type(sliced2)
<class '__main__.SubclassedSeries'>

```

Define original properties

To let original data structures have additional properties, you should let `pandas` know what properties are added. `pandas` maps unknown properties to data names overriding `__getattr__`. Defining original properties can be done in one of 2 ways:

1. Define `_internal_names` and `_internal_names_set` for temporary properties which WILL NOT be passed to manipulation results.
2. Define `_metadata` for normal properties which will be passed to manipulation results.

Below is an example to define two original properties, “`internal_cache`” as a temporary property and “`added_property`” as a normal property

```

class SubclassedDataFrame2(pd.DataFrame):

    # temporary properties
    _internal_names = pd.DataFrame._internal_names + ['internal_cache']
    _internal_names_set = set(_internal_names)

    # normal properties
    _metadata = ['added_property']

```

(continues on next page)

(continued from previous page)

```
@property
def _constructor(self):
    return SubclassedDataFrame2
```

```
>>> df = SubclassedDataFrame2({'A': [1, 2, 3], 'B': [4, 5, 6], 'C': [7, 8, 9]})
>>> df
   A  B  C
0  1  4  7
1  2  5  8
2  3  6  9

>>> df.internal_cache = 'cached'
>>> df.added_property = 'property'

>>> df.internal_cache
cached
>>> df.added_property
property

# properties defined in _internal_names is reset after manipulation
>>> df[['A', 'B']].internal_cache
AttributeError: 'SubclassedDataFrame2' object has no attribute 'internal_cache'

# properties defined in _metadata are retained
>>> df[['A', 'B']].added_property
property
```

7.3.4 Plotting backends

Starting in 0.25 pandas can be extended with third-party plotting backends. The main idea is letting users select a plotting backend different than the provided one based on Matplotlib. For example:

```
>>> pd.set_option('plotting.backend', 'backend.module')
>>> pd.Series([1, 2, 3]).plot()
```

This would be more or less equivalent to:

```
>>> import backend.module
>>> backend.module.plot(pd.Series([1, 2, 3]))
```

The backend module can then use other visualization tools (Bokeh, Altair,...) to generate the plots.

Libraries implementing the plotting backend should use [entry points](#) to make their backend discoverable to pandas. The key is "pandas_plotting_backends". For example, pandas registers the default "matplotlib" backend as follows.

```
# in setup.py
setup( # noqa: F821
    ...,
    entry_points={
        "pandas_plotting_backends": [
```

(continues on next page)

(continued from previous page)

```

        "matplotlib = pandas:plotting._matplotlib",
    ],
},
)

```

More information on how to implement a third-party plotting backend can be found at https://github.com/pandas-dev/pandas/blob/master/pandas/plotting/___init___py#L1. {{ header }}

7.4 Developer

This section will focus on downstream applications of pandas.

7.4.1 Storing pandas DataFrame objects in Apache Parquet format

The Apache Parquet format provides key-value metadata at the file and column level, stored in the footer of the Parquet file:

```
5: optional list<KeyValue> key_value_metadata
```

where KeyValue is

```

struct KeyValue {
  1: required string key
  2: optional string value
}

```

So that a `pandas.DataFrame` can be faithfully reconstructed, we store a `pandas` metadata key in the `FileMetaData` with the value stored as :

```

{'index_columns': ['__index_level_0__', '__index_level_1__', ...],
 'column_indexes': [<ci0>, <ci1>, ..., <ciN>],
 'columns': [<c0>, <c1>, ...],
 'pandas_version': $VERSION}

```

Here, `<c0>/<ci0>` and so forth are dictionaries containing the metadata for each column, *including the index columns*. This has JSON form:

```

{'name': column_name,
 'field_name': parquet_column_name,
 'pandas_type': pandas_type,
 'numpy_type': numpy_type,
 'metadata': metadata}

```

Note: Every index column is stored with a name matching the pattern `__index_level_\d+__` and its corresponding column information is can be found with the following code snippet.

Following this naming convention isn't strictly necessary, but strongly suggested for compatibility with Arrow.

Here's an example of how the index metadata is structured in pyarrow:

```
# assuming there's at least 3 levels in the index
index_columns = metadata['index_columns'] # noqa: F821
columns = metadata['columns'] # noqa: F821
ith_index = 2
assert index_columns[ith_index] == '__index_level_2__'
ith_index_info = columns[-len(index_columns):][ith_index]
ith_index_level_name = ith_index_info['name']
```

`pandas_type` is the logical type of the column, and is one of:

- Boolean: 'bool'
- Integers: 'int8', 'int16', 'int32', 'int64', 'uint8', 'uint16', 'uint32', 'uint64'
- Floats: 'float16', 'float32', 'float64'
- Date and Time Types: 'datetime', 'datetimetz', 'timedelta'
- String: 'unicode', 'bytes'
- Categorical: 'categorical'
- Other Python objects: 'object'

The `numpy_type` is the physical storage type of the column, which is the result of `str(dtype)` for the underlying NumPy array that holds the data. So for `datetimetz` this is `datetime64[ns]` and for categorical, it may be any of the supported integer categorical types.

The `metadata` field is `None` except for:

- `datetimetz`: {'timezone': zone, 'unit': 'ns'}, e.g. {'timezone': 'America/New_York', 'unit': 'ns'}. The 'unit' is optional, and if omitted it is assumed to be nanoseconds.
- `categorical`: {'num_categories': K, 'ordered': is_ordered, 'type': \$TYPE}
 - Here 'type' is optional, and can be a nested pandas type specification here (but not categorical)
- `unicode`: {'encoding': encoding}
 - The encoding is optional, and if not present is UTF-8
- `object`: {'encoding': encoding}. Objects can be serialized and stored in `BYTE_ARRAY` Parquet columns. The encoding can be one of:
 - 'pickle'
 - 'msgpack'
 - 'bson'
 - 'json'
- `timedelta`: {'unit': 'ns'}. The 'unit' is optional, and if omitted it is assumed to be nanoseconds. This metadata is optional altogether

For types other than these, the `'metadata'` key can be omitted. Implementations can assume `None` if the key is not present.

As an example of fully-formed metadata:

```
{'index_columns': ['__index_level_0__'],
 'column_indexes': [
   {'name': None,
```

(continues on next page)

(continued from previous page)

```

    'field_name': 'None',
    'pandas_type': 'unicode',
    'numpy_type': 'object',
    'metadata': {'encoding': 'UTF-8'}}
],
'columns': [
    {'name': 'c0',
     'field_name': 'c0',
     'pandas_type': 'int8',
     'numpy_type': 'int8',
     'metadata': None},
    {'name': 'c1',
     'field_name': 'c1',
     'pandas_type': 'bytes',
     'numpy_type': 'object',
     'metadata': None},
    {'name': 'c2',
     'field_name': 'c2',
     'pandas_type': 'categorical',
     'numpy_type': 'int16',
     'metadata': {'num_categories': 1000, 'ordered': False}},
    {'name': 'c3',
     'field_name': 'c3',
     'pandas_type': 'datetimetz',
     'numpy_type': 'datetime64[ns]',
     'metadata': {'timezone': 'America/Los_Angeles'}},
    {'name': 'c4',
     'field_name': 'c4',
     'pandas_type': 'object',
     'numpy_type': 'object',
     'metadata': {'encoding': 'pickle'}},
    {'name': None,
     'field_name': '__index_level_0__',
     'pandas_type': 'int64',
     'numpy_type': 'int64',
     'metadata': None}
],
'pandas_version': '0.20.0'}

```

7.5 Roadmap

This page provides an overview of the major themes in pandas' development. Each of these items requires a relatively large amount of effort to implement. These may be achieved more quickly with dedicated funding or interest from contributors.

An item being on the roadmap does not mean that it will *necessarily* happen, even with unlimited funding. During the implementation period we may discover issues preventing the adoption of the feature.

Additionally, an item *not* being on the roadmap does not exclude it from inclusion in pandas. The roadmap is intended for larger, fundamental changes to the project that are likely to take months or years of developer time. Smaller-scoped items will continue to be tracked on our [issue tracker](#).

See *Roadmap Evolution* for proposing changes to this document.

7.5.1 Extensibility

Pandas *Extension types* allow for extending NumPy types with custom data types and array storage. Pandas uses extension types internally, and provides an interface for 3rd-party libraries to define their own custom data types.

Many parts of pandas still unintentionally convert data to a NumPy array. These problems are especially pronounced for nested data.

We'd like to improve the handling of extension arrays throughout the library, making their behavior more consistent with the handling of NumPy arrays. We'll do this by cleaning up pandas' internals and adding new methods to the extension array interface.

7.5.2 String data type

Currently, pandas stores text data in an `object`-dtype NumPy array. The current implementation has two primary drawbacks: First, `object`-dtype is not specific to strings: any Python object can be stored in an `object`-dtype array, not just strings. Second: this is not efficient. The NumPy memory model isn't especially well-suited to variable width text data.

To solve the first issue, we propose a new extension type for string data. This will initially be opt-in, with users explicitly requesting `dtype="string"`. The array backing this string dtype may initially be the current implementation: an `object`-dtype NumPy array of Python strings.

To solve the second issue (performance), we'll explore alternative in-memory array libraries (for example, Apache Arrow). As part of the work, we may need to implement certain operations expected by pandas users (for example the algorithm used in, `Series.str.upper`). That work may be done outside of pandas.

7.5.3 Apache Arrow interoperability

[Apache Arrow](#) is a cross-language development platform for in-memory data. The Arrow logical types are closely aligned with typical pandas use cases.

We'd like to provide better-integrated support for Arrow memory and data types within pandas. This will let us take advantage of its I/O capabilities and provide for better interoperability with other languages and libraries using Arrow.

7.5.4 Block manager rewrite

We'd like to replace pandas current internal data structures (a collection of 1 or 2-D arrays) with a simpler collection of 1-D arrays.

Pandas internal data model is quite complex. A `DataFrame` is made up of one or more 2-dimensional "blocks", with one or more blocks per dtype. This collection of 2-D arrays is managed by the `BlockManager`.

The primary benefit of the `BlockManager` is improved performance on certain operations (construction from a 2D array, binary operations, reductions across the columns), especially for wide `DataFrames`. However, the `BlockManager` substantially increases the complexity and maintenance burden of pandas.

By replacing the `BlockManager` we hope to achieve

- Substantially simpler code

- Easier extensibility with new logical types
- Better user control over memory use and layout
- Improved micro-performance
- Option to provide a C / Cython API to pandas' internals

See [these design documents](#) for more.

7.5.5 Decoupling of indexing and internals

The code for getting and setting values in pandas' data structures needs refactoring. In particular, we must clearly separate code that converts keys (e.g., the argument to `DataFrame.loc`) to positions from code that uses these positions to get or set values. This is related to the proposed BlockManager rewrite. Currently, the BlockManager sometimes uses label-based, rather than position-based, indexing. We propose that it should only work with positional indexing, and the translation of keys to positions should be entirely done at a higher level.

Indexing is a complicated API with many subtleties. This refactor will require care and attention. More details are discussed at [https://github.com/pandas-dev/pandas/wiki/\(Tentative\)-rules-for-restructuring-indexing-code](https://github.com/pandas-dev/pandas/wiki/(Tentative)-rules-for-restructuring-indexing-code)

7.5.6 Numba-accelerated operations

Numba is a JIT compiler for Python code. We'd like to provide ways for users to apply their own Numba-jitted functions where pandas accepts user-defined functions (for example, `Series.apply()`, `DataFrame.apply()`, `DataFrame.applymap()`, and in groupby and window contexts). This will improve the performance of user-defined-functions in these operations by staying within compiled code.

7.5.7 Documentation improvements

We'd like to improve the content, structure, and presentation of the pandas documentation. Some specific goals include

- Overhaul the HTML theme with a modern, responsive design ([GH15556](#))
- Improve the "Getting Started" documentation, designing and writing learning paths for users different backgrounds (e.g. brand new to programming, familiar with other languages like R, already familiar with Python).
- Improve the overall organization of the documentation and specific subsections of the documentation to make navigation and finding content easier.

7.5.8 Package docstring validation

To improve the quality and consistency of pandas docstrings, we've developed tooling to check docstrings in a variety of ways. https://github.com/pandas-dev/pandas/blob/master/scripts/validate_docstrings.py contains the checks.

Like many other projects, pandas uses the `numpydoc` style for writing docstrings. With the collaboration of the `numpydoc` maintainers, we'd like to move the checks to a package other than pandas so that other projects can easily use them as well.

7.5.9 Performance monitoring

Pandas uses `airspeed velocity` to monitor for performance regressions. ASV itself is a fabulous tool, but requires some additional work to be integrated into an open source project's workflow.

The `asv-runner` organization, currently made up of pandas maintainers, provides tools built on top of ASV. We have a physical machine for running a number of project's benchmarks, and tools managing the benchmark runs and reporting on results.

We'd like to fund improvements and maintenance of these tools to

- Be more stable. Currently, they're maintained on the nights and weekends when a maintainer has free time.
- Tune the system for benchmarks to improve stability, following <https://pyperf.readthedocs.io/en/latest/system.html>
- Build a GitHub bot to request ASV runs *before* a PR is merged. Currently, the benchmarks are only run nightly.

7.5.10 Roadmap Evolution

Pandas continues to evolve. The direction is primarily determined by community interest. Everyone is welcome to review existing items on the roadmap and to propose a new item.

Each item on the roadmap should be a short summary of a larger design proposal. The proposal should include

1. Short summary of the changes, which would be appropriate for inclusion in the roadmap if accepted.
2. Motivation for the changes.
3. An explanation of why the change is in scope for pandas.
4. Detailed design: Preferably with example-usage (even if not implemented yet) and API documentation
5. API Change: Any API changes that may result from the proposal.

That proposal may then be submitted as a GitHub issue, where the pandas maintainers can review and comment on the design. The `pandas mailing list` should be notified of the proposal.

When there's agreement that an implementation would be welcome, the roadmap should be updated to include the summary and a link to the discussion issue. {{ header }}

RELEASE NOTES

This is the list of changes to pandas between each release. For full details, see the commit logs at <http://github.com/pandas-dev/pandas>. For install and upgrade instructions, see [Installing statsmodels](#).

8.1 Version 0.25

8.1.1 What's new in 0.25.1 (August 21, 2019)

These are the changes in pandas 0.25.1. See release for a full changelog including other versions of pandas.

I/O and LZMA

Some users may unknowingly have an incomplete Python installation lacking the *lzma* module from the standard library. In this case, `import pandas` failed due to an `ImportError` (:issue: 27575). Pandas will now warn, rather than raising an `ImportError` if the *lzma* module is not present. Any subsequent attempt to use *lzma* methods will raise a `RuntimeError`. A possible fix for the lack of the *lzma* module is to ensure you have the necessary libraries and then re-install Python. For example, on MacOS installing Python with *pyenv* may lead to an incomplete Python installation due to unmet system dependencies at compilation time (like *xz*). Compilation will succeed, but Python might fail at run time. The issue can be solved by installing the necessary dependencies and then re-installing Python.

Bug fixes

Categorical

- Bug in `Categorical.fillna()` that would replace all values, not just those that are NaN ([GH26215](#))

Datetimelike

- Bug in `to_datetime()` where passing a timezone-naive `DatetimeArray` or `DatetimeIndex` and `utc=True` would incorrectly return a timezone-naive result ([GH27733](#))
- Bug in `Period.to_timestamp()` where a `Period` outside the `Timestamp` implementation bounds (roughly 1677-09-21 to 2262-04-11) would return an incorrect `Timestamp` instead of raising `OutOfBoundsDatetime` ([GH19643](#))
- Bug in iterating over `DatetimeIndex` when the underlying data is read-only ([GH28055](#))

Timezones

- Bug in `Index` where a numpy object array with a timezone aware `Timestamp` and `np.nan` would not return a `DatetimeIndex` ([GH27011](#))

Numeric

- Bug in `Series.interpolate()` when using a timezone aware `DatetimeIndex` ([GH27548](#))
- Bug when printing negative floating point complex numbers would raise an `IndexError` ([GH27484](#))
- Bug where `DataFrame` arithmetic operators such as `DataFrame.mul()` with a `Series` with `axis=1` would raise an `AttributeError` on `DataFrame` larger than the minimum threshold to invoke `numexpr` ([GH27636](#))
- Bug in `DataFrame` arithmetic where missing values in results were incorrectly masked with `NaN` instead of `Inf` ([GH27464](#))

Conversion

- Improved the warnings for the deprecated methods `Series.real()` and `Series.imag()` ([GH27610](#))

Interval

- Bug in `IntervalIndex` where `dir(obj)` would raise `ValueError` ([GH27571](#))

Indexing

- Bug in partial-string indexing returning a NumPy array rather than a `Series` when indexing with a scalar like `.loc['2015']` ([GH27516](#))
- Break reference cycle involving `Index` and other index classes to allow garbage collection of index objects without running the GC. ([GH27585](#), [GH27840](#))
- Fix regression in assigning values to a single column of a `DataFrame` with a `MultiIndex` columns ([GH27841](#)).
- Fix regression in `.ix` fallback with an `IntervalIndex` ([GH27865](#)).

Missing

- Bug in `pandas.isnull()` or `pandas.isna()` when the input is a type e.g. `type(pandas.Series())` ([GH27482](#))

I/O

- Avoid calling `S3File.s3` when reading parquet, as this was removed in `s3fs` version 0.3.0 ([GH27756](#))
- Better error message when a negative header is passed in `pandas.read_csv()` ([GH27779](#))
- Follow the `min_rows` display option (introduced in v0.25.0) correctly in the HTML repr in the notebook ([GH27991](#)).

Plotting

- Added a `pandas_plotting_backends` entrypoint group for registering plot backends. See *Plotting backends* for more ([GH26747](#)).
- Fixed the re-instatement of Matplotlib datetime converters after calling `pandas.plotting.deregister_matplotlib_converters()` ([GH27481](#)).
- Fix compatibility issue with matplotlib when passing a pandas `Index` to a plot call ([GH27775](#)).

Groupby/resample/rolling

- Fixed regression in `pandas.core.groupby.DataFrameGroupBy.quantile()` raising when multiple quantiles are given ([GH27526](#))
- Bug in `pandas.core.groupby.DataFrameGroupBy.transform()` where applying a timezone conversion lambda function would drop timezone information ([GH27496](#))
- Bug in `pandas.core.groupby.GroupBy.nth()` where `observed=False` was being ignored for Categorical groupers ([GH26385](#))
- Bug in windowing over read-only arrays ([GH27766](#))
- Fixed segfault in `pandas.core.groupby.DataFrameGroupBy.quantile` when an invalid quantile was passed ([GH27470](#))

Reshaping

- A `KeyError` is now raised if `.unstack()` is called on a `Series` or `DataFrame` with a flat `Index` passing a name which is not the correct one ([GH18303](#))
- Bug `merge_asof()` could not merge `Timedelta` objects when passing `tolerance` kwarg ([GH27642](#))
- Bug in `DataFrame.crosstab()` when `margins` set to `True` and `normalize` is not `False`, an error is raised. ([GH27500](#))
- `DataFrame.join()` now suppresses the `FutureWarning` when the `sort` parameter is specified ([GH21952](#))
- Bug in `DataFrame.join()` raising with readonly arrays ([GH27943](#))

Sparse

- Bug in reductions for `Series` with Sparse dtypes ([GH27080](#))

Other

- Bug in `Series.replace()` and `DataFrame.replace()` when replacing timezone-aware timestamps using a dict-like replacer ([GH27720](#))
- Bug in `Series.rename()` when using a custom type indexer. Now any value that isn't callable or dict-like is treated as a scalar. ([GH27814](#))

Contributors

A total of 7 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

8.1.2 What’s new in 0.25.0 (July 18, 2019)

Warning: Starting with the 0.25.x series of releases, pandas only supports Python 3.5.3 and higher. See [Dropping Python 2.7](#) for more details.

Warning: The minimum supported Python version will be bumped to 3.6 in a future release.

Warning: *Panel* has been fully removed. For N-D labeled data structures, please use `xarray`

Warning: `read_pickle()` and `read_msgpack()` are only guaranteed backwards compatible back to pandas version 0.20.3 ([GH27082](#))

{{ header }}

These are the changes in pandas 0.25.0. See release for a full changelog including other versions of pandas.

Enhancements

Groupby aggregation with relabeling

Pandas has added special groupby behavior, known as “named aggregation”, for naming the output columns when applying multiple aggregation functions to specific columns ([GH18366](#), [GH26512](#)).

```
In [1]: animals = pd.DataFrame({'kind': ['cat', 'dog', 'cat', 'dog'],
...:                          'height': [9.1, 6.0, 9.5, 34.0],
...:                          'weight': [7.9, 7.5, 9.9, 198.0]})
...:
```

```
In [2]: animals
Out[2]:
```

```

   kind  height  weight
0  cat     9.1     7.9
1  dog     6.0     7.5
2  cat     9.5     9.9
3  dog    34.0   198.0

```

```
[4 rows x 3 columns]
```

```

In [3]: animals.groupby("kind").agg(
...:     min_height=pd.NamedAgg(column='height', aggfunc='min'),
...:     max_height=pd.NamedAgg(column='height', aggfunc='max'),
...:     average_weight=pd.NamedAgg(column='weight', aggfunc=np.mean),
...: )
...:

```

```

Out[3]:
   min_height  max_height  average_weight
kind
cat         9.1         9.5             8.90
dog         6.0        34.0          102.75

```

```
[2 rows x 3 columns]
```

Pass the desired columns names as the `**kwargs` to `.agg`. The values of `**kwargs` should be tuples where the first element is the column selection, and the second element is the aggregation function to apply. Pandas provides the `pandas.NamedAgg` namedtuple to make it clearer what the arguments to the function are, but plain tuples are accepted as well.

```

In [4]: animals.groupby("kind").agg(
...:     min_height=('height', 'min'),
...:     max_height=('height', 'max'),
...:     average_weight=('weight', np.mean),
...: )
...:

```

```

Out[4]:
   min_height  max_height  average_weight
kind
cat         9.1         9.5             8.90
dog         6.0        34.0          102.75

```

```
[2 rows x 3 columns]
```

Named aggregation is the recommended replacement for the deprecated “dict-of-dicts” approach to naming the output of column-specific aggregations (*Deprecate `groupby.agg()` with a dictionary when renaming*).

A similar approach is now available for Series groupby objects as well. Because there’s no need for column selection, the values can just be the functions to apply

```

In [5]: animals.groupby("kind").height.agg(
...:     min_height="min",
...:     max_height="max",
...: )
...:

```

```

Out[5]:
   min_height  max_height
kind

```

(continues on next page)

(continued from previous page)

```
cat      9.1      9.5
dog      6.0     34.0
```

```
[2 rows x 2 columns]
```

This type of aggregation is the recommended alternative to the deprecated behavior when passing a dict to a Series groupby aggregation (*Deprecate groupby.agg() with a dictionary when renaming*).

See *Named aggregation* for more.

Groupby Aggregation with multiple lambdas

You can now provide multiple lambda functions to a list-like aggregation in `pandas.core.groupby.GroupBy.agg` (GH26430).

```
In [6]: animals.groupby('kind').height.agg([
...:     lambda x: x.iloc[0], lambda x: x.iloc[-1]
...: ])
...:
```

```
Out[6]:
```

```
<lambda_0> <lambda_1>
kind
cat      9.1      9.5
dog      6.0     34.0
```

```
[2 rows x 2 columns]
```

```
In [7]: animals.groupby('kind').agg([
...:     lambda x: x.iloc[0] - x.iloc[1],
...:     lambda x: x.iloc[0] + x.iloc[1]
...: ])
...:
```

```
Out[7]:
```

```
      height      weight
<lambda_0> <lambda_1> <lambda_0> <lambda_1>
kind
cat      -0.4     18.6     -2.0     17.8
dog     -28.0     40.0    -190.5    205.5
```

```
[2 rows x 4 columns]
```

Previously, these raised a `SpecificationError`.

Better repr for MultiIndex

Printing of `MultiIndex` instances now shows tuples of each row and ensures that the tuple items are vertically aligned, so it's now easier to understand the structure of the `MultiIndex`. (GH13480):

The repr now looks like this:

```
In [8]: pd.MultiIndex.from_product(['a', 'abc'], range(500))
Out[8]:
```

(continues on next page)

(continued from previous page)

```
MultiIndex([( 'a',  0),
            ( 'a',  1),
            ( 'a',  2),
            ( 'a',  3),
            ( 'a',  4),
            ( 'a',  5),
            ( 'a',  6),
            ( 'a',  7),
            ( 'a',  8),
            ( 'a',  9),
            ...
            ('abc', 490),
            ('abc', 491),
            ('abc', 492),
            ('abc', 493),
            ('abc', 494),
            ('abc', 495),
            ('abc', 496),
            ('abc', 497),
            ('abc', 498),
            ('abc', 499)],
           length=1000)
```

Previously, outputting a `MultiIndex` printed all the levels and codes of the `MultiIndex`, which was visually unappealing and made the output more difficult to navigate. For example (limiting the range to 5):

```
In [1]: pd.MultiIndex.from_product(['a', 'abc'], range(5))
Out[1]: MultiIndex(levels=[['a', 'abc'], [0, 1, 2, 3]],
    ....:               codes=[[0, 0, 0, 0, 1, 1, 1, 1], [0, 1, 2, 3, 0, 1, 2, 3]])
```

In the new repr, all values will be shown, if the number of rows is smaller than `options.display.max_seq_items` (default: 100 items). Horizontally, the output will truncate, if it's wider than `options.display.width` (default: 80 characters).

Shorter truncated repr for Series and DataFrame

Currently, the default display options of pandas ensure that when a `Series` or `DataFrame` has more than 60 rows, its repr gets truncated to this maximum of 60 rows (the `display.max_rows` option). However, this still gives a repr that takes up a large part of the vertical screen estate. Therefore, a new option `display.min_rows` is introduced with a default of 10 which determines the number of rows showed in the truncated repr:

- For small `Series` or `DataFrames`, up to `max_rows` number of rows is shown (default: 60).
- For larger `Series` or `DataFrame` with a length above `max_rows`, only `min_rows` number of rows is shown (default: 10, i.e. the first and last 5 rows).

This dual option allows to still see the full content of relatively small objects (e.g. `df.head(20)` shows all 20 rows), while giving a brief repr for large objects.

To restore the previous behaviour of a single threshold, set `pd.options.display.min_rows = None`.

Json normalize with max_level param support

`json_normalize()` normalizes the provided input dict to all nested levels. The new `max_level` parameter provides more control over which level to end normalization ([GH23843](#)):

The repr now looks like this:

```
In [9]: from pandas.io.json import json_normalize

In [10]: data = [{
.....:     'CreatedBy': {'Name': 'User001'},
.....:     'Lookup': {'TextField': 'Some text',
.....:               'UserField': {'Id': 'ID001', 'Name': 'Name001'}},
.....:     'Image': {'a': 'b'}
.....: }]

In [11]: json_normalize(data, max_level=1)
Out[11]:
   CreatedBy.Name Lookup.TextField Lookup.UserField Image.a
0      User001   Some text  {'Id': 'ID001', 'Name': 'Name001'}      b

[1 rows x 4 columns]
```

Series.explode to split list-like values to rows

Series and DataFrame have gained the `DataFrame.explode()` methods to transform list-likes to individual rows. See *section on Exploding list-like column* in docs for more information ([GH16538](#), [GH10511](#))

Here is a typical usecase. You have comma separated string in a column.

```
In [12]: df = pd.DataFrame([{'var1': 'a,b,c', 'var2': 1},
.....:                      {'var1': 'd,e,f', 'var2': 2}])
.....:

In [13]: df
Out[13]:
   var1  var2
0  a,b,c    1
1  d,e,f    2

[2 rows x 2 columns]
```

Creating a long form DataFrame is now straightforward using chained operations

```
In [14]: df.assign(var1=df.var1.str.split(',')).explode('var1')
Out[14]:
   var1  var2
0     a     1
0     b     1
0     c     1
1     d     2
1     e     2
```

(continues on next page)

(continued from previous page)

```
1    f    2
[6 rows x 2 columns]
```

Other enhancements

- `DataFrame.plot()` keywords `logy`, `logx` and `loglog` can now accept the value `'sym'` for symlog scaling. (GH24867)
- Added support for ISO week year format (`'%G-%V-%u'`) when parsing datetimes using `to_datetime()` (GH16607)
- Indexing of `DataFrame` and `Series` now accepts zerodim `np.ndarray` (GH24919)
- `Timestamp.replace()` now supports the `fold` argument to disambiguate DST transition times (GH25017)
- `DataFrame.at_time()` and `Series.at_time()` now support `datetime.time` objects with timezones (GH24043)
- `DataFrame.pivot_table()` now accepts an `observed` parameter which is passed to underlying calls to `DataFrame.groupby()` to speed up grouping categorical data. (GH24923)
- `Series.str` has gained `Series.str.casefold()` method to removes all case distinctions present in a string (GH25405)
- `DataFrame.set_index()` now works for instances of `abc.Iterator`, provided their output is of the same length as the calling frame (GH22484, GH24984)
- `DatetimeIndex.union()` now supports the `sort` argument. The behavior of the `sort` parameter matches that of `Index.union()` (GH24994)
- `RangeIndex.union()` now supports the `sort` argument. If `sort=False` an unsorted `Int64Index` is always returned. `sort=None` is the default and returns a monotonically increasing `RangeIndex` if possible or a sorted `Int64Index` if not (GH24471)
- `TimedeltaIndex.intersection()` now also supports the `sort` keyword (GH24471)
- `DataFrame.rename()` now supports the `errors` argument to raise errors when attempting to rename nonexistent keys (GH13473)
- Added *Sparse accessor* for working with a `DataFrame` whose values are sparse (GH25681)
- `RangeIndex` has gained `start`, `stop`, and `step` attributes (GH25710)
- `datetime.timezone` objects are now supported as arguments to `timezone` methods and constructors (GH25065)
- `DataFrame.query()` and `DataFrame.eval()` now supports quoting column names with backticks to refer to names with spaces (GH6508)
- `merge_asof()` now gives a more clear error message when merge keys are categoricals that are not equal (GH26136)
- `pandas.core.window.Rolling()` supports exponential (or Poisson) window type (GH21303)
- Error message for missing required imports now includes the original import error's text (GH23868)
- `DatetimeIndex` and `TimedeltaIndex` now have a `mean` method (GH24757)
- `DataFrame.describe()` now formats integer percentiles without decimal point (GH26660)

- Added support for reading SPSS .sav files using `read_spss()` (GH26537)
- Added new option `plotting.backend` to be able to select a plotting backend different than the existing matplotlib one. Use `pandas.set_option('plotting.backend', '<backend-module>')` where `<backend-module>` is a library implementing the pandas plotting API (GH14130)
- `pandas.offsets.BusinessHour` supports multiple opening hours intervals (GH15481)
- `read_excel()` can now use `openpyxl` to read Excel files via the `engine='openpyxl'` argument. This will become the default in a future release (GH11499)
- `pandas.io.excel.read_excel()` supports reading OpenDocument tables. Specify `engine='odf'` to enable. Consult the *IO User Guide* for more details (GH9070)
- `Interval`, `IntervalIndex`, and `IntervalArray` have gained an `is_empty` attribute denoting if the given interval(s) are empty (GH27219)

Backwards incompatible API changes

Indexing with date strings with UTC offsets

Indexing a `DataFrame` or `Series` with a `DatetimeIndex` with a date string with a UTC offset would previously ignore the UTC offset. Now, the UTC offset is respected in indexing. (GH24076, GH16785)

```
In [15]: df = pd.DataFrame([0], index=pd.DatetimeIndex(['2019-01-01'], tz='US/Pacific'))
In [16]: df
Out[16]:
                0
2019-01-01 00:00:00-08:00  0

[1 rows x 1 columns]
```

Previous behavior:

```
In [3]: df['2019-01-01 00:00:00+04:00':'2019-01-01 01:00:00+04:00']
Out[3]:
                0
2019-01-01 00:00:00-08:00  0
```

New behavior:

```
In [17]: df['2019-01-01 12:00:00+04:00':'2019-01-01 13:00:00+04:00']
Out[17]:
                0
2019-01-01 00:00:00-08:00  0

[1 rows x 1 columns]
```

MultiIndex constructed from levels and codes

Constructing a `MultiIndex` with `NaN` levels or codes value `< -1` was allowed previously. Now, construction with codes value `< -1` is not allowed and `NaN` levels' corresponding codes would be reassigned as `-1`. (GH19387)

Previous behavior:

```
In [1]: pd.MultiIndex(levels=[[np.nan, None, pd.NaT, 128, 2]],
...:                  codes=[[0, -1, 1, 2, 3, 4]])
...:
Out[1]: MultiIndex(levels=[[nan, None, NaT, 128, 2]],
                  codes=[[0, -1, 1, 2, 3, 4]])

In [2]: pd.MultiIndex(levels=[[1, 2]], codes=[[0, -2]])
Out[2]: MultiIndex(levels=[[1, 2]],
                  codes=[[0, -2]])
```

New behavior:

```
In [18]: pd.MultiIndex(levels=[[np.nan, None, pd.NaT, 128, 2]],
...:                  codes=[[0, -1, 1, 2, 3, 4]])
...:
Out[18]:
MultiIndex([(nan,),
            (nan,),
            (nan,),
            (nan,),
            (128,),
            ( 2,)],
           )
```

```
In [19]: pd.MultiIndex(levels=[[1, 2]], codes=[[0, -2]])
```

```

```

Groupby.apply on DataFrame evaluates first group only once

The implementation of `DataFrameGroupBy.apply()` previously evaluated the supplied function consistently twice on the first group to infer if it is safe to use a fast code path. Particularly for functions with side effects, this was an undesired behavior and may have led to surprises. (GH2936, GH2656, GH7739, GH10519, GH12155, GH20084, GH21417)

Now every group is evaluated only a single time.

```
In [20]: df = pd.DataFrame({"a": ["x", "y"], "b": [1, 2]})

In [21]: df
Out[21]:
   a  b
0  x  1
1  y  2

[2 rows x 2 columns]

In [22]: def func(group):
.....:     print(group.name)
.....:     return group
.....:
```

Previous behavior:

```
In [3]: df.groupby('a').apply(func)
x
x
y
Out[3]:
   a  b
0  x  1
1  y  2
```

New behavior:

```
In [23]: df.groupby("a").apply(func)
x
y
Out[23]:
   a  b
0  x  1
1  y  2

[2 rows x 2 columns]
```

Concatenating sparse values

When passed DataFrames whose values are sparse, `concat()` will now return a `Series` or `DataFrame` with sparse values, rather than a `SparseDataFrame` (GH25702).

```
In [24]: df = pd.DataFrame({"A": pd.SparseArray([0, 1])})
```

Previous behavior:

```
In [2]: type(pd.concat([df, df]))
pandas.core.sparse.frame.SparseDataFrame
```

New behavior:

```
In [25]: type(pd.concat([df, df]))
Out[25]: pandas.core.frame.DataFrame
```

This now matches the existing behavior of `concat` on `Series` with sparse values. `concat()` will continue to return a `SparseDataFrame` when all the values are instances of `SparseDataFrame`.

This change also affects routines using `concat()` internally, like `get_dummies()`, which now returns a `DataFrame` in all cases (previously a `SparseDataFrame` was returned if all the columns were dummy encoded, and a `DataFrame` otherwise).

Providing any `SparseSeries` or `SparseDataFrame` to `concat()` will cause a `SparseSeries` or `SparseDataFrame` to be returned, as before.

The `.str`-accessor performs stricter type checks

Due to the lack of more fine-grained dtypes, `Series.str` so far only checked whether the data was of object dtype. `Series.str` will now infer the dtype data *within* the Series; in particular, 'bytes'-only data will raise an exception (except for `Series.str.decode()`, `Series.str.get()`, `Series.str.len()`, `Series.str.slice()`), see [GH23163](#), [GH23011](#), [GH23551](#).

Previous behavior:

```
In [1]: s = pd.Series(np.array(['a', 'ba', 'cba'], 'S'), dtype=object)

In [2]: s
Out[2]:
0    b'a'
1    b'ba'
2    b'cba'
dtype: object

In [3]: s.str.startswith(b'a')
Out[3]:
0    True
1    False
2    False
dtype: bool
```

New behavior:

```
In [26]: s = pd.Series(np.array(['a', 'ba', 'cba'], 'S'), dtype=object)

In [27]: s
Out[27]:
0    b'a'
1    b'ba'
```

```
2    b'cba'
Length: 3, dtype: object
```

```
In [28]: s.str.startswith(b'a')
```

```
-----
TypeError                                 Traceback (most recent call last)
<ipython-input-28-ac784692b361> in <module>
----> 1 s.str.startswith(b'a')

~/sandbox/pandas-doc/pandas/core/strings.py in wrapper(self, *args, **kwargs)
    1840         )
    1841     )
-> 1842         raise TypeError(msg)
    1843     return func(self, *args, **kwargs)
    1844
```

TypeError: Cannot use .str.startswith with values of inferred dtype 'bytes'.

Categorical dtypes are preserved during groupby

Previously, columns that were categorical, but not the groupby key(s) would be converted to object dtype during groupby operations. Pandas now will preserve these dtypes. ([GH18502](#))

```
In [29]: cat = pd.Categorical(["foo", "bar", "bar", "qux"], ordered=True)
```

```
In [30]: df = pd.DataFrame({'payload': [-1, -2, -1, -2], 'col': cat})
```

```
In [31]: df
```

```
Out[31]:
   payload  col
0        -1  foo
1        -2  bar
2        -1  bar
3        -2  qux
```

```
[4 rows x 2 columns]
```

```
In [32]: df.dtypes
```

```
Out[32]:
payload    int64
col        category
Length: 2, dtype: object
```

Previous Behavior:

```
In [5]: df.groupby('payload').first().col.dtype
Out[5]: dtype('O')
```

New Behavior:

```
In [33]: df.groupby('payload').first().col.dtype
Out[33]: CategoricalDtype(categories=['bar', 'foo', 'qux'], ordered=True)
```

Incompatible Index type unions

When performing `Index.union()` operations between objects of incompatible dtypes, the result will be a base `Index` of dtype `object`. This behavior holds true for unions between `Index` objects that previously would have been prohibited. The dtype of empty `Index` objects will now be evaluated before performing union operations rather than simply returning the other `Index` object. `Index.union()` can now be considered commutative, such that `A.union(B) == B.union(A)` ([GH23525](#)).

Previous behavior:

```
In [1]: pd.period_range('19910905', periods=2).union(pd.Int64Index([1, 2, 3]))
...
ValueError: can only call with other PeriodIndex-ed objects

In [2]: pd.Index([], dtype=object).union(pd.Index([1, 2, 3]))
Out[2]: Int64Index([1, 2, 3], dtype='int64')
```

New behavior:

```
In [34]: pd.period_range('19910905', periods=2).union(pd.Int64Index([1, 2, 3]))
Out[34]: Index([1991-09-05, 1991-09-06, 1, 2, 3], dtype='object')

In [35]: pd.Index([], dtype=object).union(pd.Index([1, 2, 3]))
Out[35]: Index([1, 2, 3], dtype='object')
```

Note that integer- and floating-dtype indexes are considered “compatible”. The integer values are coerced to floating point, which may result in loss of precision. See *Set operations on Index objects* for more.

DataFrame groupby ffill/bfill no longer return group labels

The methods `ffill`, `bfill`, `pad` and `backfill` of `DataFrameGroupBy` previously included the group labels in the return value, which was inconsistent with other groupby transforms. Now only the filled values are returned. ([GH21521](#))

```
In [36]: df = pd.DataFrame({"a": ["x", "y"], "b": [1, 2]})

In [37]: df
Out[37]:
   a  b
0  x  1
1  y  2

[2 rows x 2 columns]
```

Previous behavior:

```
In [3]: df.groupby("a").ffill()
Out[3]:
   a  b
0  x  1
1  y  2
```

New behavior:

```
In [38]: df.groupby("a").ffill()
Out[38]:
   b
0  1
1  2

[2 rows x 1 columns]
```

DataFrame describe on an empty categorical / object column will return top and freq

When calling `DataFrame.describe()` with an empty categorical / object column, the ‘top’ and ‘freq’ columns were previously omitted, which was inconsistent with the output for non-empty columns. Now the ‘top’ and ‘freq’ columns will always be included, with `numpy.nan` in the case of an empty DataFrame ([GH26397](#))

```
In [39]: df = pd.DataFrame({"empty_col": pd.Categorical([])})

In [40]: df
Out[40]:
Empty DataFrame
Columns: [empty_col]
Index: []

[0 rows x 1 columns]
```

Previous behavior:

```
In [3]: df.describe()
Out[3]:
   empty_col
count      0
unique      0
```

New behavior:

```
In [41]: df.describe()
Out[41]:
   empty_col
count      0
unique      0
top        NaN
freq        NaN

[4 rows x 1 columns]
```

__str__ methods now call __repr__ rather than vice versa

Pandas has until now mostly defined string representations in a Pandas object’s `__str__`/`__unicode__`/`__bytes__` methods, and called `__str__` from the `__repr__` method, if a specific `__repr__` method is not found. This is not needed for Python3. In Pandas 0.25, the string representations of Pandas objects are now generally defined in `__repr__`, and calls to `__str__` in general now pass the call on to the `__repr__`, if a specific `__str__` method doesn’t exist, as is standard for Python.

This change is backward compatible for direct usage of Pandas, but if you subclass Pandas objects *and* give your subclasses specific `__str__`/`__repr__` methods, you may have to adjust your `__str__`/`__repr__` methods (GH26495).

Indexing an IntervalIndex with Interval objects

Indexing methods for `IntervalIndex` have been modified to require exact matches only for `Interval` queries. `IntervalIndex` methods previously matched on any overlapping `Interval`. Behavior with scalar points, e.g. querying with an integer, is unchanged (GH16316).

```
In [42]: ii = pd.IntervalIndex.from_tuples([(0, 4), (1, 5), (5, 8)])
```

```
In [43]: ii
```

```
Out[43]:
IntervalIndex([(0, 4], (1, 5], (5, 8]],
              closed='right',
              dtype='interval[int64]')
```

The `in` operator (`__contains__`) now only returns `True` for exact matches to `Intervals` in the `IntervalIndex`, whereas this would previously return `True` for any `Interval` overlapping an `Interval` in the `IntervalIndex`.

Previous behavior:

```
In [4]: pd.Interval(1, 2, closed='neither') in ii
Out[4]: True
```

```
In [5]: pd.Interval(-10, 10, closed='both') in ii
Out[5]: True
```

New behavior:

```
In [44]: pd.Interval(1, 2, closed='neither') in ii
Out[44]: False
```

```
In [45]: pd.Interval(-10, 10, closed='both') in ii
Out[45]: False
```

The `get_loc()` method now only returns locations for exact matches to `Interval` queries, as opposed to the previous behavior of returning locations for overlapping matches. A `KeyError` will be raised if an exact match is not found.

Previous behavior:

```
In [6]: ii.get_loc(pd.Interval(1, 5))
Out[6]: array([0, 1])
```

```
In [7]: ii.get_loc(pd.Interval(2, 6))
Out[7]: array([0, 1, 2])
```

New behavior:

```
In [6]: ii.get_loc(pd.Interval(1, 5))
Out[6]: 1
```

(continues on next page)

(continued from previous page)

```
In [7]: ii.get_loc(pd.Interval(2, 6))
```

```
-----
KeyError: Interval(2, 6, closed='right')
```

Likewise, `get_indexer()` and `get_indexer_non_unique()` will also only return locations for exact matches to `Interval` queries, with `-1` denoting that an exact match was not found.

These indexing changes extend to querying a `Series` or `DataFrame` with an `IntervalIndex` index.

```
In [46]: s = pd.Series(list('abc'), index=ii)
```

```
In [47]: s
```

```
Out[47]:
```

```
(0, 4]    a
```

```
(1, 5]    b
```

```
(5, 8]    c
```

```
Length: 3, dtype: object
```

Selecting from a `Series` or `DataFrame` using `[]` (`__getitem__`) or `loc` now only returns exact matches for `Interval` queries.

Previous behavior:

```
In [8]: s[pd.Interval(1, 5)]
```

```
Out[8]:
```

```
(0, 4]    a
```

```
(1, 5]    b
```

```
dtype: object
```

```
In [9]: s.loc[pd.Interval(1, 5)]
```

```
Out[9]:
```

```
(0, 4]    a
```

```
(1, 5]    b
```

```
dtype: object
```

New behavior:

```
In [48]: s[pd.Interval(1, 5)]
```

```
Out[48]: 'b'
```

```
In [49]: s.loc[pd.Interval(1, 5)]
```

```
Out[49]: 'b'
```

Similarly, a `KeyError` will be raised for non-exact matches instead of returning overlapping matches.

Previous behavior:

```
In [9]: s[pd.Interval(2, 3)]
```

```
Out[9]:
```

```
(0, 4]    a
```

```
(1, 5]    b
```

```
dtype: object
```

```
In [10]: s.loc[pd.Interval(2, 3)]
```

```
Out[10]:
```

(continues on next page)

(continued from previous page)

```
(0, 4]    a
(1, 5]    b
dtype: object
```

New behavior:

```
In [6]: s[pd.Interval(2, 3)]
-----
KeyError: Interval(2, 3, closed='right')

In [7]: s.loc[pd.Interval(2, 3)]
-----
KeyError: Interval(2, 3, closed='right')
```

The `overlaps()` method can be used to create a boolean indexer that replicates the previous behavior of returning overlapping matches.

New behavior:

```
In [50]: idxr = s.index.overlaps(pd.Interval(2, 3))

In [51]: idxr
Out[51]: array([ True,  True, False])

In [52]: s[idxr]
Out[52]:
(0, 4]    a
(1, 5]    b
Length: 2, dtype: object

In [53]: s.loc[idxr]
Out[53]:
(0, 4]    a
(1, 5]    b
Length: 2, dtype: object
```

Binary ufuncs on Series now align

Applying a binary ufunc like `numpy.power()` now aligns the inputs when both are `Series` ([GH23293](#)).

```
In [54]: s1 = pd.Series([1, 2, 3], index=['a', 'b', 'c'])
```

```
In [55]: s2 = pd.Series([3, 4, 5], index=['d', 'c', 'b'])
```

```
In [56]: s1
Out[56]:
a    1
b    2
c    3
Length: 3, dtype: int64
```

```
In [57]: s2
Out[57]:
```

```
d    3
c    4
b    5
Length: 3, dtype: int64
```

Previous behavior

```
In [5]: np.power(s1, s2)
Out[5]:
a      1
b     16
c    243
dtype: int64
```

New behavior

```
In [58]: np.power(s1, s2)
Out[58]:
a      1.0
b     32.0
c     81.0
d      NaN
Length: 4, dtype: float64
```

This matches the behavior of other binary operations in pandas, like `Series.add()`. To retain the previous behavior, convert the other `Series` to an array before applying the ufunc.

```
In [59]: np.power(s1, s2.array)
Out[59]:
a      1
b     16
c    243
Length: 3, dtype: int64
```

Categorical.argsort now places missing values at the end

`Categorical.argsort()` now places missing values at the end of the array, making it consistent with NumPy and the rest of pandas (GH21801).

```
In [60]: cat = pd.Categorical(['b', None, 'a'], categories=['a', 'b'], ordered=True)
```

Previous behavior

```
In [2]: cat = pd.Categorical(['b', None, 'a'], categories=['a', 'b'], ordered=True)

In [3]: cat.argsort()
Out[3]: array([1, 2, 0])

In [4]: cat[cat.argsort()]
Out[4]:
[NaN, a, b]
categories (2, object): [a < b]
```

New behavior

```
In [61]: cat.argsort()
Out[61]: array([2, 0, 1])
```

```
In [62]: cat[cat.argsort()]
Out[62]:
[a, b, NaN]
Categories (2, object): [a < b]
```

Column order is preserved when passing a list of dicts to DataFrame

Starting with Python 3.7 the key-order of `dict` is [guaranteed](#). In practice, this has been true since Python 3.6. The `DataFrame` constructor now treats a list of dicts in the same way as it does a list of `OrderedDict`, i.e. preserving the order of the dicts. This change applies only when pandas is running on Python ≥ 3.6 ([GH27309](#)).

```
In [63]: data = [
.....:     {'name': 'Joe', 'state': 'NY', 'age': 18},
.....:     {'name': 'Jane', 'state': 'KY', 'age': 19, 'hobby': 'Minecraft'},
.....:     {'name': 'Jean', 'state': 'OK', 'age': 20, 'finances': 'good'}
.....: ]
.....:
```

Previous Behavior:

The columns were lexicographically sorted previously,

```
In [1]: pd.DataFrame(data)
Out[1]:
   age finances      hobby name state
0   18      NaN      NaN   Joe   NY
1   19      NaN  Minecraft  Jane   KY
2   20     good      NaN   Jean   OK
```

New Behavior:

The column order now matches the insertion-order of the keys in the `dict`, considering all the records from top to bottom. As a consequence, the column order of the resulting `DataFrame` has changed compared to previous pandas versions.

```
In [64]: pd.DataFrame(data)
Out[64]:
   name state age      hobby finances
0   Joe   NY  18      NaN      NaN
1  Jane   KY  19  Minecraft      NaN
2  Jean   OK  20      NaN     good

[3 rows x 5 columns]
```

Increased minimum versions for dependencies

Due to dropping support for Python 2.7, a number of optional dependencies have updated minimum versions ([GH25725](#), [GH24942](#), [GH25752](#)). Independently, some minimum supported versions of dependencies were updated ([GH23519](#), [GH25554](#)). If installed, we now require:

| Package | Minimum Version | Required |
|-----------------|-----------------|----------|
| numpy | 1.13.3 | X |
| pytz | 2015.4 | X |
| python-dateutil | 2.6.1 | X |
| bottleneck | 1.2.1 | |
| numexpr | 2.6.2 | |
| pytest (dev) | 4.0.2 | |

For [optional libraries](#) the general recommendation is to use the latest version. The following table lists the lowest version per library that is currently being tested throughout the development of pandas. Optional libraries below the lowest tested version may still work, but are not considered supported.

| Package | Minimum Version |
|----------------|-----------------|
| beautifulsoup4 | 4.6.0 |
| fastparquet | 0.2.1 |
| gcsfs | 0.2.2 |
| lxml | 3.8.0 |
| matplotlib | 2.2.2 |
| openpyxl | 2.4.8 |
| pyarrow | 0.9.0 |
| pymysql | 0.7.1 |
| pytables | 3.4.2 |
| scipy | 0.19.0 |
| sqlalchemy | 1.1.4 |
| xarray | 0.8.2 |
| xlrd | 1.1.0 |
| xlsxwriter | 0.9.8 |
| xlwt | 1.2.0 |

See [Dependencies](#) and [Optional dependencies](#) for more.

Other API changes

- `DatetimeTZDtype` will now standardize pytz timezones to a common timezone instance ([GH24713](#))
- `Timestamp` and `Timedelta` scalars now implement the `to_numpy()` method as aliases to `Timestamp.to_datetime64()` and `Timedelta.to_timedelta64()`, respectively. ([GH24653](#))
- `Timestamp.strptime()` will now raise a `NotImplementedError` ([GH25016](#))
- Comparing `Timestamp` with unsupported objects now returns `NotImplemented` instead of raising `TypeError`. This implies that unsupported rich comparisons are delegated to the other object, and are now consistent with Python 3 behavior for `datetime` objects ([GH24011](#))
- Bug in `DatetimeIndex.snap()` which didn't preserving the name of the input `Index` ([GH25575](#))
- The `arg` argument in `pandas.core.groupby.DataFrameGroupBy.agg()` has been renamed to `func` ([GH26089](#))
- The `arg` argument in `pandas.core.window.Window.aggregate()` has been renamed to `func` ([GH26372](#))
- Most Pandas classes had a `__bytes__` method, which was used for getting a python2-style bytestring representation of the object. This method has been removed as a part of dropping Python2 ([GH26447](#))

- The `.str`-accessor has been disabled for 1-level `MultiIndex`, use `MultiIndex.to_flat_index()` if necessary ([GH23679](#))
- Removed support of `gtk` package for clipboards ([GH26563](#))
- Using an unsupported version of Beautiful Soup 4 will now raise an `ImportError` instead of a `ValueError` ([GH27063](#))
- `Series.to_excel()` and `DataFrame.to_excel()` will now raise a `ValueError` when saving timezone aware data. ([GH27008](#), [GH7056](#))
- `ExtensionArray.argsort()` places NA values at the end of the sorted array. ([GH21801](#))
- `DataFrame.to_hdf()` and `Series.to_hdf()` will now raise a `NotImplementedError` when saving a `MultiIndex` with extension data types for a fixed format. ([GH7775](#))
- Passing duplicate names in `read_csv()` will now raise a `ValueError` ([GH17346](#))

Deprecations

Sparse subclasses

The `SparseSeries` and `SparseDataFrame` subclasses are deprecated. Their functionality is better-provided by a `Series` or `DataFrame` with sparse values.

Previous way

```
In [65]: df = pd.SparseDataFrame({"A": [0, 0, 1, 2]})
```

```
In [66]: df.dtypes
```

```
Out[66]:
```

```
A    Sparse[int64, nan]
Length: 1, dtype: object
```

New way

```
In [67]: df = pd.DataFrame({"A": pd.SparseArray([0, 0, 1, 2])})
```

```
In [68]: df.dtypes
```

```
Out[68]:
```

```
A    Sparse[int64, 0]
Length: 1, dtype: object
```

The memory usage of the two approaches is identical. See *Migrating* for more ([GH19239](#)).

msgpack format

The `msgpack` format is deprecated as of 0.25 and will be removed in a future version. It is recommended to use `pyarrow` for on-the-wire transmission of pandas objects. ([GH27084](#))

Other deprecations

- The deprecated `.ix[]` indexer now raises a more visible `FutureWarning` instead of `DeprecationWarning` ([GH26438](#)).

- Deprecated the `units=M` (months) and `units=Y` (year) parameters for `units` of `pandas.to_timedelta()`, `pandas.Timedelta()` and `pandas.TimedeltaIndex()` (GH16344)
- `pandas.concat()` has deprecated the `join_axes`-keyword. Instead, use `DataFrame.reindex()` or `DataFrame.reindex_like()` on the result or on the inputs (GH21951)
- The `SparseArray.values` attribute is deprecated. You can use `np.asarray(...)` or the `SparseArray.to_dense()` method instead (GH26421).
- The functions `pandas.to_datetime()` and `pandas.to_timedelta()` have deprecated the `box` keyword. Instead, use `to_numpy()` or `Timestamp.to_datetime64()` or `Timedelta.to_timedelta64()`. (GH24416)
- The `DataFrame.compound()` and `Series.compound()` methods are deprecated and will be removed in a future version (GH26405).
- The internal attributes `_start`, `_stop` and `_step` attributes of `RangeIndex` have been deprecated. Use the public attributes `start`, `stop` and `step` instead (GH26581).
- The `Series.ftype()`, `Series.ftypes()` and `DataFrame.ftypes()` methods are deprecated and will be removed in a future version. Instead, use `Series.dtype()` and `DataFrame.dtypes()` (GH26705).
- The `Series.get_values()`, `DataFrame.get_values()`, `Index.get_values()`, `SparseArray.get_values()` and `Categorical.get_values()` methods are deprecated. One of `np.asarray(...)` or `to_numpy()` can be used instead (GH19617).
- The ‘outer’ method on NumPy ufuncs, e.g. `np.subtract.outer` has been deprecated on `Series` objects. Convert the input to an array with `Series.array` first (GH27186)
- `Timedelta.resolution()` is deprecated and replaced with `Timedelta.resolution_string()`. In a future version, `Timedelta.resolution()` will be changed to behave like the standard library `datetime.timedelta.resolution` (GH21344)
- `read_table()` has been undeprecated. (GH25220)
- `Index.dtype_str` is deprecated. (GH18262)
- `Series.imag` and `Series.real` are deprecated. (GH18262)
- `Series.put()` is deprecated. (GH18262)
- `Index.item()` and `Series.item()` is deprecated. (GH18262)
- The default value `ordered=None` in `CategoricalDtype` has been deprecated in favor of `ordered=False`. When converting between categorical types `ordered=True` must be explicitly passed in order to be preserved. (GH26336)
- `Index.contains()` is deprecated. Use `key` in `index` (`__contains__`) instead (GH17753).
- `DataFrame.get_dtype_counts()` is deprecated. (GH18262)
- `Categorical.ravel()` will return a `Categorical` instead of a `np.ndarray` (GH27199)

Removal of prior version deprecations/changes

- Removed `Panel` (GH25047, GH25191, GH25231)
- Removed the previously deprecated `sheetname` keyword in `read_excel()` (GH16442, GH20938)
- Removed the previously deprecated `TimeGrouper` (GH16942)
- Removed the previously deprecated `parse_cols` keyword in `read_excel()` (GH16488)
- Removed the previously deprecated `pd.options.html.border` (GH16970)

- Removed the previously deprecated `convert_objects` (GH11221)
- Removed the previously deprecated `select` method of `DataFrame` and `Series` (GH17633)
- Removed the previously deprecated behavior of `Series` treated as list-like in `rename_categories()` (GH17982)
- Removed the previously deprecated `DataFrame.reindex_axis` and `Series.reindex_axis` (GH17842)
- Removed the previously deprecated behavior of altering column or index labels with `Series.rename_axis()` or `DataFrame.rename_axis()` (GH17842)
- Removed the previously deprecated `tupleize_cols` keyword argument in `read_html()`, `read_csv()`, and `DataFrame.to_csv()` (GH17877, GH17820)
- Removed the previously deprecated `DataFrame.from_csv` and `Series.from_csv` (GH17812)
- Removed the previously deprecated `raise_on_error` keyword argument in `DataFrame.where()` and `DataFrame.mask()` (GH17744)
- Removed the previously deprecated `ordered` and `categories` keyword arguments in `astype` (GH17742)
- Removed the previously deprecated `cdate_range` (GH17691)
- Removed the previously deprecated `True` option for the `dropna` keyword argument in `SeriesGroupBy.nth()` (GH17493)
- Removed the previously deprecated `convert` keyword argument in `Series.take()` and `DataFrame.take()` (GH17352)

Performance improvements

- Significant speedup in `SparseArray` initialization that benefits most operations, fixing performance regression introduced in v0.20.0 (GH24985)
- `DataFrame.to_stata()` is now faster when outputting data with any string or non-native endian columns (GH25045)
- Improved performance of `Series.searchsorted()`. The speedup is especially large when the dtype is `int8/int16/int32` and the searched key is within the integer bounds for the dtype (GH22034)
- Improved performance of `pandas.core.groupby.GroupBy.quantile()` (GH20405)
- Improved performance of slicing and other selected operation on a `RangeIndex` (GH26565, GH26617, GH26722)
- `RangeIndex` now performs standard lookup without instantiating an actual hashtable, hence saving memory (GH16685)
- Improved performance of `read_csv()` by faster tokenizing and faster parsing of small float numbers (GH25784)
- Improved performance of `read_csv()` by faster parsing of N/A and boolean values (GH25804)
- Improved performance of `IntervalIndex.is_monotonic`, `IntervalIndex.is_monotonic_increasing` and `IntervalIndex.is_monotonic_decreasing` by removing conversion to `MultiIndex` (GH24813)
- Improved performance of `DataFrame.to_csv()` when writing datetime dtypes (GH25708)
- Improved performance of `read_csv()` by much faster parsing of `MM/YYYY` and `DD/MM/YYYY` datetime formats (GH25922)

- Improved performance of `nanops` for dtypes that cannot store NaNs. Speedup is particularly prominent for `Series.all()` and `Series.any()` ([GH25070](#))
- Improved performance of `Series.map()` for dictionary mappers on categorical series by mapping the categories instead of mapping all values ([GH23785](#))
- Improved performance of `IntervalIndex.intersection()` ([GH24813](#))
- Improved performance of `read_csv()` by faster concatenating date columns without extra conversion to string for integer/float zero and float NaN; by faster checking the string for the possibility of being a date ([GH25754](#))
- Improved performance of `IntervalIndex.is_unique` by removing conversion to `MultiIndex` ([GH24813](#))
- Restored performance of `DatetimeIndex.__iter__()` by re-enabling specialized code path ([GH26702](#))
- Improved performance when building `MultiIndex` with at least one `CategoricalIndex` level ([GH22044](#))
- Improved performance by removing the need for a garbage collect when checking for `SettingWithCopyWarning` ([GH27031](#))
- For `to_datetime()` changed default value of `cache` parameter to `True` ([GH26043](#))
- Improved performance of `DatetimeIndex` and `PeriodIndex` slicing given non-unique, monotonic data ([GH27136](#)).
- Improved performance of `pd.read_json()` for index-oriented data. ([GH26773](#))
- Improved performance of `MultiIndex.shape()` ([GH27384](#)).

Bug fixes

Categorical

- Bug in `DataFrame.at()` and `Series.at()` that would raise exception if the index was a `CategoricalIndex` ([GH20629](#))
- Fixed bug in comparison of ordered `Categorical` that contained missing values with a scalar which sometimes incorrectly resulted in `True` ([GH26504](#))
- Bug in `DataFrame.dropna()` when the `DataFrame` has a `CategoricalIndex` containing `Interval` objects incorrectly raised a `TypeError` ([GH25087](#))

Datetimelike

- Bug in `to_datetime()` which would raise an (incorrect) `ValueError` when called with a date far into the future and the `format` argument specified instead of raising `OutOfBoundsDatetime` ([GH23830](#))
- Bug in `to_datetime()` which would raise `InvalidIndexError: Reindexing only valid with uniquely valued Index objects` when called with `cache=True`, with `arg` including at least two different elements from the set `{None, numpy.nan, pandas.NaT}` ([GH22305](#))
- Bug in `DataFrame` and `Series` where timezone aware data with `dtype='datetime64[ns]` was not cast to naive ([GH25843](#))
- Improved `Timestamp` type checking in various datetime functions to prevent exceptions when using a subclassed `datetime` ([GH25851](#))

- Bug in `Series` and `DataFrame` repr where `np.datetime64('NaT')` and `np.timedelta64('NaT')` with `dtype=object` would be represented as `NaN` (GH25445)
- Bug in `to_datetime()` which does not replace the invalid argument with `NaT` when error is set to `coerce` (GH26122)
- Bug in adding `DateOffset` with nonzero month to `DatetimeIndex` would raise `ValueError` (GH26258)
- Bug in `to_datetime()` which raises unhandled `OverflowError` when called with mix of invalid dates and `NaN` values with `format='%Y%m%d'` and `error='coerce'` (GH25512)
- Bug in `isin()` for datetimelike indexes; `DatetimeIndex`, `TimedeltaIndex` and `PeriodIndex` where the `levels` parameter was ignored. (GH26675)
- Bug in `to_datetime()` which raises `TypeError` for `format='%Y%m%d'` when called for invalid integer dates with length ≥ 6 digits with `errors='ignore'`
- Bug when comparing a `PeriodIndex` against a zero-dimensional numpy array (GH26689)
- Bug in constructing a `Series` or `DataFrame` from a numpy `datetime64` array with a non-ns unit and out-of-bound timestamps generating rubbish data, which will now correctly raise an `OutOfBoundsDatetime` error (GH26206).
- Bug in `date_range()` with unnecessary `OverflowError` being raised for very large or very small dates (GH26651)
- Bug where adding `Timestamp` to a `np.timedelta64` object would raise instead of returning a `Timestamp` (GH24775)
- Bug where comparing a zero-dimensional numpy array containing a `np.datetime64` object to a `Timestamp` would incorrect raise `TypeError` (GH26916)
- Bug in `to_datetime()` which would raise `ValueError: Tz-aware datetime.datetime cannot be converted to datetime64 unless utc=True` when called with `cache=True`, with `arg` including datetime strings with different offset (GH26097)
-

Timedelta

- Bug in `TimedeltaIndex.intersection()` where for non-monotonic indices in some cases an empty `Index` was returned when in fact an intersection existed (GH25913)
- Bug with comparisons between `Timedelta` and `NaT` raising `TypeError` (GH26039)
- Bug when adding or subtracting a `BusinessHour` to a `Timestamp` with the resulting time landing in a following or prior day respectively (GH26381)
- Bug when comparing a `TimedeltaIndex` against a zero-dimensional numpy array (GH26689)

Timezones

- Bug in `DatetimeIndex.to_frame()` where timezone aware data would be converted to timezone naive data (GH25809)
- Bug in `to_datetime()` with `utc=True` and datetime strings that would apply previously parsed UTC offsets to subsequent arguments (GH24992)
- Bug in `Timestamp.tz_localize()` and `Timestamp.tz_convert()` does not propagate `freq` (GH25241)
- Bug in `Series.at()` where setting `Timestamp` with timezone raises `TypeError` (GH25506)

- Bug in `DataFrame.update()` when updating with timezone aware data would return timezone naive data ([GH25807](#))
- Bug in `to_datetime()` where an uninformative `RuntimeError` was raised when passing a naive `Timestamp` with datetime strings with mixed UTC offsets ([GH25978](#))
- Bug in `to_datetime()` with `unit='ns'` would drop timezone information from the parsed argument ([GH26168](#))
- Bug in `DataFrame.join()` where joining a timezone aware index with a timezone aware column would result in a column of `NaN` ([GH26335](#))
- Bug in `date_range()` where ambiguous or nonexistent start or end times were not handled by the `ambiguous` or `nonexistent` keywords respectively ([GH27088](#))
- Bug in `DatetimeIndex.union()` when combining a timezone aware and timezone unaware `DatetimeIndex` ([GH21671](#))
- Bug when applying a numpy reduction function (e.g. `numpy.minimum()`) to a timezone aware `Series` ([GH15552](#))

Numeric

- Bug in `to_numeric()` in which large negative numbers were being improperly handled ([GH24910](#))
- Bug in `to_numeric()` in which numbers were being coerced to float, even though `errors` was not `coerce` ([GH24910](#))
- Bug in `to_numeric()` in which invalid values for `errors` were being allowed ([GH26466](#))
- Bug in `format` in which floating point complex numbers were not being formatted to proper display precision and trimming ([GH25514](#))
- Bug in error messages in `DataFrame.corr()` and `Series.corr()`. Added the possibility of using a callable. ([GH25729](#))
- Bug in `Series.divmod()` and `Series.rdivmod()` which would raise an (incorrect) `ValueError` rather than return a pair of `Series` objects as result ([GH25557](#))
- Raises a helpful exception when a non-numeric index is sent to `interpolate()` with methods which require numeric index. ([GH21662](#))
- Bug in `eval()` when comparing floats with scalar operators, for example: `x < -0.1` ([GH25928](#))
- Fixed bug where casting all-boolean array to integer extension array failed ([GH25211](#))
- Bug in `divmod` with a `Series` object containing zeros incorrectly raising `AttributeError` ([GH26987](#))
- Inconsistency in `Series` floor-division (`//`) and `divmod` filling positive//zero with `NaN` instead of `Inf` ([GH27321](#))
-

Conversion

- Bug in `DataFrame.astype()` when passing a dict of columns and types the `errors` parameter was ignored. ([GH25905](#))
-
-

Strings

- Bug in the `__name__` attribute of several methods of `Series.str`, which were set incorrectly (GH23551)
- Improved error message when passing `Series` of wrong dtype to `Series.str.cat()` (GH22722)
-

Interval

- Construction of `Interval` is restricted to numeric, `Timestamp` and `Timedelta` endpoints (GH23013)
- Fixed bug in `Series/DataFrame` not displaying NaN in `IntervalIndex` with missing values (GH25984)
- Bug in `IntervalIndex.get_loc()` where a `KeyError` would be incorrectly raised for a decreasing `IntervalIndex` (GH25860)
- Bug in `Index` constructor where passing mixed closed `Interval` objects would result in a `ValueError` instead of an object dtype `Index` (GH27172)

Indexing

- Improved exception message when calling `DataFrame.iloc()` with a list of non-numeric objects (GH25753).
- Improved exception message when calling `.iloc` or `.loc` with a boolean indexer with different length (GH26658).
- Bug in `KeyError` exception message when indexing a `MultiIndex` with a non-existent key not displaying the original key (GH27250).
- Bug in `.iloc` and `.loc` with a boolean indexer not raising an `IndexError` when too few items are passed (GH26658).
- Bug in `DataFrame.loc()` and `Series.loc()` where `KeyError` was not raised for a `MultiIndex` when the key was less than or equal to the number of levels in the `MultiIndex` (GH14885).
- Bug in which `DataFrame.append()` produced an erroneous warning indicating that a `KeyError` will be thrown in the future when the data to be appended contains new columns (GH22252).
- Bug in which `DataFrame.to_csv()` caused a segfault for a reindexed data frame, when the indices were single-level `MultiIndex` (GH26303).
- Fixed bug where assigning a `arrays.PandasArray` to a `pandas.core.frame.DataFrame` would raise error (GH26390)
- Allow keyword arguments for callable local reference used in the `DataFrame.query()` string (GH26426)
- Fixed a `KeyError` when indexing a `MultiIndex` level with a list containing exactly one label, which is missing (GH27148)
- Bug which produced `AttributeError` on partial matching `Timestamp` in a `MultiIndex` (GH26944)
- Bug in `Categorical` and `CategoricalIndex` with `Interval` values when using the `in` operator (`__contains__`) with objects that are not comparable to the values in the `Interval` (GH23705)
- Bug in `DataFrame.loc()` and `DataFrame.iloc()` on a `DataFrame` with a single timezone-aware date-time64[ns] column incorrectly returning a scalar instead of a `Series` (GH27110)
- Bug in `CategoricalIndex` and `Categorical` incorrectly raising `ValueError` instead of `TypeError` when a list is passed using the `in` operator (`__contains__`) (GH21729)

- Bug in setting a new value in a `Series` with a `Timedelta` object incorrectly casting the value to an integer ([GH22717](#))
- Bug in `Series` setting a new key (`__setitem__`) with a timezone-aware datetime incorrectly raising `ValueError` ([GH12862](#))
- Bug in `DataFrame.iloc()` when indexing with a read-only indexer ([GH17192](#))
- Bug in `Series` setting an existing tuple key (`__setitem__`) with timezone-aware datetime values incorrectly raising `TypeError` ([GH20441](#))

Missing

- Fixed misleading exception message in `Series.interpolate()` if argument `order` is required, but omitted ([GH10633](#), [GH24014](#)).
- Fixed class type displayed in exception message in `DataFrame.dropna()` if invalid `axis` parameter passed ([GH25555](#))
- A `ValueError` will now be thrown by `DataFrame.fillna()` when `limit` is not a positive integer ([GH27042](#))
-

Multindex

- Bug in which incorrect exception raised by `Timedelta` when testing the membership of `MultiIndex` ([GH24570](#))
-

I/O

- Bug in `DataFrame.to_html()` where values were truncated using display options instead of outputting the full content ([GH17004](#))
- Fixed bug in missing text when using `to_clipboard()` if copying utf-16 characters in Python 3 on Windows ([GH25040](#))
- Bug in `read_json()` for `orient='table'` when it tries to infer dtypes by default, which is not applicable as dtypes are already defined in the JSON schema ([GH21345](#))
- Bug in `read_json()` for `orient='table'` and float index, as it infers index dtype by default, which is not applicable because index dtype is already defined in the JSON schema ([GH25433](#))
- Bug in `read_json()` for `orient='table'` and string of float column names, as it makes a column name type conversion to `Timestamp`, which is not applicable because column names are already defined in the JSON schema ([GH25435](#))
- Bug in `json_normalize()` for `errors='ignore'` where missing values in the input data, were filled in resulting `DataFrame` with the string `"nan"` instead of `numpy.nan` ([GH25468](#))
- `DataFrame.to_html()` now raises `TypeError` when using an invalid type for the `classes` parameter instead of `AssertionError` ([GH25608](#))
- Bug in `DataFrame.to_string()` and `DataFrame.to_latex()` that would lead to incorrect output when the `header` keyword is used ([GH16718](#))

- Bug in `read_csv()` not properly interpreting the UTF8 encoded filenames on Windows on Python 3.6+ (GH15086)
- Improved performance in `pandas.read_stata()` and `pandas.io.stata.StataReader` when converting columns that have missing values (GH25772)
- Bug in `DataFrame.to_html()` where header numbers would ignore display options when rounding (GH17280)
- Bug in `read_hdf()` where reading a table from an HDF5 file written directly with PyTables fails with a `ValueError` when using a sub-selection via the `start` or `stop` arguments (GH11188)
- Bug in `read_hdf()` not properly closing store after a `KeyError` is raised (GH25766)
- Improved the explanation for the failure when value labels are repeated in Stata dta files and suggested work-arounds (GH25772)
- Improved `pandas.read_stata()` and `pandas.io.stata.StataReader` to read incorrectly formatted 118 format files saved by Stata (GH25960)
- Improved the `col_space` parameter in `DataFrame.to_html()` to accept a string so CSS length values can be set correctly (GH25941)
- Fixed bug in loading objects from S3 that contain `#` characters in the URL (GH25945)
- Adds `use_bqstorage_api` parameter to `read_gbq()` to speed up downloads of large data frames. This feature requires version 0.10.0 of the `pandas-gbq` library as well as the `google-cloud-bigquery-storage` and `fastavro` libraries. (GH26104)
- Fixed memory leak in `DataFrame.to_json()` when dealing with numeric data (GH24889)
- Bug in `read_json()` where date strings with Z were not converted to a UTC timezone (GH26168)
- Added `cache_dates=True` parameter to `read_csv()`, which allows to cache unique dates when they are parsed (GH25990)
- `DataFrame.to_excel()` now raises a `ValueError` when the caller's dimensions exceed the limitations of Excel (GH26051)
- Fixed bug in `pandas.read_csv()` where a BOM would result in incorrect parsing using `engine='python'` (GH26545)
- `read_excel()` now raises a `ValueError` when input is of type `pandas.io.excel.ExcelFile` and `engine` param is passed since `pandas.io.excel.ExcelFile` has an engine defined (GH26566)
- Bug while selecting from `HDFStore` with `where=''` specified (GH26610).
- Fixed bug in `DataFrame.to_excel()` where custom objects (i.e. `PeriodIndex`) inside merged cells were not being converted into types safe for the Excel writer (GH27006)
- Bug in `read_hdf()` where reading a timezone aware `DatetimeIndex` would raise a `TypeError` (GH11926)
- Bug in `to_msgpack()` and `read_msgpack()` which would raise a `ValueError` rather than a `FileNotFoundError` for an invalid path (GH27160)
- Fixed bug in `DataFrame.to_parquet()` which would raise a `ValueError` when the dataframe had no columns (GH27339)
- Allow parsing of `PeriodDtype` columns when using `read_csv()` (GH26934)

Plotting

- Fixed bug where `api.extensions.ExtensionArray` could not be used in matplotlib plotting (GH25587)
- Bug in an error message in `DataFrame.plot()`. Improved the error message if non-numeric are passed to `DataFrame.plot()` (GH25481)
- Bug in incorrect ticklabel positions when plotting an index that are non-numeric / non-datetime (GH7612, GH15912, GH22334)
- Fixed bug causing plots of `PeriodIndex` timeseries to fail if the frequency is a multiple of the frequency rule code (GH14763)
- Fixed bug when plotting a `DatetimeIndex` with `datetime.timezone.utc` timezone (GH17173)
-
-

Groupby/resample/rolling

- Bug in `pandas.core.resample.Resampler.agg()` with a timezone aware index where `OverflowError` would raise when passing a list of functions (GH22660)
- Bug in `pandas.core.groupby.DataFrameGroupBy.nunique()` in which the names of column levels were lost (GH23222)
- Bug in `pandas.core.groupby.GroupBy.agg()` when applying an aggregation function to timezone aware data (GH23683)
- Bug in `pandas.core.groupby.GroupBy.first()` and `pandas.core.groupby.GroupBy.last()` where timezone information would be dropped (GH21603)
- Bug in `pandas.core.groupby.GroupBy.size()` when grouping only NA values (GH23050)
- Bug in `Series.groupby()` where observed kwarg was previously ignored (GH24880)
- Bug in `Series.groupby()` where using `groupby` with a `MultiIndex` Series with a list of labels equal to the length of the series caused incorrect grouping (GH25704)
- Ensured that ordering of outputs in `groupby` aggregation functions is consistent across all versions of Python (GH25692)
- Ensured that result group order is correct when grouping on an ordered `Categorical` and specifying `observed=True` (GH25871, GH25167)
- Bug in `pandas.core.window.Rolling.min()` and `pandas.core.window.Rolling.max()` that caused a memory leak (GH25893)
- Bug in `pandas.core.window.Rolling.count()` and `pandas.core.window.Expanding.count` was previously ignoring the `axis` keyword (GH13503)
- Bug in `pandas.core.groupby.GroupBy.idxmax()` and `pandas.core.groupby.GroupBy.idxmin()` with datetime column would return incorrect dtype (GH25444, GH15306)
- Bug in `pandas.core.groupby.GroupBy.cumsum()`, `pandas.core.groupby.GroupBy.cumprod()`, `pandas.core.groupby.GroupBy.cummin()` and `pandas.core.groupby.GroupBy.cummax()` with categorical column having absent categories, would return incorrect result or segfault (GH16771)
- Bug in `pandas.core.groupby.GroupBy.nth()` where NA values in the grouping would return incorrect results (GH26011)

- Bug in `pandas.core.groupby.SeriesGroupBy.transform()` where transforming an empty group would raise a `ValueError` (GH26208)
- Bug in `pandas.core.frame.DataFrame.groupby()` where passing a `pandas.core.groupby.grouper.Grouper` would return incorrect groups when using the `.groups` accessor (GH26326)
- Bug in `pandas.core.groupby.GroupBy.agg()` where incorrect results are returned for uint64 columns. (GH26310)
- Bug in `pandas.core.window.Rolling.median()` and `pandas.core.window.Rolling.quantile()` where `MemoryError` is raised with empty window (GH26005)
- Bug in `pandas.core.window.Rolling.median()` and `pandas.core.window.Rolling.quantile()` where incorrect results are returned with `closed='left'` and `closed='neither'` (GH26005)
- Improved `pandas.core.window.Rolling`, `pandas.core.window.Window` and `pandas.core.window.EWM` functions to exclude nuisance columns from results instead of raising errors and raise a `DataError` only if all columns are nuisance (GH12537)
- Bug in `pandas.core.window.Rolling.max()` and `pandas.core.window.Rolling.min()` where incorrect results are returned with an empty variable window (GH26005)
- Raise a helpful exception when an unsupported weighted window function is used as an argument of `pandas.core.window.Window.aggregate()` (GH26597)

Reshaping

- Bug in `pandas.merge()` adds a string of `None`, if `None` is assigned in suffixes instead of remain the column name as-is (GH24782).
- Bug in `merge()` when merging by index name would sometimes result in an incorrectly numbered index (missing index values are now assigned `NA`) (GH24212, GH25009)
- `to_records()` now accepts dtypes to its `column_dtypes` parameter (GH24895)
- Bug in `concat()` where order of `OrderedDict` (and `dict` in Python 3.6+) is not respected, when passed in as `objs` argument (GH21510)
- Bug in `pivot_table()` where columns with `NaN` values are dropped even if `dropna` argument is `False`, when the `aggfunc` argument contains a `list` (GH22159)
- Bug in `concat()` where the resulting `freq` of two `DatetimeIndex` with the same `freq` would be dropped (GH3232).
- Bug in `merge()` where merging with equivalent `Categorical` dtypes was raising an error (GH22501)
- bug in `DataFrame` instantiating with a dict of iterators or generators (e.g. `pd.DataFrame({'A': reversed(range(3))})`) raised an error (GH26349).
- Bug in `DataFrame` instantiating with a `range` (e.g. `pd.DataFrame(range(3))`) raised an error (GH26342).
- Bug in `DataFrame` constructor when passing non-empty tuples would cause a segmentation fault (GH25691)
- Bug in `Series.apply()` failed when the series is a timezone aware `DatetimeIndex` (GH25959)
- Bug in `pandas.cut()` where large bins could incorrectly raise an error due to an integer overflow (GH26045)
- Bug in `DataFrame.sort_index()` where an error is thrown when a multi-indexed `DataFrame` is sorted on all levels with the initial level sorted last (GH26053)

- Bug in `Series.nlargest()` treats `True` as smaller than `False` (GH26154)
- Bug in `DataFrame.pivot_table()` with a `IntervalIndex` as pivot index would raise `TypeError` (GH25814)
- Bug in which `DataFrame.from_dict()` ignored order of `OrderedDict` when `orient='index'` (GH8425).
- Bug in `DataFrame.transpose()` where transposing a `DataFrame` with a timezone-aware datetime column would incorrectly raise `ValueError` (GH26825)
- Bug in `pivot_table()` when pivoting a timezone aware column as the `values` would remove timezone information (GH14948)
- Bug in `merge_asof()` when specifying multiple `by` columns where one is `datetime64[ns, tz]` dtype (GH26649)

Sparse

- Significant speedup in `SparseArray` initialization that benefits most operations, fixing performance regression introduced in v0.20.0 (GH24985)
- Bug in `SparseFrame` constructor where passing `None` as the data would cause `default_fill_value` to be ignored (GH16807)
- Bug in `SparseDataFrame` when adding a column in which the length of values does not match length of index, `AssertionError` is raised instead of raising `ValueError` (GH25484)
- Introduce a better error message in `Series.sparse.from_coo()` so it returns a `TypeError` for inputs that are not `coo` matrices (GH26554)
- Bug in `numpy.modf()` on a `SparseArray`. Now a tuple of `SparseArray` is returned (GH26946).

Build Changes

- Fix install error with PyPy on macOS (GH26536)

ExtensionArray

- Bug in `factorize()` when passing an `ExtensionArray` with a custom `na_sentinel` (GH25696).
- `Series.count()` miscounts NA values in `ExtensionArrays` (GH26835)
- Added `Series.__array_ufunc__` to better handle NumPy ufuncs applied to `Series` backed by extension arrays (GH23293).
- Keyword argument `deep` has been removed from `ExtensionArray.copy()` (GH27083)

Other

- Removed unused C functions from vendored UltraJSON implementation (GH26198)
- Allow `Index` and `RangeIndex` to be passed to `numpy.min` and `numpy.max` functions (GH26125)
- Use actual class name in repr of empty objects of a `Series` subclass (GH27001).
- Bug in `DataFrame` where passing an object array of timezone-aware `datetime` objects would incorrectly raise `ValueError` (GH13287)

Contributors

8.2 Version 0.24

8.2.1 Whats new in 0.24.2 (March 12, 2019)

Warning: The 0.24.x series of releases will be the last to support Python 2. Future feature releases will support Python 3 only. See [Dropping Python 2.7](#) for more.

{{ header }}

These are the changes in pandas 0.24.2. See [release](#) for a full changelog including other versions of pandas.

Fixed regressions

- Fixed regression in `DataFrame.all()` and `DataFrame.any()` where `bool_only=True` was ignored ([GH25101](#))
- Fixed issue in `DataFrame` construction with passing a mixed list of mixed types could segfault. ([GH25075](#))
- Fixed regression in `DataFrame.apply()` causing `RecursionError` when dict-like classes were passed as argument. ([GH25196](#))
- Fixed regression in `DataFrame.replace()` where `regex=True` was only replacing patterns matching the start of the string ([GH25259](#))
- Fixed regression in `DataFrame.duplicated()`, where empty dataframe was not returning a boolean dtyped Series. ([GH25184](#))
- Fixed regression in `Series.min()` and `Series.max()` where `numeric_only=True` was ignored when the `Series` contained `Categorical` data ([GH25299](#))
- Fixed regression in subtraction between `Series` objects with `datetime64[ns]` dtype incorrectly raising `OverflowError` when the `Series` on the right contains null values ([GH25317](#))
- Fixed regression in `TimedeltaIndex` where `np.sum(index)` incorrectly returned a zero-dimensional object instead of a scalar ([GH25282](#))
- Fixed regression in `IntervalDtype` construction where passing an incorrect string with 'Interval' as a prefix could result in a `RecursionError`. ([GH25338](#))
- Fixed regression in creating a period-dtype array from a read-only NumPy array of period objects. ([GH25403](#))
- Fixed regression in `Categorical`, where constructing it from a categorical `Series` and an explicit `categories=` that differed from that in the `Series` created an invalid object which could trigger segfaults. ([GH25318](#))
- Fixed regression in `to_timedelta()` losing precision when converting floating data to `Timedelta` data ([GH25077](#)).
- Fixed pip installing from source into an environment without NumPy ([GH25193](#))
- Fixed regression in `DataFrame.replace()` where large strings of numbers would be coerced into `int64`, causing an `OverflowError` ([GH25616](#))

- Fixed regression in `factorize()` when passing a custom `na_sentinel` value with `sort=True` (GH25409).
- Fixed regression in `DataFrame.to_csv()` writing duplicate line endings with gzip compress (GH25311)

Bug fixes

I/O

- Better handling of terminal printing when the terminal dimensions are not known (GH25080)
- Bug in reading a HDF5 table-format `DataFrame` created in Python 2, in Python 3 (GH24925)
- Bug in reading a JSON with `orient='table'` generated by `DataFrame.to_json()` with `index=False` (GH25170)
- Bug where float indexes could have misaligned values when printing (GH25061)

Categorical

- Bug where calling `Series.replace()` on categorical data could return a `Series` with incorrect dimensions (GH24971)
-
-

Reshaping

- Bug in `transform()` where applying a function to a timezone aware column would return a timezone naive result (GH24198)
- Bug in `DataFrame.join()` when joining on a timezone aware `DatetimeIndex` (GH23931)

Visualization

- Bug in `Series.plot()` where a secondary y axis could not be set to log scale (GH25545)

Other

- Bug in `Series.is_unique()` where single occurrences of NaN were not considered unique (GH25180)
- Bug in `merge()` when merging an empty `DataFrame` with an `Int64` column or a non-empty `DataFrame` with an `Int64` column that is all NaN (GH25183)
- Bug in `IntervalTree` where a `RecursionError` occurs upon construction due to an overflow when adding endpoints, which also causes `IntervalIndex` to crash during indexing operations (GH25485)
- Bug in `Series.size` raising for some extension-array-backed `Series`, rather than returning the size (GH25580)
- Bug in resampling raising for nullable integer-dtype columns (GH25580)

8.2.2 Whats new in 0.24.1 (February 3, 2019)

Warning: The 0.24.x series of releases will be the last to support Python 2. Future feature releases will support Python 3 only. See [Dropping Python 2.7](#) for more.

{{ header }}

These are the changes in pandas 0.24.1. See release for a full changelog including other versions of pandas. See *What's new in 0.24.0 (January 25, 2019)* for the 0.24.0 changelog.

API changes

Changing the sort parameter for Index set operations

The default `sort` value for `Index.union()` has changed from `True` to `None` ([GH24959](#)). The default *behavior*, however, remains the same: the result is sorted, unless

1. `self` and `other` are identical
2. `self` or `other` is empty
3. `self` or `other` contain values that can not be compared (a `RuntimeWarning` is raised).

This change will allow `sort=True` to mean “always sort” in a future release.

The same change applies to `Index.difference()` and `Index.symmetric_difference()`, which would not sort the result when the values could not be compared.

The `sort` option for `Index.intersection()` has changed in three ways.

1. The default has changed from `True` to `False`, to restore the pandas 0.23.4 and earlier behavior of not sorting by default.
2. The behavior of `sort=True` can now be obtained with `sort=None`. This will sort the result only if the values in `self` and `other` are not identical.
3. The value `sort=True` is no longer allowed. A future version of pandas will properly support `sort=True` meaning “always sort”.

Fixed regressions

- Fixed regression in `DataFrame.to_dict()` with `records` orient raising an `AttributeError` when the `DataFrame` contained more than 255 columns, or wrongly converting column names that were not valid python identifiers ([GH24939](#), [GH24940](#)).
- Fixed regression in `read_sql()` when passing certain queries with MySQL/pymysql ([GH24988](#)).
- Fixed regression in `Index.intersection` incorrectly sorting the values by default ([GH24959](#)).
- Fixed regression in `merge()` when merging an empty `DataFrame` with multiple timezone-aware columns on one of the timezone-aware columns ([GH25014](#)).
- Fixed regression in `Series.rename_axis()` and `DataFrame.rename_axis()` where passing `None` failed to remove the axis name ([GH25034](#)).
- Fixed regression in `to_timedelta()` with `box=False` incorrectly returning a `datetime64` object instead of a `timedelta64` object ([GH24961](#)).
- Fixed regression where custom hashable types could not be used as column keys in `DataFrame.set_index()` ([GH24969](#)).

Bug fixes

Reshaping

- Bug in `DataFrame.groupby()` with `Grouper` when there is a time change (DST) and grouping frequency is `'1d'` ([GH24972](#))

Visualization

- Fixed the warning for implicitly registered matplotlib converters not showing. See *Restore Matplotlib datetime converter registration* for more ([GH24963](#)).

Other

- Fixed `AttributeError` when printing a `DataFrame`'s HTML repr after accessing the IPython config object ([GH25036](#))

8.2.3 What’s new in 0.24.0 (January 25, 2019)

Warning: The 0.24.x series of releases will be the last to support Python 2. Future feature releases will support Python 3 only. See [Dropping Python 2.7](#) for more details.

{{ header }}

This is a major release from 0.23.4 and includes a number of API changes, new features, enhancements, and performance improvements along with a large number of bug fixes.

Highlights include:

- *Optional Integer NA Support*
- *New APIs for accessing the array backing a Series or Index*
- *A new top-level method for creating arrays*
- *Store Interval and Period data in a Series or DataFrame*
- *Support for joining on two MultiIndexes*

Check the *API Changes* and *deprecations* before updating.

These are the changes in pandas 0.24.0. See release for a full changelog including other versions of pandas.

Enhancements

Optional integer NA support

Pandas has gained the ability to hold integer dtypes with missing values. This long requested feature is enabled through the use of *extension types*.

Note: IntegerArray is currently experimental. Its API or implementation may change without warning.

We can construct a `Series` with the specified dtype. The dtype string `Int64` is a pandas `ExtensionDtype`. Specifying a list or array using the traditional missing value marker of `np.nan` will infer to integer dtype.

The display of the `Series` will also use the `NaN` to indicate missing values in string outputs. (GH20700, GH20747, GH22441, GH21789, GH22346)

```
In [1]: s = pd.Series([1, 2, np.nan], dtype='Int64')

In [2]: s
Out[2]:
0      1
1      2
2     NaN
Length: 3, dtype: Int64
```

Operations on these dtypes will propagate `NaN` as other pandas operations.

```
# arithmetic
```

```
In [3]: s + 1
Out[3]:
0      2
1      3
2     NaN
Length: 3, dtype: Int64
```

```
# comparison
```

```
In [4]: s == 1
Out[4]:
0     True
1    False
2    False
Length: 3, dtype: bool
```

```
# indexing
```

```
In [5]: s.iloc[1:3]
Out[5]:
1      2
2     NaN
Length: 2, dtype: Int64
```

```
# operate with other dtypes
```

```
In [6]: s + s.iloc[1:3].astype('Int8')
Out[6]:
0     NaN
1      4
2     NaN
Length: 3, dtype: Int64
```

```
# coerce when needed
```

```
In [7]: s + 0.01
Out[7]:
0     1.01
1     2.01
2     NaN
Length: 3, dtype: float64
```

These dtypes can operate as part of a `DataFrame`.

```
In [8]: df = pd.DataFrame({'A': s, 'B': [1, 1, 3], 'C': list('aab')})
```

```
In [9]: df
Out[9]:
   A B C
0  1 1 a
1  2 1 a
2 NaN 3 b

[3 rows x 3 columns]
```

```
In [10]: df.dtypes
Out[10]:
A      Int64
B      int64
C      object
Length: 3, dtype: object
```

These dtypes can be merged, reshaped, and casted.

```
In [11]: pd.concat([df[['A']], df[['B', 'C']]], axis=1).dtypes
Out[11]:
A      Int64
B      int64
C      object
Length: 3, dtype: object
```

```
In [12]: df['A'].astype(float)
Out[12]:
0    1.0
1    2.0
2    NaN
Name: A, Length: 3, dtype: float64
```

Reduction and groupby operations such as `sum` work.

```
In [13]: df.sum()
Out[13]:
A      3
B      5
C    aab
Length: 3, dtype: object

In [14]: df.groupby('B').A.sum()
Out[14]:
B
1      3
3      0
Name: A, Length: 2, dtype: Int64
```

Warning: The Integer NA support currently uses the capitalized dtype version, e.g. `Int8` as compared to the traditional `int8`. This may be changed at a future date.

See *Nullable integer data type* for more.

Accessing the values in a Series or Index

`Series.array` and `Index.array` have been added for extracting the array backing a `Series` or `Index`. (GH19954, GH23623)

```
In [15]: idx = pd.period_range('2000', periods=4)
```

```
In [16]: idx.array
```

```
Out[16]:
```

```
<PeriodArray>
```

```
['2000-01-01', '2000-01-02', '2000-01-03', '2000-01-04']
```

```
Length: 4, dtype: period[D]
```

```
In [17]: pd.Series(idx).array
```

```
Out[17]:
```

```
<PeriodArray>
```

```
['2000-01-01', '2000-01-02', '2000-01-03', '2000-01-04']
```

```
Length: 4, dtype: period[D]
```

Historically, this would have been done with `series.values`, but with `.values` it was unclear whether the returned value would be the actual array, some transformation of it, or one of pandas custom arrays (like `Categorical`). For example, with `PeriodIndex`, `.values` generates a new ndarray of period objects each time.

```
In [18]: idx.values
```

```
Out[18]:
```

```
array([Period('2000-01-01', 'D'), Period('2000-01-02', 'D'),  
       Period('2000-01-03', 'D'), Period('2000-01-04', 'D')], dtype=object)
```

```
In [19]: id(idx.values)
```

```
Out[19]: 5645036320
```

```
In [20]: id(idx.values)
```

```
Out[20]: 5616686224
```

If you need an actual NumPy array, use `Series.to_numpy()` or `Index.to_numpy()`.

```
In [21]: idx.to_numpy()
```

```
Out[21]:
```

```
array([Period('2000-01-01', 'D'), Period('2000-01-02', 'D'),  
       Period('2000-01-03', 'D'), Period('2000-01-04', 'D')], dtype=object)
```

```
In [22]: pd.Series(idx).to_numpy()
```

```
Out[22]:
```

```
array([Period('2000-01-01', 'D'), Period('2000-01-02', 'D'),  
       Period('2000-01-03', 'D'), Period('2000-01-04', 'D')], dtype=object)
```

For `Series` and `Indexes` backed by normal NumPy arrays, `Series.array` will return a new `arrays.PandasArray`, which is a thin (no-copy) wrapper around a `numpy.ndarray`. `PandasArray` isn't especially useful on its own, but it does provide the same interface as any extension array defined in pandas or by a third-party library.

```
In [23]: ser = pd.Series([1, 2, 3])
```

```
In [24]: ser.array
```

```
Out[24]:
```

```
<PandasArray>
```

```
[1, 2, 3]
Length: 3, dtype: int64
```

```
In [25]: ser.to_numpy()
Out[25]: array([1, 2, 3])
```

We haven't removed or deprecated `Series.values` or `DataFrame.values`, but we highly recommend and using `.array` or `.to_numpy()` instead.

See *Dtypes* and *Attributes and Underlying Data* for more.

pandas.array: a new top-level method for creating arrays

A new top-level method `array()` has been added for creating 1-dimensional arrays (GH22860). This can be used to create any *extension array*, including extension arrays registered by *3rd party libraries*. See the *dtypes docs* for more on extension arrays.

```
In [26]: pd.array([1, 2, np.nan], dtype='Int64')
Out[26]:
<IntegerArray>
[1, 2, NaN]
Length: 3, dtype: Int64
```

```
In [27]: pd.array(['a', 'b', 'c'], dtype='category')
Out[27]:
[a, b, c]
Categories (3, object): [a, b, c]
```

Passing data for which there isn't dedicated extension type (e.g. float, integer, etc.) will return a new `arrays.PandasArray`, which is just a thin (no-copy) wrapper around a `numpy.ndarray` that satisfies the pandas extension array interface.

```
In [28]: pd.array([1, 2, 3])
Out[28]:
<PandasArray>
[1, 2, 3]
Length: 3, dtype: int64
```

On their own, a `PandasArray` isn't a very useful object. But if you need write low-level code that works generically for any *ExtensionArray*, `PandasArray` satisfies that need.

Notice that by default, if no `dtype` is specified, the `dtype` of the returned array is inferred from the data. In particular, note that the first example of `[1, 2, np.nan]` would have returned a floating-point array, since `NaN` is a float.

```
In [29]: pd.array([1, 2, np.nan])
Out[29]:
<PandasArray>
[1.0, 2.0, nan]
Length: 3, dtype: float64
```

Storing Interval and Period data in Series and DataFrame

Interval and Period data may now be stored in a `Series` or `DataFrame`, in addition to an `IntervalIndex` and `PeriodIndex` like previously (GH19453, GH22862).

```
In [30]: ser = pd.Series(pd.interval_range(0, 5))
```

```
In [31]: ser
```

```
Out[31]:
```

```
0    (0, 1]
```

```
1    (1, 2]
```

```
2    (2, 3]
```

```
3    (3, 4]
```

```
4    (4, 5]
```

```
Length: 5, dtype: interval
```

```
In [32]: ser.dtype
```

```
Out[32]: interval[int64]
```

For periods:

```
In [33]: pser = pd.Series(pd.period_range("2000", freq="D", periods=5))
```

```
In [34]: pser
```

```
Out[34]:
```

```
0    2000-01-01
```

```
1    2000-01-02
```

```
2    2000-01-03
```

```
3    2000-01-04
```

```
4    2000-01-05
```

```
Length: 5, dtype: period[D]
```

```
In [35]: pser.dtype
```

```
Out[35]: period[D]
```

Previously, these would be cast to a NumPy array with object dtype. In general, this should result in better performance when storing an array of intervals or periods in a `Series` or column of a `DataFrame`.

Use `Series.array` to extract the underlying array of intervals or periods from the `Series`:

```
In [36]: ser.array
```

```
Out[36]:
```

```
IntervalArray([(0, 1], (1, 2], (2, 3], (3, 4], (4, 5]],
              closed='right',
              dtype='interval[int64]')
```

```
In [37]: pser.array
```

```
Out[37]:
```

```
<PeriodArray>
```

```
['2000-01-01', '2000-01-02', '2000-01-03', '2000-01-04', '2000-01-05']
```

```
Length: 5, dtype: period[D]
```

These return an instance of `arrays.IntervalArray` or `arrays.PeriodArray`, the new extension arrays that back interval and period data.

Warning: For backwards compatibility, `Series.values` continues to return a NumPy array of objects for Interval and Period data. We recommend using `Series.array` when you need the array of data stored in the `Series`, and `Series.to_numpy()` when you know you need a NumPy array.

See *Dtypes* and *Attributes and Underlying Data* for more.

Joining with two multi-indexes

`DataFrame.merge()` and `DataFrame.join()` can now be used to join multi-indexed Dataframe instances on the overlapping index levels ([GH6360](#))

See the *Merge, join, and concatenate* documentation section.

```
In [38]: index_left = pd.MultiIndex.from_tuples([('K0', 'X0'), ('K0', 'X1'),
.....:                                         ('K1', 'X2')],
.....:                                         names=['key', 'X'])
.....:

In [39]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2'],
.....:                       'B': ['B0', 'B1', 'B2']}, index=index_left)
.....:

In [40]: index_right = pd.MultiIndex.from_tuples([('K0', 'Y0'), ('K1', 'Y1'),
.....:                                           ('K2', 'Y2'), ('K2', 'Y3')],
.....:                                           names=['key', 'Y'])
.....:

In [41]: right = pd.DataFrame({'C': ['C0', 'C1', 'C2', 'C3'],
.....:                         'D': ['D0', 'D1', 'D2', 'D3']}, index=index_right)
.....:

In [42]: left.join(right)
Out[42]:
      A  B  C  D
key X  Y
K0  X0 Y0 A0 B0 C0 D0
     X1 Y0 A1 B1 C0 D0
K1  X2 Y1 A2 B2 C1 D1

[3 rows x 4 columns]
```

For earlier versions this can be done using the following.

```
In [43]: pd.merge(left.reset_index(), right.reset_index(),
.....:              on=['key'], how='inner').set_index(['key', 'X', 'Y'])
.....:

Out[43]:
      A  B  C  D
key X  Y
K0  X0 Y0 A0 B0 C0 D0
     X1 Y0 A1 B1 C0 D0
K1  X2 Y1 A2 B2 C1 D1

[3 rows x 4 columns]
```

read_html Enhancements

`read_html()` previously ignored `colspan` and `rowspan` attributes. Now it understands them, treating them as sequences of cells with the same value. ([GH17054](#))

```
In [44]: result = pd.read_html("""
.....: <table>
.....:   <thead>
.....:     <tr>
.....:       <th>A</th><th>B</th><th>C</th>
.....:     </tr>
.....:   </thead>
.....:   <tbody>
.....:     <tr>
.....:       <td colspan="2">1</td><td>2</td>
.....:     </tr>
.....:   </tbody>
.....: </table>""")
.....:
```

Previous behavior:

```
In [13]: result
Out [13]:
[  A  B  C
 0  1  2 NaN]
```

New behavior:

```
In [45]: result
Out [45]:
[  A  B  C
 0  1  1  2

[1 rows x 3 columns]]
```

New `Styler.pipe()` method

The `Styler` class has gained a `pipe()` method. This provides a convenient way to apply users' predefined styling functions, and can help reduce “boilerplate” when using `DataFrame` styling functionality repeatedly within a notebook. (GH23229)

```
In [46]: df = pd.DataFrame({'N': [1250, 1500, 1750], 'X': [0.25, 0.35, 0.50]})

In [47]: def format_and_align(styler):
.....:     return (styler.format({'N': '{:,}', 'X': '{:.1%}'})
.....:             .set_properties(**{'text-align': 'right'}))
.....:

In [48]: df.style.pipe(format_and_align).set_caption('Summary of results.')
Out [48]: <pandas.io.formats.style.Styler at 0x153e7f610>
```

Similar methods already exist for other classes in pandas, including `DataFrame.pipe()`, `GroupBy.pipe()`, and `Resampler.pipe()`.

Renaming names in a MultiIndex

`DataFrame.rename_axis()` now supports `index` and `columns` arguments and `Series.rename_axis()` supports `index` argument (GH19978).

This change allows a dictionary to be passed so that some of the names of a `MultiIndex` can be changed.

Example:

```
In [49]: mi = pd.MultiIndex.from_product([list('AB'), list('CD'), list('EF')],
....:                                   names=['AB', 'CD', 'EF'])
....:
```

```
In [50]: df = pd.DataFrame([i for i in range(len(mi))], index=mi, columns=['N'])
```

```
In [51]: df
```

```
Out[51]:
```

				N
AB	CD	EF		
A	C	E	0	
		F	1	
	D	E	2	
		F	3	
B	C	E	4	
		F	5	
	D	E	6	
		F	7	

[8 rows x 1 columns]

```
In [52]: df.rename_axis(index={'CD': 'New'})
```

```
Out[52]:
```

				N
AB	New	EF		
A	C	E	0	
		F	1	
	D	E	2	
		F	3	
B	C	E	4	
		F	5	
	D	E	6	
		F	7	

[8 rows x 1 columns]

See the *Advanced documentation on renaming* for more details.

Other enhancements

- `merge()` now directly allows merge between objects of type `DataFrame` and named `Series`, without the need to convert the `Series` object into a `DataFrame` beforehand (GH21220)
- `ExcelWriter` now accepts `mode` as a keyword argument, enabling append to existing workbooks when using the `openpyxl` engine (GH3441)

- `FrozenList` has gained the `.union()` and `.difference()` methods. This functionality greatly simplifies groupby's that rely on explicitly excluding certain columns. See *Splitting an object into groups* for more information ([GH15475](#), [GH15506](#)).
- `DataFrame.to_parquet()` now accepts `index` as an argument, allowing the user to override the engine's default behavior to include or omit the dataframe's indexes from the resulting Parquet file. ([GH20768](#))
- `read_feather()` now accepts `columns` as an argument, allowing the user to specify which columns should be read. ([GH24025](#))
- `DataFrame.corr()` and `Series.corr()` now accept a callable for generic calculation methods of correlation, e.g. histogram intersection ([GH22684](#))
- `DataFrame.to_string()` now accepts `decimal` as an argument, allowing the user to specify which decimal separator should be used in the output. ([GH23614](#))
- `DataFrame.to_html()` now accepts `render_links` as an argument, allowing the user to generate HTML with links to any URLs that appear in the DataFrame. See the *section on writing HTML* in the IO docs for example usage. ([GH2679](#))
- `pandas.read_csv()` now supports pandas extension types as an argument to `dtype`, allowing the user to use pandas extension types when reading CSVs. ([GH23228](#))
- The `shift()` method now accepts `fill_value` as an argument, allowing the user to specify a value which will be used instead of NA/NaT in the empty periods. ([GH15486](#))
- `to_datetime()` now supports the `%Z` and `%z` directive when passed into `format` ([GH13486](#))
- `Series.mode()` and `DataFrame.mode()` now support the `dropna` parameter which can be used to specify whether NaN/NaT values should be considered ([GH17534](#))
- `DataFrame.to_csv()` and `Series.to_csv()` now support the `compression` keyword when a file handle is passed. ([GH21227](#))
- `Index.droplevel()` is now implemented also for flat indexes, for compatibility with `MultiIndex` ([GH21115](#))
- `Series.droplevel()` and `DataFrame.droplevel()` are now implemented ([GH20342](#))
- Added support for reading from/writing to Google Cloud Storage via the `gcsfs` library ([GH19454](#), [GH23094](#))
- `DataFrame.to_gbq()` and `read_gbq()` signature and documentation updated to reflect changes from the `Pandas-GBQ` library version 0.8.0. Adds a `credentials` argument, which enables the use of any kind of `google-auth` credentials. ([GH21627](#), [GH22557](#), [GH23662](#))
- New method `HDFStore.walk()` will recursively walk the group hierarchy of an HDF5 file ([GH10932](#))
- `read_html()` copies cell data across `colspan` and `rowspan`, and it treats all-th table rows as headers if `header` kwarg is not given and there is no `thead` ([GH17054](#))
- `Series.nlargest()`, `Series.nsmallest()`, `DataFrame.nlargest()`, and `DataFrame.nsmallest()` now accept the value "all" for the `keep` argument. This keeps all ties for the nth largest/smallest value ([GH16818](#))
- `IntervalIndex` has gained the `set_closed()` method to change the existing `closed` value ([GH21670](#))
- `to_csv()`, `to_csv()`, `to_json()`, and `to_json()` now support `compression='infer'` to infer compression based on filename extension ([GH15008](#)). The default compression for `to_csv`, `to_json`, and `to_pickle` methods has been updated to 'infer' ([GH22004](#)).
- `DataFrame.to_sql()` now supports writing `TIMESTAMP WITH TIME ZONE` types for supported databases. For databases that don't support timezones, datetime data will be stored as timezone unaware local timestamps. See the *Datetime data types* for implications ([GH9086](#)).

- `to_timedelta()` now supports iso-formatted timedelta strings (GH21877)
- `Series` and `DataFrame` now support `Iterable` objects in the constructor (GH2193)
- `DatetimeIndex` has gained the `DatetimeIndex.timetz` attribute. This returns the local time with timezone information. (GH21358)
- `round()`, `ceil()`, and `floor()` for `DatetimeIndex` and `Timestamp` now support an `ambiguous` argument for handling datetimes that are rounded to ambiguous times (GH18946) and a `nonexistent` argument for handling datetimes that are rounded to nonexistent times. See *Nonexistent times when localizing* (GH22647)
- The result of `resample()` is now iterable similar to `groupby()` (GH15314).
- `Series.resample()` and `DataFrame.resample()` have gained the `pandas.core.resample.Resampler.quantile()` (GH15023).
- `DataFrame.resample()` and `Series.resample()` with a `PeriodIndex` will now respect the base argument in the same fashion as with a `DatetimeIndex`. (GH23882)
- `pandas.api.types.is_list_like()` has gained a keyword `allow_sets` which is `True` by default; if `False`, all instances of `set` will not be considered “list-like” anymore (GH23061)
- `Index.to_frame()` now supports overriding column name(s) (GH22580).
- `Categorical.from_codes()` now can take a `dtype` parameter as an alternative to passing `categories` and `ordered` (GH24398).
- New attribute `__git_version__` will return git commit sha of current build (GH21295).
- Compatibility with Matplotlib 3.0 (GH22790).
- Added `Interval.overlaps()`, `arrays.IntervalArray.overlaps()`, and `IntervalIndex.overlaps()` for determining overlaps between interval-like objects (GH21998)
- `read_fwf()` now accepts keyword `infer_nrows` (GH15138).
- `to_parquet()` now supports writing a `DataFrame` as a directory of parquet files partitioned by a subset of the columns when `engine = 'pyarrow'` (GH23283)
- `Timestamp.tz_localize()`, `DatetimeIndex.tz_localize()`, and `Series.tz_localize()` have gained the `nonexistent` argument for alternative handling of nonexistent times. See *Nonexistent times when localizing* (GH8917, GH24466)
- `Index.difference()`, `Index.intersection()`, `Index.union()`, and `Index.symmetric_difference()` now have an optional `sort` parameter to control whether the results should be sorted if possible (GH17839, GH24471)
- `read_excel()` now accepts `usecols` as a list of column names or callable (GH18273)
- `MultiIndex.to_flat_index()` has been added to flatten multiple levels into a single-level `Index` object.
- `DataFrame.to_stata()` and `pandas.io.stata.StataWriter117` can write mixed sting columns to Stata `strl` format (GH23633)
- `DataFrame.between_time()` and `DataFrame.at_time()` have gained the `axis` parameter (GH8839)
- `DataFrame.to_records()` now accepts `index_dtypes` and `column_dtypes` parameters to allow different data types in stored column and index records (GH18146)
- `IntervalIndex` has gained the `is_overlapping` attribute to indicate if the `IntervalIndex` contains any overlapping intervals (GH23309)

- `pandas.DataFrame.to_sql()` has gained the `method` argument to control SQL insertion clause. See the *insertion method* section in the documentation. (GH8953)
- `DataFrame.corrwith()` now supports Spearman's rank correlation, Kendall's tau as well as callable correlation methods. (GH21925)
- `DataFrame.to_json()`, `DataFrame.to_csv()`, `DataFrame.to_pickle()`, and other export methods now support tilde(~) in path argument. (GH23473)

Backwards incompatible API changes

Pandas 0.24.0 includes a number of API breaking changes.

Increased minimum versions for dependencies

We have updated our minimum supported versions of dependencies (GH21242, GH18742, GH23774, GH24767). If installed, we now require:

Package	Minimum Version	Required
numpy	1.12.0	X
bottleneck	1.2.0	
fastparquet	0.2.1	
matplotlib	2.0.0	
numexpr	2.6.1	
pandas-gbq	0.8.0	
pyarrow	0.9.0	
pytables	3.4.2	
scipy	0.18.1	
xlrd	1.0.0	
pytest (dev)	3.6	

Additionally we no longer depend on `feather-format` for feather based storage and replaced it with references to `pyarrow` (GH21639 and GH23053).

`os.linesep` is used for `line_terminator` of `DataFrame.to_csv`

`DataFrame.to_csv()` now uses `os.linesep()` rather than `'\n'` for the default line terminator (GH20353). This change only affects when running on Windows, where `'\r\n'` was used for line terminator even when `'\n'` was passed in `line_terminator`.

Previous behavior on Windows:

```
In [1]: data = pd.DataFrame({"string_with_lf": ["a\nbc"],
...:                       "string_with_crlf": ["a\r\nbc"]})

In [2]: # When passing file PATH to to_csv,
...: # line_terminator does not work, and csv is saved with '\r\n'.
...: # Also, this converts all '\n's in the data to '\r\n'.
...: data.to_csv("test.csv", index=False, line_terminator='\n')

In [3]: with open("test.csv", mode='rb') as f:
```

(continues on next page)

(continued from previous page)

```

...:     print(f.read())
Out[3]: b'string_with_lf,string_with_crlf\r\n"a\r\nbc","a\r\nbc"\r\n'

In [4]: # When passing file OBJECT with newline option to
...: # to_csv, line_terminator works.
...: with open("test2.csv", mode='w', newline='\n') as f:
...:     data.to_csv(f, index=False, line_terminator='\n')

In [5]: with open("test2.csv", mode='rb') as f:
...:     print(f.read())
Out[5]: b'string_with_lf,string_with_crlf\n"a\nbc","a\r\nbc"\n'

```

New behavior on Windows:

Passing `line_terminator` explicitly, set the line terminator to that character.

```

In [1]: data = pd.DataFrame({"string_with_lf": ["a\nbc"],
...:                        "string_with_crlf": ["a\r\nbc"]})

In [2]: data.to_csv("test.csv", index=False, line_terminator='\n')

In [3]: with open("test.csv", mode='rb') as f:
...:     print(f.read())
Out[3]: b'string_with_lf,string_with_crlf\n"a\nbc","a\r\nbc"\n'

```

On Windows, the value of `os.linesep` is `'\r\n'`, so if `line_terminator` is not set, `'\r\n'` is used for line terminator.

```

In [1]: data = pd.DataFrame({"string_with_lf": ["a\nbc"],
...:                        "string_with_crlf": ["a\r\nbc"]})

In [2]: data.to_csv("test.csv", index=False)

In [3]: with open("test.csv", mode='rb') as f:
...:     print(f.read())
Out[3]: b'string_with_lf,string_with_crlf\r\n"a\nbc","a\r\nbc"\r\n'

```

For file objects, specifying `newline` is not sufficient to set the line terminator. You must pass in the `line_terminator` explicitly, even in this case.

```

In [1]: data = pd.DataFrame({"string_with_lf": ["a\nbc"],
...:                        "string_with_crlf": ["a\r\nbc"]})

In [2]: with open("test2.csv", mode='w', newline='\n') as f:
...:     data.to_csv(f, index=False)

In [3]: with open("test2.csv", mode='rb') as f:
...:     print(f.read())
Out[3]: b'string_with_lf,string_with_crlf\r\n"a\nbc","a\r\nbc"\r\n'

```

Proper handling of *np.NaN* in a string data-typed column with the Python engine

There was bug in `read_excel()` and `read_csv()` with the Python engine, where missing values turned to 'nan' with `dtype=str` and `na_filter=True`. Now, these missing values are converted to the string missing indicator, `np.nan`. (GH20377)

Previous behavior:

```
In [5]: data = 'a,b,c\n1,,3\n4,5,6'
In [6]: df = pd.read_csv(StringIO(data), engine='python', dtype=str, na_filter=True)
In [7]: df.loc[0, 'b']
Out[7]:
'nan'
```

New behavior:

```
In [53]: data = 'a,b,c\n1,,3\n4,5,6'
In [54]: df = pd.read_csv(StringIO(data), engine='python', dtype=str, na_filter=True)
In [55]: df.loc[0, 'b']
Out[55]: nan
```

Notice how we now instead output `np.nan` itself instead of a stringified form of it.

Parsing datetime strings with timezone offsets

Previously, parsing datetime strings with UTC offsets with `to_datetime()` or `DatetimeIndex` would automatically convert the datetime to UTC without timezone localization. This is inconsistent from parsing the same datetime string with `Timestamp` which would preserve the UTC offset in the `tz` attribute. Now, `to_datetime()` preserves the UTC offset in the `tz` attribute when all the datetime strings have the same UTC offset (GH17697, GH11736, GH22457)

Previous behavior:

```
In [2]: pd.to_datetime("2015-11-18 15:30:00+05:30")
Out[2]: Timestamp('2015-11-18 10:00:00')

In [3]: pd.Timestamp("2015-11-18 15:30:00+05:30")
Out[3]: Timestamp('2015-11-18 15:30:00+0530', tz='pytz.FixedOffset(330)')

# Different UTC offsets would automatically convert the datetimes to UTC (without a UTC
↳timezone)
In [4]: pd.to_datetime(["2015-11-18 15:30:00+05:30", "2015-11-18 16:30:00+06:30"])
Out[4]: DatetimeIndex(['2015-11-18 10:00:00', '2015-11-18 10:00:00'], dtype=
↳'datetime64[ns]', freq=None)
```

New behavior:

```
In [56]: pd.to_datetime("2015-11-18 15:30:00+05:30")
Out[56]: Timestamp('2015-11-18 15:30:00+0530', tz='pytz.FixedOffset(330)')

In [57]: pd.Timestamp("2015-11-18 15:30:00+05:30")
Out[57]: Timestamp('2015-11-18 15:30:00+0530', tz='pytz.FixedOffset(330)')
```

Parsing datetime strings with the same UTC offset will preserve the UTC offset in the tz

```
In [58]: pd.to_datetime(["2015-11-18 15:30:00+05:30"] * 2)
Out[58]: DatetimeIndex(['2015-11-18 15:30:00+05:30', '2015-11-18 15:30:00+05:30'], dtype=
↳ 'datetime64[ns, pytz.FixedOffset(330)]', freq=None)
```

Parsing datetime strings with different UTC offsets will now create an Index of `datetime.datetime` objects with different UTC offsets

```
In [59]: idx = pd.to_datetime(["2015-11-18 15:30:00+05:30",
.....:                        "2015-11-18 16:30:00+06:30"])
.....:
```

```
In [60]: idx
Out[60]: Index([2015-11-18 15:30:00+05:30, 2015-11-18 16:30:00+06:30], dtype='object')
```

```
In [61]: idx[0]
Out[61]: datetime.datetime(2015, 11, 18, 15, 30, tzinfo=tzoffset(None, 19800))
```

```
In [62]: idx[1]
Out[62]: datetime.datetime(2015, 11, 18, 16, 30, tzinfo=tzoffset(None, 23400))
```

Passing `utc=True` will mimic the previous behavior but will correctly indicate that the dates have been converted to UTC

```
In [63]: pd.to_datetime(["2015-11-18 15:30:00+05:30",
.....:                  "2015-11-18 16:30:00+06:30"], utc=True)
.....:
Out[63]: DatetimeIndex(['2015-11-18 10:00:00+00:00', '2015-11-18 10:00:00+00:00'], dtype=
↳ 'datetime64[ns, UTC]', freq=None)
```

Parsing mixed-timezones with `read_csv()`

`read_csv()` no longer silently converts mixed-timezone columns to UTC ([GH24987](#)).

Previous behavior

```
>>> import io
>>> content = """\
... a
... 2000-01-01T00:00:00+05:00
... 2000-01-01T00:00:00+06:00"""
>>> df = pd.read_csv(io.StringIO(content), parse_dates=['a'])
>>> df.a
0    1999-12-31 19:00:00
1    1999-12-31 18:00:00
Name: a, dtype: datetime64[ns]
```

New behavior

```
In [64]: import io
In [65]: content = """\
.....: a
```

(continues on next page)

(continued from previous page)

```

.....: 2000-01-01T00:00:00+05:00
.....: 2000-01-01T00:00:00+06:00"""
.....:

In [66]: df = pd.read_csv(io.StringIO(content), parse_dates=['a'])

In [67]: df.a
Out[67]:
0    2000-01-01 00:00:00+05:00
1    2000-01-01 00:00:00+06:00
Name: a, Length: 2, dtype: object

```

As can be seen, the `dtype` is object; each value in the column is a string. To convert the strings to an array of datetimes, the `date_parser` argument

```

In [68]: df = pd.read_csv(io.StringIO(content), parse_dates=['a'],
.....:                    date_parser=lambda col: pd.to_datetime(col, utc=True))
.....:

In [69]: df.a
Out[69]:
0    1999-12-31 19:00:00+00:00
1    1999-12-31 18:00:00+00:00
Name: a, Length: 2, dtype: datetime64[ns, UTC]

```

See *Parsing datetime strings with timezone offsets* for more.

Time values in `dt.end_time` and `to_timestamp(how='end')`

The time values in `Period` and `PeriodIndex` objects are now set to `'23:59:59.999999999'` when calling `Series.dt.end_time`, `Period.end_time`, `PeriodIndex.end_time`, `Period.to_timestamp()` with `how='end'`, or `PeriodIndex.to_timestamp()` with `how='end'` ([GH17157](#))

Previous behavior:

```

In [2]: p = pd.Period('2017-01-01', 'D')
In [3]: pi = pd.PeriodIndex([p])

In [4]: pd.Series(pi).dt.end_time[0]
Out[4]: Timestamp(2017-01-01 00:00:00)

In [5]: p.end_time
Out[5]: Timestamp(2017-01-01 23:59:59.999999999)

```

New behavior:

Calling `Series.dt.end_time` will now result in a time of `'23:59:59.999999999'` as is the case with `Period.end_time`, for example

```

In [70]: p = pd.Period('2017-01-01', 'D')

In [71]: pi = pd.PeriodIndex([p])

In [72]: pd.Series(pi).dt.end_time[0]

```

```
Out[72]: Timestamp('2017-01-01 23:59:59.999999999')
```

```
In [73]: p.end_time
```

```
Out[73]: Timestamp('2017-01-01 23:59:59.999999999')
```

Series.unique for Timezone-Aware Data

The return type of `Series.unique()` for datetime with timezone values has changed from an `numpy.ndarray` of `Timestamp` objects to a `arrays.DatetimeArray` ([GH24024](#)).

```
In [74]: ser = pd.Series([pd.Timestamp('2000', tz='UTC'),
.....:                    pd.Timestamp('2000', tz='UTC')])
.....:
```

Previous behavior:

```
In [3]: ser.unique()
Out[3]: array([Timestamp('2000-01-01 00:00:00+0000', tz='UTC')], dtype=object)
```

New behavior:

```
In [75]: ser.unique()
Out[75]:
<DatetimeArray>
['2000-01-01 00:00:00+00:00']
Length: 1, dtype: datetime64[ns, UTC]
```

Sparse data structure refactor

`SparseArray`, the array backing `SparseSeries` and the columns in a `SparseDataFrame`, is now an extension array ([GH21978](#), [GH19056](#), [GH22835](#)). To conform to this interface and for consistency with the rest of pandas, some API breaking changes were made:

- `SparseArray` is no longer a subclass of `numpy.ndarray`. To convert a `SparseArray` to a NumPy array, use `numpy.asarray()`.
- `SparseArray.dtype` and `SparseSeries.dtype` are now instances of `SparseDtype`, rather than `np.dtype`. Access the underlying dtype with `SparseDtype.subtype`.
- `numpy.asarray(sparse_array)` now returns a dense array with all the values, not just the non-fill-value values ([GH14167](#)).
- `SparseArray.take` now matches the API of `pandas.api.extensions.ExtensionArray.take()` ([GH19506](#)):
 - The default value of `allow_fill` has changed from `False` to `True`.
 - The `out` and `mode` parameters are now longer accepted (previously, this raised if they were specified).
 - Passing a scalar for `indices` is no longer allowed.
- The result of `concat()` with a mix of sparse and dense Series is a Series with sparse values, rather than a `SparseSeries`.

- `SparseDataFrame.combine` and `DataFrame.combine_first` no longer supports combining a sparse column with a dense column while preserving the sparse subtype. The result will be an object-dtype `SparseArray`.
- Setting `SparseArray.fill_value` to a fill value with a different dtype is now allowed.
- `DataFrame[column]` is now a `Series` with sparse values, rather than a `SparseSeries`, when slicing a single column with sparse values ([GH23559](#)).
- The result of `Series.where()` is now a `Series` with sparse values, like with other extension arrays ([GH24077](#))

Some new warnings are issued for operations that require or are likely to materialize a large dense array:

- A `errors.PerformanceWarning` is issued when using `fillna` with a `method`, as a dense array is constructed to create the filled array. Filling with a `value` is the efficient way to fill a sparse array.
- A `errors.PerformanceWarning` is now issued when concatenating sparse `Series` with differing fill values. The fill value from the first sparse array continues to be used.

In addition to these API breaking changes, many *Performance Improvements and Bug Fixes have been made*.

Finally, a `Series.sparse` accessor was added to provide sparse-specific methods like `Series.sparse.from_coo()`.

```
In [76]: s = pd.Series([0, 0, 1, 1, 1], dtype='Sparse[int]')
In [77]: s.sparse.density
Out[77]: 0.6
```

`get_dummies()` always returns a `DataFrame`

Previously, when `sparse=True` was passed to `get_dummies()`, the return value could be either a `DataFrame` or a `SparseDataFrame`, depending on whether all or a just a subset of the columns were dummy-encoded. Now, a `DataFrame` is always returned ([GH24284](#)).

Previous behavior

The first `get_dummies()` returns a `DataFrame` because the column A is not dummy encoded. When just ["B", "C"] are passed to `get_dummies`, then all the columns are dummy-encoded, and a `SparseDataFrame` was returned.

```
In [2]: df = pd.DataFrame({"A": [1, 2], "B": ['a', 'b'], "C": ['a', 'a']})
In [3]: type(pd.get_dummies(df, sparse=True))
Out[3]: pandas.core.frame.DataFrame

In [4]: type(pd.get_dummies(df[['B', 'C']], sparse=True))
Out[4]: pandas.core.sparse.frame.SparseDataFrame
```

New behavior

Now, the return type is consistently a `DataFrame`.

```
In [78]: type(pd.get_dummies(df, sparse=True))
Out[78]: pandas.core.frame.DataFrame

In [79]: type(pd.get_dummies(df[['B', 'C']], sparse=True))
Out[79]: pandas.core.frame.DataFrame
```

Note: There's no difference in memory usage between a `SparseDataFrame` and a `DataFrame` with sparse values. The memory usage will be the same as in the previous version of pandas.

Raise `ValueError` in `DataFrame.to_dict(orient='index')`

Bug in `DataFrame.to_dict()` raises `ValueError` when used with `orient='index'` and a non-unique index instead of losing data ([GH22801](#))

```
In [80]: df = pd.DataFrame({'a': [1, 2], 'b': [0.5, 0.75]}, index=['A', 'A'])
```

```
In [81]: df
```

```
Out[81]:
```

```
   a    b
A  1  0.5
A  2  0.75
```

```
[2 rows x 2 columns]
```

```
In [82]: df.to_dict(orient='index')
```

```
-----
ValueError                                Traceback (most recent call last)
<ipython-input-82-f5309a7c6adb> in <module>
----> 1 df.to_dict(orient='index')

    1389         elif orient.lower().startswith("i"):
    1390             if not self.index.is_unique:
-> 1391                 raise ValueError("DataFrame index must be unique for or_
↳ orient='index'.")
    1392         return into_c(
    1393             (t[0], dict(zip(self.columns, t[1:])))
```

```
ValueError: DataFrame index must be unique for orient='index'.
```

Tick `DateOffset` normalize restrictions

Creating a `Tick` object (`Day`, `Hour`, `Minute`, `Second`, `Milli`, `Micro`, `Nano`) with `normalize=True` is no longer supported. This prevents unexpected behavior where addition could fail to be monotone or associative. ([GH21427](#))

Previous behavior:

```
In [2]: ts = pd.Timestamp('2018-06-11 18:01:14')

In [3]: ts
Out[3]: Timestamp('2018-06-11 18:01:14')

In [4]: tic = pd.offsets.Hour(n=2, normalize=True)
...:
```

(continues on next page)

(continued from previous page)

```
In [5]: tic
Out[5]: <2 * Hours>

In [6]: ts + tic
Out[6]: Timestamp('2018-06-11 00:00:00')

In [7]: ts + tic + tic + tic == ts + (tic + tic + tic)
Out[7]: False
```

New behavior:

```
In [83]: ts = pd.Timestamp('2018-06-11 18:01:14')

In [84]: tic = pd.offsets.Hour(n=2)

In [85]: ts + tic + tic + tic == ts + (tic + tic + tic)
Out[85]: True
```

Period subtraction

Subtraction of a `Period` from another `Period` will give a `DateOffset`. instead of an integer ([GH21314](#))

Previous behavior:

```
In [2]: june = pd.Period('June 2018')

In [3]: april = pd.Period('April 2018')

In [4]: june - april
Out [4]: 2
```

New behavior:

```
In [86]: june = pd.Period('June 2018')

In [87]: april = pd.Period('April 2018')

In [88]: june - april
Out[88]: <2 * MonthEnds>
```

Similarly, subtraction of a `Period` from a `PeriodIndex` will now return an `Index` of `DateOffset` objects instead of an `Int64Index`

Previous behavior:

```
In [2]: pi = pd.period_range('June 2018', freq='M', periods=3)

In [3]: pi - pi[0]
Out[3]: Int64Index([0, 1, 2], dtype='int64')
```

New behavior:

```
In [89]: pi = pd.period_range('June 2018', freq='M', periods=3)
In [90]: pi - pi[0]
Out[90]: Index([<0 * MonthEnds>, <MonthEnd>, <2 * MonthEnds>], dtype='object')
```

Addition/subtraction of NaN from DataFrame

Adding or subtracting NaN from a DataFrame column with `timedelta64[ns]` dtype will now raise a `TypeError` instead of returning all-NaT. This is for compatibility with `TimedeltaIndex` and `Series` behavior (GH22163)

```
In [91]: df = pd.DataFrame([pd.Timedelta(days=1)])
In [92]: df
Out[92]:
      0
0 1 days

[1 rows x 1 columns]
```

Previous behavior:

```
In [4]: df = pd.DataFrame([pd.Timedelta(days=1)])
In [5]: df - np.nan
Out[5]:
      0
0 NaT
```

New behavior:

```
In [2]: df - np.nan
...
TypeError: unsupported operand type(s) for -: 'TimedeltaIndex' and 'float'
```

DataFrame comparison operations broadcasting changes

Previously, the broadcasting behavior of DataFrame comparison operations (`==`, `!=`, ...) was inconsistent with the behavior of arithmetic operations (`+`, `-`, ...). The behavior of the comparison operations has been changed to match the arithmetic operations in these cases. (GH22880)

The affected cases are:

- operating against a 2-dimensional `np.ndarray` with either 1 row or 1 column will now broadcast the same way a `np.ndarray` would (GH23000).
- a list or tuple with length matching the number of rows in the DataFrame will now raise `ValueError` instead of operating column-by-column (GH22880).
- a list or tuple with length matching the number of columns in the DataFrame will now operate row-by-row instead of raising `ValueError` (GH22880).

```
In [93]: arr = np.arange(6).reshape(3, 2)
```

```
In [94]: df = pd.DataFrame(arr)
```

```
In [95]: df
```

```
Out[95]:
```

```
   0  1
0  0  1
1  2  3
2  4  5
```

```
[3 rows x 2 columns]
```

Previous behavior:

```
In [5]: df == arr[[0], :]
```

```
...: # comparison previously broadcast where arithmetic would raise
```

```
Out[5]:
```

```
   0    1
0  True  True
1 False False
2 False False
```

```
In [6]: df + arr[[0], :]
```

```
...
```

```
ValueError: Unable to coerce to DataFrame, shape must be (3, 2): given (1, 2)
```

```
In [7]: df == (1, 2)
```

```

```

```
In [7]: df + (1, 2, 3)
```

```
...
```

```
ValueError: Unable to coerce to Series, length must be 2: given 3
```

DataFrame arithmetic operations broadcasting changes

DataFrame arithmetic operations when operating with 2-dimensional `np.ndarray` objects now broadcast in the same way as `np.ndarray` broadcast. (GH23000)

```
In [100]: arr = np.arange(6).reshape(3, 2)
```

```
In [101]: df = pd.DataFrame(arr)
```

(continues on next page)

(continued from previous page)

```
In [102]: df
Out[102]:
   0  1
0  0  1
1  2  3
2  4  5

[3 rows x 2 columns]
```

Previous behavior:

```
In [5]: df + arr[[0], :] # 1 row, 2 columns
...
ValueError: Unable to coerce to DataFrame, shape must be (3, 2): given (1, 2)
In [6]: df + arr[:, [1]] # 1 column, 3 rows
...
ValueError: Unable to coerce to DataFrame, shape must be (3, 2): given (3, 1)
```

New behavior:

```
In [103]: df + arr[[0], :] # 1 row, 2 columns
Out[103]:
   0  1
0  0  2
1  2  4
2  4  6

[3 rows x 2 columns]

In [104]: df + arr[:, [1]] # 1 column, 3 rows
Out[104]:
   0  1
0  1  2
1  5  6
2  9 10

[3 rows x 2 columns]
```

Series and Index data-dtype incompatibilities

Series and Index constructors now raise when the data is incompatible with a passed dtype= ([GH15832](#))

Previous behavior:

```
In [4]: pd.Series([-1], dtype="uint64")
Out [4]:
0    18446744073709551615
dtype: uint64
```

New behavior:

```
In [4]: pd.Series([-1], dtype="uint64")
Out [4]:
...
OverflowError: Trying to coerce negative values to unsigned integers
```

Concatenation Changes

Calling `pandas.concat()` on a `Categorical` of ints with NA values now causes them to be processed as objects when concatenating with anything other than another `Categorical` of ints ([GH19214](#))

```
In [105]: s = pd.Series([0, 1, np.nan])
In [106]: c = pd.Series([0, 1, np.nan], dtype="category")
```

Previous behavior

```
In [3]: pd.concat([s, c])
Out [3]:
0    0.0
1    1.0
2    NaN
0    0.0
1    1.0
2    NaN
dtype: float64
```

New behavior

```
In [107]: pd.concat([s, c])
Out [107]:
0     0
1     1
2    NaN
0     0
1     1
2    NaN
Length: 6, dtype: object
```

Datetimelike API changes

- For `DatetimeIndex` and `TimedeltaIndex` with non-None `freq` attribute, addition or subtraction of integer-dtyped array or `Index` will return an object of the same class ([GH19959](#))
- `DateOffset` objects are now immutable. Attempting to alter one of these will now raise `AttributeError` ([GH21341](#))
- `PeriodIndex` subtraction of another `PeriodIndex` will now return an object-dtype `Index` of `DateOffset` objects instead of raising a `TypeError` ([GH20049](#))
- `cut()` and `qcut()` now returns a `DatetimeIndex` or `TimedeltaIndex` bins when the input is datetime or timedelta dtype respectively and `retbins=True` ([GH19891](#))

- `DatetimeIndex.to_period()` and `Timestamp.to_period()` will issue a warning when timezone information will be lost (GH21333)
- `PeriodIndex.tz_convert()` and `PeriodIndex.tz_localize()` have been removed (GH21781)

Other API changes

- A newly constructed empty `DataFrame` with integer as the `dtype` will now only be cast to `float64` if index is specified (GH22858)
- `Series.str.cat()` will now raise if `others` is a `set` (GH23009)
- Passing scalar values to `DatetimeIndex` or `TimedeltaIndex` will now raise `TypeError` instead of `ValueError` (GH23539)
- `max_rows` and `max_cols` parameters removed from `HTMLFormatter` since truncation is handled by `DataFrameFormatter` (GH23818)
- `read_csv()` will now raise a `ValueError` if a column with missing values is declared as having `dtype bool` (GH20591)
- The column order of the resultant `DataFrame` from `MultiIndex.to_frame()` is now guaranteed to match the `MultiIndex.names` order. (GH22420)
- Incorrectly passing a `DatetimeIndex` to `MultiIndex.from_tuples()`, rather than a sequence of tuples, now raises a `TypeError` rather than a `ValueError` (GH24024)
- `pd.offsets.generate_range()` argument `time_rule` has been removed; use `offset` instead (GH24157)
- In 0.23.x, pandas would raise a `ValueError` on a merge of a numeric column (e.g. `int` dtyped column) and an `object` dtyped column (GH9780). We have re-enabled the ability to merge `object` and other dtypes; pandas will still raise on a merge between a numeric and an `object` dtyped column that is composed only of strings (GH21681)
- Accessing a level of a `MultiIndex` with a duplicate name (e.g. in `get_level_values()`) now raises a `ValueError` instead of a `KeyError` (GH21678).
- Invalid construction of `IntervalDtype` will now always raise a `TypeError` rather than a `ValueError` if the subtype is invalid (GH21185)
- Trying to reindex a `DataFrame` with a non unique `MultiIndex` now raises a `ValueError` instead of an `Exception` (GH21770)
- Index subtraction will attempt to operate element-wise instead of raising `TypeError` (GH19369)
- `pandas.io.formats.style.Styler` supports a `number-format` property when using `to_excel()` (GH22015)
- `DataFrame.corr()` and `Series.corr()` now raise a `ValueError` along with a helpful error message instead of a `KeyError` when supplied with an invalid method (GH22298)
- `shift()` will now always return a copy, instead of the previous behaviour of returning self when shifting by 0 (GH22397)
- `DataFrame.set_index()` now gives a better (and less frequent) `KeyError`, raises a `ValueError` for incorrect types, and will not fail on duplicate column names with `drop=True`. (GH22484)
- Slicing a single row of a `DataFrame` with multiple `ExtensionArrays` of the same type now preserves the `dtype`, rather than coercing to `object` (GH22784)
- `DateOffset` attribute `_cacheable` and method `_should_cache` have been removed (GH23118)

- `Series.searchsorted()`, when supplied a scalar value to search for, now returns a scalar instead of an array (GH23801).
- `Categorical.searchsorted()`, when supplied a scalar value to search for, now returns a scalar instead of an array (GH23466).
- `Categorical.searchsorted()` now raises a `KeyError` rather than a `ValueError`, if a searched for key is not found in its categories (GH23466).
- `Index.hasnans()` and `Series.hasnans()` now always return a python boolean. Previously, a python or a numpy boolean could be returned, depending on circumstances (GH23294).
- The order of the arguments of `DataFrame.to_html()` and `DataFrame.to_string()` is rearranged to be consistent with each other. (GH23614)
- `CategoricalIndex.reindex()` now raises a `ValueError` if the target index is non-unique and not equal to the current index. It previously only raised if the target index was not of a categorical dtype (GH23963).
- `Series.to_list()` and `Index.to_list()` are now aliases of `Series.tolist` respectively `Index.tolist` (GH8826)
- The result of `SparseSeries.unstack` is now a `DataFrame` with sparse values, rather than a `SparseDataFrame` (GH24372).
- `DatetimeIndex` and `TimedeltaIndex` no longer ignore the dtype precision. Passing a non-nanosecond resolution dtype will raise a `ValueError` (GH24753)

Extension type changes

Equality and hashability

Pandas now requires that extension dtypes be hashable (i.e. the respective `ExtensionDtype` objects; hashability is not a requirement for the values of the corresponding `ExtensionArray`). The base class implements a default `__eq__` and `__hash__`. If you have a parametrized dtype, you should update the `ExtensionDtype._metadata` tuple to match the signature of your `__init__` method. See `pandas.api.extensions.ExtensionDtype` for more (GH22476).

New and changed methods

- `dropna()` has been added (GH21185)
- `repeat()` has been added (GH24349)
- The `ExtensionArray` constructor, `_from_sequence` now take the keyword arg `copy=False` (GH21185)
- `pandas.api.extensions.ExtensionArray.shift()` added as part of the basic `ExtensionArray` interface (GH22387).
- `searchsorted()` has been added (GH24350)
- Support for reduction operations such as `sum`, `mean` via opt-in base class method override (GH22762)
- `ExtensionArray.isna()` is allowed to return an `ExtensionArray` (GH22325).

Dtype changes

- `ExtensionDtype` has gained the ability to instantiate from string dtypes, e.g. `decimal` would instantiate a registered `DecimalDtype`; furthermore the `ExtensionDtype` has gained the method `construct_array_type` (GH21185)
- Added `ExtensionDtype._is_numeric` for controlling whether an extension dtype is considered numeric (GH22290).

- Added `pandas.api.types.register_extension_dtype()` to register an extension type with pandas (GH22664)
- Updated the `.type` attribute for `PeriodDtype`, `DatetimeTZDtype`, and `IntervalDtype` to be instances of the dtype (`Period`, `Timestamp`, and `Interval` respectively) (GH22938)

Operator support

A `Series` based on an `ExtensionArray` now supports arithmetic and comparison operators (GH19577). There are two approaches for providing operator support for an `ExtensionArray`:

1. Define each of the operators on your `ExtensionArray` subclass.
2. Use an operator implementation from pandas that depends on operators that are already defined on the underlying elements (scalars) of the `ExtensionArray`.

See the *ExtensionArray Operator Support* documentation section for details on both ways of adding operator support.

Other changes

- A default repr for `pandas.api.extensions.ExtensionArray` is now provided (GH23601).
- `ExtensionArray._formatting_values()` is deprecated. Use `ExtensionArray._formatter` instead. (GH23601)
- An `ExtensionArray` with a boolean dtype now works correctly as a boolean indexer. `pandas.api.types.is_bool_dtype()` now properly considers them boolean (GH22326)

Bug fixes

- Bug in `Series.get()` for `Series` using `ExtensionArray` and integer index (GH21257)
- `shift()` now dispatches to `ExtensionArray.shift()` (GH22386)
- `Series.combine()` works correctly with `ExtensionArray` inside of `Series` (GH20825)
- `Series.combine()` with scalar argument now works for any function type (GH21248)
- `Series.astype()` and `DataFrame.astype()` now dispatch to `ExtensionArray.astype()` (GH21185).
- Slicing a single row of a `DataFrame` with multiple `ExtensionArrays` of the same type now preserves the dtype, rather than coercing to object (GH22784)
- Bug when concatenating multiple `Series` with different extension dtypes not casting to object dtype (GH22994)
- `Series` backed by an `ExtensionArray` now work with `util.hash_pandas_object()` (GH23066)
- `DataFrame.stack()` no longer converts to object dtype for `DataFrames` where each column has the same extension dtype. The output `Series` will have the same dtype as the columns (GH23077).
- `Series.unstack()` and `DataFrame.unstack()` no longer convert extension arrays to object-dtype ndarrays. Each column in the output `DataFrame` will now have the same dtype as the input (GH23077).
- Bug when grouping `Dataframe.groupby()` and aggregating on `ExtensionArray` it was not returning the actual `ExtensionArray` dtype (GH23227).
- Bug in `pandas.merge()` when merging on an extension array-backed column (GH23020).

Deprecations

- `MultiIndex.labels` has been deprecated and replaced by `MultiIndex.codes`. The functionality is unchanged. The new name better reflects the natures of these codes and makes the `MultiIndex` API

more similar to the API for `CategoricalIndex` (GH13443). As a consequence, other uses of the name `labels` in `MultiIndex` have also been deprecated and replaced with `codes`:

- You should initialize a `MultiIndex` instance using a parameter named `codes` rather than `labels`.
 - `MultiIndex.set_labels` has been deprecated in favor of `MultiIndex.set_codes()`.
 - For method `MultiIndex.copy()`, the `labels` parameter has been deprecated and replaced by a `codes` parameter.
- `DataFrame.to_stata()`, `read_stata()`, `StataReader` and `StataWriter` have deprecated the `encoding` argument. The encoding of a Stata dta file is determined by the file type and cannot be changed (GH21244)
 - `MultiIndex.to_hierarchical()` is deprecated and will be removed in a future version (GH21613)
 - `Series.ptp()` is deprecated. Use `numpy.ptp` instead (GH21614)
 - `Series.compress()` is deprecated. Use `Series[condition]` instead (GH18262)
 - The signature of `Series.to_csv()` has been uniformed to that of `DataFrame.to_csv()`: the name of the first argument is now `path_or_buf`, the order of subsequent arguments has changed, the `header` argument now defaults to `True`. (GH19715)
 - `Categorical.from_codes()` has deprecated providing float values for the `codes` argument. (GH21767)
 - `pandas.read_table()` is deprecated. Instead, use `read_csv()` passing `sep='\t'` if necessary. This deprecation has been removed in 0.25.0. (GH21948)
 - `Series.str.cat()` has deprecated using arbitrary list-likes *within* list-likes. A list-like container may still contain many `Series`, `Index` or 1-dimensional `np.ndarray`, or alternatively, only scalar values. (GH21950)
 - `FrozenNDArray.searchsorted()` has deprecated the `v` parameter in favor of `value` (GH14645)
 - `DatetimeIndex.shift()` and `PeriodIndex.shift()` now accept `periods` argument instead of `n` for consistency with `Index.shift()` and `Series.shift()`. Using `n` throws a deprecation warning (GH22458, GH22912)
 - The `fastpath` keyword of the different `Index` constructors is deprecated (GH23110).
 - `Timestamp.tz_localize()`, `DatetimeIndex.tz_localize()`, and `Series.tz_localize()` have deprecated the `errors` argument in favor of the `nonexistent` argument (GH8917)
 - The class `FrozenNDArray` has been deprecated. When unpickling, `FrozenNDArray` will be unpickled to `np.ndarray` once this class is removed (GH9031)
 - The methods `DataFrame.update()` and `Panel.update()` have deprecated the `raise_conflict=False|True` keyword in favor of `errors='ignore'|'raise'` (GH23585)
 - The methods `Series.str.partition()` and `Series.str.rpartition()` have deprecated the `pat` keyword in favor of `sep` (GH22676)
 - Deprecated the `nthreads` keyword of `pandas.read_feather()` in favor of `use_threads` to reflect the changes in `pyarrow`>=0.11.0. (GH23053)
 - `pandas.read_excel()` has deprecated accepting `usecols` as an integer. Please pass in a list of ints from 0 to `usecols` inclusive instead (GH23527)
 - Constructing a `TimedeltaIndex` from data with `datetime64`-typed data is deprecated, will raise `TypeError` in a future version (GH23539)
 - Constructing a `DatetimeIndex` from data with `timedelta64`-typed data is deprecated, will raise `TypeError` in a future version (GH23675)

- The `keep_tz=False` option (the default) of the `keep_tz` keyword of `DatetimeIndex.to_series()` is deprecated (GH17832).
- Timezone converting a tz-aware `datetime.datetime` or `Timestamp` with `Timestamp` and the `tz` argument is now deprecated. Instead, use `Timestamp.tz_convert()` (GH23579)
- `pandas.api.types.is_period()` is deprecated in favor of `pandas.api.types.is_period_dtype` (GH23917)
- `pandas.api.types.is_datetimetz()` is deprecated in favor of `pandas.api.types.is_datetime64tz` (GH23917)
- Creating a `TimedeltaIndex`, `DatetimeIndex`, or `PeriodIndex` by passing range arguments `start`, `end`, and `periods` is deprecated in favor of `timedelta_range()`, `date_range()`, or `period_range()` (GH23919)
- Passing a string alias like `'datetime64[ns, UTC]'` as the `unit` parameter to `DatetimeTZDtype` is deprecated. Use `DatetimeTZDtype.construct_from_string` instead (GH23990).
- The `skipna` parameter of `infer_dtype()` will switch to `True` by default in a future version of pandas (GH17066, GH24050)
- In `Series.where()` with Categorical data, providing an `other` that is not present in the categories is deprecated. Convert the categorical to a different dtype or add the `other` to the categories first (GH24077).
- `Series.clip_lower()`, `Series.clip_upper()`, `DataFrame.clip_lower()` and `DataFrame.clip_upper()` are deprecated and will be removed in a future version. Use `Series.clip(lower=threshold)`, `Series.clip(upper=threshold)` and the equivalent `DataFrame` methods (GH24203)
- `Series.nonzero()` is deprecated and will be removed in a future version (GH18262)
- Passing an integer to `Series.fillna()` and `DataFrame.fillna()` with `timedelta64[ns]` dtypes is deprecated, will raise `TypeError` in a future version. Use `obj.fillna(pd.Timedelta(...))` instead (GH24694)
- `Series.cat.categorical`, `Series.cat.name` and `Series.cat.index` have been deprecated. Use the attributes on `Series.cat` or `Series` directly. (GH24751).
- Passing a dtype without a precision like `np.dtype('datetime64')` or `timedelta64` to `Index`, `DatetimeIndex` and `TimedeltaIndex` is now deprecated. Use the nanosecond-precision dtype instead (GH24753).

Integer addition/subtraction with datetimes and timedeltas is deprecated

In the past, users could—in some cases—add or subtract integers or integer-dtype arrays from `Timestamp`, `DatetimeIndex` and `TimedeltaIndex`.

This usage is now deprecated. Instead add or subtract integer multiples of the object's `freq` attribute (GH21939, GH23878).

Previous behavior:

```
In [5]: ts = pd.Timestamp('1994-05-06 12:15:16', freq=pd.offsets.Hour())
In [6]: ts + 2
Out[6]: Timestamp('1994-05-06 14:15:16', freq='H')

In [7]: tdi = pd.timedelta_range('1D', periods=2)
```

(continues on next page)

(continued from previous page)

```
In [8]: tdi = np.array([2, 1])
Out[8]: TimedeltaIndex(['-1 days', '1 days'], dtype='timedelta64[ns]', freq=None)

In [9]: dti = pd.date_range('2001-01-01', periods=2, freq='7D')
In [10]: dti + pd.Index([1, 2])
Out[10]: DatetimeIndex(['2001-01-08', '2001-01-22'], dtype='datetime64[ns]', freq=None)
```

New behavior:

```
In [108]: ts = pd.Timestamp('1994-05-06 12:15:16', freq=pd.offsets.Hour())

In [109]: ts + 2 * ts.freq
Out[109]: Timestamp('1994-05-06 14:15:16', freq='H')

In [110]: tdi = pd.timedelta_range('1D', periods=2)

In [111]: tdi - np.array([2 * tdi.freq, 1 * tdi.freq])
Out[111]: TimedeltaIndex(['-1 days', '1 days'], dtype='timedelta64[ns]', freq=None)

In [112]: dti = pd.date_range('2001-01-01', periods=2, freq='7D')

In [113]: dti + pd.Index([1 * dti.freq, 2 * dti.freq])
Out[113]: DatetimeIndex(['2001-01-08', '2001-01-22'], dtype='datetime64[ns]', freq=None)
```

Passing integer data and a timezone to datetimeindex

The behavior of `DatetimeIndex` when passed integer data and a timezone is changing in a future version of pandas. Previously, these were interpreted as wall times in the desired timezone. In the future, these will be interpreted as wall times in UTC, which are then converted to the desired timezone ([GH24559](#)).

The default behavior remains the same, but issues a warning:

```
In [3]: pd.DatetimeIndex([9466848000000000], tz="US/Central")
/bin/ipython:1: FutureWarning:
    Passing integer-dtype data and a timezone to DatetimeIndex. Integer values
    will be interpreted differently in a future version of pandas. Previously,
    these were viewed as datetime64[ns] values representing the wall time
    *in the specified timezone*. In the future, these will be viewed as
    datetime64[ns] values representing the wall time *in UTC*. This is similar
    to a nanosecond-precision UNIX epoch. To accept the future behavior, use

        pd.to_datetime(integer_data, utc=True).tz_convert(tz)

    To keep the previous behavior, use

        pd.to_datetime(integer_data).tz_localize(tz)

#!/bin/python3
Out[3]: DatetimeIndex(['2000-01-01 00:00:00-06:00'], dtype='datetime64[ns, US/Central]',
→ freq=None)
```

As the warning message explains, opt in to the future behavior by specifying that the integer values are

UTC, and then converting to the final timezone:

```
In [114]: pd.to_datetime([946684800000000000], utc=True).tz_convert('US/Central')
Out[114]: DatetimeIndex(['1999-12-31 18:00:00-06:00'], dtype='datetime64[ns, US/Central]
↳', freq=None)
```

The old behavior can be retained with by localizing directly to the final timezone:

```
In [115]: pd.to_datetime([946684800000000000]).tz_localize('US/Central')
Out[115]: DatetimeIndex(['2000-01-01 00:00:00-06:00'], dtype='datetime64[ns, US/Central]
↳', freq=None)
```

Converting timezone-aware Series and Index to NumPy arrays

The conversion from a `Series` or `Index` with timezone-aware datetime data will change to preserve timezones by default (GH23569).

NumPy doesn't have a dedicated dtype for timezone-aware datetimes. In the past, converting a `Series` or `DatetimeIndex` with timezone-aware datetimes would convert to a NumPy array by

1. converting the tz-aware data to UTC
2. dropping the timezone-info
3. returning a `numpy.ndarray` with `datetime64[ns]` dtype

Future versions of pandas will preserve the timezone information by returning an object-dtype NumPy array where each value is a `Timestamp` with the correct timezone attached

```
In [116]: ser = pd.Series(pd.date_range('2000', periods=2, tz="CET"))
In [117]: ser
Out[117]:
0    2000-01-01 00:00:00+01:00
1    2000-01-02 00:00:00+01:00
Length: 2, dtype: datetime64[ns, CET]
```

The default behavior remains the same, but issues a warning

```
In [8]: np.asarray(ser)
/bin/ipython:1: FutureWarning: Converting timezone-aware DatetimeArray to timezone-naive
ndarray with 'datetime64[ns]' dtype. In the future, this will return an ndarray
with 'object' dtype where each element is a 'pandas.Timestamp' with the correct 'tz
↳'.

    To accept the future behavior, pass 'dtype=object'.
    To keep the old behavior, pass 'dtype="datetime64[ns]"'.
#!/bin/python3
Out[8]:
array(['1999-12-31T23:00:00.000000000', '2000-01-01T23:00:00.000000000'],
      dtype='datetime64[ns]')
```

The previous or future behavior can be obtained, without any warnings, by specifying the dtype

Previous behavior

```
In [118]: np.asarray(ser, dtype='datetime64[ns]')
Out[118]:
array(['1999-12-31T23:00:00.000000000', '2000-01-01T23:00:00.000000000'],
      dtype='datetime64[ns]')
```

Future behavior

```
# New behavior
In [119]: np.asarray(ser, dtype=object)
Out[119]:
array([Timestamp('2000-01-01 00:00:00+0100', tz='CET', freq='D'),
      Timestamp('2000-01-02 00:00:00+0100', tz='CET', freq='D')],
      dtype=object)
```

Or by using `Series.to_numpy()`

```
In [120]: ser.to_numpy()
Out[120]:
array([Timestamp('2000-01-01 00:00:00+0100', tz='CET', freq='D'),
      Timestamp('2000-01-02 00:00:00+0100', tz='CET', freq='D')],
      dtype=object)
```

```
In [121]: ser.to_numpy(dtype="datetime64[ns]")
Out[121]:
array(['1999-12-31T23:00:00.000000000', '2000-01-01T23:00:00.000000000'],
      dtype='datetime64[ns]')
```

All the above applies to a `DatetimeIndex` with tz-aware values as well.

Removal of prior version deprecations/changes

- The `LongPanel` and `WidePanel` classes have been removed ([GH10892](#))
- `Series.repeat()` has renamed the `reps` argument to `repeats` ([GH14645](#))
- Several private functions were removed from the (non-public) module `pandas.core.common` ([GH22001](#))
- Removal of the previously deprecated module `pandas.core.datetools` ([GH14105](#), [GH14094](#))
- Strings passed into `DataFrame.groupby()` that refer to both column and index levels will raise a `ValueError` ([GH14432](#))
- `Index.repeat()` and `MultiIndex.repeat()` have renamed the `n` argument to `repeats` ([GH14645](#))
- The `Series` constructor and `.astype` method will now raise a `ValueError` if timestamp dtypes are passed in without a unit (e.g. `np.datetime64`) for the `dtype` parameter ([GH15987](#))
- Removal of the previously deprecated `as_indexer` keyword completely from `str.match()` ([GH22356](#), [GH6581](#))
- The modules `pandas.types`, `pandas.computation`, and `pandas.util.decorators` have been removed ([GH16157](#), [GH16250](#))
- Removed the `pandas.formats.style` shim for `pandas.io.formats.style.Styler` ([GH16059](#))
- `pandas.pnow`, `pandas.match`, `pandas.groupby`, `pd.get_store`, `pd.Expr`, and `pd.Term` have been removed ([GH15538](#), [GH15940](#))

- `Categorical.searchsorted()` and `Series.searchsorted()` have renamed the `v` argument to `value` (GH14645)
- `pandas.parser`, `pandas.lib`, and `pandas.tslib` have been removed (GH15537)
- `Index.searchsorted()` have renamed the `key` argument to `value` (GH14645)
- `DataFrame consolidate` and `Series consolidate` have been removed (GH15501)
- Removal of the previously deprecated module `pandas.json` (GH19944)
- The module `pandas.tools` has been removed (GH15358, GH16005)
- `SparseArray.get_values()` and `SparseArray.to_dense()` have dropped the `fill` parameter (GH14686)
- `DataFrame.sortlevel` and `Series.sortlevel` have been removed (GH15099)
- `SparseSeries.to_dense()` has dropped the `sparse_only` parameter (GH14686)
- `DataFrame.astype()` and `Series.astype()` have renamed the `raise_on_error` argument to `errors` (GH14967)
- `is_sequence`, `is_any_int_dtype`, and `is_floating_dtype` have been removed from `pandas.api.types` (GH16163, GH16189)

Performance improvements

- Slicing `Series` and `DataFrames` with an monotonically increasing `CategoricalIndex` is now very fast and has speed comparable to slicing with an `Int64Index`. The speed increase is both when indexing by label (using `.loc`) and position (`.iloc`) (GH20395) Slicing a monotonically increasing `CategoricalIndex` itself (i.e. `ci[1000:2000]`) shows similar speed improvements as above (GH21659)
- Improved performance of `CategoricalIndex.equals()` when comparing to another `CategoricalIndex` (GH24023)
- Improved performance of `Series.describe()` in case of numeric dtypes (GH21274)
- Improved performance of `pandas.core.groupby.GroupBy.rank()` when dealing with tied rankings (GH21237)
- Improved performance of `DataFrame.set_index()` with columns consisting of `Period` objects (GH21582, GH21606)
- Improved performance of `Series.at()` and `Index.get_value()` for Extension Arrays values (e.g. `Categorical`) (GH24204)
- Improved performance of membership checks in `Categorical` and `CategoricalIndex` (i.e. `x in cat`-style checks are much faster). `CategoricalIndex.contains()` is likewise much faster (GH21369, GH21508)
- Improved performance of `HDFStore.groups()` (and dependent functions like `HDFStore.keys()`). (i.e. `x in store` checks are much faster) (GH21372)
- Improved the performance of `pandas.get_dummies()` with `sparse=True` (GH21997)
- Improved performance of `IndexEngine.get_indexer_non_unique()` for sorted, non-unique indexes (GH9466)
- Improved performance of `PeriodIndex.unique()` (GH23083)
- Improved performance of `concat()` for `Series` objects (GH23404)

- Improved performance of `DatetimeIndex.normalize()` and `Timestamp.normalize()` for timezone naive or UTC datetimes ([GH23634](#))
- Improved performance of `DatetimeIndex.tz_localize()` and various `DatetimeIndex` attributes with dateutil UTC timezone ([GH23772](#))
- Fixed a performance regression on Windows with Python 3.7 of `read_csv()` ([GH23516](#))
- Improved performance of `Categorical` constructor for `Series` objects ([GH23814](#))
- Improved performance of `where()` for `Categorical` data ([GH24077](#))
- Improved performance of iterating over a `Series`. Using `DataFrame.itertuples()` now creates iterators without internally allocating lists of all elements ([GH20783](#))
- Improved performance of `Period` constructor, additionally benefitting `PeriodArray` and `PeriodIndex` creation ([GH24084](#), [GH24118](#))
- Improved performance of tz-aware `DatetimeArray` binary operations ([GH24491](#))

Bug fixes

Categorical

- Bug in `Categorical.from_codes()` where NaN values in `codes` were silently converted to 0 ([GH21767](#)). In the future this will raise a `ValueError`. Also changes the behavior of `.from_codes([1.1, 2.0])`.
- Bug in `Categorical.sort_values()` where NaN values were always positioned in front regardless of `na_position` value. ([GH22556](#)).
- Bug when indexing with a boolean-valued `Categorical`. Now a boolean-valued `Categorical` is treated as a boolean mask ([GH22665](#))
- Constructing a `CategoricalIndex` with empty values and boolean categories was raising a `ValueError` after a change to dtype coercion ([GH22702](#)).
- Bug in `Categorical.take()` with a user-provided `fill_value` not encoding the `fill_value`, which could result in a `ValueError`, incorrect results, or a segmentation fault ([GH23296](#)).
- In `Series.unstack()`, specifying a `fill_value` not present in the categories now raises a `TypeError` rather than ignoring the `fill_value` ([GH23284](#))
- Bug when resampling `DataFrame.resample()` and aggregating on categorical data, the categorical dtype was getting lost. ([GH23227](#))
- Bug in many methods of the `.str`-accessor, which always failed on calling the `CategoricalIndex.str` constructor ([GH23555](#), [GH23556](#))
- Bug in `Series.where()` losing the categorical dtype for categorical data ([GH24077](#))
- Bug in `Categorical.apply()` where NaN values could be handled unpredictably. They now remain unchanged ([GH24241](#))
- Bug in `Categorical` comparison methods incorrectly raising `ValueError` when operating against a `DataFrame` ([GH24630](#))
- Bug in `Categorical.set_categories()` where setting fewer new categories with `rename=True` caused a segmentation fault ([GH24675](#))

Datetimelike

- Fixed bug where two `DateOffset` objects with different `normalize` attributes could evaluate as equal ([GH21404](#))
- Fixed bug where `Timestamp.resolution()` incorrectly returned 1-microsecond `timedelta` instead of 1-nanosecond `Timedelta` ([GH21336](#), [GH21365](#))
- Bug in `to_datetime()` that did not consistently return an `Index` when `box=True` was specified ([GH21864](#))
- Bug in `DatetimeIndex` comparisons where string comparisons incorrectly raises `TypeError` ([GH22074](#))
- Bug in `DatetimeIndex` comparisons when comparing against `timedelta64[ns]` dtyped arrays; in some cases `TypeError` was incorrectly raised, in others it incorrectly failed to raise ([GH22074](#))
- Bug in `DatetimeIndex` comparisons when comparing against object-dtyped arrays ([GH22074](#))
- Bug in `DataFrame` with `datetime64[ns]` dtype addition and subtraction with `Timedelta`-like objects ([GH22005](#), [GH22163](#))
- Bug in `DataFrame` with `datetime64[ns]` dtype addition and subtraction with `DateOffset` objects returning an object dtype instead of `datetime64[ns]` dtype ([GH21610](#), [GH22163](#))
- Bug in `DataFrame` with `datetime64[ns]` dtype comparing against `NaT` incorrectly ([GH22242](#), [GH22163](#))
- Bug in `DataFrame` with `datetime64[ns]` dtype subtracting `Timestamp`-like object incorrectly returned `datetime64[ns]` dtype instead of `timedelta64[ns]` dtype ([GH8554](#), [GH22163](#))
- Bug in `DataFrame` with `datetime64[ns]` dtype subtracting `np.datetime64` object with non-nanosecond unit failing to convert to nanoseconds ([GH18874](#), [GH22163](#))
- Bug in `DataFrame` comparisons against `Timestamp`-like objects failing to raise `TypeError` for inequality checks with mismatched types ([GH8932](#), [GH22163](#))
- Bug in `DataFrame` with mixed dtypes including `datetime64[ns]` incorrectly raising `TypeError` on equality comparisons ([GH13128](#), [GH22163](#))
- Bug in `DataFrame.values` returning a `DatetimeIndex` for a single-column `DataFrame` with tz-aware datetime values. Now a 2-D `numpy.ndarray` of `Timestamp` objects is returned ([GH24024](#))
- Bug in `DataFrame.eq()` comparison against `NaT` incorrectly returning `True` or `NaN` ([GH15697](#), [GH22163](#))
- Bug in `DatetimeIndex` subtraction that incorrectly failed to raise `OverflowError` ([GH22492](#), [GH22508](#))
- Bug in `DatetimeIndex` incorrectly allowing indexing with `Timedelta` object ([GH20464](#))
- Bug in `DatetimeIndex` where frequency was being set if original frequency was `None` ([GH22150](#))
- Bug in rounding methods of `DatetimeIndex` (`round()`, `ceil()`, `floor()`) and `Timestamp` (`round()`, `ceil()`, `floor()`) could give rise to loss of precision ([GH22591](#))
- Bug in `to_datetime()` with an `Index` argument that would drop the `name` from the result ([GH21697](#))
- Bug in `PeriodIndex` where adding or subtracting a `timedelta` or `Tick` object produced incorrect results ([GH22988](#))
- Bug in the `Series` repr with period-dtype data missing a space before the data ([GH23601](#))
- Bug in `date_range()` when decrementing a start date to a past end date by a negative frequency ([GH23270](#))

- Bug in `Series.min()` which would return `NaN` instead of `NaT` when called on a series of `NaT` (GH23282)
- Bug in `Series.combine_first()` not properly aligning categoricals, so that missing values in `self` where not filled by valid values from `other` (GH24147)
- Bug in `DataFrame.combine()` with datetimelike values raising a `TypeError` (GH23079)
- Bug in `date_range()` with frequency of `Day` or higher where dates sufficiently far in the future could wrap around to the past instead of raising `OutOfBoundsDatetime` (GH14187)
- Bug in `period_range()` ignoring the frequency of `start` and `end` when those are provided as `Period` objects (GH20535).
- Bug in `PeriodIndex` with attribute `freq.n` greater than 1 where adding a `DateOffset` object would return incorrect results (GH23215)
- Bug in `Series` that interpreted string indices as lists of characters when setting datetimelike values (GH23451)
- Bug in `DataFrame` when creating a new column from an `ndarray` of `Timestamp` objects with timezones creating an object-dtype column, rather than `datetime` with `timezone` (GH23932)
- Bug in `Timestamp` constructor which would drop the frequency of an input `Timestamp` (GH22311)
- Bug in `DatetimeIndex` where calling `np.array(dtindex, dtype=object)` would incorrectly return an array of `long` objects (GH23524)
- Bug in `Index` where passing a timezone-aware `DatetimeIndex` and `dtype=object` would incorrectly raise a `ValueError` (GH23524)
- Bug in `Index` where calling `np.array(dtindex, dtype=object)` on a timezone-naive `DatetimeIndex` would return an array of `datetime` objects instead of `Timestamp` objects, potentially losing nanosecond portions of the timestamps (GH23524)
- Bug in `Categorical.__setitem__` not allowing setting with another `Categorical` when both are unordered and have the same categories, but in a different order (GH24142)
- Bug in `date_range()` where using dates with millisecond resolution or higher could return incorrect values or the wrong number of values in the index (GH24110)
- Bug in `DatetimeIndex` where constructing a `DatetimeIndex` from a `Categorical` or `CategoricalIndex` would incorrectly drop timezone information (GH18664)
- Bug in `DatetimeIndex` and `TimedeltaIndex` where indexing with `Ellipsis` would incorrectly lose the index's `freq` attribute (GH21282)
- Clarified error message produced when passing an incorrect `freq` argument to `DatetimeIndex` with `NaT` as the first entry in the passed data (GH11587)
- Bug in `to_datetime()` where `box` and `utc` arguments were ignored when passing a `DataFrame` or `dict` of unit mappings (GH23760)
- Bug in `Series.dt` where the cache would not update properly after an in-place operation (GH24408)
- Bug in `PeriodIndex` where comparisons against an array-like object with length 1 failed to raise `ValueError` (GH23078)
- Bug in `DatetimeIndex.astype()`, `PeriodIndex.astype()` and `TimedeltaIndex.astype()` ignoring the sign of the `dtype` for unsigned integer dtypes (GH24405).
- Fixed bug in `Series.max()` with `datetime64[ns]`-dtype failing to return `NaT` when nulls are present and `skipna=False` is passed (GH24265)
- Bug in `to_datetime()` where arrays of `datetime` objects containing both timezone-aware and timezone-naive `datetimes` would fail to raise `ValueError` (GH24569)

- Bug in `to_datetime()` with invalid datetime format doesn't coerce input to NaT even if `errors='coerce'` (GH24763)

Timedelta

- Bug in `DataFrame` with `timedelta64[ns]` dtype division by `Timedelta`-like scalar incorrectly returning `timedelta64[ns]` dtype instead of `float64` dtype (GH20088, GH22163)
- Bug in adding a `Index` with object dtype to a `Series` with `timedelta64[ns]` dtype incorrectly raising (GH22390)
- Bug in multiplying a `Series` with numeric dtype against a `timedelta` object (GH22390)
- Bug in `Series` with numeric dtype when adding or subtracting an array or `Series` with `timedelta64` dtype (GH22390)
- Bug in `Index` with numeric dtype when multiplying or dividing an array with dtype `timedelta64` (GH22390)
- Bug in `TimedeltaIndex` incorrectly allowing indexing with `Timestamp` object (GH20464)
- Fixed bug where subtracting `Timedelta` from an object-dtyped array would raise `TypeError` (GH21980)
- Fixed bug in adding a `DataFrame` with all-`timedelta64[ns]` dtypes to a `DataFrame` with all-integer dtypes returning incorrect results instead of raising `TypeError` (GH22696)
- Bug in `TimedeltaIndex` where adding a timezone-aware datetime scalar incorrectly returned a timezone-naive `DatetimeIndex` (GH23215)
- Bug in `TimedeltaIndex` where adding `np.timedelta64('NaT')` incorrectly returned an all-NaT `DatetimeIndex` instead of an all-NaT `TimedeltaIndex` (GH23215)
- Bug in `Timedelta` and `to_timedelta()` have inconsistencies in supported unit string (GH21762)
- Bug in `TimedeltaIndex` division where dividing by another `TimedeltaIndex` raised `TypeError` instead of returning a `Float64Index` (GH23829, GH22631)
- Bug in `TimedeltaIndex` comparison operations where comparing against non-`Timedelta`-like objects would raise `TypeError` instead of returning all-`False` for `__eq__` and all-`True` for `__ne__` (GH24056)
- Bug in `Timedelta` comparisons when comparing with a `Tick` object incorrectly raising `TypeError` (GH24710)

Timezones

- Bug in `Index.shift()` where an `AssertionError` would raise when shifting across DST (GH8616)
- Bug in `Timestamp` constructor where passing an invalid timezone offset designator (Z) would not raise a `ValueError` (GH8910)
- Bug in `Timestamp.replace()` where replacing at a DST boundary would retain an incorrect offset (GH7825)
- Bug in `Series.replace()` with `datetime64[ns, tz]` data when replacing NaT (GH11792)
- Bug in `Timestamp` when passing different string date formats with a timezone offset would produce different timezone offsets (GH12064)
- Bug when comparing a tz-naive `Timestamp` to a tz-aware `DatetimeIndex` which would coerce the `DatetimeIndex` to tz-naive (GH12601)

- Bug in `Series.truncate()` with a tz-aware `DatetimeIndex` which would cause a core dump ([GH9243](#))
- Bug in `Series` constructor which would coerce tz-aware and tz-naive `Timestamp` to tz-aware ([GH13051](#))
- Bug in `Index` with `datetime64[ns, tz]` dtype that did not localize integer data correctly ([GH20964](#))
- Bug in `DatetimeIndex` where constructing with an integer and tz would not localize correctly ([GH12619](#))
- Fixed bug where `DataFrame.describe()` and `Series.describe()` on tz-aware datetimes did not show *first* and *last* result ([GH21328](#))
- Bug in `DatetimeIndex` comparisons failing to raise `TypeError` when comparing timezone-aware `DatetimeIndex` against `np.datetime64` ([GH22074](#))
- Bug in `DataFrame` assignment with a timezone-aware scalar ([GH19843](#))
- Bug in `DataFrame.asof()` that raised a `TypeError` when attempting to compare tz-naive and tz-aware timestamps ([GH21194](#))
- Bug when constructing a `DatetimeIndex` with `Timestamp` constructed with the `replace` method across DST ([GH18785](#))
- Bug when setting a new value with `DataFrame.loc()` with a `DatetimeIndex` with a DST transition ([GH18308](#), [GH20724](#))
- Bug in `Index.unique()` that did not re-localize tz-aware dates correctly ([GH21737](#))
- Bug when indexing a `Series` with a DST transition ([GH21846](#))
- Bug in `DataFrame.resample()` and `Series.resample()` where an `AmbiguousTimeError` or `NonExistentTimeError` would raise if a timezone aware timeseries ended on a DST transition ([GH19375](#), [GH10117](#))
- Bug in `DataFrame.drop()` and `Series.drop()` when specifying a tz-aware `Timestamp` key to drop from a `DatetimeIndex` with a DST transition ([GH21761](#))
- Bug in `DatetimeIndex` constructor where `NaT` and `dateutil.tz.tzlocal` would raise an `OutOfBoundsDatetime` error ([GH23807](#))
- Bug in `DatetimeIndex.tz_localize()` and `Timestamp.tz_localize()` with `dateutil.tz.tzlocal` near a DST transition that would return an incorrectly localized datetime ([GH23807](#))
- Bug in `Timestamp` constructor where a `dateutil.tz.tzutc` timezone passed with a `datetime.datetime` argument would be converted to a `pytz.UTC` timezone ([GH23807](#))
- Bug in `to_datetime()` where `utc=True` was not respected when specifying a `unit` and `errors='ignore'` ([GH23758](#))
- Bug in `to_datetime()` where `utc=True` was not respected when passing a `Timestamp` ([GH24415](#))
- Bug in `DataFrame.any()` returns wrong value when `axis=1` and the data is of datetimelike type ([GH23070](#))
- Bug in `DatetimeIndex.to_period()` where a timezone aware index was converted to UTC first before creating `PeriodIndex` ([GH22905](#))
- Bug in `DataFrame.tz_localize()`, `DataFrame.tz_convert()`, `Series.tz_localize()`, and `Series.tz_convert()` where `copy=False` would mutate the original argument inplace ([GH6326](#))
- Bug in `DataFrame.max()` and `DataFrame.min()` with `axis=1` where a `Series` with `NaN` would be returned when all columns contained the same timezone ([GH10390](#))

Offsets

- Bug in FY5253 where date offsets could incorrectly raise an `AssertionError` in arithmetic operations (GH14774)
- Bug in `DateOffset` where keyword arguments `week` and `milliseconds` were accepted and ignored. Passing these will now raise `ValueError` (GH19398)
- Bug in adding `DateOffset` with `DataFrame` or `PeriodIndex` incorrectly raising `TypeError` (GH23215)
- Bug in comparing `DateOffset` objects with non-`DateOffset` objects, particularly strings, raising `ValueError` instead of returning `False` for equality checks and `True` for not-equal checks (GH23524)

Numeric

- Bug in `Series` `__rmatmul__` doesn't support matrix vector multiplication (GH21530)
- Bug in `factorize()` fails with read-only array (GH12813)
- Fixed bug in `unique()` handled signed zeros inconsistently: for some inputs 0.0 and -0.0 were treated as equal and for some inputs as different. Now they are treated as equal for all inputs (GH21866)
- Bug in `DataFrame.agg()`, `DataFrame.transform()` and `DataFrame.apply()` where, when supplied with a list of functions and `axis=1` (e.g. `df.apply(['sum', 'mean'], axis=1)`), a `TypeError` was wrongly raised. For all three methods such calculation are now done correctly. (GH16679).
- Bug in `Series` comparison against datetime-like scalars and arrays (GH22074)
- Bug in `DataFrame` multiplication between boolean dtype and integer returning object dtype instead of integer dtype (GH22047, GH22163)
- Bug in `DataFrame.apply()` where, when supplied with a string argument and additional positional or keyword arguments (e.g. `df.apply('sum', min_count=1)`), a `TypeError` was wrongly raised (GH22376)
- Bug in `DataFrame.astype()` to extension dtype may raise `AttributeError` (GH22578)
- Bug in `DataFrame` with `timedelta64[ns]` dtype arithmetic operations with `ndarray` with integer dtype incorrectly treating the ndarray as `timedelta64[ns]` dtype (GH23114)
- Bug in `Series.rpow()` with object dtype NaN for `1 ** NA` instead of 1 (GH22922).
- `Series.agg()` can now handle numpy NaN-aware methods like `numpy.nansum()` (GH19629)
- Bug in `Series.rank()` and `DataFrame.rank()` when `pct=True` and more than 2^{24} rows are present resulted in percentages greater than 1.0 (GH18271)
- Calls such as `DataFrame.round()` with a non-unique `CategoricalIndex()` now return expected data. Previously, data would be improperly duplicated (GH21809).
- Added `log10`, `floor` and `ceil` to the list of supported functions in `DataFrame.eval()` (GH24139, GH24353)
- Logical operations `&`, `|`, `^` between `Series` and `Index` will no longer raise `ValueError` (GH22092)
- Checking PEP 3141 numbers in `is_scalar()` function returns `True` (GH22903)
- Reduction methods like `Series.sum()` now accept the default value of `keepdims=False` when called from a NumPy ufunc, rather than raising a `TypeError`. Full support for `keepdims` has not been implemented (GH24356).

Conversion

- Bug in `DataFrame.combine_first()` in which column types were unexpectedly converted to float (GH20699)
- Bug in `DataFrame.clip()` in which column types are not preserved and casted to float (GH24162)
- Bug in `DataFrame.clip()` when order of columns of dataframes doesn't match, result observed is wrong in numeric values (GH20911)
- Bug in `DataFrame.astype()` where converting to an extension dtype when duplicate column names are present causes a `RecursionError` (GH24704)

Strings

- Bug in `Index.str.partition()` was not nan-safe (GH23558).
- Bug in `Index.str.split()` was not nan-safe (GH23677).
- Bug `Series.str.contains()` not respecting the `na` argument for a `Categorical` dtype `Series` (GH22158)
- Bug in `Index.str.cat()` when the result contained only `NaN` (GH24044)

Interval

- Bug in the `IntervalIndex` constructor where the `closed` parameter did not always override the inferred `closed` (GH19370)
- Bug in the `IntervalIndex` repr where a trailing comma was missing after the list of intervals (GH20611)
- Bug in `Interval` where scalar arithmetic operations did not retain the `closed` value (GH22313)
- Bug in `IntervalIndex` where indexing with datetime-like values raised a `KeyError` (GH20636)
- Bug in `IntervalTree` where data containing `NaN` triggered a warning and resulted in incorrect indexing queries with `IntervalIndex` (GH23352)

Indexing

- Bug in `DataFrame.ne()` fails if columns contain column name "dtype" (GH22383)
- The traceback from a `KeyError` when asking `.loc` for a single missing label is now shorter and more clear (GH21557)
- `PeriodIndex` now emits a `KeyError` when a malformed string is looked up, which is consistent with the behavior of `DatetimeIndex` (GH22803)
- When `.ix` is asked for a missing integer label in a `MultiIndex` with a first level of integer type, it now raises a `KeyError`, consistently with the case of a flat `Int64Index`, rather than falling back to positional indexing (GH21593)
- Bug in `Index.reindex()` when reindexing a tz-naive and tz-aware `DatetimeIndex` (GH8306)
- Bug in `Series.reindex()` when reindexing an empty series with a `datetime64[ns, tz]` dtype (GH20869)
- Bug in `DataFrame` when setting values with `.loc` and a timezone aware `DatetimeIndex` (GH11365)

- `DataFrame.__getitem__` now accepts dictionaries and dictionary keys as list-likes of labels, consistently with `Series.__getitem__` (GH21294)
- Fixed `DataFrame[np.nan]` when columns are non-unique (GH21428)
- Bug when indexing `DatetimeIndex` with nanosecond resolution dates and timezones (GH11679)
- Bug where indexing with a Numpy array containing negative values would mutate the indexer (GH21867)
- Bug where mixed indexes wouldn't allow integers for `.at` (GH19860)
- `Float64Index.get_loc` now raises `KeyError` when boolean key passed. (GH19087)
- Bug in `DataFrame.loc()` when indexing with an `IntervalIndex` (GH19977)
- `Index` no longer mangles `None`, `NaN` and `NaT`, i.e. they are treated as three different keys. However, for numeric `Index` all three are still coerced to a `NaN` (GH22332)
- Bug in `scalar in Index` if scalar is a float while the `Index` is of integer dtype (GH22085)
- Bug in `MultiIndex.set_levels()` when levels value is not subscriptable (GH23273)
- Bug where setting a `timedelta` column by `Index` causes it to be casted to double, and therefore lose precision (GH23511)
- Bug in `Index.union()` and `Index.intersection()` where name of the `Index` of the result was not computed correctly for certain cases (GH9943, GH9862)
- Bug in `Index` slicing with boolean `Index` may raise `TypeError` (GH22533)
- Bug in `PeriodArray.__setitem__` when accepting slice and list-like value (GH23978)
- Bug in `DatetimeIndex`, `TimedeltaIndex` where indexing with `Ellipsis` would lose their `freq` attribute (GH21282)
- Bug in `iat` where using it to assign an incompatible value would create a new column (GH23236)

Missing

- Bug in `DataFrame.fillna()` where a `ValueError` would raise when one column contained a `datetime64[ns, tz]` dtype (GH15522)
- Bug in `Series.hasnans()` that could be incorrectly cached and return incorrect answers if null elements are introduced after an initial call (GH19700)
- `Series.isin()` now treats all `NaN`-floats as equal also for `np.object-dtype`. This behavior is consistent with the behavior for `float64` (GH22119)
- `unique()` no longer mangles `NaN`-floats and the `NaT`-object for `np.object-dtype`, i.e. `NaT` is no longer coerced to a `NaN`-value and is treated as a different entity. (GH22295)
- `DataFrame` and `Series` now properly handle numpy masked arrays with hardened masks. Previously, constructing a `DataFrame` or `Series` from a masked array with a hard mask would create a pandas object containing the underlying value, rather than the expected `NaN`. (GH24574)
- Bug in `DataFrame` constructor where `dtype` argument was not honored when handling numpy masked record arrays. (GH24874)

MultiIndex

- Bug in `io.formats.style.Styler.applymap()` where `subset=` with `MultiIndex` slice would reduce to `Series` (GH19861)
- Removed compatibility for `MultiIndex` pickles prior to version 0.8.0; compatibility with `MultiIndex` pickles from version 0.13 forward is maintained (GH21654)
- `MultiIndex.get_loc_level()` (and as a consequence, `.loc` on a `Series` or `DataFrame` with a `MultiIndex` index) will now raise a `KeyError`, rather than returning an empty slice, if asked a label which is present in the `levels` but is unused (GH22221)
- `MultiIndex` has gained the `MultiIndex.from_frame()`, it allows constructing a `MultiIndex` object from a `DataFrame` (GH22420)
- Fix `TypeError` in Python 3 when creating `MultiIndex` in which some levels have mixed types, e.g. when some labels are tuples (GH15457)

I/O

- Bug in `read_csv()` in which a column specified with `CategoricalDtype` of boolean categories was not being correctly coerced from string values to booleans (GH20498)
- Bug in `read_csv()` in which unicode column names were not being properly recognized with Python 2.x (GH13253)
- Bug in `DataFrame.to_sql()` when writing timezone aware data (`datetime64[ns, tz]` dtype) would raise a `TypeError` (GH9086)
- Bug in `DataFrame.to_sql()` where a naive `DatetimeIndex` would be written as `TIMESTAMP WITH TIMEZONE` type in supported databases, e.g. PostgreSQL (GH23510)
- Bug in `read_excel()` when `parse_cols` is specified with an empty dataset (GH9208)
- `read_html()` no longer ignores all-whitespace `<tr>` within `<thead>` when considering the `skiprows` and `header` arguments. Previously, users had to decrease their `header` and `skiprows` values on such tables to work around the issue. (GH21641)
- `read_excel()` will correctly show the deprecation warning for previously deprecated `sheetname` (GH17994)
- `read_csv()` and `read_table()` will throw `UnicodeError` and not `coredump` on badly encoded strings (GH22748)
- `read_csv()` will correctly parse timezone-aware datetimes (GH22256)
- Bug in `read_csv()` in which memory management was prematurely optimized for the C engine when the data was being read in chunks (GH23509)
- Bug in `read_csv()` in unnamed columns were being improperly identified when extracting a multi-index (GH23687)
- `read_sas()` will parse numbers in `sas7bdat`-files that have width less than 8 bytes correctly. (GH21616)
- `read_sas()` will correctly parse `sas7bdat` files with many columns (GH22628)
- `read_sas()` will correctly parse `sas7bdat` files with data page types having also bit 7 set (so page type is $128 + 256 = 384$) (GH16615)
- Bug in `read_sas()` in which an incorrect error was raised on an invalid file format. (GH24548)

- Bug in `detect_client_encoding()` where potential `IOError` goes unhandled when importing in a `mod_wsgi` process due to restricted access to `stdout`. (GH21552)
- Bug in `DataFrame.to_html()` with `index=False` misses truncation indicators (...) on truncated `DataFrame` (GH15019, GH22783)
- Bug in `DataFrame.to_html()` with `index=False` when both columns and row index are `MultiIndex` (GH22579)
- Bug in `DataFrame.to_html()` with `index_names=False` displaying index name (GH22747)
- Bug in `DataFrame.to_html()` with `header=False` not displaying row index names (GH23788)
- Bug in `DataFrame.to_html()` with `sparsify=False` that caused it to raise `TypeError` (GH22887)
- Bug in `DataFrame.to_string()` that broke column alignment when `index=False` and width of first column's values is greater than the width of first column's header (GH16839, GH13032)
- Bug in `DataFrame.to_string()` that caused representations of `DataFrame` to not take up the whole window (GH22984)
- Bug in `DataFrame.to_csv()` where a single level `MultiIndex` incorrectly wrote a tuple. Now just the value of the index is written (GH19589).
- `HDFStore` will raise `ValueError` when the `format` kwarg is passed to the constructor (GH13291)
- Bug in `HDFStore.append()` when appending a `DataFrame` with an empty string column and `min_itemsize < 8` (GH12242)
- Bug in `read_csv()` in which memory leaks occurred in the C engine when parsing NaN values due to insufficient cleanup on completion or error (GH21353)
- Bug in `read_csv()` in which incorrect error messages were being raised when `skipfooter` was passed in along with `nrows`, `iterator`, or `chunksize` (GH23711)
- Bug in `read_csv()` in which `MultiIndex` index names were being improperly handled in the cases when they were not provided (GH23484)
- Bug in `read_csv()` in which unnecessary warnings were being raised when the dialect's values conflicted with the default arguments (GH23761)
- Bug in `read_html()` in which the error message was not displaying the valid flavors when an invalid one was provided (GH23549)
- Bug in `read_excel()` in which extraneous header names were extracted, even though none were specified (GH11733)
- Bug in `read_excel()` in which column names were not being properly converted to string sometimes in Python 2.x (GH23874)
- Bug in `read_excel()` in which `index_col=None` was not being respected and parsing index columns anyway (GH18792, GH20480)
- Bug in `read_excel()` in which `usecols` was not being validated for proper column names when passed in as a string (GH20480)
- Bug in `DataFrame.to_dict()` when the resulting dict contains non-Python scalars in the case of numeric data (GH23753)
- `DataFrame.to_string()`, `DataFrame.to_html()`, `DataFrame.to_latex()` will correctly format output when a string is passed as the `float_format` argument (GH21625, GH22270)
- Bug in `read_csv()` that caused it to raise `OverflowError` when trying to use 'inf' as `na_value` with integer index column (GH17128)

- Bug in `read_csv()` that caused the C engine on Python 3.6+ on Windows to improperly read CSV filenames with accented or special characters ([GH15086](#))
- Bug in `read_fwf()` in which the compression type of a file was not being properly inferred ([GH22199](#))
- Bug in `pandas.io.json.json_normalize()` that caused it to raise `TypeError` when two consecutive elements of `record_path` are dicts ([GH22706](#))
- Bug in `DataFrame.to_stata()`, `pandas.io.stata.StataWriter` and `pandas.io.stata.StataWriter117` where an exception would leave a partially written and invalid dta file ([GH23573](#))
- Bug in `DataFrame.to_stata()` and `pandas.io.stata.StataWriter117` that produced invalid files when using `strLs` with non-ASCII characters ([GH23573](#))
- Bug in `HDFStore` that caused it to raise `ValueError` when reading a Dataframe in Python 3 from fixed format written in Python 2 ([GH24510](#))
- Bug in `DataFrame.to_string()` and more generally in the floating `repr` formatter. Zeros were not trimmed if `inf` was present in a column while it was the case with NA values. Zeros are now trimmed as in the presence of NA ([GH24861](#)).
- Bug in the `repr` when truncating the number of columns and having a wide last column ([GH24849](#)).

Plotting

- Bug in `DataFrame.plot.scatter()` and `DataFrame.plot.hexbin()` caused x-axis label and ticklabels to disappear when `colorbar` was on in IPython inline backend ([GH10611](#), [GH10678](#), and [GH20455](#))
- Bug in plotting a Series with datetimes using `matplotlib.axes.Axes.scatter()` ([GH22039](#))
- Bug in `DataFrame.plot.bar()` caused bars to use multiple colors instead of a single one ([GH20585](#))
- Bug in validating color parameter caused extra color to be appended to the given color array. This happened to multiple plotting functions using `matplotlib`. ([GH20726](#))

Groupby/resample/rolling

- Bug in `pandas.core.window.Rolling.min()` and `pandas.core.window.Rolling.max()` with `closed='left'`, a datetime-like index and only one entry in the series leading to segfault ([GH24718](#))
- Bug in `pandas.core.groupby.GroupBy.first()` and `pandas.core.groupby.GroupBy.last()` with `as_index=False` leading to the loss of timezone information ([GH15884](#))
- Bug in `DateFrame.resample()` when downsampling across a DST boundary ([GH8531](#))
- Bug in date anchoring for `DateFrame.resample()` with offset Day when `n > 1` ([GH24127](#))
- Bug where `ValueError` is wrongly raised when calling `count()` method of a `SeriesGroupBy` when the grouping variable only contains NaNs and numpy version `< 1.13` ([GH21956](#)).
- Multiple bugs in `pandas.core.window.Rolling.min()` with `closed='left'` and a datetime-like index leading to incorrect results and also segfault. ([GH21704](#))
- Bug in `pandas.core.resample.Resampler.apply()` when passing positional arguments to applied func ([GH14615](#)).
- Bug in `Series.resample()` when passing `numpy.timedelta64` to `loffset` kwarg ([GH7687](#)).
- Bug in `pandas.core.resample.Resampler.asfreq()` when frequency of `TimedeltaIndex` is a subperiod of a new frequency ([GH13022](#)).

- Bug in `pandas.core.groupby.SeriesGroupBy.mean()` when values were integral but could not fit inside of int64, overflowing instead. (GH22487)
- `pandas.core.groupby.RollingGroupby.agg()` and `pandas.core.groupby.ExpandingGroupby.agg()` now support multiple aggregation functions as parameters (GH15072)
- Bug in `DataFrame.resample()` and `Series.resample()` when resampling by a weekly offset ('W') across a DST transition (GH9119, GH21459)
- Bug in `DataFrame.expanding()` in which the axis argument was not being respected during aggregations (GH23372)
- Bug in `pandas.core.groupby.GroupBy.transform()` which caused missing values when the input function can accept a DataFrame but renames it (GH23455).
- Bug in `pandas.core.groupby.GroupBy.nth()` where column order was not always preserved (GH20760)
- Bug in `pandas.core.groupby.GroupBy.rank()` with `method='dense'` and `pct=True` when a group has only one member would raise a `ZeroDivisionError` (GH23666).
- Calling `pandas.core.groupby.GroupBy.rank()` with empty groups and `pct=True` was raising a `ZeroDivisionError` (GH22519)
- Bug in `DataFrame.resample()` when resampling NaT in `TimeDeltaIndex` (GH13223).
- Bug in `DataFrame.groupby()` did not respect the `observed` argument when selecting a column and instead always used `observed=False` (GH23970)
- Bug in `pandas.core.groupby.SeriesGroupBy.pct_change()` or `pandas.core.groupby.DataFrameGroupBy.pct_change()` would previously work across groups when calculating the percent change, where it now correctly works per group (GH21200, GH21235).
- Bug preventing hash table creation with very large number (2^{32}) of rows (GH22805)
- Bug in groupby when grouping on categorical causes `ValueError` and incorrect grouping if `observed=True` and `nan` is present in categorical column (GH24740, GH21151).

Reshaping

- Bug in `pandas.concat()` when joining resampled DataFrames with timezone aware index (GH13783)
- Bug in `pandas.concat()` when joining only `Series` the `names` argument of `concat` is no longer ignored (GH23490)
- Bug in `Series.combine_first()` with `datetime64[ns, tz]` dtype which would return tz-naive result (GH21469)
- Bug in `Series.where()` and `DataFrame.where()` with `datetime64[ns, tz]` dtype (GH21546)
- Bug in `DataFrame.where()` with an empty DataFrame and empty `cond` having non-bool dtype (GH21947)
- Bug in `Series.mask()` and `DataFrame.mask()` with list conditionals (GH21891)
- Bug in `DataFrame.replace()` raises `RecursionError` when converting `OutOfBounds datetime64[ns, tz]` (GH20380)
- `pandas.core.groupby.GroupBy.rank()` now raises a `ValueError` when an invalid value is passed for argument `na_option` (GH22124)
- Bug in `get_dummies()` with Unicode attributes in Python 2 (GH22084)

- Bug in `DataFrame.replace()` raises `RecursionError` when replacing empty lists ([GH22083](#))
- Bug in `Series.replace()` and `DataFrame.replace()` when dict is used as the `to_replace` value and one key in the dict is another key's value, the results were inconsistent between using integer key and using string key ([GH20656](#))
- Bug in `DataFrame.drop_duplicates()` for empty `DataFrame` which incorrectly raises an error ([GH20516](#))
- Bug in `pandas.wide_to_long()` when a string is passed to the `stubnames` argument and a column name is a substring of that stubname ([GH22468](#))
- Bug in `merge()` when merging `datetime64[ns, tz]` data that contained a DST transition ([GH18885](#))
- Bug in `merge_asof()` when merging on float values within defined tolerance ([GH22981](#))
- Bug in `pandas.concat()` when concatenating a multicolumn `DataFrame` with tz-aware data against a `DataFrame` with a different number of columns ([GH22796](#))
- Bug in `merge_asof()` where confusing error message raised when attempting to merge with missing values ([GH23189](#))
- Bug in `DataFrame.nsmallest()` and `DataFrame.nlargest()` for dataframes that have a `MultiIndex` for columns ([GH23033](#)).
- Bug in `pandas.melt()` when passing column names that are not present in `DataFrame` ([GH23575](#))
- Bug in `DataFrame.append()` with a `Series` with a dateutil timezone would raise a `TypeError` ([GH23682](#))
- Bug in `Series` construction when passing no data and `dtype=str` ([GH22477](#))
- Bug in `cut()` with `bins` as an overlapping `IntervalIndex` where multiple bins were returned per item instead of raising a `ValueError` ([GH23980](#))
- Bug in `pandas.concat()` when joining `Series` `datetimetz` with `Series` category would lose timezone ([GH23816](#))
- Bug in `DataFrame.join()` when joining on partial `MultiIndex` would drop names ([GH20452](#)).
- `DataFrame.nlargest()` and `DataFrame.nsmallest()` now returns the correct `n` values when `keep != 'all'` also when tied on the first columns ([GH22752](#))
- Constructing a `DataFrame` with an index argument that wasn't already an instance of `Index` was broken ([GH22227](#)).
- Bug in `DataFrame` prevented list subclasses to be used to construction ([GH21226](#))
- Bug in `DataFrame.unstack()` and `DataFrame.pivot_table()` returning a misleading error message when the resulting `DataFrame` has more elements than `int32` can handle. Now, the error message is improved, pointing towards the actual problem ([GH20601](#))
- Bug in `DataFrame.unstack()` where a `ValueError` was raised when unstacking timezone aware values ([GH18338](#))
- Bug in `DataFrame.stack()` where timezone aware values were converted to timezone naive values ([GH19420](#))
- Bug in `merge_asof()` where a `TypeError` was raised when `by_col` were timezone aware values ([GH21184](#))
- Bug showing an incorrect shape when throwing error during `DataFrame` construction. ([GH20742](#))

Sparse

- Updating a boolean, datetime, or timedelta column to be Sparse now works (GH22367)
- Bug in `Series.to_sparse()` with Series already holding sparse data not constructing properly (GH22389)
- Providing a `sparse_index` to the `SparseArray` constructor no longer defaults the na-value to `np.nan` for all dtypes. The correct `na_value` for `data.dtype` is now used.
- Bug in `SparseArray.nbytes` under-reporting its memory usage by not including the size of its sparse index.
- Improved performance of `Series.shift()` for non-NA `fill_value`, as values are no longer converted to a dense array.
- Bug in `DataFrame.groupby` not including `fill_value` in the groups for non-NA `fill_value` when grouping by a sparse column (GH5078)
- Bug in unary inversion operator (`~`) on a `SparseSeries` with boolean values. The performance of this has also been improved (GH22835)
- Bug in `SparseArray.unique()` not returning the unique values (GH19595)
- Bug in `SparseArray.nonzero()` and `SparseDataFrame.dropna()` returning shifted/incorrect results (GH21172)
- Bug in `DataFrame.apply()` where dtypes would lose sparseness (GH23744)
- Bug in `concat()` when concatenating a list of `Series` with all-sparse values changing the `fill_value` and converting to a dense `Series` (GH24371)

Style

- `background_gradient()` now takes a `text_color_threshold` parameter to automatically lighten the text color based on the luminance of the background color. This improves readability with dark background colors without the need to limit the background colormap range. (GH21258)
- `background_gradient()` now also supports tablewise application (in addition to rowwise and columnwise) with `axis=None` (GH15204)
- `bar()` now also supports tablewise application (in addition to rowwise and columnwise) with `axis=None` and setting clipping range with `vmin` and `vmax` (GH21548 and GH21526). NaN values are also handled properly.

Build changes

- Building pandas for development now requires `cython >= 0.28.2` (GH21688)
- Testing pandas now requires `hypothesis >= 3.58`. You can find the [Hypothesis docs here](#), and a pandas-specific introduction *in the contributing guide*. (GH22280)
- Building pandas on macOS now targets minimum macOS 10.9 if run on macOS 10.9 or above (GH23424)

Other

- Bug where C variables were declared with external linkage causing import errors if certain other C libraries were imported before Pandas. (GH24113)

8.3 Version 0.23

8.3.1 What's new in 0.23.4 (August 3, 2018)

{{ header }}

This is a minor bug-fix release in the 0.23.x series and includes some small regression fixes and bug fixes. We recommend that all users upgrade to this version.

Warning: Starting January 1, 2019, pandas feature releases will support Python 3 only. See [Dropping Python 2.7](#) for more.

What's new in v0.23.4

- *Fixed regressions*
- *Bug fixes*
- *Contributors*

Fixed regressions

- Python 3.7 with Windows gave all missing values for rolling variance calculations (GH21813)

Bug fixes

Groupby/resample/rolling

- Bug where calling `DataFrameGroupBy.agg()` with a list of functions including `ohlcv` as the non-initial element would raise a `ValueError` (GH21716)
- Bug in `roll_quantile` caused a memory leak when calling `.rolling(...).quantile(q)` with `q` in `(0,1)` (GH21965)

Missing

- Bug in `Series.clip()` and `DataFrame.clip()` cannot accept list-like threshold containing `NaN` (GH19992)

Contributors

A total of 6 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

- Jeff Reback
- MeeseeksMachine +
- Tom Augspurger
- chris-b1
- h-vetinari
- meeseeksdev[bot]

8.3.2 What’s new in 0.23.3 (July 7, 2018)

{{ header }}

This release fixes a build issue with the `sdist` for Python 3.7 (GH21785) There are no other changes.

Contributors

A total of 2 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

- Tom Augspurger
- meeseeksdev[bot] +

8.3.3 What's new in 0.23.2 (July 5, 2018)

{{ header }}

This is a minor bug-fix release in the 0.23.x series and includes some small regression fixes and bug fixes. We recommend that all users upgrade to this version.

Note: Pandas 0.23.2 is first pandas release that's compatible with Python 3.7 ([GH20552](#))

Warning: Starting January 1, 2019, pandas feature releases will support Python 3 only. See [Dropping Python 2.7](#) for more.

What's new in v0.23.2

- *Logical reductions over entire DataFrame*
- *Fixed regressions*
- *Build changes*
- *Bug fixes*
- *Contributors*

Logical reductions over entire DataFrame

`DataFrame.all()` and `DataFrame.any()` now accept `axis=None` to reduce over all axes to a scalar ([GH19976](#))

```
In [1]: df = pd.DataFrame({"A": [1, 2], "B": [True, False]})
```

```
In [2]: df.all(axis=None)
```

```
Out[2]: False
```

This also provides compatibility with NumPy 1.15, which now dispatches to `DataFrame.all`. With NumPy 1.15 and pandas 0.23.1 or earlier, `numpy.all()` will no longer reduce over every axis:

```
>>> # NumPy 1.15, pandas 0.23.1
>>> np.any(pd.DataFrame({"A": [False], "B": [False]}))
A    False
B    False
dtype: bool
```

With pandas 0.23.2, that will correctly return `False`, as it did with NumPy < 1.15.

```
In [3]: np.any(pd.DataFrame({"A": [False], "B": [False]}))
```

```
Out[3]: False
```

Fixed regressions

- Fixed regression in `to_csv()` when handling file-like object incorrectly ([GH21471](#))

- Re-allowed duplicate level names of a `MultiIndex`. Accessing a level that has a duplicate name by name still raises an error ([GH19029](#)).
- Bug in both `DataFrame.first_valid_index()` and `Series.first_valid_index()` raised for a row index having duplicate values ([GH21441](#))
- Fixed printing of DataFrames with hierarchical columns with long names ([GH21180](#))
- Fixed regression in `reindex()` and `groupby()` with a `MultiIndex` or multiple keys that contains categorical datetime-like values ([GH21390](#)).
- Fixed regression in unary negative operations with object dtype ([GH21380](#))
- Bug in `Timestamp.ceil()` and `Timestamp.floor()` when timestamp is a multiple of the rounding frequency ([GH21262](#))
- Fixed regression in `to_clipboard()` that defaulted to copying dataframes with space delimited instead of tab delimited ([GH21104](#))

Build changes

- The source and binary distributions no longer include test data files, resulting in smaller download sizes. Tests relying on these data files will be skipped when using `pandas.test()`. ([GH19320](#))

Bug fixes

Conversion

- Bug in constructing `Index` with an iterator or generator ([GH21470](#))
- Bug in `Series.nlargest()` for signed and unsigned integer dtypes when the minimum value is present ([GH21426](#))

Indexing

- Bug in `Index.get_indexer_non_unique()` with categorical key ([GH21448](#))
- Bug in comparison operations for `MultiIndex` where error was raised on equality / inequality comparison involving a `MultiIndex` with `nlevels == 1` ([GH21149](#))
- Bug in `DataFrame.drop()` behaviour is not consistent for unique and non-unique indexes ([GH21494](#))
- Bug in `DataFrame.duplicated()` with a large number of columns causing a 'maximum recursion depth exceeded' ([GH21524](#)).

I/O

- Bug in `read_csv()` that caused it to incorrectly raise an error when `nrows=0`, `low_memory=True`, and `index_col` was not `None` ([GH21141](#))
- Bug in `json_normalize()` when formatting the `record_prefix` with integer columns ([GH21536](#))

Categorical

- Bug in rendering `Series` with `Categorical` dtype in rare conditions under Python 2.7 ([GH21002](#))

Timezones

- Bug in `Timestamp` and `DatetimeIndex` where passing a `Timestamp` localized after a DST transition would return a datetime before the DST transition ([GH20854](#))
- Bug in comparing `DataFrame` with tz-aware `DatetimeIndex` columns with a DST transition that raised a `KeyError` ([GH19970](#))

- Bug in `DatetimeIndex.shift()` where an `AssertionError` would raise when shifting across DST (GH8616)
- Bug in `Timestamp` constructor where passing an invalid timezone offset designator (Z) would not raise a `ValueError` (GH8910)
- Bug in `Timestamp.replace()` where replacing at a DST boundary would retain an incorrect offset (GH7825)
- Bug in `DatetimeIndex.reindex()` when reindexing a tz-naive and tz-aware `DatetimeIndex` (GH8306)
- Bug in `DatetimeIndex.resample()` when downsampling across a DST boundary (GH8531)

Timedelta

- Bug in `Timedelta` where non-zero timedeltas shorter than 1 microsecond were considered `False` (GH21484)

8.3.4 What’s new in 0.23.1 (June 12, 2018)

{{ header }}

This is a minor bug-fix release in the 0.23.x series and includes some small regression fixes and bug fixes. We recommend that all users upgrade to this version.

Warning: Starting January 1, 2019, pandas feature releases will support Python 3 only. See [Dropping Python 2.7](#) for more.

What's new in v0.23.1

- *Fixed regressions*
- *Performance improvements*
- *Bug fixes*
- *Contributors*

Fixed regressions

Comparing Series with `datetime.date`

We've reverted a 0.23.0 change to comparing a `Series` holding datetimes and a `datetime.date` object (GH21152). In pandas 0.22 and earlier, comparing a `Series` holding datetimes and `datetime.date` objects would coerce the `datetime.date` to a datetime before comparing. This was inconsistent with Python, NumPy, and `DatetimeIndex`, which never consider a datetime and `datetime.date` equal.

In 0.23.0, we unified operations between `DatetimeIndex` and `Series`, and in the process changed comparisons between a `Series` of datetimes and `datetime.date` without warning.

We've temporarily restored the 0.22.0 behavior, so datetimes and dates may again compare equal, but restore the 0.23.0 behavior in a future release.

To summarize, here's the behavior in 0.22.0, 0.23.0, 0.23.1:

```
# 0.22.0... Silently coerce the datetime.date
>>> import datetime
>>> pd.Series(pd.date_range('2017', periods=2)) == datetime.date(2017, 1, 1)
0    True
1    False
dtype: bool

# 0.23.0... Do not coerce the datetime.date
>>> pd.Series(pd.date_range('2017', periods=2)) == datetime.date(2017, 1, 1)
0    False
1    False
dtype: bool

# 0.23.1... Coerce the datetime.date with a warning
>>> pd.Series(pd.date_range('2017', periods=2)) == datetime.date(2017, 1, 1)
/bin/python:1: FutureWarning: Comparing Series of datetimes with 'datetime.date'.
↳Currently, the
'datetime.date' is coerced to a datetime. In the future pandas will
not coerce, and the values not compare equal to the 'datetime.date'.
To retain the current behavior, convert the 'datetime.date' to a
datetime with 'pd.Timestamp'.
#!/bin/python3
0    True
```

(continues on next page)

(continued from previous page)

```
1 False
dtype: bool
```

In addition, ordering comparisons will raise a `TypeError` in the future.

Other fixes

- Reverted the ability of `to_sql()` to perform multivalue inserts as this caused regression in certain cases (GH21103). In the future this will be made configurable.
- Fixed regression in the `DatetimeIndex.date` and `DatetimeIndex.time` attributes in case of timezone-aware data: `DatetimeIndex.time` returned a tz-aware time instead of tz-naive (GH21267) and `DatetimeIndex.date` returned incorrect date when the input date has a non-UTC timezone (GH21230).
- Fixed regression in `pandas.io.json.json_normalize()` when called with `None` values in nested levels in JSON, and to not drop keys with value as `None` (GH21158, GH21356).
- Bug in `to_csv()` causes encoding error when compression and encoding are specified (GH21241, GH21118)
- Bug preventing pandas from being importable with -OO optimization (GH21071)
- Bug in `Categorical.fillna()` incorrectly raising a `TypeError` when `value` the individual categories are iterable and `value` is an iterable (GH21097, GH19788)
- Fixed regression in constructors coercing NA values like `None` to strings when passing `dtype=str` (GH21083)
- Regression in `pivot_table()` where an ordered `Categorical` with missing values for the pivot's index would give a mis-aligned result (GH21133)
- Fixed regression in merging on boolean index/columns (GH21119).

Performance improvements

- Improved performance of `CategoricalIndex.is_monotonic_increasing()`, `CategoricalIndex.is_monotonic_decreasing()` and `CategoricalIndex.is_monotonic()` (GH21025)
- Improved performance of `CategoricalIndex.is_unique()` (GH21107)

Bug fixes

Groupby/resample/rolling

- Bug in `DataFrame.agg()` where applying multiple aggregation functions to a `DataFrame` with duplicated column names would cause a stack overflow (GH21063)
- Bug in `pandas.core.groupby.GroupBy.ffill()` and `pandas.core.groupby.GroupBy.bfill()` where the fill within a grouping would not always be applied as intended due to the implementations' use of a non-stable sort (GH21207)
- Bug in `pandas.core.groupby.GroupBy.rank()` where results did not scale to 100% when specifying `method='dense'` and `pct=True`
- Bug in `pandas.DataFrame.rolling()` and `pandas.Series.rolling()` which incorrectly accepted a 0 window size rather than raising (GH21286)

Data-type specific

- Bug in `Series.str.replace()` where the method throws `TypeError` on Python 3.5.2 (GH21078)
- Bug in `Timedelta` where passing a float with a unit would prematurely round the float precision (GH14156)
- Bug in `pandas.testing.assert_index_equal()` which raised `AssertionError` incorrectly, when comparing two `CategoricalIndex` objects with param `check_categorical=False` (GH19776)

Sparse

- Bug in `SparseArray.shape` which previously only returned the shape `SparseArray.sp_values` (GH21126)

Indexing

- Bug in `Series.reset_index()` where appropriate error was not raised with an invalid level name (GH20925)
- Bug in `interval_range()` when `start/periods` or `end/periods` are specified with float `start` or `end` (GH21161)
- Bug in `MultiIndex.set_names()` where error raised for a `MultiIndex` with `nlevels == 1` (GH21149)
- Bug in `IntervalIndex` constructors where creating an `IntervalIndex` from categorical data was not fully supported (GH21243, GH21253)
- Bug in `MultiIndex.sort_index()` which was not guaranteed to sort correctly with `level=1`; this was also causing data misalignment in particular `DataFrame.stack()` operations (GH20994, GH20945, GH21052)

Plotting

- New keywords (`sharex`, `sharey`) to turn on/off sharing of x/y-axis by subplots generated with `pandas.DataFrame().groupby().boxplot()` (GH20968)

I/O

- Bug in IO methods specifying `compression='zip'` which produced uncompressed zip archives (GH17778, GH21144)
- Bug in `DataFrame.to_stata()` which prevented exporting DataFrames to buffers and most file-like objects (GH21041)
- Bug in `read_stata()` and `StataReader` which did not correctly decode utf-8 strings on Python 3 from Stata 14 files (dta version 118) (GH21244)
- Bug in IO JSON `read_json()` reading empty JSON schema with `orient='table'` back to `DataFrame` caused an error (GH21287)

Reshaping

- Bug in `concat()` where error was raised in concatenating `Series` with numpy scalar and tuple names (GH21015)
- Bug in `concat()` warning message providing the wrong guidance for future behavior (GH21101)

Other

- Tab completion on `Index` in IPython no longer outputs deprecation warnings (GH21125)
- Bug preventing pandas being used on Windows without C++ redistributable installed (GH21106)

8.3.5 What's new in 0.23.0 (May 15, 2018)

{{ header }}

This is a major release from 0.22.0 and includes a number of API changes, deprecations, new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

- *Round-trippable JSON format with 'table' orient.*
- *Instantiation from dicts respects order for Python 3.6+.*
- *Dependent column arguments for assign.*
- *Merging / sorting on a combination of columns and index levels.*
- *Extending pandas with custom types.*
- *Excluding unobserved categories from groupby.*
- *Changes to make output shape of DataFrame.apply consistent.*

Check the *API Changes* and *deprecations* before updating.

Warning: Starting January 1, 2019, pandas feature releases will support Python 3 only. See [Dropping Python 2.7](#) for more.

What's new in v0.23.0

- *New features*
 - *JSON read/write round-trippable with orient='table'*
 - *.assign() accepts dependent arguments*
 - *Merging on a combination of columns and index levels*
 - *Sorting by a combination of columns and index levels*
 - *Extending pandas with custom types (experimental)*
 - *New observed keyword for excluding unobserved categories in groupby*
 - *Rolling/Expanding.apply() accepts raw=False to pass a Series to the function*
 - *DataFrame.interpolate has gained the limit_area kwarg*
 - *get_dummies now supports dtype argument*
 - *Timedelta mod method*
 - *.rank() handles inf values when NaN are present*
 - *Series.str.cat has gained the join kwarg*
 - *DataFrame.astype performs column-wise conversion to Categorical*
 - *Other enhancements*
- *Backwards incompatible API changes*
 - *Dependencies have increased minimum versions*

- *Instantiation from dicts preserves dict insertion order for python 3.6+*
- *Deprecate Panel*
- *pandas.core.common removals*
- *Changes to make output of DataFrame.apply consistent*
- *Concatenation will no longer sort*
- *Build changes*
- *Index division by zero fills correctly*
- *Extraction of matching patterns from strings*
- *Default value for the ordered parameter of CategoricalDtype*
- *Better pretty-printing of DataFrames in a terminal*
- *Datetimelike API changes*
- *Other API changes*
- *Deprecations*
- *Removal of prior version deprecations/changes*
- *Performance improvements*
- *Documentation changes*
- *Bug fixes*
 - *Categorical*
 - *Datetimelike*
 - *Timedelta*
 - *Timezones*
 - *Offsets*
 - *Numeric*
 - *Strings*
 - *Indexing*
 - *MultiIndex*
 - *I/O*
 - *Plotting*
 - *Groupby/resample/rolling*
 - *Sparse*
 - *Reshaping*
 - *Other*
- *Contributors*

New features

JSON read/write round-trippable with orient='table'

A `DataFrame` can now be written to and subsequently read back via JSON while preserving metadata through usage of the `orient='table'` argument (see [GH18912](#) and [GH9146](#)). Previously, none of the available `orient` values guaranteed the preservation of dtypes and index names, amongst other metadata.

```
In [1]: df = pd.DataFrame({'foo': [1, 2, 3, 4],
...:                      'bar': ['a', 'b', 'c', 'd'],
...:                      'baz': pd.date_range('2018-01-01', freq='d', periods=4),
...:                      'qux': pd.Categorical(['a', 'b', 'c', 'c'])},
...:                      index=pd.Index(range(4), name='idx'))
...:
```

```
In [2]: df
Out[2]:
```

	foo	bar	baz	qux
idx				
0	1	a	2018-01-01	a
1	2	b	2018-01-02	b
2	3	c	2018-01-03	c
3	4	d	2018-01-04	c

```
[4 rows x 4 columns]
```

```
In [3]: df.dtypes
Out[3]:
```

foo	int64
bar	object
baz	datetime64[ns]
qux	category

```
Length: 4, dtype: object
```

```
In [4]: df.to_json('test.json', orient='table')
```

```
In [5]: new_df = pd.read_json('test.json', orient='table')
```

```
In [6]: new_df
Out[6]:
```

	foo	bar	baz	qux
idx				
0	1	a	2018-01-01	a
1	2	b	2018-01-02	b
2	3	c	2018-01-03	c
3	4	d	2018-01-04	c

```
[4 rows x 4 columns]
```

```
In [7]: new_df.dtypes
Out[7]:
```

foo	int64
bar	object
baz	datetime64[ns]
qux	category

```
Length: 4, dtype: object
```

Please note that the string *index* is not supported with the round trip format, as it is used by default in `write_json` to indicate a missing index name.

```
In [8]: df.index.name = 'index'
```

```
In [9]: df.to_json('test.json', orient='table')
```

```
In [10]: new_df = pd.read_json('test.json', orient='table')
```

```
In [11]: new_df
```

```
Out[11]:
```

```
   foo bar      baz qux
0    1  a 2018-01-01  a
1    2  b 2018-01-02  b
2    3  c 2018-01-03  c
3    4  d 2018-01-04  c
```

```
[4 rows x 4 columns]
```

```
In [12]: new_df.dtypes
```

```
Out[12]:
```

```
foo          int64
bar          object
baz  datetime64[ns]
qux          category
Length: 4, dtype: object
```

`.assign()` accepts dependent arguments

The `DataFrame.assign()` now accepts dependent keyword arguments for python version later than 3.6 (see also [PEP 468](#)). Later keyword arguments may now refer to earlier ones if the argument is a callable. See the [documentation here](#) ([GH14207](#))

```
In [13]: df = pd.DataFrame({'A': [1, 2, 3]})
```

```
In [14]: df
```

```
Out[14]:
```

```
   A
0  1
1  2
2  3
```

```
[3 rows x 1 columns]
```

```
In [15]: df.assign(B=df.A, C=lambda x: x['A'] + x['B'])
```

```
Out[15]:
```

```
   A  B  C
0  1  1  2
1  2  2  4
2  3  3  6
```

```
[3 rows x 3 columns]
```

Warning: This may subtly change the behavior of your code when you're using `.assign()` to update an existing column. Previously, callables referring to other variables being updated would get the "old" values

Previous behavior:

```
In [2]: df = pd.DataFrame({"A": [1, 2, 3]})

In [3]: df.assign(A=lambda df: df.A + 1, C=lambda df: df.A * -1)
Out[3]:
   A  C
0  2 -1
1  3 -2
2  4 -3
```

New behavior:

```
In [16]: df.assign(A=df.A + 1, C=lambda df: df.A * -1)
Out[16]:
   A  C
0  2 -2
1  3 -3
2  4 -4

[3 rows x 2 columns]
```

Merging on a combination of columns and index levels

Strings passed to `DataFrame.merge()` as the `on`, `left_on`, and `right_on` parameters may now refer to either column names or index level names. This enables merging `DataFrame` instances on a combination of index levels and columns without resetting indexes. See the *Merge on columns and levels* documentation section. (GH14355)

```
In [17]: left_index = pd.Index(['K0', 'K0', 'K1', 'K2'], name='key1')

In [18]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2', 'A3'],
.....:                       'B': ['B0', 'B1', 'B2', 'B3'],
.....:                       'key2': ['K0', 'K1', 'K0', 'K1']},
.....:                       index=left_index)
.....:

In [19]: right_index = pd.Index(['K0', 'K1', 'K2', 'K2'], name='key1')

In [20]: right = pd.DataFrame({'C': ['C0', 'C1', 'C2', 'C3'],
.....:                          'D': ['D0', 'D1', 'D2', 'D3'],
.....:                          'key2': ['K0', 'K0', 'K0', 'K1']},
.....:                          index=right_index)
.....:

In [21]: left.merge(right, on=['key1', 'key2'])
Out[21]:
   A  B key2  C  D
key1
```

(continues on next page)

(continued from previous page)

```
K0  A0  B0  K0  C0  D0
K1  A2  B2  K0  C1  D1
K2  A3  B3  K1  C3  D3
```

```
[3 rows x 5 columns]
```

Sorting by a combination of columns and index levels

Strings passed to `DataFrame.sort_values()` as the `by` parameter may now refer to either column names or index level names. This enables sorting `DataFrame` instances by a combination of index levels and columns without resetting indexes. See the *Sorting by Indexes and Values* documentation section. (GH14353)

```
# Build MultiIndex
```

```
In [22]: idx = pd.MultiIndex.from_tuples([('a', 1), ('a', 2), ('a', 2),
.....:                                  ('b', 2), ('b', 1), ('b', 1)])
.....:
```

```
In [23]: idx.names = ['first', 'second']
```

```
# Build DataFrame
```

```
In [24]: df_multi = pd.DataFrame({'A': np.arange(6, 0, -1)},
.....:                           index=idx)
.....:
```

```
In [25]: df_multi
```

```
Out[25]:
```

```
      A
first second
a      1      6
      2      5
      2      4
b      2      3
      1      2
      1      1
```

```
[6 rows x 1 columns]
```

```
# Sort by 'second' (index) and 'A' (column)
```

```
In [26]: df_multi.sort_values(by=['second', 'A'])
```

```
Out[26]:
```

```
      A
first second
b      1      1
      1      2
a      1      6
b      2      3
a      2      4
      2      5
```

```
[6 rows x 1 columns]
```

Extending pandas with custom types (experimental)

Pandas now supports storing array-like objects that aren't necessarily 1-D NumPy arrays as columns in a DataFrame or values in a Series. This allows third-party libraries to implement extensions to NumPy's types, similar to how pandas implemented categoricals, datetimes with timezones, periods, and intervals.

As a demonstration, we'll use `cyberpandas`, which provides an `IPArray` type for storing ip addresses.

```
In [1]: from cyberpandas import IPArray

In [2]: values = IPArray([
...:     0,
...:     3232235777,
...:     42540766452641154071740215577757643572
...: ])
...:
...:
```

`IPArray` isn't a normal 1-D NumPy array, but because it's a pandas *ExtensionArray*, it can be stored properly inside pandas' containers.

```
In [3]: ser = pd.Series(values)

In [4]: ser
Out[4]:
0          0.0.0.0
1      192.168.1.1
2  2001:db8:85a3::8a2e:370:7334
dtype: ip
```

Notice that the dtype is `ip`. The missing value semantics of the underlying array are respected:

```
In [5]: ser.isna()
Out[5]:
0     True
1    False
2    False
dtype: bool
```

For more, see the *extension types* documentation. If you build an extension array, publicize it on our *ecosystem page*.

New observed keyword for excluding unobserved categories in groupby

Grouping by a categorical includes the unobserved categories in the output. When grouping by multiple categorical columns, this means you get the cartesian product of all the categories, including combinations where there are no observations, which can result in a large number of groups. We have added a keyword `observed` to control this behavior, it defaults to `observed=False` for backward-compatibility. (GH14942, GH8138, GH15217, GH17594, GH8669, GH20583, GH20902)

```
In [27]: cat1 = pd.Categorical(["a", "a", "b", "b"],
...:                           categories=["a", "b", "z"], ordered=True)
...:
```

(continues on next page)

(continued from previous page)

```
In [28]: cat2 = pd.Categorical(["c", "d", "c", "d"],
.....:                        categories=["c", "d", "y"], ordered=True)
.....:

In [29]: df = pd.DataFrame({"A": cat1, "B": cat2, "values": [1, 2, 3, 4]})

In [30]: df['C'] = ['foo', 'bar'] * 2

In [31]: df
Out[31]:
   A B  values  C
0  a c        1 foo
1  a d        2 bar
2  b c        3 foo
3  b d        4 bar

[4 rows x 4 columns]
```

To show all values, the previous behavior:

```
In [32]: df.groupby(['A', 'B', 'C'], observed=False).count()
Out[32]:
      values
A B C
a c bar    NaN
   foo    1.0
   d bar    1.0
   foo    NaN
   y bar    NaN
   foo    NaN
b c bar    NaN
   foo    1.0
   d bar    1.0
   foo    NaN
   y bar    NaN
   foo    NaN
z c bar    NaN
   foo    NaN
   d bar    NaN
   foo    NaN
   y bar    NaN
   foo    NaN

[18 rows x 1 columns]
```

To show only observed values:

```
In [33]: df.groupby(['A', 'B', 'C'], observed=True).count()
Out[33]:
      values
A B C
```

(continues on next page)

(continued from previous page)

```
a c foo      1
d bar       1
b c foo      1
d bar       1

[4 rows x 1 columns]
```

For pivoting operations, this behavior is *already* controlled by the `dropna` keyword:

```
In [34]: cat1 = pd.Categorical(["a", "a", "b", "b"],
.....:                        categories=["a", "b", "z"], ordered=True)
.....:

In [35]: cat2 = pd.Categorical(["c", "d", "c", "d"],
.....:                        categories=["c", "d", "y"], ordered=True)
.....:

In [36]: df = pd.DataFrame({"A": cat1, "B": cat2, "values": [1, 2, 3, 4]})

In [37]: df
Out[37]:
   A B  values
0  a c      1

Rolling/Expanding.apply() accepts raw=False to pass a Series to the function

`Series.rolling().apply()`, `DataFrame.rolling().apply()`, `Series.expanding().apply()`, and `DataFrame.expanding().apply()` have gained a `raw=None` parameter. This is similar to `DataFrame.apply()`. This parameter, if `True` allows one to send a `np.ndarray` to the applied function. If `False` a `Series` will be passed. The default is `None`, which preserves backward compatibility, so this will default to `True`, sending an `np.ndarray`. In a future version the default will be changed to `False`, sending a `Series`. (GH5071, GH20584)

```
In [40]: s = pd.Series(np.arange(5), np.arange(5) + 1)
```

```
In [41]: s
```

```
Out [41]:
```

```
1    0
2    1
3    2
4    3
5    4
```

```
Length: 5, dtype: int64
```

Pass a Series:

```
In [42]: s.rolling(2, min_periods=1).apply(lambda x: x.iloc[-1], raw=False)
```

```
Out [42]:
```

```
1    0.0
2    1.0
3    2.0
4    3.0
5    4.0
```

```
Length: 5, dtype: float64
```

Mimic the original behavior of passing a ndarray:

```
In [43]: s.rolling(2, min_periods=1).apply(lambda x: x[-1], raw=True)
```

```
Out [43]:
```

```
1    0.0
2    1.0
3    2.0
4    3.0
5    4.0
```

```
Length: 5, dtype: float64
```

DataFrame.interpolate has gained the limit_area kwarg

DataFrame.interpolate() has gained a limit_area parameter to allow further control of which NaNs are replaced. Use limit_area='inside' to fill only NaNs surrounded by valid values or use limit_area='outside' to fill only NaNs outside the existing valid values while preserving those inside. (GH16284) See the [full documentation here](#).

```
In [44]: ser = pd.Series([np.nan, np.nan, 5, np.nan, np.nan,
.....:                  np.nan, 13, np.nan, np.nan])
.....:
```

```
In [45]: ser
```

```
Out [45]:
```

```
0    NaN
1    NaN
2    5.0
3    NaN
4    NaN
5    NaN
6    13.0
7    NaN
8    NaN
Length: 9, dtype: float64
```

Fill one consecutive inside value in both directions

```
In [46]: ser.interpolate(limit_direction='both', limit_area='inside', limit=1)
```

```
Out [46]:
```

```
0    NaN
1    NaN
2    5.0
3    7.0
4    NaN
5    11.0
6    13.0
7    NaN
8    NaN
Length: 9, dtype: float64
```

Fill all consecutive outside values backward

```
In [47]: ser.interpolate(limit_direction='backward', limit_area='outside')
```

```
Out [47]:
```

```
0    5.0
1    5.0
2    5.0
3    NaN
4    NaN
5    NaN
6    13.0
7    NaN
8    NaN
Length: 9, dtype: float64
```

Fill all consecutive outside values in both directions

```
In [48]: ser.interpolate(limit_direction='both', limit_area='outside')
Out[48]:
0      5.0
1      5.0
2      5.0
3      NaN
4      NaN
5      NaN
6     13.0
7     13.0
8     13.0
Length: 9, dtype: float64
```

get_dummies now supports dtype argument

The `get_dummies()` now accepts a `dtype` argument, which specifies a dtype for the new columns. The default remains `uint8`. ([GH18330](#))

```
In [49]: df = pd.DataFrame({'a': [1, 2], 'b': [3, 4], 'c': [5, 6]})
```

```
In [50]: pd.get_dummies(df, columns=['c']).dtypes
```

```
Out[50]:
a      int64
b      int64
c_5    uint8
c_6    uint8
Length: 4, dtype: object
```

```
In [51]: pd.get_dummies(df, columns=['c'], dtype=bool).dtypes
```

```
Out[51]:
a      int64
b      int64
c_5    bool
c_6    bool
Length: 4, dtype: object
```

Timedelta mod method

`mod (%)` and `divmod` operations are now defined on `Timedelta` objects when operating with either `timedelta`-like or with numeric arguments. See the *documentation here*. ([GH19365](#))

```
In [52]: td = pd.Timedelta(hours=37)

In [53]: td % pd.Timedelta(minutes=45)
Out[53]: Timedelta('0 days 00:15:00')
```

.rank() handles inf values when NaN are present

In previous versions, .rank() would assign inf elements NaN as their ranks. Now ranks are calculated properly. (GH6945)

```
In [54]: s = pd.Series([-np.inf, 0, 1, np.nan, np.inf])

In [55]: s
Out[55]:
0    -inf
1     0.0
2     1.0
3     NaN
4     inf
Length: 5, dtype: float64
```

Previous behavior:

```
In [11]: s.rank()
Out[11]:
0     1.0
1     2.0
2     3.0
3     NaN
4     NaN
dtype: float64
```

Current behavior:

```
In [56]: s.rank()
Out[56]:
0     1.0
1     2.0
2     3.0
3     NaN
4     4.0
Length: 5, dtype: float64
```

Furthermore, previously if you rank inf or -inf values together with NaN values, the calculation won't distinguish NaN from infinity when using 'top' or 'bottom' argument.

```
In [57]: s = pd.Series([np.nan, np.nan, -np.inf, -np.inf])

In [58]: s
Out[58]:
0     NaN
1     NaN
2    -inf
3    -inf
Length: 4, dtype: float64
```

Previous behavior:

```
In [15]: s.rank(na_option='top')
Out[15]:
0    2.5
1    2.5
2    2.5
3    2.5
dtype: float64
```

Current behavior:

```
In [59]: s.rank(na_option='top')
Out[59]:
0    1.5
1    1.5
2    3.5
3    3.5
Length: 4, dtype: float64
```

These bugs were squashed:

- Bug in `DataFrame.rank()` and `Series.rank()` when `method='dense'` and `pct=True` in which percentile ranks were not being used with the number of distinct observations ([GH15630](#))
- Bug in `Series.rank()` and `DataFrame.rank()` when `ascending='False'` failed to return correct ranks for infinity if `NaN` were present ([GH19538](#))
- Bug in `DataFrameGroupBy.rank()` where ranks were incorrect when both infinity and `NaN` were present ([GH20561](#))

`Series.str.cat` has gained the `join` kwarg

Previously, `Series.str.cat()` did not – in contrast to most of `pandas` – align `Series` on their index before concatenation (see [GH18657](#)). The method has now gained a keyword `join` to control the manner of alignment, see examples below and [here](#).

In v.0.23 `join` will default to `None` (meaning no alignment), but this default will change to `'left'` in a future version of `pandas`.

```
In [60]: s = pd.Series(['a', 'b', 'c', 'd'])
```

```
In [61]: t = pd.Series(['b', 'd', 'e', 'c'], index=[1, 3, 4, 2])
```

```
In [62]: s.str.cat(t)
Out[62]:
0    ab
1    bd
2    ce
3    dc
Length: 4, dtype: object
```

```
In [63]: s.str.cat(t, join='left', na_rep='-')
Out[63]:
0    a-
1    bb
2    cc
```

```
3    dd
Length: 4, dtype: object
```

Furthermore, `Series.str.cat()` now works for `CategoricalIndex` as well (previously raised a `ValueError`; see [GH20842](#)).

DataFrame.astype performs column-wise conversion to Categorical

`DataFrame.astype()` can now perform column-wise conversion to `Categorical` by supplying the string `'category'` or a `CategoricalDtype`. Previously, attempting this would raise a `NotImplementedError`. See the *Object creation* section of the documentation for more details and examples. ([GH12860](#), [GH18099](#))

Supplying the string `'category'` performs column-wise conversion, with only labels appearing in a given column set as categories:

```
In [64]: df = pd.DataFrame({'A': list('abca'), 'B': list('bccd')})
```

```
In [65]: df = df.astype('category')
```

```
In [66]: df['A'].dtype
```

```
Out[66]: CategoricalDtype(categories=['a', 'b', 'c'], ordered=False)
```

```
In [67]: df['B'].dtype
```

```
Out[67]: CategoricalDtype(categories=['b', 'c', 'd'], ordered=False)
```

Supplying a `CategoricalDtype` will make the categories in each column consistent with the supplied dtype:

```
In [68]: from pandas.api.types import CategoricalDtype
```

```
In [69]: df = pd.DataFrame({'A': list('abca'), 'B': list('bccd')})
```

```
In [70]: cdt = CategoricalDtype(categories=list('abcd'), ordered=True)
```

```
In [71]: df = df.astype(cdt)
```

```
In [72]: df['A'].dtype
```

```
Out[72]: CategoricalDtype(categories=['a', 'b', 'c', 'd'], ordered=True)
```

```
In [73]: df['B'].dtype
```

```
Out[73]: CategoricalDtype(categories=['a', 'b', 'c', 'd'], ordered=True)
```

Other enhancements

- Unary `+` now permitted for `Series` and `DataFrame` as numeric operator ([GH16073](#))
- Better support for `to_excel()` output with the `xlsxwriter` engine. ([GH16149](#))
- `pandas.tseries.frequencies.to_offset()` now accepts leading `'+'` signs e.g. `'+1h'`. ([GH18171](#))
- `MultiIndex.unique()` now supports the `level=` argument, to get unique values from a specific index level ([GH17896](#))
- `pandas.io.formats.style.Styler` now has method `hide_index()` to determine whether the index will be rendered in output ([GH14194](#))
- `pandas.io.formats.style.Styler` now has method `hide_columns()` to determine whether columns will be hidden in output ([GH14194](#))

- Improved wording of `ValueError` raised in `to_datetime()` when `unit=` is passed with a non-convertible value (GH14350)
- `Series.fillna()` now accepts a `Series` or a `dict` as a `value` for a categorical dtype (GH17033)
- `pandas.read_clipboard()` updated to use `qtpy`, falling back to `PyQt5` and then `PyQt4`, adding compatibility with Python3 and multiple `python-qt` bindings (GH17722)
- Improved wording of `ValueError` raised in `read_csv()` when the `usecols` argument cannot match all columns. (GH17301)
- `DataFrame.corrwith()` now silently drops non-numeric columns when passed a `Series`. Before, an exception was raised (GH18570).
- `IntervalIndex` now supports time zone aware `Interval` objects (GH18537, GH18538)
- `Series()` / `DataFrame()` tab completion also returns identifiers in the first level of a `MultiIndex()`. (GH16326)
- `read_excel()` has gained the `nrows` parameter (GH16645)
- `DataFrame.append()` can now in more cases preserve the type of the calling dataframe's columns (e.g. if both are `CategoricalIndex`) (GH18359)
- `DataFrame.to_json()` and `Series.to_json()` now accept an `index` argument which allows the user to exclude the index from the JSON output (GH17394)
- `IntervalIndex.to_tuples()` has gained the `na_tuple` parameter to control whether NA is returned as a tuple of NA, or NA itself (GH18756)
- `Categorical.rename_categories`, `CategoricalIndex.rename_categories` and `Series.cat.rename_categories` can now take a callable as their argument (GH18862)
- `Interval` and `IntervalIndex` have gained a `length` attribute (GH18789)
- `Resampler` objects now have a functioning `pipe` method. Previously, calls to `pipe` were diverted to the `mean` method (GH17905).
- `is_scalar()` now returns `True` for `DateOffset` objects (GH18943).
- `DataFrame.pivot()` now accepts a list for the `values=` kwarg (GH17160).
- Added `pandas.api.extensions.register_dataframe_accessor()`, `pandas.api.extensions.register_series_accessor()`, and `pandas.api.extensions.register_index_accessor()`, accessor for libraries downstream of pandas to register custom accessors like `.cat` on pandas objects. See *Registering Custom Accessors* for more (GH14781).
- `IntervalIndex.astype` now supports conversions between subtypes when passed an `IntervalDtype` (GH19197)
- `IntervalIndex` and its associated constructor methods (`from_arrays`, `from_breaks`, `from_tuples`) have gained a `dtype` parameter (GH19262)
- Added `pandas.core.groupby.SeriesGroupBy.is_monotonic_increasing()` and `pandas.core.groupby.SeriesGroupBy.is_monotonic_decreasing()` (GH17015)
- For subclassed `DataFrames`, `DataFrame.apply()` will now preserve the `Series` subclass (if defined) when passing the data to the applied function (GH19822)
- `DataFrame.from_dict()` now accepts a `columns` argument that can be used to specify the column names when `orient='index'` is used (GH18529)
- Added option `display.html.use_mathjax` so `MathJax` can be disabled when rendering tables in Jupyter notebooks (GH19856, GH19824)

- `DataFrame.replace()` now supports the `method` parameter, which can be used to specify the replacement method when `to_replace` is a scalar, list or tuple and `value` is `None` (GH19632)
- `Timestamp.month_name()`, `DatetimeIndex.month_name()`, and `Series.dt.month_name()` are now available (GH12805)
- `Timestamp.day_name()` and `DatetimeIndex.day_name()` are now available to return day names with a specified locale (GH12806)
- `DataFrame.to_sql()` now performs a multi-value insert if the underlying connection supports itk rather than inserting row by row. SQLAlchemy dialects supporting multi-value inserts include: `mysql`, `postgresql`, `sqlite` and any dialect with `supports_multivalues_insert`. (GH14315, GH8953)
- `read_html()` now accepts a `displayed_only` keyword argument to controls whether or not hidden elements are parsed (`True` by default) (GH20027)
- `read_html()` now reads all `<tbody>` elements in a `<table>`, not just the first. (GH20690)
- `quantile()` and `quantile()` now accept the `interpolation` keyword, `linear` by default (GH20497)
- zip compression is supported via `compression=zip` in `DataFrame.to_pickle()`, `Series.to_pickle()`, `DataFrame.to_csv()`, `Series.to_csv()`, `DataFrame.to_json()`, `Series.to_json()`. (GH17778)
- `WeekOfMonth` constructor now supports `n=0` (GH20517).
- `DataFrame` and `Series` now support matrix multiplication (`@`) operator (GH10259) for `Python>=3.5`
- Updated `DataFrame.to_gbq()` and `pandas.read_gbq()` signature and documentation to reflect changes from the Pandas-GBQ library version 0.4.0. Adds intersphinx mapping to Pandas-GBQ library. (GH20564)
- Added new writer for exporting Stata dta files in version 117, `StataWriter117`. This format supports exporting strings up to 2,000,000 characters (GH16450)
- `to_hdf()` and `read_hdf()` now accept an `errors` keyword argument to control encoding error handling (GH20835)
- `cut()` has gained the `duplicates='raise'|'drop'` option to control whether to raise on duplicated edges (GH20947)
- `date_range()`, `timedelta_range()`, and `interval_range()` now return a linearly spaced index if `start`, `stop`, and `periods` are specified, but `freq` is not. (GH20808, GH20983, GH20976)

Backwards incompatible API changes

Dependencies have increased minimum versions

We have updated our minimum supported versions of dependencies (GH15184). If installed, we now require:

Package	Minimum Version	Required	Issue
python-dateutil	2.5.0	X	GH15184
openpyxl	2.4.0		GH15184
beautifulsoup4	4.2.1		GH20082
setuptools	24.2.0		GH20698

Instantiation from dicts preserves dict insertion order for python 3.6+

Until Python 3.6, dicts in Python had no formally defined ordering. For Python version 3.6 and later, dicts are ordered by insertion order, see [PEP 468](#). Pandas will use the dict's insertion order, when creating a `Series` or `DataFrame` from a dict and you're using Python version 3.6 or higher. ([GH19884](#))

Previous behavior (and current behavior if on Python < 3.6):

```
In [16]: pd.Series({'Income': 2000,
.....:             'Expenses': -1500,
.....:             'Taxes': -200,
.....:             'Net result': 300})
Out[16]:
Expenses    -1500
Income      2000
Net result   300
Taxes       -200
dtype: int64
```

Note the Series above is ordered alphabetically by the index values.

New behavior (for Python >= 3.6):

```
In [74]: pd.Series({'Income': 2000,
.....:             'Expenses': -1500,
.....:             'Taxes': -200,
.....:             'Net result': 300})
.....:
Out[74]:
Income      2000
Expenses    -1500
Taxes       -200
Net result   300
Length: 4, dtype: int64
```

Notice that the Series is now ordered by insertion order. This new behavior is used for all relevant pandas types (`Series`, `DataFrame`, `SparseSeries` and `SparseDataFrame`).

If you wish to retain the old behavior while using Python >= 3.6, you can use `.sort_index()`:

```
In [75]: pd.Series({'Income': 2000,
.....:             'Expenses': -1500,
.....:             'Taxes': -200,
.....:             'Net result': 300}).sort_index()
.....:
Out[75]:
Expenses    -1500
Income      2000
Net result   300
Taxes       -200
Length: 4, dtype: int64
```

Deprecate Panel

Panel was deprecated in the 0.20.x release, showing as a `DeprecationWarning`. Using Panel will now show a `FutureWarning`. The recommended way to represent 3-D data are with a `MultiIndex` on a `DataFrame` via the `to_frame()` or with the `xarray` package. Pandas provides a `to_xarray()` method to automate this conversion ([GH13563](#), [GH18324](#)).

```
In [75]: import pandas.util.testing as tm

In [76]: p = tm.makePanel()

In [77]: p
Out[77]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 3 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemC
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-05 00:00:00
Minor_axis axis: A to D
```

Convert to a `MultiIndex DataFrame`

```
In [78]: p.to_frame()
Out[78]:
```

major	minor	ItemA	ItemB	ItemC
2000-01-03	A	0.469112	0.721555	0.404705
	B	-1.135632	0.271860	-1.039268
	C	0.119209	0.276232	-1.344312
	D	-2.104569	0.113648	-0.109050
2000-01-04	A	-0.282863	-0.706771	0.577046
	B	1.212112	-0.424972	-0.370647
	C	-1.044236	-1.087401	0.844885
	D	-0.494929	-1.478427	1.643563
2000-01-05	A	-1.509059	-1.039575	-1.715002
	B	-0.173215	0.567020	-1.157892
	C	-0.861849	-0.673690	1.075770
	D	1.071804	0.524988	-1.469388

[12 rows x 3 columns]

Convert to an `xarray DataArray`

```
In [79]: p.to_xarray()
Out[79]:
<xarray.DataArray (items: 3, major_axis: 3, minor_axis: 4)>
array([[[ 0.469112, -1.135632,  0.119209, -2.104569],
        [-0.282863,  1.212112, -1.044236, -0.494929],
        [-1.509059, -0.173215, -0.861849,  1.071804]],

        [[ 0.721555,  0.27186 ,  0.276232,  0.113648],
        [-0.706771, -0.424972, -1.087401, -1.478427],
        [-1.039575,  0.56702 , -0.67369 ,  0.524988]],

        [[ 0.404705, -1.039268, -1.344312, -0.109050],
        [ 0.577046, -0.370647,  0.844885,  1.643563],
        [-1.715002, -1.157892,  1.075770, -1.469388]]])
```

(continues on next page)

(continued from previous page)

```

[[ 0.404705, -1.039268, -1.344312, -0.10905 ],
 [ 0.577046, -0.370647,  0.844885,  1.643563],
 [-1.715002, -1.157892,  1.07577 , -1.469388]]])
Coordinates:
* items      (items) object 'ItemA' 'ItemB' 'ItemC'
* major_axis (major_axis) datetime64[ns] 2000-01-03 2000-01-04 2000-01-05
* minor_axis (minor_axis) object 'A' 'B' 'C' 'D'

```

pandas.core.common removals

The following error & warning messages are removed from `pandas.core.common` (GH13634, GH19769):

- PerformanceWarning
- UnsupportedFunctionCall
- UnsortedIndexError
- AbstractMethodError

These are available from import from `pandas.errors` (since 0.19.0).

Changes to make output of `DataFrame.apply` consistent

`DataFrame.apply()` was inconsistent when applying an arbitrary user-defined-function that returned a list-like with `axis=1`. Several bugs and inconsistencies are resolved. If the applied function returns a `Series`, then pandas will return a `DataFrame`; otherwise a `Series` will be returned, this includes the case where a list-like (e.g. `tuple` or `list` is returned) (GH16353, GH17437, GH17970, GH17348, GH17892, GH18573, GH17602, GH18775, GH18901, GH18919).

```

In [76]: df = pd.DataFrame(np.tile(np.arange(3), 6).reshape(6, -1) + 1,
.....:                    columns=['A', 'B', 'C'])
.....:

In [77]: df
Out[77]:
   A  B  C
0  1  2  3
1  1  2  3
2  1  2  3
3  1  2  3
4  1  2  3
5  1  2  3

[6 rows x 3 columns]

```

Previous behavior: if the returned shape happened to match the length of original columns, this would return a `DataFrame`. If the return shape did not match, a `Series` with lists was returned.

```

In [3]: df.apply(lambda x: [1, 2, 3], axis=1)
Out[3]:
   A  B  C

```

(continues on next page)

(continued from previous page)

```
0 1 2 3
1 1 2 3
2 1 2 3
3 1 2 3
4 1 2 3
5 1 2 3
```

```
In [4]: df.apply(lambda x: [1, 2], axis=1)
```

```
Out[4]:
```

```
0 [1, 2]
1 [1, 2]
2 [1, 2]
3 [1, 2]
4 [1, 2]
5 [1, 2]
```

```
dtype: object
```

New behavior: When the applied function returns a list-like, this will now *always* return a **Series**.

```
In [78]: df.apply(lambda x: [1, 2, 3], axis=1)
```

```
Out[78]:
```

```
0 [1, 2, 3]
1 [1, 2, 3]
2 [1, 2, 3]
3 [1, 2, 3]
4 [1, 2, 3]
5 [1, 2, 3]
```

```
Length: 6, dtype: object
```

```
In [79]: df.apply(lambda x: [1, 2], axis=1)
```

```
Out[79]:
```

```
0 [1, 2]
1 [1, 2]
2 [1, 2]
3 [1, 2]
4 [1, 2]
5 [1, 2]
```

```
Length: 6, dtype: object
```

To have expanded columns, you can use `result_type='expand'`

```
In [80]: df.apply(lambda x: [1, 2, 3], axis=1, result_type='expand')
```

```
Out[80]:
```

```
0 1 2
0 1 2 3
1 1 2 3
2 1 2 3
3 1 2 3
4 1 2 3
5 1 2 3
```

```
[6 rows x 3 columns]
```

To broadcast the result across the original columns (the old behaviour for list-likes of the correct length),

you can use `result_type='broadcast'`. The shape must match the original columns.

```
In [81]: df.apply(lambda x: [1, 2, 3], axis=1, result_type='broadcast')
Out[81]:
   A  B  C
0  1  2  3
1  1  2  3
2  1  2  3
3  1  2  3
4  1  2  3
5  1  2  3

[6 rows x 3 columns]
```

Returning a `Series` allows one to control the exact return structure and column names:

```
In [82]: df.apply(lambda x: pd.Series([1, 2, 3], index=['D', 'E', 'F']), axis=1)
Out[82]:
   D  E  F
0  1  2  3
1  1  2  3
2  1  2  3
3  1  2  3
4  1  2  3
5  1  2  3

[6 rows x 3 columns]
```

Concatenation will no longer sort

In a future version of pandas `pandas.concat()` will no longer sort the non-concatenation axis when it is not already aligned. The current behavior is the same as the previous (sorting), but now a warning is issued when `sort` is not specified and the non-concatenation axis is not aligned (GH4588).

```
In [83]: df1 = pd.DataFrame({"a": [1, 2], "b": [1, 2]}, columns=['b', 'a'])
In [84]: df2 = pd.DataFrame({"a": [4, 5]})
In [85]: pd.concat([df1, df2])
Out[85]:
   a  b
0  1  1.0
1  2  2.0
0  4  NaN
1  5  NaN

[4 rows x 2 columns]
```

To keep the previous behavior (sorting) and silence the warning, pass `sort=True`

```
In [86]: pd.concat([df1, df2], sort=True)
Out[86]:
```

(continues on next page)

(continued from previous page)

```

   a   b
0  1  1.0
1  2  2.0
0  4  NaN
1  5  NaN

[4 rows x 2 columns]
```

To accept the future behavior (no sorting), pass `sort=False`

Note that this change also applies to `DataFrame.append()`, which has also received a `sort` keyword for controlling this behavior.

Build changes

- Building pandas for development now requires `cython >= 0.24` (GH18613)
- Building from source now explicitly requires `setuptools` in `setup.py` (GH18113)
- Updated conda recipe to be in compliance with conda-build 3.0+ (GH18002)

Index division by zero fills correctly

Division operations on `Index` and subclasses will now fill division of positive numbers by zero with `np.inf`, division of negative numbers by zero with `-np.inf` and `0 / 0` with `np.nan`. This matches existing `Series` behavior. (GH19322, GH19347)

Previous behavior:

```

In [6]: index = pd.Int64Index([-1, 0, 1])

In [7]: index / 0
Out[7]: Int64Index([0, 0, 0], dtype='int64')

# Previous behavior yielded different results depending on the type of zero in the
↳divisor
In [8]: index / 0.0
Out[8]: Float64Index([-inf, nan, inf], dtype='float64')

In [9]: index = pd.UInt64Index([0, 1])

In [10]: index / np.array([0, 0], dtype=np.uint64)
Out[10]: UInt64Index([0, 0], dtype='uint64')

In [11]: pd.RangeIndex(1, 5) / 0
ZeroDivisionError: integer division or modulo by zero
```

Current behavior:

```

In [87]: index = pd.Int64Index([-1, 0, 1])

# division by zero gives -infinity where negative,
# +infinity where positive, and NaN for 0 / 0
```

```
In [88]: index / 0
Out[88]: Float64Index([-inf, nan, inf], dtype='float64')

# The result of division by zero should not depend on
# whether the zero is int or float
In [89]: index / 0.0
Out[89]: Float64Index([-inf, nan, inf], dtype='float64')

In [90]: index = pd.UInt64Index([0, 1])

In [91]: index / np.array([0, 0], dtype=np.uint64)
Out[91]: Float64Index([nan, inf], dtype='float64')

In [92]: pd.RangeIndex(1, 5) / 0
Out[92]: Float64Index([inf, inf, inf, inf], dtype='float64')
```

Extraction of matching patterns from strings

By default, extracting matching patterns from strings with `str.extract()` used to return a `Series` if a single group was being extracted (a `DataFrame` if more than one group was extracted). As of Pandas 0.23.0 `str.extract()` always returns a `DataFrame`, unless `expand` is set to `False`. Finally, `None` was an accepted value for the `expand` parameter (which was equivalent to `False`), but now raises a `ValueError`. (GH11386)

Previous behavior:

```
In [1]: s = pd.Series(['number 10', '12 eggs'])
In [2]: extracted = s.str.extract(r'.*(\d\d).*')
In [3]: extracted
Out [3]:
0    10
1    12
dtype: object
In [4]: type(extracted)
Out [4]:
pandas.core.series.Series
```

New behavior:

```
In [93]: s = pd.Series(['number 10', '12 eggs'])
In [94]: extracted = s.str.extract(r'.*(\d\d).*')
In [95]: extracted
Out[95]:
      0
0    10
1    12

[2 rows x 1 columns]
In [96]: type(extracted)
```

```
Out[96]: pandas.core.frame.DataFrame
```

To restore previous behavior, simply set `expand` to `False`:

```
In [97]: s = pd.Series(['number 10', '12 eggs'])
```

```
In [98]: extracted = s.str.extract(r'.*(\d\d).*', expand=False)
```

```
In [99]: extracted
```

```
Out[99]:
```

```
0    10
```

```
1    12
```

```
Length: 2, dtype: object
```

```
In [100]: type(extracted)
```

```
Out[100]: pandas.core.series.Series
```

Default value for the ordered parameter of CategoricalDtype

The default value of the `ordered` parameter for `CategoricalDtype` has changed from `False` to `None` to allow updating of `categories` without impacting `ordered`. Behavior should remain consistent for downstream objects, such as `Categorical` ([GH18790](#))

In previous versions, the default value for the `ordered` parameter was `False`. This could potentially lead to the `ordered` parameter unintentionally being changed from `True` to `False` when users attempt to update `categories` if `ordered` is not explicitly specified, as it would silently default to `False`. The new behavior for `ordered=None` is to retain the existing value of `ordered`.

New behavior:

```
In [2]: from pandas.api.types import CategoricalDtype

In [3]: cat = pd.Categorical(list('abcaba'), ordered=True, categories=list('cba'))

In [4]: cat
Out[4]:
[a, b, c, a, b, a]
Categories (3, object): [c < b < a]

In [5]: cdt = CategoricalDtype(categories=list('cbad'))

In [6]: cat.astype(cdt)
Out[6]:
[a, b, c, a, b, a]
Categories (4, object): [c < b < a < d]
```

Notice in the example above that the converted `Categorical` has retained `ordered=True`. Had the default value for `ordered` remained as `False`, the converted `Categorical` would have become `unordered`, despite `ordered=False` never being explicitly specified. To change the value of `ordered`, explicitly pass it to the new dtype, e.g. `CategoricalDtype(categories=list('cbad'), ordered=False)`.

Note that the unintentional conversion of `ordered` discussed above did not arise in previous versions due to separate bugs that prevented `astype` from doing any type of category to category conversion ([GH10696](#), [GH18593](#)). These bugs have been fixed in this release, and motivated changing the default value of `ordered`.

Better pretty-printing of DataFrames in a terminal

Previously, the default value for the maximum number of columns was `pd.options.display.max_columns=20`. This meant that relatively wide data frames would not fit within the terminal width, and pandas would introduce line breaks to display these 20 columns. This resulted in an output that was relatively difficult to read:

```
Terminal
[In [1]: import pandas as pd
[In [2]: import numpy as np
[In [3]: pd.DataFrame(np.random.rand(5, 10))
Out[3]:
   0      1      2      3      4      5      6  \
0  0.146401  0.933153  0.577028  0.617467  0.195179  0.929250  0.603845
1  0.670827  0.885104  0.152909  0.028042  0.016283  0.843786  0.824537
2  0.261850  0.370457  0.281256  0.461355  0.094714  0.763125  0.086964
3  0.789373  0.357872  0.894594  0.434197  0.266116  0.061527  0.375119
4  0.256396  0.407358  0.740593  0.820019  0.962911  0.647236  0.323111

   7      8      9
0  0.004801  0.659965  0.989170
1  0.517137  0.673154  0.829435
2  0.154479  0.463588  0.252917
3  0.266601  0.146791  0.776635
4  0.607805  0.209150  0.374892

In [4]: █
```

If Python runs in a terminal, the maximum number of columns is now determined automatically so that the printed data frame fits within the current terminal width (`pd.options.display.max_columns=0`) (GH17023). If Python runs as a Jupyter kernel (such as the Jupyter QtConsole or a Jupyter notebook, as well as in many IDEs), this value cannot be inferred automatically and is thus set to `20` as in previous versions. In a terminal, this results in a much nicer output:

```
Terminal
[In [1]: import pandas as pd

[In [2]: import numpy as np

[In [3]: pd.DataFrame(np.random.rand(5, 10))
Out[3]:
      0         1         2         3  ...         6         7         8         9
0  0.107275  0.394007  0.024795  0.551991  ...  0.689395  0.680411  0.586967  0.293906
1  0.466061  0.402324  0.430669  0.193347  ...  0.621158  0.756752  0.217444  0.558097
2  0.910215  0.063291  0.192110  0.012359  ...  0.025301  0.185118  0.820985  0.208302
3  0.491853  0.612078  0.791199  0.588150  ...  0.841104  0.612280  0.025687  0.443693
4  0.171760  0.921853  0.063030  0.448301  ...  0.268901  0.292862  0.420582  0.608949

[5 rows x 10 columns]

In [4]: █
```

Note that if you don't like the new default, you can always set this option yourself. To revert to the old setting, you can run this line:

```
pd.options.display.max_columns = 20
```

Datetimelike API changes

- The default `Timedelta` constructor now accepts an ISO 8601 `Duration` string as an argument (GH19040)
- Subtracting `NaT` from a `Series` with `dtype='datetime64[ns]'` returns a `Series` with `dtype='timedelta64[ns]'` instead of `dtype='datetime64[ns]'` (GH18808)

- Addition or subtraction of NaT from `TimedeltaIndex` will return `TimedeltaIndex` instead of `DatetimeIndex` (GH19124)
- `DatetimeIndex.shift()` and `TimedeltaIndex.shift()` will now raise `NullFrequencyError` (which subclasses `ValueError`, which was raised in older versions) when the index object frequency is `None` (GH19147)
- Addition and subtraction of NaN from a `Series` with `dtype='timedelta64[ns]'` will raise a `TypeError` instead of treating the NaN as NaT (GH19274)
- NaT division with `datetime.timedelta` will now return NaN instead of raising (GH17876)
- Operations between a `Series` with `dtype='datetime64[ns]'` and a `PeriodIndex` will correctly raise `TypeError` (GH18850)
- Subtraction of `Series` with timezone-aware `dtype='datetime64[ns]'` with mis-matched timezones will raise `TypeError` instead of `ValueError` (GH18817)
- `Timestamp` will no longer silently ignore unused or invalid `tz` or `tzinfo` keyword arguments (GH17690)
- `Timestamp` will no longer silently ignore invalid `freq` arguments (GH5168)
- `CacheableOffset` and `WeekDay` are no longer available in the `pandas.tseries.offsets` module (GH17830)
- `pandas.tseries.frequencies.get_freq_group()` and `pandas.tseries.frequencies.DAYS` are removed from the public API (GH18034)
- `Series.truncate()` and `DataFrame.truncate()` will raise a `ValueError` if the index is not sorted instead of an unhelpful `KeyError` (GH17935)
- `Series.first` and `DataFrame.first` will now raise a `TypeError` rather than `NotImplementedError` when index is not a `DatetimeIndex` (GH20725).
- `Series.last` and `DataFrame.last` will now raise a `TypeError` rather than `NotImplementedError` when index is not a `DatetimeIndex` (GH20725).
- Restricted `DateOffset` keyword arguments. Previously, `DateOffset` subclasses allowed arbitrary keyword arguments which could lead to unexpected behavior. Now, only valid arguments will be accepted. (GH17176, GH18226).
- `pandas.merge()` provides a more informative error message when trying to merge on timezone-aware and timezone-naive columns (GH15800)
- For `DatetimeIndex` and `TimedeltaIndex` with `freq=None`, addition or subtraction of integer-dtyped array or `Index` will raise `NullFrequencyError` instead of `TypeError` (GH19895)
- `Timestamp` constructor now accepts a `nanosecond` keyword or positional argument (GH18898)
- `DatetimeIndex` will now raise an `AttributeError` when the `tz` attribute is set after instantiation (GH3746)
- `DatetimeIndex` with a `pytz` timezone will now return a consistent `pytz` timezone (GH18595)

Other API changes

- `Series.astype()` and `Index.astype()` with an incompatible `dtype` will now raise a `TypeError` rather than a `ValueError` (GH18231)
- `Series` construction with an `object` dtyped tz-aware `datetime` and `dtype=object` specified, will now return an `object` dtyped `Series`, previously this would infer the `datetime` `dtype` (GH18231)

- A `Series` of `dtype=category` constructed from an empty `dict` will now have categories of `dtype=object` rather than `dtype=float64`, consistently with the case in which an empty list is passed ([GH18515](#))
- All-`NaN` levels in a `MultiIndex` are now assigned `float` rather than `object` dtype, promoting consistency with `Index` ([GH17929](#)).
- Levels names of a `MultiIndex` (when not `None`) are now required to be unique: trying to create a `MultiIndex` with repeated names will raise a `ValueError` ([GH18872](#))
- Both construction and renaming of `Index/MultiIndex` with non-hashable `name/names` will now raise `TypeError` ([GH20527](#))
- `Index.map()` can now accept `Series` and dictionary input objects ([GH12756](#), [GH18482](#), [GH18509](#)).
- `DataFrame.unstack()` will now default to filling with `np.nan` for `object` columns. ([GH12815](#))
- `IntervalIndex` constructor will raise if the `closed` parameter conflicts with how the input data is inferred to be closed ([GH18421](#))
- Inserting missing values into indexes will work for all types of indexes and automatically insert the correct type of missing value (`NaN`, `NaT`, etc.) regardless of the type passed in ([GH18295](#))
- When created with duplicate labels, `MultiIndex` now raises a `ValueError`. ([GH17464](#))
- `Series.fillna()` now raises a `TypeError` instead of a `ValueError` when passed a list, tuple or `DataFrame` as a `value` ([GH18293](#))
- `pandas.DataFrame.merge()` no longer casts a `float` column to `object` when merging on `int` and `float` columns ([GH16572](#))
- `pandas.merge()` now raises a `ValueError` when trying to merge on incompatible data types ([GH9780](#))
- The default `NA` value for `UInt64Index` has changed from `0` to `NaN`, which impacts methods that mask with `NA`, such as `UInt64Index.where()` ([GH18398](#))
- Refactored `setup.py` to use `find_packages` instead of explicitly listing out all subpackages ([GH18535](#))
- Rearranged the order of keyword arguments in `read_excel()` to align with `read_csv()` ([GH16672](#))
- `wide_to_long()` previously kept numeric-like suffixes as `object` dtype. Now they are cast to numeric if possible ([GH17627](#))
- In `read_excel()`, the `comment` argument is now exposed as a named parameter ([GH18735](#))
- Rearranged the order of keyword arguments in `read_excel()` to align with `read_csv()` ([GH16672](#))
- The options `html.border` and `mode.use_inf_as_null` were deprecated in prior versions, these will now show `FutureWarning` rather than a `DeprecationWarning` ([GH19003](#))
- `IntervalIndex` and `IntervalDtype` no longer support categorical, `object`, and `string` subtypes ([GH19016](#))
- `IntervalDtype` now returns `True` when compared against `'interval'` regardless of subtype, and `IntervalDtype.name` now returns `'interval'` regardless of subtype ([GH18980](#))
- `KeyError` now raises instead of `ValueError` in `drop()`, `drop()`, `drop()`, `drop()` when dropping a non-existent element in an axis with duplicates ([GH19186](#))
- `Series.to_csv()` now accepts a `compression` argument that works in the same way as the `compression` argument in `DataFrame.to_csv()` ([GH18958](#))
- Set operations (union, difference...) on `IntervalIndex` with incompatible index types will now raise a `TypeError` rather than a `ValueError` ([GH19329](#))

- `DateOffset` objects render more simply, e.g. `<DateOffset: days=1>` instead of `<DateOffset: kwds={'days': 1}>` (GH19403)
- `Categorical.fillna` now validates its `value` and `method` keyword arguments. It now raises when both or none are specified, matching the behavior of `Series.fillna()` (GH19682)
- `pd.to_datetime('today')` now returns a `datetime`, consistent with `pd.Timestamp('today')`; previously `pd.to_datetime('today')` returned a `.normalized()` `datetime` (GH19935)
- `Series.str.replace()` now takes an optional `regex` keyword which, when set to `False`, uses literal string replacement rather than regex replacement (GH16808)
- `DatetimeIndex.strftime()` and `PeriodIndex.strftime()` now return an `Index` instead of a numpy array to be consistent with similar accessors (GH20127)
- Constructing a `Series` from a list of length 1 no longer broadcasts this list when a longer index is specified (GH19714, GH20391).
- `DataFrame.to_dict()` with `orient='index'` no longer casts int columns to float for a `DataFrame` with only int and float columns (GH18580)
- A user-defined-function that is passed to `Series.rolling().aggregate()`, `DataFrame.rolling().aggregate()`, or its expanding cousins, will now *always* be passed a `Series`, rather than a `np.array`; `.apply()` only has the `raw` keyword, see *here*. This is consistent with the signatures of `.aggregate()` across pandas (GH20584)
- Rolling and Expanding types raise `NotImplementedError` upon iteration (GH11704).

Deprecations

- `Series.from_array` and `SparseSeries.from_array` are deprecated. Use the normal constructor `Series(...)` and `SparseSeries(...)` instead (GH18213).
- `DataFrame.as_matrix` is deprecated. Use `DataFrame.values` instead (GH18458).
- `Series.asobject`, `DatetimeIndex.asobject`, `PeriodIndex.asobject` and `TimeDeltaIndex.asobject` have been deprecated. Use `.astype(object)` instead (GH18572)
- Grouping by a tuple of keys now emits a `FutureWarning` and is deprecated. In the future, a tuple passed to 'by' will always refer to a single key that is the actual tuple, instead of treating the tuple as multiple keys. To retain the previous behavior, use a list instead of a tuple (GH18314)
- `Series.valid` is deprecated. Use `Series.dropna()` instead (GH18800).
- `read_excel()` has deprecated the `skip_footer` parameter. Use `skipfooter` instead (GH18836)
- `ExcelFile.parse()` has deprecated `sheetname` in favor of `sheet_name` for consistency with `read_excel()` (GH20920).
- The `is_copy` attribute is deprecated and will be removed in a future version (GH18801).
- `IntervalIndex.from_intervals` is deprecated in favor of the `IntervalIndex` constructor (GH19263)
- `DataFrame.from_items` is deprecated. Use `DataFrame.from_dict()` instead, or `DataFrame.from_dict(OrderedDict())` if you wish to preserve the key order (GH17320, GH17312)
- Indexing a `MultiIndex` or a `FloatIndex` with a list containing some missing keys will now show a `FutureWarning`, which is consistent with other types of indexes (GH17758).
- The `broadcast` parameter of `.apply()` is deprecated in favor of `result_type='broadcast'` (GH18577)
- The `reduce` parameter of `.apply()` is deprecated in favor of `result_type='reduce'` (GH18577)

- The `order` parameter of `factorize()` is deprecated and will be removed in a future release (GH19727)
- `Timestamp.weekday_name`, `DatetimeIndex.weekday_name`, and `Series.dt.weekday_name` are deprecated in favor of `Timestamp.day_name()`, `DatetimeIndex.day_name()`, and `Series.dt.day_name()` (GH12806)
- `pandas.tseries.plotting.tsplot` is deprecated. Use `Series.plot()` instead (GH18627)
- `Index.summary()` is deprecated and will be removed in a future version (GH18217)
- `NDFrame.get_ftype_counts()` is deprecated and will be removed in a future version (GH18243)
- The `convert_datetime64` parameter in `DataFrame.to_records()` has been deprecated and will be removed in a future version. The NumPy bug motivating this parameter has been resolved. The default value for this parameter has also changed from `True` to `None` (GH18160).
- `Series.rolling().apply()`, `DataFrame.rolling().apply()`, `Series.expanding().apply()`, and `DataFrame.expanding().apply()` have deprecated passing an `np.array` by default. One will need to pass the new `raw` parameter to be explicit about what is passed (GH20584)
- The `data`, `base`, `strides`, `flags` and `itemsize` properties of the `Series` and `Index` classes have been deprecated and will be removed in a future version (GH20419).
- `DatetimeIndex.offset` is deprecated. Use `DatetimeIndex.freq` instead (GH20716)
- Floor division between an integer ndarray and a `Timedelta` is deprecated. Divide by `Timedelta.value` instead (GH19761)
- Setting `PeriodIndex.freq` (which was not guaranteed to work correctly) is deprecated. Use `PeriodIndex.asfreq()` instead (GH20678)
- `Index.get_duplicates()` is deprecated and will be removed in a future version (GH20239)
- The previous default behavior of negative indices in `Categorical.take` is deprecated. In a future version it will change from meaning missing values to meaning positional indices from the right. The future behavior is consistent with `Series.take()` (GH20664).
- Passing multiple axes to the `axis` parameter in `DataFrame.dropna()` has been deprecated and will be removed in a future version (GH20987)

Removal of prior version deprecations/changes

- Warnings against the obsolete usage `Categorical(codes, categories)`, which were emitted for instance when the first two arguments to `Categorical()` had different dtypes, and recommended the use of `Categorical.from_codes`, have now been removed (GH8074)
- The `levels` and `labels` attributes of a `MultiIndex` can no longer be set directly (GH4039).
- `pd.tseries.util.pivot_annual` has been removed (deprecated since v0.19). Use `pivot_table` instead (GH18370)
- `pd.tseries.util.isleapyear` has been removed (deprecated since v0.19). Use `.is_leap_year` property in `Datetime`-likes instead (GH18370)
- `pd.ordered_merge` has been removed (deprecated since v0.19). Use `pd.merge_ordered` instead (GH18459)
- The `SparseList` class has been removed (GH14007)
- The `pandas.io.wb` and `pandas.io.data` stub modules have been removed (GH13735)
- `Categorical.from_array` has been removed (GH13854)

- The `freq` and `how` parameters have been removed from the `rolling/expanding/ewm` methods of `DataFrame` and `Series` (deprecated since v0.18). Instead, `resample` before calling the methods. (GH18601 & GH18668)
- `DatetimeIndex.to_datetime`, `Timestamp.to_datetime`, `PeriodIndex.to_datetime`, and `Index.to_datetime` have been removed (GH8254, GH14096, GH14113)
- `read_csv()` has dropped the `skip_footer` parameter (GH13386)
- `read_csv()` has dropped the `as_reccarray` parameter (GH13373)
- `read_csv()` has dropped the `buffer_lines` parameter (GH13360)
- `read_csv()` has dropped the `compact_ints` and `use_unsigned` parameters (GH13323)
- The `Timestamp` class has dropped the `offset` attribute in favor of `freq` (GH13593)
- The `Series`, `Categorical`, and `Index` classes have dropped the `reshape` method (GH13012)
- `pandas.tseries.frequencies.get_standard_freq` has been removed in favor of `pandas.tseries.frequencies.to_offset(freq).rule_code` (GH13874)
- The `freqstr` keyword has been removed from `pandas.tseries.frequencies.to_offset` in favor of `freq` (GH13874)
- The `Panel4D` and `PanelND` classes have been removed (GH13776)
- The `Panel` class has dropped the `to_long` and `toLong` methods (GH19077)
- The options `display.line_with` and `display.height` are removed in favor of `display.width` and `display.max_rows` respectively (GH4391, GH19107)
- The `labels` attribute of the `Categorical` class has been removed in favor of `Categorical.codes` (GH7768)
- The `flavor` parameter have been removed from `func:to_sql` method (GH13611)
- The modules `pandas.tools.hashing` and `pandas.util.hashing` have been removed (GH16223)
- The top-level functions `pd.rolling_*`, `pd.expanding_*` and `pd.ewm*` have been removed (Deprecated since v0.18). Instead, use the `DataFrame/Series` methods `rolling`, `expanding` and `ewm` (GH18723)
- Imports from `pandas.core.common` for functions such as `is_datetime64_dtype` are now removed. These are located in `pandas.api.types`. (GH13634, GH19769)
- The `infer_dst` keyword in `Series.tz_localize()`, `DatetimeIndex.tz_localize()` and `DatetimeIndex` have been removed. `infer_dst=True` is equivalent to `ambiguous='infer'`, and `infer_dst=False` to `ambiguous='raise'` (GH7963).
- When `.resample()` was changed from an eager to a lazy operation, like `.groupby()` in v0.18.0, we put in place compatibility (with a `FutureWarning`), so operations would continue to work. This is now fully removed, so a `Resampler` will no longer forward compat operations (GH20554)
- Remove long deprecated `axis=None` parameter from `.replace()` (GH20271)

Performance improvements

- Indexers on `Series` or `DataFrame` no longer create a reference cycle (GH17956)
- Added a keyword argument, `cache`, to `to_datetime()` that improved the performance of converting duplicate datetime arguments (GH11665)
- `DateOffset` arithmetic performance is improved (GH18218)

- Converting a `Series` of `Timedelta` objects to days, seconds, etc... sped up through vectorization of underlying methods ([GH18092](#))
- Improved performance of `.map()` with a `Series`/dict input ([GH15081](#))
- The overridden `Timedelta` properties of days, seconds and microseconds have been removed, leveraging their built-in Python versions instead ([GH18242](#))
- `Series` construction will reduce the number of copies made of the input data in certain cases ([GH17449](#))
- Improved performance of `Series.dt.date()` and `DatetimeIndex.date()` ([GH18058](#))
- Improved performance of `Series.dt.time()` and `DatetimeIndex.time()` ([GH18461](#))
- Improved performance of `IntervalIndex.symmetric_difference()` ([GH18475](#))
- Improved performance of `DatetimeIndex` and `Series` arithmetic operations with `Business-Month` and `Business-Quarter` frequencies ([GH18489](#))
- `Series()` / `DataFrame()` tab completion limits to 100 values, for better performance. ([GH18587](#))
- Improved performance of `DataFrame.median()` with `axis=1` when `bottleneck` is not installed ([GH16468](#))
- Improved performance of `MultiIndex.get_loc()` for large indexes, at the cost of a reduction in performance for small ones ([GH18519](#))
- Improved performance of `MultiIndex.remove_unused_levels()` when there are no unused levels, at the cost of a reduction in performance when there are ([GH19289](#))
- Improved performance of `Index.get_loc()` for non-unique indexes ([GH19478](#))
- Improved performance of pairwise `.rolling()` and `.expanding()` with `.cov()` and `.corr()` operations ([GH17917](#))
- Improved performance of `pandas.core.groupby.GroupBy.rank()` ([GH15779](#))
- Improved performance of variable `.rolling()` on `.min()` and `.max()` ([GH19521](#))
- Improved performance of `pandas.core.groupby.GroupBy.ffill()` and `pandas.core.groupby.GroupBy.bfill()` ([GH11296](#))
- Improved performance of `pandas.core.groupby.GroupBy.any()` and `pandas.core.groupby.GroupBy.all()` ([GH15435](#))
- Improved performance of `pandas.core.groupby.GroupBy.pct_change()` ([GH19165](#))
- Improved performance of `Series.isin()` in the case of categorical dtypes ([GH20003](#))
- Improved performance of `getattr(Series, attr)` when the `Series` has certain index types. This manifested in slow printing of large `Series` with a `DatetimeIndex` ([GH19764](#))
- Fixed a performance regression for `GroupBy.nth()` and `GroupBy.last()` with some object columns ([GH19283](#))
- Improved performance of `pandas.core.arrays.Categorical.from_codes()` ([GH18501](#))

Documentation changes

Thanks to all of the contributors who participated in the Pandas Documentation Sprint, which took place on March 10th. We had about 500 participants from over 30 locations across the world. You should notice that many of the *API docstrings* have greatly improved.

There were too many simultaneous contributions to include a release note for each improvement, but this [GitHub search](#) should give you an idea of how many docstrings were improved.

Special thanks to [Marc Garcia](#) for organizing the sprint. For more information, read the [NumFOCUS blogpost](#) recapping the sprint.

- Changed spelling of “numpy” to “NumPy”, and “python” to “Python”. ([GH19017](#))
- Consistency when introducing code samples, using either colon or period. Rewrote some sentences for greater clarity, added more dynamic references to functions, methods and classes. ([GH18941](#), [GH18948](#), [GH18973](#), [GH19017](#))
- Added a reference to `DataFrame.assign()` in the concatenate section of the merging documentation ([GH18665](#))

Bug fixes

Categorical

Warning: A class of bugs were introduced in pandas 0.21 with `CategoricalDtype` that affects the correctness of operations like `merge`, `concat`, and indexing when comparing multiple unordered `Categorical` arrays that have the same categories, but in a different order. We highly recommend upgrading or manually aligning your categories before doing these operations.

- Bug in `Categorical.equals` returning the wrong result when comparing two unordered `Categorical` arrays with the same categories, but in a different order ([GH16603](#))
- Bug in `pandas.api.types.union_categoricals()` returning the wrong result when for unordered categoricals with the categories in a different order. This affected `pandas.concat()` with `Categorical` data ([GH19096](#)).
- Bug in `pandas.merge()` returning the wrong result when joining on an unordered `Categorical` that had the same categories but in a different order ([GH19551](#))
- Bug in `CategoricalIndex.get_indexer()` returning the wrong result when `target` was an unordered `Categorical` that had the same categories as `self` but in a different order ([GH19551](#))
- Bug in `Index.astype()` with a categorical dtype where the resultant index is not converted to a `CategoricalIndex` for all types of index ([GH18630](#))
- Bug in `Series.astype()` and `Categorical.astype()` where an existing categorical data does not get updated ([GH10696](#), [GH18593](#))
- Bug in `Series.str.split()` with `expand=True` incorrectly raising an `IndexError` on empty strings ([GH20002](#)).
- Bug in `Index` constructor with `dtype=CategoricalDtype(...)` where `categories` and `ordered` are not maintained ([GH19032](#))
- Bug in `Series` constructor with scalar and `dtype=CategoricalDtype(...)` where `categories` and `ordered` are not maintained ([GH19565](#))
- Bug in `Categorical.__iter__` not converting to Python types ([GH19909](#))
- Bug in `pandas.factorize()` returning the unique codes for the `uniques`. This now returns a `Categorical` with the same dtype as the input ([GH19721](#))
- Bug in `pandas.factorize()` including an item for missing values in the `uniques` return value ([GH19721](#))
- Bug in `Series.take()` with categorical data interpreting `-1` in `indices` as missing value markers, rather than the last element of the `Series` ([GH20664](#))

Datetimelike

- Bug in `Series.__sub__()` subtracting a non-nanosecond `np.datetime64` object from a `Series` gave incorrect results ([GH7996](#))
- Bug in `DatetimeIndex`, `TimedeltaIndex` addition and subtraction of zero-dimensional integer arrays gave incorrect results ([GH19012](#))
- Bug in `DatetimeIndex` and `TimedeltaIndex` where adding or subtracting an array-like of `DateOffset` objects either raised (`np.array`, `pd.Index`) or broadcast incorrectly (`pd.Series`) ([GH18849](#))
- Bug in `Series.__add__()` adding `Series` with dtype `timedelta64[ns]` to a timezone-aware `DatetimeIndex` incorrectly dropped timezone information ([GH13905](#))
- Adding a `Period` object to a `datetime` or `Timestamp` object will now correctly raise a `TypeError` ([GH17983](#))
- Bug in `Timestamp` where comparison with an array of `Timestamp` objects would result in a `RecursionError` ([GH15183](#))
- Bug in `Series` floor-division where operating on a scalar `timedelta` raises an exception ([GH18846](#))
- Bug in `DatetimeIndex` where the repr was not showing high-precision time values at the end of a day (e.g., `23:59:59.999999999`) ([GH19030](#))
- Bug in `.astype()` to non-ns `timedelta` units would hold the incorrect dtype ([GH19176](#), [GH19223](#), [GH12425](#))
- Bug in subtracting `Series` from `NaT` incorrectly returning `NaT` ([GH19158](#))
- Bug in `Series.truncate()` which raises `TypeError` with a monotonic `PeriodIndex` ([GH17717](#))
- Bug in `pct_change()` using `periods` and `freq` returned different length outputs ([GH7292](#))
- Bug in comparison of `DatetimeIndex` against `None` or `datetime.date` objects raising `TypeError` for `==` and `!=` comparisons instead of `all-False` and `all-True`, respectively ([GH19301](#))
- Bug in `Timestamp` and `to_datetime()` where a string representing a barely out-of-bounds timestamp would be incorrectly rounded down instead of raising `OutOfBoundsDatetime` ([GH19382](#))
- Bug in `Timestamp.floor()` `DatetimeIndex.floor()` where time stamps far in the future and past were not rounded correctly ([GH19206](#))
- Bug in `to_datetime()` where passing an out-of-bounds datetime with `errors='coerce'` and `utc=True` would raise `OutOfBoundsDatetime` instead of parsing to `NaT` ([GH19612](#))
- Bug in `DatetimeIndex` and `TimedeltaIndex` addition and subtraction where name of the returned object was not always set consistently. ([GH19744](#))
- Bug in `DatetimeIndex` and `TimedeltaIndex` addition and subtraction where operations with numpy arrays raised `TypeError` ([GH19847](#))
- Bug in `DatetimeIndex` and `TimedeltaIndex` where setting the `freq` attribute was not fully supported ([GH20678](#))

Timedelta

- Bug in `Timedelta.__mul__()` where multiplying by `NaT` returned `NaT` instead of raising a `TypeError` ([GH19819](#))
- Bug in `Series` with dtype `'timedelta64[ns]'` where addition or subtraction of `TimedeltaIndex` had results cast to dtype `'int64'` ([GH17250](#))

- Bug in `Series` with `dtype='timedelta64[ns]'` where addition or subtraction of `TimedeltaIndex` could return a `Series` with an incorrect name ([GH19043](#))
- Bug in `Timedelta.__floordiv__()` and `Timedelta.__rfloordiv__()` dividing by many incompatible numpy objects was incorrectly allowed ([GH18846](#))
- Bug where dividing a scalar timedelta-like object with `TimedeltaIndex` performed the reciprocal operation ([GH19125](#))
- Bug in `TimedeltaIndex` where division by a `Series` would return a `TimedeltaIndex` instead of a `Series` ([GH19042](#))
- Bug in `Timedelta.__add__()`, `Timedelta.__sub__()` where adding or subtracting a `np.timedelta64` object would return another `np.timedelta64` instead of a `Timedelta` ([GH19738](#))
- Bug in `Timedelta.__floordiv__()`, `Timedelta.__rfloordiv__()` where operating with a `Tick` object would raise a `TypeError` instead of returning a numeric value ([GH19738](#))
- Bug in `Period.asfreq()` where periods near `datetime(1, 1, 1)` could be converted incorrectly ([GH19643](#), [GH19834](#))
- Bug in `Timedelta.total_seconds()` causing precision errors, for example `Timedelta('30S').total_seconds()==30.000000000000004` ([GH19458](#))
- Bug in `Timedelta.__rmod__()` where operating with a `numpy.timedelta64` returned a `timedelta64` object instead of a `Timedelta` ([GH19820](#))
- Multiplication of `TimedeltaIndex` by `TimedeltaIndex` will now raise `TypeError` instead of raising `ValueError` in cases of length mis-match ([GH19333](#))
- Bug in indexing a `TimedeltaIndex` with a `np.timedelta64` object which was raising a `TypeError` ([GH20393](#))

Timezones

- Bug in creating a `Series` from an array that contains both tz-naive and tz-aware values will result in a `Series` whose `dtype` is tz-aware instead of object ([GH16406](#))
- Bug in comparison of timezone-aware `DatetimeIndex` against `NaT` incorrectly raising `TypeError` ([GH19276](#))
- Bug in `DatetimeIndex.astype()` when converting between timezone aware dtypes, and converting from timezone aware to naive ([GH18951](#))
- Bug in comparing `DatetimeIndex`, which failed to raise `TypeError` when attempting to compare timezone-aware and timezone-naive datetimelike objects ([GH18162](#))
- Bug in localization of a naive, datetime string in a `Series` constructor with a `datetime64[ns, tz]` dtype ([GH174151](#))
- `Timestamp.replace()` will now handle Daylight Savings transitions gracefully ([GH18319](#))
- Bug in tz-aware `DatetimeIndex` where addition/subtraction with a `TimedeltaIndex` or array with `dtype='timedelta64[ns]'` was incorrect ([GH17558](#))
- Bug in `DatetimeIndex.insert()` where inserting `NaT` into a timezone-aware index incorrectly raised ([GH16357](#))
- Bug in `DataFrame` constructor, where tz-aware `Datetimeindex` and a given column name will result in an empty `DataFrame` ([GH19157](#))

- Bug in `Timestamp.tz_localize()` where localizing a timestamp near the minimum or maximum valid values could overflow and return a timestamp with an incorrect nanosecond value (GH12677)
- Bug when iterating over `DatetimeIndex` that was localized with fixed timezone offset that rounded nanosecond precision to microseconds (GH19603)
- Bug in `DataFrame.diff()` that raised an `IndexError` with tz-aware values (GH18578)
- Bug in `melt()` that converted tz-aware dtypes to tz-naive (GH15785)
- Bug in `Dataframe.count()` that raised an `ValueError`, if `Dataframe.dropna()` was called for a single column with timezone-aware values. (GH13407)

Offsets

- Bug in `WeekOfMonth` and `Week` where addition and subtraction did not roll correctly (GH18510, GH18672, GH18864)
- Bug in `WeekOfMonth` and `LastWeekOfMonth` where default keyword arguments for constructor raised `ValueError` (GH19142)
- Bug in `FY5253Quarter`, `LastWeekOfMonth` where rollback and rollforward behavior was inconsistent with addition and subtraction behavior (GH18854)
- Bug in `FY5253` where `datetime` addition and subtraction incremented incorrectly for dates on the year-end but not normalized to midnight (GH18854)
- Bug in `FY5253` where date offsets could incorrectly raise an `AssertionError` in arithmetic operations (GH14774)

Numeric

- Bug in `Series` constructor with an int or float list where specifying `dtype=str`, `dtype='str'` or `dtype='U'` failed to convert the data elements to strings (GH16605)
- Bug in `Index` multiplication and division methods where operating with a `Series` would return an `Index` object instead of a `Series` object (GH19042)
- Bug in the `DataFrame` constructor in which data containing very large positive or very large negative numbers was causing `OverflowError` (GH18584)
- Bug in `Index` constructor with `dtype='uint64'` where int-like floats were not coerced to `UInt64Index` (GH18400)
- Bug in `DataFrame` flex arithmetic (e.g. `df.add(other, fill_value=foo)`) with a `fill_value` other than `None` failed to raise `NotImplementedError` in corner cases where either the frame or `other` has length zero (GH19522)
- Multiplication and division of numeric-dtyped `Index` objects with timedelta-like scalars returns `TimedeltaIndex` instead of raising `TypeError` (GH19333)
- Bug where `NaN` was returned instead of `0` by `Series.pct_change()` and `DataFrame.pct_change()` when `fill_method` is not `None` (GH19873)

Strings

- Bug in `Series.str.get()` with a dictionary in the values and the index not in the keys, raising `KeyError` (GH20671)

Indexing

- Bug in `Index` construction from list of mixed type tuples (GH18505)
- Bug in `Index.drop()` when passing a list of both tuples and non-tuples (GH18304)
- Bug in `DataFrame.drop()`, `Panel.drop()`, `Series.drop()`, `Index.drop()` where no `KeyError` is raised when dropping a non-existent element from an axis that contains duplicates (GH19186)
- Bug in indexing a datetimelike `Index` that raised `ValueError` instead of `IndexError` (GH18386).
- `Index.to_series()` now accepts `index` and `name` kwargs (GH18699)
- `DatetimeIndex.to_series()` now accepts `index` and `name` kwargs (GH18699)
- Bug in indexing non-scalar value from `Series` having non-unique `Index` will return value flattened (GH17610)
- Bug in indexing with iterator containing only missing keys, which raised no error (GH20748)
- Fixed inconsistency in `.ix` between list and scalar keys when the index has integer dtype and does not include the desired keys (GH20753)
- Bug in `__setitem__` when indexing a `DataFrame` with a 2-d boolean ndarray (GH18582)
- Bug in `str.extractall` when there were no matches empty `Index` was returned instead of appropriate `MultiIndex` (GH19034)
- Bug in `IntervalIndex` where empty and purely NA data was constructed inconsistently depending on the construction method (GH18421)
- Bug in `IntervalIndex.symmetric_difference()` where the symmetric difference with a non-`IntervalIndex` did not raise (GH18475)
- Bug in `IntervalIndex` where set operations that returned an empty `IntervalIndex` had the wrong dtype (GH19101)
- Bug in `DataFrame.drop_duplicates()` where no `KeyError` is raised when passing in columns that don't exist on the `DataFrame` (GH19726)
- Bug in `Index` subclasses constructors that ignore unexpected keyword arguments (GH19348)
- Bug in `Index.difference()` when taking difference of an `Index` with itself (GH20040)
- Bug in `DataFrame.first_valid_index()` and `DataFrame.last_valid_index()` in presence of entire rows of NaNs in the middle of values (GH20499).
- Bug in `IntervalIndex` where some indexing operations were not supported for overlapping or non-monotonic `uint64` data (GH20636)
- Bug in `Series.is_unique` where extraneous output in `stderr` is shown if `Series` contains objects with `__ne__` defined (GH20661)
- Bug in `.loc` assignment with a single-element list-like incorrectly assigns as a list (GH19474)
- Bug in partial string indexing on a `Series/DataFrame` with a monotonic decreasing `DatetimeIndex` (GH19362)
- Bug in performing in-place operations on a `DataFrame` with a duplicate `Index` (GH17105)
- Bug in `IntervalIndex.get_loc()` and `IntervalIndex.get_indexer()` when used with an `IntervalIndex` containing a single interval (GH17284, GH20921)
- Bug in `.loc` with a `uint64` indexer (GH20722)

MultiIndex

- Bug in `MultiIndex.__contains__()` where non-tuple keys would return `True` even if they had been dropped ([GH19027](#))
- Bug in `MultiIndex.set_labels()` which would cause casting (and potentially clipping) of the new labels if the `level` argument is not 0 or a list like `[0, 1, ...]` ([GH19057](#))
- Bug in `MultiIndex.get_level_values()` which would return an invalid index on level of ints with missing values ([GH17924](#))
- Bug in `MultiIndex.unique()` when called on empty `MultiIndex` ([GH20568](#))
- Bug in `MultiIndex.unique()` which would not preserve level names ([GH20570](#))
- Bug in `MultiIndex.remove_unused_levels()` which would fill nan values ([GH18417](#))
- Bug in `MultiIndex.from_tuples()` which would fail to take zipped tuples in python3 ([GH18434](#))
- Bug in `MultiIndex.get_loc()` which would fail to automatically cast values between float and int ([GH18818](#), [GH15994](#))
- Bug in `MultiIndex.get_loc()` which would cast boolean to integer labels ([GH19086](#))
- Bug in `MultiIndex.get_loc()` which would fail to locate keys containing `NaN` ([GH18485](#))
- Bug in `MultiIndex.get_loc()` in large `MultiIndex`, would fail when levels had different dtypes ([GH18520](#))
- Bug in indexing where nested indexers having only numpy arrays are handled incorrectly ([GH19686](#))

I/O

- `read_html()` now rewinds seekable IO objects after parse failure, before attempting to parse with a new parser. If a parser errors and the object is non-seekable, an informative error is raised suggesting the use of a different parser ([GH17975](#))
- `DataFrame.to_html()` now has an option to add an id to the leading `<table>` tag ([GH8496](#))
- Bug in `read_msgpack()` with a non-existent file is passed in Python 2 ([GH15296](#))
- Bug in `read_csv()` where a `MultiIndex` with duplicate columns was not being mangled appropriately ([GH18062](#))
- Bug in `read_csv()` where missing values were not being handled properly when `keep_default_na=False` with dictionary `na_values` ([GH19227](#))
- Bug in `read_csv()` causing heap corruption on 32-bit, big-endian architectures ([GH20785](#))
- Bug in `read_sas()` where a file with 0 variables gave an `AttributeError` incorrectly. Now it gives an `EmptyDataError` ([GH18184](#))
- Bug in `DataFrame.to_latex()` where pairs of braces meant to serve as invisible placeholders were escaped ([GH18667](#))
- Bug in `DataFrame.to_latex()` where a `NaN` in a `MultiIndex` would cause an `IndexError` or incorrect output ([GH14249](#))
- Bug in `DataFrame.to_latex()` where a non-string index-level name would result in an `AttributeError` ([GH19981](#))
- Bug in `DataFrame.to_latex()` where the combination of an index name and the `index_names=False` option would result in incorrect output ([GH18326](#))

- Bug in `DataFrame.to_latex()` where a `MultiIndex` with an empty string as its name would result in incorrect output ([GH18669](#))
- Bug in `DataFrame.to_latex()` where missing space characters caused wrong escaping and produced non-valid latex in some cases ([GH20859](#))
- Bug in `read_json()` where large numeric values were causing an `OverflowError` ([GH18842](#))
- Bug in `DataFrame.to_parquet()` where an exception was raised if the write destination is S3 ([GH19134](#))
- `Interval` now supported in `DataFrame.to_excel()` for all Excel file types ([GH19242](#))
- `Timedelta` now supported in `DataFrame.to_excel()` for all Excel file types ([GH19242](#), [GH9155](#), [GH19900](#))
- Bug in `pandas.io.stata.StataReader.value_labels()` raising an `AttributeError` when called on very old files. Now returns an empty dict ([GH19417](#))
- Bug in `read_pickle()` when unpickling objects with `TimedeltaIndex` or `Float64Index` created with pandas prior to version 0.20 ([GH19939](#))
- Bug in `pandas.io.json.json_normalize()` where sub-records are not properly normalized if any sub-records values are `NoneType` ([GH20030](#))
- Bug in `usecols` parameter in `read_csv()` where error is not raised correctly when passing a string. ([GH20529](#))
- Bug in `HDFStore.keys()` when reading a file with a soft link causes exception ([GH20523](#))
- Bug in `HDFStore.select_column()` where a key which is not a valid store raised an `AttributeError` instead of a `KeyError` ([GH17912](#))

Plotting

- Better error message when attempting to plot but `matplotlib` is not installed ([GH19810](#)).
- `DataFrame.plot()` now raises a `ValueError` when the `x` or `y` argument is improperly formed ([GH18671](#))
- Bug in `DataFrame.plot()` when `x` and `y` arguments given as positions caused incorrect referenced columns for line, bar and area plots ([GH20056](#))
- Bug in formatting tick labels with `datetime.time()` and fractional seconds ([GH18478](#)).
- `Series.plot.kde()` has exposed the args `ind` and `bw_method` in the docstring ([GH18461](#)). The argument `ind` may now also be an integer (number of sample points).
- `DataFrame.plot()` now supports multiple columns to the `y` argument ([GH19699](#))

Groupby/resample/rolling

- Bug when grouping by a single column and aggregating with a class like `list` or `tuple` ([GH18079](#))
- Fixed regression in `DataFrame.groupby()` which would not emit an error when called with a tuple key not in the index ([GH18798](#))
- Bug in `DataFrame.resample()` which silently ignored unsupported (or mistyped) options for `label`, `closed` and `convention` ([GH19303](#))
- Bug in `DataFrame.groupby()` where tuples were interpreted as lists of keys rather than as keys ([GH17979](#), [GH18249](#))

- Bug in `DataFrame.groupby()` where aggregation by `first/last/min/max` was causing timestamps to lose precision ([GH19526](#))
- Bug in `DataFrame.transform()` where particular aggregation functions were being incorrectly cast to match the `dtype(s)` of the grouped data ([GH19200](#))
- Bug in `DataFrame.groupby()` passing the `on=` kwarg, and subsequently using `.apply()` ([GH17813](#))
- Bug in `DataFrame.resample().aggregate` not raising a `KeyError` when aggregating a non-existent column ([GH16766](#), [GH19566](#))
- Bug in `DataFrameGroupBy.cumsum()` and `DataFrameGroupBy.cumprod()` when `skipna` was passed ([GH19806](#))
- Bug in `DataFrame.resample()` that dropped timezone information ([GH13238](#))
- Bug in `DataFrame.groupby()` where transformations using `np.all` and `np.any` were raising a `ValueError` ([GH20653](#))
- Bug in `DataFrame.resample()` where `ffill`, `bfill`, `pad`, `backfill`, `fillna`, `interpolate`, and `asfreq` were ignoring `loffset`. ([GH20744](#))
- Bug in `DataFrame.groupby()` when applying a function that has mixed data types and the user supplied function can fail on the grouping column ([GH20949](#))
- Bug in `DataFrameGroupBy.rolling().apply()` where operations performed against the associated `DataFrameGroupBy` object could impact the inclusion of the grouped item(s) in the result ([GH14013](#))

Sparse

- Bug in which creating a `SparseDataFrame` from a dense `Series` or an unsupported type raised an uncontrolled exception ([GH19374](#))
- Bug in `SparseDataFrame.to_csv` causing exception ([GH19384](#))
- Bug in `SparseSeries.memory_usage` which caused segfault by accessing non sparse elements ([GH19368](#))
- Bug in constructing a `SparseArray`: if `data` is a scalar and `index` is defined it will coerce to `float64` regardless of scalar's `dtype`. ([GH19163](#))

Reshaping

- Bug in `DataFrame.merge()` where referencing a `CategoricalIndex` by name, where the `by` kwarg would `KeyError` ([GH20777](#))
- Bug in `DataFrame.stack()` which fails trying to sort mixed type levels under Python 3 ([GH18310](#))
- Bug in `DataFrame.unstack()` which casts `int` to `float` if `columns` is a `MultiIndex` with unused levels ([GH17845](#))
- Bug in `DataFrame.unstack()` which raises an error if `index` is a `MultiIndex` with unused labels on the unstacked level ([GH18562](#))
- Fixed construction of a `Series` from a `dict` containing `NaN` as key ([GH18480](#))
- Fixed construction of a `DataFrame` from a `dict` containing `NaN` as key ([GH18455](#))
- Disabled construction of a `Series` where `len(index) > len(data) = 1`, which previously would broadcast the data item, and now raises a `ValueError` ([GH18819](#))

- Suppressed error in the construction of a `DataFrame` from a `dict` containing scalar values when the corresponding keys are not included in the passed index ([GH18600](#))
- Fixed (changed from `object` to `float64`) dtype of `DataFrame` initialized with axes, no data, and `dtype=int` ([GH19646](#))
- Bug in `Series.rank()` where `Series` containing `NaT` modifies the `Series` inplace ([GH18521](#))
- Bug in `cut()` which fails when using readonly arrays ([GH18773](#))
- Bug in `DataFrame.pivot_table()` which fails when the `aggfunc` arg is of type string. The behavior is now consistent with other methods like `agg` and `apply` ([GH18713](#))
- Bug in `DataFrame.merge()` in which merging using `Index` objects as vectors raised an `Exception` ([GH19038](#))
- Bug in `DataFrame.stack()`, `DataFrame.unstack()`, `Series.unstack()` which were not returning subclasses ([GH15563](#))
- Bug in timezone comparisons, manifesting as a conversion of the index to UTC in `.concat()` ([GH18523](#))
- Bug in `concat()` when concatenating sparse and dense series it returns only a `SparseDataFrame`. Should be a `DataFrame`. ([GH18914](#), [GH18686](#), and [GH16874](#))
- Improved error message for `DataFrame.merge()` when there is no common merge key ([GH19427](#))
- Bug in `DataFrame.join()` which does an `outer` instead of a `left` join when being called with multiple `DataFrames` and some have non-unique indices ([GH19624](#))
- `Series.rename()` now accepts `axis` as a kwarg ([GH18589](#))
- Bug in `rename()` where an `Index` of same-length tuples was converted to a `MultiIndex` ([GH19497](#))
- Comparisons between `Series` and `Index` would return a `Series` with an incorrect name, ignoring the `Index`'s name attribute ([GH19582](#))
- Bug in `qcut()` where datetime and timedelta data with `NaT` present raised a `ValueError` ([GH19768](#))
- Bug in `DataFrame.iterrows()`, which would infer strings not compliant to `ISO8601` to datetimes ([GH19671](#))
- Bug in `Series` constructor with `Categorical` where a `ValueError` is not raised when an index of different length is given ([GH19342](#))
- Bug in `DataFrame.astype()` where column metadata is lost when converting to categorical or a dictionary of dtypes ([GH19920](#))
- Bug in `cut()` and `qcut()` where timezone information was dropped ([GH19872](#))
- Bug in `Series` constructor with a `dtype=str`, previously raised in some cases ([GH19853](#))
- Bug in `get_dummies()`, and `select_dtypes()`, where duplicate column names caused incorrect behavior ([GH20848](#))
- Bug in `isna()`, which cannot handle ambiguous typed lists ([GH20675](#))
- Bug in `concat()` which raises an error when concatenating TZ-aware dataframes and all-`NaT` dataframes ([GH12396](#))
- Bug in `concat()` which raises an error when concatenating empty TZ-aware series ([GH18447](#))

Other

- Improved error message when attempting to use a Python keyword as an identifier in a `numexpr` backed query ([GH18221](#))
- Bug in accessing a `pandas.get_option()`, which raised `KeyError` rather than `OptionError` when looking up a non-existent option key in some cases ([GH19789](#))
- Bug in `testing.assert_series_equal()` and `testing.assert_frame_equal()` for Series or DataFrames with differing unicode data ([GH20503](#))

8.4 Version 0.22

8.4.1 v0.22.0 (December 29, 2017)

{{ header }}

This is a major release from 0.21.1 and includes a single, API-breaking change. We recommend that all users upgrade to this version after carefully reading the release note (singular!).

Backwards incompatible API changes

Pandas 0.22.0 changes the handling of empty and all-*NA* sums and products. The summary is that

- The sum of an empty or all-*NA* **Series** is now 0
- The product of an empty or all-*NA* **Series** is now 1
- We've added a `min_count` parameter to `.sum()` and `.prod()` controlling the minimum number of valid values for the result to be valid. If fewer than `min_count` non-*NA* values are present, the result is *NA*. The default is 0. To return `NaN`, the 0.21 behavior, use `min_count=1`.

Some background: In pandas 0.21, we fixed a long-standing inconsistency in the return value of all-*NA* series depending on whether or not bottleneck was installed. See *Sum/Prod of all-`NaN` or empty Series/DataFrames is now consistently `NaN`*. At the same time, we changed the sum and prod of an empty **Series** to also be `NaN`.

Based on feedback, we've partially reverted those changes.

Arithmetic operations

The default sum for empty or all-*NA* Series is now 0.

pandas 0.21.x

```
In [1]: pd.Series([]).sum()
Out[1]: nan

In [2]: pd.Series([np.nan]).sum()
Out[2]: nan
```

pandas 0.22.0

```
In [1]: pd.Series([]).sum()
Out[1]: 0.0

In [2]: pd.Series([np.nan]).sum()
Out[2]: 0.0
```

The default behavior is the same as pandas 0.20.3 with bottleneck installed. It also matches the behavior of NumPy's `np.nansum` on empty and all-*NA* arrays.

To have the sum of an empty series return NaN (the default behavior of pandas 0.20.3 without bottleneck, or pandas 0.21.x), use the `min_count` keyword.

```
In [3]: pd.Series([]).sum(min_count=1)
Out[3]: nan
```

Thanks to the `skipna` parameter, the `.sum` on an all-*NA* series is conceptually the same as the `.sum` of an empty one with `skipna=True` (the default).

```
In [4]: pd.Series([np.nan]).sum(min_count=1) # skipna=True by default
Out[4]: nan
```

The `min_count` parameter refers to the minimum number of *non-null* values required for a non-*NA* sum or product.

`Series.prod()` has been updated to behave the same as `Series.sum()`, returning 1 instead.

```
In [5]: pd.Series([]).prod()
Out[5]: 1.0

In [6]: pd.Series([np.nan]).prod()
Out[6]: 1.0

In [7]: pd.Series([]).prod(min_count=1)
Out[7]: nan
```

These changes affect `DataFrame.sum()` and `DataFrame.prod()` as well. Finally, a few less obvious places in pandas are affected by this change.

Grouping by a categorical

Grouping by a `Categorical` and summing now returns 0 instead of NaN for categories with no observations. The product now returns 1 instead of NaN.

pandas 0.21.x

```
In [8]: grouper = pd.Categorical(['a', 'a'], categories=['a', 'b'])
In [9]: pd.Series([1, 2]).groupby(grouper).sum()
Out[9]:
a    3.0
b    NaN
dtype: float64
```

pandas 0.22

```
In [8]: grouper = pd.Categorical(['a', 'a'], categories=['a', 'b'])
In [9]: pd.Series([1, 2]).groupby(grouper).sum()
Out[9]:
a    3
b    0
Length: 2, dtype: int64
```

To restore the 0.21 behavior of returning NaN for unobserved groups, use `min_count>=1`.

```
In [10]: pd.Series([1, 2]).groupby(grouper).sum(min_count=1)
Out[10]:
a    3.0
b    NaN
Length: 2, dtype: float64
```

Resample

The sum and product of all-NA bins has changed from NaN to 0 for sum and 1 for product.

pandas 0.21.x

```
In [11]: s = pd.Series([1, 1, np.nan, np.nan],
.....:                  index=pd.date_range('2017', periods=4))
.....: s
Out[11]:
2017-01-01    1.0
2017-01-02    1.0
2017-01-03    NaN
2017-01-04    NaN
Freq: D, dtype: float64

In [12]: s.resample('2d').sum()
Out[12]:
2017-01-01    2.0
2017-01-03    NaN
Freq: 2D, dtype: float64
```

pandas 0.22.0

```
In [11]: s = pd.Series([1, 1, np.nan, np.nan],
.....:                 index=pd.date_range('2017', periods=4))
.....:

In [12]: s.resample('2d').sum()
Out[12]:
2017-01-01    2.0
2017-01-03    0.0
Freq: 2D, Length: 2, dtype: float64
```

To restore the 0.21 behavior of returning NaN, use `min_count>=1`.

```
In [13]: s.resample('2d').sum(min_count=1)
Out[13]:
2017-01-01    2.0
2017-01-03    NaN
Freq: 2D, Length: 2, dtype: float64
```

In particular, upsampling and taking the sum or product is affected, as upsampling introduces missing values even if the original series was entirely valid.

pandas 0.21.x

```
In [14]: idx = pd.DatetimeIndex(['2017-01-01', '2017-01-02'])

In [15]: pd.Series([1, 2], index=idx).resample('12H').sum()
Out[15]:
2017-01-01 00:00:00    1.0
2017-01-01 12:00:00    NaN
2017-01-02 00:00:00    2.0
Freq: 12H, dtype: float64
```

pandas 0.22.0

```
In [14]: idx = pd.DatetimeIndex(['2017-01-01', '2017-01-02'])

In [15]: pd.Series([1, 2], index=idx).resample("12H").sum()
Out[15]:
2017-01-01 00:00:00    1
2017-01-01 12:00:00    0
2017-01-02 00:00:00    2
Freq: 12H, Length: 3, dtype: int64
```

Once again, the `min_count` keyword is available to restore the 0.21 behavior.

```
In [16]: pd.Series([1, 2], index=idx).resample("12H").sum(min_count=1)
Out[16]:
2017-01-01 00:00:00    1.0
2017-01-01 12:00:00    NaN
2017-01-02 00:00:00    2.0
Freq: 12H, Length: 3, dtype: float64
```

Rolling and expanding

Rolling and expanding already have a `min_periods` keyword that behaves similar to `min_count`. The only case that changes is when doing a rolling or expanding sum with `min_periods=0`. Previously this returned `NaN`, when fewer than `min_periods` non-*NA* values were in the window. Now it returns 0.

pandas 0.21.1

```
In [17]: s = pd.Series([np.nan, np.nan])
In [18]: s.rolling(2, min_periods=0).sum()
Out[18]:
0    NaN
1    NaN
dtype: float64
```

pandas 0.22.0

```
In [17]: s = pd.Series([np.nan, np.nan])
In [18]: s.rolling(2, min_periods=0).sum()
Out[18]:
0    0.0
1    0.0
Length: 2, dtype: float64
```

The default behavior of `min_periods=None`, implying that `min_periods` equals the window size, is unchanged.

Compatibility

If you maintain a library that should work across pandas versions, it may be easiest to exclude pandas 0.21 from your requirements. Otherwise, all your `sum()` calls would need to check if the `Series` is empty before summing.

With `setuptools`, in your `setup.py` use:

```
install_requires=['pandas!=0.21.*', ...]
```

With `conda`, use

```
requirements:
run:
- pandas !=0.21.0,!=0.21.1
```

Note that the inconsistency in the return value for all-*NA* series is still there for pandas 0.20.3 and earlier. Avoiding pandas 0.21 will only help with the empty case.

Contributors

A total of 1 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

- Tom Augspurger

8.5 Version 0.21

8.5.1 v0.21.1 (December 12, 2017)

{{ header }}

This is a minor bug-fix release in the 0.21.x series and includes some small regression fixes, bug fixes and performance improvements. We recommend that all users upgrade to this version.

Highlights include:

- Temporarily restore matplotlib datetime plotting functionality. This should resolve issues for users who implicitly relied on pandas to plot datetimes with matplotlib. See *here*.
- Improvements to the Parquet IO functions introduced in 0.21.0. See *here*.

What's new in v0.21.1

- *Restore Matplotlib datetime converter registration*
- *New features*
 - *Improvements to the Parquet IO functionality*
 - *Other enhancements*
- *Deprecations*
- *Performance improvements*
- *Bug fixes*
 - *Conversion*
 - *Indexing*
 - *I/O*
 - *Plotting*
 - *Groupby/resample/rolling*
 - *Reshaping*
 - *Numeric*
 - *Categorical*
 - *String*
- *Contributors*

Restore Matplotlib datetime converter registration

Pandas implements some matplotlib converters for nicely formatting the axis labels on plots with `datetime` or `Period` values. Prior to pandas 0.21.0, these were implicitly registered with matplotlib, as a side effect of `import pandas`.

In pandas 0.21.0, we required users to explicitly register the converter. This caused problems for some users who relied on those converters being present for regular `matplotlib.pyplot` plotting methods, so we're

temporarily reverting that change; pandas 0.21.1 again registers the converters on import, just like before 0.21.0.

We've added a new option to control the converters: `pd.options.plotting.matplotlib.register_converters`. By default, they are registered. Toggling this to `False` removes pandas' formatters and restore any converters we overwrote when registering them (GH18301).

We're working with the matplotlib developers to make this easier. We're trying to balance user convenience (automatically registering the converters) with import performance and best practices (importing pandas shouldn't have the side effect of overwriting any custom converters you've already set). In the future we hope to have most of the datetime formatting functionality in matplotlib, with just the pandas-specific converters in pandas. We'll then gracefully deprecate the automatic registration of converters in favor of users explicitly registering them when they want them.

New features

Improvements to the Parquet IO functionality

- `DataFrame.to_parquet()` will now write non-default indexes when the underlying engine supports it. The indexes will be preserved when reading back in with `read_parquet()` (GH18581).
- `read_parquet()` now allows to specify the columns to read from a parquet file (GH18154)
- `read_parquet()` now allows to specify kwargs which are passed to the respective engine (GH18216)

Other enhancements

- `Timestamp.timestamp()` is now available in Python 2.7. (GH17329)
- `Grouper` and `TimeGrouper` now have a friendly repr output (GH18203).

Deprecations

- `pandas.tseries.register` has been renamed to `pandas.plotting.register_matplotlib_converters()` (GH18301)

Performance improvements

- Improved performance of plotting large series/dataframes (GH18236).

Bug fixes

Conversion

- Bug in `TimedeltaIndex` subtraction could incorrectly overflow when `NaT` is present (GH17791)
- Bug in `DatetimeIndex` subtracting datetimelike from `DatetimeIndex` could fail to overflow (GH18020)
- Bug in `IntervalIndex.copy()` when copying and `IntervalIndex` with non-default `closed` (GH18339)
- Bug in `DataFrame.to_dict()` where columns of datetime that are tz-aware were not converted to required arrays when used with `orient='records'`, raising `TypeError` (GH18372)

- Bug in `DateTimeIndex` and `date_range()` where mismatching tz-aware `start` and `end` timezones would not raise an err if `end.tzinfo` is `None` ([GH18431](#))
- Bug in `Series.fillna()` which raised when passed a long integer on Python 2 ([GH18159](#)).

Indexing

- Bug in a boolean comparison of a `datetime.datetime` and a `datetime64[ns]` dtype `Series` ([GH17965](#))
- Bug where a `MultiIndex` with more than a million records was not raising `AttributeError` when trying to access a missing attribute ([GH18165](#))
- Bug in `IntervalIndex` constructor when a list of intervals is passed with non-default `closed` ([GH18334](#))
- Bug in `Index.putmask` when an invalid mask passed ([GH18368](#))
- Bug in masked assignment of a `timedelta64[ns]` dtype `Series`, incorrectly coerced to float ([GH18493](#))

I/O

- Bug in class: `~pandas.io.stata.StataReader` not converting date/time columns with display formatting addressed ([GH17990](#)). Previously columns with display formatting were normally left as ordinal numbers and not converted to datetime objects.
- Bug in `read_csv()` when reading a compressed UTF-16 encoded file ([GH18071](#))
- Bug in `read_csv()` for handling null values in index columns when specifying `na_filter=False` ([GH5239](#))
- Bug in `read_csv()` when reading numeric category fields with high cardinality ([GH18186](#))
- Bug in `DataFrame.to_csv()` when the table had `MultiIndex` columns, and a list of strings was passed in for `header` ([GH5539](#))
- Bug in parsing integer datetime-like columns with specified format in `read_sql` ([GH17855](#)).
- Bug in `DataFrame.to_msgpack()` when serializing data of the `numpy.bool_` datatype ([GH18390](#))
- Bug in `read_json()` not decoding when reading line delimited JSON from S3 ([GH17200](#))
- Bug in `pandas.io.json.json_normalize()` to avoid modification of `meta` ([GH18610](#))
- Bug in `to_latex()` where repeated `MultiIndex` values were not printed even though a higher level index differed from the previous row ([GH14484](#))
- Bug when reading NaN-only categorical columns in `HDFStore` ([GH18413](#))
- Bug in `DataFrame.to_latex()` with `longtable=True` where a latex multicolumn always spanned over three columns ([GH17959](#))

Plotting

- Bug in `DataFrame.plot()` and `Series.plot()` with `DatetimeIndex` where a figure generated by them is not pickleable in Python 3 ([GH18439](#))

Groupby/resample/rolling

- Bug in `DataFrame.resample(...).apply(...)` when there is a callable that returns different columns (GH15169)
- Bug in `DataFrame.resample(...)` when there is a time change (DST) and resampling frequency is 12h or higher (GH15549)
- Bug in `pd.DataFrameGroupBy.count()` when counting over a datetimelike column (GH13393)
- Bug in `rolling.var` where calculation is inaccurate with a zero-valued array (GH18430)

Reshaping

- Error message in `pd.merge_asof()` for key datatype mismatch now includes datatype of left and right key (GH18068)
- Bug in `pd.concat` when empty and non-empty DataFrames or Series are concatenated (GH18178 GH18187)
- Bug in `DataFrame.filter(...)` when `unicode` is passed as a condition in Python 2 (GH13101)
- Bug when merging empty DataFrames when `np.seterr(divide='raise')` is set (GH17776)

Numeric

- Bug in `pd.Series.rolling.skew()` and `rolling.kurt()` with all equal values has floating issue (GH18044)

Categorical

- Bug in `DataFrame.astype()` where casting to 'category' on an empty DataFrame causes a segmentation fault (GH18004)
- Error messages in the testing module have been improved when items have different `CategoricalDtype` (GH18069)
- `CategoricalIndex` can now correctly take a `pd.api.types.CategoricalDtype` as its dtype (GH18116)
- Bug in `Categorical.unique()` returning read-only codes array when all categories were NaN (GH18051)
- Bug in `DataFrame.groupby(axis=1)` with a `CategoricalIndex` (GH18432)

String

- `Series.str.split()` will now propagate NaN values across all expanded columns instead of None (GH18450)

8.5.2 v0.21.0 (October 27, 2017)

{{ header }}

This is a major release from 0.20.3 and includes a number of API changes, deprecations, new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

- Integration with [Apache Parquet](#), including a new top-level `read_parquet()` function and `DataFrame.to_parquet()` method, see [here](#).
- New user-facing `pandas.api.types.CategoricalDtype` for specifying categoricals independent of the data, see [here](#).
- The behavior of `sum` and `prod` on all-NaN Series/DataFrames is now consistent and no longer depends on whether `bottleneck` is installed, and `sum` and `prod` on empty Series now return NaN instead of 0, see [here](#).
- Compatibility fixes for pypy, see [here](#).
- Additions to the `drop`, `reindex` and `rename` API to make them more consistent, see [here](#).
- Addition of the new methods `DataFrame.infer_objects` (see [here](#)) and `GroupBy.pipe` (see [here](#)).
- Indexing with a list of labels, where one or more of the labels is missing, is deprecated and will raise a `KeyError` in a future version, see [here](#).

Check the *API Changes* and *deprecations* before updating.

What's new in v0.21.0

- *New features*
 - *Integration with Apache Parquet file format*
 - *infer_objects type conversion*

- *Improved warnings when attempting to create columns*
- *drop now also accepts index/columns keywords*
- *rename, reindex now also accept axis keyword*
- *CategoricalDtype for specifying categoricals*
- *GroupBy objects now have a pipe method*
- *Categorical.rename_categories accepts a dict-like*
- *Other enhancements*
- *Backwards incompatible API changes*
 - *Dependencies have increased minimum versions*
 - *Sum/Prod of all-NaN or empty Series/DataFrames is now consistently NaN*
 - *Indexing with a list with missing labels is deprecated*
 - *NA naming changes*
 - *Iteration of Series/Index will now return Python scalars*
 - *Indexing with a Boolean Index*
 - *PeriodIndex resampling*
 - *Improved error handling during item assignment in pd.eval*
 - *Dtype conversions*
 - *MultiIndex constructor with a single level*
 - *UTC Localization with Series*
 - *Consistency of range functions*
 - *No automatic Matplotlib converters*
 - *Other API changes*
- *Deprecations*
 - *Series.select and DataFrame.select*
 - *Series.argmax and Series.argmin*
- *Removal of prior version deprecations/changes*
- *Performance improvements*
- *Documentation changes*
- *Bug fixes*
 - *Conversion*
 - *Indexing*
 - *I/O*
 - *Plotting*
 - *Groupby/resample/rolling*
 - *Sparse*

- *Reshaping*
- *Numeric*
- *Categorical*
- *PyPy*
- *Other*
- *Contributors*

New features

Integration with Apache Parquet file format

Integration with [Apache Parquet](#), including a new top-level `read_parquet()` and `DataFrame.to_parquet()` method, see [here](#) (GH15838, GH17438).

[Apache Parquet](#) provides a cross-language, binary file format for reading and writing data frames efficiently. Parquet is designed to faithfully serialize and de-serialize `DataFrame`s, supporting all of the pandas dtypes, including extension dtypes such as datetime with timezones.

This functionality depends on either the [pyarrow](#) or [fastparquet](#) library. For more details, see [the IO docs on Parquet](#).

`infer_objects` type conversion

The `DataFrame.infer_objects()` and `Series.infer_objects()` methods have been added to perform dtype inference on object columns, replacing some of the functionality of the deprecated `convert_objects` method. See the documentation [here](#) for more details. (GH11221)

This method only performs soft conversions on object columns, converting Python objects to native types, but not any coercive conversions. For example:

```
In [1]: df = pd.DataFrame({'A': [1, 2, 3],
...:                      'B': np.array([1, 2, 3], dtype='object'),
...:                      'C': ['1', '2', '3']})
...:
```

```
In [2]: df.dtypes
```

```
Out[2]:
A      int64
B      object
C      object
Length: 3, dtype: object
```

```
In [3]: df.infer_objects().dtypes
```

```
Out[3]:
A      int64
B      int64
C      object
Length: 3, dtype: object
```

Note that column 'C' was not converted - only scalar numeric types will be converted to a new type. Other types of conversion should be accomplished using the `to_numeric()` function (or `to_datetime()`, `to_timedelta()`).

```
In [4]: df = df.infer_objects()

In [5]: df['C'] = pd.to_numeric(df['C'], errors='coerce')

In [6]: df.dtypes
Out[6]:
A    int64
B    int64
C    int64
Length: 3, dtype: object
```

Improved warnings when attempting to create columns

New users are often puzzled by the relationship between column operations and attribute access on `DataFrame` instances (GH7175). One specific instance of this confusion is attempting to create a new column by setting an attribute on the `DataFrame`:

```
In [1]: df = pd.DataFrame({'one': [1., 2., 3.]})
In [2]: df.two = [4, 5, 6]
```

This does not raise any obvious exceptions, but also does not create a new column:

```
In [3]: df
Out[3]:
   one
0  1.0
1  2.0
2  3.0
```

Setting a list-like data structure into a new attribute now raises a `UserWarning` about the potential for unexpected behavior. See *Attribute Access*.

drop now also accepts index/columns keywords

The `drop()` method has gained `index/columns` keywords as an alternative to specifying the `axis`. This is similar to the behavior of `reindex` (GH12392).

For example:

```
In [7]: df = pd.DataFrame(np.arange(8).reshape(2, 4),
...:                      columns=['A', 'B', 'C', 'D'])
...:

In [8]: df
Out[8]:
   A  B  C  D
0  0  1  2  3
1  4  5  6  7
```

```
[2 rows x 4 columns]
```

```
In [9]: df.drop(['B', 'C'], axis=1)
```

```
Out[9]:
```

```
   A  D
0  0  3
1  4  7
```

```
[2 rows x 2 columns]
```

```
# the following is now equivalent
```

```
In [10]: df.drop(columns=['B', 'C'])
```

```
Out[10]:
```

```
   A  D
0  0  3
1  4  7
```

```
[2 rows x 2 columns]
```

rename, reindex now also accept axis keyword

The `DataFrame.rename()` and `DataFrame.reindex()` methods have gained the `axis` keyword to specify the axis to target with the operation ([GH12392](#)).

Here's rename:

```
In [11]: df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6]})
```

```
In [12]: df.rename(str.lower, axis='columns')
```

```
Out[12]:
```

```
   a  b
0  1  4
1  2  5
2  3  6
```

```
[3 rows x 2 columns]
```

```
In [13]: df.rename(id, axis='index')
```

```
Out[13]:
```

```
      A  B
4510573680  1  4
4510573712  2  5
4510573744  3  6
```

```
[3 rows x 2 columns]
```

And reindex:

```
In [14]: df.reindex(['A', 'B', 'C'], axis='columns')
```

```
Out[14]:
```

```
   A  B  C
0  1  4 NaN
1  2  5 NaN
2  3  6 NaN
```

```
[3 rows x 3 columns]
```

```
In [15]: df.reindex([0, 1, 3], axis='index')
```

```
Out[15]:
```

```
   A    B
0  1.0  4.0
1  2.0  5.0
3  NaN  NaN
```

```
[3 rows x 2 columns]
```

The “index, columns” style continues to work as before.

```
In [16]: df.rename(index=id, columns=str.lower)
```

```
Out[16]:
```

```
      a  b
4510573680  1  4
4510573712  2  5
4510573744  3  6
```

```
[3 rows x 2 columns]
```

```
In [17]: df.reindex(index=[0, 1, 3], columns=['A', 'B', 'C'])
```

```
Out[17]:
```

```
   A    B    C
0  1.0  4.0 NaN
1  2.0  5.0 NaN
3  NaN  NaN NaN
```

```
[3 rows x 3 columns]
```

We *highly* encourage using named arguments to avoid confusion when using either style.

CategoricalDtype for specifying categoricals

`pandas.api.types.CategoricalDtype` has been added to the public API and expanded to include the `categories` and `ordered` attributes. A `CategoricalDtype` can be used to specify the set of categories and orderedness of an array, independent of the data. This can be useful for example, when converting string data to a `Categorical` ([GH14711](#), [GH15078](#), [GH16015](#), [GH17643](#)):

```
In [18]: from pandas.api.types import CategoricalDtype
```

```
In [19]: s = pd.Series(['a', 'b', 'c', 'a']) # strings
```

```
In [20]: dtype = CategoricalDtype(categories=['a', 'b', 'c', 'd'], ordered=True)
```

```
In [21]: s.astype(dtype)
```

```
Out[21]:
```

```
0    a
1    b
2    c
3    a
Length: 4, dtype: category
Categories (4, object): [a < b < c < d]
```

One place that deserves special mention is in `read_csv()`. Previously, with `dtype={'col': 'category'}`, the returned values and categories would always be strings.

```
In [22]: data = 'A,B\na,1\nb,2\nc,3'
```

```
In [23]: pd.read_csv(StringIO(data), dtype={'B': 'category'}).B.cat.categories
```

```
Out[23]: Index(['1', '2', '3'], dtype='object')
```

Notice the “object” dtype.

With a `CategoricalDtype` of all numerics, datetimes, or timedeltas, we can automatically convert to the correct type

```
In [24]: dtype = {'B': CategoricalDtype([1, 2, 3])}
```

```
In [25]: pd.read_csv(StringIO(data), dtype=dtype).B.cat.categories
```

```
Out[25]: Int64Index([1, 2, 3], dtype='int64')
```

The values have been correctly interpreted as integers.

The `.dtype` property of a `Categorical`, `CategoricalIndex` or a `Series` with categorical type will now return an instance of `CategoricalDtype`. While the repr has changed, `str(CategoricalDtype())` is still the string `'category'`. We’ll take this moment to remind users that the *preferred* way to detect categorical data is to use `pandas.api.types.is_categorical_dtype()`, and not `str(dtype) == 'category'`.

See the *CategoricalDtype docs* for more.

GroupBy objects now have a pipe method

`GroupBy` objects now have a `pipe` method, similar to the one on `DataFrame` and `Series`, that allow for functions that take a `GroupBy` to be composed in a clean, readable syntax. ([GH17871](#))

For a concrete example on combining `.groupby` and `.pipe`, imagine having a `DataFrame` with columns for stores, products, revenue and sold quantity. We’d like to do a groupwise calculation of *prices* (i.e. revenue/quantity) per store and per product. We could do this in a multi-step operation, but expressing it in terms of piping can make the code more readable.

First we set the data:

```
In [26]: import numpy as np
```

```
In [27]: n = 1000
```

```
In [28]: df = pd.DataFrame({'Store': np.random.choice(['Store_1', 'Store_2'], n),
.....:                    'Product': np.random.choice(['Product_1',
.....:                                                  'Product_2',
.....:                                                  'Product_3']
.....:                    ], n),
.....:                    'Revenue': (np.random.random(n) * 50 + 10).round(2),
.....:                    'Quantity': np.random.randint(1, 10, size=n)})
.....:
```

```
In [29]: df.head(2)
```

```
Out[29]:
   Store  Product  Revenue  Quantity
```

(continues on next page)

(continued from previous page)

```
0 Store_2 Product_2 44.13 6
1 Store_1 Product_3 53.06 1

[2 rows x 4 columns]
```

Now, to find prices per store/product, we can simply do:

```
In [30]: (df.groupby(['Store', 'Product'])
.....:        .pipe(lambda grp: grp.Revenue.sum() / grp.Quantity.sum())
.....:        .unstack().round(2))
.....:
Out[30]:
Product  Product_1  Product_2  Product_3
Store
Store_1         7.44         7.10         6.93
Store_2         6.45         6.43         7.14

[2 rows x 3 columns]
```

See the [documentation](#) for more.

Categorical.rename_categories accepts a dict-like

`rename_categories()` now accepts a dict-like argument for `new_categories`. The previous categories are looked up in the dictionary's keys and replaced if found. The behavior of missing and extra keys is the same as in `DataFrame.rename()`.

```
In [31]: c = pd.Categorical(['a', 'a', 'b'])

In [32]: c.rename_categories({"a": "eh", "b": "bee"})
Out[32]:
[eh, eh, bee]
Categories (2, object): [eh, bee]
```

Warning: To assist with upgrading pandas, `rename_categories` treats `Series` as list-like. Typically, `Series` are considered to be dict-like (e.g. in `.rename`, `.map`). In a future version of pandas `rename_categories` will change to treat them as dict-like. Follow the warning message's recommendations for writing future-proof code.

```
In [33]: c.rename_categories(pd.Series([0, 1], index=['a', 'c']))
FutureWarning: Treating Series 'new_categories' as a list-like and using the values.
In a future version, 'rename_categories' will treat Series like a dictionary.
For dict-like, use 'new_categories.to_dict()'
For list-like, use 'new_categories.values'.
Out[33]:
[0, 0, 1]
Categories (2, int64): [0, 1]
```

Other enhancements

New functions or methods

- `nearest()` is added to support nearest-neighbor upsampling ([GH17496](#)).
- `Index` has added support for a `to_frame` method ([GH15230](#)).

New keywords

- Added a `skipna` parameter to `infer_dtype()` to support type inference in the presence of missing values ([GH17059](#)).
- `Series.to_dict()` and `DataFrame.to_dict()` now support an `into` keyword which allows you to specify the `collections.Mapping` subclass that you would like returned. The default is `dict`, which is backwards compatible. ([GH16122](#))
- `Series.set_axis()` and `DataFrame.set_axis()` now support the `inplace` parameter. ([GH14636](#))
- `Series.to_pickle()` and `DataFrame.to_pickle()` have gained a `protocol` parameter ([GH16252](#)). By default, this parameter is set to `HIGHEST_PROTOCOL`
- `read_feather()` has gained the `nthreads` parameter for multi-threaded operations ([GH16359](#))
- `DataFrame.clip()` and `Series.clip()` have gained an `inplace` argument. ([GH15388](#))
- `crosstab()` has gained a `margins_name` parameter to define the name of the row / column that will contain the totals when `margins=True`. ([GH15972](#))
- `read_json()` now accepts a `chunksize` parameter that can be used when `lines=True`. If `chunksize` is passed, `read_json` now returns an iterator which reads in `chunksize` lines with each iteration. ([GH17048](#))
- `read_json()` and `to_json()` now accept a `compression` argument which allows them to transparently handle compressed files. ([GH17798](#))

Various enhancements

- Improved the import time of pandas by about 2.25x. ([GH16764](#))
- Support for [PEP 519](#) – Adding a file system path protocol on most readers (e.g. `read_csv()`) and writers (e.g. `DataFrame.to_csv()`) ([GH13823](#)).
- Added a `__fspath__` method to `pd.HDFStore`, `pd.ExcelFile`, and `pd.ExcelWriter` to work properly with the file system path protocol ([GH13823](#)).
- The `validate` argument for `merge()` now checks whether a merge is one-to-one, one-to-many, many-to-one, or many-to-many. If a merge is found to not be an example of specified merge type, an exception of type `MergeError` will be raised. For more, see [here](#) ([GH16270](#))
- Added support for [PEP 518](#) (`pyproject.toml`) to the build system ([GH16745](#))
- `RangeIndex.append()` now returns a `RangeIndex` object when possible ([GH16212](#))
- `Series.rename_axis()` and `DataFrame.rename_axis()` with `inplace=True` now return `None` while renaming the axis inplace. ([GH15704](#))
- `api.types.infer_dtype()` now infers decimals. ([GH15690](#))
- `DataFrame.select_dtypes()` now accepts scalar values for include/exclude as well as list-like. ([GH16855](#))
- `date_range()` now accepts 'YS' in addition to 'AS' as an alias for start of year. ([GH9313](#))

- `date_range()` now accepts 'Y' in addition to 'A' as an alias for end of year. (GH9313)
- `DataFrame.add_prefix()` and `DataFrame.add_suffix()` now accept strings containing the '%' character. (GH17151)
- Read/write methods that infer compression (`read_csv()`, `read_table()`, `read_pickle()`, and `to_pickle()`) can now infer from path-like objects, such as `pathlib.Path`. (GH17206)
- `read_sas()` now recognizes much more of the most frequently used date (datetime) formats in SAS7BDAT files. (GH15871)
- `DataFrame.items()` and `Series.items()` are now present in both Python 2 and 3 and is lazy in all cases. (GH13918, GH17213)
- `pandas.io.formats.style.Styler.where()` has been implemented as a convenience for `pandas.io.formats.style.Styler.applymap()`. (GH17474)
- `MultiIndex.is_monotonic_decreasing()` has been implemented. Previously returned `False` in all cases. (GH16554)
- `read_excel()` raises `ImportError` with a better message if `xlrd` is not installed. (GH17613)
- `DataFrame.assign()` will preserve the original order of `**kwargs` for Python 3.6+ users instead of sorting the column names. (GH14207)
- `Series.reindex()`, `DataFrame.reindex()`, `Index.get_indexer()` now support list-like argument for tolerance. (GH17367)

Backwards incompatible API changes

Dependencies have increased minimum versions

We have updated our minimum supported versions of dependencies (GH15206, GH15543, GH15214). If installed, we now require:

Package	Minimum Version	Required
Numpy	1.9.0	X
Matplotlib	1.4.3	
Scipy	0.14.0	
Bottleneck	1.0.0	

Additionally, support has been dropped for Python 3.4 (GH15251).

Sum/Prod of all-NaN or empty Series/DataFrames is now consistently NaN

Note: The changes described here have been partially reverted. See the *v0.22.0 Whatsnew* for more.

The behavior of `sum` and `prod` on all-NaN Series/DataFrames no longer depends on whether `bottleneck` is installed, and return value of `sum` and `prod` on an empty Series has changed (GH9422, GH15507).

Calling `sum` or `prod` on an empty or all-NaN Series, or columns of a DataFrame, will result in NaN. See the *docs*.

```
In [33]: s = pd.Series([np.nan])
```

Previously WITHOUT bottleneck installed:

```
In [2]: s.sum()
Out[2]: np.nan
```

Previously WITH bottleneck:

```
In [2]: s.sum()
Out[2]: 0.0
```

New behavior, without regard to the bottleneck installation:

```
In [34]: s.sum()
Out[34]: 0.0
```

Note that this also changes the sum of an empty `Series`. Previously this always returned 0 regardless of a `bottleneck` installation:

```
In [1]: pd.Series([]).sum()
Out[1]: 0
```

but for consistency with the all-`NaN` case, this was changed to return `NaN` as well:

```
In [35]: pd.Series([]).sum()
Out[35]: 0.0
```

Indexing with a list with missing labels is deprecated

Previously, selecting with a list of labels, where one or more labels were missing would always succeed, returning `NaN` for missing labels. This will now show a `FutureWarning`. In the future this will raise a `KeyError` ([GH15747](#)). This warning will trigger on a `DataFrame` or a `Series` for using `.loc[]` or `[][]` when passing a list-of-labels with at least 1 missing label. See the [deprecation docs](#).

```
In [36]: s = pd.Series([1, 2, 3])

In [37]: s
Out[37]:
0    1
1    2
2    3
Length: 3, dtype: int64
```

Previous behavior

```
In [4]: s.loc[[1, 2, 3]]
Out[4]:
1    2.0
2    3.0
3    NaN
dtype: float64
```

Current behavior

```
In [4]: s.loc[[1, 2, 3]]
Passing list-likes to .loc or [] with any missing label will raise
KeyError in the future, you can use .reindex() as an alternative.

See the documentation here:
http://pandas.pydata.org/pandas-docs/stable/indexing.html#deprecate-loc-reindex-listlike

Out[4]:
1    2.0
2    3.0
3     NaN
dtype: float64
```

The idiomatic way to achieve selecting potentially not-found elements is via `.reindex()`

```
In [38]: s.reindex([1, 2, 3])
Out[38]:
1    2.0
2    3.0
3     NaN
Length: 3, dtype: float64
```

Selection with all keys found is unchanged.

```
In [39]: s.loc[[1, 2]]
Out[39]:
1    2
2    3
Length: 2, dtype: int64
```

NA naming changes

In order to promote more consistency among the pandas API, we have added additional top-level functions `isna()` and `notna()` that are aliases for `isnull()` and `notnull()`. The naming scheme is now more consistent with methods like `.dropna()` and `.fillna()`. Furthermore in all cases where `.isnull()` and `.notnull()` methods are defined, these have additional methods named `.isna()` and `.notna()`, these are included for classes `Categorical`, `Index`, `Series`, and `DataFrame`. (GH15001).

The configuration option `pd.options.mode.use_inf_as_null` is deprecated, and `pd.options.mode.use_inf_as_na` is added as a replacement.

Iteration of Series/Index will now return Python scalars

Previously, when using certain iteration methods for a `Series` with dtype `int` or `float`, you would receive a `numpy` scalar, e.g. a `np.int64`, rather than a Python `int`. Issue (GH10904) corrected this for `Series.tolist()` and `list(Series)`. This change makes all iteration methods consistent, in particular, for `__iter__()` and `.map()`; note that this only affects `int/float` dtypes. (GH13236, GH13258, GH14216).

```
In [40]: s = pd.Series([1, 2, 3])

In [41]: s
```

(continues on next page)

(continued from previous page)

```
Out [41]:
0    1
1    2
2    3
Length: 3, dtype: int64
```

Previously:

```
In [2]: type(list(s)[0])
Out[2]: numpy.int64
```

New behavior:

```
In [42]: type(list(s)[0])
Out[42]: int
```

Furthermore this will now correctly box the results of iteration for `DataFrame.to_dict()` as well.

```
In [43]: d = {'a': [1], 'b': ['b']}
```

```
In [44]: df = pd.DataFrame(d)
```

Previously:

```
In [8]: type(df.to_dict()['a'][0])
Out[8]: numpy.int64
```

New behavior:

```
In [45]: type(df.to_dict()['a'][0])
Out[45]: int
```

Indexing with a Boolean Index

Previously when passing a boolean `Index` to `.loc`, if the index of the `Series/DataFrame` had boolean labels, you would get a label based selection, potentially duplicating result labels, rather than a boolean indexing selection (where `True` selects elements), this was inconsistent how a boolean numpy array indexed. The new behavior is to act like a boolean numpy array indexer. ([GH17738](#))

Previous behavior:

```
In [46]: s = pd.Series([1, 2, 3], index=[False, True, False])
```

```
In [47]: s
Out[47]:
False    1
True     2
False    3
Length: 3, dtype: int64
```

```
In [59]: s.loc[pd.Index([True, False, True])]
Out[59]:
```

(continues on next page)

(continued from previous page)

```
True    2
False   1
False   3
True    2
dtype: int64
```

Current behavior

```
In [48]: s.loc[pd.Index([True, False, True])]
Out[48]:
False    1
False    3
Length: 2, dtype: int64
```

Furthermore, previously if you had an index that was non-numeric (e.g. strings), then a boolean Index would raise a `KeyError`. This will now be treated as a boolean indexer.

Previously behavior:

```
In [49]: s = pd.Series([1, 2, 3], index=['a', 'b', 'c'])

In [50]: s
Out[50]:
a    1
b    2
c    3
Length: 3, dtype: int64
```

```
In [39]: s.loc[pd.Index([True, False, True])]
KeyError: "None of [Index([True, False, True], dtype='object')] are in the [index]"
```

Current behavior

```
In [51]: s.loc[pd.Index([True, False, True])]
Out[51]:
a    1
c    3
Length: 2, dtype: int64
```

PeriodIndex resampling

In previous versions of pandas, resampling a `Series/DataFrame` indexed by a `PeriodIndex` returned a `DatetimeIndex` in some cases (GH12884). Resampling to a multiplied frequency now returns a `PeriodIndex` (GH15944). As a minor enhancement, resampling a `PeriodIndex` can now handle `NaT` values (GH13224)

Previous behavior:

```
In [1]: pi = pd.period_range('2017-01', periods=12, freq='M')

In [2]: s = pd.Series(np.arange(12), index=pi)

In [3]: resampled = s.resample('2Q').mean()
```

(continues on next page)

(continued from previous page)

```

In [4]: resampled
Out[4]:
2017-03-31    1.0
2017-09-30    5.5
2018-03-31   10.0
Freq: 2Q-DEC, dtype: float64

In [5]: resampled.index
Out[5]: DatetimeIndex(['2017-03-31', '2017-09-30', '2018-03-31'], dtype='datetime64[ns]',
  → freq='2Q-DEC')

```

New behavior:

```
In [52]: pi = pd.period_range('2017-01', periods=12, freq='M')
```

```
In [53]: s = pd.Series(np.arange(12), index=pi)
```

```
In [54]: resampled = s.resample('2Q').mean()
```

```

In [55]: resampled
Out[55]:
2017Q1    2.5
2017Q3    8.5
Freq: 2Q-DEC, Length: 2, dtype: float64

```

```

In [56]: resampled.index
Out[56]: PeriodIndex(['2017Q1', '2017Q3'], dtype='period[2Q-DEC]', freq='2Q-DEC')

```

Upsampling and calling `.ohlc()` previously returned a `Series`, basically identical to calling `.asfreq()`. OHLC upsampling now returns a `DataFrame` with columns `open`, `high`, `low` and `close` (GH13083). This is consistent with downsampling and `DatetimeIndex` behavior.

Previous behavior:

```

In [1]: pi = pd.period_range(start='2000-01-01', freq='D', periods=10)

In [2]: s = pd.Series(np.arange(10), index=pi)

In [3]: s.resample('H').ohlc()
Out[3]:
2000-01-01 00:00    0.0
          ...
2000-01-10 23:00    NaN
Freq: H, Length: 240, dtype: float64

In [4]: s.resample('M').ohlc()
Out[4]:
          open  high  low  close
2000-01      0     9     0     9

```

New behavior:

```
In [57]: pi = pd.period_range(start='2000-01-01', freq='D', periods=10)
```

```
In [58]: s = pd.Series(np.arange(10), index=pi)
```

```
In [59]: s.resample('H').ohlc()
```

```
Out[59]:
```

	open	high	low	close
2000-01-01 00:00	0.0	0.0	0.0	0.0
2000-01-01 01:00	NaN	NaN	NaN	NaN
2000-01-01 02:00	NaN	NaN	NaN	NaN
2000-01-01 03:00	NaN	NaN	NaN	NaN
2000-01-01 04:00	NaN	NaN	NaN	NaN
...
2000-01-10 19:00	NaN	NaN	NaN	NaN
2000-01-10 20:00	NaN	NaN	NaN	NaN
2000-01-10 21:00	NaN	NaN	NaN	NaN
2000-01-10 22:00	NaN	NaN	NaN	NaN
2000-01-10 23:00	NaN	NaN	NaN	NaN

```
[240 rows x 4 columns]
```

```
In [60]: s.resample('M').ohlc()
```

```
Out[60]:
```

	open	high	low	close
2000-01	0	9	0	9

```
[1 rows x 4 columns]
```

Improved error handling during item assignment in pd.eval

`eval()` will now raise a `ValueError` when item assignment malfunctions, or inplace operations are specified, but there is no item assignment in the expression ([GH16732](#))

```
In [61]: arr = np.array([1, 2, 3])
```

Previously, if you attempted the following expression, you would get a not very helpful error message:

```
In [3]: pd.eval("a = 1 + 2", target=arr, inplace=True)
...
IndexError: only integers, slices (:`:`), ellipsis (:`...`), numpy.newaxis (None)
and integer or boolean arrays are valid indices
```

This is a very long way of saying numpy arrays don't support string-item indexing. With this change, the error message is now this:

```
In [3]: pd.eval("a = 1 + 2", target=arr, inplace=True)
...
ValueError: Cannot assign expression output to target
```

It also used to be possible to evaluate expressions inplace, even if there was no item assignment:

```
In [4]: pd.eval("1 + 2", target=arr, inplace=True)
Out[4]: 3
```

However, this input does not make much sense because the output is not being assigned to the target. Now, a `ValueError` will be raised when such an input is passed in:

```
In [4]: pd.eval("1 + 2", target=arr, inplace=True)
...
ValueError: Cannot operate inplace if there is no assignment
```

Dtype conversions

Previously assignments, `.where()` and `.fillna()` with a `bool` assignment, would coerce to same the type (e.g. `int / float`), or raise for datetimelikes. These will now preserve the bools with `object` dtypes. (GH16821).

```
In [62]: s = pd.Series([1, 2, 3])
```

```
In [5]: s[1] = True
```

```
In [6]: s
Out[6]:
0    1
1    1
2    3
dtype: int64
```

New behavior

```
In [63]: s[1] = True
```

```
In [64]: s
Out[64]:
0    1
1   True
2    3
Length: 3, dtype: object
```

Previously, as assignment to a datetimelike with a non-datetimelike would coerce the non-datetime-like item being assigned (GH14145).

```
In [65]: s = pd.Series([pd.Timestamp('2011-01-01'), pd.Timestamp('2012-01-01')])
```

```
In [1]: s[1] = 1
```

```
In [2]: s
Out[2]:
0    2011-01-01 00:00:00.000000000
1    1970-01-01 00:00:00.000000001
dtype: datetime64[ns]
```

These now coerce to `object` dtype.

```
In [66]: s[1] = 1
```

```
In [67]: s
Out[67]:
```

(continues on next page)

(continued from previous page)

```
0    2011-01-01 00:00:00
1
Length: 2, dtype: object
```

- Inconsistent behavior in `.where()` with datetimelikes which would raise rather than coerce to `object` (GH16402)
- Bug in assignment against `int64` data with `np.ndarray` with `float64` dtype may keep `int64` dtype (GH14001)

Multindex constructor with a single level

The `MultiIndex` constructors no longer squeezes a `MultiIndex` with all length-one levels down to a regular `Index`. This affects all the `MultiIndex` constructors. (GH17178)

Previous behavior:

```
In [2]: pd.MultiIndex.from_tuples([('a',), ('b',)])
Out[2]: Index(['a', 'b'], dtype='object')
```

Length 1 levels are no longer special-cased. They behave exactly as if you had length 2+ levels, so a `MultiIndex` is always returned from all of the `MultiIndex` constructors:

```
In [68]: pd.MultiIndex.from_tuples([('a',), ('b',)])
Out[68]:
MultiIndex([('a',),
            ('b',)],
           )
```

UTC Localization with Series

Previously, `to_datetime()` did not localize datetime `Series` data when `utc=True` was passed. Now, `to_datetime()` will correctly localize `Series` with a `datetime64[ns, UTC]` dtype to be consistent with how list-like and `Index` data are handled. (GH6415).

Previous behavior

```
In [69]: s = pd.Series(['20130101 00:00:00'] * 3)
```

```
In [12]: pd.to_datetime(s, utc=True)
Out[12]:
0    2013-01-01
1    2013-01-01
2    2013-01-01
dtype: datetime64[ns]
```

New behavior

```
In [70]: pd.to_datetime(s, utc=True)
Out[70]:
0    2013-01-01 00:00:00+00:00
```

(continues on next page)

(continued from previous page)

```

1 2013-01-01 00:00:00+00:00
2 2013-01-01 00:00:00+00:00
Length: 3, dtype: datetime64[ns, UTC]

```

Additionally, DataFrames with datetime columns that were parsed by `read_sql_table()` and `read_sql_query()` will also be localized to UTC only if the original SQL columns were timezone aware datetime columns.

Consistency of range functions

In previous versions, there were some inconsistencies between the various range functions: `date_range()`, `bdate_range()`, `period_range()`, `timedelta_range()`, and `interval_range()`. (GH17471).

One of the inconsistent behaviors occurred when the `start`, `end` and `period` parameters were all specified, potentially leading to ambiguous ranges. When all three parameters were passed, `interval_range` ignored the `period` parameter, `period_range` ignored the `end` parameter, and the other range functions raised. To promote consistency among the range functions, and avoid potentially ambiguous ranges, `interval_range` and `period_range` will now raise when all three parameters are passed.

Previous behavior:

```

In [2]: pd.interval_range(start=0, end=4, periods=6)
Out[2]:
IntervalIndex([(0, 1], (1, 2], (2, 3]]
              closed='right',
              dtype='interval[int64]')

In [3]: pd.period_range(start='2017Q1', end='2017Q4', periods=6, freq='Q')
Out[3]: PeriodIndex(['2017Q1', '2017Q2', '2017Q3', '2017Q4', '2018Q1', '2018Q2'], dtype=
↳ 'period[Q-DEC]', freq='Q-DEC')

```

New behavior:

```

In [2]: pd.interval_range(start=0, end=4, periods=6)
-----
ValueError: Of the three parameters: start, end, and periods, exactly two must be
↳ specified

In [3]: pd.period_range(start='2017Q1', end='2017Q4', periods=6, freq='Q')
-----
ValueError: Of the three parameters: start, end, and periods, exactly two must be
↳ specified

```

Additionally, the endpoint parameter `end` was not included in the intervals produced by `interval_range`. However, all other range functions include `end` in their output. To promote consistency among the range functions, `interval_range` will now include `end` as the right endpoint of the final interval, except if `freq` is specified in a way which skips `end`.

Previous behavior:

```

In [4]: pd.interval_range(start=0, end=4)
Out[4]:
IntervalIndex([(0, 1], (1, 2], (2, 3]]

```

(continues on next page)

(continued from previous page)

```
closed='right',
dtype='interval[int64]')
```

New behavior:

```
In [71]: pd.interval_range(start=0, end=4)
Out [71]:
IntervalIndex([(0, 1], (1, 2], (2, 3], (3, 4]],
              closed='right',
              dtype='interval[int64]')
```

No automatic Matplotlib converters

Pandas no longer registers our `date`, `time`, `datetime`, `datetime64`, and `Period` converters with matplotlib when pandas is imported. Matplotlib plot methods (`plt.plot`, `ax.plot`, ...), will not nicely format the x-axis for `DatetimeIndex` or `PeriodIndex` values. You must explicitly register these methods:

Pandas built-in `Series.plot` and `DataFrame.plot` will register these converters on first-use ([GH17710](#)).

Note: This change has been temporarily reverted in pandas 0.21.1, for more details see [here](#).

Other API changes

- The Categorical constructor no longer accepts a scalar for the `categories` keyword. ([GH16022](#))
- Accessing a non-existent attribute on a closed `HDFStore` will now raise an `AttributeError` rather than a `ClosedFileError` ([GH16301](#))
- `read_csv()` now issues a `UserWarning` if the `names` parameter contains duplicates ([GH17095](#))
- `read_csv()` now treats 'null' and 'n/a' strings as missing values by default ([GH16471](#), [GH16078](#))
- `pandas.HDFStore`'s string representation is now faster and less detailed. For the previous behavior, use `pandas.HDFStore.info()`. ([GH16503](#)).
- Compression defaults in HDF stores now follow pytables standards. Default is no compression and if `complib` is missing and `complevel > 0` `zlib` is used ([GH15943](#))
- `Index.get_indexer_non_unique()` now returns a `ndarray` indexer rather than an `Index`; this is consistent with `Index.get_indexer()` ([GH16819](#))
- Removed the `@slow` decorator from `pandas.util.testing`, which caused issues for some downstream packages' test suites. Use `@pytest.mark.slow` instead, which achieves the same thing ([GH16850](#))
- Moved definition of `MergeError` to the `pandas.errors` module.
- The signature of `Series.set_axis()` and `DataFrame.set_axis()` has been changed from `set_axis(axis, labels)` to `set_axis(labels, axis=0)`, for consistency with the rest of the API. The old signature is deprecated and will show a `FutureWarning` ([GH14636](#))
- `Series.argmax()` and `Series.argmin()` will now raise a `TypeError` when used with `object` dtypes, instead of a `ValueError` ([GH13595](#))
- `Period` is now immutable, and will now raise an `AttributeError` when a user tries to assign a new value to the `ordinal` or `freq` attributes ([GH17116](#)).

- `to_datetime()` when passed a tz-aware `origin=` kwarg will now raise a more informative `ValueError` rather than a `TypeError` (GH16842)
- `to_datetime()` now raises a `ValueError` when format includes `%W` or `%U` without also including day of the week and calendar year (GH16774)
- Renamed non-functional `index` to `index_col` in `read_stata()` to improve API consistency (GH16342)
- Bug in `DataFrame.drop()` caused boolean labels `False` and `True` to be treated as labels 0 and 1 respectively when dropping indices from a numeric index. This will now raise a `ValueError` (GH16877)
- Restricted `DateOffset` keyword arguments. Previously, `DateOffset` subclasses allowed arbitrary keyword arguments which could lead to unexpected behavior. Now, only valid arguments will be accepted. (GH17176).

Deprecations

- `DataFrame.from_csv()` and `Series.from_csv()` have been deprecated in favor of `read_csv()` (GH4191)
- `read_excel()` has deprecated `sheetname` in favor of `sheet_name` for consistency with `.to_excel()` (GH10559).
- `read_excel()` has deprecated `parse_cols` in favor of `usecols` for consistency with `read_csv()` (GH4988)
- `read_csv()` has deprecated the `tupleize_cols` argument. Column tuples will always be converted to a `MultiIndex` (GH17060)
- `DataFrame.to_csv()` has deprecated the `tupleize_cols` argument. `MultiIndex` columns will be always written as rows in the CSV file (GH17060)
- The `convert` parameter has been deprecated in the `.take()` method, as it was not being respected (GH16948)
- `pd.options.html.border` has been deprecated in favor of `pd.options.display.html.border` (GH15793).
- `SeriesGroupBy.nth()` has deprecated `True` in favor of `'all'` for its kwarg `dropna` (GH11038).
- `DataFrame.as_blocks()` is deprecated, as this is exposing the internal implementation (GH17302)
- `pd.TimeGrouper` is deprecated in favor of `pandas.Grouper` (GH16747)
- `cdate_range` has been deprecated in favor of `bdate_range()`, which has gained `weekmask` and `holidays` parameters for building custom frequency date ranges. See the [documentation](#) for more details (GH17596)
- passing `categories` or `ordered` kwargs to `Series.astype()` is deprecated, in favor of passing a `CategoricalDtype` (GH17636)
- `.get_value` and `.set_value` on `Series`, `DataFrame`, `Panel`, `SparseSeries`, and `SparseDataFrame` are deprecated in favor of using `.iat[]` or `.at[]` accessors (GH15269)
- Passing a non-existent column in `.to_excel(..., columns=)` is deprecated and will raise a `KeyError` in the future (GH17295)
- `raise_on_error` parameter to `Series.where()`, `Series.mask()`, `DataFrame.where()`, `DataFrame.mask()` is deprecated, in favor of `errors=` (GH14968)
- Using `DataFrame.rename_axis()` and `Series.rename_axis()` to alter index or column *labels* is now deprecated in favor of using `.rename`. `rename_axis` may still be used to alter the name of the index or columns (GH17833).

- `reindex_axis()` has been deprecated in favor of `reindex()`. See *here* for more (GH17833).

Series.select and DataFrame.select

The `Series.select()` and `DataFrame.select()` methods are deprecated in favor of using `df.loc[labels.map(crit)]` (GH12401)

```
In [72]: df = pd.DataFrame({'A': [1, 2, 3]}, index=['foo', 'bar', 'baz'])
```

```
In [3]: df.select(lambda x: x in ['bar', 'baz'])
```

```
FutureWarning: select is deprecated and will be removed in a future release. You can use
↳ .loc[crit] as a replacement
```

```
Out [3]:
```

```
      A
bar  2
baz  3
```

```
In [73]: df.loc[df.index.map(lambda x: x in ['bar', 'baz'])]
```

```
Out [73]:
```

```
      A
bar  2
baz  3
```

```
[2 rows x 1 columns]
```

Series.argmax and Series.argmin

The behavior of `Series.argmax()` and `Series.argmin()` have been deprecated in favor of `Series.idxmax()` and `Series.idxmin()`, respectively (GH16830).

For compatibility with NumPy arrays, `pd.Series` implements `argmax` and `argmin`. Since pandas 0.13.0, `argmax` has been an alias for `pandas.Series.idxmax()`, and `argmin` has been an alias for `pandas.Series.idxmin()`. They return the *label* of the maximum or minimum, rather than the *position*.

We've deprecated the current behavior of `Series.argmax` and `Series.argmin`. Using either of these will emit a `FutureWarning`. Use `Series.idxmax()` if you want the label of the maximum. Use `Series.values.argmax()` if you want the position of the maximum. Likewise for the minimum. In a future release `Series.argmax` and `Series.argmin` will return the position of the maximum or minimum.

Removal of prior version deprecations/changes

- `read_excel()` has dropped the `has_index_names` parameter (GH10967)
- The `pd.options.display.height` configuration has been dropped (GH3663)
- The `pd.options.display.line_width` configuration has been dropped (GH2881)
- The `pd.options.display.mpl_style` configuration has been dropped (GH12190)
- `Index` has dropped the `.sym_diff()` method in favor of `.symmetric_difference()` (GH12591)
- `Categorical` has dropped the `.order()` and `.sort()` methods in favor of `.sort_values()` (GH12882)
- `eval()` and `DataFrame.eval()` have changed the default of `inplace` from `None` to `False` (GH11149)

- The function `get_offset_name` has been dropped in favor of the `.freqstr` attribute for an offset (GH11834)
- pandas no longer tests for compatibility with hdf5-files created with pandas < 0.11 (GH17404).

Performance improvements

- Improved performance of instantiating `SparseDataFrame` (GH16773)
- `Series.dt` no longer performs frequency inference, yielding a large speedup when accessing the attribute (GH17210)
- Improved performance of `set_categories()` by not materializing the values (GH17508)
- `Timestamp.microsecond` no longer re-computes on attribute access (GH17331)
- Improved performance of the `CategoricalIndex` for data that is already categorical dtype (GH17513)
- Improved performance of `RangeIndex.min()` and `RangeIndex.max()` by using `RangeIndex` properties to perform the computations (GH17607)

Documentation changes

- Several `NaT` method docstrings (e.g. `NaT.ctime()`) were incorrect (GH17327)
- The documentation has had references to versions < v0.17 removed and cleaned up (GH17442, GH17442, GH17404 & GH17504)

Bug fixes

Conversion

- Bug in assignment against datetime-like data with `int` may incorrectly convert to datetime-like (GH14145)
- Bug in assignment against `int64` data with `np.ndarray` with `float64` dtype may keep `int64` dtype (GH14001)
- Fixed the return type of `IntervalIndex.is_non_overlapping_monotonic` to be a Python `bool` for consistency with similar attributes/methods. Previously returned a `numpy.bool_`. (GH17237)
- Bug in `IntervalIndex.is_non_overlapping_monotonic` when intervals are closed on both sides and overlap at a point (GH16560)
- Bug in `Series.fillna()` returns frame when `inplace=True` and `value` is dict (GH16156)
- Bug in `Timestamp.weekday_name` returning a UTC-based weekday name when localized to a timezone (GH17354)
- Bug in `Timestamp.replace` when replacing `tzinfo` around DST changes (GH15683)
- Bug in `Timedelta` construction and arithmetic that would not propagate the `Overflow` exception (GH17367)
- Bug in `astype()` converting to object dtype when passed extension type classes (`DatetimeTZDtype`, `CategoricalDtype`) rather than instances. Now a `TypeError` is raised when a class is passed (GH17780).
- Bug in `to_numeric()` in which elements were not always being coerced to numeric when `errors='coerce'` (GH17007, GH17125)

- Bug in `DataFrame` and `Series` constructors where `range` objects are converted to `int32` dtype on Windows instead of `int64` (GH16804)

Indexing

- When called with a null slice (e.g. `df.iloc[:]`), the `.iloc` and `.loc` indexers return a shallow copy of the original object. Previously they returned the original object. (GH13873).
- When called on an unsorted `MultiIndex`, the `loc` indexer now will raise `UnsortedIndexError` only if proper slicing is used on non-sorted levels (GH16734).
- Fixes regression in 0.20.3 when indexing with a string on a `TimedeltaIndex` (GH16896).
- Fixed `TimedeltaIndex.get_loc()` handling of `np.timedelta64` inputs (GH16909).
- Fix `MultiIndex.sort_index()` ordering when `ascending` argument is a list, but not all levels are specified, or are in a different order (GH16934).
- Fixes bug where indexing with `np.inf` caused an `OverflowError` to be raised (GH16957)
- Bug in reindexing on an empty `CategoricalIndex` (GH16770)
- Fixes `DataFrame.loc` for setting with alignment and tz-aware `DatetimeIndex` (GH16889)
- Avoids `IndexError` when passing an `Index` or `Series` to `.iloc` with older numpy (GH17193)
- Allow unicode empty strings as placeholders in multilevel columns in Python 2 (GH17099)
- Bug in `.iloc` when used with inplace addition or assignment and an `int` indexer on a `MultiIndex` causing the wrong indexes to be read from and written to (GH17148)
- Bug in `.isin()` in which checking membership in empty `Series` objects raised an error (GH16991)
- Bug in `CategoricalIndex` reindexing in which specified indices containing duplicates were not being respected (GH17323)
- Bug in intersection of `RangeIndex` with negative step (GH17296)
- Bug in `IntervalIndex` where performing a scalar lookup fails for included right endpoints of non-overlapping monotonic decreasing indexes (GH16417, GH17271)
- Bug in `DataFrame.first_valid_index()` and `DataFrame.last_valid_index()` when no valid entry (GH17400)
- Bug in `Series.rename()` when called with a callable, incorrectly alters the name of the `Series`, rather than the name of the `Index`. (GH17407)
- Bug in `String.str_get()` raises `IndexError` instead of inserting NaNs when using a negative index. (GH17704)

I/O

- Bug in `read_hdf()` when reading a timezone aware index from `fixed` format `HDFStore` (GH17618)
- Bug in `read_csv()` in which columns were not being thoroughly de-duplicated (GH17060)
- Bug in `read_csv()` in which specified column names were not being thoroughly de-duplicated (GH17095)
- Bug in `read_csv()` in which non integer values for the header argument generated an unhelpful / unrelated error message (GH16338)

- Bug in `read_csv()` in which memory management issues in exception handling, under certain conditions, would cause the interpreter to segfault (GH14696, GH16798).
- Bug in `read_csv()` when called with `low_memory=False` in which a CSV with at least one column > 2GB in size would incorrectly raise a `MemoryError` (GH16798).
- Bug in `read_csv()` when called with a single-element list `header` would return a `DataFrame` of all NaN values (GH7757)
- Bug in `DataFrame.to_csv()` defaulting to 'ascii' encoding in Python 3, instead of 'utf-8' (GH17097)
- Bug in `read_stata()` where value labels could not be read when using an iterator (GH16923)
- Bug in `read_stata()` where the index was not set (GH16342)
- Bug in `read_html()` where import check fails when run in multiple threads (GH16928)
- Bug in `read_csv()` where automatic delimiter detection caused a `TypeError` to be thrown when a bad line was encountered rather than the correct error message (GH13374)
- Bug in `DataFrame.to_html()` with `notebook=True` where `DataFrames` with named indices or non-`MultiIndex` indices had undesired horizontal or vertical alignment for column or row labels, respectively (GH16792)
- Bug in `DataFrame.to_html()` in which there was no validation of the `justify` parameter (GH17527)
- Bug in `HDFStore.select()` when reading a contiguous mixed-data table featuring `VArray` (GH17021)
- Bug in `to_json()` where several conditions (including objects with unprintable symbols, objects with deep recursion, overlong labels) caused segfaults instead of raising the appropriate exception (GH14256)

Plotting

- Bug in plotting methods using `secondary_y` and `fontsize` not setting secondary axis font size (GH12565)
- Bug when plotting `timedelta` and `datetime` dtypes on y-axis (GH16953)
- Line plots no longer assume monotonic x data when calculating xlims, they show the entire lines now even for unsorted x data. (GH11310, GH11471)
- With matplotlib 2.0.0 and above, calculation of x limits for line plots is left to matplotlib, so that its new default settings are applied. (GH15495)
- Bug in `Series.plot.bar` or `DataFrame.plot.bar` with `y` not respecting user-passed `color` (GH16822)
- Bug causing `plotting.parallel_coordinates` to reset the random seed when using random colors (GH17525)

Groupby/resample/rolling

- Bug in `DataFrame.resample(...).size()` where an empty `DataFrame` did not return a `Series` (GH14962)
- Bug in `infer_freq()` causing indices with 2-day gaps during the working week to be wrongly inferred as business daily (GH16624)
- Bug in `.rolling(...).quantile()` which incorrectly used different defaults than `Series.quantile()` and `DataFrame.quantile()` (GH9413, GH16211)
- Bug in `groupby.transform()` that would coerce boolean dtypes back to float (GH16875)

- Bug in `Series.resample(...).apply()` where an empty `Series` modified the source index and did not return the name of a `Series` ([GH14313](#))
- Bug in `.rolling(...).apply(...)` with a `DataFrame` with a `DatetimeIndex`, a window of a `timedelta`-convertible and `min_periods >= 1` ([GH15305](#))
- Bug in `DataFrame.groupby` where index and column keys were not recognized correctly when the number of keys equaled the number of elements on the `groupby` axis ([GH16859](#))
- Bug in `groupby.nunique()` with `TimeGrouper` which cannot handle `NaT` correctly ([GH17575](#))
- Bug in `DataFrame.groupby` where a single level selection from a `MultiIndex` unexpectedly sorts ([GH17537](#))
- Bug in `DataFrame.groupby` where spurious warning is raised when `Grouper` object is used to override ambiguous column name ([GH17383](#))
- Bug in `TimeGrouper` differs when passes as a list and as a scalar ([GH17530](#))

Sparse

- Bug in `SparseSeries` raises `AttributeError` when a dictionary is passed in as data ([GH16905](#))
- Bug in `SparseDataFrame.fillna()` not filling all `NaNs` when frame was instantiated from SciPy sparse matrix ([GH16112](#))
- Bug in `SparseSeries.unstack()` and `SparseDataFrame.stack()` ([GH16614](#), [GH15045](#))
- Bug in `make_sparse()` treating two numeric/boolean data, which have same bits, as same when array `dtype` is `object` ([GH17574](#))
- `SparseArray.all()` and `SparseArray.any()` are now implemented to handle `SparseArray`, these were used but not implemented ([GH17570](#))

Reshaping

- Joining/Merging with a non unique `PeriodIndex` raised a `TypeError` ([GH16871](#))
- Bug in `crosstab()` where non-aligned series of integers were casted to float ([GH17005](#))
- Bug in merging with categorical dtypes with `datetimelikes` incorrectly raised a `TypeError` ([GH16900](#))
- Bug when using `isin()` on a large object series and large comparison array ([GH16012](#))
- Fixes regression from 0.20, `Series.aggregate()` and `DataFrame.aggregate()` allow dictionaries as return values again ([GH16741](#))
- Fixes `dtype` of result with integer `dtype` input, from `pivot_table()` when called with `margins=True` ([GH17013](#))
- Bug in `crosstab()` where passing two `Series` with the same name raised a `KeyError` ([GH13279](#))
- `Series.argmax()`, `Series.argmin()`, and their counterparts on `DataFrame` and `groupby` objects work correctly with floating point data that contains infinite values ([GH13595](#)).
- Bug in `unique()` where checking a tuple of strings raised a `TypeError` ([GH17108](#))
- Bug in `concat()` where order of result index was unpredictable if it contained non-comparable elements ([GH17344](#))
- Fixes regression when sorting by multiple columns on a `datetime64` `dtype` `Series` with `NaT` values ([GH16836](#))

- Bug in `pivot_table()` where the result's columns did not preserve the categorical dtype of columns when `dropna` was `False` (GH17842)
- Bug in `DataFrame.drop_duplicates` where dropping with non-unique column names raised a `ValueError` (GH17836)
- Bug in `unstack()` which, when called on a list of levels, would discard the `fillna` argument (GH13971)
- Bug in the alignment of `range` objects and other list-likes with `DataFrame` leading to operations being performed row-wise instead of column-wise (GH17901)

Numeric

- Bug in `.clip()` with `axis=1` and a list-like for `threshold` is passed; previously this raised `ValueError` (GH15390)
- `Series.clip()` and `DataFrame.clip()` now treat NA values for upper and lower arguments as `None` instead of raising `ValueError` (GH17276).

Categorical

- Bug in `Series.isin()` when called with a categorical (GH16639)
- Bug in the categorical constructor with empty values and categories causing the `.categories` to be an empty `Float64Index` rather than an empty `Index` with object dtype (GH17248)
- Bug in categorical operations with `Series.cat` not preserving the original Series' name (GH17509)
- Bug in `DataFrame.merge()` failing for categorical columns with boolean/int data types (GH17187)
- Bug in constructing a `Categorical/CategoricalDtype` when the specified `categories` are of categorical type (GH17884).

PyPy

- Compatibility with PyPy in `read_csv()` with `usecols=[<unsorted ints>]` and `read_json()` (GH17351)
- Split tests into cases for CPython and PyPy where needed, which highlights the fragility of index matching with `float('nan')`, `np.nan` and `NAT` (GH17351)
- Fix `DataFrame.memory_usage()` to support PyPy. Objects on PyPy do not have a fixed size, so an approximation is used instead (GH17228)

Other

- Bug where some inplace operators were not being wrapped and produced a copy when invoked (GH12962)
- Bug in `eval()` where the `inplace` parameter was being incorrectly handled (GH16732)

8.6 Version 0.20

8.6.1 v0.20.3 (July 7, 2017)

{{ header }}

This is a minor bug-fix release in the 0.20.x series and includes some small regression fixes and bug fixes. We recommend that all users upgrade to this version.

What's new in v0.20.3

- *Bug fixes*
 - *Conversion*
 - *Indexing*
 - *I/O*
 - *Plotting*
 - *Reshaping*
 - *Categorical*
- *Contributors*

Bug fixes

- Fixed a bug in failing to compute rolling computations of a column-MultiIndexed DataFrame (GH16789, GH16825)
- Fixed a pytest marker failing downstream packages' tests suites (GH16680)

Conversion

- Bug in pickle compat prior to the v0.20.x series, when UTC is a timezone in a Series/DataFrame/Index (GH16608)
- Bug in Series construction when passing a Series with dtype='category' (GH16524).
- Bug in DataFrame.astype() when passing a Series as the dtype kwarg. (GH16717).

Indexing

- Bug in Float64Index causing an empty array instead of None to be returned from .get(np.nan) on a Series whose index did not contain any NaN s (GH8569)
- Bug in MultiIndex.isin causing an error when passing an empty iterable (GH16777)
- Fixed a bug in a slicing DataFrame/Series that have a TimedeltaIndex (GH16637)

I/O

- Bug in read_csv() in which files weren't opened as binary files by the C engine on Windows, causing EOF characters mid-field, which would fail (GH16039, GH16559, GH16675)
- Bug in read_hdf() in which reading a Series saved to an HDF file in 'fixed' format fails when an explicit mode='r' argument is supplied (GH16583)
- Bug in DataFrame.to_latex() where bold_rows was wrongly specified to be True by default, whereas in reality row labels remained non-bold whatever parameter provided. (GH16707)
- Fixed an issue with DataFrame.style() where generated element ids were not unique (GH16780)

- Fixed loading a `DataFrame` with a `PeriodIndex`, from a `format='fixed'` `HDFStore`, in Python 3, that was written in Python 2 ([GH16781](#))

Plotting

- Fixed regression that prevented RGB and RGBA tuples from being used as color arguments ([GH16233](#))
- Fixed an issue with `DataFrame.plot.scatter()` that incorrectly raised a `KeyError` when categorical data is used for plotting ([GH16199](#))

Reshaping

- `PeriodIndex / TimedeltaIndex.join` was missing the `sort=` kwarg ([GH16541](#))
- Bug in joining on a `MultiIndex` with a `category` dtype for a level ([GH16627](#)).
- Bug in `merge()` when merging/joining with multiple categorical columns ([GH16767](#))

Categorical

- Bug in `DataFrame.sort_values` not respecting the `kind` parameter with categorical data ([GH16793](#))

8.6.2 v0.20.2 (June 4, 2017)

{{ header }}

This is a minor bug-fix release in the 0.20.x series and includes some small regression fixes, bug fixes and performance improvements. We recommend that all users upgrade to this version.

What's new in v0.20.2

- *Enhancements*
- *Performance improvements*
- *Bug fixes*
 - *Conversion*
 - *Indexing*
 - *I/O*
 - *Plotting*
 - *Groupby/resample/rolling*
 - *Sparse*
 - *Reshaping*
 - *Numeric*
 - *Categorical*
 - *Other*
- *Contributors*

Enhancements

- Unblocked access to additional compression types supported in pytables: 'blosc:blosclz', 'blosc:lz4', 'blosc:lz4hc', 'blosc:snappy', 'blosc:zlib', 'blosc:zstd' (GH14478)
- `Series` provides a `to_latex` method (GH16180)
- A new groupby method `ngroup()`, parallel to the existing `cumcount()`, has been added to return the group order (GH11642); see [here](#).

Performance improvements

- Performance regression fix when indexing with a list-like (GH16285)
- Performance regression fix for MultiIndexes (GH16319, GH16346)
- Improved performance of `.clip()` with scalar arguments (GH15400)

- Improved performance of groupby with categorical groupers (GH16413)
- Improved performance of `MultiIndex.remove_unused_levels()` (GH16556)

Bug fixes

- Silenced a warning on some Windows environments about “tput: terminal attributes: No such device or address” when detecting the terminal size. This fix only applies to python 3 (GH16496)
- Bug in using `pathlib.Path` or `py.path.local` objects with io functions (GH16291)
- Bug in `Index.symmetric_difference()` on two equal `MultiIndex`’s, results in a `TypeError` (GH13490)
- Bug in `DataFrame.update()` with `overwrite=False` and NaN values (GH15593)
- Passing an invalid engine to `read_csv()` now raises an informative `ValueError` rather than `UnboundLocalError`. (GH16511)
- Bug in `unique()` on an array of tuples (GH16519)
- Bug in `cut()` when `labels` are set, resulting in incorrect label ordering (GH16459)
- Fixed a compatibility issue with IPython 6.0’s tab completion showing deprecation warnings on `Categoricals` (GH16409)

Conversion

- Bug in `to_numeric()` in which empty data inputs were causing a segfault of the interpreter (GH16302)
- Silence numpy warnings when broadcasting `DataFrame` to `Series` with comparison ops (GH16378, GH16306)

Indexing

- Bug in `DataFrame.reset_index(level=)` with single level index (GH16263)
- Bug in partial string indexing with a monotonic, but not strictly-monotonic, index incorrectly reversing the slice bounds (GH16515)
- Bug in `MultiIndex.remove_unused_levels()` that would not return a `MultiIndex` equal to the original. (GH16556)

I/O

- Bug in `read_csv()` when `comment` is passed in a space delimited text file (GH16472)
- Bug in `read_csv()` not raising an exception with nonexistent columns in `usecols` when it had the correct length (GH14671)
- Bug that would force importing of the clipboard routines unnecessarily, potentially causing an import error on startup (GH16288)
- Bug that raised `IndexError` when HTML-rendering an empty `DataFrame` (GH15953)
- Bug in `read_csv()` in which tarfile object inputs were raising an error in Python 2.x for the C engine (GH16530)
- Bug where `DataFrame.to_html()` ignored the `index_names` parameter (GH16493)

- Bug where `pd.read_hdf()` returns numpy strings for index names ([GH13492](#))
- Bug in `HDFStore.select_as_multiple()` where start/stop arguments were not respected ([GH16209](#))

Plotting

- Bug in `DataFrame.plot` with a single column and a list-like `color` ([GH3486](#))
- Bug in `plot` where `NaT` in `DatetimeIndex` results in `Timestamp.min` ([GH12405](#))
- Bug in `DataFrame.boxplot` where `figsize` keyword was not respected for non-grouped boxplots ([GH11959](#))

Groupby/resample/rolling

- Bug in creating a time-based rolling window on an empty `DataFrame` ([GH15819](#))
- Bug in `rolling.cov()` with offset window ([GH16058](#))
- Bug in `.resample()` and `.groupby()` when aggregating on integers ([GH16361](#))

Sparse

- Bug in construction of `SparseDataFrame` from `scipy.sparse.dok_matrix` ([GH16179](#))

Reshaping

- Bug in `DataFrame.stack` with unsorted levels in `MultiIndex` columns ([GH16323](#))
- Bug in `pd.wide_to_long()` where no error was raised when `i` was not a unique identifier ([GH16382](#))
- Bug in `Series.isin(..)` with a list of tuples ([GH16394](#))
- Bug in construction of a `DataFrame` with mixed dtypes including an all-`NaT` column. ([GH16395](#))
- Bug in `DataFrame.agg()` and `Series.agg()` with aggregating on non-callable attributes ([GH16405](#))

Numeric

- Bug in `.interpolate()`, where `limit_direction` was not respected when `limit=None` (default) was passed ([GH16282](#))

Categorical

- Fixed comparison operations considering the order of the categories when both categoricals are un-ordered ([GH16014](#))

Other

- Bug in `DataFrame.drop()` with an empty-list with non-unique indices ([GH16270](#))

8.6.3 v0.20.1 (May 5, 2017)

{{ header }}

This is a major release from 0.19.2 and includes a number of API changes, deprecations, new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

- New `.agg()` API for Series/DataFrame similar to the groupby-rolling-resample API's, see [here](#)
- Integration with the `feather-format`, including a new top-level `pd.read_feather()` and `DataFrame.to_feather()` method, see [here](#).
- The `.ix` indexer has been deprecated, see [here](#)
- `Panel` has been deprecated, see [here](#)
- Addition of an `IntervalIndex` and `Interval` scalar type, see [here](#)
- Improved user API when grouping by index levels in `.groupby()`, see [here](#)
- Improved support for `UInt64` dtypes, see [here](#)
- A new orient for JSON serialization, `orient='table'`, that uses the Table Schema spec and that gives the possibility for a more interactive repr in the Jupyter Notebook, see [here](#)
- Experimental support for exporting styled DataFrames (`DataFrame.style`) to Excel, see [here](#)
- Window binary corr/cov operations now return a MultiIndexed DataFrame rather than a Panel, as `Panel` is now deprecated, see [here](#)
- Support for S3 handling now uses `s3fs`, see [here](#)
- Google BigQuery support now uses the `pandas-gbq` library, see [here](#)

Warning: Pandas has changed the internal structure and layout of the code base. This can affect imports that are not from the top-level `pandas.*` namespace, please see the changes [here](#).

Check the *API Changes* and *deprecations* before updating.

Note: This is a combined release for 0.20.0 and 0.20.1. Version 0.20.1 contains one additional change for backwards-compatibility with downstream projects using pandas' `utils` routines. ([GH16250](#))

What's new in v0.20.0

- *New features*
 - *agg* API for DataFrame/Series
 - *dtype* keyword for data IO
 - *.to_datetime()* has gained an *origin* parameter
 - *Groupby* enhancements

- Better support for compressed URLs in `read_csv`
- Pickle file I/O now supports compression
- `UInt64` support improved
- `GroupBy` on categoricals
- Table schema output
- SciPy sparse matrix from/to `SparseDataFrame`
- Excel output for styled `DataFrames`
- `IntervalIndex`
- Other enhancements
- Backwards incompatible API changes
 - Possible incompatibility for HDF5 formats created with pandas < 0.13.0
 - Map on Index types now return other Index types
 - Accessing datetime fields of Index now return Index
 - `pd.unique` will now be consistent with extension types
 - S3 file handling
 - Partial string indexing changes
 - Concat of different float dtypes will not automatically upcast
 - Pandas Google BigQuery support has moved
 - Memory usage for Index is more accurate
 - `DataFrame.sort_index` changes
 - `Groupby` describe formatting
 - Window binary corr/cov operations return a `MultiIndex DataFrame`
 - `HDFStore` where string comparison
 - `Index.intersection` and `inner join` now preserve the order of the left Index
 - Pivot table always returns a `DataFrame`
 - Other API changes
- Reorganization of the library: privacy changes
 - Modules privacy has changed
 - `pandas.errors`
 - `pandas.testing`
 - `pandas.plotting`
 - Other Development Changes
- Deprecations
 - Deprecate `.ix`
 - Deprecate Panel

- Deprecate `groupby.agg()` with a dictionary when renaming
- Deprecate `.plotting`
- Other deprecations
- Removal of prior version deprecations/changes
- Performance improvements
- Bug fixes
 - Conversion
 - Indexing
 - I/O
 - Plotting
 - Groupby/resample/rolling
 - Sparse
 - Reshaping
 - Numeric
 - Other
- Contributors

New features

agg API for DataFrame/Series

Series & DataFrame have been enhanced to support the aggregation API. This is a familiar API from `groupby`, window operations, and resampling. This allows aggregation operations in a concise way by using `agg()` and `transform()`. The full documentation is [here](#) (GH1623).

Here is a sample

```
In [1]: df = pd.DataFrame(np.random.randn(10, 3), columns=['A', 'B', 'C'],
...:                      index=pd.date_range('1/1/2000', periods=10))
...:
```

```
In [2]: df.iloc[3:7] = np.nan
```

```
In [3]: df
```

```
Out [3]:
```

	A	B	C
2000-01-01	-1.392054	1.153922	1.181944
2000-01-02	0.391371	-0.881047	0.295080
2000-01-03	1.863801	-1.712274	-1.407085
2000-01-04	NaN	NaN	NaN
2000-01-05	NaN	NaN	NaN
2000-01-06	NaN	NaN	NaN
2000-01-07	NaN	NaN	NaN
2000-01-08	1.076541	0.363177	1.893680

(continues on next page)

(continued from previous page)

```
2000-01-09 -0.485753  0.387674  0.023558
2000-01-10 -0.660230 -0.318685 -0.722662
```

```
[10 rows x 3 columns]
```

One can operate using string function names, callables, lists, or dictionaries of these.

Using a single function is equivalent to `.apply`.

```
In [4]: df.agg('sum')
Out[4]:
A    0.793677
B   -1.007232
C    1.264515
Length: 3, dtype: float64
```

Multiple aggregations with a list of functions.

```
In [5]: df.agg(['sum', 'min'])
Out[5]:
      A      B      C
sum  0.793677 -1.007232  1.264515
min -1.392054 -1.712274 -1.407085
```

```
[2 rows x 3 columns]
```

Using a dict provides the ability to apply specific aggregations per column. You will get a matrix-like output of all of the aggregators. The output has one column per unique function. Those functions applied to a particular column will be NaN:

```
In [6]: df.agg({'A': ['sum', 'min'], 'B': ['min', 'max']})
Out[6]:
      A      B
max   NaN  1.153922
min -1.392054 -1.712274
sum  0.793677      NaN
```

```
[3 rows x 2 columns]
```

The API also supports a `.transform()` function for broadcasting results.

```
In [7]: df.transform(['abs', lambda x: x - x.min()])
Out[7]:
      A      B      C
abs  <lambda>  abs  <lambda>  abs  <lambda>
2000-01-01  1.392054  0.000000  1.153922  2.866196  1.181944  2.589029
2000-01-02  0.391371  1.783426  0.881047  0.831227  0.295080  1.702165
2000-01-03  1.863801  3.255855  1.712274  0.000000  1.407085  0.000000
2000-01-04      NaN      NaN      NaN      NaN      NaN      NaN
2000-01-05      NaN      NaN      NaN      NaN      NaN      NaN
2000-01-06      NaN      NaN      NaN      NaN      NaN      NaN
2000-01-07      NaN      NaN      NaN      NaN      NaN      NaN
2000-01-08  1.076541  2.468595  0.363177  2.075451  1.893680  3.300764
```

(continues on next page)

(continued from previous page)

```
2000-01-09 0.485753 0.906301 0.387674 2.099948 0.023558 1.430642
2000-01-10 0.660230 0.731825 0.318685 1.393589 0.722662 0.684422
```

```
[10 rows x 6 columns]
```

When presented with mixed dtypes that cannot be aggregated, `.agg()` will only take the valid aggregations. This is similar to how `groupby .agg()` works. (GH15015)

```
In [8]: df = pd.DataFrame({'A': [1, 2, 3],
...:                      'B': [1., 2., 3.],
...:                      'C': ['foo', 'bar', 'baz'],
...:                      'D': pd.date_range('20130101', periods=3)})
...:
```

```
In [9]: df.dtypes
```

```
Out[9]:
```

```
A          int64
B          float64
C          object
D    datetime64[ns]
Length: 4, dtype: object
```

```
In [10]: df.agg(['min', 'sum'])
```

```
Out[10]:
```

```
   A  B      C      D
min 1  1.0    bar 2013-01-01
sum 6  6.0 foobarbaz      NaT
```

```
[2 rows x 4 columns]
```

dtype keyword for data IO

The 'python' engine for `read_csv()`, as well as the `read_fwf()` function for parsing fixed-width text files and `read_excel()` for parsing Excel files, now accept the `dtype` keyword argument for specifying the types of specific columns (GH14295). See the *io docs* for more information.

```
In [11]: data = "a  b\n1  2\n3  4"
```

```
In [12]: pd.read_fwf(StringIO(data)).dtypes
```

```
Out[12]:
```

```
a    int64
b    int64
Length: 2, dtype: object
```

```
In [13]: pd.read_fwf(StringIO(data), dtype={'a': 'float64', 'b': 'object'}).dtypes
```

```
Out[13]:
```

```
a    float64
b    object
Length: 2, dtype: object
```

.to_datetime() has gained an origin parameter

`to_datetime()` has gained a new parameter, `origin`, to define a reference date from where to compute the resulting timestamps when parsing numerical values with a specific unit specified. (GH11276, GH11745)

For example, with 1960-01-01 as the starting date:

```
In [14]: pd.to_datetime([1, 2, 3], unit='D', origin=pd.Timestamp('1960-01-01'))
Out[14]: DatetimeIndex(['1960-01-02', '1960-01-03', '1960-01-04'], dtype='datetime64[ns]
↳', freq=None)
```

The default is set at `origin='unix'`, which defaults to 1970-01-01 00:00:00, which is commonly called 'unix epoch' or POSIX time. This was the previous default, so this is a backward compatible change.

```
In [15]: pd.to_datetime([1, 2, 3], unit='D')
Out[15]: DatetimeIndex(['1970-01-02', '1970-01-03', '1970-01-04'], dtype='datetime64[ns]
↳', freq=None)
```

Groupby enhancements

Strings passed to `DataFrame.groupby()` as the `by` parameter may now reference either column names or index level names. Previously, only column names could be referenced. This allows to easily group by a column and index level at the same time. (GH5677)

```
In [16]: arrays = [['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'],
.....:              ['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two']]
.....:
```

```
In [17]: index = pd.MultiIndex.from_arrays(arrays, names=['first', 'second'])
```

```
In [18]: df = pd.DataFrame({'A': [1, 1, 1, 1, 2, 2, 3, 3],
.....:                     'B': np.arange(8)},
.....:                     index=index)
.....:
```

```
In [19]: df
Out[19]:
```

		A	B
first	second		
bar	one	1	0
	two	1	1
baz	one	1	2
	two	1	3
foo	one	2	4
	two	2	5
qux	one	3	6
	two	3	7

[8 rows x 2 columns]

```
In [20]: df.groupby(['second', 'A']).sum()
```

```
Out[20]:
```

```
      B
second A
```

```
one    1  2
       2  4
       3  6
two    1  4
       2  5
       3  7
```

```
[6 rows x 1 columns]
```

Better support for compressed URLs in read_csv

The compression code was refactored (GH12688). As a result, reading dataframes from URLs in `read_csv()` or `read_table()` now supports additional compression methods: `xz`, `bz2`, and `zip` (GH14570). Previously, only `gzip` compression was supported. By default, compression of URLs and paths are now inferred using their file extensions. Additionally, support for `bz2` compression in the python 2 C-engine improved (GH14874).

```
In [21]: url = ('https://github.com/{repo}/raw/{branch}/{path}'
.....:         .format(repo='pandas-dev/pandas',
.....:                 branch='master',
.....:                 path='pandas/tests/io/parser/data/salaries.csv.bz2'))
.....:

# default, infer compression
In [22]: df = pd.read_csv(url, sep='\t', compression='infer')

# explicitly specify compression
In [23]: df = pd.read_csv(url, sep='\t', compression='bz2')

In [24]: df.head(2)
Out[24]:
      S  X  E  M
0  13876  1  1  1
1  11608  1  3  0

[2 rows x 4 columns]
```

Pickle file I/O now supports compression

`read_pickle()`, `DataFrame.to_pickle()` and `Series.to_pickle()` can now read from and write to compressed pickle files. Compression methods can be an explicit parameter or be inferred from the file extension. See *the docs here*.

```
In [25]: df = pd.DataFrame({'A': np.random.randn(1000),
.....:                     'B': 'foo',
.....:                     'C': pd.date_range('20130101', periods=1000, freq='s')})
.....:
```

Using an explicit compression type

```
In [26]: df.to_pickle("data.pkl.compress", compression="gzip")

In [27]: rt = pd.read_pickle("data.pkl.compress", compression="gzip")

In [28]: rt.head()
Out[28]:
```

	A	B	C
0	0.177387	foo	2013-01-01 00:00:00
1	0.983513	foo	2013-01-01 00:00:01
2	0.023505	foo	2013-01-01 00:00:02
3	0.553777	foo	2013-01-01 00:00:03
4	0.353769	foo	2013-01-01 00:00:04

```
[5 rows x 3 columns]
```

The default is to infer the compression type from the extension (`compression='infer'`):

```
In [29]: df.to_pickle("data.pkl.gz")

In [30]: rt = pd.read_pickle("data.pkl.gz")

In [31]: rt.head()
Out[31]:
```

	A	B	C
0	0.177387	foo	2013-01-01 00:00:00
1	0.983513	foo	2013-01-01 00:00:01
2	0.023505	foo	2013-01-01 00:00:02
3	0.553777	foo	2013-01-01 00:00:03
4	0.353769	foo	2013-01-01 00:00:04

```
[5 rows x 3 columns]

In [32]: df["A"].to_pickle("s1.pkl.bz2")

In [33]: rt = pd.read_pickle("s1.pkl.bz2")

In [34]: rt.head()
Out[34]:
```

0	0.177387
1	0.983513
2	0.023505
3	0.553777
4	0.353769

```
Name: A, Length: 5, dtype: float64
```

UInt64 support improved

Pandas has significantly improved support for operations involving unsigned, or purely non-negative, integers. Previously, handling these integers would result in improper rounding or data-type casting, leading to incorrect results. Notably, a new numerical index, `UInt64Index`, has been created ([GH14937](#))

```
In [35]: idx = pd.UInt64Index([1, 2, 3])

In [36]: df = pd.DataFrame({'A': ['a', 'b', 'c']}, index=idx)

In [37]: df.index
Out[37]: UInt64Index([1, 2, 3], dtype='uint64')
```

- Bug in converting object elements of array-like objects to unsigned 64-bit integers ([GH4471](#), [GH14982](#))
- Bug in `Series.unique()` in which unsigned 64-bit integers were causing overflow ([GH14721](#))
- Bug in `DataFrame` construction in which unsigned 64-bit integer elements were being converted to objects ([GH14881](#))
- Bug in `pd.read_csv()` in which unsigned 64-bit integer elements were being improperly converted to the wrong data types ([GH14983](#))
- Bug in `pd.unique()` in which unsigned 64-bit integers were causing overflow ([GH14915](#))
- Bug in `pd.value_counts()` in which unsigned 64-bit integers were being erroneously truncated in the output ([GH14934](#))

GroupBy on categoricals

In previous versions, `.groupby(..., sort=False)` would fail with a `ValueError` when grouping on a categorical series with some categories not appearing in the data. ([GH13179](#))

```
In [38]: chromosomes = np.r_[np.arange(1, 23).astype(str), ['X', 'Y']]

In [39]: df = pd.DataFrame({
.....:     'A': np.random.randint(100),
.....:     'B': np.random.randint(100),
.....:     'C': np.random.randint(100),
.....:     'chromosomes': pd.Categorical(np.random.choice(chromosomes, 100),
.....:                                     categories=chromosomes,
.....:                                     ordered=True)})
.....:

In [40]: df
Out[40]:
   A  B  C chromosomes
0  64 56 54          1
1  64 56 54          Y
2  64 56 54          Y
3  64 56 54          Y
4  64 56 54         11
..  ..  ..  ..      ...
95 64 56 54         14
96 64 56 54         10
97 64 56 54         13
98 64 56 54         18
99 64 56 54          8

[100 rows x 4 columns]
```

Previous behavior:

```
In [3]: df[df.chromosomes != '1'].groupby('chromosomes', sort=False).sum()
-----
ValueError: items in new_categories are not the same as in old categories
```

New behavior:

```
In [41]: df[df.chromosomes != '1'].groupby('chromosomes', sort=False).sum()
Out[41]:
```

chromosomes	A	B	C
2	128	112	108
3	128	112	108
4	256	224	216
5	256	224	216
6	384	336	324
7	192	168	162
8	192	168	162
9	384	336	324

22	256	224	216
X	128	112	108
Y	576	504	486
1	0	0	0

```
[24 rows x 3 columns]
```

Table schema output

The new orient 'table' for DataFrame.to_json() will generate a [Table Schema](#) compatible string representation of the data.

```
In [42]: df = pd.DataFrame(
.....:     {'A': [1, 2, 3],
.....:      'B': ['a', 'b', 'c'],
.....:      'C': pd.date_range('2016-01-01', freq='d', periods=3)},
.....:     index=pd.Index(range(3), name='idx'))
.....:
```

```
In [43]: df
```

```
Out[43]:
```

```

      A B      C
idx
0    1 a 2016-01-01
1    2 b 2016-01-02
2    3 c 2016-01-03

```

```
[3 rows x 3 columns]
```

```

In [44]: df.to_json(orient='table')
Out[44]: '{"schema": {"fields": [{"name": "idx", "type": "integer"}, {"name": "A",
↪ "type": "integer"}, {"name": "B", "type": "string"}, {"name": "C", "type": "datetime"}]},
↪ "primaryKey": ["idx"], "pandas_version": "0.20.0"}, "data": [{"idx": 0, "A": 1, "B": "a",
↪ "C": "2016-01-01T00:00:00.000Z"}, {"idx": 1, "A": 2, "B": "b", "C": "2016-01-02T00:00:00.000Z"},
↪ {"idx": 2, "A": 3, "B": "c", "C": "2016-01-03T00:00:00.000Z"}]}'

```

See *IO: Table Schema for more information*.

Additionally, the repr for `DataFrame` and `Series` can now publish this JSON Table schema representation of the Series or DataFrame if you are using IPython (or another frontend like `nteract` using the Jupyter messaging protocol). This gives frontends like the Jupyter notebook and `nteract` more flexibility in how they display pandas objects, since they have more information about the data. You must enable this by setting the `display.html.table_schema` option to `True`.

SciPy sparse matrix from/to SparseDataFrame

Pandas now supports creating sparse dataframes directly from `scipy.sparse.spmatrix` instances. See the *documentation* for more information. (GH4343)

All sparse formats are supported, but matrices that are not in `COOrdinate` format will be converted, copying data as needed.

```

In [45]: from scipy.sparse import csr_matrix

In [46]: arr = np.random.random(size=(1000, 5))

In [47]: arr[arr < .9] = 0

In [48]: sp_arr = csr_matrix(arr)

In [49]: sp_arr
Out[49]:
<1000x5 sparse matrix of type '<class 'numpy.float64''>'
with 491 stored elements in Compressed Sparse Row format>

In [50]: sdf = pd.SparseDataFrame(sp_arr)

In [51]: sdf
Out[51]:
      0      1      2      3      4
0  NaN  0.97914 NaN NaN NaN
1  NaN      NaN NaN NaN NaN
2  NaN      NaN NaN NaN NaN
3  NaN      NaN NaN NaN NaN
4  NaN      NaN NaN NaN NaN

```

(continues on next page)

(continued from previous page)

```

.. ..      ... .. .. ..
995 NaN      NaN NaN NaN NaN
996 NaN      NaN NaN NaN NaN
997 NaN      NaN NaN NaN NaN
998 NaN      NaN NaN NaN NaN
999 NaN      NaN NaN NaN NaN

[1000 rows x 5 columns]

```

To convert a `SparseDataFrame` back to sparse SciPy matrix in COO format, you can use:

```

In [52]: sdf.to_coo()
Out[52]:
<1000x5 sparse matrix of type '<class 'numpy.float64''>'
      with 491 stored elements in COOrdinate format>

```

Excel output for styled DataFrames

Experimental support has been added to export `DataFrame.style` formats to Excel using the `openpyxl` engine. (GH15530)

For example, after running the following, `styled.xlsx` renders as below:

```

In [53]: np.random.seed(24)

In [54]: df = pd.DataFrame({'A': np.linspace(1, 10, 10)})

In [55]: df = pd.concat([df, pd.DataFrame(np.random.RandomState(24).randn(10, 4),
.....:                                     columns=list('BCDE'))],
.....:                   axis=1)
.....:

In [56]: df.iloc[0, 2] = np.nan

In [57]: df
Out[57]:
   A         B         C         D         E
0  1.0  1.329212      NaN -0.316280 -0.990810
1  2.0 -1.070816 -1.438713  0.564417  0.295722
2  3.0 -1.626404  0.219565  0.678805  1.889273
3  4.0  0.961538  0.104011 -0.481165  0.850229
4  5.0  1.453425  1.057737  0.165562  0.515018
5  6.0 -1.336936  0.562861  1.392855 -0.063328
6  7.0  0.121668  1.207603 -0.002040  1.627796
7  8.0  0.354493  1.037528 -0.385684  0.519818
8  9.0  1.686583 -1.325963  1.428984 -2.089354
9 10.0 -0.129820  0.631523 -0.586538  0.290720

[10 rows x 5 columns]

In [58]: styled = (df.style

```

(continues on next page)

(continued from previous page)

```

.....:         .applymap(lambda val: 'color: %s' % 'red' if val < 0 else 'black')
.....:         .highlight_max()
.....:

```

```
In [59]: styled.to_excel('styled.xlsx', engine='openpyxl')
```

	A	B	C	D	E	F

10	8	9	1.686583	-1.325963	1.428984	-2.089354
11	9	10	-0.12982	0.631523	-0.586538	0.29072

See the *Style documentation* for more detail.

IntervalIndex

pandas has gained an `IntervalIndex` with its own dtype, `interval` as well as the `Interval` scalar type. These allow first-class support for interval notation, specifically as a return type for the categories in `cut()` and `qcut()`. The `IntervalIndex` allows some unique indexing, see the *docs*. (GH7640, GH8625)

Warning: These indexing behaviors of the `IntervalIndex` are provisional and may change in a future version of pandas. Feedback on usage is welcome.

Previous behavior:

The returned categories were strings, representing Intervals

```

In [1]: c = pd.cut(range(4), bins=2)

In [2]: c
Out[2]:
[(-0.003, 1.5], (-0.003, 1.5], (1.5, 3], (1.5, 3]]
Categories (2, object): [(-0.003, 1.5] < (1.5, 3]]

In [3]: c.categories
Out[3]: Index(['(-0.003, 1.5]', '(1.5, 3]'], dtype='object')

```

New behavior:

```
In [60]: c = pd.cut(range(4), bins=2)
```

```
In [61]: c
```

```
Out[61]:
[(-0.003, 1.5], (-0.003, 1.5], (1.5, 3.0], (1.5, 3.0]]
Categories (2, interval[float64]): [(-0.003, 1.5] < (1.5, 3.0]]
```

```
In [62]: c.categories
Out[62]:
IntervalIndex([(-0.003, 1.5], (1.5, 3.0]],
              closed='right',
              dtype='interval[float64]')
```

Furthermore, this allows one to bin *other* data with these same bins, with NaN representing a missing value similar to other dtypes.

```
In [63]: pd.cut([0, 3, 5, 1], bins=c.categories)
Out[63]:
[(-0.003, 1.5], (1.5, 3.0], NaN, (-0.003, 1.5]]
Categories (2, interval[float64]): [(-0.003, 1.5] < (1.5, 3.0]]
```

An IntervalIndex can also be used in Series and DataFrame as the index.

```
In [64]: df = pd.DataFrame({'A': range(4),
.....:                    'B': pd.cut([0, 3, 1, 1], bins=c.categories)
.....:                    }).set_index('B')
.....:

In [65]: df
Out[65]:
           A
B
(-0.003, 1.5]  0
(1.5, 3.0]     1
(-0.003, 1.5]  2
(-0.003, 1.5]  3

[4 rows x 1 columns]
```

Selecting via a specific interval:

```
In [66]: df.loc[pd.Interval(1.5, 3.0)]
Out[66]:
A    1
Name: (1.5, 3.0], Length: 1, dtype: int64
```

Selecting via a scalar value that is contained *in* the intervals.

```
In [67]: df.loc[0]
Out[67]:
           A
B
(-0.003, 1.5]  0
(-0.003, 1.5]  2
(-0.003, 1.5]  3

[3 rows x 1 columns]
```

Other enhancements

- `DataFrame.rolling()` now accepts the parameter `closed='right'|'left'|'both'|'neither'` to choose the rolling window-endpoint closedness. See the [documentation](#) (GH13965)
- Integration with the `feather-format`, including a new top-level `pd.read_feather()` and `DataFrame.to_feather()` method, see [here](#).
- `Series.str.replace()` now accepts a callable, as replacement, which is passed to `re.sub` (GH15055)
- `Series.str.replace()` now accepts a compiled regular expression as a pattern (GH15446)
- `Series.sort_index` accepts parameters `kind` and `na_position` (GH13589, GH14444)
- `DataFrame` and `DataFrame.groupby()` have gained a `nunique()` method to count the distinct values over an axis (GH14336, GH15197).
- `DataFrame` has gained a `melt()` method, equivalent to `pd.melt()`, for unpivoting from a wide to long format (GH12640).
- `pd.read_excel()` now preserves sheet order when using `sheetname=None` (GH9930)
- Multiple offset aliases with decimal points are now supported (e.g. `0.5min` is parsed as `30s`) (GH8419)
- `.isnull()` and `.notnull()` have been added to `Index` object to make them more consistent with the `Series` API (GH15300)
- New `UnsortedIndexError` (subclass of `KeyError`) raised when indexing/slicing into an unsorted `MultiIndex` (GH11897). This allows differentiation between errors due to lack of sorting or an incorrect key. See [here](#)
- `MultiIndex` has gained a `.to_frame()` method to convert to a `DataFrame` (GH12397)
- `pd.cut` and `pd.qcut` now support `datetime64` and `timedelta64` dtypes (GH14714, GH14798)
- `pd.qcut` has gained the `duplicates='raise'|'drop'` option to control whether to raise on duplicated edges (GH7751)
- `Series` provides a `to_excel` method to output Excel files (GH8825)
- The `usecols` argument in `pd.read_csv()` now accepts a callable function as a value (GH14154)
- The `skiprows` argument in `pd.read_csv()` now accepts a callable function as a value (GH10882)
- The `nrows` and `chunksize` arguments in `pd.read_csv()` are supported if both are passed (GH6774, GH15755)
- `DataFrame.plot` now prints a title above each subplot if `suplots=True` and `title` is a list of strings (GH14753)
- `DataFrame.plot` can pass the matplotlib 2.0 default color cycle as a single string as color parameter, see [here](#). (GH15516)
- `Series.interpolate()` now supports `timedelta` as an index type with `method='time'` (GH6424)
- Addition of a `level` keyword to `DataFrame/Series.rename` to rename labels in the specified level of a `MultiIndex` (GH4160).
- `DataFrame.reset_index()` will now interpret a tuple `index.name` as a key spanning across levels of columns, if this is a `MultiIndex` (GH16164)
- `Timedelta.isoformat` method added for formatting `Timedeltas` as an ISO 8601 duration. See the [Timedelta docs](#) (GH15136)
- `.select_dtypes()` now allows the string `datetimetz` to generically select datetimes with `tz` (GH14910)

- The `.to_latex()` method will now accept `multicolumn` and `multirow` arguments to use the accompanying LaTeX enhancements
- `pd.merge_asof()` gained the option `direction='backward'|'forward'|'nearest'` (GH14887)
- `Series/DataFrame.asfreq()` have gained a `fill_value` parameter, to fill missing values (GH3715).
- `Series/DataFrame.resample.asfreq` have gained a `fill_value` parameter, to fill missing values during resampling (GH3715).
- `pandas.util.hash_pandas_object()` has gained the ability to hash a `MultiIndex` (GH15224)
- `Series/DataFrame.squeeze()` have gained the `axis` parameter. (GH15339)
- `DataFrame.to_excel()` has a new `freeze_panes` parameter to turn on Freeze Panes when exporting to Excel (GH15160)
- `pd.read_html()` will parse multiple header rows, creating a `MultiIndex` header. (GH13434).
- HTML table output skips `colspan` or `rowspan` attribute if equal to 1. (GH15403)
- `pandas.io.formats.style.Styler` template now has blocks for easier extension, see the *example notebook* (GH15649)
- `Styler.render()` now accepts `**kwargs` to allow user-defined variables in the template (GH15649)
- Compatibility with Jupyter notebook 5.0; `MultiIndex` column labels are left-aligned and `MultiIndex` row-labels are top-aligned (GH15379)
- `TimedeltaIndex` now has a custom date-tick formatter specifically designed for nanosecond level precision (GH8711)
- `pd.api.types.union_categoricals` gained the `ignore_ordered` argument to allow ignoring the ordered attribute of unioned categoricals (GH13410). See the *categorical union docs* for more information.
- `DataFrame.to_latex()` and `DataFrame.to_string()` now allow optional header aliases. (GH15536)
- Re-enable the `parse_dates` keyword of `pd.read_excel()` to parse string columns as dates (GH14326)
- Added `.empty` property to subclasses of `Index`. (GH15270)
- Enabled floor division for `Timedelta` and `TimedeltaIndex` (GH15828)
- `pandas.io.json.json_normalize()` gained the option `errors='ignore'|'raise'`; the default is `errors='raise'` which is backward compatible. (GH14583)
- `pandas.io.json.json_normalize()` with an empty `list` will return an empty `DataFrame` (GH15534)
- `pandas.io.json.json_normalize()` has gained a `sep` option that accepts `str` to separate joined fields; the default is `" "`, which is backward compatible. (GH14883)
- `MultiIndex.remove_unused_levels()` has been added to facilitate *removing unused levels*. (GH15694)
- `pd.read_csv()` will now raise a `ParserError` error whenever any parsing error occurs (GH15913, GH15925)
- `pd.read_csv()` now supports the `error_bad_lines` and `warn_bad_lines` arguments for the Python parser (GH15925)
- The `display.show_dimensions` option can now also be used to specify whether the length of a `Series` should be shown in its repr (GH7117).
- `parallel_coordinates()` has gained a `sort_labels` keyword argument that sorts class labels and the colors assigned to them (GH15908)
- Options added to allow one to turn on/off using `bottleneck` and `numexpr`, see *here* (GH16157)

- `DataFrame.style.bar()` now accepts two more options to further customize the bar chart. Bar alignment is set with `align='left'|'mid'|'zero'`, the default is “left”, which is backward compatible; You can now pass a list of `color=[color_negative, color_positive]`. (GH14757)

Backwards incompatible API changes

Possible incompatibility for HDF5 formats created with pandas < 0.13.0

`pd.TimeSeries` was deprecated officially in 0.17.0, though has already been an alias since 0.13.0. It has been dropped in favor of `pd.Series`. (GH15098).

This *may* cause HDF5 files that were created in prior versions to become unreadable if `pd.TimeSeries` was used. This is most likely to be for pandas < 0.13.0. If you find yourself in this situation. You can use a recent prior version of pandas to read in your HDF5 files, then write them out again after applying the procedure below.

```
In [2]: s = pd.TimeSeries([1, 2, 3], index=pd.date_range('20130101', periods=3))
```

```
In [3]: s
```

```
Out[3]:
```

```
2013-01-01    1
2013-01-02    2
2013-01-03    3
Freq: D, dtype: int64
```

```
In [4]: type(s)
```

```
Out[4]: pandas.core.series.TimeSeries
```

```
In [5]: s = pd.Series(s)
```

```
In [6]: s
```

```
Out[6]:
```

```
2013-01-01    1
2013-01-02    2
2013-01-03    3
Freq: D, dtype: int64
```

```
In [7]: type(s)
```

```
Out[7]: pandas.core.series.Series
```

Map on Index types now return other Index types

`map` on an Index now returns an Index, not a numpy array (GH12766)

```
In [68]: idx = pd.Index([1, 2])
```

```
In [69]: idx
```

```
Out[69]: Int64Index([1, 2], dtype='int64')
```

```
In [70]: mi = pd.MultiIndex.from_tuples([(1, 2), (2, 4)])
```

(continues on next page)

(continued from previous page)

```
In [71]: mi
Out[71]:
MultiIndex([(1, 2),
            (2, 4)],
            )
```

Previous behavior:

```
In [5]: idx.map(lambda x: x * 2)
Out[5]: array([2, 4])

In [6]: idx.map(lambda x: (x, x * 2))
Out[6]: array([(1, 2), (2, 4)], dtype=object)

In [7]: mi.map(lambda x: x)
Out[7]: array([(1, 2), (2, 4)], dtype=object)

In [8]: mi.map(lambda x: x[0])
Out[8]: array([1, 2])
```

New behavior:

```
In [72]: idx.map(lambda x: x * 2)
Out[72]: Int64Index([2, 4], dtype='int64')
```

```
In [73]: idx.map(lambda x: (x, x * 2))
Out[73]:
MultiIndex([(1, 2),
            (2, 4)],
            )
```

```
In [74]: mi.map(lambda x: x)
Out[74]:
MultiIndex([(1, 2),
            (2, 4)],
            )
```

```
In [75]: mi.map(lambda x: x[0])
Out[75]: Int64Index([1, 2], dtype='int64')
```

map on a Series with datetime64 values may return int64 dtypes rather than int32

```
In [76]: s = pd.Series(pd.date_range('2011-01-02T00:00', '2011-01-02T02:00', freq='H')
.....:                    .tz_localize('Asia/Tokyo'))
.....:

In [77]: s
Out[77]:
0    2011-01-02 00:00:00+09:00
1    2011-01-02 01:00:00+09:00
2    2011-01-02 02:00:00+09:00
Length: 3, dtype: datetime64[ns, Asia/Tokyo]
```

Previous behavior:

```
In [9]: s.map(lambda x: x.hour)
Out[9]:
0    0
1    1
2    2
dtype: int32
```

New behavior:

```
In [78]: s.map(lambda x: x.hour)
Out[78]:
0    0
1    1
2    2
Length: 3, dtype: int64
```

Accessing datetime fields of Index now return Index

The datetime-related attributes (see *here* for an overview) of `DatetimeIndex`, `PeriodIndex` and `TimedeltaIndex` previously returned numpy arrays. They will now return a new `Index` object, except in the case of a boolean field, where the result will still be a boolean ndarray. (GH15022)

Previous behaviour:

```
In [1]: idx = pd.date_range("2015-01-01", periods=5, freq='10H')
In [2]: idx.hour
Out[2]: array([ 0, 10, 20,  6, 16], dtype=int32)
```

New behavior:

```
In [79]: idx = pd.date_range("2015-01-01", periods=5, freq='10H')
In [80]: idx.hour
Out[80]: Int64Index([0, 10, 20, 6, 16], dtype='int64')
```

This has the advantage that specific `Index` methods are still available on the result. On the other hand, this might have backward incompatibilities: e.g. compared to numpy arrays, `Index` objects are not mutable. To get the original ndarray, you can always convert explicitly using `np.asarray(idx.hour)`.

pd.unique will now be consistent with extension types

In prior versions, using `Series.unique()` and `pandas.unique()` on `Categorical` and tz-aware data-types would yield different return types. These are now made consistent. (GH15903)

- Datetime tz-aware

Previous behaviour:

```
# Series
In [5]: pd.Series([pd.Timestamp('20160101', tz='US/Eastern'),
...:               pd.Timestamp('20160101', tz='US/Eastern')]).unique()
```

(continues on next page)

(continued from previous page)

```

Out [5]: array([Timestamp('2016-01-01 00:00:00-0500', tz='US/Eastern')],
↳dtype=object)

In [6]: pd.unique(pd.Series([pd.Timestamp('20160101', tz='US/Eastern'),
...:                        pd.Timestamp('20160101', tz='US/Eastern')]))
Out [6]: array(['2016-01-01T05:00:00.000000000'], dtype='datetime64[ns]')

# Index
In [7]: pd.Index([pd.Timestamp('20160101', tz='US/Eastern'),
...:              pd.Timestamp('20160101', tz='US/Eastern')]).unique()
Out [7]: DatetimeIndex(['2016-01-01 00:00:00-05:00'], dtype='datetime64[ns, US/
↳Eastern]', freq=None)

In [8]: pd.unique([pd.Timestamp('20160101', tz='US/Eastern'),
...:               pd.Timestamp('20160101', tz='US/Eastern')])
Out [8]: array(['2016-01-01T05:00:00.000000000'], dtype='datetime64[ns]')

```

New behavior:

```

# Series, returns an array of Timestamp tz-aware
In [81]: pd.Series([pd.Timestamp(r'20160101', tz=r'US/Eastern'),
...:                pd.Timestamp(r'20160101', tz=r'US/Eastern')]).unique()
...:
Out [81]:
<DatetimeArray>
['2016-01-01 00:00:00-05:00']
Length: 1, dtype: datetime64[ns, US/Eastern]

In [82]: pd.unique(pd.Series([pd.Timestamp('20160101', tz='US/Eastern'),
...:                          pd.Timestamp('20160101', tz='US/Eastern')]))
...:
Out [82]:
<DatetimeArray>
['2016-01-01 00:00:00-05:00']
Length: 1, dtype: datetime64[ns, US/Eastern]

# Index, returns a DatetimeIndex
In [83]: pd.Index([pd.Timestamp('20160101', tz='US/Eastern'),
...:               pd.Timestamp('20160101', tz='US/Eastern')]).unique()
...:
Out [83]: DatetimeIndex(['2016-01-01 00:00:00-05:00'], dtype='datetime64[ns, US/
↳Eastern]', freq=None)

In [84]: pd.unique(pd.Index([pd.Timestamp('20160101', tz='US/Eastern'),
...:                          pd.Timestamp('20160101', tz='US/Eastern')]))
...:
Out [84]: DatetimeIndex(['2016-01-01 00:00:00-05:00'], dtype='datetime64[ns, US/
↳Eastern]', freq=None)

```

- Categoricals

Previous behaviour:

```
In [1]: pd.Series(list('baabc'), dtype='category').unique()
Out[1]:
[b, a, c]
Categories (3, object): [b, a, c]

In [2]: pd.unique(pd.Series(list('baabc'), dtype='category'))
Out[2]: array(['b', 'a', 'c'], dtype=object)
```

New behavior:

```
# returns a Categorical
In [85]: pd.Series(list('baabc'), dtype='category').unique()
Out[85]:
[b, a, c]
Categories (3, object): [b, a, c]

In [86]: pd.unique(pd.Series(list('baabc'), dtype='category'))
Out[86]:
[b, a, c]
Categories (3, object): [b, a, c]
```

S3 file handling

pandas now uses `s3fs` for handling S3 connections. This shouldn't break any code. However, since `s3fs` is not a required dependency, you will need to install it separately, like `boto` in prior versions of pandas. (GH11915).

Partial string indexing changes

DatetimeIndex Partial String Indexing now works as an exact match, provided that string resolution coincides with index resolution, including a case when both are seconds (GH14826). See *Slice vs. Exact Match* for details.

```
In [87]: df = pd.DataFrame({'a': [1, 2, 3]}, pd.DatetimeIndex(['2011-12-31 23:59:59',
.....:                                                         '2012-01-01 00:00:00',
.....:                                                         '2012-01-01 00:00:01']))
.....:
```

Previous behavior:

```
In [4]: df['2011-12-31 23:59:59']
Out[4]:
           a
2011-12-31 23:59:59  1

In [5]: df['a']['2011-12-31 23:59:59']
Out[5]:
2011-12-31 23:59:59    1
Name: a, dtype: int64
```

New behavior:

```
In [4]: df['2011-12-31 23:59:59']
KeyError: '2011-12-31 23:59:59'

In [5]: df['a']['2011-12-31 23:59:59']
Out[5]: 1
```

Concat of different float dtypes will not automatically upcast

Previously, `concat` of multiple objects with different `float` dtypes would automatically upcast results to a dtype of `float64`. Now the smallest acceptable dtype will be used ([GH13247](#))

```
In [88]: df1 = pd.DataFrame(np.array([1.0], dtype=np.float32, ndmin=2))

In [89]: df1.dtypes
Out[89]:
0    float32
Length: 1, dtype: object

In [90]: df2 = pd.DataFrame(np.array([np.nan], dtype=np.float32, ndmin=2))

In [91]: df2.dtypes
Out[91]:
0    float32
Length: 1, dtype: object
```

Previous behavior:

```
In [7]: pd.concat([df1, df2]).dtypes
Out[7]:
0    float64
dtype: object
```

New behavior:

```
In [92]: pd.concat([df1, df2]).dtypes
Out[92]:
0    float32
Length: 1, dtype: object
```

Pandas Google BigQuery support has moved

pandas has split off Google BigQuery support into a separate package `pandas-gbq`. You can `conda install pandas-gbq -c conda-forge` or `pip install pandas-gbq` to get it. The functionality of `read_gbq()` and `DataFrame.to_gbq()` remain the same with the currently released version of `pandas-gbq=0.1.4`. Documentation is now hosted [here](#) ([GH15347](#))

Memory usage for Index is more accurate

In previous versions, showing `.memory_usage()` on a pandas structure that has an index, would only include actual index values and not include structures that facilitated fast indexing. This will generally be different

for Index and MultiIndex and less-so for other index types. (GH15237)

Previous behavior:

```
In [8]: index = pd.Index(['foo', 'bar', 'baz'])
In [9]: index.memory_usage(deep=True)
Out[9]: 180
In [10]: index.get_loc('foo')
Out[10]: 0
In [11]: index.memory_usage(deep=True)
Out[11]: 180
```

New behavior:

```
In [8]: index = pd.Index(['foo', 'bar', 'baz'])
In [9]: index.memory_usage(deep=True)
Out[9]: 180
In [10]: index.get_loc('foo')
Out[10]: 0
In [11]: index.memory_usage(deep=True)
Out[11]: 260
```

DataFrame.sort_index changes

In certain cases, calling `.sort_index()` on a MultiIndexed DataFrame would return the *same* DataFrame without seeming to sort. This would happen with a `lexsorted`, but non-monotonic levels. (GH15622, GH15687, GH14015, GH13431, GH15797)

This is *unchanged* from prior versions, but shown for illustration purposes:

```
In [93]: df = pd.DataFrame(np.arange(6), columns=['value'],
.....:                      index=pd.MultiIndex.from_product([list('BA'), range(3)]))
.....:

In [94]: df
Out[94]:
   value
B 0     0
  1     1
  2     2
A 0     3
  1     4
  2     5

[6 rows x 1 columns]
```

```
In [95]: df.index.is_lexsorted()
Out[95]: False
```

```
In [96]: df.index.is_monotonic
Out[96]: False
```

Sorting works as expected

```
In [97]: df.sort_index()
```

```
Out[97]:
```

```
      value
A 0      3
  1      4
  2      5
B 0      0
  1      1
  2      2
```

```
[6 rows x 1 columns]
```

```
In [98]: df.sort_index().index.is_lexsorted()
```

```
Out[98]: True
```

```
In [99]: df.sort_index().index.is_monotonic
```

```
Out[99]: True
```

However, this example, which has a non-monotonic 2nd level, doesn't behave as desired.

```
In [100]: df = pd.DataFrame({'value': [1, 2, 3, 4]},
.....:                      index=pd.MultiIndex([[ 'a', 'b'], [ 'bb', 'aa']],
.....:                                           [[0, 0, 1, 1], [0, 1, 0, 1]]))
.....:
```

```
In [101]: df
```

```
Out[101]:
```

```
      value
a bb      1
  aa      2
b bb      3
  aa      4
```

```
[4 rows x 1 columns]
```

Previous behavior:

```
In [11]: df.sort_index()
```

```
Out[11]:
```

```
      value
a bb      1
  aa      2
b bb      3
  aa      4
```

```
In [14]: df.sort_index().index.is_lexsorted()
```

```
Out[14]: True
```

```
In [15]: df.sort_index().index.is_monotonic
```

(continues on next page)

(continued from previous page)

```
Out[15]: False
```

New behavior:

```
In [102]: df.sort_index()
```

```
Out[102]:
```

```
      value
a aa      2
  bb      1
b aa      4
  bb      3
```

```
[4 rows x 1 columns]
```

```
In [103]: df.sort_index().index.is_lexsorted()
```

```
Out[103]: True
```

```
In [104]: df.sort_index().index.is_monotonic
```

```
Out[104]: True
```

Groupby describe formatting

The output formatting of `groupby.describe()` now labels the `describe()` metrics in the columns instead of the index. This format is consistent with `groupby.agg()` when applying multiple functions at once. (GH4792)

Previous behavior:

```
In [1]: df = pd.DataFrame({'A': [1, 1, 2, 2], 'B': [1, 2, 3, 4]})
```

```
In [2]: df.groupby('A').describe()
```

```
Out[2]:
```

```
      B
A
1 count  2.000000
  mean   1.500000
  std    0.707107
  min    1.000000
  25%    1.250000
  50%    1.500000
  75%    1.750000
  max    2.000000
2 count  2.000000
  mean   3.500000
  std    0.707107
  min    3.000000
  25%    3.250000
  50%    3.500000
  75%    3.750000
  max    4.000000
```

```
In [3]: df.groupby('A').agg([np.mean, np.std, np.min, np.max])
```

(continues on next page)

(continued from previous page)

Out [3]:

	B			
	mean	std	amin	amax
A				
1	1.5	0.707107	1	2
2	3.5	0.707107	3	4

New behavior:

In [105]: `df = pd.DataFrame({'A': [1, 1, 2, 2], 'B': [1, 2, 3, 4]})`In [106]: `df.groupby('A').describe()`

Out [106]:

	B							
	count	mean	std	min	25%	50%	75%	max
A								
1	2.0	1.5	0.707107	1.0	1.25	1.5	1.75	2.0
2	2.0	3.5	0.707107	3.0	3.25	3.5	3.75	4.0

[2 rows x 8 columns]

In [107]: `df.groupby('A').agg([np.mean, np.std, np.min, np.max])`

Out [107]:

	B			
	mean	std	amin	amax
A				
1	1.5	0.707107	1	2
2	3.5	0.707107	3	4

[2 rows x 4 columns]

Window binary corr/cov operations return a MultiIndex DataFrame

A binary window operation, like `.corr()` or `.cov()`, when operating on a `.rolling(..)`, `.expanding(..)`, or `.ewm(..)` object, will now return a 2-level `MultiIndexed DataFrame` rather than a `Panel`, as `Panel` is now deprecated, see *here*. These are equivalent in function, but a `MultiIndexed DataFrame` enjoys more support in pandas. See the section on *Windowed Binary Operations* for more information. (GH15677)

In [108]: `np.random.seed(1234)`

```
In [109]: df = pd.DataFrame(np.random.rand(100, 2),
.....:                      columns=pd.Index(['A', 'B'], name='bar'),
.....:                      index=pd.date_range('20160101',
.....:                                          periods=100, freq='D', name='foo'))
```

In [110]: `df.tail()`

Out [110]:

HDFStore where string comparison

In previous versions most types could be compared to string column in a `HDFStore` usually resulting in an invalid comparison, returning an empty result frame. These comparisons will now raise a `TypeError` ([GH15492](#))

```
In [114]: df = pd.DataFrame({'unparsed_date': ['2014-01-01', '2014-01-01']})

In [115]: df.to_hdf('store.h5', 'key', format='table', data_columns=True)

In [116]: df.dtypes
Out[116]:
unparsed_date    object
Length: 1, dtype: object
```

Previous behavior:

```
In [4]: pd.read_hdf('store.h5', 'key', where='unparsed_date > ts')
File "<string>", line 1
      (unparsed_date > 1970-01-01 00:00:01.388552400)
                        ^
SyntaxError: invalid token
```

New behavior:

```
In [18]: ts = pd.Timestamp('2014-01-01')

In [19]: pd.read_hdf('store.h5', 'key', where='unparsed_date > ts')
TypeError: Cannot compare 2014-01-01 00:00:00 of
type <class 'pandas.tslib.Timestamp'> to string column
```

Index.intersection and inner join now preserve the order of the left Index

`Index.intersection()` now preserves the order of the calling Index (left) instead of the other Index (right) (GH15582). This affects inner joins, `DataFrame.join()` and `merge()`, and the `.align` method.

- `Index.intersection`

```
In [117]: left = pd.Index([2, 1, 0])

In [118]: left
Out[118]: Int64Index([2, 1, 0], dtype='int64')

In [119]: right = pd.Index([1, 2, 3])

In [120]: right
Out[120]: Int64Index([1, 2, 3], dtype='int64')
```

Previous behavior:

```
In [4]: left.intersection(right)
Out[4]: Int64Index([1, 2], dtype='int64')
```

New behavior:

```
In [121]: left.intersection(right)
Out[121]: Int64Index([2, 1], dtype='int64')
```

- `DataFrame.join` and `pd.merge`

```
In [122]: left = pd.DataFrame({'a': [20, 10, 0]}, index=[2, 1, 0])

In [123]: left
Out[123]:
   a
2  20
1  10
0   0

[3 rows x 1 columns]

In [124]: right = pd.DataFrame({'b': [100, 200, 300]}, index=[1, 2, 3])

In [125]: right
Out[125]:
   b
1  100
2  200
3  300

[3 rows x 1 columns]
```

Previous behavior:

```
In [4]: left.join(right, how='inner')
Out[4]:
   a  b
1  10 100
2  20 200
```

New behavior:

```
In [126]: left.join(right, how='inner')
Out[126]:
   a  b
2  20 200
1  10 100

[2 rows x 2 columns]
```

Pivot table always returns a DataFrame

The documentation for `pivot_table()` states that a `DataFrame` is *always* returned. Here a bug is fixed that allowed this to return a `Series` under certain circumstance. (GH4386)

```
In [127]: df = pd.DataFrame({'col1': [3, 4, 5],
.....:                      'col2': ['C', 'D', 'E'],
.....:                      'col3': [1, 3, 9]})
.....:

In [128]: df
Out[128]:
```

(continues on next page)

(continued from previous page)

```

   col1 col2 col3
0     3    C    1
1     4    D    3
2     5    E    9

[3 rows x 3 columns]
```

Previous behavior:

```

In [2]: df.pivot_table('col1', index=['col3', 'col2'], aggfunc=np.sum)
Out[2]:
col3 col2
1     C    3
3     D    4
9     E    5
Name: col1, dtype: int64
```

New behavior:

```

In [129]: df.pivot_table('col1', index=['col3', 'col2'], aggfunc=np.sum)
Out[129]:
           col1
col3 col2
1     C    3
3     D    4
9     E    5

[3 rows x 1 columns]
```

Other API changes

- `numexpr` version is now required to be $\geq 2.4.6$ and it will not be used at all if this requisite is not fulfilled (GH15213).
- `CParserError` has been renamed to `ParserError` in `pd.read_csv()` and will be removed in the future (GH12665)
- `SparseArray.cumsum()` and `SparseSeries.cumsum()` will now always return `SparseArray` and `SparseSeries` respectively (GH12855)
- `DataFrame.applymap()` with an empty `DataFrame` will return a copy of the empty `DataFrame` instead of a `Series` (GH8222)
- `Series.map()` now respects default values of dictionary subclasses with a `__missing__` method, such as `collections.Counter` (GH15999)
- `.loc` has compat with `.ix` for accepting iterators, and `NamedTuples` (GH15120)
- `interpolate()` and `fillna()` will raise a `ValueError` if the `limit` keyword argument is not greater than 0. (GH9217)
- `pd.read_csv()` will now issue a `ParserWarning` whenever there are conflicting values provided by the `dialect` parameter and the user (GH14898)
- `pd.read_csv()` will now raise a `ValueError` for the C engine if the quote character is larger than than one byte (GH11592)

- inplace arguments now require a boolean value, else a `ValueError` is thrown ([GH14189](#))
- `pandas.api.types.is_datetime64_ns_dtype` will now report `True` on a tz-aware dtype, similar to `pandas.api.types.is_datetime64_any_dtype`
- `DataFrame.asof()` will return a null filled `Series` instead the scalar `NaN` if a match is not found ([GH15118](#))
- Specific support for `copy.copy()` and `copy.deepcopy()` functions on `NDFrame` objects ([GH15444](#))
- `Series.sort_values()` accepts a one element list of bool for consistency with the behavior of `DataFrame.sort_values()` ([GH15604](#))
- `.merge()` and `.join()` on category dtype columns will now preserve the category dtype when possible ([GH10409](#))
- `SparseDataFrame.default_fill_value` will be 0, previously was `nan` in the return from `pd.get_dummies(..., sparse=True)` ([GH15594](#))
- The default behaviour of `Series.str.match` has changed from extracting groups to matching the pattern. The extracting behaviour was deprecated since pandas version 0.13.0 and can be done with the `Series.str.extract` method ([GH5224](#)). As a consequence, the `as_indexer` keyword is ignored (no longer needed to specify the new behaviour) and is deprecated.
- `NaT` will now correctly report `False` for datetimelike boolean operations such as `is_month_start` ([GH15781](#))
- `NaT` will now correctly return `np.nan` for `Timedelta` and `Period` accessors such as `days` and `quarter` ([GH15782](#))
- `NaT` will now returns `NaT` for `tz_localize` and `tz_convert` methods ([GH15830](#))
- `DataFrame` and `Panel` constructors with invalid input will now raise `ValueError` rather than `PandasError`, if called with scalar inputs and not axes ([GH15541](#))
- `DataFrame` and `Panel` constructors with invalid input will now raise `ValueError` rather than `pandas.core.common.PandasError`, if called with scalar inputs and not axes; The exception `PandasError` is removed as well. ([GH15541](#))
- The exception `pandas.core.common.AmbiguousIndexError` is removed as it is not referenced ([GH15541](#))

Reorganization of the library: privacy changes

Modules privacy has changed

Some formerly public python/c/c++/cython extension modules have been moved and/or renamed. These are all removed from the public API. Furthermore, the `pandas.core`, `pandas.compat`, and `pandas.util` top-level modules are now considered to be PRIVATE. If indicated, a deprecation warning will be issued if you reference theses modules. ([GH12588](#))

Previous Location	New Location	Deprecated
pandas.lib	pandas._libs.lib	X
pandas.tslib	pandas._libs.tslib	X
pandas.computation	pandas.core.computation	X
pandas.msgpack	pandas.io.msgpack

pandas._hash	pandas._libs.hashing	
pandas._period	pandas._libs.period	
pandas._sparse	pandas._libs.sparse	
pandas._testing	pandas._libs.testing	
pandas._window	pandas._libs.window	

Some new subpackages are created with public functionality that is not directly exposed in the top-level namespace: `pandas.errors`, `pandas.plotting` and `pandas.testing` (more details below). Together with `pandas.api.types` and certain functions in the `pandas.io` and `pandas.tseries` submodules, these are now the public subpackages.

Further changes:

- The function `union_categoricals()` is now importable from `pandas.api.types`, formerly from `pandas.types.concat` ([GH15998](#))
- The type import `pandas.tslib.NaTType` is deprecated and can be replaced by using `type(pandas.NaT)` ([GH16146](#))
- The public functions in `pandas.tools.hashing` deprecated from that locations, but are now importable from `pandas.util` ([GH16223](#))
- The modules in `pandas.util`: `decorators`, `print_versions`, `doctools`, `validators`, `depr_module` are now private. Only the functions exposed in `pandas.util` itself are public ([GH16223](#))

`pandas.errors`

We are adding a standard public module for all pandas exceptions & warnings `pandas.errors`. ([GH14800](#)). Previously these exceptions & warnings could be imported from `pandas.core.common` or `pandas.io.common`. These exceptions and warnings will be removed from the `*.common` locations in a future release. ([GH15541](#))

The following are now part of this API:

```
['DtypeWarning',
 'EmptyDataError',
 'OutOfBoundsDatetime',
 'ParserError',
```

(continues on next page)

(continued from previous page)

```
'ParserWarning',
'PerformanceWarning',
'UnsortedIndexError',
'UnsupportedFunctionCall']
```

`pandas.testing`

We are adding a standard module that exposes the public testing functions in `pandas.testing` (GH9895). Those functions can be used when writing tests for functionality using pandas objects.

The following testing functions are now part of this API:

- `testing.assert_frame_equal()`
- `testing.assert_series_equal()`
- `testing.assert_index_equal()`

`pandas.plotting`

A new public `pandas.plotting` module has been added that holds plotting functionality that was previously in either `pandas.tools.plotting` or in the top-level namespace. See the *deprecations sections* for more details.

Other Development Changes

- Building pandas for development now requires `cython >= 0.23` (GH14831)
- Require at least 0.23 version of cython to avoid problems with character encodings (GH14699)
- Switched the test framework to use `pytest` (GH13097)
- Reorganization of tests directory layout (GH14854, GH15707).

Deprecations

Deprecate `.ix`

The `.ix` indexer is deprecated, in favor of the more strict `.iloc` and `.loc` indexers. `.ix` offers a lot of magic on the inference of what the user wants to do. To wit, `.ix` can decide to index *positionally* OR via *labels*, depending on the data type of the index. This has caused quite a bit of user confusion over the years. The full indexing documentation is *here*. (GH14218)

The recommended methods of indexing are:

- `.loc` if you want to *label* index
- `.iloc` if you want to *positionally* index.

Using `.ix` will now show a `DeprecationWarning` with a link to some examples of how to convert code *here*.

```
In [130]: df = pd.DataFrame({'A': [1, 2, 3],
.....:                      'B': [4, 5, 6]},
.....:                      index=list('abc'))
.....:
```

```
In [131]: df
```

```
Out[131]:
```

```
   A  B
a  1  4
b  2  5
c  3  6
```

```
[3 rows x 2 columns]
```

Previous behavior, where you wish to get the 0th and the 2nd elements from the index in the 'A' column.

```
In [3]: df.ix[[0, 2], 'A']
```

```
Out[3]:
```

```
a    1
c    3
```

```
Name: A, dtype: int64
```

Using `.loc`. Here we will select the appropriate indexes from the index, then use *label* indexing.

```
In [132]: df.loc[df.index[[0, 2]], 'A']
```

```
Out[132]:
```

```
a    1
c    3
```

```
Name: A, Length: 2, dtype: int64
```

Using `.iloc`. Here we will get the location of the 'A' column, then use *positional* indexing to select things.

```
In [133]: df.iloc[[0, 2], df.columns.get_loc('A')]
```

```
Out[133]:
```

```
a    1
c    3
```

```
Name: A, Length: 2, dtype: int64
```

Deprecate Panel

Panel is deprecated and will be removed in a future version. The recommended way to represent 3-D data are with a `MultiIndex` on a `DataFrame` via the `to_frame()` or with the `xarray` package. Pandas provides a `to_xarray()` method to automate this conversion ([GH13563](#)).

```
In [133]: import pandas.util.testing as tm
```

```
In [134]: p = tm.makePanel()
```

```
In [135]: p
```

```
Out[135]:
```

```
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 3 (major_axis) x 4 (minor_axis)
```

(continues on next page)

(continued from previous page)

```
Items axis: ItemA to ItemC
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-05 00:00:00
Minor_axis axis: A to D
```

Convert to a MultiIndex DataFrame

```
In [136]: p.to_frame()
Out[136]:
```

		ItemA	ItemB	ItemC
major	minor			
2000-01-03	A	0.628776	-1.409432	0.209395
	B	0.988138	-1.347533	-0.896581
	C	-0.938153	1.272395	-0.161137
	D	-0.223019	-0.591863	-1.051539
2000-01-04	A	0.186494	1.422986	-0.592886
	B	-0.072608	0.363565	1.104352
	C	-1.239072	-1.449567	0.889157
	D	2.123692	-0.414505	-0.319561
2000-01-05	A	0.952478	-2.147855	-1.473116
	B	-0.550603	-0.014752	-0.431550
	C	0.139683	-1.195524	0.288377
	D	0.122273	-1.425795	-0.619993

```
[12 rows x 3 columns]
```

Convert to an xarray DataArray

```
In [137]: p.to_xarray()
Out[137]:
```

```
<xarray.DataArray (items: 3, major_axis: 3, minor_axis: 4)>
array([[[ 0.628776,  0.988138, -0.938153, -0.223019],
        [ 0.186494, -0.072608, -1.239072,  2.123692],
        [ 0.952478, -0.550603,  0.139683,  0.122273]],

       [[-1.409432, -1.347533,  1.272395, -0.591863],
        [ 1.422986,  0.363565, -1.449567, -0.414505],
        [-2.147855, -0.014752, -1.195524, -1.425795]],

       [[ 0.209395, -0.896581, -0.161137, -1.051539],
        [-0.592886,  1.104352,  0.889157, -0.319561],
        [-1.473116, -0.43155 ,  0.288377, -0.619993]])
```

```
Coordinates:
  * items      (items) object 'ItemA' 'ItemB' 'ItemC'
  * major_axis (major_axis) datetime64[ns] 2000-01-03 2000-01-04 2000-01-05
  * minor_axis (minor_axis) object 'A' 'B' 'C' 'D'
```

Deprecate `groupby.agg()` with a dictionary when renaming

The `.groupby(..).agg(..)`, `.rolling(..).agg(..)`, and `.resample(..).agg(..)` syntax can accept a variable of inputs, including scalars, list, and a dict of column names to scalars or lists. This provides a useful syntax for constructing multiple (potentially different) aggregations.

However, `.agg(...)` can *also* accept a dict that allows ‘renaming’ of the result columns. This is a complicated and confusing syntax, as well as not consistent between `Series` and `DataFrame`. We are deprecating this ‘renaming’ functionality.

- We are deprecating passing a dict to a grouped/rolled/resampled `Series`. This allowed one to **rename** the resulting aggregation, but this had a completely different meaning than passing a dictionary to a grouped `DataFrame`, which accepts column-to-aggregations.
- We are deprecating passing a dict-of-dicts to a grouped/rolled/resampled `DataFrame` in a similar manner.

This is an illustrative example:

```
In [134]: df = pd.DataFrame({'A': [1, 1, 1, 2, 2],
.....:                      'B': range(5),
.....:                      'C': range(5)})
.....:
```

```
In [135]: df
```

```
Out[135]:
```

	A	B	C
0	1	0	0
1	1	1	1
2	1	2	2
3	2	3	3
4	2	4	4

```
[5 rows x 3 columns]
```

Here is a typical useful syntax for computing different aggregations for different columns. This is a natural, and useful syntax. We aggregate from the dict-to-list by taking the specified columns and applying the list of functions. This returns a `MultiIndex` for the columns (this is *not* deprecated).

```
In [136]: df.groupby('A').agg({'B': 'sum', 'C': 'min'})
```

```
Out[136]:
```

	B	C
A		
1	3	0
2	7	3

```
[2 rows x 2 columns]
```

Here’s an example of the first deprecation, passing a dict to a grouped `Series`. This is a combination aggregation & renaming:

```
In [6]: df.groupby('A').B.agg({'foo': 'count'})
```

```
FutureWarning: using a dict on a Series for aggregation
is deprecated and will be removed in a future version
```

```
Out[6]:
```

	foo
A	
1	3
2	2

You can accomplish the same operation, more idiomatically by:

```
In [137]: df.groupby('A').B.agg(['count']).rename(columns={'count': 'foo'})
Out[137]:
   foo
A
1    3
2    2

[2 rows x 1 columns]
```

Here's an example of the second deprecation, passing a dict-of-dict to a grouped DataFrame:

```
In [23]: (df.groupby('A')
...:      .agg({'B': {'foo': 'sum'}, 'C': {'bar': 'min'}})
...:      )
FutureWarning: using a dict with renaming is deprecated and
will be removed in a future version

Out[23]:
   B  C
   foo bar
A
1  3  0
2  7  3
```

You can accomplish nearly the same by:

```
In [138]: (df.groupby('A')
.....:      .agg({'B': 'sum', 'C': 'min'})
.....:      .rename(columns={'B': 'foo', 'C': 'bar'})
.....:      )
.....:
Out[138]:
   foo bar
A
1    3  0
2    7  3

[2 rows x 2 columns]
```

Deprecate .plotting

The `pandas.tools.plotting` module has been deprecated, in favor of the top level `pandas.plotting` module. All the public plotting functions are now available from `pandas.plotting` (GH12548).

Furthermore, the top-level `pandas.scatter_matrix` and `pandas.plot_params` are deprecated. Users can import these from `pandas.plotting` as well.

Previous script:

```
pd.tools.plotting.scatter_matrix(df)
pd.scatter_matrix(df)
```

Should be changed to:

```
pd.plotting.scatter_matrix(df)
```

Other deprecations

- `SparseArray.to_dense()` has deprecated the `fill` parameter, as that parameter was not being respected (GH14647)
- `SparseSeries.to_dense()` has deprecated the `sparse_only` parameter (GH14647)
- `Series.repeat()` has deprecated the `reps` parameter in favor of `repeats` (GH12662)
- The `Series` constructor and `.astype` method have deprecated accepting timestamp dtypes without a frequency (e.g. `np.datetime64`) for the `dtype` parameter (GH15524)
- `Index.repeat()` and `MultiIndex.repeat()` have deprecated the `n` parameter in favor of `repeats` (GH12662)
- `Categorical.searchsorted()` and `Series.searchsorted()` have deprecated the `v` parameter in favor of `value` (GH12662)
- `TimedeltaIndex.searchsorted()`, `DatetimeIndex.searchsorted()`, and `PeriodIndex.searchsorted()` have deprecated the `key` parameter in favor of `value` (GH12662)
- `DataFrame.astype()` has deprecated the `raise_on_error` parameter in favor of `errors` (GH14878)
- `Series.sortlevel` and `DataFrame.sortlevel` have been deprecated in favor of `Series.sort_index` and `DataFrame.sort_index` (GH15099)
- importing `concat` from `pandas.tools.merge` has been deprecated in favor of imports from the `pandas` namespace. This should only affect explicit imports (GH15358)
- `Series/DataFrame/Panel consolidate()` been deprecated as a public method. (GH15483)
- The `as_indexer` keyword of `Series.str.match()` has been deprecated (ignored keyword) (GH15257).
- The following top-level pandas functions have been deprecated and will be removed in a future version (GH13790, GH15940)
 - `pd.pnow()`, replaced by `Period.now()`
 - `pd.Term`, is removed, as it is not applicable to user code. Instead use in-line string expressions in the `where` clause when searching in `HDFStore`
 - `pd.Expr`, is removed, as it is not applicable to user code.
 - `pd.match()`, is removed.
 - `pd.groupby()`, replaced by using the `.groupby()` method directly on a `Series/DataFrame`
 - `pd.get_store()`, replaced by a direct call to `pd.HDFStore(...)`
- `is_any_int_dtype`, `is_floating_dtype`, and `is_sequence` are deprecated from `pandas.api.types` (GH16042)

Removal of prior version deprecations/changes

- The `pandas.rpy` module is removed. Similar functionality can be accessed through the `rpy2` project. See the [R interfacing docs](#) for more details.
- The `pandas.io.ga` module with a `google-analytics` interface is removed (GH11308). Similar functionality can be found in the [Google2Pandas](#) package.

- `pd.to_datetime` and `pd.to_timedelta` have dropped the `coerce` parameter in favor of `errors` (GH13602)
- `pandas.stats.fama_macbeth`, `pandas.stats.ols`, `pandas.stats.plm` and `pandas.stats.var`, as well as the top-level `pandas.fama_macbeth` and `pandas.ols` routines are removed. Similar functionality can be found in the `statsmodels` package. (GH11898)
- The `TimeSeries` and `SparseTimeSeries` classes, aliases of `Series` and `SparseSeries`, are removed (GH10890, GH15098).
- `Series.is_time_series` is dropped in favor of `Series.index.is_all_dates` (GH15098)
- The deprecated `irow`, `icol`, `iget` and `iget_value` methods are removed in favor of `iloc` and `iat` as explained *here* (GH10711).
- The deprecated `DataFrame.iterkv()` has been removed in favor of `DataFrame.iteritems()` (GH10711)
- The `Categorical` constructor has dropped the `name` parameter (GH10632)
- `Categorical` has dropped support for NaN categories (GH10748)
- The `take_last` parameter has been dropped from `duplicated()`, `drop_duplicates()`, `nlargest()`, and `nsmallest()` methods (GH10236, GH10792, GH10920)
- `Series`, `Index`, and `DataFrame` have dropped the `sort` and `order` methods (GH10726)
- Where clauses in `pytables` are only accepted as strings and expressions types and not other data-types (GH12027)
- `DataFrame` has dropped the `combineAdd` and `combineMult` methods in favor of `add` and `mul` respectively (GH10735)

Performance improvements

- Improved performance of `pd.wide_to_long()` (GH14779)
- Improved performance of `pd.factorize()` by releasing the GIL with `object` dtype when inferred as strings (GH14859, GH16057)
- Improved performance of timeseries plotting with an irregular `DatetimeIndex` (or with `compat_x=True`) (GH15073).
- Improved performance of `groupby().cummin()` and `groupby().cummax()` (GH15048, GH15109, GH15561, GH15635)
- Improved performance and reduced memory when indexing with a `MultiIndex` (GH15245)
- When reading buffer object in `read_sas()` method without specified format, filepath string is inferred rather than buffer object. (GH14947)
- Improved performance of `.rank()` for categorical data (GH15498)
- Improved performance when using `.unstack()` (GH15503)
- Improved performance of merge/join on `category` columns (GH10409)
- Improved performance of `drop_duplicates()` on `bool` columns (GH12963)
- Improve performance of `pd.core.groupby.GroupBy.apply` when the applied function used the `.name` attribute of the group `DataFrame` (GH15062).
- Improved performance of `iloc` indexing with a list or array (GH15504).
- Improved performance of `Series.sort_index()` with a monotonic index (GH15694)

- Improved performance in `pd.read_csv()` on some platforms with buffered reads ([GH16039](#))

Bug fixes

Conversion

- Bug in `Timestamp.replace` now raises `TypeError` when incorrect argument names are given; previously this raised `ValueError` ([GH15240](#))
- Bug in `Timestamp.replace` with `compat` for passing long integers ([GH15030](#))
- Bug in `Timestamp` returning UTC based time/date attributes when a timezone was provided ([GH13303](#), [GH6538](#))
- Bug in `Timestamp` incorrectly localizing timezones during construction ([GH11481](#), [GH15777](#))
- Bug in `TimedeltaIndex` addition where overflow was being allowed without error ([GH14816](#))
- Bug in `TimedeltaIndex` raising a `ValueError` when boolean indexing with `loc` ([GH14946](#))
- Bug in catching an overflow in `Timestamp + Timedelta/Offset` operations ([GH15126](#))
- Bug in `DatetimeIndex.round()` and `Timestamp.round()` floating point accuracy when rounding by milliseconds or less ([GH14440](#), [GH15578](#))
- Bug in `astype()` where `inf` values were incorrectly converted to integers. Now raises error now with `astype()` for `Series` and `DataFrames` ([GH14265](#))
- Bug in `DataFrame(...).apply(to_numeric)` when values are of type `decimal.Decimal`. ([GH14827](#))
- Bug in `describe()` when passing a numpy array which does not contain the median to the `percentiles` keyword argument ([GH14908](#))
- Cleaned up `PeriodIndex` constructor, including raising on floats more consistently ([GH13277](#))
- Bug in using `__deepcopy__` on empty `NDFrame` objects ([GH15370](#))
- Bug in `.replace()` may result in incorrect dtypes. ([GH12747](#), [GH15765](#))
- Bug in `Series.replace` and `DataFrame.replace` which failed on empty replacement dicts ([GH15289](#))
- Bug in `Series.replace` which replaced a numeric by string ([GH15743](#))
- Bug in `Index` construction with `NaN` elements and integer dtype specified ([GH15187](#))
- Bug in `Series` construction with a `datetimetz` ([GH14928](#))
- Bug in `Series.dt.round()` inconsistent behaviour on `NaT` 's with different arguments ([GH14940](#))
- Bug in `Series` constructor when both `copy=True` and `dtype` arguments are provided ([GH15125](#))
- Incorrect dtyped `Series` was returned by comparison methods (e.g., `lt`, `gt`, ...) against a constant for an empty `DataFrame` ([GH15077](#))
- Bug in `Series.ffill()` with mixed dtypes containing tz-aware datetimes. ([GH14956](#))
- Bug in `DataFrame.fillna()` where the argument `downcast` was ignored when `fillna` value was of type `dict` ([GH15277](#))
- Bug in `.asfreq()`, where frequency was not set for empty `Series` ([GH14320](#))
- Bug in `DataFrame` construction with nulls and datetimes in a list-like ([GH15869](#))
- Bug in `DataFrame.fillna()` with tz-aware datetimes ([GH15855](#))

- Bug in `is_string_dtype`, `is_timedelta64_ns_dtype`, and `is_string_like_dtype` in which an error was raised when `None` was passed in ([GH15941](#))
- Bug in the return type of `pd.unique` on a `Categorical`, which was returning an `ndarray` and not a `Categorical` ([GH15903](#))
- Bug in `Index.to_series()` where the index was not copied (and so mutating later would change the original), ([GH15949](#))
- Bug in indexing with partial string indexing with a len-1 `DataFrame` ([GH16071](#))
- Bug in `Series` construction where passing invalid dtype didn't raise an error. ([GH15520](#))

Indexing

- Bug in `Index` power operations with reversed operands ([GH14973](#))
- Bug in `DataFrame.sort_values()` when sorting by multiple columns where one column is of type `int64` and contains `NaT` ([GH14922](#))
- Bug in `DataFrame.reindex()` in which `method` was ignored when passing `columns` ([GH14992](#))
- Bug in `DataFrame.loc` with indexing a `MultiIndex` with a `Series` indexer ([GH14730](#), [GH15424](#))
- Bug in `DataFrame.loc` with indexing a `MultiIndex` with a numpy array ([GH15434](#))
- Bug in `Series.asof` which raised if the series contained all `np.nan` ([GH15713](#))
- Bug in `.at` when selecting from a tz-aware column ([GH15822](#))
- Bug in `Series.where()` and `DataFrame.where()` where array-like conditionals were being rejected ([GH15414](#))
- Bug in `Series.where()` where TZ-aware data was converted to float representation ([GH15701](#))
- Bug in `.loc` that would not return the correct dtype for scalar access for a `DataFrame` ([GH11617](#))
- Bug in output formatting of a `MultiIndex` when names are integers ([GH12223](#), [GH15262](#))
- Bug in `Categorical.searchsorted()` where alphabetical instead of the provided categorical order was used ([GH14522](#))
- Bug in `Series.iloc` where a `Categorical` object for list-like indexes input was returned, where a `Series` was expected. ([GH14580](#))
- Bug in `DataFrame.isin` comparing datetimelike to empty frame ([GH15473](#))
- Bug in `.reset_index()` when an all `NaN` level of a `MultiIndex` would fail ([GH6322](#))
- Bug in `.reset_index()` when raising error for index name already present in `MultiIndex` columns ([GH16120](#))
- Bug in creating a `MultiIndex` with tuples and not passing a list of names; this will now raise `ValueError` ([GH15110](#))
- Bug in the HTML display with with a `MultiIndex` and truncation ([GH14882](#))
- Bug in the display of `.info()` where a qualifier (+) would always be displayed with a `MultiIndex` that contains only non-strings ([GH15245](#))
- Bug in `pd.concat()` where the names of `MultiIndex` of resulting `DataFrame` are not handled correctly when `None` is presented in the names of `MultiIndex` of input `DataFrame` ([GH15787](#))
- Bug in `DataFrame.sort_index()` and `Series.sort_index()` where `na_position` doesn't work with a `MultiIndex` ([GH14784](#), [GH16604](#))

- Bug in `pd.concat()` when combining objects with a `CategoricalIndex` (GH16111)
- Bug in indexing with a scalar and a `CategoricalIndex` (GH16123)

I/O

- Bug in `pd.to_numeric()` in which float and unsigned integer elements were being improperly casted (GH14941, GH15005)
- Bug in `pd.read_fwf()` where the `skiprows` parameter was not being respected during column width inference (GH11256)
- Bug in `pd.read_csv()` in which the `dialect` parameter was not being verified before processing (GH14898)
- Bug in `pd.read_csv()` in which missing data was being improperly handled with `usecols` (GH6710)
- Bug in `pd.read_csv()` in which a file containing a row with many columns followed by rows with fewer columns would cause a crash (GH14125)
- Bug in `pd.read_csv()` for the C engine where `usecols` were being indexed incorrectly with `parse_dates` (GH14792)
- Bug in `pd.read_csv()` with `parse_dates` when multi-line headers are specified (GH15376)
- Bug in `pd.read_csv()` with `float_precision='round_trip'` which caused a segfault when a text entry is parsed (GH15140)
- Bug in `pd.read_csv()` when an index was specified and no values were specified as null values (GH15835)
- Bug in `pd.read_csv()` in which certain invalid file objects caused the Python interpreter to crash (GH15337)
- Bug in `pd.read_csv()` in which invalid values for `nrows` and `chunksize` were allowed (GH15767)
- Bug in `pd.read_csv()` for the Python engine in which unhelpful error messages were being raised when parsing errors occurred (GH15910)
- Bug in `pd.read_csv()` in which the `skipfooter` parameter was not being properly validated (GH15925)
- Bug in `pd.to_csv()` in which there was numeric overflow when a timestamp index was being written (GH15982)
- Bug in `pd.util.hashing.hash_pandas_object()` in which hashing of categoricals depended on the ordering of categories, instead of just their values. (GH15143)
- Bug in `.to_json()` where `lines=True` and contents (keys or values) contain escaped characters (GH15096)
- Bug in `.to_json()` causing single byte ascii characters to be expanded to four byte unicode (GH15344)
- Bug in `.to_json()` for the C engine where rollover was not correctly handled for case where `frac` is odd and `diff` is exactly 0.5 (GH15716, GH15864)
- Bug in `pd.read_json()` for Python 2 where `lines=True` and contents contain non-ascii unicode characters (GH15132)
- Bug in `pd.read_msgpack()` in which `Series` categoricals were being improperly processed (GH14901)
- Bug in `pd.read_msgpack()` which did not allow loading of a dataframe with an index of type `CategoricalIndex` (GH15487)

- Bug in `pd.read_msgpack()` when deserializing a `CategoricalIndex` (GH15487)
- Bug in `DataFrame.to_records()` with converting a `DatetimeIndex` with a timezone (GH13937)
- Bug in `DataFrame.to_records()` which failed with unicode characters in column names (GH11879)
- Bug in `.to_sql()` when writing a `DataFrame` with numeric index names (GH15404).
- Bug in `DataFrame.to_html()` with `index=False` and `max_rows` raising in `IndexError` (GH14998)
- Bug in `pd.read_hdf()` passing a `Timestamp` to the `where` parameter with a non date column (GH15492)
- Bug in `DataFrame.to_stata()` and `StataWriter` which produces incorrectly formatted files to be produced for some locales (GH13856)
- Bug in `StataReader` and `StataWriter` which allows invalid encodings (GH15723)
- Bug in the `Series` repr not showing the length when the output was truncated (GH15962).

Plotting

- Bug in `DataFrame.hist` where `plt.tight_layout` caused an `AttributeError` (use `matplotlib >= 2.0.1`) (GH9351)
- Bug in `DataFrame.boxplot` where `fontsize` was not applied to the tick labels on both axes (GH15108)
- Bug in the date and time converters pandas registers with `matplotlib` not handling multiple dimensions (GH16026)
- Bug in `pd.scatter_matrix()` could accept either `color` or `c`, but not both (GH14855)

Groupby/resample/rolling

- Bug in `.groupby(...).resample()` when passed the `on=` kwarg. (GH15021)
- Properly set `__name__` and `__qualname__` for `Groupby.*` functions (GH14620)
- Bug in `GroupBy.get_group()` failing with a categorical grouper (GH15155)
- Bug in `.groupby(...).rolling(...)` when `on` is specified and using a `DatetimeIndex` (GH15130, GH13966)
- Bug in groupby operations with `timedelta64` when passing `numeric_only=False` (GH5724)
- Bug in `groupby.apply()` coercing `object` dtypes to numeric types, when not all values were numeric (GH14423, GH15421, GH15670)
- Bug in `resample`, where a non-string `loffset` argument would not be applied when resampling a timeseries (GH13218)
- Bug in `DataFrame.groupby().describe()` when grouping on `Index` containing tuples (GH14848)
- Bug in `groupby().nunique()` with a datetimelike-grouper where bins counts were incorrect (GH13453)
- Bug in `groupby.transform()` that would coerce the resultant dtypes back to the original (GH10972, GH11444)
- Bug in `groupby.agg()` incorrectly localizing timezone on `datetime` (GH15426, GH10668, GH13046)
- Bug in `.rolling/expanding()` functions where `count()` was not counting `np.Inf`, nor handling `object` dtypes (GH12541)

- Bug in `.rolling()` where `pd.Timedelta` or `datetime.timedelta` was not accepted as a window argument ([GH15440](#))
- Bug in `Rolling.quantile` function that caused a segmentation fault when called with a quantile value outside of the range `[0, 1]` ([GH15463](#))
- Bug in `DataFrame.resample().median()` if duplicate column names are present ([GH14233](#))

Sparse

- Bug in `SparseSeries.reindex` on single level with list of length 1 ([GH15447](#))
- Bug in repr-formatting a `SparseDataFrame` after a value was set on (a copy of) one of its series ([GH15488](#))
- Bug in `SparseDataFrame` construction with lists not coercing to dtype ([GH15682](#))
- Bug in sparse array indexing in which indices were not being validated ([GH15863](#))

Reshaping

- Bug in `pd.merge_asof()` where `left_index` or `right_index` caused a failure when multiple by was specified ([GH15676](#))
- Bug in `pd.merge_asof()` where `left_index/right_index` together caused a failure when `tolerance` was specified ([GH15135](#))
- Bug in `DataFrame.pivot_table()` where `dropna=True` would not drop all-NaN columns when the columns was a `category` dtype ([GH15193](#))
- Bug in `pd.melt()` where passing a tuple value for `value_vars` caused a `TypeError` ([GH15348](#))
- Bug in `pd.pivot_table()` where no error was raised when `values` argument was not in the columns ([GH14938](#))
- Bug in `pd.concat()` in which concatenating with an empty dataframe with `join='inner'` was being improperly handled ([GH15328](#))
- Bug with `sort=True` in `DataFrame.join` and `pd.merge` when joining on indexes ([GH15582](#))
- Bug in `DataFrame.nsmallest` and `DataFrame.nlargest` where identical values resulted in duplicated rows ([GH15297](#))
- Bug in `pandas.pivot_table()` incorrectly raising `UnicodeError` when passing unicode input for `margins` keyword ([GH13292](#))

Numeric

- Bug in `.rank()` which incorrectly ranks ordered categories ([GH15420](#))
- Bug in `.corr()` and `.cov()` where the column and index were the same object ([GH14617](#))
- Bug in `.mode()` where `mode` was not returned if was only a single value ([GH15714](#))
- Bug in `pd.cut()` with a single bin on an all 0s array ([GH15428](#))
- Bug in `pd.qcut()` with a single quantile and an array with identical values ([GH15431](#))
- Bug in `pandas.tools.utils.cartesian_product()` with large input can cause overflow on windows ([GH15265](#))

- Bug in `.eval()` which caused multi-line evals to fail with local variables not on the first line ([GH15342](#))

Other

- Compat with SciPy 0.19.0 for testing on `.interpolate()` ([GH15662](#))
- Compat for 32-bit platforms for `.qcut/cut`; bins will now be `int64` dtype ([GH14866](#))
- Bug in interactions with Qt when a `QtApplication` already exists ([GH14372](#))
- Avoid use of `np.finfo()` during `import pandas` removed to mitigate deadlock on Python GIL misuse ([GH14641](#))

8.7 Version 0.19

8.7.1 v0.19.2 (December 24, 2016)

{{ header }}

This is a minor bug-fix release in the 0.19.x series and includes some small regression fixes, bug fixes and performance improvements. We recommend that all users upgrade to this version.

Highlights include:

- Compatibility with Python 3.6
- Added a [Pandas Cheat Sheet](#). (GH13202).

What's new in v0.19.2

- *Enhancements*
- *Performance improvements*
- *Bug fixes*
- *Contributors*

Enhancements

The `pd.merge_asof()`, added in 0.19.0, gained some improvements:

- `pd.merge_asof()` gained `left_index/right_index` and `left_by/right_by` arguments (GH14253)
- `pd.merge_asof()` can take multiple columns in `by` parameter and has specialized dtypes for better performance (GH13936)

Performance improvements

- Performance regression with `PeriodIndex` (GH14822)
- Performance regression in indexing with `getitem` (GH14930)
- Improved performance of `.replace()` (GH12745)
- Improved performance `Series` creation with a datetime index and dictionary data (GH14894)

Bug fixes

- Compat with python 3.6 for pickling of some offsets (GH14685)
- Compat with python 3.6 for some indexing exception types (GH14684, GH14689)
- Compat with python 3.6 for deprecation warnings in the test suite (GH14681)
- Compat with python 3.6 for `Timestamp` pickles (GH14689)
- Compat with `dateutil==2.6.0`; `sefault` reported in the testing suite (GH14621)
- Allow nanoseconds in `Timestamp.replace` as a kwarg (GH14621)

- Bug in `pd.read_csv` in which aliasing was being done for `na_values` when passed in as a dictionary (GH14203)
- Bug in `pd.read_csv` in which column indices for a dict-like `na_values` were not being respected (GH14203)
- Bug in `pd.read_csv` where reading files fails, if the number of headers is equal to the number of lines in the file (GH14515)
- Bug in `pd.read_csv` for the Python engine in which an unhelpful error message was being raised when multi-char delimiters were not being respected with quotes (GH14582)
- Fix bugs (GH14734, GH13654) in `pd.read_sas` and `pandas.io.sas.sas7bdat.SAS7BDATReader` that caused problems when reading a SAS file incrementally.
- Bug in `pd.read_csv` for the Python engine in which an unhelpful error message was being raised when `skipfooter` was not being respected by Python's CSV library (GH13879)
- Bug in `.fillna()` in which timezone aware `datetime64` values were incorrectly rounded (GH14872)
- Bug in `.groupby(..., sort=True)` of a non-lexsorted `MultiIndex` when grouping with multiple levels (GH14776)
- Bug in `pd.cut` with negative values and a single bin (GH14652)
- Bug in `pd.to_numeric` where a 0 was not unsigned on a `downcast='unsigned'` argument (GH14401)
- Bug in plotting regular and irregular timeseries using shared axes (`sharex=True` or `ax.twinx()`) (GH13341, GH14322).
- Bug in not propagating exceptions in parsing invalid datetimes, noted in python 3.6 (GH14561)
- Bug in resampling a `DatetimeIndex` in local TZ, covering a DST change, which would raise `AmbiguousTimeError` (GH14682)
- Bug in indexing that transformed `RecursionError` into `KeyError` or `IndexingError` (GH14554)
- Bug in `HDFStore` when writing a `MultiIndex` when using `data_columns=True` (GH14435)
- Bug in `HDFStore.append()` when writing a `Series` and passing a `min_itemsize` argument containing a value for the `index` (GH11412)
- Bug when writing to a `HDFStore` in `table` format with a `min_itemsize` value for the `index` and without asking to append (GH10381)
- Bug in `Series.groupby.nunique()` raising an `IndexError` for an empty `Series` (GH12553)
- Bug in `DataFrame.nlargest` and `DataFrame.nsmallest` when the `index` had duplicate values (GH13412)
- Bug in clipboard functions on linux with python2 with unicode and separators (GH13747)
- Bug in clipboard functions on Windows 10 and python 3 (GH14362, GH12807)
- Bug in `.to_clipboard()` and Excel compat (GH12529)
- Bug in `DataFrame.combine_first()` for integer columns (GH14687).
- Bug in `pd.read_csv()` in which the `dtype` parameter was not being respected for empty data (GH14712)
- Bug in `pd.read_csv()` in which the `nrows` parameter was not being respected for large input when using the C engine for parsing (GH7626)
- Bug in `pd.merge_asof()` could not handle timezone-aware `DatetimeIndex` when a tolerance was specified (GH14844)

- Explicit check in `to_stata` and `StataWriter` for out-of-range values when writing doubles ([GH14618](#))
- Bug in `.plot(kind='kde')` which did not drop missing values to generate the KDE Plot, instead generating an empty plot. ([GH14821](#))
- Bug in `unstack()` if called with a list of column(s) as an argument, regardless of the dtypes of all columns, they get coerced to `object` ([GH11847](#))

8.7.2 v0.19.1 (November 3, 2016)

{{ header }}

This is a minor bug-fix release from 0.19.0 and includes some small regression fixes, bug fixes and performance improvements. We recommend that all users upgrade to this version.

What's new in v0.19.1

- *Performance improvements*
- *Bug fixes*
- *Contributors*

Performance improvements

- Fixed performance regression in factorization of `Period` data ([GH14338](#))
- Fixed performance regression in `Series.asof(when)` when `when` is a scalar ([GH14461](#))
- Improved performance in `DataFrame.asof(when)` when `when` is a scalar ([GH14461](#))
- Improved performance in `.to_json()` when `lines=True` ([GH14408](#))
- Improved performance in certain types of *loc* indexing with a `MultiIndex` ([GH14551](#)).

Bug fixes

- Source installs from PyPI will now again work without `cython` installed, as in previous versions ([GH14204](#))
- Compat with Cython 0.25 for building ([GH14496](#))
- Fixed regression where user-provided file handles were closed in `read_csv` (c engine) ([GH14418](#)).
- Fixed regression in `DataFrame.quantile` when missing values were present in some columns ([GH14357](#)).
- Fixed regression in `Index.difference` where the `freq` of a `DatetimeIndex` was incorrectly set ([GH14323](#))
- Added back `pandas.core.common.array_equivalent` with a deprecation warning ([GH14555](#)).
- Bug in `pd.read_csv` for the C engine in which quotation marks were improperly parsed in skipped rows ([GH14459](#))
- Bug in `pd.read_csv` for Python 2.x in which Unicode quote characters were no longer being respected ([GH14477](#))

- Fixed regression in `Index.append` when categorical indices were appended (GH14545).
- Fixed regression in `pd.DataFrame` where constructor fails when given dict with `None` value (GH14381)
- Fixed regression in `DatetimeIndex._maybe_cast_slice_bound` when index is empty (GH14354).
- Bug in localizing an ambiguous timezone when a boolean is passed (GH14402)
- Bug in `TimedeltaIndex` addition with a `Datetime`-like object where addition overflow in the negative direction was not being caught (GH14068, GH14453)
- Bug in string indexing against data with object `Index` may raise `AttributeError` (GH14424)
- Correctly raise `ValueError` on empty input to `pd.eval()` and `df.query()` (GH13139)
- Bug in `RangeIndex.intersection` when result is a empty set (GH14364).
- Bug in groupby-transform broadcasting that could cause incorrect dtype coercion (GH14457)
- Bug in `Series.__setitem__` which allowed mutating read-only arrays (GH14359).
- Bug in `DataFrame.insert` where multiple calls with duplicate columns can fail (GH14291)
- `pd.merge()` will raise `ValueError` with non-boolean parameters in passed boolean type arguments (GH14434)
- Bug in `Timestamp` where dates very near the minimum (1677-09) could underflow on creation (GH14415)
- Bug in `pd.concat` where names of the keys were not propagated to the resulting `MultiIndex` (GH14252)
- Bug in `pd.concat` where axis cannot take string parameters 'rows' or 'columns' (GH14369)
- Bug in `pd.concat` with dataframes heterogeneous in length and tuple keys (GH14438)
- Bug in `MultiIndex.set_levels` where illegal level values were still set after raising an error (GH13754)
- Bug in `DataFrame.to_json` where `lines=True` and a value contained a `}` character (GH14391)
- Bug in `df.groupby` causing an `AttributeError` when grouping a single index frame by a column and the index level (GH14327)
- Bug in `df.groupby` where `TypeError` raised when `pd.Grouper(key=...)` is passed in a list (GH14334)
- Bug in `pd.pivot_table` may raise `TypeError` or `ValueError` when `index` or `columns` is not scalar and `values` is not specified (GH14380)

8.7.3 v0.19.0 (October 2, 2016)

{{ header }}

This is a major release from 0.18.1 and includes number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

- `merge_asof()` for asof-style time-series joining, see *here*
- `.rolling()` is now time-series aware, see *here*
- `read_csv()` now supports parsing `Categorical` data, see *here*
- A function `union_categorical()` has been added for combining categoricals, see *here*
- `PeriodIndex` now has its own `period` dtype, and changed to be more consistent with other `Index` classes. See *here*
- Sparse data structures gained enhanced support of `int` and `bool` dtypes, see *here*

- Comparison operations with `Series` no longer ignores the index, see *here* for an overview of the API changes.
- Introduction of a pandas development API for utility functions, see *here*.
- Deprecation of `Panel4D` and `PanelND`. We recommend to represent these types of n-dimensional data with the `xarray` package.
- Removal of the previously deprecated modules `pandas.io.data`, `pandas.io.wb`, `pandas.tools.rplot`.

Warning: pandas \geq 0.19.0 will no longer silence numpy ufunc warnings upon import, see *here*.

What's new in v0.19.0

- *New features*
 - *merge_asof* for asof-style time-series joining
 - *.rolling()* is now time-series aware
 - *read_csv* has improved support for duplicate column names
 - *read_csv* supports parsing `Categorical` directly
 - *Categorical* concatenation
 - *Semi-month* offsets
 - *New Index* methods
 - *Google BigQuery* Enhancements
 - *Fine-grained numpy* errstate
 - *get_dummies* now returns integer dtypes
 - *Downcast* values to smallest possible dtype in *to_numeric*
 - *pandas* development API
 - *Other enhancements*
- *API changes*
 - *Series.tolist()* will now return Python types
 - *Series* operators for different indexes
 - * *Arithmetic operators*
 - * *Comparison operators*
 - * *Logical operators*
 - * *Flexible comparison methods*
 - *Series* type promotion on assignment
 - *.to_datetime()* changes
 - *Merging* changes
 - *.describe()* changes
 - *Period* changes

- * *PeriodIndex* now has *period* dtype
- * *Period('NaT')* now returns *pd.NaT*
- * *PeriodIndex.values* now returns array of *Period* object
- *Index + / -* no longer used for set operations
- *Index.difference* and *.symmetric_difference* changes
- *Index.unique* consistently returns *Index*
- *MultiIndex* constructors, *groupby* and *set_index* preserve categorical dtypes
- *read_csv* will progressively enumerate chunks
- *Sparse Changes*
 - * *int64* and *bool* support enhancements
 - * Operators now preserve dtypes
 - * Other sparse fixes
- *Indexer* dtype changes
- Other API changes
- *Deprecations*
- *Removal of prior version deprecations/changes*
- *Performance improvements*
- *Bug fixes*
- *Contributors*

New features

`merge_asof` for asof-style time-series joining

A long-time requested feature has been added through the `merge_asof()` function, to support asof style joining of time-series ([GH1870](#), [GH13695](#), [GH13709](#), [GH13902](#)). Full documentation is [here](#).

The `merge_asof()` performs an asof merge, which is similar to a left-join except that we match on nearest key rather than equal keys.

```
In [1]: left = pd.DataFrame({'a': [1, 5, 10],
...:                        'left_val': ['a', 'b', 'c']})
...:
```

```
In [2]: right = pd.DataFrame({'a': [1, 2, 3, 6, 7],
...:                          'right_val': [1, 2, 3, 6, 7]})
...:
```

```
In [3]: left
Out[3]:
   a left_val
0  1         a
1  5         b
2 10         c
```

```
[3 rows x 2 columns]
```

```
In [4]: right
```

```
Out[4]:
```

```
   a  right_val
0  1           1
1  2           2
2  3           3
3  6           6
4  7           7
```

```
[5 rows x 2 columns]
```

We typically want to match exactly when possible, and use the most recent value otherwise.

```
In [5]: pd.merge_asof(left, right, on='a')
```

```
Out[5]:
```

```
   a  left_val  right_val
0  1           a         1
1  5           b         3
2 10           c         7
```

```
[3 rows x 3 columns]
```

We can also match rows ONLY with prior data, and not an exact match.

```
In [6]: pd.merge_asof(left, right, on='a', allow_exact_matches=False)
```

```
Out[6]:
```

```
   a  left_val  right_val
0  1           a         NaN
1  5           b         3.0
2 10           c         7.0
```

```
[3 rows x 3 columns]
```

In a typical time-series example, we have `trades` and `quotes` and we want to `asof`-join them. This also illustrates using the `by` parameter to group data before merging.

```
In [7]: trades = pd.DataFrame({
...:     'time': pd.to_datetime(['20160525 13:30:00.023',
...:                             '20160525 13:30:00.038',
...:                             '20160525 13:30:00.048',
...:                             '20160525 13:30:00.048',
...:                             '20160525 13:30:00.048']),
...:     'ticker': ['MSFT', 'MSFT',
...:                 'GOOG', 'GOOG', 'AAPL'],
...:     'price': [51.95, 51.95,
...:                720.77, 720.92, 98.00],
...:     'quantity': [75, 155,
...:                  100, 100, 100]},
...:     columns=['time', 'ticker', 'price', 'quantity'])
...:
```

(continues on next page)

(continued from previous page)

```
In [8]: quotes = pd.DataFrame({
...:     'time': pd.to_datetime(['20160525 13:30:00.023',
...:                             '20160525 13:30:00.023',
...:                             '20160525 13:30:00.030',
...:                             '20160525 13:30:00.041',

3	2016-05-25 13:30:00.048	GOOG	720.92	100	720.50	720.93
4	2016-05-25 13:30:00.048	AAPL	98.00	100	NaN	NaN

[5 rows x 6 columns]

This returns a merged DataFrame with the entries in the same order as the original left passed DataFrame (`trades` in this case), with the fields of the `quotes` merged.

`.rolling()` is now time-series aware

`.rolling()` objects are now time-series aware and can accept a time-series offset (or convertible) for the window argument ([GH13327](#), [GH12995](#)). See the full documentation [here](#).

```
In [12]: dft = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]},
.....:                      index=pd.date_range('20130101 09:00:00',
.....:                      periods=5, freq='s'))
.....:

In [13]: dft
Out[13]:
```

	B
2013-01-01 09:00:00	0.0
2013-01-01 09:00:01	1.0
2013-01-01 09:00:02	2.0
2013-01-01 09:00:03	NaN
2013-01-01 09:00:04	4.0

[5 rows x 1 columns]

This is a regular frequency index. Using an integer window parameter works to roll along the window frequency.

```
In [14]: dft.rolling(2).sum()
Out[14]:
```

	B
2013-01-01 09:00:00	NaN
2013-01-01 09:00:01	1.0
2013-01-01 09:00:02	3.0
2013-01-01 09:00:03	NaN
2013-01-01 09:00:04	NaN

[5 rows x 1 columns]

```
In [15]: dft.rolling(2, min_periods=1).sum()
Out[15]:
```

	B
2013-01-01 09:00:00	0.0
2013-01-01 09:00:01	1.0

```
2013-01-01 09:00:02 3.0
2013-01-01 09:00:03 2.0
2013-01-01 09:00:04 4.0
```

```
[5 rows x 1 columns]
```

Specifying an offset allows a more intuitive specification of the rolling frequency.

```
In [16]: dft.rolling('2s').sum()
```

```
Out[16]:
```

```
          B
2013-01-01 09:00:00 0.0
2013-01-01 09:00:01 1.0
2013-01-01 09:00:02 3.0
2013-01-01 09:00:03 2.0
2013-01-01 09:00:04 4.0
```

```
[5 rows x 1 columns]
```

Using a non-regular, but still monotonic index, rolling with an integer window does not impart any special calculation.

```
In [17]: dft = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]},
    ....:                    index=pd.Index([pd.Timestamp('20130101 09:00:00'),
    ....:                                     pd.Timestamp('20130101 09:00:02'),
    ....:                                     pd.Timestamp('20130101 09:00:03'),
    ....:                                     pd.Timestamp('20130101 09:00:05'),
    ....:                                     pd.Timestamp('20130101 09:00:06')]),
    ....:                    name='foo'))
```

```
In [18]: dft
```

```
Out[18]:
```

```
          B
foo
2013-01-01 09:00:00 0.0
2013-01-01 09:00:02 1.0
2013-01-01 09:00:03 2.0
2013-01-01 09:00:05 NaN
2013-01-01 09:00:06 4.0
```

```
[5 rows x 1 columns]
```

```
In [19]: dft.rolling(2).sum()
```

```
Out[19]:
```

```
          B
foo
2013-01-01 09:00:00 NaN
2013-01-01 09:00:02 1.0
2013-01-01 09:00:03 3.0
2013-01-01 09:00:05 NaN
2013-01-01 09:00:06 NaN
```

```
[5 rows x 1 columns]
```

Using the time-specification generates variable windows for this sparse data.

```
In [20]: dft.rolling('2s').sum()
```

```
Out [20]:
```

```

           B
foo
2013-01-01 09:00:00  0.0
2013-01-01 09:00:02  1.0
2013-01-01 09:00:03  3.0
2013-01-01 09:00:05  NaN
2013-01-01 09:00:06  4.0
```

```
[5 rows x 1 columns]
```

Furthermore, we now allow an optional `on` parameter to specify a column (rather than the default of the index) in a DataFrame.

```
In [21]: dft = dft.reset_index()
```

```
In [22]: dft
```

```
Out [22]:
```

```

           foo    B
0 2013-01-01 09:00:00  0.0
1 2013-01-01 09:00:02  1.0
2 2013-01-01 09:00:03  2.0
3 2013-01-01 09:00:05  NaN
4 2013-01-01 09:00:06  4.0
```

```
[5 rows x 2 columns]
```

```
In [23]: dft.rolling('2s', on='foo').sum()
```

```
Out [23]:
```

```

           foo    B
0 2013-01-01 09:00:00  0.0
1 2013-01-01 09:00:02  1.0
2 2013-01-01 09:00:03  3.0
3 2013-01-01 09:00:05  NaN
4 2013-01-01 09:00:06  4.0
```

```
[5 rows x 2 columns]
```

`read_csv` has improved support for duplicate column names

Duplicate column names are now supported in `read_csv()` whether they are in the file or passed in as the `names` parameter ([GH7160](#), [GH9424](#))

```
In [24]: data = '0,1,2\n3,4,5'
```

```
In [25]: names = ['a', 'b', 'a']
```

Previous behavior:

```
In [2]: pd.read_csv(StringIO(data), names=names)
```

```
Out [2]:
```

(continues on next page)

(continued from previous page)

```

  a  b  a
0  2  1  2
1  5  4  5

```

The first `a` column contained the same data as the second `a` column, when it should have contained the values `[0, 3]`.

New behavior:

```

In [26]: pd.read_csv(StringIO(data), names=names)
-----
ValueError                                Traceback (most recent call last)

    422     return names
    423

ValueError: Duplicate names are not allowed.

```

read_csv supports parsing Categorical directly

The `read_csv()` function now supports parsing a `Categorical` column when specified as a `dtype` ([GH10153](#)). Depending on the structure of the data, this can result in a faster parse time and lower memory usage compared to converting to `Categorical` after parsing. See the [io docs here](#).

```
In [27]: data = 'col1,col2,col3\na,b,1\na,b,2\nc,d,3'
```

```
In [28]: pd.read_csv(StringIO(data))
```

```
Out[28]:
   col1 col2 col3
0     a    b     1
1     a    b     2
2     c    d     3
```

```
[3 rows x 3 columns]
```

```
In [29]: pd.read_csv(StringIO(data)).dtypes
```

```
Out[29]:
col1    object
col2    object
col3    int64
Length: 3, dtype: object
```

```
In [30]: pd.read_csv(StringIO(data), dtype='category').dtypes
```

```
Out[30]:
col1    category
col2    category
col3    category
Length: 3, dtype: object
```

Individual columns can be parsed as a `Categorical` using a dict specification

```
In [31]: pd.read_csv(StringIO(data), dtype={'col1': 'category'}).dtypes
```

```
Out[31]:
col1    category
col2    object
col3    int64
Length: 3, dtype: object
```

Note: The resulting categories will always be parsed as strings (object dtype). If the categories are numeric they can be converted using the `to_numeric()` function, or as appropriate, another converter such as `to_datetime()`.

```
In [32]: df = pd.read_csv(StringIO(data), dtype='category')
```

```
In [33]: df.dtypes
```

```
Out[33]:
col1    category
col2    category
col3    category
Length: 3, dtype: object
```

```
In [34]: df['col3']
```

```
Out[34]:
0     1
1     2
2     3
Name: col3, Length: 3, dtype: category
Categories (3, object): [1, 2, 3]
```

```
In [35]: df['col3'].cat.categories = pd.to_numeric(df['col3'].cat.categories)
```

```
In [36]: df['col3']
```

```
Out[36]:
```

```
0    1
```

```
1    2
```

```
2    3
```

```
Name: col3, Length: 3, dtype: category
```

```
Categories (3, int64): [1, 2, 3]
```

Categorical concatenation

- A function `union_categoricals()` has been added for combining categoricals, see *Unioning Categoricals* (GH13361, GH13763, GH13846, GH14173)

```
In [37]: from pandas.api.types import union_categoricals
```

```
In [38]: a = pd.Categorical(["b", "c"])
```

```
In [39]: b = pd.Categorical(["a", "b"])
```

```
In [40]: union_categoricals([a, b])
```

```
Out[40]:
```

```
[b, c, a, b]
```

```
Categories (3, object): [b, c, a]
```

- `concat` and `append` now can concat category dtypes with different categories as object dtype (GH13524)

```
In [41]: s1 = pd.Series(['a', 'b'], dtype='category')
```

```
In [42]: s2 = pd.Series(['b', 'c'], dtype='category')
```

Previous behavior:

```
In [1]: pd.concat([s1, s2])
```

```
ValueError: incompatible categories in categorical concat
```

New behavior:

```
In [43]: pd.concat([s1, s2])
```

```
Out[43]:
```

```
0    a
```

```
1    b
```

```
0    b
```

```
1    c
```

```
Length: 4, dtype: object
```

Semi-month offsets

Pandas has gained new frequency offsets, `SemiMonthEnd` ('SM') and `SemiMonthBegin` ('SMS'). These provide date offsets anchored (by default) to the 15th and end of month, and 15th and 1st of month respectively.

(GH1543)

```
In [44]: from pandas.tseries.offsets import SemiMonthEnd, SemiMonthBegin
```

SemiMonthEnd:

```
In [45]: pd.Timestamp('2016-01-01') + SemiMonthEnd()
Out[45]: Timestamp('2016-01-15 00:00:00')
```

```
In [46]: pd.date_range('2015-01-01', freq='SM', periods=4)
Out[46]: DatetimeIndex(['2015-01-15', '2015-01-31', '2015-02-15', '2015-02-28'],
↳dtype='datetime64[ns]', freq='SM-15')
```

SemiMonthBegin:

```
In [47]: pd.Timestamp('2016-01-01') + SemiMonthBegin()
Out[47]: Timestamp('2016-01-15 00:00:00')
```

```
In [48]: pd.date_range('2015-01-01', freq='SMS', periods=4)
Out[48]: DatetimeIndex(['2015-01-01', '2015-01-15', '2015-02-01', '2015-02-15'],
↳dtype='datetime64[ns]', freq='SMS-15')
```

Using the anchoring suffix, you can also specify the day of month to use instead of the 15th.

```
In [49]: pd.date_range('2015-01-01', freq='SMS-16', periods=4)
Out[49]: DatetimeIndex(['2015-01-01', '2015-01-16', '2015-02-01', '2015-02-16'],
↳dtype='datetime64[ns]', freq='SMS-16')
```

```
In [50]: pd.date_range('2015-01-01', freq='SM-14', periods=4)
Out[50]: DatetimeIndex(['2015-01-14', '2015-01-31', '2015-02-14', '2015-02-28'],
↳dtype='datetime64[ns]', freq='SM-14')
```

New Index methods

The following methods and options are added to `Index`, to be more consistent with the `Series` and `DataFrame` API.

`Index` now supports the `.where()` function for same shape indexing (GH13170)

```
In [51]: idx = pd.Index(['a', 'b', 'c'])
In [52]: idx.where([True, False, True])
Out[52]: Index(['a', nan, 'c'], dtype='object')
```

`Index` now supports `.dropna()` to exclude missing values (GH6194)

```
In [53]: idx = pd.Index([1, 2, np.nan, 4])
In [54]: idx.dropna()
Out[54]: Float64Index([1.0, 2.0, 4.0], dtype='float64')
```

For `MultiIndex`, values are dropped if any level is missing by default. Specifying `how='all'` only drops values where all levels are missing.

```
In [55]: midx = pd.MultiIndex.from_arrays([[1, 2, np.nan, 4],
.....:                                     [1, 2, np.nan, np.nan]])
.....:
```

```
In [56]: midx
Out[56]:
MultiIndex([(1.0, 1.0),
            (2.0, 2.0),
            (nan, nan),
            (4.0, nan)],
           )
```

```
In [57]: midx.dropna()
Out[57]:
MultiIndex([(1, 1),
            (2, 2)],
           )
```

```
In [58]: midx.dropna(how='all')
Out[58]:
MultiIndex([(1, 1.0),
            (2, 2.0),
            (4, nan)],
           )
```

Index now supports `.str.extractall()` which returns a `DataFrame`, see the [docs here](#) (GH10008, GH13156)

```
In [59]: idx = pd.Index(["a1a2", "b1", "c1"])
In [60]: idx.str.extractall(r"[ab](?P<digit>\d)")
Out[60]:
      digit
match
0 0      1
  1      2
1 0      1

[3 rows x 1 columns]
```

`Index.astype()` now accepts an optional boolean argument `copy`, which allows optional copying if the requirements on dtype are satisfied (GH13209)

Google BigQuery Enhancements

- The `read_gbq()` method has gained the `dialect` argument to allow users to specify whether to use BigQuery's legacy SQL or BigQuery's standard SQL. See the [docs](#) for more details (GH13615).
- The `to_gbq()` method now allows the `DataFrame` column order to differ from the destination table schema (GH11359).

Fine-grained numpy errstate

Previous versions of pandas would permanently silence numpy's ufunc error handling when pandas was imported. Pandas did this in order to silence the warnings that would arise from using numpy ufuncs on missing data, which are usually represented as NaN s. Unfortunately, this silenced legitimate warnings arising in non-pandas code in the application. Starting with 0.19.0, pandas will use the `numpy.errstate` context

manager to silence these warnings in a more fine-grained manner, only around where these operations are actually used in the pandas code base. (GH13109, GH13145)

After upgrading pandas, you may see *new RuntimeWarnings* being issued from your code. These are likely legitimate, and the underlying cause likely existed in the code when using previous versions of pandas that simply silenced the warning. Use `numpy.errstate` around the source of the `RuntimeWarning` to control how these conditions are handled.

get_dummies now returns integer dtypes

The `pd.get_dummies` function now returns dummy-encoded columns as small integers, rather than floats (GH8725). This should provide an improved memory footprint.

Previous behavior:

```
In [1]: pd.get_dummies(['a', 'b', 'a', 'c']).dtypes

Out[1]:
a    float64
b    float64
c    float64
dtype: object
```

New behavior:

```
In [61]: pd.get_dummies(['a', 'b', 'a', 'c']).dtypes
Out[61]:
a    uint8
b    uint8
c    uint8
Length: 3, dtype: object
```

Downcast values to smallest possible dtype in to_numeric

`pd.to_numeric()` now accepts a `downcast` parameter, which will downcast the data if possible to smallest specified numerical dtype (GH13352)

```
In [62]: s = ['1', 2, 3]
```

```
In [63]: pd.to_numeric(s, downcast='unsigned')
Out[63]: array([1, 2, 3], dtype=uint8)
```

```
In [64]: pd.to_numeric(s, downcast='integer')
Out[64]: array([1, 2, 3], dtype=int8)
```

pandas development API

As part of making pandas API more uniform and accessible in the future, we have created a standard sub-package of pandas, `pandas.api` to hold public API's. We are starting by exposing type introspection functions in `pandas.api.types`. More sub-packages and officially sanctioned API's will be published in future versions of pandas (GH13147, GH13634)

The following are now part of this API:

```
In [65]: import pprint

In [66]: from pandas.api import types

In [67]: funcs = [f for f in dir(types) if not f.startswith('_')]

In [68]: pprint.pprint(funcs)
['CategoricalDtype',
 'DatetimeTZDtype',
 'IntervalDtype',
 'PeriodDtype',
 'infer_dtype',
 'is_array_like',
 'is_bool',
 'is_bool_dtype',
 'is_categorical',
 'is_categorical_dtype',
 'is_complex',
 'is_complex_dtype',
 'is_datetime64_any_dtype',
 'is_datetime64_dtype',
 'is_datetime64_ns_dtype',
 'is_datetime64tz_dtype',
 'is_datetimetz',
 'is_dict_like',
 'is_dtype_equal',
 'is_extension_array_dtype',
 'is_extension_type',
 'is_file_like',
 'is_float',
 'is_float_dtype',
 'is_hashable',
 'is_int64_dtype',
 'is_integer',
 'is_integer_dtype',
 'is_interval',
 'is_interval_dtype',
 'is_iterator',
 'is_list_like',
 'is_named_tuple',
 'is_number',
 'is_numeric_dtype',
 'is_object_dtype',
 'is_period',
 'is_period_dtype',
 'is_re',
 'is_re_compilable',
 'is_scalar',
 'is_signed_integer_dtype',
 'is_sparse',
 'is_string_dtype',
 'is_timedelta64_dtype',
```

(continues on next page)

(continued from previous page)

```
'is_timedelta64_ns_dtype',
'is_unsigned_integer_dtype',
'pandas_dtype',
'union_categoricals']
```

Note: Calling these functions from the internal module `pandas.core.common` will now show a `DeprecationWarning` ([GH13990](#))

Other enhancements

- `Timestamp` can now accept positional and keyword parameters similar to `datetime.datetime()` ([GH10758](#), [GH11630](#))

```
In [69]: pd.Timestamp(2012, 1, 1)
Out[69]: Timestamp('2012-01-01 00:00:00')
```

```
In [70]: pd.Timestamp(year=2012, month=1, day=1, hour=8, minute=30)
Out[70]: Timestamp('2012-01-01 08:30:00')
```

- The `.resample()` function now accepts a `on=` or `level=` parameter for resampling on a datetimelike column or `MultiIndex` level ([GH13500](#))

```
In [71]: df = pd.DataFrame({'date': pd.date_range('2015-01-01', freq='W',
↳ periods=5),
    ....:                    'a': np.arange(5)},
    ....:                    index=pd.MultiIndex.from_arrays([[1, 2, 3, 4, 5],
    ....:                                                         pd.date_range('2015-01-
↳ 01',
    ....:                                                         freq='W',
    ....:                                                         periods=5)
    ....:                                                         ], names=['v', 'd']))
```

```
In [72]: df
Out[72]:
```

	date	a
v d		
1 2015-01-04	2015-01-04	0
2 2015-01-11	2015-01-11	1
3 2015-01-18	2015-01-18	2
4 2015-01-25	2015-01-25	3
5 2015-02-01	2015-02-01	4

```
[5 rows x 2 columns]
```

```
In [73]: df.resample('M', on='date').sum()
Out[73]:
```

date	a
2015-01-31	6
2015-02-28	4

```
[2 rows x 1 columns]
```

```
In [74]: df.resample('M', level='d').sum()
```

```
Out[74]:
```

```
          a
d
2015-01-31  6
2015-02-28  4
```

```
[2 rows x 1 columns]
```

- The `.get_credentials()` method of `GbqConnector` can now first try to fetch [the application default credentials](#). See the docs for more details ([GH13577](#)).
- The `.tz_localize()` method of `DatetimeIndex` and `Timestamp` has gained the `errors` keyword, so you can potentially coerce nonexistent timestamps to `NaT`. The default behavior remains to raising a `NonExistentTimeError` ([GH13057](#)).
- `.to_hdf/read_hdf()` now accept path objects (e.g. `pathlib.Path`, `py.path.local`) for the file path ([GH11773](#)).
- The `pd.read_csv()` with `engine='python'` has gained support for the `decimal` ([GH12933](#)), `na_filter` ([GH13321](#)) and the `memory_map` option ([GH13381](#)).
- Consistent with the Python API, `pd.read_csv()` will now interpret `+inf` as positive infinity ([GH13274](#)).
- The `pd.read_html()` has gained support for the `na_values`, `converters`, `keep_default_na` options ([GH13461](#)).
- `Categorical.astype()` now accepts an optional boolean argument `copy`, effective when dtype is categorical ([GH13209](#)).
- `DataFrame` has gained the `.asof()` method to return the last non-`NaN` values according to the selected subset ([GH13358](#)).
- The `DataFrame` constructor will now respect key ordering if a list of `OrderedDict` objects are passed in ([GH13304](#)).
- `pd.read_html()` has gained support for the `decimal` option ([GH12907](#)).
- `Series` has gained the properties `.is_monotonic`, `.is_monotonic_increasing`, `.is_monotonic_decreasing`, similar to `Index` ([GH13336](#)).
- `DataFrame.to_sql()` now allows a single value as the SQL type for all columns ([GH11886](#)).
- `Series.append` now supports the `ignore_index` option ([GH13677](#)).
- `.to_stata()` and `StataWriter` can now write variable labels to Stata dta files using a dictionary to make column names to labels ([GH13535](#), [GH13536](#)).
- `.to_stata()` and `StataWriter` will automatically convert `datetime64[ns]` columns to Stata format `%tc`, rather than raising a `ValueError` ([GH12259](#)).
- `read_stata()` and `StataReader` raise with a more explicit error message when reading Stata files with repeated value labels when `convert_categoricals=True` ([GH13923](#)).
- `DataFrame.style` will now render sparsified `MultiIndexes` ([GH11655](#)).
- `DataFrame.style` will now show column level names (e.g. `DataFrame.columns.names`) ([GH13775](#)).
- `DataFrame` has gained support to re-order the columns based on the values in a row using `df.sort_values(by='...', axis=1)` ([GH10806](#)).

```
In [75]: df = pd.DataFrame({'A': [2, 7], 'B': [3, 5], 'C': [4, 8]},
    ....:                    index=['row1', 'row2'])
    ....:
```

```
In [76]: df
```

```
Out[76]:
   A  B  C
row1 2  3  4
row2 7  5  8
```

```
[2 rows x 3 columns]
```

```
In [77]: df.sort_values(by='row2', axis=1)
```

```
Out[77]:
   B  A  C
row1 3  2  4
row2 5  7  8
```

```
[2 rows x 3 columns]
```

- Added documentation to *I/O* regarding the perils of reading in columns with mixed dtypes and how to handle it ([GH13746](#))
- `to_html()` now has a `border` argument to control the value in the opening `<table>` tag. The default is the value of the `html.border` option, which defaults to 1. This also affects the notebook HTML repr, but since Jupyter's CSS includes a border-width attribute, the visual effect is the same. ([GH11563](#)).
- Raise `ImportError` in the sql functions when `sqlalchemy` is not installed and a connection string is used ([GH11920](#)).
- Compatibility with matplotlib 2.0. Older versions of pandas should also work with matplotlib 2.0 ([GH13333](#))
- `Timestamp`, `Period`, `DatetimeIndex`, `PeriodIndex` and `.dt` accessor have gained a `.is_leap_year` property to check whether the date belongs to a leap year. ([GH13727](#))
- `astype()` will now accept a dict of column name to data types mapping as the `dtype` argument. ([GH12086](#))
- The `pd.read_json` and `DataFrame.to_json` has gained support for reading and writing json lines with `lines` option see *Line delimited json* ([GH9180](#))
- `read_excel()` now supports the `true_values` and `false_values` keyword arguments ([GH13347](#))
- `groupby()` will now accept a scalar and a single-element list for specifying `level` on a non-`MultiIndex` grouper. ([GH13907](#))
- Non-convertible dates in an excel date column will be returned without conversion and the column will be `object` dtype, rather than raising an exception ([GH10001](#)).
- `pd.Timedelta(None)` is now accepted and will return `NaT`, mirroring `pd.Timestamp` ([GH13687](#))
- `pd.read_stata()` can now handle some format 111 files, which are produced by SAS when generating Stata dta files ([GH11526](#))
- `Series` and `Index` now support `divmod` which will return a tuple of series or indices. This behaves like a standard binary operator with regards to broadcasting rules ([GH14208](#)).

API changes

Series.tolist() will now return Python types

Series.tolist() will now return Python types in the output, mimicking NumPy .tolist() behavior (GH10904)

```
In [78]: s = pd.Series([1, 2, 3])
```

Previous behavior:

```
In [7]: type(s.tolist()[0])
Out[7]:
<class 'numpy.int64'>
```

New behavior:

```
In [79]: type(s.tolist()[0])
Out[79]: int
```

Series operators for different indexes

Following Series operators have been changed to make all operators consistent, including DataFrame (GH1134, GH4581, GH13538)

- Series comparison operators now raise ValueError when index are different.
- Series logical operators align both index of left and right hand side.

Warning: Until 0.18.1, comparing Series with the same length, would succeed even if the .index are different (the result ignores .index). As of 0.19.0, this will raises ValueError to be more strict. This section also describes how to keep previous behavior or align different indexes, using the flexible comparison methods like .eq.

As a result, Series and DataFrame operators behave as below:

Arithmetic operators

Arithmetic operators align both index (no changes).

```
In [80]: s1 = pd.Series([1, 2, 3], index=list('ABC'))
In [81]: s2 = pd.Series([2, 2, 2], index=list('ABD'))

In [82]: s1 + s2
Out[82]:
A    3.0
B    4.0
C     NaN
D     NaN
Length: 4, dtype: float64

In [83]: df1 = pd.DataFrame([1, 2, 3], index=list('ABC'))
```

(continues on next page)

(continued from previous page)

```
In [84]: df2 = pd.DataFrame([2, 2, 2], index=list('ABD'))
In [85]: df1 + df2
Out[85]:
      0
A  3.0
B  4.0
C  NaN
D  NaN

[4 rows x 1 columns]
```

Comparison operators

Comparison operators raise `ValueError` when `.index` are different.

Previous behavior (Series):

`Series` compared values ignoring the `.index` as long as both had the same length:

```
In [1]: s1 == s2
Out[1]:
A    False
B     True
C    False
dtype: bool
```

New behavior (Series):

```
In [2]: s1 == s2
Out[2]:
ValueError: Can only compare identically-labeled Series objects
```

Note: To achieve the same result as previous versions (compare values based on locations ignoring `.index`), compare both `.values`.

```
In [86]: s1.values == s2.values
Out[86]: array([False,  True,  False])
```

If you want to compare `Series` aligning its `.index`, see flexible comparison methods section below:

```
In [87]: s1.eq(s2)
Out[87]:
A    False
B     True
C    False
D    False
Length: 4, dtype: bool
```

Current behavior (DataFrame, no change):

```
In [3]: df1 == df2
Out[3]:
ValueError: Can only compare identically-labeled DataFrame objects
```

Logical operators

Logical operators align both `.index` of left and right hand side.

Previous behavior (Series), only left hand side index was kept:

```
In [4]: s1 = pd.Series([True, False, True], index=list('ABC'))
In [5]: s2 = pd.Series([True, True, True], index=list('ABD'))
In [6]: s1 & s2
Out[6]:
A      True
B     False
C     False
dtype: bool
```

New behavior (Series):

```
In [88]: s1 = pd.Series([True, False, True], index=list('ABC'))
In [89]: s2 = pd.Series([True, True, True], index=list('ABD'))

In [90]: s1 & s2
Out[90]:
A      True
B     False
C     False
D     False
Length: 4, dtype: bool
```

Note: Series logical operators fill a NaN result with False.

Note: To achieve the same result as previous versions (compare values based on only left hand side index), you can use `reindex_like`:

```
In [91]: s1 & s2.reindex_like(s1)
Out[91]:
A      True
B     False
C     False
Length: 3, dtype: bool
```

Current behavior (DataFrame, no change):

```
In [92]: df1 = pd.DataFrame([True, False, True], index=list('ABC'))
```

(continues on next page)

(continued from previous page)

```
In [93]: df2 = pd.DataFrame([True, True, True], index=list('ABD'))
```

```
In [94]: df1 & df2
```

```
Out[94]:
```

```
0
A  True
B  False
C   NaN
D   NaN
```

```
[4 rows x 1 columns]
```

Flexible comparison methods

`Series` flexible comparison methods like `eq`, `ne`, `le`, `lt`, `ge` and `gt` now align both `index`. Use these operators if you want to compare two `Series` which has the different `index`.

```
In [95]: s1 = pd.Series([1, 2, 3], index=['a', 'b', 'c'])
```

```
In [96]: s2 = pd.Series([2, 2, 2], index=['b', 'c', 'd'])
```

```
In [97]: s1.eq(s2)
```

```
Out[97]:
```

```
a  False
b   True
c  False
d  False
```

```
Length: 4, dtype: bool
```

```
In [98]: s1.ge(s2)
```

```
Out[98]:
```

```
a  False
b   True
c   True
d  False
```

```
Length: 4, dtype: bool
```

Previously, this worked the same as comparison operators (see above).

Series type promotion on assignment

A `Series` will now correctly promote its dtype for assignment with incompat values to the current dtype (GH13234)

```
In [99]: s = pd.Series()
```

Previous behavior:

```
In [2]: s["a"] = pd.Timestamp("2016-01-01")
```

(continues on next page)

(continued from previous page)

```
In [3]: s["b"] = 3.0
TypeError: invalid type promotion
```

New behavior:

```
In [100]: s["a"] = pd.Timestamp("2016-01-01")
```

```
In [101]: s["b"] = 3.0
```

```
In [102]: s
Out[102]:
a    2016-01-01 00:00:00
b                3
Length: 2, dtype: object
```

```
In [103]: s.dtype
Out[103]: dtype('O')
```

.to_datetime() changes

Previously if `.to_datetime()` encountered mixed integers/floats and strings, but no datetimes with `errors='coerce'` it would convert all to `NaT`.

Previous behavior:

```
In [2]: pd.to_datetime([1, 'foo'], errors='coerce')
Out[2]: DatetimeIndex(['NaT', 'NaT'], dtype='datetime64[ns]', freq=None)
```

Current behavior:

This will now convert integers/floats with the default unit of `ns`.

```
In [104]: pd.to_datetime([1, 'foo'], errors='coerce')
Out[104]: DatetimeIndex(['1970-01-01 00:00:00.000000001', 'NaT'], dtype='datetime64[ns]',
↳ freq=None)
```

Bug fixes related to `.to_datetime()`:

- Bug in `pd.to_datetime()` when passing integers or floats, and no unit and `errors='coerce'` (GH13180).
- Bug in `pd.to_datetime()` when passing invalid data types (e.g. `bool`); will now respect the `errors` keyword (GH13176)
- Bug in `pd.to_datetime()` which overflowed on `int8`, and `int16` dtypes (GH13451)
- Bug in `pd.to_datetime()` raise `AttributeError` with `NaN` and the other string is not valid when `errors='ignore'` (GH12424)
- Bug in `pd.to_datetime()` did not cast floats correctly when `unit` was specified, resulting in truncated datetime (GH13834)

Merging changes

Merging will now preserve the dtype of the join keys (GH8596)

```
In [105]: df1 = pd.DataFrame({'key': [1], 'v1': [10]})

In [106]: df1
Out[106]:
   key  v1
0    1  10

[1 rows x 2 columns]

In [107]: df2 = pd.DataFrame({'key': [1, 2], 'v1': [20, 30]})

In [108]: df2
Out[108]:
   key  v1
0    1  20
1    2  30

[2 rows x 2 columns]
```

Previous behavior:

```
In [5]: pd.merge(df1, df2, how='outer')
Out[5]:
   key  v1
0  1.0  10.0
1  1.0  20.0
2  2.0  30.0

In [6]: pd.merge(df1, df2, how='outer').dtypes
Out[6]:
key    float64
v1     float64
dtype: object
```

New behavior:

We are able to preserve the join keys

```
In [109]: pd.merge(df1, df2, how='outer')
Out[109]:
   key  v1
0    1  10
1    1  20
2    2  30

[3 rows x 2 columns]

In [110]: pd.merge(df1, df2, how='outer').dtypes
Out[110]:
key    int64
v1     int64
Length: 2, dtype: object
```

Of course if you have missing values that are introduced, then the resulting dtype will be upcast, which is unchanged from previous.

```
In [111]: pd.merge(df1, df2, how='outer', on='key')
```

```
Out[111]:
   key  v1_x  v1_y
0    1  10.0   20
1    2   NaN   30
```

```
[2 rows x 3 columns]
```

```
In [112]: pd.merge(df1, df2, how='outer', on='key').dtypes
```

```
Out[112]:
key          int64
v1_x        float64
v1_y          int64
Length: 3, dtype: object
```

`.describe()` changes

Percentile identifiers in the index of a `.describe()` output will now be rounded to the least precision that keeps them distinct ([GH13104](#))

```
In [113]: s = pd.Series([0, 1, 2, 3, 4])
```

```
In [114]: df = pd.DataFrame([0, 1, 2, 3, 4])
```

Previous behavior:

The percentiles were rounded to at most one decimal place, which could raise `ValueError` for a data frame if the percentiles were duplicated.

```
In [3]: s.describe(percentiles=[0.0001, 0.0005, 0.001, 0.999, 0.9995, 0.9999])
```

```
Out[3]:
count      5.000000
mean       2.000000
std        1.581139

max     4.000000
```

```
[12 rows x 1 columns]
```

Furthermore:

- Passing duplicated `percentiles` will now raise a `ValueError`.
- Bug in `.describe()` on a `DataFrame` with a mixed-dtype column index, which would previously raise a `TypeError` ([GH13288](#))

Period changes

PeriodIndex now has period dtype

`PeriodIndex` now has its own `period` dtype. The `period` dtype is a pandas extension dtype like `category` or the *timezone aware dtype* (`datetime64[ns, tz]`) ([GH13941](#)). As a consequence of this change, `PeriodIndex` no longer has an integer dtype:

Previous behavior:

```
In [1]: pi = pd.PeriodIndex(['2016-08-01'], freq='D')

In [2]: pi
Out[2]: PeriodIndex(['2016-08-01'], dtype='int64', freq='D')
```

(continues on next page)

(continued from previous page)

```
In [3]: pd.api.types.is_integer_dtype(pi)
Out[3]: True

In [4]: pi.dtype
Out[4]: dtype('int64')
```

New behavior:

```
In [117]: pi = pd.PeriodIndex(['2016-08-01'], freq='D')

In [118]: pi
Out[118]: PeriodIndex(['2016-08-01'], dtype='period[D]', freq='D')

In [119]: pd.api.types.is_integer_dtype(pi)
Out[119]: False

In [120]: pd.api.types.is_period_dtype(pi)
Out[120]: True

In [121]: pi.dtype
Out[121]: period[D]

In [122]: type(pi.dtype)
Out[122]: pandas.core.dtypes.dtypes.PeriodDtype
```

Period('NaT') now returns pd.NaT

Previously, Period has its own Period('NaT') representation different from pd.NaT. Now Period('NaT') has been changed to return pd.NaT. ([GH12759](#), [GH13582](#))

Previous behavior:

```
In [5]: pd.Period('NaT', freq='D')
Out[5]: Period('NaT', 'D')
```

New behavior:

These result in pd.NaT without providing freq option.

```
In [123]: pd.Period('NaT')
Out[123]: NaT

In [124]: pd.Period(None)
Out[124]: NaT
```

To be compatible with Period addition and subtraction, pd.NaT now supports addition and subtraction with int. Previously it raised ValueError.

Previous behavior:

```
In [5]: pd.NaT + 1
...
ValueError: Cannot add integral value to Timestamp without freq.
```

New behavior:

```
In [125]: pd.NaT + 1
Out[125]: NaT
```

```
In [126]: pd.NaT - 1
Out[126]: NaT
```

PeriodIndex.values now returns array of Period object

.values is changed to return an array of Period objects, rather than an array of integers (GH13988).

Previous behavior:

```
In [6]: pi = pd.PeriodIndex(['2011-01', '2011-02'], freq='M')
In [7]: pi.values
Out[7]: array([492, 493])
```

New behavior:

```
In [127]: pi = pd.PeriodIndex(['2011-01', '2011-02'], freq='M')

In [128]: pi.values
Out[128]: array([Period('2011-01', 'M'), Period('2011-02', 'M')], dtype=object)
```

Index + / - no longer used for set operations

Addition and subtraction of the base Index type and of DatetimeIndex (not the numeric index types) previously performed set operations (set union and difference). This behavior was already deprecated since 0.15.0 (in favor using the specific .union() and .difference() methods), and is now disabled. When possible, + and - are now used for element-wise operations, for example for concatenating strings or subtracting datetimes (GH8227, GH14127).

Previous behavior:

```
In [1]: pd.Index(['a', 'b']) + pd.Index(['a', 'c'])
FutureWarning: using '+' to provide set union with Indexes is deprecated, use '|' or .
->.union()
Out[1]: Index(['a', 'b', 'c'], dtype='object')
```

New behavior: the same operation will now perform element-wise addition:

```
In [129]: pd.Index(['a', 'b']) + pd.Index(['a', 'c'])
Out[129]: Index(['aa', 'bc'], dtype='object')
```

Note that numeric Index objects already performed element-wise operations. For example, the behavior of adding two integer Indexes is unchanged. The base Index is now made consistent with this behavior.

```
In [130]: pd.Index([1, 2, 3]) + pd.Index([2, 3, 4])
Out[130]: Int64Index([3, 5, 7], dtype='int64')
```

Further, because of this change, it is now possible to subtract two DatetimeIndex objects resulting in a TimedeltaIndex:

Previous behavior:

```
In [1]: (pd.DatetimeIndex(['2016-01-01', '2016-01-02'])
...: - pd.DatetimeIndex(['2016-01-02', '2016-01-03']))
FutureWarning: using '-' to provide set differences with datetimelike Indexes is
↳ deprecated, use .difference()
Out[1]: DatetimeIndex(['2016-01-01'], dtype='datetime64[ns]', freq=None)
```

New behavior:

```
In [131]: (pd.DatetimeIndex(['2016-01-01', '2016-01-02'])
.....: - pd.DatetimeIndex(['2016-01-02', '2016-01-03']))
.....:
Out[131]: TimedeltaIndex(['-1 days', '-1 days'], dtype='timedelta64[ns]', freq=None)
```

Index.difference and .symmetric_difference changes

Index.difference and Index.symmetric_difference will now, more consistently, treat NaN values as any other values. (GH13514)

```
In [132]: idx1 = pd.Index([1, 2, 3, np.nan])
```

```
In [133]: idx2 = pd.Index([0, 1, np.nan])
```

Previous behavior:

```
In [3]: idx1.difference(idx2)
Out[3]: Float64Index([nan, 2.0, 3.0], dtype='float64')

In [4]: idx1.symmetric_difference(idx2)
Out[4]: Float64Index([0.0, nan, 2.0, 3.0], dtype='float64')
```

New behavior:

```
In [134]: idx1.difference(idx2)
Out[134]: Float64Index([2.0, 3.0], dtype='float64')

In [135]: idx1.symmetric_difference(idx2)
Out[135]: Float64Index([0.0, 2.0, 3.0], dtype='float64')
```

Index.unique consistently returns Index

Index.unique() now returns unique values as an Index of the appropriate dtype. (GH13395). Previously, most Index classes returned np.ndarray, and DatetimeIndex, TimedeltaIndex and PeriodIndex returned Index to keep metadata like timezone.

Previous behavior:

```
In [1]: pd.Index([1, 2, 3]).unique()
Out[1]: array([1, 2, 3])

In [2]: pd.DatetimeIndex(['2011-01-01', '2011-01-02',
...:                       '2011-01-03'], tz='Asia/Tokyo').unique()
Out[2]:
```

(continues on next page)

(continued from previous page)

```
DatetimeIndex(['2011-01-01 00:00:00+09:00', '2011-01-02 00:00:00+09:00',
              '2011-01-03 00:00:00+09:00'],
              dtype='datetime64[ns, Asia/Tokyo]', freq=None)
```

New behavior:

```
In [136]: pd.Index([1, 2, 3]).unique()
Out[136]: Int64Index([1, 2, 3], dtype='int64')

In [137]: pd.DatetimeIndex(['2011-01-01', '2011-01-02', '2011-01-03'],
    .....:                  tz='Asia/Tokyo').unique()
    .....:
Out[137]:
DatetimeIndex(['2011-01-01 00:00:00+09:00', '2011-01-02 00:00:00+09:00',
              '2011-01-03 00:00:00+09:00'],
              dtype='datetime64[ns, Asia/Tokyo]', freq=None)
```

MultiIndex constructors, groupby and set_index preserve categorical dtypes

MultiIndex.from_arrays and MultiIndex.from_product will now preserve categorical dtype in MultiIndex levels (GH13743, GH13854).

```
In [138]: cat = pd.Categorical(['a', 'b'], categories=list("bac"))
In [139]: lvl1 = ['foo', 'bar']
In [140]: midx = pd.MultiIndex.from_arrays([cat, lvl1])
In [141]: midx
Out[141]:
MultiIndex([( 'a', 'foo'),
            ( 'b', 'bar')],
           )
```

Previous behavior:

```
In [4]: midx.levels[0]
Out[4]: Index(['b', 'a', 'c'], dtype='object')

In [5]: midx.get_level_values[0]
Out[5]: Index(['a', 'b'], dtype='object')
```

New behavior: the single level is now a CategoricalIndex:

```
In [142]: midx.levels[0]
Out[142]: CategoricalIndex(['b', 'a', 'c'], categories=['b', 'a', 'c'], ordered=False,
    ↪ dtype='category')

In [143]: midx.get_level_values(0)
Out[143]: CategoricalIndex(['a', 'b'], categories=['b', 'a', 'c'], ordered=False,
    ↪ dtype='category')
```

An analogous change has been made to MultiIndex.from_product. As a consequence, groupby and set_index also preserve categorical dtypes in indexes

```
In [144]: df = pd.DataFrame({'A': [0, 1], 'B': [10, 11], 'C': cat})
In [145]: df_grouped = df.groupby(by=['A', 'C']).first()
In [146]: df_set_idx = df.set_index(['A', 'C'])
```

Previous behavior:

```
In [11]: df_grouped.index.levels[1]
Out[11]: Index(['b', 'a', 'c'], dtype='object', name='C')
In [12]: df_grouped.reset_index().dtypes
Out[12]:
A      int64
C      object
B      float64
dtype: object

In [13]: df_set_idx.index.levels[1]
Out[13]: Index(['b', 'a', 'c'], dtype='object', name='C')
In [14]: df_set_idx.reset_index().dtypes
Out[14]:
A      int64
C      object
B      int64
dtype: object
```

New behavior:

```
In [147]: df_grouped.index.levels[1]
Out[147]: CategoricalIndex(['b', 'a', 'c'], categories=['b', 'a', 'c'], ordered=False,
↳ name='C', dtype='category')
```

```
In [148]: df_grouped.reset_index().dtypes
Out[148]:
A      int64
C      category
B      float64
Length: 3, dtype: object
```

```
In [149]: df_set_idx.index.levels[1]
Out[149]: CategoricalIndex(['b', 'a', 'c'], categories=['b', 'a', 'c'], ordered=False,
↳ name='C', dtype='category')
```

```
In [150]: df_set_idx.reset_index().dtypes
Out[150]:
A      int64
C      category
B      int64
Length: 3, dtype: object
```

read_csv will progressively enumerate chunks

When `read_csv()` is called with `chunksize=n` and without specifying an index, each chunk used to have an independently generated index from 0 to `n-1`. They are now given instead a progressive index, starting from 0 for the first chunk, from `n` for the second, and so on, so that, when concatenated, they are identical to the result of calling `read_csv()` without the `chunksize=` argument ([GH12185](#)).

```
In [151]: data = 'A,B\n0,1\n2,3\n4,5\n6,7'
```

Previous behavior:

```
In [2]: pd.concat(pd.read_csv(StringIO(data), chunksize=2))
Out[2]:
   A  B
0  0  1
1  2  3
0  4  5
1  6  7
```

New behavior:

```
In [152]: pd.concat(pd.read_csv(StringIO(data), chunksize=2))
Out[152]:
   A  B
0  0  1
1  2  3
2  4  5
3  6  7

[4 rows x 2 columns]
```

Sparse Changes

These changes allow pandas to handle sparse data with more dtypes, and for work to make a smoother experience with data handling.

int64 and bool support enhancements

Sparse data structures now gained enhanced support of `int64` and `bool` dtype ([GH667](#), [GH13849](#)).

Previously, sparse data were `float64` dtype by default, even if all inputs were of `int` or `bool` dtype. You had to specify `dtype` explicitly to create sparse data with `int64` dtype. Also, `fill_value` had to be specified explicitly because the default was `np.nan` which doesn't appear in `int64` or `bool` data.

```
In [1]: pd.SparseArray([1, 2, 0, 0])
Out[1]:
[1.0, 2.0, 0.0, 0.0]
Fill: nan
IntIndex
Indices: array([0, 1, 2, 3], dtype=int32)

# specifying int64 dtype, but all values are stored in sp_values because
```

(continues on next page)

(continued from previous page)

```
# fill_value default is np.nan
In [2]: pd.SparseArray([1, 2, 0, 0], dtype=np.int64)
Out[2]:
[1, 2, 0, 0]
Fill: nan
IntIndex
Indices: array([0, 1, 2, 3], dtype=int32)

In [3]: pd.SparseArray([1, 2, 0, 0], dtype=np.int64, fill_value=0)
Out[3]:
[1, 2, 0, 0]
Fill: 0
IntIndex
Indices: array([0, 1], dtype=int32)
```

As of v0.19.0, sparse data keeps the input dtype, and uses more appropriate `fill_value` defaults (0 for `int64` dtype, `False` for `bool` dtype).

```
In [153]: pd.SparseArray([1, 2, 0, 0], dtype=np.int64)
Out[153]:
[1, 2, 0, 0]
Fill: 0
IntIndex
Indices: array([0, 1], dtype=int32)
```

```
In [154]: pd.SparseArray([True, False, False, False])
Out[154]:
[True, False, False, False]
Fill: False
IntIndex
Indices: array([0], dtype=int32)
```

See the *docs* for more details.

Operators now preserve dtypes

- Sparse data structure now can preserve `dtype` after arithmetic ops ([GH13848](#))

```
In [155]: s = pd.SparseSeries([0, 2, 0, 1], fill_value=0, dtype=np.int64)
```

```
In [156]: s.dtype
Out[156]: Sparse[int64, 0]
```

```
In [157]: s + 1
Out[157]:
0    1
1    3
2    1
3    2
Length: 4, dtype: Sparse[int64, 1]
BlockIndex
Block locations: array([1, 3], dtype=int32)
Block lengths: array([1, 1], dtype=int32)
```

- Sparse data structure now support `astype` to convert internal `dtype` (GH13900)

```
In [158]: s = pd.SparseSeries([1., 0., 2., 0.], fill_value=0)
```

```
In [159]: s
Out[159]:
0    1.0
1    0.0
2    2.0
3    0.0
Length: 4, dtype: Sparse[float64, 0]
BlockIndex
Block locations: array([0, 2], dtype=int32)
Block lengths: array([1, 1], dtype=int32)
```

```
In [160]: s.astype(np.int64)
Out[160]:
0    1
1    0
2    2
3    0
Length: 4, dtype: Sparse[int64, 0]
BlockIndex
Block locations: array([0, 2], dtype=int32)
Block lengths: array([1, 1], dtype=int32)
```

`astype` fails if data contains values which cannot be converted to specified `dtype`. Note that the limitation is applied to `fill_value` which default is `np.nan`.

```
In [7]: pd.SparseSeries([1., np.nan, 2., np.nan], fill_value=np.nan).astype(np.int64)
Out[7]:
ValueError: unable to coerce current fill_value nan to int64 dtype
```

Other sparse fixes

- Subclassed `SparseDataFrame` and `SparseSeries` now preserve class types when slicing or transposing. (GH13787)
- `SparseArray` with `bool` `dtype` now supports logical (`bool`) operators (GH14000)
- Bug in `SparseSeries` with `MultiIndex []` indexing may raise `IndexError` (GH13144)
- Bug in `SparseSeries` with `MultiIndex []` indexing result may have normal `Index` (GH13144)
- Bug in `SparseDataFrame` in which `axis=None` did not default to `axis=0` (GH13048)
- Bug in `SparseSeries` and `SparseDataFrame` creation with object `dtype` may raise `TypeError` (GH11633)
- Bug in `SparseDataFrame` doesn't respect passed `SparseArray` or `SparseSeries` 's `dtype` and `fill_value` (GH13866)
- Bug in `SparseArray` and `SparseSeries` don't apply `ufunc` to `fill_value` (GH13853)
- Bug in `SparseSeries.abs` incorrectly keeps negative `fill_value` (GH13853)
- Bug in single row slicing on multi-type `SparseDataFrame` `s`, types were previously forced to `float` (GH13917)

- Bug in `SparseSeries` slicing changes integer dtype to float (GH8292)
- Bug in `SparseDataFrame` comparison ops may raise `TypeError` (GH13001)
- Bug in `SparseDataFrame.isnull` raises `ValueError` (GH8276)
- Bug in `SparseSeries` representation with bool dtype may raise `IndexError` (GH13110)
- Bug in `SparseSeries` and `SparseDataFrame` of bool or int64 dtype may display its values like float64 dtype (GH13110)
- Bug in sparse indexing using `SparseArray` with bool dtype may return incorrect result (GH13985)
- Bug in `SparseArray` created from `SparseSeries` may lose dtype (GH13999)
- Bug in `SparseSeries` comparison with dense returns normal `Series` rather than `SparseSeries` (GH13999)

Indexer dtype changes

Note: This change only affects 64 bit python running on Windows, and only affects relatively advanced indexing operations

Methods such as `Index.get_indexer` that return an indexer array, coerce that array to a “platform int”, so that it can be directly used in 3rd party library operations like `numpy.take`. Previously, a platform int was defined as `np.int_` which corresponds to a C integer, but the correct type, and what is being used now, is `np.intp`, which corresponds to the C integer size that can hold a pointer (GH3033, GH13972).

These types are the same on many platform, but for 64 bit python on Windows, `np.int_` is 32 bits, and `np.intp` is 64 bits. Changing this behavior improves performance for many operations on that platform.

Previous behavior:

```
In [1]: i = pd.Index(['a', 'b', 'c'])
In [2]: i.get_indexer(['b', 'b', 'c']).dtype
Out[2]: dtype('int32')
```

New behavior:

```
In [1]: i = pd.Index(['a', 'b', 'c'])
In [2]: i.get_indexer(['b', 'b', 'c']).dtype
Out[2]: dtype('int64')
```

Other API changes

- `Timestamp.to_pydatetime` will issue a `UserWarning` when `warn=True`, and the instance has a non-zero number of nanoseconds, previously this would print a message to stdout (GH14101).
- `Series.unique()` with datetime and timezone now returns return array of `Timestamp` with timezone (GH13565).
- `Panel.to_sparse()` will raise a `NotImplementedError` exception when called (GH13778).
- `Index.reshape()` will raise a `NotImplementedError` exception when called (GH12882).

- `.filter()` enforces mutual exclusion of the keyword arguments ([GH12399](#)).
- `eval`'s upcasting rules for `float32` types have been updated to be more consistent with NumPy's rules. New behavior will not upcast to `float64` if you multiply a pandas `float32` object by a scalar `float64` ([GH12388](#)).
- An `UnsupportedFunctionCall` error is now raised if NumPy ufuncs like `np.mean` are called on groupby or resample objects ([GH12811](#)).
- `__setitem__` will no longer apply a callable rhs as a function instead of storing it. Call `where` directly to get the previous behavior ([GH13299](#)).
- Calls to `.sample()` will respect the random seed set via `numpy.random.seed(n)` ([GH13161](#)).
- `Styler.apply` is now more strict about the outputs your function must return. For `axis=0` or `axis=1`, the output shape must be identical. For `axis=None`, the output must be a `DataFrame` with identical columns and index labels ([GH13222](#)).
- `Float64Index.astype(int)` will now raise `ValueError` if `Float64Index` contains `NaN` values ([GH13149](#)).
- `TimedeltaIndex.astype(int)` and `DatetimeIndex.astype(int)` will now return `Int64Index` instead of `np.array` ([GH13209](#)).
- Passing `Period` with multiple frequencies to normal `Index` now returns `Index` with `object` dtype ([GH13664](#)).
- `PeriodIndex.fillna` with `Period` has different `freq` now coerces to `object` dtype ([GH13664](#)).
- Faceted boxplots from `DataFrame.boxplot(by=col)` now return a `Series` when `return_type` is not `None`. Previously these returned an `OrderedDict`. Note that when `return_type=None`, the default, these still return a 2-D NumPy array ([GH12216](#), [GH7096](#)).
- `pd.read_hdf` will now raise a `ValueError` instead of `KeyError`, if a mode other than `r`, `r+` and `a` is supplied. ([GH13623](#))
- `pd.read_csv()`, `pd.read_table()`, and `pd.read_hdf()` raise the builtin `FileNotFoundError` exception for Python 3.x when called on a nonexistent file; this is back-ported as `IOError` in Python 2.x ([GH14086](#))
- More informative exceptions are passed through the csv parser. The exception type would now be the original exception type instead of `CParserError` ([GH13652](#)).
- `pd.read_csv()` in the C engine will now issue a `ParserWarning` or raise a `ValueError` when `sep` encoded is more than one character long ([GH14065](#))
- `DataFrame.values` will now return `float64` with a `DataFrame` of mixed `int64` and `uint64` dtypes, conforming to `np.find_common_type` ([GH10364](#), [GH13917](#))
- `.groupby.groups` will now return a dictionary of `Index` objects, rather than a dictionary of `np.ndarray` or `lists` ([GH14293](#))

Deprecations

- `Series.reshape` and `Categorical.reshape` have been deprecated and will be removed in a subsequent release ([GH12882](#), [GH12882](#))
- `PeriodIndex.to_datetime` has been deprecated in favor of `PeriodIndex.to_timestamp` ([GH8254](#))
- `Timestamp.to_datetime` has been deprecated in favor of `Timestamp.to_pydatetime` ([GH8254](#))
- `Index.to_datetime` and `DatetimeIndex.to_datetime` have been deprecated in favor of `pd.to_datetime` ([GH8254](#))

- `pandas.core.datetools` module has been deprecated and will be removed in a subsequent release (GH14094)
- `SparseList` has been deprecated and will be removed in a future version (GH13784)
- `DataFrame.to_html()` and `DataFrame.to_latex()` have dropped the `colSpace` parameter in favor of `col_space` (GH13857)
- `DataFrame.to_sql()` has deprecated the `flavor` parameter, as it is superfluous when SQLAlchemy is not installed (GH13611)
- Deprecated `read_csv` keywords:
 - `compact_ints` and `use_unsigned` have been deprecated and will be removed in a future version (GH13320)
 - `buffer_lines` has been deprecated and will be removed in a future version (GH13360)
 - `as_rearray` has been deprecated and will be removed in a future version (GH13373)
 - `skip_footer` has been deprecated in favor of `skipfooter` and will be removed in a future version (GH13349)
- top-level `pd.ordered_merge()` has been renamed to `pd.merge_ordered()` and the original name will be removed in a future version (GH13358)
- `Timestamp.offset` property (and named arg in the constructor), has been deprecated in favor of `freq` (GH12160)
- `pd.tseries.util.pivot_annual` is deprecated. Use `pivot_table` as alternative, an example is *here* (GH736)
- `pd.tseries.util.isleapyear` has been deprecated and will be removed in a subsequent release. Datetime-likes now have a `.is_leap_year` property (GH13727)
- `Panel4D` and `PanelND` constructors are deprecated and will be removed in a future version. The recommended way to represent these types of n-dimensional data are with the `xarray` package. Pandas provides a `to_xarray()` method to automate this conversion (GH13564).
- `pandas.tseries.frequencies.get_standard_freq` is deprecated. Use `pandas.tseries.frequencies.to_offset(freq).rule_code` instead (GH13874)
- `pandas.tseries.frequencies.to_offset`'s `freqstr` keyword is deprecated in favor of `freq` (GH13874)
- `Categorical.from_array` has been deprecated and will be removed in a future version (GH13854)

Removal of prior version deprecations/changes

- The `SparsePanel` class has been removed (GH13778)
- The `pd.sandbox` module has been removed in favor of the external library `pandas-qt` (GH13670)
- The `pandas.io.data` and `pandas.io.wb` modules are removed in favor of the `pandas-datereader` package (GH13724).
- The `pandas.tools.rplot` module has been removed in favor of the `seaborn` package (GH13855)
- `DataFrame.to_csv()` has dropped the `engine` parameter, as was deprecated in 0.17.1 (GH11274, GH13419)
- `DataFrame.to_dict()` has dropped the `outtype` parameter in favor of `orient` (GH13627, GH8486)

- `pd.Categorical` has dropped setting of the `ordered` attribute directly in favor of the `set_ordered` method ([GH13671](#))
- `pd.Categorical` has dropped the `levels` attribute in favor of `categories` ([GH8376](#))
- `DataFrame.to_sql()` has dropped the `mysql` option for the `flavor` parameter ([GH13611](#))
- `Panel.shift()` has dropped the `lags` parameter in favor of `periods` ([GH14041](#))
- `pd.Index` has dropped the `diff` method in favor of `difference` ([GH13669](#))
- `pd.DataFrame` has dropped the `to_wide` method in favor of `to_panel` ([GH14039](#))
- `Series.to_csv` has dropped the `nanRep` parameter in favor of `na_rep` ([GH13804](#))
- `Series.xs`, `DataFrame.xs`, `Panel.xs`, `Panel.major_xs`, and `Panel.minor_xs` have dropped the `copy` parameter ([GH13781](#))
- `str.split` has dropped the `return_type` parameter in favor of `expand` ([GH13701](#))
- Removal of the legacy time rules (offset aliases), deprecated since 0.17.0 (this has been alias since 0.8.0) ([GH13590](#), [GH13868](#)). Now legacy time rules raises `ValueError`. For the list of currently supported offsets, see [here](#).
- The default value for the `return_type` parameter for `DataFrame.plot.box` and `DataFrame.boxplot` changed from `None` to `"axes"`. These methods will now return a matplotlib axes by default instead of a dictionary of artists. See [here](#) ([GH6581](#)).
- The `tquery` and `uquery` functions in the `pandas.io.sql` module are removed ([GH5950](#)).

Performance improvements

- Improved performance of sparse `IntIndex.intersect` ([GH13082](#))
- Improved performance of sparse arithmetic with `BlockIndex` when the number of blocks are large, though recommended to use `IntIndex` in such cases ([GH13082](#))
- Improved performance of `DataFrame.quantile()` as it now operates per-block ([GH11623](#))
- Improved performance of float64 hash table operations, fixing some very slow indexing and groupby operations in python 3 ([GH13166](#), [GH13334](#))
- Improved performance of `DataFrameGroupBy.transform` ([GH12737](#))
- Improved performance of `Index` and `Series.duplicated` ([GH10235](#))
- Improved performance of `Index.difference` ([GH12044](#))
- Improved performance of `RangeIndex.is_monotonic_increasing` and `is_monotonic_decreasing` ([GH13749](#))
- Improved performance of datetime string parsing in `DatetimeIndex` ([GH13692](#))
- Improved performance of hashing `Period` ([GH12817](#))
- Improved performance of `factorize` of datetime with timezone ([GH13750](#))
- Improved performance of by lazily creating indexing hashtables on larger `Indexes` ([GH14266](#))
- Improved performance of `groupby.groups` ([GH14293](#))
- Unnecessary materializing of a `MultiIndex` when introspecting for memory usage ([GH14308](#))

Bug fixes

- Bug in `groupby().shift()`, which could cause a segfault or corruption in rare circumstances when grouping by columns with missing values ([GH13813](#))
- Bug in `groupby().cumsum()` calculating `cumprod` when `axis=1`. ([GH13994](#))
- Bug in `pd.to_timedelta()` in which the `errors` parameter was not being respected ([GH13613](#))
- Bug in `io.json.json_normalize()`, where non-ascii keys raised an exception ([GH13213](#))
- Bug when passing a not-default-indexed `Series` as `xerr` or `yerr` in `.plot()` ([GH11858](#))
- Bug in area plot draws legend incorrectly if subplot is enabled or legend is moved after plot (matplotlib 1.5.0 is required to draw area plot legend properly) ([GH9161](#), [GH13544](#))
- Bug in `DataFrame` assignment with an object-dtyped `Index` where the resultant column is mutable to the original object. ([GH13522](#))
- Bug in matplotlib `AutoDataFormatter`; this restores the second scaled formatting and re-adds micro-second scaled formatting ([GH13131](#))
- Bug in selection from a `HDFStore` with a fixed format and `start` and/or `stop` specified will now return the selected range ([GH8287](#))
- Bug in `Categorical.from_codes()` where an unhelpful error was raised when an invalid `ordered` parameter was passed in ([GH14058](#))
- Bug in `Series` construction from a tuple of integers on windows not returning default dtype (`int64`) ([GH13646](#))
- Bug in `TimedeltaIndex` addition with a `Datetime`-like object where addition overflow was not being caught ([GH14068](#))
- Bug in `.groupby(...).resample(...)` when the same object is called multiple times ([GH13174](#))
- Bug in `.to_records()` when index name is a unicode string ([GH13172](#))
- Bug in calling `.memory_usage()` on object which doesn't implement ([GH12924](#))
- Regression in `Series.quantile` with nans (also shows up in `.median()` and `.describe()`); furthermore now names the `Series` with the quantile ([GH13098](#), [GH13146](#))
- Bug in `SeriesGroupBy.transform` with datetime values and missing groups ([GH13191](#))
- Bug where empty `Series` were incorrectly coerced in datetime-like numeric operations ([GH13844](#))
- Bug in `Categorical` constructor when passed a `Categorical` containing datetimes with timezones ([GH14190](#))
- Bug in `Series.str.extractall()` with `str` index raises `ValueError` ([GH13156](#))
- Bug in `Series.str.extractall()` with single group and quantifier ([GH13382](#))
- Bug in `DatetimeIndex` and `Period` subtraction raises `ValueError` or `AttributeError` rather than `TypeError` ([GH13078](#))
- Bug in `Index` and `Series` created with `NaN` and `NaT` mixed data may not have `datetime64` dtype ([GH13324](#))
- Bug in `Index` and `Series` may ignore `np.datetime64('nat')` and `np.timedelta64('nat')` to infer dtype ([GH13324](#))
- Bug in `PeriodIndex` and `Period` subtraction raises `AttributeError` ([GH13071](#))
- Bug in `PeriodIndex` construction returning a `float64` index in some circumstances ([GH13067](#))

- Bug in `.resample(..)` with a `PeriodIndex` not changing its `freq` appropriately when empty ([GH13067](#))
- Bug in `.resample(..)` with a `PeriodIndex` not retaining its type or name with an empty `DataFrame` appropriately when empty ([GH13212](#))
- Bug in `groupby(..).apply(..)` when the passed function returns scalar values per group ([GH13468](#)).
- Bug in `groupby(..).resample(..)` where passing some keywords would raise an exception ([GH13235](#))
- Bug in `.tz_convert` on a `tz-aware DateTimeIndex` that relied on index being sorted for correct results ([GH13306](#))
- Bug in `.tz_localize` with `dateutil.tz.tzlocal` may return incorrect result ([GH13583](#))
- Bug in `DatetimeTZDtype` dtype with `dateutil.tz.tzlocal` cannot be regarded as valid dtype ([GH13583](#))
- Bug in `pd.read_hdf()` where attempting to load an HDF file with a single dataset, that had one or more categorical columns, failed unless the `key` argument was set to the name of the dataset. ([GH13231](#))
- Bug in `.rolling()` that allowed a negative integer window in construction of the `Rolling()` object, but would later fail on aggregation ([GH13383](#))
- Bug in `Series` indexing with tuple-valued data and a numeric index ([GH13509](#))
- Bug in printing `pd.DataFrame` where unusual elements with the `object` dtype were causing segfaults ([GH13717](#))
- Bug in ranking `Series` which could result in segfaults ([GH13445](#))
- Bug in various index types, which did not propagate the name of passed index ([GH12309](#))
- Bug in `DatetimeIndex`, which did not honour the `copy=True` ([GH13205](#))
- Bug in `DatetimeIndex.is_normalized` returns incorrectly for normalized `date_range` in case of local timezones ([GH13459](#))
- Bug in `pd.concat` and `.append` may coerces `datetime64` and `timedelta` to `object` dtype containing python built-in `datetime` or `timedelta` rather than `Timestamp` or `Timedelta` ([GH13626](#))
- Bug in `PeriodIndex.append` may raises `AttributeError` when the result is `object` dtype ([GH13221](#))
- Bug in `CategoricalIndex.append` may accept normal list ([GH13626](#))
- Bug in `pd.concat` and `.append` with the same timezone get reset to UTC ([GH7795](#))
- Bug in `Series` and `DataFrame.append` raises `AmbiguousTimeError` if data contains `datetime` near DST boundary ([GH13626](#))
- Bug in `DataFrame.to_csv()` in which float values were being quoted even though quotations were specified for non-numeric values only ([GH12922](#), [GH13259](#))
- Bug in `DataFrame.describe()` raising `ValueError` with only boolean columns ([GH13898](#))
- Bug in `MultiIndex` slicing where extra elements were returned when level is non-unique ([GH12896](#))
- Bug in `.str.replace` does not raise `TypeError` for invalid replacement ([GH13438](#))
- Bug in `MultiIndex.from_arrays` which didn't check for input array lengths matching ([GH13599](#))
- Bug in `cartesian_product` and `MultiIndex.from_product` which may raise with empty input arrays ([GH12258](#))
- Bug in `pd.read_csv()` which may cause a segfault or corruption when iterating in large chunks over a stream/file under rare circumstances ([GH13703](#))

- Bug in `pd.read_csv()` which caused errors to be raised when a dictionary containing scalars is passed in for `na_values` (GH12224)
- Bug in `pd.read_csv()` which caused BOM files to be incorrectly parsed by not ignoring the BOM (GH4793)
- Bug in `pd.read_csv()` with `engine='python'` which raised errors when a numpy array was passed in for `usecols` (GH12546)
- Bug in `pd.read_csv()` where the index columns were being incorrectly parsed when parsed as dates with a `thousands` parameter (GH14066)
- Bug in `pd.read_csv()` with `engine='python'` in which NaN values weren't being detected after data was converted to numeric values (GH13314)
- Bug in `pd.read_csv()` in which the `nrows` argument was not properly validated for both engines (GH10476)
- Bug in `pd.read_csv()` with `engine='python'` in which infinities of mixed-case forms were not being interpreted properly (GH13274)
- Bug in `pd.read_csv()` with `engine='python'` in which trailing NaN values were not being parsed (GH13320)
- Bug in `pd.read_csv()` with `engine='python'` when reading from a `tempfile.TemporaryFile` on Windows with Python 3 (GH13398)
- Bug in `pd.read_csv()` that prevents `usecols` kwarg from accepting single-byte unicode strings (GH13219)
- Bug in `pd.read_csv()` that prevents `usecols` from being an empty set (GH13402)
- Bug in `pd.read_csv()` in the C engine where the NULL character was not being parsed as NULL (GH14012)
- Bug in `pd.read_csv()` with `engine='c'` in which NULL quotechar was not accepted even though `quoting` was specified as `None` (GH13411)
- Bug in `pd.read_csv()` with `engine='c'` in which fields were not properly cast to float when quoting was specified as non-numeric (GH13411)
- Bug in `pd.read_csv()` in Python 2.x with non-UTF8 encoded, multi-character separated data (GH3404)
- Bug in `pd.read_csv()`, where aliases for utf-xx (e.g. UTF-xx, UTF_xx, utf_xx) raised `UnicodeDecodeError` (GH13549)
- Bug in `pd.read_csv`, `pd.read_table`, `pd.read_fwf`, `pd.read_stata` and `pd.read_sas` where files were opened by parsers but not closed if both `chunksize` and `iterator` were `None`. (GH13940)
- Bug in `StataReader`, `StataWriter`, `XportReader` and `SAS7BDATReader` where a file was not properly closed when an error was raised. (GH13940)
- Bug in `pd.pivot_table()` where `margins_name` is ignored when `aggfunc` is a list (GH13354)
- Bug in `pd.Series.str.zfill`, `center`, `ljust`, `rjust`, and `pad` when passing non-integers, did not raise `TypeError` (GH13598)
- Bug in checking for any null objects in a `TimedeltaIndex`, which always returned `True` (GH13603)
- Bug in `Series` arithmetic raises `TypeError` if it contains datetime-like as `object` dtype (GH13043)
- Bug `Series.isnull()` and `Series.notnull()` ignore `Period('NaT')` (GH13737)
- Bug `Series.fillna()` and `Series.dropna()` don't affect to `Period('NaT')` (GH13737)

- Bug in `.fillna(value=np.nan)` incorrectly raises `KeyError` on a `category` dtyped `Series` (GH14021)
- Bug in extension dtype creation where the created types were not is/identical (GH13285)
- Bug in `.resample(...)` where incorrect warnings were triggered by IPython introspection (GH13618)
- Bug in `NaT - Period` raises `AttributeError` (GH13071)
- Bug in `Series` comparison may output incorrect result if rhs contains `NaT` (GH9005)
- Bug in `Series` and `Index` comparison may output incorrect result if it contains `NaT` with `object` dtype (GH13592)
- Bug in `Period` addition raises `TypeError` if `Period` is on right hand side (GH13069)
- Bug in `Period` and `Series` or `Index` comparison raises `TypeError` (GH13200)
- Bug in `pd.set_eng_float_format()` that would prevent `NaN` and `Inf` from formatting (GH11981)
- Bug in `.unstack` with `Categorical` dtype resets `.ordered` to `True` (GH13249)
- Clean some compile time warnings in datetime parsing (GH13607)
- Bug in `factorize` raises `AmbiguousTimeError` if data contains datetime near DST boundary (GH13750)
- Bug in `.set_index` raises `AmbiguousTimeError` if new index contains DST boundary and multi levels (GH12920)
- Bug in `.shift` raises `AmbiguousTimeError` if data contains datetime near DST boundary (GH13926)
- Bug in `pd.read_hdf()` returns incorrect result when a `DataFrame` with a `category` column and a query which doesn't match any values (GH13792)
- Bug in `.iloc` when indexing with a non lexsorted `MultiIndex` (GH13797)
- Bug in `.loc` when indexing with date strings in a reverse sorted `DatetimeIndex` (GH14316)
- Bug in `Series` comparison operators when dealing with zero dim NumPy arrays (GH13006)
- Bug in `.combine_first` may return incorrect dtype (GH7630, GH10567)
- Bug in `groupby` where `apply` returns different result depending on whether first result is `None` or not (GH12824)
- Bug in `groupby(...).nth()` where the group key is included inconsistently if called after `.head()/tail()` (GH12839)
- Bug in `.to_html`, `.to_latex` and `.to_string` silently ignore custom datetime formatter passed through the `formatters` key word (GH10690)
- Bug in `DataFrame.iterrows()`, not yielding a `Series` subclasse if defined (GH13977)
- Bug in `pd.to_numeric` when `errors='coerce'` and input contains non-hashable objects (GH13324)
- Bug in invalid `Timedelta` arithmetic and comparison may raise `ValueError` rather than `TypeError` (GH13624)
- Bug in invalid datetime parsing in `to_datetime` and `DatetimeIndex` may raise `TypeError` rather than `ValueError` (GH11169, GH11287)
- Bug in `Index` created with tz-aware `Timestamp` and mismatched `tz` option incorrectly coerces timezone (GH13692)
- Bug in `DatetimeIndex` with nanosecond frequency does not include timestamp specified with `end` (GH13672)
- Bug in `Series` when setting a slice with a `np.timedelta64` (GH14155)

- Bug in `Index` raises `OutOfBoundsDatetime` if `datetime` exceeds `datetime64[ns]` bounds, rather than coercing to object dtype ([GH13663](#))
- Bug in `Index` may ignore specified `datetime64` or `timedelta64` passed as `dtype` ([GH13981](#))
- Bug in `RangeIndex` can be created without no arguments rather than raises `TypeError` ([GH13793](#))
- Bug in `.value_counts()` raises `OutOfBoundsDatetime` if data exceeds `datetime64[ns]` bounds ([GH13663](#))
- Bug in `DatetimeIndex` may raise `OutOfBoundsDatetime` if input `np.datetime64` has other unit than `ns` ([GH9114](#))
- Bug in `Series` creation with `np.datetime64` which has other unit than `ns` as object dtype results in incorrect values ([GH13876](#))
- Bug in `resample` with `timedelta` data where data was casted to float ([GH13119](#)).
- Bug in `pd.isnull()` `pd.notnull()` raise `TypeError` if input `datetime`-like has other unit than `ns` ([GH13389](#))
- Bug in `pd.merge()` may raise `TypeError` if input `datetime`-like has other unit than `ns` ([GH13389](#))
- Bug in `HDFStore/read_hdf()` discarded `DatetimeIndex.name` if `tz` was set ([GH13884](#))
- Bug in `Categorical.remove_unused_categories()` changes `.codes` dtype to platform int ([GH13261](#))
- Bug in `groupby` with `as_index=False` returns all NaN's when grouping on multiple columns including a categorical one ([GH13204](#))
- Bug in `df.groupby(...)[...]` where getitem with `Int64Index` raised an error ([GH13731](#))
- Bug in the CSS classes assigned to `DataFrame.style` for index names. Previously they were assigned `"col_heading level<n> col<c>"` where `n` was the number of levels + 1. Now they are assigned `"index_name level<n>"`, where `n` is the correct level for that `MultiIndex`.
- Bug where `pd.read_gbq()` could throw `ImportError: No module named discovery` as a result of a naming conflict with another python package called `apiclient` ([GH13454](#))
- Bug in `Index.union` returns an incorrect result with a named empty index ([GH13432](#))
- Bugs in `Index.difference` and `DataFrame.join` raise in Python3 when using mixed-integer indexes ([GH13432](#), [GH12814](#))
- Bug in subtract `tz-aware datetime.datetime` from `tz-aware datetime64` series ([GH14088](#))
- Bug in `.to_excel()` when `DataFrame` contains a `MultiIndex` which contains a label with a NaN value ([GH13511](#))
- Bug in invalid frequency offset string like "D1", "-2-3H" may not raise `ValueError` ([GH13930](#))
- Bug in `concat` and `groupby` for hierarchical frames with `RangeIndex` levels ([GH13542](#)).
- Bug in `Series.str.contains()` for `Series` containing only NaN values of object dtype ([GH14171](#))
- Bug in `agg()` function on `groupby` dataframe changes dtype of `datetime64[ns]` column to `float64` ([GH12821](#))
- Bug in using NumPy `ufunc` with `PeriodIndex` to add or subtract integer raise `IncompatibleFrequency`. Note that using standard operator like `+` or `-` is recommended, because standard operators use more efficient path ([GH13980](#))
- Bug in operations on `NaT` returning `float` instead of `datetime64[ns]` ([GH12941](#))
- Bug in `Series` flexible arithmetic methods (like `.add()`) raises `ValueError` when `axis=None` ([GH13894](#))

- Bug in `DataFrame.to_csv()` with `MultiIndex` columns in which a stray empty line was added ([GH6618](#))
- Bug in `DatetimeIndex`, `TimedeltaIndex` and `PeriodIndex.equals()` may return `True` when input isn't `Index` but contains the same values ([GH13107](#))
- Bug in assignment against datetime with timezone may not work if it contains datetime near DST boundary ([GH14146](#))
- Bug in `pd.eval()` and `HDFStore` query truncating long float literals with python 2 ([GH14241](#))
- Bug in `Index` raises `KeyError` displaying incorrect column when column is not in the df and columns contains duplicate values ([GH13822](#))
- Bug in `Period` and `PeriodIndex` creating wrong dates when frequency has combined offset aliases ([GH13874](#))
- Bug in `.to_string()` when called with an integer `line_width` and `index=False` raises an `UnboundLocalError` exception because `idx` referenced before assignment.
- Bug in `eval()` where the `resolvers` argument would not accept a list ([GH14095](#))
- Bugs in `stack`, `get_dummies`, `make_axis_dummies` which don't preserve categorical dtypes in (multi)indexes ([GH13854](#))
- `PeriodIndex` can now accept `list` and `array` which contains `pd.NaT` ([GH13430](#))
- Bug in `df.groupby` where `.median()` returns arbitrary values if grouped dataframe contains empty bins ([GH13629](#))
- Bug in `Index.copy()` where `name` parameter was ignored ([GH14302](#))

8.8 Version 0.18

8.8.1 v0.18.1 (May 3, 2016)

{{ header }}

This is a minor bug-fix release from 0.18.0 and includes a large number of bug fixes along with several new features, enhancements, and performance improvements. We recommend that all users upgrade to this version.

Highlights include:

- `.groupby(...)` has been enhanced to provide convenient syntax when working with `.rolling(...)`, `.expanding(...)` and `.resample(...)` per group, see [here](#)
- `pd.to_datetime()` has gained the ability to assemble dates from a `DataFrame`, see [here](#)
- Method chaining improvements, see [here](#).
- Custom business hour offset, see [here](#).
- Many bug fixes in the handling of `sparse`, see [here](#)
- Expanded the [Tutorials section](#) with a feature on modern pandas, courtesy of [@TomAugsburger](#). (GH13045).

What's new in v0.18.1

- *New features*
 - *Custom business hour*
 - *.groupby(..) syntax with window and resample operations*
 - *Method chaining improvements*
 - * *.where() and .mask()*
 - * *.loc[], .iloc[], .ix[]*
 - * *[] indexing*
 - *Partial string indexing on DateTimeIndex when part of a MultiIndex*
 - *Assembling datetimes*
 - *Other enhancements*
- *Sparse changes*
- *API changes*
 - *.groupby(..).nth() changes*
 - *numpy function compatibility*
 - *Using .apply on groupby resampling*
 - *Changes in read_csv exceptions*
 - *to_datetime error changes*
 - *Other API changes*
 - *Deprecations*
- *Performance improvements*
- *Bug fixes*
- *Contributors*

New features

Custom business hour

The `CustomBusinessHour` is a mixture of `BusinessHour` and `CustomBusinessDay` which allows you to specify arbitrary holidays. For details, see *Custom Business Hour* (GH11514)

```
In [1]: from pandas.tseries.offsets import CustomBusinessHour
In [2]: from pandas.tseries.holiday import USFederalHolidayCalendar
In [3]: bhour_us = CustomBusinessHour(calendar=USFederalHolidayCalendar())
```

Friday before MLK Day

```
In [4]: import datetime
In [5]: dt = datetime.datetime(2014, 1, 17, 15)
In [6]: dt + bhour_us
Out[6]: Timestamp('2014-01-17 16:00:00')
```

Tuesday after MLK Day (Monday is skipped because it's a holiday)

```
In [7]: dt + bhour_us * 2
Out[7]: Timestamp('2014-01-20 09:00:00')
```

`.groupby(..)` syntax with window and resample operations

`.groupby(...)` has been enhanced to provide convenient syntax when working with `.rolling(..)`, `.expanding(..)` and `.resample(..)` per group, see (GH12486, GH12738).

You can now use `.rolling(..)` and `.expanding(..)` as methods on groupbys. These return another deferred object (similar to what `.rolling()` and `.expanding()` do on ungrouped pandas objects). You can then operate on these `RollingGroupby` objects in a similar manner.

Previously you would have to do this to get a rolling window mean per-group:

```
In [8]: df = pd.DataFrame({'A': [1] * 20 + [2] * 12 + [3] * 8,
...:                      'B': np.arange(40)})
...:
...:
In [9]: df
Out[9]:
   A  B
0  1  0
1  1  1
2  1  2
3  1  3
4  1  4
5  1  5
6  1  6
7  1  7
```

(continues on next page)

   39    37.5
Name: B, Length: 40, dtype: float64

```

For `.resample(..)` type of operations, previously you would have to:

```

In [12]: df = pd.DataFrame({'date': pd.date_range(start='2016-01-01',
.....:                                     periods=4,
.....:                                     freq='W'),
.....:                    'group': [1, 1, 2, 2],
.....:                    'val': [5, 6, 7, 8]}).set_index('date')
.....:

```

```
In [13]: df
```

```
Out[13]:
```

	group	val
date		
2016-01-03	1	5
2016-01-10	1	6
2016-01-17	2	7
2016-01-24	2	8

```
[4 rows x 2 columns]
```

```
In [14]: df.groupby('group').apply(lambda x: x.resample('1D').ffill())
```

```
Out[14]:
```

	group	val
group date		
1 2016-01-03	1	5
2016-01-04	1	5
2016-01-05	1	5
2016-01-06	1	5

(continues on next page)

(continued from previous page)

```

2016-01-07      1    5
2016-01-08      1    5
2016-01-09      1    5
2016-01-10      1    6
2    2016-01-17      2    7
2016-01-18      2    7
2016-01-19      2    7

      2016-01-23      2    7
      2016-01-24      2    8

[16 rows x 2 columns]
```

Method chaining improvements

The following methods / indexers now accept a `callable`. It is intended to make these more useful in method chains, see the [documentation](#). (GH11485, GH12533)

- `.where()` and `.mask()`
- `.loc[]`, `.iloc[]` and `.ix[]`
- `[]` indexing

`.where()` and `.mask()`

These can accept a callable for the condition and other arguments.

```
In [16]: df = pd.DataFrame({'A': [1, 2, 3],
.....:                    'B': [4, 5, 6],
.....:                    'C': [7, 8, 9]})
.....:

In [17]: df.where(lambda x: x > 4, lambda x: x + 10)
Out[17]:
   A  B  C
0  11 14  7
1  12  5  8
2  13  6  9

[3 rows x 3 columns]
```

`.loc[]`, `.iloc[]`, `.ix[]`

These can accept a callable, and a tuple of callable as a slicer. The callable can return a valid boolean indexer or anything which is valid for these indexer's input.

callable returns bool indexer

```
In [18]: df.loc[lambda x: x.A >= 2, lambda x: x.sum() > 10]
```

```
Out[18]:
```

```
   B  C
1  5  8
2  6  9
```

```
[2 rows x 2 columns]
```

callable returns list of labels

```
In [19]: df.loc[lambda x: [1, 2], lambda x: ['A', 'B']]
```

```
Out[19]:
```

```
   A  B
1  2  5
2  3  6
```

```
[2 rows x 2 columns]
```

`[]` indexing

Finally, you can use a callable in `[]` indexing of Series, DataFrame and Panel. The callable must return a valid input for `[]` indexing depending on its class and index type.

```
In [20]: df[lambda x: 'A']
Out[20]:
0    1
1    2
2    3
Name: A, Length: 3, dtype: int64
```

Using these methods / indexers, you can chain data selection operations without using temporary variable.

```
In [21]: bb = pd.read_csv('data/baseball.csv', index_col='id')

In [22]: (bb.groupby(['year', 'team'])
.....:         .sum()
.....:         .loc[lambda df: df.r > 100])
.....:
Out[22]:
```

Partial string indexing on DateTimeIndex when part of a MultiIndex

Partial string indexing now matches on DateTimeIndex when part of a MultiIndex (GH10331)

```
In [23]: dft2 = pd.DataFrame(
.....:     np.random.randn(20, 1),
.....:     columns=['A'],
.....:     index=pd.MultiIndex.from_product([pd.date_range('20130101',
.....:                                                     periods=10,
.....:                                                     freq='12H'),
.....:                                     ['a', 'b']]))
.....:
```

```
In [24]: dft2
```

```

[4 rows x 1 columns]
```

Assembling datetimes

`pd.to_datetime()` has gained the ability to assemble datetimes from a passed in `DataFrame` or a dict. (GH8158).

```
In [30]: df = pd.DataFrame({'year': [2015, 2016],
.....:                    'month': [2, 3],
.....:                    'day': [4, 5],
.....:                    'hour': [2, 3]})
.....:
```

```
In [31]: df
```

```
Out[31]:
```

```

   year  month  day  hour
0  2015     2    4     2
1  2016     3    5     3
```

```
[2 rows x 4 columns]
```

Assembling using the passed frame.

```
In [32]: pd.to_datetime(df)
```

```
Out[32]:
```

```
0    2015-02-04 02:00:00
1    2016-03-05 03:00:00
```

```
Length: 2, dtype: datetime64[ns]
```

You can pass only the columns that you need to assemble.

```
In [33]: pd.to_datetime(df[['year', 'month', 'day']])
```

```
Out[33]:
```

```
0    2015-02-04
1    2016-03-05
```

```
Length: 2, dtype: datetime64[ns]
```

Other enhancements

- `pd.read_csv()` now supports `delim_whitespace=True` for the Python engine (GH12958)
- `pd.read_csv()` now supports opening ZIP files that contains a single CSV, via extension inference or explicit `compression='zip'` (GH12175)
- `pd.read_csv()` now supports opening files using xz compression, via extension inference or explicit `compression='xz'` is specified; xz compressions is also supported by `DataFrame.to_csv` in the same way (GH11852)
- `pd.read_msgpack()` now always gives writeable ndarrays even when compression is used (GH12359).
- `pd.read_msgpack()` now supports serializing and de-serializing categoricals with msgpack (GH12573)
- `.to_json()` now supports NDFrames that contain categorical and sparse data (GH10778)
- `interpolate()` now supports `method='akima'` (GH7588).
- `pd.read_excel()` now accepts path objects (e.g. `pathlib.Path`, `py.path.local`) for the file path, in line with other `read_*` functions (GH12655)
- Added `.weekday_name` property as a component to `DatetimeIndex` and the `.dt` accessor. (GH11128)
- `Index.take` now handles `allow_fill` and `fill_value` consistently (GH12631)

```
In [34]: idx = pd.Index([1., 2., 3., 4.], dtype='float')
```

```
# default, allow_fill=True, fill_value=None
```

```
In [35]: idx.take([2, -1])
```

```
Out[35]: Float64Index([3.0, 4.0], dtype='float64')
```

```
In [36]: idx.take([2, -1], fill_value=True)
```

```
Out[36]: Float64Index([3.0, nan], dtype='float64')
```

- `Index` now supports `.str.get_dummies()` which returns `MultiIndex`, see *Creating Indicator Variables* (GH10008, GH10103)

```
In [37]: idx = pd.Index(['a|b', 'a|c', 'b|c'])
```

```
In [38]: idx.str.get_dummies('|')
```

```
Out[38]:
```

```
MultiIndex([(1, 1, 0),
            (1, 0, 1),
            (0, 1, 1)],
           names=['a', 'b', 'c'])
```

- `pd.crosstab()` has gained a `normalize` argument for normalizing frequency tables (GH12569). Examples in the updated docs [here](#).
- `.resample(..).interpolate()` is now supported (GH12925)
- `.isin()` now accepts passed `sets` (GH12988)

Sparse changes

These changes conform sparse handling to return the correct types and work to make a smoother experience with indexing.

`SparseArray.take` now returns a scalar for scalar input, `SparseArray` for others. Furthermore, it handles a negative indexer with the same rule as `Index` (GH10560, GH12796)

```
s = pd.SparseArray([np.nan, np.nan, 1, 2, 3, np.nan, 4, 5, np.nan, 6])
s.take(0)
s.take([1, 2, 3])
```

- Bug in `SparseSeries[]` indexing with `Ellipsis` raises `KeyError` (GH9467)
- Bug in `SparseArray[]` indexing with tuples are not handled properly (GH12966)
- Bug in `SparseSeries.loc[]` with list-like input raises `TypeError` (GH10560)
- Bug in `SparseSeries.iloc[]` with scalar input may raise `IndexError` (GH10560)
- Bug in `SparseSeries.loc[], .iloc[]` with slice returns `SparseArray`, rather than `SparseSeries` (GH10560)
- Bug in `SparseDataFrame.loc[], .iloc[]` may results in dense `Series`, rather than `SparseSeries` (GH12787)
- Bug in `SparseArray` addition ignores `fill_value` of right hand side (GH12910)
- Bug in `SparseArray` mod raises `AttributeError` (GH12910)
- Bug in `SparseArray` pow calculates `1 ** np.nan` as `np.nan` which must be 1 (GH12910)
- Bug in `SparseArray` comparison output may incorrect result or raise `ValueError` (GH12971)
- Bug in `SparseSeries.__repr__` raises `TypeError` when it is longer than `max_rows` (GH10560)
- Bug in `SparseSeries.shape` ignores `fill_value` (GH10452)
- Bug in `SparseSeries` and `SparseArray` may have different `dtype` from its dense values (GH12908)
- Bug in `SparseSeries.reindex` incorrectly handle `fill_value` (GH12797)
- Bug in `SparseArray.to_frame()` results in `DataFrame`, rather than `SparseDataFrame` (GH9850)
- Bug in `SparseSeries.value_counts()` does not count `fill_value` (GH6749)
- Bug in `SparseArray.to_dense()` does not preserve `dtype` (GH10648)
- Bug in `SparseArray.to_dense()` incorrectly handle `fill_value` (GH12797)
- Bug in `pd.concat()` of `SparseSeries` results in dense (GH10536)
- Bug in `pd.concat()` of `SparseDataFrame` incorrectly handle `fill_value` (GH9765)
- Bug in `pd.concat()` of `SparseDataFrame` may raise `AttributeError` (GH12174)
- Bug in `SparseArray.shift()` may raise `NameError` or `TypeError` (GH12908)

API changes

`.groupby(...).nth()` changes

The index in `.groupby(...).nth()` output is now more consistent when the `as_index` argument is passed (GH11039):

```
In [39]: df = pd.DataFrame({'A': ['a', 'b', 'a'],
.....:                    'B': [1, 2, 3]})
.....:

In [40]: df
Out[40]:
   A  B
0  a  1
1  b  2
2  a  3

[3 rows x 2 columns]
```

Previous behavior:

```
In [3]: df.groupby('A', as_index=True)['B'].nth(0)
Out[3]:
0    1
1    2
Name: B, dtype: int64

In [4]: df.groupby('A', as_index=False)['B'].nth(0)
Out[4]:
0    1
1    2
Name: B, dtype: int64
```

New behavior:

```
In [41]: df.groupby('A', as_index=True)['B'].nth(0)
Out[41]:
A
a    1
b    2
Name: B, Length: 2, dtype: int64

In [42]: df.groupby('A', as_index=False)['B'].nth(0)
Out[42]:
0    1
1    2
Name: B, Length: 2, dtype: int64
```

Furthermore, previously, a `.groupby` would always sort, regardless if `sort=False` was passed with `.nth()`.

```
In [43]: np.random.seed(1234)

In [44]: df = pd.DataFrame(np.random.randn(100, 2), columns=['a', 'b'])

In [45]: df['c'] = np.random.randint(0, 4, 100)
```

Previous behavior:

```
In [4]: df.groupby('c', sort=True).nth(1)
Out[4]:
```

(continues on next page)

(continued from previous page)

```

      a      b
c
0 -0.334077  0.002118
1  0.036142 -2.074978
2 -0.720589  0.887163
3  0.859588 -0.636524

In [5]: df.groupby('c', sort=False).nth(1)
Out[5]:
      a      b
c
0 -0.334077  0.002118
1  0.036142 -2.074978
2 -0.720589  0.887163
3  0.859588 -0.636524

```

New behavior:

```
In [46]: df.groupby('c', sort=True).nth(1)
Out[46]:
```

```

      a      b
c
0 -0.334077  0.002118
1  0.036142 -2.074978
2 -0.720589  0.887163
3  0.859588 -0.636524

```

[4 rows x 2 columns]

```
In [47]: df.groupby('c', sort=False).nth(1)
Out[47]:
```

```

      a      b
c
2 -0.720589  0.887163
3  0.859588 -0.636524
0 -0.334077  0.002118
1  0.036142 -2.074978

```

[4 rows x 2 columns]

numpy function compatibility

Compatibility between pandas array-like methods (e.g. `sum` and `take`) and their `numpy` counterparts has been greatly increased by augmenting the signatures of the `pandas` methods so as to accept arguments that can be passed in from `numpy`, even if they are not necessarily used in the `pandas` implementation ([GH12644](#), [GH12638](#), [GH12687](#))

- `.searchsorted()` for `Index` and `TimedeltaIndex` now accept a `sorter` argument to maintain compatibility with `numpy`'s `searchsorted` function ([GH12238](#))
- Bug in `numpy` compatibility of `np.round()` on a `Series` ([GH12600](#))

An example of this signature augmentation is illustrated below:

```
In [48]: sp = pd.SparseDataFrame([1, 2, 3])
```

```
In [49]: sp
```

```
Out[49]:
```

```
0
0 1
1 2
2 3
```

```
[3 rows x 1 columns]
```

Previous behaviour:

```
In [2]: np.cumsum(sp, axis=0)
```

```
...
```

```
TypeError: cumsum() takes at most 2 arguments (4 given)
```

New behaviour:

```
In [50]: np.cumsum(sp, axis=0)
```

```
Out[50]:
```

```
0
0 1
1 3
2 6
```

```
[3 rows x 1 columns]
```

Using `.apply` on groupby resampling

Using `apply` on resampling groupby operations (using a `pd.TimeGrouper`) now has the same output types as similar `apply` calls on other groupby operations. (GH11742).

```
In [51]: df = pd.DataFrame({'date': pd.to_datetime(['10/10/2000', '11/10/2000']),
.....:                      'value': [10, 13]})
.....:
```

```
In [52]: df
```

```
Out[52]:
```

```
   date      value
0 2000-10-10      10
1 2000-11-10      13
```

```
[2 rows x 2 columns]
```

Previous behavior:

```
In [1]: df.groupby(pd.TimeGrouper(key='date',
.....:                             freq='M')).apply(lambda x: x.value.sum())
```

```
Out[1]:
```

```
...
```

```
TypeError: cannot concatenate a non-NDFrame object
```

(continues on next page)

(continued from previous page)

```
# Output is a Series
In [2]: df.groupby(pd.TimeGrouper(key='date',
...:                               freq='M')).apply(lambda x: x[['value']].sum())
Out[2]:
date
2000-10-31  value    10
2000-11-30  value    13
dtype: int64
```

New behavior:

```
# Output is a Series
In [55]: df.groupby(pd.TimeGrouper(key='date',
...:                               freq='M')).apply(lambda x: x.value.sum())
Out[55]:
date
2000-10-31    10
2000-11-30    13
Freq: M, dtype: int64

# Output is a DataFrame
In [56]: df.groupby(pd.TimeGrouper(key='date',
...:                               freq='M')).apply(lambda x: x[['value']].sum())
Out[56]:
      value
date
2000-10-31    10
2000-11-30    13
```

Changes in read_csv exceptions

In order to standardize the `read_csv` API for both the `c` and `python` engines, both will now raise an `EmptyDataError`, a subclass of `ValueError`, in response to empty columns or header ([GH12493](#), [GH12506](#))

Previous behaviour:

```
In [1]: import io

In [2]: df = pd.read_csv(io.StringIO(''), engine='c')
...
ValueError: No columns to parse from file

In [3]: df = pd.read_csv(io.StringIO(''), engine='python')
...
StopIteration
```

New behaviour:

```
In [1]: df = pd.read_csv(io.StringIO(''), engine='c')
...
```

(continues on next page)

(continued from previous page)

```
pandas.io.common.EmptyDataError: No columns to parse from file
In [2]: df = pd.read_csv(io.StringIO(''), engine='python')
...
pandas.io.common.EmptyDataError: No columns to parse from file
```

In addition to this error change, several others have been made as well:

- `CParserError` now sub-classes `ValueError` instead of just a `Exception` ([GH12551](#))
- A `CParserError` is now raised instead of a generic `Exception` in `read_csv` when the `c` engine cannot parse a column ([GH12506](#))
- A `ValueError` is now raised instead of a generic `Exception` in `read_csv` when the `c` engine encounters a `NaN` value in an integer column ([GH12506](#))
- A `ValueError` is now raised instead of a generic `Exception` in `read_csv` when `true_values` is specified, and the `c` engine encounters an element in a column containing unencodable bytes ([GH12506](#))
- `pandas.parser.OverflowError` exception has been removed and has been replaced with Python's built-in `OverflowError` exception ([GH12506](#))
- `pd.read_csv()` no longer allows a combination of strings and integers for the `usecols` parameter ([GH12678](#))

to_datetime error changes

Bugs in `pd.to_datetime()` when passing a unit with convertible entries and `errors='coerce'` or non-convertible with `errors='ignore'`. Furthermore, an `OutOfBoundsDatetime` exception will be raised when an out-of-range value is encountered for that unit when `errors='raise'`. ([GH11758](#), [GH13052](#), [GH13059](#))

Previous behaviour:

```
In [27]: pd.to_datetime(1420043460, unit='s', errors='coerce')
Out[27]: NaT

In [28]: pd.to_datetime(11111111, unit='D', errors='ignore')
OverflowError: Python int too large to convert to C long

In [29]: pd.to_datetime(11111111, unit='D', errors='raise')
OverflowError: Python int too large to convert to C long
```

New behaviour:

```
In [2]: pd.to_datetime(1420043460, unit='s', errors='coerce')
Out[2]: Timestamp('2014-12-31 16:31:00')

In [3]: pd.to_datetime(11111111, unit='D', errors='ignore')
Out[3]: 11111111

In [4]: pd.to_datetime(11111111, unit='D', errors='raise')
OutOfBoundsDatetime: cannot convert input with unit 'D'
```

Other API changes

- `.swaplevel()` for `Series`, `DataFrame`, `Panel`, and `MultiIndex` now features defaults for its first two parameters `i` and `j` that swap the two innermost levels of the index. (GH12934)
- `.searchsorted()` for `Index` and `TimedeltaIndex` now accept a `sorter` argument to maintain compatibility with numpy's `searchsorted` function (GH12238)
- `Period` and `PeriodIndex` now raises `IncompatibleFrequency` error which inherits `ValueError` rather than raw `ValueError` (GH12615)
- `Series.apply` for category dtype now applies the passed function to each of the `.categories` (and not the `.codes`), and returns a `category` dtype if possible (GH12473)
- `read_csv` will now raise a `TypeError` if `parse_dates` is neither a boolean, list, or dictionary (matches the doc-string) (GH5636)
- The default for `.query()/eval()` is now `engine=None`, which will use `numexpr` if it's installed; otherwise it will fallback to the `python` engine. This mimics the pre-0.18.1 behavior if `numexpr` is installed (and which, previously, if `numexpr` was not installed, `.query()/eval()` would raise). (GH12749)
- `pd.show_versions()` now includes `pandas_datareader` version (GH12740)
- Provide a proper `__name__` and `__qualname__` attributes for generic functions (GH12021)
- `pd.concat(ignore_index=True)` now uses `RangeIndex` as default (GH12695)
- `pd.merge()` and `DataFrame.join()` will show a `UserWarning` when merging/joining a single- with a multi-leveled dataframe (GH9455, GH12219)
- Compat with `scipy > 0.17` for deprecated `piecewise_polynomial` interpolation method; support for the replacement `from_derivatives` method (GH12887)

Deprecations

- The method name `Index.sym_diff()` is deprecated and can be replaced by `Index.symmetric_difference()` (GH12591)
- The method name `Categorical.sort()` is deprecated in favor of `Categorical.sort_values()` (GH12882)

Performance improvements

- Improved speed of SAS reader (GH12656, GH12961)
- Performance improvements in `.groupby(...).cumcount()` (GH11039)
- Improved memory usage in `pd.read_csv()` when using `skiprows=an_integer` (GH13005)
- Improved performance of `DataFrame.to_sql` when checking case sensitivity for tables. Now only checks if table has been created correctly when table name is not lower case. (GH12876)
- Improved performance of `Period` construction and time series plotting (GH12903, GH11831).
- Improved performance of `.str.encode()` and `.str.decode()` methods (GH13008)
- Improved performance of `to_numeric` if input is numeric dtype (GH12777)
- Improved performance of sparse arithmetic with `IntIndex` (GH13036)

Bug fixes

- `usecols` parameter in `pd.read_csv` is now respected even when the lines of a CSV file are not even (GH12203)
- Bug in `groupby.transform(..)` when `axis=1` is specified with a non-monotonic ordered index (GH12713)
- Bug in `Period` and `PeriodIndex` creation raises `KeyError` if `freq="Minute"` is specified. Note that “Minute” `freq` is deprecated in v0.17.0, and recommended to use `freq="T"` instead (GH11854)
- Bug in `.resample(...).count()` with a `PeriodIndex` always raising a `TypeError` (GH12774)
- Bug in `.resample(...)` with a `PeriodIndex` casting to a `DatetimeIndex` when empty (GH12868)
- Bug in `.resample(...)` with a `PeriodIndex` when resampling to an existing frequency (GH12770)
- Bug in printing data which contains `Period` with different `freq` raises `ValueError` (GH12615)
- Bug in `Series` construction with `Categorical` and `dtype='category'` is specified (GH12574)
- Bugs in concatenation with a coercible `dtype` was too aggressive, resulting in different `dtypes` in output formatting when an object was longer than `display.max_rows` (GH12411, GH12045, GH11594, GH10571, GH12211)
- Bug in `float_format` option with option not being validated as a callable. (GH12706)
- Bug in `GroupBy.filter` when `dropna=False` and no groups fulfilled the criteria (GH12768)
- Bug in `__name__` of `.cum*` functions (GH12021)
- Bug in `.astype()` of a `Float64Index/Int64Index` to an `Int64Index` (GH12881)
- Bug in round tripping an integer based index in `.to_json()/read_json()` when `orient='index'` (the default) (GH12866)
- Bug in plotting `Categorical` `dtypes` cause error when attempting stacked bar plot (GH13019)
- Compat with `>= numpy 1.11` for `NaT` comparisons (GH12969)
- Bug in `.drop()` with a non-unique `MultiIndex`. (GH12701)
- Bug in `.concat` of datetime tz-aware and naive `DataFrames` (GH12467)
- Bug in correctly raising a `ValueError` in `.resample(..).fillna(..)` when passing a non-string (GH12952)
- Bug fixes in various encoding and header processing issues in `pd.read_sas()` (GH12659, GH12654, GH12647, GH12809)
- Bug in `pd.crosstab()` where would silently ignore `aggfunc` if `values=None` (GH12569).
- Potential segfault in `DataFrame.to_json` when serialising `datetime.time` (GH11473).
- Potential segfault in `DataFrame.to_json` when attempting to serialise `0d` array (GH11299).
- Segfault in `to_json` when attempting to serialise a `DataFrame` or `Series` with non-ndarray values; now supports serialization of `category`, `sparse`, and `datetime64[ns, tz]` `dtypes` (GH10778).
- Bug in `DataFrame.to_json` with unsupported `dtype` not passed to default handler (GH12554).
- Bug in `.align` not returning the sub-class (GH12983)
- Bug in aligning a `Series` with a `DataFrame` (GH13037)
- Bug in `ABCPanel` in which `Panel4D` was not being considered as a valid instance of this generic type (GH12810)

- Bug in consistency of `.name` on `.groupby(...).apply(...)` cases ([GH12363](#))
- Bug in `Timestamp.__repr__` that caused `pprint` to fail in nested structures ([GH12622](#))
- Bug in `Timedelta.min` and `Timedelta.max`, the properties now report the true minimum/maximum `timedeltas` as recognized by pandas. See the *documentation*. ([GH12727](#))
- Bug in `.quantile()` with interpolation may coerce to `float` unexpectedly ([GH12772](#))
- Bug in `.quantile()` with empty `Series` may return scalar rather than empty `Series` ([GH12772](#))
- Bug in `.loc` with out-of-bounds in a large indexer would raise `IndexError` rather than `KeyError` ([GH12527](#))
- Bug in resampling when using a `TimedeltaIndex` and `.asfreq()`, would previously not include the final fencepost ([GH12926](#))
- Bug in equality testing with a `Categorical` in a `DataFrame` ([GH12564](#))
- Bug in `GroupBy.first()`, `.last()` returns incorrect row when `TimeGrouper` is used ([GH7453](#))
- Bug in `pd.read_csv()` with the `c` engine when specifying `skiprows` with newlines in quoted items ([GH10911](#), [GH12775](#))
- Bug in `DataFrame` timezone lost when assigning tz-aware datetime `Series` with alignment ([GH12981](#))
- Bug in `.value_counts()` when `normalize=True` and `dropna=True` where nulls still contributed to the normalized count ([GH12558](#))
- Bug in `Series.value_counts()` loses name if its dtype is `category` ([GH12835](#))
- Bug in `Series.value_counts()` loses timezone info ([GH12835](#))
- Bug in `Series.value_counts(normalize=True)` with `Categorical` raises `UnboundLocalError` ([GH12835](#))
- Bug in `Panel.fillna()` ignoring `inplace=True` ([GH12633](#))
- Bug in `pd.read_csv()` when specifying `names`, `usecols`, and `parse_dates` simultaneously with the `c` engine ([GH9755](#))
- Bug in `pd.read_csv()` when specifying `delim_whitespace=True` and `lineterminator` simultaneously with the `c` engine ([GH12912](#))
- Bug in `Series.rename`, `DataFrame.rename` and `DataFrame.rename_axis` not treating `Series` as mappings to relabel ([GH12623](#)).
- Clean in `.rolling.min` and `.rolling.max` to enhance dtype handling ([GH12373](#))
- Bug in `groupby` where complex types are coerced to `float` ([GH12902](#))
- Bug in `Series.map` raises `TypeError` if its dtype is `category` or tz-aware datetime ([GH12473](#))
- Bugs on 32bit platforms for some test comparisons ([GH12972](#))
- Bug in index coercion when falling back from `RangeIndex` construction ([GH12893](#))
- Better error message in window functions when invalid argument (e.g. a float window) is passed ([GH12669](#))
- Bug in slicing subclassed `DataFrame` defined to return subclassed `Series` may return normal `Series` ([GH11559](#))
- Bug in `.str` accessor methods may raise `ValueError` if input has name and the result is `DataFrame` or `MultiIndex` ([GH12617](#))

- Bug in `DataFrame.last_valid_index()` and `DataFrame.first_valid_index()` on empty frames (GH12800)
- Bug in `CategoricalIndex.get_loc` returns different result from regular `Index` (GH12531)
- Bug in `PeriodIndex.resample` where name not propagated (GH12769)
- Bug in `date_range` closed keyword and timezones (GH12684).
- Bug in `pd.concat` raises `AttributeError` when input data contains tz-aware datetime and timedelta (GH12620)
- Bug in `pd.concat` did not handle empty `Series` properly (GH11082)
- Bug in `.plot.bar` alignment when `width` is specified with `int` (GH12979)
- Bug in `fill_value` is ignored if the argument to a binary operator is a constant (GH12723)
- Bug in `pd.read_html()` when using bs4 flavor and parsing table with a header and only one column (GH9178)
- Bug in `.pivot_table` when `margins=True` and `dropna=True` where nulls still contributed to margin count (GH12577)
- Bug in `.pivot_table` when `dropna=False` where table index/column names disappear (GH12133)
- Bug in `pd.crosstab()` when `margins=True` and `dropna=False` which raised (GH12642)
- Bug in `Series.name` when `name` attribute can be a hashable type (GH12610)
- Bug in `.describe()` resets categorical columns information (GH11558)
- Bug where `loffset` argument was not applied when calling `resample().count()` on a timeseries (GH12725)
- `pd.read_excel()` now accepts column names associated with keyword argument `names` (GH12870)
- Bug in `pd.to_numeric()` with `Index` returns `np.ndarray`, rather than `Index` (GH12777)
- Bug in `pd.to_numeric()` with datetime-like may raise `TypeError` (GH12777)
- Bug in `pd.to_numeric()` with scalar raises `ValueError` (GH12777)

8.8.2 v0.18.0 (March 13, 2016)

{{ header }}

This is a major release from 0.17.1 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Warning: pandas \geq 0.18.0 no longer supports compatibility with Python version 2.6 and 3.3 ([GH7718](#), [GH11273](#))

Warning: numexpr version 2.4.4 will now show a warning and not be used as a computation back-end for pandas because of some buggy behavior. This does not affect other versions (\geq 2.1 and \geq 2.4.6). ([GH12489](#))

Highlights include:

- Moving and expanding window functions are now methods on Series and DataFrame, similar to `.groupby`, see [here](#).
- Adding support for a `RangeIndex` as a specialized form of the `Int64Index` for memory savings, see [here](#).
- API breaking change to the `.resample` method to make it more `.groupby` like, see [here](#).
- Removal of support for positional indexing with floats, which was deprecated since 0.14.0. This will now raise a `TypeError`, see [here](#).
- The `.to_xarray()` function has been added for compatibility with the `xarray` package, see [here](#).
- The `read_sas` function has been enhanced to read `sas7bdat` files, see [here](#).

- Addition of the `.str.extractall()` method, and API changes to the `.str.extract()` method and `.str.cat()` method.
- `pd.test()` top-level nose test runner is available (GH4327).

Check the *API Changes* and *deprecations* before updating.

What's new in v0.18.0

- *New features*
 - *Window functions are now methods*
 - *Changes to rename*
 - *Range index*
 - *Changes to str.extract*
 - *Addition of str.extractall*
 - *Changes to str.cat*
 - *Datetimelike rounding*
 - *Formatting of integers in FloatIndex*
 - *Changes to dtype assignment behaviors*
 - *to_xarray*
 - *Latex representation*
 - *pd.read_sas() changes*
 - *Other enhancements*
- *Backwards incompatible API changes*
 - *NaT and Timedelta operations*
 - *Changes to msgpack*
 - *Signature change for .rank*
 - *Bug in QuarterBegin with n=0*
 - *Resample API*
 - * *Downsampling*
 - * *Upsampling*
 - * *Previous API will work but with deprecations*
 - *Changes to eval*
 - *Other API changes*
 - *Deprecations*
 - *Removal of deprecated float indexers*
 - *Removal of prior version deprecations/changes*
- *Performance improvements*
- *Bug Fixes*

- *Contributors*

New features

Window functions are now methods

Window functions have been refactored to be methods on `Series/DataFrame` objects, rather than top-level functions, which are now deprecated. This allows these window-type functions, to have a similar API to that of `.groupby`. See the full documentation *here* ([GH11603](#), [GH12373](#))

```
In [1]: np.random.seed(1234)

In [2]: df = pd.DataFrame({'A': range(10), 'B': np.random.randn(10)})

In [3]: df
Out[3]:
   A      B
0  0  0.471435
1  1 -1.190976
2  2  1.432707
3  3 -0.312652
4  4 -0.720589
5  5  0.887163
6  6  0.859588
7  7 -0.636524
8  8  0.015696
9  9 -2.242685

[10 rows x 2 columns]
```

Previous behavior:

```
In [8]: pd.rolling_mean(df, window=3)
FutureWarning: pd.rolling_mean is deprecated for DataFrame and will be removed.
↳ in a future version, replace with
      DataFrame.rolling(window=3,center=False).mean()

Out[8]:
   A      B
0 NaN    NaN
1 NaN    NaN
2  1  0.237722
3  2 -0.023640
4  3  0.133155
5  4 -0.048693
6  5  0.342054
7  6  0.370076
8  7  0.079587
9  8 -0.954504
```

New behavior:

```
In [4]: r = df.rolling(window=3)
```

These show a descriptive repr

```
In [5]: r
Out[5]: Rolling [window=3,center=False,axis=0]
```

with tab-completion of available methods and properties.

```
In [9]: r.<TAB> # noqa E225, E999
r.A      r.agg      r.apply      r.count      r.exclusions  r.max      r.
↳median  r.name      r.skew      r.sum
r.B      r.aggregate  r.corr      r.cov      r.kurt      r.mean      r.
↳min     r.quantile  r.std      r.var
```

The methods operate on the Rolling object itself

```
In [6]: r.mean()
Out[6]:
   A      B
0 NaN    NaN
1 NaN    NaN
2 1.0  0.237722
3 2.0 -0.023640
4 3.0  0.133155
5 4.0 -0.048693
6 5.0  0.342054
7 6.0  0.370076
8 7.0  0.079587
9 8.0 -0.954504

[10 rows x 2 columns]
```

They provide getitem accessors

```
In [7]: r['A'].mean()
Out[7]:
0    NaN
1    NaN
2    1.0
3    2.0
4    3.0
5    4.0
6    5.0
7    6.0
8    7.0
9    8.0
Name: A, Length: 10, dtype: float64
```

And multiple aggregations

```
In [8]: r.agg({'A': ['mean', 'std'],
...:         'B': ['mean', 'std']})
...:
```

(continues on next page)

(continued from previous page)

Out [8]:

	A		B	
	mean	std	mean	std
0	NaN	NaN	NaN	NaN
1	NaN	NaN	NaN	NaN
2	1.0	1.0	0.237722	1.327364
3	2.0	1.0	-0.023640	1.335505
4	3.0	1.0	0.133155	1.143778
5	4.0	1.0	-0.048693	0.835747
6	5.0	1.0	0.342054	0.920379
7	6.0	1.0	0.370076	0.871850
8	7.0	1.0	0.079587	0.750099
9	8.0	1.0	-0.954504	1.162285

[10 rows x 4 columns]

Changes to rename

`Series.rename` and `NDFrame.rename_axis` can now take a scalar or list-like argument for altering the Series or axis *name*, in addition to their old behaviors of altering labels. (GH9494, GH11965)

In [9]: `s = pd.Series(np.random.randn(5))`In [10]: `s.rename('newname')`

Out [10]:

```
0    1.150036
1    0.991946
2    0.953324
3   -2.021255
4   -0.334077
```

Name: newname, Length: 5, dtype: float64

In [11]: `df = pd.DataFrame(np.random.randn(5, 2))`

```
In [12]: (df.rename_axis("indexname")
.....:      .rename_axis("columns_name", axis="columns")
.....: )
```

Out [12]:

	columns_name	0	1
indexname			
0		0.002118	0.405453
1		0.289092	1.321158
2		-1.546906	-0.202646
3		-0.655969	0.193421
4		0.553439	1.318152

[5 rows x 2 columns]

The new functionality works well in method chains. Previously these methods only accepted functions or dicts mapping a *label* to a new label. This continues to work as before for function or dict-like values.

Range index

A `RangeIndex` has been added to the `Int64Index` sub-classes to support a memory saving alternative for common use cases. This has a similar implementation to the python `range` object (`xrange` in python 2), in that it only stores the start, stop, and step values for the index. It will transparently interact with the user API, converting to `Int64Index` if needed.

This will now be the default constructed index for `NDFrame` objects, rather than previous an `Int64Index`. (GH939, GH12070, GH12071, GH12109, GH12888)

Previous behavior:

```
In [3]: s = pd.Series(range(1000))

In [4]: s.index
Out[4]:
Int64Index([ 0,  1,  2,  3,  4,  5,  6,  7,  8,  9,
            ...
            990, 991, 992, 993, 994, 995, 996, 997, 998, 999], dtype='int64',
↳length=1000)

In [6]: s.index.nbytes
Out[6]: 8000
```

New behavior:

```
In [13]: s = pd.Series(range(1000))

In [14]: s.index
Out[14]: RangeIndex(start=0, stop=1000, step=1)

In [15]: s.index.nbytes
Out[15]: 128
```

Changes to `str.extract`

The `.str.extract` method takes a regular expression with capture groups, finds the first match in each subject string, and returns the contents of the capture groups (GH11386).

In v0.18.0, the `expand` argument was added to `extract`.

- `expand=False`: it returns a `Series`, `Index`, or `DataFrame`, depending on the subject and regular expression pattern (same behavior as pre-0.18.0).
- `expand=True`: it always returns a `DataFrame`, which is more consistent and less confusing from the perspective of a user.

Currently the default is `expand=None` which gives a `FutureWarning` and uses `expand=False`. To avoid this warning, please explicitly specify `expand`.

```
In [1]: pd.Series(['a1', 'b2', 'c3']).str.extract(r'[ab](\d)', expand=None)
FutureWarning: currently extract(expand=None) means expand=False (return Index/Series/
↳DataFrame)
but in a future version of pandas this will be changed to expand=True (return DataFrame)

Out[1]:
```

(continues on next page)

(continued from previous page)

```

0      1
1      2
2      NaN
dtype: object

```

Extracting a regular expression with one group returns a Series if `expand=False`.

```

In [16]: pd.Series(['a1', 'b2', 'c3']).str.extract(r'[ab](\d)', expand=False)
Out[16]:
0      1
1      2
2      NaN
Length: 3, dtype: object

```

It returns a DataFrame with one column if `expand=True`.

```

In [17]: pd.Series(['a1', 'b2', 'c3']).str.extract(r'[ab](\d)', expand=True)
Out[17]:
   0
0  1
1  2
2  NaN

[3 rows x 1 columns]

```

Calling on an Index with a regex with exactly one capture group returns an Index if `expand=False`.

```
In [18]: s = pd.Series(["a1", "b2", "c3"], ["A11", "B22", "C33"])
```

```
In [19]: s.index
```

```
Out[19]: Index(['A11', 'B22', 'C33'], dtype='object')
```

```
In [20]: s.index.str.extract("(?P<letter>[a-zA-Z])", expand=False)
```

```
Out[20]: Index(['A', 'B', 'C'], dtype='object', name='letter')
```

It returns a DataFrame with one column if `expand=True`.

```

In [21]: s.index.str.extract("(?P<letter>[a-zA-Z])", expand=True)
Out[21]:
  letter
0      A
1      B
2      C

[3 rows x 1 columns]

```

Calling on an Index with a regex with more than one capture group raises `ValueError` if `expand=False`.

```

>>> s.index.str.extract("(?P<letter>[a-zA-Z])([0-9]+)", expand=False)
ValueError: only one regex group is supported with Index

```

It returns a DataFrame if `expand=True`.

```
In [22]: s.index.str.extract("(?P<letter>[a-zA-Z])([0-9]+)", expand=True)
Out[22]:
   letter  1
0      A  11
1      B  22
2      C  33

[3 rows x 2 columns]
```

In summary, `extract(expand=True)` always returns a `DataFrame` with a row for every subject string, and a column for every capture group.

Addition of `str.extractall`

The `.str.extractall` method was added (GH11386). Unlike `extract`, which returns only the first match.

```
In [23]: s = pd.Series(["a1a2", "b1", "c1"], ["A", "B", "C"])
```

```
In [24]: s
Out[24]:
A    a1a2
B     b1
C     c1
Length: 3, dtype: object
```

```
In [25]: s.str.extract(r"(?P<letter>[ab])(?P<digit>\d)", expand=False)
Out[25]:
   letter digit
A      a     1
B      b     1
C    NaN    NaN
```

```
[3 rows x 2 columns]
```

The `extractall` method returns all matches.

```
In [26]: s.str.extractall(r"(?P<letter>[ab])(?P<digit>\d)")
Out[26]:
   letter digit
match
A 0      a     1
  1      a     2
B 0      b     1

[3 rows x 2 columns]
```

Changes to `str.cat`

The method `.str.cat()` concatenates the members of a `Series`. Before, if `NaN` values were present in the `Series`, calling `.str.cat()` on it would return `NaN`, unlike the rest of the `Series.str.*` API. This behavior has been amended to ignore `NaN` values by default. (GH11435).

A new, friendlier `ValueError` is added to protect against the mistake of supplying the `sep` as an arg, rather than as a kwarg. (GH11334).

```
In [27]: pd.Series(['a', 'b', np.nan, 'c']).str.cat(sep=' ')
Out[27]: 'a b c'
```

```
In [28]: pd.Series(['a', 'b', np.nan, 'c']).str.cat(sep=' ', na_rep='?')
Out[28]: 'a b ? c'
```

```
In [2]: pd.Series(['a', 'b', np.nan, 'c']).str.cat(' ')
ValueError: Did you mean to supply a `sep` keyword?
```

Datetimelike rounding

`DatetimeIndex`, `Timestamp`, `TimedeltaIndex`, `Timedelta` have gained the `.round()`, `.floor()` and `.ceil()` method for datetimelike rounding, flooring and ceiling. (GH4314, GH11963)

Naive datetimes

```
In [29]: dr = pd.date_range('20130101 09:12:56.1234', periods=3)
```

```
In [30]: dr
Out[30]:
DatetimeIndex(['2013-01-01 09:12:56.123400', '2013-01-02 09:12:56.123400',
              '2013-01-03 09:12:56.123400'],
              dtype='datetime64[ns]', freq='D')
```

```
In [31]: dr.round('s')
Out[31]:
DatetimeIndex(['2013-01-01 09:12:56', '2013-01-02 09:12:56',
              '2013-01-03 09:12:56'],
              dtype='datetime64[ns]', freq=None)
```

Timestamp scalar

```
In [32]: dr[0]
Out[32]: Timestamp('2013-01-01 09:12:56.123400', freq='D')
```

```
In [33]: dr[0].round('10s')
Out[33]: Timestamp('2013-01-01 09:13:00')
```

Tz-aware are rounded, floored and ceiled in local times

```
In [34]: dr = dr.tz_localize('US/Eastern')
```

```
In [35]: dr
Out[35]:
DatetimeIndex(['2013-01-01 09:12:56.123400-05:00',
              '2013-01-02 09:12:56.123400-05:00',
              '2013-01-03 09:12:56.123400-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq='D')
```

```
In [36]: dr.round('s')
Out[36]:
DatetimeIndex(['2013-01-01 09:12:56-05:00', '2013-01-02 09:12:56-05:00',
              '2013-01-03 09:12:56-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq='D')
```

```
dtype='datetime64[ns, US/Eastern]', freq=None)
```

Timedeltas

```
In [37]: t = pd.timedelta_range('1 days 2 hr 13 min 45 us', periods=3, freq='d')
```

```
In [38]: t
```

```
Out[38]:
```

```
TimedeltaIndex(['1 days 02:13:00.000045', '2 days 02:13:00.000045',
                '3 days 02:13:00.000045'],
               dtype='timedelta64[ns]', freq='D')
```

```
In [39]: t.round('10min')
```

```
Out[39]: TimedeltaIndex(['1 days 02:10:00', '2 days 02:10:00', '3 days 02:10:00'],
                        dtype='timedelta64[ns]', freq=None)
```

Timedelta scalar

```
In [40]: t[0]
```

```
Out[40]: Timedelta('1 days 02:13:00.000045')
```

```
In [41]: t[0].round('2h')
```

```
Out[41]: Timedelta('1 days 02:00:00')
```

In addition, `.round()`, `.floor()` and `.ceil()` will be available through the `.dt` accessor of `Series`.

```
In [42]: s = pd.Series(dr)
```

```
In [43]: s
```

```
Out[43]:
```

```
0    2013-01-01 09:12:56.123400-05:00
1    2013-01-02 09:12:56.123400-05:00
2    2013-01-03 09:12:56.123400-05:00
Length: 3, dtype: datetime64[ns, US/Eastern]
```

```
In [44]: s.dt.round('D')
```

```
Out[44]:
```

```
0    2013-01-01 00:00:00-05:00
1    2013-01-02 00:00:00-05:00
2    2013-01-03 00:00:00-05:00
Length: 3, dtype: datetime64[ns, US/Eastern]
```

Formatting of integers in FloatIndex

Integers in `FloatIndex`, e.g. 1., are now formatted with a decimal point and a 0 digit, e.g. 1.0 ([GH11713](#)) This change not only affects the display to the console, but also the output of IO methods like `.to_csv` or `.to_html`.

Previous behavior:

```
In [2]: s = pd.Series([1, 2, 3], index=np.arange(3.))
```

```
In [3]: s
```

```
Out[3]:
```

```
0    1
1    2
```

(continues on next page)

(continued from previous page)

```

2    3
dtype: int64

In [4]: s.index
Out[4]: Float64Index([0.0, 1.0, 2.0], dtype='float64')

In [5]: print(s.to_csv(path=None))
0,1
1,2
2,3

```

New behavior:

```
In [45]: s = pd.Series([1, 2, 3], index=np.arange(3.))
```

```
In [46]: s
Out[46]:
0.0    1
1.0    2
2.0    3
Length: 3, dtype: int64
```

```
In [47]: s.index
Out[47]: Float64Index([0.0, 1.0, 2.0], dtype='float64')
```

```
In [48]: print(s.to_csv(path_or_buf=None, header=False))
0.0,1
1.0,2
2.0,3
```

Changes to dtype assignment behaviors

When a DataFrame's slice is updated with a new slice of the same dtype, the dtype of the DataFrame will now remain the same. (GH10503)

Previous behavior:

```
In [5]: df = pd.DataFrame({'a': [0, 1, 1],
                          'b': pd.Series([100, 200, 300], dtype='uint32')})

In [7]: df.dtypes
Out[7]:
a    int64
b    uint32
dtype: object

In [8]: ix = df['a'] == 1

In [9]: df.loc[ix, 'b'] = df.loc[ix, 'b']

In [11]: df.dtypes
Out[11]:
```

(continues on next page)

(continued from previous page)

```
a    int64
b    int64
dtype: object
```

New behavior:

```
In [49]: df = pd.DataFrame({'a': [0, 1, 1],
.....:                    'b': pd.Series([100, 200, 300], dtype='uint32')})
.....:

In [50]: df.dtypes
Out[50]:
a    int64
b    uint32
Length: 2, dtype: object

In [51]: ix = df['a'] == 1

In [52]: df.loc[ix, 'b'] = df.loc[ix, 'b']

In [53]: df.dtypes
Out[53]:
a    int64
b    uint32
Length: 2, dtype: object
```

When a DataFrame's integer slice is partially updated with a new slice of floats that could potentially be down-casted to integer without losing precision, the dtype of the slice will be set to float instead of integer.

Previous behavior:

```
In [4]: df = pd.DataFrame(np.array(range(1,10)).reshape(3,3),
.....:                   columns=list('abc'),
.....:                   index=[[4,4,8], [8,10,12]])

In [5]: df
Out[5]:
   a  b  c
4 8  1  2  3
10 4  4  5  6
8 12 7  8  9

In [7]: df.ix[4, 'c'] = np.array([0., 1.])

In [8]: df
Out[8]:
   a  b  c
4 8  1  2  0
10 4  4  5  1
8 12 7  8  9
```

New behavior:

```
In [54]: df = pd.DataFrame(np.array(range(1,10)).reshape(3,3),
.....:                    columns=list('abc'),
.....:                    index=[[4,4,8], [8,10,12]])
.....:
```

```
In [55]: df
```

```
Out[55]:
      a  b  c
4 8    1  2  3
      10  4  5  6
8 12    7  8  9
```

```
[3 rows x 3 columns]
```

```
In [56]: df.loc[4, 'c'] = np.array([0., 1.])
```

```
In [57]: df
```

```
Out[57]:
      a  b    c
4 8    1  2  0.0
      10  4  5  1.0
8 12    7  8  9.0
```

```
[3 rows x 3 columns]
```

to_xarray

In a future version of pandas, we will be deprecating `Panel` and other > 2 ndim objects. In order to provide for continuity, all `NDFrame` objects have gained the `.to_xarray()` method in order to convert to `xarray` objects, which has a pandas-like interface for > 2 ndim. (GH11972)

See the [xarray full-documentation](#) here.

```
In [1]: p = Panel(np.arange(2*3*4).reshape(2,3,4))
```

```
In [2]: p.to_xarray()
```

```
Out[2]:
<xarray.DataArray (items: 2, major_axis: 3, minor_axis: 4)>
array([[[ 0,  1,  2,  3],
        [ 4,  5,  6,  7],
        [ 8,  9, 10, 11]],
       [[12, 13, 14, 15],
        [16, 17, 18, 19],
        [20, 21, 22, 23]])
```

```
Coordinates:
```

```
* items      (items) int64 0 1
* major_axis (major_axis) int64 0 1 2
* minor_axis (minor_axis) int64 0 1 2 3
```

Latex representation

`DataFrame` has gained a `._repr_latex_()` method in order to allow for conversion to latex in a ipython/jupyter notebook using `nbconvert`. (GH11778)

Note that this must be activated by setting the option `pd.display.latex.repr=True` (GH12182)

For example, if you have a jupyter notebook you plan to convert to latex using `nbconvert`, place the statement `pd.display.latex.repr=True` in the first cell to have the contained `DataFrame` output also stored as latex.

The options `display.latex.escape` and `display.latex.longtable` have also been added to the configuration and are used automatically by the `to_latex` method. See the *available options docs* for more info.

`pd.read_sas()` changes

`read_sas` has gained the ability to read SAS7BDAT files, including compressed files. The files can be read in entirety, or incrementally. For full details see *here*. (GH4052)

Other enhancements

- Handle truncated floats in SAS xport files (GH11713)
- Added option to hide index in `Series.to_string` (GH11729)
- `read_excel` now supports s3 urls of the format `s3://bucketname/filename` (GH11447)
- add support for `AWS_S3_HOST` env variable when reading from s3 (GH12198)
- A simple version of `Panel.round()` is now implemented (GH11763)
- For Python 3.x, `round(DataFrame)`, `round(Series)`, `round(Panel)` will work (GH11763)
- `sys.getsizeof(obj)` returns the memory usage of a pandas object, including the values it contains (GH11597)
- `Series` gained an `is_unique` attribute (GH11946)
- `DataFrame.quantile` and `Series.quantile` now accept `interpolation` keyword (GH10174).
- Added `DataFrame.style.format` for more flexible formatting of cell values (GH11692)
- `DataFrame.select_dtypes` now allows the `np.float16` type code (GH11990)
- `pivot_table()` now accepts most iterables for the `values` parameter (GH12017)
- Added Google BigQuery service account authentication support, which enables authentication on remote servers. (GH11881, GH12572). For further details see *here*
- `HDFStore` is now iterable: `for k in store` is equivalent to `for k in store.keys()` (GH12221).
- Add missing methods/fields to `.dt` for `Period` (GH8848)
- The entire code base has been PEP-ified (GH12096)

Backwards incompatible API changes

- the leading white spaces have been removed from the output of `.to_string(index=False)` method (GH11833)
- the `out` parameter has been removed from the `Series.round()` method. (GH11763)

- `DataFrame.round()` leaves non-numeric columns unchanged in its return, rather than raises. (GH11885)
- `DataFrame.head(0)` and `DataFrame.tail(0)` return empty frames, rather than `self`. (GH11937)
- `Series.head(0)` and `Series.tail(0)` return empty series, rather than `self`. (GH11937)
- `to_msgpack` and `read_msgpack` encoding now defaults to 'utf-8'. (GH12170)
- the order of keyword arguments to text file parsing functions (`.read_csv()`, `.read_table()`, `.read_fwf()`) changed to group related arguments. (GH11555)
- `NaTType.isoformat` now returns the string 'NaT' to allow the result to be passed to the constructor of `Timestamp`. (GH12300)

NaT and Timedelta operations

`NaT` and `Timedelta` have expanded arithmetic operations, which are extended to `Series` arithmetic where applicable. Operations defined for `datetime64[ns]` or `timedelta64[ns]` are now also defined for `NaT` (GH11564).

`NaT` now supports arithmetic operations with integers and floats.

```
In [58]: pd.NaT * 1
Out[58]: NaT
```

```
In [59]: pd.NaT * 1.5
Out[59]: NaT
```

```
In [60]: pd.NaT / 2
Out[60]: NaT
```

```
In [61]: pd.NaT * np.nan
Out[61]: NaT
```

`NaT` defines more arithmetic operations with `datetime64[ns]` and `timedelta64[ns]`.

```
In [62]: pd.NaT / pd.NaT
Out[62]: nan
```

```
In [63]: pd.Timedelta('1s') / pd.NaT
Out[63]: nan
```

`NaT` may represent either a `datetime64[ns]` null or a `timedelta64[ns]` null. Given the ambiguity, it is treated as a `timedelta64[ns]`, which allows more operations to succeed.

```
In [64]: pd.NaT + pd.NaT
Out[64]: NaT
```

same as

```
In [65]: pd.Timedelta('1s') + pd.Timedelta('1s')
Out[65]: Timedelta('0 days 00:00:02')
```

as opposed to

```
In [3]: pd.Timestamp('19900315') + pd.Timestamp('19900315')
TypeError: unsupported operand type(s) for +: 'Timestamp' and 'Timestamp'
```

However, when wrapped in a Series whose dtype is `datetime64[ns]` or `timedelta64[ns]`, the dtype information is respected.

```
In [1]: pd.Series([pd.NaT], dtype='<M8[ns]') + pd.Series([pd.NaT], dtype='<M8[ns]')
TypeError: can only operate on a datetimes for subtraction,
        but the operator [__add__] was passed
```

```
In [66]: pd.Series([pd.NaT], dtype='<m8[ns]') + pd.Series([pd.NaT], dtype='<m8[ns]')
Out[66]:
0    NaT
Length: 1, dtype: timedelta64[ns]
```

Timedelta division by floats now works.

```
In [67]: pd.Timedelta('1s') / 2.0
Out[67]: Timedelta('0 days 00:00:00.500000')
```

Subtraction by Timedelta in a Series by a Timestamp works ([GH11925](#))

```
In [68]: ser = pd.Series(pd.timedelta_range('1 day', periods=3))
```

```
In [69]: ser
Out[69]:
0    1 days
1    2 days
2    3 days
Length: 3, dtype: timedelta64[ns]
```

```
In [70]: pd.Timestamp('2012-01-01') - ser
Out[70]:
0    2011-12-31
1    2011-12-30
2    2011-12-29
Length: 3, dtype: datetime64[ns]
```

`NaT.isoformat()` now returns `'NaT'`. This change allows allows `pd.Timestamp` to rehydrate any timestamp like object from its `isoformat` ([GH12300](#)).

Changes to msgpack

Forward incompatible changes in `msgpack` writing format were made over 0.17.0 and 0.18.0; older versions of pandas cannot read files packed by newer versions ([GH12129](#), [GH10527](#))

Bugs in `to_msgpack` and `read_msgpack` introduced in 0.17.0 and fixed in 0.18.0, caused files packed in Python 2 unreadable by Python 3 ([GH12142](#)). The following table describes the backward and forward compat of msgpacks.

Warning:		
Packed with	Can be unpacked with	
pre-0.17 / Python 2	any	
pre-0.17 / Python 3	any	
0.17 / Python 2	<ul style="list-style-type: none"> ==0.17 / Python 2 >=0.18 / any Python 	
0.18	>=0.18 / any Python	2605
0.18	>= 0.18	

0.18.0 is backward-compatible for reading files packed by older versions, except for files packed with 0.17 in Python 2, in which case only they can only be unpacked in Python 2.

Signature change for `.rank`

`Series.rank` and `DataFrame.rank` now have the same signature ([GH11759](#))

Previous signature

```
In [3]: pd.Series([0,1]).rank(method='average', na_option='keep',
                             ascending=True, pct=False)

Out[3]:
0    1
1    2
dtype: float64

In [4]: pd.DataFrame([0,1]).rank(axis=0, numeric_only=None,
                                 method='average', na_option='keep',
                                 ascending=True, pct=False)

Out[4]:
    0
0   1
1   2
```

New signature

```
In [71]: pd.Series([0,1]).rank(axis=0, method='average', numeric_only=None,
    ....:                    na_option='keep', ascending=True, pct=False)
    ....:

Out[71]:
0    1.0
1    2.0
Length: 2, dtype: float64

In [72]: pd.DataFrame([0,1]).rank(axis=0, method='average', numeric_only=None,
    ....:                    na_option='keep', ascending=True, pct=False)
    ....:

Out[72]:
    0
0   1.0
1   2.0

[2 rows x 1 columns]
```

Bug in `QuarterBegin` with `n=0`

In previous versions, the behavior of the `QuarterBegin` offset was inconsistent depending on the date when the `n` parameter was 0. ([GH11406](#))

The general semantics of anchored offsets for `n=0` is to not move the date when it is an anchor point (e.g., a quarter start date), and otherwise roll forward to the next anchor point.

```
In [73]: d = pd.Timestamp('2014-02-01')
```

```
In [74]: d
```

```
Out[74]: Timestamp('2014-02-01 00:00:00')
```

```
In [75]: d + pd.offsets.QuarterBegin(n=0, startingMonth=2)
```

```
Out[75]: Timestamp('2014-02-01 00:00:00')
```

```
In [76]: d + pd.offsets.QuarterBegin(n=0, startingMonth=1)
```

```
Out[76]: Timestamp('2014-04-01 00:00:00')
```

For the `QuarterBegin` offset in previous versions, the date would be rolled *backwards* if date was in the same month as the quarter start date.

```
In [3]: d = pd.Timestamp('2014-02-15')
```

```
In [4]: d + pd.offsets.QuarterBegin(n=0, startingMonth=2)
```

```
Out[4]: Timestamp('2014-02-01 00:00:00')
```

This behavior has been corrected in version 0.18.0, which is consistent with other anchored offsets like `MonthBegin` and `YearBegin`.

```
In [77]: d = pd.Timestamp('2014-02-15')
```

```
In [78]: d + pd.offsets.QuarterBegin(n=0, startingMonth=2)
```

```
Out[78]: Timestamp('2014-05-01 00:00:00')
```

Resample API

Like the change in the window functions API *above*, `.resample(...)` is changing to have a more groupby-like API. (GH11732, GH12702, GH12202, GH12332, GH12334, GH12348, GH12448).

```
In [79]: np.random.seed(1234)
```

```
In [80]: df = pd.DataFrame(np.random.rand(10,4),
.....:                      columns=list('ABCD'),
.....:                      index=pd.date_range('2010-01-01 09:00:00',
.....:                                           periods=10, freq='s'))
.....:
```

```
In [81]: df
```

```
Out[81]:
```

	A	B	C	D
2010-01-01 09:00:00	0.191519	0.622109	0.437728	0.785359

(continues on next page)

(continued from previous page)

[10 rows x 4 columns]

Previous API:

You would write a resampling operation that immediately evaluates. If a `how` parameter was not provided, it would default to `how='mean'`.

In [6]: `df.resample('2s')`**Out [6]:**

	A	B	C	D
2010-01-01 09:00:00	0.485748	0.447351	0.357096	0.793615
2010-01-01 09:00:02	0.820801	0.794317	0.364034	0.531096
2010-01-01 09:00:04	0.433985	0.314582	0.424104	0.625733
2010-01-01 09:00:06	0.624988	0.609738	0.633165	0.612452
2010-01-01 09:00:08	0.510470	0.534317	0.573201	0.806949

You could also specify a `how` directly

In [7]: `df.resample('2s', how='sum')`**Out [7]:**

	A	B	C	D
2010-01-01 09:00:00	0.971495	0.894701	0.714192	1.587231
2010-01-01 09:00:02	1.641602	1.588635	0.728068	1.062191
2010-01-01 09:00:04	0.867969	0.629165	0.848208	1.251465
2010-01-01 09:00:06	1.249976	1.219477	1.266330	1.224904
2010-01-01 09:00:08	1.020940	1.068634	1.146402	1.613897

New API:

Now, you can write `.resample(...)` as a 2-stage operation like `.groupby(...)`, which yields a `Resampler`.

In [82]: `r = df.resample('2s')`**In [83]:** `r`**Out [83]:** <pandas.core.resample.DatetimeIndexResampler object at 0x155beecd0>**Downsampling**

You can then use this object to perform operations. These are downsampling operations (going from a higher frequency to a lower one).

In [84]: `r.mean()`**Out [84]:**

	A	B	C	D
2010-01-01 09:00:00	0.485748	0.447351	0.357096	0.793615
2010-01-01 09:00:02	0.820801	0.794317	0.364034	0.531096
2010-01-01 09:00:04	0.433985	0.314582	0.424104	0.625733
2010-01-01 09:00:06	0.624988	0.609738	0.633165	0.612452
2010-01-01 09:00:08	0.510470	0.534317	0.573201	0.806949

[5 rows x 4 columns]

```
In [85]: r.sum()
Out [85]:
```

	A	B	C	D
2010-01-01 09:00:00	0.971495	0.894701	0.714192	1.587231
2010-01-01 09:00:02	1.641602	1.588635	0.728068	1.062191
2010-01-01 09:00:04	0.867969	0.629165	0.848208	1.251465
2010-01-01 09:00:06	1.249976	1.219477	1.266330	1.224904
2010-01-01 09:00:08	1.020940	1.068634	1.146402	1.613897

[5 rows x 4 columns]

Furthermore, `resample` now supports `getitem` operations to perform the resample on specific columns.

```
In [86]: r[['A', 'C']].mean()
Out [86]:
```

	A	C
2010-01-01 09:00:00	0.485748	0.357096
2010-01-01 09:00:02	0.820801	0.364034
2010-01-01 09:00:04	0.433985	0.424104
2010-01-01 09:00:06	0.624988	0.633165
2010-01-01 09:00:08	0.510470	0.573201

[5 rows x 2 columns]

and `.aggregate` type operations.

```
In [87]: r.agg({'A' : 'mean', 'B' : 'sum'})
Out [87]:
```

	A	B
2010-01-01 09:00:00	0.485748	0.894701
2010-01-01 09:00:02	0.820801	1.588635
2010-01-01 09:00:04	0.433985	0.629165
2010-01-01 09:00:06	0.624988	1.219477
2010-01-01 09:00:08	0.510470	1.068634

[5 rows x 2 columns]

These accessors can of course, be combined

```
In [88]: r[['A', 'B']].agg(['mean', 'sum'])
Out [88]:
```

	A		B	
	mean	sum	mean	sum
2010-01-01 09:00:00	0.485748	0.971495	0.447351	0.894701
2010-01-01 09:00:02	0.820801	1.641602	0.794317	1.588635
2010-01-01 09:00:04	0.433985	0.867969	0.314582	0.629165
2010-01-01 09:00:06	0.624988	1.249976	0.609738	1.219477
2010-01-01 09:00:08	0.510470	1.020940	0.534317	1.068634

[5 rows x 4 columns]

Upsampling

Upsampling operations take you from a lower frequency to a higher frequency. These are now performed with the Resampler objects with `backfill()`, `ffill()`, `fillna()` and `asfreq()` methods.

```
In [89]: s = pd.Series(np.arange(5, dtype='int64'),
.....:                 index=pd.date_range('2010-01-01', periods=5, freq='Q'))
.....:

In [90]: s

2010-12-31    3
2011-01-31    3
2011-02-28    3
```

(continues on next page)

(continued from previous page)

```
2011-03-31    4
Freq: M, Length: 13, dtype: int64
```

Note: In the new API, you can either downsample OR upsample. The prior implementation would allow you to pass an aggregator function (like `mean`) even though you were upsampling, providing a bit of confusion.

Previous API will work but with deprecations

Warning: This new API for `resample` includes some internal changes for the prior-to-0.18.0 API, to work with a deprecation warning in most cases, as the `resample` operation returns a deferred object. We can intercept operations and just do what the (pre 0.18.0) API did (with a warning). Here is a typical use case:

```
In [4]: r = df.resample('2s')
```

```
In [6]: r*10
```

```
pandas/tseries/resample.py:80: FutureWarning: .resample() is now a deferred operation
use .resample(...).mean() instead of .resample(...)
```

```
Out[6]:
```

	A	B	C	D
2010-01-01 09:00:00	4.857476	4.473507	3.570960	7.936154
2010-01-01 09:00:02	8.208011	7.943173	3.640340	5.310957
2010-01-01 09:00:04	4.339846	3.145823	4.241039	6.257326
2010-01-01 09:00:06	6.249881	6.097384	6.331650	6.124518
2010-01-01 09:00:08	5.104699	5.343172	5.732009	8.069486

However, getting and assignment operations directly on a `Resampler` will raise a `ValueError`:

```
In [7]: r.iloc[0] = 5
```

```
ValueError: .resample() is now a deferred operation
use .resample(...).mean() instead of .resample(...)
```

There is a situation where the new API can not perform all the operations when using original code. This code is intending to resample every 2s, take the `mean` AND then take the `min` of those results.

```
In [4]: df.resample('2s').min()
```

```
Out[4]:
```

```
A    0.433985
B    0.314582
C    0.357096
D    0.531096
dtype: float64
```

The new API will:

```
In [92]: df.resample('2s').min()
```

```
Out[92]:
```

	A	B	C	D
2010-01-01 09:00:00	0.191519	0.272593	0.276464	0.785359
2010-01-01 09:00:02	0.683463	0.712702	0.357817	0.500995
2010-01-01 09:00:04	0.364886	0.013768	0.075381	0.368824
2010-01-01 09:00:06	0.316836	0.568099	0.397203	0.436173
2010-01-01 09:00:08	0.218792	0.143767	0.442141	0.704581

```
[5 rows x 4 columns]
```

The good news is the return dimensions will differ between the new API and the old API, so this should loudly raise an exception.

To replicate the original operation

```
In [93]: df.resample('2s').mean().min()
Out[93]:
A    0.433985
B    0.314582
C    0.357096
D    0.531096
Length: 4, dtype: float64
```

Changes to eval

In prior versions, new columns assignments in an `eval` expression resulted in an inplace change to the `DataFrame`. (GH9297, GH8664, GH10486)

```
In [94]: df = pd.DataFrame({'a': np.linspace(0, 10, 5), 'b': range(5)})

In [95]: df
Out[95]:
   a  b
0  0.0  0
1  2.5  1
2  5.0  2
3  7.5  3
4 10.0  4

[5 rows x 2 columns]
```

```
In [12]: df.eval('c = a + b')
FutureWarning: eval expressions containing an assignment currently default to operating
inplace.
This will change in a future version of pandas, use inplace=True to avoid this warning.

In [13]: df
Out[13]:
   a  b    c
0  0.0  0  0.0
1  2.5  1  3.5
2  5.0  2  7.0
3  7.5  3 10.5
4 10.0  4 14.0
```

In version 0.18.0, a new `inplace` keyword was added to choose whether the assignment should be done inplace or return a copy.

```
In [96]: df
Out[96]:
   a  b    c
0  0.0  0  0.0
1  2.5  1  3.5
```

```
2  5.0  2  7.0
3  7.5  3 10.5
4 10.0  4 14.0
```

```
[5 rows x 3 columns]
```

```
In [97]: df.eval('d = c - b', inplace=False)
Out[97]:
```

```
   a  b    c    d
0  0.0  0  0.0  0.0
1  2.5  1  3.5  2.5
2  5.0  2  7.0  5.0
3  7.5  3 10.5  7.5
4 10.0  4 14.0 10.0
```

```
[5 rows x 4 columns]
```

```
In [98]: df
Out[98]:
```

```
   a  b    c
0  0.0  0  0.0
1  2.5  1  3.5
2  5.0  2  7.0
3  7.5  3 10.5
4 10.0  4 14.0
```

```
[5 rows x 3 columns]
```

```
In [99]: df.eval('d = c - b', inplace=True)
```

```
In [100]: df
Out[100]:
```

```
   a  b    c    d
0  0.0  0  0.0  0.0
1  2.5  1  3.5  2.5
2  5.0  2  7.0  5.0
3  7.5  3 10.5  7.5
4 10.0  4 14.0 10.0
```

```
[5 rows x 4 columns]
```

Warning: For backwards compatibility, `inplace` defaults to `True` if not specified. This will change in a future version of pandas. If your code depends on an inplace assignment you should update to explicitly set `inplace=True`

The `inplace` keyword parameter was also added the `query` method.

```
In [101]: df.query('a > 5')
Out[101]:
```

```
   a  b    c    d
3  7.5  3 10.5  7.5
4 10.0  4 14.0 10.0
```

(continues on next page)

(continued from previous page)

```
[2 rows x 4 columns]
In [102]: df.query('a > 5', inplace=True)
In [103]: df
Out[103]:
     a  b    c    d
3  7.5  3  10.5  7.5
4  10.0 4  14.0  10.0

[2 rows x 4 columns]
```

Warning: Note that the default value for `inplace` in a query is `False`, which is consistent with prior versions.

`eval` has also been updated to allow multi-line expressions for multiple assignments. These expressions will be evaluated one at a time in order. Only assignments are valid for multi-line expressions.

```
In [104]: df
Out[104]:
     a  b    c    d
3  7.5  3  10.5  7.5
4  10.0 4  14.0  10.0

[2 rows x 4 columns]
In [105]: df.eval("""
.....: e = d + a
.....: f = e - 22
.....: g = f / 2.0""", inplace=True)
.....:
In [106]: df
Out[106]:
     a  b    c    d     e    f    g
3  7.5  3  10.5  7.5  15.0 -7.0 -3.5
4  10.0 4  14.0  10.0  20.0 -2.0 -1.0

[2 rows x 7 columns]
```

Other API changes

- `DataFrame.between_time` and `Series.between_time` now only parse a fixed set of time strings. Parsing of date strings is no longer supported and raises a `ValueError`. (GH11818)

```
In [107]: s = pd.Series(range(10), pd.date_range('2015-01-01', freq='H',
↳ periods=10))
```

(continues on next page)

(continued from previous page)

```
In [108]: s.between_time("7:00am", "9:00am")
Out[108]:
2015-01-01 07:00:00    7
2015-01-01 08:00:00    8
2015-01-01 09:00:00    9
Freq: H, Length: 3, dtype: int64
```

This will now raise.

```
In [2]: s.between_time('20150101 07:00:00', '20150101 09:00:00')
ValueError: Cannot convert arg ['20150101 07:00:00'] to a time.
```

- `.memory_usage()` now includes values in the index, as does `memory_usage` in `.info()` (GH11597)
- `DataFrame.to_latex()` now supports non-ascii encodings (eg `utf-8`) in Python 2 with the parameter `encoding` (GH7061)
- `pandas.merge()` and `DataFrame.merge()` will show a specific error message when trying to merge with an object that is not of type `DataFrame` or a subclass (GH12081)
- `DataFrame.unstack` and `Series.unstack` now take `fill_value` keyword to allow direct replacement of missing values when an unstack results in missing values in the resulting `DataFrame`. As an added benefit, specifying `fill_value` will preserve the data type of the original stacked data. (GH9746)
- As part of the new API for *window functions* and *resampling*, aggregation functions have been clarified, raising more informative error messages on invalid aggregations. (GH9052). A full set of examples are presented in *groupby*.
- Statistical functions for `NDFrame` objects (like `sum()`, `mean()`, `min()`) will now raise if non-numpy-compatible arguments are passed in for `**kwargs` (GH12301)
- `.to_latex` and `.to_html` gain a `decimal` parameter like `.to_csv`; the default is `'.'` (GH12031)
- More helpful error message when constructing a `DataFrame` with empty data but with indices (GH8020)
- `.describe()` will now properly handle `bool` dtype as a categorical (GH6625)
- More helpful error message with an invalid `.transform` with user defined input (GH10165)
- Exponentially weighted functions now allow specifying `alpha` directly (GH10789) and raise `ValueError` if parameters violate $0 < \alpha \leq 1$ (GH12492)

Deprecations

- The functions `pd.rolling_*`, `pd.expanding_*`, and `pd.ewm*` are deprecated and replaced by the corresponding method call. Note that the new suggested syntax includes all of the arguments (even if default) (GH11603)

```
In [1]: s = pd.Series(range(3))

In [2]: pd.rolling_mean(s, window=2, min_periods=1)
FutureWarning: pd.rolling_mean is deprecated for Series and
              will be removed in a future version, replace with
              Series.rolling(min_periods=1, window=2, center=False).mean()

Out[2]:
0    0.0
```

(continues on next page)

(continued from previous page)

```

1    0.5
2    1.5
dtype: float64

In [3]: pd.rolling_cov(s, s, window=2)
FutureWarning: pd.rolling_cov is deprecated for Series and
             will be removed in a future version, replace with
             Series.rolling(window=2).cov(other=<Series>)

Out [3]:
0    NaN
1    0.5
2    0.5
dtype: float64

```

- The `freq` and `how` arguments to the `.rolling`, `.expanding`, and `.ewm` (new) functions are deprecated, and will be removed in a future version. You can simply resample the input prior to creating a window function. (GH11603).

For example, instead of `s.rolling(window=5, freq='D').max()` to get the max value on a rolling 5 Day window, one could use `s.resample('D').mean().rolling(window=5).max()`, which first resamples the data to daily data, then provides a rolling 5 day window.

- `pd.tseries.frequencies.get_offset_name` function is deprecated. Use `offset's .freqstr` property as alternative (GH11192)
- `pandas.stats.fama_macbeth` routines are deprecated and will be removed in a future version (GH6077)
- `pandas.stats.ols`, `pandas.stats.plm` and `pandas.stats.var` routines are deprecated and will be removed in a future version (GH6077)
- show a `FutureWarning` rather than a `DeprecationWarning` on using long-time deprecated syntax in `HDFStore.select`, where the `where` clause is not a string-like (GH12027)
- The `pandas.options.display.mpl_style` configuration has been deprecated and will be removed in a future version of pandas. This functionality is better handled by matplotlib's `style sheets` (GH11783).

Removal of deprecated float indexers

In GH4892 indexing with floating point numbers on a non-Float64Index was deprecated (in version 0.14.0). In 0.18.0, this deprecation warning is removed and these will now raise a `TypeError`. (GH12165, GH12333)

```

In [109]: s = pd.Series([1, 2, 3], index=[4, 5, 6])

In [110]: s
Out [110]:
4    1
5    2
6    3
Length: 3, dtype: int64

In [111]: s2 = pd.Series([1, 2, 3], index=list('abc'))

In [112]: s2

```

(continues on next page)

(continued from previous page)

```
Out[112]:
a    1
b    2
c    3
Length: 3, dtype: int64
```

Previous behavior:

```
# this is label indexing
In [2]: s[5.0]
FutureWarning: scalar indexers for index type Int64Index should be integers and not
↳floating point
Out[2]: 2

# this is positional indexing
In [3]: s.iloc[1.0]
FutureWarning: scalar indexers for index type Int64Index should be integers and not
↳floating point
Out[3]: 2

# this is label indexing
In [4]: s.loc[5.0]
FutureWarning: scalar indexers for index type Int64Index should be integers and not
↳floating point
Out[4]: 2

# .ix would coerce 1.0 to the positional 1, and index
In [5]: s2.ix[1.0] = 10
FutureWarning: scalar indexers for index type Index should be integers and not floating
↳point

In [6]: s2
Out[6]:
a    1
b   10
c    3
dtype: int64
```

New behavior:

For iloc, getting & setting via a float scalar will always raise.

```
In [3]: s.iloc[2.0]
TypeError: cannot do label indexing on <class 'pandas.indexes.numeric.Int64Index'> with
↳these indexers [2.0] of <type 'float'>
```

Other indexers will coerce to a like integer for both getting and setting. The FutureWarning has been dropped for .loc, .ix and [].

```
In [113]: s[5.0]
Out[113]: 2
```

```
In [114]: s.loc[5.0]
Out[114]: 2
```

and setting

```
In [115]: s_copy = s.copy()

In [116]: s_copy[5.0] = 10

In [117]: s_copy
Out[117]:
4    1
5   10
6    3
Length: 3, dtype: int64

In [118]: s_copy = s.copy()

In [119]: s_copy.loc[5.0] = 10

In [120]: s_copy
Out[120]:
4    1
5   10
6    3
Length: 3, dtype: int64
```

Positional setting with `.ix` and a float indexer will ADD this value to the index, rather than previously setting the value by position.

```
In [3]: s2.ix[1.0] = 10
In [4]: s2
Out[4]:
a    1
b    2
c    3
1.0  10
dtype: int64
```

Slicing will also coerce integer-like floats to integers for a non-Float64Index.

```
In [121]: s.loc[5.0:6]
Out[121]:
5    2
6    3
Length: 2, dtype: int64
```

Note that for floats that are NOT coercible to ints, the label based bounds will be excluded

```
In [122]: s.loc[5.1:6]
Out[122]:
6    3
Length: 1, dtype: int64
```

Float indexing on a Float64Index is unchanged.

```
In [123]: s = pd.Series([1, 2, 3], index=np.arange(3.))
```

```
In [124]: s[1.0]
Out[124]: 2
```

```
In [125]: s[1.0:2.5]
Out[125]:
1.0    2
2.0    3
Length: 2, dtype: int64
```

Removal of prior version deprecations/changes

- Removal of `rolling_corr_pairwise` in favor of `.rolling().corr(pairwise=True)` (GH4950)
- Removal of `expanding_corr_pairwise` in favor of `.expanding().corr(pairwise=True)` (GH4950)
- Removal of `DataMatrix` module. This was not imported into the pandas namespace in any event (GH12111)
- Removal of `cols` keyword in favor of `subset` in `DataFrame.duplicated()` and `DataFrame.drop_duplicates()` (GH6680)
- Removal of the `read_frame` and `frame_query` (both aliases for `pd.read_sql`) and `write_frame` (alias of `to_sql`) functions in the `pd.io.sql` namespace, deprecated since 0.14.0 (GH6292).
- Removal of the `order` keyword from `.factorize()` (GH6930)

Performance improvements

- Improved performance of `andrews_curves` (GH11534)
- Improved huge `DatetimeIndex`, `PeriodIndex` and `TimedeltaIndex`'s ops performance including `NaT` (GH10277)
- Improved performance of `pandas.concat` (GH11958)
- Improved performance of `StataReader` (GH11591)
- Improved performance in construction of `Categoricals` with `Series` of datetimes containing `NaT` (GH12077)
- Improved performance of ISO 8601 date parsing for dates without separators (GH11899), leading zeros (GH11871) and with white space preceding the time zone (GH9714)

Bug Fixes

- Bug in `GroupBy.size` when data-frame is empty. (GH11699)
- Bug in `Period.end_time` when a multiple of time period is requested (GH11738)
- Regression in `.clip` with tz-aware datetimes (GH11838)
- Bug in `date_range` when the boundaries fell on the frequency (GH11804, GH12409)
- Bug in consistency of passing nested dicts to `.groupby(...).agg(...)` (GH9052)
- Accept unicode in `Timedelta` constructor (GH11995)
- Bug in value label reading for `StataReader` when reading incrementally (GH12014)
- Bug in vectorized `DateOffset` when `n` parameter is 0 (GH11370)

- Compat for numpy 1.11 w.r.t. NaT comparison changes ([GH12049](#))
- Bug in `read_csv` when reading from a `StringIO` in threads ([GH11790](#))
- Bug in not treating NaT as a missing value in datetimelikes when factorizing & with `Categoricals` ([GH12077](#))
- Bug in `getitem` when the values of a `Series` were tz-aware ([GH12089](#))
- Bug in `Series.str.get_dummies` when one of the variables was 'name' ([GH12180](#))
- Bug in `pd.concat` while concatenating tz-aware NaT series. ([GH11693](#), [GH11755](#), [GH12217](#))
- Bug in `pd.read_stata` with version `<= 108` files ([GH12232](#))
- Bug in `Series.resample` using a frequency of `Nano` when the index is a `DatetimeIndex` and contains non-zero nanosecond parts ([GH12037](#))
- Bug in resampling with `.nunique` and a sparse index ([GH12352](#))
- Removed some compiler warnings ([GH12471](#))
- Work around compat issues with `boto` in python 3.5 ([GH11915](#))
- Bug in NaT subtraction from `Timestamp` or `DatetimeIndex` with timezones ([GH11718](#))
- Bug in subtraction of `Series` of a single tz-aware `Timestamp` ([GH12290](#))
- Use compat iterators in PY2 to support `.next()` ([GH12299](#))
- Bug in `Timedelta.round` with negative values ([GH11690](#))
- Bug in `.loc` against `CategoricalIndex` may result in normal `Index` ([GH11586](#))
- Bug in `DataFrame.info` when duplicated column names exist ([GH11761](#))
- Bug in `.copy` of datetime tz-aware objects ([GH11794](#))
- Bug in `Series.apply` and `Series.map` where `timedelta64` was not boxed ([GH11349](#))
- Bug in `DataFrame.set_index()` with tz-aware `Series` ([GH12358](#))
- Bug in subclasses of `DataFrame` where `AttributeError` did not propagate ([GH11808](#))
- Bug `groupby` on tz-aware data where selection not returning `Timestamp` ([GH11616](#))
- Bug in `pd.read_clipboard` and `pd.to_clipboard` functions not supporting Unicode; upgrade included `pyperclip` to v1.5.15 ([GH9263](#))
- Bug in `DataFrame.query` containing an assignment ([GH8664](#))
- Bug in `from_msgpack` where `__contains__()` fails for columns of the unpacked `DataFrame`, if the `DataFrame` has object columns. ([GH11880](#))
- Bug in `.resample` on categorical data with `TimedeltaIndex` ([GH12169](#))
- Bug in timezone info lost when broadcasting scalar datetime to `DataFrame` ([GH11682](#))
- Bug in `Index` creation from `Timestamp` with mixed tz coerces to UTC ([GH11488](#))
- Bug in `to_numeric` where it does not raise if input is more than one dimension ([GH11776](#))
- Bug in parsing timezone offset strings with non-zero minutes ([GH11708](#))
- Bug in `df.plot` using incorrect colors for bar plots under `matplotlib 1.5+` ([GH11614](#))
- Bug in the `groupby` `plot` method when using keyword arguments ([GH11805](#)).
- Bug in `DataFrame.duplicated` and `drop_duplicates` causing spurious matches when setting `keep=False` ([GH11864](#))

- Bug in `.loc` result with duplicated key may have `Index` with incorrect dtype (GH11497)
- Bug in `pd.rolling_median` where memory allocation failed even with sufficient memory (GH11696)
- Bug in `DataFrame.style` with spurious zeros (GH12134)
- Bug in `DataFrame.style` with integer columns not starting at 0 (GH12125)
- Bug in `.style.bar` may not rendered properly using specific browser (GH11678)
- Bug in rich comparison of `Timedelta` with a `numpy.array` of `Timedelta` that caused an infinite recursion (GH11835)
- Bug in `DataFrame.round` dropping column index name (GH11986)
- Bug in `df.replace` while replacing value in mixed dtype `Dataframe` (GH11698)
- Bug in `Index` prevents copying name of passed `Index`, when a new name is not provided (GH11193)
- Bug in `read_excel` failing to read any non-empty sheets when empty sheets exist and `sheetname=None` (GH11711)
- Bug in `read_excel` failing to raise `NotImplemented` error when keywords `parse_dates` and `date_parser` are provided (GH11544)
- Bug in `read_sql` with `pymysql` connections failing to return chunked data (GH11522)
- Bug in `.to_csv` ignoring formatting parameters `decimal`, `na_rep`, `float_format` for float indexes (GH11553)
- Bug in `Int64Index` and `Float64Index` preventing the use of the modulo operator (GH9244)
- Bug in `MultiIndex.drop` for not lexsorted `MultiIndexes` (GH12078)
- Bug in `DataFrame` when masking an empty `DataFrame` (GH11859)
- Bug in `.plot` potentially modifying the `colors` input when the number of columns didn't match the number of series provided (GH12039).
- Bug in `Series.plot` failing when index has a `CustomBusinessDay` frequency (GH7222).
- Bug in `.to_sql` for `datetime.time` values with `sqlite` fallback (GH8341)
- Bug in `read_excel` failing to read data with one column when `squeeze=True` (GH12157)
- Bug in `read_excel` failing to read one empty column (GH12292, GH9002)
- Bug in `.groupby` where a `KeyError` was not raised for a wrong column if there was only one row in the dataframe (GH11741)
- Bug in `.read_csv` with dtype specified on empty data producing an error (GH12048)
- Bug in `.read_csv` where strings like '2E' are treated as valid floats (GH12237)
- Bug in building `pandas` with debugging symbols (GH12123)
- Removed `millisecond` property of `DatetimeIndex`. This would always raise a `ValueError` (GH12019).
- Bug in `Series` constructor with read-only data (GH11502)
- Removed `pandas.util.testing.choice()`. Should use `np.random.choice()`, instead. (GH12386)
- Bug in `.loc` setitem indexer preventing the use of a TZ-aware `DatetimeIndex` (GH12050)
- Bug in `.style` indexes and `MultiIndexes` not appearing (GH11655)
- Bug in `to_msgpack` and `from_msgpack` which did not correctly serialize or deserialize `NaT` (GH12307).
- Bug in `.skew` and `.kurt` due to roundoff error for highly similar values (GH11974)

- Bug in `Timestamp` constructor where microsecond resolution was lost if HHMMSS were not separated with ':' (GH10041)
- Bug in `buffer_rd_bytes` `src->buffer` could be freed more than once if reading failed, causing a segfault (GH12098)
- Bug in `crosstab` where arguments with non-overlapping indexes would return a `KeyError` (GH10291)
- Bug in `DataFrame.apply` in which reduction was not being prevented for cases in which `dtype` was not a numpy dtype (GH12244)
- Bug when initializing categorical series with a scalar value. (GH12336)
- Bug when specifying a UTC `DatetimeIndex` by setting `utc=True` in `.to_datetime` (GH11934)
- Bug when increasing the buffer size of CSV reader in `read_csv` (GH12494)
- Bug when setting columns of a `DataFrame` with duplicate column names (GH12344)

8.9 Version 0.17

8.9.1 v0.17.1 (November 21, 2015)

{{ header }}

Note: We are proud to announce that *pandas* has become a sponsored project of the (NumFOCUS organization). This will help ensure the success of development of *pandas* as a world-class open-source project.

This is a minor bug-fix release from 0.17.0 and includes a large number of bug fixes along several new features, enhancements, and performance improvements. We recommend that all users upgrade to this version.

Highlights include:

- Support for Conditional HTML Formatting, see *here*
- Releasing the GIL on the csv reader & other ops, see *here*
- Fixed regression in `DataFrame.drop_duplicates` from 0.16.2, causing incorrect results on integer values (GH11376)

What's new in v0.17.1

- *New features*
 - *Conditional HTML formatting*
- *Enhancements*
- *API changes*
 - *Deprecations*
- *Performance improvements*
- *Bug fixes*
- *Contributors*

New features

Conditional HTML formatting

Warning: This is a new feature and is under active development. We'll be adding features and possibly making breaking changes in future releases. Feedback is [welcome](#).

We've added *experimental* support for conditional HTML formatting: the visual styling of a DataFrame based on the data. The styling is accomplished with HTML and CSS. Accesses the styler class with the `pandas.DataFrame.style`, attribute, an instance of `Styler` with your data attached.

Here's a quick example:

```
In [1]: np.random.seed(123)

In [2]: df = pd.DataFrame(np.random.randn(10, 5), columns=list('abcde'))

In [3]: html = df.style.background_gradient(cmap='viridis', low=.5)
```

We can render the HTML to get the following table.

`Styler` interacts nicely with the Jupyter Notebook. See the *documentation* for more.

Enhancements

- `DatetimeIndex` now supports conversion to strings with `astype(str)` (GH10442)
- Support for compression (`gzip/bz2`) in `pandas.DataFrame.to_csv()` (GH7615)
- `pd.read_*` functions can now also accept `pathlib.Path`, or `py._path.local.LocalPath` objects for the `filepath_or_buffer` argument. (GH11033) - The `DataFrame` and `Series` functions `.to_csv()`, `.to_html()` and `.to_latex()` can now handle paths beginning with tildes (e.g. `~/Documents/`) (GH11438)
- `DataFrame` now uses the fields of a `namedtuple` as columns, if columns are not supplied (GH11181)
- `DataFrame.itertuples()` now returns `namedtuple` objects, when possible. (GH11269, GH11625)
- Added `axvlines_kwds` to parallel coordinates plot (GH10709)
- Option to `.info()` and `.memory_usage()` to provide for deep introspection of memory consumption. Note that this can be expensive to compute and therefore is an optional parameter. (GH11595)

```
In [4]: df = pd.DataFrame({'A': ['foo'] * 1000}) # noqa: F821
```

```
In [5]: df['B'] = df['A'].astype('category')
```

```
# shows the '+' as we have object dtypes
```

```
In [6]: df.info()
```

```
<class 'pandas.core.frame.DataFrame'>
```

```
RangeIndex: 1000 entries, 0 to 999
```

```
Data columns (total 2 columns):
```

```
A    1000 non-null object
```

```
B    1000 non-null category
```

```
dtypes: category(1), object(1)
```

```
memory usage: 9.0+ KB
```

```
# we have an accurate memory assessment (but can be expensive to compute this)
```

```
In [7]: df.info(memory_usage='deep')
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 1000 entries, 0 to 999
Data columns (total 2 columns):
A    1000 non-null object
B    1000 non-null category
dtypes: category(1), object(1)
memory usage: 75.5 KB
```

- Index now has a `fillna` method ([GH10089](#))

```
In [8]: pd.Index([1, np.nan, 3]).fillna(2)
Out[8]: Float64Index([1.0, 2.0, 3.0], dtype='float64')
```

- Series of type `category` now make `.str.<...>` and `.dt.<...>` accessor methods / properties available, if the categories are of that type. ([GH10661](#))

```
In [9]: s = pd.Series(list('aabb')).astype('category')
```

```
In [10]: s
Out[10]:
0    a
1    a
2    b
3    b
Length: 4, dtype: category
Categories (2, object): [a, b]
```

```
In [11]: s.str.contains("a")
Out[11]:
0    True
1    True
2    False
3    False
Length: 4, dtype: bool
```

```
In [12]: date = pd.Series(pd.date_range('1/1/2015', periods=5)).astype('category')
```

```
In [13]: date
Out[13]:
0    2015-01-01
1    2015-01-02
2    2015-01-03
3    2015-01-04
4    2015-01-05
Length: 5, dtype: category
Categories (5, datetime64[ns]): [2015-01-01, 2015-01-02, 2015-01-03, 2015-01-04,
↪2015-01-05]
```

```
In [14]: date.dt.day
Out[14]:
0    1
1    2
2    3
3    4
```

```
4    5
Length: 5, dtype: int64
```

- `pivot_table` now has a `margins_name` argument so you can use something other than the default of 'All' (GH3335)
- Implement export of `datetime64[ns, tz]` dtypes with a fixed HDF5 store (GH11411)
- Pretty printing sets (e.g. in DataFrame cells) now uses set literal syntax (`{x, y}`) instead of Legacy Python syntax (`set([x, y])`) (GH11215)
- Improve the error message in `pandas.io.gbq.to_gbq()` when a streaming insert fails (GH11285) and when the DataFrame does not match the schema of the destination table (GH11359)

API changes

- raise `NotImplementedError` in `Index.shift` for non-supported index types (GH8038)
- `min` and `max` reductions on `datetime64` and `timedelta64` dtyped series now result in `NaT` and not `nan` (GH11245).
- Indexing with a null key will raise a `TypeError`, instead of a `ValueError` (GH11356)
- `Series.ptp` will now ignore missing values by default (GH11163)

Deprecations

- The `pandas.io.ga` module which implements `google-analytics` support is deprecated and will be removed in a future version (GH11308)
- Deprecate the `engine` keyword in `.to_csv()`, which will be removed in a future version (GH11274)

Performance improvements

- Checking monotonic-ness before sorting on an index (GH11080)
- `Series.dropna` performance improvement when its dtype can't contain `NaN` (GH11159)
- Release the GIL on most datetime field operations (e.g. `DatetimeIndex.year`, `Series.dt.year`), normalization, and conversion to and from `Period`, `DatetimeIndex.to_period` and `PeriodIndex.to_timestamp` (GH11263)
- Release the GIL on some rolling algos: `rolling_median`, `rolling_mean`, `rolling_max`, `rolling_min`, `rolling_var`, `rolling_kurt`, `rolling_skew` (GH11450)
- Release the GIL when reading and parsing text files in `read_csv`, `read_table` (GH11272)
- Improved performance of `rolling_median` (GH11450)
- Improved performance of `to_excel` (GH11352)
- Performance bug in repr of `Categorical` categories, which was rendering the strings before chopping them for display (GH11305)
- Performance improvement in `Categorical.remove_unused_categories`, (GH11643).
- Improved performance of `Series` constructor with no data and `DatetimeIndex` (GH11433)
- Improved performance of `shift`, `cumprod`, and `cumsum` with `groupby` (GH4095)

Bug fixes

- `SparseArray.__iter__()` now does not cause `PendingDeprecationWarning` in Python 3.5 (GH11622)
- Regression from 0.16.2 for output formatting of long floats/nan, restored in (GH11302)
- `Series.sort_index()` now correctly handles the `inplace` option (GH11402)
- Incorrectly distributed `.c` file in the build on PyPi when reading a csv of floats and passing `na_values=<a scalar>` would show an exception (GH11374)
- Bug in `.to_latex()` output broken when the index has a name (GH10660)
- Bug in `HDFStore.append` with strings whose encoded length exceeded the max unencoded length (GH11234)
- Bug in merging `datetime64[ns, tz]` dtypes (GH11405)
- Bug in `HDFStore.select` when comparing with a numpy scalar in a where clause (GH11283)
- Bug in using `DataFrame.ix` with a `MultiIndex` indexer (GH11372)
- Bug in `date_range` with ambiguous endpoints (GH11626)
- Prevent adding new attributes to the accessors `.str`, `.dt` and `.cat`. Retrieving such a value was not possible, so error out on setting it. (GH10673)
- Bug in tz-conversions with an ambiguous time and `.dt` accessors (GH11295)
- Bug in output formatting when using an index of ambiguous times (GH11619)
- Bug in comparisons of `Series` vs list-likes (GH11339)
- Bug in `DataFrame.replace` with a `datetime64[ns, tz]` and a non-compatible `to_replace` (GH11326, GH11153)
- Bug in `isnull` where `numpy.datetime64('NaT')` in a `numpy.array` was not determined to be null (GH11206)
- Bug in list-like indexing with a mixed-integer `Index` (GH11320)
- Bug in `pivot_table` with `margins=True` when indexes are of `Categorical` dtype (GH10993)
- Bug in `DataFrame.plot` cannot use hex strings colors (GH10299)
- Regression in `DataFrame.drop_duplicates` from 0.16.2, causing incorrect results on integer values (GH11376)
- Bug in `pd.eval` where unary ops in a list error (GH11235)
- Bug in `squeeze()` with zero length arrays (GH11230, GH8999)
- Bug in `describe()` dropping column names for hierarchical indexes (GH11517)
- Bug in `DataFrame.pct_change()` not propagating `axis` keyword on `.fillna` method (GH11150)
- Bug in `.to_csv()` when a mix of integer and string column names are passed as the `columns` parameter (GH11637)
- Bug in indexing with a `range`, (GH11652)
- Bug in inference of numpy scalars and preserving dtype when setting columns (GH11638)
- Bug in `to_sql` using unicode column names giving `UnicodeEncodeError` with (GH11431).
- Fix regression in setting of `xticks` in `plot` (GH11529).

- Bug in `holiday.dates` where observance rules could not be applied to holiday and doc enhancement (GH11477, GH11533)
- Fix plotting issues when having plain `Axes` instances instead of `SubplotAxes` (GH11520, GH11556).
- Bug in `DataFrame.to_latex()` produces an extra rule when `header=False` (GH7124)
- Bug in `df.groupby(...).apply(func)` when a func returns a `Series` containing a new datetimelike column (GH11324)
- Bug in `pandas.json` when file to load is big (GH11344)
- Bugs in `to_excel` with duplicate columns (GH11007, GH10982, GH10970)
- Fixed a bug that prevented the construction of an empty series of dtype `datetime64[ns, tz]` (GH11245).
- Bug in `read_excel` with `MultiIndex` containing integers (GH11317)
- Bug in `to_excel` with `openpyxl` 2.2+ and merging (GH11408)
- Bug in `DataFrame.to_dict()` produces a `np.datetime64` object instead of `Timestamp` when only `datetime` is present in data (GH11327)
- Bug in `DataFrame.corr()` raises exception when computes Kendall correlation for `DataFrames` with boolean and not boolean columns (GH11560)
- Bug in the link-time error caused by `C inline` functions on FreeBSD 10+ (with `clang`) (GH10510)
- Bug in `DataFrame.to_csv` in passing through arguments for formatting `MultiIndexes`, including `date_format` (GH7791)
- Bug in `DataFrame.join()` with `how='right'` producing a `TypeError` (GH11519)
- Bug in `Series.quantile` with empty list results has `Index` with `object` dtype (GH11588)
- Bug in `pd.merge` results in empty `Int64Index` rather than `Index(dtype=object)` when the merge result is empty (GH11588)
- Bug in `Categorical.remove_unused_categories` when having `NaN` values (GH11599)
- Bug in `DataFrame.to_sparse()` loses column names for `MultiIndexes` (GH11600)
- Bug in `DataFrame.round()` with non-unique column index producing a Fatal Python error (GH11611)
- Bug in `DataFrame.round()` with `decimals` being a non-unique indexed `Series` producing extra columns (GH11618)

8.9.2 v0.17.0 (October 9, 2015)

{{ header }}

This is a major release from 0.16.2 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Warning: pandas \geq 0.17.0 will no longer support compatibility with Python version 3.2 ([GH9118](#))

Warning: The `pandas.io.data` package is deprecated and will be replaced by the `pandas-datareader` package. This will allow the data modules to be independently updated to your pandas installation. The API for `pandas-datareader` v0.1.1 is exactly the same as in pandas v0.17.0 ([GH8961](#), [GH10861](#)).

After installing `pandas-datareader`, you can easily change your imports:

```
from pandas.io import data, wb
```

becomes

```
from pandas_datareader import data, wb
```

Highlights include:

- Release the Global Interpreter Lock (GIL) on some cython operations, see [here](#)
- Plotting methods are now available as attributes of the `.plot` accessor, see [here](#)
- The sorting API has been revamped to remove some long-time inconsistencies, see [here](#)
- Support for a `datetime64[ns]` with timezones as a first-class dtype, see [here](#)
- The default for `to_datetime` will now be to `raise` when presented with unparseable formats, previously this would return the original input. Also, date parse functions now return consistent results. See [here](#)
- The default for `dropna` in `HDFStore` has changed to `False`, to store by default all rows even if they are all `NaN`, see [here](#)
- Datetime accessor (`dt`) now supports `Series.dt.strftime` to generate formatted strings for datetime-likes, and `Series.dt.total_seconds` to generate each duration of the timedelta in seconds. See [here](#)
- `Period` and `PeriodIndex` can handle multiplied freq like `3D`, which corresponding to 3 days span. See [here](#)
- Development installed versions of pandas will now have PEP440 compliant version strings ([GH9518](#))
- Development support for benchmarking with the [Air Speed Velocity](#) library ([GH8361](#))
- Support for reading SAS xport files, see [here](#)
- Documentation comparing SAS to *pandas*, see [here](#)
- Removal of the automatic TimeSeries broadcasting, deprecated since 0.8.0, see [here](#)
- Display format with plain text can optionally align with Unicode East Asian Width, see [here](#)
- Compatibility with Python 3.5 ([GH11097](#))
- Compatibility with matplotlib 1.5.0 ([GH11111](#))

Check the *API Changes* and *deprecations* before updating.

What's new in v0.17.0

- *New features*
 - *Datetime with TZ*
 - *Releasing the GIL*
 - *Plot submethods*
 - *Additional methods for dt accessor*
 - * *strftime*
 - * *total_seconds*
 - *Period frequency enhancement*
 - *Support for SAS XPORT files*
 - *Support for math functions in .eval()*
 - *Changes to Excel with MultiIndex*
 - *Google BigQuery enhancements*
 - *Display alignment with Unicode East Asian width*

- *Other enhancements*
- *Backwards incompatible API changes*
 - *Changes to sorting API*
 - *Changes to `to_datetime` and `to_timedelta`*
 - * *Error handling*
 - * *Consistent parsing*
 - *Changes to Index comparisons*
 - *Changes to boolean comparisons vs. `None`*
 - *HDFStore dropna behavior*
 - *Changes to `display.precision` option*
 - *Changes to `Categorical.unique`*
 - *Changes to `bool` passed as `header` in parsers*
 - *Other API changes*
 - *Deprecations*
 - *Removal of prior version deprecations/changes*
- *Performance improvements*
- *Bug fixes*
- *Contributors*

New features

Datetime with TZ

We are adding an implementation that natively supports datetime with timezones. A `Series` or a `DataFrame` column previously *could* be assigned a datetime with timezones, and would work as an `object` dtype. This had performance issues with a large number rows. See the *docs* for more details. ([GH8260](#), [GH10763](#), [GH11034](#)).

The new implementation allows for having a single-timezone across all rows, with operations in a performant manner.

```
In [1]: df = pd.DataFrame({'A': pd.date_range('20130101', periods=3),
...:                      'B': pd.date_range('20130101', periods=3, tz='US/Eastern'),
...:                      'C': pd.date_range('20130101', periods=3, tz='CET')})
...:
```

```
In [2]: df
```

```
Out[2]:
```

	A	B	C
0	2013-01-01	2013-01-01 00:00:00-05:00	2013-01-01 00:00:00+01:00
1	2013-01-02	2013-01-02 00:00:00-05:00	2013-01-02 00:00:00+01:00
2	2013-01-03	2013-01-03 00:00:00-05:00	2013-01-03 00:00:00+01:00

```
[3 rows x 3 columns]
```

```
In [3]: df.dtypes
```

```
Out[3]:
```

```
A          datetime64[ns]
B  datetime64[ns, US/Eastern]
C          datetime64[ns, CET]
Length: 3, dtype: object
```

```
In [4]: df.B
```

```
Out[4]:
```

```
0    2013-01-01 00:00:00-05:00
1    2013-01-02 00:00:00-05:00
2    2013-01-03 00:00:00-05:00
Name: B, Length: 3, dtype: datetime64[ns, US/Eastern]
```

```
In [5]: df.B.dt.tz_localize(None)
```

```
Out[5]:
```

```
0    2013-01-01
1    2013-01-02
2    2013-01-03
Name: B, Length: 3, dtype: datetime64[ns]
```

This uses a new-dtype representation as well, that is very similar in look-and-feel to its numpy cousin `datetime64[ns]`

```
In [6]: df['B'].dtype
```

```
Out[6]: datetime64[ns, US/Eastern]
```

```
In [7]: type(df['B'].dtype)
```

```
Out[7]: pandas.core.dtypes.dtypes.DatetimeTZDtype
```

Note: There is a slightly different string repr for the underlying `DatetimeIndex` as a result of the dtype changes, but functionally these are the same.

Previous behavior:

```
In [1]: pd.date_range('20130101', periods=3, tz='US/Eastern')
Out[1]: DatetimeIndex(['2013-01-01 00:00:00-05:00', '2013-01-02 00:00:00-05:00',
                        '2013-01-03 00:00:00-05:00'],
                        dtype='datetime64[ns]', freq='D', tz='US/Eastern')

In [2]: pd.date_range('20130101', periods=3, tz='US/Eastern').dtype
Out[2]: dtype('<M8[ns]>')
```

New behavior:

```
In [8]: pd.date_range('20130101', periods=3, tz='US/Eastern')
```

```
Out[8]:
```

```
DatetimeIndex(['2013-01-01 00:00:00-05:00', '2013-01-02 00:00:00-05:00',
                '2013-01-03 00:00:00-05:00'],
                dtype='datetime64[ns, US/Eastern]', freq='D')
```

```
In [9]: pd.date_range('20130101', periods=3, tz='US/Eastern').dtype
```

```
Out[9]: datetime64[ns, US/Eastern]
```

Releasing the GIL

We are releasing the global-interpreter-lock (GIL) on some cython operations. This will allow other threads to run simultaneously during computation, potentially allowing performance improvements from multi-threading. Notably `groupby`, `nsmallest`, `value_counts` and some indexing operations benefit from this. (GH8882)

For example the `groupby` expression in the following code will have the GIL released during the factorization step, e.g. `df.groupby('key')` as well as the `.sum()` operation.

```
N = 1000000
ngroups = 10
df = DataFrame({'key': np.random.randint(0, ngroups, size=N),
               'data': np.random.randn(N)})
df.groupby('key')['data'].sum()
```

Releasing of the GIL could benefit an application that uses threads for user interactions (e.g. `QT`), or performing multi-threaded computations. A nice example of a library that can handle these types of computation-in-parallel is the `dask` library.

Plot submethods

The `Series` and `DataFrame` `.plot()` method allows for customizing *plot types* by supplying the `kind` keyword arguments. Unfortunately, many of these kinds of plots use different required and optional keyword arguments, which makes it difficult to discover what any given plot kind uses out of the dozens of possible arguments.

To alleviate this issue, we have added a new, optional plotting interface, which exposes each kind of plot as a method of the `.plot` attribute. Instead of writing `series.plot(kind=<kind>, ...)`, you can now also use `series.plot.<kind>(...)`:

```
In [10]: df = pd.DataFrame(np.random.rand(10, 2), columns=['a', 'b'])
```

```
In [11]: df.plot.bar()
```

As a result of this change, these methods are now all discoverable via tab-completion:

```
In [12]: df.plot.<TAB> # noqa: E225, E999
df.plot.area      df.plot.barh      df.plot.density  df.plot.hist      df.plot.line      df.
↳plot.scatter
df.plot.bar       df.plot.box       df.plot.hexbin   df.plot.kde       df.plot.pie
```

Each method signature only includes relevant arguments. Currently, these are limited to required arguments, but in the future these will include optional arguments, as well. For an overview, see the new *Plotting API* documentation.

Additional methods for dt accessor

strftime

We are now supporting a `Series.dt.strftime` method for datetime-likes to generate a formatted string (GH10110). Examples:

```
# DatetimeIndex
```

```
In [13]: s = pd.Series(pd.date_range('20130101', periods=4))
```

```
In [14]: s
```

```
Out[14]:
```

```
0    2013-01-01
```

```
1    2013-01-02
```

```
2    2013-01-03
```

```
3    2013-01-04
```

```
Length: 4, dtype: datetime64[ns]
```

```
In [15]: s.dt.strftime('%Y/%m/%d')
```

```
Out[15]:
```

```
0    2013/01/01
```

```
1    2013/01/02
```

```
2    2013/01/03
```

```
3    2013/01/04
```

```
Length: 4, dtype: object
```

```
# PeriodIndex
```

```
In [16]: s = pd.Series(pd.period_range('20130101', periods=4))
```

```
In [17]: s
```

```
Out[17]:
```

```
0    2013-01-01
```

```
1    2013-01-02
```

```
2    2013-01-03
```

```
3    2013-01-04
```

```
Length: 4, dtype: period[D]
```

```
In [18]: s.dt.strftime('%Y/%m/%d')
```

```
Out[18]:
```

```
0    2013/01/01
```

```
1    2013/01/02
```

```
2    2013/01/03
```

```
3    2013/01/04
```

```
Length: 4, dtype: object
```

The string format is as the python standard library and details can be found [here](#)

total_seconds

pd.Series of type timedelta64 has new method `.dt.total_seconds()` returning the duration of the timedelta in seconds ([GH10817](#))

```
# TimedeltaIndex
In [19]: s = pd.Series(pd.timedelta_range('1 minutes', periods=4))
```

```
In [20]: s
Out[20]:
0    0 days 00:01:00
1    1 days 00:01:00
2    2 days 00:01:00
3    3 days 00:01:00
Length: 4, dtype: timedelta64[ns]
```

```
In [21]: s.dt.total_seconds()
Out[21]:
0         60.0
1       86460.0
2      172860.0
3      259260.0
Length: 4, dtype: float64
```

Period frequency enhancement

Period, PeriodIndex and period_range can now accept multiplied freq. Also, Period.freq and PeriodIndex.freq are now stored as a DateOffset instance like DatetimeIndex, and not as str ([GH7811](#))

A multiplied freq represents a span of corresponding length. The example below creates a period of 3 days. Addition and subtraction will shift the period by its span.

```
In [22]: p = pd.Period('2015-08-01', freq='3D')
```

```
In [23]: p
Out[23]: Period('2015-08-01', '3D')
```

```
In [24]: p + 1
Out[24]: Period('2015-08-04', '3D')
```

```
In [25]: p - 2
Out[25]: Period('2015-07-26', '3D')
```

```
In [26]: p.to_timestamp()
Out[26]: Timestamp('2015-08-01 00:00:00')
```

```
In [27]: p.to_timestamp(how='E')
Out[27]: Timestamp('2015-08-03 23:59:59.999999999')
```

You can use the multiplied freq in PeriodIndex and period_range.

```
In [28]: idx = pd.period_range('2015-08-01', periods=4, freq='2D')
```

```
In [29]: idx
Out[29]: PeriodIndex(['2015-08-01', '2015-08-03', '2015-08-05', '2015-08-07'],
↳dtype='period[2D]', freq='2D')
```

```
In [30]: idx + 1
Out[30]: PeriodIndex(['2015-08-03', '2015-08-05', '2015-08-07', '2015-08-09'],
↳dtype='period[2D]', freq='2D')
```

Support for SAS XPORT files

`read_sas()` provides support for reading *SAS XPORT* format files. (GH4052).

```
df = pd.read_sas('sas_xport.xpt')
```

It is also possible to obtain an iterator and read an XPORT file incrementally.

```
for df in pd.read_sas('sas_xport.xpt', chunksize=10000):
    do_something(df)
```

See the *docs* for more details.

Support for math functions in `.eval()`

`eval()` now supports calling math functions (GH4893)

```
df = pd.DataFrame({'a': np.random.randn(10)})
df.eval("b = sin(a)")
```

The support math functions are *sin*, *cos*, *exp*, *log*, *expm1*, *log1p*, *sqrt*, *sinh*, *cosh*, *tanh*, *arcsin*, *arccos*, *arctan*, *arccosh*, *arcsinh*, *arctanh*, *abs* and *arctan2*.

These functions map to the intrinsics for the NumExpr engine. For the Python engine, they are mapped to NumPy calls.

Changes to Excel with MultiIndex

In version 0.16.2 a `DataFrame` with `MultiIndex` columns could not be written to Excel via `to_excel`. That functionality has been added (GH10564), along with updating `read_excel` so that the data can be read back with, no loss of information, by specifying which columns/rows make up the `MultiIndex` in the `header` and `index_col` parameters (GH4679)

See the *documentation* for more details.

```
In [31]: df = pd.DataFrame([[1, 2, 3, 4], [5, 6, 7, 8]],
.....:                      columns=pd.MultiIndex.from_product(
.....:                      [['foo', 'bar'], ['a', 'b']], names=['col1', 'col2']),
.....:                      index=pd.MultiIndex.from_product(['j'], ['1', 'k']],
.....:                      names=['i1', 'i2'])
.....:
In [32]: df
```

(continues on next page)

(continued from previous page)

```

Out [32]:
col1  foo    bar
col2   a  b   a  b
i1 i2
j  1    1  2   3  4
   k    5  6   7  8

[2 rows x 4 columns]

In [33]: df.to_excel('test.xlsx')

In [34]: df = pd.read_excel('test.xlsx', header=[0, 1], index_col=[0, 1])

In [35]: df
Out [35]:
col1  foo    bar
col2   a  b   a  b
i1 i2
j  1    1  2   3  4
   k    5  6   7  8

[2 rows x 4 columns]

```

Previously, it was necessary to specify the `has_index_names` argument in `read_excel`, if the serialized data had index names. For version 0.17.0 the output format of `to_excel` has been changed to make this keyword unnecessary - the change is shown below.

Old

	A	B	C	D	E	F
1		A	B	C	D	
2	idx_name					
3	2000-01-07 00:00:00	0.968129	0.906529	0.05343	0.02619	
4	2000-01-10 00:00:00	-0.16632	1.981993	1.833093	0.803685	
5	2000-01-11 00:00:00	0.121057	0.36946	-0.02888	1.683975	
6	2000-01-12 00:00:00	-1.70456	-0.73098	-0.38088	0.020946	
7	2000-01-13 00:00:00	-1.20024	1.907733	0.629318	1.507033	
8	2000-01-14 00:00:00	-0.66344	0.073188	1.583482	0.735205	
9	2000-01-17 00:00:00	0.716635	-2.07952	1.760536	0.970309	

New

	A	B	C	D	E
1	idx_name	A	B	C	D
2	2000-01-07 00:00:00	0.968129	0.906529	0.05343	0.02619
3	2000-01-10 00:00:00	-0.16632	1.981993	1.833093	0.803685
4	2000-01-11 00:00:00	0.121057	0.36946	-0.02888	1.683975
5	2000-01-12 00:00:00	-1.70456	-0.73098	-0.38088	0.020946
6	2000-01-13 00:00:00	-1.20024	1.907733	0.629318	1.507033
7	2000-01-14 00:00:00	-0.66344	0.073188	1.583482	0.735205
8	2000-01-17 00:00:00	0.716635	-2.07952	1.760536	0.970309
9	2000-01-18 00:00:00	0.727628	2.22267	2.706276	0.681842

Warning: Excel files saved in version 0.16.2 or prior that had index names will still be able to be read in, but the `has_index_names` argument must be specified to `True`.

Google BigQuery enhancements

- Added ability to automatically create a table/dataset using the `pandas.io.gbq.to_gbq()` function if the destination table/dataset does not exist. (GH8325, GH11121).
- Added ability to replace an existing table and schema when calling the `pandas.io.gbq.to_gbq()` function via the `if_exists` argument. See the docs for more details (GH8325).
- `InvalidColumnOrder` and `InvalidPageToken` in the `gbq` module will raise `ValueError` instead of `IOError`.
- The `generate_bq_schema()` function is now deprecated and will be removed in a future version (GH11121)
- The `gbq` module will now support Python 3 (GH11094).

Display alignment with Unicode East Asian width

Warning: Enabling this option will affect the performance for printing of `DataFrame` and `Series` (about 2 times slower). Use only when it is actually required.

Some East Asian countries use Unicode characters its width is corresponding to 2 alphabets. If a `DataFrame` or `Series` contains these characters, the default output cannot be aligned properly. The following options are added to enable precise handling for these characters.

- `display.unicode.east_asian_width`: Whether to use the Unicode East Asian Width to calculate the display text width. (GH2612)
- `display.unicode.ambiguous_as_wide`: Whether to handle Unicode characters belong to Ambiguous as Wide. (GH11102)

```
In [36]: df = pd.DataFrame({'u' : ['UK', u' '], 'u' : ['Alice', u' '])
```

```
In [37]: df;
```

```
>>> df = pd.DataFrame({'国籍': ['UK', u'日本'], '名前': ['Alice', u'しのぶ']})
>>> df
   名前  国籍
0  Alice  UK
1  しのぶ  日本
```

```
In [38]: pd.set_option('display.unicode.east_asian_width', True)
```

```
In [39]: df;
```

```
>>> pd.set_option('display.unicode.east_asian_width', True)
>>> df
   名前  国籍
0  Alice  UK
1  しのぶ  日本
```

For further details, see [here](#)

Other enhancements

- Support for `openpyxl >= 2.2`. The API for style support is now stable (GH10125)
- `merge` now accepts the argument `indicator` which adds a Categorical-type column (by default called `_merge`) to the output object that takes on the values (GH8790)

Observation Origin	<code>_merge</code> value
Merge key only in 'left' frame	<code>left_only</code>
Merge key only in 'right' frame	<code>right_only</code>
Merge key in both frames	<code>both</code>

```
In [40]: df1 = pd.DataFrame({'col1':[0,1], 'col_left':['a','b']})
```

```
In [41]: df2 = pd.DataFrame({'col1':[1,2,2], 'col_right':[2,2,2]})
```

```
In [42]: pd.merge(df1, df2, on='col1', how='outer', indicator=True)
```

```
Out[42]:
```

```
   col1  col_left  col_right  _merge
0     0         a         NaN  left_only
1     1         b         2.0    both
2     2         NaN         2.0  right_only
3     2         NaN         2.0  right_only
```

```
[4 rows x 4 columns]
```

For more, see the [updated docs](#)

- `pd.to_numeric` is a new function to coerce strings to numbers (possibly with coercion) (GH11133)
- `pd.merge` will now allow duplicate column names if they are not merged upon (GH10639).
- `pd.pivot` will now allow passing `index` as `None` (GH3962).
- `pd.concat` will now use existing Series names if provided (GH10698).

```
In [43]: foo = pd.Series([1, 2], name='foo')
```

```
In [44]: bar = pd.Series([1, 2])
```

```
In [45]: baz = pd.Series([4, 5])
```

Previous behavior:

```
In [1]: pd.concat([foo, bar, baz], 1)
```

```
Out[1]:
   0  1  2
0  1  1  4
1  2  2  5
```

New behavior:

```
In [46]: pd.concat([foo, bar, baz], 1)
```

```
Out[46]:
```

```
   foo  0  1
0    1  1  4
1    2  2  5
```

```
[2 rows x 3 columns]
```

- DataFrame has gained the `nlargest` and `nsmallest` methods ([GH10393](#))
- Add a `limit_direction` keyword argument that works with `limit` to enable `interpolate` to fill NaN values forward, backward, or both ([GH9218](#), [GH10420](#), [GH11115](#))

```
In [47]: ser = pd.Series([np.nan, np.nan, 5, np.nan, np.nan, np.nan, 13])
```

```
In [48]: ser.interpolate(limit=1, limit_direction='both')
```

```
Out[48]:
```

```
0    NaN
1    5.0
2    5.0
3    7.0
4    NaN
5   11.0
6   13.0
```

```
Length: 7, dtype: float64
```

- Added a `DataFrame.round` method to round the values to a variable number of decimal places ([GH10568](#)).

```
In [49]: df = pd.DataFrame(np.random.random([3, 3]),
   ....:                    columns=['A', 'B', 'C'],
   ....:                    index=['first', 'second', 'third'])
   ....:
```

```
In [50]: df
```

```
Out[50]:
           A         B         C
first  0.865702  0.618053  0.874058
second 0.262670  0.058815  0.042868
```

```
third    0.321131    0.244171    0.973007
```

```
[3 rows x 3 columns]
```

```
In [51]: df.round(2)
```

```
Out[51]:
```

```
      A      B      C
first 0.87 0.62 0.87
second 0.26 0.06 0.04
third 0.32 0.24 0.97
```

```
[3 rows x 3 columns]
```

```
In [52]: df.round({'A': 0, 'C': 2})
```

```
Out[52]:
```

```
      A      B      C
first 1.0 0.618053 0.87
second 0.0 0.058815 0.04
third 0.0 0.244171 0.97
```

```
[3 rows x 3 columns]
```

- `drop_duplicates` and `duplicated` now accept a `keep` keyword to target first, last, and all duplicates. The `take_last` keyword is deprecated, see *here* (GH6511, GH8505)

```
In [53]: s = pd.Series(['A', 'B', 'C', 'A', 'B', 'D'])
```

```
In [54]: s.drop_duplicates()
```

```
Out[54]:
```

```
0    A
1    B
2    C
5    D
Length: 4, dtype: object
```

```
In [55]: s.drop_duplicates(keep='last')
```

```
Out[55]:
```

```
2    C
3    A
4    B
5    D
Length: 4, dtype: object
```

```
In [56]: s.drop_duplicates(keep=False)
```

```
Out[56]:
```

```
2    C
5    D
Length: 2, dtype: object
```

- `Reindex` now has a `tolerance` argument that allows for finer control of *Limits on filling while reindexing* (GH10411):

```
In [57]: df = pd.DataFrame({'x': range(5),
.....:                      't': pd.date_range('2000-01-01', periods=5)})
.....:
```

(continues on next page)

(continued from previous page)

```
In [58]: df.reindex([0.1, 1.9, 3.5],
.....:              method='nearest',
.....:              tolerance=0.2)
.....:
Out[58]:
      x      t
0.1  0.0 2000-01-01
1.9  2.0 2000-01-03
3.5  NaN      NaT

[3 rows x 2 columns]
```

When used on a `DatetimeIndex`, `TimedeltaIndex` or `PeriodIndex`, `tolerance` will be coerced into a `Timedelta` if possible. This allows you to specify tolerance with a string:

```
In [59]: df = df.set_index('t')

In [60]: df.reindex(pd.to_datetime(['1999-12-31']),
.....:              method='nearest',
.....:              tolerance='1 day')
.....:
Out[60]:
      x
1999-12-31  0

[1 rows x 1 columns]
```

`tolerance` is also exposed by the lower level `Index.get_indexer` and `Index.get_loc` methods.

- Added functionality to use the `base` argument when resampling a `TimeDeltaIndex` ([GH10530](#))
- `DatetimeIndex` can be instantiated using strings contains `NaT` ([GH7599](#))
- `to_datetime` can now accept the `yearfirst` keyword ([GH7599](#))
- `pandas.tseries.offsets` larger than the `Day` offset can now be used with a `Series` for addition/subtraction ([GH10699](#)). See the *docs* for more details.
- `pd.Timedelta.total_seconds()` now returns `Timedelta` duration to ns precision (previously microsecond precision) ([GH10939](#))
- `PeriodIndex` now supports arithmetic with `np.ndarray` ([GH10638](#))
- Support pickling of `Period` objects ([GH10439](#))
- `.as_blocks` will now take a `copy` optional argument to return a copy of the data, default is to copy (no change in behavior from prior versions), ([GH9607](#))
- `regex` argument to `DataFrame.filter` now handles numeric column names instead of raising `ValueError` ([GH10384](#)).
- Enable reading gzip compressed files via URL, either by explicitly setting the compression parameter or by inferring from the presence of the HTTP Content-Encoding header in the response ([GH8685](#))
- Enable writing Excel files in *memory* using `StringIO/BytesIO` ([GH7074](#))
- Enable serialization of lists and dicts to strings in `ExcelWriter` ([GH8188](#))

- SQL io functions now accept a SQLAlchemy connectable. (GH7877)
- `pd.read_sql` and `to_sql` can accept database URI as `con` parameter (GH10214)
- `read_sql_table` will now allow reading from views (GH10750).
- Enable writing complex values to `HDFStores` when using the `table` format (GH10447)
- Enable `pd.read_hdf` to be used without specifying a key when the HDF file contains a single dataset (GH10443)
- `pd.read_stata` will now read Stata 118 type files. (GH9882)
- `msgpack` submodule has been updated to 0.4.6 with backward compatibility (GH10581)
- `DataFrame.to_dict` now accepts `orient='index'` keyword argument (GH10844).
- `DataFrame.apply` will return a Series of dicts if the passed function returns a dict and `reduce=True` (GH8735).
- Allow passing *kwargs* to the interpolation methods (GH10378).
- Improved error message when concatenating an empty iterable of `Dataframe` objects (GH9157)
- `pd.read_csv` can now read bz2-compressed files incrementally, and the C parser can read bz2-compressed files from AWS S3 (GH11070, GH11072).
- In `pd.read_csv`, recognize `s3n://` and `s3a://` URLs as designating S3 file storage (GH11070, GH11071).
- Read CSV files from AWS S3 incrementally, instead of first downloading the entire file. (Full file download still required for compressed files in Python 2.) (GH11070, GH11073)
- `pd.read_csv` is now able to infer compression type for files read from AWS S3 storage (GH11070, GH11074).

Backwards incompatible API changes

Changes to sorting API

The sorting API has had some longtime inconsistencies. (GH9816, GH8239).

Here is a summary of the API **PRIOR** to 0.17.0:

- `Series.sort` is **INPLACE** while `DataFrame.sort` returns a new object.
- `Series.order` returns a new object
- It was possible to use `Series/DataFrame.sort_index` to sort by **values** by passing the `by` keyword.
- `Series/DataFrame.sortlevel` worked only on a `MultiIndex` for sorting by index.

To address these issues, we have revamped the API:

- We have introduced a new method, `DataFrame.sort_values()`, which is the merger of `DataFrame.sort()`, `Series.sort()`, and `Series.order()`, to handle sorting of **values**.
- The existing methods `Series.sort()`, `Series.order()`, and `DataFrame.sort()` have been deprecated and will be removed in a future version.
- The `by` argument of `DataFrame.sort_index()` has been deprecated and will be removed in a future version.
- The existing method `.sort_index()` will gain the `level` keyword to enable level sorting.

We now have two distinct and non-overlapping methods of sorting. A * marks items that will show a FutureWarning.

To sort by the **values**:

Previous	Replacement
* <code>Series.order()</code>	<code>Series.sort_values()</code>
* <code>Series.sort()</code>	<code>Series.sort_values(inplace=True)</code>
* <code>DataFrame.sort(columns=...)</code>	<code>DataFrame.sort_values(by=...)</code>

To sort by the **index**:

Previous	Replacement
<code>Series.sort_index()</code>	<code>Series.sort_index()</code>
<code>Series.sortlevel(level=...)</code>	<code>Series.sort_index(level=...)</code>
<code>DataFrame.sort_index()</code>	<code>DataFrame.sort_index()</code>
<code>DataFrame.sortlevel(level=...)</code>	<code>DataFrame.sort_index(level=...)</code>
* <code>DataFrame.sort()</code>	<code>DataFrame.sort_index()</code>

We have also deprecated and changed similar methods in two Series-like classes, `Index` and `Categorical`.

Previous	Replacement
* <code>Index.order()</code>	<code>Index.sort_values()</code>
* <code>Categorical.order()</code>	<code>Categorical.sort_values()</code>

Changes to `to_datetime` and `to_timedelta`

Error handling

The default for `pd.to_datetime` error handling has changed to `errors='raise'`. In prior versions it was `errors='ignore'`. Furthermore, the `coerce` argument has been deprecated in favor of `errors='coerce'`. This means that invalid parsing will raise rather than return the original input as in previous versions. (GH10636)

Previous behavior:

```
In [2]: pd.to_datetime(['2009-07-31', 'asd'])
Out[2]: array(['2009-07-31', 'asd'], dtype=object)
```

New behavior:

```
In [3]: pd.to_datetime(['2009-07-31', 'asd'])
ValueError: Unknown string format
```

Of course you can coerce this as well.

```
In [61]: pd.to_datetime(['2009-07-31', 'asd'], errors='coerce')
Out[61]: DatetimeIndex(['2009-07-31', 'NaT'], dtype='datetime64[ns]', freq=None)
```

To keep the previous behavior, you can use `errors='ignore'`:

```
In [62]: pd.to_datetime(['2009-07-31', 'asd'], errors='ignore')
Out [62]: Index(['2009-07-31', 'asd'], dtype='object')
```

Furthermore, `pd.to_timedelta` has gained a similar API, of `errors='raise'|'ignore'|'coerce'`, and the `coerce` keyword has been deprecated in favor of `errors='coerce'`.

Consistent parsing

The string parsing of `to_datetime`, `Timestamp` and `DatetimeIndex` has been made consistent. ([GH7599](#))

Prior to v0.17.0, `Timestamp` and `to_datetime` may parse year-only datetime-string incorrectly using today's date, otherwise `DatetimeIndex` uses the beginning of the year. `Timestamp` and `to_datetime` may raise `ValueError` in some types of datetime-string which `DatetimeIndex` can parse, such as a quarterly string.

Previous behavior:

```
In [1]: pd.Timestamp('2012Q2')
Traceback
...
ValueError: Unable to parse 2012Q2

# Results in today's date.
In [2]: pd.Timestamp('2014')
Out [2]: 2014-08-12 00:00:00
```

v0.17.0 can parse them as below. It works on `DatetimeIndex` also.

New behavior:

```
In [63]: pd.Timestamp('2012Q2')
Out [63]: Timestamp('2012-04-01 00:00:00')

In [64]: pd.Timestamp('2014')
Out [64]: Timestamp('2014-01-01 00:00:00')

In [65]: pd.DatetimeIndex(['2012Q2', '2014'])
Out [65]: DatetimeIndex(['2012-04-01', '2014-01-01'], dtype='datetime64[ns]', freq=None)
```

Note: If you want to perform calculations based on today's date, use `Timestamp.now()` and `pandas.tseries.offsets`.

```
In [66]: import pandas.tseries.offsets as offsets

In [67]: pd.Timestamp.now()
Out [67]: Timestamp('2019-10-23 14:33:09.105786')

In [68]: pd.Timestamp.now() + offsets.DateOffset(years=1)
Out [68]: Timestamp('2020-10-23 14:33:09.107154')
```

Changes to Index comparisons

Operator equal on `Index` should behavior similarly to `Series` ([GH9947](#), [GH10637](#))

Starting in v0.17.0, comparing `Index` objects of different lengths will raise a `ValueError`. This is to be consistent with the behavior of `Series`.

Previous behavior:

```
In [2]: pd.Index([1, 2, 3]) == pd.Index([1, 4, 5])
Out[2]: array([ True, False, False], dtype=bool)

In [3]: pd.Index([1, 2, 3]) == pd.Index([2])
Out[3]: array([False,  True, False], dtype=bool)

In [4]: pd.Index([1, 2, 3]) == pd.Index([1, 2])
Out[4]: False
```

New behavior:

```
In [8]: pd.Index([1, 2, 3]) == pd.Index([1, 4, 5])
Out[8]: array([ True, False, False], dtype=bool)

In [9]: pd.Index([1, 2, 3]) == pd.Index([2])
ValueError: Lengths must match to compare

In [10]: pd.Index([1, 2, 3]) == pd.Index([1, 2])
ValueError: Lengths must match to compare
```

Note that this is different from the `numpy` behavior where a comparison can be broadcast:

```
In [69]: np.array([1, 2, 3]) == np.array([1])
Out[69]: array([ True, False, False])
```

or it can return `False` if broadcasting can not be done:

```
In [70]: np.array([1, 2, 3]) == np.array([1, 2])
Out[70]: False
```

Changes to boolean comparisons vs. `None`

Boolean comparisons of a `Series` vs `None` will now be equivalent to comparing with `np.nan`, rather than raise `TypeError`. (GH1079).

```
In [71]: s = pd.Series(range(3))

In [72]: s.iloc[1] = None

In [73]: s
Out[73]:
0    0.0
1    NaN
2    2.0
Length: 3, dtype: float64
```

Previous behavior:

```
In [5]: s == None
TypeError: Could not compare <type 'NoneType'> type with Series
```

New behavior:

```
In [74]: s == None
Out[74]:
0    False
1    False
2    False
Length: 3, dtype: bool
```

Usually you simply want to know which values are null.

```
In [75]: s.isnull()
Out[75]:
0    False
1     True
2    False
Length: 3, dtype: bool
```

Warning: You generally will want to use `isnull/notnull` for these types of comparisons, as `isnull/notnull` tells you which elements are null. One has to be mindful that `nan`'s don't compare equal, but `None`'s do. Note that Pandas/numpy uses the fact that `np.nan != np.nan`, and treats `None` like `np.nan`.

```
In [76]: None == None
Out[76]: True

In [77]: np.nan == np.nan
Out[77]: False
```

HDFStore dropna behavior

The default behavior for `HDFStore` write functions with `format='table'` is now to keep rows that are all missing. Previously, the behavior was to drop rows that were all missing save the index. The previous behavior can be replicated using the `dropna=True` option. ([GH9382](#))

Previous behavior:

```
In [78]: df_with_missing = pd.DataFrame({'col1': [0, np.nan, 2],
....:                                  'col2': [1, np.nan, np.nan]})
....:

In [79]: df_with_missing
Out[79]:
   col1  col2
0    0.0    1.0
1    NaN    NaN
2    2.0    NaN

[3 rows x 2 columns]
```

```
In [27]:
df_with_missing.to_hdf('file.h5',
                       'df_with_missing',
                       format='table',
                       mode='w')

In [28]: pd.read_hdf('file.h5', 'df_with_missing')
```

```
Out [28]:
   col1  col2
0      0     1
2      2  NaN
```

New behavior:

```
In [80]: df_with_missing.to_hdf('file.h5',
.....:                             'df_with_missing',
.....:                             format='table',
.....:                             mode='w')
.....:
```

```
In [81]: pd.read_hdf('file.h5', 'df_with_missing')
Out[81]:
   col1  col2
0  0.0  1.0
1  NaN  NaN
2  2.0  NaN

[3 rows x 2 columns]
```

See the *docs* for more details.

Changes to display.precision option

The `display.precision` option has been clarified to refer to decimal places (GH10451).

Earlier versions of pandas would format floating point numbers to have one less decimal place than the value in `display.precision`.

```
In [1]: pd.set_option('display.precision', 2)

In [2]: pd.DataFrame({'x': [123.456789]})
Out[2]:
   x
0  123.5
```

If interpreting precision as “significant figures” this did work for scientific notation but that same interpretation did not work for values with standard formatting. It was also out of step with how numpy handles formatting.

Going forward the value of `display.precision` will directly control the number of places after the decimal, for regular formatting as well as scientific notation, similar to how numpy’s `precision` print option works.

```
In [82]: pd.set_option('display.precision', 2)
```

```
In [83]: pd.DataFrame({'x': [123.456789]})
```

```
Out[83]:
```

```
      x
0  123.46

[1 rows x 1 columns]
```

To preserve output behavior with prior versions the default value of `display.precision` has been reduced to 6 from 7.

Changes to `Categorical.unique`

`Categorical.unique` now returns new `Categoricals` with categories and codes that are unique, rather than returning `np.array` ([GH10508](#))

- unordered category: values and categories are sorted by appearance order.
- ordered category: values are sorted by appearance order, categories keep existing order.

```
In [84]: cat = pd.Categorical(['C', 'A', 'B', 'C'],
.....:                        categories=['A', 'B', 'C'],
.....:                        ordered=True)
.....:
```

```
In [85]: cat
Out[85]:
[C, A, B, C]
Categories (3, object): [A < B < C]
```

```
In [86]: cat.unique()
Out[86]:
[C, A, B]
Categories (3, object): [A < B < C]
```

```
In [87]: cat = pd.Categorical(['C', 'A', 'B', 'C'],
.....:                        categories=['A', 'B', 'C'])
.....:
```

```
In [88]: cat
Out[88]:
[C, A, B, C]
Categories (3, object): [A, B, C]
```

```
In [89]: cat.unique()
Out[89]:
[C, A, B]
Categories (3, object): [C, A, B]
```

Changes to bool passed as header in parsers

In earlier versions of pandas, if a bool was passed the `header` argument of `read_csv`, `read_excel`, or `read_html` it was implicitly converted to an integer, resulting in `header=0` for `False` and `header=1` for `True` (GH6113)

A bool input to `header` will now raise a `TypeError`

```
In [29]: df = pd.read_csv('data.csv', header=False)
TypeError: Passing a bool to header is invalid. Use header=None for no header or
header=int or list-like of ints to specify the row(s) making up the column names
```

Other API changes

- Line and kde plot with `subplots=True` now uses default colors, not all black. Specify `color='k'` to draw all lines in black (GH9894)
- Calling the `.value_counts()` method on a Series with a categorical dtype now returns a Series with a `CategoricalIndex` (GH10704)
- The metadata properties of subclasses of pandas objects will now be serialized (GH10553).
- `groupby` using `Categorical` follows the same rule as `Categorical.unique` described above (GH10508)
- When constructing `DataFrame` with an array of `complex64` dtype previously meant the corresponding column was automatically promoted to the `complex128` dtype. Pandas will now preserve the itemsize of the input for complex data (GH10952)
- some numeric reduction operators would return `ValueError`, rather than `TypeError` on object types that includes strings and numbers (GH11131)
- Passing currently unsupported `chunksize` argument to `read_excel` or `ExcelFile.parse` will now raise `NotImplementedError` (GH8011)
- Allow an `ExcelFile` object to be passed into `read_excel` (GH11198)
- `DatetimeIndex.union` does not infer `freq` if `self` and the input have `None` as `freq` (GH11086)
- `NaT`'s methods now either raise `ValueError`, or return `np.nan` or `NaT` (GH9513)

Behavior	Methods
return <code>np.nan</code>	<code>weekday</code> , <code>isoweekday</code>
return <code>NaT</code>	<code>date</code> , <code>now</code> , <code>replace</code> , <code>to_datetime</code> , <code>today</code>
return <code>np.datetime64('NaT')</code>	<code>to_datetime64</code> (unchanged)
raise <code>ValueError</code>	All other public methods (names not beginning with underscores)

Deprecations

- For `Series` the following indexing functions are deprecated (GH10177).

Deprecated Function	Replacement
<code>.irow(i)</code>	<code>.iloc[i]</code> or <code>.iat[i]</code>
<code>.iget(i)</code>	<code>.iloc[i]</code> or <code>.iat[i]</code>
<code>.iget_value(i)</code>	<code>.iloc[i]</code> or <code>.iat[i]</code>

- For DataFrame the following indexing functions are deprecated ([GH10177](#)).

Deprecated Function	Replacement
<code>.irow(i)</code>	<code>.iloc[i]</code>
<code>.iget_value(i, j)</code>	<code>.iloc[i, j]</code> or <code>.iat[i, j]</code>
<code>.icol(j)</code>	<code>.iloc[:, j]</code>

Note: These indexing function have been deprecated in the documentation since 0.11.0.

- `Categorical.name` was deprecated to make `Categorical` more `numpy.ndarray` like. Use `Series(cat, name="whatever")` instead ([GH10482](#)).
- Setting missing values (NaN) in a `Categorical`'s `categories` will issue a warning ([GH10748](#)). You can still have missing values in the `values`.
- `drop_duplicates` and `duplicated`'s `take_last` keyword was deprecated in favor of `keep`. ([GH6511](#), [GH8505](#))
- `Series.nsmallest` and `nlargest`'s `take_last` keyword was deprecated in favor of `keep`. ([GH10792](#))
- `DataFrame.combineAdd` and `DataFrame.combineMult` are deprecated. They can easily be replaced by using the `add` and `mul` methods: `DataFrame.add(other, fill_value=0)` and `DataFrame.mul(other, fill_value=1.)` ([GH10735](#)).
- `TimeSeries` deprecated in favor of `Series` (note that this has been an alias since 0.13.0), ([GH10890](#))
- `SparsePanel` deprecated and will be removed in a future version ([GH11157](#)).
- `Series.is_time_series` deprecated in favor of `Series.index.is_all_dates` ([GH11135](#))
- Legacy offsets (like 'A@JAN') are deprecated (note that this has been alias since 0.8.0) ([GH10878](#))
- `WidePanel` deprecated in favor of `Panel`, `LongPanel` in favor of `DataFrame` (note these have been aliases since < 0.11.0), ([GH10892](#))
- `DataFrame.convert_objects` has been deprecated in favor of type-specific functions `pd.to_datetime`, `pd.to_timestamp` and `pd.to_numeric` (new in 0.17.0) ([GH11133](#)).

Removal of prior version deprecations/changes

- Removal of `na_last` parameters from `Series.order()` and `Series.sort()`, in favor of `na_position`. ([GH5231](#))
- Remove of `percentile_width` from `.describe()`, in favor of `percentiles`. ([GH7088](#))
- Removal of `colSpace` parameter from `DataFrame.to_string()`, in favor of `col_space`, circa 0.8.0 version.
- Removal of automatic time-series broadcasting ([GH2304](#))

```
In [90]: np.random.seed(1234)

In [91]: df = pd.DataFrame(np.random.randn(5, 2),
.....:                    columns=list('AB'),
.....:                    index=pd.date_range('2013-01-01', periods=5))

- Remove `table` keyword in `HDFStore.put/append`, in favor of using `format=` (GH4645)
- Remove `kind` in `read_excel/ExcelFile` as its unused (GH4712)
- Remove `infer_type` keyword from `pd.read_html` as its unused (GH4770, GH7032)
- Remove `offset` and `timeRule` keywords from `Series.tshift/shift`, in favor of `freq` (GH4853, GH4864)
- Remove `pd.load/pd.save` aliases in favor of `pd.to_pickle/pd.read_pickle` (GH3787)

Performance improvements

- Development support for benchmarking with the `Air Speed Velocity` library (GH8361)

- Added vbench benchmarks for alternative ExcelWriter engines and reading Excel files (GH7171)
- Performance improvements in `Categorical.value_counts` (GH10804)
- Performance improvements in `SeriesGroupBy.nunique` and `SeriesGroupBy.value_counts` and `SeriesGroupby.transform` (GH10820, GH11077)
- Performance improvements in `DataFrame.drop_duplicates` with integer dtypes (GH10917)
- Performance improvements in `DataFrame.duplicated` with wide frames. (GH10161, GH11180)
- 4x improvement in `timedelta` string parsing (GH6755, GH10426)
- 8x improvement in `timedelta64` and `datetime64` ops (GH6755)
- Significantly improved performance of indexing `MultiIndex` with slicers (GH10287)
- 8x improvement in `iloc` using list-like input (GH10791)
- Improved performance of `Series.isin` for datetimelike/integer Series (GH10287)
- 20x improvement in `concat` of Categoricals when categories are identical (GH10587)
- Improved performance of `to_datetime` when specified format string is ISO8601 (GH10178)
- 2x improvement of `Series.value_counts` for float dtype (GH10821)
- Enable `infer_datetime_format` in `to_datetime` when date components do not have 0 padding (GH11142)
- Regression from 0.16.1 in constructing `DataFrame` from nested dictionary (GH11084)
- Performance improvements in addition/subtraction operations for `DateOffset` with `Series` or `DatetimeIndex` (GH10744, GH11205)

Bug fixes

- Bug in incorrect computation of `.mean()` on `timedelta64[ns]` because of overflow (GH9442)
- Bug in `.isin` on older numpies (GH11232)
- Bug in `DataFrame.to_html(index=False)` renders unnecessary name row (GH10344)
- Bug in `DataFrame.to_latex()` the `column_format` argument could not be passed (GH9402)
- Bug in `DatetimeIndex` when localizing with NaT (GH10477)
- Bug in `Series.dt` ops in preserving meta-data (GH10477)
- Bug in preserving NaT when passed in an otherwise invalid `to_datetime` construction (GH10477)
- Bug in `DataFrame.apply` when function returns categorical series. (GH9573)
- Bug in `to_datetime` with invalid dates and formats supplied (GH10154)
- Bug in `Index.drop_duplicates` dropping name(s) (GH10115)
- Bug in `Series.quantile` dropping name (GH10881)
- Bug in `pd.Series` when setting a value on an empty `Series` whose index has a frequency. (GH10193)
- Bug in `pd.Series.interpolate` with invalid `order` keyword values. (GH10633)
- Bug in `DataFrame.plot` raises `ValueError` when color name is specified by multiple characters (GH10387)
- Bug in `Index` construction with a mixed list of tuples (GH10697)

- Bug in `DataFrame.reset_index` when index contains `NaT`. ([GH10388](#))
- Bug in `ExcelReader` when worksheet is empty ([GH6403](#))
- Bug in `BinGrouper.group_info` where returned values are not compatible with base class ([GH10914](#))
- Bug in clearing the cache on `DataFrame.pop` and a subsequent inplace op ([GH10912](#))
- Bug in indexing with a mixed-integer `Index` causing an `ImportError` ([GH10610](#))
- Bug in `Series.count` when index has nulls ([GH10946](#))
- Bug in pickling of a non-regular freq `DatetimeIndex` ([GH11002](#))
- Bug causing `DataFrame.where` to not respect the `axis` parameter when the frame has a symmetric shape. ([GH9736](#))
- Bug in `Table.select_column` where name is not preserved ([GH10392](#))
- Bug in `offsets.generate_range` where `start` and `end` have finer precision than `offset` ([GH9907](#))
- Bug in `pd.rolling_*` where `Series.name` would be lost in the output ([GH10565](#))
- Bug in `stack` when index or columns are not unique. ([GH10417](#))
- Bug in setting a `Panel` when an axis has a `MultiIndex` ([GH10360](#))
- Bug in `USFederalHolidayCalendar` where `USMemorialDay` and `USMartinLutherKingJr` were incorrect ([GH10278](#) and [GH9760](#))
- Bug in `.sample()` where returned object, if set, gives unnecessary `SettingWithCopyWarning` ([GH10738](#))
- Bug in `.sample()` where weights passed as `Series` were not aligned along axis before being treated positionally, potentially causing problems if weight indices were not aligned with sampled object. ([GH10738](#))
- Regression fixed in ([GH9311](#), [GH6620](#), [GH9345](#)), where `groupby` with a datetime-like converting to float with certain aggregators ([GH10979](#))
- Bug in `DataFrame.interpolate` with `axis=1` and `inplace=True` ([GH10395](#))
- Bug in `io.sql.get_schema` when specifying multiple columns as primary key ([GH10385](#)).
- Bug in `groupby(sort=False)` with datetime-like `Categorical` raises `ValueError` ([GH10505](#))
- Bug in `groupby(axis=1)` with `filter()` throws `IndexError` ([GH11041](#))
- Bug in `test_categorical` on big-endian builds ([GH10425](#))
- Bug in `Series.shift` and `DataFrame.shift` not supporting categorical data ([GH9416](#))
- Bug in `Series.map` using categorical `Series` raises `AttributeError` ([GH10324](#))
- Bug in `MultiIndex.get_level_values` including `Categorical` raises `AttributeError` ([GH10460](#))
- Bug in `pd.get_dummies` with `sparse=True` not returning `SparseDataFrame` ([GH10531](#))
- Bug in `Index` subtypes (such as `PeriodIndex`) not returning their own type for `.drop` and `.insert` methods ([GH10620](#))
- Bug in `algos.outer_join_indexer` when `right` array is empty ([GH10618](#))
- Bug in `filter` (regression from 0.16.0) and `transform` when grouping on multiple keys, one of which is datetime-like ([GH10114](#))
- Bug in `to_datetime` and `to_timedelta` causing `Index` name to be lost ([GH10875](#))

- Bug in `len(DataFrame.groupby)` causing `IndexError` when there's a column containing only NaNs ([GH11016](#))
- Bug that caused segfault when resampling an empty Series ([GH10228](#))
- Bug in `DatetimeIndex` and `PeriodIndex.value_counts` resets name from its result, but retains in result's `Index`. ([GH10150](#))
- Bug in `pd.eval` using `numexpr` engine coerces 1 element numpy array to scalar ([GH10546](#))
- Bug in `pd.concat` with `axis=0` when column is of dtype `category` ([GH10177](#))
- Bug in `read_msgpack` where input type is not always checked ([GH10369](#), [GH10630](#))
- Bug in `pd.read_csv` with kwargs `index_col=False`, `index_col=['a', 'b']` or `dtype` ([GH10413](#), [GH10467](#), [GH10577](#))
- Bug in `Series.from_csv` with `header` kwarg not setting the `Series.name` or the `Series.index.name` ([GH10483](#))
- Bug in `groupby.var` which caused variance to be inaccurate for small float values ([GH10448](#))
- Bug in `Series.plot(kind='hist')` Y Label not informative ([GH10485](#))
- Bug in `read_csv` when using a converter which generates a `uint8` type ([GH9266](#))
- Bug causes memory leak in time-series line and area plot ([GH9003](#))
- Bug when setting a `Panel` sliced along the major or minor axes when the right-hand side is a `DataFrame` ([GH11014](#))
- Bug that returns `None` and does not raise `NotImplementedError` when operator functions (e.g. `.add`) of `Panel` are not implemented ([GH7692](#))
- Bug in line and kde plot cannot accept multiple colors when `subplots=True` ([GH9894](#))
- Bug in `DataFrame.plot` raises `ValueError` when color name is specified by multiple characters ([GH10387](#))
- Bug in left and right align of `Series` with `MultiIndex` may be inverted ([GH10665](#))
- Bug in left and right join of with `MultiIndex` may be inverted ([GH10741](#))
- Bug in `read_stata` when reading a file with a different order set in `columns` ([GH10757](#))
- Bug in `Categorical` may not representing properly when category contains `tz` or `Period` ([GH10713](#))
- Bug in `Categorical.__iter__` may not returning correct `datetime` and `Period` ([GH10713](#))
- Bug in indexing with a `PeriodIndex` on an object with a `PeriodIndex` ([GH4125](#))
- Bug in `read_csv` with `engine='c'`: EOF preceded by a comment, blank line, etc. was not handled correctly ([GH10728](#), [GH10548](#))
- Reading “famafrench” data via `DataReader` results in HTTP 404 error because of the website url is changed ([GH10591](#)).
- Bug in `read_msgpack` where `DataFrame` to decode has duplicate column names ([GH9618](#))
- Bug in `io.common.get_filepath_or_buffer` which caused reading of valid S3 files to fail if the bucket also contained keys for which the user does not have read permission ([GH10604](#))
- Bug in vectorised setting of timestamp columns with python `datetime.date` and numpy `datetime64` ([GH10408](#), [GH10412](#))
- Bug in `Index.take` may add unnecessary `freq` attribute ([GH10791](#))
- Bug in `merge` with empty `DataFrame` may raise `IndexError` ([GH10824](#))

- Bug in `to_latex` where unexpected keyword argument for some documented arguments (GH10888)
- Bug in indexing of large `DataFrame` where `IndexError` is uncaught (GH10645 and GH10692)
- Bug in `read_csv` when using the `nrows` or `chunksizes` parameters if file contains only a header line (GH9535)
- Bug in serialization of `category` types in HDF5 in presence of alternate encodings. (GH10366)
- Bug in `pd.DataFrame` when constructing an empty `DataFrame` with a string dtype (GH9428)
- Bug in `pd.DataFrame.diff` when `DataFrame` is not consolidated (GH10907)
- Bug in `pd.unique` for arrays with the `datetime64` or `timedelta64` dtype that meant an array with object dtype was returned instead the original dtype (GH9431)
- Bug in `Timedelta` raising error when slicing from 0s (GH10583)
- Bug in `DatetimeIndex.take` and `TimedeltaIndex.take` may not raise `IndexError` against invalid index (GH10295)
- Bug in `Series([np.nan]).astype('M8[ms]')`, which now returns `Series([pd.NaT])` (GH10747)
- Bug in `PeriodIndex.order` reset freq (GH10295)
- Bug in `date_range` when `freq` divides `end` as nanos (GH10885)
- Bug in `iloc` allowing memory outside bounds of a `Series` to be accessed with negative integers (GH10779)
- Bug in `read_msgpack` where encoding is not respected (GH10581)
- Bug preventing access to the first index when using `iloc` with a list containing the appropriate negative integer (GH10547, GH10779)
- Bug in `TimedeltaIndex` formatter causing error while trying to save `DataFrame` with `TimedeltaIndex` using `to_csv` (GH10833)
- Bug in `DataFrame.where` when handling `Series` slicing (GH10218, GH9558)
- Bug where `pd.read_gbq` throws `ValueError` when Bigquery returns zero rows (GH10273)
- Bug in `to_json` which was causing segmentation fault when serializing 0-rank ndarray (GH9576)
- Bug in plotting functions may raise `IndexError` when plotted on `GridSpec` (GH10819)
- Bug in plot result may show unnecessary minor ticklabels (GH10657)
- Bug in `groupby` incorrect computation for aggregation on `DataFrame` with `NaT` (E.g `first`, `last`, `min`). (GH10590, GH11010)
- Bug when constructing `DataFrame` where passing a dictionary with only scalar values and specifying columns did not raise an error (GH10856)
- Bug in `.var()` causing roundoff errors for highly similar values (GH10242)
- Bug in `DataFrame.plot(subplots=True)` with duplicated columns outputs incorrect result (GH10962)
- Bug in `Index` arithmetic may result in incorrect class (GH10638)
- Bug in `date_range` results in empty if `freq` is negative annually, quarterly and monthly (GH11018)
- Bug in `DatetimeIndex` cannot infer negative `freq` (GH11018)
- Remove use of some deprecated numpy comparison operations, mainly in tests. (GH10569)
- Bug in `Index` dtype may not applied properly (GH11017)
- Bug in `io.gbq` when testing for minimum google api client version (GH10652)

- Bug in DataFrame construction from nested dict with `timedelta` keys (GH11129)
- Bug in `.fillna` against may raise `TypeError` when data contains `datetime` dtype (GH7095, GH11153)
- Bug in `.groupby` when number of keys to group by is same as length of index (GH11185)
- Bug in `convert_objects` where converted values might not be returned if all null and `coerce` (GH9589)
- Bug in `convert_objects` where `copy` keyword was not respected (GH9589)

8.10 Version 0.16

8.10.1 v0.16.2 (June 12, 2015)

{{ header }}

This is a minor bug-fix release from 0.16.1 and includes a large number of bug fixes along some new features (`pipe()` method), enhancements, and performance improvements.

We recommend that all users upgrade to this version.

Highlights include:

- A new `pipe` method, see [here](#)
- Documentation on how to use `numba` with `pandas`, see [here](#)

What's new in v0.16.2

- *New features*
 - *Pipe*
 - *Other enhancements*
- *API changes*
- *Performance improvements*
- *Bug fixes*
- *Contributors*

New features

Pipe

We've introduced a new method `DataFrame.pipe()`. As suggested by the name, `pipe` should be used to pipe data through a chain of function calls. The goal is to avoid confusing nested function calls like

```
# df is a DataFrame
# f, g, and h are functions that take and return DataFrames
f(g(h(df), arg1=1), arg2=2, arg3=3) # noqa F821
```

The logic flows from inside out, and function names are separated from their keyword arguments. This can be rewritten as

```
(df.pipe(h)
 .pipe(g, arg1=1)
 .pipe(f, arg2=2, arg3=3)
)
```

Now both the code and the logic flow from top to bottom. Keyword arguments are next to their functions. Overall the code is much more readable.

In the example above, the functions `f`, `g`, and `h` each expected the `DataFrame` as the first positional argument. When the function you wish to apply takes its data anywhere other than the first argument, pass a tuple of (function, keyword) indicating where the `DataFrame` should flow. For example:

```
In [1]: import statsmodels.formula.api as sm

In [2]: bb = pd.read_csv('data/baseball.csv', index_col='id')

# sm.ols takes (formula, data)
In [3]: (bb.query('h > 0')
...:     .assign(ln_h=lambda df: np.log(df.h))
...:     .pipe((sm.ols, 'data'), 'hr ~ ln_h + year + g + C(lg)')
...:     .fit()
...:     .summary()
...: )
...:
```

Out [3]:

```
<class 'statsmodels.iolib.summary.Summary'>
```

```
"""
```

Kurtosis:               5.225    Cond. No.                     1.49e+07
=====

Warnings:
[1] Standard Errors assume that the covariance matrix of the errors is correctly
    specified.
[2] The condition number is large, 1.49e+07. This might indicate that there are
    strong multicollinearity or other numerical problems.
"""

```

The pipe method is inspired by unix pipes, which stream text through processes. More recently `dplyr` and `magrittr` have introduced the popular `(%>%)` pipe operator for R.

See the [documentation](#) for more. (GH10129)

Other enhancements

- Added `rsplit` to Index/Series StringMethods (GH10303)
- Removed the hard-coded size limits on the DataFrame HTML representation in the IPython notebook, and leave this to IPython itself (only for IPython v3.0 or greater). This eliminates the duplicate scroll bars that appeared in the notebook with large frames (GH10231).

Note that the notebook has a `toggle output scrolling` feature to limit the display of very large frames (by clicking left of the output). You can also configure the way DataFrames are displayed using the pandas options, see here [here](#).

- `axis` parameter of `DataFrame.quantile` now accepts also `index` and `column`. (GH9543)

API changes

- `Holiday` now raises `NotImplementedError` if both `offset` and `observance` are used in the constructor instead of returning an incorrect result (GH10217).

Performance improvements

- Improved `Series.resample` performance with `dtype=datetime64[ns]` (GH7754)
- Increase performance of `str.split` when `expand=True` (GH10081)

Bug fixes

- Bug in `Series.hist` raises an error when a one row `Series` was given (GH10214)
- Bug where `HDFStore.select` modifies the passed columns list (GH7212)
- Bug in `Categorical` repr with `display.width` of `None` in Python 3 (GH10087)
- Bug in `to_json` with certain `orients` and a `CategoricalIndex` would segfault (GH10317)
- Bug where some of the nan functions do not have consistent return dtypes (GH10251)
- Bug in `DataFrame.quantile` on checking that a valid axis was passed (GH9543)
- Bug in `groupby.apply` aggregation for `Categorical` not preserving categories (GH10138)
- Bug in `to_csv` where `date_format` is ignored if the `datetime` is fractional (GH10209)
- Bug in `DataFrame.to_json` with mixed data types (GH10289)
- Bug in cache updating when consolidating (GH10264)
- Bug in `mean()` where integer dtypes can overflow (GH10172)
- Bug where `Panel.from_dict` does not set dtype when specified (GH10058)
- Bug in `Index.union` raises `AttributeError` when passing array-likes. (GH10149)
- Bug in `Timestamp`'s `microsecond`, `quarter`, `dayofyear`, `week` and `daysinmonth` properties return `np.int` type, not built-in `int`. (GH10050)
- Bug in `NaT` raises `AttributeError` when accessing to `daysinmonth`, `dayofweek` properties. (GH10096)
- Bug in `Index` repr when using the `max_seq_items=None` setting (GH10182).
- Bug in getting timezone data with `dateutil` on various platforms (GH9059, GH8639, GH9663, GH10121)
- Bug in displaying datetimes with mixed frequencies; display 'ms' datetimes to the proper precision. (GH10170)
- Bug in `setitem` where type promotion is applied to the entire block (GH10280)
- Bug in `Series` arithmetic methods may incorrectly hold names (GH10068)
- Bug in `GroupBy.get_group` when grouping on multiple keys, one of which is categorical. (GH10132)
- Bug in `DatetimeIndex` and `TimedeltaIndex` names are lost after `timedelta` arithmetics (GH9926)
- Bug in `DataFrame` construction from nested `dict` with `datetime64` (GH10160)
- Bug in `Series` construction from `dict` with `datetime64` keys (GH9456)
- Bug in `Series.plot(label="LABEL")` not correctly setting the label (GH10119)
- Bug in `plot` not defaulting to `matplotlib axes.grid` setting (GH9792)
- Bug causing strings containing an exponent, but no decimal to be parsed as `int` instead of `float` in `engine='python'` for the `read_csv` parser (GH9565)
- Bug in `Series.align` resets `name` when `fill_value` is specified (GH10067)
- Bug in `read_csv` causing index name not to be set on an empty `DataFrame` (GH10184)
- Bug in `SparseSeries.abs` resets `name` (GH10241)
- Bug in `TimedeltaIndex` slicing may reset `freq` (GH10292)
- Bug in `GroupBy.get_group` raises `ValueError` when group key contains `NaT` (GH6992)

- Bug in `SparseSeries` constructor ignores input data name ([GH10258](#))
- Bug in `Categorical.remove_categories` causing a `ValueError` when removing the NaN category if underlying dtype is floating-point ([GH10156](#))
- Bug where `infer_freq` infers time rule (WOM-5XXX) unsupported by `to_offset` ([GH9425](#))
- Bug in `DataFrame.to_hdf()` where table format would raise a seemingly unrelated error for invalid (non-string) column names. This is now explicitly forbidden. ([GH9057](#))
- Bug to handle masking empty `DataFrame` ([GH10126](#)).
- Bug where MySQL interface could not handle numeric table/column names ([GH10255](#))
- Bug in `read_csv` with a `date_parser` that returned a `datetime64` array of other time resolution than [ns] ([GH10245](#))
- Bug in `Panel.apply` when the result has `ndim=0` ([GH10332](#))
- Bug in `read_hdf` where `auto_close` could not be passed ([GH9327](#)).
- Bug in `read_hdf` where open stores could not be used ([GH10330](#)).
- Bug in adding empty `DataFrames`, now results in a `DataFrame` that `.equals` an empty `DataFrame` ([GH10181](#)).
- Bug in `to_hdf` and `HDFStore` which did not check that complib choices were valid ([GH4582](#), [GH8874](#)).

8.10.2 v0.16.1 (May 11, 2015)

{{ header }}

This is a minor bug-fix release from 0.16.0 and includes a large number of bug fixes along several new features, enhancements, and performance improvements. We recommend that all users upgrade to this version.

Highlights include:

- Support for a `CategoricalIndex`, a category based index, see [here](#)
- New section on how-to-contribute to *pandas*, see [here](#)
- Revised “Merge, join, and concatenate” documentation, including graphical examples to make it easier to understand each operations, see [here](#)
- New method `sample` for drawing random samples from Series, DataFrames and Panels. See [here](#)
- The default Index printing has changed to a more uniform format, see [here](#)
- `BusinessHour` datetime-offset is now supported, see [here](#)
- Further enhancement to the `.str` accessor to make string operations easier, see [here](#)

What’s new in v0.16.1

- *Enhancements*
 - *CategoricalIndex*
 - *Sample*

- *String methods enhancements*

Warning: In pandas 0.17.0, the sub-package `pandas.io.data` will be removed in favor of a separately installable package ([GH8961](#)).

Enhancements

CategoricalIndex

We introduce a `CategoricalIndex`, a new type of index object that is useful for supporting indexing with duplicates. This is a container around a `Categorical` (introduced in v0.15.0) and allows efficient indexing and storage of an index with a large number of duplicated elements. Prior to 0.16.1, setting the index of a `DataFrame/Series` with a `category` dtype would convert this to regular object-based `Index`.

```
In [1]: df = pd.DataFrame({'A': np.arange(6),
...:                      'B': pd.Series(list('aabbca'))
...:                      .astype('category', categories=list('cab'))
...:                      })
...:

In [2]: df
Out[2]:
   A B
0  0 a
1  1 a
2  2 b
3  3 b
4  4 c
5  5 a

In [3]: df.dtypes
Out[3]:
A      int64
B      category
dtype: object

In [4]: df.B.cat.categories
Out[4]: Index(['c', 'a', 'b'], dtype='object')
```

setting the index, will create create a `CategoricalIndex`

```
In [5]: df2 = df.set_index('B')
```

```
In [6]: df2.index
```

```
Out[6]: CategoricalIndex(['a', 'a', 'b', 'b', 'c', 'a'], categories=['c', 'a', 'b'],
↳ordered=False, name='B', dtype='category')
```

indexing with `__getitem__/.iloc/.loc/.ix` works similarly to an `Index` with duplicates. The indexers **MUST** be in the category or the operation will raise.

```
In [7]: df2.loc['a']
```

```
Out[7]:
```

```
  A
B
a  0
a  1
a  5
```

and preserves the `CategoricalIndex`

```
In [8]: df2.loc['a'].index
```

```
Out[8]: CategoricalIndex(['a', 'a', 'a'], categories=['c', 'a', 'b'], ordered=False,
↳name='B', dtype='category')
```

sorting will order by the order of the categories

```
In [9]: df2.sort_index()
```

```
Out[9]:
```

```
  A
B
c  4
a  0
a  1
a  5
b  2
b  3
```

groupby operations on the index will preserve the index nature as well

```
In [10]: df2.groupby(level=0).sum()
```

```
Out[10]:
```

```
  A
B
c  4
a  6
b  5
```

```
In [11]: df2.groupby(level=0).sum().index
```

```
Out[11]: CategoricalIndex(['c', 'a', 'b'], categories=['c', 'a', 'b'], ordered=False,
↳name='B', dtype='category')
```

reindexing operations, will return a resulting index based on the type of the passed indexer, meaning that passing a list will return a plain-old-`Index`; indexing with a `Categorical` will return a `CategoricalIndex`, indexed according to the categories of the PASSED `Categorical` dtype. This allows one to arbitrarily index these even with values NOT in the categories, similarly to how you can reindex ANY pandas index.

```

In [12]: df2.reindex(['a', 'e'])
Out[12]:
      A
B
a  0.0
a  1.0
a  5.0
e   NaN

In [13]: df2.reindex(['a', 'e']).index
Out[13]: pd.Index(['a', 'a', 'a', 'e'], dtype='object', name='B')

In [14]: df2.reindex(pd.Categorical(['a', 'e'], categories=list('abcde')))
Out[14]:
      A
B
a  0.0
a  1.0
a  5.0
e   NaN

In [15]: df2.reindex(pd.Categorical(['a', 'e'], categories=list('abcde'))).index
Out[15]: pd.CategoricalIndex(['a', 'a', 'a', 'e'],
                             categories=['a', 'b', 'c', 'd', 'e'],
                             ordered=False, name='B',
                             dtype='category')

```

See the [documentation](#) for more. ([GH7629](#), [GH10038](#), [GH10039](#))

Sample

Series, DataFrames, and Panels now have a new method: `sample()`. The method accepts a specific number of rows or columns to return, or a fraction of the total number of rows or columns. It also has options for sampling with or without replacement, for passing in a column for weights for non-uniform sampling, and for setting seed values to facilitate replication. ([GH2419](#))

```
In [1]: example_series = pd.Series([0, 1, 2, 3, 4, 5])
```

```
# When no arguments are passed, returns 1
```

```
In [2]: example_series.sample()
```

```
Out[2]:
```

```
4    4
```

```
Length: 1, dtype: int64
```

```
# One may specify either a number of rows:
```

```
In [3]: example_series.sample(n=3)
```

```
Out[3]:
```

```
0    0
```

```
2    2
```

```
1    1
```

```
Length: 3, dtype: int64
```

```
# Or a fraction of the rows:
```

```
In [4]: example_series.sample(frac=0.5)
Out[4]:
0    0
1    1
2    2
Length: 3, dtype: int64

# weights are accepted.
In [5]: example_weights = [0, 0, 0.2, 0.2, 0.2, 0.4]

In [6]: example_series.sample(n=3, weights=example_weights)
Out[6]:
5    5
2    2
3    3
Length: 3, dtype: int64

# weights will also be normalized if they do not sum to one,
# and missing values will be treated as zeros.
In [7]: example_weights2 = [0.5, 0, 0, 0, None, np.nan]

In [8]: example_series.sample(n=1, weights=example_weights2)
Out[8]:
0    0
Length: 1, dtype: int64
```

When applied to a DataFrame, one may pass the name of a column to specify sampling weights when sampling from rows.

```
In [9]: df = pd.DataFrame({'col1': [9, 8, 7, 6],
...:                      'weight_column': [0.5, 0.4, 0.1, 0]})
...:

In [10]: df.sample(n=3, weights='weight_column')
Out[10]:
   col1  weight_column
0     9             0.5
1     8             0.4
2     7             0.1

[3 rows x 2 columns]
```

String methods enhancements

Continuing from v0.16.0, the following enhancements make string operations easier and more consistent with standard python string operations.

- Added StringMethods (`.str` accessor) to Index (GH9068)

The `.str` accessor is now available for both Series and Index.

```
In [11]: idx = pd.Index([' jack', 'jill ', ' jesse ', 'frank'])
```

(continues on next page)

(continued from previous page)

```
In [12]: idx.str.strip()
Out[12]: Index(['jack', 'jill', 'jesse', 'frank'], dtype='object')
```

One special case for the `.str` accessor on `Index` is that if a string method returns `bool`, the `.str` accessor will return a `np.array` instead of a boolean `Index` (GH8875). This enables the following expression to work naturally:

```
In [13]: idx = pd.Index(['a1', 'a2', 'b1', 'b2'])
```

```
In [14]: s = pd.Series(range(4), index=idx)
```

```
In [15]: s
```

```
Out[15]:
```

```
a1    0
```

```
a2    1
```

```
b1    2
```

```
b2    3
```

```
Length: 4, dtype: int64
```

```
In [16]: idx.str.startswith('a')
```

```
Out[16]: array([ True,  True, False, False])
```

```
In [17]: s[s.index.str.startswith('a')]
```

```
Out[17]:
```

```
a1    0
```

```
a2    1
```

```
Length: 2, dtype: int64
```

- The following new methods are accessible via `.str` accessor to apply the function to each values. (GH9766, GH9773, GH10031, GH10045, GH10052)

		Methods		
<code>capitalize()</code>	<code>swapcase()</code>	<code>normalize()</code>	<code>partition()</code>	<code>rpartition()</code>
<code>index()</code>	<code>rindex()</code>	<code>translate()</code>		

- `split` now takes `expand` keyword to specify whether to expand dimensionality. `return_type` is deprecated. (GH9847)

```
In [18]: s = pd.Series(['a,b', 'a,c', 'b,c'])
```

```
# return Series
```

```
In [19]: s.str.split(',')
```

```
Out[19]:
```

```
0    [a, b]
```

```
1    [a, c]
```

```
2    [b, c]
```

```
Length: 3, dtype: object
```

```
# return DataFrame
```

```
In [20]: s.str.split(',', expand=True)
```

```
Out[20]:
```

```
   0  1
```

```
0  a  b
```

```
1  a  c
```

```

2  b  c

[3 rows x 2 columns]

In [21]: idx = pd.Index(['a,b', 'a,c', 'b,c'])

# return Index
In [22]: idx.str.split(',')
Out[22]: Index([[ 'a', 'b'], [ 'a', 'c'], [ 'b', 'c']], dtype='object')

# return MultiIndex
In [23]: idx.str.split(',', expand=True)
Out[23]:
MultiIndex([('a', 'b'),
            ('a', 'c'),
            ('b', 'c')],
           )

```

- Improved `extract` and `get_dummies` methods for `Index.str` (GH9980)

Other enhancements

- `BusinessHour` offset is now supported, which represents business hours starting from 09:00 - 17:00 on `BusinessDay` by default. See *Here* for details. (GH7905)

```

In [24]: pd.Timestamp('2014-08-01 09:00') + pd.tseries.offsets.BusinessHour()
Out[24]: Timestamp('2014-08-01 10:00:00')

```

```

In [25]: pd.Timestamp('2014-08-01 07:00') + pd.tseries.offsets.BusinessHour()
Out[25]: Timestamp('2014-08-01 10:00:00')

```

```

In [26]: pd.Timestamp('2014-08-01 16:30') + pd.tseries.offsets.BusinessHour()
Out[26]: Timestamp('2014-08-04 09:30:00')

```

- `DataFrame.diff` now takes an `axis` parameter that determines the direction of differencing (GH9727)
- Allow `clip`, `clip_lower`, and `clip_upper` to accept array-like arguments as thresholds (This is a regression from 0.11.0). These methods now have an `axis` parameter which determines how the Series or DataFrame will be aligned with the threshold(s). (GH6966)
- `DataFrame.mask()` and `Series.mask()` now support same keywords as `where` (GH8801)
- `drop` function can now accept `errors` keyword to suppress `ValueError` raised when any of label does not exist in the target data. (GH6736)

```

In [27]: df = pd.DataFrame(np.random.randn(3, 3), columns=['A', 'B', 'C'])

```

```

In [28]: df.drop(['A', 'X'], axis=1, errors='ignore')

```

```

Out[28]:
           B           C
0  0.937250  0.077640
1 -2.190412  0.936805
2 -0.003335  0.611459

```

```

[3 rows x 2 columns]

```

- Add support for separating years and quarters using dashes, for example 2014-Q1. (GH9688)
- Allow conversion of values with dtype `datetime64` or `timedelta64` to strings using `astype(str)` (GH9757)
- `get_dummies` function now accepts `sparse` keyword. If set to `True`, the return `DataFrame` is sparse, e.g. `SparseDataFrame`. (GH8823)
- `Period` now accepts `datetime64` as value input. (GH9054)
- Allow `timedelta` string conversion when leading zero is missing from time definition, ie `0:00:00` vs `00:00:00`. (GH9570)
- Allow `Panel.shift` with `axis='items'` (GH9890)
- Trying to write an excel file now raises `NotImplementedError` if the `DataFrame` has a `MultiIndex` instead of writing a broken Excel file. (GH9794)
- Allow `Categorical.add_categories` to accept `Series` or `np.array`. (GH9927)
- Add/delete `str/dt/cat` accessors dynamically from `__dir__`. (GH9910)
- Add `normalize` as a `dt` accessor method. (GH10047)
- `DataFrame` and `Series` now have `_constructor_expanddim` property as overridable constructor for one higher dimensionality data. This should be used only when it is really needed, see *here*
- `pd.lib.infer_dtype` now returns `'bytes'` in Python 3 where appropriate. (GH10032)

API changes

- When passing in an `ax` to `df.plot(..., ax=ax)`, the `sharex` kwarg will now default to `False`. The result is that the visibility of `xlabels` and `xticklabels` will not anymore be changed. You have to do that by yourself for the right axes in your figure or set `sharex=True` explicitly (but this changes the visible for all axes in the figure, not only the one which is passed in!). If pandas creates the subplots itself (e.g. no passed in `ax` kwarg), then the default is still `sharex=True` and the visibility changes are applied.
- `assign()` now inserts new columns in alphabetical order. Previously the order was arbitrary. (GH9777)
- By default, `read_csv` and `read_table` will now try to infer the compression type based on the file extension. Set `compression=None` to restore the previous behavior (no decompression). (GH9770)

Deprecations

- `Series.str.split`'s `return_type` keyword was removed in favor of `expand` (GH9847)

Index representation

The string representation of `Index` and its sub-classes have now been unified. These will show a single-line display if there are few values; a wrapped multi-line display for a lot of values (but less than `display.max_seq_items`; if lots of items ($> \text{display.max_seq_items}$) will show a truncated display (the head and tail of the data). The formatting for `MultiIndex` is unchanged (a multi-line wrapped display). The display width responds to the option `display.max_seq_items`, which is defaulted to 100. (GH6482)

Previous behavior

```

In [2]: pd.Index(range(4), name='foo')
Out[2]: Int64Index([0, 1, 2, 3], dtype='int64')

In [3]: pd.Index(range(104), name='foo')
Out[3]: Int64Index([0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19,
↳ 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40,
↳ 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62,
↳ 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83,
↳ 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, ...], dtype='int64')

In [4]: pd.date_range('20130101', periods=4, name='foo', tz='US/Eastern')
Out[4]:
<class 'pandas.tseries.index.DatetimeIndex'>
[2013-01-01 00:00:00-05:00, ..., 2013-01-04 00:00:00-05:00]
Length: 4, Freq: D, Timezone: US/Eastern

In [5]: pd.date_range('20130101', periods=104, name='foo', tz='US/Eastern')
Out[5]:
<class 'pandas.tseries.index.DatetimeIndex'>

              '2013-04-11 00:00:00-04:00', '2013-04-12 00:00:00-04:00',
              '2013-04-13 00:00:00-04:00', '2013-04-14 00:00:00-04:00'],
              dtype='datetime64[ns, US/Eastern]', name='foo', length=104, freq='D')

```

Performance improvements

- Improved csv write performance with mixed dtypes, including datetimes by up to 5x (GH9940)
- Improved csv write performance generally by 2x (GH9940)
- Improved the performance of `pd.lib.max_len_string_array` by 5-7x (GH10024)

Bug fixes

- Bug where labels did not appear properly in the legend of `DataFrame.plot()`, passing `label=` arguments works, and Series indices are no longer mutated. (GH9542)
- Bug in json serialization causing a segfault when a frame had zero length. (GH9805)
- Bug in `read_csv` where missing trailing delimiters would cause segfault. (GH5664)
- Bug in retaining index name on appending (GH9862)
- Bug in `scatter_matrix` draws unexpected axis ticklabels (GH5662)
- Fixed bug in `StataWriter` resulting in changes to input `DataFrame` upon save (GH9795).
- Bug in `transform` causing length mismatch when null entries were present and a fast aggregator was being used (GH9697)
- Bug in `equals` causing false negatives when block order differed (GH9330)
- Bug in grouping with multiple `pd.Grouper` where one is non-time based (GH10063)
- Bug in `read_sql_table` error when reading postgres table with timezone (GH7139)
- Bug in `DataFrame` slicing may not retain metadata (GH9776)
- Bug where `TimedeltaIndex` were not properly serialized in fixed `HDFStore` (GH9635)
- Bug with `TimedeltaIndex` constructor ignoring `name` when given another `TimedeltaIndex` as data (GH10025).
- Bug in `DataFrameFormatter._get_formatted_index` with not applying `max_colwidth` to the `DataFrame` index (GH7856)
- Bug in `.loc` with a read-only ndarray data source (GH10043)
- Bug in `groupby.apply()` that would raise if a passed user defined function either returned only `None` (for all input). (GH9685)
- Always use temporary files in pytables tests (GH9992)
- Bug in plotting continuously using `secondary_y` may not show legend properly. (GH9610, GH9779)
- Bug in `DataFrame.plot(kind="hist")` results in `TypeError` when `DataFrame` contains non-numeric columns (GH9853)
- Bug where repeated plotting of `DataFrame` with a `DatetimeIndex` may raise `TypeError` (GH9852)
- Bug in `setup.py` that would allow an incompat cython version to build (GH9827)
- Bug in plotting `secondary_y` incorrectly attaches `right_ax` property to secondary axes specifying itself recursively. (GH9861)
- Bug in `Series.quantile` on empty Series of type `Datetime` or `Timedelta` (GH9675)
- Bug in `where` causing incorrect results when upcasting was required (GH9731)
- Bug in `FloatArrayFormatter` where decision boundary for displaying “small” floats in decimal format is off by one order of magnitude for a given `display.precision` (GH9764)
- Fixed bug where `DataFrame.plot()` raised an error when both `color` and `style` keywords were passed and there was no color symbol in the style strings (GH9671)
- Not showing a `DeprecationWarning` on combining list-likes with an `Index` (GH10083)
- Bug in `read_csv` and `read_table` when using `skip_rows` parameter if blank lines are present. (GH9832)

- Bug in `read_csv()` interprets `index_col=True` as 1 (GH9798)
- Bug in index equality comparisons using `==` failing on `Index/MultiIndex` type incompatibility (GH9785)
- Bug in which `SparseDataFrame` could not take `nan` as a column name (GH8822)
- Bug in `to_msgpack` and `read_msgpack` zlib and blosc compression support (GH9783)
- Bug `GroupBy.size` doesn't attach index name properly if grouped by `TimeGrouper` (GH9925)
- Bug causing an exception in slice assignments because `length_of_indexer` returns wrong results (GH9995)
- Bug in csv parser causing lines with initial white space plus one non-space character to be skipped. (GH9710)
- Bug in C csv parser causing spurious NaNs when data started with newline followed by white space. (GH10022)
- Bug causing elements with a null group to spill into the final group when grouping by a `Categorical` (GH9603)
- Bug where `.iloc` and `.loc` behavior is not consistent on empty dataframes (GH9964)
- Bug in invalid attribute access on a `TimedeltaIndex` incorrectly raised `ValueError` instead of `AttributeError` (GH9680)
- Bug in unequal comparisons between categorical data and a scalar, which was not in the categories (e.g. `Series(Categorical(list("abc")), ordered=True) > "d"`. This returned `False` for all elements, but now raises a `TypeError`. Equality comparisons also now return `False` for `==` and `True` for `!=`. (GH9848)
- Bug in `DataFrame` `__setitem__` when right hand side is a dictionary (GH9874)
- Bug in `where` when `dtype` is `datetime64/timedelta64`, but `dtype` of other is not (GH9804)
- Bug in `MultiIndex.sortlevel()` results in unicode level name breaks (GH9856)
- Bug in which `groupby.transform` incorrectly enforced output dtypes to match input dtypes. (GH9807)
- Bug in `DataFrame` constructor when `columns` parameter is set, and `data` is an empty list (GH9939)
- Bug in bar plot with `log=True` raises `TypeError` if all values are less than 1 (GH9905)
- Bug in horizontal bar plot ignores `log=True` (GH9905)
- Bug in PyTables queries that did not return proper results using the index (GH8265, GH9676)
- Bug where dividing a dataframe containing values of type `Decimal` by another `Decimal` would raise. (GH9787)
- Bug where using `DataFrames` `asfreq` would remove the name of the index. (GH9885)
- Bug causing extra index point when `resample` BM/BQ (GH9756)
- Changed caching in `AbstractHolidayCalendar` to be at the instance level rather than at the class level as the latter can result in unexpected behaviour. (GH9552)
- Fixed latex output for `MultiIndexed` dataframes (GH9778)
- Bug causing an exception when setting an empty range using `DataFrame.loc` (GH9596)
- Bug in hiding ticklabels with subplots and shared axes when adding a new plot to an existing grid of axes (GH9158)
- Bug in `transform` and `filter` when grouping on a categorical variable (GH9921)
- Bug in `transform` when groups are equal in number and `dtype` to the input index (GH9700)

- Google BigQuery connector now imports dependencies on a per-method basis.(GH9713)
- Updated BigQuery connector to no longer use deprecated `oauth2client.tools.run()` (GH8327)
- Bug in subclassed `DataFrame`. It may not return the correct class, when slicing or subsetting it. (GH9632)
- Bug in `.median()` where non-float null values are not handled correctly (GH10040)
- Bug in `Series.fillna()` where it raises if a numerically convertible string is given (GH10092)

8.10.3 v0.16.0 (March 22, 2015)

{{ header }}

This is a major release from 0.15.2 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

- `DataFrame.assign` method, see [here](#)
- `Series.to_coo/from_coo` methods to interact with `scipy.sparse`, see [here](#)
- Backwards incompatible change to `Timedelta` to conform the `.seconds` attribute with `datetime.timedelta`, see [here](#)
- Changes to the `.loc` slicing API to conform with the behavior of `.ix` see [here](#)
- Changes to the default for ordering in the `Categorical` constructor, see [here](#)
- Enhancement to the `.str` accessor to make string operations easier, see [here](#)
- The `pandas.tools.rplot`, `pandas.sandbox.qtpandas` and `pandas.rpy` modules are deprecated. We refer users to external packages like `seaborn`, `pandas-qt` and `rpy2` for similar or equivalent functionality, see [here](#)

Check the *API Changes* and *deprecations* before updating.

What's new in v0.16.0

- *New features*
 - *DataFrame assign*
 - *Interaction with scipy.sparse*
 - *String methods enhancements*
 - *Other enhancements*
- *Backwards incompatible API changes*
 - *Changes in Timedelta*
 - *Indexing changes*
 - *Categorical changes*
 - *Other API changes*
 - *Deprecations*
 - *Removal of prior version deprecations/changes*
- *Performance improvements*
- *Bug fixes*
- *Contributors*

New features

DataFrame assign

Inspired by `dplyr`'s `mutate` verb, `DataFrame` has a new `assign()` method. The function signature for `assign` is simply `**kwargs`. The keys are the column names for the new fields, and the values are either a value to be inserted (for example, a `Series` or NumPy array), or a function of one argument to be called on the `DataFrame`. The new values are inserted, and the entire `DataFrame` (with all original and new columns) is returned.

```
In [1]: iris = pd.read_csv('data/iris.data')
```

```
In [2]: iris.head()
```

```
Out[2]:
```

	SepalLength	SepalWidth	PetalLength	PetalWidth	Name
0	5.1	3.5	1.4	0.2	Iris-setosa
1	4.9	3.0	1.4	0.2	Iris-setosa
2	4.7	3.2	1.3	0.2	Iris-setosa
3	4.6	3.1	1.5	0.2	Iris-setosa
4	5.0	3.6	1.4	0.2	Iris-setosa

```
[5 rows x 5 columns]
```

```
In [3]: iris.assign(sepal_ratio=iris['SepalWidth'] / iris['SepalLength']).head()
```

```
Out[3]:
```

	SepalLength	SepalWidth	PetalLength	PetalWidth	Name	sepal_ratio
0	5.1	3.5	1.4	0.2	Iris-setosa	0.686275
1	4.9	3.0	1.4	0.2	Iris-setosa	0.612245
2	4.7	3.2	1.3	0.2	Iris-setosa	0.680851
3	4.6	3.1	1.5	0.2	Iris-setosa	0.673913
4	5.0	3.6	1.4	0.2	Iris-setosa	0.720000

```
[5 rows x 6 columns]
```

Above was an example of inserting a precomputed value. We can also pass in a function to be evaluated.

```
In [4]: iris.assign(sepal_ratio=lambda x: (x['SepalWidth']
...:                                     / x['SepalLength'])).head()
```

```
Out[4]:
```

	SepalLength	SepalWidth	PetalLength	PetalWidth	Name	sepal_ratio
0	5.1	3.5	1.4	0.2	Iris-setosa	0.686275
1	4.9	3.0	1.4	0.2	Iris-setosa	0.612245
2	4.7	3.2	1.3	0.2	Iris-setosa	0.680851
3	4.6	3.1	1.5	0.2	Iris-setosa	0.673913
4	5.0	3.6	1.4	0.2	Iris-setosa	0.720000

```
[5 rows x 6 columns]
```

The power of `assign` comes when used in chains of operations. For example, we can limit the DataFrame to just those with a Sepal Length greater than 5, calculate the ratio, and plot

```
In [5]: iris = pd.read_csv('data/iris.data')
```

```
In [6]: (iris.query('SepalLength > 5')
...:      .assign(SepalRatio=lambda x: x.SepalWidth / x.SepalLength,
...:              PetalRatio=lambda x: x.PetalWidth / x.PetalLength)
...:      .plot(kind='scatter', x='SepalRatio', y='PetalRatio'))
```

```
Out[6]: <matplotlib.axes._subplots.AxesSubplot at 0x14e40a850>
```

See the [documentation](#) for more. (GH9229)

Interaction with `scipy.sparse`

Added `SparseSeries.to_coo()` and `SparseSeries.from_coo()` methods (GH8048) for converting to and from `scipy.sparse.coo_matrix` instances (see [here](#)). For example, given a `SparseSeries` with `MultiIndex` we can convert to a `scipy.sparse.coo_matrix` by specifying the row and column labels as index levels:

```
In [7]: s = pd.Series([3.0, np.nan, 1.0, 3.0, np.nan, np.nan])
```

```
In [8]: s.index = pd.MultiIndex.from_tuples([(1, 2, 'a', 0),
...:                                       (1, 2, 'a', 1),
...:                                       (1, 1, 'b', 0),
...:                                       (1, 1, 'b', 1),
...:                                       (2, 1, 'b', 0),
...:                                       (2, 1, 'b', 1)],
...:                                       names=['A', 'B', 'C', 'D'])
```

```
In [9]: s
```

```
Out[9]:
```

A	B	C	D	
1	2	a	0	3.0
			1	NaN
	1	b	0	1.0
			1	3.0
2	1	b	0	NaN
			1	NaN

```
Length: 6, dtype: float64
```

```
# SparseSeries
```

```
In [10]: ss = s.to_sparse()
```

```
In [11]: ss
```

```
Out[11]:
```

A	B	C	D	
1	2	a	0	3.0
			1	NaN
	1	b	0	1.0
			1	3.0
2	1	b	0	NaN
			1	NaN

```
Length: 6, dtype: Sparse[float64, nan]
```

```
BlockIndex
```

```
Block locations: array([0, 2], dtype=int32)
```

```
Block lengths: array([1, 2], dtype=int32)
```

```
In [12]: A, rows, columns = ss.to_coo(row_levels=['A', 'B'],
....:                                column_levels=['C', 'D'],
....:                                sort_labels=False)
....:
```

```
In [13]: A
```

```
Out[13]:
```

```
<3x4 sparse matrix of type '<class 'numpy.float64''>'
with 3 stored elements in COOrdinate format>
```

```
In [14]: A.todense()
```

```
Out[14]:
```

```
matrix([[3., 0., 0., 0.],
        [0., 0., 1., 3.],
        [0., 0., 0., 0.]])
```

```
In [15]: rows
```

```
Out[15]: [(1, 2), (1, 1), (2, 1)]
```

```
In [16]: columns
```

```
Out[16]: [('a', 0), ('a', 1), ('b', 0), ('b', 1)]
```

The `from_coo` method is a convenience method for creating a `SparseSeries` from a `scipy.sparse.coo_matrix`:

```
In [17]: from scipy import sparse
```

```
In [18]: A = sparse.coo_matrix(([3.0, 1.0, 2.0], ([1, 0, 0], [0, 2, 3])),
....:                          shape=(3, 4))
....:
```

```
In [19]: A
```

```
Out[19]:
```

```
<3x4 sparse matrix of type '<class 'numpy.float64''>'
with 3 stored elements in COOrdinate format>
```

```
In [20]: A.todense()
```

```
Out[20]:
```

```
matrix([[0., 0., 1., 2.],
        [3., 0., 0., 0.],
        [0., 0., 0., 0.]])
```

```
In [21]: ss = pd.SparseSeries.from_coo(A)
```

```
In [22]: ss
```

```
Out[22]:
```

```
0 2 1.0
```

```
3 2.0
```

```
1 0 3.0
```

```
Length: 3, dtype: Sparse[float64, nan]
```

```
BlockIndex
```

```
Block locations: array([0], dtype=int32)
```

```
Block lengths: array([3], dtype=int32)
```

String methods enhancements

- Following new methods are accessible via `.str` accessor to apply the function to each values. This is intended to make it more consistent with standard methods on strings. (GH9282, GH9352, GH9386, GH9387, GH9439)

		Methods		
<code>isalnum()</code>	<code>isalpha()</code>	<code>isdigit()</code>	<code>isdigit()</code>	<code>isspace()</code>
<code>islower()</code>	<code>isupper()</code>	<code>istitle()</code>	<code>isnumeric()</code>	<code>isdecimal()</code>
<code>find()</code>	<code>rfind()</code>	<code>ljust()</code>	<code>rjust()</code>	<code>zfill()</code>

```
In [23]: s = pd.Series(['abcd', '3456', 'EFGH'])
```

```
In [24]: s.str.isalpha()
```

```
Out[24]:
```

```
0    True
```

```
1   False
```

```
2    True
```

```
Length: 3, dtype: bool
```

```
In [25]: s.str.find('ab')
```

```
Out[25]:
```

```
0     0
```

```
1    -1
```

```
2    -1
```

```
Length: 3, dtype: int64
```

- `Series.str.pad()` and `Series.str.center()` now accept `fillchar` option to specify filling character (GH9352)

```
In [26]: s = pd.Series(['12', '300', '25'])
```

```
In [27]: s.str.pad(5, fillchar='_')
```

```
Out[27]:
```

```
0    ___12
```

```
1    __300
```

```
2    ___25
```

```
Length: 3, dtype: object
```

- Added `Series.str.slice_replace()`, which previously raised `NotImplementedError` (GH8888)

```
In [28]: s = pd.Series(['ABCD', 'EFGH', 'IJK'])
```

```
In [29]: s.str.slice_replace(1, 3, 'X')
```

```
Out[29]:
```

```
0    AXD
```

```
1    EXH
```

```
2     IX
```

```
Length: 3, dtype: object
```

```
# replaced with empty char
In [30]: s.str.slice_replace(0, 1)
Out[30]:
0    BCD
1    FGH
2     JK
Length: 3, dtype: object
```

Other enhancements

- Reindex now supports `method='nearest'` for frames or series with a monotonic increasing or decreasing index (GH9258):

```
In [31]: df = pd.DataFrame({'x': range(5)})
In [32]: df.reindex([0.2, 1.8, 3.5], method='nearest')
Out[32]:
      x
0.2  0
1.8  2
3.5  4

[3 rows x 1 columns]
```

This method is also exposed by the lower level `Index.get_indexer` and `Index.get_loc` methods.

- The `read_excel()` function's `sheetname` argument now accepts a list and `None`, to get multiple or all sheets respectively. If more than one sheet is specified, a dictionary is returned. (GH9450)

```
# Returns the 1st and 4th sheet, as a dictionary of DataFrames.
pd.read_excel('path_to_file.xls', sheetname=['Sheet1', 3])
```

- Allow Stata files to be read incrementally with an iterator; support for long strings in Stata files. See the docs [here](#) (GH9493).
- Paths beginning with `~` will now be expanded to begin with the user's home directory (GH9066)
- Added time interval selection in `get_data_yahoo` (GH9071)
- Added `Timestamp.to_datetime64()` to complement `Timedelta.to_timedelta64()` (GH9255)
- `tseries.frequencies.to_offset()` now accepts `Timedelta` as input (GH9064)
- Lag parameter was added to the autocorrelation method of `Series`, defaults to lag-1 autocorrelation (GH9192)
- `Timedelta` will now accept `nanoseconds` keyword in constructor (GH9273)
- SQL code now safely escapes table and column names (GH8986)
- Added auto-complete for `Series.str.<tab>`, `Series.dt.<tab>` and `Series.cat.<tab>` (GH9322)
- `Index.get_indexer` now supports `method='pad'` and `method='backfill'` even for any target array, not just monotonic targets. These methods also work for monotonic decreasing as well as monotonic increasing indexes (GH9258).
- `Index.asof` now works on all index types (GH9258).

- A `verbose` argument has been augmented in `io.read_excel()`, defaults to `False`. Set to `True` to print sheet names as they are parsed. (GH9450)
- Added `days_in_month` (compatibility alias `daysinmonth`) property to `Timestamp`, `DatetimeIndex`, `Period`, `PeriodIndex`, and `Series.dt` (GH9572)
- Added `decimal` option in `to_csv` to provide formatting for non-`'` decimal separators (GH781)
- Added `normalize` option for `Timestamp` to normalized to midnight (GH8794)
- Added example for `DataFrame` import to R using HDF5 file and `rhdf5` library. See the [documentation](#) for more (GH9636).

Backwards incompatible API changes

Changes in Timedelta

In v0.15.0 a new scalar type `Timedelta` was introduced, that is a sub-class of `datetime.timedelta`. Mentioned [here](#) was a notice of an API change w.r.t. the `.seconds` accessor. The intent was to provide a user-friendly set of accessors that give the ‘natural’ value for that unit, e.g. if you had a `Timedelta('1 day, 10:11:12')`, then `.seconds` would return 12. However, this is at odds with the definition of `datetime.timedelta`, which defines `.seconds` as `10 * 3600 + 11 * 60 + 12 == 36672`.

So in v0.16.0, we are restoring the API to match that of `datetime.timedelta`. Further, the component values are still available through the `.components` accessor. This affects the `.seconds` and `.microseconds` accessors, and removes the `.hours`, `.minutes`, `.milliseconds` accessors. These changes affect `TimedeltaIndex` and the `Series.dt` accessor as well. (GH9185, GH9139)

Previous behavior

```
In [2]: t = pd.Timedelta('1 day, 10:11:12.100123')
In [3]: t.days
Out[3]: 1
In [4]: t.seconds
Out[4]: 12
In [5]: t.microseconds
Out[5]: 123
```

New behavior

```
In [33]: t = pd.Timedelta('1 day, 10:11:12.100123')
In [34]: t.days
Out[34]: 1
In [35]: t.seconds
Out[35]: 36672
In [36]: t.microseconds
Out[36]: 100123
```

Using `.components` allows the full component access

```
In [37]: t.components
```

```
Out[37]: Components(days=1, hours=10, minutes=11, seconds=12, milliseconds=100,
↳microseconds=123, nanoseconds=0)
```

```
In [38]: t.components.seconds
Out[38]: 12
```

Indexing changes

The behavior of a small sub-set of edge cases for using `.loc` have changed ([GH8613](#)). Furthermore we have improved the content of the error messages that are raised:

- Slicing with `.loc` where the start and/or stop bound is not found in the index is now allowed; this previously would raise a `KeyError`. This makes the behavior the same as `.ix` in this case. This change is only for slicing, not when indexing with a single label.

```
In [39]: df = pd.DataFrame(np.random.randn(5, 4),
.....:                      columns=list('ABCD'),
.....:                      index=pd.date_range('20130101', periods=5))
.....:

In [40]: df
Out[40]:
```

	A	B	C	D
2013-01-01	0.196775	-0.858708	0.182296	0.168542
2013-01-02	-1.295414	0.781481	-0.028292	0.485222
2013-01-03	-1.024658	0.275110	-0.007452	0.044767
2013-01-04	0.827741	-1.298262	-0.338087	0.488600
2013-01-05	-1.939301	-0.344219	0.386524	2.056936

```

[5 rows x 4 columns]

In [41]: s = pd.Series(range(5), [-2, -1, 1, 2, 3])

In [42]: s
Out[42]:
-2    0
-1    1
 1    2
 2    3
 3    4
Length: 5, dtype: int64
```

Previous behavior

```
In [4]: df.loc['2013-01-02':'2013-01-10']
KeyError: 'stop bound [2013-01-10] is not in the [index]'

In [6]: s.loc[-10:3]
KeyError: 'start bound [-10] is not in the [index]'
```

New behavior

```
In [43]: df.loc['2013-01-02':'2013-01-10']
Out[43]:
```

```

           A         B         C         D
2013-01-02 -1.295414  0.781481 -0.028292  0.485222
2013-01-03 -1.024658  0.275110 -0.007452  0.044767
2013-01-04  0.827741 -1.298262 -0.338087  0.488600
2013-01-05 -1.939301 -0.344219  0.386524  2.056936

```

```
[4 rows x 4 columns]
```

```
In [44]: s.loc[-10:3]
```

```
Out[44]:
```

```

-2    0
-1    1
 1    2
 2    3
 3    4

```

```
Length: 5, dtype: int64
```

- Allow slicing with float-like values on an integer index for `.ix`. Previously this was only enabled for `.loc`:

Previous behavior

```
In [8]: s.ix[-1.0:2]
```

```

TypeError: the slice start value [-1.0] is not a proper indexer for this index type
↳ (Int64Index)

```

New behavior

```
In [2]: s.ix[-1.0:2]
```

```
Out[2]:
```

```

-1    1
 1    2
 2    3

```

```
dtype: int64
```

- Provide a useful exception for indexing with an invalid type for that index when using `.loc`. For example trying to use `.loc` on an index of type `DatetimeIndex` or `PeriodIndex` or `TimedeltaIndex`, with an integer (or a float).

Previous behavior

```
In [4]: df.loc[2:3]
```

```
KeyError: 'start bound [2] is not the [index]'
```

New behavior

```
In [4]: df.loc[2:3]
```

```

TypeError: Cannot do slice indexing on <class 'pandas.tseries.index.DatetimeIndex'>
↳ with <type 'int'> keys

```

Categorical changes

In prior versions, `Categoricals` that had an unspecified ordering (meaning no `ordered` keyword was passed) were defaulted as `ordered` `Categoricals`. Going forward, the `ordered` keyword in the `Categorical` constructor will default to `False`. Ordering must now be explicit.

Furthermore, previously you *could* change the `ordered` attribute of a Categorical by just setting the attribute, e.g. `cat.ordered=True`; This is now deprecated and you should use `cat.as_ordered()` or `cat.as_unordered()`. These will by default return a **new** object and not modify the existing object. (GH9347, GH9190)

Previous behavior

```
In [3]: s = pd.Series([0, 1, 2], dtype='category')
```

```
In [4]: s
```

```
Out[4]:
```

```
0    0
```

```

```
In [47]: s.cat.ordered
```

```
Out[47]: False
```

```
In [48]: s = s.cat.as_ordered()
```

```
In [49]: s
```

```
Out[49]:
```

```
0    0
```

```
1    1
```

```
2    2
```

```
Length: 3, dtype: category
```

```
Categories (3, int64): [0 < 1 < 2]
```

```
In [50]: s.cat.ordered
Out[50]: True
```

```
# you can set in the constructor of the Categorical
In [51]: s = pd.Series(pd.Categorical([0, 1, 2], ordered=True))
```

```
In [52]: s
Out[52]:
0    0
1    1
2    2
Length: 3, dtype: category
Categories (3, int64): [0 < 1 < 2]
```

```
In [53]: s.cat.ordered
Out[53]: True
```

For ease of creation of series of categorical data, we have added the ability to pass keywords when calling `.astype()`. These are passed directly to the constructor.

```
In [54]: s = pd.Series(["a", "b", "c", "a"]).astype('category', ordered=True)

In [55]: s
Out[55]:
0    a
1    b
2    c
3    a
dtype: category
Categories (3, object): [a < b < c]

In [56]: s = (pd.Series(["a", "b", "c", "a"])
....:         .astype('category', categories=list('abcdef'), ordered=False))

In [57]: s
Out[57]:
0    a
1    b
2    c
3    a
dtype: category
Categories (6, object): [a, b, c, d, e, f]
```

Other API changes

- `Index.duplicated` now returns `np.array(dtype=bool)` rather than `Index(dtype=object)` containing bool values. (GH8875)
- `DataFrame.to_json` now returns accurate type serialisation for each column for frames of mixed dtype (GH9037)

Previously data was coerced to a common dtype before serialisation, which for example resulted in integers being serialised to floats:

```
In [2]: pd.DataFrame({'i': [1,2], 'f': [3.0, 4.2]}).to_json()
Out[2]: '{"f":{"0":3.0,"1":4.2},"i":{"0":1.0,"1":2.0}}'
```

Now each column is serialised using its correct dtype:

```
In [2]: pd.DataFrame({'i': [1,2], 'f': [3.0, 4.2]}).to_json()
Out[2]: '{"f":{"0":3.0,"1":4.2},"i":{"0":1,"1":2}}'
```

- `DatetimeIndex`, `PeriodIndex` and `TimedeltaIndex.summary` now output the same format. (GH9116)
- `TimedeltaIndex.freqstr` now output the same string format as `DatetimeIndex`. (GH9116)
- Bar and horizontal bar plots no longer add a dashed line along the info axis. The prior style can be achieved with matplotlib's `axhline` or `axvline` methods (GH9088).
- `Series` accessors `.dt`, `.cat` and `.str` now raise `AttributeError` instead of `TypeError` if the series does not contain the appropriate type of data (GH9617). This follows Python's built-in exception hierarchy more closely and ensures that tests like `hasattr(s, 'cat')` are consistent on both Python 2 and 3.
- `Series` now supports bitwise operation for integral types (GH9016). Previously even if the input dtypes were integral, the output dtype was coerced to `bool`.

Previous behavior

```
In [2]: pd.Series([0, 1, 2, 3], list('abcd')) | pd.Series([4, 4, 4, 4], list('abcd
↪'))
Out[2]:
a    True
b    True
c    True
d    True
dtype: bool
```

New behavior. If the input dtypes are integral, the output dtype is also integral and the output values are the result of the bitwise operation.

```
In [2]: pd.Series([0, 1, 2, 3], list('abcd')) | pd.Series([4, 4, 4, 4], list('abcd
↪'))
Out[2]:
a    4
b    5
c    6
d    7
dtype: int64
```

- During division involving a `Series` or `DataFrame`, `0/0` and `0//0` now give `np.nan` instead of `np.inf`. (GH9144, GH8445)

Previous behavior

```
In [2]: p = pd.Series([0, 1])

In [3]: p / 0
Out[3]:
0    inf
```

(continues on next page)

(continued from previous page)

```

1    inf
dtype: float64

In [4]: p // 0
Out[4]:
0    inf
1    inf
dtype: float64

```

New behavior

```
In [54]: p = pd.Series([0, 1])
```

```
In [55]: p / 0
Out[55]:
0    NaN
1    inf
Length: 2, dtype: float64
```

```
In [56]: p // 0
Out[56]:
0    NaN
1    inf
Length: 2, dtype: float64
```

- `Series.values_counts` and `Series.describe` for categorical data will now put NaN entries at the end. (GH9443)
- `Series.describe` for categorical data will now give counts and frequencies of 0, not NaN, for unused categories (GH9443)
- Due to a bug fix, looking up a partial string label with `DatetimeIndex.asof` now includes values that match the string, even if they are after the start of the partial string label (GH9258).

Old behavior:

```
In [4]: pd.to_datetime(['2000-01-31', '2000-02-28']).asof('2000-02')
Out[4]: Timestamp('2000-01-31 00:00:00')
```

Fixed behavior:

```
In [57]: pd.to_datetime(['2000-01-31', '2000-02-28']).asof('2000-02')
Out[57]: Timestamp('2000-02-28 00:00:00')
```

To reproduce the old behavior, simply add more precision to the label (e.g., use 2000-02-01 instead of 2000-02).

Deprecations

- The `rplot` trellis plotting interface is deprecated and will be removed in a future version. We refer to external packages like `seaborn` for similar but more refined functionality (GH3445). The documentation includes some examples how to convert your existing code using `rplot` to `seaborn`: [rplot docs](#).
- The `pandas.sandbox.qtpandas` interface is deprecated and will be removed in a future version. We refer users to the external package `pandas-qt`. (GH9615)

- The `pandas.rpy` interface is deprecated and will be removed in a future version. Similar functionality can be accessed through the `rpy2` project ([GH9602](#))
- Adding `DatetimeIndex/PeriodIndex` to another `DatetimeIndex/PeriodIndex` is being deprecated as a set-operation. This will be changed to a `TypeError` in a future version. `.union()` should be used for the union set operation. ([GH9094](#))
- Subtracting `DatetimeIndex/PeriodIndex` from another `DatetimeIndex/PeriodIndex` is being deprecated as a set-operation. This will be changed to an actual numeric subtraction yielding a `TimeDeltaIndex` in a future version. `.difference()` should be used for the differencing set operation. ([GH9094](#))

Removal of prior version deprecations/changes

- `DataFrame.pivot_table` and `crosstab`'s `rows` and `cols` keyword arguments were removed in favor of `index` and `columns` ([GH6581](#))
- `DataFrame.to_excel` and `DataFrame.to_csv` `cols` keyword argument was removed in favor of `columns` ([GH6581](#))
- Removed `convert_dummies` in favor of `get_dummies` ([GH6581](#))
- Removed `value_range` in favor of `describe` ([GH6581](#))

Performance improvements

- Fixed a performance regression for `.loc` indexing with an array or list-like ([GH9126](#)).
- `DataFrame.to_json` 30x performance improvement for mixed dtype frames. ([GH9037](#))
- Performance improvements in `MultiIndex.duplicated` by working with labels instead of values ([GH9125](#))
- Improved the speed of `nunique` by calling `unique` instead of `value_counts` ([GH9129](#), [GH7771](#))
- Performance improvement of up to 10x in `DataFrame.count` and `DataFrame.dropna` by taking advantage of homogeneous/heterogeneous dtypes appropriately ([GH9136](#))
- Performance improvement of up to 20x in `DataFrame.count` when using a `MultiIndex` and the `level` keyword argument ([GH9163](#))
- Performance and memory usage improvements in `merge` when key space exceeds `int64` bounds ([GH9151](#))
- Performance improvements in multi-key `groupby` ([GH9429](#))
- Performance improvements in `MultiIndex.sortlevel` ([GH9445](#))
- Performance and memory usage improvements in `DataFrame.duplicated` ([GH9398](#))
- Cythonized `Period` ([GH9440](#))
- Decreased memory usage on `to_hdf` ([GH9648](#))

Bug fixes

- Changed `.to_html` to remove leading/trailing spaces in table body ([GH4987](#))
- Fixed issue using `read_csv` on s3 with Python 3 ([GH9452](#))

- Fixed compatibility issue in `DatetimeIndex` affecting architectures where `numpy.int_` defaults to `numpy.int32` (GH8943)
- Bug in Panel indexing with an object-like (GH9140)
- Bug in the returned `Series.dt.components` index was reset to the default index (GH9247)
- Bug in `Categorical.__getitem__/_setitem__` with listlike input getting incorrect results from indexer coercion (GH9469)
- Bug in partial setting with a `DatetimeIndex` (GH9478)
- Bug in `groupby` for integer and `datetime64` columns when applying an aggregator that caused the value to be changed when the number was sufficiently large (GH9311, GH6620)
- Fixed bug in `to_sql` when mapping a `Timestamp` object column (datetime column with timezone info) to the appropriate sqlalchemy type (GH9085).
- Fixed bug in `to_sql dtype` argument not accepting an instantiated SQLAlchemy type (GH9083).
- Bug in `.loc` partial setting with a `np.datetime64` (GH9516)
- Incorrect dtypes inferred on datetimelike looking `Series` & on `.xs` slices (GH9477)
- Items in `Categorical.unique()` (and `s.unique()` if `s` is of dtype `category`) now appear in the order in which they are originally found, not in sorted order (GH9331). This is now consistent with the behavior for other dtypes in pandas.
- Fixed bug on big endian platforms which produced incorrect results in `StataReader` (GH8688).
- Bug in `MultiIndex.has_duplicates` when having many levels causes an indexer overflow (GH9075, GH5873)
- Bug in `pivot` and `unstack` where `nan` values would break index alignment (GH4862, GH7401, GH7403, GH7405, GH7466, GH9497)
- Bug in left `join` on `MultiIndex` with `sort=True` or null values (GH9210).
- Bug in `MultiIndex` where inserting new keys would fail (GH9250).
- Bug in `groupby` when key space exceeds `int64` bounds (GH9096).
- Bug in `unstack` with `TimedeltaIndex` or `DatetimeIndex` and nulls (GH9491).
- Bug in `rank` where comparing floats with tolerance will cause inconsistent behaviour (GH8365).
- Fixed character encoding bug in `read_stata` and `StataReader` when loading data from a URL (GH9231).
- Bug in adding `offsets.Nano` to other offsets raises `TypeError` (GH9284)
- Bug in `DatetimeIndex` iteration, related to (GH8890), fixed in (GH9100)
- Bugs in `resample` around DST transitions. This required fixing offset classes so they behave correctly on DST transitions. (GH5172, GH8744, GH8653, GH9173, GH9468).
- Bug in binary operator method (eg `.mul()`) alignment with integer levels (GH9463).
- Bug in `boxplot`, `scatter` and `hexbin` plot may show an unnecessary warning (GH8877)
- Bug in `subplot` with `layout` kw may show unnecessary warning (GH9464)
- Bug in using grouper functions that need passed through arguments (e.g. `axis`), when using wrapped function (e.g. `fillna`), (GH9221)
- `DataFrame` now properly supports simultaneous `copy` and `dtype` arguments in constructor (GH9099)
- Bug in `read_csv` when using `skiprows` on a file with CR line endings with the c engine. (GH9079)

- `isnull` now detects `NaT` in `PeriodIndex` (GH9129)
- Bug in `groupby .nth()` with a multiple column `groupby` (GH8979)
- Bug in `DataFrame.where` and `Series.where` coerce numerics to string incorrectly (GH9280)
- Bug in `DataFrame.where` and `Series.where` raise `ValueError` when string list-like is passed. (GH9280)
- Accessing `Series.str` methods on with non-string values now raises `TypeError` instead of producing incorrect results (GH9184)
- Bug in `DatetimeIndex.__contains__` when index has duplicates and is not monotonic increasing (GH9512)
- Fixed division by zero error for `Series.kurt()` when all values are equal (GH9197)
- Fixed issue in the `xlsxwriter` engine where it added a default ‘General’ format to cells if no other format was applied. This prevented other row or column formatting being applied. (GH9167)
- Fixes issue with `index_col=False` when `usecols` is also specified in `read_csv`. (GH9082)
- Bug where `wide_to_long` would modify the input stub names list (GH9204)
- Bug in `to_sql` not storing float64 values using double precision. (GH9009)
- `SparseSeries` and `SparsePanel` now accept zero argument constructors (same as their non-sparse counterparts) (GH9272).
- Regression in merging `Categorical` and `object` dtypes (GH9426)
- Bug in `read_csv` with buffer overflows with certain malformed input files (GH9205)
- Bug in `groupby MultiIndex` with missing pair (GH9049, GH9344)
- Fixed bug in `Series.groupby` where grouping on `MultiIndex` levels would ignore the `sort` argument (GH9444)
- Fix bug in `DataFrame.Groupby` where `sort=False` is ignored in the case of `Categorical` columns. (GH8868)
- Fixed bug with reading CSV files from Amazon S3 on python 3 raising a `TypeError` (GH9452)
- Bug in the Google BigQuery reader where the ‘jobComplete’ key may be present but `False` in the query results (GH8728)
- Bug in `Series.values_counts` with excluding `NaN` for categorical type `Series` with `dropna=True` (GH9443)
- Fixed missing `numeric_only` option for `DataFrame.std/var/sem` (GH9201)
- Support constructing `Panel` or `Panel4D` with scalar data (GH8285)
- `Series` text representation disconnected from `max_rows/max_columns` (GH7508).
- `Series` number formatting inconsistent when truncated (GH8532).

Previous behavior

```
In [2]: pd.options.display.max_rows = 10
In [3]: s = pd.Series([1,1,1,1,1,1,1,1,1,1,0.9999,1,1]*10)
In [4]: s
Out[4]:
0    1
1    1
```

(continues on next page)

(continued from previous page)

```

2      1
...
127    0.9999
128    1.0000
129    1.0000
Length: 130, dtype: float64

```

New behavior

```

0      1.0000
1      1.0000
2      1.0000
3      1.0000
4      1.0000
...
125    1.0000
126    1.0000
127    0.9999
128    1.0000
129    1.0000
dtype: float64

```

- A Spurious `SettingWithCopy` Warning was generated when setting a new item in a frame in some cases (GH8730)

The following would previously report a `SettingWithCopy` Warning.

```

In [58]: df1 = pd.DataFrame({'x': pd.Series(['a', 'b', 'c']),
.....:                      'y': pd.Series(['d', 'e', 'f'])})
.....:

In [59]: df2 = df1[['x']]

In [60]: df2['y'] = ['g', 'h', 'i']

```

8.11 Version 0.15

8.11.1 v0.15.2 (December 12, 2014)

{{ header }}

This is a minor release from 0.15.1 and includes a large number of bug fixes along with several new features, enhancements, and performance improvements. A small number of API changes were necessary to fix existing bugs. We recommend that all users upgrade to this version.

- *Enhancements*
- *API Changes*
- *Performance Improvements*
- *Bug Fixes*

API changes

- Indexing in `MultiIndex` beyond lex-sort depth is now supported, though a lexically sorted index will have a better performance. ([GH2646](#))

```
In [1]: df = pd.DataFrame({'jim':[0, 0, 1, 1],
...:                      'joe':['x', 'x', 'z', 'y'],
...:                      'jolie':np.random.rand(4)}).set_index(['jim', 'joe'])
...:
```

```
In [2]: df
```

```
Out [2]:
           jolie
```

```
jim joe
0  x    0.823868
   x    0.400987
1  z    0.310430
   y    0.142428
```

```
[4 rows x 1 columns]
```

```
In [3]: df.index.lexsort_depth
Out[3]: 1
```

```
# in prior versions this would raise a KeyError
# will now show a PerformanceWarning
```

```
In [4]: df.loc[(1, 'z')]

1  z    0.31043
```

```
[1 rows x 1 columns]
```

- Bug in unique of Series with `category` dtype, which returned all categories regardless whether they were “used” or not (see [GH8559](#) for the discussion). Previous behaviour was to return all categories:

```
In [3]: cat = pd.Categorical(['a', 'b', 'a'], categories=['a', 'b', 'c'])
In [4]: cat
Out[4]:
[a, b, a]
```

(continues on next page)

(continued from previous page)

```
Categories (3, object): [a < b < c]
```

```
In [5]: cat.unique()
```

```
Out[5]: array(['a', 'b', 'c'], dtype=object)
```

Now, only the categories that do effectively occur in the array are returned:

```
In [9]: cat = pd.Categorical(['a', 'b', 'a'], categories=['a', 'b', 'c'])
```

```
In [10]: cat.unique()
```

```
Out[10]:
```

```
[a, b]
```

```
Categories (2, object): [a, b]
```

- `Series.all` and `Series.any` now support the `level` and `skipna` parameters. `Series.all`, `Series.any`, `Index.all`, and `Index.any` no longer support the `out` and `keepdims` parameters, which existed for compatibility with `ndarray`. Various index types no longer support the `all` and `any` aggregation functions and will now raise `TypeError`. (GH8302).
- Allow equality comparisons of `Series` with a categorical dtype and object dtype; previously these would raise `TypeError` (GH8938)
- Bug in `NDFrame`: conflicting attribute/column names now behave consistently between getting and setting. Previously, when both a column and attribute named `y` existed, `data.y` would return the attribute, while `data.y = z` would update the column (GH8994)

```
In [11]: data = pd.DataFrame({'x': [1, 2, 3]})
```

```
In [12]: data.y = 2
```

```
In [13]: data['y'] = [2, 4, 6]
```

```
In [14]: data
```

```
Out[14]:
```

```
   x  y
0  1  2
1  2  4
2  3  6
```

```
[3 rows x 2 columns]
```

```
# this assignment was inconsistent
```

```
In [15]: data.y = 5
```

Old behavior:

```
In [6]: data.y
```

```
Out[6]: 2
```

```
In [7]: data['y'].values
```

```
Out[7]: array([5, 5, 5])
```

New behavior:

```
In [16]: data.y
```

```
Out[16]: 5
```

```
In [17]: data['y'].values
Out[17]: array([2, 4, 6])
```

- `Timestamp('now')` is now equivalent to `Timestamp.now()` in that it returns the local time rather than UTC. Also, `Timestamp('today')` is now equivalent to `Timestamp.today()` and both have `tz` as a possible argument. (GH9000)
- Fix negative step support for label-based slices (GH8753)

Old behavior:

```
In [1]: s = pd.Series(np.arange(3), ['a', 'b', 'c'])
Out[1]:
a    0
b    1
c    2
dtype: int64

In [2]: s.loc['c':'a':-1]
Out[2]:
c    2
dtype: int64
```

New behavior:

```
In [18]: s = pd.Series(np.arange(3), ['a', 'b', 'c'])

In [19]: s.loc['c':'a':-1]
Out[19]:
c    2
b    1
a    0
Length: 3, dtype: int64
```

Enhancements

Categorical enhancements:

- Added ability to export Categorical data to Stata (GH8633). See [here](#) for limitations of categorical variables exported to Stata data files.
- Added flag `order_categoricals` to `StataReader` and `read_stata` to select whether to order imported categorical data (GH8836). See [here](#) for more information on importing categorical variables from Stata data files.
- Added ability to export Categorical data to to/from HDF5 (GH7621). Queries work the same as if it was an object array. However, the `category` dtyped data is stored in a more efficient manner. See [here](#) for an example and caveats w.r.t. prior versions of pandas.
- Added support for `searchsorted()` on `Categorical` class (GH8420).

Other enhancements:

- Added the ability to specify the SQL type of columns when writing a DataFrame to a database (GH8778). For example, specifying to use the sqlalchemy `String` type instead of the default `Text` type for string columns:

```
from sqlalchemy.types import String
data.to_sql('data_dtype', engine, dtype={'Col_1': String}) # noqa F821
```

- `Series.all` and `Series.any` now support the `level` and `skipna` parameters (GH8302):

```
In [20]: s = pd.Series([False, True, False], index=[0, 0, 1])
In [21]: s.any(level=0)
Out[21]:
0    True
1   False
Length: 2, dtype: bool
```

- `Panel` now supports the `all` and `any` aggregation functions. (GH8302):

```
>>> p = pd.Panel(np.random.rand(2, 5, 4) > 0.1)
>>> p.all()
      0      1      2      3
0  True  True  True  True
1  True False  True  True
2  True  True  True  True
3 False  True False  True
4  True  True  True  True
```

- Added support for `utcfromtimestamp()`, `fromtimestamp()`, and `combine()` on `Timestamp` class (GH5351).
- Added Google Analytics (*pandas.io.ga*) basic documentation (GH8835). See [here](#).
- `Timedelta` arithmetic returns `NotImplemented` in unknown cases, allowing extensions by custom classes (GH8813).
- `Timedelta` now supports arithmetic with `numpy.ndarray` objects of the appropriate dtype (numpy 1.8 or newer only) (GH8884).
- Added `Timedelta.to_timedelta64()` method to the public API (GH8884).
- Added `gbq.generate_bq_schema()` function to the `gbq` module (GH8325).
- `Series` now works with map objects the same way as generators (GH8909).
- Added context manager to `HDFStore` for automatic closing (GH8791).
- `to_datetime` gains an `exact` keyword to allow for a format to not require an exact match for a provided format string (if its `False`). `exact` defaults to `True` (meaning that exact matching is still the default) (GH8904)
- Added `axvlines` boolean option to `parallel_coordinates` plot function, determines whether vertical lines will be printed, default is `True`
- Added ability to read table footers to `read_html` (GH8552)
- `to_sql` now infers data types of non-NA values for columns that contain NA values and have dtype object (GH8778).

Performance

- Reduce memory usage when `skiprows` is an integer in `read_csv` (GH8681)

- Performance boost for `to_datetime` conversions with a passed `format=`, and the `exact=False` (GH8904)

Bug fixes

- Bug in `concat` of Series with `category` dtype which were coercing to `object`. (GH8641)
- Bug in `Timestamp-Timestamp` not returning a `Timedelta` type and `datelike-datelike` ops with `timezones` (GH8865)
- Made consistent a `timezone mismatch` exception (either `tz` operated with `None` or incompatible `time-zone`), will now return `TypeError` rather than `ValueError` (a couple of edge cases only), (GH8865)
- Bug in using a `pd.Grouper(key=...)` with no `level/axis` or `level` only (GH8795, GH8866)
- Report a `TypeError` when `invalid/no` parameters are passed in a `groupby` (GH8015)
- Bug in packaging pandas with `py2app/cx_Freeze` (GH8602, GH8831)
- Bug in `groupby` signatures that didn't include `*args` or `**kwargs` (GH8733).
- `io.data.Options` now raises `RemoteDataError` when no expiry dates are available from Yahoo and when it receives no data from Yahoo (GH8761), (GH8783).
- Unclear error message in `csv` parsing when passing `dtype` and `names` and the parsed data is a different data type (GH8833)
- Bug in slicing a `MultiIndex` with an empty list and at least one boolean indexer (GH8781)
- `io.data.Options` now raises `RemoteDataError` when no expiry dates are available from Yahoo (GH8761).
- `Timedelta` kwargs may now be `numpy ints` and `floats` (GH8757).
- Fixed several outstanding bugs for `Timedelta` arithmetic and comparisons (GH8813, GH5963, GH5436).
- `sql_schema` now generates dialect appropriate `CREATE TABLE` statements (GH8697)
- `slice` string method now takes `step` into account (GH8754)
- Bug in `BlockManager` where setting values with different type would break block integrity (GH8850)
- Bug in `DatetimeIndex` when using `time` object as key (GH8667)
- Bug in `merge` where `how='left'` and `sort=False` would not preserve left frame order (GH7331)
- Bug in `MultiIndex.reindex` where reindexing at level would not reorder labels (GH4088)
- Bug in certain operations with `dateutil timezones`, manifesting with `dateutil 2.3` (GH8639)
- Regression in `DatetimeIndex` iteration with a `Fixed/Local offset` timezone (GH8890)
- Bug in `to_datetime` when parsing a `nanoseconds` using the `%f` format (GH8989)
- `io.data.Options` now raises `RemoteDataError` when no expiry dates are available from Yahoo and when it receives no data from Yahoo (GH8761), (GH8783).
- Fix: The font size was only set on x axis if vertical or the y axis if horizontal. (GH8765)
- Fixed division by 0 when reading big `csv` files in `python 3` (GH8621)
- Bug in outputting a `MultiIndex` with `to_html,index=False` which would add an extra column (GH8452)

- Imported categorical variables from Stata files retain the ordinal information in the underlying data (GH8836).
- Defined `.size` attribute across `NDFrame` objects to provide compat with numpy $\geq 1.9.1$; buggy with `np.array_split` (GH8846)
- Skip testing of histogram plots for `matplotlib` ≤ 1.2 (GH8648).
- Bug where `get_data_google` returned object dtypes (GH3995)
- Bug in `DataFrame.stack(..., dropna=False)` when the `DataFrame`'s `columns` is a `MultiIndex` whose `labels` do not reference all its `levels`. (GH8844)
- Bug in that `Option` context applied on `__enter__` (GH8514)
- Bug in `resample` that causes a `ValueError` when resampling across multiple days and the last offset is not calculated from the start of the range (GH8683)
- Bug where `DataFrame.plot(kind='scatter')` fails when checking if an `np.array` is in the `DataFrame` (GH8852)
- Bug in `pd.infer_freq/DataFrame.inferred_freq` that prevented proper sub-daily frequency inference when the index contained DST days (GH8772).
- Bug where index name was still used when plotting a series with `use_index=False` (GH8558).
- Bugs when trying to stack multiple columns, when some (or all) of the level names are numbers (GH8584).
- Bug in `MultiIndex` where `__contains__` returns wrong result if index is not lexically sorted or unique (GH7724)
- BUG CSV: fix problem with trailing white space in skipped rows, (GH8679), (GH8661), (GH8983)
- Regression in `Timestamp` does not parse 'Z' zone designator for UTC (GH8771)
- Bug in `StataWriter` the produces writes strings with 244 characters irrespective of actual size (GH8969)
- Fixed `ValueError` raised by `cummin/cummax` when `datetime64` Series contains `NaT`. (GH8965)
- Bug in `DataReader` returns object dtype if there are missing values (GH8980)
- Bug in plotting if `sharex` was enabled and index was a timeseries, would show labels on multiple axes (GH3964).
- Bug where passing a unit to the `TimedeltaIndex` constructor applied the to nano-second conversion twice. (GH9011).
- Bug in plotting of a period-like array (GH9012)

8.11.2 v0.15.1 (November 9, 2014)

{{ header }}

This is a minor bug-fix release from 0.15.0 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

- *Enhancements*
- *API Changes*
- *Bug Fixes*

API changes

- `s.dt.hour` and other `.dt` accessors will now return `np.nan` for missing values (rather than previously `-1`), (GH8689)

```
In [1]: s = pd.Series(pd.date_range('20130101', periods=5, freq='D'))
In [2]: s.iloc[2] = np.nan
In [3]: s
Out[3]:
0    2013-01-01
1    2013-01-02
2             NaT
3    2013-01-04
4    2013-01-05
Length: 5, dtype: datetime64[ns]
```

previous behavior:

```
In [6]: s.dt.hour
Out[6]:
0     0
1     0
2    -1
3     0
4     0
dtype: int64
```

current behavior:

```
In [4]: s.dt.hour
Out[4]:
0    0.0
1    0.0
2    NaN
3    0.0
4    0.0
Length: 5, dtype: float64
```

- `groupby` with `as_index=False` will not add erroneous extra columns to result (GH8582):

```
In [5]: np.random.seed(2718281)

In [6]: df = pd.DataFrame(np.random.randint(0, 100, (10, 2)),
...:                      columns=['jim', 'joe'])
...:

In [7]: df.head()
Out[7]:
   jim  joe
0   61   81
1   96   49
2   55   65
3   72   51
4   77   12

[5 rows x 2 columns]

In [8]: ts = pd.Series(5 * np.random.randint(0, 3, 10))
```

previous behavior:

```
In [4]: df.groupby(ts, as_index=False).max()
Out[4]:
   NaN  jim  joe
0     0   72  83
1     5   77  84
2    10   96  65
```

current behavior:

```
In [9]: df.groupby(ts, as_index=False).max()
Out[9]:
   jim  joe
0   72   83
1   77   84
2   96   65

[3 rows x 2 columns]
```

- `groupby` will not erroneously exclude columns if the column name conflicts with the grouper name (GH8112):

```
In [10]: df = pd.DataFrame({'jim': range(5), 'joe': range(5, 10)})
```

```
In [11]: df
```

```
Out[11]:
```

```
   jim  joe
0    0    5
1    1    6
2    2    7
3    3    8
4    4    9
```

```
[5 rows x 2 columns]
```

```
In [12]: gr = df.groupby(df['jim'] < 2)
```

previous behavior (excludes 1st column from output):

```
In [4]: gr.apply(sum)
```

```
Out[4]:
```

```
   joe
jim
False 24
True  11
```

current behavior:

```
In [13]: gr.apply(sum)
```

```
Out[13]:
```

```
   jim  joe
jim
False  9  24
True   1  11
```

```
[2 rows x 2 columns]
```

- Support for slicing with monotonic decreasing indexes, even if `start` or `stop` is not found in the index (GH7860):

```
In [14]: s = pd.Series(['a', 'b', 'c', 'd'], [4, 3, 2, 1])
```

```
In [15]: s
```

```
Out[15]:
```

```
4    a
3    b
2    c
1    d
Length: 4, dtype: object
```

previous behavior:

```
In [8]: s.loc[3.5:1.5]
```

```
KeyError: 3.5
```

current behavior:

```
In [16]: s.loc[3.5:1.5]
Out[16]:
3    b
2    c
Length: 2, dtype: object
```

- `io.data.Options` has been fixed for a change in the format of the Yahoo Options page ([GH8612](#)), ([GH8741](#))

Note: As a result of a change in Yahoo's option page layout, when an expiry date is given, `Options` methods now return data for a single expiry date. Previously, methods returned all data for the selected month.

The `month` and `year` parameters have been undeprecated and can be used to get all options data for a given month.

If an expiry date that is not valid is given, data for the next expiry after the given date is returned.

Option data frames are now saved on the instance as `callsYYMMDD` or `putsYYMMDD`. Previously they were saved as `callsMMYY` and `putsMMYY`. The next expiry is saved as `calls` and `puts`.

New features:

- The expiry parameter can now be a single date or a list-like object containing dates.
- A new property `expiry_dates` was added, which returns all available expiry dates.

Current behavior:

```
In [17]: from pandas.io.data import Options
In [18]: aapl = Options('aapl', 'yahoo')
In [19]: aapl.get_call_data().iloc[0:5, 0:1]
Out[19]:
```

Strike	Expiry	Type	Symbol	Last
80	2014-11-14	call	AAPL141114C00080000	29.05
84	2014-11-14	call	AAPL141114C00084000	24.80
85	2014-11-14	call	AAPL141114C00085000	24.05
86	2014-11-14	call	AAPL141114C00086000	22.76
87	2014-11-14	call	AAPL141114C00087000	21.74

```
In [20]: aapl.expiry_dates
Out[20]:
[datetime.date(2014, 11, 14),
 datetime.date(2014, 11, 22),
 datetime.date(2014, 11, 28),
 datetime.date(2014, 12, 5),
 datetime.date(2014, 12, 12),
 datetime.date(2014, 12, 20),
 datetime.date(2015, 1, 17),
 datetime.date(2015, 2, 20),
 datetime.date(2015, 4, 17),
 datetime.date(2015, 7, 17),
```

(continues on next page)

(continued from previous page)

```
datetime.date(2016, 1, 15),
datetime.date(2017, 1, 20)]
```

```
In [21]: aapl.get_near_stock_price(expiry=aapl.expiry_dates[0:3]).iloc[0:5, 0:1]
```

```
Out [21]:
```

Strike	Expiry	Type	Symbol	Last
109	2014-11-22	call	AAPL141122C00109000	1.48
	2014-11-28	call	AAPL141128C00109000	1.79
110	2014-11-14	call	AAPL141114C00110000	0.55
	2014-11-22	call	AAPL141122C00110000	1.02
	2014-11-28	call	AAPL141128C00110000	1.32

- pandas now also registers the `datetime64` dtype in matplotlib's units registry to plot such values as datetimes. This is activated once pandas is imported. In previous versions, plotting an array of `datetime64` values will have resulted in plotted integer values. To keep the previous behaviour, you can do `del matplotlib.units.registry[np.datetime64]` (GH8614).

Enhancements

- `concat` permits a wider variety of iterables of pandas objects to be passed as the first parameter (GH8645):

```
In [17]: from collections import deque
```

```
In [18]: df1 = pd.DataFrame([1, 2, 3])
```

```
In [19]: df2 = pd.DataFrame([4, 5, 6])
```

previous behavior:

```
In [7]: pd.concat(deque((df1, df2)))
```

```
TypeError: first argument must be a list-like of pandas objects, you passed an
↳object of type "deque"
```

current behavior:

```
In [20]: pd.concat(deque((df1, df2)))
```

```
Out [20]:
```

```
0
0 1
1 2
2 3
0 4
1 5
2 6
```

```
[6 rows x 1 columns]
```

- Represent `MultiIndex` labels with a dtype that utilizes memory based on the level size. In prior versions, the memory usage was a constant 8 bytes per element in each level. In addition, in prior versions, the *reported* memory usage was incorrect as it didn't show the usage for the memory occupied by the underlying data array. (GH8456)

```
In [21]: dfi = pd.DataFrame(1, index=pd.MultiIndex.from_product([[ 'a' ],
.....:                                     range(1000)]), columns=[ 'A' ])
.....:
```

previous behavior:

```
# this was underreported in prior versions
In [1]: dfi.memory_usage(index=True)
Out[1]:
Index      8000 # took about 24008 bytes in < 0.15.1
A           8000
dtype: int64
```

current behavior:

```
In [22]: dfi.memory_usage(index=True)
Out[22]:
Index      52080
A           8000
Length: 2, dtype: int64
```

- Added Index properties *is_monotonic_increasing* and *is_monotonic_decreasing* (GH8680).
- Added option to select columns when importing Stata files (GH7935)
- Qualify memory usage in `DataFrame.info()` by adding `+` if it is a lower bound (GH8578)
- Raise errors in certain aggregation cases where an argument such as `numeric_only` is not handled (GH8592).
- Added support for 3-character ISO and non-standard country codes in `io.wb.download()` (GH8482)
- World Bank data requests now will warn/raise based on an `errors` argument, as well as a list of hard-coded country codes and the World Bank's JSON response. In prior versions, the error messages didn't look at the World Bank's JSON response. Problem-inducing input were simply dropped prior to the request. The issue was that many good countries were cropped in the hard-coded approach. All countries will work now, but some bad countries will raise exceptions because some edge cases break the entire response. (GH8482)
- Added option to `Series.str.split()` to return a `DataFrame` rather than a `Series` (GH8428)
- Added option to `df.info(null_counts=None|True|False)` to override the default display options and force showing of the null-counts (GH8701)

Bug fixes

- Bug in unpickling of a `CustomBusinessDay` object (GH8591)
- Bug in coercing `Categorical` to a records array, e.g. `df.to_records()` (GH8626)
- Bug in `Categorical` not created properly with `Series.to_frame()` (GH8626)
- Bug in coercing in astype of a `Categorical` of a passed `pd.Categorical` (this now raises `TypeError` correctly), (GH8626)
- Bug in `cut/qcut` when using `Series` and `retbins=True` (GH8589)
- Bug in writing `Categorical` columns to an SQL database with `to_sql` (GH8624).

- Bug in comparing `Categorical` of datetime raising when being compared to a scalar datetime (GH8687)
- Bug in selecting from a `Categorical` with `.iloc` (GH8623)
- Bug in groupby-transform with a `Categorical` (GH8623)
- Bug in duplicated/drop_duplicates with a `Categorical` (GH8623)
- Bug in `Categorical` reflected comparison operator raising if the first argument was a numpy array scalar (e.g. `np.int64`) (GH8658)
- Bug in Panel indexing with a list-like (GH8710)
- Compat issue is `DataFrame.dtypes` when `options.mode.use_inf_as_null` is True (GH8722)
- Bug in `read_csv`, `dialect` parameter would not take a string (GH8703)
- Bug in slicing a `MultiIndex` level with an empty-list (GH8737)
- Bug in numeric index operations of add/sub with `Float/Index Index` with numpy arrays (GH8608)
- Bug in setitem with empty indexer and unwanted coercion of dtypes (GH8669)
- Bug in ix/loc block splitting on setitem (manifests with integer-like dtypes, e.g. `datetime64`) (GH8607)
- Bug when doing label based indexing with integers not found in the index for non-unique but monotonic indexes (GH8680).
- Bug when indexing a `Float64Index` with `np.nan` on numpy 1.7 (GH8980).
- Fix `shape` attribute for `MultiIndex` (GH8609)
- Bug in `GroupBy` where a name conflict between the grouper and columns would break `groupby` operations (GH7115, GH8112)
- Fixed a bug where plotting a column `y` and specifying a label would mutate the index name of the original `DataFrame` (GH8494)
- Fix regression in plotting of a `DatetimeIndex` directly with `matplotlib` (GH8614).
- Bug in `date_range` where partially-specified dates would incorporate current date (GH6961)
- Bug in Setting by indexer to a scalar value with a mixed-dtype `Panel4d` was failing (GH8702)
- Bug where `DataReader`'s would fail if one of the symbols passed was invalid. Now returns data for valid symbols and `np.nan` for invalid (GH8494)
- Bug in `get_quote_yahoo` that wouldn't allow non-float return values (GH5229).

8.11.3 v0.15.0 (October 18, 2014)

{{ header }}

This is a major release from 0.14.1 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Warning: pandas \geq 0.15.0 will no longer support compatibility with NumPy versions $<$ 1.7.0. If you want to use the latest versions of pandas, please upgrade to NumPy \geq 1.7.0 (GH7711)

- Highlights include:
 - The `Categorical` type was integrated as a first-class pandas type, see [here](#)
 - New scalar type `Timedelta`, and a new index type `TimedeltaIndex`, see [here](#)
 - New datetimelike properties accessor `.dt` for Series, see *Datetimelike Properties*
 - New DataFrame default display for `df.info()` to include memory usage, see *Memory Usage*
 - `read_csv` will now by default ignore blank lines when parsing, see [here](#)
 - API change in using Indexes in set operations, see [here](#)
 - Enhancements in the handling of timezones, see [here](#)
 - A lot of improvements to the rolling and expanding moment functions, see [here](#)
 - Internal refactoring of the `Index` class to no longer sub-class `ndarray`, see *Internal Refactoring*

- dropping support for PyTables less than version 3.0.0, and numexpr less than version 2.1 (GH7990)
- Split indexing documentation into *Indexing and Selecting Data* and *MultiIndex / Advanced Indexing*
- Split out string methods documentation into *Working with Text Data*
- Check the *API Changes* and *deprecations* before updating
- *Other Enhancements*
- *Performance Improvements*
- *Bug Fixes*

Warning: In 0.15.0 `Index` has internally been refactored to no longer sub-class `ndarray` but instead subclass `PandasObject`, similarly to the rest of the pandas objects. This change allows very easy subclassing and creation of new index types. This should be a transparent change with only very limited API implications (See the *Internal Refactoring*)

Warning: The refactoring in *Categorical* changed the two argument constructor from “codes/labels and levels” to “values and levels (now called ‘categories’)”. This can lead to subtle bugs. If you use *Categorical* directly, please audit your code before updating to this pandas version and change it to use the `from_codes()` constructor. See more on *Categorical* [here](#)

New features

Categoricals in Series/DataFrame

Categorical can now be included in *Series* and *DataFrames* and gained new methods to manipulate. Thanks to Jan Schulz for much of this API/implementation. (GH3943, GH5313, GH5314, GH7444, GH7839, GH7848, GH7864, GH7914, GH7768, GH8006, GH3678, GH8075, GH8076, GH8143, GH8453, GH8518).

For full docs, see the *categorical introduction* and the *API documentation*.

```
In [1]: df = pd.DataFrame({"id": [1, 2, 3, 4, 5, 6],
...:                      "raw_grade": ['a', 'b', 'b', 'a', 'a', 'e']})
...:
```

```
In [2]: df["grade"] = df["raw_grade"].astype("category")
```

```
In [3]: df["grade"]
```

```
Out[3]:
```

```
0    a
1    b
2    b
3    a
4    a
5    e
```

```
Name: grade, Length: 6, dtype: category
```

```
Categories (3, object): [a, b, e]
```

```
# Rename the categories
In [4]: df["grade"].cat.categories = ["very good", "good", "very bad"]

# Reorder the categories and simultaneously add the missing categories
In [5]: df["grade"] = df["grade"].cat.set_categories(["very bad", "bad",
...:                                               "medium", "good", "very good"])
...:

In [6]: df["grade"]
Out[6]:
0    very good
1         good
2         good
3    very good
4    very good
5    very bad
Name: grade, Length: 6, dtype: category
Categories (5, object): [very bad, bad, medium, good, very good]

In [7]: df.sort_values("grade")
Out[7]:
   id raw_grade  grade
5   6         e  very bad
1   2         b    good
2   3         b    good
0   1         a  very good
3   4         a  very good
4   5         a  very good

[6 rows x 3 columns]

In [8]: df.groupby("grade").size()
Out[8]:
grade
very bad    1
bad         0
medium      0
good        2
very good   3
Length: 5, dtype: int64
```

- `pandas.core.group_agg` and `pandas.core.factor_agg` were removed. As an alternative, construct a dataframe and use `df.groupby(<group>).agg(<func>)`.
- Supplying “codes/labels and levels” to the *Categorical* constructor is not supported anymore. Supplying two arguments to the constructor is now interpreted as “values and levels (now called ‘categories’)”. Please change your code to use the *from_codes()* constructor.
- The `Categorical.labels` attribute was renamed to `Categorical.codes` and is read only. If you want to manipulate codes, please use one of the *API methods on Categoricals*.
- The `Categorical.levels` attribute is renamed to `Categorical.categories`.

TimedeltaIndex/Scalar

We introduce a new scalar type `Timedelta`, which is a subclass of `datetime.timedelta`, and behaves in a similar manner, but allows compatibility with `np.timedelta64` types as well as a host of custom representation, parsing, and attributes. This type is very similar to how `Timestamp` works for `datetimes`. It is a nice-API box for the type. See the *docs*. (GH3009, GH4533, GH8209, GH8187, GH8190, GH7869, GH7661, GH8345, GH8471)

Warning: `Timedelta` scalars (and `TimedeltaIndex`) component fields are *not the same* as the component fields on a `datetime.timedelta` object. For example, `.seconds` on a `datetime.timedelta` object returns the total number of seconds combined between hours, minutes and seconds. In contrast, the pandas `Timedelta` breaks out hours, minutes, microseconds and nanoseconds separately.

```
# Timedelta accessor
In [9]: tds = pd.Timedelta('31 days 5 min 3 sec')

In [10]: tds.minutes
Out[10]: 5L

In [11]: tds.seconds
Out[11]: 3L

# datetime.timedelta accessor
# this is 5 minutes * 60 + 3 seconds
In [12]: tds.to_pytimedelta().seconds
Out[12]: 303
```

Note: this is no longer true starting from v0.16.0, where full compatibility with `datetime.timedelta` is introduced. See the *0.16.0 whatsnew entry*

Warning: Prior to 0.15.0 `pd.to_timedelta` would return a `Series` for list-like/`Series` input, and a `np.timedelta64` for scalar input. It will now return a `TimedeltaIndex` for list-like input, `Series` for `Series` input, and `Timedelta` for scalar input.

The arguments to `pd.to_timedelta` are now `(arg,unit='ns',box=True,coerce=False)`, previously were `(arg,box=True,unit='ns')` as these are more logical.

Construct a scalar

```
In [9]: pd.Timedelta('1 days 06:05:01.00003')
Out[9]: Timedelta('1 days 06:05:01.000030')

In [10]: pd.Timedelta('15.5us')
Out[10]: Timedelta('0 days 00:00:00.000015')

In [11]: pd.Timedelta('1 hour 15.5us')
Out[11]: Timedelta('0 days 01:00:00.000015')

# negative Timedeltas have this string repr
# to be more consistent with datetime.timedelta conventions
In [12]: pd.Timedelta('-1us')
Out[12]: Timedelta('-1 days +23:59:59.999999')
```

```
# a NaT
```

```
In [13]: pd.Timedelta('nan')
```

```
Out[13]: NaT
```

Access fields for a Timedelta

```
In [14]: td = pd.Timedelta('1 hour 3m 15.5us')
```

```
In [15]: td.seconds
```

```
Out[15]: 3780
```

```
In [16]: td.microseconds
```

```
Out[16]: 16
```

```
In [17]: td.nanoseconds
```

```
Out[17]: 500
```

Construct a TimedeltaIndex

```
In [18]: pd.TimedeltaIndex(['1 days', '1 days, 00:00:05',
.....:                      np.timedelta64(2, 'D'),
.....:                      datetime.timedelta(days=2, seconds=2)])
.....:
```

```
Out[18]:
```

```
TimedeltaIndex(['1 days 00:00:00', '1 days 00:00:05', '2 days 00:00:00',
                '2 days 00:00:02'],
                dtype='timedelta64[ns]', freq=None)
```

Constructing a TimedeltaIndex with a regular range

```
In [19]: pd.timedelta_range('1 days', periods=5, freq='D')
```

```
Out[19]: TimedeltaIndex(['1 days', '2 days', '3 days', '4 days', '5 days'],
                        dtype='timedelta64[ns]', freq='D')
```

```
In [20]: pd.timedelta_range(start='1 days', end='2 days', freq='30T')
```

```
Out[20]:
```

```
TimedeltaIndex(['1 days 00:00:00', '1 days 00:30:00', '1 days 01:00:00',
                '1 days 01:30:00', '1 days 02:00:00', '1 days 02:30:00',
                '1 days 03:00:00', '1 days 03:30:00', '1 days 04:00:00',
                '1 days 04:30:00', '1 days 05:00:00', '1 days 05:30:00',
                '1 days 06:00:00', '1 days 06:30:00', '1 days 07:00:00',
                '1 days 07:30:00', '1 days 08:00:00', '1 days 08:30:00',
                '1 days 09:00:00', '1 days 09:30:00', '1 days 10:00:00',
                '1 days 10:30:00', '1 days 11:00:00', '1 days 11:30:00',
                '1 days 12:00:00', '1 days 12:30:00', '1 days 13:00:00',
                '1 days 13:30:00', '1 days 14:00:00', '1 days 14:30:00',
                '1 days 15:00:00', '1 days 15:30:00', '1 days 16:00:00',
                '1 days 16:30:00', '1 days 17:00:00', '1 days 17:30:00',
                '1 days 18:00:00', '1 days 18:30:00', '1 days 19:00:00',
                '1 days 19:30:00', '1 days 20:00:00', '1 days 20:30:00',
                '1 days 21:00:00', '1 days 21:30:00', '1 days 22:00:00',
                '1 days 22:30:00', '1 days 23:00:00', '1 days 23:30:00',
                '2 days 00:00:00'],
                dtype='timedelta64[ns]', freq='30T')
```

You can now use a TimedeltaIndex as the index of a pandas object

```
In [21]: s = pd.Series(np.arange(5),
.....:                  index=pd.timedelta_range('1 days', periods=5, freq='s'))
.....:

In [22]: s
Out[22]:
1 days 00:00:00    0
1 days 00:00:01    1
1 days 00:00:02    2
1 days 00:00:03    3
1 days 00:00:04    4
Freq: S, Length: 5, dtype: int64
```

You can select with partial string selections

```
In [23]: s['1 day 00:00:02']
Out[23]: 2
```

```
In [24]: s['1 day':'1 day 00:00:02']
Out[24]:
1 days 00:00:00    0
1 days 00:00:01    1
1 days 00:00:02    2
Freq: S, Length: 3, dtype: int64
```

Finally, the combination of `TimedeltaIndex` with `DatetimeIndex` allow certain combination operations that are `NaT` preserving:

```
In [25]: tdi = pd.TimedeltaIndex(['1 days', pd.NaT, '2 days'])
```

```
In [26]: tdi.tolist()
Out[26]: [Timedelta('1 days 00:00:00'), NaT, Timedelta('2 days 00:00:00')]
```

```
In [27]: dti = pd.date_range('20130101', periods=3)
```

```
In [28]: dti.tolist()
Out[28]:
[Timestamp('2013-01-01 00:00:00', freq='D'),
 Timestamp('2013-01-02 00:00:00', freq='D'),
 Timestamp('2013-01-03 00:00:00', freq='D')]
```

```
In [29]: (dti + tdi).tolist()
Out[29]: [Timestamp('2013-01-02 00:00:00'), NaT, Timestamp('2013-01-05 00:00:00')]
```

```
In [30]: (dti - tdi).tolist()
Out[30]: [Timestamp('2012-12-31 00:00:00'), NaT, Timestamp('2013-01-01 00:00:00')]
```

- iteration of a `Series` e.g. `list(Series(...))` of `timedelta64[ns]` would prior to v0.15.0 return `np.timedelta64` for each element. These will now be wrapped in `Timedelta`.

Memory usage

Implemented methods to find memory usage of a `DataFrame`. See the *FAQ* for more. ([GH6852](#)).

A new display option `display.memory_usage` (see options) sets the default behavior of the `memory_usage` argument in the `df.info()` method. By default `display.memory_usage` is `True`.

```
In [31]: dtypes = ['int64', 'float64', 'datetime64[ns]', 'timedelta64[ns]',
.....:             'complex128', 'object', 'bool']
.....:

In [32]: n = 5000

In [33]: data = {t: np.random.randint(100, size=n).astype(t) for t in dtypes}

In [34]: df = pd.DataFrame(data)

In [35]: df['categorical'] = df['object'].astype('category')

In [36]: df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5000 entries, 0 to 4999
Data columns (total 8 columns):
int64          5000 non-null int64
float64        5000 non-null float64
datetime64[ns] 5000 non-null datetime64[ns]
timedelta64[ns] 5000 non-null timedelta64[ns]
complex128     5000 non-null complex128
object         5000 non-null object
bool           5000 non-null bool
categorical    5000 non-null category
dtypes: bool(1), category(1), complex128(1), datetime64[ns](1), float64(1), int64(1),
→object(1), timedelta64[ns](1)
memory usage: 289.1+ KB
```

Additionally `memory_usage()` is an available method for a dataframe object which returns the memory usage of each column.

```
In [37]: df.memory_usage(index=True)
Out[37]:
Index          128
int64          40000
float64        40000
datetime64[ns] 40000
timedelta64[ns] 40000
complex128     80000
object         40000
bool           5000
categorical    10920
Length: 9, dtype: int64
```

.dt accessor

`Series` has gained an accessor to succinctly return datetime like properties for the *values* of the Series, if its a datetime/period like Series. (GH7207) This will return a Series, indexed like the existing Series. See the [docs](#)

```
# datetime
In [38]: s = pd.Series(pd.date_range('20130101 09:10:12', periods=4))
```

```
In [39]: s
Out[39]:
0    2013-01-01 09:10:12
1    2013-01-02 09:10:12
2    2013-01-03 09:10:12
3    2013-01-04 09:10:12
Length: 4, dtype: datetime64[ns]
```

```
In [40]: s.dt.hour
Out[40]:
0     9
1     9
2     9
3     9
Length: 4, dtype: int64
```

```
In [41]: s.dt.second
Out[41]:
0    12
1    12
2    12
3    12
Length: 4, dtype: int64
```

```
In [42]: s.dt.day
Out[42]:
0     1
1     2
2     3
3     4
Length: 4, dtype: int64
```

```
In [43]: s.dt.freq
Out[43]: 'D'
```

This enables nice expressions like this:

```
In [44]: s[s.dt.day == 2]
Out[44]:
1    2013-01-02 09:10:12
Length: 1, dtype: datetime64[ns]
```

You can easily produce tz aware transformations:

```
In [45]: stz = s.dt.tz_localize('US/Eastern')
```

```
In [46]: stz
Out[46]:
0    2013-01-01 09:10:12-05:00
1    2013-01-02 09:10:12-05:00
2    2013-01-03 09:10:12-05:00
3    2013-01-04 09:10:12-05:00
```

Length: 4, dtype: datetime64[ns, US/Eastern]

In [47]: stz.dt.tz

Out[47]: <DstTzInfo 'US/Eastern' LMT-1 day, 19:04:00 STD>

You can also chain these types of operations:

```
In [48]: s.dt.tz_localize('UTC').dt.tz_convert('US/Eastern')
```

Out[48]:

```
0    2013-01-01 04:10:12-05:00
```

```
1    2013-01-02 04:10:12-05:00
```

```
2    2013-01-03 04:10:12-05:00
```

```
3    2013-01-04 04:10:12-05:00
```

Length: 4, dtype: datetime64[ns, US/Eastern]

The `.dt` accessor works for period and timedelta dtypes.

period

```
In [49]: s = pd.Series(pd.period_range('20130101', periods=4, freq='D'))
```

In [50]: s

Out[50]:

```
0    2013-01-01
```

```
1    2013-01-02
```

```
2    2013-01-03
```

```
3    2013-01-04
```

Length: 4, dtype: period[D]

In [51]: s.dt.year

Out[51]:

```
0    2013
```

```
1    2013
```

```
2    2013
```

```
3    2013
```

Length: 4, dtype: int64

In [52]: s.dt.day

Out[52]:

```
0    1
```

```
1    2
```

```
2    3
```

```
3    4
```

Length: 4, dtype: int64

timedelta

```
In [53]: s = pd.Series(pd.timedelta_range('1 day 00:00:05', periods=4, freq='s'))
```

In [54]: s

Out[54]:

```
0    1 days 00:00:05
```

```
1    1 days 00:00:06
```

```
2    1 days 00:00:07
```

```
3    1 days 00:00:08
```

Length: 4, dtype: timedelta64[ns]

In [55]: s.dt.days

```
Out[55]:
```

```
0    1
1    1
2    1
3    1
```

[4 rows x 7 columns]
```

Timezone handling improvements

- `tz_localize(None)` for `tz`-aware `Timestamp` and `DatetimeIndex` now removes timezone holding local time, previously this resulted in `Exception` or `TypeError` ([GH7812](#))

```
In [58]: ts = pd.Timestamp('2014-08-01 09:00', tz='US/Eastern')
```

```
In [59]: ts
```

```
Out[59]: Timestamp('2014-08-01 09:00:00-0400', tz='US/Eastern')
```

```
In [60]: ts.tz_localize(None)
```

```
Out[60]: Timestamp('2014-08-01 09:00:00')
```

```
In [61]: didx = pd.DatetimeIndex(start='2014-08-01 09:00', freq='H',
```

```
.....:                               periods=10, tz='US/Eastern')
```

```
.....:
```

```
In [62]: didx
```

```
Out[62]:
```

```
DatetimeIndex(['2014-08-01 09:00:00-04:00', '2014-08-01 10:00:00-04:00',
               '2014-08-01 11:00:00-04:00', '2014-08-01 12:00:00-04:00',
               '2014-08-01 13:00:00-04:00', '2014-08-01 14:00:00-04:00',
               '2014-08-01 15:00:00-04:00', '2014-08-01 16:00:00-04:00',
               '2014-08-01 17:00:00-04:00', '2014-08-01 18:00:00-04:00'],
              dtype='datetime64[ns, US/Eastern]', freq='H')
```

```
In [63]: didx.tz_localize(None)
```

```
Out[63]:
```

```
DatetimeIndex(['2014-08-01 09:00:00', '2014-08-01 10:00:00',
              '2014-08-01 11:00:00', '2014-08-01 12:00:00',
              '2014-08-01 13:00:00', '2014-08-01 14:00:00',
              '2014-08-01 15:00:00', '2014-08-01 16:00:00',
              '2014-08-01 17:00:00', '2014-08-01 18:00:00'],
              dtype='datetime64[ns]', freq='H')
```

- `tz_localize` now accepts the `ambiguous` keyword which allows for passing an array of bools indicating whether the date belongs in DST or not, `'NaT'` for setting transition times to NaT, `'infer'` for inferring DST/non-DST, and `'raise'` (default) for an `AmbiguousTimeError` to be raised. See *the docs* for more details ([GH7943](#))
- `DataFrame.tz_localize` and `DataFrame.tz_convert` now accepts an optional `level` argument for localizing a specific level of a `MultiIndex` ([GH7846](#))
- `Timestamp.tz_localize` and `Timestamp.tz_convert` now raise `TypeError` in error cases, rather than `Exception` ([GH8025](#))
- a timeseries/index localized to UTC when inserted into a `Series/DataFrame` will preserve the UTC timezone (rather than being a naive `datetime64[ns]`) as `object` dtype ([GH8411](#))
- `Timestamp.__repr__` displays `dateutil.tz.tzoffset` info ([GH7907](#))

Rolling/expanding moments improvements

- `rolling_min()`, `rolling_max()`, `rolling_cov()`, and `rolling_corr()` now return objects with all NaN when `len(arg) < min_periods <= window` rather than raising. (This makes all rolling functions consistent in this behavior). ([GH7766](#))

Prior to 0.15.0

```
In [64]: s = pd.Series([10, 11, 12, 13])
```

```
In [15]: pd.rolling_min(s, window=10, min_periods=5)
ValueError: min_periods (5) must be <= window (4)
```

New behavior

```
In [4]: pd.rolling_min(s, window=10, min_periods=5)
Out[4]:
0    NaN
1    NaN
2    NaN
3    NaN
dtype: float64
```

- `rolling_max()`, `rolling_min()`, `rolling_sum()`, `rolling_mean()`, `rolling_median()`, `rolling_std()`, `rolling_var()`, `rolling_skew()`, `rolling_kurt()`, `rolling_quantile()`, `rolling_cov()`, `rolling_corr()`, `rolling_corr_pairwise()`, `rolling_window()`, and `rolling_apply()` with `center=True` previously would return a result of the same structure as the input `arg` with NaN in the final $(window-1)/2$ entries.

Now the final $(window-1)/2$ entries of the result are calculated as if the input `arg` were followed by $(window-1)/2$ NaN values (or with shrinking windows, in the case of `rolling_apply()`). ([GH7925](#), [GH8269](#))

Prior behavior (note final value is NaN):

```
In [7]: pd.rolling_sum(Series(range(4)), window=3, min_periods=0, center=True)
Out[7]:
0      1
1      3
2      6
3     NaN
dtype: float64
```

New behavior (note final value is 5 = `sum([2, 3, NaN])`):

```
In [7]: pd.rolling_sum(pd.Series(range(4)), window=3,
...:                  min_periods=0, center=True)
Out[7]:
0      1
1      3
2      6
3      5
dtype: float64
```

- `rolling_window()` now normalizes the weights properly in rolling mean mode (`mean=True`) so that the calculated weighted means (e.g. 'triang', 'gaussian') are distributed about the same means as those calculated without weighting (i.e. 'boxcar'). See *the note on normalization* for further details. (GH7618)

```
In [65]: s = pd.Series([10.5, 8.8, 11.4, 9.7, 9.3])
```

Behavior prior to 0.15.0:

```
In [39]: pd.rolling_window(s, window=3, win_type='triang', center=True)
Out[39]:
0         NaN
1     6.583333
2     6.883333
3     6.683333
4         NaN
dtype: float64
```

New behavior

```
In [10]: pd.rolling_window(s, window=3, win_type='triang', center=True)
Out[10]:
0         NaN
1     9.875
2    10.325
3    10.025
4         NaN
dtype: float64
```

- Removed `center` argument from all `expanding_` functions (see *list*), as the results produced when `center=True` did not make much sense. (GH7925)
- Added optional `ddof` argument to `expanding_cov()` and `rolling_cov()`. The default value of 1 is backwards-compatible. (GH8279)
- Documented the `ddof` argument to `expanding_var()`, `expanding_std()`, `rolling_var()`, and

`rolling_std()`. These functions' support of a `ddof` argument (with a default value of 1) was previously undocumented. (GH8064)

- `ewma()`, `ewmstd()`, `ewmvol()`, `ewmvar()`, `ewmcov()`, and `ewmcorr()` now interpret `min_periods` in the same manner that the `rolling_*`() and `expanding_*`() functions do: a given result entry will be `NaN` if the (expanding, in this case) window does not contain at least `min_periods` values. The previous behavior was to set to `NaN` the `min_periods` entries starting with the first non-`NaN` value. (GH7977)

Prior behavior (note values start at index 2, which is `min_periods` after index 0 (the index of the first non-empty value)):

```
In [66]: s = pd.Series([1, None, None, None, 2, 3])
```

```
In [51]: ewma(s, com=3., min_periods=2)
```

```
Out [51]:
0         NaN
1         NaN
2    1.000000
3    1.000000
4    1.571429
5    2.189189
dtype: float64
```

New behavior (note values start at index 4, the location of the 2nd (since `min_periods=2`) non-empty value):

```
In [2]: pd.ewma(s, com=3., min_periods=2)
```

```
Out [2]:
0         NaN
1         NaN
2         NaN
3         NaN
4    1.759644
5    2.383784
dtype: float64
```

- `ewmstd()`, `ewmvol()`, `ewmvar()`, `ewmcov()`, and `ewmcorr()` now have an optional `adjust` argument, just like `ewma()` does, affecting how the weights are calculated. The default value of `adjust` is `True`, which is backwards-compatible. See *Exponentially weighted moment functions* for details. (GH7911)
- `ewma()`, `ewmstd()`, `ewmvol()`, `ewmvar()`, `ewmcov()`, and `ewmcorr()` now have an optional `ignore_na` argument. When `ignore_na=False` (the default), missing values are taken into account in the weights calculation. When `ignore_na=True` (which reproduces the pre-0.15.0 behavior), missing values are ignored in the weights calculation. (GH7543)

```
In [7]: pd.ewma(pd.Series([None, 1., 8.]), com=2.)
```

```
Out [7]:
0     NaN
1     1.0
2     5.2
dtype: float64
```

```
In [8]: pd.ewma(pd.Series([1., None, 8.]), com=2.,
....:           ignore_na=True) # pre-0.15.0 behavior
```

```
Out [8]:
```

(continues on next page)

(continued from previous page)

```

0    1.0
1    1.0
2    5.2
dtype: float64

In [9]: pd.ewm(pd.Series([1., None, 8.]), com=2.,
....:         ignore_na=False) # new default
Out [9]:
0    1.000000
1    1.000000
2    5.846154
dtype: float64

```

Warning: By default (`ignore_na=False`) the `ewm*()` functions' weights calculation in the presence of missing values is different than in pre-0.15.0 versions. To reproduce the pre-0.15.0 calculation of weights in the presence of missing values one must specify explicitly `ignore_na=True`.

- Bug in `expanding_cov()`, `expanding_corr()`, `rolling_cov()`, `rolling_cor()`, `ewmcov()`, and `ewmcorr()` returning results with columns sorted by name and producing an error for non-unique columns; now handles non-unique columns and returns columns in original order (except for the case of two DataFrames with `pairwise=False`, where behavior is unchanged) ([GH7542](#))
- Bug in `rolling_count()` and `expanding_*()` functions unnecessarily producing error message for zero-length data ([GH8056](#))
- Bug in `rolling_apply()` and `expanding_apply()` interpreting `min_periods=0` as `min_periods=1` ([GH8080](#))
- Bug in `expanding_std()` and `expanding_var()` for a single value producing a confusing error message ([GH7900](#))
- Bug in `rolling_std()` and `rolling_var()` for a single value producing 0 rather than NaN ([GH7900](#))
- Bug in `ewmstd()`, `ewmvol()`, `ewmvar()`, and `ewmcov()` calculation of de-biasing factors when `bias=False` (the default). Previously an incorrect constant factor was used, based on `adjust=True`, `ignore_na=True`, and an infinite number of observations. Now a different factor is used for each entry, based on the actual weights (analogous to the usual $N/(N-1)$ factor). In particular, for a single point a value of NaN is returned when `bias=False`, whereas previously a value of (approximately) 0 was returned.

For example, consider the following pre-0.15.0 results for `ewmvar(..., bias=False)`, and the corresponding debiasing factors:

```
In [67]: s = pd.Series([1., 2., 0., 4.])
```

```
In [89]: ewmvar(s, com=2., bias=False)
Out [89]:
0    -2.775558e-16
1     3.000000e-01
2     9.556787e-01
3     3.585799e+00
dtype: float64

```

(continues on next page)

(continued from previous page)

```
In [90]: ewmvar(s, com=2., bias=False) / ewmvar(s, com=2., bias=True)
Out [90]:
0    1.25
1    1.25
2    1.25
3    1.25
dtype: float64
```

Note that entry 0 is approximately 0, and the debiasing factors are a constant 1.25. By comparison, the following 0.15.0 results have a NaN for entry 0, and the debiasing factors are decreasing (towards 1.25):

```
In [14]: pd.ewmvar(s, com=2., bias=False)
Out [14]:
0         NaN
1    0.500000
2    1.210526
3    4.089069
dtype: float64

In [15]: pd.ewmvar(s, com=2., bias=False) / pd.ewmvar(s, com=2., bias=True)
Out [15]:
0         NaN
1    2.083333
2    1.583333
3    1.425439
dtype: float64
```

See *Exponentially weighted moment functions* for details. (GH7912)

Improvements in the sql io module

- Added support for a `chunksize` parameter to `to_sql` function. This allows DataFrame to be written in chunks and avoid packet-size overflow errors (GH8062).
- Added support for a `chunksize` parameter to `read_sql` function. Specifying this argument will return an iterator through chunks of the query result (GH2908).
- Added support for writing `datetime.date` and `datetime.time` object columns with `to_sql` (GH6932).
- Added support for specifying a `schema` to read from/write to with `read_sql_table` and `to_sql` (GH7441, GH7952). For example:

```
df.to_sql('table', engine, schema='other_schema') # noqa F821
pd.read_sql_table('table', engine, schema='other_schema') # noqa F821
```

- Added support for writing NaN values with `to_sql` (GH2754).
- Added support for writing `datetime64` columns with `to_sql` for all database flavors (GH7103).

Backwards incompatible API changes

Breaking changes

API changes related to `Categorical` (see *here* for more details):

- The `Categorical` constructor with two arguments changed from “codes/labels and levels” to “values and levels (now called ‘categories’)”. This can lead to subtle bugs. If you use `Categorical` directly, please audit your code by changing it to use the `from_codes()` constructor.

An old function call like (prior to 0.15.0):

```
pd.Categorical([0,1,0,2,1], levels=['a', 'b', 'c'])
```

will have to adapted to the following to keep the same behaviour:

```
In [2]: pd.Categorical.from_codes([0,1,0,2,1], categories=['a', 'b', 'c'])
Out[2]:
[a, b, a, c, b]
Categories (3, object): [a, b, c]
```

API changes related to the introduction of the `Timedelta` scalar (see *above* for more details):

- Prior to 0.15.0 `to_timedelta()` would return a `Series` for list-like/`Series` input, and a `np.timedelta64` for scalar input. It will now return a `TimedeltaIndex` for list-like input, `Series` for `Series` input, and `Timedelta` for scalar input.

For API changes related to the rolling and expanding functions, see detailed overview *above*.

Other notable API changes:

- Consistency when indexing with `.loc` and a list-like indexer when no values are found.

```
In [68]: df = pd.DataFrame([[ 'a' ], [ 'b' ]], index=[1, 2])

In [69]: df
Out[69]:
   0
1  a
2  b

[2 rows x 1 columns]
```

In prior versions there was a difference in these two constructs:

- `df.loc[[3]]` would return a frame reindexed by 3 (with all `np.nan` values)
- `df.loc[[3],:]` would raise `KeyError`.

Both will now raise a `KeyError`. The rule is that *at least 1* indexer must be found when using a list-like and `.loc` ([GH7999](#))

Furthermore in prior versions these were also different:

- `df.loc[[1,3]]` would return a frame reindexed by [1,3]
- `df.loc[[1,3],:]` would raise `KeyError`.

Both will now return a frame reindex by [1,3]. E.g.

```
In [3]: df.loc[[1, 3]]
Out[3]:
      0
1     a
3    NaN

In [4]: df.loc[[1, 3], :]
Out[4]:
      0
1     a
3    NaN
```

This can also be seen in multi-axis indexing with a Panel.

```
>>> p = pd.Panel(np.arange(2 * 3 * 4).reshape(2, 3, 4),
...              items=['ItemA', 'ItemB'],
...              major_axis=[1, 2, 3],
...              minor_axis=['A', 'B', 'C', 'D'])
>>> p
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 3 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemB
Major_axis axis: 1 to 3
Minor_axis axis: A to D
```

The following would raise `KeyError` prior to 0.15.0:

```
In [5]:
Out[5]:
      ItemA  ItemD
1         3     NaN
2         7     NaN
3        11     NaN
```

Furthermore, `.loc` will raise `If` no values are found in a `MultiIndex` with a list-like indexer:

```
In [70]: s = pd.Series(np.arange(3, dtype='int64'),
.....:                 index=pd.MultiIndex.from_product(['A'],
.....:                                                  ['foo', 'bar', 'baz']],
.....:                 names=['one', 'two'])
.....:                 ).sort_index()
.....:

In [71]: s
Out[71]:
one two
A   bar  1
    baz  2
    foo  0
Length: 3, dtype: int64

In [72]: try:
.....:     s.loc[['D']]
```

(continues on next page)

(continued from previous page)

```

.....: except KeyError as e:
.....:     print("KeyError: " + str(e))
.....:

```

- Assigning values to `None` now considers the dtype when choosing an ‘empty’ value (GH7941).

Previously, assigning to `None` in numeric containers changed the dtype to object (or errored, depending on the call). It now uses `NaN`:

```
In [73]: s = pd.Series([1, 2, 3])
```

```
In [74]: s.loc[0] = None
```

```
In [75]: s
```

```
Out[75]:
```

```
0    NaN
```

```
1    2.0
```

```
2    3.0
```

```
Length: 3, dtype: float64
```

`NaT` is now used similarly for datetime containers.

For object containers, we now preserve `None` values (previously these were converted to `NaN` values).

```
In [76]: s = pd.Series(["a", "b", "c"])
```

```
In [77]: s.loc[0] = None
```

```
In [78]: s
```

```
Out[78]:
```

```
0    None
```

```
1     b
```

```
2     c
```

```
Length: 3, dtype: object
```

To insert a `NaN`, you must explicitly use `np.nan`. See the *docs*.

- In prior versions, updating a pandas object inplace would not reflect in other python references to this object. (GH8511, GH5104)

```
In [79]: s = pd.Series([1, 2, 3])
```

```
In [80]: s2 = s
```

```
In [81]: s += 1.5
```

Behavior prior to v0.15.0

```
# the original object
```

```
In [5]: s
```

```
Out[5]:
```

```
0    2.5
```

```
1    3.5
```

```
2    4.5
```

(continues on next page)

(continued from previous page)

```
dtype: float64

# a reference to the original object
In [7]: s2
Out[7]:
0    1
1    2
2    3
dtype: int64
```

This is now the correct behavior

```
# the original object
In [82]: s
Out[82]:
0    2.5
1    3.5
2    4.5
Length: 3, dtype: float64
```

```
# a reference to the original object
In [83]: s2
Out[83]:
0    2.5
1    3.5
2    4.5
Length: 3, dtype: float64
```

- Made both the C-based and Python engines for `read_csv` and `read_table` ignore empty lines in input as well as white space-filled lines, as long as `sep` is not white space. This is an API change that can be controlled by the keyword parameter `skip_blank_lines`. See *the docs* (GH4466)
- A timeseries/index localized to UTC when inserted into a Series/DataFrame will preserve the UTC timezone and inserted as object dtype rather than being converted to a naive `datetime64[ns]` (GH8411).
- Bug in passing a `DatetimeIndex` with a timezone that was not being retained in DataFrame construction from a dict (GH7822)

In prior versions this would drop the timezone, now it retains the timezone, but gives a column of object dtype:

```
In [84]: i = pd.date_range('1/1/2011', periods=3, freq='10s', tz='US/Eastern')
```

```
In [85]: i
Out[85]:
DatetimeIndex(['2011-01-01 00:00:00-05:00', '2011-01-01 00:00:10-05:00',
              '2011-01-01 00:00:20-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq='10S')
```

```
In [86]: df = pd.DataFrame({'a': i})
```

```
In [87]: df
Out[87]:
```

a

```
0 2011-01-01 00:00:00-05:00
1 2011-01-01 00:00:10-05:00
2 2011-01-01 00:00:20-05:00
```

```
[3 rows x 1 columns]
```

```
In [88]: df.dtypes
Out[88]:
a    datetime64[ns, US/Eastern]
Length: 1, dtype: object
```

Previously this would have yielded a column of `datetime64` dtype, but without timezone info.

The behaviour of assigning a column to an existing dataframe as `df['a'] = i` remains unchanged (this already returned an `object` column with a timezone).

- When passing multiple levels to `stack()`, it will now raise a `ValueError` when the levels aren't all level names or all level numbers (GH7660). See *Reshaping by stacking and unstacking*.
- Raise a `ValueError` in `df.to_hdf` with 'fixed' format, if `df` has non-unique columns as the resulting file will be broken (GH7761)
- `SettingWithCopy` raise/warnings (according to the option `mode.chained_assignment`) will now be issued when setting a value on a sliced mixed-dtype DataFrame using chained-assignment. (GH7845, GH7950)

```
In [1]: df = pd.DataFrame(np.arange(0, 9), columns=['count'])

In [2]: df['group'] = 'b'

In [3]: df.iloc[0:5]['group'] = 'a'
/usr/local/bin/ipython:1: SettingWithCopyWarning:
A value is trying to be set on a copy of a slice from a DataFrame.
Try using .loc[row_indexer,col_indexer] = value instead

See the caveats in the documentation: http://pandas.pydata.org/pandas-docs/stable/
↪indexing.html#indexing-view-versus-copy
```

- `merge`, `DataFrame.merge`, and `ordered_merge` now return the same type as the left argument (GH7737).
- Previously an enlargement with a mixed-dtype frame would act unlike `.append` which will preserve dtypes (related GH2578, GH8176):

```
In [89]: df = pd.DataFrame([[True, 1], [False, 2]],
.....:                      columns=["female", "fitness"])
.....:
```

```
In [90]: df
Out[90]:
   female  fitness
0    True         1
1   False         2
```

```
[2 rows x 2 columns]
```

```
In [91]: df.dtypes
Out[91]:
```

```
female      bool
fitness    int64
Length: 2, dtype: object
```

```
# dtypes are now preserved
In [92]: df.loc[2] = df.loc[1]
```

```
In [93]: df
Out[93]:
   female  fitness
0     True         1
1    False         2
2    False         2
```

```
[3 rows x 2 columns]
```

```
In [94]: df.dtypes
Out[94]:
female      bool
fitness    int64
Length: 2, dtype: object
```

- `Series.to_csv()` now returns a string when `path=None`, matching the behaviour of `DataFrame.to_csv()` ([GH8215](#)).
- `read_hdf` now raises `IOError` when a file that doesn't exist is passed in. Previously, a new, empty file was created, and a `KeyError` raised ([GH7715](#)).
- `DataFrame.info()` now ends its output with a newline character ([GH8114](#))
- Concatenating no objects will now raise a `ValueError` rather than a bare `Exception`.
- Merge errors will now be sub-classes of `ValueError` rather than raw `Exception` ([GH8501](#))
- `DataFrame.plot` and `Series.plot` keywords are now have consistent orders ([GH8037](#))

Internal refactoring

In 0.15.0 `Index` has internally been refactored to no longer sub-class `ndarray` but instead subclass `PandasObject`, similarly to the rest of the pandas objects. This change allows very easy sub-classing and creation of new index types. This should be a transparent change with only very limited API implications ([GH5080](#), [GH7439](#), [GH7796](#), [GH8024](#), [GH8367](#), [GH7997](#), [GH8522](#)):

- you may need to unpickle pandas version < 0.15.0 pickles using `pd.read_pickle` rather than `pickle.load`. See [pickle docs](#)
- when plotting with a `PeriodIndex`, the matplotlib internal axes will now be arrays of `Period` rather than a `PeriodIndex` (this is similar to how a `DatetimeIndex` passes arrays of `datetimes` now)
- `MultiIndexes` will now raise similarly to other pandas objects w.r.t. truth testing, see [here](#) ([GH7897](#)).
- When plotting a `DatetimeIndex` directly with matplotlib's `plot` function, the axis labels will no longer be formatted as dates but as integers (the internal representation of a `datetime64`). **UPDATE** This is fixed in 0.15.1, see [here](#).

Deprecations

- The attributes `Categorical` labels and `levels` attributes are deprecated and renamed to `codes` and `categories`.
- The `outtype` argument to `pd.DataFrame.to_dict` has been deprecated in favor of `orient`. (GH7840)
- The `convert_dummies` method has been deprecated in favor of `get_dummies` (GH8140)
- The `infer_dst` argument in `tz_localize` will be deprecated in favor of `ambiguous` to allow for more flexibility in dealing with DST transitions. Replace `infer_dst=True` with `ambiguous='infer'` for the same behavior (GH7943). See *the docs* for more details.
- The top-level `pd.value_range` has been deprecated and can be replaced by `.describe()` (GH8481)
- The `Index` set operations `+` and `-` were deprecated in order to provide these for numeric type operations on certain index types. `+` can be replaced by `.union()` or `|`, and `-` by `.difference()`. Further the method name `Index.diff()` is deprecated and can be replaced by `Index.difference()` (GH8226)

```
# +
pd.Index(['a', 'b', 'c']) + pd.Index(['b', 'c', 'd'])

# should be replaced by
pd.Index(['a', 'b', 'c']).union(pd.Index(['b', 'c', 'd']))
```

```
# -
pd.Index(['a', 'b', 'c']) - pd.Index(['b', 'c', 'd'])

# should be replaced by
pd.Index(['a', 'b', 'c']).difference(pd.Index(['b', 'c', 'd']))
```

- The `infer_types` argument to `read_html()` now has no effect and is deprecated (GH7762, GH7032).

Removal of prior version deprecations/changes

- Remove `DataFrame.delevel` method in favor of `DataFrame.reset_index`

Enhancements

Enhancements in the importing/exporting of Stata files:

- Added support for `bool`, `uint8`, `uint16` and `uint32` data types in `to_stata` (GH7097, GH7365)
- Added conversion option when importing Stata files (GH8527)
- `DataFrame.to_stata` and `StataWriter` check string length for compatibility with limitations imposed in dta files where fixed-width strings must contain 244 or fewer characters. Attempting to write Stata dta files with strings longer than 244 characters raises a `ValueError`. (GH7858)
- `read_stata` and `StataReader` can import missing data information into a `DataFrame` by setting the argument `convert_missing` to `True`. When using this options, missing values are returned as `StataMissingValue` objects and columns containing missing values have object data type. (GH8045)

Enhancements in the plotting functions:

- Added `layout` keyword to `DataFrame.plot`. You can pass a tuple of `(rows, columns)`, one of which can be `-1` to automatically infer (GH6667, GH8071).

- Allow to pass multiple axes to `DataFrame.plot`, `hist` and `boxplot` ([GH5353](#), [GH6970](#), [GH7069](#))
- Added support for `c`, `colormap` and `colorbar` arguments for `DataFrame.plot` with `kind='scatter'` ([GH7780](#))
- Histogram from `DataFrame.plot` with `kind='hist'` ([GH7809](#)), See *the docs*.
- Boxplot from `DataFrame.plot` with `kind='box'` ([GH7998](#)), See *the docs*.

Other:

- `read_csv` now has a keyword parameter `float_precision` which specifies which floating-point converter the C engine should use during parsing, see [here](#) ([GH8002](#), [GH8044](#))
- Added `searchsorted` method to `Series` objects ([GH7447](#))
- `describe()` on mixed-types `DataFrames` is more flexible. Type-based column filtering is now possible via the `include/exclude` arguments. See the *docs* ([GH8164](#)).

```
In [95]: df = pd.DataFrame({'catA': ['foo', 'foo', 'bar'] * 8,
.....:                    'catB': ['a', 'b', 'c', 'd'] * 6,
.....:                    'numC': np.arange(24),
.....:                    'numD': np.arange(24.) + .5})
.....:
```

```
In [96]: df.describe(include=["object"])
```

```
Out[96]:
```

	catA	catB
count	24	24
unique	2	4
top	foo	c
freq	16	6

```
[4 rows x 2 columns]
```

```
In [97]: df.describe(include=["number", "object"], exclude=["float"])
```

```
Out[97]:
```

	catA	catB	numC
count	24	24	24.000000
unique	2	4	NaN
top	foo	c	NaN
freq	16	6	NaN
mean	NaN	NaN	11.500000
std	NaN	NaN	7.071068
min	NaN	NaN	0.000000
25%	NaN	NaN	5.750000
50%	NaN	NaN	11.500000
75%	NaN	NaN	17.250000
max	NaN	NaN	23.000000

```
[11 rows x 3 columns]
```

Requesting all columns is possible with the shorthand 'all'

```
In [98]: df.describe(include='all')
```

```
Out[98]:
```

	catA	catB	numC	numD
count	24	24	24.000000	24.000000

(continues on next page)

(continued from previous page)

```

unique    2    4    NaN    NaN
top      foo    c    NaN    NaN
freq     16    6    NaN    NaN
mean     NaN  NaN  11.500000  12.000000
std      NaN  NaN   7.071068   7.071068
min      NaN  NaN   0.000000   0.500000
25%      NaN  NaN   5.750000   6.250000
50%      NaN  NaN  11.500000  12.000000
75%      NaN  NaN  17.250000  17.750000
max      NaN  NaN  23.000000  23.500000

```

[11 rows x 4 columns]

Without those arguments, `describe` will behave as before, including only numerical columns or, if none are, only categorical columns. See also the *docs*

- Added `split` as an option to the `orient` argument in `pd.DataFrame.to_dict`. (GH7840)
- The `get_dummies` method can now be used on DataFrames. By default only categorical columns are encoded as 0's and 1's, while other columns are left untouched.

```

In [99]: df = pd.DataFrame({'A': ['a', 'b', 'a'], 'B': ['c', 'c', 'b'],
.....:                    'C': [1, 2, 3]})
.....:

```

```

In [100]: pd.get_dummies(df)

```

```

Out[100]:

```

```

   C  A_a  A_b  B_b  B_c
0  1    1    0    0    1
1  2    0    1    0    1
2  3    1    0    1    0

```

[3 rows x 5 columns]

- `PeriodIndex` supports `resolution` as the same as `DatetimeIndex` (GH7708)
- `pandas.tseries.holiday` has added support for additional holidays and ways to observe holidays (GH7070)
- `pandas.tseries.holiday.Holiday` now supports a list of offsets in Python3 (GH7070)
- `pandas.tseries.holiday.Holiday` now supports a `days_of_week` parameter (GH7070)
- `GroupBy.nth()` now supports selecting multiple `nth` values (GH7910)

```

In [101]: business_dates = pd.date_range(start='4/1/2014', end='6/30/2014', freq='B
->')

```

```

In [102]: df = pd.DataFrame(1, index=business_dates, columns=['a', 'b'])

```

```

# get the first, 4th, and last date index for each month

```

```

In [103]: df.groupby([df.index.year, df.index.month]).nth([0, 3, -1])

```

```

Out[103]:

```

```

      a  b
2014 4  1  1

```

 In [109]: `idx`
 Out[109]: `PeriodIndex(['2014-07', '2014-08', '2014-09', '2014-10', '2014-11'],`
`↪dtype='period[M]', freq='M')`
 In [110]: `idx + pd.offsets.MonthEnd(3)`
 Out[110]: `PeriodIndex(['2014-10', '2014-11', '2014-12', '2015-01', '2015-02'],`
`↪dtype='period[M]', freq='M')`
- Added experimental compatibility with `openpyxl` for versions `>= 2.0`. The `DataFrame.to_excel` method `engine` keyword now recognizes `openpyxl1` and `openpyxl2` which will explicitly require `openpyxl v1` and `v2` respectively, failing if the requested version is not available. The `openpyxl` engine is a now a meta-engine that automatically uses whichever version of `openpyxl` is installed. ([GH7177](#))
- `DataFrame.fillna` can now accept a `DataFrame` as a fill value ([GH8377](#))
- Passing multiple levels to `stack()` will now work when multiple level numbers are passed ([GH7660](#)). See *Reshaping by stacking and unstacking*.

- `set_names()`, `set_labels()`, and `set_levels()` methods now take an optional `level` keyword argument to all modification of specific level(s) of a `MultiIndex`. Additionally `set_names()` now accepts a scalar string value when operating on an `Index` or on a specific level of a `MultiIndex` ([GH7792](#))

```
In [111]: idx = pd.MultiIndex.from_product(['a'], range(3), list("pqr")),
.....:                                     names=['foo', 'bar', 'baz'])
.....:
```

```
In [112]: idx.set_names('qux', level=0)
```

```
Out[112]:
```

```
MultiIndex([(a, 0, 'p'),
            (a, 0, 'q'),
            (a, 0, 'r'),
            (a, 1, 'p'),
            (a, 1, 'q'),
            (a, 1, 'r'),
            (a, 2, 'p'),
            (a, 2, 'q'),
            (a, 2, 'r')],
           names=['qux', 'bar', 'baz'])
```

```
In [113]: idx.set_names(['qux', 'corge'], level=[0, 1])
```

```
Out[113]:
```

```

        ('a', 'c', 2),
        ('a', 'c', 3)],
        names=['foo', 'bar', 'baz'])

```

- `Index.isin` now supports a `level` argument to specify which index level to use for membership tests ([GH7892](#), [GH7890](#))

```

In [1]: idx = pd.MultiIndex.from_product([[0, 1], ['a', 'b', 'c']])
In [2]: idx.values
Out[2]: array([(0, 'a'), (0, 'b'), (0, 'c'), (1, 'a'), (1, 'b'), (1, 'c')],
              dtype=object)
In [3]: idx.isin(['a', 'c', 'e'], level=1)
Out[3]: array([ True, False,  True,  True, False,  True], dtype=bool)

```

- `Index` now supports duplicated and `drop_duplicates`. ([GH4060](#))

```

In [116]: idx = pd.Index([1, 2, 3, 4, 1, 2])

In [117]: idx
Out[117]: Int64Index([1, 2, 3, 4, 1, 2], dtype='int64')

In [118]: idx.duplicated()
Out[118]: array([False, False, False, False,  True,  True])

In [119]: idx.drop_duplicates()
Out[119]: Int64Index([1, 2, 3, 4], dtype='int64')

```

- add `copy=True` argument to `pd.concat` to enable pass through of complete blocks ([GH8252](#))
- Added support for numpy 1.8+ data types (`bool_`, `int_`, `float_`, `string_`) for conversion to R dataframe ([GH8400](#))

Performance

- Performance improvements in `DatetimeIndex.__iter__` to allow faster iteration ([GH7683](#))
- Performance improvements in `Period` creation (and `PeriodIndex` setitem) ([GH5155](#))
- Improvements in `Series.transform` for significant performance gains (revised) ([GH6496](#))
- Performance improvements in `StataReader` when reading large files ([GH8040](#), [GH8073](#))
- Performance improvements in `StataWriter` when writing large files ([GH8079](#))
- Performance and memory usage improvements in multi-key `groupby` ([GH8128](#))
- Performance improvements in `groupby` `.agg` and `.apply` where builtins `max/min` were not mapped to numpy/cythonized versions ([GH7722](#))
- Performance improvement in writing to sql (`to_sql`) of up to 50% ([GH8208](#)).
- Performance benchmarking of `groupby` for large value of `ngroups` ([GH6787](#))
- Performance improvement in `CustomBusinessDay`, `CustomBusinessMonth` ([GH8236](#))

- Performance improvement for `MultiIndex.values` for multi-level indexes containing datetimes (GH8543)

Bug fixes

- Bug in `pivot_table`, when using margins and a dict aggfunc (GH8349)
- Bug in `read_csv` where `squeeze=True` would return a view (GH8217)
- Bug in checking of table name in `read_sql` in certain cases (GH7826).
- Bug in `DataFrame.groupby` where `Groupby` does not recognize level when frequency is specified (GH7885)
- Bug in multiindexes dtypes getting mixed up when `DataFrame` is saved to SQL table (GH8021)
- Bug in `Series` 0-division with a float and integer operand dtypes (GH7785)
- Bug in `Series.astype("unicode")` not calling `unicode` on the values correctly (GH7758)
- Bug in `DataFrame.as_matrix()` with mixed `datetime64[ns]` and `timedelta64[ns]` dtypes (GH7778)
- Bug in `HDFStore.select_column()` not preserving UTC timezone info when selecting a `DatetimeIndex` (GH7777)
- Bug in `to_datetime` when `format='%Y%m%d'` and `coerce=True` are specified, where previously an object array was returned (rather than a coerced time-series with `NaT`), (GH7930)
- Bug in `DatetimeIndex` and `PeriodIndex` in-place addition and subtraction cause different result from normal one (GH6527)
- Bug in adding and subtracting `PeriodIndex` with `PeriodIndex` raise `TypeError` (GH7741)
- Bug in `combine_first` with `PeriodIndex` data raises `TypeError` (GH3367)
- Bug in `MultiIndex` slicing with missing indexers (GH7866)
- Bug in `MultiIndex` slicing with various edge cases (GH8132)
- Regression in `MultiIndex` indexing with a non-scalar type object (GH7914)
- Bug in `Timestamp` comparisons with `==` and `int64` dtype (GH8058)
- Bug in pickles contains `DateOffset` may raise `AttributeError` when `normalize` attribute is referred internally (GH7748)
- Bug in `Panel` when using `major_xs` and `copy=False` is passed (deprecation warning fails because of missing warnings) (GH8152).
- Bug in pickle deserialization that failed for pre-0.14.1 containers with dup items trying to avoid ambiguity when matching block and manager items, when there's only one block there's no ambiguity (GH7794)
- Bug in putting a `PeriodIndex` into a `Series` would convert to `int64` dtype, rather than object of `Periods` (GH7932)
- Bug in `HDFStore` iteration when passing a `where` (GH8014)
- Bug in `DataFrameGroupby.transform` when transforming with a passed non-sorted key (GH8046, GH8430)
- Bug in repeated timeseries line and area plot may result in `ValueError` or incorrect kind (GH7733)
- Bug in inference in a `MultiIndex` with `datetime.date` inputs (GH7888)
- Bug in `get` where an `IndexError` would not cause the default value to be returned (GH7725)

- Bug in `offsets.apply`, `rollforward` and `rollback` may reset nanosecond (GH7697)
- Bug in `offsets.apply`, `rollforward` and `rollback` may raise `AttributeError` if `Timestamp` has `dateutil tzinfo` (GH7697)
- Bug in sorting a `MultiIndex` frame with a `Float64Index` (GH8017)
- Bug in inconsistent panel setitem with a rhs of a `DataFrame` for alignment (GH7763)
- Bug in `is_superperiod` and `is_subperiod` cannot handle higher frequencies than S (GH7760, GH7772, GH7803)
- Bug in 32-bit platforms with `Series.shift` (GH8129)
- Bug in `PeriodIndex.unique` returns `int64 np.ndarray` (GH7540)
- Bug in `groupby.apply` with a non-affecting mutation in the function (GH8467)
- Bug in `DataFrame.reset_index` which has `MultiIndex` contains `PeriodIndex` or `DatetimeIndex` with `tz` raises `ValueError` (GH7746, GH7793)
- Bug in `DataFrame.plot` with `subplots=True` may draw unnecessary minor `xticks` and `yticks` (GH7801)
- Bug in `StataReader` which did not read variable labels in 117 files due to difference between Stata documentation and implementation (GH7816)
- Bug in `StataReader` where strings were always converted to 244 characters-fixed width irrespective of underlying string size (GH7858)
- Bug in `DataFrame.plot` and `Series.plot` may ignore `rot` and `fontsize` keywords (GH7844)
- Bug in `DatetimeIndex.value_counts` doesn't preserve `tz` (GH7735)
- Bug in `PeriodIndex.value_counts` results in `Int64Index` (GH7735)
- Bug in `DataFrame.join` when doing left join on index and there are multiple matches (GH5391)
- Bug in `GroupBy.transform()` where int groups with a transform that didn't preserve the index were incorrectly truncated (GH7972).
- Bug in `groupby` where callable objects without name attributes would take the wrong path, and produce a `DataFrame` instead of a `Series` (GH7929)
- Bug in `groupby` error message when a `DataFrame` grouping column is duplicated (GH7511)
- Bug in `read_html` where the `infer_types` argument forced coercion of date-likes incorrectly (GH7762, GH7032).
- Bug in `Series.str.cat` with an index which was filtered as to not include the first item (GH7857)
- Bug in `Timestamp` cannot parse `nanosecond` from string (GH7878)
- Bug in `Timestamp` with string offset and `tz` results incorrect (GH7833)
- Bug in `tslib.tz_convert` and `tslib.tz_convert_single` may return different results (GH7798)
- Bug in `DatetimeIndex.intersection` of non-overlapping timestamps with `tz` raises `IndexError` (GH7880)
- Bug in alignment with `TimeOps` and non-unique indexes (GH8363)
- Bug in `GroupBy.filter()` where fast path vs. slow path made the filter return a non scalar value that appeared valid but wasn't (GH7870).
- Bug in `date_range()/DatetimeIndex()` when the timezone was inferred from input dates yet incorrect times were returned when crossing DST boundaries (GH7835, GH7901).

- Bug in `to_excel()` where a negative sign was being prepended to positive infinity and was absent for negative infinity (GH7949)
- Bug in area plot draws legend with incorrect `alpha` when `stacked=True` (GH8027)
- `Period` and `PeriodIndex` addition/subtraction with `np.timedelta64` results in incorrect internal representations (GH7740)
- Bug in `Holiday` with no offset or observance (GH7987)
- Bug in `DataFrame.to_latex` formatting when columns or index is a `MultiIndex` (GH7982).
- Bug in `DateOffset` around Daylight Savings Time produces unexpected results (GH5175).
- Bug in `DataFrame.shift` where empty columns would throw `ZeroDivisionError` on numpy 1.7 (GH8019)
- Bug in installation where `html_encoding/*.html` wasn't installed and therefore some tests were not running correctly (GH7927).
- Bug in `read_html` where `bytes` objects were not tested for in `_read` (GH7927).
- Bug in `DataFrame.stack()` when one of the column levels was a datelike (GH8039)
- Bug in broadcasting numpy scalars with `DataFrame` (GH8116)
- Bug in `pivot_table` performed with nameless `index` and `columns` raises `KeyError` (GH8103)
- Bug in `DataFrame.plot(kind='scatter')` draws points and errorbars with different colors when the color is specified by `c` keyword (GH8081)
- Bug in `Float64Index` where `iat` and `at` were not testing and were failing (GH8092).
- Bug in `DataFrame.boxplot()` where y-limits were not set correctly when producing multiple axes (GH7528, GH5517).
- Bug in `read_csv` where line comments were not handled correctly given a custom line terminator or `delim_whitespace=True` (GH8122).
- Bug in `read_html` where empty tables caused a `StopIteration` (GH7575)
- Bug in casting when setting a column in a same-dtype block (GH7704)
- Bug in accessing groups from a `GroupBy` when the original grouper was a tuple (GH8121).
- Bug in `.at` that would accept integer indexers on a non-integer index and do fallback (GH7814)
- Bug with kde plot and NaNs (GH8182)
- Bug in `GroupBy.count` with float32 data type were nan values were not excluded (GH8169).
- Bug with stacked barplots and NaNs (GH8175).
- Bug in `resample` with non evenly divisible offsets (e.g. '7s') (GH8371)
- Bug in interpolation methods with the `limit` keyword when no values needed interpolating (GH7173).
- Bug where `col_space` was ignored in `DataFrame.to_string()` when `header=False` (GH8230).
- Bug with `DatetimeIndex.asof` incorrectly matching partial strings and returning the wrong date (GH8245).
- Bug in plotting methods modifying the global matplotlib rcParams (GH8242).
- Bug in `DataFrame.__setitem__` that caused errors when setting a dataframe column to a sparse array (GH8131)
- Bug where `Dataframe.boxplot()` failed when entire column was empty (GH8181).

- Bug with messed variables in `radviz` visualization ([GH8199](#)).
- Bug in interpolation methods with the `limit` keyword when no values needed interpolating ([GH7173](#)).
- Bug where `col_space` was ignored in `DataFrame.to_string()` when `header=False` ([GH8230](#)).
- Bug in `to_clipboard` that would clip long column data ([GH8305](#)).
- Bug in `DataFrame` terminal display: Setting `max_column/max_rows` to zero did not trigger auto-resizing of dfs to fit terminal width/height ([GH7180](#)).
- Bug in OLS where running with “cluster” and “nw_lags” parameters did not work correctly, but also did not throw an error ([GH5884](#)).
- Bug in `DataFrame.dropna` that interpreted non-existent columns in the subset argument as the ‘last column’ ([GH8303](#)).
- Bug in `Index.intersection` on non-monotonic non-unique indexes ([GH8362](#)).
- Bug in masked series assignment where mismatching types would break alignment ([GH8387](#)).
- Bug in `NDFrame.equals` gives false negatives with `dtype=object` ([GH8437](#)).
- Bug in assignment with indexer where type diversity would break alignment ([GH8258](#)).
- Bug in `NDFrame.loc` indexing when row/column names were lost when target was a list/ndarray ([GH6552](#)).
- Regression in `NDFrame.loc` indexing when rows/columns were converted to `Float64Index` if target was an empty list/ndarray ([GH7774](#)).
- Bug in `Series` that allows it to be indexed by a `DataFrame` which has unexpected results. Such indexing is no longer permitted ([GH8444](#)).
- Bug in item assignment of a `DataFrame` with `MultiIndex` columns where right-hand-side columns were not aligned ([GH7655](#)).
- Suppress `FutureWarning` generated by `NumPy` when comparing object arrays containing `NaN` for equality ([GH7065](#)).
- Bug in `DataFrame.eval()` where the `dtype` of the `not` operator (`~`) was not correctly inferred as `bool`.

8.12 Version 0.14

8.12.1 v0.14.1 (July 11, 2014)

{{ header }}

This is a minor release from 0.14.0 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

- Highlights include:
 - New methods `select_dtypes()` to select columns based on the dtype and `sem()` to calculate the standard error of the mean.
 - Support for dateutil timezones (see *docs*).
 - Support for ignoring full line comments in the `read_csv()` text parser.
 - New documentation section on *Options and Settings*.
 - Lots of bug fixes.
- *Enhancements*
- *API Changes*
- *Performance Improvements*
- *Experimental Changes*
- *Bug Fixes*

API changes

- Openpyxl now raises a `ValueError` on construction of the openpyxl writer instead of warning on pandas import ([GH7284](#)).
- For `StringMethods.extract`, when no match is found, the result - only containing NaN values - now also has `dtype=object` instead of `float` ([GH7242](#)).
- `Period` objects no longer raise a `TypeError` when compared using `==` with another object that *isn't* a `Period`. Instead when comparing a `Period` with another object using `==` if the other object isn't a `Period` `False` is returned. ([GH7376](#))
- Previously, the behaviour on resetting the time or not in `offsets.apply`, `rollforward` and `rollback` operations differed between offsets. With the support of the `normalize` keyword for all offsets (see below) with a default value of `False` (preserve time), the behaviour changed for certain offsets (`BusinessMonthBegin`, `MonthEnd`, `BusinessMonthEnd`, `CustomBusinessMonthEnd`, `BusinessYearBegin`, `LastWeekOfMonth`, `FY5253Quarter`, `LastWeekOfMonth`, `Easter`):

```
In [6]: from pandas.tseries import offsets

In [7]: d = pd.Timestamp('2014-01-01 09:00')

# old behaviour < 0.14.1
In [8]: d + offsets.MonthEnd()
Out[8]: pd.Timestamp('2014-01-31 00:00:00')
```

Starting from 0.14.1 all offsets preserve time by default. The old behaviour can be obtained with `normalize=True`

```
# new behaviour
```

```
In [1]: d + offsets.MonthEnd()
```

```
Out[1]: Timestamp('2014-01-31 09:00:00')
```

```
In [2]: d + offsets.MonthEnd(normalize=True)
```

```
Out[2]: Timestamp('2014-01-31 00:00:00')
```

Note that for the other offsets the default behaviour did not change.

- Add back `#N/A N/A` as a default NA value in text parsing, (regression from 0.12) ([GH5521](#))
- Raise a `TypeError` on inplace-setting with a `.where` and a non `np.nan` value as this is inconsistent with a set-item expression like `df[mask] = None` ([GH7656](#))

Enhancements

- Add `dropna` argument to `value_counts` and `nunique` ([GH5569](#)).
- Add `select_dtypes()` method to allow selection of columns based on dtype ([GH7316](#)). See *the docs*.
- All offsets supports the `normalize` keyword to specify whether `offsets.apply`, `rollforward` and `rollback` resets the time (hour, minute, etc) or not (default `False`, preserves time) ([GH7156](#)):

```
import pandas.tseries.offsets as offsets

day = offsets.Day()
day.apply(pd.Timestamp('2014-01-01 09:00'))

day = offsets.Day(normalize=True)
day.apply(pd.Timestamp('2014-01-01 09:00'))
```

- `PeriodIndex` is represented as the same format as `DatetimeIndex` ([GH7601](#))
- `StringMethods` now work on empty Series ([GH7242](#))
- The file parsers `read_csv` and `read_table` now ignore line comments provided by the parameter `comment`, which accepts only a single character for the C reader. In particular, they allow for comments before file data begins ([GH2685](#))
- Add `NotImplementedError` for simultaneous use of `chunksize` and `nrows` for `read_csv()` ([GH6774](#)).
- Tests for basic reading of public S3 buckets now exist ([GH7281](#)).
- `read_html` now sports an `encoding` argument that is passed to the underlying parser library. You can use this to read non-ascii encoded web pages ([GH7323](#)).
- `read_excel` now supports reading from URLs in the same way that `read_csv` does. ([GH6809](#))
- Support for dateutil timezones, which can now be used in the same way as pytz timezones across pandas. ([GH4688](#))

```
In [3]: rng = pd.date_range('3/6/2012 00:00', periods=10, freq='D',
...:                       tz='dateutil/Europe/London')
...:
...:

In [4]: rng.tz
Out[4]: tzfile('/usr/share/zoneinfo/Europe/London')
```

See *the docs*.

- Implemented `sem` (standard error of the mean) operation for `Series`, `DataFrame`, `Panel`, and `Groupby` ([GH6897](#))
- Add `nlargest` and `nsmallest` to the `Series` `groupby` whitelist, which means you can now use these methods on a `SeriesGroupBy` object ([GH7053](#)).
- All offsets apply, `rollforward` and `rollback` can now handle `np.datetime64`, previously results in `ApplyTypeError` ([GH7452](#))
- `Period` and `PeriodIndex` can contain `NaT` in its values ([GH7485](#))
- Support pickling `Series`, `DataFrame` and `Panel` objects with non-unique labels along *item* axis (`index`, `columns` and `items` respectively) ([GH7370](#)).
- Improved inference of `datetime/timedelta` with mixed null objects. Regression from 0.13.1 in interpretation of an object `Index` with all null elements ([GH7431](#))

Performance

- Improvements in `dtype` inference for numeric operations involving yielding performance gains for `dtypes`: `int64`, `timedelta64`, `datetime64` ([GH7223](#))
- Improvements in `Series.transform` for significant performance gains ([GH6496](#))
- Improvements in `DataFrame.transform` with `ufuncs` and built-in grouper functions for significant performance gains ([GH7383](#))
- Regression in `groupby` aggregation of `datetime64` `dtypes` ([GH7555](#))
- Improvements in `MultiIndex.from_product` for large iterables ([GH7627](#))

Experimental

- `pandas.io.data.Options` has a new method, `get_all_data` method, and now consistently returns a `MultiIndexed DataFrame` ([GH5602](#))
- `io.gbq.read_gbq` and `io.gbq.to_gbq` were refactored to remove the dependency on the Google `bq.py` command line client. This submodule now uses `httplib2` and the Google `apiclient` and `oauth2client` API client libraries which should be more stable and, therefore, reliable than `bq.py`. See *the docs*. ([GH6937](#)).

Bug fixes

- Bug in `DataFrame.where` with a symmetric shaped frame and a passed other of a `DataFrame` ([GH7506](#))
- Bug in `Panel` indexing with a `MultiIndex` axis ([GH7516](#))
- Regression in `datetimelike` slice indexing with a duplicated index and non-exact end-points ([GH7523](#))
- Bug in `setitem` with list-of-lists and single vs mixed types ([GH7551](#):)
- Bug in time ops with non-aligned `Series` ([GH7500](#))
- Bug in `timedelta` inference when assigning an incomplete `Series` ([GH7592](#))
- Bug in `groupby` `.nth` with a `Series` and integer-like column name ([GH7559](#))
- Bug in `Series.get` with a boolean accessor ([GH7407](#))

- Bug in `value_counts` where `NaT` did not qualify as missing (`NaN`) (GH7423)
- Bug in `to_timedelta` that accepted invalid units and misinterpreted 'm/h' (GH7611, GH6423)
- Bug in line plot doesn't set correct `xlim` if `secondary_y=True` (GH7459)
- Bug in grouped `hist` and `scatter` plots use old `figsize` default (GH7394)
- Bug in plotting subplots with `DataFrame.plot`, `hist` clears passed `ax` even if the number of subplots is one (GH7391).
- Bug in plotting subplots with `DataFrame.boxplot` with `by` kw raises `ValueError` if the number of subplots exceeds 1 (GH7391).
- Bug in subplots displays `ticklabels` and `labels` in different rule (GH5897)
- Bug in `Panel.apply` with a `MultiIndex` as an axis (GH7469)
- Bug in `DatetimeIndex.insert` doesn't preserve `name` and `tz` (GH7299)
- Bug in `DatetimeIndex.asobject` doesn't preserve `name` (GH7299)
- Bug in `MultiIndex` slicing with datetimelike ranges (strings and `Timestamps`), (GH7429)
- Bug in `Index.min` and `max` doesn't handle `nan` and `NaT` properly (GH7261)
- Bug in `PeriodIndex.min/max` results in `int` (GH7609)
- Bug in `resample` where `fill_method` was ignored if you passed `how` (GH2073)
- Bug in `TimeGrouper` doesn't exclude column specified by `key` (GH7227)
- Bug in `DataFrame` and `Series` `bar` and `barh` plot raises `TypeError` when `bottom` and `left` keyword is specified (GH7226)
- Bug in `DataFrame.hist` raises `TypeError` when it contains non numeric column (GH7277)
- Bug in `Index.delete` does not preserve `name` and `freq` attributes (GH7302)
- Bug in `DataFrame.query()/eval` where local string variables with the `@` sign were being treated as temporaries attempting to be deleted (GH7300).
- Bug in `Float64Index` which didn't allow duplicates (GH7149).
- Bug in `DataFrame.replace()` where truthy values were being replaced (GH7140).
- Bug in `StringMethods.extract()` where a single match group `Series` would use the matcher's name instead of the group name (GH7313).
- Bug in `isnull()` when `mode.use_inf_as_null == True` where `isnull` wouldn't test `True` when it encountered an `inf/-inf` (GH7315).
- Bug in `inferred_freq` results in `None` for eastern hemisphere timezones (GH7310)
- Bug in `Easter` returns incorrect date when offset is negative (GH7195)
- Bug in broadcasting with `.div`, integer dtypes and divide-by-zero (GH7325)
- Bug in `CustomBusinessDay.apply` raises `NameError` when `np.datetime64` object is passed (GH7196)
- Bug in `MultiIndex.append`, `concat` and `pivot_table` don't preserve timezone (GH6606)
- Bug in `.loc` with a list of indexers on a single-multi index level (that is not nested) (GH7349)
- Bug in `Series.map` when mapping a dict with tuple keys of different lengths (GH7333)
- Bug all `StringMethods` now work on empty `Series` (GH7242)
- Fix delegation of `read_sql` to `read_sql_query` when query does not contain 'select' (GH7324).

- Bug where a string column name assignment to a DataFrame with a Float64Index raised a TypeError during a call to `np.isnan` (GH7366).
- Bug where `NDFrame.replace()` didn't correctly replace objects with Period values (GH7379).
- Bug in `.ix` getitem should always return a Series (GH7150)
- Bug in MultiIndex slicing with incomplete indexers (GH7399)
- Bug in MultiIndex slicing with a step in a sliced level (GH7400)
- Bug where negative indexers in `DatetimeIndex` were not correctly sliced (GH7408)
- Bug where `NaT` wasn't repr'd correctly in a `MultiIndex` (GH7406, GH7409).
- Bug where bool objects were converted to `nan` in `convert_objects` (GH7416).
- Bug in `quantile` ignoring the axis keyword argument (GH7306)
- Bug where `nanops._maybe_null_out` doesn't work with complex numbers (GH7353)
- Bug in several `nanops` functions when `axis==0` for 1-dimensional `nan` arrays (GH7354)
- Bug where `nanops.nanmedian` doesn't work when `axis==None` (GH7352)
- Bug where `nanops._has_infs` doesn't work with many dtypes (GH7357)
- Bug in `StataReader.data` where reading a 0-observation dta failed (GH7369)
- Bug in `StataReader` when reading Stata 13 (117) files containing fixed width strings (GH7360)
- Bug in `StataWriter` where encoding was ignored (GH7286)
- Bug in `DatetimeIndex` comparison doesn't handle `NaT` properly (GH7529)
- Bug in passing input with `tzinfo` to some offsets `apply`, `rollforward` or `rollback` resets `tzinfo` or raises `ValueError` (GH7465)
- Bug in `DatetimeIndex.to_period`, `PeriodIndex.asobject`, `PeriodIndex.to_timestamp` doesn't preserve name (GH7485)
- Bug in `DatetimeIndex.to_period` and `PeriodIndex.to_timestamp` handle `NaT` incorrectly (GH7228)
- Bug in `offsets.apply`, `rollforward` and `rollback` may return normal `datetime` (GH7502)
- Bug in `resample` raises `ValueError` when target contains `NaT` (GH7227)
- Bug in `Timestamp.tz_localize` resets `nanosecond` info (GH7534)
- Bug in `DatetimeIndex.asobject` raises `ValueError` when it contains `NaT` (GH7539)
- Bug in `Timestamp.__new__` doesn't preserve `nanosecond` properly (GH7610)
- Bug in `Index.astype(float)` where it would return an object dtype `Index` (GH7464).
- Bug in `DataFrame.reset_index` loses `tz` (GH3950)
- Bug in `DatetimeIndex.freqstr` raises `AttributeError` when `freq` is `None` (GH7606)
- Bug in `GroupBy.size` created by `TimeGrouper` raises `AttributeError` (GH7453)
- Bug in single column bar plot is misaligned (GH7498).
- Bug in area plot with tz-aware time series raises `ValueError` (GH7471)
- Bug in non-monotonic `Index.union` may preserve `name` incorrectly (GH7458)
- Bug in `DatetimeIndex.intersection` doesn't preserve timezone (GH4690)
- Bug in `rolling_var` where a window larger than the array would raise an error (GH7297)

- Bug with last plotted timeseries dictating `xlim` (GH2960)
- Bug with `secondary_y` axis not being considered for timeseries `xlim` (GH3490)
- Bug in `Float64Index` assignment with a non scalar indexer (GH7586)
- Bug in `pandas.core.strings.str_contains` does not properly match in a case insensitive fashion when `regex=False` and `case=False` (GH7505)
- Bug in `expanding_cov`, `expanding_corr`, `rolling_cov`, and `rolling_corr` for two arguments with mismatched index (GH7512)
- Bug in `to_sql` taking the boolean column as text column (GH7678)
- Bug in grouped `hist` doesn't handle `rot` kw and `sharex` kw properly (GH7234)
- Bug in `.loc` performing fallback integer indexing with `object` dtype indices (GH7496)
- Bug (regression) in `PeriodIndex` constructor when passed `Series` objects (GH7701).

8.12.2 v0.14.0 (May 31 , 2014)

{{ header }}

This is a major release from 0.13.1 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

- Highlights include:
 - Officially support Python 3.4
 - SQL interfaces updated to use `sqlalchemy`, See *Here*.
 - Display interface changes, See *Here*
 - MultiIndexing Using Slicers, See *Here*.
 - Ability to join a singly-indexed DataFrame with a MultiIndexed DataFrame, see *Here*
 - More consistency in groupby results and more flexible groupby specifications, See *Here*

- Holiday calendars are now supported in `CustomBusinessDay`, see *Here*
- Several improvements in plotting functions, including: hexbin, area and pie plots, see *Here*.
- Performance doc section on I/O operations, See *Here*
- *Other Enhancements*
- *API Changes*
- *Text Parsing API Changes*
- *Groupby API Changes*
- *Performance Improvements*
- *Prior Deprecations*
- *Deprecations*
- *Known Issues*
- *Bug Fixes*

Warning: In 0.14.0 all `NDFrame` based containers have undergone significant internal refactoring. Before that each block of homogeneous data had its own labels and extra care was necessary to keep those in sync with the parent container's labels. This should not have any visible user/API behavior changes (GH6745)

API changes

- `read_excel` uses 0 as the default sheet (GH6573)
- `iloc` will now accept out-of-bounds indexers for slices, e.g. a value that exceeds the length of the object being indexed. These will be excluded. This will make pandas conform more with python/numpy indexing of out-of-bounds values. A single indexer that is out-of-bounds and drops the dimensions of the object will still raise `IndexError` (GH6296, GH6299). This could result in an empty axis (e.g. an empty `DataFrame` being returned)

```
In [1]: df1 = pd.DataFrame(np.random.randn(5, 2), columns=list('AB'))
```

```
In [2]: df1
```

```
Out[2]:
```

```
      A          B
0  0.245972  0.319442
1  1.378512  0.292502
2  0.329791  1.392047
3  0.769914 -2.472300
4 -0.611151  1.044829
```

```
[5 rows x 2 columns]
```

```
In [3]: df1.iloc[:, 2:3]
```

```
Out[3]:
```

```
Empty DataFrame
```

```
Columns: []
```

```
Index: [0, 1, 2, 3, 4]
```

```
[5 rows x 0 columns]
```

```
In [4]: dfl.iloc[:, 1:3]
```

```
Out[4]:
```

```
      B
0  0.319442
1  0.292502
2  1.392047
3 -2.472300
4  1.044829
```

```
[5 rows x 1 columns]
```

```
In [5]: dfl.iloc[4:6]
```

```
Out[5]:
```

```
      A      B
4 -0.611151  1.044829
```

```
[1 rows x 2 columns]
```

These are out-of-bounds selections

```
>>> dfl.iloc[[4, 5, 6]]
IndexError: positional indexers are out-of-bounds

>>> dfl.iloc[:, 4]
IndexError: single positional indexer is out-of-bounds
```

- Slicing with negative start, stop & step values handles corner cases better (GH6531):
 - `df.iloc[: -len(df)]` is now empty
 - `df.iloc[len(df)::-1]` now enumerates all elements in reverse
- The `DataFrame.interpolate()` keyword `downcast` default has been changed from `infer` to `None`. This is to preserve the original dtype unless explicitly requested otherwise (GH6290).
- When converting a dataframe to HTML it used to return *Empty DataFrame*. This special case has been removed, instead a header with the column names is returned (GH6062).
- `Series` and `Index` now internally share more common operations, e.g. `factorize()`, `nunique()`, `value_counts()` are now supported on `Index` types as well. The `Series.weekday` property from is removed from `Series` for API consistency. Using a `DatetimeIndex/PeriodIndex` method on a `Series` will now raise a `TypeError`. (GH4551, GH4056, GH5519, GH6380, GH7206).
- Add `is_month_start`, `is_month_end`, `is_quarter_start`, `is_quarter_end`, `is_year_start`, `is_year_end` accessors for `DatetimeIndex / Timestamp` which return a boolean array of whether the timestamp(s) are at the start/end of the month/quarter/year defined by the frequency of the `DatetimeIndex / Timestamp` (GH4565, GH6998)
- Local variable usage has changed in `pandas.eval()/DataFrame.eval()/DataFrame.query()` (GH5987). For the *DataFrame* methods, two things have changed
 - Column names are now given precedence over locals
 - Local variables must be referred to explicitly. This means that even if you have a local variable that is *not* a column you must still refer to it with the '@' prefix.
 - You can have an expression like `df.query('@a < a')` with no complaints from pandas about ambiguity of the name `a`.

- The top-level `pandas.eval()` function does not allow you use the '@' prefix and provides you with an error message telling you so.
- `NameResolutionError` was removed because it isn't necessary anymore.
- Define and document the order of column vs index names in query/eval ([GH6676](#))
- `concat` will now concatenate mixed Series and DataFrames using the Series name or numbering columns as needed ([GH2385](#)). See *the docs*
- Slicing and advanced/boolean indexing operations on `Index` classes as well as `Index.delete()` and `Index.drop()` methods will no longer change the type of the resulting index ([GH6440](#), [GH7040](#))

```
In [6]: i = pd.Index([1, 2, 3, 'a', 'b', 'c'])
```

```
In [7]: i[[0, 1, 2]]
```

```
Out[7]: Index([1, 2, 3], dtype='object')
```

```
In [8]: i.drop(['a', 'b', 'c'])
```

```
Out[8]: Index([1, 2, 3], dtype='object')
```

Previously, the above operation would return `Int64Index`. If you'd like to do this manually, use `Index.astype()`

```
In [9]: i[[0, 1, 2]].astype(np.int_)
Out[9]: Int64Index([1, 2, 3], dtype='int64')
```

- `set_index` no longer converts `MultiIndex`s to an `Index` of tuples. For example, the old behavior returned an `Index` in this case ([GH6459](#)):

```
# Old behavior, casted MultiIndex to an Index
```

```
In [10]: tuple_ind
```

```
Out[10]: Index([('a', 'c'), ('a', 'd'), ('b', 'c'), ('b', 'd')], dtype='object')
```

```
In [11]: df_multi.set_index(tuple_ind)
```

```
Out[11]:
```

```

           0         1
(a, c)  0.471435 -1.190976
(a, d)  1.432707 -0.312652
(b, c) -0.720589  0.887163
(b, d)  0.859588 -0.636524
```

```
[4 rows x 2 columns]
```

```
# New behavior
```

```
In [12]: mi
```

```
Out[12]:
```

```
MultiIndex([('a', 'c'),
            ('a', 'd'),
            ('b', 'c'),
            ('b', 'd')],
           )
```

```
In [13]: df_multi.set_index(mi)
```

```
Out[13]:
```

```

           0         1
a c  0.471435 -1.190976
d  1.432707 -0.312652
```

```
b c -0.720589  0.887163
d  0.859588 -0.636524
```

```
[4 rows x 2 columns]
```

This also applies when passing multiple indices to `set_index`:

```
# Old output, 2-level MultiIndex of tuples
In [14]: df_multi.set_index([df_multi.index, df_multi.index])
Out[14]:
```

	0	1
(a, c) (a, c)	0.471435	-1.190976
(a, d) (a, d)	1.432707	-0.312652
(b, c) (b, c)	-0.720589	0.887163
(b, d) (b, d)	0.859588	-0.636524

```
[4 rows x 2 columns]

# New output, 4-level MultiIndex
In [15]: df_multi.set_index([df_multi.index, df_multi.index])
Out[15]:
```

	0	1
a c a c	0.471435	-1.190976
d a d	1.432707	-0.312652
b c b c	-0.720589	0.887163
d b d	0.859588	-0.636524

```
[4 rows x 2 columns]
```

- `pairwise` keyword was added to the statistical moment functions `rolling_cov`, `rolling_corr`, `ewmcov`, `ewmcorr`, `expanding_cov`, `expanding_corr` to allow the calculation of moving window covariance and correlation matrices (GH4950). See *Computing rolling pairwise covariances and correlations* in the docs.

```
In [1]: df = pd.DataFrame(np.random.randn(10, 4), columns=list('ABCD'))

In [4]: covs = pd.rolling_cov(df[['A', 'B', 'C']],
.....:                        df[['B', 'C', 'D']],
.....:                        5,
.....:                        pairwise=True)

In [5]: covs[df.index[-1]]
Out[5]:
```

	B	C	D
A	0.035310	0.326593	-0.505430
B	0.137748	-0.006888	-0.005383
C	-0.006888	0.861040	0.020762

- `Series.iteritems()` is now lazy (returns an iterator rather than a list). This was the documented behavior prior to 0.14. (GH6760)
- Added `nunique` and `value_counts` functions to `Index` for counting unique elements. (GH6734)
- `stack` and `unstack` now raise a `ValueError` when the `level` keyword refers to a non-unique item in the `Index` (previously raised a `KeyError`). (GH6738)

- drop unused order argument from `Series.sort`; args now are in the same order as `Series.order`; add `na_position` arg to conform to `Series.order` (GH6847)
- default sorting algorithm for `Series.order` is now quicksort, to conform with `Series.sort` (and numpy defaults)
- add `inplace` keyword to `Series.order/sort` to make them inverses (GH6859)
- `DataFrame.sort` now places NaNs at the beginning or end of the sort according to the `na_position` parameter. (GH3917)
- accept `TextFileReader` in `concat`, which was affecting a common user idiom (GH6583), this was a regression from 0.13.1
- Added `factorize` functions to `Index` and `Series` to get indexer and unique values (GH7090)
- `describe` on a `DataFrame` with a mix of `Timestamp` and string like objects returns a different `Index` (GH7088). Previously the index was unintentionally sorted.
- Arithmetic operations with **only** `bool` dtypes now give a warning indicating that they are evaluated in Python space for `+`, `-`, and `*` operations and raise for all others (GH7011, GH6762, GH7015, GH7210)

```

>>> x = pd.Series(np.random.rand(10) > 0.5)
>>> y = True
>>> x + y # warning generated: should do x / y instead
UserWarning: evaluating in Python space because the '+' operator is not
supported by numexpr for the bool dtype, use '|' instead
>>> x / y # this raises because it doesn't make sense
NotImplementedError: operator '/' not implemented for bool dtypes

```

- In `HDFStore`, `select_as_multiple` will always raise a `KeyError`, when a key or the selector is not found (GH6177)
- `df['col'] = value` and `df.loc[:, 'col'] = value` are now completely equivalent; previously the `.loc` would not necessarily coerce the dtype of the resultant series (GH6149)
- `dtypes` and `ftypes` now return a series with `dtype=object` on empty containers (GH5740)
- `df.to_csv` will now return a string of the CSV data if neither a target path nor a buffer is provided (GH6061)
- `pd.infer_freq()` will now raise a `TypeError` if given an invalid `Series/Index` type (GH6407, GH6463)
- A tuple passed to `DataFrame.sort_index` will be interpreted as the levels of the index, rather than requiring a list of tuple (GH4370)
- all offset operations now return `Timestamp` types (rather than `datetime`), `Business/Week` frequencies were incorrect (GH4069)
- `to_excel` now converts `np.inf` into a string representation, customizable by the `inf_rep` keyword argument (Excel has no native inf representation) (GH6782)
- Replace `pandas.compat.scipy.scoreatpercentile` with `numpy.percentile` (GH6810)
- `.quantile` on a `datetime[ns]` series now returns `Timestamp` instead of `np.datetime64` objects (GH6810)
- change `AssertionError` to `TypeError` for invalid types passed to `concat` (GH6583)
- Raise a `TypeError` when `DataFrame` is passed an iterator as the `data` argument (GH5357)

Display changes

- The default way of printing large DataFrames has changed. DataFrames exceeding `max_rows` and/or `max_columns` are now displayed in a centrally truncated view, consistent with the printing of a *pandas.Series* (GH5603).

In previous versions, a DataFrame was truncated once the dimension constraints were reached and an ellipse (...) signaled that part of the data was cut off.

```
In [1]: import pandas as pd
```

```
In [2]: import numpy as np
```

```
In [3]: pd.options.display.max_rows = 6
```

```
In [4]: pd.options.display.max_columns = 6
```

```
In [5]: index = pd.DatetimeIndex(start='20010101', freq='D', periods=10)
```

```
In [6]: pd.DataFrame(np.arange(10*10).reshape((10,10)), index=index)
```

```
Out[6]:
```

```

      0  1  2  3  4  5  ...
2001-01-01  0  1  2  3  4  5  ...
2001-01-02 10 11 12 13 14 15  ...
2001-01-03 20 21 22 23 24 25  ...
2001-01-04 30 31 32 33 34 35  ...
2001-01-05 40 41 42 43 44 45  ...
2001-01-06 50 51 52 53 54 55  ...
      ... .. ... .. ... ..
```

```
[10 rows x 10 columns]
```

In the current version, large DataFrames are centrally truncated, showing a preview of head and tail in both dimensions.

```
In [24]: pd.DataFrame(np.arange(10*10).reshape((10,10)), index=index)
```

```
Out[24]:
```

```

      0  1  2  ...  7  8  9
2001-01-01  0  1  2  ...  7  8  9
2001-01-02 10 11 12  ... 17 18 19
2001-01-03 20 21 22  ... 27 28 29
...
2001-01-08 70 71 72  ... 77 78 79
2001-01-09 80 81 82  ... 87 88 89
2001-01-10 90 91 92  ... 97 98 99
```

```
[10 rows x 10 columns]
```

- allow option 'truncate' for `display.show_dimensions` to only show the dimensions if the frame is truncated (GH6547).

The default for `display.show_dimensions` will now be `truncate`. This is consistent with how Series display length.

```
In [16]: dfd = pd.DataFrame(np.arange(25).reshape(-1, 5),
.....:                      index=[0, 1, 2, 3, 4],
.....:                      columns=[0, 1, 2, 3, 4])
.....:

# show dimensions since this is truncated
In [17]: with pd.option_context('display.max_rows', 2, 'display.max_columns', 2,
.....:                          'display.show_dimensions', 'truncate'):
.....:     print(dfd)
.....:
      0 ... 4
0     0 ... 4
..  .. ... ..
4    20 ... 24

[5 rows x 5 columns]
```

```
# will not show dimensions since it is not truncated
In [18]: with pd.option_context('display.max_rows', 10, 'display.max_columns', 40,
.....:                          'display.show_dimensions', 'truncate'):
.....:     print(dfd)
.....:
      0  1  2  3  4
0     0  1  2  3  4
1     5  6  7  8  9
2    10 11 12 13 14
3    15 16 17 18 19
4    20 21 22 23 24
```

- Regression in the display of a MultiIndexed Series with `display.max_rows` is less than the length of the series ([GH7101](#))
- Fixed a bug in the HTML repr of a truncated Series or DataFrame not showing the class name with the `large_repr` set to 'info' ([GH7105](#))
- The `verbose` keyword in `DataFrame.info()`, which controls whether to shorten the `info` representation, is now `None` by default. This will follow the global setting in `display.max_info_columns`. The global setting can be overridden with `verbose=True` or `verbose=False`.
- Fixed a bug with the `info` repr not honoring the `display.max_info_columns` setting ([GH6939](#))
- Offset/freq info now in Timestamp `__repr__` ([GH4553](#))

Text parsing API changes

`read_csv()/read_table()` will now be noisier w.r.t invalid options rather than falling back to the `PythonParser`.

- Raise `ValueError` when `sep` specified with `delim_whitespace=True` in `read_csv()/read_table()` ([GH6607](#))
- Raise `ValueError` when `engine='c'` specified with unsupported options in `read_csv()/read_table()` ([GH6607](#))
- Raise `ValueError` when fallback to python parser causes options to be ignored ([GH6607](#))

- Produce `ParserWarning` on fallback to python parser when no options are ignored ([GH6607](#))
- Translate `sep='\s+'` to `delim_whitespace=True` in `read_csv()/read_table()` if no other C-unsupported options specified ([GH6607](#))

Groupby API changes

More consistent behavior for some groupby methods:

- groupby `head` and `tail` now act more like `filter` rather than an aggregation:

```
In [19]: df = pd.DataFrame([[1, 2], [1, 4], [5, 6]], columns=['A', 'B'])
```

```
In [20]: g = df.groupby('A')
```

```
In [21]: g.head(1) # filters DataFrame
```

```
Out[21]:
```

```
   A  B
0  1  2
2  5  6
```

```
[2 rows x 2 columns]
```

```
In [22]: g.apply(lambda x: x.head(1)) # used to simply fall-through
```

```
Out[22]:
```

```
   A  B
A
1  0  1  2
5  2  5  6
```

```
[2 rows x 2 columns]
```

- groupby `head` and `tail` respect column selection:

```
In [23]: g[['B']].head(1)
```

```
Out[23]:
```

```
   B
0  2
2  6
```

```
[2 rows x 1 columns]
```

- groupby `nth` now reduces by default; filtering can be achieved by passing `as_index=False`. With an optional `dropna` argument to ignore NaN. See [the docs](#).

Reducing

```
In [24]: df = pd.DataFrame([[1, np.nan], [1, 4], [5, 6]], columns=['A', 'B'])
```

```
In [25]: g = df.groupby('A')
```

```
In [26]: g.nth(0)
```

```
Out[26]:
```

```
   B
A
1  NaN
```

```
5 6.0
```

```
[2 rows x 1 columns]
```

```
# this is equivalent to g.first()
```

```
In [27]: g.nth(0, dropna='any')
```

```
Out[27]:
```

```
      B
A
1  4.0
5  6.0
```

```
[2 rows x 1 columns]
```

```
# this is equivalent to g.last()
```

```
In [28]: g.nth(-1, dropna='any')
```

```
Out[28]:
```

```
      B
A
1  4.0
5  6.0
```

```
[2 rows x 1 columns]
```

```
Filtering
```

```
In [29]: gf = df.groupby('A', as_index=False)
```

```
In [30]: gf.nth(0)
```

```
Out[30]:
```

```
   A  B
0  1 NaN
2  5 6.0
```

```
[2 rows x 2 columns]
```

```
In [31]: gf.nth(0, dropna='any')
```

```
Out[31]:
```

```
   A  B
A
1  1 4.0
5  5 6.0
```

```
[2 rows x 2 columns]
```

- `groupby` will now not return the grouped column for non-cython functions ([GH5610](#), [GH5614](#), [GH6732](#)), as its already the index

```
In [32]: df = pd.DataFrame([[1, np.nan], [1, 4], [5, 6], [5, 8]], columns=['A', 'B'])
```

```
In [33]: g = df.groupby('A')
```

```
In [34]: g.count()
```

```
Out[34]:
```

```
      B
```

```
A
1 1
5 2
```

```
[2 rows x 1 columns]
```

```
In [35]: g.describe()
```

```
Out[35]:
```

```
      B
count mean      std  min  25%  50%  75%  max
A
1   1.0  4.0      NaN  4.0  4.0  4.0  4.0
5   2.0  7.0  1.414214  6.0  6.5  7.0  7.5  8.0
```

```
[2 rows x 8 columns]
```

- passing `as_index` will leave the grouped column in-place (this is not change in 0.14.0)

```
In [36]: df = pd.DataFrame([[1, np.nan], [1, 4], [5, 6], [5, 8]], columns=['A', 'B'])
```

```
In [37]: g = df.groupby('A', as_index=False)
```

```
In [38]: g.count()
```

```
Out[38]:
```

```
   A  B
0  1  1
1  5  2
```

```
[2 rows x 2 columns]
```

```
In [39]: g.describe()
```

```
Out[39]:
```

```
      A      B
count mean  std  min  25%  50%  75%  max count mean      std  min  25%  50%  75%  max
0   2.0  1.0  0.0  1.0  1.0  1.0  1.0  1.0  1.0  4.0      NaN  4.0  4.0  4.0  4.0
1   2.0  5.0  0.0  5.0  5.0  5.0  5.0  5.0  2.0  7.0  1.414214  6.0  6.5  7.0  7.5  8.0
```

```
[2 rows x 16 columns]
```

- Allow specification of a more complex groupby via `pd.Grouper`, such as grouping by a Time and a string field simultaneously. See *the docs*. (GH3794)
- Better propagation/preservation of Series names when performing groupby operations:
 - `SeriesGroupBy.agg` will ensure that the name attribute of the original series is propagated to the result (GH6265).
 - If the function provided to `GroupBy.apply` returns a named series, the name of the series will be kept as the name of the column index of the DataFrame returned by `GroupBy.apply` (GH6124). This facilitates `DataFrame.stack` operations where the name of the column index is used as the name of the inserted column containing the pivoted data.

SQL

The SQL reading and writing functions now support more database flavors through SQLAlchemy (GH2717, GH4163, GH5950, GH6292). All databases supported by SQLAlchemy can be used, such as PostgreSQL, MySQL, Oracle, Microsoft SQL server (see documentation of SQLAlchemy on [included dialects](#)).

The functionality of providing DBAPI connection objects will only be supported for sqlite3 in the future. The 'mysql' flavor is deprecated.

The new functions `read_sql_query()` and `read_sql_table()` are introduced. The function `read_sql()` is kept as a convenience wrapper around the other two and will delegate to specific function depending on the provided input (database table name or sql query).

In practice, you have to provide a SQLAlchemy `engine` to the sql functions. To connect with SQLAlchemy you use the `create_engine()` function to create an engine object from database URI. You only need to create the engine once per database you are connecting to. For an in-memory sqlite database:

```
In [40]: from sqlalchemy import create_engine

# Create your connection.
In [41]: engine = create_engine('sqlite:///memory:')
```

This `engine` can then be used to write or read data to/from this database:

```
In [42]: df = pd.DataFrame({'A': [1, 2, 3], 'B': ['a', 'b', 'c']})

In [43]: df.to_sql('db_table', engine, index=False)
```

You can read data from a database by specifying the table name:

```
In [44]: pd.read_sql_table('db_table', engine)
Out[44]:
   A B
0  1 a
1  2 b
2  3 c

[3 rows x 2 columns]
```

or by specifying a sql query:

```
In [45]: pd.read_sql_query('SELECT * FROM db_table', engine)
Out[45]:
   A B
0  1 a
1  2 b
2  3 c

[3 rows x 2 columns]
```

Some other enhancements to the sql functions include:

- support for writing the index. This can be controlled with the `index` keyword (default is True).
- specify the column label to use when writing the index with `index_label`.
- specify string columns to parse as datetimes with the `parse_dates` keyword in `read_sql_query()` and `read_sql_table()`.

Warning: Some of the existing functions or function aliases have been deprecated and will be removed in future versions. This includes: `tquery`, `uquery`, `read_frame`, `frame_query`, `write_frame`.

Warning: The support for the ‘mysql’ flavor when using DBAPI connection objects has been deprecated. MySQL will be further supported with SQLAlchemy engines (GH6900).

Multindexing using slicers

In 0.14.0 we added a new way to slice MultiIndexed objects. You can slice a MultiIndex by providing multiple indexers.

You can provide any of the selectors as if you are indexing by label, see *Selection by Label*, including slices, lists of labels, labels, and boolean indexers.

You can use `slice(None)` to select all the contents of *that* level. You do not need to specify all the *deeper* levels, they will be implied as `slice(None)`.

As usual, **both sides** of the slicers are included as this is label indexing.

See *the docs* See also issues (GH6134, GH4036, GH3057, GH2598, GH5641, GH7106)

Warning:

You should specify all axes in the `.loc` specifier, meaning the indexer for the **index** and for the **columns**. There are some ambiguous cases where the passed indexer could be mis-interpreted as indexing *both* axes, rather than into say the MultiIndex for the rows.

You should do this:

```
>>> df.loc[(slice('A1', 'A3'), ...), :] # noqa: E901
```

rather than this:

```
>>> df.loc[(slice('A1', 'A3'), ...)] # noqa: E901
```

Warning: You will need to make sure that the selection axes are fully lexsorted!

```
In [46]: def mklbl(prefix, n):
.....:     return ["%s%s" % (prefix, i) for i in range(n)]
.....:

In [47]: index = pd.MultiIndex.from_product([mklbl('A', 4),
.....:                                       mklbl('B', 2),

      D1  188   190
A3 B0 C1 D0  200   202
      D1  204   206
      C3 D0  216   218
```

```

      D1  220  222
B1 C1 D0  232  234
      D1  236  238
      C3 D0  248  250
      D1  252  254

```

[32 rows x 2 columns]

Using a boolean indexer you can provide selection related to the *values*.

```

In [56]: mask = df[('a', 'foo')] > 200

In [57]: df.loc[idx[mask, :], ['C1', 'C3']], idx[:, 'foo']]
Out[57]:
lvl0      a      b
lvl1      foo  foo
A3 B0 C1 D1  204  206
      C3 D0  216  218
      D1  220  222
      B1 C1 D0  232  234
      D1  236  238
      C3 D0  248  250
      D1  252  254

[7 rows x 2 columns]

```

You can also specify the `axis` argument to `.loc` to interpret the passed slicers on a single axis.

```

In [58]: df.loc(axis=0)[:, :, ['C1', 'C3']]
Out[58]:
lvl0      a      b
lvl1      bar  foo  bah  foo
A0 B0 C1 D0    9    8   11   10
      D1   13   12   15   14
      C3 D0   25   24   27   26
      D1   29   28   31   30
      B1 C1 D0   41   40   43   42
      D1   45   44   47   46
      C3 D0   57   56   59   58
      D1   61   60   63   62
A1 B0 C1 D0   73   72   75   74
      D1   77   76   79   78
      C3 D0   89   88   91   90
      D1   93   92   95   94
      B1 C1 D0  105  104  107  106
      D1  109  108  111  110
      C3 D0  121  120  123  122
      D1  125  124  127  126
A2 B0 C1 D0  137  136  139  138
      D1  141  140  143  142
      C3 D0  153  152  155  154
      D1  157  156  159  158
      B1 C1 D0  169  168  171  170
      D1  173  172  175  174

```

(continues on next page)

(continued from previous page)

```

      C3 D0 185 184 187 186
          D1 189 188 191 190
A3 B0 C1 D0 201 200 203 202
          D1 205 204 207 206
      C3 D0 217 216 219 218
          D1 221 220 223 222
      B1 C1 D0 233 232 235 234
          D1 237 236 239 238
      C3 D0 249 248 251 250
          D1 253 252 255 254

```

[32 rows x 4 columns]

Furthermore you can *set* the values using these methods

```
In [59]: df2 = df.copy()
```

```
In [60]: df2.loc(axis=0)[: , :, ['C1', 'C3']] = -10
```

```
In [61]: df2
```

```
Out[61]:
```

```

lv10          a          b
lv11          bar  foo  bah  foo
A0 B0 C0 D0    1    0    3    2
          D1    5    4    7    6
          C1 D0 -10 -10 -10 -10
          D1 -10 -10 -10 -10
          C2 D0  17  16  19  18
...
A3 B1 C1 D1 -10 -10 -10 -10
          C2 D0 241 240 243 242
          D1 245 244 247 246
          C3 D0 -10 -10 -10 -10
          D1 -10 -10 -10 -10

```

[64 rows x 4 columns]

You can use a right-hand-side of an alignable object as well.

```
In [62]: df2 = df.copy()
```

```
In [63]: df2.loc[idx[: , :, ['C1', 'C3']], :] = df2 * 1000
```

```
In [64]: df2
```

```
Out[64]:
```

```

lv10          a          b
lv11          bar    foo    bah    foo
A0 B0 C0 D0    1    0    3    2
          D1    5    4    7    6
          C1 D0 9000 8000 11000 10000
          D1 13000 12000 15000 14000
          C2 D0    17    16    19    18

```

(continues on next page)

[64 rows x 4 columns]

Plotting

- Hexagonal bin plots from `DataFrame.plot` with `kind='hexbin'` ([GH5478](#)), See *the docs*.
- `DataFrame.plot` and `Series.plot` now supports area plot with specifying `kind='area'` ([GH6656](#)), See *the docs*
- Pie plots from `Series.plot` and `DataFrame.plot` with `kind='pie'` ([GH6976](#)), See *the docs*.
- Plotting with Error Bars is now supported in the `.plot` method of `DataFrame` and `Series` objects ([GH3796](#), [GH6834](#)), See *the docs*.
- `DataFrame.plot` and `Series.plot` now support a `table` keyword for plotting `matplotlib.Table`, See *the docs*. The `table` keyword can receive the following values.
 - `False`: Do nothing (default).
 - `True`: Draw a table using the `DataFrame` or `Series` called `plot` method. Data will be transposed to meet `matplotlib`'s default layout.
 - `DataFrame` or `Series`: Draw `matplotlib.table` using the passed data. The data will be drawn as displayed in print method (not transposed automatically). Also, helper function `pandas.tools.plotting.table` is added to create a table from `DataFrame` and `Series`, and add it to an `matplotlib.Axes`.
- `plot(legend='reverse')` will now reverse the order of legend labels for most plot kinds. ([GH6014](#))
- Line plot and area plot can be stacked by `stacked=True` ([GH6656](#))
- Following keywords are now acceptable for `DataFrame.plot()` with `kind='bar'` and `kind='barh'`:
 - `width`: Specify the bar width. In previous versions, static value 0.5 was passed to `matplotlib` and it cannot be overwritten. ([GH6604](#))
 - `align`: Specify the bar alignment. Default is `center` (different from `matplotlib`). In previous versions, `pandas` passes `align='edge'` to `matplotlib` and adjust the location to `center` by itself, and it results `align` keyword is not applied as expected. ([GH4525](#))
 - `position`: Specify relative alignments for bar plot layout. From 0 (left/bottom-end) to 1(right/top-end). Default is 0.5 (center). ([GH6604](#))

Because of the default `align` value changes, coordinates of bar plots are now located on integer values (0.0, 1.0, 2.0 ...). This is intended to make bar plot be located on the same coordinates as line plot. However, bar plot may differs unexpectedly when you manually adjust the bar location or drawing area, such as using `set_xlim`, `set_ylim`, etc. In this cases, please modify your script to meet with new coordinates.

- The `parallel_coordinates()` function now takes argument `color` instead of `colors`. A `FutureWarning` is raised to alert that the old `colors` argument will not be supported in a future release. ([GH6956](#))

- The `parallel_coordinates()` and `andrews_curves()` functions now take positional argument `frame` instead of `data`. A `FutureWarning` is raised if the old `data` argument is used by name. (GH6956)
- `DataFrame.boxplot()` now supports `layout` keyword (GH6769)
- `DataFrame.boxplot()` has a new keyword argument, `return_type`. It accepts 'dict', 'axes', or 'both', in which case a namedtuple with the matplotlib axes and a dict of matplotlib Lines is returned.

Prior version deprecations/changes

There are prior version deprecations that are taking effect as of 0.14.0.

- Remove `DateRange` in favor of `DatetimeIndex` (GH6816)
- Remove `column` keyword from `DataFrame.sort` (GH4370)
- Remove `precision` keyword from `set_eng_float_format()` (GH395)
- Remove `force_unicode` keyword from `DataFrame.to_string()`, `DataFrame.to_latex()`, and `DataFrame.to_html()`; these function encode in unicode by default (GH2224, GH2225)
- Remove `nanRep` keyword from `DataFrame.to_csv()` and `DataFrame.to_string()` (GH275)
- Remove `unique` keyword from `HDFStore.select_column()` (GH3256)
- Remove `inferTimeRule` keyword from `Timestamp.offset()` (GH391)
- Remove `name` keyword from `get_data_yahoo()` and `get_data_google()` (commit b921d1a)
- Remove `offset` keyword from `DatetimeIndex` constructor (commit 3136390)
- Remove `time_rule` from several rolling-moment statistical functions, such as `rolling_sum()` (GH1042)
- Removed `neg -` boolean operations on numpy arrays in favor of `inv ~`, as this is going to be deprecated in numpy 1.9 (GH6960)

Deprecations

- The `pivot_table()/DataFrame.pivot_table()` and `crosstab()` functions now take arguments `index` and `columns` instead of `rows` and `cols`. A `FutureWarning` is raised to alert that the old `rows` and `cols` arguments will not be supported in a future release (GH5505)
- The `DataFrame.drop_duplicates()` and `DataFrame.duplicated()` methods now take argument `subset` instead of `cols` to better align with `DataFrame.dropna()`. A `FutureWarning` is raised to alert that the old `cols` arguments will not be supported in a future release (GH6680)
- The `DataFrame.to_csv()` and `DataFrame.to_excel()` functions now takes argument `columns` instead of `cols`. A `FutureWarning` is raised to alert that the old `cols` arguments will not be supported in a future release (GH6645)
- Indexers will warn `FutureWarning` when used with a scalar indexer and a non-floating point Index (GH4892, GH6960)

```
# non-floating point indexes can only be indexed by integers / labels
In [1]: pd.Series(1, np.arange(5))[3.0]
pandas/core/index.py:469: FutureWarning: scalar indexers for index type
↳Int64Index should be integers and not floating point
Out[1]: 1

In [2]: pd.Series(1, np.arange(5)).iloc[3.0]
```

(continues on next page)

(continued from previous page)

In [5]: pd.Series(1, np.arange(5.))[3.0]
Out[6]: 1

```

- Numpy 1.9 compat w.r.t. deprecation warnings ([GH6960](#))
- `Panel.shift()` now has a function signature that matches `DataFrame.shift()`. The old positional argument `lags` has been changed to a keyword argument `periods` with a default value of 1. A `FutureWarning` is raised if the old argument `lags` is used by name. ([GH6910](#))
- The `order` keyword argument of `factorize()` will be removed. ([GH6926](#)).
- Remove the `copy` keyword from `DataFrame.xs()`, `Panel.major_xs()`, `Panel.minor_xs()`. A view will be returned if possible, otherwise a copy will be made. Previously the user could think that `copy=False` would ALWAYS return a view. ([GH6894](#))
- The `parallel_coordinates()` function now takes argument `color` instead of `colors`. A `FutureWarning` is raised to alert that the old `colors` argument will not be supported in a future release. ([GH6956](#))
- The `parallel_coordinates()` and `andrews_curves()` functions now take positional argument `frame` instead of `data`. A `FutureWarning` is raised if the old `data` argument is used by name. ([GH6956](#))
- The support for the 'mysql' flavor when using DBAPI connection objects has been deprecated. MySQL will be further supported with SQLAlchemy engines ([GH6900](#)).
- The following `io.sql` functions have been deprecated: `tquery`, `uquery`, `read_frame`, `frame_query`, `write_frame`.
- The `percentile_width` keyword argument in `describe()` has been deprecated. Use the `percentiles` keyword instead, which takes a list of percentiles to display. The default output is unchanged.
- The default return type of `boxplot()` will change from a dict to a matplotlib Axes in a future release. You can use the future behavior now by passing `return_type='axes'` to `boxplot`.

Known issues

- OpenPyXL 2.0.0 breaks backwards compatibility ([GH7169](#))

Enhancements

- `DataFrame` and `Series` will create a `MultiIndex` object if passed a tuples dict, See *the docs* ([GH3323](#))

```
In [65]: pd.Series({'a', 'b'): 1, ('a', 'a'): 0,
.....:             ('a', 'c'): 2, ('b', 'a'): 3, ('b', 'b'): 4})
.....:
```

```
Out[65]:
```

```

C   2.0  3.0  6.0  7.0   NaN
D   NaN  NaN  NaN  NaN   9.0
```

```
[3 rows x 5 columns]
```

- Added the `sym_diff` method to `Index` ([GH5543](#))
- `DataFrame.to_latex` now takes a `longtable` keyword, which if `True` will return a table in a `longtable` environment. ([GH6617](#))
- Add option to turn off escaping in `DataFrame.to_latex` ([GH6472](#))
- `pd.read_clipboard` will, if the keyword `sep` is unspecified, try to detect data copied from a spreadsheet and parse accordingly. ([GH6223](#))
- Joining a singly-indexed `DataFrame` with a `MultiIndexed DataFrame` ([GH3662](#))

See *the docs*. Joining `MultiIndex DataFrame`s on both the left and right is not yet supported ATM.

```
In [67]: household = pd.DataFrame({'household_id': [1, 2, 3],

```
[6 rows x 6 columns]
```

- `quotechar`, `doublequote`, and `escapechar` can now be specified when using `DataFrame.to_csv` ([GH5414](#), [GH4528](#))
- Partially sort by only the specified levels of a MultiIndex with the `sort_remaining` boolean kwarg. ([GH3984](#))

- Added `to_julian_date` to `TimeStamp` and `DatetimeIndex`. The Julian Date is used primarily in astronomy and represents the number of days from noon, January 1, 4713 BC. Because nanoseconds are used to define the time in pandas the actual range of dates that you can use is 1678 AD to 2262 AD. (GH4041)
- `DataFrame.to_stata` will now check data for compatibility with Stata data types and will upcast when needed. When it is not possible to losslessly upcast, a warning is issued (GH6327)
- `DataFrame.to_stata` and `StataWriter` will accept keyword arguments `time_stamp` and `data_label` which allow the time stamp and dataset label to be set when creating a file. (GH6545)
- `pandas.io.gbq` now handles reading unicode strings properly. (GH5940)
- *Holidays Calendars* are now available and can be used with the `CustomBusinessDay` offset (GH6719)
- `Float64Index` is now backed by a `float64` dtype ndarray instead of an object dtype array (GH6471).
- Implemented `Panel.pct_change` (GH6904)
- Added `how` option to rolling-moment functions to dictate how to handle resampling; `rolling_max()` defaults to max, `rolling_min()` defaults to min, and all others default to mean (GH6297)
- `CustomBusinessMonthBegin` and `CustomBusinessMonthEnd` are now available (GH6866)
- `Series.quantile()` and `DataFrame.quantile()` now accept an array of quantiles.
- `describe()` now accepts an array of percentiles to include in the summary statistics (GH4196)
- `pivot_table` can now accept `Groupby` by `index` and `columns` keywords (GH6913)

- `read_excel` can now read milliseconds in Excel dates and times with `xlrd >= 0.9.3`. (GH5945)
- `pd.stats.moments.rolling_var` now uses Welford's method for increased numerical stability (GH6817)
- `pd.expanding_apply` and `pd.rolling_apply` now take args and kwargs that are passed on to the func (GH6289)
- `DataFrame.rank()` now has a percentage rank option (GH5971)
- `Series.rank()` now has a percentage rank option (GH5971)
- `Series.rank()` and `DataFrame.rank()` now accept `method='dense'` for ranks without gaps (GH6514)
- Support passing `encoding` with `xlwt` (GH3710)
- Refactor Block classes removing `Block.items` attributes to avoid duplication in item handling (GH6745, GH6988).
- Testing statements updated to use specialized asserts (GH6175)

Performance

- Performance improvement when converting `DatetimeIndex` to floating ordinals using `DatetimeConverter` (GH6636)
- Performance improvement for `DataFrame.shift` (GH5609)
- Performance improvement in indexing into a `MultiIndexed Series` (GH5567)
- Performance improvements in single-dtyped indexing (GH6484)
- Improve performance of `DataFrame` construction with certain offsets, by removing faulty caching (e.g. `MonthEnd`, `BusinessMonthEnd`), (GH6479)
- Improve performance of `CustomBusinessDay` (GH6584)
- improve performance of slice indexing on `Series` with string keys (GH6341, GH6372)
- Performance improvement for `DataFrame.from_records` when reading a specified number of rows from an iterable (GH6700)
- Performance improvements in `timedelta` conversions for integer dtypes (GH6754)
- Improved performance of compatible pickles (GH6899)
- Improve performance in certain reindexing operations by optimizing `take_2d` (GH6749)
- `GroupBy.count()` is now implemented in Cython and is much faster for large numbers of groups (GH7016).

Experimental

There are no experimental changes in 0.14.0

Bug Fixes

- Bug in Series ValueError when index doesn't match data (GH6532)
- Prevent segfault due to MultiIndex not being supported in HDFStore table format (GH1848)
- Bug in `pd.DataFrame.sort_index` where mergesort wasn't stable when `ascending=False` (GH6399)
- Bug in `pd.tseries.frequencies.to_offset` when argument has leading zeros (GH6391)
- Bug in version string gen. for dev versions with shallow clones / install from tarball (GH6127)
- Inconsistent tz parsing `Timestamp` / `to_datetime` for current year (GH5958)
- Indexing bugs with reordered indexes (GH6252, GH6254)
- Bug in `.xs` with a Series multiindex (GH6258, GH5684)
- Bug in conversion of a string types to a `DatetimeIndex` with a specified frequency (GH6273, GH6274)
- Bug in `eval` where type-promotion failed for large expressions (GH6205)
- Bug in `interpolate` with `inplace=True` (GH6281)
- `HDFStore.remove` now handles start and stop (GH6177)
- `HDFStore.select_as_multiple` handles start and stop the same way as `select` (GH6177)
- `HDFStore.select_as_coordinates` and `select_column` works with a `where` clause that results in filters (GH6177)
- Regression in join of `non_unique_indexes` (GH6329)
- Issue with `groupby.agg` with a single function and a a mixed-type frame (GH6337)
- Bug in `DataFrame.replace()` when passing a non-bool `to_replace` argument (GH6332)
- Raise when trying to align on different levels of a `MultiIndex` assignment (GH3738)
- Bug in setting complex dtypes via boolean indexing (GH6345)
- Bug in `TimeGrouper/resample` when presented with a non-monotonic `DatetimeIndex` that would return invalid results. (GH4161)
- Bug in index name propagation in `TimeGrouper/resample` (GH4161)
- `TimeGrouper` has a more compatible API to the rest of the groupers (e.g. `groups` was missing) (GH3881)
- Bug in multiple grouping with a `TimeGrouper` depending on target column order (GH6764)
- Bug in `pd.eval` when parsing strings with possible tokens like `'&'` (GH6351)
- Bug correctly handle placements of `-inf` in `Panels` when dividing by integer 0 (GH6178)
- `DataFrame.shift` with `axis=1` was raising (GH6371)
- Disabled clipboard tests until release time (run locally with `nosetests -A disabled`) (GH6048).
- Bug in `DataFrame.replace()` when passing a nested dict that contained keys not in the values to be replaced (GH6342)
- `str.match` ignored the `na` flag (GH6609).

- Bug in take with duplicate columns that were not consolidated (GH6240)
- Bug in interpolate changing dtypes (GH6290)
- Bug in Series.get, was using a buggy access method (GH6383)
- Bug in hdfstore queries of the form where=[('date', '>=', datetime(2013,1,1)), ('date', '<=', datetime(2014,1,1))] (GH6313)
- Bug in DataFrame.dropna with duplicate indices (GH6355)
- Regression in chained getitem indexing with embedded list-like from 0.12 (GH6394)
- Float64Index with nans not comparing correctly (GH6401)
- eval/query expressions with strings containing the @ character will now work (GH6366).
- Bug in Series.reindex when specifying a method with some nan values was inconsistent (noted on a resample) (GH6418)
- Bug in DataFrame.replace() where nested dicts were erroneously depending on the order of dictionary keys and values (GH5338).
- Performance issue in concatenating with empty objects (GH3259)
- Clarify sorting of sym_diff on Index objects with NaN values (GH6444)
- Regression in MultiIndex.from_product with a DatetimeIndex as input (GH6439)
- Bug in str.extract when passed a non-default index (GH6348)
- Bug in str.split when passed pat=None and n=1 (GH6466)
- Bug in io.data.DataReader when passed "F-F_Momentum_Factor" and data_source="famafrench" (GH6460)
- Bug in sum of a timedelta64[ns] series (GH6462)
- Bug in resample with a timezone and certain offsets (GH6397)
- Bug in iat/iloc with duplicate indices on a Series (GH6493)
- Bug in read_html where nan's were incorrectly being used to indicate missing values in text. Should use the empty string for consistency with the rest of pandas (GH5129).
- Bug in read_html tests where redirected invalid URLs would make one test fail (GH6445).
- Bug in multi-axis indexing using .loc on non-unique indices (GH6504)
- Bug that caused _ref_locs corruption when slice indexing across columns axis of a DataFrame (GH6525)
- Regression from 0.13 in the treatment of numpy datetime64 non-ns dtypes in Series creation (GH6529)
- .names attribute of MultiIndexes passed to set_index are now preserved (GH6459).
- Bug in setitem with a duplicate index and an alignable rhs (GH6541)
- Bug in setitem with .loc on mixed integer Indexes (GH6546)
- Bug in pd.read_stata which would use the wrong data types and missing values (GH6327)
- Bug in DataFrame.to_stata that lead to data loss in certain cases, and could be exported using the wrong data types and missing values (GH6335)
- StataWriter replaces missing values in string columns by empty string (GH6802)
- Inconsistent types in Timestamp addition/subtraction (GH6543)

- Bug in preserving frequency across Timestamp addition/subtraction (GH4547)
- Bug in empty list lookup caused `IndexError` exceptions (GH6536, GH6551)
- `Series.quantile` raising on an object dtype (GH6555)
- Bug in `.xs` with a `nan` in level when dropped (GH6574)
- Bug in `fillna` with `method='bfill/ffill'` and `datetime64[ns]` dtype (GH6587)
- Bug in sql writing with mixed dtypes possibly leading to data loss (GH6509)
- Bug in `Series.pop` (GH6600)
- Bug in `iloc` indexing when positional indexer matched `Int64Index` of the corresponding axis and no reordering happened (GH6612)
- Bug in `fillna` with `limit` and `value` specified
- Bug in `DataFrame.to_stata` when columns have non-string names (GH4558)
- Bug in `compat` with `np.compress`, surfaced in (GH6658)
- Bug in binary operations with a rhs of a Series not aligning (GH6681)
- Bug in `DataFrame.to_stata` which incorrectly handles nan values and ignores `with_index` keyword argument (GH6685)
- Bug in `resample` with extra bins when using an evenly divisible frequency (GH4076)
- Bug in consistency of `groupby` aggregation when passing a custom function (GH6715)
- Bug in `resample` when `how=None` resample freq is the same as the axis frequency (GH5955)
- Bug in downcasting inference with empty arrays (GH6733)
- Bug in `obj.blocks` on sparse containers dropping all but the last items of same for dtype (GH6748)
- Bug in unpickling `NaT` (`NaTType`) (GH4606)
- Bug in `DataFrame.replace()` where regex meta characters were being treated as regex even when `regex=False` (GH6777).
- Bug in `timedelta` ops on 32-bit platforms (GH6808)
- Bug in setting a tz-aware index directly via `.index` (GH6785)
- Bug in `expressions.py` where `numexpr` would try to evaluate arithmetic ops (GH6762).
- Bug in `Makefile` where it didn't remove Cython generated C files with `make clean` (GH6768)
- Bug with `numpy < 1.7.2` when reading long strings from `HDFStore` (GH6166)
- Bug in `DataFrame._reduce` where non bool-like (0/1) integers were being converted into bools. (GH6806)
- Regression from 0.13 with `fillna` and a Series on datetime-like (GH6344)
- Bug in adding `np.timedelta64` to `DatetimeIndex` with `timezone` outputs incorrect results (GH6818)
- Bug in `DataFrame.replace()` where changing a dtype through replacement would only replace the first occurrence of a value (GH6689)
- Better error message when passing a frequency of 'MS' in `Period` construction (GH5332)
- Bug in `Series.__unicode__` when `max_rows=None` and the Series has more than 1000 rows. (GH6863)
- Bug in `groupby.get_group` where a datelike wasn't always accepted (GH5267)
- Bug in `groupBy.get_group` created by `TimeGrouper` raises `AttributeError` (GH6914)

- Bug in `DatetimeIndex.tz_localize` and `DatetimeIndex.tz_convert` converting NaT incorrectly (GH5546)
- Bug in arithmetic operations affecting NaT (GH6873)
- Bug in `Series.str.extract` where the resulting `Series` from a single group match wasn't renamed to the group name
- Bug in `DataFrame.to_csv` where setting `index=False` ignored the `header` kwarg (GH6186)
- Bug in `DataFrame.plot` and `Series.plot`, where the legend behave inconsistently when plotting to the same axes repeatedly (GH6678)
- Internal tests for patching `__finalize__` / bug in merge not finalizing (GH6923, GH6927)
- accept `TextFileReader` in `concat`, which was affecting a common user idiom (GH6583)
- Bug in C parser with leading white space (GH3374)
- Bug in C parser with `delim_whitespace=True` and `\r`-delimited lines
- Bug in python parser with explicit `MultiIndex` in row following column header (GH6893)
- Bug in `Series.rank` and `DataFrame.rank` that caused small floats ($<1e-13$) to all receive the same rank (GH6886)
- Bug in `DataFrame.apply` with functions that used `*args` or `**kwargs` and returned an empty result (GH6952)
- Bug in `sum/mean` on 32-bit platforms on overflows (GH6915)
- Moved `Panel.shift` to `NDFrame.slice_shift` and fixed to respect multiple dtypes. (GH6959)
- Bug in enabling `subplots=True` in `DataFrame.plot` only has single column raises `TypeError`, and `Series.plot` raises `AttributeError` (GH6951)
- Bug in `DataFrame.plot` draws unnecessary axes when enabling `subplots` and `kind=scatter` (GH6951)
- Bug in `read_csv` from a filesystem with non-utf-8 encoding (GH6807)
- Bug in `iloc` when setting / aligning (GH6766)
- Bug causing `UnicodeEncodeError` when `get_dummies` called with unicode values and a prefix (GH6885)
- Bug in `timeseries-with-frequency` plot cursor display (GH5453)
- Bug surfaced in `groupby.plot` when using a `Float64Index` (GH7025)
- Stopped tests from failing if options data isn't able to be downloaded from Yahoo (GH7034)
- Bug in `parallel_coordinates` and `radviz` where reordering of class column caused possible color/class mismatch (GH6956)
- Bug in `radviz` and `andrews_curves` where multiple values of 'color' were being passed to plotting method (GH6956)
- Bug in `Float64Index.isin()` where containing `nan` s would make indices claim that they contained all the things (GH7066).
- Bug in `DataFrame.boxplot` where it failed to use the axis passed as the `ax` argument (GH3578)
- Bug in the `XlsxWriter` and `XlwtWriter` implementations that resulted in datetime columns being formatted without the time (GH7075) were being passed to plotting method
- `read_fwf()` treats `None` in `colspec` like regular python slices. It now reads from the beginning or until the end of the line when `colspec` contains a `None` (previously raised a `TypeError`)

- Bug in cache coherence with chained indexing and slicing; add `_is_view` property to `NDFrame` to correctly predict views; mark `is_copy` on `xs` only if its an actual copy (and not a view) (GH7084)
- Bug in `DatetimeIndex` creation from string ndarray with `dayfirst=True` (GH5917)
- Bug in `MultiIndex.from_arrays` created from `DatetimeIndex` doesn't preserve `freq` and `tz` (GH7090)
- Bug in `unstack` raises `ValueError` when `MultiIndex` contains `PeriodIndex` (GH4342)
- Bug in `boxplot` and `hist` draws unnecessary axes (GH6769)
- Regression in `groupby.nth()` for out-of-bounds indexers (GH6621)
- Bug in `quantile` with datetime values (GH6965)
- Bug in `Dataframe.set_index`, `reindex` and `pivot` don't preserve `DatetimeIndex` and `PeriodIndex` attributes (GH3950, GH5878, GH6631)
- Bug in `MultiIndex.get_level_values` doesn't preserve `DatetimeIndex` and `PeriodIndex` attributes (GH7092)
- Bug in `Groupby` doesn't preserve `tz` (GH3950)
- Bug in `PeriodIndex` partial string slicing (GH6716)
- Bug in the HTML repr of a truncated Series or DataFrame not showing the class name with the `large_repr` set to 'info' (GH7105)
- Bug in `DatetimeIndex` specifying `freq` raises `ValueError` when passed value is too short (GH7098)
- Fixed a bug with the `info` repr not honoring the `display.max_info_columns` setting (GH6939)
- Bug `PeriodIndex` string slicing with out of bounds values (GH5407)
- Fixed a memory error in the hashtable implementation/factorizer on resizing of large tables (GH7157)
- Bug in `isnull` when applied to 0-dimensional object arrays (GH7176)
- Bug in `query/eval` where global constants were not looked up correctly (GH7178)
- Bug in recognizing out-of-bounds positional list indexers with `iloc` and a multi-axis tuple indexer (GH7189)
- Bug in `setitem` with a single value, `MultiIndex` and integer indices (GH7190, GH7218)
- Bug in expressions evaluation with reversed ops, showing in series-dataframe ops (GH7198, GH7192)
- Bug in multi-axis indexing with `> 2` ndim and a `MultiIndex` (GH7199)
- Fix a bug where invalid eval/query operations would blow the stack (GH5198)

8.13 Version 0.13

8.13.1 v0.13.1 (February 3, 2014)

{{ header }}

This is a minor release from 0.13.0 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

- Added `infer_datetime_format` keyword to `read_csv/to_datetime` to allow speedups for homogeneously formatted datetimes.
- Will intelligently limit display precision for datetime/timedelta formats.
- Enhanced Panel `apply()` method.
- Suggested tutorials in new *Tutorials* section.
- Our pandas ecosystem is growing, We now feature related projects in a new *Pandas Ecosystem* section.
- Much work has been taking place on improving the docs, and a new *Contributing* section has been added.
- Even though it may only be of interest to devs, we <3 our new CI status page: [ScatterCI](#).

Warning: 0.13.1 fixes a bug that was caused by a combination of having numpy < 1.8, and doing chained assignment on a string-like array. Please review *the docs*, chained indexing can have unexpected results and should generally be avoided.

This would previously segfault:

```
In [1]: df = pd.DataFrame({'A': np.array(['foo', 'bar', 'bah', 'foo', 'bar'])})
```

```
In [2]: df['A'].iloc[0] = np.nan
```

```
In [3]: df
```

```
Out[3]:
```

```
   A
0 NaN
1 bar
2 bah
3 foo
4 bar
```

The recommended way to do this type of assignment is:

```
In [4]: df = pd.DataFrame({'A': np.array(['foo', 'bar', 'bah', 'foo', 'bar'])})
```

```
In [5]: df.loc[0, 'A'] = np.nan
```

```
In [6]: df
```

```
Out[6]:
```

```
   A
0 NaN
1 bar
2 bah
3 foo
4 bar
```

Output formatting enhancements

- `df.info()` view now display dtype info per column (GH5682)
- `df.info()` now honors the option `max_info_rows`, to disable null counts for large frames (GH5974)

```
In [7]: max_info_rows = pd.get_option('max_info_rows')
```

```
In [8]: df = pd.DataFrame({'A': np.random.randn(10),
...:                      'B': np.random.randn(10),
...:                      'C': pd.date_range('20130101', periods=10)
...:                      })
...:
```

```
In [9]: df.iloc[3:6, [0, 2]] = np.nan
```

```
# set to not display the null counts
```

```
In [10]: pd.set_option('max_info_rows', 0)
```

(continues on next page)

(continued from previous page)

```
In [11]: df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 10 entries, 0 to 9
Data columns (total 3 columns):
A    float64
B    float64
C    datetime64[ns]
dtypes: datetime64[ns](1), float64(2)
memory usage: 368.0 bytes
```

```
# this is the default (same as in 0.13.0)
In [12]: pd.set_option('max_info_rows', max_info_rows)

In [13]: df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 10 entries, 0 to 9
Data columns (total 3 columns):
A    7 non-null float64
B    10 non-null float64
C    7 non-null datetime64[ns]
dtypes: datetime64[ns](1), float64(2)
memory usage: 368.0 bytes
```

- Add `show_dimensions` display option for the new `DataFrame` repr to control whether the dimensions print.

```
In [14]: df = pd.DataFrame([[1, 2], [3, 4]])

In [15]: pd.set_option('show_dimensions', False)

In [16]: df
Out[16]:
   0  1
0  1  2
1  3  4

In [17]: pd.set_option('show_dimensions', True)

In [18]: df
Out[18]:
   0  1
0  1  2
1  3  4

[2 rows x 2 columns]
```

- The `ArrayFormatter` for `datetime` and `timedelta64` now intelligently limit precision based on the values in the array (GH3401)

Previously output might look like:

age	today	diff

(continues on next page)

(continued from previous page)

```
0 2001-01-01 00:00:00 2013-04-19 00:00:00 4491 days, 00:00:00
1 2004-06-01 00:00:00 2013-04-19 00:00:00 3244 days, 00:00:00
```

Now the output looks like:

```
In [19]: df = pd.DataFrame([pd.Timestamp('20010101'),
.....:                      pd.Timestamp('20040601')], columns=['age'])
.....:

In [20]: df['today'] = pd.Timestamp('20130419')

In [21]: df['diff'] = df['today'] - df['age']

In [22]: df
Out[22]:
      age      today      diff
0 2001-01-01 2013-04-19 4491 days
1 2004-06-01 2013-04-19 3244 days

[2 rows x 3 columns]
```

API changes

- Add `-NaN` and `-nan` to the default set of NA values (GH5952). See *NA Values*.
- Added `Series.str.get_dummies` vectorized string method (GH6021), to extract dummy/indicator variables for separated string columns:

```
In [23]: s = pd.Series(['a', 'a|b', np.nan, 'a|c'])

In [24]: s.str.get_dummies(sep='|')
Out[24]:
      a  b  c
0  1  0  0
1  1  1  0
2  0  0  0
3  1  0  1

[4 rows x 3 columns]
```

- Added the `NDFrame.equals()` method to compare if two NDFrames are equal have equal axes, dtypes, and values. Added the `array_equivalent` function to compare if two ndarrays are equal. NaNs in identical locations are treated as equal. (GH5283) See also *the docs* for a motivating example.

```
df = pd.DataFrame({'col': ['foo', 0, np.nan]})
df2 = pd.DataFrame({'col': [np.nan, 0, 'foo']}, index=[2, 1, 0])
df.equals(df2)
df.equals(df2.sort_index())
```

- `DataFrame.apply` will use the `reduce` argument to determine whether a `Series` or a `DataFrame` should be returned when the `DataFrame` is empty (GH6007).

Previously, calling `DataFrame.apply` on an empty `DataFrame` would return either a `DataFrame` if there were no columns, or the function being applied would be called with an empty `Series` to guess whether a `Series` or `DataFrame` should be returned:

```
In [32]: def applied_func(col):
...:     print("Apply function being called with: ", col)
...:     return col.sum()
...:

In [33]: empty = DataFrame(columns=['a', 'b'])

In [34]: empty.apply(applied_func)
Apply function being called with: Series([], Length: 0, dtype: float64)
Out[34]:
a    NaN
b    NaN
Length: 2, dtype: float64
```

Now, when `apply` is called on an empty `DataFrame`: if the `reduce` argument is `True` a `Series` will be returned, if it is `False` a `DataFrame` will be returned, and if it is `None` (the default) the function being applied will be called with an empty `Series` to try and guess the return type.

```
In [35]: empty.apply(applied_func, reduce=True)
Out[35]:
a    NaN
b    NaN
Length: 2, dtype: float64

In [36]: empty.apply(applied_func, reduce=False)
Out[36]:
Empty DataFrame
Columns: [a, b]
Index: []

[0 rows x 2 columns]
```

Prior version deprecations/changes

There are no announced changes in 0.13 or prior that are taking effect as of 0.13.1

Deprecations

There are no deprecations of prior behavior in 0.13.1

Enhancements

- `pd.read_csv` and `pd.to_datetime` learned a new `infer_datetime_format` keyword which greatly improves parsing perf in many cases. Thanks to @lexical for suggesting and @danbirken for rapidly implementing. ([GH5490](#), [GH6021](#))

If `parse_dates` is enabled and this flag is set, pandas will attempt to infer the format of the datetime strings in the columns, and if it can be inferred, switch to a faster method of parsing them. In some

cases this can increase the parsing speed by ~5-10x.

```
# Try to infer the format for the index column
df = pd.read_csv('foo.csv', index_col=0, parse_dates=True,
                 infer_datetime_format=True)
```

- `date_format` and `datetime_format` keywords can now be specified when writing to excel files (GH4133)
- `MultiIndex.from_product` convenience function for creating a MultiIndex from the cartesian product of a set of iterables (GH6055):

```
In [25]: shades = ['light', 'dark']

In [26]: colors = ['red', 'green', 'blue']

In [27]: pd.MultiIndex.from_product([shades, colors], names=['shade', 'color'])
Out[27]:
MultiIndex([( 'light',  'red'),
            ( 'light',  'green'),
            ( 'light',  'blue'),
            (  'dark',  'red'),
            (  'dark',  'green'),
            (  'dark',  'blue')],
           names=['shade', 'color'])
```

- Panel `apply()` will work on non-ufuncs. See *the docs*.

```
In [28]: import pandas.util.testing as tm

In [29]: panel = tm.makePanel(5)

In [30]: panel
Out[30]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 5 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemC
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-07 00:00:00
Minor_axis axis: A to D

In [31]: panel['ItemA']
Out[31]:
```

	A	B	C	D
2000-01-03	-0.673690	0.577046	-1.344312	-1.469388
2000-01-04	0.113648	-1.715002	0.844885	0.357021
2000-01-05	-1.478427	-1.039268	1.075770	-0.674600
2000-01-06	0.524988	-0.370647	-0.109050	-1.776904
2000-01-07	0.404705	-1.157892	1.643563	-0.968914

```
[5 rows x 4 columns]
```

Specifying an `apply` that operates on a Series (to return a single element)

```
In [32]: panel.apply(lambda x: x.dtype, axis='items')
Out[32]:
```

(continues on next page)

(continued from previous page)

	A	B	C	D
2000-01-03	float64	float64	float64	float64
2000-01-04	float64	float64	float64	float64
2000-01-05	float64	float64	float64	float64
2000-01-06	float64	float64	float64	float64
2000-01-07	float64	float64	float64	float64

[5 rows x 4 columns]

A similar reduction type operation

```
In [33]: panel.apply(lambda x: x.sum(), axis='major_axis')
```

Out [33]:

	ItemA	ItemB	ItemC
A	-1.108775	-1.090118	-2.984435
B	-3.705764	0.409204	1.866240
C	2.110856	2.960500	-0.974967
D	-4.532785	0.303202	-3.685193

[4 rows x 3 columns]

This is equivalent to

```
In [34]: panel.sum('major_axis')
```

Out [34]:

	ItemA	ItemB	ItemC
A	-1.108775	-1.090118	-2.984435
B	-3.705764	0.409204	1.866240
C	2.110856	2.960500	-0.974967
D	-4.532785	0.303202	-3.685193

[4 rows x 3 columns]

A transformation operation that returns a Panel, but is computing the z-score across the major_axis

```
In [35]: result = panel.apply(lambda x: (x - x.mean()) / x.std(),
....:                          axis='major_axis')
....:
```

In [36]: result

Out [36]:

```
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 5 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemC
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-07 00:00:00
Minor_axis axis: A to D
```

```
In [37]: result['ItemA'] # noqa E999
```

Performance

Performance improvements for 0.13.1

- Series datetime/timedelta binary operations ([GH5801](#))
- DataFrame count/dropna for axis=1
- Series.str.contains now has a *regex=False* keyword which can be faster for plain (non-regex) string patterns. ([GH5879](#))
- Series.str.extract ([GH5944](#))
- dtypes/ftypes methods ([GH5968](#))
- indexing with object dtypes ([GH5968](#))
- DataFrame.apply ([GH6013](#))
- Regression in JSON IO ([GH5765](#))
- Index construction from Series ([GH6150](#))

Experimental

There are no experimental changes in 0.13.1

Bug fixes

- Bug in `io.wb.get_countries` not including all countries ([GH6008](#))
- Bug in Series replace with timestamp dict ([GH5797](#))
- `read_csv/read_table` now respects the *prefix* kwarg ([GH5732](#)).
- Bug in selection with missing values via `.ix` from a duplicate indexed DataFrame failing ([GH5835](#))
- Fix issue of boolean comparison on empty DataFrames ([GH5808](#))
- Bug in `isnull` handling `NaN` in an object array ([GH5443](#))
- Bug in `to_datetime` when passed a `np.nan` or integer datelike and a format string ([GH5863](#))
- Bug in groupby dtype conversion with datetimelike ([GH5869](#))
- Regression in handling of empty Series as indexers to Series ([GH5877](#))
- Bug in internal caching, related to ([GH5727](#))
- Testing bug in reading JSON/msgpack from a non-filepath on windows under py3 ([GH5874](#))
- Bug when assigning to `.ix[tuple(...)]` ([GH5896](#))
- Bug in fully reindexing a Panel ([GH5905](#))
- Bug in `idxmin/max` with object dtypes ([GH5914](#))

- Bug in `BusinessDay` when adding `n` days to a date not on offset when $n > 5$ and $n \% 5 == 0$ (GH5890)
- Bug in assigning to chained series with a series via `ix` (GH5928)
- Bug in creating an empty `DataFrame`, copying, then assigning (GH5932)
- Bug in `DataFrame.tail` with empty frame (GH5846)
- Bug in propagating metadata on `resample` (GH5862)
- Fixed string-representation of `NaT` to be “NaT” (GH5708)
- Fixed string-representation for `Timestamp` to show nanoseconds if present (GH5912)
- `pd.match` not returning passed sentinel
- `Panel.to_frame()` no longer fails when `major_axis` is a `MultiIndex` (GH5402).
- Bug in `pd.read_msgpack` with inferring a `DateTimeIndex` frequency incorrectly (GH5947)
- Fixed `to_datetime` for array with both Tz-aware datetimes and `NaT`'s (GH5961)
- Bug in rolling skew/kurtosis when passed a `Series` with bad data (GH5749)
- Bug in `scipy.interpolate` methods with a `datetime` index (GH5975)
- Bug in `NaT` comparison if a mixed `datetime/np.datetime64` with `NaT` were passed (GH5968)
- Fixed bug with `pd.concat` losing dtype information if all inputs are empty (GH5742)
- Recent changes in IPython cause warnings to be emitted when using previous versions of pandas in `QTConsole`, now fixed. If you're using an older version and need to suppress the warnings, see (GH5922).
- Bug in merging `timedelta` dtypes (GH5695)
- Bug in `plotting.scatter_matrix` function. Wrong alignment among diagonal and off-diagonal plots, see (GH5497).
- Regression in `Series` with a `MultiIndex` via `ix` (GH6018)
- Bug in `Series.xs` with a `MultiIndex` (GH6018)
- Bug in `Series` construction of mixed type with datelike and an integer (which should result in object type and not automatic conversion) (GH6028)
- Possible segfault when chained indexing with an object array under NumPy 1.7.1 (GH6026, GH6056)
- Bug in setting using fancy indexing a single element with a non-scalar (e.g. a list), (GH6043)
- `to_sql` did not respect `if_exists` (GH4110 GH4304)
- Regression in `.get(None)` indexing from 0.12 (GH5652)
- Subtle `iloc` indexing bug, surfaced in (GH6059)
- Bug with insert of strings into `DatetimeIndex` (GH5818)
- Fixed unicode bug in `to_html/HTML` repr (GH6098)
- Fixed missing arg validation in `get_options_data` (GH6105)
- Bug in assignment with duplicate columns in a frame where the locations are a slice (e.g. next to each other) (GH6120)
- Bug in propagating `__ref_locs` during construction of a `DataFrame` with dups index/columns (GH6121)
- Bug in `DataFrame.apply` when using mixed datelike reductions (GH6125)
- Bug in `DataFrame.append` when appending a row with different columns (GH6129)

- Bug in DataFrame construction with recarray and non-ns datetime dtype (GH6140)
- Bug in `.loc` setitem indexing with a dataframe on rhs, multiple item setting, and a datetimelike (GH6152)
- Fixed a bug in `query/eval` during lexicographic string comparisons (GH6155).
- Fixed a bug in `query` where the index of a single-element Series was being thrown away (GH6148).
- Bug in HDFStore on appending a dataframe with MultiIndexed columns to an existing table (GH6167)
- Consistency with dtypes in setting an empty DataFrame (GH6171)
- Bug in selecting on a MultiIndex HDFStore even in the presence of under specified column spec (GH6169)
- Bug in `nanops.var` with `ddof=1` and 1 elements would sometimes return `inf` rather than `nan` on some platforms (GH6136)
- Bug in Series and DataFrame bar plots ignoring the `use_index` keyword (GH6209)
- Bug in groupby with mixed str/int under python3 fixed; `argsort` was failing (GH6212)

8.13.2 v0.13.0 (January 3, 2014)

{{ header }}

This is a major release from 0.12.0 and includes a number of API changes, several new features and enhancements along with a large number of bug fixes.

Highlights include:

- support for a new index type `Float64Index`, and other Indexing enhancements
- `HDFStore` has a new string based syntax for query specification
- support for new methods of interpolation
- updated `timedelta` operations
- a new string manipulation method `extract`
- Nanosecond support for Offsets
- `isin` for DataFrames

Several experimental features are added, including:

- new `eval/query` methods for expression evaluation
- support for `msgpack` serialization
- an i/o interface to Google's `BigQuery`

There are several new or updated docs sections including:

- *Comparison with SQL*, which should be useful for those familiar with SQL but still learning pandas.
- *Comparison with R*, idiom translations from R to pandas.
- *Enhancing Performance*, ways to enhance pandas performance with `eval/query`.

Warning: In 0.13.0 `Series` has internally been refactored to no longer sub-class `ndarray` but instead subclass `NDFrame`, similar to the rest of the pandas containers. This should be a transparent change with only very limited API implications. See *Internal Refactoring*

API changes

- `read_excel` now supports an integer in its `sheetname` argument giving the index of the sheet to read in (GH4301).
- Text parser now treats anything that reads like `inf` (“inf”, “Inf”, “-Inf”, “iNF”, etc.) as infinity. (GH4220, GH4219), affecting `read_table`, `read_csv`, etc.
- `pandas` now is Python 2/3 compatible without the need for 2to3 thanks to @jtratner. As a result, `pandas` now uses iterators more extensively. This also led to the introduction of substantive parts of the Benjamin Peterson's `six` library into `compat`. (GH4384, GH4375, GH4372)
- `pandas.util.compat` and `pandas.util.py3compat` have been merged into `pandas.compat`. `pandas.compat` now includes many functions allowing 2/3 compatibility. It contains both list and iterator versions of `range`, `filter`, `map` and `zip`, plus other necessary elements for Python 3 compatibility. `lmap`, `lzip`, `lrange` and `lfilter` all produce lists instead of iterators, for compatibility with `numpy`, subscripting and `pandas` constructors. (GH4384, GH4375, GH4372)
- `Series.get` with negative indexers now returns the same as `[]` (GH4390)

- Changes to how Index and MultiIndex handle metadata (levels, labels, and names) (GH4039):

```
# previously, you would have set levels or labels directly
>>> pd.index.levels = [[1, 2, 3, 4], [1, 2, 4, 4]]

# now, you use the set_levels or set_labels methods
>>> index = pd.index.set_levels([[1, 2, 3, 4], [1, 2, 4, 4]])

# similarly, for names, you can rename the object
# but setting names is not deprecated
>>> index = pd.index.set_names(["bob", "cranberry"])

# and all methods take an inplace kwarg - but return None
>>> pd.index.set_names(["bob", "cranberry"], inplace=True)
```

- All division with NDFrame objects is now *truedivision*, regardless of the future import. This means that operating on pandas objects will by default use *floating point* division, and return a floating point dtype. You can use `//` and `floordiv` to do integer division.

Integer division

```
In [3]: arr = np.array([1, 2, 3, 4])
In [4]: arr2 = np.array([5, 3, 2, 1])
In [5]: arr / arr2
Out[5]: array([0, 0, 1, 4])

In [6]: pd.Series(arr) // pd.Series(arr2)
Out[6]:
0    0
1    0
2    1
3    4
dtype: int64
```

True Division

```
In [7]: pd.Series(arr) / pd.Series(arr2) # no future import required
Out[7]:
0    0.200000
1    0.666667
2    1.500000
3    4.000000
dtype: float64
```

- Infer and downcast dtype if `downcast='infer'` is passed to `fillna/ffill/bfill` (GH4604)
- `__nonzero__` for all NDFrame objects, will now raise a `ValueError`, this reverts back to (GH1073, GH4633) behavior. See *gotchas* for a more detailed discussion.

This prevents doing boolean comparison on *entire* pandas objects, which is inherently ambiguous. These all will raise a `ValueError`.

```

>>> df = pd.DataFrame({'A': np.random.randn(10),
...                    'B': np.random.randn(10),
...                    'C': pd.date_range('20130101', periods=10)
...                    })
...
>>> if df:
...     pass
...
Traceback (most recent call last):
...
ValueError: The truth value of a DataFrame is ambiguous. Use a.empty,
a.bool(), a.item(), a.any() or a.all().

>>> df1 = df
>>> df2 = df
>>> df1 and df2
Traceback (most recent call last):
...
ValueError: The truth value of a DataFrame is ambiguous. Use a.empty,
a.bool(), a.item(), a.any() or a.all().

>>> d = [1, 2, 3]
>>> s1 = pd.Series(d)
>>> s2 = pd.Series(d)
>>> s1 and s2
Traceback (most recent call last):
...
ValueError: The truth value of a DataFrame is ambiguous. Use a.empty,
a.bool(), a.item(), a.any() or a.all().

```

Added the `.bool()` method to `NDFrame` objects to facilitate evaluating of single-element boolean Series:

```
In [1]: pd.Series([True]).bool()
Out[1]: True
```

```
In [2]: pd.Series([False]).bool()
Out[2]: False
```

```
In [3]: pd.DataFrame([[True]]).bool()
Out[3]: True
```

```
In [4]: pd.DataFrame([[False]]).bool()
Out[4]: False
```

- All non-Index `NDFrames` (`Series`, `DataFrame`, `Panel`, `Panel4D`, `SparsePanel`, etc.), now support the entire set of arithmetic operators and arithmetic flex methods (`add`, `sub`, `mul`, etc.). `SparsePanel` does not support `pow` or `mod` with non-scalars. (GH3765)
- `Series` and `DataFrame` now have a `mode()` method to calculate the statistical mode(s) by axis/`Series`. (GH5367)
- Chained assignment will now by default warn if the user is assigning to a copy. This can be changed with the option `mode.chained_assignment`, allowed options are `raise/warn/None`. See *the docs*.

```
In [5]: dfc = pd.DataFrame({'A': ['aaa', 'bbb', 'ccc'], 'B': [1, 2, 3]})
In [6]: pd.set_option('chained_assignment', 'warn')
```

The following warning / exception will show if this is attempted.

```
In [7]: dfc.loc[0]['A'] = 1111
```

```
Traceback (most recent call last)
...
SettingWithCopyWarning:
  A value is trying to be set on a copy of a slice from a DataFrame.
  Try using .loc[row_index,col_indexer] = value instead
```

Here is the correct method of assignment.

```
In [8]: dfc.loc[0, 'A'] = 11
```

```
In [9]: dfc
Out[9]:
   A  B
0  11  1
1  bbb  2
2  ccc  3
```

- `Panel.reindex` has the following call signature `Panel.reindex(items=None, major_axis=None, minor_axis=None)` to conform with other `NDFrame` objects. See *Internal Refactoring* for more information.
- `Series.argmax` and `Series.argmin` are now aliased to `Series.idxmin` and `Series.idxmax`. These return the min or max element respectively. Prior to 0.13.0 these would return the position of the min / max element. (GH6214)

Prior version deprecations/changes

These were announced changes in 0.12 or prior that are taking effect as of 0.13.0

- Remove deprecated `Factor` (GH3650)
- Remove deprecated `set_printoptions/reset_printoptions` (GH3046)
- Remove deprecated `_verbose_info` (GH3215)
- Remove deprecated `read_clipboard/to_clipboard/ExcelFile/ExcelWriter` from `pandas.io.parsers` (GH3717) These are available as functions in the main pandas namespace (e.g. `pd.read_clipboard`)
- default for `tupleize_cols` is now `False` for both `to_csv` and `read_csv`. Fair warning in 0.12 (GH3604)
- default for `display.max_seq_len` is now 100 rather than `None`. This activates truncated display (“...”) of long sequences in various places. (GH3391)

Deprecations

Deprecated in 0.13.0

- deprecated `iterkv`, which will be removed in a future release (this was an alias of `iteritems` used to bypass 2to3's changes). (GH4384, GH4375, GH4372)
- deprecated the string method `match`, whose role is now performed more idiomatically by `extract`. In a future release, the default behavior of `match` will change to become analogous to `contains`, which returns a boolean indexer. (Their distinction is strictness: `match` relies on `re.match` while `contains` relies on `re.search`.) In this release, the deprecated behavior is the default, but the new behavior is available through the keyword argument `as_indexer=True`.

Indexing API changes

Prior to 0.13, it was impossible to use a label indexer (`.loc/.ix`) to set a value that was not contained in the index of a particular axis. (GH2578). See *the docs*

In the `Series` case this is effectively an appending operation

```
In [10]: s = pd.Series([1, 2, 3])
```

```
In [11]: s
```

```
Out[11]:
0    1
1    2
2    3
dtype: int64
```

```
In [12]: s[5] = 5.
```

```
In [13]: s
```

```
Out[13]:
0    1.0
1    2.0
2    3.0
5    5.0
dtype: float64
```

```
In [14]: dfi = pd.DataFrame(np.arange(6).reshape(3, 2),
.....:                      columns=['A', 'B'])
.....:
```

```
In [15]: dfi
```

```
Out[15]:
   A  B
0  0  1
1  2  3
2  4  5
```

This would previously `KeyError`

```
In [16]: dfi.loc[:, 'C'] = dfi.loc[:, 'A']
```

```
In [17]: dfi
```

```
Out[17]:
   A  B  C
0  0  1  0
1  2  3  2
2  4  5  4
```

(continues on next page)

(continued from previous page)

```
0 0 1 0
1 2 3 2
2 4 5 4
```

This is like an append operation.

```
In [18]: dfi.loc[3] = 5
```

```
In [19]: dfi
```

```
Out[19]:
   A  B  C
0  0  1  0
1  2  3  2
2  4  5  4
3  5  5  5
```

A Panel setting operation on an arbitrary axis aligns the input to the Panel

```
In [20]: p = pd.Panel(np.arange(16).reshape(2, 4, 2),
.....:                items=['Item1', 'Item2'],
.....:                major_axis=pd.date_range('2001/1/12', periods=4),
.....:                minor_axis=['A', 'B'], dtype='float64')
.....:
```

```
In [21]: p
```

```
Out[21]:
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 4 (major_axis) x 2 (minor_axis)
Items axis: Item1 to Item2
Major_axis axis: 2001-01-12 00:00:00 to 2001-01-15 00:00:00
Minor_axis axis: A to B
```

```
In [22]: p.loc[:, :, 'C'] = pd.Series([30, 32], index=p.items)
```

```
In [23]: p
```

```
Out[23]:
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 4 (major_axis) x 3 (minor_axis)
Items axis: Item1 to Item2
Major_axis axis: 2001-01-12 00:00:00 to 2001-01-15 00:00:00
Minor_axis axis: A to C
```

```
In [24]: p.loc[:, :, 'C']
```

```
Out[24]:
           Item1  Item2
2001-01-12    30.0    32.0
2001-01-13    30.0    32.0
2001-01-14    30.0    32.0
2001-01-15    30.0    32.0
```

Float64Index API change

- Added a new index type, `Float64Index`. This will be automatically created when passing floating values in index creation. This enables a pure label-based slicing paradigm that makes `[]`, `.ix`, `.loc` for scalar indexing and slicing work exactly the same. See *the docs*, (GH263)

Construction is by default for floating type values.

```
In [20]: index = pd.Index([1.5, 2, 3, 4.5, 5])
In [21]: index
Out[21]: Float64Index([1.5, 2.0, 3.0, 4.5, 5.0], dtype='float64')
In [22]: s = pd.Series(range(5), index=index)
In [23]: s
Out[23]:
1.5    0
2.0    1
3.0    2
4.5    3
5.0    4
dtype: int64
```

Scalar selection for `[]`, `.ix`, `.loc` will always be label based. An integer will match an equal float index (e.g. 3 is equivalent to 3.0)

```
In [24]: s[3]
Out[24]: 2
```

```
In [25]: s.loc[3]
Out[25]: 2
```

The only positional indexing is via `iloc`

```
In [26]: s.iloc[3]
Out[26]: 3
```

A scalar index that is not found will raise `KeyError`

Slicing is ALWAYS on the values of the index, for `[]`, `.ix`, `.loc` and ALWAYS positional with `iloc`

```
In [27]: s[2:4]
Out[27]:
2.0    1
3.0    2
dtype: int64
```

```
In [28]: s.loc[2:4]
Out[28]:
2.0    1
3.0    2
dtype: int64
```

```
In [29]: s.iloc[2:4]
Out[29]:
3.0    2
```

```
4.5    3
dtype: int64
```

In float indexes, slicing using floats are allowed

```
In [30]: s[2.1:4.6]
Out[30]:
3.0    2
4.5    3
dtype: int64
```

```
In [31]: s.loc[2.1:4.6]
Out[31]:
3.0    2
4.5    3
dtype: int64
```

- Indexing on other index types are preserved (and positional fallback for `[],ix`), with the exception, that floating point slicing on indexes on non `Float64Index` will now raise a `TypeError`.

```
In [1]: pd.Series(range(5))[3.5]
TypeError: the label [3.5] is not a proper indexer for this index type (Int64Index)

In [1]: pd.Series(range(5))[3.5:4.5]
TypeError: the slice start [3.5] is not a proper indexer for this index type
↳ (Int64Index)
```

Using a scalar float indexer will be deprecated in a future version, but is allowed for now.

```
In [3]: pd.Series(range(5))[3.0]
Out[3]: 3
```

HDFStore API changes

- Query Format Changes. A much more string-like query format is now supported. See *the docs*.

```
In [32]: path = 'test.h5'

In [33]: dfq = pd.DataFrame(np.random.randn(10, 4),
.....:                      columns=list('ABCD'),
.....:                      index=pd.date_range('20130101', periods=10))
.....:

In [34]: dfq.to_hdf(path, 'dfq', format='table', data_columns=True)
```

Use boolean expressions, with in-line function evaluation.

```
In [35]: pd.read_hdf(path, 'dfq',
.....:                where="index>Timestamp('20130104') & columns=['A', 'B']")
.....:
Out[35]:
```

	A	B
2013-01-05	-0.271020	1.288393
2013-01-06	0.846974	-0.685597

(continues on next page)

(continued from previous page)

```

2013-01-07  0.625555 -0.059268
2013-01-08 -1.087532  1.998044
2013-01-09  0.886313 -1.350722
2013-01-10  1.920906 -0.388231

```

Use an inline column reference

```

In [36]: pd.read_hdf(path, 'dfq',
.....:               where="A>0 or C>0")
.....:
Out [36]:
           A         B         C         D
2013-01-02 -0.486768  1.685148  0.112572 -1.495309
2013-01-03  0.898435 -0.148217 -1.596070  0.159653
2013-01-04  0.262136  0.036220  0.184735 -0.255069
2013-01-05 -0.271020  1.288393  0.294633 -1.165787
2013-01-06  0.846974 -0.685597  0.609099 -0.303961
2013-01-07  0.625555 -0.059268  0.249698  1.103949
2013-01-09  0.886313 -1.350722 -0.886348 -1.013316
2013-01-10  1.920906 -0.388231 -2.314394  0.665508

```

- the `format` keyword now replaces the `table` keyword; allowed values are `fixed(f)` or `table(t)` the same defaults as prior < 0.13.0 remain, e.g. `put` implies `fixed` format and `append` implies `table` format. This default format can be set as an option by setting `io.hdf.default_format`.

```

In [37]: path = 'test.h5'

In [38]: df = pd.DataFrame(np.random.randn(10, 2))

In [39]: df.to_hdf(path, 'df_table', format='table')

In [40]: df.to_hdf(path, 'df_table2', append=True)

In [41]: df.to_hdf(path, 'df_fixed')

In [42]: with pd.HDFStore(path) as store:
.....:     print(store)
.....:
<class 'pandas.io.pytables.HDFStore'>
File path: test.h5

```

- Significant table writing performance improvements
- handle a passed `Series` in table format (GH4330)
- can now serialize a `timedelta64[ns]` dtype in a table (GH3577), See *the docs*.
- added an `is_open` property to indicate if the underlying file handle is `_open`; a closed store will now report 'CLOSED' when viewing the store (rather than raising an error) (GH4409)
- a close of a `HDFStore` now will close that instance of the `HDFStore` but will only close the actual file if the ref count (by `PyTables`) w.r.t. all of the open handles are 0. Essentially you have a local instance of `HDFStore` referenced by a variable. Once you close it, it will report closed. Other references (to the same file) will continue to operate until they themselves are closed. Performing an action on a closed file will raise `ClosedFileError`

```
In [43]: path = 'test.h5'

In [44]: df = pd.DataFrame(np.random.randn(10, 2))

In [45]: store1 = pd.HDFStore(path)

In [46]: store2 = pd.HDFStore(path)

In [47]: store1.append('df', df)

In [48]: store2.append('df2', df)

In [49]: store1
Out[49]:
<class 'pandas.io.pytables.HDFStore'>
File path: test.h5

In [50]: store2
Out[50]:
<class 'pandas.io.pytables.HDFStore'>
File path: test.h5

In [51]: store1.close()

In [52]: store2
Out[52]:
<class 'pandas.io.pytables.HDFStore'>
File path: test.h5

In [53]: store2.close()

In [54]: store2
Out[54]:
<class 'pandas.io.pytables.HDFStore'>
File path: test.h5
```

- removed the `_quiet` attribute, replace by a `DuplicateWarning` if retrieving duplicate rows from a table ([GH4367](#))
- removed the `warn` argument from `open`. Instead a `PossibleDataLossError` exception will be raised if you try to use `mode='w'` with an OPEN file handle ([GH4367](#))
- allow a passed locations array or mask as a `where` condition ([GH4467](#)). See *the docs* for an example.
- add the keyword `dropna=True` to `append` to change whether ALL nan rows are not written to the store (default is True, ALL nan rows are NOT written), also settable via the option `io.hdf.dropna_table` ([GH4625](#))
- pass through store creation arguments; can be used to support in-memory stores

DataFrame repr changes

The HTML and plain text representations of `DataFrame` now show a truncated view of the table once it exceeds a certain size, rather than switching to the short info view ([GH4886](#), [GH5550](#)). This makes the representation more consistent as small `DataFrames` get larger.

2010-03-29	13.70	13.88	13.39	13.57	158225000	12.98
2010-03-30	13.55	13.64	13.18	13.28	142055200	12.70

771 rows × 6 columns

To get the info view, call `DataFrame.info()`. If you prefer the info view as the repr for large DataFrames, you can set this by running `set_option('display.large_repr', 'info')`.

Enhancements

- `df.to_clipboard()` learned a new `excel` keyword that let's you paste df data directly into excel (enabled by default). (GH5070).
- `read_html` now raises a `URLLError` instead of catching and raising a `ValueError` (GH4303, GH4305)
- Added a test for `read_clipboard()` and `to_clipboard()` (GH4282)
- Clipboard functionality now works with PySide (GH4282)
- Added a more informative error message when plot arguments contain overlapping color and style arguments (GH4402)
- `to_dict` now takes `records` as a possible out type. Returns an array of column-keyed dictionaries. (GH4936)
- NaN handling in `get_dummies` (GH4446) with `dummy_na`

```
# previously, nan was erroneously counted as 2 here
```

```
# now it is not counted at all
```

```
In [55]: pd.get_dummies([1, 2, np.nan])
```

```
Out[55]:
```

```
   1.0  2.0
0     1     0
1     0     1
2     0     0
```

```
# unless requested
```

```
In [56]: pd.get_dummies([1, 2, np.nan], dummy_na=True)
```

```
Out[56]:
```

```
   1.0  2.0  NaN
0     1     0     0
1     0     1     0
2     0     0     1
```

- `timedelta64[ns]` operations. See *the docs*.

Warning: Most of these operations require `numpy >= 1.7`

Using the new top-level `to_timedelta`, you can convert a scalar or array from the standard `timedelta` format (produced by `to_csv`) into a `timedelta` type (`np.timedelta64` in nanoseconds).

```
In [57]: pd.to_timedelta('1 days 06:05:01.00003')
```

```
Out[57]: Timedelta('1 days 06:05:01.000030')
```

```
In [58]: pd.to_timedelta('15.5us')
Out[58]: Timedelta('0 days 00:00:00.000015')

In [59]: pd.to_timedelta(['1 days 06:05:01.00003', '15.5us', 'nan'])
Out[59]: TimedeltaIndex(['1 days 06:05:01.000030', '0 days 00:00:00.000015', NaT],
↳dtype='timedelta64[ns]', freq=None)

In [60]: pd.to_timedelta(np.arange(5), unit='s')
Out[60]: TimedeltaIndex(['00:00:00', '00:00:01', '00:00:02', '00:00:03',
↳'00:00:04'], dtype='timedelta64[ns]', freq=None)
```

```
In [61]: pd.to_timedelta(np.arange(5), unit='d')
Out[61]: TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'],
↳dtype='timedelta64[ns]', freq=None)
```

A Series of dtype `timedelta64[ns]` can now be divided by another `timedelta64[ns]` object, or astyped to yield a `float64` dtyped Series. This is frequency conversion. See *the docs* for the docs.

```
In [62]: import datetime
```

```
In [63]: td = pd.Series(pd.date_range('20130101', periods=4)) - pd.Series(
.....:     pd.date_range('20121201', periods=4))
.....:
```

```
In [64]: td[2] += np.timedelta64(datetime.timedelta(minutes=5, seconds=3))
```

```
In [65]: td[3] = np.nan
```

```
In [66]: td
Out[66]:
0    31 days 00:00:00
1    31 days 00:00:00
2    31 days 00:05:03
3                NaT
dtype: timedelta64[ns]
```

```
# to days
```

```
In [67]: td / np.timedelta64(1, 'D')
Out[67]:
0    31.000000
1    31.000000
2    31.003507
3           NaN
dtype: float64
```

```
In [68]: td.astype('timedelta64[D]')
```

```
Out[68]:
0    31.0
1    31.0
2    31.0
3     NaN
dtype: float64
```

```
# to seconds
```

```
In [69]: td / np.timedelta64(1, 's')
Out[69]:
0    2678400.0
1    2678400.0
2    2678703.0
3         NaN
dtype: float64
```

```
In [70]: td.astype('timedelta64[s]')
Out[70]:
0    2678400.0
1    2678400.0
2    2678703.0
3         NaN
dtype: float64
```

Dividing or multiplying a `timedelta64[ns]` Series by an integer or integer Series

```
In [71]: td * -1
Out[71]:
0   -31 days +00:00:00
1   -31 days +00:00:00
2   -32 days +23:54:57
3                NaT
dtype: timedelta64[ns]
```

```
In [72]: td * pd.Series([1, 2, 3, 4])
Out[72]:
0   31 days 00:00:00
1   62 days 00:00:00
2   93 days 00:15:09
3                NaT
dtype: timedelta64[ns]
```

Absolute `DateOffset` objects can act equivalently to `timedeltas`

```
In [73]: from pandas import offsets

In [74]: td + offsets.Minute(5) + offsets.Milli(5)
Out[74]:
0   31 days 00:05:00.005000
1   31 days 00:05:00.005000
2   31 days 00:10:03.005000
3                NaT
dtype: timedelta64[ns]
```

Fillna is now supported for `timedeltas`

```
In [75]: td.fillna(pd.Timedelta(0))
Out[75]:
0   31 days 00:00:00
1   31 days 00:00:00
2   31 days 00:05:03
3    0 days 00:00:00
dtype: timedelta64[ns]
```

```
In [76]: td.fillna(datetime.timedelta(days=1, seconds=5))
Out[76]:
0    31 days 00:00:00
1    31 days 00:00:00
2    31 days 00:05:03
3     1 days 00:00:05
dtype: timedelta64[ns]
```

You can do numeric reduction operations on timedeltas.

```
In [77]: td.mean()
Out[77]: Timedelta('31 days 00:01:41')
```

```
In [78]: td.quantile(.1)
Out[78]: Timedelta('31 days 00:00:00')
```

- `plot(kind='kde')` now accepts the optional parameters `bw_method` and `ind`, passed to `scipy.stats.gaussian_kde()` (for `scipy >= 0.11.0`) to set the bandwidth, and to `gkde.evaluate()` to specify the indices at which it is evaluated, respectively. See [scipy docs](#). (GH4298)
- `DataFrame` constructor now accepts a numpy masked record array (GH3478)
- The new vectorized string method `extract` return regular expression matches more conveniently.

```
In [79]: pd.Series(['a1', 'b2', 'c3']).str.extract('[ab](\d)')
Out[79]:
      0
0     1
1     2
2  NaN
```

Elements that do not match return `NaN`. Extracting a regular expression with more than one group returns a `DataFrame` with one column per group.

```
In [80]: pd.Series(['a1', 'b2', 'c3']).str.extract('([ab])(\d)')
Out[80]:
      0  1
0     a  1
1     b  2
2  NaN NaN
```

Elements that do not match return a row of `NaN`. Thus, a `Series` of messy strings can be *converted* into a like-indexed `Series` or `DataFrame` of cleaned-up or more useful strings, without necessitating `get()` to access tuples or `re.match` objects.

Named groups like

```
In [81]: pd.Series(['a1', 'b2', 'c3']).str.extract(
.....:     '(?P<letter>[ab])(?P<digit>\d)')
.....:
Out[81]:
  letter digit
0      a      1
1      b      2
2   NaN   NaN
```

and optional groups can also be used.

```
In [82]: pd.Series(['a1', 'b2', '3']).str.extract(
.....:      '(?P<letter>[ab])?(?P<digit>\\d)')
.....:
Out [82]:
   letter digit
0      a      1
1      b      2
2     NaN      3
```

- `read_stata` now accepts Stata 13 format ([GH4291](#))
- `read_fwf` now infers the column specifications from the first 100 rows of the file if the data has correctly separated and properly aligned columns using the delimiter provided to the function ([GH4488](#)).
- support for nanosecond times as an offset

Warning: These operations require `numpy >= 1.7`

Period conversions in the range of seconds and below were reworked and extended up to nanoseconds. Periods in the nanosecond range are now available.

```
In [83]: pd.date_range('2013-01-01', periods=5, freq='5N')
Out [83]:
DatetimeIndex([
    '2013-01-01 00:00:00',
    '2013-01-01 00:00:00.000000005',
    '2013-01-01 00:00:00.000000010',
    '2013-01-01 00:00:00.000000015',
    '2013-01-01 00:00:00.000000020'],
              dtype='datetime64[ns]', freq='5N')
```

or with frequency as offset

```
In [84]: pd.date_range('2013-01-01', periods=5, freq=pd.offsets.Nano(5))
Out [84]:
DatetimeIndex([
    '2013-01-01 00:00:00',
    '2013-01-01 00:00:00.000000005',
    '2013-01-01 00:00:00.000000010',
    '2013-01-01 00:00:00.000000015',
    '2013-01-01 00:00:00.000000020'],
              dtype='datetime64[ns]', freq='5N')
```

Timestamps can be modified in the nanosecond range

```
In [85]: t = pd.Timestamp('20130101 09:01:02')
In [86]: t + pd.tseries.offsets.Nano(123)
Out [86]: Timestamp('2013-01-01 09:01:02.000000123')
```

- A new method, `isin` for DataFrames, which plays nicely with boolean indexing. The argument to `isin`, what we're comparing the DataFrame to, can be a DataFrame, Series, dict, or array of values. See [the docs](#) for more.

To get the rows where any of the conditions are met:

```
In [87]: dfi = pd.DataFrame({'A': [1, 2, 3, 4], 'B': ['a', 'b', 'f', 'n']})
```

```
In [88]: dfi
```

```
Out[88]:
```

```
   A  B
0  1  a
1  2  b
2  3  f
3  4  n
```

```
In [89]: other = pd.DataFrame({'A': [1, 3, 3, 7], 'B': ['e', 'f', 'f', 'e']})
```

```
In [90]: mask = dfi.isin(other)
```

```
In [91]: mask
```

```
Out[91]:
```

```
   A      B
0  True  False
1  False False
2  True   True
3  False False
```

```
In [92]: dfi[mask.any(1)]
```

```
Out[92]:
```

```
   A  B
0  1  a
2  3  f
```

- Series now supports a `to_frame` method to convert it to a single-column DataFrame (GH5164)
- All R datasets listed here <http://stat.ethz.ch/R-manual/R-devel/library/datasets/html/00Index.html> can now be loaded into Pandas objects

```
# note that pandas.rpy was deprecated in v0.16.0
import pandas.rpy.common as com
com.load_data('Titanic')
```

- `tz_localize` can infer a fall daylight savings transition based on the structure of the unlocalized data (GH4230), see *the docs*
- `DatetimeIndex` is now in the API documentation, see *the docs*
- `json_normalize()` is a new method to allow you to create a flat table from semi-structured JSON data. See *the docs* (GH1067)
- Added PySide support for the `qtpandas DataFrameModel` and `DataFrameWidget`.
- Python csv parser now supports `usecols` (GH4335)
- Frequencies gained several new offsets:
 - `LastWeekOfMonth` (GH4637)
 - `FY5253`, and `FY5253Quarter` (GH4511)
- DataFrame has a new `interpolate` method, similar to Series (GH4434, GH1892)

```
In [93]: df = pd.DataFrame({'A': [1, 2.1, np.nan, 4.7, 5.6, 6.8],
.....:                      'B': [.25, np.nan, np.nan, 4, 12.2, 14.4]})
```

(continues on next page)

(continued from previous page)

```

.....:
In [94]: df.interpolate()
Out[94]:
   A      B
0  1.0  0.25
1  2.1  1.50
2  3.4  2.75
3  4.7  4.00
4  5.6 12.20
5  6.8 14.40

```

Additionally, the method argument to `interpolate` has been expanded to include 'nearest', 'zero', 'slinear', 'quadratic', 'cubic', 'barycentric', 'krogh', 'piecewise_polynomial', 'pchip', 'polynomial', 'spline'. The new methods require `scipy`. Consult the [Scipy reference guide](#) and [documentation](#) for more information about when the various methods are appropriate. See [the docs](#).

Interpolate now also accepts a `limit` keyword argument. This works similar to `fillna`'s `limit`:

```

In [95]: ser = pd.Series([1, 3, np.nan, np.nan, np.nan, 11])

In [96]: ser.interpolate(limit=2)
Out[96]:
0    1.0
1    3.0
2    5.0
3    7.0
4    NaN
5   11.0
dtype: float64

```

- Added `wide_to_long` panel data convenience function. See [the docs](#).

```

In [97]: np.random.seed(123)

In [98]: df = pd.DataFrame({"A1970" : {0 : "a", 1 : "b", 2 : "c"},
.....:                    "A1980" : {0 : "d", 1 : "e", 2 : "f"},
.....:                    "B1970" : {0 : 2.5, 1 : 1.2, 2 : .7},
.....:                    "B1980" : {0 : 3.2, 1 : 1.3, 2 : .1},
.....:                    "X"      : dict(zip(range(3), np.random.randn(3)))
.....:                    })

In [99]: df["id"] = df.index

In [100]: df
Out[100]:
   A1970 A1980 B1970 B1980      X id
0     a     d   2.5   3.2 -1.085631  0
1     b     e   1.2   1.3  0.997345  1
2     c     f   0.7   0.1  0.282978  2

In [101]: pd.wide_to_long(df, ["A", "B"], i="id", j="year")

```

Out[101]:

```

           X  A    B
id year
0 1970 -1.085631  a  2.5
1 1970  0.997345  b  1.2
2 1970  0.282978  c  0.7
0 1980 -1.085631  d  3.2
1 1980  0.997345  e  1.3
2 1980  0.282978  f  0.1

```

- `to_csv` now takes a `date_format` keyword argument that specifies how output datetime objects should be formatted. Datetimes encountered in the index, columns, and values will all have this formatting applied. (GH4313)
- `DataFrame.plot` will scatter plot `x` versus `y` by passing `kind='scatter'` (GH2215)
- Added support for Google Analytics v3 API segment IDs that also supports v2 IDs. (GH5271)

Experimental

- The new `eval()` function implements expression evaluation using `numexpr` behind the scenes. This results in large speedups for complicated expressions involving large `DataFrames`/`Series`. For example,

```
In [102]: nrows, ncols = 20000, 100
```

```
In [103]: df1, df2, df3, df4 = [pd.DataFrame(np.random.randn(nrows, ncols))
.....:                               for _ in range(4)]
.....:
```

```
# eval with NumExpr backend
```

```
In [104]: %timeit pd.eval('df1 + df2 + df3 + df4')
7.25 ms +- 301 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

```
# pure Python evaluation
```

```
In [105]: %timeit df1 + df2 + df3 + df4
11 ms +- 609 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

For more details, see the *the docs*

- Similar to `pandas.eval`, `DataFrame` has a new `DataFrame.eval` method that evaluates an expression in the context of the `DataFrame`. For example,

```
In [106]: df = pd.DataFrame(np.random.randn(10, 2), columns=['a', 'b'])
```

```
In [107]: df.eval('a + b')
```

```
Out[107]:
0    -0.685204
1     1.589745
2     0.325441
3    -1.784153
4    -0.432893
5     0.171850
6     1.895919
7     3.065587
```

(continues on next page)

(continued from previous page)

```
8  -0.092759
9   1.391365
dtype: float64
```

- `query()` method has been added that allows you to select elements of a `DataFrame` using a natural query syntax nearly identical to Python syntax. For example,

```
In [108]: n = 20

In [109]: df = pd.DataFrame(np.random.randint(n, size=(n, 3)), columns=['a', 'b', 'c'
↳])

In [110]: df.query('a < b < c')
Out[110]:
   a  b  c
11  1  5  8
15  8 16 19
```

selects all the rows of `df` where `a < b < c` evaluates to `True`. For more details see the [the docs](#).

- `pd.read_msgpack()` and `pd.to_msgpack()` are now a supported method of serialization of arbitrary pandas (and python objects) in a lightweight portable binary format. See [the docs](#)

Warning: Since this is an EXPERIMENTAL LIBRARY, the storage format may not be stable until a future release.

```
In [111]: df = pd.DataFrame(np.random.rand(5, 2), columns=list('AB'))

In [112]: df.to_msgpack('foo.msg')

In [113]: pd.read_msgpack('foo.msg')
Out[113]:
   A      B
0  0.251082  0.017357
1  0.347915  0.929879
2  0.546233  0.203368
3  0.064942  0.031722
4  0.355309  0.524575

In [114]: s = pd.Series(np.random.rand(5), index=pd.date_range('20130101',
↳periods=5))

In [115]: pd.to_msgpack('foo.msg', df, s)

In [116]: pd.read_msgpack('foo.msg')
Out[116]:
[
   A      B
0  0.251082  0.017357
1  0.347915  0.929879
2  0.546233  0.203368
3  0.064942  0.031722
```

(continues on next page)

(continued from previous page)

2013-01-04 0.193225
2013-01-05 0.110977
Freq: D, dtype: float64

```

- `pandas.io.gbq` provides a simple way to extract from, and load data into, Google's BigQuery Data Sets by way of pandas DataFrames. BigQuery is a high performance SQL-like database service, useful for performing ad-hoc queries against extremely large datasets. *See the docs*

```

from pandas.io import gbq

# A query to select the average monthly temperatures in the
# in the year 2000 across the USA. The dataset,
# publicdata:samples.gsod, is available on all BigQuery accounts,
# and is based on NOAA gsod data.

query = """SELECT station_number as STATION,
month as MONTH, AVG(mean_temp) as MEAN_TEMP
FROM publicdata:samples.gsod
WHERE YEAR = 2000
GROUP BY STATION, MONTH
ORDER BY STATION, MONTH ASC"""

# Fetch the result set for this query

# Your Google BigQuery Project ID
# To find this, see your dashboard:
# https://console.developers.google.com/iam-admin/projects?authuser=0
projectid = 'xxxxxxxxx'
df = gbq.read_gbq(query, project_id=projectid)

# Use pandas to process and reshape the dataset

```

(continues on next page)

(continued from previous page)

```
df2 = df.pivot(index='STATION', columns='MONTH', values='MEAN_TEMP')
df3 = pd.concat([df2.min(), df2.mean(), df2.max()],
                axis=1, keys=["Min Tem", "Mean Temp", "Max Temp"])
```

The resulting DataFrame is:

```
> df3
      Min Tem  Mean Temp  Max Temp
MONTH
1    -53.336667  39.827892  89.770968
2    -49.837500  43.685219  93.437932
3    -77.926087  48.708355  96.099998
4    -82.892858  55.070087  97.317240
5    -92.378261  61.428117  102.042856
6    -77.703334  65.858888  102.900000
7    -87.821428  68.169663  106.510714
8    -89.431999  68.614215  105.500000
9    -86.611112  63.436935  107.142856
10   -78.209677  56.880838  92.103333
11   -50.125000  48.861228  94.996428
12   -50.332258  42.286879  94.396774
```

Warning: To use this module, you will need a BigQuery account. See <<https://cloud.google.com/products/big-query>> for details.

As of 10/10/13, there is a bug in Google's API preventing result sets from being larger than 100,000 rows. A patch is scheduled for the week of 10/14/13.

Internal refactoring

In 0.13.0 there is a major refactor primarily to subclass `Series` from `NDFrame`, which is the base class currently for `DataFrame` and `Panel`, to unify methods and behaviors. `Series` formerly subclassed directly from `ndarray`. (GH4080, GH3862, GH816)

Warning: There are two potential incompatibilities from < 0.13.0

- Using certain numpy functions would previously return a `Series` if passed a `Series` as an argument. This seems only to affect `np.ones_like`, `np.empty_like`, `np.diff` and `np.where`. These now return `ndarrays`.

```
In [118]: s = pd.Series([1, 2, 3, 4])
```

Numpy Usage

```
In [119]: np.ones_like(s)
Out[119]: array([1, 1, 1, 1])
```

```
In [120]: np.diff(s)
Out[120]: array([1, 1, 1])
```

```
In [121]: np.where(s > 1, s, np.nan)
Out[121]: array([nan,  2.,  3.,  4.]
```

Pandonic Usage

```
In [122]: pd.Series(1, index=s.index)
```

```
Out[122]:
```

```
0    1
1    1
2    1
3    1
```

```
dtype: int64
```

```
In [123]: s.diff()
```

```
Out[123]:
```

```
0    NaN
1    1.0
2    1.0
3    1.0
```

```
dtype: float64
```

```
In [124]: s.where(s > 1)
```

```
Out[124]:
```

```
0    NaN
1    2.0
2    3.0
3    4.0
```

```
dtype: float64
```

- Passing a `Series` directly to a cython function expecting an `ndarray` type will no longer work directly, you must pass `Series.values`, See *Enhancing Performance*
- `Series(0.5)` would previously return the scalar `0.5`, instead this will return a 1-element `Series`
- This change breaks `rpy2<=2.3.8`. An Issue has been opened against `rpy2` and a workaround is detailed in [GH5698](#). Thanks @JanSchulz.

- Pickle compatibility is preserved for pickles created prior to 0.13. These must be unpickled with `pd.read_pickle`, see *Pickling*.
- Refactor of `series.py/frame.py/panel.py` to move common code to `generic.py`
 - added `_setup_axes` to created generic NDFrame structures
 - moved methods
 - * `from_axes, _wrap_array, axes, ix, loc, iloc, shape, empty, swapaxes, transpose, pop`
 - * `__iter__, keys, __contains__, __len__, __neg__, __invert__`
 - * `convert_objects, as_blocks, as_matrix, values`
 - * `__getstate__, __setstate__` (compat remains in frame/panel)
 - * `__getattr__, __setattr__`
 - * `_indexed_same, reindex_like, align, where, mask`
 - * `fillna, replace` (`Series` replace is now consistent with `DataFrame`)
 - * `filter` (also added axis argument to selectively filter on a different axis)

- * `reindex, reindex_axis, take`
- * `truncate` (moved to become part of `NDFrame`)
- These are API changes which make `Panel` more consistent with `DataFrame`
 - `swapaxes` on a `Panel` with the same axes specified now return a copy
 - support attribute access for setting
 - filter supports the same API as the original `DataFrame` filter
- Reindex called with no arguments will now return a copy of the input object
- `TimeSeries` is now an alias for `Series`. the property `is_time_series` can be used to distinguish (if desired)
- Refactor of Sparse objects to use `BlockManager`
 - Created a new block type in internals, `SparseBlock`, which can hold multi-dtypes and is non-consolidatable. `SparseSeries` and `SparseDataFrame` now inherit more methods from their hierarchy (`Series/DataFrame`), and no longer inherit from `SparseArray` (which instead is the object of the `SparseBlock`)
 - Sparse suite now supports integration with non-sparse data. Non-float sparse data is supportable (partially implemented)
 - Operations on sparse structures within `DataFrames` should preserve sparseness, merging type operations will convert to dense (and back to sparse), so might be somewhat inefficient
 - enable `setitem` on `SparseSeries` for boolean/integer/slices
 - `SparsePanels` implementation is unchanged (e.g. not using `BlockManager`, needs work)
- added `ftypes` method to `Series/DataFrame`, similar to `dtypes`, but indicates if the underlying is sparse/dense (as well as the dtype)
- All `NDFrame` objects can now use `__finalize__()` to specify various values to propagate to new objects from an existing one (e.g. `name` in `Series` will follow more automatically now)
- Internal type checking is now done via a suite of generated classes, allowing `isinstance(value, klass)` without having to directly import the class, courtesy of @jtratner
- Bug in `Series` update where the parent frame is not updating its cache based on changes ([GH4080](#)) or types ([GH3217](#)), `fillna` ([GH3386](#))
- Indexing with dtype conversions fixed ([GH4463](#), [GH4204](#))
- Refactor `Series.reindex` to `core/generic.py` ([GH4604](#), [GH4618](#)), allow `method=` in reindexing on a `Series` to work
- `Series.copy` no longer accepts the `order` parameter and is now consistent with `NDFrame` copy
- Refactor `rename` methods to `core/generic.py`; fixes `Series.rename` for ([GH4605](#)), and adds `rename` with the same signature for `Panel`
- Refactor `clip` methods to `core/generic.py` ([GH4798](#))
- Refactor of `_get_numeric_data/_get_bool_data` to `core/generic.py`, allowing `Series/Panel` functionality
- `Series` (for index) / `Panel` (for items) now allow attribute access to its elements ([GH1903](#))

```
In [125]: s = pd.Series([1, 2, 3], index=list('abc'))

In [126]: s.b
Out[126]: 2

In [127]: s.a = 5

In [128]: s
Out[128]:
a    5
b    2
c    3
dtype: int64
```

Bug fixes

- **HDFStore**
 - raising an invalid `TypeError` rather than `ValueError` when appending with a different block ordering ([GH4096](#))
 - `read_hdf` was not respecting `as` passed mode ([GH4504](#))
 - appending a 0-len table will work correctly ([GH4273](#))
 - `to_hdf` was raising when passing both arguments `append` and `table` ([GH4584](#))
 - reading from a store with duplicate columns across dtypes would raise ([GH4767](#))
 - Fixed a bug where `ValueError` wasn't correctly raised when column names weren't strings ([GH4956](#))
 - A zero length series written in Fixed format not deserializing properly. ([GH4708](#))
 - Fixed decoding perf issue on py3 ([GH5441](#))
 - Validate levels in a `MultiIndex` before storing ([GH5527](#))
 - Correctly handle `data_columns` with a `Panel` ([GH5717](#))
- Fixed bug in `tslib.tz_convert(vals, tz1, tz2)`: it could raise `IndexError` exception while trying to access `trans[pos + 1]` ([GH4496](#))
- The `by` argument now works correctly with the `layout` argument ([GH4102](#), [GH4014](#)) in `*.hist` plotting methods
- Fixed bug in `PeriodIndex.map` where using `str` would return the `str` representation of the index ([GH4136](#))
- Fixed test failure `test_time_series_plot_color_with_empty_kwargs` when using custom matplotlib default colors ([GH4345](#))
- Fix running of stata IO tests. Now uses temporary files to write ([GH4353](#))
- Fixed an issue where `DataFrame.sum` was slower than `DataFrame.mean` for integer valued frames ([GH4365](#))
- `read_html` tests now work with Python 2.6 ([GH4351](#))
- Fixed bug where `network` testing was throwing `NameError` because a local variable was undefined ([GH4381](#))

- In `to_json`, raise if a passed `orient` would cause loss of data because of a duplicate index (GH4359)
- In `to_json`, fix date handling so milliseconds are the default timestamp as the docstring says (GH4362).
- `as_index` is no longer ignored when doing groupby apply (GH4648, GH3417)
- JSON NaT handling fixed, NaTs are now serialized to `null` (GH4498)
- Fixed JSON handling of escapable characters in JSON object keys (GH4593)
- Fixed passing `keep_default_na=False` when `na_values=None` (GH4318)
- Fixed bug with `values` raising an error on a DataFrame with duplicate columns and mixed dtypes, surfaced in (GH4377)
- Fixed bug with duplicate columns and type conversion in `read_json` when `orient='split'` (GH4377)
- Fixed JSON bug where locales with decimal separators other than `'.'` threw exceptions when encoding / decoding certain values. (GH4918)
- Fix `.iat` indexing with a `PeriodIndex` (GH4390)
- Fixed an issue where `PeriodIndex` joining with self was returning a new instance rather than the same instance (GH4379); also adds a test for this for the other index types
- Fixed a bug with all the dtypes being converted to object when using the CSV parser with the `usecols` parameter (GH3192)
- Fix an issue in merging blocks where the resulting DataFrame had partially set `__ref_locs` (GH4403)
- Fixed an issue where hist subplots were being overwritten when they were called using the top level matplotlib API (GH4408)
- Fixed a bug where calling `Series.astype(str)` would truncate the string (GH4405, GH4437)
- Fixed a py3 compat issue where bytes were being repr'd as tuples (GH4455)
- Fixed Panel attribute naming conflict if item is named `'a'` (GH3440)
- Fixed an issue where duplicate indexes were raising when plotting (GH4486)
- Fixed an issue where `cumsum` and `cumprod` didn't work with bool dtypes (GH4170, GH4440)
- Fixed Panel slicing issued in `xs` that was returning an incorrect dimmed object (GH4016)
- Fix resampling bug where custom reduce function not used if only one group (GH3849, GH4494)
- Fixed Panel assignment with a transposed frame (GH3830)
- Raise on set indexing with a Panel and a Panel as a value which needs alignment (GH3777)
- frozenset objects now raise in the `Series` constructor (GH4482, GH4480)
- Fixed issue with sorting a duplicate MultiIndex that has multiple dtypes (GH4516)
- Fixed bug in `DataFrame.set_values` which was causing name attributes to be lost when expanding the index. (GH3742, GH4039)
- Fixed issue where individual `names`, `levels` and `labels` could be set on `MultiIndex` without validation (GH3714, GH4039)
- Fixed (GH3334) in `pivot_table`. Margins did not compute if values is the index.
- Fix bug in having a rhs of `np.timedelta64` or `np.offsets.DateOffset` when operating with datetimes (GH4532)
- Fix arithmetic with series/datetimeindex and `np.timedelta64` not working the same (GH4134) and buggy `timedelta` in NumPy 1.6 (GH4135)

- Fix bug in `pd.read_clipboard` on windows with PY3 (GH4561); not decoding properly
- `tslib.get_period_field()` and `tslib.get_period_field_arr()` now raise if code argument out of range (GH4519, GH4520)
- Fix boolean indexing on an empty series loses index names (GH4235), `infer_dtype` works with empty arrays.
- Fix reindexing with multiple axes; if an axes match was not replacing the current axes, leading to a possible lazy frequency inference issue (GH3317)
- Fixed issue where `DataFrame.apply` was reraising exceptions incorrectly (causing the original stack trace to be truncated).
- Fix selection with `ix/loc` and `non_unique` selectors (GH4619)
- Fix assignment with `iloc/loc` involving a dtype change in an existing column (GH4312, GH5702) have internal `setitem_with_indexer` in `core/indexing` to use `Block.setitem`
- Fixed bug where thousands operator was not handled correctly for floating point numbers in `csv_import` (GH4322)
- Fix an issue with `CacheableOffset` not properly being used by many `DateOffset`; this prevented the `DateOffset` from being cached (GH4609)
- Fix boolean comparison with a `DataFrame` on the lhs, and a list/tuple on the rhs (GH4576)
- Fix error/dtype conversion with `setitem` of `None` on `Series/DataFrame` (GH4667)
- Fix decoding based on a passed in non-default encoding in `pd.read_stata` (GH4626)
- Fix `DataFrame.from_records` with a plain-vanilla `ndarray`. (GH4727)
- Fix some inconsistencies with `Index.rename` and `MultiIndex.rename`, etc. (GH4718, GH4628)
- Bug in using `iloc/loc` with a cross-sectional and duplicate indices (GH4726)
- Bug with using `QUOTE_NONE` with `to_csv` causing `Exception`. (GH4328)
- Bug with `Series` indexing not raising an error when the right-hand-side has an incorrect length (GH2702)
- Bug in `MultiIndexing` with a partial string selection as one part of a `MultiIndex` (GH4758)
- Bug with reindexing on the index with a non-unique index will now raise `ValueError` (GH4746)
- Bug in setting with `loc/ix` a single indexer with a `MultiIndex` axis and a `NumPy` array, related to (GH3777)
- Bug in concatenation with duplicate columns across dtypes not merging with `axis=0` (GH4771, GH4975)
- Bug in `iloc` with a slice index failing (GH4771)
- Incorrect error message with no colspecs or width in `read_fwf`. (GH4774)
- Fix bugs in indexing in a `Series` with a duplicate index (GH4548, GH4550)
- Fixed bug with reading compressed files with `read_fwf` in Python 3. (GH3963)
- Fixed an issue with a duplicate index and assignment with a dtype change (GH4686)
- Fixed bug with reading compressed files in as `bytes` rather than `str` in Python 3. Simplifies bytes-producing file-handling in Python 3 (GH3963, GH4785).
- Fixed an issue related to `ticklocs/ticklabels` with log scale bar plots across different versions of `matplotlib` (GH4789)
- Suppressed `DeprecationWarning` associated with internal calls issued by `repr()` (GH4391)

- Fixed an issue with a duplicate index and duplicate selector with `.loc` (GH4825)
- Fixed an issue with `DataFrame.sort_index` where, when sorting by a single column and passing a list for `ascending`, the argument for `ascending` was being interpreted as `True` (GH4839, GH4846)
- Fixed `Panel.tshift` not working. Added `freq` support to `Panel.shift` (GH4853)
- Fix an issue in `TextFileReader` w/ Python engine (i.e. `PythonParser`) with thousands != “,” (GH4596)
- Bug in `getitem` with a duplicate index when using `where` (GH4879)
- Fix Type inference code coerces float column into datetime (GH4601)
- Fixed `_ensure_numeric` does not check for complex numbers (GH4902)
- Fixed a bug in `Series.hist` where two figures were being created when the `by` argument was passed (GH4112, GH4113).
- Fixed a bug in `convert_objects` for `> 2` ndims (GH4937)
- Fixed a bug in `DataFrame/Panel` cache insertion and subsequent indexing (GH4939, GH5424)
- Fixed string methods for `FrozenNDArray` and `FrozenList` (GH4929)
- Fixed a bug with setting invalid or out-of-range values in indexing enlargement scenarios (GH4940)
- Tests for `fillna` on empty Series (GH4346), thanks @immerrr
- Fixed `copy()` to shallow copy axes/indices as well and thereby keep separate metadata. (GH4202, GH4830)
- Fixed `skiprows` option in Python parser for `read_csv` (GH4382)
- Fixed bug preventing `cut` from working with `np.inf` levels without explicitly passing labels (GH3415)
- Fixed wrong check for overlapping in `DatetimeIndex.union` (GH4564)
- Fixed conflict between thousands separator and date parser in `csv_parser` (GH4678)
- Fix appending when dtypes are not the same (error showing mixing float/np.datetime64) (GH4993)
- Fix repr for `DateOffset`. No longer show duplicate entries in kwds. Removed unused offset fields. (GH4638)
- Fixed wrong index name during `read_csv` if using `usecols`. Applies to `c` parser only. (GH4201)
- `Timestamp` objects can now appear in the left hand side of a comparison operation with a `Series` or `DataFrame` object (GH4982).
- Fix a bug when indexing with `np.nan` via `iloc/loc` (GH5016)
- Fixed a bug where low memory `c` parser could create different types in different chunks of the same file. Now coerces to numerical type or raises warning. (GH3866)
- Fix a bug where reshaping a `Series` to its own shape raised `TypeError` (GH4554) and other reshaping issues.
- Bug in setting with `ix/loc` and a mixed int/string index (GH4544)
- Make sure series-series boolean comparisons are label based (GH4947)
- Bug in multi-level indexing with a `Timestamp` partial indexer (GH4294)
- Tests/fix for `MultiIndex` construction of an all-nan frame (GH4078)
- Fixed a bug where `read_html()` wasn't correctly inferring values of tables with commas (GH5029)
- Fixed a bug where `read_html()` wasn't providing a stable ordering of returned tables (GH4770, GH5029).

- Fixed a bug where `read_html()` was incorrectly parsing when passed `index_col=0` (GH5066).
- Fixed a bug where `read_html()` was incorrectly inferring the type of headers (GH5048).
- Fixed a bug where `DatetimeIndex` joins with `PeriodIndex` caused a stack overflow (GH3899).
- Fixed a bug where `groupby` objects didn't allow plots (GH5102).
- Fixed a bug where `groupby` objects weren't tab-completing column names (GH5102).
- Fixed a bug where `groupby.plot()` and friends were duplicating figures multiple times (GH5102).
- Provide automatic conversion of `object` dtypes on `fillna`, related (GH5103)
- Fixed a bug where default options were being overwritten in the option parser cleaning (GH5121).
- Treat a list/ndarray identically for `iloc` indexing with list-like (GH5006)
- Fix `MultiIndex.get_level_values()` with missing values (GH5074)
- Fix bound checking for `Timestamp()` with `datetime64` input (GH4065)
- Fix a bug where `TestReadHtml` wasn't calling the correct `read_html()` function (GH5150).
- Fix a bug with `NDFrame.replace()` which made replacement appear as though it was (incorrectly) using regular expressions (GH5143).
- Fix better error message for `to_datetime` (GH4928)
- Made sure different locales are tested on `travis-ci` (GH4918). Also adds a couple of utilities for getting locales and setting locales with a context manager.
- Fixed segfault on `isnull(MultiIndex)` (now raises an error instead) (GH5123, GH5125)
- Allow duplicate indices when performing operations that align (GH5185, GH5639)
- Compound dtypes in a constructor raise `NotImplementedError` (GH5191)
- Bug in comparing duplicate frames (GH4421) related
- Bug in `describe` on duplicate frames
- Bug in `to_datetime` with a format and `coerce=True` not raising (GH5195)
- Bug in `loc` setting with multiple indexers and a rhs of a Series that needs broadcasting (GH5206)
- Fixed bug where `inplace` setting of levels or labels on `MultiIndex` would not clear cached `values` property and therefore return wrong `values`. (GH5215)
- Fixed bug where filtering a grouped `DataFrame` or `Series` did not maintain the original ordering (GH4621).
- Fixed `Period` with a business date freq to always roll-forward if on a non-business date. (GH5203)
- Fixed bug in Excel writers where frames with duplicate column names weren't written correctly. (GH5235)
- Fixed issue with `drop` and a non-unique index on `Series` (GH5248)
- Fixed segfault in C parser caused by passing more names than columns in the file. (GH5156)
- Fix `Series.isin` with date/time-like dtypes (GH5021)
- C and Python Parser can now handle the more common `MultiIndex` column format which doesn't have a row for index names (GH4702)
- Bug when trying to use an out-of-bounds date as an object dtype (GH5312)
- Bug when trying to display an embedded `PandasObject` (GH5324)

- Allows operating of Timestamps to return a datetime if the result is out-of-bounds related ([GH5312](#))
- Fix return value/type signature of `initObjToJSON()` to be compatible with numpy's `import_array()` ([GH5334](#), [GH5326](#))
- Bug when renaming then `set_index` on a DataFrame ([GH5344](#))
- Test suite no longer leaves around temporary files when testing graphics. ([GH5347](#)) (thanks for catching this [@yarikoptic!](#))
- Fixed html tests on win32. ([GH4580](#))
- Make sure that `head/tail` are `iloc` based, ([GH5370](#))
- Fixed bug for `PeriodIndex` string representation if there are 1 or 2 elements. ([GH5372](#))
- The `GroupBy` methods `transform` and `filter` can be used on Series and DataFrames that have repeated (non-unique) indices. ([GH4620](#))
- Fix empty series not printing name in repr ([GH4651](#))
- Make tests create temp files in temp directory by default. ([GH5419](#))
- `pd.to_timedelta` of a scalar returns a scalar ([GH5410](#))
- `pd.to_timedelta` accepts `NaN` and `NaT`, returning `NaT` instead of raising ([GH5437](#))
- performance improvements in `isnull` on larger size pandas objects
- Fixed various `setitem` with 1d ndarray that does not have a matching length to the indexer ([GH5508](#))
- Bug in `getitem` with a `MultiIndex` and `iloc` ([GH5528](#))
- Bug in `delitem` on a Series ([GH5542](#))
- Bug fix in `apply` when using custom function and objects are not mutated ([GH5545](#))
- Bug in selecting from a non-unique index with `loc` ([GH5553](#))
- Bug in `groupby` returning non-consistent types when user function returns a `None`, ([GH5592](#))
- Work around regression in numpy 1.7.0 which erroneously raises `IndexError` from `ndarray.item` ([GH5666](#))
- Bug in repeated indexing of object with resultant non-unique index ([GH5678](#))
- Bug in `fillna` with Series and a passed series/dict ([GH5703](#))
- Bug in `groupby` transform with a datetime-like grouper ([GH5712](#))
- Bug in `MultiIndex` selection in PY3 when using certain keys ([GH5725](#))
- Row-wise concat of differing dtypes failing in certain cases ([GH5754](#))

8.14 Version 0.12

8.14.1 v0.12.0 (July 24, 2013)

```
{{ header }}
```

This is a major release from 0.11.0 and includes several new features and enhancements along with a large number of bug fixes.

Highlights include a consistent I/O API naming scheme, routines to read html, write MultiIndexes to csv files, read & write STATA data files, read & write JSON format files, Python 3 support for HDFStore, filtering of groupby expressions via `filter`, and a revamped `replace` routine that accepts regular expressions.

API changes

- The I/O API is now much more consistent with a set of top level `reader` functions accessed like `pd.read_csv()` that generally return a `pandas` object.

```
- read_csv
- read_excel
- read_hdf
- read_sql
- read_json
- read_html
- read_stata
- read_clipboard
```

The corresponding `writer` functions are object methods that are accessed like `df.to_csv()`

```
- to_csv
- to_excel
- to_hdf
- to_sql
- to_json
- to_html
- to_stata
- to_clipboard
```

- Fix modulo and integer division on Series, DataFrames to act similarly to `float` dtypes to return `np.nan` or `np.inf` as appropriate (GH3590). This correct a numpy bug that treats `integer` and `float` dtypes differently.

```
In [1]: p = pd.DataFrame({'first': [4, 5, 8], 'second': [0, 0, 3]})
```

```
In [2]: p % 0
```

```
Out[2]:
   first  second
0    NaN     NaN
1    NaN     NaN
```

```
2    NaN    NaN
```

```
In [3]: p % p
```

```
Out[3]:
   first second
0    0.0    NaN
1    0.0    NaN
2    0.0    0.0
```

```
In [4]: p / p
```

```
Out[4]:
   first second
0    1.0    NaN
1    1.0    NaN
2    1.0    1.0
```

```
In [5]: p / 0
```

```
Out[5]:
   first second
0    inf    NaN
1    inf    NaN
2    inf    inf
```

- Add `squeeze` keyword to `groupby` to allow reduction from DataFrame -> Series if groups are unique. This is a Regression from 0.10.1. We are reverting back to the prior behavior. This means `groupby` will return the same shaped objects whether the groups are unique or not. Revert this issue ([GH2893](#)) with ([GH3596](#)).

```
In [6]: df2 = pd.DataFrame([{"val1": 1, "val2": 20},
...:                        {"val1": 1, "val2": 19},
...:                        {"val1": 1, "val2": 27},
...:                        {"val1": 1, "val2": 12}])
...:
```

```
In [7]: def func(dataf):
...:     return dataf["val2"] - dataf["val2"].mean()
...:
```

```
# squeezing the result frame to a series (because we have unique groups)
```

```
In [8]: df2.groupby("val1", squeeze=True).apply(func)
```

```
Out[8]:
0    0.5
1   -0.5
2    7.5
3   -7.5
Name: 1, dtype: float64
```

```
# no squeezing (the default, and behavior in 0.10.1)
```

```
In [9]: df2.groupby("val1").apply(func)
```

```
Out[9]:
val2  0  1  2  3
val1
1     0.5 -0.5  7.5 -7.5
```

- Raise on `iloc` when boolean indexing with a label based indexer mask e.g. a boolean Series, even

with integer labels, will raise. Since `iloc` is purely positional based, the labels on the Series are not alignable ([GH3631](#))

This case is rarely used, and there are plenty of alternatives. This preserves the `iloc` API to be *purely* positional based.

```
In [10]: df = pd.DataFrame(range(5), index=list('ABCDE'), columns=['a'])
```

```
In [11]: mask = (df.a % 2 == 0)
```

```
In [12]: mask
```

```
Out[12]:
```

```
A    True
```

```
B   False
```

```
C    True
```

```
D   False
```

```
E    True
```

```
Name: a, dtype: bool
```

```
# this is what you should use
```

```
In [13]: df.loc[mask]
```

```
Out[13]:
```

```
   a
A  0
C  2
E  4
```

```
# this will work as well
```

```
In [14]: df.iloc[mask.values]
```

```
Out[14]:
```

```
   a
A  0
C  2
E  4
```

```
df.iloc[mask] will raise a ValueError
```

- The `raise_on_error` argument to plotting functions is removed. Instead, plotting functions raise a `TypeError` when the `dtype` of the object is `object` to remind you to avoid `object` arrays whenever possible and thus you should cast to an appropriate numeric `dtype` if you need to plot something.
- Add `colormap` keyword to DataFrame plotting methods. Accepts either a matplotlib colormap object (ie, `matplotlib.cm.jet`) or a string name of such an object (ie, `'jet'`). The colormap is sampled to select the color for each column. Please see [Colormaps](#) for more information. ([GH3860](#))
- `DataFrame.interpolate()` is now deprecated. Please use `DataFrame.fillna()` and `DataFrame.replace()` instead. ([GH3582](#), [GH3675](#), [GH3676](#))
- the `method` and `axis` arguments of `DataFrame.replace()` are deprecated
- `DataFrame.replace`'s `infer_types` parameter is removed and now performs conversion by default. ([GH3907](#))
- Add the keyword `allow_duplicates` to `DataFrame.insert` to allow a duplicate column to be inserted if `True`, default is `False` (same as prior to 0.12) ([GH3679](#))
- Implement `__nonzero__` for NDFrame objects ([GH3691](#), [GH3696](#))
- IO api

- added top-level function `read_excel` to replace the following, The original API is deprecated and will be removed in a future version

```
from pandas.io.parsers import ExcelFile
xls = ExcelFile('path_to_file.xls')
xls.parse('Sheet1', index_col=None, na_values=['NA'])
```

With

```
import pandas as pd
pd.read_excel('path_to_file.xls', 'Sheet1', index_col=None, na_values=['NA'])
```

- added top-level function `read_sql` that is equivalent to the following

```
from pandas.io.sql import read_frame
read_frame(...)
```

- `DataFrame.to_html` and `DataFrame.to_latex` now accept a path for their first argument (GH3702)
- Do not allow astypes on `datetime64[ns]` except to object, and `timedelta64[ns]` to object/int (GH3425)
- The behavior of `datetime64` dtypes has changed with respect to certain so-called reduction operations (GH3726). The following operations now raise a `TypeError` when performed on a `Series` and return an *empty Series* when performed on a `DataFrame` similar to performing these operations on, for example, a `DataFrame` of slice objects:
 - sum, prod, mean, std, var, skew, kurt, corr, and cov
- `read_html` now defaults to `None` when reading, and falls back on `bs4` + `html5lib` when `lxml` fails to parse. a list of parsers to try until success is also valid
- The internal pandas class hierarchy has changed (slightly). The previous `PandasObject` now is called `PandasContainer` and a new `PandasObject` has become the base class for `PandasContainer` as well as `Index`, `Categorical`, `GroupBy`, `SparseList`, and `SparseArray` (+ their base classes). Currently, `PandasObject` provides string methods (from `StringMixin`). (GH4090, GH4092)
- New `StringMixin` that, given a `__unicode__` method, gets python 2 and python 3 compatible string methods (`__str__`, `__bytes__`, and `__repr__`). Plus string safety throughout. Now employed in many places throughout the pandas library. (GH4090, GH4092)

I/O enhancements

- `pd.read_html()` can now parse HTML strings, files or urls and return `DataFrames`, courtesy of @cpcloud. (GH3477, GH3605, GH3606, GH3616). It works with a *single* parser backend: `BeautifulSoup4` + `html5lib` *See the docs*

You can use `pd.read_html()` to read the output from `DataFrame.to_html()` like so

```
In [15]: df = pd.DataFrame({'a': range(3), 'b': list('abc')})

In [16]: print(df)
   a  b
0  0  a
1  1  b
2  2  c
```

(continues on next page)

(continued from previous page)

```
In [17]: html = df.to_html()

In [18]: alist = pd.read_html(html, index_col=0)

In [19]: print(df == alist[0])
      a      b
0  True  True
1  True  True
2  True  True
```

Note that `alist` here is a Python list so `pd.read_html()` and `DataFrame.to_html()` are not inverses.

– `pd.read_html()` no longer performs hard conversion of date strings (GH3656).

Warning: You may have to install an older version of BeautifulSoup4, *See the installation docs*

- Added module for reading and writing Stata files: `pandas.io.stata` (GH1512) accessible via `read_stata` top-level function for reading, and `to_stata` DataFrame method for writing, *See the docs*
- Added module for reading and writing json format files: `pandas.io.json` accessible via `read_json` top-level function for reading, and `to_json` DataFrame method for writing, *See the docs* various issues (GH1226, GH3804, GH3876, GH3867, GH1305)
- `MultiIndex` column support for reading and writing csv format files
 - The `header` option in `read_csv` now accepts a list of the rows from which to read the index.
 - The option, `tupleize_cols` can now be specified in both `to_csv` and `read_csv`, to provide compatibility for the pre 0.12 behavior of writing and reading `MultiIndex` columns via a list of tuples. The default in 0.12 is to write lists of tuples and *not* interpret list of tuples as a `MultiIndex` column.

Note: The default behavior in 0.12 remains unchanged from prior versions, but starting with 0.13, the default *to* write and read `MultiIndex` columns will be in the new format. (GH3571, GH1651, GH3141)

- If an `index_col` is not specified (e.g. you don't have an index, or wrote it with `df.to_csv(..., index=False)`), then any names on the columns index will be *lost*.

```
In [20]: from pandas.util.testing import makeCustomDataframe as mkdf
```

```
In [21]: df = mkdf(5, 3, r_idx_nlevels=2, c_idx_nlevels=4)
```

```
In [22]: df.to_csv('mi.csv')
```

```
In [23]: print(open('mi.csv').read())
```

```

- Support for HDFStore (via PyTables 3.0.0) on Python3
- Iterator support via `read_hdf` that automatically opens and closes the store when iteration is finished. This is only for *tables*

```
In [25]: path = 'store_iterator.h5'
```

```
In [26]: pd.DataFrame(np.random.randn(10, 2)).to_hdf(path, 'df', table=True)
```

```
In [27]: for df in pd.read_hdf(path, 'df', chunksize=3):
```

```
.....:     print(df)
```

```
.....:
```

```
      0      1
0  0.713216 -0.778461
1 -0.661062  0.862877
2  0.344342  0.149565
      0      1
3 -0.626968 -0.875772
4 -0.930687 -0.218983
5  0.949965 -0.442354
      0      1
6 -0.402985  1.111358
7 -0.241527 -0.670477
8  0.049355  0.632633
      0      1
9 -1.502767 -1.225492
```

- `read_csv` will now throw a more informative error message when a file contains no columns, e.g., all newline characters

Other enhancements

- `DataFrame.replace()` now allows regular expressions on contained `Series` with object dtype. See the examples section in the regular docs *Replacing via String Expression*

For example you can do

```
In [25]: df = pd.DataFrame({'a': list('ab..'), 'b': [1, 2, 3, 4]})
```

```
In [26]: df.replace(regex=r'\s*\.\s*', value=np.nan)
```

```
Out [26]:
```

```
   a  b
0  a  1
1  b  2
2 NaN 3
3 NaN 4
```

to replace all occurrences of the string '.' with zero or more instances of surrounding white space with NaN.

Regular string replacement still works as expected. For example, you can do

```
In [27]: df.replace('.', np.nan)
```

```
Out [27]:
```

```
   a  b
0  a  1
1  b  2
2 NaN 3
3 NaN 4
```

to replace all occurrences of the string '.' with NaN.

- `pd.melt()` now accepts the optional parameters `var_name` and `value_name` to specify custom column names of the returned DataFrame.
- `pd.set_option()` now allows N option, value pairs (GH3667).

Let's say that we had an option 'a.b' and another option 'b.c'. We can set them at the same time:

```
In [31]: pd.get_option('a.b')
```

```
Out [31]: 2
```

```
In [32]: pd.get_option('b.c')
```

```
Out [32]: 3
```

```
In [33]: pd.set_option('a.b', 1, 'b.c', 4)
```

```
In [34]: pd.get_option('a.b')
```

```
Out [34]: 1
```

```
In [35]: pd.get_option('b.c')
```

```
Out [35]: 4
```

- The `filter` method for group objects returns a subset of the original object. Suppose we want to take only elements that belong to groups with a group sum greater than 2.

```
In [28]: sf = pd.Series([1, 1, 2, 3, 3, 3])
```

```
In [29]: sf.groupby(sf).filter(lambda x: x.sum() > 2)
```

```
Out [29]:
```

```
3    3
4    3
```

(continues on next page)

(continued from previous page)

```
5    3
dtype: int64
```

The argument of `filter` must a function that, applied to the group as a whole, returns `True` or `False`. Another useful operation is filtering out elements that belong to groups with only a couple members.

```
In [30]: dff = pd.DataFrame({'A': np.arange(8), 'B': list('aabbbbcc')})
```

```
In [31]: dff.groupby('B').filter(lambda x: len(x) > 2)
```

```
Out [31]:
```

```
   A  B
2  2  b
3  3  b
4  4  b
5  5  b
```

Alternatively, instead of dropping the offending groups, we can return a like-indexed objects where the groups that do not pass the filter are filled with NaNs.

```
In [32]: dff.groupby('B').filter(lambda x: len(x) > 2, dropna=False)
```

```
Out [32]:
```

```
   A    B
0 NaN NaN
1 NaN NaN
2 2.0  b
3 3.0  b
4 4.0  b
5 5.0  b
6 NaN NaN
7 NaN NaN
```

- Series and DataFrame `hist` methods now take a `figsize` argument ([GH3834](#))
- DatetimeIndexes no longer try to convert mixed-integer indexes during join operations ([GH3877](#))
- `Timestamp.min` and `Timestamp.max` now represent valid `Timestamp` instances instead of the default `datetime.min` and `datetime.max` (respectively), thanks [@SleepingPills](#)
- `read_html` now raises when no tables are found and `BeautifulSoup==4.2.0` is detected ([GH4214](#))

Experimental features

- Added experimental `CustomBusinessDay` class to support `DateOffsets` with custom holiday calendars and custom weekmasks. ([GH2301](#))

Note: This uses the `numpy.busdaycalendar` API introduced in Numpy 1.7 and therefore requires Numpy 1.7.0 or newer.

```
In [33]: from pandas.tseries.offsets import CustomBusinessDay
```

```
In [34]: from datetime import datetime
```

(continues on next page)

(continued from previous page)

```

# As an interesting example, let's look at Egypt where
# a Friday-Saturday weekend is observed.
In [35]: weekmask_egypt = 'Sun Mon Tue Wed Thu'

# They also observe International Workers' Day so let's
# add that for a couple of years
In [36]: holidays = ['2012-05-01', datetime(2013, 5, 1), np.datetime64('2014-05-01
→')]

In [37]: bday_egypt = CustomBusinessDay(holidays=holidays, weekmask=weekmask_egypt)

In [38]: dt = datetime(2013, 4, 30)

In [39]: print(dt + 2 * bday_egypt)
2013-05-05 00:00:00

In [40]: dts = pd.date_range(dt, periods=5, freq=bday_egypt)

In [41]: print(pd.Series(dts.weekday, dts).map(pd.Series('Mon Tue Wed Thu Fri Sat_
→Sun'.split()))))
2013-04-30    Tue
2013-05-02    Thu
2013-05-05    Sun
2013-05-06    Mon
2013-05-07    Tue
Freq: C, dtype: object

```

Bug fixes

- Plotting functions now raise a `TypeError` before trying to plot anything if the associated objects have a dtype of `object` (GH1818, GH3572, GH3911, GH3912), but they will try to convert object arrays to numeric arrays if possible so that you can still plot, for example, an object array with floats. This happens before any drawing takes place which eliminates any spurious plots from showing up.
- `fillna` methods now raise a `TypeError` if the `value` parameter is a list or tuple.
- `Series.str` now supports iteration (GH3638). You can iterate over the individual elements of each string in the `Series`. Each iteration yields a `Series` with either a single character at each index of the original `Series` or `NaN`. For example,

```
In [42]: strs = 'go', 'bow', 'joe', 'slow'
```

```
In [43]: ds = pd.Series(strs)
```

```
In [44]: for s in ds.str:
```

```
....:     print(s)
....:
```

```
0    g
1    b
2    j
3    s
dtype: object
```

```

0    o
1    o
2    o
3    l
dtype: object
0    NaN
1     w
2     e
3     o
dtype: object
0    NaN
1    NaN
2    NaN
3     w
dtype: object

```

```

In [45]: s
Out[45]:
0    NaN
1    NaN
2    NaN
3     w
dtype: object

```

```

In [46]: s.dropna().values.item() == 'w'
Out[46]: True

```

The last element yielded by the iterator will be a `Series` containing the last element of the longest string in the `Series` with all other elements being `NaN`. Here since `'slow'` is the longest string and there are no other strings with the same length `'w'` is the only non-null string in the yielded `Series`.

- `HDFStore`
 - will retain index attributes (`freq,tz,name`) on recreation ([GH3499](#))
 - will warn with a `AttributeConflictWarning` if you are attempting to append an index with a different frequency than the existing, or attempting to append an index with a different name than the existing
 - support datelike columns with a timezone as `data_columns` ([GH2852](#))
- Non-unique index support clarified ([GH3468](#)).
 - Fix assigning a new index to a duplicate index in a `DataFrame` would fail ([GH3468](#))
 - Fix construction of a `DataFrame` with a duplicate index
 - `ref_locs` support to allow duplicative indices across dtypes, allows `iget` support to always find the index (even across dtypes) ([GH2194](#))
 - `applymap` on a `DataFrame` with a non-unique index now works (removed warning) ([GH2786](#)), and fix ([GH3230](#))
 - Fix `to_csv` to handle non-unique columns ([GH3495](#))
 - Duplicate indexes with `getitem` will return items in the correct order ([GH3455](#), [GH3457](#)) and handle missing elements like unique indices ([GH3561](#))
 - Duplicate indexes with and empty `DataFrame.from_records` will return a correct frame ([GH3562](#))
 - Concat to produce a non-unique columns when duplicates are across dtypes is fixed ([GH3602](#))

- Allow insert/delete to non-unique columns (GH3679)
- Non-unique indexing with a slice via `loc` and friends fixed (GH3659)
- Allow insert/delete to non-unique columns (GH3679)
- Extend `reindex` to correctly deal with non-unique indices (GH3679)
- `DataFrame.itertuples()` now works with frames with duplicate column names (GH3873)
- Bug in non-unique indexing via `iloc` (GH4017); added `takeable` argument to `reindex` for location-based taking
- Allow non-unique indexing in series via `.ix/.loc` and `__getitem__` (GH4246)
- Fixed non-unique indexing memory allocation issue with `.ix/.loc` (GH4280)
- `DataFrame.from_records` did not accept empty recarrays (GH3682)
- `read_html` now correctly skips tests (GH3741)
- Fixed a bug where `DataFrame.replace` with a compiled regular expression in the `to_replace` argument wasn't working (GH3907)
- Improved `network` test decorator to catch `IOError` (and therefore `URLError` as well). Added `with_connectivity_check` decorator to allow explicitly checking a website as a proxy for seeing if there is network connectivity. Plus, new `optional_args` decorator factory for decorators. (GH3910, GH3914)
- Fixed testing issue where too many sockets were open thus leading to a connection reset issue (GH3982, GH3985, GH4028, GH4054)
- Fixed failing tests in `test_yahoo`, `test_google` where symbols were not retrieved but were being accessed (GH3982, GH3985, GH4028, GH4054)
- `Series.hist` will now take the figure from the current environment if one is not passed
- Fixed bug where a 1xN `DataFrame` would barf on a 1xN mask (GH4071)
- Fixed running of `tox` under python3 where the pickle import was getting rewritten in an incompatible way (GH4062, GH4063)
- Fixed bug where `sharex` and `sharey` were not being passed to `grouped_hist` (GH4089)
- Fixed bug in `DataFrame.replace` where a nested dict wasn't being iterated over when `regex=False` (GH4115)
- Fixed bug in the parsing of microseconds when using the `format` argument in `to_datetime` (GH4152)
- Fixed bug in `PandasAutoDateLocator` where `invert_xaxis` triggered incorrectly `MilliSecondLocator` (GH3990)
- Fixed bug in plotting that wasn't raising on invalid colormap for matplotlib 1.1.1 (GH4215)
- Fixed the legend displaying in `DataFrame.plot(kind='kde')` (GH4216)
- Fixed bug where `Index` slices weren't carrying the name attribute (GH4226)
- Fixed bug in initializing `DatetimeIndex` with an array of strings in a certain time zone (GH4229)
- Fixed bug where `html5lib` wasn't being properly skipped (GH4265)
- Fixed bug where `get_data_famafrench` wasn't using the correct file edges (GH4281)

See the *full release notes* or issue tracker on GitHub for a complete list.

8.15 Version 0.11

8.15.1 v0.11.0 (April 22, 2013)

{{ header }}

This is a major release from 0.10.1 and includes many new features and enhancements along with a large number of bug fixes. The methods of Selecting Data have had quite a number of additions, and Dtype support is now full-fledged. There are also a number of important API changes that long-time pandas users should pay close attention to.

There is a new section in the documentation, *10 Minutes to Pandas*, primarily geared to new users.

There is a new section in the documentation, *Cookbook*, a collection of useful recipes in pandas (and that we want contributions!).

There are several libraries that are now *Recommended Dependencies*

Selection choices

Starting in 0.11.0, object selection has had a number of user-requested additions in order to support more explicit location based indexing. Pandas now supports three types of multi-axis indexing.

- `.loc` is strictly label based, will raise `KeyError` when the items are not found, allowed inputs are:
 - A single label, e.g. `5` or `'a'`, (note that `5` is interpreted as a *label* of the index. This use is **not** an integer position along the index)
 - A list or array of labels `['a', 'b', 'c']`

- A slice object with labels 'a':'f', (note that contrary to usual python slices, **both** the start and the stop are included!)
- A boolean array

See more at *Selection by Label*

- `.iloc` is strictly integer position based (from 0 to `length-1` of the axis), will raise `IndexError` when the requested indices are out of bounds. Allowed inputs are:
 - An integer e.g. 5
 - A list or array of integers [4, 3, 0]
 - A slice object with ints 1:7
 - A boolean array

See more at *Selection by Position*

- `.ix` supports mixed integer and label based access. It is primarily label based, but will fallback to integer positional access. `.ix` is the most general and will support any of the inputs to `.loc` and `.iloc`, as well as support for floating point label schemes. `.ix` is especially useful when dealing with mixed positional and label based hierarchical indexes.

As using integer slices with `.ix` have different behavior depending on whether the slice is interpreted as position based or label based, it's usually better to be explicit and use `.iloc` or `.loc`.

See more at *Advanced Indexing* and *Advanced Hierarchical*.

Selection deprecations

Starting in version 0.11.0, these methods *may* be deprecated in future versions.

- `irow`
- `icol`
- `iget_value`

See the section *Selection by Position* for substitutes.

Dtypes

Numeric dtypes will propagate and can coexist in DataFrames. If a dtype is passed (either directly via the `dtype` keyword, a passed `ndarray`, or a passed `Series`, then it will be preserved in DataFrame operations. Furthermore, different numeric dtypes will **NOT** be combined. The following example will give you a taste.

```
In [1]: df1 = pd.DataFrame(np.random.randn(8, 1), columns=['A'], dtype='float32')
```

```
In [2]: df1
```

```
Out[2]:
```

```

      A
0 -1.061137
1 -0.232825
2  0.430793
3 -0.665478
4  1.829808
5 -1.406509
6  1.078248
```

```
7 0.322774
```

```
In [3]: df1.dtypes
```

```
Out[3]:
```

```
A    float32
dtype: object
```

```
In [4]: df2 = pd.DataFrame({'A': pd.Series(np.random.randn(8), dtype='float16'),
...:                        'B': pd.Series(np.random.randn(8)),
...:                        'C': pd.Series(range(8), dtype='uint8')})
...:
```

```
In [5]: df2
```

```
Out[5]:
```

```
      A          B  C
0  0.200317 -0.116619  0
1  0.890137  0.295575  1
2  0.194824 -1.047704  2
3  0.351562  1.640556  3
4  0.448975  1.905836  4
5 -0.197876  2.772115  5

```

```
In [6]: df2.dtypes
```

```
Out[6]:
```

```
A    float16
B    float64
C      uint8
dtype: object
```

```
# here you get some upcasting
```

```
In [7]: df3 = df1.reindex_like(df2).fillna(value=0.0) + df2
```

```
In [8]: df3
```

```
Out[8]:
```

```
      A          B  C
0 -0.860820 -0.116619  0.0
1  0.657312  0.295575  1.0
2  0.625618 -1.047704  2.0
3 -0.313915  1.640556  3.0
4  2.278782  1.905836  4.0
5 -1.604385  2.772115  5.0
6  2.044068  0.088787  6.0
7 -1.199687 -1.144197  7.0
```

```
In [9]: df3.dtypes
```

```
Out[9]:
```

```
A    float32
B    float64
C    float64
dtype: object
```

Dtype conversion

This is lower-common-denominator upcasting, meaning you get the dtype which can accommodate all of the types

```
In [10]: df3.values.dtype
Out[10]: dtype('float64')
```

Conversion

```
In [11]: df3.astype('float32').dtypes
Out[11]:
A    float32
B    float32
C    float32
dtype: object
```

Mixed conversion

```
In [12]: df3['D'] = '1.'
In [13]: df3['E'] = '1'
In [14]: df3.convert_objects(convert_numeric=True).dtypes
Out[14]:
A    float32
B    float64
C    float64
D    float64
E     int64
dtype: object

# same, but specific dtype conversion
In [15]: df3['D'] = df3['D'].astype('float16')
In [16]: df3['E'] = df3['E'].astype('int32')
In [17]: df3.dtypes
Out[17]:
A    float32
B    float64
C    float64
D    float16
E     int32
dtype: object
```

Forcing date coercion (and setting NaT when not datelike)

```
In [18]: import datetime
In [19]: s = pd.Series([datetime.datetime(2001, 1, 1, 0, 0), 'foo', 1.0, 1,
.....:                  pd.Timestamp('20010104'), '20010105'], dtype='O')
.....:
```

(continues on next page)

(continued from previous page)

```
In [20]: s.convert_objects(convert_dates='coerce')
Out[20]:
0    2001-01-01
1           NaT
2           NaT
3           NaT
4    2001-01-04
5    2001-01-05
dtype: datetime64[ns]
```

Dtype gotchas

Platform gotchas

Starting in 0.11.0, construction of DataFrame/Series will use default dtypes of `int64` and `float64`, *regardless of platform*. This is not an apparent change from earlier versions of pandas. If you specify dtypes, they *WILL* be respected, however (GH2837)

The following will all result in `int64` dtypes

```
In [21]: pd.DataFrame([1, 2], columns=['a']).dtypes
Out[21]:
a    int64
dtype: object

In [22]: pd.DataFrame({'a': [1, 2]}).dtypes
Out[22]:
a    int64
dtype: object

In [23]: pd.DataFrame({'a': 1}, index=range(2)).dtypes
Out[23]:
a    int64
dtype: object
```

Keep in mind that `DataFrame(np.array([1,2]))` **WILL** result in `int32` on 32-bit platforms!

Upcasting gotchas

Performing indexing operations on integer type data can easily upcast the data. The dtype of the input data will be preserved in cases where nans are not introduced.

```
In [24]: dfi = df3.astype('int32')

In [25]: dfi['D'] = dfi['D'].astype('int64')

In [26]: dfi
Out[26]:
   A  B  C  D  E
0  0  0  0  1  1
1 -2  0  1  1  1
2 -2  0  2  1  1
3  0 -1  3  1  1
```

(continues on next page)

(continued from previous page)

```

4 1 0 4 1 1
5 0 0 5 1 1
6 0 -1 6 1 1
7 0 0 7 1 1

```

```
In [27]: dfi.dtypes
```

```
Out[27]:
```

```

A    int32
B    int32
C    int32
D    int64
E    int32
dtype: object

```

```
In [28]: casted = dfi[dfi > 0]
```

```
In [29]: casted
```

```
Out[29]:
```

```

   A  B  C  D  E
0 NaN NaN NaN 1  1
1 NaN NaN 1.0 1  1
2 NaN NaN 2.0 1  1
3 NaN NaN 3.0 1  1
4 1.0 NaN 4.0 1  1
5 NaN NaN 5.0 1  1
6 NaN NaN 6.0 1  1
7 NaN NaN 7.0 1  1

```

```
In [30]: casted.dtypes
```

```
Out[30]:
```

```

A    float64
B    float64
C    float64
D     int64
E     int32
dtype: object

```

While float dtypes are unchanged.

```
In [31]: df4 = df3.copy()
```

```
In [32]: df4['A'] = df4['A'].astype('float32')
```

```
In [33]: df4.dtypes
```

```
Out[33]:
```

```

A    float32
B    float64
C    float64
D    float16
E     int32
dtype: object

```

(continues on next page)

(continued from previous page)

```

In [34]: casted = df4[df4 > 0]

In [35]: casted
Out[35]:
   A         B     C     D  E
0  NaN      NaN  NaN  1.0  1
1  NaN  0.567020  1.0  1.0  1

7  NaN  0.524988  7.0  1.0  1

In [36]: casted.dtypes
Out[36]:
A    float32
B    float64
C    float64
D    float16
E     int32
dtype: object

```

Datetimes conversion

Datetime64[ns] columns in a DataFrame (or a Series) allow the use of `np.nan` to indicate a nan value, in addition to the traditional `NaT`, or not-a-time. This allows convenient nan setting in a generic way. Furthermore `datetime64[ns]` columns are created by default, when passed datetimelike objects (*this change was introduced in 0.10.1*) ([GH2809](#), [GH2810](#))

```

In [12]: df = pd.DataFrame(np.random.randn(6, 2), pd.date_range('20010102', periods=6),
.....:                      columns=['A', ' B'])
.....:

```

```

In [13]: df['timestamp'] = pd.Timestamp('20010103')

```

```

In [14]: df
Out[14]:
   A         B  timestamp
2001-01-02 -0.633372  0.925372  2001-01-03
2001-01-03 -0.006438 -0.820408  2001-01-03
2001-01-04 -0.600874 -1.039266  2001-01-03
2001-01-05  0.824758 -0.824095  2001-01-03
2001-01-06 -0.337730 -0.927764  2001-01-03
2001-01-07 -0.840123  0.248505  2001-01-03

```

```

# datetime64[ns] out of the box

```

```

In [15]: df.dtypes.value_counts()
Out[15]:
float64          2
datetime64[ns]  1
dtype: int64

```

```
# use the traditional nan, which is mapped to NaT internally
In [16]: df.loc[df.index[2:4], ['A', 'timestamp']] = np.nan
```

```
In [17]: df
Out[17]:
```

	A	B	timestamp
2001-01-02	-0.633372	0.925372	2001-01-03
2001-01-03	-0.006438	-0.820408	2001-01-03
2001-01-04	NaN	-1.039266	NaT
2001-01-05	NaN	-0.824095	NaT
2001-01-06	-0.337730	-0.927764	2001-01-03
2001-01-07	-0.840123	0.248505	2001-01-03

Astype conversion on `datetime64[ns]` to object, implicitly converts `NaT` to `np.nan`

```
In [18]: s = pd.Series([datetime.datetime(2001, 1, 2, 0, 0) for i in range(3)])
```

```
In [19]: s.dtype
Out[19]: dtype('<M8[ns]')
```

```
In [20]: s[1] = np.nan
```

```
In [21]: s
Out[21]:
0    2001-01-02
1         NaT
2    2001-01-02
dtype: datetime64[ns]
```

```
In [22]: s.dtype
Out[22]: dtype('<M8[ns]')
```

```
In [23]: s = s.astype('O')
```

```
In [24]: s
Out[24]:
0    2001-01-02 00:00:00
1         NaT
2    2001-01-02 00:00:00
dtype: object
```

```
In [25]: s.dtype
Out[25]: dtype('O')
```

API changes

- Added `to_series()` method to indices, to facilitate the creation of indexers ([GH3275](#))
- `HDFStore`
 - added the method `select_column` to select a single column from a table as a Series.
 - deprecated the `unique` method, can be replicated by `select_column(key, column).unique()`
 - `min_itemsize` parameter to `append` will now automatically create `data_columns` for passed keys

Enhancements

- Improved performance of `df.to_csv()` by up to 10x in some cases. (GH3059)
- Numexpr is now a *Recommended Dependencies*, to accelerate certain types of numerical and boolean operations
- Bottleneck is now a *Recommended Dependencies*, to accelerate certain types of nan operations
- HDFStore
 - support `read_hdf/to_hdf` API similar to `read_csv/to_csv`

```
In [26]: df = pd.DataFrame({'A': range(5), 'B': range(5)})
In [27]: df.to_hdf('store.h5', 'table', append=True)
In [28]: pd.read_hdf('store.h5', 'table', where=['index > 2'])
Out[28]:
   A  B
3  3  3
4  4  4
```

- provide dotted attribute access to `get` from stores, e.g. `store.df == store['df']`
- new keywords `iterator=boolean`, and `chunksize=number_in_a_chunk` are provided to support iteration on `select` and `select_as_multiple` (GH3076)
- You can now select timestamps from an *unordered* timeseries similarly to an *ordered* timeseries (GH2437)
- You can now select with a string from a DataFrame with a datelike index, in a similar way to a Series (GH3070)

```
In [29]: idx = pd.date_range("2001-10-1", periods=5, freq='M')
In [30]: ts = pd.Series(np.random.rand(len(idx)), index=idx)
In [31]: ts['2001']
Out[31]:
2001-10-31    0.927156
2001-11-30    0.163463
2001-12-31    0.961265
Freq: M, dtype: float64
In [32]: df = pd.DataFrame({'A': ts})
In [33]: df['2001']
Out[33]:
           A
2001-10-31  0.927156
2001-11-30  0.163463
2001-12-31  0.961265
```

- Squeeze to possibly remove length 1 dimensions from an object.

```

>>> p = pd.Panel(np.random.randn(3, 4, 4), items=['ItemA', 'ItemB', 'ItemC'],
...             major_axis=pd.date_range('20010102', periods=4),
...             minor_axis=['A', 'B', 'C', 'D'])
>>> p
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 4 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemC
Major_axis axis: 2001-01-02 00:00:00 to 2001-01-05 00:00:00
Minor_axis axis: A to D

>>> p.reindex(items=['ItemA']).squeeze()
           A          B          C          D
2001-01-02  0.926089 -2.026458  0.501277 -0.204683
2001-01-03 -0.076524  1.081161  1.141361  0.479243
2001-01-04  0.641817 -0.185352  1.824568  0.809152
2001-01-05  0.575237  0.669934  1.398014 -0.399338

2001-01-05    0.669934
Freq: D, Name: B, dtype: float64

```

- In `pd.io.data.Options`,
 - Fix bug when trying to fetch data for the current month when already past expiry.
 - Now using `lxml` to scrape html instead of `BeautifulSoup` (`lxml` was faster).
 - New instance variables for calls and puts are automatically created when a method that creates them is called. This works for current month where the instance variables are simply `calls` and `puts`. Also works for future expiry months and save the instance variable as `callsMMYY` or `putsMMYY`, where `MMYY` are, respectively, the month and year of the option's expiry.
 - `Options.get_near_stock_price` now allows the user to specify the month for which to get relevant options data.
 - `Options.get_forward_data` now has optional kwargs `near` and `above_below`. This allows the user to specify if they would like to only return forward looking data for options near the current stock price. This just obtains the data from `Options.get_near_stock_price` instead of `Options.get_XXX_data()` (GH2758).
- Cursor coordinate information is now displayed in time-series plots.
- added option `display.max_seq_items` to control the number of elements printed per sequence printing it. (GH2979)
- added option `display.chop_threshold` to control display of small numerical values. (GH2739)
- added option `display.max_info_rows` to prevent verbose `_info` from being calculated for frames above 1M rows (configurable). (GH2807, GH2918)
- `value_counts()` now accepts a “normalize” argument, for normalized histograms. (GH2710).
- `DataFrame.from_records` now accepts not only dicts but any instance of the `collections.Mapping` ABC.
- added option `display.mpl_style` providing a sleeker visual style for plots. Based on <https://gist.github.com/huyng/816622> (GH3075).

- Treat boolean values as integers (values 1 and 0) for numeric operations. (GH2641)
- `to_html()` now accepts an optional “escape” argument to control reserved HTML character escaping (enabled by default) and escapes `&`, in addition to `<` and `>`. (GH2919)

See the *full release notes* or issue tracker on GitHub for a complete list.

8.16 Version 0.10

8.16.1 v0.10.1 (January 22, 2013)

{{ header }}

This is a minor release from 0.10.0 and includes new features, enhancements, and bug fixes. In particular, there is substantial new HDFStore functionality contributed by Jeff Reback.

An undesired API breakage with functions taking the `inplace` option has been reverted and deprecation warnings added.

API changes

- Functions taking an `inplace` option return the calling object as before. A deprecation message has been added
- Groupby aggregations Max/Min no longer exclude non-numeric data ([GH2700](#))
- Resampling an empty DataFrame now returns an empty DataFrame instead of raising an exception ([GH2640](#))

- The file reader will now raise an exception when NA values are found in an explicitly specified integer column instead of converting the column to float (GH2631)
- DatetimeIndex.unique now returns a DatetimeIndex with the same name and
- timezone instead of an array (GH2563)

New features

- MySQL support for database (contribution from Dan Allan)

HDFStore

You may need to upgrade your existing data files. Please visit the **compatibility** section in the main docs.

You can designate (and index) certain columns that you want to be able to perform queries on a table, by passing a list to `data_columns`

```
In [1]: store = pd.HDFStore('store.h5')

In [2]: df = pd.DataFrame(np.random.randn(8, 3),
...:                      index=pd.date_range('1/1/2000', periods=8),
...:                      columns=['A', 'B', 'C'])
...:

In [3]: df['string'] = 'foo'

In [4]: df.loc[df.index[4:6], 'string'] = np.nan

In [5]: df.loc[df.index[7:9], 'string'] = 'bar'

In [6]: df['string2'] = 'cool'

In [7]: df
Out[7]:
```

	A	B	C	string	string2
2000-01-01	0.323586	-0.641630	-0.587514	foo	cool
2000-01-02	0.053897	0.194889	-0.381994	foo	cool
2000-01-03	0.318587	2.089075	-0.728293	foo	cool
2000-01-04	-0.090255	-0.748199	1.318931	foo	cool
2000-01-05	-2.029766	0.792652	0.461007	NaN	cool
2000-01-06	-0.542749	-0.305384	-0.479195	NaN	cool
2000-01-07	0.095031	-0.270099	-0.707140	foo	cool
2000-01-08	-0.773882	0.229453	0.304418	bar	cool

```
# on-disk operations
In [8]: store.append('df', df, data_columns=['B', 'C', 'string', 'string2'])

In [9]: store.select('df', "B>0 and string=='foo'")
Out[9]:
```

	A	B	C	string	string2
2000-01-02	0.053897	0.194889	-0.381994	foo	cool
2000-01-03	0.318587	2.089075	-0.728293	foo	cool

```
# this is in-memory version of this type of selection
```

```
In [10]: df[(df.B > 0) & (df.string == 'foo')]
Out[10]:
```

	A	B	C	string	string2
2000-01-02	0.053897	0.194889	-0.381994	foo	cool
2000-01-03	0.318587	2.089075	-0.728293	foo	cool

Retrieving unique values in an indexable or data column.

```
# note that this is deprecated as of 0.14.0
# can be replicated by: store.select_column('df', 'index').unique()
store.unique('df', 'index')
store.unique('df', 'string')
```

You can now store datetime64 in data columns

```
In [11]: df_mixed = df.copy()

In [12]: df_mixed['datetime64'] = pd.Timestamp('20010102')

In [13]: df_mixed.loc[df_mixed.index[3:4], ['A', 'B']] = np.nan

In [14]: store.append('df_mixed', df_mixed)

In [15]: df_mixed1 = store.select('df_mixed')

In [16]: df_mixed1
Out[16]:
```

	A	B	C	string	string2	datetime64
2000-01-01	0.323586	-0.641630	-0.587514	foo	cool	2001-01-02
2000-01-02	0.053897	0.194889	-0.381994	foo	cool	2001-01-02
2000-01-03	0.318587	2.089075	-0.728293	foo	cool	2001-01-02
2000-01-04	NaN	NaN	1.318931	foo	cool	2001-01-02
2000-01-05	-2.029766	0.792652	0.461007	NaN	cool	2001-01-02
2000-01-06	-0.542749	-0.305384	-0.479195	NaN	cool	2001-01-02
2000-01-07	0.095031	-0.270099	-0.707140	foo	cool	2001-01-02
2000-01-08	-0.773882	0.229453	0.304418	bar	cool	2001-01-02

```
In [17]: df_mixed1.dtypes.value_counts()
Out[17]:
float64      3
object       2
datetime64[ns] 1
dtype: int64
```

You can pass columns keyword to select to filter a list of the return columns, this is equivalent to passing a Term('columns', list_of_columns_to_filter)

```
In [18]: store.select('df', columns=['A', 'B'])
Out[18]:
```

	A	B
2000-01-01	0.323586	-0.641630
2000-01-02	0.053897	0.194889
2000-01-03	0.318587	2.089075
2000-01-04	-0.090255	-0.748199
2000-01-05	-2.029766	0.792652

(continues on next page)

(continued from previous page)

2000-01-07  0.095031 -0.270099
2000-01-08 -0.773882  0.229453

```

HDFStore now serializes MultiIndex dataframes when appending tables.

```

In [19]: index = pd.MultiIndex(levels=[['foo', 'bar', 'baz', 'qux'],
....:                               ['one', 'two', 'three']],
....:                          labels=[[0, 0, 0, 1, 1, 2, 2, 3, 3, 3],
....:                                [0, 1, 2, 0, 1, 1, 2, 0, 1, 2]],
....:                          names=['foo', 'bar'])
....:

In [20]: df = pd.DataFrame(np.random.randn(10, 3), index=index,
....:                      columns=['A', 'B', 'C'])
....:

In [21]: df
Out[21]:
           A         B         C
foo bar
foo one  -0.116619  0.295575 -1.047704
   two   1.640556  1.905836  2.772115
   three 0.088787 -1.144197 -0.633372
bar one   0.925372 -0.006438 -0.820408
   two  -0.600874 -1.039266  0.824758

In [24]: store.select('mi', "foo='bar'")
Out[24]:

```

(continues on next page)

(continued from previous page)

	A	B	C
foo bar			
bar one	0.925372	-0.006438	-0.820408
two	-0.600874	-1.039266	0.824758

Multi-table creation via `append_to_multiple` and selection via `select_as_multiple` can create/select from multiple tables and return a combined result, by using `where` on a selector table.

```
In [19]: df_mt = pd.DataFrame(np.random.randn(8, 6),
.....:                        index=pd.date_range('1/1/2000', periods=8),
.....:                        columns=['A', 'B', 'C', 'D', 'E', 'F'])
.....:
```

```
In [20]: df_mt['foo'] = 'bar'
```

you can also create the tables individually

```
In [21]: store.append_to_multiple({'df1_mt': ['A', 'B'], 'df2_mt': None},
.....:                            df_mt, selector='df1_mt')
.....:
```

```
In [22]: store
```

```
Out[22]:
```

```
<class 'pandas.io.pytables.HDFStore'>
```

```
File path: store.h5
```

individual tables were created

```
In [23]: store.select('df1_mt')
```

```
Out[23]:
```

```

Enhancements

- `HDFStore` now can read native PyTables table format tables
- You can pass `nan_rep = 'my_nan_rep'` to `append`, to change the default nan representation on disk (which converts to/from `np.nan`), this defaults to `nan`.
- You can pass `index` to `append`. This defaults to `True`. This will automatically create indices on the *indexables* and *data columns* of the table
- You can pass `chunksize=an integer` to `append`, to change the writing chunksize (default is 50000). This will significantly lower your memory usage on writing.
- You can pass `expectedrows=an integer` to the first `append`, to set the TOTAL number of expected rows that PyTables will expected. This will optimize read/write performance.
- `Select` now supports passing `start` and `stop` to provide selection space limiting in selection.
- Greatly improved ISO8601 (e.g., yyyy-mm-dd) date parsing for file parsers ([GH2698](#))
- Allow `DataFrame.merge` to handle combinatorial sizes too large for 64-bit integer ([GH2690](#))
- Series now has unary negation (`-series`) and inversion (`~series`) operators ([GH2686](#))
- `DataFrame.plot` now includes a `logx` parameter to change the x-axis to log scale ([GH2327](#))
- Series arithmetic operators can now handle constant and ndarray input ([GH2574](#))
- `ExcelFile` now takes a `kind` argument to specify the file type ([GH2613](#))
- A faster implementation for Series.str methods ([GH2602](#))

Bug Fixes

- `HDFStore` tables can now store `float32` types correctly (cannot be mixed with `float64` however)
- Fixed Google Analytics prefix when specifying request segment ([GH2713](#)).
- Function to reset Google Analytics token store so users can recover from improperly setup client secrets ([GH2687](#)).
- Fixed groupby bug resulting in segfault when passing in `MultiIndex` ([GH2706](#))
- Fixed bug where passing a Series with `datetime64` values into `to_datetime` results in bogus output values ([GH2699](#))
- Fixed bug in `pattern` in `HDFStore` expressions when `pattern` is not a valid regex ([GH2694](#))
- Fixed performance issues while aggregating boolean data ([GH2692](#))
- When given a boolean mask key and a Series of new values, Series `__setitem__` will now align the incoming values with the original Series ([GH2686](#))
- Fixed `MemoryError` caused by performing counting sort on sorting `MultiIndex` levels with a very large number of combinatorial values ([GH2684](#))
- Fixed bug that causes plotting to fail when the index is a `DatetimeIndex` with a fixed-offset timezone ([GH2683](#))
- Corrected business day subtraction logic when the offset is more than 5 bdays and the starting date is on a weekend ([GH2680](#))

- Fixed C file parser behavior when the file has more columns than data (GH2668)
- Fixed file reader bug that misaligned columns with data in the presence of an implicit column and a specified *usecols* value
- DataFrames with numerical or datetime indices are now sorted prior to plotting (GH2609)
- Fixed DataFrame.from_records error when passed columns, index, but empty records (GH2633)
- Several bug fixed for Series operations when dtype is datetime64 (GH2689, GH2629, GH2626)

See the *full release notes* or issue tracker on GitHub for a complete list.

8.16.2 v0.10.0 (December 17, 2012)

{{ header }}

This is a major release from 0.9.1 and includes many new features and enhancements along with a large number of bug fixes. There are also a number of important API changes that long-time pandas users should pay close attention to.

File parsing new features

The delimited file parsing engine (the guts of `read_csv` and `read_table`) has been rewritten from the ground up and now uses a fraction the amount of memory while parsing, while being 40% or more faster in most use cases (in some cases much faster).

There are also many new features:

- Much-improved Unicode handling via the `encoding` option.
- Column filtering (`usecols`)
- Dtype specification (`dtype` argument)
- Ability to specify strings to be recognized as True/False
- Ability to yield NumPy record arrays (`as_reccarray`)
- High performance `delim_whitespace` option
- Decimal format (e.g. European format) specification
- Easier CSV dialect options: `escapechar`, `lineterminator`, `quotechar`, etc.
- More robust handling of many exceptional kinds of files observed in the wild

API changes

Deprecated DataFrame BINOP TimeSeries special case behavior

The default behavior of binary operations between a DataFrame and a Series has always been to align on the DataFrame's columns and broadcast down the rows, **except** in the special case that the DataFrame contains time series. Since there are now method for each binary operator enabling you to specify how you want to broadcast, we are phasing out this special case (Zen of Python: *Special cases aren't special enough to break the rules*). Here's what I'm talking about:

```
In [1]: import pandas as pd
```

```
In [2]: df = pd.DataFrame(np.random.randn(6, 4),
...:                      index=pd.date_range('1/1/2000', periods=6))
...:
```

```
In [3]: df
```

```
Out[3]:
```

2000-01-06  0.0  0.673365  0.942776  0.291820

```

You will get a deprecation warning in the 0.10.x series, and the deprecated functionality will be removed in 0.11 or later.

Altered resample default behavior

The default time series `resample` binning behavior of daily D and *higher* frequencies has been changed to `closed='left'`, `label='left'`. Lower frequencies are unaffected. The prior defaults were causing a great deal of confusion for users, especially resampling data to daily frequency (which labeled the aggregated group with the end of the interval: the next day).

```
In [1]: dates = pd.date_range('1/1/2000', '1/5/2000', freq='4h')
```

```
In [2]: series = pd.Series(np.arange(len(dates)), index=dates)
```

```
In [3]: series
```

```
Out[3]:
```

```

```

- Infinity and negative infinity are no longer treated as NA by `isnull` and `notnull`. That they ever were was a relic of early pandas. This behavior can be re-enabled globally by the `mode.use_inf_as_null` option:

```

In [6]: s = pd.Series([1.5, np.inf, 3.4, -np.inf])

In [7]: pd.isnull(s)
Out[7]:
0    False
1    False
2    False
3    False
Length: 4, dtype: bool

In [8]: s.fillna(0)
Out[8]:
0    1.500000
1         inf
2    3.400000
3         -inf
Length: 4, dtype: float64

In [9]: pd.set_option('use_inf_as_null', True)

```

(continues on next page)

(continued from previous page)

```
In [10]: pd.isnull(s)
Out[10]:
0    False
1     True
2    False
3     True
Length: 4, dtype: bool
```

```
In [11]: s.fillna(0)
Out[11]:
0    1.5
1     0.0
2     3.4
3     0.0
Length: 4, dtype: float64
```

```
In [12]: pd.reset_option('use_inf_as_null')
```

- Methods with the `inplace` option now all return `None` instead of the calling object. E.g. code written like `df = df.fillna(0, inplace=True)` may stop working. To fix, simply delete the unnecessary variable assignment.
- `pandas.merge` no longer sorts the group keys (`sort=False`) by default. This was done for performance reasons: the group-key sorting is often one of the more expensive parts of the computation and is often unnecessary.
- The default column names for a file with no header have been changed to the integers 0 through $N - 1$. This is to create consistency with the `DataFrame` constructor with no columns specified. The v0.9.0 behavior (names `X0`, `X1`, ...) can be reproduced by specifying `prefix='X'`:

```
In [6]: import io
```

```
In [7]: data = ('a,b,c\n'
...:          '1,Yes,2\n'
...:          '3,No,4')
...:
```

```
In [8]: print(data)
a,b,c
1,Yes,2
3,No,4
```

```
In [9]: pd.read_csv(io.StringIO(data), header=None)
Out[9]:
   0  1  2
0  a  b  c
1  1  Yes 2
2  3  No  4
```

```
In [10]: pd.read_csv(io.StringIO(data), header=None, prefix='X')
Out[10]:
   X0  X1 X2
0  a   b  c
```

```
1 1 Yes 2
2 3 No 4
```

- Values like 'Yes' and 'No' are not interpreted as boolean by default, though this can be controlled by new `true_values` and `false_values` arguments:

```
In [11]: print(data)
a,b,c
1,Yes,2
3,No,4
```

```
In [12]: pd.read_csv(io.StringIO(data))
Out[12]:
   a  b  c
0  1  Yes 2
1  3  No  4
```

```
In [13]: pd.read_csv(io.StringIO(data), true_values=['Yes'], false_values=['No'])
Out[13]:
   a    b  c
0  1  True 2
1  3 False 4
```

- The file parsers will not recognize non-string values arising from a converter function as NA if passed in the `na_values` argument. It's better to do post-processing using the `replace` function instead.
- Calling `fillna` on Series or DataFrame with no arguments is no longer valid code. You must either specify a fill value or an interpolation method:

```
In [14]: s = pd.Series([np.nan, 1., 2., np.nan, 4])
```

```
In [15]: s
Out[15]:
0    NaN
1    1.0
2    2.0
3    NaN
4    4.0
dtype: float64
```

```
In [16]: s.fillna(0)
Out[16]:
0    0.0
1    1.0
2    2.0
3    0.0
4    4.0
dtype: float64
```

```
In [17]: s.fillna(method='pad')
Out[17]:
0    NaN
1    1.0
2    2.0
3    2.0
4    4.0
```

dtype: float64

Convenience methods `ffill` and `bfill` have been added:

```
In [18]: s.ffill()
Out[18]:
0      NaN
1      1.0
2      2.0
3      2.0
4      4.0
dtype: float64
```

- `Series.apply` will now operate on a returned value from the applied function, that is itself a series, and possibly upcast the result to a `DataFrame`

```
In [19]: def f(x):
...:     return pd.Series([x, x**2], index=['x', 'x^2'])
...:
```

```
In [20]: s = pd.Series(np.random.rand(5))
```

```
In [21]: s
Out[21]:
0    0.123872
1    0.924168
2    0.325076
3    0.303746
4    0.116822
dtype: float64
```

```
In [22]: s.apply(f)
Out[22]:
      x      x^2
0  0.123872  0.015344
1  0.924168  0.854086
2  0.325076  0.105674
3  0.303746  0.092262
4  0.116822  0.013647
```

- New API functions for working with pandas options ([GH2097](#)):
 - `get_option` / `set_option` - get/set the value of an option. Partial names are accepted.
 - `reset_option` - reset one or more options to their default value. Partial names are accepted.
 - `describe_option` - print a description of one or more options. When called with no arguments, print all registered options.

Note: `set_printoptions` / `reset_printoptions` are now deprecated (but functioning), the print options now live under “`display.XYZ`”. For example:

```
In [23]: pd.get_option("display.max_rows")
Out[23]: 60
```

- `to_string()` methods now always return unicode strings ([GH2224](#)).

New features

Wide DataFrame printing

Instead of printing the summary information, pandas now splits the string representation across multiple rows by default:

```
In [24]: wide_frame = pd.DataFrame(np.random.randn(5, 16))

In [25]: wide_frame
Out[25]:
```

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
0	-0.711411	-2.122599	1.962935	1.672027	-0.880984	0.997289	-1.693316	-0.179129	-1.598062	0.936914	0.912560	-1.003401	1.632781	-0.724626	0.178219	0.310610
1	-0.108002	-0.974226	-1.147708	-2.281374	0.760010	-0.742532	1.533318	2.495362	-0.432771	-0.068954	0.043520	0.112246	0.871721	-0.816064	-0.784880	1.030659
2	0.187483	-1.933946	0.377312	0.734122	2.141616	-0.011225	0.048869	-1.360687	-0.479010	-0.859661	-0.231595	-0.527750	-1.296337	0.150680	0.123836	0.571764
3	1.555563	-0.823761	0.535420	-1.032853	1.469725	1.304124	1.449735	0.203109	-1.032011	0.969818	-0.962723	1.382083	-0.938794	0.669142	-0.433567	-0.273610
4	0.680433	-0.308450	-0.276099	-1.821168	-1.993606	-1.927385	-2.027924	1.624972	0.551135	3.059267	0.455264	-0.030740	0.935716	1.061192	-2.107852	0.199905

The old behavior of printing out summary information can be achieved via the 'expand_frame_repr' print option:

```
In [26]: pd.set_option('expand_frame_repr', False)

In [27]: wide_frame
Out[27]:
```

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
0	-0.711411	-2.122599	1.962935	1.672027	-0.880984	0.997289	-1.693316	-0.179129	-1.598062	0.936914	0.912560	-1.003401	1.632781	-0.724626	0.178219	0.310610
1	-0.108002	-0.974226	-1.147708	-2.281374	0.760010	-0.742532	1.533318	2.495362	-0.432771	-0.068954	0.043520	0.112246	0.871721	-0.816064	-0.784880	1.030659
2	0.187483	-1.933946	0.377312	0.734122	2.141616	-0.011225	0.048869	-1.360687	-0.479010	-0.859661	-0.231595	-0.527750	-1.296337	0.150680	0.123836	0.571764
3	1.555563	-0.823761	0.535420	-1.032853	1.469725	1.304124	1.449735	0.203109	-1.032011	0.969818	-0.962723	1.382083	-0.938794	0.669142	-0.433567	-0.273610
4	0.680433	-0.308450	-0.276099	-1.821168	-1.993606	-1.927385	-2.027924	1.624972	0.551135	3.059267	0.455264	-0.030740	0.935716	1.061192	-2.107852	0.199905

The width of each line can be changed via 'line_width' (80 by default):

```
pd.set_option('line_width', 40)
```

```
wide_frame
```

Updated PyTables support

Docs for PyTables Table format & several enhancements to the api. Here is a taste of what to expect.

```
In [41]: store = pd.HDFStore('store.h5')

In [42]: df = pd.DataFrame(np.random.randn(8, 3),
.....:                    index=pd.date_range('1/1/2000', periods=8),
.....:                    columns=['A', 'B', 'C'])

In [43]: df

[8 rows x 5 columns]

In [69]: df1.get_dtype_counts()

```

(continues on next page)

(continued from previous page)

```
Out [69]:
float64    3
int64      1
object     1
dtype: int64
```

- performance improvements on table writing
- support for arbitrarily indexed dimensions
- `SparseSeries` now has a `density` property (GH2384)
- enable `Series.str.strip/lstrip/rstrip` methods to take an input argument to strip arbitrary characters (GH2411)
- implement `value_vars` in `melt` to limit values to certain columns and add `melt` to pandas namespace (GH2412)

Bug Fixes

- added `Term` method of specifying where conditions (GH1996).
- `del store['df']` now call `store.remove('df')` for store deletion
- deleting of consecutive rows is much faster than before
- `min_itemsize` parameter can be specified in table creation to force a minimum size for indexing columns (the previous implementation would set the column size based on the first append)
- indexing support via `create_table_index` (requires PyTables \geq 2.3) (GH698).
- appending on a store would fail if the table was not first created via `put`
- fixed issue with missing attributes after loading a pickled dataframe (GH2431)
- minor change to `select` and `remove`: require a table ONLY if where is also provided (and not None)

Compatibility

0.10 of `HDFStore` is backwards compatible for reading tables created in a prior version of pandas, however, query terms using the prior (undocumented) methodology are unsupported. You must read in the entire file and write it out using the new format to take advantage of the updates.

N dimensional Panels (experimental)

Adding experimental support for `Panel4D` and factory functions to create n-dimensional named panels. Here is a taste of what to expect.

```
In [58]: p4d = Panel4D(randn(2, 2, 5, 4),
....:    labels=['Label1', 'Label2'],
....:    items=['Item1', 'Item2'],
....:    major_axis=date_range('1/1/2000', periods=5),
....:    minor_axis=['A', 'B', 'C', 'D'])
....:

In [59]: p4d
Out [59]:
<class 'pandas.core.panelnd.Panel4D'>
Dimensions: 2 (labels) x 2 (items) x 5 (major_axis) x 4 (minor_axis)
```

(continues on next page)

(continued from previous page)

```
Labels axis: Label1 to Label2
Items axis: Item1 to Item2
Major_axis axis: 2000-01-01 00:00:00 to 2000-01-05 00:00:00
Minor_axis axis: A to D
```

See the *full release notes* or issue tracker on GitHub for a complete list.

8.17 Version 0.9

8.17.1 v0.9.1 (November 14, 2012)

```
{{ header }}
```

This is a bug fix release from 0.9.0 and includes several new features and enhancements along with a large number of bug fixes. The new features include by-column sort order for DataFrame and Series, improved NA handling for the rank method, masking functions for DataFrame, and intraday time-series filtering for DataFrame.

New features

- *Series.sort*, *DataFrame.sort*, and *DataFrame.sort_index* can now be specified in a per-column manner to support multiple sort orders (GH928)

```
In [2]: df = pd.DataFrame(np.random.randint(0, 2, (6, 3)),
...:                      columns=['A', 'B', 'C'])

In [3]: df.sort(['A', 'B'], ascending=[1, 0])
```

```
Out [3]:
   A  B  C
3  0  1  1
4  0  1  1
2  0  0  1
0  1  0  0
1  1  0  0
5  1  0  0
```

- *DataFrame.rank* now supports additional argument values for the *na_option* parameter so missing values can be assigned either the largest or the smallest rank (GH1508, GH2159)

```
In [1]: df = pd.DataFrame(np.random.randn(6, 3), columns=['A', 'B', 'C'])
```

```
In [2]: df.loc[2:4] = np.nan
```

```
In [3]: df.rank()
```

```
Out [3]:
   A    B    C
0  2.0  3.0  3.0
1  3.0  1.0  1.0
2  NaN  NaN  NaN
3  NaN  NaN  NaN
4  NaN  NaN  NaN
5  1.0  2.0  2.0
```

```
[6 rows x 3 columns]
```

```
In [4]: df.rank(na_option='top')
```

```
Out [4]:
   A    B    C
0  5.0  6.0  6.0
```

```

1  6.0  4.0  4.0
2  2.0  2.0  2.0
3  2.0  2.0  2.0
4  2.0  2.0  2.0
5  4.0  5.0  5.0

```

```
[6 rows x 3 columns]
```

```
In [5]: df.rank(na_option='bottom')
```

```
Out[5]:
   A    B    C
0  2.0  3.0  3.0
1  3.0  1.0  1.0
2  5.0  5.0  5.0
3  5.0  5.0  5.0
4  5.0  5.0  5.0
5  1.0  2.0  2.0

```

```
[6 rows x 3 columns]
```

- DataFrame has new *where* and *mask* methods to select values according to a given boolean mask ([GH2109](#), [GH2151](#))

DataFrame currently supports slicing via a boolean vector the same length as the DataFrame (inside the `[[]]`). The returned DataFrame has the same number of columns as the original, but is sliced on its index.

```
In [6]: df = DataFrame(np.random.randn(5, 3), columns = ['A', 'B', 'C'])
```

```
In [7]: df
```

```
Out[7]:
   A          B          C
0 -1.170647 -0.881989 -0.485793
1  0.174369 -1.500438  0.155944
2 -1.426978  0.189856 -0.465137
3 -1.226494  1.017240  0.715402
4 -0.640726 -1.196583  0.110529

```

```
[5 rows x 3 columns]
```

```
In [8]: df[df['A'] > 0]
```

```
Out[8]:
   A          B          C
1  0.174369 -1.500438  0.155944

```

```
[1 rows x 3 columns]
```

If a DataFrame is sliced with a DataFrame based boolean condition (with the same size as the original DataFrame), then a DataFrame the same size (index and columns) as the original is returned, with elements that do not meet the boolean condition as *NaN*. This is accomplished via the new method *DataFrame.where*. In addition, *where* takes an optional *other* argument for replacement.

```
In [9]: df[df>0]
```

```
Out[9]:
   A          B          C

```

```

0      NaN      NaN      NaN
1  0.174369      NaN  0.155944
2      NaN  0.189856      NaN
3      NaN  1.017240  0.715402
4      NaN      NaN  0.110529

```

```
[5 rows x 3 columns]
```

```
In [10]: df.where(df>0)
```

```
Out[10]:
```

```

      A      B      C
0      NaN      NaN      NaN
1  0.174369      NaN  0.155944
2      NaN  0.189856      NaN
3      NaN  1.017240  0.715402
4      NaN      NaN  0.110529

```

```
[5 rows x 3 columns]
```

```
In [11]: df.where(df>0,-df)
```

```
Out[11]:
```

```

      A      B      C
0  1.170647  0.881989  0.485793
1  0.174369  1.500438  0.155944
2  1.426978  0.189856  0.465137
3  1.226494  1.017240  0.715402
4  0.640726  1.196583  0.110529

```

```
[5 rows x 3 columns]
```

Furthermore, *where* now aligns the input boolean condition (ndarray or DataFrame), such that partial selection with setting is possible. This is analogous to partial setting via *ix* (but on the contents rather than the axis labels)

```
In [12]: df2 = df.copy()
```

```
In [13]: df2[ df2[1:4] > 0 ] = 3
```

```
In [14]: df2
```

```
Out[14]:
```

```

      A      B      C
0 -1.170647 -0.881989 -0.485793
1  3.000000 -1.500438  3.000000
2 -1.426978  3.000000 -0.465137
3 -1.226494  3.000000  3.000000
4 -0.640726 -1.196583  0.110529

```

```
[5 rows x 3 columns]
```

DataFrame.mask is the inverse boolean operation of *where*.

```
In [15]: df.mask(df<=0)
```

```
Out[15]:
```

```

      A      B      C

```

(continues on next page)

(continued from previous page)

```

0      NaN      NaN      NaN
1  0.174369      NaN  0.155944
2      NaN  0.189856      NaN
3      NaN  1.017240  0.715402
4      NaN      NaN  0.110529

```

[5 rows x 3 columns]

- Enable referencing of Excel columns by their column names (GH1936)

```

In [16]: xl = pd.ExcelFile('data/test.xls')

In [17]: xl.parse('Sheet1', index_col=0, parse_dates=True,
.....:           parse_cols='A:D')
.....:

```

Out [17]:

	A	B	C	D
2000-01-03	0.980269	3.685731	-0.364217	-1.159738
2000-01-04	1.047916	-0.041232	-0.161812	0.212549
2000-01-05	0.498581	0.731168	-0.537677	1.346270

2000-01-11	-0.157161	1.340307	1.195778	-1.097007

[7 rows x 4 columns]

- Added option to disable pandas-style tick locators and formatters using `series.plot(x_compat=True)` or `pandas.plot_params['x_compat'] = True` (GH2205)
- Existing TimeSeries methods `at_time` and `between_time` were added to DataFrame (GH2149)
- DataFrame.dot can now accept ndarrays (GH2042)
- DataFrame.drop now supports non-unique indexes (GH2101)
- Panel.shift now supports negative periods (GH2164)
- DataFrame now support unary `~` operator (GH2110)

API changes

- Upsampling data with a PeriodIndex will result in a higher frequency TimeSeries that spans the original time window

```

In [1]: prng = pd.period_range('2012Q1', periods=2, freq='Q')

```

```

In [2]: s = pd.Series(np.random.randn(len(prng)), prng)

```

```

In [4]: s.resample('M')

```

```

Out [4]:
2012-01    -1.471992
2012-02         NaN
2012-03         NaN

```

(continues on next page)

(continued from previous page)

```

2012-04    -0.493593
2012-05         NaN
2012-06         NaN
Freq: M, dtype: float64

```

- `Period.end_time` now returns the last nanosecond in the time interval ([GH2124](#), [GH2125](#), [GH1764](#))

```

In [18]: p = pd.Period('2012')

In [19]: p.end_time
Out[19]: Timestamp('2012-12-31 23:59:59.999999999')

```

- File parsers no longer coerce to float or bool for columns that have custom converters specified ([GH2184](#))

```

In [20]: import io

In [21]: data = ('A,B,C\n'
.....:          '00001,001,5\n'
.....:          '00002,002,6')
.....:

In [22]: pd.read_csv(io.StringIO(data), converters={'A': lambda x: x.strip()})
Out[22]:
   A  B  C
0  00001  1  5
1  00002  2  6

[2 rows x 3 columns]

```

```

8.17.2 v0.9.0 (October 7, 2012)

This is a major release from 0.8.1 and includes several new features and enhancements along with a large number of bug fixes. New features include vectorized unicode encoding/decoding for `Series.str`, `to_latex` method to `DataFrame`, more flexible parsing of boolean values, and enabling the download of options data from Yahoo! Finance.

New features

- Add `encode` and `decode` for unicode handling to *vectorized string processing methods* in `Series.str` (GH1706)
- Add `DataFrame.to_latex` method (GH1735)
- Add convenient expanding window equivalents of all `rolling_*` ops (GH1785)
- Add `Options` class to `pandas.io.data` for fetching options data from Yahoo! Finance (GH1748, GH1739)
- More flexible parsing of boolean values (Yes, No, TRUE, FALSE, etc) (GH1691, GH1295)
- Add `level` parameter to `Series.reset_index`
- `TimeSeries.between_time` can now select times across midnight (GH1871)
- `Series` constructor can now handle generator as input (GH1679)
- `DataFrame.dropna` can now take multiple axes (tuple/list) as input (GH924)
- Enable `skip_footer` parameter in `ExcelFile.parse` (GH1843)

API changes

- The default column names when `header=None` and no columns names passed to functions like `read_csv` has changed to be more Pythonic and amenable to attribute access:

```
In [1]: import io

In [2]: data = ('0,0,1\n'
...:          '1,1,0\n'
...:          '0,1,0')
...:

In [3]: df = pd.read_csv(io.StringIO(data), header=None)

In [4]: df
Out[4]:
   0  1  2
0  0  0  1
1  1  1  0
2  0  1  0

[3 rows x 3 columns]
```

- Creating a Series from another Series, passing an index, will cause reindexing to happen inside rather than treating the Series like an ndarray. Technically improper usages like `Series(df[col1], index=df[col2])` that worked before “by accident” (this was never intended) will lead to all NA Series in some cases. To be perfectly clear:

```
In [5]: s1 = pd.Series([1, 2, 3])

In [6]: s1
Out[6]:
0    1
1    2
2    3
Length: 3, dtype: int64

In [7]: s2 = pd.Series(s1, index=['foo', 'bar', 'baz'])

In [8]: s2
Out[8]:
foo    NaN
bar    NaN
baz    NaN
Length: 3, dtype: float64
```

- Deprecated `day_of_year` API removed from `PeriodIndex`, use `dayofyear` (GH1723)
- Don't modify NumPy `suppress_printoption` to `True` at import time
- The internal HDF5 data arrangement for DataFrames has been transposed. Legacy files will still be readable by `HDFStore` (GH1834, GH1824)
- Legacy cruft removed: `pandas.stats.misc.quantileTS`
- Use ISO8601 format for `Period` repr: `monthly`, `daily`, and `on down` (GH1776)
- Empty `DataFrame` columns are now created as `object` dtype. This will prevent a class of `TypeError`s that was occurring in code where the dtype of a column would depend on the presence of data or not (e.g. a SQL query having results) (GH1783)
- Setting parts of `DataFrame/Panel` using `ix` now aligns input `Series/DataFrame` (GH1630)
- `first` and `last` methods in `GroupBy` no longer drop non-numeric columns (GH1809)
- Resolved inconsistencies in specifying custom NA values in text parser. `na_values` of type `dict` no longer override default NAs unless `keep_default_na` is set to `false` explicitly (GH1657)
- `DataFrame.dot` will not do data alignment, and also work with `Series` (GH1915)

See the *full release notes* or issue tracker on GitHub for a complete list.

8.18 Version 0.8

8.18.1 v0.8.1 (July 22, 2012)

{{ header }}

This release includes a few new features, performance enhancements, and over 30 bug fixes from 0.8.0. New features include notably NA friendly string processing functionality and a series of new plot types and options.

New features

- Add *vectorized string processing methods* accessible via `Series.str` (GH620)
- Add option to disable adjustment in EWMA (GH1584)
- *Radviz plot* (GH1566)
- *Parallel coordinates plot*
- *Bootstrap plot*

- Per column styles and secondary y-axis plotting ([GH1559](#))
- New datetime converters millisecond plotting ([GH1599](#))
- Add option to disable “sparse” display of hierarchical indexes ([GH1538](#))
- Series/DataFrame’s `set_index` method can *append levels* to an existing Index/MultiIndex ([GH1569](#), [GH1577](#))

Performance improvements

- Improved implementation of rolling min and max (thanks to Bottleneck !)
- Add accelerated 'median' GroupBy option ([GH1358](#))
- Significantly improve the performance of parsing ISO8601-format date strings with `DatetimeIndex` or `to_datetime` ([GH1571](#))
- Improve the performance of GroupBy on single-key aggregations and use with Categorical types
- Significant datetime parsing performance improvements

Contributors

A total of 5 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

- Vytautas Jancauskas
- Wes McKinney

8.18.2 v0.8.0 (June 29, 2012)

{{ header }}

This is a major release from 0.7.3 and includes extensive work on the time series handling and processing infrastructure as well as a great deal of new functionality throughout the library. It includes over 700 commits from more than 20 distinct authors. Most pandas 0.7.3 and earlier users should not experience any issues upgrading, but due to the migration to the NumPy `datetime64` dtype, there may be a number of bugs and incompatibilities lurking. Lingering incompatibilities will be fixed ASAP in a 0.8.1 release if necessary. See the *full release notes* or issue tracker on GitHub for a complete list.

Support for non-unique indexes

All objects can now work with non-unique indexes. Data alignment / join operations work according to SQL join semantics (including, if application, index duplication in many-to-many joins)

NumPy datetime64 dtype and 1.6 dependency

Time series data are now represented using NumPy's datetime64 dtype; thus, pandas 0.8.0 now requires at least NumPy 1.6. It has been tested and verified to work with the development version (1.7+) of NumPy as well which includes some significant user-facing API changes. NumPy 1.6 also has a number of bugs having to do with nanosecond resolution data, so I recommend that you steer clear of NumPy 1.6's datetime64 API functions (though limited as they are) and only interact with this data using the interface that pandas provides.

See the end of the 0.8.0 section for a “porting” guide listing potential issues for users migrating legacy code bases from pandas 0.7 or earlier to 0.8.0.

Bug fixes to the 0.7.x series for legacy NumPy < 1.6 users will be provided as they arise. There will be no more further development in 0.7.x beyond bug fixes.

Time series changes and improvements

Note: With this release, legacy scikits.timeseries users should be able to port their code to use pandas.

Note: See [documentation](#) for overview of pandas timeseries API.

- New datetime64 representation **speeds up join operations and data alignment, reduces memory usage**, and improve serialization / deserialization performance significantly over datetime.datetime
- High performance and flexible **resample** method for converting from high-to-low and low-to-high frequency. Supports interpolation, user-defined aggregation functions, and control over how the intervals and result labeling are defined. A suite of high performance Cython/C-based resampling functions (including Open-High-Low-Close) have also been implemented.
- Revamp of *frequency aliases* and support for **frequency shortcuts** like ‘15min’, or ‘1h30min’
- New *DatetimeIndex class* supports both fixed frequency and irregular time series. Replaces now deprecated DateRange class
- New *PeriodIndex* and *Period* classes for representing *time spans* and performing **calendar logic**, including the *12 fiscal quarterly frequencies* `<timeseries.quarterly>`. This is a partial port of, and a substantial enhancement to, elements of the scikits.timeseries code base. Support for conversion between PeriodIndex and DatetimeIndex
- New Timestamp data type subclasses *datetime.datetime*, providing the same interface while enabling working with nanosecond-resolution data. Also provides *easy time zone conversions*.
- Enhanced support for *time zones*. Add *tz_convert* and *tz_localize* methods to TimeSeries and DataFrame. All timestamps are stored as UTC; Timestamps from DatetimeIndex objects with time zone set will be localized to local time. Time zone conversions are therefore essentially free. User needs to know very little about pytz library now; only time zone names as strings are required. Time zone-aware timestamps are equal if and only if their UTC timestamps match. Operations between time zone-aware time series with different time zones will result in a UTC-indexed time series.
- Time series **string indexing conveniences** / shortcuts: slice years, year and month, and index values with strings
- Enhanced time series **plotting**; adaptation of scikits.timeseries matplotlib-based plotting code
- New *date_range*, *bdate_range*, and *period_range factory functions*

- Robust **frequency inference** function `infer_freq` and `inferred_freq` property of `DatetimeIndex`, with option to infer frequency on construction of `DatetimeIndex`
- `to_datetime` function efficiently **parses array of strings** to `DatetimeIndex`. `DatetimeIndex` will parse array or list of strings to `datetime64`
- **Optimized** support for `datetime64`-dtype data in `Series` and `DataFrame` columns
- New `NaT` (Not-a-Time) type to represent **NA** in timestamp arrays
- Optimize `Series.asof` for looking up “**as of**” values for arrays of timestamps
- Milli, Micro, Nano date offset objects
- Can index time series with `datetime.time` objects to select all data at particular **time of day** (`TimeSeries.at_time`) or **between two times** (`TimeSeries.between_time`)
- Add `tshift` method for leading/lagging using the frequency (if any) of the index, as opposed to a naive lead/lag using `shift`

Other new features

- New `cut` and `qcut` functions (like R’s `cut` function) for computing a categorical variable from a continuous variable by binning values either into value-based (`cut`) or quantile-based (`qcut`) bins
- Rename `Factor` to `Categorical` and add a number of usability features
- Add `limit` argument to `fillna/reindex`
- More flexible multiple function application in `GroupBy`, and can pass list (name, function) tuples to get result in particular order with given names
- Add flexible `replace` method for efficiently substituting values
- Enhanced `read_csv/read_table` for reading time series data and converting multiple columns to dates
- Add `comments` option to parser functions: `read_csv`, etc.
- Add `dayfirst` option to parser functions for parsing international DD/MM/YYYY dates
- Allow the user to specify the CSV reader `dialect` to control quoting etc.
- Handling `thousands` separators in `read_csv` to improve integer parsing.
- Enable unstacking of multiple levels in one shot. Alleviate `pivot_table` bugs (empty columns being introduced)
- Move to `klib`-based hash tables for indexing; better performance and less memory usage than Python’s `dict`
- Add `first`, `last`, `min`, `max`, and `prod` optimized `GroupBy` functions
- New `ordered_merge` function
- Add flexible `comparison` instance methods `eq`, `ne`, `lt`, `gt`, etc. to `DataFrame`, `Series`
- Improve `scatter_matrix` plotting function and add histogram or kernel density estimates to diagonal
- Add `'kde'` plot option for density plots
- Support for converting `DataFrame` to R `data.frame` through `rpy2`
- Improved support for complex numbers in `Series` and `DataFrame`
- Add `pct_change` method to all data structures
- Add `max_colwidth` configuration option for `DataFrame` console output

- *Interpolate* Series values using index values
- Can select multiple columns from GroupBy
- Add *update* methods to Series/DataFrame for updating values in place
- Add *any* and *all* method to DataFrame

New plotting methods

Series.plot now supports a `secondary_y` option:

```
In [1]: plt.figure()
```

```
Out[1]: <Figure size 640x480 with 0 Axes>
```

```
In [2]: fx['FR'].plot(style='g')
```

```
Out[2]: <matplotlib.axes._subplots.AxesSubplot at 0x1481cb790>
```

```
In [3]: fx['IT'].plot(style='k--', secondary_y=True)
```

```
Out[3]: <matplotlib.axes._subplots.AxesSubplot at 0x1493cfe10>
```

Vytautas Jancauskas, the 2012 GSOC participant, has added many new plot types. For example, 'kde' is a new option:

```
In [4]: s = pd.Series(np.concatenate((np.random.randn(1000),
...:                                 np.random.randn(1000) * 0.5 + 3)))
...:
```

```
In [5]: plt.figure()
```

```
Out[5]: <Figure size 640x480 with 0 Axes>
```

```
In [6]: s.hist(density=True, alpha=0.2)
```

```
Out[6]: <matplotlib.axes._subplots.AxesSubplot at 0x1464cbe50>
```

```
In [7]: s.plot(kind='kde')
```

```
Out[7]: <matplotlib.axes._subplots.AxesSubplot at 0x1464cbe50>
```

See [the plotting page](#) for much more.

Other API changes

- Deprecation of `offset`, `time_rule`, and `timeRule` arguments names in time series functions. Warnings will be printed until pandas 0.9 or 1.0.

Potential porting issues for pandas <= 0.7.3 users

The major change that may affect you in pandas 0.8.0 is that time series indexes use NumPy's `datetime64` data type instead of `dtype=object` arrays of Python's built-in `datetime.datetime` objects. `DateRange` has been replaced by `DatetimeIndex` but otherwise behaved identically. But, if you have code that converts `DateRange` or `Index` objects that used to contain `datetime.datetime` values to plain NumPy arrays, you may have bugs lurking with code using scalar values because you are handing control over to NumPy:

```
In [8]: import datetime
```

```
In [9]: rng = pd.date_range('1/1/2000', periods=10)
```

```
In [10]: rng[5]
Out[10]: Timestamp('2000-01-06 00:00:00', freq='D')
```

```
In [11]: isinstance(rng[5], datetime.datetime)
Out[11]: True
```

```
In [12]: rng_asarray = np.asarray(rng)
```

```
In [13]: scalar_val = rng_asarray[5]
```

```
In [14]: type(scalar_val)
Out[14]: numpy.datetime64
```

pandas's `Timestamp` object is a subclass of `datetime.datetime` that has nanosecond support (the `nanosecond` field store the nanosecond value between 0 and 999). It should substitute directly into any code that used `datetime.datetime` values before. Thus, I recommend not casting `DatetimeIndex` to regular NumPy arrays.

If you have code that requires an array of `datetime.datetime` objects, you have a couple of options. First, the `astype(object)` method of `DatetimeIndex` produces an array of `Timestamp` objects:

```
In [15]: stamp_array = rng.astype(object)
```

```
In [16]: stamp_array
Out[16]:
Index([2000-01-01 00:00:00, 2000-01-02 00:00:00, 2000-01-03 00:00:00,
       2000-01-04 00:00:00, 2000-01-05 00:00:00, 2000-01-06 00:00:00,
       2000-01-07 00:00:00, 2000-01-08 00:00:00, 2000-01-09 00:00:00,
       2000-01-10 00:00:00],
      dtype='object')
```

```
In [17]: stamp_array[5]
Out[17]: Timestamp('2000-01-06 00:00:00', freq='D')
```

To get an array of proper `datetime.datetime` objects, use the `to_pydatetime` method:

```
In [18]: dt_array = rng.to_pydatetime()
```

```
In [19]: dt_array
Out[19]:
array([datetime.datetime(2000, 1, 1, 0, 0),
       datetime.datetime(2000, 1, 2, 0, 0),
       datetime.datetime(2000, 1, 3, 0, 0),
       datetime.datetime(2000, 1, 4, 0, 0),
       datetime.datetime(2000, 1, 5, 0, 0),
       datetime.datetime(2000, 1, 6, 0, 0),
       datetime.datetime(2000, 1, 7, 0, 0),
       datetime.datetime(2000, 1, 8, 0, 0),
       datetime.datetime(2000, 1, 9, 0, 0),
       datetime.datetime(2000, 1, 10, 0, 0)], dtype=object)
```

```
In [20]: dt_array[5]
Out[20]: datetime.datetime(2000, 1, 6, 0, 0)
```

matplotlib knows how to handle `datetime.datetime` but not `Timestamp` objects. While I recommend that you plot time series using `TimeSeries.plot`, you can either use `to_pydatetime` or register a converter for the `Timestamp` type. See [matplotlib documentation](#) for more on this.

Warning: There are bugs in the user-facing API with the nanosecond `datetime64` unit in NumPy 1.6. In particular, the string version of the array shows garbage values, and conversion to `dtype=object` is similarly broken.

```
In [21]: rng = pd.date_range('1/1/2000', periods=10)
```

```
In [22]: rng
```

```
Out[22]:
```

```
DatetimeIndex(['2000-01-01', '2000-01-02', '2000-01-03', '2000-01-04',
               '2000-01-05', '2000-01-06', '2000-01-07', '2000-01-08',
               '2000-01-09', '2000-01-10'],
              dtype='datetime64[ns]', freq='D')
```

```
In [23]: np.asarray(rng)
```

```
Out[23]:
```

```
array(['2000-01-01T00:00:00.000000000', '2000-01-02T00:00:00.000000000',
       '2000-01-03T00:00:00.000000000', '2000-01-04T00:00:00.000000000',
       '2000-01-05T00:00:00.000000000', '2000-01-06T00:00:00.000000000',
       '2000-01-07T00:00:00.000000000', '2000-01-08T00:00:00.000000000',
       '2000-01-09T00:00:00.000000000', '2000-01-10T00:00:00.000000000'],
      dtype='datetime64[ns]')
```

```
In [24]: converted = np.asarray(rng, dtype=object)
```

```
In [25]: converted[5]
```

```
Out[25]: Timestamp('2000-01-06 00:00:00', freq='D')
```

Trust me: don't panic. If you are using NumPy 1.6 and restrict your interaction with `datetime64` values to pandas's API you will be just fine. There is nothing wrong with the data-type (a 64-bit integer internally); all of the important data processing happens in pandas and is heavily tested. I strongly recommend that you **do not work directly with `datetime64` arrays in NumPy 1.6** and only use the pandas API.

Support for non-unique indexes: In the latter case, you may have code inside a `try:... catch:` block that failed due to the index not being unique. In many cases it will no longer fail (some method like `append` still check for uniqueness unless disabled). However, all is not lost: you can inspect `index.is_unique` and raise an exception explicitly if it is `False` or go to a different code branch.

8.19 Version 0.7

8.19.1 v.0.7.3 (April 12, 2012)

{{ header }}

This is a minor release from 0.7.2 and fixes many minor bugs and adds a number of nice new features. There are also a couple of API changes to note; these should not affect very many users, and we are inclined to call them “bug fixes” even though they do constitute a change in behavior. See the *full release notes* or issue tracker on GitHub for a complete list.

New features

- New *fixed width file reader*, `read_fwf`
- New *scatter_matrix* function for making a scatter plot matrix

```
from pandas.tools.plotting import scatter_matrix
scatter_matrix(df, alpha=0.2)          # noqa F821
```

- Add `stacked` argument to `Series` and `DataFrame`'s `plot` method for *stacked bar plots*.

```
df.plot(kind='bar', stacked=True) # noqa F821
```

```
df.plot(kind='barh', stacked=True) # noqa F821
```

- Add log x and y *scaling options* to `DataFrame.plot` and `Series.plot`
- Add kurt methods to `Series` and `DataFrame` for computing kurtosis

NA Boolean comparison API change

Reverted some changes to how NA values (represented typically as `NaN` or `None`) are handled in non-numeric Series:

```
In [1]: series = pd.Series(['Steve', np.nan, 'Joe'])
```

```
In [2]: series == 'Steve'
```

```
Out[2]:
```

```
0    True
```

```
1    False
```

```
2    False
```

```
Length: 3, dtype: bool
```

```
In [3]: series != 'Steve'
```

```
Out[3]:
```

```
0    False
```

```
1     True
```

```
2     True
```

```
Length: 3, dtype: bool
```

In comparisons, NA / NaN will always come through as `False` except with `!=` which is `True`. *Be very careful* with boolean arithmetic, especially negation, in the presence of NA data. You may wish to add an explicit NA filter into boolean array operations if you are worried about this:

```
In [4]: mask = series == 'Steve'
```

```
In [5]: series[mask & series.notnull()]
```

```
Out[5]:
```

(continues on next page)

(continued from previous page)

```
0    Steve
Length: 1, dtype: object
```

While propagating NA in comparisons may seem like the right behavior to some users (and you could argue on purely technical grounds that this is the right thing to do), the evaluation was made that propagating NA everywhere, including in numerical arrays, would cause a large amount of problems for users. Thus, a “practicality beats purity” approach was taken. This issue may be revisited at some point in the future.

Other API changes

When calling `apply` on a grouped Series, the return value will also be a Series, to be more consistent with the `groupby` behavior with DataFrame:

```
In [6]: df = pd.DataFrame({'A': ['foo', 'bar', 'foo', 'bar',
...:                            'foo', 'bar', 'foo', 'foo'],
...:                      'B': ['one', 'one', 'two', 'three',
...:                            'two', 'two', 'one', 'three'],
...:                      'C': np.random.randn(8), 'D': np.random.randn(8)})
...:
```

```
In [7]: df
```

```
Out[7]:
```

	A	B	C	D
0	foo	one	0.669989	-0.368946
1	bar	one	-0.138094	-0.073951
2	foo	two	0.058206	-0.799669
3	bar	three	-0.780498	0.124687
4	foo	two	0.337542	-1.289728
5	bar	two	-0.166920	1.292333
6	foo	one	0.105766	-1.292147
7	foo	three	0.044486	1.322568

```
[8 rows x 4 columns]
```

```
In [8]: grouped = df.groupby('A')['C']
```

```
In [9]: grouped.describe()
```

```
Out[9]:
```

	count	mean	std	min	25%	50%	75%	max
A								
bar	3.0	-0.361837	0.362857	-0.780498	-0.473709	-0.166920	-0.152507	-0.138094
foo	5.0	0.243198	0.266293	0.044486	0.058206	0.105766	0.337542	0.669989

```
[2 rows x 8 columns]
```

```
In [10]: grouped.apply(lambda x: x.sort_values()[-2:]) # top 2 values
```

```
Out[10]:
```

A		
bar	5	-0.166920
	1	-0.138094
foo	4	0.337542
	0	0.669989

Name: C, Length: 4, dtype: float64

8.19.2 v.0.7.2 (March 16, 2012)

{{ header }}

This release targets bugs in 0.7.1, and adds a few minor features.

New features

- Add additional tie-breaking methods in `DataFrame.rank` (GH874)
- Add ascending parameter to rank in `Series`, `DataFrame` (GH875)
- Add `coerce_float` option to `DataFrame.from_records` (GH893)
- Add `sort_columns` parameter to allow unsorted plots (GH918)
- Enable column access via attributes on `GroupBy` (GH882)
- Can pass dict of values to `DataFrame.fillna` (GH661)
- Can select multiple hierarchical groups by passing list of values in `.ix` (GH134)
- Add `axis` option to `DataFrame.fillna` (GH174)
- Add `level` keyword to `drop` for dropping values from a level (GH159)

Performance improvements

- Use khash for Series.value_counts, add raw function to algorithms.py (GH861)
- Intercept `__builtin__.sum` in groupby (GH885)

Contributors

A total of 12 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

8.19.3 v.0.7.1 (February 29, 2012)

{{ header }}

This release includes a few new features and addresses over a dozen bugs in 0.7.0.

New features

- Add `to_clipboard` function to pandas namespace for writing objects to the system clipboard (GH774)
- Add `itertuples` method to DataFrame for iterating through the rows of a dataframe as tuples (GH818)
- Add ability to pass `fill_value` and `method` to DataFrame and Series `align` method (GH806, GH807)
- Add `fill_value` option to `reindex`, `align` methods (GH784)
- Enable `concat` to produce DataFrame from Series (GH787)
- Add `between` method to Series (GH802)
- Add HTML representation hook to DataFrame for the IPython HTML notebook (GH773)
- Support for reading Excel 2007 XML documents using `openpyxl`

Performance improvements

- Improve performance and memory usage of fillna on DataFrame
- Can concatenate a list of Series along axis=1 to obtain a DataFrame (GH787)

Contributors

8.19.4 v.0.7.0 (February 9, 2012)

{{ header }}

New features

- New unified *merge function* for efficiently performing full gamut of database / relational-algebra operations. Refactored existing join methods to use the new infrastructure, resulting in substantial performance gains (GH220, GH249, GH267)
- New *unified concatenation function* for concatenating Series, DataFrame or Panel objects along an axis. Can form union or intersection of the other axes. Improves performance of `Series.append` and `DataFrame.append` (GH468, GH479, GH273)
- *Can* pass multiple DataFrames to `DataFrame.append` to concatenate (stack) and multiple Series to `Series.append` too
- *Can* pass list of dicts (e.g., a list of JSON objects) to DataFrame constructor (GH526)
- You can now *set multiple columns* in a DataFrame via `__getitem__`, useful for transformation (GH342)
- Handle differently-indexed output values in `DataFrame.apply` (GH498)

```
In [1]: df = pd.DataFrame(np.random.randn(10, 4))
```

```
In [2]: df.apply(lambda x: x.describe())
```

```
Out[2]:
```

```
          0          1          2          3
count  10.000000  10.000000  10.000000  10.000000
```

(continues on next page)

[8 rows x 4 columns]

- *Add* `reorder_levels` method to Series and DataFrame (GH534)
- *Add* dict-like `get` function to DataFrame and Panel (GH521)
- *Add* `DataFrame.iterrows` method for efficiently iterating through the rows of a DataFrame
- Add `DataFrame.to_panel` with code adapted from `LongPanel.to_long`
- *Add* `reindex_axis` method added to DataFrame
- *Add* `level` option to binary arithmetic functions on DataFrame and Series
- *Add* `level` option to the `reindex` and `align` methods on Series and DataFrame for broadcasting values across a level (GH542, GH552, others)
- Add attribute-based item access to Panel and add IPython completion (GH563)
- *Add* `logy` option to `Series.plot` for log-scaling on the Y axis
- *Add* `index` and `header` options to `DataFrame.to_string`
- *Can* pass multiple DataFrames to `DataFrame.join` to join on index (GH115)
- *Can* pass multiple Panels to `Panel.join` (GH115)
- *Added* `justify` argument to `DataFrame.to_string` to allow different alignment of column headers
- *Add* `sort` option to `GroupBy` to allow disabling sorting of the group keys for potential speedups (GH595)
- *Can* pass `MaskedArray` to Series constructor (GH563)
- Add Panel item access via attributes and IPython completion (GH554)
- Implement `DataFrame.lookup`, fancy-indexing analogue for retrieving values given a sequence of row and column labels (GH338)
- *Can* pass a *list of functions* to aggregate with `groupby` on a DataFrame, yielding an aggregated result with hierarchical columns (GH166)
- *Can* call `cummin` and `cummax` on Series and DataFrame to get cumulative minimum and maximum, respectively (GH647)
- `value_range` added as utility function to get min and max of a dataframe (GH288)
- *Added* `encoding` argument to `read_csv`, `read_table`, `to_csv` and `from_csv` for non-ascii text (GH717)
- *Added* `abs` method to pandas objects
- *Added* `crosstab` function for easily computing frequency tables
- *Added* `isin` method to index objects
- *Added* `level` argument to `xs` method of DataFrame.

API changes to integer indexing

One of the potentially riskiest API changes in 0.7.0, but also one of the most important, was a complete review of how **integer indexes** are handled with regard to label-based indexing. Here is an example:

```
In [3]: s = pd.Series(np.random.randn(10), index=range(0, 20, 2))
```

```
In [4]: s
```

```
Out[4]:
```

```
0    0.241988
2   -0.140924
4   -0.653255
6    1.735856
8    0.493223
10   0.699761
12  -0.490215
14   0.296281
16   0.574774
18  -0.505160
```

```
Length: 10, dtype: float64
```

```
In [5]: s[0]
```

```
Out[5]: 0.2419875382715906
```

```
In [6]: s[2]
```

```
Out[6]: -0.14092373781454884
```

```
In [7]: s[4]
```

```
Out[7]: -0.6532545931074317
```

This is all exactly identical to the behavior before. However, if you ask for a key **not** contained in the Series, in versions 0.6.1 and prior, Series would *fall back* on a location-based lookup. This now raises a `KeyError`:

```
In [2]: s[1]
```

```
KeyError: 1
```

This change also has the same impact on DataFrame:

```
In [3]: df = pd.DataFrame(np.random.randn(8, 4), index=range(0, 16, 2))
```

```
In [4]: df
```

```
   0         1         2         3
0  0.88427  0.3363 -0.1787  0.03162
2  0.14451 -0.1415  0.2504  0.58374
4 -1.44779 -0.9186 -1.4996  0.27163
6 -0.26598 -2.4184 -0.2658  0.11503
8 -0.58776  0.3144 -0.8566  0.61941
10  0.10940 -0.7175 -1.0108  0.47990
12 -1.16919 -0.3087 -0.6049 -0.43544
14 -0.07337  0.3410  0.0424 -0.16037
```

```
In [5]: df.ix[3]
```

```
KeyError: 3
```

In order to support purely integer-based indexing, the following methods have been added:

Method	Description
<code>Series.iget_value(i)</code>	Retrieve value stored at location <code>i</code>
<code>Series.iget(i)</code>	Alias for <code>iget_value</code>
<code>DataFrame.irow(i)</code>	Retrieve the <code>i</code> -th row
<code>DataFrame.icol(j)</code>	Retrieve the <code>j</code> -th column
<code>DataFrame.iget_value(i, j)</code>	Retrieve the value at row <code>i</code> and column <code>j</code>

API tweaks regarding label-based slicing

Label-based slicing using `ix` now requires that the index be sorted (monotonic) **unless** both the start and endpoint are contained in the index:

```
In [1]: s = pd.Series(np.random.randn(6), index=list('gmkaec'))

In [2]: s
Out[2]:
g    -1.182230
m    -0.276183
k    -0.243550
a     1.628992
e     0.073308
c    -0.539890
dtype: float64
```

Then this is OK:

```
In [3]: s.ix['k':'e']
Out[3]:
k    -0.243550
a     1.628992
e     0.073308
dtype: float64
```

But this is not:

```
In [12]: s.ix['b':'h']
KeyError 'b'
```

If the index had been sorted, the “range selection” would have been possible:

```
In [4]: s2 = s.sort_index()

In [5]: s2
Out[5]:
a     1.628992
c    -0.539890
e     0.073308
g    -1.182230
k    -0.243550
m    -0.276183
dtype: float64
```

(continues on next page)

(continued from previous page)

```
In [6]: s2.ix['b':'h']
Out[6]:
c    -0.539890
e     0.073308
g    -1.182230
dtype: float64
```

Changes to Series [] operator

As a notational convenience, you can pass a sequence of labels or a label slice to a Series when getting and setting values via [] (i.e. the `__getitem__` and `__setitem__` methods). The behavior will be the same as passing similar input to `ix` **except in the case of integer indexing**:

```
In [8]: s = pd.Series(np.random.randn(6), index=list('acegkm'))
```

```
In [9]: s
Out[9]:
a    0.702548
c   -0.554585
e    0.728336
g   -1.243858
k   -1.107822
m   -0.426698
Length: 6, dtype: float64
```

```
In [10]: s[['m', 'a', 'c', 'e']]
Out[10]:
m   -0.426698
a    0.702548
c   -0.554585
e    0.728336
Length: 4, dtype: float64
```

```
In [11]: s['b':'l']
Out[11]:
c   -0.554585
e    0.728336
g   -1.243858
k   -1.107822
Length: 4, dtype: float64
```

```
In [12]: s['c':'k']
Out[12]:
c   -0.554585
e    0.728336
g   -1.243858
k   -1.107822
Length: 4, dtype: float64
```

In the case of integer indexes, the behavior will be exactly as before (shadowing `ndarray`):

```
In [13]: s = pd.Series(np.random.randn(6), index=range(0, 12, 2))
```

```
In [14]: s[[4, 0, 2]]
Out[14]:
4    -1.234677
0    -2.755651
2    -1.148347
Length: 3, dtype: float64
```

```
In [15]: s[1:5]
Out[15]:
2    -1.148347
4    -1.234677
6    -0.589450
8    -1.313248
Length: 4, dtype: float64
```

If you wish to do indexing with sequences and slicing on an integer index with label semantics, use `ix`.

Other API changes

- The deprecated `LongPanel` class has been completely removed
- If `Series.sort` is called on a column of a `DataFrame`, an exception will now be raised. Before it was possible to accidentally mutate a `DataFrame`'s column by doing `df[col].sort()` instead of the side-effect free method `df[col].order()` ([GH316](#))
- Miscellaneous renames and deprecations which will (harmlessly) raise `FutureWarning`
- `drop` added as an optional parameter to `DataFrame.reset_index` ([GH699](#))

Performance improvements

- *Cythonized GroupBy aggregations* no longer presort the data, thus achieving a significant speedup ([GH93](#)). `GroupBy` aggregations with Python functions significantly sped up by clever manipulation of the `ndarray` data type in Cython ([GH496](#)).
- Better error message in `DataFrame` constructor when passed column labels don't match data ([GH497](#))
- Substantially improve performance of multi-`GroupBy` aggregation when a Python function is passed, reuse `ndarray` object in Cython ([GH496](#))
- Can store objects indexed by tuples and floats in `HDFStore` ([GH492](#))
- Don't print length by default in `Series.to_string`, add *length* option ([GH489](#))
- Improve Cython code for multi-groupby to aggregate without having to sort the data ([GH93](#))
- Improve `MultiIndex` reindexing speed by storing tuples in the `MultiIndex`, test for backwards unpickling compatibility
- Improve column reindexing performance by using specialized Cython take function
- Further performance tweaking of `Series.__getitem__` for standard use cases
- Avoid `Index` dict creation in some cases (i.e. when getting slices, etc.), regression from prior versions
- Friendlier error message in `setup.py` if `NumPy` not installed
- Use common set of NA-handling operations (sum, mean, etc.) in `Panel` class also ([GH536](#))
- Default name assignment when calling `reset_index` on `DataFrame` with a regular (non-hierarchical) index ([GH476](#))

- Use Cythonized groupers when possible in Series/DataFrame stat ops with `level` parameter passed (GH545)
- Ported skiplist data structure to C to speed up `rolling_median` by about 5-10x in most typical use cases (GH374)

8.20 Version 0.6

8.20.1 v.0.6.1 (December 13, 2011)

New features

- Can *append single rows* (as Series) to a DataFrame
- Add Spearman and Kendall rank *correlation* options to `Series.corr` and `DataFrame.corr` (GH428)
- *Added* `get_value` and `set_value` methods to Series, DataFrame, and Panel for very low-overhead access (>2x faster in many cases) to scalar elements (GH437, GH438). `set_value` is capable of producing an enlarged object.
- Add PyQt table widget to sandbox (GH435)

- `DataFrame.align` can *accept Series arguments* and an *axis option* (GH461)
- Implement new *SparseArray* and *SparseList* data structures. `SparseSeries` now derives from `SparseArray` (GH463)
- *Better console printing options* (GH453)
- Implement fast *data ranking* for `Series` and `DataFrame`, fast versions of `scipy.stats.rankdata` (GH428)
- Implement `DataFrame.from_items` alternate constructor (GH444)
- `DataFrame.convert_objects` method for *inferring better dtypes* for object columns (GH302)
- Add `rolling_corr_pairwise` function for computing Panel of correlation matrices (GH189)
- Add `margins` option to `pivot_table` for computing subgroup aggregates (GH114)
- Add `Series.from_csv` function (GH482)
- *Can pass DataFrame/DataFrame and DataFrame/Series to rolling_corr/rolling_cov* (GH #462)
- `MultiIndex.get_level_values` can *accept the level name*

Performance improvements

- Improve memory usage of `DataFrame.describe` (do not copy data unnecessarily) (PR #425)
- Optimize scalar value lookups in the general case by 25% or more in `Series` and `DataFrame`
- Fix performance regression in cross-sectional count in `DataFrame`, affecting `DataFrame.dropna` speed
- Column deletion in `DataFrame` copies no data (computes views on blocks) (GH #158)

Contributors

A total of 7 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

- Dieter Vandenbussche
- Fernando Perez +
- Jev Kuznetsov +
- Joon Ro
- Ralph Bean +
- Wes McKinney
- Wouter Overmeire

8.20.2 v.0.6.0 (November 25, 2011)

{{ header }}

New features

- *Added* melt function to `pandas.core.reshape`
- *Added* level parameter to group by level in Series and DataFrame descriptive statistics (GH313)
- *Added* head and tail methods to Series, analogous to DataFrame (GH296)
- *Added* Series.isin function which checks if each value is contained in a passed sequence (GH289)
- *Added* float_format option to Series.to_string
- *Added* skip_footer (GH291) and converters (GH343) options to read_csv and read_table
- *Added* drop_duplicates and duplicated functions for removing duplicate DataFrame rows and checking for duplicate rows, respectively (GH319)
- *Implemented* operators '&', '|', '^', '-' on DataFrame (GH347)
- *Added* Series.mad, mean absolute deviation
- *Added* QuarterEnd DateOffset (GH321)
- *Added* dot to DataFrame (GH65)
- *Added* orient option to Panel.from_dict (GH359, GH301)
- *Added* orient option to DataFrame.from_dict
- *Added* passing list of tuples or list of lists to DataFrame.from_records (GH357)
- *Added* multiple levels to groupby (GH103)
- *Allow* multiple columns in by argument of DataFrame.sort_index (GH92, GH362)
- *Added* fast get_value and put_value methods to DataFrame (GH360)
- *Added* cov instance methods to Series and DataFrame (GH194, GH362)
- *Added* kind='bar' option to DataFrame.plot (GH348)
- *Added* idxmin and idxmax to Series and DataFrame (GH286)
- *Added* read_clipboard function to parse DataFrame from clipboard (GH300)
- *Added* nunique function to Series for counting unique elements (GH297)
- *Made* DataFrame constructor use Series name if no columns passed (GH373)
- *Support* regular expressions in read_table/read_csv (GH364)
- *Added* DataFrame.to_html for writing DataFrame to HTML (GH387)
- *Added* support for MaskedArray data in DataFrame, masked values converted to NaN (GH396)
- *Added* DataFrame.boxplot function (GH368)
- *Can* pass extra args, kwds to DataFrame.apply (GH376)
- *Implement* DataFrame.join with vector on argument (GH312)
- *Added* legend boolean flag to DataFrame.plot (GH324)
- *Can* pass multiple levels to stack and unstack (GH370)
- *Can* pass multiple values columns to pivot_table (GH381)
- *Use* Series name in GroupBy for result index (GH363)
- *Added* raw option to DataFrame.apply for performance if only need ndarray (GH309)

- Added proper, tested weighted least squares to standard and panel OLS (GH303)

Performance enhancements

- VBENCH Cythonized `cache_readonly`, resulting in substantial micro-performance enhancements throughout the code base (GH361)
- VBENCH Special Cython matrix iterator for applying arbitrary reduction operations with 3-5x better performance than `np.apply_along_axis` (GH309)
- VBENCH Improved performance of `MultiIndex.from_tuples`
- VBENCH Special Cython matrix iterator for applying arbitrary reduction operations
- VBENCH + DOCUMENT Add `raw` option to `DataFrame.apply` for getting better performance when
- VBENCH Faster cythonized count by level in Series and DataFrame (GH341)
- VBENCH? Significant GroupBy performance enhancement with multiple keys with many “empty” combinations
- VBENCH New Cython vectorized function `map_infer` speeds up `Series.apply` and `Series.map` significantly when passed elementwise Python function, motivated by (GH355)
- VBENCH Significantly improved performance of `Series.order`, which also makes `np.unique` called on a Series faster (GH327)
- VBENCH Vastly improved performance of GroupBy on axes with a MultiIndex (GH299)

Contributors

8.21 Version 0.5

8.21.1 v.0.5.0 (October 24, 2011)

{{ header }}

New features

- *Added* `DataFrame.align` method with standard join options
- *Added* `parse_dates` option to `read_csv` and `read_table` methods to optionally try to parse dates in the index columns
- *Added* `nrows`, `chunks`, and `iterator` arguments to `read_csv` and `read_table`. The last two return a new `TextParser` class capable of lazily iterating through chunks of a flat file (GH242)
- *Added* ability to join on multiple columns in `DataFrame.join` (GH214)
- Added private `_get_duplicates` function to `Index` for identifying duplicate values more easily (ENH5c)
- *Added* column attribute access to `DataFrame`.
- *Added* Python tab completion hook for `DataFrame` columns. (GH233, GH230)
- *Implemented* `Series.describe` for `Series` containing objects (GH241)
- *Added* inner join option to `DataFrame.join` when joining on key(s) (GH248)
- *Implemented* selecting `DataFrame` columns by passing a list to `__getitem__` (GH253)
- *Implemented* `&` and `|` to intersect / union `Index` objects, respectively (GH261)
- *Added* `pivot_table` convenience function to pandas namespace (GH234)
- *Implemented* `Panel.rename_axis` function (GH243)
- `DataFrame` will show index level names in console output (GH334)
- *Implemented* `Panel.take`
- *Added* `set_eng_float_format` for alternate `DataFrame` floating point string formatting (ENH61)
- *Added* convenience `set_index` function for creating a `DataFrame` index from its existing columns
- *Implemented* `groupby` hierarchical index level name (GH223)
- *Added* support for different delimiters in `DataFrame.to_csv` (GH244)
- TODO: DOCS ABOUT TAKE METHODS

Performance enhancements

- VBENCH Major performance improvements in file parsing functions `read_csv` and `read_table`
- VBENCH Added Cython function for converting tuples to ndarray very fast. Speeds up many `MultiIndex`-related operations
- VBENCH Refactored merging / joining code into a tidy class and disabled unnecessary computations in the float/object case, thus getting about 10% better performance (GH211)
- VBENCH Improved speed of `DataFrame.xs` on mixed-type `DataFrame` objects by about 5x, regression from 0.3.0 (GH215)
- VBENCH With new `DataFrame.align` method, speeding up binary operations between differently-indexed `DataFrame` objects by 10-25%.
- VBENCH Significantly sped up conversion of nested dict into `DataFrame` (GH212)
- VBENCH Significantly speed up `DataFrame.__repr__` and `count` on large mixed-type `DataFrame` objects

Contributors

8.22 Version 0.4

8.22.1 v.0.4.1 through v0.4.3 (September 25 - October 9, 2011)

{{ header }}

New features

- Added Python 3 support using 2to3 (GH200)
- *Added* name attribute to Series, now prints as part of Series.__repr__
- *Added* instance methods isnull and notnull to Series (GH209, GH203)
- *Added* Series.align method for aligning two series with choice of join method (ENH56)
- *Added* method get_level_values to MultiIndex (GH188)
- Set values in mixed-type DataFrame objects via .ix indexing attribute (GH135)
- Added new DataFrame *methods* get_dtype_counts and property dtypes (ENHdc)
- Added *ignore_index* option to DataFrame.append to stack DataFrames (ENH1b)
- read_csv tries to *sniff* delimiters using csv.Sniffer (GH146)
- read_csv can *read* multiple columns into a MultiIndex; DataFrame’s to_csv method writes out a corresponding MultiIndex (GH151)
- DataFrame.rename has a new copy parameter to *rename* a DataFrame in place (ENHed)
- *Enable* unstacking by name (GH142)
- *Enable* sortlevel to work by level (GH141)

Performance enhancements

- Altered binary operations on differently-indexed SparseSeries objects to use the integer-based (dense) alignment logic which is faster with a larger number of blocks ([GH205](#))
- Wrote faster Cython data alignment / merging routines resulting in substantial speed increases
- Improved performance of `isnull` and `notnull`, a regression from v0.3.0 ([GH187](#))
- Refactored code related to `DataFrame.join` so that intermediate aligned copies of the data in each `DataFrame` argument do not need to be created. Substantial performance increases result ([GH176](#))
- Substantially improved performance of generic `Index.intersection` and `Index.union`
- Implemented `BlockManager.take` resulting in significantly faster `take` performance on mixed-type `DataFrame` objects ([GH104](#))
- Improved performance of `Series.sort_index`
- Significant groupby performance enhancement: removed unnecessary integrity checks in `DataFrame` internals that were slowing down slicing operations to retrieve groups
- Optimized `_ensure_index` function resulting in performance savings in type-checking `Index` objects
- Wrote fast time series merging / joining methods in Cython. Will be integrated later into `DataFrame.join` and related functions
