
**pandas: powerful Python data analysis
toolkit**

Release 0.25.2

Wes McKinney & PyData Development Team

Oct 23, 2019

CONTENTS

Date: Oct 23, 2019 **Version:** 0.25.2

Download documentation: [PDF Version](#) | [Zipped HTML](#)

Useful links: [Binary Installers](#) | [Source Repository](#) | [Issues & Ideas](#) | [Q&A Support](#) | [Mailing List](#)

pandas is an open source, BSD-licensed library providing high-performance, easy-to-use data structures and data analysis tools for the [Python](#) programming language.

See the [overview](#) for more detail about what's in the library.

WHAT'S NEW IN 0.25.2 (OCTOBER 15, 2019)

These are the changes in pandas 0.25.2. See release for a full changelog including other versions of pandas.

Note: Pandas 0.25.2 adds compatibility for Python 3.8 (GH28147).

1.1 Bug fixes

1.1.1 Indexing

- Fix regression in `DataFrame.reindex()` not following the `limit` argument (GH28631).
- Fix regression in `RangeIndex.get_indexer()` for decreasing `RangeIndex` where target values may be improperly identified as missing/present (GH28678)

1.1.2 I/O

- Fix regression in notebook display where `<th>` tags were missing for `DataFrame.index` values (GH28204).
- Regression in `to_csv()` where writing a `Series` or `DataFrame` indexed by an `IntervalIndex` would incorrectly raise a `TypeError` (GH28210)
- Fix `to_csv()` with `ExtensionArray` with list-like values (GH28840).

1.1.3 Groupby/resample/rolling

- Bug incorrectly raising an `IndexError` when passing a list of quantiles to `pandas.core.groupby.DataFrameGroupBy.quantile()` (GH28113).
- Bug in `pandas.core.groupby.GroupBy.shift()`, `pandas.core.groupby.GroupBy.bfill()` and `pandas.core.groupby.GroupBy.ffill()` where timezone information would be dropped (GH19995, GH27992)

-
- Compatibility with Python 3.8 in `DataFrame.query()` (GH27261)
 - Fix to ensure that tab-completion in an IPython console does not raise warnings for deprecated attributes (GH27900).

1.2 Contributors

A total of 6 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

- Felix Divo +
- Jeremy Schendel
- Joris Van den Bossche
- MeeseeksMachine
- Tom Augspurger
- jbrockmendel

{{ header }}

INSTALLATION

The easiest way to install pandas is to install it as part of the [Anaconda](#) distribution, a cross platform distribution for data analysis and scientific computing. This is the recommended installation method for most users.

Instructions for installing from source, [PyPI](#), [ActivePython](#), various Linux distributions, or a [development version](#) are also provided.

2.1 Python version support

Officially Python 3.5.3 and above, 3.6, 3.7, and 3.8.

2.2 Installing pandas

2.2.1 Installing with Anaconda

Installing pandas and the rest of the [NumPy](#) and [SciPy](#) stack can be a little difficult for inexperienced users.

The simplest way to install not only pandas, but Python and the most popular packages that make up the [SciPy](#) stack ([IPython](#), [NumPy](#), [Matplotlib](#), ...) is with [Anaconda](#), a cross-platform (Linux, Mac OS X, Windows) Python distribution for data analytics and scientific computing.

After running the installer, the user will have access to pandas and the rest of the [SciPy](#) stack without needing to install anything else, and without needing to wait for any software to be compiled.

Installation instructions for [Anaconda](#) can be found [here](#).

A full list of the packages available as part of the [Anaconda](#) distribution can be found [here](#).

Another advantage to installing Anaconda is that you don't need admin rights to install it. Anaconda can install in the user's home directory, which makes it trivial to delete Anaconda if you decide (just delete that folder).

2.2.2 Installing with Miniconda

The previous section outlined how to get pandas installed as part of the [Anaconda](#) distribution. However this approach means you will install well over one hundred packages and involves downloading the installer which is a few hundred megabytes in size.

If you want to have more control on which packages, or have a limited internet bandwidth, then installing pandas with [Miniconda](#) may be a better solution.

[Conda](#) is the package manager that the [Anaconda](#) distribution is built upon. It is a package manager that is both cross-platform and language agnostic (it can play a similar role to a pip and virtualenv combination).

[Miniconda](#) allows you to create a minimal self contained Python installation, and then use the [Conda](#) command to install additional packages.

First you will need [Conda](#) to be installed and downloading and running the [Miniconda](#) will do this for you. The installer [can be found here](#)

The next step is to create a new conda environment. A conda environment is like a virtualenv that allows you to specify a specific version of Python and set of libraries. Run the following commands from a terminal window:

```
conda create -n name_of_my_env python
```

This will create a minimal environment with only Python installed in it. To put your self inside this environment run:

```
source activate name_of_my_env
```

On Windows the command is:

```
activate name_of_my_env
```

The final step required is to install pandas. This can be done with the following command:

```
conda install pandas
```

To install a specific pandas version:

```
conda install pandas=0.20.3
```

To install other packages, IPython for example:

```
conda install ipython
```

To install the full [Anaconda](#) distribution:

```
conda install anaconda
```

If you need packages that are available to pip but not conda, then install pip, and then use pip to install those packages:

```
conda install pip
pip install django
```

2.2.3 Installing from PyPI

pandas can be installed via pip from [PyPI](#).

```
pip install pandas
```

2.2.4 Installing with ActivePython

Installation instructions for [ActivePython](#) can be found [here](#). Versions 2.7 and 3.5 include pandas.

2.2.5 Installing using your Linux distribution's package manager.

The commands in this table will install pandas for Python 3 from your distribution. To install pandas for Python 2, you may need to use the `python-pandas` package.

Distribution	Status	Download / Repository Link	Install method
Debian	stable	official Debian repository	<code>sudo apt-get install python3-pandas</code>
Debian & Ubuntu	unstable (latest packages)	NeuroDebian	<code>sudo apt-get install python3-pandas</code>
Ubuntu	stable	official Ubuntu repository	<code>sudo apt-get install python3-pandas</code>
OpenSuse	stable	OpenSuse Repository	<code>zypper in python3-pandas</code>
Fedora	stable	official Fedora repository	<code>dnf install python3-pandas</code>
Centos/RHEL	stable	EPEL repository	<code>yum install python3-pandas</code>

However, the packages in the linux package managers are often a few versions behind, so to get the newest version of pandas, it's recommended to install using the `pip` or `conda` methods described above.

2.2.6 Installing from source

See the *contributing guide* for complete instructions on building from the git source tree. Further, see *creating a development environment* if you wish to create a *pandas* development environment.

2.3 Running the test suite

pandas is equipped with an exhaustive set of unit tests, covering about 97% of the code base as of this writing. To run it on your machine to verify that everything is working (and that you have all of the dependencies, soft and hard, installed), make sure you have `pytest` \geq 4.0.2 and `Hypothesis` \geq 3.58, then run:

```
>>> pd.test()
running: pytest --skip-slow --skip-network C:\Users\TP\Anaconda3\envs\py36\lib\site-
↳ packages\pandas
===== test session starts =====
platform win32 -- Python 3.6.2, pytest-3.6.0, py-1.4.34, pluggy-0.4.0
rootdir: C:\Users\TP\Documents\Python\pandasdev\pandas, inifile: setup.cfg
collected 12145 items / 3 skipped

.....S.....
.....S.....
.....

===== 12130 passed, 12 skipped in 368.339 seconds =====
```

2.4 Dependencies

Package	Minimum supported version
setuptools	24.2.0
NumPy	1.13.3
python-dateutil	2.6.1
pytz	2017.2

2.4.1 Recommended dependencies

- `numexpr`: for accelerating certain numerical operations. `numexpr` uses multiple cores as well as smart chunking and caching to achieve large speedups. If installed, must be Version 2.6.2 or higher.
- `bottleneck`: for accelerating certain types of `nan` evaluations. `bottleneck` uses specialized cython routines to achieve large speedups. If installed, must be Version 1.2.1 or higher.

Note: You are highly encouraged to install these libraries, as they provide speed improvements, especially when working with large data sets.

2.4.2 Optional dependencies

Pandas has many optional dependencies that are only used for specific methods. For example, `pandas.read_hdf()` requires the `pytables` package. If the optional dependency is not installed, pandas will raise an `ImportError` when the method requiring that dependency is called.

Dependency	Minimum Version	Notes
BeautifulSoup4	4.6.0	HTML parser for <code>read_html</code> (see <i>note</i>)
Jinja2		Conditional formatting with <code>DataFrame.style</code>
PyQt4		Clipboard I/O
PyQt5		Clipboard I/O
PyTables	3.4.2	HDF5-based reading / writing
SQLAlchemy	1.1.4	SQL support for databases other than sqlite
SciPy	0.19.0	Miscellaneous statistical functions
XLsxWriter	0.9.8	Excel writing
blosc		Compression for msgpack
fastparquet	0.2.1	Parquet reading / writing
gcsfs	0.2.2	Google Cloud Storage access
html5lib		HTML parser for <code>read_html</code> (see <i>note</i>)
lxml	3.8.0	HTML parser for <code>read_html</code> (see <i>note</i>)
matplotlib	2.2.2	Visualization
openpyxl	2.4.8	Reading / writing for xlsx files
pandas-gbq	0.8.0	Google Big Query access
psycopg2		PostgreSQL engine for sqlalchemy
pyarrow	0.9.0	Parquet and feather reading / writing
pymysql	0.7.11	MySQL engine for sqlalchemy
pyreadstat		SPSS files (.sav) reading
pytables	3.4.2	HDF5 reading / writing
qtpy		Clipboard I/O
s3fs	0.0.8	Amazon S3 access
xarray	0.8.2	pandas-like API for N-dimensional data
xclip		Clipboard I/O on linux
xlrd	1.1.0	Excel reading
xlwt	1.2.0	Excel writing
xsel		Clipboard I/O on linux
zlib		Compression for msgpack

Optional dependencies for parsing HTML

One of the following combinations of libraries is needed to use the top-level `read_html()` function:

Changed in version 0.23.0.

- BeautifulSoup4 and html5lib
- BeautifulSoup4 and lxml
- BeautifulSoup4 and html5lib and lxml
- Only lxml, although see *HTML Table Parsing* for reasons as to why you should probably **not** take this approach.

Warning:

- if you install BeautifulSoup4 you must install either lxml or html5lib or both. `read_html()` will **not** work with *only* BeautifulSoup4 installed.
- You are highly encouraged to read *HTML Table Parsing gotchas*. It explains issues surrounding the installation and usage of the above three libraries.

{{ header }}

GETTING STARTED

{{ header }}

3.1 Package overview

pandas is a **Python** package providing fast, flexible, and expressive data structures designed to make working with “relational” or “labeled” data both easy and intuitive. It aims to be the fundamental high-level building block for doing practical, **real world** data analysis in Python. Additionally, it has the broader goal of becoming **the most powerful and flexible open source data analysis / manipulation tool available in any language**. It is already well on its way toward this goal.

pandas is well suited for many different kinds of data:

- Tabular data with heterogeneously-typed columns, as in an SQL table or Excel spreadsheet
- Ordered and unordered (not necessarily fixed-frequency) time series data.
- Arbitrary matrix data (homogeneously typed or heterogeneous) with row and column labels
- Any other form of observational / statistical data sets. The data actually need not be labeled at all to be placed into a pandas data structure

The two primary data structures of pandas, **Series** (1-dimensional) and **DataFrame** (2-dimensional), handle the vast majority of typical use cases in finance, statistics, social science, and many areas of engineering. For R users, **DataFrame** provides everything that R’s **data.frame** provides and much more. pandas is built on top of **NumPy** and is intended to integrate well within a scientific computing environment with many other 3rd party libraries.

Here are just a few of the things that pandas does well:

- Easy handling of **missing data** (represented as NaN) in floating point as well as non-floating point data
- Size mutability: columns can be **inserted and deleted** from DataFrame and higher dimensional objects
- Automatic and explicit **data alignment**: objects can be explicitly aligned to a set of labels, or the user can simply ignore the labels and let *Series*, *DataFrame*, etc. automatically align the data for you in computations
- Powerful, flexible **group by** functionality to perform split-apply-combine operations on data sets, for both aggregating and transforming data
- Make it **easy to convert** ragged, differently-indexed data in other Python and NumPy data structures into DataFrame objects
- Intelligent label-based **slicing, fancy indexing, and subsetting** of large data sets

- Intuitive **merging** and **joining** data sets
- Flexible **reshaping** and pivoting of data sets
- **Hierarchical** labeling of axes (possible to have multiple labels per tick)
- Robust IO tools for loading data from **flat files** (CSV and delimited), Excel files, databases, and saving / loading data from the ultrafast **HDF5 format**
- **Time series**-specific functionality: date range generation and frequency conversion, moving window statistics, moving window linear regressions, date shifting and lagging, etc.

Many of these principles are here to address the shortcomings frequently experienced using other languages / scientific research environments. For data scientists, working with data is typically divided into multiple stages: munging and cleaning data, analyzing / modeling it, then organizing the results of the analysis into a form suitable for plotting or tabular display. pandas is the ideal tool for all of these tasks.

Some other notes

- pandas is **fast**. Many of the low-level algorithmic bits have been extensively tweaked in [Cython](#) code. However, as with anything else generalization usually sacrifices performance. So if you focus on one feature for your application you may be able to create a faster specialized tool.
- pandas is a dependency of [statsmodels](#), making it an important part of the statistical computing ecosystem in Python.
- pandas has been used extensively in production in financial applications.

3.1.1 Data structures

Dimensions	Name	Description
1	Series	1D labeled homogeneously-typed array
2	DataFrame	General 2D labeled, size-mutable tabular structure with potentially heterogeneously-typed column

Why more than one data structure?

The best way to think about the pandas data structures is as flexible containers for lower dimensional data. For example, DataFrame is a container for Series, and Series is a container for scalars. We would like to be able to insert and remove objects from these containers in a dictionary-like fashion.

Also, we would like sensible default behaviors for the common API functions which take into account the typical orientation of time series and cross-sectional data sets. When using ndarrays to store 2- and 3-dimensional data, a burden is placed on the user to consider the orientation of the data set when writing functions; axes are considered more or less equivalent (except when C- or Fortran-contiguity matters for performance). In pandas, the axes are intended to lend more semantic meaning to the data; i.e., for a particular data set there is likely to be a “right” way to orient the data. The goal, then, is to reduce the amount of mental effort required to code up data transformations in downstream functions.

For example, with tabular data (DataFrame) it is more semantically helpful to think of the **index** (the rows) and the **columns** rather than axis 0 and axis 1. Iterating through the columns of the DataFrame thus results in more readable code:

```
for col in df.columns:
    series = df[col]
    # do something with series
```

3.1.2 Mutability and copying of data

All pandas data structures are value-mutable (the values they contain can be altered) but not always size-mutable. The length of a Series cannot be changed, but, for example, columns can be inserted into a DataFrame. However, the vast majority of methods produce new objects and leave the input data untouched. In general we like to **favor immutability** where sensible.

3.1.3 Getting support

The first stop for pandas issues and ideas is the [Github Issue Tracker](#). If you have a general question, pandas community experts can answer through [Stack Overflow](#).

3.1.4 Community

pandas is actively supported today by a community of like-minded individuals around the world who contribute their valuable time and energy to help make open source pandas possible. Thanks to all of our contributors.

If you're interested in contributing, please visit the *contributing guide*.

pandas is a NumFOCUS sponsored project. This will help ensure the success of development of pandas as a world-class open-source project, and makes it possible to [donate](#) to the project.

3.1.5 Project governance

The governance process that pandas project has used informally since its inception in 2008 is formalized in [Project Governance documents](#). The documents clarify how decisions are made and how the various elements of our community interact, including the relationship between open source collaborative development and work that may be funded by for-profit or non-profit entities.

Wes McKinney is the Benevolent Dictator for Life (BDFL).

3.1.6 Development team

The list of the Core Team members and more detailed information can be found on the [people's page](#) of the governance repo.

3.1.7 Institutional partners

The information about current institutional partners can be found on [pandas website page](#).

3.1.8 License

BSD 3-Clause License

Copyright (c) 2008-2012, AQR Capital Management, LLC, Lambda Foundry, Inc. and PyData Development Team
All rights reserved.

```
{{ header }}
```

3.2 10 minutes to pandas

This is a short introduction to pandas, geared mainly for new users. You can see more complex recipes in the *Cookbook*.

Customarily, we import as follows:

```
In [1]: import numpy as np
In [2]: import pandas as pd
```

3.2.1 Object creation

See the *Data Structure Intro section*.

Creating a `Series` by passing a list of values, letting pandas create a default integer index:

```
In [3]: s = pd.Series([1, 3, 5, np.nan, 6, 8])
In [4]: s
Out[4]:
0    1.0
1    3.0
```

(continues on next page)

(continued from previous page)

```

2    5.0
3    NaN
4    6.0
5    8.0
dtype: float64

```

Creating a `DataFrame` by passing a NumPy array, with a datetime index and labeled columns:

```

In [5]: dates = pd.date_range('20130101', periods=6)

In [6]: dates
Out[6]:
DatetimeIndex(['2013-01-01', '2013-01-02', '2013-01-03', '2013-01-04',
              '2013-01-05', '2013-01-06'],
              dtype='datetime64[ns]', freq='D')

In [7]: df = pd.DataFrame(np.random.randn(6, 4), index=dates, columns=list('ABCD'))

In [8]: df
Out[8]:
              A          B          C          D
2013-01-01  1.363830  0.773775 -2.275815 -0.733332
2013-01-02  1.775862 -0.867224  1.214459  1.846233
2013-01-03  0.747247  0.166559 -0.694008 -0.686417
2013-01-04  0.347708  0.060473 -1.393855 -1.249877
2013-01-05  0.578869  0.782500  0.045559 -0.490189
2013-01-06  0.587491 -0.675389 -0.433293 -0.583037

```

Creating a `DataFrame` by passing a dict of objects that can be converted to series-like.

```

In [9]: df2 = pd.DataFrame({'A': 1.,
...:                       'B': pd.Timestamp('20130102'),
...:                       'C': pd.Series(1, index=list(range(4)), dtype='float32'),
...:                       'D': np.array([3] * 4, dtype='int32'),
...:                       'E': pd.Categorical(["test", "train", "test", "train"]),
...:                       'F': 'foo'})
...:

In [10]: df2
Out[10]:
   A      B      C  D  E  F
0  1.0 2013-01-02  1.0  3  test  foo
1  1.0 2013-01-02  1.0  3  train  foo
2  1.0 2013-01-02  1.0  3  test  foo
3  1.0 2013-01-02  1.0  3  train  foo

```

The columns of the resulting `DataFrame` have different *dtypes*.

```

In [11]: df2.dtypes
Out[11]:
A          float64
B    datetime64[ns]

```

(continues on next page)

(continued from previous page)

```
C          float32
D          int32
E          category
F          object
dtype: object
```

If you're using IPython, tab completion for column names (as well as public attributes) is automatically enabled. Here's a subset of the attributes that will be completed:

```
In [12]: df2.<TAB> # noqa: E225, E999
df2.A          df2.bool
df2.abs        df2.boxplot
df2.add        df2.C
df2.add_prefix df2.clip
df2.add_suffix df2.clip_lower
df2.align      df2.clip_upper
df2.all        df2.columns
df2.any        df2.combine
df2.append     df2.combine_first
df2.apply      df2.compound
df2.applymap   df2.consolidate
df2.D
```

As you can see, the columns A, B, C, and D are automatically tab completed. E is there as well; the rest of the attributes have been truncated for brevity.

3.2.2 Viewing data

See the *Basics section*.

Here is how to view the top and bottom rows of the frame:

```
In [13]: df.head()
Out[13]:
```

	A	B	C	D
2013-01-01	1.363830	0.773775	-2.275815	-0.733332
2013-01-02	1.775862	-0.867224	1.214459	1.846233
2013-01-03	0.747247	0.166559	-0.694008	-0.686417
2013-01-04	0.347708	0.060473	-1.393855	-1.249877
2013-01-05	0.578869	0.782500	0.045559	-0.490189

```
In [14]: df.tail(3)
Out[14]:
```

	A	B	C	D
2013-01-04	0.347708	0.060473	-1.393855	-1.249877
2013-01-05	0.578869	0.782500	0.045559	-0.490189
2013-01-06	0.587491	-0.675389	-0.433293	-0.583037

Display the index, columns:

```
In [15]: df.index
Out[15]:
DatetimeIndex(['2013-01-01', '2013-01-02', '2013-01-03', '2013-01-04',
               '2013-01-05', '2013-01-06'],
```

```
dtype='datetime64[ns]', freq='D')
```

```
In [16]: df.columns
```

```
Out[16]: Index(['A', 'B', 'C', 'D'], dtype='object')
```

`DataFrame.to_numpy()` gives a NumPy representation of the underlying data. Note that this can be an expensive operation when your `DataFrame` has columns with different data types, which comes down to a fundamental difference between pandas and NumPy: **NumPy arrays have one dtype for the entire array, while pandas DataFrames have one dtype per column.** When you call `DataFrame.to_numpy()`, pandas will find the NumPy dtype that can hold *all* of the dtypes in the `DataFrame`. This may end up being `object`, which requires casting every value to a Python object.

For `df`, our `DataFrame` of all floating-point values, `DataFrame.to_numpy()` is fast and doesn't require copying data.

```
In [17]: df.to_numpy()
```

```
Out[17]:
```

```
array([[ 1.36382983,  0.77377516, -2.2758147 , -0.73333194],
       [ 1.77586181, -0.86722409,  1.21445884,  1.84623251],
       [ 0.74724665,  0.1665589 , -0.69400832, -0.68641742],
       [ 0.34770833,  0.06047343, -1.39385516, -1.24987716],
       [ 0.57886924,  0.78250045,  0.04555881, -0.49018939],
       [ 0.58749057, -0.67538866, -0.43329251, -0.58303716]])
```

For `df2`, the `DataFrame` with multiple dtypes, `DataFrame.to_numpy()` is relatively expensive.

```
In [18]: df2.to_numpy()
```

```
Out[18]:
```

```
array([[1.0, Timestamp('2013-01-02 00:00:00'), 1.0, 3, 'test', 'foo'],
       [1.0, Timestamp('2013-01-02 00:00:00'), 1.0, 3, 'train', 'foo'],
       [1.0, Timestamp('2013-01-02 00:00:00'), 1.0, 3, 'test', 'foo'],
       [1.0, Timestamp('2013-01-02 00:00:00'), 1.0, 3, 'train', 'foo']],
      dtype=object)
```

Note: `DataFrame.to_numpy()` does *not* include the index or column labels in the output.

`describe()` shows a quick statistic summary of your data:

```
In [19]: df.describe()
```

```
Out[19]:
```

	A	B	C	D
count	6.000000	6.000000	6.000000	6.000000
mean	0.900168	0.040116	-0.589492	-0.316103
std	0.549803	0.698714	1.198627	1.091824
min	0.347708	-0.867224	-2.275815	-1.249877
25%	0.581025	-0.491423	-1.218893	-0.721603
50%	0.667369	0.113516	-0.563650	-0.634727
75%	1.209684	0.621971	-0.074154	-0.513401
max	1.775862	0.782500	1.214459	1.846233

Transposing your data:

```
In [20]: df.T
Out [20]:
```

	2013-01-01	2013-01-02	2013-01-03	2013-01-04	2013-01-05	2013-01-06
A	1.363830	1.775862	0.747247	0.347708	0.578869	0.587491
B	0.773775	-0.867224	0.166559	0.060473	0.782500	-0.675389
C	-2.275815	1.214459	-0.694008	-1.393855	0.045559	-0.433293
D	-0.733332	1.846233	-0.686417	-1.249877	-0.490189	-0.583037

Sorting by an axis:

```
In [21]: df.sort_index(axis=1, ascending=False)
Out [21]:
```

	D	C	B	A
2013-01-01	-0.733332	-2.275815	0.773775	1.363830
2013-01-02	1.846233	1.214459	-0.867224	1.775862
2013-01-03	-0.686417	-0.694008	0.166559	0.747247
2013-01-04	-1.249877	-1.393855	0.060473	0.347708
2013-01-05	-0.490189	0.045559	0.782500	0.578869
2013-01-06	-0.583037	-0.433293	-0.675389	0.587491

Sorting by values:

```
In [22]: df.sort_values(by='B')
Out [22]:
```

	A	B	C	D
2013-01-02	1.775862	-0.867224	1.214459	1.846233
2013-01-06	0.587491	-0.675389	-0.433293	-0.583037
2013-01-04	0.347708	0.060473	-1.393855	-1.249877
2013-01-03	0.747247	0.166559	-0.694008	-0.686417
2013-01-01	1.363830	0.773775	-2.275815	-0.733332
2013-01-05	0.578869	0.782500	0.045559	-0.490189

3.2.3 Selection

Note: While standard Python / Numpy expressions for selecting and setting are intuitive and come in handy for interactive work, for production code, we recommend the optimized pandas data access methods, `.at`, `.iat`, `.loc` and `.iloc`.

See the indexing documentation *Indexing and Selecting Data* and *MultiIndex / Advanced Indexing*.

Getting

Selecting a single column, which yields a **Series**, equivalent to `df.A`:

```
In [23]: df['A']
Out [23]:
```

2013-01-01	1.363830
2013-01-02	1.775862
2013-01-03	0.747247
2013-01-04	0.347708

(continues on next page)

(continued from previous page)

```
2013-01-05    0.578869
2013-01-06    0.587491
Freq: D, Name: A, dtype: float64
```

Selecting via `[]`, which slices the rows.

```
In [24]: df[0:3]
Out[24]:
```

	A	B	C	D
2013-01-01	1.363830	0.773775	-2.275815	-0.733332
2013-01-02	1.775862	-0.867224	1.214459	1.846233
2013-01-03	0.747247	0.166559	-0.694008	-0.686417

```
In [25]: df['20130102':'20130104']
Out[25]:
```

	A	B	C	D
2013-01-02	1.775862	-0.867224	1.214459	1.846233
2013-01-03	0.747247	0.166559	-0.694008	-0.686417
2013-01-04	0.347708	0.060473	-1.393855	-1.249877

Selection by label

See more in [Selection by Label](#).

For getting a cross section using a label:

```
In [26]: df.loc[dates[0]]
Out[26]:
```

	A	B	C	D
2013-01-01 00:00:00	1.363830	0.773775	-2.275815	-0.733332

Name: 2013-01-01 00:00:00, dtype: float64

Selecting on a multi-axis by label:

```
In [27]: df.loc[:, ['A', 'B']]
Out[27]:
```

	A	B
2013-01-01	1.363830	0.773775
2013-01-02	1.775862	-0.867224
2013-01-03	0.747247	0.166559
2013-01-04	0.347708	0.060473
2013-01-05	0.578869	0.782500
2013-01-06	0.587491	-0.675389

Showing label slicing, both endpoints are *included*:

```
In [28]: df.loc['20130102':'20130104', ['A', 'B']]
Out[28]:
```

	A	B
2013-01-02	1.775862	-0.867224

(continues on next page)

(continued from previous page)

```
2013-01-03  0.747247  0.166559
2013-01-04  0.347708  0.060473
```

Reduction in the dimensions of the returned object:

```
In [29]: df.loc['20130102', ['A', 'B']]
Out[29]:
A    1.775862
B   -0.867224
Name: 2013-01-02 00:00:00, dtype: float64
```

For getting a scalar value:

```
In [30]: df.loc[dates[0], 'A']
Out[30]: 1.3638298274671674
```

For getting fast access to a scalar (equivalent to the prior method):

```
In [31]: df.at[dates[0], 'A']
Out[31]: 1.3638298274671674
```

Selection by position

See more in *Selection by Position*.

Select via the position of the passed integers:

```
In [32]: df.iloc[3]
Out[32]:
A    0.347708
B    0.060473
C   -1.393855
D   -1.249877
Name: 2013-01-04 00:00:00, dtype: float64
```

By integer slices, acting similar to numpy/python:

```
In [33]: df.iloc[3:5, 0:2]
Out[33]:
           A          B
2013-01-04  0.347708  0.060473
2013-01-05  0.578869  0.782500
```

By lists of integer position locations, similar to the numpy/python style:

```
In [34]: df.iloc[[1, 2, 4], [0, 2]]
Out[34]:
           A          C
2013-01-02  1.775862  1.214459
2013-01-03  0.747247 -0.694008
2013-01-05  0.578869  0.045559
```

For slicing rows explicitly:

```
In [35]: df.iloc[1:3, :]
Out[35]:
```

	A	B	C	D
2013-01-02	1.775862	-0.867224	1.214459	1.846233
2013-01-03	0.747247	0.166559	-0.694008	-0.686417

For slicing columns explicitly:

```
In [36]: df.iloc[:, 1:3]
Out[36]:
```

	B	C
2013-01-01	0.773775	-2.275815
2013-01-02	-0.867224	1.214459
2013-01-03	0.166559	-0.694008
2013-01-04	0.060473	-1.393855
2013-01-05	0.782500	0.045559
2013-01-06	-0.675389	-0.433293

For getting a value explicitly:

```
In [37]: df.iloc[1, 1]
Out[37]: -0.8672240914412521
```

For getting fast access to a scalar (equivalent to the prior method):

```
In [38]: df.iat[1, 1]
Out[38]: -0.8672240914412521
```

Boolean indexing

Using a single column's values to select data.

```
In [39]: df[df.A > 0]
Out[39]:
```

	A	B	C	D
2013-01-01	1.363830	0.773775	-2.275815	-0.733332
2013-01-02	1.775862	-0.867224	1.214459	1.846233
2013-01-03	0.747247	0.166559	-0.694008	-0.686417
2013-01-04	0.347708	0.060473	-1.393855	-1.249877
2013-01-05	0.578869	0.782500	0.045559	-0.490189
2013-01-06	0.587491	-0.675389	-0.433293	-0.583037

Selecting values from a DataFrame where a boolean condition is met.

```
In [40]: df[df > 0]
Out[40]:
```

	A	B	C	D
2013-01-01	1.363830	0.773775	NaN	NaN
2013-01-02	1.775862	NaN	1.214459	1.846233
2013-01-03	0.747247	0.166559	NaN	NaN
2013-01-04	0.347708	0.060473	NaN	NaN
2013-01-05	0.578869	0.782500	0.045559	NaN
2013-01-06	0.587491	NaN	NaN	NaN

Using the `isin()` method for filtering:

```
In [41]: df2 = df.copy()
```

```
In [42]: df2['E'] = ['one', 'one', 'two', 'three', 'four', 'three']
```

```
In [43]: df2
```

```
Out[43]:
```

	A	B	C	D	E
2013-01-01	1.363830	0.773775	-2.275815	-0.733332	one
2013-01-02	1.775862	-0.867224	1.214459	1.846233	one
2013-01-03	0.747247	0.166559	-0.694008	-0.686417	two
2013-01-04	0.347708	0.060473	-1.393855	-1.249877	three
2013-01-05	0.578869	0.782500	0.045559	-0.490189	four
2013-01-06	0.587491	-0.675389	-0.433293	-0.583037	three

```
In [44]: df2[df2['E'].isin(['two', 'four'])]
```

```
Out[44]:
```

	A	B	C	D	E
2013-01-03	0.747247	0.166559	-0.694008	-0.686417	two
2013-01-05	0.578869	0.782500	0.045559	-0.490189	four

Setting

Setting a new column automatically aligns the data by the indexes.

```
In [45]: s1 = pd.Series([1, 2, 3, 4, 5, 6], index=pd.date_range('20130102', periods=6))
```

```
In [46]: s1
```

```
Out[46]:
```

```
2013-01-02    1
2013-01-03    2
2013-01-04    3
2013-01-05    4
2013-01-06    5
2013-01-07    6
Freq: D, dtype: int64
```

```
In [47]: df['F'] = s1
```

Setting values by label:

```
In [48]: df.at[dates[0], 'A'] = 0
```

Setting values by position:

```
In [49]: df.iat[0, 1] = 0
```

Setting by assigning with a NumPy array:

```
In [50]: df.loc[:, 'D'] = np.array([5] * len(df))
```

The result of the prior setting operations.

```
In [51]: df
Out[51]:
```

	A	B	C	D	F
2013-01-01	0.000000	0.000000	-2.275815	5	NaN
2013-01-02	1.775862	-0.867224	1.214459	5	1.0
2013-01-03	0.747247	0.166559	-0.694008	5	2.0
2013-01-04	0.347708	0.060473	-1.393855	5	3.0
2013-01-05	0.578869	0.782500	0.045559	5	4.0
2013-01-06	0.587491	-0.675389	-0.433293	5	5.0

A where operation with setting.

```
In [52]: df2 = df.copy()
In [53]: df2[df2 > 0] = -df2
In [54]: df2
Out[54]:
```

	A	B	C	D	F
2013-01-01	0.000000	0.000000	-2.275815	-5	NaN
2013-01-02	-1.775862	-0.867224	-1.214459	-5	-1.0
2013-01-03	-0.747247	-0.166559	-0.694008	-5	-2.0
2013-01-04	-0.347708	-0.060473	-1.393855	-5	-3.0
2013-01-05	-0.578869	-0.782500	-0.045559	-5	-4.0
2013-01-06	-0.587491	-0.675389	-0.433293	-5	-5.0

3.2.4 Missing data

pandas primarily uses the value `np.nan` to represent missing data. It is by default not included in computations. See the [Missing Data section](#).

Reindexing allows you to change/add/delete the index on a specified axis. This returns a copy of the data.

```
In [55]: df1 = df.reindex(index=dates[0:4], columns=list(df.columns) + ['E'])
In [56]: df1.loc[dates[0]:dates[1], 'E'] = 1
In [57]: df1
Out[57]:
```

	A	B	C	D	F	E
2013-01-01	0.000000	0.000000	-2.275815	5	NaN	1.0
2013-01-02	1.775862	-0.867224	1.214459	5	1.0	1.0
2013-01-03	0.747247	0.166559	-0.694008	5	2.0	NaN
2013-01-04	0.347708	0.060473	-1.393855	5	3.0	NaN

To drop any rows that have missing data.

```
In [58]: df1.dropna(how='any')
Out[58]:
```

	A	B	C	D	F	E
2013-01-02	1.775862	-0.867224	1.214459	5	1.0	1.0

Filling missing data.

```
In [59]: df1.fillna(value=5)
Out [59]:
```

	A	B	C	D	F	E
2013-01-01	0.000000	0.000000	-2.275815	5	5.0	1.0
2013-01-02	1.775862	-0.867224	1.214459	5	1.0	1.0
2013-01-03	0.747247	0.166559	-0.694008	5	2.0	5.0
2013-01-04	0.347708	0.060473	-1.393855	5	3.0	5.0

To get the boolean mask where values are `nan`.

```
In [60]: pd.isna(df1)
Out [60]:
```

	A	B	C	D	F	E
2013-01-01	False	False	False	False	True	False
2013-01-02	False	False	False	False	False	False
2013-01-03	False	False	False	False	False	True
2013-01-04	False	False	False	False	False	True

3.2.5 Operations

See the *Basic section on Binary Ops*.

Stats

Operations in general *exclude* missing data.

Performing a descriptive statistic:

```
In [61]: df.mean()
Out [61]:
```

A	0.672863
B	-0.088847
C	-0.589492
D	5.000000
F	3.000000

dtype: float64

Same operation on the other axis:

```
In [62]: df.mean(1)
Out [62]:
```

2013-01-01	0.681046
2013-01-02	1.624619
2013-01-03	1.443959
2013-01-04	1.402865
2013-01-05	2.081386
2013-01-06	1.895762

Freq: D, dtype: float64

Operating with objects that have different dimensionality and need alignment. In addition, pandas automatically broadcasts along the specified dimension.

```
In [63]: s = pd.Series([1, 3, 5, np.nan, 6, 8], index=dates).shift(2)
```

```
In [64]: s
```

```
Out[64]:
```

```
2013-01-01    NaN
2013-01-02    NaN
2013-01-03     1.0
2013-01-04     3.0
2013-01-05     5.0
2013-01-06    NaN
```

```
Freq: D, dtype: float64
```

```
In [65]: df.sub(s, axis='index')
```

```
Out[65]:
```

	A	B	C	D	F
2013-01-01	NaN	NaN	NaN	NaN	NaN
2013-01-02	NaN	NaN	NaN	NaN	NaN
2013-01-03	-0.252753	-0.833441	-1.694008	4.0	1.0
2013-01-04	-2.652292	-2.939527	-4.393855	2.0	0.0
2013-01-05	-4.421131	-4.217500	-4.954441	0.0	-1.0
2013-01-06	NaN	NaN	NaN	NaN	NaN

Apply

Applying functions to the data:

```
In [66]: df.apply(np.cumsum)
```

```
Out[66]:
```

	A	B	C	D	F

dtype: float64
```

Histogramming

See more at [Histogramming and Discretization](#).

```
In [68]: s = pd.Series(np.random.randint(0, 7, size=10))
```

```
In [69]: s
```

```
Out[69]:
```

```
0    3
```

```
1    2
2    4
3    5
4    1
5    1
6    3
7    2
8    4
9    0
dtype: int64
```

```

3    2
2    2
1    2
5    1
0    1
dtype: int64
```

String Methods

Series is equipped with a set of string processing methods in the *str* attribute that make it easy to operate on each element of the array, as in the code snippet below. Note that pattern-matching in *str* generally uses regular expressions by default (and in some cases always uses them). See more at *Vectorized String Methods*.

```
In [71]: s = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca', np.nan, 'CABA', 'dog', 'cat'])
In [72]: s.str.lower()
Out[72]:
0      a
1      b
2      c
3    aaba
4    baca
5     NaN
6    caba
7     dog
8     cat
dtype: object
```

3.2.6 Merge

Concat

pandas provides various facilities for easily combining together Series and DataFrame objects with various kinds of set logic for the indexes and relational algebra functionality in the case of join / merge-type operations.

See the *Merging section*.

Concatenating pandas objects together with `concat()`:

```
In [73]: df = pd.DataFrame(np.random.randn(10, 4))
```

```
In [74]: df
```

```
Out[74]:
```

	0	1	2	3
0	2.215176	-1.315908	-0.317116	-0.842397
1	2.213106	-0.596732	0.409649	1.286960
2	1.006929	-1.120177	0.230672	0.537003
3	-2.502802	0.785754	-0.228391	0.063769
4	-0.469153	-0.620792	1.997251	-0.360238
5	1.116982	-3.165350	-1.410497	-0.466197
6	0.712124	0.581404	0.715763	1.044883
7	-2.015823	0.212701	0.841041	0.089602
8	-1.633435	0.535489	-1.146539	0.930138
9	-0.219756	-0.913111	-0.769806	-0.355672

```
# break it into pieces
```

```
In [75]: pieces = [df[:3], df[3:7], df[7:]]
```

```
In [76]: pd.concat(pieces)
```

```
Out[76]:
```

	0	1	2	3
0	2.215176	-1.315908	-0.317116	-0.842397
1	2.213106	-0.596732	0.409649	1.286960
2	1.006929	-1.120177	0.230672	0.537003
3	-2.502802	0.785754	-0.228391	0.063769
4	-0.469153	-0.620792	1.997251	-0.360238
5	1.116982	-3.165350	-1.410497	-0.466197
6	0.712124	0.581404	0.715763	1.044883
7	-2.015823	0.212701	0.841041	0.089602
8	-1.633435	0.535489	-1.146539	0.930138
9	-0.219756	-0.913111	-0.769806	-0.355672

Join

SQL style merges. See the *Database style joining* section.

```
In [77]: left = pd.DataFrame({'key': ['foo', 'foo'], 'lval': [1, 2]})
```

```
In [78]: right = pd.DataFrame({'key': ['foo', 'foo'], 'rval': [4, 5]})
```

```
In [79]: left
```

```
Out[79]:
```

	key	lval
0	foo	1
1	foo	2

```
In [80]: right
```

```
Out[80]:
```

	key	rval
0	foo	4
1	foo	5

```
In [81]: pd.merge(left, right, on='key')
Out[81]:
```

```
   key  lval  rval
0  foo     1     4
1  foo     1     5
2  foo     2     4
3  foo     2     5
```

Another example that can be given is:

```
In [82]: left = pd.DataFrame({'key': ['foo', 'bar'], 'lval': [1, 2]})
```

```
In [83]: right = pd.DataFrame({'key': ['foo', 'bar'], 'rval': [4, 5]})
```

```
In [84]: left
```

```
Out[84]:
   key  lval
0  foo     1
1  bar     2
```

```
In [85]: right
```

```
Out[85]:
   key  rval
0  foo     4
1  bar     5
```

```
In [86]: pd.merge(left, right, on='key')
```

```
Out[86]:
   key  lval  rval
0  foo     1     4
1  bar     2     5
```

Append

Append rows to a dataframe. See the *Appending* section.

```
In [87]: df = pd.DataFrame(np.random.randn(8, 4), columns=['A', 'B', 'C', 'D'])
```

```
In [88]: df
```

```
Out[88]:
   A         B         C         D
0  0.292785 -0.036327 -0.303377  0.132313
1 -1.437443 -0.521953  0.693930 -0.556417
2  2.246185 -0.175934  1.702784  2.475101
3  0.040067 -0.987877 -0.741536  1.142627
4 -1.657556 -0.812830  0.587969  1.347117
5  0.433323 -0.045170 -0.694659 -0.954585
6 -1.258443 -0.380086  1.610889  0.841358
7 -0.660989  0.519592 -0.360741 -1.441424
```

```
In [89]: s = df.iloc[3]
```

```
In [90]: df.append(s, ignore_index=True)
```

```
Out[90]:
```

(continues on next page)

(continued from previous page)

	A	B	C	D
0	0.292785	-0.036327	-0.303377	0.132313
1	-1.437443	-0.521953	0.693930	-0.556417
2	2.246185	-0.175934	1.702784	2.475101
3	0.040067	-0.987877	-0.741536	1.142627
4	-1.657556	-0.812830	0.587969	1.347117

6	-1.258443	-0.380086	1.610889	0.841358
7	-0.660989	0.519592	-0.360741	-1.441424
8	0.040067	-0.987877	-0.741536	1.142627

3.2.7 Grouping

By “group by” we are referring to a process involving one or more of the following steps:

- **Splitting** the data into groups based on some criteria
- **Applying** a function to each group independently
- **Combining** the results into a data structure

See the *Grouping section*.

```
In [91]: df = pd.DataFrame({'A': ['foo', 'bar', 'foo', 'bar',
.....:                          'foo', 'bar', 'foo', 'foo'],
.....:                    'B': ['one', 'one', 'two', 'three',
.....:                          'two', 'two', 'one', 'three'],
.....:                    'C': np.random.randn(8),
.....:                    'D': np.random.randn(8)})
.....:
```

```
In [92]: df
```

```
Out[92]:
```

	A	B	C	D
0	foo	one	-1.593566	1.125380
1	bar	one	0.854244	1.315419
2	foo	two	1.218171	1.511499
3	bar	three	-0.028648	0.726054
4	foo	two	1.632905	0.664038
5	bar	two	-0.637469	-0.707051
6	foo	one	-0.512159	-1.576752
7	foo	three	0.312766	0.831920

Grouping and then applying the `sum()` function to the resulting groups.

```
In [93]: df.groupby('A').sum()
```

```
Out[93]:
```

	C	D
A		
bar	0.188127	1.334423
foo	1.058118	2.556085

Grouping by multiple columns forms a hierarchical index, and again we can apply the `sum` function.

```
In [94]: df.groupby(['A', 'B']).sum()
```

```
Out[94]:
```

		C	D
A	B		
bar	one	0.854244	1.315419
	three	-0.028648	0.726054
	two	-0.637469	-0.707051
foo	one	-2.105725	-0.451372
	three	0.312766	0.831920
	two	2.851077	2.175537

3.2.8 Reshaping

See the sections on *Hierarchical Indexing* and *Reshaping*.

Stack

```
In [95]: tuples = list(zip(*(['bar', 'bar', 'baz', 'baz',
.....:                       'foo', 'foo', 'qux', 'qux'],
.....:                       ['one', 'two', 'one', 'two',
.....:                       'one', 'two', 'one', 'two'])))
.....:
```

```
In [96]: index = pd.MultiIndex.from_tuples(tuples, names=['first', 'second'])
```

```
In [97]: df = pd.DataFrame(np.random.randn(8, 2), index=index, columns=['A', 'B'])
```

```
In [98]: df2 = df[:4]
```

```
In [99]: df2
```

```
Out[99]:
```

		A	B
first	second		
bar	one	1.374920	0.502088
	two	-0.304574	-1.021713
baz	one	0.713245	0.315322
	two	0.591517	0.543840

The `stack()` method “compresses” a level in the DataFrame’s columns.

```
In [100]: stacked = df2.stack()
```

```
In [101]: stacked
```

```
Out[101]:
```

first	second		
bar	one	A	1.374920
		B	0.502088
	two	A	-0.304574
		B	-1.021713
baz	one	A	0.713245

(continues on next page)

(continued from previous page)

```

           B    0.315322
two       A    0.591517
           B    0.543840
dtype: float64

```

With a “stacked” DataFrame or Series (having a `MultiIndex` as the `index`), the inverse operation of `stack()` is `unstack()`, which by default unstacks the **last** level:

```

In [102]: stacked.unstack()
Out[102]:
           A      B
first second
bar  one    1.374920  0.502088
     two   -0.304574 -1.021713
baz   one    0.713245  0.315322
     two    0.591517  0.543840

```

```

In [103]: stacked.unstack(1)
Out[103]:
second      one      two
first
bar  A  1.374920 -0.304574
     B  0.502088 -1.021713
baz  A  0.713245  0.591517
     B  0.315322  0.543840

```

```

In [104]: stacked.unstack(0)
Out[104]:
first      bar      baz
second
one  A  1.374920  0.713245
     B  0.502088  0.315322
two  A -0.304574  0.591517
     B -1.021713  0.543840

```

Pivot tables

See the section on *Pivot Tables*.

```

In [105]: df = pd.DataFrame({'A': ['one', 'one', 'two', 'three'] * 3,
.....:                      'B': ['A', 'B', 'C'] * 4,
.....:                      'C': ['foo', 'foo', 'foo', 'bar', 'bar', 'bar'] * 2,
.....:                      'D': np.random.randn(12),
.....:                      'E': np.random.randn(12)})

In [106]: df
Out[106]:
   A B  C      D      E
0  one A  foo -0.278531  0.004556
1  one B  foo  0.940889 -2.481391
2  two C  foo  1.256053  1.125308

```

(continues on next page)

(continued from previous page)

```

3  three  A  bar  0.336610  0.521860
4   one   B  bar  1.391023  0.326947
5   one   C  bar  0.280735  0.468253
6   two   A  foo  0.766009 -0.302657
7  three  B  foo  0.752167 -0.107777
8   one   C  foo -1.228431 -0.397928
9   one   A  bar -0.423429 -0.479562
10  two   B  bar -0.846409  0.760181
11  three  C  bar  1.372452 -0.137678

```

We can produce pivot tables from this data very easily:

```

In [107]: pd.pivot_table(df, values='D', index=['A', 'B'], columns=['C'])
Out[107]:
C          bar          foo
A    B
one  A -0.423429 -0.278531
     B  1.391023  0.940889
     C  0.280735 -1.228431
three A  0.336610         NaN
     B         NaN  0.752167
     C  1.372452         NaN
two   A         NaN  0.766009
     B -0.846409         NaN
     C         NaN  1.256053

```

3.2.9 Time series

pandas has simple, powerful, and efficient functionality for performing resampling operations during frequency conversion (e.g., converting secondly data into 5-minutely data). This is extremely common in, but not limited to, financial applications. See the *Time Series section*.

```

In [108]: rng = pd.date_range('1/1/2012', periods=100, freq='S')
In [109]: ts = pd.Series(np.random.randint(0, 500, len(rng)), index=rng)
In [110]: ts.resample('5Min').sum()
Out[110]:
2012-01-01    26405
Freq: 5T, dtype: int64

```

Time zone representation:

```

In [111]: rng = pd.date_range('3/6/2012 00:00', periods=5, freq='D')
In [112]: ts = pd.Series(np.random.randn(len(rng)), rng)
In [113]: ts
Out[113]:
2012-03-06    1.106290
2012-03-07   -1.917986

```

(continues on next page)

(continued from previous page)

```

2012-03-08    1.099233
2012-03-09   -1.180562
2012-03-10   -0.140211
Freq: D, dtype: float64

```

```
In [114]: ts_utc = ts.tz_localize('UTC')
```

```
In [115]: ts_utc
```

```

Out[115]:
2012-03-06 00:00:00+00:00    1.106290
2012-03-07 00:00:00+00:00   -1.917986
2012-03-08 00:00:00+00:00    1.099233
2012-03-09 00:00:00+00:00   -1.180562
2012-03-10 00:00:00+00:00   -0.140211
Freq: D, dtype: float64

```

Converting to another time zone:

```
In [116]: ts_utc.tz_convert('US/Eastern')
```

```

Out[116]:
2012-03-05 19:00:00-05:00    1.106290
2012-03-06 19:00:00-05:00   -1.917986
2012-03-07 19:00:00-05:00    1.099233
2012-03-08 19:00:00-05:00   -1.180562
2012-03-09 19:00:00-05:00   -0.140211
Freq: D, dtype: float64

```

Converting between time span representations:

```
In [117]: rng = pd.date_range('1/1/2012', periods=5, freq='M')
```

```
In [118]: ts = pd.Series(np.random.randn(len(rng)), index=rng)
```

```
In [119]: ts
```

```

Out[119]:
2012-01-31    0.471911
2012-02-29   -1.370620
2012-03-31   -0.267019
2012-04-30    0.111729
2012-05-31    0.611299
Freq: M, dtype: float64

```

```
In [120]: ps = ts.to_period()
```

```
In [121]: ps
```

```

Out[121]:
2012-01    0.471911
2012-02   -1.370620
2012-03   -0.267019
2012-04    0.111729
2012-05    0.611299
Freq: M, dtype: float64

```

```
In [122]: ps.to_timestamp()
Out[122]:
2012-01-01    0.471911
2012-02-01   -1.370620
2012-03-01   -0.267019
2012-04-01    0.111729
2012-05-01    0.611299
Freq: MS, dtype: float64
```

Converting between period and timestamp enables some convenient arithmetic functions to be used. In the following example, we convert a quarterly frequency with year ending in November to 9am of the end of the month following the quarter end:

```
In [123]: prng = pd.period_range('1990Q1', '2000Q4', freq='Q-NOV')
In [124]: ts = pd.Series(np.random.randn(len(prng)), prng)
In [125]: ts.index = (prng.asfreq('M', 'e') + 1).asfreq('H', 's') + 9
In [126]: ts.head()
Out[126]:
1990-03-01 09:00   -1.315293
1990-06-01 09:00   -0.487557
1990-09-01 09:00   -0.778802
1990-12-01 09:00   -0.221309
1991-03-01 09:00    0.174483
Freq: H, dtype: float64
```

3.2.10 Categoricals

pandas can include categorical data in a `DataFrame`. For full docs, see the *categorical introduction* and the *API documentation*.

```
In [127]: df = pd.DataFrame({"id": [1, 2, 3, 4, 5, 6],
.....:                      "raw_grade": ['a', 'b', 'b', 'a', 'a', 'e']})
.....:
```

Convert the raw grades to a categorical data type.

```
In [128]: df["grade"] = df["raw_grade"].astype("category")
In [129]: df["grade"]
Out[129]:
0    a
1    b
2    b
3    a
4    a
5    e
Name: grade, dtype: category
Categories (3, object): [a, b, e]
```

Rename the categories to more meaningful names (assigning to `Series.cat.categories` is inplace!).

```
In [130]: df["grade"].cat.categories = ["very good", "good", "very bad"]
```

Reorder the categories and simultaneously add the missing categories (methods under `Series .cat` return a new `Series` by default).

```
In [131]: df["grade"] = df["grade"].cat.set_categories(["very bad", "bad", "medium",
.....:                                                "good", "very good"])
.....:
```

```
In [132]: df["grade"]
```

```
Out[132]:
```

```
0    very good
1         good
2         good
3    very good
4    very good
5    very bad
```

```
Name: grade, dtype: category
```

```
Categories (5, object): [very bad, bad, medium, good, very good]
```

Sorting is per order in the categories, not lexical order.

```
In [133]: df.sort_values(by="grade")
```

```
Out[133]:
```

	id	raw_grade	grade
5	6	e	very bad
1	2	b	good
2	3	b	good
0	1	a	very good
3	4	a	very good
4	5	a	very good

Grouping by a categorical column also shows empty categories.

```
In [134]: df.groupby("grade").size()
```

```
Out[134]:
```

```
grade
very bad    1
bad         0
medium      0
good        2
very good   3
dtype: int64
```

3.2.11 Plotting

See the *Plotting* docs.

```
In [135]: ts = pd.Series(np.random.randn(1000),
.....:                    index=pd.date_range('1/1/2000', periods=1000))
.....:
```

(continues on next page)

(continued from previous page)

```
In [136]: ts = ts.cumsum()
```

```
In [137]: ts.plot()
```

```
Out[137]: <matplotlib.axes._subplots.AxesSubplot at 0x127495750>
```

On a DataFrame, the `plot()` method is a convenience to plot all of the columns with labels:

```
In [138]: df = pd.DataFrame(np.random.randn(1000, 4), index=ts.index,
.....:                      columns=['A', 'B', 'C', 'D'])
.....:
```

```
In [139]: df = df.cumsum()
```

```
In [140]: plt.figure()
```

```
Out[140]: <Figure size 640x480 with 0 Axes>
```

```
In [141]: df.plot()
```

```
Out[141]: <matplotlib.axes._subplots.AxesSubplot at 0x1277a0a90>
```

```
In [142]: plt.legend(loc='best')
```

```
Out[142]: <matplotlib.legend.Legend at 0x1277a5310>
```

3.2.12 Getting data in/out

CSV

Writing to a csv file.

```
In [143]: df.to_csv('foo.csv')
```

Reading from a csv file.

```
In [144]: pd.read_csv('foo.csv')
```

Out[144]:

	Unnamed: 0	A	B	C	D
0	2000-01-01	0.714384	1.118691	0.214306	-0.209375

```

3.2.13 Gotchas

If you are attempting to perform an operation you might see an exception like:

```

>>> if pd.Series([False, True, False]):
...     print("I was true")
Traceback
...
ValueError: The truth value of an array is ambiguous. Use a.empty, a.any() or a.all().

```

See [Comparisons](#) for an explanation and what to do.

See [Gotchas](#) as well. {{ header }}

3.3 Essential basic functionality

Here we discuss a lot of the essential functionality common to the pandas data structures. Here's how to create some of the objects used in the examples from the previous section:

```

In [1]: index = pd.date_range('1/1/2000', periods=8)

In [2]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])

In [3]: df = pd.DataFrame(np.random.randn(8, 3), index=index,
...:                       columns=['A', 'B', 'C'])
...:
...:

```

3.3.1 Head and tail

To view a small sample of a Series or DataFrame object, use the `head()` and `tail()` methods. The default number of elements to display is five, but you may pass a custom number.

```
In [4]: long_series = pd.Series(np.random.randn(1000))
```

```
In [5]: long_series.head()
```

```

Out[5]:
0    -1.353625
1     0.446611
2     1.600544
3    -0.602700
4     0.096528

```

```
dtype: float64
```

```
In [6]: long_series.tail(3)
Out[6]:
997    -0.933084
998    -1.895481
999    -1.109266
dtype: float64
```

3.3.2 Attributes and underlying data

pandas objects have a number of attributes enabling you to access the metadata

- **shape**: gives the axis dimensions of the object, consistent with ndarray
- **Axis labels**
 - **Series**: *index* (only axis)
 - **DataFrame**: *index* (rows) and *columns*

Note, these attributes can be safely assigned to!

```
In [7]: df[:2]
Out[7]:
           A         B         C
2000-01-01  0.717501 -0.936966  0.634588
2000-01-02 -0.712106 -0.600773  0.676949

In [8]: df.columns = [x.lower() for x in df.columns]

In [9]: df
Out[9]:
           a         b         c
2000-01-01  0.717501 -0.936966  0.634588
2000-01-02 -0.712106 -0.600773  0.676949
2000-01-03  1.578377 -0.108295  0.317850
2000-01-04  1.020407 -0.220174  0.719467
2000-01-05  0.423406  0.742788 -0.047665
2000-01-06  1.516605 -0.287212 -0.086036
2000-01-07  0.411242  0.988457 -1.187729
2000-01-08 -0.053553  0.930622  1.334235
```

Pandas objects (**Index**, **Series**, **DataFrame**) can be thought of as containers for arrays, which hold the actual data and do the actual computation. For many types, the underlying array is a `numpy.ndarray`. However, pandas and 3rd party libraries may *extend* NumPy's type system to add support for custom arrays (see *dtypes*).

To get the actual data inside a **Index** or **Series**, use the `.array` property

```
In [10]: s.array
Out[10]:
<PandasArray>
[ -1.245150154666457, -1.1212737834640922,  0.14371758135167426,
  1.6052453659926817,  0.49430022914548555]
Length: 5, dtype: float64
```

```
In [11]: s.index.array
Out[11]:
<PandasArray>
['a', 'b', 'c', 'd', 'e']
Length: 5, dtype: object
```

array will always be an *ExtensionArray*. The exact details of what an *ExtensionArray* is and why pandas uses them is a bit beyond the scope of this introduction. See [dtypes](#) for more.

If you know you need a NumPy array, use `to_numpy()` or `numpy.asarray()`.

```
In [12]: s.to_numpy()
Out[12]: array([-1.24515015, -1.12127378,  0.14371758,  1.60524537,  0.49430023])
```

```
In [13]: np.asarray(s)
Out[13]: array([-1.24515015, -1.12127378,  0.14371758,  1.60524537,  0.49430023])
```

When the Series or Index is backed by an *ExtensionArray*, `to_numpy()` may involve copying data and coercing values. See [dtypes](#) for more.

`to_numpy()` gives some control over the `dtype` of the resulting `numpy.ndarray`. For example, consider datetimes with timezones. NumPy doesn't have a dtype to represent timezone-aware datetimes, so there are two possibly useful representations:

1. An object-dtype `numpy.ndarray` with `Timestamp` objects, each with the correct `tz`
2. A `datetime64[ns]` -dtype `numpy.ndarray`, where the values have been converted to UTC and the timezone discarded

Timezones may be preserved with `dtype=object`

```
In [14]: ser = pd.Series(pd.date_range('2000', periods=2, tz="CET"))
In [15]: ser.to_numpy(dtype=object)
Out[15]:
array([Timestamp('2000-01-01 00:00:00+0100', tz='CET', freq='D'),
       Timestamp('2000-01-02 00:00:00+0100', tz='CET', freq='D')],
      dtype=object)
```

Or thrown away with `dtype='datetime64[ns]'`

```
In [16]: ser.to_numpy(dtype="datetime64[ns]")
Out[16]:
array(['1999-12-31T23:00:00.000000000', '2000-01-01T23:00:00.000000000'],
      dtype='datetime64[ns]')
```

Getting the “raw data” inside a `DataFrame` is possibly a bit more complex. When your `DataFrame` only has a single data type for all the columns, `DataFrame.to_numpy()` will return the underlying data:

```
In [17]: df.to_numpy()
Out[17]:
array([[ 0.71750128, -0.93696585,  0.63458795],
       [-0.71210567, -0.60077296,  0.67694886],
       [ 1.57837673, -0.10829478,  0.31785043],
       [ 1.02040735, -0.22017439,  0.71946677],
       [ 0.42340608,  0.74278775, -0.04766533],
       [ 1.51660469, -0.28721192, -0.08603582],
```

(continues on next page)

(continued from previous page)

```
[ 0.41124237,  0.98845749, -1.18772875],
 [-0.05355332,  0.93062244,  1.33423531]]])
```

If a `DataFrame` contains homogeneously-typed data, the `ndarray` can actually be modified in-place, and the changes will be reflected in the data structure. For heterogeneous data (e.g. some of the `DataFrame`'s columns are not all the same dtype), this will not be the case. The values attribute itself, unlike the axis labels, cannot be assigned to.

Note: When working with heterogeneous data, the dtype of the resulting `ndarray` will be chosen to accommodate all of the data involved. For example, if strings are involved, the result will be of object dtype. If there are only floats and integers, the resulting array will be of float dtype.

In the past, pandas recommended `Series.values` or `DataFrame.values` for extracting the data from a `Series` or `DataFrame`. You'll still find references to these in old code bases and online. Going forward, we recommend avoiding `.values` and using `.array` or `.to_numpy()`. `.values` has the following drawbacks:

1. When your `Series` contains an *extension type*, it's unclear whether `Series.values` returns a NumPy array or the extension array. `Series.array` will always return an `ExtensionArray`, and will never copy data. `Series.to_numpy()` will always return a NumPy array, potentially at the cost of copying / coercing values.
2. When your `DataFrame` contains a mixture of data types, `DataFrame.values` may involve copying data and coercing values to a common dtype, a relatively expensive operation. `DataFrame.to_numpy()`, being a method, makes it clearer that the returned NumPy array may not be a view on the same data in the `DataFrame`.

3.3.3 Accelerated operations

pandas has support for accelerating certain types of binary numerical and boolean operations using the `numexpr` library and the `bottleneck` libraries.

These libraries are especially useful when dealing with large data sets, and provide large speedups. `numexpr` uses smart chunking, caching, and multiple cores. `bottleneck` is a set of specialized cython routines that are especially fast when dealing with arrays that have `nans`.

Here is a sample (using 100 column x 100,000 row `DataFrames`):

Operation	0.11.0 (ms)	Prior Version (ms)	Ratio to Prior
<code>df1 > df2</code>	13.32	125.35	0.1063
<code>df1 * df2</code>	21.71	36.63	0.5928
<code>df1 + df2</code>	22.04	36.50	0.6039

You are highly encouraged to install both libraries. See the section *Recommended Dependencies* for more installation info.

These are both enabled to be used by default, you can control this by setting the options:

New in version 0.20.0.

```
pd.set_option('compute.use_bottleneck', False)
pd.set_option('compute.use_numexpr', False)
```

3.3.4 Flexible binary operations

With binary operations between pandas data structures, there are two key points of interest:

- Broadcasting behavior between higher- (e.g. DataFrame) and lower-dimensional (e.g. Series) objects.
- Missing data in computations.

We will demonstrate how to manage these issues independently, though they can be handled simultaneously.

Matching / broadcasting behavior

DataFrame has the methods `add()`, `sub()`, `mul()`, `div()` and related functions `radd()`, `rsub()`, ... for carrying out binary operations. For broadcasting behavior, Series input is of primary interest. Using these functions, you can use to either match on the *index* or *columns* via the `axis` keyword:

```
In [18]: df = pd.DataFrame({
....:     'one': pd.Series(np.random.randn(3), index=['a', 'b', 'c']),
....:     'two': pd.Series(np.random.randn(4), index=['a', 'b', 'c', 'd']),
....:     'three': pd.Series(np.random.randn(3), index=['b', 'c', 'd'])})
....:
```

```
In [19]: df
Out[19]:
```

	one	two	three
a	-0.466716	0.029137	NaN
b	-0.965699	1.967624	-0.384693
c	0.544505	0.612498	0.566326
d	NaN	-0.191558	0.106820

```
In [20]: row = df.iloc[1]
```

```
In [21]: column = df['two']
```

```
In [22]: df.sub(row, axis='columns')
Out[22]:
```

	one	two	three
a	0.498982	-1.938487	NaN
b	0.000000	0.000000	0.000000
c	1.510204	-1.355125	0.951019
d	NaN	-2.159182	0.491513

```
In [23]: df.sub(row, axis=1)
Out[23]:
```

	one	two	three
a	0.498982	-1.938487	NaN
b	0.000000	0.000000	0.000000
c	1.510204	-1.355125	0.951019
d	NaN	-2.159182	0.491513

```
In [24]: df.sub(column, axis='index')
Out[24]:
```

	one	two	three
a	-0.495853	0.0	NaN
b	-2.933322	0.0	-2.352317

```
c -0.067993  0.0 -0.046172
d           NaN  0.0  0.298378
```

```
In [25]: df.sub(column, axis=0)
Out[25]:
```

```
      one  two  three
a -0.495853  0.0   NaN
b -2.933322  0.0 -2.352317
c -0.067993  0.0 -0.046172
d           NaN  0.0  0.298378
```

Furthermore you can align a level of a MultiIndexed DataFrame with a Series.

```
In [26]: dfmi = df.copy()
```

```
In [27]: dfmi.index = pd.MultiIndex.from_tuples([(1, 'a'), (1, 'b'),
.....:                                     (1, 'c'), (2, 'a')],
.....:                                     names=['first', 'second'])
.....:
```

```
In [28]: dfmi.sub(column, axis=0, level='second')
```

```
Out[28]:
```

		one	two	three
first	second			
1	a	-0.495853	0.000000	NaN
	b	-2.933322	0.000000	-2.352317
	c	-0.067993	0.000000	-0.046172
2	a	NaN	-0.220695	0.077683

Series and Index also support the `divmod()` builtin. This function takes the floor division and modulo operation at the same time returning a two-tuple of the same type as the left hand side. For example:

```
In [29]: s = pd.Series(np.arange(10))
```

```
In [30]: s
```

```
Out[30]:
```

```
0    0
1    1
2    2
3    3
4    4
5    5
6    6
7    7
8    8
9    9
dtype: int64
```

```
In [31]: div, rem = divmod(s, 3)
```

```
In [32]: div
```

```
Out[32]:
```

```
0    0
1    0
2    0
```

```
3    1
4    1
5    1
6    2
7    2
8    2
9    3
dtype: int64
```

```
In [33]: rem
Out[33]:
0    0
1    1
2    2
3    0
4    1
5    2
6    0
7    1
8    2
9    0
dtype: int64
```

```
In [34]: idx = pd.Index(np.arange(10))
```

```
In [35]: idx
Out[35]: Int64Index([0, 1, 2, 3, 4, 5, 6, 7, 8, 9], dtype='int64')
```

```
In [36]: div, rem = divmod(idx, 3)
```

```
In [37]: div
Out[37]: Int64Index([0, 0, 0, 1, 1, 1, 2, 2, 2, 3], dtype='int64')
```

```
In [38]: rem
Out[38]: Int64Index([0, 1, 2, 0, 1, 2, 0, 1, 2, 0], dtype='int64')
```

We can also do elementwise `divmod()`:

```
In [39]: div, rem = divmod(s, [2, 2, 3, 3, 4, 4, 5, 5, 6, 6])
```

```
In [40]: div
Out[40]:
0    0
1    0
2    0
3    1
4    1
5    1
6    1
7    1
8    1
9    1
dtype: int64
```

```
In [41]: rem
```

```
Out [41]:
0    0
1    1
2    2
3    0
4    0
5    1
6    1
7    2
8    2
9    3
dtype: int64
```

Missing data / operations with fill values

In Series and DataFrame, the arithmetic functions have the option of inputting a *fill_value*, namely a value to substitute when at most one of the values at a location are missing. For example, when adding two DataFrame objects, you may wish to treat NaN as 0 unless both DataFrames are missing that value, in which case the result will be NaN (you can later replace NaN with some other value using `fillna` if you wish).

```
In [42]: df
```

```
Out [42]:
```

	one	two	three
a	-0.466716	0.029137	NaN
b	-0.965699	1.967624	-0.384693
c	0.544505	0.612498	0.566326
d	NaN	-0.191558	0.106820

```
In [43]: df2
```

```
Out [43]:
```

	one	two	three
a	-0.466716	0.029137	1.000000
b	-0.965699	1.967624	-0.384693
c	0.544505	0.612498	0.566326
d	NaN	-0.191558	0.106820

```
In [44]: df + df2
```

```
Out [44]:
```

	one	two	three
a	-0.933433	0.058274	NaN
b	-1.931397	3.935247	-0.769386
c	1.089011	1.224997	1.132652
d	NaN	-0.383116	0.213640

```
In [45]: df.add(df2, fill_value=0)
```

```
Out [45]:
```

	one	two	three
a	-0.933433	0.058274	1.000000
b	-1.931397	3.935247	-0.769386
c	1.089011	1.224997	1.132652
d	NaN	-0.383116	0.213640

Flexible comparisons

Series and DataFrame have the binary comparison methods `eq`, `ne`, `lt`, `gt`, `le`, and `ge` whose behavior is analogous to the binary arithmetic operations described above:

```
In [46]: df.gt(df2)
Out[46]:
      one  two  three
a  False False False
b  False False False
c  False False False
d  False False False
```

```
In [47]: df2.ne(df)
Out[47]:
      one  two  three
a  False False  True
b  False False False
c  False False False
d   True False False
```

These operations produce a pandas object of the same type as the left-hand-side input that is of dtype `bool`. These `boolean` objects can be used in indexing operations, see the section on *Boolean indexing*.

Boolean reductions

You can apply the reductions: `empty`, `any()`, `all()`, and `bool()` to provide a way to summarize a boolean result.

```
In [48]: (df > 0).all()
Out[48]:
one      False
two      False
three    False
dtype: bool
```

```
In [49]: (df > 0).any()
Out[49]:
one      True
two      True
three    True
dtype: bool
```

You can reduce to a final boolean value.

```
In [50]: (df > 0).any().any()
Out[50]: True
```

You can test if a pandas object is empty, via the `empty` property.

```
In [51]: df.empty
Out[51]: False
```

```
In [52]: pd.DataFrame(columns=list('ABC')).empty
Out[52]: True
```

To evaluate single-element pandas objects in a boolean context, use the method `bool()`:

```
In [53]: pd.Series([True]).bool()
Out[53]: True
```

```
In [54]: pd.Series([False]).bool()
Out[54]: False
```

```
In [55]: pd.DataFrame([[True]]).bool()
Out[55]: True
```

```
In [56]: pd.DataFrame([[False]]).bool()
Out[56]: False
```

Warning: You might be tempted to do the following:

```
>>> if df:
...     pass
```

Or

```
>>> df and df2
```

These will both raise errors, as you are trying to compare multiple values.:

```
ValueError: The truth value of an array is ambiguous. Use a.empty, a.any() or a.all().
```

See *gotchas* for a more detailed discussion.

Comparing if objects are equivalent

Often you may find that there is more than one way to compute the same result. As a simple example, consider `df + df` and `df * 2`. To test that these two computations produce the same result, given the tools shown above, you might imagine using `(df + df == df * 2).all()`. But in fact, this expression is False:

```
In [57]: df + df == df * 2
Out[57]:
```

```
   one  two  three
a  True  True  False
b  True  True   True
c  True  True   True
d  False True   True
```

```
In [58]: (df + df == df * 2).all()
```

```
Out[58]:
one      False
two       True
three    False
dtype: bool
```

Notice that the boolean DataFrame `df + df == df * 2` contains some False values! This is because NaNs do not compare as equals:

```
In [59]: np.nan == np.nan
Out[59]: False
```

So, NDFrames (such as Series and DataFrames) have an `equals()` method for testing equality, with NaNs in corresponding locations treated as equal.

```
In [60]: (df + df).equals(df * 2)
Out[60]: True
```

Note that the Series or DataFrame index needs to be in the same order for equality to be True:

```
In [61]: df1 = pd.DataFrame({'col': ['foo', 0, np.nan]})
```

```
In [62]: df2 = pd.DataFrame({'col': [np.nan, 0, 'foo']}, index=[2, 1, 0])
```

```
In [63]: df1.equals(df2)
Out[63]: False
```

```
In [64]: df1.equals(df2.sort_index())
Out[64]: True
```

Comparing array-like objects

You can conveniently perform element-wise comparisons when comparing a pandas data structure with a scalar value:

```
In [65]: pd.Series(['foo', 'bar', 'baz']) == 'foo'
Out[65]:
0    True
1   False
2   False
dtype: bool
```

```
In [66]: pd.Index(['foo', 'bar', 'baz']) == 'foo'
Out[66]: array([ True, False, False])
```

Pandas also handles element-wise comparisons between different array-like objects of the same length:

```
In [67]: pd.Series(['foo', 'bar', 'baz']) == pd.Index(['foo', 'bar', 'qux'])
Out[67]:
0    True
1    True
2   False
dtype: bool
```

```
In [68]: pd.Series(['foo', 'bar', 'baz']) == np.array(['foo', 'bar', 'qux'])
Out[68]:
0    True
1    True
2   False
dtype: bool
```

Trying to compare Index or Series objects of different lengths will raise a ValueError:

```
In [55]: pd.Series(['foo', 'bar', 'baz']) == pd.Series(['foo', 'bar'])
ValueError: Series lengths must match to compare
```

```
In [56]: pd.Series(['foo', 'bar', 'baz']) == pd.Series(['foo'])
ValueError: Series lengths must match to compare
```

Note that this is different from the NumPy behavior where a comparison can be broadcast:

```
In [69]: np.array([1, 2, 3]) == np.array([2])
Out[69]: array([False,  True, False])
```

or it can return False if broadcasting can not be done:

```
In [70]: np.array([1, 2, 3]) == np.array([1, 2])
Out[70]: False
```

Combining overlapping data sets

A problem occasionally arising is the combination of two similar data sets where values in one are preferred over the other. An example would be two data series representing a particular economic indicator where one is considered to be of “higher quality”. However, the lower quality series might extend further back in history or have more complete data coverage. As such, we would like to combine two DataFrame objects where missing values in one DataFrame are conditionally filled with like-labeled values from the other DataFrame. The function implementing this operation is `combine_first()`, which we illustrate:

```
In [71]: df1 = pd.DataFrame({'A': [1., np.nan, 3., 5., np.nan],
.....:                      'B': [np.nan, 2., 3., np.nan, 6.]})
.....:
```

```
In [72]: df2 = pd.DataFrame({'A': [5., 2., 4., np.nan, 3., 7.],
.....:                      'B': [np.nan, np.nan, 3., 4., 6., 8.]})
.....:
```

```
In [73]: df1
Out[73]:
```

	A	B
0	1.0	NaN
1	NaN	2.0
2	3.0	3.0
3	5.0	NaN
4	NaN	6.0

```
In [74]: df2
Out[74]:
```

	A	B
0	5.0	NaN
1	2.0	NaN
2	4.0	3.0
3	NaN	4.0
4	3.0	6.0
5	7.0	8.0

```
In [75]: df1.combine_first(df2)
Out[75]:
```

	A	B
0	1.0	NaN
1	2.0	2.0
2	3.0	3.0
3	5.0	4.0
4	3.0	6.0

5 7.0 8.0

General DataFrame combine

The `combine_first()` method above calls the more general `DataFrame.combine()`. This method takes another `DataFrame` and a combiner function, aligns the input `DataFrame` and then passes the combiner function pairs of `Series` (i.e., columns whose names are the same).

So, for instance, to reproduce `combine_first()` as above:

```
In [76]: def combiner(x, y):
...:     return np.where(pd.isna(x), y, x)
...:
```

3.3.5 Descriptive statistics

There exists a large number of methods for computing descriptive statistics and other related operations on *Series*, *DataFrame*. Most of these are aggregations (hence producing a lower-dimensional result) like `sum()`, `mean()`, and `quantile()`, but some of them, like `cumsum()` and `cumprod()`, produce an object of the same size. Generally speaking, these methods take an `axis` argument, just like `ndarray.{sum, std, ...}`, but the axis can be specified by name or integer:

- **Series:** no axis argument needed
- **DataFrame:** “index” (axis=0, default), “columns” (axis=1)

For example:

```
In [77]: df
```

```
Out[77]:
```

	one	two	three
a	-0.466716	0.029137	NaN
b	-0.965699	1.967624	-0.384693
c	0.544505	0.612498	0.566326
d	NaN	-0.191558	0.106820

```
In [78]: df.mean(0)
```

```
Out[78]:
```

```
one      -0.295970
two       0.604425
three    0.096151
dtype: float64
```

```
In [79]: df.mean(1)
```

```
Out[79]:
```

```
a      -0.218790
b       0.205744
c       0.574443
d      -0.042369
dtype: float64
```

All such methods have a `skipna` option signaling whether to exclude missing data (`True` by default):

```
In [80]: df.sum(0, skipna=False)
```

```
Out[80]:
```

```
one      NaN
```

```
two      2.417701
three    NaN
dtype: float64
```

```
In [81]: df.sum(axis=1, skipna=True)
Out[81]:
a    -0.437579
b     0.617232
c     1.723330
d    -0.084738
dtype: float64
```

Combined with the broadcasting / arithmetic behavior, one can describe various statistical procedures, like standardization (rendering data zero mean and standard deviation 1), very concisely:

```
In [82]: ts_stand = (df - df.mean()) / df.std()

In [83]: ts_stand.std()
Out[83]:
one      1.0
two      1.0
three    1.0
dtype: float64

In [84]: xs_stand = df.sub(df.mean(1), axis=0).div(df.std(1), axis=0)

In [85]: xs_stand.std(1)
Out[85]:
a      1.0
b      1.0
c      1.0
d      1.0
dtype: float64
```

Note that methods like `cumsum()` and `cumprod()` preserve the location of NaN values. This is somewhat different from `expanding()` and `rolling()`. For more details please see [this note](#).

```
In [86]: df.cumsum()
Out[86]:
      one      two      three
a -0.466716  0.029137      NaN
b -1.432415  1.996760 -0.384693
c -0.887909  2.609259  0.181633
d      NaN  2.417701  0.288453
```

Here is a quick reference summary table of common functions. Each also takes an optional `level` parameter which applies only if the object has a *hierarchical index*.

Function	Description
<code>count</code>	Number of non-NA observations
<code>sum</code>	Sum of values
<code>mean</code>	Mean of values
<code>mad</code>	Mean absolute deviation
<code>median</code>	Arithmetic median of values
<code>min</code>	Minimum
<code>max</code>	Maximum
<code>mode</code>	Mode
<code>abs</code>	Absolute Value
<code>prod</code>	Product of values
<code>std</code>	Bessel-corrected sample standard deviation
<code>var</code>	Unbiased variance
<code>sem</code>	Standard error of the mean
<code>skew</code>	Sample skewness (3rd moment)
<code>kurt</code>	Sample kurtosis (4th moment)
<code>quantile</code>	Sample quantile (value at %)
<code>cumsum</code>	Cumulative sum
<code>cumprod</code>	Cumulative product
<code>cummax</code>	Cumulative maximum
<code>cummin</code>	Cumulative minimum

Note that by chance some NumPy methods, like `mean`, `std`, and `sum`, will exclude NAs on Series input by default:

```
In [87]: np.mean(df['one'])
Out[87]: -0.29596980138380163
```

```
In [88]: np.mean(df['one'].to_numpy())
Out[88]: nan
```

`Series.unique()` will return the number of unique non-NA values in a Series:

```
In [89]: series = pd.Series(np.random.randn(500))
In [90]: series[20:500] = np.nan
In [91]: series[10:20] = 5
In [92]: series.unique()
Out[92]: 11
```

Summarizing data: `describe`

There is a convenient `describe()` function which computes a variety of summary statistics about a Series or the columns of a DataFrame (excluding NAs of course):

```
In [93]: series = pd.Series(np.random.randn(1000))
In [94]: series[::2] = np.nan
In [95]: series.describe()
```

(continues on next page)

(continued from previous page)

```

Out [95]:
count      500.000000
mean        0.008270
std         0.957001
min        -2.832536
25%        -0.652563
50%         0.011414
75%         0.659473
max         3.179873
dtype: float64

In [96]: frame = pd.DataFrame(np.random.randn(1000, 5),
.....:                        columns=['a', 'b', 'c', 'd', 'e'])
.....:

In [97]: frame.iloc[:,2] = np.nan

In [98]: frame.describe()
Out [98]:

```

	a	b	c	d	e
count	500.000000	500.000000	500.000000	500.000000	500.000000
mean	-0.051793	0.014006	-0.088499	-0.065968	0.099254
std	0.946751	0.953261	1.012176	1.021467	0.939771
min	-2.778772	-2.932532	-3.194228	-2.490294	-2.640602
25%	-0.701138	-0.632182	-0.716483	-0.787017	-0.546624
50%	-0.075766	0.010519	-0.061189	-0.076329	0.095151
75%	0.620752	0.681123	0.642695	0.673043	0.743923
max	2.470484	2.415173	2.952825	2.850750	3.220515

You can select specific percentiles to include in the output:

```

In [99]: series.describe(percentiles=[.05, .25, .75, .95])
Out [99]:
count      500.000000
mean        0.008270
std         0.957001
min        -2.832536
5%         -1.640749
25%        -0.652563
50%         0.011414
75%         0.659473
95%         1.524857
max         3.179873
dtype: float64

```

By default, the median is always included.

For a non-numerical Series object, `describe()` will give a simple summary of the number of unique values and most frequently occurring values:

```

In [100]: s = pd.Series(['a', 'a', 'b', 'b', 'a', 'a', np.nan, 'c', 'd', 'a'])
In [101]: s.describe()

```

(continues on next page)

(continued from previous page)

```

Out [101]:
count      9
unique     4
top        a
freq       5
dtype: object

```

Note that on a mixed-type DataFrame object, `describe()` will restrict the summary to include only numerical columns or, if none are, only categorical columns:

```

In [102]: frame = pd.DataFrame({'a': ['Yes', 'Yes', 'No', 'No'], 'b': range(4)})

In [103]: frame.describe()
Out [103]:
           b
count  4.000000
mean   1.500000
std    1.290994
min    0.000000
25%    0.750000
50%    1.500000
75%    2.250000
max    3.000000

```

This behavior can be controlled by providing a list of types as `include/exclude` arguments. The special value `all` can also be used:

```

In [104]: frame.describe(include=['object'])
Out [104]:
           a
count     4
unique    2
top      Yes
freq     2

```

```

In [105]: frame.describe(include=['number'])
Out [105]:
           b
count  4.000000
mean   1.500000
std    1.290994
min    0.000000
25%    0.750000
50%    1.500000
75%    2.250000
max    3.000000

```

```

In [106]: frame.describe(include='all')
Out [106]:
           a           b
count     4  4.000000
unique    2           NaN
top      Yes           NaN

```

```
freq      2      NaN
mean     NaN  1.500000
std      NaN  1.290994
min      NaN  0.000000
25%     NaN  0.750000
50%     NaN  1.500000
75%     NaN  2.250000
max      NaN  3.000000
```

That feature relies on `select_dtypes`. Refer to there for details about accepted inputs.

Index of min/max values

The `idxmin()` and `idxmax()` functions on Series and DataFrame compute the index labels with the minimum and maximum corresponding values:

```
In [107]: s1 = pd.Series(np.random.randn(5))
```

```
In [108]: s1
Out[108]:
0   -1.882481
1    0.007554
2    0.851716
3   -0.395161
4   -0.304605
dtype: float64
```

```
In [109]: s1.idxmin(), s1.idxmax()
Out[109]: (0, 2)
```

```
In [110]: df1 = pd.DataFrame(np.random.randn(5, 3), columns=['A', 'B', 'C'])
```

```
In [111]: df1
Out[111]:
           A          B          C
0  0.029120 -1.109406 -0.690599
1 -1.083192  0.419577 -1.165015
2  1.112228  0.169718 -1.251593
3 -0.313268 -0.517805 -0.736270
4 -0.354983  0.601455  0.452575
```

```
In [112]: df1.idxmin(axis=0)
Out[112]:
A    1
B    0
C    2
dtype: int64
```

```
In [113]: df1.idxmax(axis=1)
Out[113]:
0    A
1    B
2    A
3    A
```

```
4    B
dtype: object
```

When there are multiple rows (or columns) matching the minimum or maximum value, `idxmin()` and `idxmax()` return the first matching index:

```
In [114]: df3 = pd.DataFrame([2, 1, 1, 3, np.nan], columns=['A'], index=list('edcba'))
```

```
In [115]: df3
Out[115]:
```

```
   A
e  2.0
d  1.0
c  1.0
b  3.0
a  NaN
```

```
In [116]: df3['A'].idxmin()
Out[116]: 'd'
```

Note: `idxmin` and `idxmax` are called `argmin` and `argmax` in NumPy.

Value counts (histogramming) / mode

The `value_counts()` Series method and top-level function computes a histogram of a 1D array of values. It can also be used as a function on regular arrays:

```
In [117]: data = np.random.randint(0, 7, size=50)
```

```
In [118]: data
```

```
Out[118]:
array([1, 1, 0, 4, 1, 3, 4, 5, 2, 3, 0, 6, 5, 1, 5, 4, 5, 2, 6, 3, 6, 6,
       1, 2, 0, 3, 3, 3, 4, 3, 2, 4, 4, 0, 3, 2, 5, 3, 5, 5, 6, 5, 1, 3,
       6, 5, 0, 6, 1, 1])
```

```
In [119]: s = pd.Series(data)
```

```
In [120]: s.value_counts()
```

```
Out[120]:
3    10
5     9
1     8
6     7
4     6
2     5
0     5
dtype: int64
```

```
In [121]: pd.value_counts(data)
```

```
Out[121]:
3    10
5     9
1     8
```

```
6    7
4    6
2    5
0    5
dtype: int64
```

Similarly, you can get the most frequently occurring value(s) (the mode) of the values in a Series or DataFrame:

```
In [122]: s5 = pd.Series([1, 1, 3, 3, 3, 5, 5, 7, 7, 7])

In [123]: s5.mode()
Out[123]:
0    3
1    7
dtype: int64

In [124]: df5 = pd.DataFrame({"A": np.random.randint(0, 7, size=50),
.....:                       "B": np.random.randint(-10, 15, size=50)})
.....:

In [125]: df5.mode()
Out[125]:
   A  B
0  1  1
1  4  2
```

Discretization and quantiling

Continuous values can be discretized using the `cut()` (bins based on values) and `qcut()` (bins based on sample quantiles) functions:

```
In [126]: arr = np.random.randn(20)

In [127]: factor = pd.cut(arr, 4)

In [128]: factor
Out[128]:
[(0.631, 1.318], (0.631, 1.318], (0.631, 1.318], (-0.0556, 0.631], (-0.742, -0.0556], ...
↪ (-0.742, -0.0556], (-0.742, -0.0556], (-0.742, -0.0556], (-0.0556, 0.631], (0.631, 1.
↪ 318]]
Length: 20
Categories (4, interval[float64]): [(-1.432, -0.742] < (-0.742, -0.0556] < (-0.0556, 0.
↪ 631] <
                                     (0.631, 1.318]]

In [129]: factor = pd.cut(arr, [-5, -1, 0, 1, 5])

In [130]: factor
Out[130]:
[(0, 1], (0, 1], (0, 1], (0, 1], (-1, 0], ..., (-1, 0], (-1, 0], (-1, 0], (0, 1], (1, 5]]
Length: 20
Categories (4, interval[int64]): [(-5, -1] < (-1, 0] < (0, 1] < (1, 5]]
```

`qcut()` computes sample quantiles. For example, we could slice up some normally distributed data into equal-size quartiles like so:

```
In [131]: arr = np.random.randn(30)
```

```
In [132]: factor = pd.qcut(arr, [0, .25, .5, .75, 1])
```

```
In [133]: factor
```

```
Out[133]:
```

```
[(-0.69, 0.0118], (0.874, 2.622], (0.0118, 0.874], (-0.69, 0.0118], (0.874, 2.622], ...,  
↪ (-1.7619999999999998, -0.69], (0.874, 2.622], (0.0118, 0.874], (0.874, 2.622], (0.0118,  
↪ 0.874]]
```

```
Length: 30
```

```
Categories (4, interval[float64]): [(-1.7619999999999998, -0.69] < (-0.69, 0.0118] < (0.  
↪ 0118, 0.874] <  
                                     (0.874, 2.622]]
```

```
In [134]: pd.value_counts(factor)
```

```
Out[134]:
```

```
(0.874, 2.622]      8  
(-1.7619999999999998, -0.69]  8  
(0.0118, 0.874]    7  
(-0.69, 0.0118]   7  
dtype: int64
```

We can also pass infinite values to define the bins:

```
In [135]: arr = np.random.randn(20)
```

```
In [136]: factor = pd.cut(arr, [-np.inf, 0, np.inf])
```

```
In [137]: factor
```

```
Out[137]:
```

```
[(-inf, 0.0], (0.0, inf], (-inf, 0.0], (-inf, 0.0], (0.0, inf], ..., (0.0, inf], (0.0,  
↪ inf], (0.0, inf], (-inf, 0.0], (0.0, inf]]
```

```
Length: 20
```

```
Categories (2, interval[float64]): [(-inf, 0.0] < (0.0, inf]]
```

3.3.6 Function application

To apply your own or another library's functions to pandas objects, you should be aware of the three methods below. The appropriate method to use depends on whether your function expects to operate on an entire `DataFrame` or `Series`, row- or column-wise, or elementwise.

1. *Tablewise Function Application*: `pipe()`
2. *Row or Column-wise Function Application*: `apply()`
3. *Aggregation API*: `agg()` and `transform()`
4. *Applying Elementwise Functions*: `applymap()`

Tablewise function application

`DataFrames` and `Series` can of course just be passed into functions. However, if the function needs to be called in a chain, consider using the `pipe()` method. Compare the following

```
# f, g, and h are functions taking and returning ``DataFrames``
>>> f(g(h(df), arg1=1), arg2=2, arg3=3)
```

with the equivalent

```
>>> (df.pipe(h)
...   .pipe(g, arg1=1)
...   .pipe(f, arg2=2, arg3=3))
```

Pandas encourages the second style, which is known as method chaining. `pipe` makes it easy to use your own or another library's functions in method chains, alongside pandas' methods.

In the example above, the functions `f`, `g`, and `h` each expected the `DataFrame` as the first positional argument. What if the function you wish to apply takes its data as, say, the second argument? In this case, provide `pipe` with a tuple of (callable, data_keyword). `.pipe` will route the `DataFrame` to the argument specified in the tuple.

For example, we can fit a regression using `statsmodels`. Their API expects a formula first and a `DataFrame` as the second argument, `data`. We pass in the function, keyword pair (`sm.ols`, `'data'`) to `pipe`:

```
In [138]: import statsmodels.formula.api as sm
In [139]: bb = pd.read_csv('data/baseball.csv', index_col='id')
In [140]: (bb.query('h > 0')
.....:      .assign(ln_h=lambda df: np.log(df.h))
.....:      .pipe((sm.ols, 'data'), 'hr ~ ln_h + year + g + C(lg)')
.....:      .fit()
.....:      .summary()
.....:      )
.....: )
```

Out[140]:

```
<class 'statsmodels.iolib.summary.Summary'>
"""
```

```

    specified.
[2] The condition number is large, 1.49e+07. This might indicate that there are
    strong multicollinearity or other numerical problems.
"""

```

The pipe method is inspired by unix pipes and more recently `dplyr` and `magrittr`, which have introduced the popular `%>%` (read pipe) operator for R. The implementation of `pipe` here is quite clean and feels right at home in python. We encourage you to view the source code of `pipe()`.

Row or column-wise function application

Arbitrary functions can be applied along the axes of a DataFrame using the `apply()` method, which, like the descriptive statistics methods, takes an optional `axis` argument:

```
In [141]: df.apply(np.mean)
```

```
Out[141]:
one      -0.295970
two       0.604425
three    0.096151
dtype: float64
```

```
In [142]: df.apply(np.mean, axis=1)
```

```
Out[142]:
a      -0.218790
b       0.205744
c       0.574443
d      -0.042369
dtype: float64
```

```
In [143]: df.apply(lambda x: x.max() - x.min())
```

```
Out[143]:
one      1.510204
two      2.159182
three    0.951019
dtype: float64
```

```
In [144]: df.apply(np.cumsum)
```

```
Out[144]:
      one      two      three
a -0.466716  0.029137      NaN
```

```
b -1.432415  1.996760 -0.384693
c -0.887909  2.609259  0.181633
d          NaN  2.417701  0.288453
```

```
In [145]: df.apply(np.exp)
Out[145]:
```

	one	two	three
a	0.627058	1.029566	NaN
b	0.380717	7.153656	0.680659
c	1.723756	1.845035	1.761782
d	NaN	0.825672	1.112734

The `apply()` method will also dispatch on a string method name.

```
In [146]: df.apply('mean')
Out[146]:
```

one	-0.295970
two	0.604425
three	0.096151

dtype: float64

```
In [147]: df.apply('mean', axis=1)
Out[147]:
```

a	-0.218790
b	0.205744
c	0.574443
d	-0.042369

dtype: float64

The return type of the function passed to `apply()` affects the type of the final output from `DataFrame.apply` for the default behaviour:

- If the applied function returns a `Series`, the final output is a `DataFrame`. The columns match the index of the `Series` returned by the applied function.
- If the applied function returns any other type, the final output is a `Series`.

This default behaviour can be overridden using the `result_type`, which accepts three options: `reduce`, `broadcast`, and `expand`. These will determine how list-like return values expand (or not) to a `DataFrame`.

`apply()` combined with some cleverness can be used to answer many questions about a data set. For example, suppose we wanted to extract the date where the maximum value for each column occurred:

```
In [148]: tsdf = pd.DataFrame(np.random.randn(1000, 3), columns=['A', 'B', 'C'],
.....:                        index=pd.date_range('1/1/2000', periods=1000))
.....:

In [149]: tsdf.apply(lambda x: x.idxmax())
Out[149]:
```

A	2002-01-27
B	2000-12-15
C	2001-05-30

dtype: datetime64[ns]

You may also pass additional arguments and keyword arguments to the `apply()` method. For instance, consider the following function you would like to apply:

```
def subtract_and_divide(x, sub, divide=1):
    return (x - sub) / divide
```

You may then apply this function as follows:

```
df.apply(subtract_and_divide, args=(5,), divide=3)
```

Another useful feature is the ability to pass Series methods to carry out some Series operation on each column or row:

```
In [150]: tsdf
```

```
Out[150]:
```

	A	B	C
2000-01-01	0.752721	-0.364275	0.134481
2000-01-02	0.826213	1.208276	-0.154643
2000-01-03	0.041831	0.479876	-0.956380
2000-01-04	NaN	NaN	NaN
2000-01-05	NaN	NaN	NaN
2000-01-06	NaN	NaN	NaN
2000-01-07	NaN	NaN	NaN
2000-01-08	-1.549128	1.145240	0.320799
2000-01-09	0.507849	-1.142744	-0.155781
2000-01-10	-0.169863	1.813758	0.771396

```
In [151]: tsdf.apply(pd.Series.interpolate)
```

```
Out[151]:
```

	A	B	C
2000-01-01	0.752721	-0.364275	0.134481
2000-01-02	0.826213	1.208276	-0.154643
2000-01-03	0.041831	0.479876	-0.956380
2000-01-04	-0.276361	0.612949	-0.700945
2000-01-05	-0.594552	0.746021	-0.445509
2000-01-06	-0.912744	0.879094	-0.190073
2000-01-07	-1.230936	1.012167	0.065363
2000-01-08	-1.549128	1.145240	0.320799
2000-01-09	0.507849	-1.142744	-0.155781
2000-01-10	-0.169863	1.813758	0.771396

Finally, `apply()` takes an argument `raw` which is `False` by default, which converts each row or column into a Series before applying the function. When set to `True`, the passed function will instead receive an ndarray object, which has positive performance implications if you do not need the indexing functionality.

Aggregation API

New in version 0.20.0.

The aggregation API allows one to express possibly multiple aggregation operations in a single concise way. This API is similar across pandas objects, see [groupby API](#), the [window functions API](#), and the [resample API](#). The entry point for aggregation is `DataFrame.aggregate()`, or the alias `DataFrame.agg()`.

We will use a similar starting frame from above:

```
In [152]: tsdf = pd.DataFrame(np.random.randn(10, 3), columns=['A', 'B', 'C'],
.....:                        index=pd.date_range('1/1/2000', periods=10))
```

(continues on next page)

(continued from previous page)

```

.....:
In [153]: tsdf.iloc[3:7] = np.nan
In [154]: tsdf
Out[154]:
           A         B         C
2000-01-01 -0.096512  0.747788  0.465973
2000-01-02  1.596492 -1.093022 -0.571837
2000-01-03  0.090216 -1.615127 -0.025061
2000-01-04         NaN         NaN         NaN
2000-01-05         NaN         NaN         NaN
2000-01-06         NaN         NaN         NaN
2000-01-07         NaN         NaN         NaN
2000-01-08 -0.051882 -0.369806 -1.363744
2000-01-09  2.243620 -1.063587  0.448386
2000-01-10  0.096756  0.781555 -1.912402

```

Using a single function is equivalent to `apply()`. You can also pass named methods as strings. These will return a `Series` of the aggregated output:

```

In [155]: tsdf.agg(np.sum)
Out[155]:
A    3.878691
B   -2.612201
C   -2.958685
dtype: float64

```

```

In [156]: tsdf.agg('sum')
Out[156]:
A    3.878691
B   -2.612201
C   -2.958685
dtype: float64

```

these are equivalent to a ```.sum()``` because we are aggregating
on a single function

```

In [157]: tsdf.sum()
Out[157]:
A    3.878691
B   -2.612201
C   -2.958685
dtype: float64

```

Single aggregations on a `Series` this will return a scalar value:

```

In [158]: tsdf.A.agg('sum')
Out[158]: 3.8786905103802636

```

Aggregating with multiple functions

You can pass multiple aggregation arguments as a list. The results of each of the passed functions will be a row in the resulting `DataFrame`. These are naturally named from the aggregation function.

```
In [159]: tsdf.agg(['sum'])
Out[159]:
```

	A	B	C
sum	3.878691	-2.612201	-2.958685

Multiple functions yield multiple rows:

```
In [160]: tsdf.agg(['sum', 'mean'])
Out[160]:
```

	A	B	C
sum	3.878691	-2.612201	-2.958685
mean	0.646448	-0.435367	-0.493114

On a `Series`, multiple functions return a `Series`, indexed by the function names:

```
In [161]: tsdf.A.agg(['sum', 'mean'])
Out[161]:
```

sum	3.878691
mean	0.646448

Name: A, dtype: float64

Passing a lambda function will yield a `<lambda>` named row:

```
In [162]: tsdf.A.agg(['sum', lambda x: x.mean()])
Out[162]:
```

sum	3.878691
<lambda>	0.646448

Name: A, dtype: float64

Passing a named function will yield that name for the row:

```
In [163]: def mymean(x):
.....:     return x.mean()
.....:

In [164]: tsdf.A.agg(['sum', mymean])
Out[164]:
```

sum	3.878691
mymean	0.646448

Name: A, dtype: float64

Aggregating with a dict

Passing a dictionary of column names to a scalar or a list of scalars, to `DataFrame.agg` allows you to customize which functions are applied to which columns. Note that the results are not in any particular order, you can use an `OrderedDict` instead to guarantee ordering.

```
In [165]: tsdf.agg({'A': 'mean', 'B': 'sum'})
Out[165]:
A    0.646448
B   -2.612201
dtype: float64
```

Passing a list-like will generate a `DataFrame` output. You will get a matrix-like output of all of the aggregators. The output will consist of all unique functions. Those that are not noted for a particular column will be `NaN`:

```
In [166]: tsdf.agg({'A': ['mean', 'min'], 'B': 'sum'})
Out[166]:
```

	A	B
mean	0.646448	NaN
min	-0.096512	NaN
sum	NaN	-2.612201

Mixed dtypes

When presented with mixed dtypes that cannot aggregate, `.agg` will only take the valid aggregations. This is similar to how `groupby .agg` works.

```
In [167]: mdf = pd.DataFrame({'A': [1, 2, 3],
.....:                       'B': [1., 2., 3.],
.....:                       'C': ['foo', 'bar', 'baz'],
.....:                       'D': pd.date_range('20130101', periods=3)})

In [168]: mdf.dtypes
Out[168]:
A          int64
B         float64
C          object
D    datetime64[ns]
dtype: object
```

```
In [169]: mdf.agg(['min', 'sum'])
Out[169]:
```

	A	B	C	D
min	1	1.0	bar	2013-01-01
sum	6	6.0	foobarbaz	NaT

Custom describe

With `.agg()` it is possible to easily create a custom describe function, similar to the built in *describe function*.

```
In [170]: from functools import partial

In [171]: q_25 = partial(pd.Series.quantile, q=0.25)
```

(continues on next page)

(continued from previous page)

```
In [172]: q_25.__name__ = '25%'

In [173]: q_75 = partial(pd.Series.quantile, q=0.75)

In [174]: q_75.__name__ = '75%'

In [175]: tsdf.agg(['count', 'mean', 'std', 'min', q_25, 'median', q_75, 'max'])
Out[175]:
```

	A	B	C
count	6.000000	6.000000	6.000000
mean	0.646448	-0.435367	-0.493114
std	1.010421	1.010352	0.980195
min	-0.096512	-1.615127	-1.912402
25%	-0.016358	-1.085664	-1.165767
median	0.093486	-0.716697	-0.298449
75%	1.221558	0.468389	0.330024
max	2.243620	0.781555	0.465973

Transform API

New in version 0.20.0.

The `transform()` method returns an object that is indexed the same (same size) as the original. This API allows you to provide *multiple* operations at the same time rather than one-by-one. Its API is quite similar to the `.agg` API.

We create a frame similar to the one used in the above sections.

```
In [176]: tsdf = pd.DataFrame(np.random.randn(10, 3), columns=['A', 'B', 'C'],
.....:                        index=pd.date_range('1/1/2000', periods=10))
.....:

In [177]: tsdf.iloc[3:7] = np.nan

In [178]: tsdf
Out[178]:
```

	A	B	C
2000-01-01	-0.646172	0.316546	0.442399
2000-01-02	-0.656399	-2.103519	0.373859
2000-01-03	0.479981	-0.047075	-0.002847
2000-01-04	NaN	NaN	NaN
2000-01-05	NaN	NaN	NaN
2000-01-06	NaN	NaN	NaN
2000-01-07	NaN	NaN	NaN
2000-01-08	1.029689	0.548916	0.960356
2000-01-09	0.800346	0.604359	0.324512
2000-01-10	-1.402090	-0.915210	0.541518

Transform the entire frame. `.transform()` allows input functions as: a NumPy function, a string function name or a user defined function.

```
In [179]: tsdf.transform(np.abs)
Out[179]:
```

	A	B	C
2000-01-01	0.646172	0.316546	0.442399
2000-01-02	0.656399	2.103519	0.373859
2000-01-03	0.479981	0.047075	0.002847
2000-01-04	NaN	NaN	NaN
2000-01-05	NaN	NaN	NaN
2000-01-06	NaN	NaN	NaN
2000-01-07	NaN	NaN	NaN
2000-01-08	1.029689	0.548916	0.960356
2000-01-09	0.800346	0.604359	0.324512
2000-01-10	1.402090	0.915210	0.541518

```
In [180]: tsdf.transform('abs')
```

```
Out[180]:
```

	A	B	C
2000-01-01	0.646172	0.316546	0.442399
2000-01-02	0.656399	2.103519	0.373859
2000-01-03	0.479981	0.047075	0.002847
2000-01-04	NaN	NaN	NaN
2000-01-05	NaN	NaN	NaN
2000-01-06	NaN	NaN	NaN
2000-01-07	NaN	NaN	NaN
2000-01-08	1.029689	0.548916	0.960356
2000-01-09	0.800346	0.604359	0.324512
2000-01-10	1.402090	0.915210	0.541518

```
In [181]: tsdf.transform(lambda x: x.abs())
```

```
Out[181]:
```

	A	B	C
2000-01-01	0.646172	0.316546	0.442399
2000-01-02	0.656399	2.103519	0.373859
2000-01-03	0.479981	0.047075	0.002847
2000-01-04	NaN	NaN	NaN
2000-01-05	NaN	NaN	NaN
2000-01-06	NaN	NaN	NaN
2000-01-07	NaN	NaN	NaN
2000-01-08	1.029689	0.548916	0.960356
2000-01-09	0.800346	0.604359	0.324512
2000-01-10	1.402090	0.915210	0.541518

Here `transform()` received a single function; this is equivalent to a `ufunc` application.

```
In [182]: np.abs(tsdf)
```

```
Out[182]:
```

	A	B	C
2000-01-01	0.646172	0.316546	0.442399
2000-01-02	0.656399	2.103519	0.373859
2000-01-03	0.479981	0.047075	0.002847
2000-01-04	NaN	NaN	NaN
2000-01-05	NaN	NaN	NaN
2000-01-06	NaN	NaN	NaN
2000-01-07	NaN	NaN	NaN
2000-01-08	1.029689	0.548916	0.960356
2000-01-09	0.800346	0.604359	0.324512

(continues on next page)

(continued from previous page)

```
2000-01-10  1.402090  0.915210  0.541518
```

Passing a single function to `.transform()` with a `Series` will yield a single `Series` in return.

```
In [183]: tsdf.A.transform(np.abs)
```

```
Out [183]:
```

```
2000-01-01    0.646172
2000-01-02    0.656399
2000-01-03    0.479981
2000-01-04         NaN
2000-01-05         NaN
2000-01-06         NaN
2000-01-07         NaN
2000-01-08    1.029689
2000-01-09    0.800346
2000-01-10    1.402090
Freq: D, Name: A, dtype: float64
```

Transform with multiple functions

Passing multiple functions will yield a column MultiIndexed DataFrame. The first level will be the original frame column names; the second level will be the names of the transforming functions.

```
In [184]: tsdf.transform([np.abs, lambda x: x + 1])
```

```
Out [184]:
```

	A		B		C	
	absolute	<lambda>	absolute	<lambda>	absolute	<lambda>
2000-01-01	0.646172	0.353828	0.316546	1.316546	0.442399	1.442399
2000-01-02	0.656399	0.343601	2.103519	-1.103519	0.373859	1.373859
2000-01-03	0.479981	1.479981	0.047075	0.952925	0.002847	0.997153
2000-01-04	NaN	NaN	NaN	NaN	NaN	NaN
2000-01-05	NaN	NaN	NaN	NaN	NaN	NaN
2000-01-06	NaN	NaN	NaN	NaN	NaN	NaN
2000-01-07	NaN	NaN	NaN	NaN	NaN	NaN
2000-01-08	1.029689	2.029689	0.548916	1.548916	0.960356	1.960356
2000-01-09	0.800346	1.800346	0.604359	1.604359	0.324512	1.324512
2000-01-10	1.402090	-0.402090	0.915210	0.084790	0.541518	1.541518

Passing multiple functions to a `Series` will yield a `DataFrame`. The resulting column names will be the transforming functions.

```
In [185]: tsdf.A.transform([np.abs, lambda x: x + 1])
```

```
Out [185]:
```

	absolute	<lambda>
2000-01-01	0.646172	0.353828
2000-01-02	0.656399	0.343601
2000-01-03	0.479981	1.479981
2000-01-04	NaN	NaN
2000-01-05	NaN	NaN
2000-01-06	NaN	NaN
2000-01-07	NaN	NaN

(continues on next page)

(continued from previous page)

```

2000-01-08  1.029689  2.029689
2000-01-09  0.800346  1.800346
2000-01-10  1.402090 -0.402090

```

Transforming with a dict

Passing a dict of functions will allow selective transforming per column.

```
In [186]: tsdf.transform({'A': np.abs, 'B': lambda x: x + 1})
```

```
Out [186]:
```

	A	B
2000-01-01	0.646172	1.316546
2000-01-02	0.656399	-1.103519
2000-01-03	0.479981	0.952925
2000-01-04	NaN	NaN
2000-01-05	NaN	NaN
2000-01-06	NaN	NaN
2000-01-07	NaN	NaN
2000-01-08	1.029689	1.548916
2000-01-09	0.800346	1.604359
2000-01-10	1.402090	0.084790

Passing a dict of lists will generate a MultiIndexed DataFrame with these selective transforms.

```
In [187]: tsdf.transform({'A': np.abs, 'B': [lambda x: x + 1, 'sqrt']})
```

```
Out [187]:
```

	A	B	
	absolute	<lambda>	sqrt
2000-01-01	0.646172	1.316546	0.562625
2000-01-02	0.656399	-1.103519	NaN
2000-01-03	0.479981	0.952925	NaN
2000-01-04	NaN	NaN	NaN
2000-01-05	NaN	NaN	NaN
2000-01-06	NaN	NaN	NaN
2000-01-07	NaN	NaN	NaN
2000-01-08	1.029689	1.548916	0.740889
2000-01-09	0.800346	1.604359	0.777405
2000-01-10	1.402090	0.084790	NaN

Applying elementwise functions

Since not all functions can be vectorized (accept NumPy arrays and return another array or value), the methods `applymap()` on DataFrame and analogously `map()` on Series accept any Python function taking a single value and returning a single value. For example:

```
In [188]: df4
```

```
Out [188]:
```

	one	two	three
a	-0.466716	0.029137	NaN
b	-0.965699	1.967624	-0.384693
c	0.544505	0.612498	0.566326

```
d      NaN -0.191558  0.106820
```

```
In [189]: def f(x):
.....:     return len(str(x))
.....:
```

```
In [190]: df4['one'].map(f)
Out[190]:
a      19
b      19
c      17
d       3
Name: one, dtype: int64
```

```
In [191]: df4.applymap(f)
Out[191]:
   one  two  three
a   19   20     3
b   19   18    19
c   17   17    18
d    3   20    18
```

`Series.map()` has an additional feature; it can be used to easily “link” or “map” values defined by a secondary series. This is closely related to *merging/joining functionality*:

```
In [192]: s = pd.Series(['six', 'seven', 'six', 'seven', 'six'],
.....:                  index=['a', 'b', 'c', 'd', 'e'])
.....:
```

```
In [193]: t = pd.Series({'six': 6., 'seven': 7.})
```

```
In [194]: s
Out[194]:
a      six
b     seven
c      six
d     seven
e      six
dtype: object
```

```
In [195]: s.map(t)
Out[195]:
a     6.0
b     7.0
c     6.0
d     7.0
e     6.0
dtype: float64
```

3.3.7 Reindexing and altering labels

`reindex()` is the fundamental data alignment method in pandas. It is used to implement nearly all other features relying on label-alignment functionality. To *reindex* means to conform the data to match a given set of labels along a particular axis. This accomplishes several things:

- Reorders the existing data to match a new set of labels
- Inserts missing value (NA) markers in label locations where no data for that label existed
- If specified, **fill** data for missing labels using logic (highly relevant to working with time series data)

Here is a simple example:

```
In [196]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])
```

```
In [197]: s
Out[197]:
a    1.910501
b   -0.247105
c   -1.134167
d   -1.591918
e    0.243080
dtype: float64
```

```
In [198]: s.reindex(['e', 'b', 'f', 'd'])
Out[198]:
e    0.243080
b   -0.247105
f         NaN
d   -1.591918
dtype: float64
```

Here, the `f` label was not contained in the Series and hence appears as `NaN` in the result.

With a DataFrame, you can simultaneously reindex the index and columns:

```
In [199]: df
Out[199]:
```

	one	two	three
a	-0.466716	0.029137	NaN
b	-0.965699	1.967624	-0.384693
c	0.544505	0.612498	0.566326
d	NaN	-0.191558	0.106820

```
In [200]: df.reindex(index=['c', 'f', 'b'], columns=['three', 'two', 'one'])
Out[200]:
```

	three	two	one
c	0.566326	0.612498	0.544505
f	NaN	NaN	NaN
b	-0.384693	1.967624	-0.965699

You may also use `reindex` with an `axis` keyword:

```
In [201]: df.reindex(['c', 'f', 'b'], axis='index')
Out[201]:
```

	one	two	three
c	0.544505	0.612498	0.566326
f	NaN	NaN	NaN
b	-0.965699	1.967624	-0.384693

Note that the `Index` objects containing the actual axis labels can be **shared** between objects. So if we have a Series and a DataFrame, the following can be done:

```
In [202]: rs = s.reindex(df.index)
```

```
In [203]: rs
Out[203]:
a    1.910501
b   -0.247105
c   -1.134167
d   -1.591918
dtype: float64
```

```
In [204]: rs.index is df.index
Out[204]: True
```

This means that the reindexed Series's index is the same Python object as the DataFrame's index.

New in version 0.21.0.

`DataFrame.reindex()` also supports an “axis-style” calling convention, where you specify a single `labels` argument and the `axis` it applies to.

```
In [205]: df.reindex(['c', 'f', 'b'], axis='index')
Out[205]:
      one    two    three
c  0.544505  0.612498  0.566326
f      NaN     NaN     NaN
b -0.965699  1.967624 -0.384693
```

```
In [206]: df.reindex(['three', 'two', 'one'], axis='columns')
Out[206]:
      three    two    one
a      NaN  0.029137 -0.466716
b -0.384693  1.967624 -0.965699
c  0.566326  0.612498  0.544505
d  0.106820 -0.191558     NaN
```

MultiIndex / Advanced Indexing is an even more concise way of doing reindexing.

Note: When writing performance-sensitive code, there is a good reason to spend some time becoming a reindexing ninja: **many operations are faster on pre-aligned data**. Adding two unaligned DataFrames internally triggers a reindexing step. For exploratory analysis you will hardly notice the difference (because `reindex` has been heavily optimized), but when CPU cycles matter sprinkling a few explicit `reindex` calls here and there can have an impact.

Reindexing to align with another object

You may wish to take an object and reindex its axes to be labeled the same as another object. While the syntax for this is straightforward albeit verbose, it is a common enough operation that the `reindex_like()` method is available to make this simpler:

```
In [207]: df2
Out[207]:
      one    two
a -0.466716  0.029137
b -0.965699  1.967624
```

```
c 0.544505 0.612498
```

```
In [208]: df3
```

```
Out[208]:
```

```
      one      two
a -0.170747 -0.840616
b -0.669729  1.097871
c  0.840475 -0.257255
```

```
In [209]: df.reindex_like(df2)
```

```
Out[209]:
```

```
      one      two
a -0.466716  0.029137
b -0.965699  1.967624
c  0.544505  0.612498
```

Aligning objects with each other with align

The `align()` method is the fastest way to simultaneously align two objects. It supports a `join` argument (related to *joining and merging*):

- `join='outer'`: take the union of the indexes (default)
- `join='left'`: use the calling object's index
- `join='right'`: use the passed object's index
- `join='inner'`: intersect the indexes

It returns a tuple with both of the reindexed Series:

```
In [210]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])
```

```
In [211]: s1 = s[:4]
```

```
In [212]: s2 = s[1:]
```

```
In [213]: s1.align(s2)
```

```
Out[213]:
```

```
(a  -1.362711
 b   0.385943
 c  -0.538184
 d   0.502612
 e         NaN
dtype: float64, a         NaN
 b   0.385943
 c  -0.538184
 d   0.502612
 e  -1.491718
dtype: float64)
```

```
In [214]: s1.align(s2, join='inner')
```

```
Out[214]:
```

```
(b   0.385943
 c  -0.538184
 d   0.502612)
```

```
dtype: float64, b    0.385943
c   -0.538184
d    0.502612
dtype: float64)
```

```
In [215]: s1.align(s2, join='left')
```

```
Out[215]:
```

```
(a   -1.362711
b    0.385943
c   -0.538184
d    0.502612
dtype: float64, a           NaN
b    0.385943
c   -0.538184
d    0.502612
dtype: float64)
```

For DataFrames, the join method will be applied to both the index and the columns by default:

```
In [216]: df.align(df2, join='inner')
```

```
Out[216]:
```

```
(      one      two
a -0.466716  0.029137
b -0.965699  1.967624
c  0.544505  0.612498,      one      two
a -0.466716  0.029137
b -0.965699  1.967624
c  0.544505  0.612498)
```

You can also pass an axis option to only align on the specified axis:

```
In [217]: df.align(df2, join='inner', axis=0)
```

```
Out[217]:
```

```
(      one      two      three
a -0.466716  0.029137      NaN
b -0.965699  1.967624 -0.384693
c  0.544505  0.612498  0.566326,      one      two
a -0.466716  0.029137
b -0.965699  1.967624
c  0.544505  0.612498)
```

If you pass a Series to `DataFrame.align()`, you can choose to align both objects either on the DataFrame's index or columns using the `axis` argument:

```
In [218]: df.align(df2.iloc[0], axis=1)
```

```
Out[218]:
```

```
(      one      three      two
a -0.466716      NaN  0.029137
b -0.965699 -0.384693  1.967624
c  0.544505  0.566326  0.612498
d      NaN  0.106820 -0.191558, one      -0.466716
three      NaN
two      0.029137
Name: a, dtype: float64)
```

Filling while reindexing

`reindex()` takes an optional parameter `method` which is a filling method chosen from the following table:

Method	Action
pad / ffill	Fill values forward
bfill / backfill	Fill values backward
nearest	Fill from the nearest index value

We illustrate these fill methods on a simple Series:

```
In [219]: rng = pd.date_range('1/3/2000', periods=8)
```

```
In [220]: ts = pd.Series(np.random.randn(8), index=rng)
```

```
In [221]: ts2 = ts[[0, 3, 6]]
```

```
In [222]: ts
```

```
Out[222]:
```

```
2000-01-03   -0.267818
2000-01-04    0.951544
2000-01-05    1.220097

```

```

In [226]: ts2.reindex(ts.index, method='bfill')
Out[226]:
2000-01-03   -0.267818
2000-01-04    1.083557
2000-01-05    1.083557
2000-01-06    1.083557
2000-01-07    0.617631
2000-01-08    0.617631
2000-01-09    0.617631
2000-01-10         NaN
Freq: D, dtype: float64

```

```

In [227]: ts2.reindex(ts.index, method='nearest')
Out[227]:
2000-01-03   -0.267818
2000-01-04   -0.267818
2000-01-05    1.083557
2000-01-06    1.083557
2000-01-07    1.083557
2000-01-08    0.617631
2000-01-09    0.617631
2000-01-10    0.617631
Freq: D, dtype: float64

```

These methods require that the indexes are **ordered** increasing or decreasing.

Note that the same result could have been achieved using *fillna* (except for `method='nearest'`) or *interpolate*:

```

In [228]: ts2.reindex(ts.index).fillna(method='ffill')
Out[228]:
2000-01-03   -0.267818
2000-01-04   -0.267818
2000-01-05   -0.267818
2000-01-06    1.083557
2000-01-07    1.083557
2000-01-08    1.083557
2000-01-09    0.617631
2000-01-10    0.617631
Freq: D, dtype: float64

```

`reindex()` will raise a `ValueError` if the index is not monotonically increasing or decreasing. `fillna()` and `interpolate()` will not perform any checks on the order of the index.

Limits on filling while reindexing

The `limit` and `tolerance` arguments provide additional control over filling while reindexing. `Limit` specifies the maximum count of consecutive matches:

```
In [229]: ts2.reindex(ts.index, method='ffill', limit=1)
Out [229]:
2000-01-03    -0.267818
2000-01-04    -0.267818
2000-01-05         NaN
2000-01-06     1.083557
2000-01-07     1.083557
2000-01-08         NaN
2000-01-09     0.617631
2000-01-10     0.617631
Freq: D, dtype: float64
```

In contrast, `tolerance` specifies the maximum distance between the index and indexer values:

```
In [230]: ts2.reindex(ts.index, method='ffill', tolerance='1 day')
Out [230]:
2000-01-03    -0.267818
2000-01-04    -0.267818
2000-01-05         NaN
2000-01-06     1.083557
2000-01-07     1.083557
2000-01-08         NaN
2000-01-09     0.617631
2000-01-10     0.617631
Freq: D, dtype: float64
```

Notice that when used on a `DatetimeIndex`, `TimedeltaIndex` or `PeriodIndex`, `tolerance` will be coerced into a `Timedelta` if possible. This allows you to specify tolerance with appropriate strings.

Dropping labels from an axis

A method closely related to `reindex` is the `drop()` function. It removes a set of labels from an axis:

```
In [231]: df
Out [231]:
      one    two    three
a -0.466716  0.029137    NaN
b -0.965699  1.967624 -0.384693
c  0.544505  0.612498  0.566326
d         NaN -0.191558  0.106820
```

```
In [232]: df.drop(['a', 'd'], axis=0)
Out [232]:
      one    two    three
b -0.965699  1.967624 -0.384693
c  0.544505  0.612498  0.566326
```

```
In [233]: df.drop(['one'], axis=1)
Out [233]:
      two    three
a  0.029137    NaN
b  1.967624 -0.384693
c  0.612498  0.566326
```

```
d -0.191558  0.106820
```

Note that the following also works, but is a bit less obvious / clean:

```
In [234]: df.reindex(df.index.difference(['a', 'd']))
```

```
Out[234]:
```

```
      one      two      three
b -0.965699  1.967624 -0.384693
c  0.544505  0.612498  0.566326
```

Renaming / mapping labels

The `rename()` method allows you to relabel an axis based on some mapping (a dict or Series) or an arbitrary function.

```
In [235]: s
```

```
Out[235]:
```

```
a  -1.362711
b   0.385943
c  -0.538184
d   0.502612
e  -1.491718
dtype: float64
```

```
In [236]: s.rename(str.upper)
```

```
Out[236]:
```

```
A  -1.362711
B   0.385943
C  -0.538184
D   0.502612
E  -1.491718
dtype: float64
```

If you pass a function, it must return a value when called with any of the labels (and must produce a set of unique values). A dict or Series can also be used:

```
In [237]: df.rename(columns={'one': 'foo', 'two': 'bar'},
.....:                index={'a': 'apple', 'b': 'banana', 'd': 'durian'})
.....:
```

```
Out[237]:
```

```
      foo      bar      three
apple -0.466716  0.029137      NaN
banana -0.965699  1.967624 -0.384693
c       0.544505  0.612498  0.566326
durian      NaN -0.191558  0.106820
```

If the mapping doesn't include a column/index label, it isn't renamed. Note that extra labels in the mapping don't throw an error.

New in version 0.21.0.

`DataFrame.rename()` also supports an “axis-style” calling convention, where you specify a single mapper and the axis to apply that mapping to.

```
In [238]: df.rename({'one': 'foo', 'two': 'bar'}, axis='columns')
```

```
Out[238]:
```

```

      foo      bar      three
a -0.466716  0.029137      NaN
b -0.965699  1.967624 -0.384693
c  0.544505  0.612498  0.566326
d      NaN -0.191558  0.106820

```

```
In [239]: df.rename({'a': 'apple', 'b': 'banana', 'd': 'durian'}, axis='index')
Out[239]:
```

```

      one      two      three
apple -0.466716  0.029137      NaN
banana -0.965699  1.967624 -0.384693
c      0.544505  0.612498  0.566326
durian      NaN -0.191558  0.106820

```

The `rename()` method also provides an `inplace` named parameter that is by default `False` and copies the underlying data. Pass `inplace=True` to rename the data in place.

New in version 0.18.0.

Finally, `rename()` also accepts a scalar or list-like for altering the `Series.name` attribute.

```

In [240]: s.rename("scalar-name")
Out[240]:
a    -1.362711
b     0.385943
c    -0.538184
d     0.502612
e    -1.491718
Name: scalar-name, dtype: float64

```

New in version 0.24.0.

The methods `rename_axis()` and `rename_index()` allow specific names of a *MultiIndex* to be changed (as opposed to the labels).

```

In [241]: df = pd.DataFrame({'x': [1, 2, 3, 4, 5, 6],
.....:                      'y': [10, 20, 30, 40, 50, 60]},
.....:                      index=pd.MultiIndex.from_product(['a', 'b', 'c'], [1, 2]),
.....:                      names=['let', 'num'])
.....:

```

```
In [242]: df
```

```

Out[242]:
      x  y
let num
a  1  1  10
   2  2  20
b  1  3  30
   2  4  40
c  1  5  50
   2  6  60

```

```
In [243]: df.rename_axis(index={'let': 'abc'})
```

```

Out[243]:
      x  y
abc num
a  1  1  10

```

```

      2    2  20
b     1    3  30
      2    4  40
c     1    5  50
      2    6  60

```

```
In [244]: df.rename_axis(index=str.upper)
Out[244]:
```

```

      x    y
LET NUM
a     1    1  10
      2    2  20
b     1    3  30
      2    4  40
c     1    5  50
      2    6  60

```

3.3.8 Iteration

The behavior of basic iteration over pandas objects depends on the type. When iterating over a Series, it is regarded as array-like, and basic iteration produces the values. DataFrames follow the dict-like convention of iterating over the “keys” of the objects.

In short, basic iteration (`for i in object`) produces:

- **Series:** values
- **DataFrame:** column labels

Thus, for example, iterating over a DataFrame gives you the column names:

```
In [245]: df = pd.DataFrame({'col1': np.random.randn(3),
.....:                      'col2': np.random.randn(3)}, index=['a', 'b', 'c'])
.....:

In [246]: for col in df:
.....:     print(col)
.....:
col1
col2
```

Pandas objects also have the dict-like `items()` method to iterate over the (key, value) pairs.

To iterate over the rows of a DataFrame, you can use the following methods:

- `iterrows()`: Iterate over the rows of a DataFrame as (index, Series) pairs. This converts the rows to Series objects, which can change the dtypes and has some performance implications.
- `itertuples()`: Iterate over the rows of a DataFrame as namedtuples of the values. This is a lot faster than `iterrows()`, and is in most cases preferable to use to iterate over the values of a DataFrame.

Warning: Iterating through pandas objects is generally **slow**. In many cases, iterating manually over the rows is not needed and can be avoided with one of the following approaches:

- Look for a *vectorized* solution: many operations can be performed using built-in methods or NumPy functions, (boolean) indexing, ...

- When you have a function that cannot work on the full DataFrame/Series at once, it is better to use `apply()` instead of iterating over the values. See the docs on *function application*.
- If you need to do iterative manipulations on the values but performance is important, consider writing the inner loop with cython or numba. See the *enhancing performance* section for some examples of this approach.

Warning: You should **never modify** something you are iterating over. This is not guaranteed to work in all cases. Depending on the data types, the iterator returns a copy and not a view, and writing to it will have no effect!

For example, in the following case setting the value has no effect:

```
In [247]: df = pd.DataFrame({'a': [1, 2, 3], 'b': ['a', 'b', 'c']})

In [248]: for index, row in df.iterrows():
.....:     row['a'] = 10
.....:

In [249]: df
Out[249]:
   a b
0  1 a
1  2 b
2  3 c
```

items

Consistent with the dict-like interface, `items()` iterates through key-value pairs:

- **Series:** (index, scalar value) pairs
- **DataFrame:** (column, Series) pairs

For example:

```
In [250]: for label, ser in df.items():
.....:     print(label)
.....:     print(ser)
.....:

a
0    1
1    2
2    3
Name: a, dtype: int64

b
0    a
1    b
2    c
Name: b, dtype: object
```

iterrows

`iterrows()` allows you to iterate through the rows of a DataFrame as Series objects. It returns an iterator yielding each index value along with a Series containing the data in each row:

```
In [251]: for row_index, row in df.iterrows():
.....:     print(row_index, row, sep='\n')
.....:
0
a    1
b    a
Name: 0, dtype: object
1
a    2
b    b
Name: 1, dtype: object
2
a    3
b    c
Name: 2, dtype: object
```

Note: Because `iterrows()` returns a Series for each row, it does **not** preserve dtypes across the rows (dtypes are preserved across columns for DataFrames). For example,

```
In [252]: df_orig = pd.DataFrame([[1, 1.5]], columns=['int', 'float'])

In [253]: df_orig.dtypes
Out[253]:
int          int64
float       float64
dtype: object

In [254]: row = next(df_orig.iterrows())[1]

In [255]: row
Out[255]:
int          1.0
float        1.5
Name: 0, dtype: float64
```

All values in `row`, returned as a Series, are now upcasted to floats, also the original integer value in column `x`:

```
In [256]: row['int'].dtype
Out[256]: dtype('float64')
```

```
In [257]: df_orig['int'].dtype
Out[257]: dtype('int64')
```

To preserve dtypes while iterating over the rows, it is better to use `itertuples()` which returns namedtuples of the values and which is generally much faster than `iterrows()`.

For instance, a contrived way to transpose the DataFrame would be:

```
In [258]: df2 = pd.DataFrame({'x': [1, 2, 3], 'y': [4, 5, 6]})
```

```
In [259]: print(df2)
```

```
   x  y
0  1  4
1  2  5
2  3  6
```

```
In [260]: print(df2.T)
```

```
   0  1  2
x  1  2  3
y  4  5  6
```

```
In [261]: df2_t = pd.DataFrame({idx: values for idx, values in df2.iterrows()})
```

```
In [262]: print(df2_t)
```

```
   0  1  2
x  1  2  3
y  4  5  6
```

itertuples

The `itertuples()` method will return an iterator yielding a namedtuple for each row in the DataFrame. The first element of the tuple will be the row's corresponding index value, while the remaining values are the row values.

For instance:

```
In [263]: for row in df.itertuples():
.....:     print(row)
.....:
Pandas(Index=0, a=1, b='a')
Pandas(Index=1, a=2, b='b')
Pandas(Index=2, a=3, b='c')
```

This method does not convert the row to a Series object; it merely returns the values inside a namedtuple. Therefore, `itertuples()` preserves the data type of the values and is generally faster as `iterrows()`.

Note: The column names will be renamed to positional names if they are invalid Python identifiers, repeated, or start with an underscore. With a large number of columns (>255), regular tuples are returned.

3.3.9 .dt accessor

`Series` has an accessor to succinctly return datetime like properties for the *values* of the Series, if it is a datetime/period like Series. This will return a Series, indexed like the existing Series.

```
# datetime
```

```
In [264]: s = pd.Series(pd.date_range('20130101 09:10:12', periods=4))
```

```
In [265]: s
```

```
Out[265]:
```

```
0    2013-01-01 09:10:12
```

```

1 2013-01-02 09:10:12
2 2013-01-03 09:10:12
3 2013-01-04 09:10:12
dtype: datetime64[ns]

```

```

In [266]: s.dt.hour
Out[266]:
0    9
1    9
2    9
3    9
dtype: int64

```

```

In [267]: s.dt.second
Out[267]:
0    12
1    12
2    12
3    12
dtype: int64

```

```

In [268]: s.dt.day
Out[268]:
0    1
1    2
2    3
3    4
dtype: int64

```

This enables nice expressions like this:

```

In [269]: s[s.dt.day == 2]
Out[269]:
1 2013-01-02 09:10:12
dtype: datetime64[ns]

```

You can easily produce tz aware transformations:

```
In [270]: stz = s.dt.tz_localize('US/Eastern')
```

```

In [271]: stz
Out[271]:
0 2013-01-01 09:10:12-05:00
1 2013-01-02 09:10:12-05:00
2 2013-01-03 09:10:12-05:00
3 2013-01-04 09:10:12-05:00
dtype: datetime64[ns, US/Eastern]

```

```

In [272]: stz.dt.tz
Out[272]: <DstTzInfo 'US/Eastern' LMT-1 day, 19:04:00 STD>

```

You can also chain these types of operations:

```

In [273]: s.dt.tz_localize('UTC').dt.tz_convert('US/Eastern')
Out[273]:

```

(continues on next page)

(continued from previous page)

```
0    2013-01-01 04:10:12-05:00
1    2013-01-02 04:10:12-05:00
2    2013-01-03 04:10:12-05:00
3    2013-01-04 04:10:12-05:00
dtype: datetime64[ns, US/Eastern]
```

You can also format datetime values as strings with `Series.dt.strftime()` which supports the same format as the standard `strftime()`.

```
# DatetimeIndex
In [274]: s = pd.Series(pd.date_range('20130101', periods=4))
```

```
In [275]: s
Out[275]:
0    2013-01-01
1    2013-01-02
2    2013-01-03
3    2013-01-04
dtype: datetime64[ns]
```

```
In [276]: s.dt.strftime('%Y/%m/%d')
Out[276]:
0    2013/01/01
1    2013/01/02
2    2013/01/03
3    2013/01/04
dtype: object
```

```
# PeriodIndex
In [277]: s = pd.Series(pd.period_range('20130101', periods=4))
```

```
In [278]: s
Out[278]:
0    2013-01-01
1    2013-01-02
2    2013-01-03
3    2013-01-04
dtype: period[D]
```

```
In [279]: s.dt.strftime('%Y/%m/%d')
Out[279]:
0    2013/01/01
1    2013/01/02
2    2013/01/03
3    2013/01/04
dtype: object
```

The `.dt` accessor works for period and timedelta dtypes.

```
# period
In [280]: s = pd.Series(pd.period_range('20130101', periods=4, freq='D'))
```

```
In [281]: s
Out[281]:
0    2013-01-01
```

```
1    2013-01-02
2    2013-01-03
3    2013-01-04
dtype: period[D]

In [282]: s.dt.year
Out[282]:
0    2013
1    2013
2    2013
3    2013
dtype: int64

In [283]: s.dt.day
Out[283]:
0    1
1    2
2    3
3    4
dtype: int64

# timedelta
In [284]: s = pd.Series(pd.timedelta_range('1 day 00:00:05', periods=4, freq='s'))

In [285]: s
Out[285]:
0    1 days 00:00:05
1    1 days 00:00:06
2    1 days 00:00:07
3    1 days 00:00:08
dtype: timedelta64[ns]

In [286]: s.dt.days
Out[286]:
0    1
1    1
2    1
3    1
dtype: int64

In [287]: s.dt.seconds
Out[287]:
0    5
1    6
2    7
3    8
dtype: int64

In [288]: s.dt.components
Out[288]:
   days  hours  minutes  seconds  milliseconds  microseconds  nanoseconds
0     1     0         0         5             0             0             0
1     1     0         0         6             0             0             0
2     1     0         0         7             0             0             0
```

3 1 0 0 8 0 0 0

Note: `Series.dt` will raise a `TypeError` if you access with a non-datetime-like values.

3.3.10 Vectorized string methods

`Series` is equipped with a set of string processing methods that make it easy to operate on each element of the array. Perhaps most importantly, these methods exclude missing/NA values automatically. These are accessed via the `Series`'s `str` attribute and generally have names matching the equivalent (scalar) built-in string methods. For example:

```
In [289]: s = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca', np.nan, 'CABA', 'dog',
↳ 'cat'])

In [290]: s.str.lower()
Out[290]:
0      a
1      b
2      c
3    aaba
4    baca
5     NaN
6    caba
7     dog
8     cat
dtype: object
```

Powerful pattern-matching methods are provided as well, but note that pattern-matching generally uses regular expressions by default (and in some cases always uses them).

Please see *Vectorized String Methods* for a complete description.

3.3.11 Sorting

Pandas supports three kinds of sorting: sorting by index labels, sorting by column values, and sorting by a combination of both.

By index

The `Series.sort_index()` and `DataFrame.sort_index()` methods are used to sort a pandas object by its index levels.

```
In [291]: df = pd.DataFrame({
.....:     'one': pd.Series(np.random.randn(3), index=['a', 'b', 'c']),
.....:     'two': pd.Series(np.random.randn(4), index=['a', 'b', 'c', 'd']),
.....:     'three': pd.Series(np.random.randn(3), index=['b', 'c', 'd'])})
.....:
```

```
In [292]: unsorted_df = df.reindex(index=['a', 'd', 'c', 'b'],
.....:                               columns=['three', 'two', 'one'])
.....:
```

```

In [293]: unsorted_df
Out[293]:
      three      two      one
a      NaN  0.498142 -0.579017
d -1.636064 -0.051421      NaN
c  0.439120 -1.425223 -1.211745
b  1.021821  0.226007  1.192046

# DataFrame
In [294]: unsorted_df.sort_index()
Out[294]:
      three      two      one
a      NaN  0.498142 -0.579017
b  1.021821  0.226007  1.192046
c  0.439120 -1.425223 -1.211745
d -1.636064 -0.051421      NaN

In [295]: unsorted_df.sort_index(ascending=False)
Out[295]:
      three      two      one
d -1.636064 -0.051421      NaN
c  0.439120 -1.425223 -1.211745
b  1.021821  0.226007  1.192046
a      NaN  0.498142 -0.579017

In [296]: unsorted_df.sort_index(axis=1)
Out[296]:
      one      three      two
a -0.579017      NaN  0.498142
d      NaN -1.636064 -0.051421
c -1.211745  0.439120 -1.425223
b  1.192046  1.021821  0.226007

# Series
In [297]: unsorted_df['three'].sort_index()
Out[297]:
a      NaN
b  1.021821
c  0.439120
d  -1.636064
Name: three, dtype: float64

```

By values

The `Series.sort_values()` method is used to sort a *Series* by its values. The `DataFrame.sort_values()` method is used to sort a *DataFrame* by its column or row values. The optional `by` parameter to `DataFrame.sort_values()` may be used to specify one or more columns to use to determine the sorted order.

```

In [298]: df1 = pd.DataFrame({'one': [2, 1, 1, 1],
.....:                       'two': [1, 3, 2, 4],
.....:                       'three': [5, 4, 3, 2]})
.....:

```

(continues on next page)

(continued from previous page)

```
In [299]: df1.sort_values(by='two')
```

```
Out[299]:
```

	one	two	three
0	2	1	5
2	1	2	3
1	1	3	4
3	1	4	2

The `by` parameter can take a list of column names, e.g.:

```
In [300]: df1[['one', 'two', 'three']].sort_values(by=['one', 'two'])
```

```
Out[300]:
```

	one	two	three
2	1	2	3
1	1	3	4
3	1	4	2
0	2	1	5

These methods have special treatment of NA values via the `na_position` argument:

```
In [301]: s[2] = np.nan
```

```
In [302]: s.sort_values()
```

```
Out[302]:
```

0	A
3	Aaba
1	B
4	Baca
6	CABA
8	cat
7	dog
2	NaN
5	NaN

dtype: object

```
In [303]: s.sort_values(na_position='first')
```

```
Out[303]:
```

2	NaN
5	NaN
0	A
3	Aaba
1	B
4	Baca
6	CABA
8	cat
7	dog

dtype: object

By indexes and values

New in version 0.23.0.

Strings passed as the `by` parameter to `DataFrame.sort_values()` may refer to either columns or index level names.

```
# Build MultiIndex
In [304]: idx = pd.MultiIndex.from_tuples([('a', 1), ('a', 2), ('a', 2),
.....:                                   ('b', 2), ('b', 1), ('b', 1)])
.....:

In [305]: idx.names = ['first', 'second']

# Build DataFrame
In [306]: df_multi = pd.DataFrame({'A': np.arange(6, 0, -1)},
.....:                             index=idx)
.....:

In [307]: df_multi
Out[307]:
```

		A
first	second	
a	1	6
	2	5
	2	4
b	2	3
	1	2
	1	1

Sort by 'second' (index) and 'A' (column)

```
In [308]: df_multi.sort_values(by=['second', 'A'])
Out[308]:
```

		A
first	second	
b	1	1
	1	2
a	1	6
b	2	3
a	2	4
	2	5

Note: If a string matches both a column name and an index level name then a warning is issued and the column takes precedence. This will result in an ambiguity error in a future version.

searchsorted

Series has the `searchsorted()` method, which works similarly to `numpy.ndarray.searchsorted()`.

```
In [309]: ser = pd.Series([1, 2, 3])
```

```
In [310]: ser.searchsorted([0, 3])
Out[310]: array([0, 2])
```

```
In [311]: ser.searchsorted([0, 4])
```

```
Out[311]: array([0, 3])
```

```
In [312]: ser.searchsorted([1, 3], side='right')
Out[312]: array([1, 3])
```

```
In [313]: ser.searchsorted([1, 3], side='left')
Out[313]: array([0, 2])
```

```
In [314]: ser = pd.Series([3, 1, 2])
```

```
In [315]: ser.searchsorted([0, 3], sorter=np.argsort(ser))
Out[315]: array([0, 2])
```

smallest / largest values

Series has the `nsmallest()` and `nlargest()` methods which return the smallest or largest n values. For a large Series this can be much faster than sorting the entire Series and calling `head(n)` on the result.

```
In [316]: s = pd.Series(np.random.permutation(10))
```

```
In [317]: s
```

```
Out[317]:
```

```
0    3
1    0
2    2
3    6
4    9
5    7
6    4
7    1
8    8
9    5
```

```
dtype: int64
```

```
In [318]: s.sort_values()
```

```
Out[318]:
```

```
1    0
7    1
2    2
0    3
6    4
9    5
3    6
5    7
8    8
4    9
```

```
dtype: int64
```

```
In [319]: s.nsmallest(3)
```

```
Out[319]:
```

```
1    0
7    1
2    2
```

```
dtype: int64
```

```
In [320]: s.nlargest(3)
```

```
Out[320]:
```

```
4    9
8    8
5    7
```

```
dtype: int64
```

DataFrame also has the `nlargest` and `nsmallest` methods.

```
In [321]: df = pd.DataFrame({'a': [-2, -1, 1, 10, 8, 11, -1],
.....:                      'b': list('abdceff'),
.....:                      'c': [1.0, 2.0, 4.0, 3.2, np.nan, 3.0, 4.0]})
.....:
```

```
In [322]: df.nlargest(3, 'a')
```

```
Out[322]:
```

```
   a  b  c
5  11 f  3.0
3  10 c  3.2
4   8 e  NaN
```

```
In [323]: df.nlargest(5, ['a', 'c'])
```

```
Out[323]:
```

```
   a  b  c
5  11 f  3.0
3  10 c  3.2
4   8 e  NaN
2   1 d  4.0
6  -1 f  4.0
```

```
In [324]: df.nsmallest(3, 'a')
```

```
Out[324]:
```

```
   a  b  c
0  -2 a  1.0
1  -1 b  2.0
6  -1 f  4.0
```

```
In [325]: df.nsmallest(5, ['a', 'c'])
```

```
Out[325]:
```

```
   a  b  c
0  -2 a  1.0
1  -1 b  2.0
6  -1 f  4.0
2   1 d  4.0
4   8 e  NaN
```

Sorting by a MultiIndex column

You must be explicit about sorting when the column is a MultiIndex, and fully specify all levels to by.

```
In [326]: df1.columns = pd.MultiIndex.from_tuples([('a', 'one'),
.....:                                          ('a', 'two'),
.....:                                          ('b', 'three')])
```

(continues on next page)

(continued from previous page)

```

.....:
In [327]: df1.sort_values(by=('a', 'two'))
Out[327]:
   a      b
one two three
0  2    1    5
2  1    2    3
1  1    3    4
3  1    4    2

```

3.3.12 Copying

The `copy()` method on pandas objects copies the underlying data (though not the axis indexes, since they are immutable) and returns a new object. Note that **it is seldom necessary to copy objects**. For example, there are only a handful of ways to alter a DataFrame *in-place*:

- Inserting, deleting, or modifying a column.
- Assigning to the `index` or `columns` attributes.
- For homogeneous data, directly modifying the values via the `values` attribute or advanced indexing.

To be clear, no pandas method has the side effect of modifying your data; almost every method returns a new object, leaving the original object untouched. If the data is modified, it is because you did so explicitly.

3.3.13 dtypes

For the most part, pandas uses NumPy arrays and dtypes for Series or individual columns of a DataFrame. NumPy provides support for `float`, `int`, `bool`, `timedelta64[ns]` and `datetime64[ns]` (note that NumPy does not support timezone-aware datetimes).

Pandas and third-party libraries *extend* NumPy's type system in a few places. This section describes the extensions pandas has made internally. See *Extension types* for how to write your own extension that works with pandas. See *Extension data types* for a list of third-party libraries that have implemented an extension.

The following table lists all of pandas extension types. See the respective documentation sections for more on each type.

Kind of Data	Data Type	Scalar	Array	Documentation
tz-aware datetime	DatetimeTZDtype	Timestamp	arrays. DatetimeArray	<i>Time zone handling</i>
Categorical	CategoricalDtype	(none)	Categorical	categorical
period (time spans)	PeriodDtype	Period	arrays.PeriodArray	<i>Time span representation</i>
sparse	SparseDtype	(none)	arrays.SparseArray	sparse
intervals	IntervalDtype	Interval	arrays. IntervalArray	<i>IntervalIndex</i>
nullable integer	Int64Dtype, ...	(none)	arrays. IntegerArray	<i>Nullable integer data type</i>

Pandas uses the `object` dtype for storing strings.

Finally, arbitrary objects may be stored using the `object` dtype, but should be avoided to the extent possible (for performance and interoperability with other libraries and methods. See [object conversion](#)).

A convenient `dtypes` attribute for `DataFrame` returns a `Series` with the data type of each column.

```
In [328]: dft = pd.DataFrame({'A': np.random.rand(3),
.....:                      'B': 1,
.....:                      'C': 'foo',
.....:                      'D': pd.Timestamp('20010102'),
.....:                      'E': pd.Series([1.0] * 3).astype('float32'),
.....:                      'F': False,
.....:                      'G': pd.Series([1] * 3, dtype='int8')})
.....:
```

```
In [329]: dft
Out[329]:
```

	A	B	C	D	E	F	G
0	0.537956	1	foo	2001-01-02	1.0	False	1
1	0.623232	1	foo	2001-01-02	1.0	False	1
2	0.558728	1	foo	2001-01-02	1.0	False	1

```
In [330]: dft.dtypes
Out[330]:
```

A	float64
B	int64
C	object
D	datetime64[ns]
E	float32
F	bool
G	int8

```
dtype: object
```

On a `Series` object, use the `dtype` attribute.

```
In [331]: dft['A'].dtype
Out[331]: dtype('float64')
```

If a pandas object contains data with multiple dtypes *in a single column*, the dtype of the column will be chosen to accommodate all of the data types (`object` is the most general).

```
# these ints are coerced to floats
In [332]: pd.Series([1, 2, 3, 4, 5, 6.])
Out[332]:
```

0	1.0
1	2.0
2	3.0
3	4.0
4	5.0
5	6.0

```
dtype: float64
```

```
# string data forces an ``object`` dtype
In [333]: pd.Series([1, 2, 3, 6., 'foo'])
Out[333]:
```

0	1
1	2

```

2      3
3      6
4      foo
dtype: object

```

The number of columns of each type in a `DataFrame` can be found by calling `DataFrame.dtypes.value_counts()`.

```
In [334]: dft.dtypes.value_counts()
```

```

Out[334]:
datetime64[ns]    1
object            1
bool             1
float64          1
int64            1
int8             1
float32          1
dtype: int64

```

Numeric dtypes will propagate and can coexist in `DataFrames`. If a dtype is passed (either directly via the `dtype` keyword, a passed `ndarray`, or a passed `Series`, then it will be preserved in `DataFrame` operations. Furthermore, different numeric dtypes will **NOT** be combined. The following example will give you a taste.

```
In [335]: df1 = pd.DataFrame(np.random.randn(8, 1), columns=['A'], dtype='float32')
```

```
In [336]: df1
```

```

Out[336]:
      A
0  1.111131
1  0.459178
2  0.633793
3  1.315839
4  0.075656
5  0.526596
6  0.442085
7 -0.224085

```

```
In [337]: df1.dtypes
```

```

Out[337]:
A    float32
dtype: object

```

```

In [338]: df2 = pd.DataFrame({'A': pd.Series(np.random.randn(8), dtype='float16'),
.....:                       'B': pd.Series(np.random.randn(8)),
.....:                       'C': pd.Series(np.array(np.random.randn(8),
.....:                                                dtype='uint8'))})
.....:

```

```
In [339]: df2
```

```

Out[339]:
      A      B  C
0 -0.809082  0.268481  0
1 -2.189453  0.991689 255
2  0.447021 -0.273606  0
3  0.072876  0.848166  1

```

```
4 -0.362061 -0.340956 255
5 -0.530273 -0.602481 0
6 -0.096802 -0.552552 0
7 1.262695 0.324815 255
```

```
In [340]: df2.dtypes
Out[340]:
A    float16
B    float64
C      uint8
dtype: object
```

defaults

By default integer types are `int64` and float types are `float64`, *regardless* of platform (32-bit or 64-bit). The following will all result in `int64` dtypes.

```
In [341]: pd.DataFrame([1, 2], columns=['a']).dtypes
Out[341]:
a    int64
dtype: object
```

```
In [342]: pd.DataFrame({'a': [1, 2]}).dtypes
Out[342]:
a    int64
dtype: object
```

```
In [343]: pd.DataFrame({'a': 1}, index=list(range(2))).dtypes
Out[343]:
a    int64
dtype: object
```

Note that Numpy will choose *platform-dependent* types when creating arrays. The following **WILL** result in `int32` on 32-bit platform.

```
In [344]: frame = pd.DataFrame(np.array([1, 2]))
```

upcasting

Types can potentially be *upcasted* when combined with other types, meaning they are promoted from the current type (e.g. `int` to `float`).

```
In [345]: df3 = df1.reindex_like(df2).fillna(value=0.0) + df2
```

```
In [346]: df3
Out[346]:
```

	A	B	C
0	0.302049	0.268481	0.0
1	-1.730275	0.991689	255.0
2	1.080814	-0.273606	0.0
3	1.388715	0.848166	1.0
4	-0.286405	-0.340956	255.0
5	-0.003677	-0.602481	0.0
6	0.345284	-0.552552	0.0

```
7 1.038611 0.324815 255.0
```

```
In [347]: df3.dtypes
```

```
Out[347]:
```

```
A    float32
```

```
B    float64
```

```
C    float64
```

```
dtype: object
```

`DataFrame.to_numpy()` will return the *lower-common-denominator* of the dtypes, meaning the dtype that can accommodate **ALL** of the types in the resulting homogeneous NumPy array. This can force some *upcasting*.

```
In [348]: df3.to_numpy().dtype
```

```
Out[348]: dtype('float64')
```

astype

You can use the `astype()` method to explicitly convert dtypes from one to another. These will by default return a copy, even if the dtype was unchanged (pass `copy=False` to change this behavior). In addition, they will raise an exception if the `astype` operation is invalid.

Upcasting is always according to the **numpy** rules. If two different dtypes are involved in an operation, then the more *general* one will be used as the result of the operation.

```
In [349]: df3
```

```
Out[349]:
```

```
      A          B      C
0  0.302049  0.268481  0.0
1 -1.730275  0.991689 255.0
2  1.080814 -0.273606  0.0
3  1.388715  0.848166  1.0
4 -0.286405 -0.340956 255.0
5 -0.003677 -0.602481  0.0
6  0.345284 -0.552552  0.0
7  1.038611  0.324815 255.0
```

```
In [350]: df3.dtypes
```

```
Out[350]:
```

```
A    float32
```

```
B    float64
```

```
C    float64
```

```
dtype: object
```

```
# conversion of dtypes
```

```
In [351]: df3.astype('float32').dtypes
```

```
Out[351]:
```

```
A    float32
```

```
B    float32
```

```
C    float32
```

```
dtype: object
```

Convert a subset of columns to a specified type using `astype()`.

```
In [352]: dft = pd.DataFrame({'a': [1, 2, 3], 'b': [4, 5, 6], 'c': [7, 8, 9]})
```

```
In [353]: dft[['a', 'b']] = dft[['a', 'b']].astype(np.uint8)
```

```
In [354]: dft
```

```
Out[354]:
   a  b  c
0  1  4  7
1  2  5  8
2  3  6  9
```

```
In [355]: dft.dtypes
```

```
Out[355]:
a    uint8
b    uint8
c    int64
dtype: object
```

New in version 0.19.0.

Convert certain columns to a specific dtype by passing a dict to `astype()`.

```
In [356]: dft1 = pd.DataFrame({'a': [1, 0, 1], 'b': [4, 5, 6], 'c': [7, 8, 9]})
```

```
In [357]: dft1 = dft1.astype({'a': np.bool, 'c': np.float64})
```

```
In [358]: dft1
```

```
Out[358]:
   a  b  c
0  True  4  7.0
1  False  5  8.0
2  True  6  9.0
```

```
In [359]: dft1.dtypes
```

```
Out[359]:
a      bool
b     int64
c    float64
dtype: object
```

Note: When trying to convert a subset of columns to a specified type using `astype()` and `loc()`, upcasting occurs.

`loc()` tries to fit in what we are assigning to the current dtypes, while `[]` will overwrite them taking the dtype from the right hand side. Therefore the following piece of code produces the unintended result.

```
In [360]: dft = pd.DataFrame({'a': [1, 2, 3], 'b': [4, 5, 6], 'c': [7, 8, 9]})
```

```
In [361]: dft.loc[:, ['a', 'b']].astype(np.uint8).dtypes
```

```
Out[361]:
a    uint8
b    uint8
dtype: object
```

```
In [362]: dft.loc[:, ['a', 'b']] = dft.loc[:, ['a', 'b']].astype(np.uint8)
```

(continues on next page)

(continued from previous page)

```
In [363]: dft.dtypes
Out[363]:
a    int64
b    int64
c    int64
dtype: object
```

object conversion

pandas offers various functions to try to force conversion of types from the `object` dtype to other types. In cases where the data is already of the correct type, but stored in an `object` array, the `DataFrame.infer_objects()` and `Series.infer_objects()` methods can be used to soft convert to the correct type.

```
In [364]: import datetime

In [365]: df = pd.DataFrame([[1, 2],
.....:                      ['a', 'b'],
.....:                      [datetime.datetime(2016, 3, 2),
.....:                      datetime.datetime(2016, 3, 2)]])

In [366]: df = df.T

In [367]: df
Out[367]:
   0  1      2
0  1  a  2016-03-02
1  2  b  2016-03-02

In [368]: df.dtypes
Out[368]:
0      object
1      object
2  datetime64[ns]
dtype: object
```

Because the data was transposed the original inference stored all columns as `object`, which `infer_objects` will correct.

```
In [369]: df.infer_objects().dtypes
Out[369]:
0      int64
1      object
2  datetime64[ns]
dtype: object
```

The following functions are available for one dimensional object arrays or scalars to perform hard conversion of objects to a specified type:

- `to_numeric()` (conversion to numeric dtypes)

```
In [370]: m = ['1.1', 2, 3]

In [371]: pd.to_numeric(m)
Out[371]: array([1.1, 2. , 3. ])
```

- `to_datetime()` (conversion to datetime objects)

```
In [372]: import datetime

In [373]: m = ['2016-07-09', datetime.datetime(2016, 3, 2)]

In [374]: pd.to_datetime(m)
Out[374]: DatetimeIndex(['2016-07-09', '2016-03-02'], dtype='datetime64[ns]',
↳freq=None)
```

- `to_timedelta()` (conversion to timedelta objects)

```
In [375]: m = ['5us', pd.Timedelta('1day')]

In [376]: pd.to_timedelta(m)
Out[376]: TimedeltaIndex(['0 days 00:00:00.000005', '1 days 00:00:00'], dtype=
↳'timedelta64[ns]', freq=None)
```

To force a conversion, we can pass in an `errors` argument, which specifies how pandas should deal with elements that cannot be converted to desired dtype or object. By default, `errors='raise'`, meaning that any errors encountered will be raised during the conversion process. However, if `errors='coerce'`, these errors will be ignored and pandas will convert problematic elements to `pd.NaT` (for datetime and timedelta) or `np.nan` (for numeric). This might be useful if you are reading in data which is mostly of the desired dtype (e.g. numeric, datetime), but occasionally has non-conforming elements intermixed that you want to represent as missing:

```
In [377]: import datetime

In [378]: m = ['apple', datetime.datetime(2016, 3, 2)]

In [379]: pd.to_datetime(m, errors='coerce')
Out[379]: DatetimeIndex(['NaT', '2016-03-02'], dtype='datetime64[ns]', freq=None)

In [380]: m = ['apple', 2, 3]

In [381]: pd.to_numeric(m, errors='coerce')
Out[381]: array([nan, 2., 3.])

In [382]: m = ['apple', pd.Timedelta('1day')]

In [383]: pd.to_timedelta(m, errors='coerce')
Out[383]: TimedeltaIndex([NaT, '1 days'], dtype='timedelta64[ns]', freq=None)
```

The `errors` parameter has a third option of `errors='ignore'`, which will simply return the passed in data if it encounters any errors with the conversion to a desired data type:

```
In [384]: import datetime
```

(continues on next page)

(continued from previous page)

```

In [385]: m = ['apple', datetime.datetime(2016, 3, 2)]

In [386]: pd.to_datetime(m, errors='ignore')
Out[386]: Index(['apple', 2016-03-02 00:00:00], dtype='object')

In [387]: m = ['apple', 2, 3]

In [388]: pd.to_numeric(m, errors='ignore')
Out[388]: array(['apple', 2, 3], dtype=object)

In [389]: m = ['apple', pd.Timedelta('1day')]

In [390]: pd.to_timedelta(m, errors='ignore')
Out[390]: array(['apple', Timedelta('1 days 00:00:00')], dtype=object)

```

In addition to object conversion, `to_numeric()` provides another argument `downcast`, which gives the option of downcasting the newly (or already) numeric data to a smaller dtype, which can conserve memory:

```

In [391]: m = ['1', 2, 3]

In [392]: pd.to_numeric(m, downcast='integer') # smallest signed int dtype
Out[392]: array([1, 2, 3], dtype=int8)

In [393]: pd.to_numeric(m, downcast='signed') # same as 'integer'
Out[393]: array([1, 2, 3], dtype=int8)

In [394]: pd.to_numeric(m, downcast='unsigned') # smallest unsigned int dtype
Out[394]: array([1, 2, 3], dtype=uint8)

In [395]: pd.to_numeric(m, downcast='float') # smallest float dtype
Out[395]: array([1., 2., 3.], dtype=float32)

```

As these methods apply only to one-dimensional arrays, lists or scalars; they cannot be used directly on multi-dimensional objects such as DataFrames. However, with `apply()`, we can “apply” the function over each column efficiently:

```

In [396]: import datetime

In [397]: df = pd.DataFrame([
.....:     ['2016-07-09', datetime.datetime(2016, 3, 2)] * 2, dtype='O')
.....:

In [398]: df
Out[398]:
           0           1
0  2016-07-09  2016-03-02 00:00:00
1  2016-07-09  2016-03-02 00:00:00

In [399]: df.apply(pd.to_datetime)
Out[399]:
           0           1
0  2016-07-09  2016-03-02
1  2016-07-09  2016-03-02

```

```
In [400]: df = pd.DataFrame([[1.1, 2, 3]] * 2, dtype='O')
```

```
In [401]: df
```

```
Out[401]:
   0  1  2
0  1.1 2  3
1  1.1 2  3
```

```
In [402]: df.apply(pd.to_numeric)
```

```
Out[402]:
   0  1  2
0  1.1 2  3
1  1.1 2  3
```

```
In [403]: df = pd.DataFrame(['5us', pd.Timedelta('1day')]] * 2, dtype='O')
```

```
In [404]: df
```

```
Out[404]:
   0  1
0  5us 1 days 00:00:00
1  5us 1 days 00:00:00
```

```
In [405]: df.apply(pd.to_timedelta)
```

```
Out[405]:
   0  1
0 00:00:00.000005 1 days
1 00:00:00.000005 1 days
```

gotchas

Performing selection operations on `integer` type data can easily upcast the data to `floating`. The `dtype` of the input data will be preserved in cases where `nans` are not introduced. See also *Support for integer NA*.

```
In [406]: dfi = df3.astype('int32')
```

```
In [407]: dfi['E'] = 1
```

```
In [408]: dfi
```

```
Out[408]:
   A  B  C  E
0  0  0  0  1
1 -1  0 255  1
2  1  0  0  1
3  1  0  1  1
4  0  0 255  1
5  0  0  0  1
6  0  0  0  1
7  1  0 255  1
```

```
In [409]: dfi.dtypes
```

```
Out[409]:
A    int32
B    int32
C    int32
```

```
E    int64
dtype: object
```

```
In [410]: casted = dfi[dfi > 0]
```

```
In [411]: casted
```

```
Out[411]:
```

	A	B	C	E
0	NaN	NaN	NaN	1
1	NaN	NaN	255.0	1
2	1.0	NaN	NaN	1
3	1.0	NaN	1.0	1
4	NaN	NaN	255.0	1
5	NaN	NaN	NaN	1
6	NaN	NaN	NaN	1
7	1.0	NaN	255.0	1

```
In [412]: casted.dtypes
```

```
Out[412]:
A    float64
B    float64
C    float64
E     int64
dtype: object
```

While float dtypes are unchanged.

```
In [413]: dfa = df3.copy()
```

```
In [414]: dfa['A'] = dfa['A'].astype('float32')
```

```
In [415]: dfa.dtypes
```

```
Out[415]:
A    float32
B    float64
C    float64
dtype: object
```

```
In [416]: casted = dfa[df2 > 0]
```

```
In [417]: casted
```

```
Out[417]:
```

	A	B	C
0	NaN	0.268481	NaN
1	NaN	0.991689	255.0
2	1.080814	NaN	NaN
3	1.388715	0.848166	1.0
4	NaN	NaN	255.0
5	NaN	NaN	NaN
6	NaN	NaN	NaN
7	1.038611	0.324815	255.0

```
In [418]: casted.dtypes
```

```
Out[418]:
A    float32
```

```
B    float64
C    float64
dtype: object
```

3.3.14 Selecting columns based on dtype

The `select_dtypes()` method implements subsetting of columns based on their dtype.

First, let's create a DataFrame with a slew of different dtypes:

```
In [419]: df = pd.DataFrame({'string': list('abc'),
.....:                      'int64': list(range(1, 4)),
.....:                      'uint8': np.arange(3, 6).astype('u1'),
.....:                      'float64': np.arange(4.0, 7.0),
.....:                      'bool1': [True, False, True],
.....:                      'bool2': [False, True, False],
.....:                      'dates': pd.date_range('now', periods=3),
.....:                      'category': pd.Series(list("ABC")).astype('category')})
.....:

In [420]: df['tdeltas'] = df.dates.diff()

In [421]: df['uint64'] = np.arange(3, 6).astype('u8')

In [422]: df['other_dates'] = pd.date_range('20130101', periods=3)

In [423]: df['tz_aware_dates'] = pd.date_range('20130101', periods=3, tz='US/Eastern')

In [424]: df
Out[424]:
```

	string	int64	uint8	float64	bool1	bool2	dates	category
↪tdeltas		uint64	other_dates			tz_aware_dates		
0	a	1	3	4.0	True	False	2019-10-23 14:27:32.265347	A
↪NaT		3	2013-01-01	2013-01-01	00:00:00-05:00			
1	b	2	4	5.0	False	True	2019-10-24 14:27:32.265347	B
↪days		4	2013-01-02	2013-01-02	00:00:00-05:00			
2	c	3	5	6.0	True	False	2019-10-25 14:27:32.265347	C
↪days		5	2013-01-03	2013-01-03	00:00:00-05:00			

And the dtypes:

```
In [425]: df.dtypes
Out[425]:
```

string	object
int64	int64
uint8	uint8
float64	float64
bool1	bool
bool2	bool
dates	datetime64[ns]
category	category
tdeltas	timedelta64[ns]
uint64	uint64

(continues on next page)

(continued from previous page)

```

other_dates          datetime64[ns]
tz_aware_dates      datetime64[ns, US/Eastern]
dtype: object

```

`select_dtypes()` has two parameters `include` and `exclude` that allow you to say “give me the columns *with* these dtypes” (`include`) and/or “give the columns *without* these dtypes” (`exclude`).

For example, to select `bool` columns:

```

In [426]: df.select_dtypes(include=[bool])
Out[426]:
   bool1  bool2
0   True  False
1  False   True
2   True  False

```

You can also pass the name of a dtype in the NumPy dtype hierarchy:

```

In [427]: df.select_dtypes(include=['bool'])
Out[427]:
   bool1  bool2
0   True  False
1  False   True
2   True  False

```

`select_dtypes()` also works with generic dtypes as well.

For example, to select all numeric and boolean columns while excluding unsigned integers:

```

In [428]: df.select_dtypes(include=['number', 'bool'], exclude=['unsignedinteger'])
Out[428]:
   int64  float64  bool1  bool2  tdeltas
0      1      4.0   True  False      NaT
1      2      5.0  False   True    1 days
2      3      6.0   True  False    1 days

```

To select string columns you must use the `object` dtype:

```

In [429]: df.select_dtypes(include=['object'])
Out[429]:
   string
0      a
1      b
2      c

```

To see all the child dtypes of a generic dtype like `numpy.number` you can define a function that returns a tree of child dtypes:

```

In [430]: def subdtypes(dtype):
.....:     subs = dtype.__subclasses__()
.....:     if not subs:
.....:         return dtype
.....:     return [dtype, [subdtypes(dt) for dt in subs]]
.....:

```

All NumPy dtypes are subclasses of `numpy.generic`:

```
In [431]: subdtypes(np.generic)
Out[431]:
[numpy.generic,
 [[numpy.number,
  [[numpy.integer,
   [[numpy.signedinteger,
    [numpy.int8,
     numpy.int16,
     numpy.int32,
     numpy.int64,
     numpy.int64,
     numpy.timedelta64]],
    [numpy.unsignedinteger,
     [numpy.uint8,
      numpy.uint16,
      numpy.uint32,
      numpy.uint64,
      numpy.uint64]]]],
  [numpy.inexact,
   [[numpy.floating,
    [numpy.float16, numpy.float32, numpy.float64, numpy.float128]],
    [numpy.complexfloating,
     [numpy.complex64, numpy.complex128, numpy.complex256]]]]]],
 [numpy.flexible,
  [[numpy.character, [numpy.bytes_, numpy.str_]],
   [numpy.void, [numpy.record]]]],
 numpy.bool_,
 numpy.datetime64,
 numpy.object_]]
```

Note: Pandas also defines the types `category`, and `datetime64[ns, tz]`, which are not integrated into the normal NumPy hierarchy and won't show up with the above function.

```
{{ header }}
```

3.4 Intro to data structures

We'll start with a quick, non-comprehensive overview of the fundamental data structures in pandas to get you started. The fundamental behavior about data types, indexing, and axis labeling / alignment apply across all of the objects. To get started, import NumPy and load pandas into your namespace:

```
In [1]: import numpy as np
```

```
In [2]: import pandas as pd
```

Here is a basic tenet to keep in mind: **data alignment is intrinsic**. The link between labels and data will not be broken unless done so explicitly by you.

We'll give a brief intro to the data structures, then consider all of the broad categories of functionality and methods in separate sections.

3.4.1 Series

Series is a one-dimensional labeled array capable of holding any data type (integers, strings, floating point numbers, Python objects, etc.). The axis labels are collectively referred to as the **index**. The basic method to create a Series is to call:

```
>>> s = pd.Series(data, index=index)
```

Here, **data** can be many different things:

- a Python dict
- an ndarray
- a scalar value (like 5)

The passed **index** is a list of axis labels. Thus, this separates into a few cases depending on what **data** is:

From ndarray

If **data** is an ndarray, **index** must be the same length as **data**. If no index is passed, one will be created having values `[0, ..., len(data) - 1]`.

```
In [3]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])
```

```
In [4]: s
Out[4]:
a    0.544055
b    0.457937
c   -0.055260
d    0.487673
e    0.021212
dtype: float64
```

```
In [5]: s.index
Out[5]: Index(['a', 'b', 'c', 'd', 'e'], dtype='object')
```

```
In [6]: pd.Series(np.random.randn(5))
Out[6]:
0   -0.269995
1   -0.453290
2    0.118795
3    0.658569
4   -0.208094
dtype: float64
```

Note: pandas supports non-unique index values. If an operation that does not support duplicate index values is attempted, an exception will be raised at that time. The reason for being lazy is nearly all performance-based (there are many instances in computations, like parts of GroupBy, where the index is not used).

From dict

Series can be instantiated from dicts:

```
In [7]: d = {'b': 1, 'a': 0, 'c': 2}
```

```
In [8]: pd.Series(d)
```

```
Out[8]:
```

```
b    1
a    0
c    2
dtype: int64
```

Note: When the data is a dict, and an index is not passed, the `Series` index will be ordered by the dict's insertion order, if you're using Python version ≥ 3.6 and Pandas version ≥ 0.23 .

If you're using Python < 3.6 or Pandas < 0.23 , and an index is not passed, the `Series` index will be the lexically ordered list of dict keys.

In the example above, if you were on a Python version lower than 3.6 or a Pandas version lower than 0.23, the `Series` would be ordered by the lexical order of the dict keys (i.e. `['a', 'b', 'c']` rather than `['b', 'a', 'c']`).

If an index is passed, the values in data corresponding to the labels in the index will be pulled out.

```
In [9]: d = {'a': 0., 'b': 1., 'c': 2.}
```

```
In [10]: pd.Series(d)
```

```
Out[10]:
```

```
a    0.0
b    1.0
c    2.0
dtype: float64
```

```
In [11]: pd.Series(d, index=['b', 'c', 'd', 'a'])
```

```
Out[11]:
```

```
b    1.0
c    2.0
d    NaN
a    0.0
dtype: float64
```

Note: NaN (not a number) is the standard missing data marker used in pandas.

From scalar value

If `data` is a scalar value, an index must be provided. The value will be repeated to match the length of `index`.

```
In [12]: pd.Series(5., index=['a', 'b', 'c', 'd', 'e'])
```

```
Out[12]:
```

```
a    5.0
b    5.0
c    5.0
d    5.0
e    5.0
dtype: float64
```

Series is ndarray-like

`Series` acts very similarly to a `ndarray`, and is a valid argument to most NumPy functions. However, operations such as slicing will also slice the index.

```
In [13]: s[0]
Out[13]: 0.544055375065062
```

```
In [14]: s[:3]
Out[14]:
a    0.544055
b    0.457937
c   -0.055260
dtype: float64
```

```
In [15]: s[s > s.median()]
Out[15]:
a    0.544055
d    0.487673
dtype: float64
```

```
In [16]: s[[4, 3, 1]]
Out[16]:
e    0.021212
d    0.487673
b    0.457937
dtype: float64
```

```
In [17]: np.exp(s)
Out[17]:
a    1.722980
b    1.580809
c    0.946239
d    1.628523
e    1.021439
dtype: float64
```

Note: We will address array-based indexing like `s[[4, 3, 1]]` in *section*.

Like a NumPy array, a pandas Series has a `dtype`.

```
In [18]: s.dtype
Out[18]: dtype('float64')
```

This is often a NumPy dtype. However, pandas and 3rd-party libraries extend NumPy's type system in a few places, in which case the dtype would be a *ExtensionDtype*. Some examples within pandas are categorical and *Nullable integer data type*. See *dtypes* for more.

If you need the actual array backing a `Series`, use `Series.array`.

```
In [19]: s.array
Out[19]:
<PandasArray>
```

(continues on next page)

(continued from previous page)

```
[ 0.544055375065062,  0.4579369393771382, -0.05526002668877243,
 0.48767341506473233, 0.021212151323940893]
Length: 5, dtype: float64
```

Accessing the array can be useful when you need to do some operation without the index (to disable *automatic alignment*, for example).

`Series.array` will always be an *ExtensionArray*. Briefly, an *ExtensionArray* is a thin wrapper around one or more *concrete* arrays like a `numpy.ndarray`. Pandas knows how to take an *ExtensionArray* and store it in a *Series* or a column of a *DataFrame*. See *dtypes* for more.

While *Series* is ndarray-like, if you need an *actual* ndarray, then use `Series.to_numpy()`.

```
In [20]: s.to_numpy()
Out[20]: array([ 0.54405538,  0.45793694, -0.05526003,  0.48767342,  0.02121215])
```

Even if the *Series* is backed by a *ExtensionArray*, `Series.to_numpy()` will return a NumPy ndarray.

Series is dict-like

A *Series* is like a fixed-size dict in that you can get and set values by index label:

```
In [21]: s['a']
Out[21]: 0.544055375065062
```

```
In [22]: s['e'] = 12.
```

```
In [23]: s
Out[23]:
a    0.544055
b    0.457937
c   -0.055260
d    0.487673
e   12.000000
dtype: float64
```

```
In [24]: 'e' in s
Out[24]: True
```

```
In [25]: 'f' in s
Out[25]: False
```

If a label is not contained, an exception is raised:

```
>>> s['f']
KeyError: 'f'
```

Using the `get` method, a missing label will return `None` or specified default:

```
In [26]: s.get('f')
In [27]: s.get('f', np.nan)
Out[27]: nan
```

See also the *section on attribute access*.

Vectorized operations and label alignment with Series

When working with raw NumPy arrays, looping through value-by-value is usually not necessary. The same is true when working with Series in pandas. Series can also be passed into most NumPy methods expecting an ndarray.

```
In [28]: s + s
Out[28]:
a      1.088111
b      0.915874
c     -0.110520
d      0.975347
e     24.000000
dtype: float64
```

```
In [29]: s * 2
Out[29]:
a      1.088111
b      0.915874
c     -0.110520
d      0.975347
e     24.000000
dtype: float64
```

```
In [30]: np.exp(s)
Out[30]:
a      1.722980
b      1.580809
c      0.946239
d      1.628523
e    162754.791419
dtype: float64
```

A key difference between Series and ndarray is that operations between Series automatically align the data based on label. Thus, you can write computations without giving consideration to whether the Series involved have the same labels.

```
In [31]: s[1:] + s[:-1]
Out[31]:
a      NaN
b      0.915874
c     -0.110520
d      0.975347
e      NaN
dtype: float64
```

The result of an operation between unaligned Series will have the **union** of the indexes involved. If a label is not found in one Series or the other, the result will be marked as missing **NaN**. Being able to write code without doing any explicit data alignment grants immense freedom and flexibility in interactive data analysis and research. The integrated data alignment features of the pandas data structures set pandas apart from the majority of related tools for working with labeled data.

Note: In general, we chose to make the default result of operations between differently indexed objects yield the **union** of the indexes in order to avoid loss of information. Having an index label, though the data

is missing, is typically important information as part of a computation. You of course have the option of dropping labels with missing data via the `dropna` function.

Name attribute

Series can also have a `name` attribute:

```
In [32]: s = pd.Series(np.random.randn(5), name='something')
```

```
In [33]: s
```

```
Out[33]:
```

```
0    0.482656
```

```
1    0.041324
```

```
2    0.376516
```

```
3    0.386480
```

```
4    0.884489
```

```
Name: something, dtype: float64
```

```
In [34]: s.name
```

```
Out[34]: 'something'
```

The Series `name` will be assigned automatically in many cases, in particular when taking 1D slices of DataFrame as you will see below.

New in version 0.18.0.

You can rename a Series with the `pandas.Series.rename()` method.

```
In [35]: s2 = s.rename("different")
```

```
In [36]: s2.name
```

```
Out[36]: 'different'
```

Note that `s` and `s2` refer to different objects.

3.4.2 DataFrame

DataFrame is a 2-dimensional labeled data structure with columns of potentially different types. You can think of it like a spreadsheet or SQL table, or a dict of Series objects. It is generally the most commonly used pandas object. Like Series, DataFrame accepts many different kinds of input:

- Dict of 1D ndarrays, lists, dicts, or Series
- 2-D numpy.ndarray
- Structured or record ndarray
- A Series
- Another DataFrame

Along with the data, you can optionally pass **index** (row labels) and **columns** (column labels) arguments. If you pass an index and / or columns, you are guaranteeing the index and / or columns of the resulting DataFrame. Thus, a dict of Series plus a specific index will discard all data not matching up to the passed index.

If axis labels are not passed, they will be constructed from the input data based on common sense rules.

Note: When the data is a dict, and `columns` is not specified, the `DataFrame` columns will be ordered by the dict's insertion order, if you are using Python version ≥ 3.6 and Pandas ≥ 0.23 .

If you are using Python < 3.6 or Pandas < 0.23 , and `columns` is not specified, the `DataFrame` columns will be the lexically ordered list of dict keys.

From dict of Series or dicts

The resulting **index** will be the **union** of the indexes of the various Series. If there are any nested dicts, these will first be converted to Series. If no columns are passed, the columns will be the ordered list of dict keys.

```
In [37]: d = {'one': pd.Series([1., 2., 3.], index=['a', 'b', 'c']),
....:        'two': pd.Series([1., 2., 3., 4.], index=['a', 'b', 'c', 'd'])}
....:
```

```
In [38]: df = pd.DataFrame(d)
```

```
In [39]: df
```

```
Out[39]:
   one  two
a  1.0  1.0
b  2.0  2.0
c  3.0  3.0
d  NaN  4.0
```

```
In [40]: pd.DataFrame(d, index=['d', 'b', 'a'])
```

```
Out[40]:
   one  two
d  NaN  4.0
b  2.0  2.0
a  1.0  1.0
```

```
In [41]: pd.DataFrame(d, index=['d', 'b', 'a'], columns=['two', 'three'])
```

```
Out[41]:
   two  three
d  4.0   NaN
b  2.0   NaN
a  1.0   NaN
```

The row and column labels can be accessed respectively by accessing the **index** and **columns** attributes:

Note: When a particular set of columns is passed along with a dict of data, the passed columns override the keys in the dict.

```
In [42]: df.index
Out[42]: Index(['a', 'b', 'c', 'd'], dtype='object')
```

```
In [43]: df.columns
Out[43]: Index(['one', 'two'], dtype='object')
```

From dict of ndarrays / lists

The ndarrays must all be the same length. If an index is passed, it must clearly also be the same length as the arrays. If no index is passed, the result will be `range(n)`, where `n` is the array length.

```
In [44]: d = {'one': [1., 2., 3., 4.],
...:        'two': [4., 3., 2., 1.]}
...:
```

```
In [45]: pd.DataFrame(d)
```

```
Out[45]:
   one  two
0  1.0  4.0
1  2.0  3.0
2  3.0  2.0
3  4.0  1.0
```

```
In [46]: pd.DataFrame(d, index=['a', 'b', 'c', 'd'])
```

```
Out[46]:
   one  two
a  1.0  4.0
b  2.0  3.0
c  3.0  2.0
d  4.0  1.0
```

From structured or record array

This case is handled identically to a dict of arrays.

```
In [47]: data = np.zeros((2, ), dtype=[('A', 'i4'), ('B', 'f4'), ('C', 'a10')])
```

```
In [48]: data[:] = [(1, 2., 'Hello'), (2, 3., "World")]
```

```
In [49]: pd.DataFrame(data)
```

```
Out[49]:
   A    B      C
0  1  2.0 b'Hello'
1  2  3.0 b'World'
```

```
In [50]: pd.DataFrame(data, index=['first', 'second'])
```

```
Out[50]:
           A    B      C
first    1  2.0 b'Hello'
second   2  3.0 b'World'
```

```
In [51]: pd.DataFrame(data, columns=['C', 'A', 'B'])
```

```
Out[51]:
           C  A    B
0  b'Hello'  1  2.0
1  b'World'  2  3.0
```

Note: DataFrame is not intended to work exactly like a 2-dimensional NumPy ndarray.

From a list of dicts

```
In [52]: data2 = [{'a': 1, 'b': 2}, {'a': 5, 'b': 10, 'c': 20}]
```

```
In [53]: pd.DataFrame(data2)
```

```
Out[53]:
   a  b    c
0  1  2  NaN
1  5 10 20.0
```

```
In [54]: pd.DataFrame(data2, index=['first', 'second'])
```

```
Out[54]:
      a  b    c
first  1  2  NaN
second 5 10 20.0
```

```
In [55]: pd.DataFrame(data2, columns=['a', 'b'])
```

```
Out[55]:
   a  b
0  1  2
1  5 10
```

From a dict of tuples

You can automatically create a MultiIndexed frame by passing a tuples dictionary.

```
In [56]: pd.DataFrame({'(a', 'b)': {'(A', 'B)': 1, '(A', 'C)': 2},
.....:                ('a', 'a)': {'(A', 'C)': 3, '(A', 'B)': 4},
.....:                ('a', 'c)': {'(A', 'B)': 5, '(A', 'C)': 6},
.....:                ('b', 'a)': {'(A', 'C)': 7, '(A', 'B)': 8},
.....:                ('b', 'b)': {'(A', 'D)': 9, '(A', 'B)': 10}})
```

```
Out[56]:
      a      b
      b  a  c  a  b
A B  1.0 4.0 5.0 8.0 10.0
C   2.0 3.0 6.0 7.0  NaN
D   NaN NaN NaN NaN  9.0
```

From a Series

The result will be a DataFrame with the same index as the input Series, and with one column whose name is the original name of the Series (only if no other column name provided).

Missing data

Much more will be said on this topic in the [Missing data](#) section. To construct a DataFrame with missing data, we use `np.nan` to represent missing values. Alternatively, you may pass a `numpy.MaskedArray` as the data argument to the DataFrame constructor, and its masked entries will be considered missing.

Alternate constructors

DataFrame.from_dict

`DataFrame.from_dict` takes a dict of dicts or a dict of array-like sequences and returns a `DataFrame`. It operates like the `DataFrame` constructor except for the `orient` parameter which is `'columns'` by default, but which can be set to `'index'` in order to use the dict keys as row labels.

```
In [57]: pd.DataFrame.from_dict(dict([('A', [1, 2, 3]), ('B', [4, 5, 6])]))
Out[57]:
   A  B
0  1  4
1  2  5
2  3  6
```

If you pass `orient='index'`, the keys will be the row labels. In this case, you can also pass the desired column names:

```
In [58]: pd.DataFrame.from_dict(dict([('A', [1, 2, 3]), ('B', [4, 5, 6])]),
.....:                             orient='index', columns=['one', 'two', 'three'])
.....:
Out[58]:
   one  two  three
A     1    2     3
B     4    5     6
```

`DataFrame.from_records`

`DataFrame.from_records` takes a list of tuples or an ndarray with structured dtype. It works analogously to the normal `DataFrame` constructor, except that the resulting `DataFrame` index may be a specific field of the structured dtype. For example:

```
In [59]: data
Out[59]:
array([(1, 2., b'Hello'), (2, 3., b'World')],
      dtype=[('A', '<i4'), ('B', '<f4'), ('C', 'S10')])
```

```
In [60]: pd.DataFrame.from_records(data, index='C')
```

```
Out[60]:
      A  B
C
b'Hello'  1  2.0
b'World'  2  3.0
```

Column selection, addition, deletion

You can treat a `DataFrame` semantically like a dict of like-indexed `Series` objects. Getting, setting, and deleting columns works with the same syntax as the analogous dict operations:

```
In [61]: df['one']
Out[61]:
a    1.0
b    2.0
c    3.0
d    NaN
Name: one, dtype: float64

In [62]: df['three'] = df['one'] * df['two']
```

(continues on next page)

(continued from previous page)

```
In [63]: df['flag'] = df['one'] > 2
```

```
In [64]: df
```

```
Out[64]:
```

```
   one  two  three  flag
a  1.0  1.0   1.0 False
b  2.0  2.0   4.0 False
c  3.0  3.0   9.0  True
d  NaN  4.0   NaN False
```

Columns can be deleted or popped like with a dict:

```
In [65]: del df['two']
```

```
In [66]: three = df.pop('three')
```

```
In [67]: df
```

```
Out[67]:
```

```
   one  flag
a  1.0 False
b  2.0 False
c  3.0  True
d  NaN False
```

When inserting a scalar value, it will naturally be propagated to fill the column:

```
In [68]: df['foo'] = 'bar'
```

```
In [69]: df
```

```
Out[69]:
```

```
   one  flag  foo
a  1.0 False bar
b  2.0 False bar
c  3.0  True bar
d  NaN False bar
```

When inserting a Series that does not have the same index as the DataFrame, it will be conformed to the DataFrame's index:

```
In [70]: df['one_trunc'] = df['one'][:2]
```

```
In [71]: df
```

```
Out[71]:
```

```
   one  flag  foo  one_trunc
a  1.0 False bar           1.0
b  2.0 False bar           2.0
c  3.0  True bar           NaN
d  NaN False bar           NaN
```

You can insert raw ndarrays but their length must match the length of the DataFrame's index.

By default, columns get inserted at the end. The `insert` function is available to insert at a particular location in the columns:

```
In [72]: df.insert(1, 'bar', df['one'])
```

```
In [73]: df
```

```
Out[73]:
```

	one	bar	flag	foo	one_trunc
a	1.0	1.0	False	bar	1.0
b	2.0	2.0	False	bar	2.0
c	3.0	3.0	True	bar	NaN
d	NaN	NaN	False	bar	NaN

Assigning new columns in method chains

Inspired by `dplyr`'s `mutate` verb, `DataFrame` has an `assign()` method that allows you to easily create new columns that are potentially derived from existing columns.

```
In [74]: iris = pd.read_csv('data/iris.data')
```

```
In [75]: iris.head()
```

```
Out[75]:
```

	SepalLength	SepalWidth	PetalLength	PetalWidth	Name
0	5.1	3.5	1.4	0.2	Iris-setosa
1	4.9	3.0	1.4	0.2	Iris-setosa
2	4.7	3.2	1.3	0.2	Iris-setosa
3	4.6	3.1	1.5	0.2	Iris-setosa
4	5.0	3.6	1.4	0.2	Iris-setosa

```
In [76]: (iris.assign(sepal_ratio=iris['SepalWidth'] / iris['SepalLength'])
```

```
.....:     .head())
```

```
.....:
```

```
Out[76]:
```

	SepalLength	SepalWidth	PetalLength	PetalWidth	Name	sepal_ratio
0	5.1	3.5	1.4	0.2	Iris-setosa	0.686275
1	4.9	3.0	1.4	0.2	Iris-setosa	0.612245
2	4.7	3.2	1.3	0.2	Iris-setosa	0.680851
3	4.6	3.1	1.5	0.2	Iris-setosa	0.673913
4	5.0	3.6	1.4	0.2	Iris-setosa	0.720000

In the example above, we inserted a precomputed value. We can also pass in a function of one argument to be evaluated on the `DataFrame` being assigned to.

```
In [77]: iris.assign(sepal_ratio=lambda x: (x['SepalWidth'] / x['SepalLength'])).head()
```

```
Out[77]:
```

	SepalLength	SepalWidth	PetalLength	PetalWidth	Name	sepal_ratio
0	5.1	3.5	1.4	0.2	Iris-setosa	0.686275
1	4.9	3.0	1.4	0.2	Iris-setosa	0.612245
2	4.7	3.2	1.3	0.2	Iris-setosa	0.680851
3	4.6	3.1	1.5	0.2	Iris-setosa	0.673913
4	5.0	3.6	1.4	0.2	Iris-setosa	0.720000

`assign` **always** returns a copy of the data, leaving the original `DataFrame` untouched.

Passing a callable, as opposed to an actual value to be inserted, is useful when you don't have a reference to the `DataFrame` at hand. This is common when using `assign` in a chain of operations. For example, we can

limit the DataFrame to just those observations with a Sepal Length greater than 5, calculate the ratio, and plot:

```
In [78]: (iris.query('SepalLength > 5')
.....:         .assign(SepalRatio=lambda x: x.SepalWidth / x.SepalLength,
.....:                 PetalRatio=lambda x: x.PetalWidth / x.PetalLength)
.....:         .plot(kind='scatter', x='SepalRatio', y='PetalRatio'))
.....:
Out[78]: <matplotlib.axes._subplots.AxesSubplot at 0x13806f910>
```

Since a function is passed in, the function is computed on the DataFrame being assigned to. Importantly, this is the DataFrame that's been filtered to those rows with sepal length greater than 5. The filtering happens first, and then the ratio calculations. This is an example where we didn't have a reference to the *filtered* DataFrame available.

The function signature for `assign` is simply `**kwargs`. The keys are the column names for the new fields, and the values are either a value to be inserted (for example, a `Series` or NumPy array), or a function of one argument to be called on the DataFrame. A *copy* of the original DataFrame is returned, with the new values inserted.

Changed in version 0.23.0.

Starting with Python 3.6 the order of `**kwargs` is preserved. This allows for *dependent* assignment, where an expression later in `**kwargs` can refer to a column created earlier in the same `assign()`.

```
In [79]: dfa = pd.DataFrame({"A": [1, 2, 3],
.....:                      "B": [4, 5, 6]})
.....:

In [80]: dfa.assign(C=lambda x: x['A'] + x['B'],
.....:              D=lambda x: x['A'] + x['C'])
.....:
Out[80]:
   A  B  C  D
0  1  4  5  6
1  2  5  7  9
2  3  6  9  12
```

In the second expression, `x['C']` will refer to the newly created column, that's equal to `dfa['A'] + dfa['B']`.

To write code compatible with all versions of Python, split the assignment in two.

```
In [81]: dependent = pd.DataFrame({"A": [1, 1, 1]})

In [82]: (dependent.assign(A=lambda x: x['A'] + 1)
.....:          .assign(B=lambda x: x['A'] + 2))
.....:
Out[82]:
   A  B
0  2  4
1  2  4
2  2  4
```

Warning: Dependent assignment may subtly change the behavior of your code between Python 3.6 and older versions of Python.

If you wish to write code that supports versions of python before and after 3.6, you'll need to take care when passing `assign` expressions that

- Update an existing column
- Refer to the newly updated column in the same `assign`

For example, we'll update column "A" and then refer to it when creating "B".

```
>>> dependent = pd.DataFrame({"A": [1, 1, 1]})
>>> dependent.assign(A=lambda x: x["A"] + 1, B=lambda x: x["A"] + 2)
```

For Python 3.5 and earlier the expression creating B refers to the "old" value of A, [1, 1, 1]. The output is then

```
   A  B
0  2  3
1  2  3
2  2  3
```

For Python 3.6 and later, the expression creating A refers to the "new" value of A, [2, 2, 2], which results in

```

   A  B
0  2  4
1  2  4
2  2  4

```

Indexing / selection

The basics of indexing are as follows:

Operation	Syntax	Result
Select column	<code>df[col]</code>	Series
Select row by label	<code>df.loc[label]</code>	Series
Select row by integer location	<code>df.iloc[loc]</code>	Series
Slice rows	<code>df[5:10]</code>	DataFrame
Select rows by boolean vector	<code>df[bool_vec]</code>	DataFrame

Row selection, for example, returns a Series whose index is the columns of the DataFrame:

```

In [83]: df.loc['b']
Out[83]:
one          2
bar          2
flag        False
foo         bar
one_trunc    2
Name: b, dtype: object

```

```

In [84]: df.iloc[2]
Out[84]:
one          3
bar          3
flag         True
foo         bar
one_trunc   NaN
Name: c, dtype: object

```

For a more exhaustive treatment of sophisticated label-based indexing and slicing, see the [section on indexing](#). We will address the fundamentals of reindexing / conforming to new sets of labels in the [section on reindexing](#).

Data alignment and arithmetic

Data alignment between DataFrame objects automatically align on **both the columns and the index (row labels)**. Again, the resulting object will have the union of the column and row labels.

```

In [85]: df = pd.DataFrame(np.random.randn(10, 4), columns=['A', 'B', 'C', 'D'])
In [86]: df2 = pd.DataFrame(np.random.randn(7, 3), columns=['A', 'B', 'C'])
In [87]: df + df2
Out[87]:

```

(continues on next page)

(continued from previous page)

	A	B	C	D
0	-0.694484	0.192766	-0.945741	NaN
1	0.292784	-0.453735	-0.159854	NaN
2	-0.904154	-0.209882	1.955291	NaN
3	2.029295	0.009923	-0.434713	NaN
4	1.166285	-1.157271	-0.100607	NaN
5	1.101510	-0.298808	-1.311913	NaN
6	0.033708	1.731677	0.180057	NaN
7	NaN	NaN	NaN	NaN
8	NaN	NaN	NaN	NaN
9	NaN	NaN	NaN	NaN

When doing an operation between DataFrame and Series, the default behavior is to align the Series **index** on the DataFrame **columns**, thus **broadcasting** row-wise. For example:

```
In [88]: df - df.iloc[0]
Out [88]:
```

	A	B	C	D
0	0.000000	0.000000	0.000000	0.000000
1	0.823010	-1.407428	1.810920	0.036966
2	-0.836963	-0.013977	3.361133	-0.321214
3	0.215511	0.136409	2.241683	-1.609052
4	0.010095	-1.006592	2.969119	-1.362727
5	1.268823	-1.691757	2.108988	-2.197647
6	0.192297	0.926025	1.937398	-0.193649
7	-1.637169	1.843618	2.244498	-2.147770
8	2.009625	-2.136301	2.017400	1.580465
9	0.027738	1.062145	3.472820	-1.503278

In the special case of working with time series data, if the DataFrame index contains dates, the broadcasting will be column-wise:

```
In [89]: index = pd.date_range('1/1/2000', periods=8)
In [90]: df = pd.DataFrame(np.random.randn(8, 3), index=index, columns=list('ABC'))
In [91]: df
Out [91]:
```

	A	B	C
2000-01-01	-0.334372	1.607388	-2.433251
2000-01-02	-0.196343	1.455554	-0.134245
2000-01-03	0.351420	1.148340	-1.691404
2000-01-04	-0.493614	0.073640	0.182179
2000-01-05	-0.203285	-0.010826	-1.539934
2000-01-06	-1.415928	-0.245523	-0.167154
2000-01-07	-0.223275	-1.167290	2.137569
2000-01-08	0.120902	-0.185518	1.927187

```
In [92]: type(df['A'])
Out [92]: pandas.core.series.Series
In [93]: df - df['A']
Out [93]:
```

```

```

Warning:

```
df - df['A']
```

is now deprecated and will be removed in a future release. The preferred way to replicate this behavior is

```
df.sub(df['A'], axis=0)
```

For explicit control over the matching and broadcasting behavior, see the section on *flexible binary operations*.

Operations with scalars are just as you would expect:

```
In [94]: df * 5 + 2
```

```
Out[94]:
```

Boolean operators work as well:

```
In [97]: df1 = pd.DataFrame({'a': [1, 0, 1], 'b': [0, 1, 1]}, dtype=bool)
```

```
In [98]: df2 = pd.DataFrame({'a': [0, 1, 1], 'b': [1, 1, 0]}, dtype=bool)
```

```
In [99]: df1 & df2
```

```
Out[99]:
```

	a	b
0	False	False
1	False	True
2	True	False

```
In [100]: df1 | df2
```

```
Out[100]:
```

	a	b
0	True	True
1	True	True
2	True	True

```
In [101]: df1 ^ df2
```

```
Out[101]:
```

	a	b
0	True	True
1	True	False
2	False	True

```
In [102]: -df1
```

```
Out[102]:
```

	a	b
0	False	True
1	True	False
2	False	False

Transposing

To transpose, access the `T` attribute (also the `transpose` function), similar to an ndarray:

```
# only show the first 5 rows
In [103]: df[:5].T
Out[103]:
      2000-01-01  2000-01-02  2000-01-03  2000-01-04  2000-01-05
A   -0.334372   -0.196343    0.351420   -0.493614   -0.203285
B    1.607388    1.455554    1.148340    0.073640   -0.010826
C   -2.433251   -0.134245   -1.691404    0.182179   -1.539934
```

DataFrame interoperability with NumPy functions

Elementwise NumPy ufuncs (log, exp, sqrt, ...) and various other NumPy functions can be used with no issues on Series and DataFrame, assuming the data within are numeric:

```
In [104]: np.exp(df)
Out[104]:
      A          B          C

```

DataFrame is not intended to be a drop-in replacement for ndarray as its indexing semantics and data model are quite different in places from an n-dimensional array.

Series implements `__array_ufunc__`, which allows it to work with NumPy's [universal functions](#).

The ufunc is applied to the underlying array in a Series.

```
In [106]: ser = pd.Series([1, 2, 3, 4])
In [107]: np.exp(ser)
Out[107]:
0    2.718282
1    7.389056
2   20.085537
```

(continues on next page)

(continued from previous page)

```
3    54.598150
dtype: float64
```

Changed in version 0.25.0: When multiple `Series` are passed to a ufunc, they are aligned before performing the operation.

Like other parts of the library, pandas will automatically align labeled inputs as part of a ufunc with multiple inputs. For example, using `numpy remainder()` on two `Series` with differently ordered labels will align before the operation.

```
In [108]: ser1 = pd.Series([1, 2, 3], index=['a', 'b', 'c'])
```

```
In [109]: ser2 = pd.Series([1, 3, 5], index=['b', 'a', 'c'])
```

```
In [110]: ser1
```

```
Out[110]:
```

```
a    1
b    2
c    3
dtype: int64
```

```
In [111]: ser2
```

```
Out[111]:
```

```
b    1
a    3
c    5
dtype: int64
```

```
In [112]: np.remainder(ser1, ser2)
```

```
Out[112]:
```

```
a    1
b    0
c    3
dtype: int64
```

As usual, the union of the two indices is taken, and non-overlapping values are filled with missing values.

```
In [113]: ser3 = pd.Series([2, 4, 6], index=['b', 'c', 'd'])
```

```
In [114]: ser3
```

```
Out[114]:
```

```
b    2
c    4
d    6
dtype: int64
```

```
In [115]: np.remainder(ser1, ser3)
```

```
Out[115]:
```

```
a    NaN
b    0.0
c    3.0
d    NaN
dtype: float64
```

When a binary ufunc is applied to a `Series` and `Index`, the `Series` implementation takes precedence and a

Series is returned.

```
In [116]: ser = pd.Series([1, 2, 3])
```

```
In [117]: idx = pd.Index([4, 5, 6])
```

```
In [118]: np.maximum(ser, idx)
```

```
Out[118]:
```

```
0    4
1    5
2    6
dtype: int64
```

NumPy ufuncs are safe to apply to **Series** backed by non-ndarray arrays, for example **SparseArray** (see *Sparse calculation*). If possible, the ufunc is applied without converting the underlying data to an ndarray.

Console display

Very large DataFrames will be truncated to display them in the console. You can also get a summary using `info()`. (Here I am reading a CSV version of the **baseball** dataset from the **plyr** R package):

```
In [119]: baseball = pd.read_csv('data/baseball.csv')
```

```
In [120]: print(baseball)
```

```
      id  player year  stint team lg  g  ab  r  h  X2b  X3b  hr  rbi  sb  ▾

```

However, using `to_string` will return a string representation of the DataFrame in tabular form, though it won't always fit the console width:

```

In [122]: print(baseball.iloc[-20:, :12].to_string())

```

	id	player	year	stint	team	lg	g	ab	r	h	X2b	X3b

Wide DataFrames will be printed across multiple rows by default:

```

In [123]: pd.DataFrame(np.random.randn(3, 12))
Out[123]:

```

	0	1	2	3	4	5	6	7	8	9	10	11	
0	-0.835921	-0.701274	1.007114	-0.587443	0.217855	-1.238129	1.317672	-1.082700	0.	↪897335	0.877220	-0.566652	-0.530428
1	1.500972	-0.190502	1.176097	-0.133727	-0.629027	0.254270	-1.944128	0.412923	-1.	↪276202	0.162727	1.015371	-1.278855
2	-1.410771	0.289453	0.644314	0.589727	0.257609	1.860029	0.782877	-0.786969	0.	↪052563	-0.863285	0.717709	1.216119

You can change how much to print on a single row by setting the `display.width` option:

```
In [124]: pd.set_option('display.width', 40) # default is 80

In [125]: pd.DataFrame(np.random.randn(3, 12))
Out[125]:
```

	0	1	2	3	4	5	6	7	8	9	10	11
0	0.909755	0.209170	-0.369342	-0.045207	0.252971	0.501157	-0.342172	0.199789	-1.001807	-0.548156	-0.720468	-0.758675
1	-1.947718	-1.745282	0.953580	0.278749	1.523093	-0.481708	2.247095	0.486608	0.885270	0.587560	0.195590	-0.485761
2	-0.216119	1.261238	-1.854250	-0.041328	-1.883850	0.427516	-0.324040	-0.376712	0.180279	-1.032801	-0.012413	2.057730

You can adjust the max width of the individual columns by setting `display.max_colwidth`

```
In [126]: datafile = {'filename': ['filename_01', 'filename_02'],
.....:                 'path': ["media/user_name/storage/folder_01/filename_01",
.....:                          "media/user_name/storage/folder_02/filename_02"]}
.....:

In [127]: pd.set_option('display.max_colwidth', 30)

In [128]: pd.DataFrame(datafile)
Out[128]:
```

	filename	path
0	filename_01	media/user_name/storage/fo...
1	filename_02	media/user_name/storage/fo...

```
In [129]: pd.set_option('display.max_colwidth', 100)

In [130]: pd.DataFrame(datafile)
Out[130]:
```

	filename	path
0	filename_01	media/user_name/storage/folder_01/filename_01
1	filename_02	media/user_name/storage/folder_02/filename_02

You can also disable this feature via the `expand_frame_repr` option. This will print the table in one block.

DataFrame column attribute access and IPython completion

If a DataFrame column label is a valid Python variable name, the column can be accessed like an attribute:

```
In [131]: df = pd.DataFrame({'foo1': np.random.randn(5),
.....:                       'foo2': np.random.randn(5)})
.....:

In [132]: df
Out[132]:
```

	foo1	foo2
0	0.175701	0.688798
1	1.857269	0.874645
2	1.062442	-0.593865
3	0.780121	0.422091

```
4 0.357684 -0.227634
```

```
In [133]: df.foo1
```

```
Out[133]:
```

```
0    0.175701
```

```
1    1.857269
```

```
2    1.062442
```

```
3    0.780121
```

```
4    0.357684
```

```
Name: foo1, dtype: float64
```

The columns are also connected to the [IPython](#) completion mechanism so they can be tab-completed:

```
In [5]: df.fo<TAB> # noqa: E225, E999
df.foo1 df.foo2
```

```
{{ header }}
```

3.5 Comparison with other tools

```
{{ header }}
```

3.5.1 Comparison with R / R libraries

Since `pandas` aims to provide a lot of the data manipulation and analysis functionality that people use `R` for, this page was started to provide a more detailed look at the [R language](#) and its many third party libraries as they relate to `pandas`. In comparisons with `R` and `CRAN` libraries, we care about the following things:

- **Functionality / flexibility:** what can/cannot be done with each tool
- **Performance:** how fast are operations. Hard numbers/benchmarks are preferable
- **Ease-of-use:** Is one tool easier/harder to use (you may have to be the judge of this, given side-by-side code comparisons)

This page is also here to offer a bit of a translation guide for users of these `R` packages.

For transfer of `DataFrame` objects from `pandas` to `R`, one option is to use `HDF5` files, see [External compatibility](#) for an example.

Quick reference

We'll start off with a quick reference guide pairing some common `R` operations using `dplyr` with `pandas` equivalents.

Querying, filtering, sampling

R	pandas
<code>dim(df)</code>	<code>df.shape</code>
<code>head(df)</code>	<code>df.head()</code>
<code>slice(df, 1:10)</code>	<code>df.iloc[:9]</code>
<code>filter(df, col1 == 1, col2 == 1)</code>	<code>df.query('col1 == 1 & col2 == 1')</code>
<code>df[df\$col1 == 1 & df\$col2 == 1,]</code>	<code>df[(df.col1 == 1) & (df.col2 == 1)]</code>
<code>select(df, col1, col2)</code>	<code>df[['col1', 'col2']]</code>
<code>select(df, col1:col3)</code>	<code>df.loc[:, 'col1':'col3']</code>
<code>select(df, -(col1:col3))</code>	<code>df.drop(cols_to_drop, axis=1)</code> but see ¹
<code>distinct(select(df, col1))</code>	<code>df[['col1']].drop_duplicates()</code>
<code>distinct(select(df, col1, col2))</code>	<code>df[['col1', 'col2']].drop_duplicates()</code>
<code>sample_n(df, 10)</code>	<code>df.sample(n=10)</code>
<code>sample_frac(df, 0.01)</code>	<code>df.sample(frac=0.01)</code>

Sorting

R	pandas
<code>arrange(df, col1, col2)</code>	<code>df.sort_values(['col1', 'col2'])</code>
<code>arrange(df, desc(col1))</code>	<code>df.sort_values('col1', ascending=False)</code>

Transforming

R	pandas
<code>select(df, col_one = col1)</code>	<code>df.rename(columns={'col1': 'col_one'})['col_one']</code>
<code>rename(df, col_one = col1)</code>	<code>df.rename(columns={'col1': 'col_one'})</code>
<code>mutate(df, c=a-b)</code>	<code>df.assign(c=df.a-df.b)</code>

Grouping and summarizing

R	pandas
<code>summary(df)</code>	<code>df.describe()</code>
<code>gdf <- group_by(df, col1)</code>	<code>gdf = df.groupby('col1')</code>
<code>summarise(gdf, avg=mean(col1, na.rm=TRUE))</code>	<code>df.groupby('col1').agg({'col1': 'mean'})</code>
<code>summarise(gdf, total=sum(col1))</code>	<code>df.groupby('col1').sum()</code>

Base R

Slicing with R's `c`

R makes it easy to access `data.frame` columns by name

¹ R's shorthand for a subrange of columns (`select(df, col1:col3)`) can be approached cleanly in pandas, if you have the list of columns, for example `df[cols[1:3]]` or `df.drop(cols[1:3])`, but doing this by column name is a bit messy.

```
df <- data.frame(a=rnorm(5), b=rnorm(5), c=rnorm(5), d=rnorm(5), e=rnorm(5))
df[, c("a", "c", "e")]
```

or by integer location

```
df <- data.frame(matrix(rnorm(1000), ncol=100))
df[, c(1:10, 25:30, 40, 50:100)]
```

Selecting multiple columns by name in pandas is straightforward

```
In [1]: df = pd.DataFrame(np.random.randn(10, 3), columns=list('abc'))
```

```
In [2]: df[['a', 'c']]
```

```
Out[2]:
```

```
      a      c
0 -0.828480  1.681178
1  1.743374  0.633181
2  0.422089  0.361566
3 -0.059013  0.317450
4  0.290561 -0.038037
5  0.470639  0.018485
6 -0.177483 -0.993452
7  0.506565 -1.156543
8 -0.522029 -0.897365
9 -2.230400  0.898255
```

```
In [3]: df.loc[:, ['a', 'c']]
```

```
Out[3]:
```

```
      a      c
0 -0.828480  1.681178
1  1.743374  0.633181
2  0.422089  0.361566
3 -0.059013  0.317450
4  0.290561 -0.038037
5  0.470639  0.018485
6 -0.177483 -0.993452
7  0.506565 -1.156543
8 -0.522029 -0.897365
9 -2.230400  0.898255
```

Selecting multiple noncontiguous columns by integer location can be achieved with a combination of the `iloc` indexer attribute and `numpy.r_`.

```
In [4]: named = list('abcdefg')
```

```
In [5]: n = 30
```

```
In [6]: columns = named + np.arange(len(named), n).tolist()
```

```
In [7]: df = pd.DataFrame(np.random.randn(n, n), columns=columns)
```

```
In [8]: df.iloc[:, np.r_[10, 24:30]]
```

```
Out[8]:
```

```
      a      b      c      d      e      f      g      7
8      9      24      25      26      27      28      29
(continues on next page)
```

(continued from previous page)

```

```

aggregate

In R you may want to split data into subsets and compute the mean for each. Using a data.frame called `df` and splitting it into groups `by1` and `by2`:

```

df <- data.frame(
  v1 = c(1,3,5,7,8,3,5,NA,4,5,7,9),
  v2 = c(11,33,55,77,88,33,55,NA,44,55,77,99),
  by1 = c("red", "blue", 1, 2, NA, "big", 1, 2, "red", 1, NA, 12),
  by2 = c("wet", "dry", 99, 95, NA, "damp", 95, 99, "red", 99, NA, NA))
aggregate(x=df[, c("v1", "v2")], by=list(mydf2$by1, mydf2$by2), FUN = mean)

```

The `groupby()` method is similar to base R `aggregate` function.

```

In [9]: df = pd.DataFrame(
...:     {'v1': [1, 3, 5, 7, 8, 3, 5, np.nan, 4, 5, 7, 9],
...:       'v2': [11, 33, 55, 77, 88, 33, 55, np.nan, 44, 55, 77, 99],
...:       'by1': ["red", "blue", 1, 2, np.nan, "big", 1, 2, "red", 1, np.nan, 12],
...:       'by2': ["wet", "dry", 99, 95, np.nan, "damp", 95, 99, "red", 99, np.nan,
...:               np.nan]})
...:

In [10]: g = df.groupby(['by1', 'by2'])

In [11]: g[['v1', 'v2']].mean()
Out[11]:

```

		v1	v2
by1	by2		
1	95	5.0	55.0
	99	5.0	55.0
2	95	7.0	77.0
	99	NaN	NaN
big	damp	3.0	33.0
blue	dry	3.0	33.0
red	red	4.0	44.0
	wet	1.0	11.0

For more details and examples see [the groupby documentation](#).

```
match / %in%
```

A common way to select data in R is using `%in%` which is defined using the function `match`. The operator `%in%` is used to return a logical vector indicating if there is a match or not:

```
s <- 0:4
s %in% c(2,4)
```

The `isin()` method is similar to R `%in%` operator:

```
In [12]: s = pd.Series(np.arange(5), dtype=np.float32)

In [13]: s.isin([2, 4])
Out[13]:
0    False
1    False
2     True
3    False
4     True
dtype: bool
```

The `match` function returns a vector of the positions of matches of its first argument in its second:

```
s <- 0:4
match(s, c(2,4))
```

For more details and examples see *the reshaping documentation*.

tapply

`tapply` is similar to `aggregate`, but data can be in a ragged array, since the subclass sizes are possibly irregular. Using a data.frame called `baseball`, and retrieving information based on the array `team`:

```
baseball <-
  data.frame(team = gl(5, 5,
    labels = paste("Team", LETTERS[1:5])),
    player = sample(letters, 25),
    batting.average = runif(25, .200, .400))

tapply(baseball$batting.average, baseball.example$team,
  max)
```

In pandas we may use `pivot_table()` method to handle this:

```
In [14]: import random

In [15]: import string

In [16]: baseball = pd.DataFrame(
.....:     {'team': ["team %d" % (x + 1) for x in range(5)] * 5,
.....:      'player': random.sample(list(string.ascii_lowercase), 25),
.....:      'batting avg': np.random.uniform(.200, .400, 25)})
.....:
```

(continues on next page)

(continued from previous page)

```
In [17]: baseball.pivot_table(values='batting avg', columns='team', aggfunc=np.max)
Out[17]:
team          team 1    team 2    team 3    team 4    team 5
batting avg  0.375407  0.386991  0.382943  0.3652    0.370616
```

For more details and examples see *the reshaping documentation*.

subset

The `query()` method is similar to the base R `subset` function. In R you might want to get the rows of a `data.frame` where one column's values are less than another column's values:

```
df <- data.frame(a=rnorm(10), b=rnorm(10))
subset(df, a <= b)
df[df$a <= df$b,] # note the comma
```

In pandas, there are a few ways to perform subsetting. You can use `query()` or pass an expression as if it were an index/slice as well as standard boolean indexing:

```
In [18]: df = pd.DataFrame({'a': np.random.randn(10), 'b': np.random.randn(10)})
```

```
In [19]: df.query('a <= b')
Out[19]:
```

```
      a          b
2 -1.356239 -0.339505
```

```
In [20]: df[df.a <= df.b]
Out[20]:
```

```
      a          b
2 -1.356239 -0.339505
```

```
In [21]: df.loc[df.a <= df.b]
Out[21]:
```

```
      a          b
2 -1.356239 -0.339505
```

For more details and examples see *the query documentation*.

with

An expression using a data.frame called `df` in R with the columns `a` and `b` would be evaluated using `with` like so:

```
df <- data.frame(a=rnorm(10), b=rnorm(10))
with(df, a + b)
df$a + df$b # same as the previous expression
```

In pandas the equivalent expression, using the `eval()` method, would be:

```
In [22]: df = pd.DataFrame({'a': np.random.randn(10), 'b': np.random.randn(10)})
```

```
In [23]: df.eval('a + b')
```

```
Out[23]:
0    1.582100
1    1.102172
2   -0.621243
3    0.059273
4   -1.744880
5    0.915561
6   -2.643852
7   -0.519496
8    0.733243
9   -2.914023
dtype: float64
```

```
In [24]: df.a + df.b # same as the previous expression
```

```
Out[24]:
0    1.582100
1    1.102172
2   -0.621243
3    0.059273
4   -1.744880
5    0.915561
6   -2.643852
7   -0.519496
8    0.733243
9   -2.914023
dtype: float64
```

In certain cases `eval()` will be much faster than evaluation in pure Python. For more details and examples see *the eval documentation*.

plyr

plyr is an R library for the split-apply-combine strategy for data analysis. The functions revolve around three data structures in R, **a** for **arrays**, **l** for **lists**, and **d** for **data.frame**. The table below shows how these data structures could be mapped in Python.

R	Python
array	list
lists	dictionary or list of objects
data.frame	dataframe

ddply

An expression using a data.frame called `df` in R where you want to summarize `x` by `month`:

```
require(plyr)
df <- data.frame(
  x = runif(120, 1, 168),
  y = runif(120, 7, 334),
  z = runif(120, 1.7, 20.7),
  month = rep(c(5,6,7,8),30),
```

(continues on next page)

(continued from previous page)

```

week = sample(1:4, 120, TRUE)
)

ddply(df, .(month, week), summarize,
      mean = round(mean(x), 2),
      sd = round(sd(x), 2))

```

In pandas the equivalent expression, using the `groupby()` method, would be:

```

In [25]: df = pd.DataFrame({'x': np.random.uniform(1., 168., 120),
.....:                    'y': np.random.uniform(7., 334., 120),
.....:                    'z': np.random.uniform(1.7, 20.7, 120),
.....:                    'month': [5, 6, 7, 8] * 30,
.....:                    'week': np.random.randint(1, 4, 120)})
.....:

In [26]: grouped = df.groupby(['month', 'week'])

In [27]: grouped['x'].agg([np.mean, np.std])
Out[27]:

```

month	week	mean	std
5	1	65.472325	45.594965
	2	69.963684	53.928648
	3	58.151030	65.291197
6	1	90.928081	51.648455
	2	95.919255	36.887073
	3	102.051638	54.414241
7	1	101.783668	39.286572
	2	81.657661	54.996207
	3	73.186147	46.615222
8	1	85.351475	54.016463
	2	88.593449	39.724889
	3	82.336311	45.392411

For more details and examples see [the groupby documentation](#).

reshape / reshape2

melt.array

An expression using a 3 dimensional array called `a` in R where you want to melt it into a data.frame:

```

a <- array(c(1:23, NA), c(2,3,4))
data.frame(melt(a))

```

In Python, since `a` is a list, you can simply use list comprehension.

```

In [28]: a = np.array(list(range(1, 24)) + [np.NaN]).reshape(2, 3, 4)

In [29]: pd.DataFrame([tuple(list(x) + [val]) for x, val in np.ndenumerate(a)])

```

(continues on next page)

(continued from previous page)

```
Out [29]:
   0  1  2   3
0  0  0  0  1.0
1  0  0  1  2.0
2  0  0  2  3.0

22 1  2  2 23.0
23 1  2  3  NaN
```

`melt.list`

An expression using a list called `a` in R where you want to melt it into a dataframe:

```
a <- as.list(c(1:4, NA))
data.frame(melt(a))
```

In Python, this list would be a list of tuples, so `DataFrame()` method would convert it to a dataframe as required.

```
In [30]: a = list(enumerate(list(range(1, 5)) + [np.NaN]))
```

```
In [31]: pd.DataFrame(a)
```

```
Out [31]:
   0  1
0  0  1.0
1  1  2.0
2  2  3.0
3  3  4.0
4  4  NaN
```

For more details and examples see *the Into to Data Structures documentation*.

`melt.data.frame`

An expression using a data.frame called `cheese` in R where you want to reshape the data.frame:

```
cheese <- data.frame(
  first = c('John', 'Mary'),
  last = c('Doe', 'Bo'),
  height = c(5.5, 6.0),
  weight = c(130, 150)
)
melt(cheese, id=c("first", "last"))
```

In Python, the `melt()` method is the R equivalent:

```
In [32]: cheese = pd.DataFrame({'first': ['John', 'Mary'],
  ....:                        'last': ['Doe', 'Bo'],
  ....:                        'height': [5.5, 6.0],
  ....:                        'weight': [130, 150]})
  ....:
```

```
In [33]: pd.melt(cheese, id_vars=['first', 'last'])
```

```
Out[33]:
   first last variable  value
0  John  Doe   height    5.5
1  Mary  Bo   height    6.0
2  John  Doe   weight   130.0
3  Mary  Bo   weight   150.0
```

```
In [34]: cheese.set_index(['first', 'last']).stack() # alternative way
```

```
Out[34]:
first last
John  Doe   height    5.5
       weight   130.0
Mary  Bo   height    6.0
       weight   150.0
dtype: float64
```

For more details and examples see [the reshaping documentation](#).

`cast`

In R `acast` is an expression using a data.frame called `df` in R to cast into a higher dimensional array:

```
df <- data.frame(
  x = runif(12, 1, 168),
  y = runif(12, 7, 334),
  z = runif(12, 1.7, 20.7),
  month = rep(c(5,6,7),4),
  week = rep(c(1,2), 6)
)

mdf <- melt(df, id=c("month", "week"))
acast(mdf, week ~ month ~ variable, mean)
```

In Python the best way is to make use of `pivot_table()`:

```
In [35]: df = pd.DataFrame({'x': np.random.uniform(1., 168., 12),
.....:                    'y': np.random.uniform(7., 334., 12),
.....:                    'z': np.random.uniform(1.7, 20.7, 12),
.....:                    'month': [5, 6, 7] * 4,
.....:                    'week': [1, 2] * 6})
.....:

In [36]: mdf = pd.melt(df, id_vars=['month', 'week'])

In [37]: pd.pivot_table(mdf, values='value', index=['variable', 'week'],
.....:                  columns=['month'], aggfunc=np.mean)
.....:

Out [37]:
```

month		5	6	7
variable	week			
x	1	33.676819	14.477056	84.573585
	2	152.619607	70.434830	53.454458
y	1	182.422131	124.361465	209.180885
	2	187.435897	256.116538	228.092618
z	1	10.668081	18.434863	11.888183
	2	18.817980	16.421603	10.912752

Similarly for `dcast` which uses a data.frame called `df` in R to aggregate information based on `Animal` and `FeedType`:

```
df <- data.frame(
  Animal = c('Animal1', 'Animal2', 'Animal3', 'Animal2', 'Animal1',
            'Animal2', 'Animal3'),
  FeedType = c('A', 'B', 'A', 'A', 'B', 'B', 'A'),
  Amount = c(10, 7, 4, 2, 5, 6, 2)
)

dcast(df, Animal ~ FeedType, sum, fill=NaN)
# Alternative method using base R
with(df, tapply(Amount, list(Animal, FeedType), sum))
```

Python can approach this in two different ways. Firstly, similar to above using `pivot_table()`:

```
In [38]: df = pd.DataFrame({
.....:   'Animal': ['Animal1', 'Animal2', 'Animal3', 'Animal2', 'Animal1',
.....:            'Animal2', 'Animal3'],
.....:   'FeedType': ['A', 'B', 'A', 'A', 'B', 'B', 'A'],
.....:   'Amount': [10, 7, 4, 2, 5, 6, 2],
.....: })
.....:

In [39]: df.pivot_table(values='Amount', index='Animal', columns='FeedType',
.....:                  aggfunc='sum')
.....:

Out [39]:
```

FeedType	A	B
Animal		

(continues on next page)

(continued from previous page)

```
Animal1  10.0  5.0
Animal2   2.0 13.0
Animal3   6.0  NaN
```

The second approach is to use the `groupby()` method:

```
In [40]: df.groupby(['Animal', 'FeedType'])['Amount'].sum()
Out[40]:
Animal  FeedType
Animal1  A           10
         B            5
Animal2  A            2
         B           13
Animal3  A            6
Name: Amount, dtype: int64
```

For more details and examples see [the reshaping documentation](#) or [the groupby documentation](#).

factor

pandas has a data type for categorical data.

```
cut(c(1,2,3,4,5,6), 3)
factor(c(1,2,3,2,2,3))
```

In pandas this is accomplished with `pd.cut` and `astype("category")`:

```
In [41]: pd.cut(pd.Series([1, 2, 3, 4, 5, 6]), 3)
Out[41]:
0    (0.995, 2.667]
1    (0.995, 2.667]
2    (2.667, 4.333]
3    (2.667, 4.333]
4    (4.333, 6.0]
5    (4.333, 6.0]
dtype: category
Categories (3, interval[float64]): [(0.995, 2.667] < (2.667, 4.333] < (4.333, 6.0]]
```

```
In [42]: pd.Series([1, 2, 3, 2, 2, 3]).astype("category")
Out[42]:
0    1
1    2
2    3
3    2
4    2
5    3
dtype: category
Categories (3, int64): [1, 2, 3]
```

For more details and examples see [categorical introduction](#) and the [API documentation](#). There is also a documentation regarding the [differences to R's factor](#). `{{ header }}`

3.5.2 Comparison with SQL

Since many potential pandas users have some familiarity with SQL, this page is meant to provide some examples of how various SQL operations would be performed using pandas.

If you're new to pandas, you might want to first read through *10 Minutes to pandas* to familiarize yourself with the library.

As is customary, we import pandas and NumPy as follows:

```
In [1]: import pandas as pd
```

```
In [2]: import numpy as np
```

Most of the examples will utilize the `tips` dataset found within pandas tests. We'll read the data into a DataFrame called `tips` and assume we have a database table of the same name and structure.

```
In [3]: url = ('https://raw.githubusercontent.com/pandas-dev'
...:         '/pandas/master/pandas/tests/data/tips.csv')
...:
```

```
In [4]: tips = pd.read_csv(url)
```

```
In [5]: tips.head()
```

```
Out[5]:
```

	total_bill	tip	sex	smoker	day	time	size
0	16.99	1.01	Female	No	Sun	Dinner	2
1	10.34	1.66	Male	No	Sun	Dinner	3
2	21.01	3.50	Male	No	Sun	Dinner	3
3	23.68	3.31	Male	No	Sun	Dinner	2
4	24.59	3.61	Female	No	Sun	Dinner	4

SELECT

In SQL, selection is done using a comma-separated list of columns you'd like to select (or a `*` to select all columns):

```
SELECT total_bill, tip, smoker, time
FROM tips
LIMIT 5;
```

With pandas, column selection is done by passing a list of column names to your DataFrame:

```
In [6]: tips[['total_bill', 'tip', 'smoker', 'time']].head(5)
```

```
Out[6]:
```

	total_bill	tip	smoker	time
0	16.99	1.01	No	Dinner
1	10.34	1.66	No	Dinner
2	21.01	3.50	No	Dinner
3	23.68	3.31	No	Dinner
4	24.59	3.61	No	Dinner

Calling the DataFrame without the list of column names would display all columns (akin to SQL's `*`).

WHERE

Filtering in SQL is done via a WHERE clause.

```
SELECT *
FROM tips
WHERE time = 'Dinner'
LIMIT 5;
```

DataFrames can be filtered in multiple ways; the most intuitive of which is using [boolean indexing](#).

```
In [7]: tips[tips['time'] == 'Dinner'].head(5)
Out[7]:
```

	total_bill	tip	sex	smoker	day	time	size
0	16.99	1.01	Female	No	Sun	Dinner	2
1	10.34	1.66	Male	No	Sun	Dinner	3
2	21.01	3.50	Male	No	Sun	Dinner	3
3	23.68	3.31	Male	No	Sun	Dinner	2
4	24.59	3.61	Female	No	Sun	Dinner	4

The above statement is simply passing a `Series` of True/False objects to the DataFrame, returning all rows with True.

```
In [8]: is_dinner = tips['time'] == 'Dinner'
```

```
In [9]: is_dinner.value_counts()
```

```
Out[9]:
True      176
False      68
Name: time, dtype: int64
```

```
In [10]: tips[is_dinner].head(5)
```

```
Out[10]:
```

	total_bill	tip	sex	smoker	day	time	size
0	16.99	1.01	Female	No	Sun	Dinner	2
1	10.34	1.66	Male	No	Sun	Dinner	3
2	21.01	3.50	Male	No	Sun	Dinner	3
3	23.68	3.31	Male	No	Sun	Dinner	2
4	24.59	3.61	Female	No	Sun	Dinner	4

Just like SQL's OR and AND, multiple conditions can be passed to a DataFrame using `|` (OR) and `&` (AND).

```
-- tips of more than $5.00 at Dinner meals
SELECT *
FROM tips
WHERE time = 'Dinner' AND tip > 5.00;
```

```
# tips of more than $5.00 at Dinner meals
In [11]: tips[(tips['time'] == 'Dinner') & (tips['tip'] > 5.00)]
Out[11]:
```

	total_bill	tip	sex	smoker	day	time	size
23	39.42	7.58	Male	No	Sat	Dinner	4
44	30.40	5.60	Male	No	Sun	Dinner	4
47	32.40	6.00	Male	No	Sun	Dinner	4

(continues on next page)

(continued from previous page)

52	34.81	5.20	Female	No	Sun	Dinner	4
59	48.27	6.73	Male	No	Sat	Dinner	4
116	29.93	5.07	Male	No	Sun	Dinner	4
155	29.85	5.14	Female	No	Sun	Dinner	5
170	50.81	10.00	Male	Yes	Sat	Dinner	3
172	7.25	5.15	Male	Yes	Sun	Dinner	2
181	23.33	5.65	Male	Yes	Sun	Dinner	2
183	23.17	6.50	Male	Yes	Sun	Dinner	4
211	25.89	5.16	Male	Yes	Sat	Dinner	4
212	48.33	9.00	Male	No	Sat	Dinner	4
214	28.17	6.50	Female	Yes	Sat	Dinner	3
239	29.03	5.92	Male	No	Sat	Dinner	3

```
-- tips by parties of at least 5 diners OR bill total was more than $45
SELECT *
FROM tips
WHERE size >= 5 OR total_bill > 45;
```

```
# tips by parties of at least 5 diners OR bill total was more than $45
In [12]: tips[(tips['size'] >= 5) | (tips['total_bill'] > 45)]
Out[12]:
   total_bill  tip  sex smoker  day  time  size
59    48.27  6.73  Male    No   Sat  Dinner    4
125    29.80  4.20  Female  No   Thur  Lunch    6
141    34.30  6.70  Male    No   Thur  Lunch    6
142    41.19  5.00  Male    No   Thur  Lunch    5
143    27.05  5.00  Female  No   Thur  Lunch    6
155    29.85  5.14  Female  No   Sun  Dinner    5
156    48.17  5.00  Male    No   Sun  Dinner    6
170    50.81 10.00  Male   Yes   Sat  Dinner    3
182    45.35  3.50  Male   Yes   Sun  Dinner    3
185    20.69  5.00  Male    No   Sun  Dinner    5
187    30.46  2.00  Male   Yes   Sun  Dinner    5
212    48.33  9.00  Male    No   Sat  Dinner    4
216    28.15  3.00  Male   Yes   Sat  Dinner    5
```

NULL checking is done using the `notna()` and `isna()` methods.

```
In [13]: frame = pd.DataFrame({'col1': ['A', 'B', np.NaN, 'C', 'D'],
   ....:                       'col2': ['F', np.NaN, 'G', 'H', 'I']})
   ....:

In [14]: frame
Out[14]:
   col1 col2
0     A    F
1     B  NaN
2  NaN    G
3     C    H
4     D    I
```

Assume we have a table of the same structure as our DataFrame above. We can see only the records where

col2 IS NULL with the following query:

```
SELECT *
FROM frame
WHERE col2 IS NULL;
```

```
In [15]: frame[frame['col2'].isna()]
Out[15]:
   col1 col2
1     B  NaN
```

Getting items where col1 IS NOT NULL can be done with *notna()*.

```
SELECT *
FROM frame
WHERE col1 IS NOT NULL;
```

```
In [16]: frame[frame['col1'].notna()]
Out[16]:
   col1 col2
0     A     F
1     B  NaN
3     C     H
4     D     I
```

GROUP BY

In pandas, SQL's GROUP BY operations are performed using the similarly named *groupby()* method. *groupby()* typically refers to a process where we'd like to split a dataset into groups, apply some function (typically aggregation), and then combine the groups together.

A common SQL operation would be getting the count of records in each group throughout a dataset. For instance, a query getting us the number of tips left by sex:

```
SELECT sex, count(*)
FROM tips
GROUP BY sex;
/*
Female      87
Male       157
*/
```

The pandas equivalent would be:

```
In [17]: tips.groupby('sex').size()
Out[17]:
sex
Female      87
Male       157
dtype: int64
```

Notice that in the pandas code we used *size()* and not *count()*. This is because *count()* applies the function to each column, returning the number of not null records within each.

```
In [18]: tips.groupby('sex').count()
Out[18]:
```

	total_bill	tip	smoker	day	time	size
sex						
Female	87	87	87	87	87	87
Male	157	157	157	157	157	157

Alternatively, we could have applied the `count()` method to an individual column:

```
In [19]: tips.groupby('sex')['total_bill'].count()
Out[19]:
```

sex	total_bill
Female	87
Male	157

Name: total_bill, dtype: int64

Multiple functions can also be applied at once. For instance, say we'd like to see how tip amount differs by day of the week - `agg()` allows you to pass a dictionary to your grouped DataFrame, indicating which functions to apply to specific columns.

```
SELECT day, AVG(tip), COUNT(*)
FROM tips
GROUP BY day;
/*
Fri 2.734737 19
Sat 2.993103 87
Sun 3.255132 76
Thur 2.771452 62
*/
```

```
In [20]: tips.groupby('day').agg({'tip': np.mean, 'day': np.size})
Out[20]:
```

	tip	day
day		
Fri	2.734737	19
Sat	2.993103	87
Sun	3.255132	76
Thur	2.771452	62

Grouping by more than one column is done by passing a list of columns to the `groupby()` method.

```
SELECT smoker, day, COUNT(*), AVG(tip)
FROM tips
GROUP BY smoker, day;
/*
smoker day
No Fri 4 2.812500
Sat 45 3.102889
Sun 57 3.167895
Thur 45 2.673778
Yes Fri 15 2.714000
Sat 42 2.875476
Sun 19 3.516842
```

(continues on next page)

(continued from previous page)

```

    Thur    17    3.030000
*/

```

```
In [21]: tips.groupby(['smoker', 'day']).agg({'tip': [np.size, np.mean]})
```

```
Out [21]:
```

		tip	
		size	mean
smoker	day		
No	Fri	4.0	2.812500
	Sat	45.0	3.102889
	Sun	57.0	3.167895
	Thur	45.0	2.673778
Yes	Fri	15.0	2.714000
	Sat	42.0	2.875476
	Sun	19.0	3.516842
	Thur	17.0	3.030000

JOIN

JOINS can be performed with *join()* or *merge()*. By default, *join()* will join the DataFrames on their indices. Each method has parameters allowing you to specify the type of join to perform (LEFT, RIGHT, INNER, FULL) or the columns to join on (column names or indices).

```
In [22]: df1 = pd.DataFrame({'key': ['A', 'B', 'C', 'D'],
    ....:                    'value': np.random.randn(4)})
    ....:
```

```
In [23]: df2 = pd.DataFrame({'key': ['B', 'D', 'D', 'E'],
    ....:                    'value': np.random.randn(4)})
    ....:
```

Assume we have two database tables of the same name and structure as our DataFrames.

Now let's go over the various types of JOINS.

INNER JOIN

```

SELECT *
FROM df1
INNER JOIN df2
  ON df1.key = df2.key;

```

```
# merge performs an INNER JOIN by default
```

```
In [24]: pd.merge(df1, df2, on='key')
```

```
Out [24]:
```

	key	value_x	value_y
0	B	-1.181780	0.292988
1	D	0.606962	0.095945
2	D	0.606962	0.245328

`merge()` also offers parameters for cases when you'd like to join one DataFrame's column with another DataFrame's index.

```
In [25]: indexed_df2 = df2.set_index('key')
```

```
In [26]: pd.merge(df1, indexed_df2, left_on='key', right_index=True)
```

```
Out[26]:
```

	key	value_x	value_y
1	B	-1.181780	0.292988
3	D	0.606962	0.095945
3	D	0.606962	0.245328

LEFT OUTER JOIN

```
-- show all records from df1
SELECT *
FROM df1
LEFT OUTER JOIN df2
  ON df1.key = df2.key;
```

```
# show all records from df1
```

```
In [27]: pd.merge(df1, df2, on='key', how='left')
```

```
Out[27]:
```

	key	value_x	value_y
0	A	-0.630829	NaN
1	B	-1.181780	0.292988
2	C	-0.290432	NaN
3	D	0.606962	0.095945
4	D	0.606962	0.245328

RIGHT JOIN

```
-- show all records from df2
SELECT *
FROM df1
RIGHT OUTER JOIN df2
  ON df1.key = df2.key;
```

```
# show all records from df2
```

```
In [28]: pd.merge(df1, df2, on='key', how='right')
```

```
Out[28]:
```

	key	value_x	value_y
0	B	-1.181780	0.292988
1	D	0.606962	0.095945
2	D	0.606962	0.245328
3	E	NaN	-0.807939

FULL JOIN

pandas also allows for FULL JOINS, which display both sides of the dataset, whether or not the joined columns find a match. As of writing, FULL JOINS are not supported in all RDBMS (MySQL).

```
-- show all records from both tables
SELECT *
FROM df1
FULL OUTER JOIN df2
  ON df1.key = df2.key;
```

```
# show all records from both frames
In [29]: pd.merge(df1, df2, on='key', how='outer')
Out[29]:
```

	key	value_x	value_y
0	A	-0.630829	NaN
1	B	-1.181780	0.292988
2	C	-0.290432	NaN
3	D	0.606962	0.095945
4	D	0.606962	0.245328
5	E	NaN	-0.807939

UNION

UNION ALL can be performed using `concat()`.

```
In [30]: df1 = pd.DataFrame({'city': ['Chicago', 'San Francisco', 'New York City'],
.....:                      'rank': range(1, 4)})
.....:

In [31]: df2 = pd.DataFrame({'city': ['Chicago', 'Boston', 'Los Angeles'],
.....:                      'rank': [1, 4, 5]})
.....:
```

```
SELECT city, rank
FROM df1
UNION ALL
SELECT city, rank
FROM df2;
/*
      city  rank
Chicago    1
San Francisco  2
New York City  3
      Chicago    1
          Boston    4
      Los Angeles  5
*/
```

```
In [32]: pd.concat([df1, df2])
Out[32]:
```

(continues on next page)

(continued from previous page)

	city	rank
0	Chicago	1
1	San Francisco	2
2	New York City	3
0	Chicago	1
1	Boston	4
2	Los Angeles	5

SQL's UNION is similar to UNION ALL, however UNION will remove duplicate rows.

```

SELECT city, rank
FROM df1
UNION
SELECT city, rank
FROM df2;
-- notice that there is only one Chicago record this time
/*
      city  rank
    Chicago    1
San Francisco    2
New York City    3
      Boston    4
    Los Angeles    5
*/

```

In pandas, you can use `concat()` in conjunction with `drop_duplicates()`.

```

In [33]: pd.concat([df1, df2]).drop_duplicates()
Out[33]:
      city  rank
0   Chicago    1
1 San Francisco    2
2 New York City    3
1     Boston    4
2  Los Angeles    5

```

Pandas equivalents for some SQL analytic and aggregate functions

Top N rows with offset

```

-- MySQL
SELECT * FROM tips
ORDER BY tip DESC
LIMIT 10 OFFSET 5;

```

```

In [34]: tips.nlargest(10 + 5, columns='tip').tail(10)
Out[34]:
   total_bill  tip  sex smoker  day  time  size
183    23.17  6.50  Male   Yes  Sun  Dinner    4
214    28.17  6.50  Female Yes  Sat  Dinner    3

```

(continues on next page)

(continued from previous page)

47	32.40	6.00	Male	No	Sun	Dinner	4
239	29.03	5.92	Male	No	Sat	Dinner	3
88	24.71	5.85	Male	No	Thur	Lunch	2
181	23.33	5.65	Male	Yes	Sun	Dinner	2
44	30.40	5.60	Male	No	Sun	Dinner	4
52	34.81	5.20	Female	No	Sun	Dinner	4
85	34.83	5.17	Female	No	Thur	Lunch	4
211	25.89	5.16	Male	Yes	Sat	Dinner	4

Top N rows per group

```
-- Oracle's ROW_NUMBER() analytic function
SELECT * FROM (
  SELECT
    t.*,
    ROW_NUMBER() OVER(PARTITION BY day ORDER BY total_bill DESC) AS rn
  FROM tips t
)
WHERE rn < 3
ORDER BY day, rn;
```

```
In [35]: (tips.assign(rn=tips.sort_values(['total_bill'], ascending=False)
.....:                .groupby(['day'])
.....:                .cumcount() + 1)
.....:         .query('rn < 3')
.....:         .sort_values(['day', 'rn']))
.....:
```

Out[35]:

	total_bill	tip	sex	smoker	day	time	size	rn
95	40.17	4.73	Male	Yes	Fri	Dinner	4	1
90	28.97	3.00	Male	Yes	Fri	Dinner	2	2
170	50.81	10.00	Male	Yes	Sat	Dinner	3	1
212	48.33	9.00	Male	No	Sat	Dinner	4	2
156	48.17	5.00	Male	No	Sun	Dinner	6	1
182	45.35	3.50	Male	Yes	Sun	Dinner	3	2
197	43.11	5.00	Female	Yes	Thur	Lunch	4	1
142	41.19	5.00	Male	No	Thur	Lunch	5	2

the same using `rank(method='first')` function

```
In [36]: (tips.assign(rnk=tips.groupby(['day'])['total_bill']
.....:                .rank(method='first', ascending=False))
.....:         .query('rnk < 3')
.....:         .sort_values(['day', 'rnk']))
.....:
```

Out[36]:

	total_bill	tip	sex	smoker	day	time	size	rnk
95	40.17	4.73	Male	Yes	Fri	Dinner	4	1.0
90	28.97	3.00	Male	Yes	Fri	Dinner	2	2.0
170	50.81	10.00	Male	Yes	Sat	Dinner	3	1.0

(continues on next page)

(continued from previous page)

212	48.33	9.00	Male	No	Sat	Dinner	4	2.0
156	48.17	5.00	Male	No	Sun	Dinner	6	1.0
182	45.35	3.50	Male	Yes	Sun	Dinner	3	2.0
197	43.11	5.00	Female	Yes	Thur	Lunch	4	1.0
142	41.19	5.00	Male	No	Thur	Lunch	5	2.0

```
-- Oracle's RANK() analytic function
SELECT * FROM (
  SELECT
    t.*,
    RANK() OVER(PARTITION BY sex ORDER BY tip) AS rnk
  FROM tips t
  WHERE tip < 2
)
WHERE rnk < 3
ORDER BY sex, rnk;
```

Let's find tips with (rank < 3) per gender group for (tips < 2). Notice that when using `rank(method='min')` function `rnk_min` remains the same for the same `tip` (as Oracle's `RANK()` function)

```
In [37]: (tips[tips['tip'] < 2]
....:      .assign(rnk_min=tips.groupby(['sex'])['tip']
....:              .rank(method='min'))
....:      .query('rnk_min < 3')
....:      .sort_values(['sex', 'rnk_min']))
....:
Out[37]:
```

	total_bill	tip	sex	smoker	day	time	size	rnk_min
67	3.07	1.00	Female	Yes	Sat	Dinner	1	1.0
92	5.75	1.00	Female	Yes	Fri	Dinner	2	1.0
111	7.25	1.00	Female	No	Sat	Dinner	1	1.0
236	12.60	1.00	Male	Yes	Sat	Dinner	2	1.0
237	32.83	1.17	Male	Yes	Sat	Dinner	2	2.0

UPDATE

```
UPDATE tips
SET tip = tip*2
WHERE tip < 2;
```

```
In [38]: tips.loc[tips['tip'] < 2, 'tip'] *= 2
```

DELETE

```
DELETE FROM tips
WHERE tip > 9;
```

In pandas we select the rows that should remain, instead of deleting them

```
In [39]: tips = tips.loc[tips['tip'] <= 9]
```

```
{{ header }}
```

3.5.3 Comparison with SAS

For potential users coming from SAS this page is meant to demonstrate how different SAS operations would be performed in pandas.

If you're new to pandas, you might want to first read through *10 Minutes to pandas* to familiarize yourself with the library.

As is customary, we import pandas and NumPy as follows:

```
In [1]: import pandas as pd
```

```
In [2]: import numpy as np
```

Note: Throughout this tutorial, the pandas `DataFrame` will be displayed by calling `df.head()`, which displays the first N (default 5) rows of the `DataFrame`. This is often used in interactive work (e.g. Jupyter notebook or terminal) - the equivalent in SAS would be:

```
proc print data=df(obs=5);
run;
```

Data structures

General terminology translation

pandas	SAS
<code>DataFrame</code>	data set
column	variable
row	observation
groupby	BY-group
NaN	.

`DataFrame` / `Series`

A `DataFrame` in pandas is analogous to a SAS data set - a two-dimensional data source with labeled columns that can be of different types. As will be shown in this document, almost any operation that can be applied to a data set using SAS's `DATA` step, can also be accomplished in pandas.

A `Series` is the data structure that represents one column of a `DataFrame`. SAS doesn't have a separate data structure for a single column, but in general, working with a `Series` is analogous to referencing a column in the `DATA` step.

Index

Every `DataFrame` and `Series` has an `Index` - which are labels on the *rows* of the data. SAS does not have an exactly analogous concept. A data set's rows are essentially unlabeled, other than an implicit integer index that can be accessed during the `DATA` step (`_N_`).

In pandas, if no index is specified, an integer index is also used by default (first row = 0, second row = 1, and so on). While using a labeled `Index` or `MultiIndex` can enable sophisticated analyses and is ultimately an important part of pandas to understand, for this comparison we will essentially ignore the `Index` and just treat the `DataFrame` as a collection of columns. Please see the [indexing documentation](#) for much more on how to use an `Index` effectively.

Data input / output

Constructing a DataFrame from values

A SAS data set can be built from specified values by placing the data after a `datalines` statement and specifying the column names.

```
data df;
  input x y;
  datalines;
  1 2
  3 4
  5 6
  ;
run;
```

A pandas `DataFrame` can be constructed in many different ways, but for a small number of values, it is often convenient to specify it as a Python dictionary, where the keys are the column names and the values are the data.

```
In [3]: df = pd.DataFrame({'x': [1, 3, 5], 'y': [2, 4, 6]})
```

```
In [4]: df
```

```
Out[4]:
   x  y
0  1  2
1  3  4
2  5  6
```

Reading external data

Like SAS, pandas provides utilities for reading in data from many formats. The `tips` dataset, found within the pandas tests (`csv`) will be used in many of the following examples.

SAS provides `PROC IMPORT` to read `csv` data into a data set.

```
proc import datafile='tips.csv' dbms=csv out=tips replace;
  getnames=yes;
run;
```

The pandas method is `read_csv()`, which works similarly.

```
In [5]: url = ('https://raw.githubusercontent.com/pandas-dev/'
...:         'pandas/master/pandas/tests/data/tips.csv')
...:
```

```
In [6]: tips = pd.read_csv(url)
```

```
In [7]: tips.head()
```

```
Out[7]:
```

	total_bill	tip	sex	smoker	day	time	size
0	16.99	1.01	Female	No	Sun	Dinner	2
1	10.34	1.66	Male	No	Sun	Dinner	3
2	21.01	3.50	Male	No	Sun	Dinner	3
3	23.68	3.31	Male	No	Sun	Dinner	2
4	24.59	3.61	Female	No	Sun	Dinner	4

Like PROC IMPORT, read_csv can take a number of parameters to specify how the data should be parsed. For example, if the data was instead tab delimited, and did not have column names, the pandas command would be:

```
tips = pd.read_csv('tips.csv', sep='\t', header=None)

# alternatively, read_table is an alias to read_csv with tab delimiter
tips = pd.read_table('tips.csv', header=None)
```

In addition to text/csv, pandas supports a variety of other data formats such as Excel, HDF5, and SQL databases. These are all read via a pd.read_* function. See the *IO documentation* for more details.

Exporting data

The inverse of PROC IMPORT in SAS is PROC EXPORT

```
proc export data=tips outfile='tips2.csv' dbms=csv;
run;
```

Similarly in pandas, the opposite of read_csv is to_csv(), and other data formats follow a similar api.

```
tips.to_csv('tips2.csv')
```

Data operations

Operations on columns

In the DATA step, arbitrary math expressions can be used on new or existing columns.

```
data tips;
  set tips;
  total_bill = total_bill - 2;
  new_bill = total_bill / 2;
run;
```

pandas provides similar vectorized operations by specifying the individual Series in the DataFrame. New columns can be assigned in the same way.

```
In [8]: tips['total_bill'] = tips['total_bill'] - 2

In [9]: tips['new_bill'] = tips['total_bill'] / 2.0

In [10]: tips.head()
Out[10]:
```

	total_bill	tip	sex	smoker	day	time	size	new_bill
0	14.99	1.01	Female	No	Sun	Dinner	2	7.495
1	8.34	1.66	Male	No	Sun	Dinner	3	4.170
2	19.01	3.50	Male	No	Sun	Dinner	3	9.505
3	21.68	3.31	Male	No	Sun	Dinner	2	10.840
4	22.59	3.61	Female	No	Sun	Dinner	4	11.295

Filtering

Filtering in SAS is done with an `if` or `where` statement, on one or more columns.

```
data tips;
  set tips;
  if total_bill > 10;
run;

data tips;
  set tips;
  where total_bill > 10;
  /* equivalent in this case - where happens before the
  DATA step begins and can also be used in PROC statements */
run;
```

DataFrames can be filtered in multiple ways; the most intuitive of which is using *boolean indexing*

```
In [11]: tips[tips['total_bill'] > 10].head()
Out[11]:
```

	total_bill	tip	sex	smoker	day	time	size
0	14.99	1.01	Female	No	Sun	Dinner	2
2	19.01	3.50	Male	No	Sun	Dinner	3
3	21.68	3.31	Male	No	Sun	Dinner	2
4	22.59	3.61	Female	No	Sun	Dinner	4
5	23.29	4.71	Male	No	Sun	Dinner	4

If/then logic

In SAS, if/then logic can be used to create new columns.

```
data tips;
  set tips;
  format bucket $4.;

  if total_bill < 10 then bucket = 'low';
  else bucket = 'high';
run;
```

The same operation in pandas can be accomplished using the `where` method from `numpy`.

```
In [12]: tips['bucket'] = np.where(tips['total_bill'] < 10, 'low', 'high')
```

```
In [13]: tips.head()
```

```
Out[13]:
```

	total_bill	tip	sex	smoker	day	time	size	bucket
0	14.99	1.01	Female	No	Sun	Dinner	2	high
1	8.34	1.66	Male	No	Sun	Dinner	3	low
2	19.01	3.50	Male	No	Sun	Dinner	3	high
3	21.68	3.31	Male	No	Sun	Dinner	2	high
4	22.59	3.61	Female	No	Sun	Dinner	4	high

Date functionality

SAS provides a variety of functions to do operations on date/datetime columns.

```
data tips;
  set tips;
  format date1 date2 date1_plusmonth mmdyy10.;
  date1 = mdy(1, 15, 2013);
  date2 = mdy(2, 15, 2015);
  date1_year = year(date1);
  date2_month = month(date2);
  * shift date to beginning of next interval;
  date1_next = intnx('MONTH', date1, 1);
  * count intervals between dates;
  months_between = intck('MONTH', date1, date2);
run;
```

The equivalent pandas operations are shown below. In addition to these functions pandas supports other Time Series features not available in Base SAS (such as resampling and custom offsets) - see the *timeseries documentation* for more details.

```
In [14]: tips['date1'] = pd.Timestamp('2013-01-15')
```

```
In [15]: tips['date2'] = pd.Timestamp('2015-02-15')
```

```
In [16]: tips['date1_year'] = tips['date1'].dt.year
```

```
In [17]: tips['date2_month'] = tips['date2'].dt.month
```

```
In [18]: tips['date1_next'] = tips['date1'] + pd.offsets.MonthBegin()
```

```
In [19]: tips['months_between'] = (
.....:     tips['date2'].dt.to_period('M') - tips['date1'].dt.to_period('M'))
.....:
```

```
In [20]: tips[['date1', 'date2', 'date1_year', 'date2_month',
.....:         'date1_next', 'months_between']].head()
.....:
```

```
Out[20]:
```

(continues on next page)

(continued from previous page)

	date1	date2	date1_year	date2_month	date1_next	months_between
0	2013-01-15	2015-02-15	2013	2	2013-02-01	<25 * MonthEnds>
1	2013-01-15	2015-02-15	2013	2	2013-02-01	<25 * MonthEnds>
2	2013-01-15	2015-02-15	2013	2	2013-02-01	<25 * MonthEnds>
3	2013-01-15	2015-02-15	2013	2	2013-02-01	<25 * MonthEnds>
4	2013-01-15	2015-02-15	2013	2	2013-02-01	<25 * MonthEnds>

Selection of columns

SAS provides keywords in the DATA step to select, drop, and rename columns.

```
data tips;
  set tips;
  keep sex total_bill tip;
run;

data tips;
  set tips;
  drop sex;
run;

data tips;
  set tips;
  rename total_bill=total_bill_2;
run;
```

The same operations are expressed in pandas below.

```
# keep
In [21]: tips[['sex', 'total_bill', 'tip']].head()
Out[21]:
   sex  total_bill  tip
0  Female     14.99  1.01
1   Male      8.34  1.66
2   Male     19.01  3.50
3   Male     21.68  3.31
4  Female     22.59  3.61

# drop
In [22]: tips.drop('sex', axis=1).head()
Out[22]:
   total_bill  tip  smoker  day  time  size
0     14.99  1.01     No  Sun  Dinner    2
1      8.34  1.66     No  Sun  Dinner    3
2     19.01  3.50     No  Sun  Dinner    3
3     21.68  3.31     No  Sun  Dinner    2
4     22.59  3.61     No  Sun  Dinner    4

# rename
In [23]: tips.rename(columns={'total_bill': 'total_bill_2'}).head()
Out[23]:
   total_bill_2  tip  sex  smoker  day  time  size
```

0	14.99	1.01	Female	No	Sun	Dinner	2
1	8.34	1.66	Male	No	Sun	Dinner	3
2	19.01	3.50	Male	No	Sun	Dinner	3
3	21.68	3.31	Male	No	Sun	Dinner	2
4	22.59	3.61	Female	No	Sun	Dinner	4

Sorting by values

Sorting in SAS is accomplished via PROC SORT

```
proc sort data=tips;
  by sex total_bill;
run;
```

pandas objects have a `sort_values()` method, which takes a list of columns to sort by.

```
In [24]: tips = tips.sort_values(['sex', 'total_bill'])
```

```
In [25]: tips.head()
```

```
Out[25]:
```

	total_bill	tip	sex	smoker	day	time	size
67	1.07	1.00	Female	Yes	Sat	Dinner	1
92	3.75	1.00	Female	Yes	Fri	Dinner	2
111	5.25	1.00	Female	No	Sat	Dinner	1
145	6.35	1.50	Female	No	Thur	Lunch	2
135	6.51	1.25	Female	No	Thur	Lunch	2

String processing

Length

SAS determines the length of a character string with the `LENGTHN` and `LENGTHC` functions. `LENGTHN` excludes trailing blanks and `LENGTHC` includes trailing blanks.

```
data _null_;
set tips;
put(LENGTHN(time));
put(LENGTHC(time));
run;
```

Python determines the length of a character string with the `len` function. `len` includes trailing blanks. Use `len` and `rstrip` to exclude trailing blanks.

```
In [26]: tips['time'].str.len().head()
```

```
Out[26]:
```

```
67    6
```

```
92    6
```

```
111   6
```

```
145   5
```

```
135   5
```

```
Name: time, dtype: int64
```

```
In [27]: tips['time'].str.rstrip().str.len().head()
```

```
Out[27]:
67      6
92      6
111     6
145     5
135     5
Name: time, dtype: int64
```

Find

SAS determines the position of a character in a string with the `FINDW` function. `FINDW` takes the string defined by the first argument and searches for the first position of the substring you supply as the second argument.

```
data _null_;
set tips;
put(FINDW(sex,'ale'));
run;
```

Python determines the position of a character in a string with the `find` function. `find` searches for the first position of the substring. If the substring is found, the function returns its position. Keep in mind that Python indexes are zero-based and the function will return -1 if it fails to find the substring.

```
In [28]: tips['sex'].str.find("ale").head()
Out[28]:
67      3
92      3
111     3
145     3
135     3
Name: sex, dtype: int64
```

Substring

SAS extracts a substring from a string based on its position with the `SUBSTR` function.

```
data _null_;
set tips;
put(substr(sex,1,1));
run;
```

With pandas you can use `[]` notation to extract a substring from a string by position locations. Keep in mind that Python indexes are zero-based.

```
In [29]: tips['sex'].str[0:1].head()
Out[29]:
67      F
92      F
111     F
145     F
135     F
Name: sex, dtype: object
```

Scan

The SAS `SCAN` function returns the *n*th word from a string. The first argument is the string you want to parse and the second argument specifies which word you want to extract.

```
data firstlast;
input String $60.;
First_Name = scan(string, 1);
Last_Name = scan(string, -1);
datalines2;
John Smith;
Jane Cook;
;;;
run;
```

Python extracts a substring from a string based on its text by using regular expressions. There are much more powerful approaches, but this just shows a simple approach.

```
In [30]: firstlast = pd.DataFrame({'String': ['John Smith', 'Jane Cook']})

In [31]: firstlast['First_Name'] = firstlast['String'].str.split(" ", expand=True)[0]

In [32]: firstlast['Last_Name'] = firstlast['String'].str.rsplit(" ", expand=True)[0]

In [33]: firstlast
Out[33]:
```

	String	First_Name	Last_Name
0	John Smith	John	John
1	Jane Cook	Jane	Jane

Uppcase, lowercase, and proppcase

The SAS `UPCASE` `LOWCASE` and `PROPCASE` functions change the case of the argument.

```
data firstlast;
input String $60.;
string_up = UPCASE(string);
string_low = LOWCASE(string);
string_prop = PROPCASE(string);
datalines2;
John Smith;
Jane Cook;
;;;
run;
```

The equivalent Python functions are `upper`, `lower`, and `title`.

```
In [34]: firstlast = pd.DataFrame({'String': ['John Smith', 'Jane Cook']})

In [35]: firstlast['string_up'] = firstlast['String'].str.upper()

In [36]: firstlast['string_low'] = firstlast['String'].str.lower()
```

(continues on next page)

(continued from previous page)

```
In [37]: firstlast['string_prop'] = firstlast['String'].str.title()
```

```
In [38]: firstlast
```

```
Out[38]:
```

	String	string_up	string_low	string_prop
0	John Smith	JOHN SMITH	john smith	John Smith
1	Jane Cook	JANE COOK	jane cook	Jane Cook

Merging

The following tables will be used in the merge examples

```
In [39]: df1 = pd.DataFrame({'key': ['A', 'B', 'C', 'D'],
.....:                      'value': np.random.randn(4)})
.....:
```

```
In [40]: df1
```

```
Out[40]:
```

	key	value
0	A	0.970270
1	B	0.438338
2	C	0.402038
3	D	-0.629526

```
In [41]: df2 = pd.DataFrame({'key': ['B', 'D', 'D', 'E'],
.....:                      'value': np.random.randn(4)})
.....:
```

```
In [42]: df2
```

```
Out[42]:
```

	key	value
0	B	-0.600662
1	D	-0.478682
2	D	-0.546915
3	E	-0.054672

In SAS, data must be explicitly sorted before merging. Different types of joins are accomplished using the `in=` dummy variables to track whether a match was found in one or both input frames.

```
proc sort data=df1;
  by key;
run;

proc sort data=df2;
  by key;
run;

data left_join inner_join right_join outer_join;
  merge df1(in=a) df2(in=b);
```

(continues on next page)

(continued from previous page)

```
if a and b then output inner_join;
if a then output left_join;
if b then output right_join;
if a or b then output outer_join;
run;
```

pandas DataFrames have a `merge()` method, which provides similar functionality. Note that the data does not have to be sorted ahead of time, and different join types are accomplished via the `how` keyword.

```
In [43]: inner_join = df1.merge(df2, on=['key'], how='inner')
```

```
In [44]: inner_join
```

```
Out[44]:
```

```
   key  value_x  value_y
0    B  0.438338 -0.600662
1    D -0.629526 -0.478682
2    D -0.629526 -0.546915
```

```
In [45]: left_join = df1.merge(df2, on=['key'], how='left')
```

```
In [46]: left_join
```

```
Out[46]:
```

```
   key  value_x  value_y
0    A  0.970270      NaN
1    B  0.438338 -0.600662
2    C  0.402038      NaN
3    D -0.629526 -0.478682
4    D -0.629526 -0.546915
```

```
In [47]: right_join = df1.merge(df2, on=['key'], how='right')
```

```
In [48]: right_join
```

```
Out[48]:
```

```
   key  value_x  value_y
0    B  0.438338 -0.600662
1    D -0.629526 -0.478682
2    D -0.629526 -0.546915
3    E         NaN -0.054672
```

```
In [49]: outer_join = df1.merge(df2, on=['key'], how='outer')
```

```
In [50]: outer_join
```

```
Out[50]:
```

```
   key  value_x  value_y
0    A  0.970270      NaN
1    B  0.438338 -0.600662
2    C  0.402038      NaN
3    D -0.629526 -0.478682
4    D -0.629526 -0.546915
5    E         NaN -0.054672
```

Missing data

Like SAS, pandas has a representation for missing data - which is the special float value NaN (not a number). Many of the semantics are the same, for example missing data propagates through numeric operations, and is ignored by default for aggregations.

```
In [51]: outer_join
```

```
Out[51]:
```

```
   key  value_x  value_y
0  A  0.970270      NaN
1  B  0.438338 -0.600662
2  C  0.402038      NaN
3  D -0.629526 -0.478682
4  D -0.629526 -0.546915
5  E           NaN -0.054672
```

```
In [52]: outer_join['value_x'] + outer_join['value_y']
```

```
Out[52]:
```

```
0      NaN
1  -0.162324
2      NaN
3  -1.108208
4  -1.176442
5      NaN
dtype: float64
```

```
In [53]: outer_join['value_x'].sum()
```

```
Out[53]: 0.5515934095727003
```

One difference is that missing data cannot be compared to its sentinel value. For example, in SAS you could do this to filter missing values.

```
data outer_join_nulls;
  set outer_join;
  if value_x = .;
run;

data outer_join_no_nulls;
  set outer_join;
  if value_x ^= .;
run;
```

Which doesn't work in pandas. Instead, the `pd.isna` or `pd.notna` functions should be used for comparisons.

```
In [54]: outer_join[pd.isna(outer_join['value_x'])]
```

```
Out[54]:
```

```
   key  value_x  value_y
5  E           NaN -0.054672
```

```
In [55]: outer_join[pd.notna(outer_join['value_x'])]
```

```
Out[55]:
```

```
   key  value_x  value_y
0  A  0.970270      NaN
1  B  0.438338 -0.600662
2  C  0.402038      NaN
3  D -0.629526 -0.478682
```

```
4 D -0.629526 -0.546915
```

pandas also provides a variety of methods to work with missing data - some of which would be challenging to express in SAS. For example, there are methods to drop all rows with any missing values, replacing missing values with a specified value, like the mean, or forward filling from previous rows. See the [missing data documentation](#) for more.

```
In [56]: outer_join.dropna()
```

```
Out[56]:
```

```
   key  value_x  value_y
1  B  0.438338 -0.600662
3  D -0.629526 -0.478682
4  D -0.629526 -0.546915
```

```
In [57]: outer_join.fillna(method='ffill')
```

```
Out[57]:
```

```
   key  value_x  value_y
0  A  0.970270      NaN
1  B  0.438338 -0.600662
2  C  0.402038 -0.600662
3  D -0.629526 -0.478682
4  D -0.629526 -0.546915
5  E -0.629526 -0.054672
```

```
In [58]: outer_join['value_x'].fillna(outer_join['value_x'].mean())
```

```
Out[58]:
```

```
0    0.970270
1    0.438338
2    0.402038
3   -0.629526
4   -0.629526
5    0.110319
```

```
Name: value_x, dtype: float64
```

GroupBy

Aggregation

SAS's PROC SUMMARY can be used to group by one or more key variables and compute aggregations on numeric columns.

```
proc summary data=tips nway;
  class sex smoker;
  var total_bill tip;
  output out=tips_summed sum=;
run;
```

pandas provides a flexible groupby mechanism that allows similar aggregations. See the [groupby documentation](#) for more details and examples.

```
In [59]: tips_summed = tips.groupby(['sex', 'smoker'])['total_bill', 'tip'].sum()
```

```
In [60]: tips_summed.head()
```

(continues on next page)

(continued from previous page)

```
Out [60]:
```

		total_bill	tip
sex	smoker		
Female	No	869.68	149.77
	Yes	527.27	96.74
Male	No	1725.75	302.00
	Yes	1217.07	183.07

Transformation

In SAS, if the group aggregations need to be used with the original frame, it must be merged back together. For example, to subtract the mean for each observation by smoker group.

```
proc summary data=tips missing nway;
  class smoker;
  var total_bill;
  output out=smoker_means mean(total_bill)=group_bill;
run;

proc sort data=tips;
  by smoker;
run;

data tips;
  merge tips(in=a) smoker_means(in=b);
  by smoker;
  adj_total_bill = total_bill - group_bill;
  if a and b;
run;
```

pandas `groupby` provides a `transform` mechanism that allows these type of operations to be succinctly expressed in one operation.

```
In [61]: gb = tips.groupby('smoker')['total_bill']

In [62]: tips['adj_total_bill'] = tips['total_bill'] - gb.transform('mean')

In [63]: tips.head()
Out [63]:
```

	total_bill	tip	sex	smoker	day	time	size	adj_total_bill
67	1.07	1.00	Female	Yes	Sat	Dinner	1	-17.686344
92	3.75	1.00	Female	Yes	Fri	Dinner	2	-15.006344
111	5.25	1.00	Female	No	Sat	Dinner	1	-11.938278
145	6.35	1.50	Female	No	Thur	Lunch	2	-10.838278
135	6.51	1.25	Female	No	Thur	Lunch	2	-10.678278

By group processing

In addition to aggregation, pandas `groupby` can be used to replicate most other by group processing from SAS. For example, this `DATA` step reads the data by sex/smoker group and filters to the first entry for each.

```

proc sort data=tips;
  by sex smoker;
run;

data tips_first;
  set tips;
  by sex smoker;
  if FIRST.sex or FIRST.smoker then output;
run;

```

In pandas this would be written as:

```

In [64]: tips.groupby(['sex', 'smoker']).first()
Out[64]:

```

sex	smoker	total_bill	tip	day	time	size	adj_total_bill
Female	No	5.25	1.00	Sat	Dinner	1	-11.938278
	Yes	1.07	1.00	Sat	Dinner	1	-17.686344
Male	No	5.51	2.00	Thur	Lunch	2	-11.678278
	Yes	5.25	5.15	Sun	Dinner	2	-13.506344

Other Considerations

Disk vs memory

pandas operates exclusively in memory, where a SAS data set exists on disk. This means that the size of data able to be loaded in pandas is limited by your machine's memory, but also that the operations on that data may be faster.

If out of core processing is needed, one possibility is the `dask.dataframe` library (currently in development) which provides a subset of pandas functionality for an on-disk `DataFrame`

Data interop

pandas provides a `read_sas()` method that can read SAS data saved in the XPORT or SAS7BDAT binary format.

```

libname xportout xport 'transport-file.xpt';
data xportout.tips;
  set tips(rename=(total_bill=tbill));
  * xport variable names limited to 6 characters;
run;

```

```

df = pd.read_sas('transport-file.xpt')
df = pd.read_sas('binary-file.sas7bdat')

```

You can also specify the file format directly. By default, pandas will try to infer the file format based on its extension.

```

df = pd.read_sas('transport-file.xpt', format='xport')
df = pd.read_sas('binary-file.sas7bdat', format='sas7bdat')

```

XPORT is a relatively limited format and the parsing of it is not as optimized as some of the other pandas readers. An alternative way to interop data between SAS and pandas is to serialize to csv.

```
# version 0.17, 10M rows

In [8]: %time df = pd.read_sas('big.xpt')
Wall time: 14.6 s

In [9]: %time df = pd.read_csv('big.csv')
Wall time: 4.86 s
```

```
{{ header }}
```

3.5.4 Comparison with Stata

For potential users coming from *Stata* this page is meant to demonstrate how different Stata operations would be performed in pandas.

If you're new to pandas, you might want to first read through *10 Minutes to pandas* to familiarize yourself with the library.

As is customary, we import pandas and NumPy as follows. This means that we can refer to the libraries as `pd` and `np`, respectively, for the rest of the document.

```
In [1]: import pandas as pd

In [2]: import numpy as np
```

Note: Throughout this tutorial, the pandas `DataFrame` will be displayed by calling `df.head()`, which displays the first N (default 5) rows of the `DataFrame`. This is often used in interactive work (e.g. *Jupyter notebook* or terminal) – the equivalent in *Stata* would be:

```
list in 1/5
```

Data structures

General terminology translation

pandas	Stata
<code>DataFrame</code>	data set
column	variable
row	observation
<code>groupby</code>	<code>bysort</code>
<code>NaN</code>	.

`DataFrame` / `Series`

A `DataFrame` in pandas is analogous to a Stata data set – a two-dimensional data source with labeled columns that can be of different types. As will be shown in this document, almost any operation that can be applied

to a data set in Stata can also be accomplished in pandas.

A **Series** is the data structure that represents one column of a **DataFrame**. Stata doesn't have a separate data structure for a single column, but in general, working with a **Series** is analogous to referencing a column of a data set in Stata.

Index

Every **DataFrame** and **Series** has an **Index** – labels on the *rows* of the data. Stata does not have an exactly analogous concept. In Stata, a data set's rows are essentially unlabeled, other than an implicit integer index that can be accessed with `_n`.

In pandas, if no index is specified, an integer index is also used by default (first row = 0, second row = 1, and so on). While using a labeled **Index** or **MultiIndex** can enable sophisticated analyses and is ultimately an important part of pandas to understand, for this comparison we will essentially ignore the **Index** and just treat the **DataFrame** as a collection of columns. Please see the [indexing documentation](#) for much more on how to use an **Index** effectively.

Data input / output

Constructing a DataFrame from values

A Stata data set can be built from specified values by placing the data after an `input` statement and specifying the column names.

```
input x y
1 2
3 4
5 6
end
```

A pandas **DataFrame** can be constructed in many different ways, but for a small number of values, it is often convenient to specify it as a Python dictionary, where the keys are the column names and the values are the data.

```
In [3]: df = pd.DataFrame({'x': [1, 3, 5], 'y': [2, 4, 6]})
```

```
In [4]: df
```

```
Out[4]:
   x  y
0  1  2
1  3  4
2  5  6
```

Reading external data

Like Stata, pandas provides utilities for reading in data from many formats. The `tips` data set, found within the pandas tests (`csv`) will be used in many of the following examples.

Stata provides `import delimited` to read csv data into a data set in memory. If the `tips.csv` file is in the current working directory, we can import it as follows.

```
import delimited tips.csv
```

The pandas method is `read_csv()`, which works similarly. Additionally, it will automatically download the data set if presented with a url.

```
In [5]: url = ('https://raw.githubusercontent.com/pandas-dev/
...:         '/pandas/master/pandas/tests/data/tips.csv')
...:
```

```
In [6]: tips = pd.read_csv(url)
```

```
In [7]: tips.head()
```

```
Out[7]:
```

	total_bill	tip	sex	smoker	day	time	size
0	16.99	1.01	Female	No	Sun	Dinner	2
1	10.34	1.66	Male	No	Sun	Dinner	3
2	21.01	3.50	Male	No	Sun	Dinner	3
3	23.68	3.31	Male	No	Sun	Dinner	2
4	24.59	3.61	Female	No	Sun	Dinner	4

Like `import delimited`, `read_csv()` can take a number of parameters to specify how the data should be parsed. For example, if the data were instead tab delimited, did not have column names, and existed in the current working directory, the pandas command would be:

```
tips = pd.read_csv('tips.csv', sep='\t', header=None)

# alternatively, read_table is an alias to read_csv with tab delimiter
tips = pd.read_table('tips.csv', header=None)
```

Pandas can also read Stata data sets in `.dta` format with the `read_stata()` function.

```
df = pd.read_stata('data.dta')
```

In addition to `text/csv` and Stata files, pandas supports a variety of other data formats such as Excel, SAS, HDF5, Parquet, and SQL databases. These are all read via a `pd.read_*` function. See the *IO documentation* for more details.

Exporting data

The inverse of `import delimited` in Stata is `export delimited`

```
export delimited tips2.csv
```

Similarly in pandas, the opposite of `read_csv` is `DataFrame.to_csv()`.

```
tips.to_csv('tips2.csv')
```

Pandas can also export to Stata file format with the `DataFrame.to_stata()` method.

```
tips.to_stata('tips2.dta')
```

Data operations

Operations on columns

In Stata, arbitrary math expressions can be used with the `generate` and `replace` commands on new or existing columns. The `drop` command drops the column from the data set.

```
replace total_bill = total_bill - 2
generate new_bill = total_bill / 2
drop new_bill
```

pandas provides similar vectorized operations by specifying the individual `Series` in the `DataFrame`. New columns can be assigned in the same way. The `DataFrame.drop()` method drops a column from the `DataFrame`.

```
In [8]: tips['total_bill'] = tips['total_bill'] - 2
In [9]: tips['new_bill'] = tips['total_bill'] / 2
In [10]: tips.head()
Out[10]:
   total_bill  tip  sex smoker  day  time  size  new_bill
0      14.99  1.01 Female   No  Sun  Dinner    2    7.495
1       8.34  1.66   Male   No  Sun  Dinner    3    4.170
2      19.01  3.50   Male   No  Sun  Dinner    3    9.505
3      21.68  3.31   Male   No  Sun  Dinner    2   10.840
4      22.59  3.61 Female   No  Sun  Dinner    4   11.295
In [11]: tips = tips.drop('new_bill', axis=1)
```

Filtering

Filtering in Stata is done with an `if` clause on one or more columns.

```
list if total_bill > 10
```

`DataFrames` can be filtered in multiple ways; the most intuitive of which is using *boolean indexing*.

```
In [12]: tips[tips['total_bill'] > 10].head()
Out[12]:
   total_bill  tip  sex smoker  day  time  size
0      14.99  1.01 Female   No  Sun  Dinner    2
2      19.01  3.50   Male   No  Sun  Dinner    3
3      21.68  3.31   Male   No  Sun  Dinner    2
4      22.59  3.61 Female   No  Sun  Dinner    4
5      23.29  4.71   Male   No  Sun  Dinner    4
```

If/then logic

In Stata, an `if` clause can also be used to create new columns.

```
generate bucket = "low" if total_bill < 10
replace bucket = "high" if total_bill >= 10
```

The same operation in pandas can be accomplished using the `where` method from `numpy`.

```
In [13]: tips['bucket'] = np.where(tips['total_bill'] < 10, 'low', 'high')

In [14]: tips.head()
Out[14]:
```

	total_bill	tip	sex	smoker	day	time	size	bucket
0	14.99	1.01	Female	No	Sun	Dinner	2	high
1	8.34	1.66	Male	No	Sun	Dinner	3	low
2	19.01	3.50	Male	No	Sun	Dinner	3	high
3	21.68	3.31	Male	No	Sun	Dinner	2	high
4	22.59	3.61	Female	No	Sun	Dinner	4	high

Date functionality

Stata provides a variety of functions to do operations on date/datetime columns.

```
generate date1 = mdy(1, 15, 2013)
generate date2 = date("Feb152015", "MDY")

generate date1_year = year(date1)
generate date2_month = month(date2)

* shift date to beginning of next month
generate date1_next = mdy(month(date1) + 1, 1, year(date1)) if month(date1) != 12
replace date1_next = mdy(1, 1, year(date1) + 1) if month(date1) == 12
generate months_between = mofd(date2) - mofd(date1)

list date1 date2 date1_year date2_month date1_next months_between
```

The equivalent pandas operations are shown below. In addition to these functions, pandas supports other Time Series features not available in Stata (such as time zone handling and custom offsets) – see the *timeseries documentation* for more details.

```
In [15]: tips['date1'] = pd.Timestamp('2013-01-15')

In [16]: tips['date2'] = pd.Timestamp('2015-02-15')

In [17]: tips['date1_year'] = tips['date1'].dt.year

In [18]: tips['date2_month'] = tips['date2'].dt.month

In [19]: tips['date1_next'] = tips['date1'] + pd.offsets.MonthBegin()

In [20]: tips['months_between'] = (tips['date2'].dt.to_period('M')
.....:                               - tips['date1'].dt.to_period('M'))
.....:

In [21]: tips[['date1', 'date2', 'date1_year', 'date2_month', 'date1_next',
.....:           'months_between']].head()
.....:
Out[21]:
```

(continues on next page)

(continued from previous page)

	date1	date2	date1_year	date2_month	date1_next	months_between
0	2013-01-15	2015-02-15	2013	2	2013-02-01	<25 * MonthEnds>
1	2013-01-15	2015-02-15	2013	2	2013-02-01	<25 * MonthEnds>
2	2013-01-15	2015-02-15	2013	2	2013-02-01	<25 * MonthEnds>
3	2013-01-15	2015-02-15	2013	2	2013-02-01	<25 * MonthEnds>
4	2013-01-15	2015-02-15	2013	2	2013-02-01	<25 * MonthEnds>

Selection of columns

Stata provides keywords to select, drop, and rename columns.

```
keep sex total_bill tip
drop sex
rename total_bill total_bill_2
```

The same operations are expressed in pandas below. Note that in contrast to Stata, these operations do not happen in place. To make these changes persist, assign the operation back to a variable.

```
# keep
In [22]: tips[['sex', 'total_bill', 'tip']].head()
Out[22]:
   sex  total_bill  tip
0  Female     14.99  1.01
1   Male      8.34  1.66
2   Male     19.01  3.50
3   Male     21.68  3.31
4  Female     22.59  3.61

# drop
In [23]: tips.drop('sex', axis=1).head()
Out[23]:
   total_bill  tip  smoker  day  time  size
0     14.99  1.01     No  Sun  Dinner    2
1      8.34  1.66     No  Sun  Dinner    3
2     19.01  3.50     No  Sun  Dinner    3
3     21.68  3.31     No  Sun  Dinner    2
4     22.59  3.61     No  Sun  Dinner    4

# rename
In [24]: tips.rename(columns={'total_bill': 'total_bill_2'}).head()
Out[24]:
   total_bill_2  tip  sex  smoker  day  time  size
0     14.99  1.01  Female     No  Sun  Dinner    2
1      8.34  1.66   Male     No  Sun  Dinner    3
2     19.01  3.50   Male     No  Sun  Dinner    3
3     21.68  3.31   Male     No  Sun  Dinner    2
4     22.59  3.61  Female     No  Sun  Dinner    4
```

Sorting by values

Sorting in Stata is accomplished via `sort`

```
sort sex total_bill
```

pandas objects have a `DataFrame.sort_values()` method, which takes a list of columns to sort by.

```
In [25]: tips = tips.sort_values(['sex', 'total_bill'])
```

```
In [26]: tips.head()
```

```
Out[26]:
```

	total_bill	tip	sex	smoker	day	time	size
67	1.07	1.00	Female	Yes	Sat	Dinner	1
92	3.75	1.00	Female	Yes	Fri	Dinner	2
111	5.25	1.00	Female	No	Sat	Dinner	1
145	6.35	1.50	Female	No	Thur	Lunch	2
135	6.51	1.25	Female	No	Thur	Lunch	2

String processing

Finding length of string

Stata determines the length of a character string with the `strlen()` and `ustrlen()` functions for ASCII and Unicode strings, respectively.

```
generate strlen_time = strlen(time)
generate ustrlen_time = ustrlen(time)
```

Python determines the length of a character string with the `len` function. In Python 3, all strings are Unicode strings. `len` includes trailing blanks. Use `len` and `rstrip` to exclude trailing blanks.

```
In [27]: tips['time'].str.len().head()
```

```
Out[27]:
```

```
67    6
92    6
111   6
145   5
135   5
```

```
Name: time, dtype: int64
```

```
In [28]: tips['time'].str.rstrip().str.len().head()
```

```
Out[28]:
```

```
67    6
92    6
111   6
145   5
135   5
```

```
Name: time, dtype: int64
```

Finding position of substring

Stata determines the position of a character in a string with the `strpos()` function. This takes the string defined by the first argument and searches for the first position of the substring you supply as the second argument.

```
generate str_position = strpos(sex, "ale")
```

Python determines the position of a character in a string with the `find()` function. `find` searches for the first position of the substring. If the substring is found, the function returns its position. Keep in mind that Python indexes are zero-based and the function will return -1 if it fails to find the substring.

```
In [29]: tips['sex'].str.find("ale").head()
Out[29]:
67      3
92      3
111     3
145     3
135     3
Name: sex, dtype: int64
```

Extracting substring by position

Stata extracts a substring from a string based on its position with the `substr()` function.

```
generate short_sex = substr(sex, 1, 1)
```

With pandas you can use `[]` notation to extract a substring from a string by position locations. Keep in mind that Python indexes are zero-based.

```
In [30]: tips['sex'].str[0:1].head()
Out[30]:
67      F
92      F
111     F
145     F
135     F
Name: sex, dtype: object
```

Extracting nth word

The Stata `word()` function returns the `nth` word from a string. The first argument is the string you want to parse and the second argument specifies which word you want to extract.

```
clear
input str20 string
"John Smith"
"Jane Cook"
end
```

(continues on next page)

(continued from previous page)

```
generate first_name = word(name, 1)
generate last_name = word(name, -1)
```

Python extracts a substring from a string based on its text by using regular expressions. There are much more powerful approaches, but this just shows a simple approach.

```
In [31]: firstlast = pd.DataFrame({'string': ['John Smith', 'Jane Cook']})
In [32]: firstlast['First_Name'] = firstlast['string'].str.split(" ", expand=True)[0]
In [33]: firstlast['Last_Name'] = firstlast['string'].str.rsplit(" ", expand=True)[0]
In [34]: firstlast
Out[34]:
      string First_Name Last_Name
0  John Smith      John      John
1   Jane Cook      Jane      Jane
```

Changing case

The Stata `strupper()`, `strlower()`, `strproper()`, `ustrupper()`, `ustrlower()`, and `ustrtitle()` functions change the case of ASCII and Unicode strings, respectively.

```
clear
input str20 string
"John Smith"
"Jane Cook"
end

generate upper = strupper(string)
generate lower = strlower(string)
generate title = strproper(string)
list
```

The equivalent Python functions are `upper`, `lower`, and `title`.

```
In [35]: firstlast = pd.DataFrame({'string': ['John Smith', 'Jane Cook']})
In [36]: firstlast['upper'] = firstlast['string'].str.upper()
In [37]: firstlast['lower'] = firstlast['string'].str.lower()
In [38]: firstlast['title'] = firstlast['string'].str.title()
In [39]: firstlast
Out[39]:
      string      upper      lower      title
0  John Smith  JOHN SMITH  john smith  John Smith
1   Jane Cook  JANE COOK   jane cook   Jane Cook
```

Merging

The following tables will be used in the merge examples

```
In [40]: df1 = pd.DataFrame({'key': ['A', 'B', 'C', 'D'],
.....:                    'value': np.random.randn(4)})
.....:

In [41]: df1
Out[41]:
   key  value
0  A -1.456807
1  B  1.779988
2  C -1.602829
3  D  0.944411

In [42]: df2 = pd.DataFrame({'key': ['B', 'D', 'D', 'E'],
.....:                    'value': np.random.randn(4)})
.....:

In [43]: df2
Out[43]:
   key  value
0  B  0.750030
1  D  0.349022
2  D  1.433851
3  E -0.720900
```

In Stata, to perform a merge, one data set must be in memory and the other must be referenced as a file name on disk. In contrast, Python must have both `DataFrames` already in memory.

By default, Stata performs an outer join, where all observations from both data sets are left in memory after the merge. One can keep only observations from the initial data set, the merged data set, or the intersection of the two by using the values created in the `_merge` variable.

```
* First create df2 and save to disk
clear
input str1 key
B
D
D
E
end
generate value = rnormal()
save df2.dta

* Now create df1 in memory
clear
input str1 key
A
B
C
D
end
```

(continues on next page)

(continued from previous page)

```

generate value = rnormal()

preserve

* Left join
merge 1:n key using df2.dta
keep if _merge == 1

* Right join
restore, preserve
merge 1:n key using df2.dta
keep if _merge == 2

* Inner join
restore, preserve
merge 1:n key using df2.dta
keep if _merge == 3

* Outer join
restore
merge 1:n key using df2.dta

```

pandas DataFrames have a `DataFrame.merge()` method, which provides similar functionality. Note that different join types are accomplished via the `how` keyword.

```

In [44]: inner_join = df1.merge(df2, on=['key'], how='inner')

In [45]: inner_join
Out[45]:
   key  value_x  value_y
0    B  1.779988  0.750030
1    D  0.944411  0.349022
2    D  0.944411  1.433851

In [46]: left_join = df1.merge(df2, on=['key'], how='left')

In [47]: left_join
Out[47]:
   key  value_x  value_y
0    A -1.456807      NaN
1    B  1.779988  0.750030
2    C -1.602829      NaN
3    D  0.944411  0.349022
4    D  0.944411  1.433851

In [48]: right_join = df1.merge(df2, on=['key'], how='right')

In [49]: right_join
Out[49]:
   key  value_x  value_y
0    B  1.779988  0.750030
1    D  0.944411  0.349022

```

(continues on next page)

(continued from previous page)

```
2 D 0.944411 1.433851
3 E      NaN -0.720900
```

```
In [50]: outer_join = df1.merge(df2, on=['key'], how='outer')
```

```
In [51]: outer_join
```

```
Out[51]:
```

```
   key  value_x  value_y
0  A -1.456807      NaN
1  B  1.779988  0.750030
2  C -1.602829      NaN
3  D  0.944411  0.349022
4  D  0.944411  1.433851
5  E      NaN -0.720900
```

Missing data

Like Stata, pandas has a representation for missing data – the special float value NaN (not a number). Many of the semantics are the same; for example missing data propagates through numeric operations, and is ignored by default for aggregations.

```
In [52]: outer_join
```

```
Out[52]:
```

```
   key  value_x  value_y
0  A -1.456807      NaN
1  B  1.779988  0.750030
2  C -1.602829      NaN
3  D  0.944411  0.349022
4  D  0.944411  1.433851
5  E      NaN -0.720900
```

```
In [53]: outer_join['value_x'] + outer_join['value_y']
```

```
Out[53]:
```

```
0      NaN
1    2.530018
2      NaN
3    1.293433
4    2.378261
5      NaN
dtype: float64
```

```
In [54]: outer_join['value_x'].sum()
```

```
Out[54]: 0.6091740246349007
```

One difference is that missing data cannot be compared to its sentinel value. For example, in Stata you could do this to filter missing values.

```
* Keep missing values
list if value_x == .
* Keep non-missing values
list if value_x != .
```

This doesn't work in pandas. Instead, the `pd.isna()` or `pd.notna()` functions should be used for comparisons.

```
In [55]: outer_join[pd.isna(outer_join['value_x'])]
```

```
Out[55]:
```

	key	value_x	value_y
5	E	NaN	-0.7209

```
In [56]: outer_join[pd.notna(outer_join['value_x'])]
```

```
Out[56]:
```

	key	value_x	value_y
0	A	-1.456807	NaN
1	B	1.779988	0.750030
2	C	-1.602829	NaN
3	D	0.944411	0.349022
4	D	0.944411	1.433851

Pandas also provides a variety of methods to work with missing data – some of which would be challenging to express in Stata. For example, there are methods to drop all rows with any missing values, replacing missing values with a specified value, like the mean, or forward filling from previous rows. See the [missing data documentation](#) for more.

```
# Drop rows with any missing value
```

```
In [57]: outer_join.dropna()
```

```
Out[57]:
```

	key	value_x	value_y
1	B	1.779988	0.750030
3	D	0.944411	0.349022
4	D	0.944411	1.433851

```
# Fill forwards
```

```
In [58]: outer_join.fillna(method='ffill')
```

```
Out[58]:
```

	key	value_x	value_y
0	A	-1.456807	NaN
1	B	1.779988	0.750030
2	C	-1.602829	0.750030
3	D	0.944411	0.349022
4	D	0.944411	1.433851
5	E	0.944411	-0.720900

```
# Impute missing values with the mean
```

```
In [59]: outer_join['value_x'].fillna(outer_join['value_x'].mean())
```

```
Out[59]:
```

0	-1.456807
1	1.779988
2	-1.602829
3	0.944411
4	0.944411
5	0.121835

Name: value_x, dtype: float64

GroupBy

Aggregation

Stata's `collapse` can be used to group by one or more key variables and compute aggregations on numeric columns.

```
collapse (sum) total_bill tip, by(sex smoker)
```

pandas provides a flexible `groupby` mechanism that allows similar aggregations. See the *groupby documentation* for more details and examples.

```
In [60]: tips_summed = tips.groupby(['sex', 'smoker'])['total_bill', 'tip'].sum()
```

```
In [61]: tips_summed.head()
```

```
Out[61]:
```

		total_bill	tip
sex	smoker		
Female	No	869.68	149.77
	Yes	527.27	96.74
Male	No	1725.75	302.00
	Yes	1217.07	183.07

Transformation

In Stata, if the group aggregations need to be used with the original data set, one would usually use `bysort` with `egen()`. For example, to subtract the mean for each observation by smoker group.

```
bysort sex smoker: egen group_bill = mean(total_bill)
generate adj_total_bill = total_bill - group_bill
```

pandas `groupby` provides a `transform` mechanism that allows these type of operations to be succinctly expressed in one operation.

```
In [62]: gb = tips.groupby('smoker')['total_bill']
```

```
In [63]: tips['adj_total_bill'] = tips['total_bill'] - gb.transform('mean')
```

```
In [64]: tips.head()
```

```
Out[64]:
```

	total_bill	tip	sex	smoker	day	time	size	adj_total_bill
67	1.07	1.00	Female	Yes	Sat	Dinner	1	-17.686344
92	3.75	1.00	Female	Yes	Fri	Dinner	2	-15.006344
111	5.25	1.00	Female	No	Sat	Dinner	1	-11.938278
145	6.35	1.50	Female	No	Thur	Lunch	2	-10.838278
135	6.51	1.25	Female	No	Thur	Lunch	2	-10.678278

By group processing

In addition to aggregation, pandas `groupby` can be used to replicate most other `bysort` processing from Stata. For example, the following example lists the first observation in the current sort order by sex/smoker group.

```
bysort sex smoker: list if _n == 1
```

In pandas this would be written as:

```
In [65]: tips.groupby(['sex', 'smoker']).first()
Out[65]:
```

sex	smoker	total_bill	tip	day	time	size	adj_total_bill
Female	No	5.25	1.00	Sat	Dinner	1	-11.938278
	Yes	1.07	1.00	Sat	Dinner	1	-17.686344
Male	No	5.51	2.00	Thur	Lunch	2	-11.678278
	Yes	5.25	5.15	Sun	Dinner	2	-13.506344

Other considerations

Disk vs memory

Pandas and Stata both operate exclusively in memory. This means that the size of data able to be loaded in pandas is limited by your machine's memory. If out of core processing is needed, one possibility is the `dask.dataframe` library, which provides a subset of pandas functionality for an on-disk `DataFrame`. `{{ header }}`

3.6 Tutorials

This is a guide to many pandas tutorials, geared mainly for new users.

3.6.1 Internal guides

pandas' own *10 Minutes to pandas*.

More complex recipes are in the *Cookbook*.

A handy pandas [cheat sheet](#).

3.6.2 Community guides

pandas Cookbook by Julia Evans

The goal of this 2015 cookbook (by [Julia Evans](#)) is to give you some concrete examples for getting started with pandas. These are examples with real-world data, and all the bugs and weirdness that entails. For the table of contents, see the [pandas-cookbook GitHub repository](#).

Learn Pandas by Hernan Rojas

A set of lesson for new pandas users: <https://bitbucket.org/hrojas/learn-pandas>

Practical data analysis with Python

This guide is an introduction to the data analysis process using the Python data ecosystem and an interesting open dataset. There are four sections covering selected topics as munging data, aggregating data, visualizing data and time series.

Exercises for new users

Practice your skills with real data sets and exercises. For more resources, please visit the main [repository](#).

{{ header }}

USER GUIDE

The User Guide covers all of pandas by topic area. Each of the subsections introduces a topic (such as “working with missing data”), and discusses how pandas approaches the problem, with many examples throughout.

Users brand-new to pandas should start with 10min.

Further information on any specific method can be obtained in the *API reference*. `{{ header }}`

4.1 IO tools (text, CSV, HDF5, ...)

The pandas I/O API is a set of top level **reader** functions accessed like `pandas.read_csv()` that generally return a pandas object. The corresponding **writer** functions are object methods that are accessed like `DataFrame.to_csv()`. Below is a table containing available **readers** and **writers**.

Format Type	Data Description	Reader	Writer
text	CSV	<code>read_csv</code>	<code>to_csv</code>
text	JSON	<code>read_json</code>	<code>to_json</code>
text	HTML	<code>read_html</code>	<code>to_html</code>
text	Local clipboard	<code>read_clipboard</code>	<code>to_clipboard</code>
binary	MS Excel	<code>read_excel</code>	<code>to_excel</code>
binary	OpenDocument	<code>read_excel</code>	
binary	HDF5 Format	<code>read_hdf</code>	<code>to_hdf</code>
binary	Feather Format	<code>read_feather</code>	<code>to_feather</code>
binary	Parquet Format	<code>read_parquet</code>	<code>to_parquet</code>
binary	Msgpack	<code>read_msgpack</code>	<code>to_msgpack</code>
binary	Stata	<code>read_stata</code>	<code>to_stata</code>
binary	SAS	<code>read_sas</code>	
binary	Python Pickle Format	<code>read_pickle</code>	<code>to_pickle</code>
SQL	SQL	<code>read_sql</code>	<code>to_sql</code>
SQL	Google Big Query	<code>read_gbq</code>	<code>to_gbq</code>

Here is an informal performance comparison for some of these IO methods.

Note: For examples that use the `StringIO` class, make sure you import it according to your Python version, i.e. `from StringIO import StringIO` for Python 2 and `from io import StringIO` for Python 3.

4.1.1 CSV & text files

The workhorse function for reading text files (a.k.a. flat files) is `read_csv()`. See the *cookbook* for some advanced strategies.

Parsing options

`read_csv()` accepts the following common arguments:

Basic

filepath_or_buffer [various] Either a path to a file (a `str`, `pathlib.Path`, or `py._path.local.LocalPath`), URL (including http, ftp, and S3 locations), or any object with a `read()` method (such as an open file or `StringIO`).

sep [`str`, defaults to `,` for `read_csv()`, `\t` for `read_table()`] Delimiter to use. If `sep` is `None`, the C engine cannot automatically detect the separator, but the Python parsing engine can, meaning the latter will be used and automatically detect the separator by Python's builtin sniffer tool, `csv.Sniffer`. In addition, separators longer than 1 character and different from `'\s+'` will be interpreted as regular expressions and will also force the use of the Python parsing engine. Note that regex delimiters are prone to ignoring quoted data. Regex example: `'\\r\\t'`.

delimiter [`str`, default `None`] Alternative argument name for `sep`.

delim_whitespace [`boolean`, default `False`] Specifies whether or not whitespace (e.g. `' '` or `'\t'`) will be used as the delimiter. Equivalent to setting `sep='\s+'`. If this option is set to `True`, nothing should be passed in for the `delimiter` parameter.

New in version 0.18.1: support for the Python parser.

Column and index locations and names

header [`int` or list of ints, default `'infer'`] Row number(s) to use as the column names, and the start of the data. Default behavior is to infer the column names: if no names are passed the behavior is identical to `header=0` and column names are inferred from the first line of the file, if column names are passed explicitly then the behavior is identical to `header=None`. Explicitly pass `header=0` to be able to replace existing names.

The header can be a list of ints that specify row locations for a MultiIndex on the columns e.g. `[0,1,3]`. Intervening rows that are not specified will be skipped (e.g. 2 in this example is skipped). Note that this parameter ignores commented lines and empty lines if `skip_blank_lines=True`, so `header=0` denotes the first line of data rather than the first line of the file.

names [`array-like`, default `None`] List of column names to use. If file contains no header row, then you should explicitly pass `header=None`. Duplicates in this list are not allowed.

index_col [`int`, `str`, sequence of `int / str`, or `False`, default `None`] Column(s) to use as the row labels of the `DataFrame`, either given as string name or column index. If a sequence of `int / str` is given, a MultiIndex is used.

Note: `index_col=False` can be used to force pandas to *not* use the first column as the index, e.g. when you have a malformed file with delimiters at the end of each line.

usecols [`list-like` or callable, default `None`] Return a subset of the columns. If list-like, all elements must either be positional (i.e. integer indices into the document columns) or strings that correspond to

column names provided either by the user in *names* or inferred from the document header row(s). For example, a valid list-like *usecols* parameter would be `[0, 1, 2]` or `['foo', 'bar', 'baz']`.

Element order is ignored, so `usecols=[0, 1]` is the same as `[1, 0]`. To instantiate a `DataFrame` from `data` with element order preserved use `pd.read_csv(data, usecols=['foo', 'bar'])[['foo', 'bar']]` for columns in `['foo', 'bar']` order or `pd.read_csv(data, usecols=['foo', 'bar'])[['bar', 'foo']]` for `['bar', 'foo']` order.

If callable, the callable function will be evaluated against the column names, returning names where the callable function evaluates to `True`:

```
In [1]: from io import StringIO, BytesIO
```

```
In [2]: data = ('col1,col2,col3\n'
...:          'a,b,1\n'
...:          'a,b,2\n'
...:          'c,d,3')
...:
```

```
In [3]: pd.read_csv(StringIO(data))
```

```
Out[3]:
   col1 col2 col3
0     a    b    1
1     a    b    2
2     c    d    3
```

```
In [4]: pd.read_csv(StringIO(data), usecols=lambda x: x.upper() in ['COL1', 'COL3'])
```

```
Out[4]:
   col1 col3
0     a    1
1     a    2
2     c    3
```

Using this parameter results in much faster parsing time and lower memory usage.

squeeze [boolean, default `False`] If the parsed data only contains one column then return a `Series`.

prefix [str, default `None`] Prefix to add to column numbers when no header, e.g. 'X' for X0, X1, ...

mangle_dupe_cols [boolean, default `True`] Duplicate columns will be specified as 'X', 'X.1'...'X.N', rather than 'X'...'X'. Passing in `False` will cause data to be overwritten if there are duplicate names in the columns.

General parsing configuration

dtype [Type name or dict of column -> type, default `None`] Data type for data or columns. E.g. `{'a': np.float64, 'b': np.int32}` (unsupported with `engine='python'`). Use *str* or *object* together with suitable `na_values` settings to preserve and not interpret dtype.

New in version 0.20.0: support for the Python parser.

engine [`{'c', 'python'}`] Parser engine to use. The C engine is faster while the Python engine is currently more feature-complete.

converters [dict, default `None`] Dict of functions for converting values in certain columns. Keys can either be integers or column labels.

true_values [list, default `None`] Values to consider as `True`.

false_values [list, default None] Values to consider as `False`.

skipinitialspace [boolean, default `False`] Skip spaces after delimiter.

skiprows [list-like or integer, default None] Line numbers to skip (0-indexed) or number of lines to skip (int) at the start of the file.

If callable, the callable function will be evaluated against the row indices, returning `True` if the row should be skipped and `False` otherwise:

```
In [5]: data = ('col1,col2,col3\n'
...:          'a,b,1\n'
...:          'a,b,2\n'
...:          'c,d,3')
...:
```

```
In [6]: pd.read_csv(StringIO(data))
```

```
Out[6]:
   col1 col2 col3
0     a    b    1
1     a    b    2
2     c    d    3
```

```
In [7]: pd.read_csv(StringIO(data), skiprows=lambda x: x % 2 != 0)
```

```
Out[7]:
   col1 col2 col3
0     a    b    2
```

skipfooter [int, default 0] Number of lines at bottom of file to skip (unsupported with engine='c').

nrows [int, default None] Number of rows of file to read. Useful for reading pieces of large files.

low_memory [boolean, default `True`] Internally process the file in chunks, resulting in lower memory use while parsing, but possibly mixed type inference. To ensure no mixed types either set `False`, or specify the type with the `dtype` parameter. Note that the entire file is read into a single `DataFrame` regardless, use the `chunksize` or `iterator` parameter to return the data in chunks. (Only valid with C parser)

memory_map [boolean, default `False`] If a filepath is provided for `filepath_or_buffer`, map the file object directly onto memory and access the data directly from there. Using this option can improve performance because there is no longer any I/O overhead.

NA and missing data handling

na_values [scalar, str, list-like, or dict, default None] Additional strings to recognize as NA/NaN. If dict passed, specific per-column NA values. See *na values const* below for a list of the values interpreted as NaN by default.

keep_default_na [boolean, default `True`] Whether or not to include the default NaN values when parsing the data. Depending on whether `na_values` is passed in, the behavior is as follows:

- If `keep_default_na` is `True`, and `na_values` are specified, `na_values` is appended to the default NaN values used for parsing.
- If `keep_default_na` is `True`, and `na_values` are not specified, only the default NaN values are used for parsing.
- If `keep_default_na` is `False`, and `na_values` are specified, only the NaN values specified `na_values` are used for parsing.

- If `keep_default_na` is `False`, and `na_values` are not specified, no strings will be parsed as NaN.

Note that if `na_filter` is passed in as `False`, the `keep_default_na` and `na_values` parameters will be ignored.

na_filter [boolean, default `True`] Detect missing value markers (empty strings and the value of `na_values`). In data without any NAs, passing `na_filter=False` can improve the performance of reading a large file.

verbose [boolean, default `False`] Indicate number of NA values placed in non-numeric columns.

skip_blank_lines [boolean, default `True`] If `True`, skip over blank lines rather than interpreting as NaN values.

Datetime handling

parse_dates [boolean or list of ints or names or list of lists or dict, default `False`.]

- If `True` -> try parsing the index.
- If `[1, 2, 3]` -> try parsing columns 1, 2, 3 each as a separate date column.
- If `[[1, 3]]` -> combine columns 1 and 3 and parse as a single date column.
- If `{'foo': [1, 3]}` -> parse columns 1, 3 as date and call result 'foo'. A fast-path exists for iso8601-formatted dates.

infer_datetime_format [boolean, default `False`] If `True` and `parse_dates` is enabled for a column, attempt to infer the datetime format to speed up the processing.

keep_date_col [boolean, default `False`] If `True` and `parse_dates` specifies combining multiple columns then keep the original columns.

date_parser [function, default `None`] Function to use for converting a sequence of string columns to an array of datetime instances. The default uses `dateutil.parser.parser` to do the conversion. pandas will try to call `date_parser` in three different ways, advancing to the next if an exception occurs: 1) Pass one or more arrays (as defined by `parse_dates`) as arguments; 2) concatenate (row-wise) the string values from the columns defined by `parse_dates` into a single array and pass that; and 3) call `date_parser` once for each row using one or more strings (corresponding to the columns defined by `parse_dates`) as arguments.

dayfirst [boolean, default `False`] DD/MM format dates, international and European format.

cache_dates [boolean, default `True`] If `True`, use a cache of unique, converted dates to apply the datetime conversion. May produce significant speed-up when parsing duplicate date strings, especially ones with timezone offsets.

New in version 0.25.0.

Iteration

iterator [boolean, default `False`] Return *TextFileReader* object for iteration or getting chunks with `get_chunk()`.

chunksize [int, default `None`] Return *TextFileReader* object for iteration. See *iterating and chunking* below.

Quoting, compression, and file format

compression [{`'infer'`, `'gzip'`, `'bz2'`, `'zip'`, `'xz'`, `None`}, default `'infer'`] For on-the-fly decompression of on-disk data. If `'infer'`, then use `gzip`, `bz2`, `zip`, or `xz` if `filepath_or_buffer` is a string ending in `'gz'`, `'bz2'`, `'zip'`, or `'xz'`, respectively, and no decompression otherwise. If using `'zip'`, the ZIP file must contain only one data file to be read in. Set to `None` for no decompression.

New in version 0.18.1: support for `'zip'` and `'xz'` compression.

Changed in version 0.24.0: `'infer'` option added and set to default.

thousands [str, default `None`] Thousands separator.

decimal [str, default `'.'`] Character to recognize as decimal point. E.g. use `,` for European data.

float_precision [string, default `None`] Specifies which converter the C engine should use for floating-point values. The options are `None` for the ordinary converter, `high` for the high-precision converter, and `round_trip` for the round-trip converter.

lineterminator [str (length 1), default `None`] Character to break file into lines. Only valid with C parser.

quotechar [str (length 1)] The character used to denote the start and end of a quoted item. Quoted items can include the delimiter and it will be ignored.

quoting [int or `csv.QUOTE_*` instance, default 0] Control field quoting behavior per `csv.QUOTE_*` constants. Use one of `QUOTE_MINIMAL` (0), `QUOTE_ALL` (1), `QUOTE_NONNUMERIC` (2) or `QUOTE_NONE` (3).

doublequote [boolean, default `True`] When `quotechar` is specified and `quoting` is not `QUOTE_NONE`, indicate whether or not to interpret two consecutive `quotechar` elements **inside** a field as a single `quotechar` element.

escapechar [str (length 1), default `None`] One-character string used to escape delimiter when quoting is `QUOTE_NONE`.

comment [str, default `None`] Indicates remainder of line should not be parsed. If found at the beginning of a line, the line will be ignored altogether. This parameter must be a single character. Like empty lines (as long as `skip_blank_lines=True`), fully commented lines are ignored by the parameter `header` but not by `skiprows`. For example, if `comment='#'`, parsing `'#empty\na,b,c\n1,2,3'` with `header=0` will result in `'a,b,c'` being treated as the header.

encoding [str, default `None`] Encoding to use for UTF when reading/writing (e.g. `'utf-8'`). [List of Python standard encodings](#).

dialect [str or `csv.Dialect` instance, default `None`] If provided, this parameter will override values (default or not) for the following parameters: `delimiter`, `doublequote`, `escapechar`, `skipinitialspace`, `quotechar`, and `quoting`. If it is necessary to override values, a `ParserWarning` will be issued. See `csv.Dialect` documentation for more details.

Error handling

error_bad_lines [boolean, default `True`] Lines with too many fields (e.g. a csv line with too many commas) will by default cause an exception to be raised, and no `DataFrame` will be returned. If `False`, then these “bad lines” will be dropped from the `DataFrame` that is returned. See [bad lines](#) below.

warn_bad_lines [boolean, default `True`] If `error_bad_lines` is `False`, and `warn_bad_lines` is `True`, a warning for each “bad line” will be output.

Specifying column data types

You can indicate the data type for the whole `DataFrame` or individual columns:

```
In [8]: data = ('a,b,c,d\n'
...:          '1,2,3,4\n'
...:          '5,6,7,8\n'
...:          '9,10,11')
```

```
In [9]: print(data)
a,b,c,d
1,2,3,4
5,6,7,8
9,10,11
```

```
In [10]: df = pd.read_csv(StringIO(data), dtype=object)
```

```
In [11]: df
Out[11]:
   a  b  c  d
0  1  2  3  4
1  5  6  7  8
2  9 10 11 NaN
```

```
In [12]: df['a'][0]
Out[12]: '1'
```

```
In [13]: df = pd.read_csv(StringIO(data),
...:                      dtype={'b': object, 'c': np.float64, 'd': 'Int64'})
...:
```

```
In [14]: df.dtypes
Out[14]:
a      int64
b      object
c      float64
d      Int64
dtype: object
```

Fortunately, pandas offers more than one way to ensure that your column(s) contain only one `dtype`. If you're unfamiliar with these concepts, you can see [here](#) to learn more about dtypes, and [here](#) to learn more about `object` conversion in pandas.

For instance, you can use the `converters` argument of `read_csv()`:

```
In [15]: data = ("col_1\n"
...:           "1\n"
...:           "2\n"
...:           "'A'\n"
...:           "4.22")
...:
```

```
In [16]: df = pd.read_csv(StringIO(data), converters={'col_1': str})
```

```
In [17]: df
```

```
Out[17]:
  col_1
0      1
1      2
2      'A'
3      4.22
```

```
In [18]: df['col_1'].apply(type).value_counts()
```

```
Out[18]:
<class 'str'>      4
Name: col_1, dtype: int64
```

Or you can use the `to_numeric()` function to coerce the dtypes after reading in the data,

```
In [19]: df2 = pd.read_csv(StringIO(data))
```

```
In [20]: df2['col_1'] = pd.to_numeric(df2['col_1'], errors='coerce')
```

```
In [21]: df2
```

```
Out[21]:
  col_1
0   1.00
1   2.00
2    NaN
3   4.22
```

```
In [22]: df2['col_1'].apply(type).value_counts()
```

```
Out[22]:
<class 'float'>    4
Name: col_1, dtype: int64
```

which will convert all valid parsing to floats, leaving the invalid parsing as `NaN`.

Ultimately, how you deal with reading in columns containing mixed dtypes depends on your specific needs. In the case above, if you wanted to `NaN` out the data anomalies, then `to_numeric()` is probably your best option. However, if you wanted for all the data to be coerced, no matter the type, then using the `converters` argument of `read_csv()` would certainly be worth trying.

New in version 0.20.0: support for the Python parser.

The `dtype` option is supported by the ‘python’ engine.

Note: In some cases, reading in abnormal data with columns containing mixed dtypes will result in an inconsistent dataset. If you rely on pandas to infer the dtypes of your columns, the parsing engine will go and infer the dtypes for different chunks of the data, rather than the whole dataset at once. Consequently, you can end up with column(s) with mixed dtypes. For example,

```
In [23]: col_1 = list(range(500000)) + ['a', 'b'] + list(range(500000))
```

```
In [24]: df = pd.DataFrame({'col_1': col_1})
```

```
In [25]: df.to_csv('foo.csv')
```

```
In [26]: mixed_df = pd.read_csv('foo.csv')
```

```
In [27]: mixed_df['col_1'].apply(type).value_counts()
```

```
Out[27]:
```

```
<class 'int'>    737858
<class 'str'>   262144
Name: col_1, dtype: int64
```

```
In [28]: mixed_df['col_1'].dtype
Out[28]: dtype('O')
```

will result with *mixed_df* containing an `int` dtype for certain chunks of the column, and `str` for others due to the mixed dtypes from the data that was read in. It is important to note that the overall column will be marked with a dtype of `object`, which is used for columns with mixed dtypes.

Specifying categorical dtype

New in version 0.19.0.

Categorical columns can be parsed directly by specifying `dtype='category'` or `dtype=CategoricalDtype(categories, ordered)`.

```
In [29]: data = ('col1,col2,col3\n'
....:          'a,b,1\n'
....:          'a,b,2\n'
....:          'c,d,3')
....:
```

```
In [30]: pd.read_csv(StringIO(data))
Out[30]:
```

```
   col1 col2 col3
0     a    b    1
1     a    b    2
2     c    d    3
```

```
In [31]: pd.read_csv(StringIO(data)).dtypes
```

```
Out[31]:
col1    object
col2    object
col3    int64
dtype: object
```

```
In [32]: pd.read_csv(StringIO(data), dtype='category').dtypes
```

```
Out[32]:
col1    category
col2    category
col3    category
dtype: object
```

Individual columns can be parsed as a `Categorical` using a dict specification:

```
In [33]: pd.read_csv(StringIO(data), dtype={'col1': 'category'}).dtypes
Out[33]:
col1    category
col2    object
col3    int64
dtype: object
```

New in version 0.21.0.

Specifying `dtype='category'` will result in an unordered `Categorical` whose categories are the unique values observed in the data. For more control on the categories and order, create a `CategoricalDtype` ahead of time, and pass that for that column's `dtype`.

```
In [34]: from pandas.api.types import CategoricalDtype
In [35]: dtype = CategoricalDtype(['d', 'c', 'b', 'a'], ordered=True)
In [36]: pd.read_csv(StringIO(data), dtype={'col1': dtype}).dtypes
Out[36]:
col1    category
col2    object
col3    int64
dtype: object
```

When using `dtype=CategoricalDtype`, “unexpected” values outside of `dtype.categories` are treated as missing values.

```
In [37]: dtype = CategoricalDtype(['a', 'b', 'd']) # No 'c'
In [38]: pd.read_csv(StringIO(data), dtype={'col1': dtype}).col1
Out[38]:
0     a
1     a
2    NaN
Name: col1, dtype: category
Categories (3, object): [a, b, d]
```

This matches the behavior of `Categorical.set_categories()`.

Note: With `dtype='category'`, the resulting categories will always be parsed as strings (object dtype). If the categories are numeric they can be converted using the `to_numeric()` function, or as appropriate, another converter such as `to_datetime()`.

When `dtype` is a `CategoricalDtype` with homogeneous categories (all numeric, all datetimes, etc.), the conversion is done automatically.

```
In [39]: df = pd.read_csv(StringIO(data), dtype='category')
```

```
In [40]: df.dtypes
```

```
Out[40]:
col1    category
col2    category
col3    category
dtype: object
```

```
In [41]: df['col3']
```

```
Out[41]:
0     1
1     2
2     3
Name: col3, dtype: category
Categories (3, object): [1, 2, 3]
```

```
In [42]: df['col3'].cat.categories = pd.to_numeric(df['col3'].cat.categories)
```

```
In [43]: df['col3']
```

```
Out[43]:
```

```
0    1
```

```
1    2
```

```
2    3
```

```
Name: col3, dtype: category
```

```
Categories (3, int64): [1, 2, 3]
```

Naming and using columns

Handling column names

A file may or may not have a header row. pandas assumes the first row should be used as the column names:

```
In [44]: data = ('a,b,c\n'
.....:          '1,2,3\n'
.....:          '4,5,6\n'
.....:          '7,8,9')
.....:
```

```
In [45]: print(data)
```

```
a,b,c
```

```
1,2,3
```

```
4,5,6
```

```
7,8,9
```

```
In [46]: pd.read_csv(StringIO(data))
```

```
Out[46]:
```

```
   a  b  c
```

```
0  1  2  3
```

```
1  4  5  6
```

```
2  7  8  9
```

By specifying the `names` argument in conjunction with `header` you can indicate other names to use and whether or not to throw away the header row (if any):

```
In [47]: print(data)
```

```
a,b,c
```

```
1,2,3
```

```
4,5,6
```

```
7,8,9
```

```
In [48]: pd.read_csv(StringIO(data), names=['foo', 'bar', 'baz'], header=0)
```

```
Out[48]:
```

```
   foo  bar  baz
```

```
0    1    2    3
```

```
1    4    5    6
```

```
2    7    8    9
```

```
In [49]: pd.read_csv(StringIO(data), names=['foo', 'bar', 'baz'], header=None)
```

```
Out [49]:
  foo bar baz
0   a   b   c
1   1   2   3
2   4   5   6
3   7   8   9
```

If the header is in a row other than the first, pass the row number to `header`. This will skip the preceding rows:

```
In [50]: data = ('skip this skip it\n'
.....:          'a,b,c\n'
.....:          '1,2,3\n'
.....:          '4,5,6\n'
.....:          '7,8,9')
.....:

In [51]: pd.read_csv(StringIO(data), header=1)
Out [51]:
   a  b  c
0  1  2  3
1  4  5  6
2  7  8  9
```

Note: Default behavior is to infer the column names: if no names are passed the behavior is identical to `header=0` and column names are inferred from the first non-blank line of the file, if column names are passed explicitly then the behavior is identical to `header=None`.

Duplicate names parsing

If the file or header contains duplicate names, pandas will by default distinguish between them so as to prevent overwriting data:

```
In [52]: data = ('a,b,a\n'
.....:          '0,1,2\n'
.....:          '3,4,5')
.....:

In [53]: pd.read_csv(StringIO(data))
Out [53]:
   a  b  a.1
0  0  1    2
1  3  4    5
```

There is no more duplicate data because `mangle_dupe_cols=True` by default, which modifies a series of duplicate columns 'X', ..., 'X' to become 'X', 'X.1', ..., 'X.N'. If `mangle_dupe_cols=False`, duplicate data can arise:

```
In [2]: data = 'a,b,a\n0,1,2\n3,4,5'
In [3]: pd.read_csv(StringIO(data), mangle_dupe_cols=False)
Out [3]:
```

(continues on next page)

(continued from previous page)

```

  a  b  a
0  2  1  2
1  5  4  5

```

To prevent users from encountering this problem with duplicate data, a `ValueError` exception is raised if `mangle_dupe_cols != True`:

```

In [2]: data = 'a,b,a\n0,1,2\n3,4,5'
In [3]: pd.read_csv(StringIO(data), mangle_dupe_cols=False)
...
ValueError: Setting mangle_dupe_cols=False is not supported yet

```

Filtering columns (`usecols`)

The `usecols` argument allows you to select any subset of the columns in a file, either using the column names, position numbers or a callable:

New in version 0.20.0: support for callable *usecols* arguments

```
In [54]: data = 'a,b,c,d\n1,2,3,foo\n4,5,6,bar\n7,8,9,baz'
```

```
In [55]: pd.read_csv(StringIO(data))
```

```

Out[55]:
   a  b  c  d
0  1  2  3  foo
1  4  5  6  bar
2  7  8  9  baz

```

```
In [56]: pd.read_csv(StringIO(data), usecols=['b', 'd'])
```

```

Out[56]:
   b  d
0  2  foo
1  5  bar
2  8  baz

```

```
In [57]: pd.read_csv(StringIO(data), usecols=[0, 2, 3])
```

```

Out[57]:
   a  c  d
0  1  3  foo
1  4  6  bar
2  7  9  baz

```

```
In [58]: pd.read_csv(StringIO(data), usecols=lambda x: x.upper() in ['A', 'C'])
```

```

Out[58]:
   a  c
0  1  3
1  4  6
2  7  9

```

The `usecols` argument can also be used to specify which columns not to use in the final result:

```
In [59]: pd.read_csv(StringIO(data), usecols=lambda x: x not in ['a', 'c'])
Out[59]:
   b  d
0  2  foo
1  5  bar
2  8  baz
```

In this case, the callable is specifying that we exclude the “a” and “c” columns from the output.

Comments and empty lines

Ignoring line comments and empty lines

If the `comment` parameter is specified, then completely commented lines will be ignored. By default, completely blank lines will be ignored as well.

```
In [60]: data = ('\n'
.....:          'a,b,c\n'
.....:          ' \n'
.....:          '# commented line\n'
.....:          '1,2,3\n'
.....:          '\n'
.....:          '4,5,6')
.....:
```

```
In [61]: print(data)
```

```
a,b,c
```

```
# commented line
1,2,3
```

```
4,5,6
```

```
In [62]: pd.read_csv(StringIO(data), comment='#')
```

```
Out[62]:
   a  b  c
0  1  2  3
1  4  5  6
```

If `skip_blank_lines=False`, then `read_csv` will not ignore blank lines:

```
In [63]: data = ('a,b,c\n'
.....:          '\n'
.....:          '1,2,3\n'
.....:          '\n'
.....:          '\n'
.....:          '4,5,6')
.....:

In [64]: pd.read_csv(StringIO(data), skip_blank_lines=False)
Out[64]:
   a  b  c
```

(continues on next page)

(continued from previous page)

```

0 NaN NaN NaN
1 1.0 2.0 3.0
2 NaN NaN NaN
3 NaN NaN NaN
4 4.0 5.0 6.0

```

Warning: The presence of ignored lines might create ambiguities involving line numbers; the parameter `header` uses row numbers (ignoring commented/empty lines), while `skiprows` uses line numbers (including commented/empty lines):

```

In [65]: data = ('#comment\n'
.....:          'a,b,c\n'
.....:          'A,B,C\n'
.....:          '1,2,3')
.....:

```

```

In [66]: pd.read_csv(StringIO(data), comment='#', header=1)

```

```

Out[66]:
  A  B  C
0  1  2  3

```

```

In [67]: data = ('A,B,C\n'
.....:          '#comment\n'
.....:          'a,b,c\n'
.....:          '1,2,3')
.....:

```

```

In [68]: pd.read_csv(StringIO(data), comment='#', skiprows=2)

```

```

Out[68]:
  a  b  c
0  1  2  3

```

If both `header` and `skiprows` are specified, `header` will be relative to the end of `skiprows`. For example:

```

In [69]: data = ('# empty\n'
.....:          '# second empty line\n'
.....:          '# third emptyline\n'
.....:          'X,Y,Z\n'
.....:          '1,2,3\n'
.....:          'A,B,C\n'
.....:          '1,2.,4.\n'
.....:          '5.,NaN,10.0\n')
.....:

```

```

In [70]: print(data)
# empty
# second empty line
# third emptyline
X,Y,Z
1,2,3
A,B,C
1,2.,4.

```

```
5.,NaN,10.0
```

```
In [71]: pd.read_csv(StringIO(data), comment='#', skiprows=4, header=1)
Out[71]:
   A    B    C
0  1.0  2.0  4.0
1  5.0  NaN 10.0
```

Comments

Sometimes comments or meta data may be included in a file:

```
In [72]: print(open('tmp.csv').read())
ID,level,category
Patient1,123000,x # really unpleasant
Patient2,23000,y # wouldn't take his medicine
Patient3,1234018,z # awesome
```

By default, the parser includes the comments in the output:

```
In [73]: df = pd.read_csv('tmp.csv')

In [74]: df
Out[74]:
   ID    level                category
0  Patient1  123000      x # really unpleasant
1  Patient2   23000  y # wouldn't take his medicine
2  Patient3 1234018                z # awesome
```

We can suppress the comments using the `comment` keyword:

```
In [75]: df = pd.read_csv('tmp.csv', comment='#')

In [76]: df
Out[76]:
   ID    level category
0  Patient1  123000      x
1  Patient2   23000      y
2  Patient3 1234018      z
```

Dealing with Unicode data

The `encoding` argument should be used for encoded unicode data, which will result in byte strings being decoded to unicode in the result:

```
In [77]: data = (b'word,length\n'
.....:           b'Tr\xc3\xa4umen,7\n'
.....:           b'Gr\xc3\xbc\xc3\x9fe,5')
.....:

In [78]: data = data.decode('utf8').encode('latin-1')
```

```
In [79]: df = pd.read_csv(BytesIO(data), encoding='latin-1')
```

```
In [80]: df
```

```
Out[80]:
   word  length
0  Träumen     7
1   Grüße     5
```

```
In [81]: df['word'][1]
```

```
Out[81]: 'Grüße'
```

Some formats which encode all characters as multiple bytes, like UTF-16, won't parse correctly at all without specifying the encoding. [Full list of Python standard encodings](#).

Index columns and trailing delimiters

If a file has one more column of data than the number of column names, the first column will be used as the `DataFrame`'s row names:

```
In [82]: data = ('a,b,c\n'
.....:          '4,apple,bat,5.7\n'
.....:          '8,orange,cow,10')
.....:
```

```
In [83]: pd.read_csv(StringIO(data))
```

```
Out[83]:
   a  b  c
4  apple bat  5.7
8  orange cow 10.0
```

```
In [84]: data = ('index,a,b,c\n'
.....:          '4,apple,bat,5.7\n'
.....:          '8,orange,cow,10')
.....:
```

```
In [85]: pd.read_csv(StringIO(data), index_col=0)
```

```
Out[85]:
   a  b  c
index
4  apple bat  5.7
8  orange cow 10.0
```

Ordinarily, you can achieve this behavior using the `index_col` option.

There are some exception cases when a file has been prepared with delimiters at the end of each data line, confusing the parser. To explicitly disable the index column inference and discard the last column, pass `index_col=False`:

```
In [86]: data = ('a,b,c\n'
.....:          '4,apple,bat,\n'
.....:          '8,orange,cow,')
.....:
```

```
In [87]: print(data)
```

```
a,b,c
```

```
4,apple,bat,  
8,orange,cow,
```

```
In [88]: pd.read_csv(StringIO(data))  
Out[88]:
```

```
      a    b    c  
4  apple bat NaN  
8  orange cow NaN
```

```
In [89]: pd.read_csv(StringIO(data), index_col=False)  
Out[89]:
```

```
      a      b      c  
0 4  apple  bat  
1 8  orange  cow
```

If a subset of data is being parsed using the `usecols` option, the `index_col` specification is based on that subset, not the original data.

```
In [90]: data = ('a,b,c\n'  
.....:         '4,apple,bat,\n'  
.....:         '8,orange,cow,')  
.....:
```

```
In [91]: print(data)  
a,b,c  
4,apple,bat,  
8,orange,cow,
```

```
In [92]: pd.read_csv(StringIO(data), usecols=['b', 'c'])  
Out[92]:
```

```
      b    c  
4  bat NaN  
8  cow NaN
```

```
In [93]: pd.read_csv(StringIO(data), usecols=['b', 'c'], index_col=0)  
Out[93]:
```

```
      b    c  
4  bat NaN  
8  cow NaN
```

Date Handling

Specifying date columns

To better facilitate working with datetime data, `read_csv()` uses the keyword arguments `parse_dates` and `date_parser` to allow users to specify a variety of columns and date/time formats to turn the input text data into `datetime` objects.

The simplest case is to just pass in `parse_dates=True`:

```
# Use a column as an index, and parse it as dates.  
In [94]: df = pd.read_csv('foo.csv', index_col=0, parse_dates=True)
```

```
In [95]: df  
Out[95]:
```

```

      A  B  C
date
2009-01-01  a  1  2
2009-01-02  b  3  4
2009-01-03  c  4  5

```

These are Python datetime objects

```
In [96]: df.index
```

```
Out[96]: DatetimeIndex(['2009-01-01', '2009-01-02', '2009-01-03'],
↳ dtype='datetime64[ns]', name='date', freq=None)
```

It is often the case that we may want to store date and time data separately, or store various date fields separately. the `parse_dates` keyword can be used to specify a combination of columns to parse the dates and/or times from.

You can specify a list of column lists to `parse_dates`, the resulting date columns will be prepended to the output (so as to not affect the existing column order) and the new column names will be the concatenation of the component column names:

```
In [97]: print(open('tmp.csv').read())
KORD,19990127, 19:00:00, 18:56:00, 0.8100
KORD,19990127, 20:00:00, 19:56:00, 0.0100
KORD,19990127, 21:00:00, 20:56:00, -0.5900
KORD,19990127, 21:00:00, 21:18:00, -0.9900
KORD,19990127, 22:00:00, 21:56:00, -0.5900
KORD,19990127, 23:00:00, 22:56:00, -0.5900
```

```
In [98]: df = pd.read_csv('tmp.csv', header=None, parse_dates=[[1, 2], [1, 3]])
```

```
In [99]: df
```

```
Out[99]:
      1_2      1_3  0  4
0 1999-01-27 19:00:00 1999-01-27 18:56:00 KORD 0.81
1 1999-01-27 20:00:00 1999-01-27 19:56:00 KORD 0.01
2 1999-01-27 21:00:00 1999-01-27 20:56:00 KORD -0.59
3 1999-01-27 21:00:00 1999-01-27 21:18:00 KORD -0.99
4 1999-01-27 22:00:00 1999-01-27 21:56:00 KORD -0.59
5 1999-01-27 23:00:00 1999-01-27 22:56:00 KORD -0.59
```

By default the parser removes the component date columns, but you can choose to retain them via the `keep_date_col` keyword:

```
In [100]: df = pd.read_csv('tmp.csv', header=None, parse_dates=[[1, 2], [1, 3]],
.....:                  keep_date_col=True)
.....:
```

```
In [101]: df
```

```
Out[101]:
      1_2      1_3  0  1  2  3  4
0 1999-01-27 19:00:00 1999-01-27 18:56:00 KORD 19990127 19:00:00 18:56:00 0.81
1 1999-01-27 20:00:00 1999-01-27 19:56:00 KORD 19990127 20:00:00 19:56:00 0.01
2 1999-01-27 21:00:00 1999-01-27 20:56:00 KORD 19990127 21:00:00 20:56:00 -0.59
3 1999-01-27 21:00:00 1999-01-27 21:18:00 KORD 19990127 21:00:00 21:18:00 -0.99
4 1999-01-27 22:00:00 1999-01-27 21:56:00 KORD 19990127 22:00:00 21:56:00 -0.59
5 1999-01-27 23:00:00 1999-01-27 22:56:00 KORD 19990127 23:00:00 22:56:00 -0.59
```

Note that if you wish to combine multiple columns into a single date column, a nested list must be used. In other words, `parse_dates=[1, 2]` indicates that the second and third columns should each be parsed as separate date columns while `parse_dates=[[1, 2]]` means the two columns should be parsed into a single column.

You can also use a dict to specify custom name columns:

```
In [102]: date_spec = {'nominal': [1, 2], 'actual': [1, 3]}

In [103]: df = pd.read_csv('tmp.csv', header=None, parse_dates=date_spec)

In [104]: df
Out[104]:
```

	nominal	actual	0	4
0	1999-01-27 19:00:00	1999-01-27 18:56:00	KORD	0.81
1	1999-01-27 20:00:00	1999-01-27 19:56:00	KORD	0.01
2	1999-01-27 21:00:00	1999-01-27 20:56:00	KORD	-0.59
3	1999-01-27 21:00:00	1999-01-27 21:18:00	KORD	-0.99
4	1999-01-27 22:00:00	1999-01-27 21:56:00	KORD	-0.59
5	1999-01-27 23:00:00	1999-01-27 22:56:00	KORD	-0.59

It is important to remember that if multiple text columns are to be parsed into a single date column, then a new column is prepended to the data. The `index_col` specification is based off of this new set of columns rather than the original data columns:

```
In [105]: date_spec = {'nominal': [1, 2], 'actual': [1, 3]}

In [106]: df = pd.read_csv('tmp.csv', header=None, parse_dates=date_spec,
.....:                      index_col=0) # index is the nominal column
.....:

In [107]: df
Out[107]:
```

	nominal	actual	0	4
1999-01-27 19:00:00	1999-01-27 18:56:00	KORD	0.81	
1999-01-27 20:00:00	1999-01-27 19:56:00	KORD	0.01	
1999-01-27 21:00:00	1999-01-27 20:56:00	KORD	-0.59	
1999-01-27 21:00:00	1999-01-27 21:18:00	KORD	-0.99	
1999-01-27 22:00:00	1999-01-27 21:56:00	KORD	-0.59	
1999-01-27 23:00:00	1999-01-27 22:56:00	KORD	-0.59	

Note: If a column or index contains an unparsable date, the entire column or index will be returned unaltered as an object data type. For non-standard datetime parsing, use `to_datetime()` after `pd.read_csv`.

Note: `read_csv` has a `fast_path` for parsing datetime strings in iso8601 format, e.g. “2000-01-01T00:01:02+00:00” and similar variations. If you can arrange for your data to store datetimes in this format, load times will be significantly faster, ~20x has been observed.

Note: When passing a dict as the `parse_dates` argument, the order of the columns prepended is not guaranteed, because `dict` objects do not impose an ordering on their keys. On Python 2.7+ you may use

collections.OrderedDict instead of a regular *dict* if this matters to you. Because of this, when using a dict for ‘`parse_dates`’ in conjunction with the `index_col` argument, it’s best to specify `index_col` as a column label rather than as an index on the resulting frame.

Date parsing functions

Finally, the parser allows you to specify a custom `date_parser` function to take full advantage of the flexibility of the date parsing API:

```
In [108]: df = pd.read_csv('tmp.csv', header=None, parse_dates=date_spec,
.....:                   date_parser=pd.io.date_converters.parse_date_time)
.....:
```

```
In [109]: df
```

```
Out[109]:
```

	nominal	actual	0	4
0	1999-01-27 19:00:00	1999-01-27 18:56:00	KORD	0.81
1	1999-01-27 20:00:00	1999-01-27 19:56:00	KORD	0.01
2	1999-01-27 21:00:00	1999-01-27 20:56:00	KORD	-0.59
3	1999-01-27 21:00:00	1999-01-27 21:18:00	KORD	-0.99
4	1999-01-27 22:00:00	1999-01-27 21:56:00	KORD	-0.59
5	1999-01-27 23:00:00	1999-01-27 22:56:00	KORD	-0.59

Pandas will try to call the `date_parser` function in three different ways. If an exception is raised, the next one is tried:

1. `date_parser` is first called with one or more arrays as arguments, as defined using `parse_dates` (e.g., `date_parser(['2013', '2013'], ['1', '2'])`).
2. If #1 fails, `date_parser` is called with all the columns concatenated row-wise into a single array (e.g., `date_parser(['2013 1', '2013 2'])`).
3. If #2 fails, `date_parser` is called once for every row with one or more string arguments from the columns indicated with `parse_dates` (e.g., `date_parser('2013', '1')` for the first row, `date_parser('2013', '2')` for the second, etc.).

Note that performance-wise, you should try these methods of parsing dates in order:

1. Try to infer the format using `infer_datetime_format=True` (see section below).
2. If you know the format, use `pd.to_datetime()`: `date_parser=lambda x: pd.to_datetime(x, format=...)`.
3. If you have a really non-standard format, use a custom `date_parser` function. For optimal performance, this should be vectorized, i.e., it should accept arrays as arguments.

You can explore the date parsing functionality in `date_converters.py` and add your own. We would love to turn this module into a community supported set of date/time parsers. To get you started, `date_converters.py` contains functions to parse dual date and time columns, year/month/day columns, and year/month/day/hour/minute/second columns. It also contains a `generic_parser` function so you can curry it with a function that deals with a single date rather than the entire array.

Parsing a CSV with mixed timezones

Pandas cannot natively represent a column or index with mixed timezones. If your CSV file contains columns with a mixture of timezones, the default result will be an object-dtype column with strings, even with `parse_dates`.

```
In [110]: content = """\
.....: a
.....: 2000-01-01T00:00:00+05:00
.....: 2000-01-01T00:00:00+06:00"""
.....:

In [111]: df = pd.read_csv(StringIO(content), parse_dates=['a'])

In [112]: df['a']
Out[112]:
0    2000-01-01 00:00:00+05:00
1    2000-01-01 00:00:00+06:00
Name: a, dtype: object
```

To parse the mixed-timezone values as a datetime column, pass a partially-applied `to_datetime()` with `utc=True` as the `date_parser`.

```
In [113]: df = pd.read_csv(StringIO(content), parse_dates=['a'],
.....:                      date_parser=lambda col: pd.to_datetime(col, utc=True))
.....:

In [114]: df['a']
Out[114]:
0    1999-12-31 19:00:00+00:00
1    1999-12-31 18:00:00+00:00
Name: a, dtype: datetime64[ns, UTC]
```

Inferring datetime format

If you have `parse_dates` enabled for some or all of your columns, and your datetime strings are all formatted the same way, you may get a large speed up by setting `infer_datetime_format=True`. If set, pandas will attempt to guess the format of your datetime strings, and then use a faster means of parsing the strings. 5-10x parsing speeds have been observed. pandas will fallback to the usual parsing if either the format cannot be guessed or the format that was guessed cannot properly parse the entire column of strings. So in general, `infer_datetime_format` should not have any negative consequences if enabled.

Here are some examples of datetime strings that can be guessed (All representing December 30th, 2011 at 00:00:00):

- “20111230”
- “2011/12/30”
- “20111230 00:00:00”
- “12/30/2011 00:00:00”
- “30/Dec/2011 00:00:00”
- “30/December/2011 00:00:00”

Note that `infer_datetime_format` is sensitive to `dayfirst`. With `dayfirst=True`, it will guess “01/12/2011” to be December 1st. With `dayfirst=False` (default) it will guess “01/12/2011” to be January 12th.

```
# Try to infer the format for the index column
In [115]: df = pd.read_csv('foo.csv', index_col=0, parse_dates=True,
.....:                    infer_datetime_format=True)
.....:

In [116]: df
Out[116]:
           A  B  C
date
2009-01-01  a  1  2
2009-01-02  b  3  4
2009-01-03  c  4  5
```

International date formats

While US date formats tend to be MM/DD/YYYY, many international formats use DD/MM/YYYY instead. For convenience, a `dayfirst` keyword is provided:

```
In [117]: print(open('tmp.csv').read())
date,value,cat
1/6/2000,5,a
2/6/2000,10,b
3/6/2000,15,c
```

```
In [118]: pd.read_csv('tmp.csv', parse_dates=[0])
Out[118]:
   date  value cat
0 2000-01-06     5  a
1 2000-02-06    10  b
2 2000-03-06    15  c
```

```
In [119]: pd.read_csv('tmp.csv', dayfirst=True, parse_dates=[0])
Out[119]:
   date  value cat
0 2000-06-01     5  a
1 2000-06-02    10  b
2 2000-06-03    15  c
```

Specifying method for floating-point conversion

The parameter `float_precision` can be specified in order to use a specific floating-point converter during parsing with the C engine. The options are the ordinary converter, the high-precision converter, and the round-trip converter (which is guaranteed to round-trip values after writing to a file). For example:

```
In [120]: val = '0.3066101993807095471566981359501369297504425048828125'
```

```
In [121]: data = 'a,b,c\n1,2,{0}'.format(val)
```

```
In [122]: abs(pd.read_csv(StringIO(data), engine='c',
```

```
.....:          float_precision=None)['c'][0] - float(val))
.....:
Out[122]: 1.1102230246251565e-16

In [123]: abs(pd.read_csv(StringIO(data), engine='c',
.....:          float_precision='high')['c'][0] - float(val))
.....:
Out[123]: 5.551115123125783e-17

In [124]: abs(pd.read_csv(StringIO(data), engine='c',
.....:          float_precision='round_trip')['c'][0] - float(val))
.....:
Out[124]: 0.0
```

Thousand separators

For large numbers that have been written with a thousands separator, you can set the `thousands` keyword to a string of length 1 so that integers will be parsed correctly:

By default, numbers with a thousands separator will be parsed as strings:

```
In [125]: print(open('tmp.csv').read())
ID|level|category
Patient1|123,000|x
Patient2|23,000|y
Patient3|1,234,018|z

In [126]: df = pd.read_csv('tmp.csv', sep='|')
```

```
In [127]: df
Out[127]:
      ID  level category
0 Patient1  123,000      x
1 Patient2   23,000      y
2 Patient3 1,234,018      z
```

```
In [128]: df.level.dtype
Out[128]: dtype('O')
```

The `thousands` keyword allows integers to be parsed correctly:

```
In [129]: print(open('tmp.csv').read())
ID|level|category
Patient1|123,000|x
Patient2|23,000|y
Patient3|1,234,018|z

In [130]: df = pd.read_csv('tmp.csv', sep='|', thousands=',')
```

```
In [131]: df
Out[131]:
      ID  level category
0 Patient1  123000      x
1 Patient2   23000      y
2 Patient3 1234018      z
```

```
In [132]: df.level.dtype
Out[132]: dtype('int64')
```

NA values

To control which values are parsed as missing values (which are signified by NaN), specify a string in `na_values`. If you specify a list of strings, then all values in it are considered to be missing values. If you specify a number (a `float`, like 5.0 or an `integer` like 5), the corresponding equivalent values will also imply a missing value (in this case effectively [5.0, 5] are recognized as NaN).

To completely override the default values that are recognized as missing, specify `keep_default_na=False`.

The default NaN recognized values are ['-1.#IND', '1.#QNAN', '1.#IND', '-1.#QNAN', '#N/A N/A', '#N/A', 'N/A', 'n/a', 'NA', '#NA', 'NULL', 'null', 'NaN', '-NaN', 'nan', '-nan', ''].

Let us consider some examples:

```
pd.read_csv('path_to_file.csv', na_values=[5])
```

In the example above 5 and 5.0 will be recognized as NaN, in addition to the defaults. A string will first be interpreted as a numerical 5, then as a NaN.

```
pd.read_csv('path_to_file.csv', keep_default_na=False, na_values=[""])
```

Above, only an empty field will be recognized as NaN.

```
pd.read_csv('path_to_file.csv', keep_default_na=False, na_values=["NA", "0"])
```

Above, both NA and 0 as strings are NaN.

```
pd.read_csv('path_to_file.csv', na_values=["Nope"])
```

The default values, in addition to the string "Nope" are recognized as NaN.

Infinity

`inf` like values will be parsed as `np.inf` (positive infinity), and `-inf` as `-np.inf` (negative infinity). These will ignore the case of the value, meaning `Inf`, will also be parsed as `np.inf`.

Returning Series

Using the `squeeze` keyword, the parser will return output with a single column as a `Series`:

```
In [133]: print(open('tmp.csv').read())
level
Patient1,123000
Patient2,23000
Patient3,1234018
```

```
In [134]: output = pd.read_csv('tmp.csv', squeeze=True)
```

```
In [135]: output
Out[135]:
Patient1    123000
```

```
Patient2      23000
Patient3      1234018
Name: level, dtype: int64
```

```
In [136]: type(output)
Out[136]: pandas.core.series.Series
```

Boolean values

The common values `True`, `False`, `TRUE`, and `FALSE` are all recognized as boolean. Occasionally you might want to recognize other values as being boolean. To do this, use the `true_values` and `false_values` options as follows:

```
In [137]: data = ('a,b,c\n'
.....:           '1,Yes,2\n'
.....:           '3,No,4')
.....:
```

```
In [138]: print(data)
a,b,c
1,Yes,2
3,No,4
```

```
In [139]: pd.read_csv(StringIO(data))
Out[139]:
   a  b  c
0  1  Yes  2
1  3  No  4
```

```
In [140]: pd.read_csv(StringIO(data), true_values=['Yes'], false_values=['No'])
Out[140]:
   a  b  c
0  1  True  2
1  3  False  4
```

Handling “bad” lines

Some files may have malformed lines with too few fields or too many. Lines with too few fields will have NA values filled in the trailing fields. Lines with too many fields will raise an error by default:

```
In [141]: data = ('a,b,c\n'
.....:           '1,2,3\n'
.....:           '4,5,6,7\n'
.....:           '8,9,10')
.....:

In [142]: pd.read_csv(StringIO(data))

~/sandbox/pandas-doc/pandas/_libs/parsers.pyx in pandas._libs.parsers.raise_parser_
↳ error()

ParserError: Error tokenizing data. C error: Expected 3 fields in line 3, saw 4

```

You can elect to skip bad lines:

```
In [29]: pd.read_csv(StringIO(data), error_bad_lines=False)
Skipping line 3: expected 3 fields, saw 4
```

```
Out[29]:
   a  b  c
0  1  2  3
1  8  9 10
```

You can also use the `usecols` parameter to eliminate extraneous column data that appear in some lines but not others:

```
In [30]: pd.read_csv(StringIO(data), usecols=[0, 1, 2])
```

```
Out[30]:
   a  b  c
0  1  2  3
1  4  5  6
2  8  9 10
```

Dialect

The `dialect` keyword gives greater flexibility in specifying the file format. By default it uses the Excel dialect but you can specify either the dialect name or a `csv.Dialect` instance.

Suppose you had data with unenclosed quotes:

```
In [143]: print(data)
label1,label2,label3
index1,"a,c,e
index2,b,d,f
```

By default, `read_csv` uses the Excel dialect and treats the double quote as the quote character, which causes it to fail when it finds a newline before it finds the closing double quote.

We can get around this using `dialect`:

```
In [144]: import csv

In [145]: dia = csv.excel()

In [146]: dia.quoting = csv.QUOTE_NONE

In [147]: pd.read_csv(StringIO(data), dialect=dia)
Out[147]:
   label1 label2 label3
index1   "a     c     e
index2    b     d     f
```

All of the dialect options can be specified separately by keyword arguments:

```
In [148]: data = 'a,b,c~1,2,3~4,5,6'

In [149]: pd.read_csv(StringIO(data), lineterminator='~')
```

(continues on next page)

(continued from previous page)

Out [149]:

```

  a  b  c
0  1  2  3
1  4  5  6

```

Another common dialect option is `skipinitialspace`, to skip any whitespace after a delimiter:

```
In [150]: data = 'a, b, c\n1, 2, 3\n4, 5, 6'
```

```
In [151]: print(data)
```

```

a, b, c
1, 2, 3
4, 5, 6

```

```
In [152]: pd.read_csv(StringIO(data), skipinitialspace=True)
```

```
Out [152]:
```

```

  a  b  c
0  1  2  3
1  4  5  6

```

The parsers make every attempt to “do the right thing” and not be fragile. Type inference is a pretty big deal. If a column can be coerced to integer dtype without altering the contents, the parser will do so. Any non-numeric columns will come through as object dtype as with the rest of pandas objects.

Quoting and Escape Characters

Quotes (and other escape characters) in embedded fields can be handled in any number of ways. One way is to use backslashes; to properly parse this data, you should pass the `escapechar` option:

```
In [153]: data = 'a,b\n"hello, \\"Bob\\", nice to see you",5'
```

```
In [154]: print(data)
```

```

a,b
"hello, \"Bob\", nice to see you",5

```

```
In [155]: pd.read_csv(StringIO(data), escapechar='\')
```

```
Out [155]:
```

```

           a  b
0  hello, "Bob", nice to see you  5

```

Files with fixed width columns

While `read_csv()` reads delimited data, the `read_fwf()` function works with data files that have known and fixed column widths. The function parameters to `read_fwf` are largely the same as `read_csv` with two extra parameters, and a different usage of the `delimiter` parameter:

- `colspecs`: A list of pairs (tuples) giving the extents of the fixed-width fields of each line as half-open intervals (i.e., `[from, to[`). String value ‘infer’ can be used to instruct the parser to try detecting the column specifications from the first 100 rows of the data. Default behavior, if not specified, is to infer.
- `widths`: A list of field widths which can be used instead of ‘colspecs’ if the intervals are contiguous.
- `delimiter`: Characters to consider as filler characters in the fixed-width file. Can be used to specify the filler character of the fields if it is not spaces (e.g., ‘~’).

Consider a typical fixed-width data file:

```
In [156]: print(open('bar.csv').read())
id8141    360.242940    149.910199    11950.7
id1594    444.953632    166.985655    11788.4
id1849    364.136849    183.628767    11806.2
id1230    413.836124    184.375703    11916.8
id1948    502.953953    173.237159    12468.3
```

In order to parse this file into a `DataFrame`, we simply need to supply the column specifications to the `read_fwf` function along with the file name:

```
# Column specifications are a list of half-intervals
In [157]: colspecs = [(0, 6), (8, 20), (21, 33), (34, 43)]

In [158]: df = pd.read_fwf('bar.csv', colspecs=colspecs, header=None, index_col=0)

In [159]: df
Out[159]:
```

	1	2	3
0			
id8141	360.242940	149.910199	11950.7
id1594	444.953632	166.985655	11788.4
id1849	364.136849	183.628767	11806.2
id1230	413.836124	184.375703	11916.8
id1948	502.953953	173.237159	12468.3

Note how the parser automatically picks column names `X.<column number>` when `header=None` argument is specified. Alternatively, you can supply just the column widths for contiguous columns:

```
# Widths are a list of integers
In [160]: widths = [6, 14, 13, 10]

In [161]: df = pd.read_fwf('bar.csv', widths=widths, header=None)

In [162]: df
Out[162]:
```

	0	1	2	3
0	id8141	360.242940	149.910199	11950.7
1	id1594	444.953632	166.985655	11788.4
2	id1849	364.136849	183.628767	11806.2
3	id1230	413.836124	184.375703	11916.8
4	id1948	502.953953	173.237159	12468.3

The parser will take care of extra white spaces around the columns so it's ok to have extra separation between the columns in the file.

By default, `read_fwf` will try to infer the file's `colspecs` by using the first 100 rows of the file. It can do it only in cases when the columns are aligned and correctly separated by the provided `delimiter` (default delimiter is whitespace).

```
In [163]: df = pd.read_fwf('bar.csv', header=None, index_col=0)

In [164]: df
```

(continues on next page)

(continued from previous page)

```
Out [164]:
```

	1	2	3
0			
id8141	360.242940	149.910199	11950.7
id1594	444.953632	166.985655	11788.4
id1849	364.136849	183.628767	11806.2
id1230	413.836124	184.375703	11916.8
id1948	502.953953	173.237159	12468.3

New in version 0.20.0.

`read_fwf` supports the `dtype` parameter for specifying the types of parsed columns to be different from the inferred type.

```
In [165]: pd.read_fwf('bar.csv', header=None, index_col=0).dtypes
```

```
Out [165]:
1    float64
2    float64
3    float64
dtype: object
```

```
In [166]: pd.read_fwf('bar.csv', header=None, dtype={2: 'object'}).dtypes
```

```
Out [166]:
0    object
1    float64
2    object
3    float64
dtype: object
```

Indexes

Files with an “implicit” index column

Consider a file with one less entry in the header than the number of data column:

```
In [167]: print(open('foo.csv').read())
A,B,C
20090101,a,1,2
20090102,b,3,4
20090103,c,4,5
```

In this special case, `read_csv` assumes that the first column is to be used as the index of the `DataFrame`:

```
In [168]: pd.read_csv('foo.csv')
Out [168]:
```

	A	B	C
20090101	a	1	2
20090102	b	3	4
20090103	c	4	5

Note that the dates weren't automatically parsed. In that case you would need to do as before:

```
In [169]: df = pd.read_csv('foo.csv', parse_dates=True)

In [170]: df.index
Out[170]: DatetimeIndex(['2009-01-01', '2009-01-02', '2009-01-03'], dtype='datetime64[ns]
↳', freq=None)
```

Reading an index with a MultiIndex

Suppose you have data indexed by two columns:

```
In [171]: print(open('data/mindex_ex.csv').read())
year,indiv,zit,xit
1977,"A",1.2,.6
1977,"B",1.5,.5
1977,"C",1.7,.8
1978,"A",.2,.06
1978,"B",.7,.2
1978,"C",.8,.3
1978,"D",.9,.5
1978,"E",1.4,.9
1979,"C",.2,.15
1979,"D",.14,.05
1979,"E",.5,.15
1979,"F",1.2,.5
1979,"G",3.4,1.9
1979,"H",5.4,2.7
1979,"I",6.4,1.2
```

The `index_col` argument to `read_csv` can take a list of column numbers to turn multiple columns into a `MultiIndex` for the index of the returned object:

```
In [172]: df = pd.read_csv("data/mindex_ex.csv", index_col=[0, 1])
```

```
In [173]: df
```

```
Out[173]:
```

		zit	xit
year	indiv		
1977	A	1.20	0.60
	B	1.50	0.50
	C	1.70	0.80
1978	A	0.20	0.06
	B	0.70	0.20
	C	0.80	0.30
	D	0.90	0.50
	E	1.40	0.90
1979	C	0.20	0.15
	D	0.14	0.05
	E	0.50	0.15
	F	1.20	0.50
	G	3.40	1.90
	H	5.40	2.70
	I	6.40	1.20

```
In [174]: df.loc[1978]
Out[174]:
```

```
      zit  xit
indiv
A      0.2  0.06
B      0.7  0.20
C      0.8  0.30
D      0.9  0.50
E      1.4  0.90
```

Reading columns with a MultiIndex

By specifying list of row locations for the `header` argument, you can read in a `MultiIndex` for the columns. Specifying non-consecutive rows will skip the intervening rows.

```
In [175]: from pandas.util.testing import makeCustomDataframe as mkdf
```

```
In [176]: df = mkdf(5, 3, r_idx_nlevels=2, c_idx_nlevels=4)
```

```
In [177]: df.to_csv('mi.csv')
```

```
In [178]: print(open('mi.csv').read())
```

```
C0,,C_10_g0,C_10_g1,C_10_g2
C1,,C_11_g0,C_11_g1,C_11_g2
C2,,C_12_g0,C_12_g1,C_12_g2
C3,,C_13_g0,C_13_g1,C_13_g2
R0,R1,,,
R_10_g0,R_11_g0,ROC0,ROC1,ROC2
R_10_g1,R_11_g1,R1C0,R1C1,R1C2
R_10_g2,R_11_g2,R2C0,R2C1,R2C2
R_10_g3,R_11_g3,R3C0,R3C1,R3C2
R_10_g4,R_11_g4,R4C0,R4C1,R4C2
```

```
In [179]: pd.read_csv('mi.csv', header=[0, 1, 2, 3], index_col=[0, 1])
```

```
Out[179]:
      C_10_g0 C_10_g1 C_10_g2
C1          C_11_g0 C_11_g1 C_11_g2
C2          C_12_g0 C_12_g1 C_12_g2
C3          C_13_g0 C_13_g1 C_13_g2
R0      R1
R_10_g0 R_11_g0      ROC0      ROC1      ROC2
R_10_g1 R_11_g1      R1C0      R1C1      R1C2
R_10_g2 R_11_g2      R2C0      R2C1      R2C2
R_10_g3 R_11_g3      R3C0      R3C1      R3C2
R_10_g4 R_11_g4      R4C0      R4C1      R4C2
```

`read_csv` is also able to interpret a more common format of multi-columns indices.

```
In [180]: print(open('mi2.csv').read())
```

```
,a,a,a,b,c,c
,q,r,s,t,u,v
one,1,2,3,4,5,6
two,7,8,9,10,11,12
```

```
In [181]: pd.read_csv('mi2.csv', header=[0, 1], index_col=0)
Out[181]:
```

```
      a      b      c
      q  r  s  t  u  v
one  1  2  3  4  5  6
two  7  8  9 10 11 12
```

Note: If an `index_col` is not specified (e.g. you don't have an index, or wrote it with `df.to_csv(..., index=False)`), then any names on the columns index will be *lost*.

Automatically “sniffing” the delimiter

`read_csv` is capable of inferring delimited (not necessarily comma-separated) files, as pandas uses the `csv.Sniffer` class of the `csv` module. For this, you have to specify `sep=None`.

```
In [182]: print(open('tmp2.csv').read())
:0:1:2:3

Reading multiple files to create a single DataFrame

It's best to use `concat()` to combine multiple files. See the *cookbook* for an example.

Iterating through files chunk by chunk

Suppose you wish to iterate through a (potentially very large) file lazily rather than reading the entire file into memory, such as the following:

```
In [184]: print(open('tmp.csv').read())
0|1|2|3
0|1.1214905765122583|-1.1011663421613171|-1.2725711408453018|0.8434589457722285
1|0.8739661419816901|-1.1622548707272122|0.12618578996106738|0.5057848504967111
2|0.6695152369722812|0.4833977900441433|-0.4383565886430891|-0.13952146077085656
3|1.6678766138462109|0.906356209978661|0.8603041052486606|-0.009413710135323125
4|-0.8075485015292924|-0.7848128653629299|-1.3155155066668116|0.6875244729698119
5|-0.1572352664979729|0.30339976035788174|-0.36340691002502046|-0.5526511482544121
6|0.41442095212262187|0.17517103850750262|-0.5295157789486404|-0.06745694327155764
7|1.058814717443789|-0.11789792502832808|-1.8534207864364352|-0.7018494437516053

9           9  0.635285 -2.178548  0.312044  1.572378
```

By specifying a `chunksize` to `read_csv`, the return value will be an iterable object of type `TextFileReader`:

```
In [187]: reader = pd.read_csv('tmp.csv', sep='|', chunksize=4)
```

```
In [188]: reader
```

```
Out[188]: <pandas.io.parsers.TextFileReader at 0x13eb31a90>
```

```
In [189]: for chunk in reader:
```

```
.....:     print(chunk)
.....:
   Unnamed: 0      0      1      2      3
0           0  1.121491 -1.101166 -1.272571  0.843459
1           1  0.873966 -1.162255  0.126186  0.505785
2           2  0.669515  0.483398 -0.438357 -0.139521
3           3  1.667877  0.906356  0.860304 -0.009414
   Unnamed: 0      0      1      2      3
4           4 -0.807549 -0.784813 -1.315516  0.687524
5           5 -0.157235  0.303400 -0.363407 -0.552651
6           6  0.414421  0.175171 -0.529516 -0.067457
7           7  1.058815 -0.117898 -1.853421 -0.701849
   Unnamed: 0      0      1      2      3
8           8  0.262396 -1.724596  0.276580  1.073024
9           9  0.635285 -2.178548  0.312044  1.572378
```

Specifying `iterator=True` will also return the `TextFileReader` object:

```
In [190]: reader = pd.read_csv('tmp.csv', sep='|', iterator=True)

In [191]: reader.get_chunk(5)
Out[191]:
   Unnamed: 0      0      1      2      3
0           0  1.121491 -1.101166 -1.272571  0.843459
1           1  0.873966 -1.162255  0.126186  0.505785
2           2  0.669515  0.483398 -0.438357 -0.139521
3           3  1.667877  0.906356  0.860304 -0.009414
4           4 -0.807549 -0.784813 -1.315516  0.687524
```

Specifying the parser engine

Under the hood pandas uses a fast and efficient parser implemented in C as well as a Python implementation which is currently more feature-complete. Where possible pandas uses the C parser (specified as `engine='c'`), but may fall back to Python if C-unsupported options are specified. Currently, C-unsupported options include:

- `sep` other than a single character (e.g. regex separators)
- `skipfooter`
- `sep=None` with `delim_whitespace=False`

Specifying any of the above options will produce a `ParserWarning` unless the python engine is selected explicitly using `engine='python'`.

Reading remote files

You can pass in a URL to a CSV file:

```
df = pd.read_csv('https://download.bls.gov/pub/time.series/cu/cu.item',
                 sep='\t')
```

S3 URLs are handled as well but require installing the `S3Fs` library:

```
df = pd.read_csv('s3://pandas-test/tips.csv')
```

If your S3 bucket requires credentials you will need to set them as environment variables or in the `~/.aws/credentials` config file, refer to the `S3Fs` documentation on `credentials`.

Writing out data

Writing to CSV format

The `Series` and `DataFrame` objects have an instance method `to_csv` which allows storing the contents of the object as a comma-separated-values file. The function takes a number of arguments. Only the first is required.

- `path_or_buf`: A string path to the file to write or a file object. If a file object it must be opened with `newline=""`
- `sep`: Field delimiter for the output file (default “,”)

- `na_rep`: A string representation of a missing value (default `''`)
- `float_format`: Format string for floating point numbers
- `columns`: Columns to write (default `None`)
- `header`: Whether to write out the column names (default `True`)
- `index`: whether to write row (index) names (default `True`)
- `index_label`: Column label(s) for index column(s) if desired. If `None` (default), and `header` and `index` are `True`, then the index names are used. (A sequence should be given if the `DataFrame` uses `MultiIndex`).
- `mode`: Python write mode, default `'w'`
- `encoding`: a string representing the encoding to use if the contents are non-ASCII, for Python versions prior to 3
- `line_terminator`: Character sequence denoting line end (default `os.linesep`)
- `quoting`: Set quoting rules as in `csv` module (default `csv.QUOTE_MINIMAL`). Note that if you have set a `float_format` then floats are converted to strings and `csv.QUOTE_NONNUMERIC` will treat them as non-numeric
- `quotechar`: Character used to quote fields (default `'\"'`)
- `doublequote`: Control quoting of `quotechar` in fields (default `True`)
- `escapechar`: Character used to escape `sep` and `quotechar` when appropriate (default `None`)
- `chunksize`: Number of rows to write at a time
- `date_format`: Format string for datetime objects

Writing a formatted string

The `DataFrame` object has an instance method `to_string` which allows control over the string representation of the object. All arguments are optional:

- `buf` default `None`, for example a `StringIO` object
- `columns` default `None`, which columns to write
- `col_space` default `None`, minimum width of each column.
- `na_rep` default `NaN`, representation of NA value
- `formatters` default `None`, a dictionary (by column) of functions each of which takes a single argument and returns a formatted string
- `float_format` default `None`, a function which takes a single (float) argument and returns a formatted string; to be applied to floats in the `DataFrame`.
- `sparsify` default `True`, set to `False` for a `DataFrame` with a hierarchical index to print every `MultiIndex` key at each row.
- `index_names` default `True`, will print the names of the indices
- `index` default `True`, will print the index (ie, row labels)
- `header` default `True`, will print the column labels
- `justify` default `left`, will print column headers left- or right-justified

The `Series` object also has a `to_string` method, but with only the `buf`, `na_rep`, `float_format` arguments. There is also a `length` argument which, if set to `True`, will additionally output the length of the `Series`.

4.1.2 JSON

Read and write JSON format files and strings.

Writing JSON

A `Series` or `DataFrame` can be converted to a valid JSON string. Use `to_json` with optional parameters:

- `path_or_buf` : the pathname or buffer to write the output This can be `None` in which case a JSON string is returned
- `orient` :
 - Series:**
 - default is `index`
 - allowed values are `{split, records, index}`
 - DataFrame:**
 - default is `columns`
 - allowed values are `{split, records, index, columns, values, table}`

The format of the JSON string

<code>split</code>	dict like <code>{index -> [index], columns -> [columns], data -> [values]}</code>
<code>records</code>	list like <code>[{column -> value}, ... , {column -> value}]</code>
<code>index</code>	dict like <code>{index -> {column -> value}}</code>
<code>columns</code>	dict like <code>{column -> {index -> value}}</code>
<code>values</code>	just the values array

- `date_format` : string, type of date conversion, 'epoch' for timestamp, 'iso' for ISO8601.
- `double_precision` : The number of decimal places to use when encoding floating point values, default 10.
- `force_ascii` : force encoded string to be ASCII, default `True`.
- `date_unit` : The time unit to encode to, governs timestamp and ISO8601 precision. One of 's', 'ms', 'us' or 'ns' for seconds, milliseconds, microseconds and nanoseconds respectively. Default 'ms'.
- `default_handler` : The handler to call if an object cannot otherwise be converted to a suitable format for JSON. Takes a single argument, which is the object to convert, and returns a serializable object.
- `lines` : If `records` orient, then will write each record per line as json.

Note `NaN`'s, `NaT`'s and `None` will be converted to `null` and `datetime` objects will be converted based on the `date_format` and `date_unit` parameters.

```
In [192]: dfj = pd.DataFrame(np.random.randn(5, 2), columns=list('AB'))
```

```
In [193]: json = dfj.to_json()
```

(continues on next page)

(continued from previous page)

```
In [194]: json
Out[194]: '{"A":{"0":2.0027932898,"1":-1.1284197337,"2":-0.2671230751,"3":0.0590811856,"4":0.2126018166},"B":{"0":0.009310115,"1":-1.2591311739,"2":1.7549089729,"3":0.9464922966,"4":-0.5276761509}}'
```

Orient options

There are a number of different options for the format of the resulting JSON file / string. Consider the following `DataFrame` and `Series`:

```
In [195]: dfjo = pd.DataFrame(dict(A=range(1, 4), B=range(4, 7), C=range(7, 10)),
.....:                          columns=list('ABC'), index=list('xyz'))
.....:
```

```
In [196]: dfjo
```

```
Out[196]:
   A  B  C
x  1  4  7
y  2  5  8
z  3  6  9
```

```
In [197]: sjo = pd.Series(dict(x=15, y=16, z=17), name='D')
```

```
In [198]: sjo
```

```
Out[198]:
x    15
y    16
z    17
Name: D, dtype: int64
```

Column oriented (the default for `DataFrame`) serializes the data as nested JSON objects with column labels acting as the primary index:

```
In [199]: dfjo.to_json(orient="columns")
Out[199]: '{"A":{"x":1,"y":2,"z":3},"B":{"x":4,"y":5,"z":6},"C":{"x":7,"y":8,"z":9}}'

# Not available for Series
```

Index oriented (the default for `Series`) similar to column oriented but the index labels are now primary:

```
In [200]: dfjo.to_json(orient="index")
Out[200]: '{"x":{"A":1,"B":4,"C":7},"y":{"A":2,"B":5,"C":8},"z":{"A":3,"B":6,"C":9}}'
```

```
In [201]: sjo.to_json(orient="index")
```

```
Out[201]: '{"x":15,"y":16,"z":17}'
```

Record oriented serializes the data to a JSON array of column -> value records, index labels are not included. This is useful for passing `DataFrame` data to plotting libraries, for example the JavaScript library `d3.js`:

```
In [202]: dfjo.to_json(orient="records")
Out[202]: '[{"A":1,"B":4,"C":7}, {"A":2,"B":5,"C":8}, {"A":3,"B":6,"C":9}]'
```

```
In [203]: sjo.to_json(orient="records")
Out[203]: '[15,16,17]'
```

Value oriented is a bare-bones option which serializes to nested JSON arrays of values only, column and index labels are not included:

```
In [204]: dfjo.to_json(orient="values")
Out[204]: '[[1,4,7],[2,5,8],[3,6,9]]'

# Not available for Series
```

Split oriented serializes to a JSON object containing separate entries for values, index and columns. Name is also included for `Series`:

```
In [205]: dfjo.to_json(orient="split")
Out[205]: '{"columns":["A","B","C"],"index":["x","y","z"],"data":[[1,4,7],[2,5,8],[3,6,9]]}'
```

```
In [206]: sjo.to_json(orient="split")
Out[206]: '{"name":"D","index":["x","y","z"],"data":[15,16,17]}'
```

Table oriented serializes to the JSON [Table Schema](#), allowing for the preservation of metadata including but not limited to dtypes and index names.

Note: Any orient option that encodes to a JSON object will not preserve the ordering of index and column labels during round-trip serialization. If you wish to preserve label ordering use the *split* option as it uses ordered containers.

Date handling

Writing in ISO date format:

```
In [207]: dfd = pd.DataFrame(np.random.randn(5, 2), columns=list('AB'))
In [208]: dfd['date'] = pd.Timestamp('20130101')
In [209]: dfd = dfd.sort_index(1, ascending=False)
In [210]: json = dfd.to_json(date_format='iso')
In [211]: json
Out[211]: '{"date":{"0":"2013-01-01T00:00:00.000Z","1":"2013-01-01T00:00:00.000Z","2":
↪ "2013-01-01T00:00:00.000Z","3":"2013-01-01T00:00:00.000Z","4":"2013-01-01T00:00:00.000Z"},

↪ "A":{"0":-1.0954121534,"1":-0.147141856,"2":0.6305826658,"3":1.5730764249,"4":0.6200376615}}'
```

Writing in ISO date format, with microseconds:

```
In [212]: json = dfd.to_json(date_format='iso', date_unit='us')
In [213]: json
Out[213]: '{"date":{"0":"2013-01-01T00:00:00.000000Z","1":"2013-01-01T00:00:00.000000Z",
↪ "2":"2013-01-01T00:00:00.000000Z","3":"2013-01-01T00:00:00.000000Z","4":"2013-01-01-
↪ 01T00:00:00.000000Z"},
↪ "B":{"0":0.3903383957,"1":-0.5223681486,"2":2.0249145293,"3":2.1144885256,"4":0.5337588359},
↪ "A":{"0":-1.0954121534,"1":-0.147141856,"2":0.6305826658,"3":1.5730764249,"4":0.6200376615}}'
```

(continued from previous page)

Epoch timestamps, in seconds:

```
In [214]: json = dfd.to_json(date_format='epoch', date_unit='s')

In [215]: json
Out[215]: '{"date":{"0":1356998400,"1":1356998400,"2":1356998400,"3":1356998400,"4
↪":1356998400},"B":{"0":0.3903383957,"1":-0.5223681486,"2":2.0249145293,"3":2.
↪1144885256,"4":0.5337588359},"A":{"0":-1.0954121534,"1":-0.147141856,"2":0.6305826658,
↪"3":1.5730764249,"4":0.6200376615}}'
```

Writing to a file, with a date index and a date column:

```
In [216]: dfj2 = dfj.copy()

In [217]: dfj2['date'] = pd.Timestamp('20130101')

In [218]: dfj2['ints'] = list(range(5))

In [219]: dfj2['bools'] = True

In [220]: dfj2.index = pd.date_range('20130101', periods=5)

In [221]: dfj2.to_json('test.json')

In [222]: with open('test.json') as fh:
.....:     print(fh.read())
.....:
{"A":{"1356998400000":2.0027932898,"1357084800000":-1.1284197337,"1357171200000":-0.
↪2671230751,"1357257600000":0.0590811856,"1357344000000":0.2126018166},"B":{"
↪1356998400000":0.009310115,"1357084800000":-1.2591311739,"1357171200000":1.7549089729,
↪1357257600000":0.9464922966,"1357344000000":-0.5276761509},"date":{"1356998400000
↪":1356998400000,"1357084800000":1356998400000,"1357171200000":1356998400000,

↪1357084800000":1,"1357171200000":2,"1357257600000":3,"1357344000000":4},"bools":{"
↪1356998400000":true,"1357084800000":true,"1357171200000":true,"1357257600000":true,
↪1357344000000":true}}
```

Fallback behavior

If the JSON serializer cannot handle the container contents directly it will fall back in the following manner:

- if the dtype is unsupported (e.g. `np.complex`) then the `default_handler`, if provided, will be called for each value, otherwise an exception is raised.
- if an object is unsupported it will attempt the following:
 - check if the object has defined a `toDict` method and call it. A `toDict` method should return a `dict` which will then be JSON serialized.
 - invoke the `default_handler` if one was provided.
 - convert the object to a `dict` by traversing its contents. However this will often fail with an `OverflowError` or give unexpected results.

In general the best approach for unsupported objects or dtypes is to provide a `default_handler`. For example:

```
>>> DataFrame([1.0, 2.0, complex(1.0, 2.0)]).to_json() # raises
RuntimeError: Unhandled numpy dtype 15
```

can be dealt with by specifying a simple `default_handler`:

```
In [223]: pd.DataFrame([1.0, 2.0, complex(1.0, 2.0)]).to_json(default_handler=str)
Out [223]: '{"0":{"0":"(1+0j)","1":"(2+0j)","2":"(1+2j)"}}'
```

Reading JSON

Reading a JSON string to pandas object can take a number of parameters. The parser will try to parse a `DataFrame` if `typ` is not supplied or is `None`. To explicitly force `Series` parsing, pass `typ=series`

- `filepath_or_buffer` : a **VALID** JSON string or file handle / StringIO. The string could be a URL. Valid URL schemes include http, ftp, S3, and file. For file URLs, a host is expected. For instance, a local file could be file `://localhost/path/to/table.json`
- `typ` : type of object to recover (series or frame), default 'frame'
- `orient` :

Series :

- default is `index`
- allowed values are `{split, records, index}`

DataFrame

- default is `columns`
- allowed values are `{split, records, index, columns, values, table}`

The format of the JSON string

<code>split</code>	dict like <code>{index -> [index], columns -> [columns], data -> [values]}</code>
<code>records</code>	list like <code>[{column -> value}, ... , {column -> value}]</code>
<code>index</code>	dict like <code>{index -> {column -> value}}</code>
<code>columns</code>	dict like <code>{column -> {index -> value}}</code>
<code>values</code>	just the values array
<code>table</code>	adhering to the JSON Table Schema

- `dtype` : if `True`, infer dtypes, if a dict of column to dtype, then use those, if `False`, then don't infer dtypes at all, default is `True`, apply only to the data.
- `convert_axes` : boolean, try to convert the axes to the proper dtypes, default is `True`
- `convert_dates` : a list of columns to parse for dates; If `True`, then try to parse date-like columns, default is `True`.
- `keep_default_dates` : boolean, default `True`. If parsing dates, then parse the default date-like columns.
- `numpy` : direct decoding to NumPy arrays. default is `False`; Supports numeric data only, although labels may be non-numeric. Also note that the JSON ordering **MUST** be the same for each term if `numpy=True`.

- `precise_float` : boolean, default `False`. Set to enable usage of higher precision (`strtod`) function when decoding string to double values. Default (`False`) is to use fast but less precise builtin functionality.
- `date_unit` : string, the timestamp unit to detect if converting dates. Default `None`. By default the timestamp precision will be detected, if this is not desired then pass one of `'s'`, `'ms'`, `'us'` or `'ns'` to force timestamp precision to seconds, milliseconds, microseconds or nanoseconds respectively.
- `lines` : reads file as one json object per line.
- `encoding` : The encoding to use to decode py3 bytes.
- `chunksize` : when used in combination with `lines=True`, return a `JsonReader` which reads in `chunksize` lines per iteration.

The parser will raise one of `ValueError/TypeError/AssertionError` if the JSON is not parseable.

If a non-default `orient` was used when encoding to JSON be sure to pass the same option here so that decoding produces sensible results, see *[Orient Options](#)* for an overview.

Data conversion

The default of `convert_axes=True`, `dtype=True`, and `convert_dates=True` will try to parse the axes, and all of the data into appropriate types, including dates. If you need to override specific dtypes, pass a dict to `dtype`. `convert_axes` should only be set to `False` if you need to preserve string-like numbers (e.g. `'1'`, `'2'`) in an axes.

Note: Large integer values may be converted to dates if `convert_dates=True` and the data and / or column labels appear 'date-like'. The exact threshold depends on the `date_unit` specified. 'date-like' means that the column label meets one of the following criteria:

- it ends with `'_at'`
- it ends with `'_time'`
- it begins with `'timestamp'`
- it is `'modified'`
- it is `'date'`

Warning: When reading JSON data, automatic coercing into dtypes has some quirks:

- an index can be reconstructed in a different order from serialization, that is, the returned order is not guaranteed to be the same as before serialization
- a column that was `float` data will be converted to `integer` if it can be done safely, e.g. a column of `1`.
- `bool` columns will be converted to `integer` on reconstruction

Thus there are times where you may want to specify specific dtypes via the `dtype` keyword argument.

Reading from a JSON string:

```
In [224]: pd.read_json(json)
Out[224]:
```

```
      date      B      A
```

(continues on next page)

(continued from previous page)

```

0 2013-01-01  0.390338 -1.095412
1 2013-01-01 -0.522368 -0.147142
2 2013-01-01  2.024915  0.630583
3 2013-01-01  2.114489  1.573076
4 2013-01-01  0.533759  0.620038

```

Reading from a file:

```

In [225]: pd.read_json('test.json')
Out[225]:
           A          B      date  ints  bools
2013-01-01  2.002793  0.009310 2013-01-01     0   True
2013-01-02 -1.128420 -1.259131 2013-01-01     1   True
2013-01-03 -0.267123  1.754909 2013-01-01     2   True
2013-01-04  0.059081  0.946492 2013-01-01     3   True
2013-01-05  0.212602 -0.527676 2013-01-01     4   True

```

Don't convert any data (but still convert axes and dates):

```

In [226]: pd.read_json('test.json', dtype=object).dtypes
Out[226]:
A          object
B          object
date       object
ints       object
bools      object
dtype: object

```

Specify dtypes for conversion:

```

In [227]: pd.read_json('test.json', dtype={'A': 'float32', 'bools': 'int8'}).dtypes
Out[227]:
A          float32
B          float64
date       datetime64[ns]
ints       int64
bools      int8
dtype: object

```

Preserve string indices:

```

In [228]: si = pd.DataFrame(np.zeros((4, 4)), columns=list(range(4)),
.....:                      index=[str(i) for i in range(4)])
.....:

```

```

In [229]: si
Out[229]:
   0  1  2  3
0  0.0  0.0  0.0  0.0
1  0.0  0.0  0.0  0.0
2  0.0  0.0  0.0  0.0
3  0.0  0.0  0.0  0.0

```

```

In [230]: si.index

```

```
Out[230]: Index(['0', '1', '2', '3'], dtype='object')
```

```
In [231]: si.columns
```

```
Out[231]: Int64Index([0, 1, 2, 3], dtype='int64')
```

```
In [232]: json = si.to_json()
```

```
In [233]: sij = pd.read_json(json, convert_axes=False)
```

```
In [234]: sij
```

```
Out[234]:
   0  1  2  3
0  0  0  0  0
1  0  0  0  0
2  0  0  0  0
3  0  0  0  0
```

```
In [235]: sij.index
```

```
Out[235]: Index(['0', '1', '2', '3'], dtype='object')
```

```
In [236]: sij.columns
```

```
Out[236]: Index(['0', '1', '2', '3'], dtype='object')
```

Dates written in nanoseconds need to be read back in nanoseconds:

```
In [237]: json = dfj2.to_json(date_unit='ns')
```

```
# Try to parse timestamps as milliseconds -> Won't Work
```

```
In [238]: dfju = pd.read_json(json, date_unit='ms')
```

```
In [239]: dfju
```

```
Out[239]:
```

	A	B	date	ints	bools
1356998400000000000	2.002793	0.009310	1356998400000000000	0	True
1357084800000000000	-1.128420	-1.259131	1356998400000000000	1	True
1357171200000000000	-0.267123	1.754909	1356998400000000000	2	True
1357257600000000000	0.059081	0.946492	1356998400000000000	3	True
1357344000000000000	0.212602	-0.527676	1356998400000000000	4	True

```
# Let pandas detect the correct precision
```

```
In [240]: dfju = pd.read_json(json)
```

```
In [241]: dfju
```

```
Out[241]:
```

	A	B	date	ints	bools
2013-01-01	2.002793	0.009310	2013-01-01	0	True
2013-01-02	-1.128420	-1.259131	2013-01-01	1	True
2013-01-03	-0.267123	1.754909	2013-01-01	2	True
2013-01-04	0.059081	0.946492	2013-01-01	3	True
2013-01-05	0.212602	-0.527676	2013-01-01	4	True

```
# Or specify that all timestamps are in nanoseconds
```

```
In [242]: dfju = pd.read_json(json, date_unit='ns')
```

(continues on next page)

(continued from previous page)

```
In [243]: dfju
```

```
Out[243]:
```

	A	B	date	ints	bools
2013-01-01	2.002793	0.009310	2013-01-01	0	True
2013-01-02	-1.128420	-1.259131	2013-01-01	1	True
2013-01-03	-0.267123	1.754909	2013-01-01	2	True
2013-01-04	0.059081	0.946492	2013-01-01	3	True
2013-01-05	0.212602	-0.527676	2013-01-01	4	True

The Numpy parameter

Note: This supports numeric data only. Index and columns labels may be non-numeric, e.g. strings, dates etc.

If `numpy=True` is passed to `read_json` an attempt will be made to sniff an appropriate dtype during deserialization and to subsequently decode directly to NumPy arrays, bypassing the need for intermediate Python objects.

This can provide speedups if you are deserialising a large amount of numeric data:

```
In [244]: randfloats = np.random.uniform(-100, 1000, 10000)
```

```
In [245]: randfloats.shape = (1000, 10)
```

```
In [246]: dffloats = pd.DataFrame(randfloats, columns=list('ABCDEFGHJIJ'))
```

```
In [247]: jsonfloats = dffloats.to_json()
```

```
In [248]: %timeit pd.read_json(jsonfloats)
10.7 ms +- 321 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

```
In [249]: %timeit pd.read_json(jsonfloats, numpy=True)
8.68 ms +- 352 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

The speedup is less noticeable for smaller datasets:

```
In [250]: jsonfloats = dffloats.head(100).to_json()
```

```
In [251]: %timeit pd.read_json(jsonfloats)
7.13 ms +- 153 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

```
In [252]: %timeit pd.read_json(jsonfloats, numpy=True)
6.36 ms +- 250 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

Warning: Direct NumPy decoding makes a number of assumptions and may fail or produce unexpected output if these assumptions are not satisfied:

- data is numeric.

- data is uniform. The dtype is sniffed from the first value decoded. A `ValueError` may be raised, or incorrect output may be produced if this condition is not satisfied.
- labels are ordered. Labels are only read from the first container, it is assumed that each subsequent row / column has been encoded in the same order. This should be satisfied if the data was encoded using `to_json` but may not be the case if the JSON is from another source.

Normalization

pandas provides a utility function to take a dict or list of dicts and *normalize* this semi-structured data into a flat table.

```
In [253]: from pandas.io.json import json_normalize
```

```
In [254]: data = [{'id': 1, 'name': {'first': 'Coleen', 'last': 'Volk'}},
.....:           {'name': {'given': 'Mose', 'family': 'Regner'}},
.....:           {'id': 2, 'name': 'Faye Raker'}]
.....:
```

```
In [255]: json_normalize(data)
```

```
Out[255]:
```

	id	name.first	name.last	name.given	name.family	name
0	1.0	Coleen	Volk	NaN	NaN	NaN
1	NaN	NaN	NaN	Mose	Regner	NaN
2	2.0	NaN	NaN	NaN	NaN	Faye Raker

```
In [256]: data = [{'state': 'Florida',
.....:             'shortname': 'FL',
.....:             'info': {'governor': 'Rick Scott'},
.....:             'counties': [{'name': 'Dade', 'population': 12345},
.....:                          {'name': 'Broward', 'population': 40000},
.....:                          {'name': 'Palm Beach', 'population': 60000}]},
.....:             {'state': 'Ohio',
.....:             'shortname': 'OH',
.....:             'info': {'governor': 'John Kasich'},
.....:             'counties': [{'name': 'Summit', 'population': 1234},
.....:                          {'name': 'Cuyahoga', 'population': 1337}]}]
.....:
```

```
In [257]: json_normalize(data, 'counties', ['state', 'shortname', ['info', 'governor']])
```

```
Out[257]:
```

	name	population	state	shortname	info.governor
0	Dade	12345	Florida	FL	Rick Scott
1	Broward	40000	Florida	FL	Rick Scott
2	Palm Beach	60000	Florida	FL	Rick Scott
3	Summit	1234	Ohio	OH	John Kasich
4	Cuyahoga	1337	Ohio	OH	John Kasich

The `max_level` parameter provides more control over which level to end normalization. With `max_level=1` the following snippet normalizes until 1st nesting level of the provided dict.

```
In [258]: data = [{'CreatedBy': {'Name': 'User001'},
.....:             'Lookup': {'TextField': 'Some text',
.....:                        'UserField': {'Id': 'ID001',
.....:                                       'Name': 'Name001'}}},
.....:             'Image': {'a': 'b'}
.....:             }]

In [259]: json_normalize(data, max_level=1)
Out[259]:
```

	CreatedBy.Name	Lookup.TextField	Lookup.UserField	Image.a
0	User001	Some text	{'Id': 'ID001', 'Name': 'Name001'}	b

Line delimited json

New in version 0.19.0.

pandas is able to read and write line-delimited json files that are common in data processing pipelines using Hadoop or Spark.

New in version 0.21.0.

For line-delimited json files, pandas can also return an iterator which reads in `chunksize` lines at a time. This can be useful for large files or to read from a stream.

```
In [260]: jsonl = '''
.....:     {"a": 1, "b": 2}
.....:     {"a": 3, "b": 4}
.....: '''
.....:

In [261]: df = pd.read_json(jsonl, lines=True)

In [262]: df
Out[262]:
```

	a	b
0	1	2
1	3	4

```
In [263]: df.to_json(orient='records', lines=True)
Out[263]: '{"a":1,"b":2}\n{"a":3,"b":4}'

# reader is an iterator that returns `chunksize` lines each iteration
In [264]: reader = pd.read_json(StringIO(jsonl), lines=True, chunksize=1)

In [265]: reader
Out[265]: <pandas.io.json._json.JsonReader at 0x13ed13b10>

In [266]: for chunk in reader:
.....:     print(chunk)
.....:

Empty DataFrame
Columns: []
Index: []
```

```

   a  b
0  1  2
   a  b
1  3  4

```

Table schema

New in version 0.20.0.

Table Schema is a spec for describing tabular datasets as a JSON object. The JSON includes information on the field names, types, and other attributes. You can use the orient `table` to build a JSON string with two fields, `schema` and `data`.

```

In [267]: df = pd.DataFrame({'A': [1, 2, 3],
.....:                      'B': ['a', 'b', 'c'],
.....:                      'C': pd.date_range('2016-01-01', freq='d', periods=3)},
.....:                      index=pd.Index(range(3), name='idx'))
.....:

```

```

In [268]: df
Out[268]:
   A  B      C
idx
0   1  a 2016-01-01
1   2  b 2016-01-02
2   3  c 2016-01-03

```

```

In [269]: df.to_json(orient='table', date_format="iso")
Out[269]: '{"schema": {"fields": [{"name": "idx", "type": "integer"}, {"name": "A",
↪ "type": "integer"}, {"name": "B", "type": "string"}, {"name": "C", "type": "datetime"}]},
↪ "primaryKey": ["idx"], "pandas_version": "0.20.0"}, "data": [{"idx": 0, "A": 1, "B": "a",
↪ "C": "2016-01-01T00:00:00.000Z"}, {"idx": 1, "A": 2, "B": "b", "C": "2016-01-02T00:00:00.000Z"},
↪ {"idx": 2, "A": 3, "B": "c", "C": "2016-01-03T00:00:00.000Z"}]}'

```

The `schema` field contains the `fields` key, which itself contains a list of column name to type pairs, including the `Index` or `MultiIndex` (see below for a list of types). The `schema` field also contains a `primaryKey` field if the (Multi)index is unique.

The second field, `data`, contains the serialized data with the `records` orient. The index is included, and any datetimes are ISO 8601 formatted, as required by the Table Schema spec.

The full list of types supported are described in the Table Schema spec. This table shows the mapping from pandas types:

Pandas type	Table Schema type
int64	integer
float64	number
bool	boolean
datetime64[ns]	datetime
timedelta64[ns]	duration
categorical	any
object	str

A few notes on the generated table schema:

- The `schema` object contains a `pandas_version` field. This contains the version of pandas' dialect of the schema, and will be incremented with each revision.
- All dates are converted to UTC when serializing. Even timezone naive values, which are treated as UTC with an offset of 0.

```
In [270]: from pandas.io.json import build_table_schema

In [271]: s = pd.Series(pd.date_range('2016', periods=4))

In [272]: build_table_schema(s)
Out[272]:
{'fields': [{'name': 'index', 'type': 'integer'},
             {'name': 'values', 'type': 'datetime'}],
 'primaryKey': ['index'],
 'pandas_version': '0.20.0'}
```

- datetimes with a timezone (before serializing), include an additional field `tz` with the time zone name (e.g. `'US/Central'`).

```
In [273]: s_tz = pd.Series(pd.date_range('2016', periods=12,
.....:                               tz='US/Central'))
.....:

In [274]: build_table_schema(s_tz)
Out[274]:
{'fields': [{'name': 'index', 'type': 'integer'},
             {'name': 'values', 'type': 'datetime', 'tz': 'US/Central'}],
 'primaryKey': ['index'],
 'pandas_version': '0.20.0'}
```

- Periods are converted to timestamps before serialization, and so have the same behavior of being converted to UTC. In addition, periods will contain an additional field `freq` with the period's frequency, e.g. `'A-DEC'`.

```
In [275]: s_per = pd.Series(1, index=pd.period_range('2016', freq='A-DEC',
.....:                                             periods=4))
.....:

In [276]: build_table_schema(s_per)
Out[276]:
{'fields': [{'name': 'index', 'type': 'datetime', 'freq': 'A-DEC'},
             {'name': 'values', 'type': 'integer'}],
 'primaryKey': ['index'],
 'pandas_version': '0.20.0'}
```

- Categoricals use the `any` type and an `enum` constraint listing the set of possible values. Additionally, an `ordered` field is included:

```
In [277]: s_cat = pd.Series(pd.Categorical(['a', 'b', 'a']))

In [278]: build_table_schema(s_cat)
Out[278]:
{'fields': [{'name': 'index', 'type': 'integer'},
```

(continues on next page)

(continued from previous page)

```
{'name': 'values',
  'type': 'any',
  'constraints': {'enum': ['a', 'b']},
  'ordered': False}],
'primaryKey': ['index'],
'pandas_version': '0.20.0'}
```

- A `primaryKey` field, containing an array of labels, is included *if the index is unique*:

```
In [279]: s_dupe = pd.Series([1, 2], index=[1, 1])

In [280]: build_table_schema(s_dupe)
Out[280]:
{'fields': [{'name': 'index', 'type': 'integer'},
            {'name': 'values', 'type': 'integer'}],
'pandas_version': '0.20.0'}
```

- The `primaryKey` behavior is the same with `MultiIndex`s, but in this case the `primaryKey` is an array:

```
In [281]: s_multi = pd.Series(1, index=pd.MultiIndex.from_product([('a', 'b'),
.....:                                                             (0, 1)]))
.....:

In [282]: build_table_schema(s_multi)
Out[282]:
{'fields': [{'name': 'level_0', 'type': 'string'},
            {'name': 'level_1', 'type': 'integer'},
            {'name': 'values', 'type': 'integer'}],
'primaryKey': FrozenList(['level_0', 'level_1']),
'pandas_version': '0.20.0'}
```

- The default naming roughly follows these rules:
 - For series, the `object.name` is used. If that's none, then the name is `values`
 - For `DataFrames`, the stringified version of the column name is used
 - For `Index` (not `MultiIndex`), `index.name` is used, with a fallback to `index` if that is `None`.
 - For `MultiIndex`, `mi.names` is used. If any level has no name, then `level_<i>` is used.

New in version 0.23.0.

`read_json` also accepts `orient='table'` as an argument. This allows for the preservation of metadata such as dtypes and index names in a round-trippable manner.

```
In [283]: df = pd.DataFrame({'foo': [1, 2, 3, 4],
.....:                      'bar': ['a', 'b', 'c', 'd'],
.....:                      'baz': pd.date_range('2018-01-01', freq='d', periods=4),
.....:                      'qux': pd.Categorical(['a', 'b', 'c', 'c'])
.....:                      }, index=pd.Index(range(4), name='idx'))
.....:
```

```
In [284]: df
Out[284]:
   foo bar      baz qux
idx
```

```
0    1    a 2018-01-01    a
1    2    b 2018-01-02    b
2    3    c 2018-01-03    c
3    4    d 2018-01-04    c
```

```
In [285]: df.dtypes
```

```
Out[285]:
```

```
foo          int64
bar          object
baz    datetime64[ns]
qux          category
dtype: object
```

```
In [286]: df.to_json('test.json', orient='table')
```

```
In [287]: new_df = pd.read_json('test.json', orient='table')
```

```
In [288]: new_df
```

```
Out[288]:
```

```
   foo bar      baz qux
idx
0    1    a 2018-01-01    a
1    2    b 2018-01-02    b
2    3    c 2018-01-03    c
3    4    d 2018-01-04    c
```

```
In [289]: new_df.dtypes
```

```
Out[289]:
```

```
foo          int64
bar          object
baz    datetime64[ns]
qux          category
dtype: object
```

Please note that the literal string ‘index’ as the name of an *Index* is not round-trippable, nor are any names beginning with ‘level_’ within a *MultiIndex*. These are used by default in `DataFrame.to_json()` to indicate missing values and the subsequent read cannot distinguish the intent.

```
In [290]: df.index.name = 'index'
In [291]: df.to_json('test.json', orient='table')
In [292]: new_df = pd.read_json('test.json', orient='table')
In [293]: print(new_df.index.name)
None
```

4.1.3 HTML

Reading HTML content

Warning: We highly encourage you to read the *HTML Table Parsing gotchas* below regarding the issues surrounding the BeautifulSoup4/html5lib/lxml parsers.

The top-level `read_html()` function can accept an HTML string/file/URL and will parse HTML tables into list of pandas `DataFrames`. Let's look at a few examples.

Note: `read_html` returns a list of `DataFrame` objects, even if there is only a single table contained in the HTML content.

Read a URL with no options:

```
In [294]: url = 'https://www.fdic.gov/bank/individual/failed/banklist.html'
```

```
In [295]: dfs = pd.read_html(url)
```

```
In [296]: dfs
```

```
Out[296]:
```

Note: The data from the above URL changes every Monday so the resulting data above and the data below may be slightly different.

Read in the content of the file from the above URL and pass it to `read_html` as a string:

```
In [297]: with open(file_path, 'r') as f:
.....:     dfs = pd.read_html(f.read())
.....:

In [298]: dfs
Out[298]:
```

[505 rows x 7 columns]
```

Note: The following examples are not run by the IPython evaluator due to the fact that having so many network-accessing functions slows down the documentation build. If you spot an error or an example that doesn't run, please do not hesitate to report it over on [pandas GitHub issues page](#).

Read a URL and match a table that contains specific text:

```
match = 'Metcalf Bank'
df_list = pd.read_html(url, match=match)
```

Specify a header row (by default `<th>` or `<td>` elements located within a `<thead>` are used to form the column index, if multiple rows are contained within `<thead>` then a MultiIndex is created); if specified, the header row is taken from the data minus the parsed header elements (`<th>` elements).

```
dfs = pd.read_html(url, header=0)
```

Specify an index column:

```
dfs = pd.read_html(url, index_col=0)
```

Specify a number of rows to skip:

```
dfs = pd.read_html(url, skiprows=0)
```

Specify a number of rows to skip using a list (`xrange` (Python 2 only) works as well):

```
dfs = pd.read_html(url, skiprows=range(2))
```

Specify an HTML attribute:

```
dfs1 = pd.read_html(url, attrs={'id': 'table'})
dfs2 = pd.read_html(url, attrs={'class': 'sortable'})
print(np.array_equal(dfs1[0], dfs2[0])) # Should be True
```

Specify values that should be converted to NaN:

```
dfs = pd.read_html(url, na_values=['No Acquirer'])
```

New in version 0.19.

Specify whether to keep the default set of NaN values:

```
dfs = pd.read_html(url, keep_default_na=False)
```

New in version 0.19.

Specify converters for columns. This is useful for numerical text data that has leading zeros. By default columns that are numerical are cast to numeric types and the leading zeros are lost. To avoid this, we can convert these columns to strings.

```
url_mcc = 'https://en.wikipedia.org/wiki/Mobile_country_code'
dfs = pd.read_html(url_mcc, match='Telekom Albania', header=0,
                  converters={'MNC': str})
```

New in version 0.19.

Use some combination of the above:

```
dfs = pd.read_html(url, match='Metcalf Bank', index_col=0)
```

Read in pandas to_html output (with some loss of floating point precision):

```
df = pd.DataFrame(np.random.randn(2, 2))
s = df.to_html(float_format='{0:.40g}'.format)
dfin = pd.read_html(s, index_col=0)
```

The lxml backend will raise an error on a failed parse if that is the only parser you provide. If you only have a single parser you can provide just a string, but it is considered good practice to pass a list with one string if, for example, the function expects a sequence of strings. You may use:

```
dfs = pd.read_html(url, 'Metcalf Bank', index_col=0, flavor=['lxml'])
```

Or you could pass flavor='lxml' without a list:

```
dfs = pd.read_html(url, 'Metcalf Bank', index_col=0, flavor='lxml')
```

However, if you have bs4 and html5lib installed and pass None or ['lxml', 'bs4'] then the parse will most likely succeed. Note that *as soon as a parse succeeds, the function will return*.

```
dfs = pd.read_html(url, 'Metcalf Bank', index_col=0, flavor=['lxml', 'bs4'])
```

Writing to HTML files

DataFrame objects have an instance method to_html which renders the contents of the DataFrame as an HTML table. The function arguments are as in the method to_string described above.

Note: Not all of the possible options for DataFrame.to_html are shown here for brevity's sake. See to_html() for the full set of options.

```
In [302]: df = pd.DataFrame(np.random.randn(2, 2))
```

```
In [303]: df
```

```
Out[303]:
      0         1
0 -1.050304  1.131622
1 -0.692581 -1.174172
```

```
In [304]: print(df.to_html()) # raw html
```

```
<table border="1" class="dataframe">
  <thead>
    <tr style="text-align: right;">
      <th></th>
      <th>0</th>
      <th>1</th>
    </tr>
  </thead>
  <tbody>
    <tr>
      <th>0</th>
      <td>-1.050304</td>
      <td>1.131622</td>
    </tr>
    <tr>
      <th>1</th>
      <td>-0.692581</td>
      <td>-1.174172</td>
    </tr>
  </tbody>
</table>
```

HTML:

The columns argument will limit the columns shown:

```
In [305]: print(df.to_html(columns=[0]))
```

```
<table border="1" class="dataframe">
  <thead>
    <tr style="text-align: right;">
      <th></th>
      <th>0</th>
    </tr>
  </thead>
  <tbody>
    <tr>
      <th>0</th>
      <td>-1.050304</td>
    </tr>
    <tr>
      <th>1</th>
      <td>-0.692581</td>
    </tr>
  </tbody>
</table>
```

HTML:

`float_format` takes a Python callable to control the precision of floating point values:

```
In [306]: print(df.to_html(float_format='{0:.10f}'.format))
<table border="1" class="dataframe">
  <thead>
    <tr style="text-align: right;">
      <th></th>
      <th>0</th>
      <th>1</th>
    </tr>
  </thead>
  <tbody>
    <tr>
      <th>0</th>
      <td>-1.0503044154</td>
      <td>1.1316218324</td>
    </tr>
    <tr>
      <th>1</th>
      <td>-0.6925807265</td>
      <td>-1.1741715747</td>
    </tr>
  </tbody>
</table>
```

HTML:

`bold_rows` will make the row labels bold by default, but you can turn that off:

```
In [307]: print(df.to_html(bold_rows=False))
<table border="1" class="dataframe">
  <thead>
    <tr style="text-align: right;">
      <th></th>
      <th>0</th>
      <th>1</th>
    </tr>
  </thead>
  <tbody>
    <tr>
      <td>0</td>
      <td>-1.050304</td>
      <td>1.131622</td>
    </tr>
    <tr>
      <td>1</td>
      <td>-0.692581</td>
      <td>-1.174172</td>
    </tr>
  </tbody>
</table>
```

The `classes` argument provides the ability to give the resulting HTML table CSS classes. Note that these

classes are *appended* to the existing 'dataframe' class.

```
In [308]: print(df.to_html(classes=['awesome_table_class', 'even_more_awesome_class']))
<table border="1" class="dataframe awesome_table_class even_more_awesome_class">
  <thead>
    <tr style="text-align: right;">
      <th></th>
      <th>0</th>
      <th>1</th>
    </tr>
  </thead>
  <tbody>
    <tr>
      <th>0</th>
      <td>-1.050304</td>
      <td>1.131622</td>
    </tr>
    <tr>
      <th>1</th>
      <td>-0.692581</td>
      <td>-1.174172</td>
    </tr>
  </tbody>
</table>
```

The `render_links` argument provides the ability to add hyperlinks to cells that contain URLs.

New in version 0.24.

```
In [309]: url_df = pd.DataFrame({
.....:     'name': ['Python', 'Pandas'],
.....:     'url': ['https://www.python.org/', 'http://pandas.pydata.org']}))
.....:

In [310]: print(url_df.to_html(render_links=True))
<table border="1" class="dataframe">
  <thead>
    <tr style="text-align: right;">
      <th></th>
      <th>name</th>
      <th>url</th>
    </tr>
  </thead>
  <tbody>
    <tr>
      <th>0</th>
      <td>Python</td>
      <td><a href="https://www.python.org/" target="_blank">https://www.python.org/</a></
↪td>
      </tr>
    <tr>
      <th>1</th>
      <td>Pandas</td>
      <td><a href="http://pandas.pydata.org" target="_blank">http://pandas.pydata.org</a>
↪</td>
```

(continues on next page)

(continued from previous page)

```

</tr>
</tbody>
</table>

```

HTML:

Finally, the `escape` argument allows you to control whether the “<”, “>” and “&” characters escaped in the resulting HTML (by default it is `True`). So to get the HTML without escaped characters pass `escape=False`

```
In [311]: df = pd.DataFrame({'a': list('&<>'), 'b': np.random.randn(3)})
```

Escaped:

```
In [312]: print(df.to_html())
<table border="1" class="dataframe">
  <thead>
    <tr style="text-align: right;">
      <th></th>
      <th>a</th>
      <th>b</th>
    </tr>
  </thead>
  <tbody>
    <tr>
      <th>0</th>
      <td>&amp;</td>
      <td>1.254800</td>
    </tr>
    <tr>
      <th>1</th>
      <td>&lt;</td>
      <td>1.131996</td>
    </tr>
    <tr>
      <th>2</th>
      <td>&gt;></td>
      <td>-1.311021</td>
    </tr>
  </tbody>
</table>

```

Not escaped:

```
In [313]: print(df.to_html(escape=False))
<table border="1" class="dataframe">
  <thead>
    <tr style="text-align: right;">
      <th></th>
      <th>a</th>
      <th>b</th>
    </tr>
  </thead>
  <tbody>

```

(continues on next page)

(continued from previous page)

```

<tr>
  <th>0</th>
  <td>&</td>
  <td>1.254800</td>
</tr>
<tr>
  <th>1</th>
  <td><</td>
  <td>1.131996</td>
</tr>
<tr>
  <th>2</th>
  <td>></td>
  <td>-1.311021</td>
</tr>
</tbody>
</table>

```

Note: Some browsers may not show a difference in the rendering of the previous two HTML tables.

HTML Table Parsing Gotchas

There are some versioning issues surrounding the libraries that are used to parse HTML tables in the top-level pandas io function `read_html`.

Issues with `lxml`

- Benefits
 - `lxml` is very fast.
 - `lxml` requires Cython to install correctly.
- Drawbacks
 - `lxml` does *not* make any guarantees about the results of its parse *unless* it is given **strictly valid markup**.
 - In light of the above, we have chosen to allow you, the user, to use the `lxml` backend, but **this backend will use `html5lib` if `lxml` fails to parse**
 - It is therefore *highly recommended* that you install both `BeautifulSoup4` and `html5lib`, so that you will still get a valid result (provided everything else is valid) even if `lxml` fails.

Issues with `BeautifulSoup4` using `lxml` as a backend

- The above issues hold here as well since `BeautifulSoup4` is essentially just a wrapper around a parser backend.

Issues with `BeautifulSoup4` using `html5lib` as a backend

- Benefits
 - `html5lib` is far more lenient than `lxml` and consequently deals with *real-life markup* in a much saner way rather than just, e.g., dropping an element without notifying you.

- `html5lib` generates valid HTML5 markup from invalid markup automatically. This is extremely important for parsing HTML tables, since it guarantees a valid document. However, that does NOT mean that it is “correct”, since the process of fixing markup does not have a single definition.
- `html5lib` is pure Python and requires no additional build steps beyond its own installation.
- Drawbacks
 - The biggest drawback to using `html5lib` is that it is slow as molasses. However consider the fact that many tables on the web are not big enough for the parsing algorithm runtime to matter. It is more likely that the bottleneck will be in the process of reading the raw text from the URL over the web, i.e., IO (input-output). For very large tables, this might not be true.

4.1.4 Excel files

The `read_excel()` method can read Excel 2003 (`.xls`) files using the `xlrd` Python module. Excel 2007+ (`.xlsx`) files can be read using either `xlrd` or `openpyxl`. The `to_excel()` instance method is used for saving a `DataFrame` to Excel. Generally the semantics are similar to working with `csv` data. See the *cookbook* for some advanced strategies.

Reading Excel files

In the most basic use-case, `read_excel` takes a path to an Excel file, and the `sheet_name` indicating which sheet to parse.

```
# Returns a DataFrame
pd.read_excel('path_to_file.xls', sheet_name='Sheet1')
```

ExcelFile class

To facilitate working with multiple sheets from the same file, the `ExcelFile` class can be used to wrap the file and can be passed into `read_excel`. There will be a performance benefit for reading multiple sheets as the file is read into memory only once.

```
xlsx = pd.ExcelFile('path_to_file.xls')
df = pd.read_excel(xlsx, 'Sheet1')
```

The `ExcelFile` class can also be used as a context manager.

```
with pd.ExcelFile('path_to_file.xls') as xls:
    df1 = pd.read_excel(xls, 'Sheet1')
    df2 = pd.read_excel(xls, 'Sheet2')
```

The `sheet_names` property will generate a list of the sheet names in the file.

The primary use-case for an `ExcelFile` is parsing multiple sheets with different parameters:

```
data = {}
# For when Sheet1's format differs from Sheet2
with pd.ExcelFile('path_to_file.xls') as xls:
    data['Sheet1'] = pd.read_excel(xls, 'Sheet1', index_col=None,
                                  na_values=['NA'])
    data['Sheet2'] = pd.read_excel(xls, 'Sheet2', index_col=1)
```

Note that if the same parsing parameters are used for all sheets, a list of sheet names can simply be passed to `read_excel` with no loss in performance.

```
# using the ExcelFile class
data = {}
with pd.ExcelFile('path_to_file.xls') as xls:
    data['Sheet1'] = pd.read_excel(xls, 'Sheet1', index_col=None,
                                  na_values=['NA'])
    data['Sheet2'] = pd.read_excel(xls, 'Sheet2', index_col=None,
                                  na_values=['NA'])

# equivalent using the read_excel function
data = pd.read_excel('path_to_file.xls', ['Sheet1', 'Sheet2'],
                    index_col=None, na_values=['NA'])
```

`ExcelFile` can also be called with a `xlrd.book.Book` object as a parameter. This allows the user to control how the excel file is read. For example, sheets can be loaded on demand by calling `xlrd.open_workbook()` with `on_demand=True`.

```
import xlrd
xlrd_book = xlrd.open_workbook('path_to_file.xls', on_demand=True)
with pd.ExcelFile(xlrd_book) as xls:
    df1 = pd.read_excel(xls, 'Sheet1')
    df2 = pd.read_excel(xls, 'Sheet2')
```

Specifying sheets

Note: The second argument is `sheet_name`, not to be confused with `ExcelFile.sheet_names`.

Note: An `ExcelFile`'s attribute `sheet_names` provides access to a list of sheets.

- The arguments `sheet_name` allows specifying the sheet or sheets to read.
- The default value for `sheet_name` is 0, indicating to read the first sheet
- Pass a string to refer to the name of a particular sheet in the workbook.
- Pass an integer to refer to the index of a sheet. Indices follow Python convention, beginning at 0.
- Pass a list of either strings or integers, to return a dictionary of specified sheets.
- Pass a `None` to return a dictionary of all available sheets.

```
# Returns a DataFrame
pd.read_excel('path_to_file.xls', 'Sheet1', index_col=None, na_values=['NA'])
```

Using the sheet index:

```
# Returns a DataFrame
pd.read_excel('path_to_file.xls', 0, index_col=None, na_values=['NA'])
```

Using all default values:

```
# Returns a DataFrame
pd.read_excel('path_to_file.xls')
```

Using None to get all sheets:

```
# Returns a dictionary of DataFrames
pd.read_excel('path_to_file.xls', sheet_name=None)
```

Using a list to get multiple sheets:

```
# Returns the 1st and 4th sheet, as a dictionary of DataFrames.
pd.read_excel('path_to_file.xls', sheet_name=['Sheet1', 3])
```

`read_excel` can read more than one sheet, by setting `sheet_name` to either a list of sheet names, a list of sheet positions, or `None` to read all sheets. Sheets can be specified by sheet index or sheet name, using an integer or string, respectively.

Reading a MultiIndex

`read_excel` can read a `MultiIndex` index, by passing a list of columns to `index_col` and a `MultiIndex` column by passing a list of rows to `header`. If either the `index` or `columns` have serialized level names those will be read in as well by specifying the rows/columns that make up the levels.

For example, to read in a `MultiIndex` index without names:

```
In [314]: df = pd.DataFrame({'a': [1, 2, 3, 4], 'b': [5, 6, 7, 8]},
.....:                      index=pd.MultiIndex.from_product(['a', 'b'], ['c', 'd']))
.....:

In [315]: df.to_excel('path_to_file.xlsx')

In [316]: df = pd.read_excel('path_to_file.xlsx', index_col=[0, 1])

In [317]: df
Out[317]:
      a  b
a c   1  5
  d   2  6
b c   3  7
  d   4  8
```

If the index has level names, they will be parsed as well, using the same parameters.

```
In [318]: df.index = df.index.set_names(['lv11', 'lv12'])

In [319]: df.to_excel('path_to_file.xlsx')

In [320]: df = pd.read_excel('path_to_file.xlsx', index_col=[0, 1])

In [321]: df
Out[321]:
      a  b
lv11 lv12
```

(continues on next page)

(continued from previous page)

a	c	1	5
	d	2	6
b	c	3	7
	d	4	8

If the source file has both `MultiIndex` index and columns, lists specifying each should be passed to `index_col` and `header`:

```
In [322]: df.columns = pd.MultiIndex.from_product(['a'], ['b', 'd']),
.....:                                     names=['c1', 'c2'])
.....:

In [323]: df.to_excel('path_to_file.xlsx')

In [324]: df = pd.read_excel('path_to_file.xlsx', index_col=[0, 1], header=[0, 1])

In [325]: df
Out[325]:
c1      a
c2      b d
lvl1 lvl2
a     c   1  5
      d   2  6
b     c   3  7
      d   4  8
```

Parsing specific columns

It is often the case that users will insert columns to do temporary computations in Excel and you may not want to read in those columns. `read_excel` takes a `usecols` keyword to allow you to specify a subset of columns to parse.

Deprecated since version 0.24.0.

Passing in an integer for `usecols` has been deprecated. Please pass in a list of ints from 0 to `usecols` inclusive instead.

If `usecols` is an integer, then it is assumed to indicate the last column to be parsed.

```
pd.read_excel('path_to_file.xls', 'Sheet1', usecols=2)
```

You can also specify a comma-delimited set of Excel columns and ranges as a string:

```
pd.read_excel('path_to_file.xls', 'Sheet1', usecols='A,C:E')
```

If `usecols` is a list of integers, then it is assumed to be the file column indices to be parsed.

```
pd.read_excel('path_to_file.xls', 'Sheet1', usecols=[0, 2, 3])
```

Element order is ignored, so `usecols=[0, 1]` is the same as `[1, 0]`.

New in version 0.24.

If `usecols` is a list of strings, it is assumed that each string corresponds to a column name provided either by the user in `names` or inferred from the document header row(s). Those strings define which columns will be parsed:

```
pd.read_excel('path_to_file.xls', 'Sheet1', usecols=['foo', 'bar'])
```

Element order is ignored, so `usecols=['baz', 'joe']` is the same as `['joe', 'baz']`.

New in version 0.24.

If `usecols` is callable, the callable function will be evaluated against the column names, returning names where the callable function evaluates to `True`.

```
pd.read_excel('path_to_file.xls', 'Sheet1', usecols=lambda x: x.isalpha())
```

Parsing dates

Datetime-like values are normally automatically converted to the appropriate dtype when reading the excel file. But if you have a column of strings that *look* like dates (but are not actually formatted as dates in excel), you can use the `parse_dates` keyword to parse those strings to datetimes:

```
pd.read_excel('path_to_file.xls', 'Sheet1', parse_dates=['date_strings'])
```

Cell converters

It is possible to transform the contents of Excel cells via the `converters` option. For instance, to convert a column to boolean:

```
pd.read_excel('path_to_file.xls', 'Sheet1', converters={'MyBools': bool})
```

This options handles missing values and treats exceptions in the converters as missing data. Transformations are applied cell by cell rather than to the column as a whole, so the array dtype is not guaranteed. For instance, a column of integers with missing values cannot be transformed to an array with integer dtype, because NaN is strictly a float. You can manually mask missing data to recover integer dtype:

```
def cfun(x):
    return int(x) if x else -1

pd.read_excel('path_to_file.xls', 'Sheet1', converters={'MyInts': cfun})
```

Dtype specifications

New in version 0.20.

As an alternative to converters, the type for an entire column can be specified using the `dtype` keyword, which takes a dictionary mapping column names to types. To interpret data with no type inference, use the type `str` or `object`.

```
pd.read_excel('path_to_file.xls', dtype={'MyInts': 'int64', 'MyText': str})
```

Writing Excel files

Writing Excel files to disk

To write a `DataFrame` object to a sheet of an Excel file, you can use the `to_excel` instance method. The arguments are largely the same as `to_csv` described above, the first argument being the name of the excel file, and the optional second argument the name of the sheet to which the `DataFrame` should be written. For example:

```
df.to_excel('path_to_file.xlsx', sheet_name='Sheet1')
```

Files with a `.xls` extension will be written using `xlwt` and those with a `.xlsx` extension will be written using `xlsxwriter` (if available) or `openpyxl`.

The `DataFrame` will be written in a way that tries to mimic the REPL output. The `index_label` will be placed in the second row instead of the first. You can place it in the first row by setting the `merge_cells` option in `to_excel()` to `False`:

```
df.to_excel('path_to_file.xlsx', index_label='label', merge_cells=False)
```

In order to write separate `DataFrames` to separate sheets in a single Excel file, one can pass an `ExcelWriter`.

```
with pd.ExcelWriter('path_to_file.xlsx') as writer:
    df1.to_excel(writer, sheet_name='Sheet1')
    df2.to_excel(writer, sheet_name='Sheet2')
```

Note: Wringing a little more performance out of `read_excel` Internally, Excel stores all numeric data as floats. Because this can produce unexpected behavior when reading in data, pandas defaults to trying to convert integers to floats if it doesn't lose information (`1.0 --> 1`). You can pass `convert_float=False` to disable this behavior, which may give a slight performance improvement.

Writing Excel files to memory

Pandas supports writing Excel files to buffer-like objects such as `StringIO` or `BytesIO` using `ExcelWriter`.

```
# Safe import for either Python 2.x or 3.x
try:
    from io import BytesIO
except ImportError:
    from cStringIO import StringIO as BytesIO

bio = BytesIO()

# By setting the 'engine' in the ExcelWriter constructor.
writer = pd.ExcelWriter(bio, engine='xlsxwriter')
df.to_excel(writer, sheet_name='Sheet1')

# Save the workbook
writer.save()

# Seek to the beginning and read to copy the workbook to a variable in memory
```

(continues on next page)

(continued from previous page)

```
bio.seek(0)
workbook = bio.read()
```

Note: `engine` is optional but recommended. Setting the engine determines the version of workbook produced. Setting `engine='xlrd'` will produce an Excel 2003-format workbook (xls). Using either `'openpyxl'` or `'xlsxwriter'` will produce an Excel 2007-format workbook (xlsx). If omitted, an Excel 2007-formatted workbook is produced.

Excel writer engines

Pandas chooses an Excel writer via two methods:

1. the `engine` keyword argument
2. the filename extension (via the default specified in config options)

By default, pandas uses the `XlsxWriter` for `.xlsx`, `openpyxl` for `.xlsm`, and `xlwt` for `.xls` files. If you have multiple engines installed, you can set the default engine through *setting the config options* `io.excel.xlsx.writer` and `io.excel.xls.writer`. pandas will fall back on `openpyxl` for `.xlsx` files if `Xlsxwriter` is not available.

To specify which writer you want to use, you can pass an engine keyword argument to `to_excel` and to `ExcelWriter`. The built-in engines are:

- `openpyxl`: version 2.4 or higher is required
- `xlsxwriter`
- `xlwt`

```
# By setting the 'engine' in the DataFrame 'to_excel()' methods.
df.to_excel('path_to_file.xlsx', sheet_name='Sheet1', engine='xlsxwriter')

# By setting the 'engine' in the ExcelWriter constructor.
writer = pd.ExcelWriter('path_to_file.xlsx', engine='xlsxwriter')

# Or via pandas configuration.
from pandas import options
options.io.excel.xlsx.writer = 'xlsxwriter' # noqa: E402

df.to_excel('path_to_file.xlsx', sheet_name='Sheet1')
```

Style and formatting

The look and feel of Excel worksheets created from pandas can be modified using the following parameters on the `DataFrame`'s `to_excel` method.

- `float_format` : Format string for floating point numbers (default `None`).
- `freeze_panes` : A tuple of two integers representing the bottommost row and rightmost column to freeze. Each of these parameters is one-based, so `(1, 1)` will freeze the first row and first column (default `None`).

Using the `Xlsxwriter` engine provides many options for controlling the format of an Excel worksheet created with the `to_excel` method. Excellent examples can be found in the `Xlsxwriter` documentation here: https://xlsxwriter.readthedocs.io/working_with_pandas.html

4.1.5 OpenDocument Spreadsheets

New in version 0.25.

The `read_excel()` method can also read OpenDocument spreadsheets using the `odfpy` module. The semantics and features for reading OpenDocument spreadsheets match what can be done for *Excel files* using `engine='odf'`.

```
# Returns a DataFrame
pd.read_excel('path_to_file.ods', engine='odf')
```

Note: Currently pandas only supports *reading* OpenDocument spreadsheets. Writing is not implemented.

4.1.6 Clipboard

A handy way to grab data is to use the `read_clipboard()` method, which takes the contents of the clipboard buffer and passes them to the `read_csv` method. For instance, you can copy the following text to the clipboard (CTRL-C on many operating systems):

```
A B C
x 1 4 p
y 2 5 q
z 3 6 r
```

And then import the data directly to a `DataFrame` by calling:

```
>>> clipdf = pd.read_clipboard()
>>> clipdf
  A B C
x 1 4 p
y 2 5 q
z 3 6 r
```

The `to_clipboard` method can be used to write the contents of a `DataFrame` to the clipboard. Following which you can paste the clipboard contents into other applications (CTRL-V on many operating systems). Here we illustrate writing a `DataFrame` into clipboard and reading it back.

```
>>> df = pd.DataFrame({'A': [1, 2, 3],
...                    'B': [4, 5, 6],
...                    'C': ['p', 'q', 'r']},
...                    index=['x', 'y', 'z'])
>>> df
  A B C
x 1 4 p
y 2 5 q
z 3 6 r
>>> df.to_clipboard()
```

(continues on next page)

(continued from previous page)

```
>>> pd.read_clipboard()
  A B C
x 1 4 p
y 2 5 q
z 3 6 r
```

We can see that we got the same content back, which we had earlier written to the clipboard.

Note: You may need to install `xclip` or `xsel` (with `PyQt5`, `PyQt4` or `qtpy`) on Linux to use these methods.

4.1.7 Pickling

All pandas objects are equipped with `to_pickle` methods which use Python's `cPickle` module to save data structures to disk using the pickle format.

```
In [326]: df
```

```
Out [326]:
c1          a
c2          b d
lvl1 lvl2
a    c    1  5
     d    2  6
b    c    3  7
     d    4  8
```

```
In [327]: df.to_pickle('foo.pkl')
```

The `read_pickle` function in the `pandas` namespace can be used to load any pickled pandas object (or any other pickled object) from file:

```
In [328]: pd.read_pickle('foo.pkl')
```

```
Out [328]:
c1          a
c2          b d
lvl1 lvl2
a    c    1  5
     d    2  6
b    c    3  7
     d    4  8
```

Warning: Loading pickled data received from untrusted sources can be unsafe.

See: <https://docs.python.org/3/library/pickle.html>

Warning: `read_pickle()` is only guaranteed backwards compatible back to pandas version 0.20.3

Compressed pickle files

New in version 0.20.0.

`read_pickle()`, `DataFrame.to_pickle()` and `Series.to_pickle()` can read and write compressed pickle files. The compression types of `gzip`, `bz2`, `xz` are supported for reading and writing. The `zip` file format only supports reading and must contain only one data file to be read.

The compression type can be an explicit parameter or be inferred from the file extension. If 'infer', then use `gzip`, `bz2`, `zip`, or `xz` if filename ends in `'.gz'`, `'.bz2'`, `'.zip'`, or `'.xz'`, respectively.

```
In [329]: df = pd.DataFrame({
.....:     'A': np.random.randn(1000),
.....:     'B': 'foo',
.....:     'C': pd.date_range('20130101', periods=1000, freq='s')})
.....:
```

```
In [330]: df
```

```
Out[330]:
```

	A	B	C
0	-0.053113	foo	2013-01-01 00:00:00
1	0.348832	foo	2013-01-01 00:00:01
2	-0.162729	foo	2013-01-01 00:00:02
3	-1.269943	foo	2013-01-01 00:00:03
4	-0.481824	foo	2013-01-01 00:00:04
..
995	-1.001718	foo	2013-01-01 00:16:35
996	-0.471336	foo	2013-01-01 00:16:36
997	-0.071712	foo	2013-01-01 00:16:37
998	0.578273	foo	2013-01-01 00:16:38
999	0.595708	foo	2013-01-01 00:16:39

```
[1000 rows x 3 columns]
```

Using an explicit compression type:

```
In [331]: df.to_pickle("data.pkl.compress", compression="gzip")
```

```
In [332]: rt = pd.read_pickle("data.pkl.compress", compression="gzip")
```

```
In [333]: rt
```

```
Out[333]:
```

	A	B	C
0	-0.053113	foo	2013-01-01 00:00:00
1	0.348832	foo	2013-01-01 00:00:01
2	-0.162729	foo	2013-01-01 00:00:02

```

4.1.8 msgpack

pandas supports the `msgpack` format for object serialization. This is a lightweight portable binary format, similar to binary JSON, that is highly space efficient, and provides good performance both on the writing (serialization), and reading (deserialization).

Warning: The `msgpack` format is deprecated as of 0.25 and will be removed in a future version. It is recommended to use `pyarrow` for on-the-wire transmission of pandas objects.

Warning: `read_msgpack()` is only guaranteed backwards compatible back to pandas version 0.20.3

```
In [343]: df = pd.DataFrame(np.random.rand(5, 2), columns=list('AB'))
In [344]: df.to_msgpack('foo.msg')
In [345]: pd.read_msgpack('foo.msg')
Out[345]:
   A         B
0  0.541029  0.554672
1  0.150831  0.503287
2  0.834267  0.881894
3  0.706066  0.726912
4  0.639300  0.067928

In [346]: s = pd.Series(np.random.rand(5), index=pd.date_range('20130101', periods=5))
```

You can pass a list of objects and you will receive them back on deserialization.

```
In [347]: pd.to_msgpack('foo.msg', df, 'foo', np.array([1, 2, 3]), s)
In [348]: pd.read_msgpack('foo.msg')
```

(continues on next page)

(continued from previous page)

```

Out [348]:
[
   A      B
0  0.541029  0.554672
1  0.150831  0.503287
2  0.834267  0.881894
3  0.706066  0.726912
4  0.639300  0.067928, 'foo', array([1, 2, 3]), 2013-01-01    0.753932
2013-01-02    0.676180
2013-01-03    0.924728
2013-01-04    0.338661
2013-01-05    0.592241
Freq: D, dtype: float64]

```

You can pass `iterator=True` to iterate over the unpacked results:

```

In [349]: for o in pd.read_msgpack('foo.msg', iterator=True):
.....:     print(o)
.....:
           A      B
0  0.541029  0.554672
1  0.150831  0.503287
2  0.834267  0.881894
3  0.706066  0.726912
4  0.639300  0.067928
foo
[1 2 3]
2013-01-01    0.753932
2013-01-02    0.676180
2013-01-03    0.924728
2013-01-04    0.338661
2013-01-05    0.592241
Freq: D, dtype: float64

```

You can pass `append=True` to the writer to append to an existing pack:

```

In [350]: df.to_msgpack('foo.msg', append=True)

In [351]: pd.read_msgpack('foo.msg')
Out [351]:
[
   A      B
0  0.541029  0.554672
1  0.150831  0.503287
2  0.834267  0.881894
3  0.706066  0.726912
4  0.639300  0.067928, 'foo', array([1, 2, 3]), 2013-01-01    0.753932
2013-01-02    0.676180
2013-01-03    0.924728
2013-01-04    0.338661
2013-01-05    0.592241
Freq: D, dtype: float64,           A      B
0  0.541029  0.554672
1  0.150831  0.503287

```

(continues on next page)

(continued from previous page)

```

2  0.834267  0.881894
3  0.706066  0.726912
4  0.639300  0.067928]

```

Unlike other io methods, `to_msgpack` is available on both a per-object basis, `df.to_msgpack()` and using the top-level `pd.to_msgpack(...)` where you can pack arbitrary collections of Python lists, dicts, scalars, while intermixing pandas objects.

```

In [352]: pd.to_msgpack('foo2.msg', {'dict': [{'df': df}, {'string': 'foo'},
.....:                                     {'scalar': 1.}, {'s': s}])
.....:

```

```

In [353]: pd.read_msgpack('foo2.msg')

```

```

Out [353]:
{'dict': ({'df':
   A      B
0  0.541029  0.554672
1  0.150831  0.503287
2  0.834267  0.881894
3  0.706066  0.726912
4  0.639300  0.067928},
{'string': 'foo'},
{'scalar': 1.0},
{'s': 2013-01-01    0.753932
2013-01-02    0.676180
2013-01-03    0.924728
2013-01-04    0.338661
2013-01-05    0.592241
Freq: D, dtype: float64})}

```

Read/write API

Msgpacks can also be read from and written to strings.

```

In [354]: df.to_msgpack()

```

```

Out [354]: b"\x84\xa3typ\xadblock_
↪manager\xa5klass\xa9DataFrame\xa4axes\x92\x86\xa3typ\xa5index\xa5klass\xa5Index\xa4name\x00\xa5dtype\
↪index\xa5klass\xaaRangeIndex\xa4name\x00\xa5start\x00\xa4stop\x05\xa4step\x01\xa6blocks\x91\x86\xa4lo
↪`) \x0c3kN\xc3?\xac\xa1: JQ\xb2\xea?\x8c|\xa87\x17\x98\xe6?\xf3H\x83*&u\xe4?\xd4S\xff
↪{\xe0\xbf\xe1?\xd3'2\ea\xed\x1a\xe0?6\x00'gy8\xec?S\x98/\xe7\xdcB\xe7?
↪`\xdbc\xed\xbac\xb1?
↪\xa5shape\x92\x02\x05\xa5dtype\xa7float64\xa5klass\xaaFloatBlock\xa8compress\x0"

```

Furthermore you can concatenate the strings to produce a list of the original objects.

```

In [355]: pd.read_msgpack(df.to_msgpack() + s.to_msgpack())

```

```

Out [355]:
[
   A      B
0  0.541029  0.554672
1  0.150831  0.503287
2  0.834267  0.881894
3  0.706066  0.726912

```

2013-01-03 0.924728
2013-01-04 0.338661
2013-01-05 0.592241
Freq: D, dtype: float64]

```

4.1.9 HDF5 (PyTables)

`HDFStore` is a dict-like object which reads and writes pandas using the high performance HDF5 format using the excellent `PyTables` library. See the *cookbook* for some advanced strategies

Warning: pandas requires `PyTables` $\geq 3.0.0$. There is a indexing bug in `PyTables` < 3.2 which may appear when querying stores using an index. If you see a subset of results being returned, upgrade to `PyTables` ≥ 3.2 . Stores created previously will need to be rewritten using the updated version.

```
In [356]: store = pd.HDFStore('store.h5')
```

```
In [357]: print(store)
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5
```

Objects can be written to the file just like adding key-value pairs to a dict:

```
In [358]: index = pd.date_range('1/1/2000', periods=8)

In [359]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])

In [360]: df = pd.DataFrame(np.random.randn(8, 3), index=index,
.....:                      columns=['A', 'B', 'C'])
.....:

# store.put('s', s) is an equivalent method
In [361]: store['s'] = s

In [362]: store['df'] = df

In [363]: store
Out[363]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5
```

In a current or later Python session, you can retrieve stored objects:

```
# store.get('df') is an equivalent method
In [364]: store['df']
Out[364]:
```

	A	B	C
2000-01-01	0.263806	1.913465	-0.274536
2000-01-02	0.283334	1.798001	-0.053258

```

2000-01-03  0.799684 -0.733715  1.205089
2000-01-04  0.131478  0.100995 -0.764260
2000-01-05  1.891112 -1.410251  0.752883
2000-01-06 -0.274852 -0.667027 -0.688782
2000-01-07  0.621607 -1.300199  0.050119
2000-01-08 -0.999591 -0.320658 -1.922640

```

dotted (attribute) access provides get as well

```
In [365]: store.df
```

```
Out[365]:
```

```

           A           B           C
2000-01-01  0.263806  1.913465 -0.274536
2000-01-02  0.283334  1.798001 -0.053258
2000-01-03  0.799684 -0.733715  1.205089
2000-01-04  0.131478  0.100995 -0.764260
2000-01-05  1.891112 -1.410251  0.752883
2000-01-06 -0.274852 -0.667027 -0.688782
2000-01-07  0.621607 -1.300199  0.050119
2000-01-08 -0.999591 -0.320658 -1.922640

```

Deletion of the object specified by the key:

```
# store.remove('df') is an equivalent method
```

```
In [366]: del store['df']
```

```
In [367]: store
```

```
Out[367]:
```

```
<class 'pandas.io.pytables.HDFStore'>
```

```
File path: store.h5
```

Closing a Store and using a context manager:

```
In [368]: store.close()
```

```
In [369]: store
```

```
Out[369]:
```

```
<class 'pandas.io.pytables.HDFStore'>
```

```
File path: store.h5
```

```
In [370]: store.is_open
```

```
Out[370]: False
```

Working with, and automatically closing the store using a context manager

```
In [371]: with pd.HDFStore('store.h5') as store:
```

```
.....:     store.keys()
```

```
.....:
```

Read/write API

HDFStore supports a top-level API using `read_hdf` for reading and `to_hdf` for writing, similar to how `read_csv` and `to_csv` work.

```
In [372]: df_t1 = pd.DataFrame({'A': list(range(5)), 'B': list(range(5))})
```

(continues on next page)

(continued from previous page)

```
In [373]: df_t1.to_hdf('store_t1.h5', 'table', append=True)
```

```
In [374]: pd.read_hdf('store_t1.h5', 'table', where=['index>2'])
```

```
Out[374]:
```

```
   A  B
3  3  3
4  4  4
```

HDFStore will by default not drop rows that are all missing. This behavior can be changed by setting `dropna=True`.

```
In [375]: df_with_missing = pd.DataFrame({'col1': [0, np.nan, 2],
.....:                                  'col2': [1, np.nan, np.nan]})
.....:
```

```
In [376]: df_with_missing
```

```
Out[376]:
```

```
   col1  col2
0    0.0    1.0
1    NaN    NaN
2    2.0    NaN
```

```
In [377]: df_with_missing.to_hdf('file.h5', 'df_with_missing',
.....:                          format='table', mode='w')
.....:
```

```
In [378]: pd.read_hdf('file.h5', 'df_with_missing')
```

```
Out[378]:
```

```
   col1  col2
0    0.0    1.0
1    NaN    NaN
2    2.0    NaN
```

```
In [379]: df_with_missing.to_hdf('file.h5', 'df_with_missing',
.....:                          format='table', mode='w', dropna=True)
.....:
```

```
In [380]: pd.read_hdf('file.h5', 'df_with_missing')
```

```
Out[380]:
```

```
   col1  col2
0    0.0    1.0
2    2.0    NaN
```

Fixed format

The examples above show storing using `put`, which write the HDF5 to PyTables in a fixed array format, called the **fixed** format. These types of stores are **not** appendable once written (though you can simply remove them and rewrite). Nor are they **queryable**; they must be retrieved in their entirety. They also do not support dataframes with non-unique column names. The **fixed** format stores offer very fast writing and slightly faster reading than **table** stores. This format is specified by default when using `put` or `to_hdf` or by `format='fixed'` or `format='f'`.

Warning: A fixed format will raise a `TypeError` if you try to retrieve using a `where`:

```
>>> pd.DataFrame(np.random.randn(10, 2)).to_hdf('test_fixed.h5', 'df')
>>> pd.read_hdf('test_fixed.h5', 'df', where='index>5')
TypeError: cannot pass a where specification when reading a fixed format.
        this store must be selected in its entirety
```

Table format

`HDFStore` supports another PyTables format on disk, the `table` format. Conceptually a `table` is shaped very much like a `DataFrame`, with rows and columns. A `table` may be appended to in the same or other sessions. In addition, delete and query type operations are supported. This format is specified by `format='table'` or `format='t'` to `append` or `put` or `to_hdf`.

This format can be set as an option as well `pd.set_option('io.hdf.default_format', 'table')` to enable `put/append/to_hdf` to by default store in the `table` format.

```
In [381]: store = pd.HDFStore('store.h5')
```

```
In [382]: df1 = df[0:4]
```

```
In [383]: df2 = df[4:]
```

```
# append data (creates a table automatically)
```

```
In [384]: store.append('df', df1)
```

```
In [385]: store.append('df', df2)
```

```
In [386]: store
```

```
Out[386]:
```

```
<class 'pandas.io.pytables.HDFStore'>
```

```
File path: store.h5
```

```
# select the entire object
```

```
In [387]: store.select('df')
```

```
Out[387]:
```

	A	B	C
2000-01-01	0.263806	1.913465	-0.274536
2000-01-02	0.283334	1.798001	-0.053258
2000-01-03	0.799684	-0.733715	1.205089
2000-01-04	0.131478	0.100995	-0.764260
2000-01-05	1.891112	-1.410251	0.752883
2000-01-06	-0.274852	-0.667027	-0.688782
2000-01-07	0.621607	-1.300199	0.050119
2000-01-08	-0.999591	-0.320658	-1.922640

```
# the type of stored data
```

```
In [388]: store.root.df._v_attrs.pandas_type
```

```
Out[388]: 'frame_table'
```

Note: You can also create a `table` by passing `format='table'` or `format='t'` to a `put` operation.

Hierarchical keys

Keys to a store can be specified as a string. These can be in a hierarchical path-name like format (e.g. `foo/bar/bah`), which will generate a hierarchy of sub-stores (or **Groups** in PyTables parlance). Keys can be specified with out the leading `/` and are **always** absolute (e.g. `foo` refers to `/foo`). Removal operations can remove everything in the sub-store and **below**, so be *careful*.

```
In [389]: store.put('foo/bar/bah', df)
```

```
In [390]: store.append('food/orange', df)
```

```
In [391]: store.append('food/apple', df)
```

```
In [392]: store
```

```
Out[392]:
```

```
<class 'pandas.io.pytables.HDFStore'>
```

```
File path: store.h5
```

```
# a list of keys are returned
```

```
In [393]: store.keys()
```

```
Out[393]: ['/df', '/food/apple', '/food/orange', '/foo/bar/bah']
```

```
# remove all nodes under this level
```

```
In [394]: store.remove('food')
```

```
In [395]: store
```

```
Out[395]:
```

```
<class 'pandas.io.pytables.HDFStore'>
```

```
File path: store.h5
```

You can walk through the group hierarchy using the `walk` method which will yield a tuple for each group key along with the relative keys of its contents.

New in version 0.24.0.

```
In [396]: for (path, subgroups, subkeys) in store.walk():
.....:     for subgroup in subgroups:
.....:         print('GROUP: {}/{}'.format(path, subgroup))
.....:     for subkey in subkeys:
.....:         key = '/'.join([path, subkey])
.....:         print('KEY: {}'.format(key))
.....:         print(store.get(key))
.....:
GROUP: /foo
KEY: /df
           A           B           C

2000-01-08 -0.999591 -0.320658 -1.922640
```

Warning: Hierarchical keys cannot be retrieved as dotted (attribute) access as described above for items stored under the root node.

```
In [8]: store.foo.bar.bah
AttributeError: 'HDFStore' object has no attribute 'foo'

# you can directly access the actual PyTables node but using the root node
In [9]: store.root.foo.bar.bah
Out[9]:
/foo/bar/bah (Group) ''
  children := ['block0_items' (Array), 'block0_values' (Array), 'axis0' (Array),
  ↪ 'axis1' (Array)]
```

Instead, use explicit string based keys:

```
In [397]: store['foo/bar/bah']
Out[397]:
      A          B          C
2000-01-01  0.263806  1.913465 -0.274536
2000-01-02  0.283334  1.798001 -0.053258
2000-01-03  0.799684 -0.733715  1.205089
2000-01-04  0.131478  0.100995 -0.764260
2000-01-05  1.891112 -1.410251  0.752883
2000-01-06 -0.274852 -0.667027 -0.688782
2000-01-07  0.621607 -1.300199  0.050119
2000-01-08 -0.999591 -0.320658 -1.922640
```

Storing types

Storing mixed types in a table

Storing mixed-dtype data is supported. Strings are stored as a fixed-width using the maximum size of the appended column. Subsequent attempts at appending longer strings will raise a `ValueError`.

Passing `min_itemsize={'values': size}` as a parameter to append will set a larger minimum for the string columns. Storing floats, strings, ints, bools, `datetime64` are currently supported. For string columns, passing `nan_rep = 'nan'` to append will change the default nan representation on disk (which converts to/from `np.nan`), this defaults to `nan`.

```
In [398]: df_mixed = pd.DataFrame({'A': np.random.randn(8),
  .....:                          'B': np.random.randn(8),
```

```

.....:          'C': np.array(np.random.randn(8), dtype='float32'),
.....:          'string': 'string',
.....:          'int': 1,
.....:          'bool': True,
.....:          'datetime64': pd.Timestamp('20010102')},
.....:          index=list(range(8)))
.....:

In [399]: df_mixed.loc[df_mixed.index[3:5],
.....:          ['A', 'B', 'string', 'datetime64']] = np.nan
.....:

```

```
In [400]: store.append('df_mixed', df_mixed, min_itemsize={'values': 50})
```

```
In [401]: df_mixed1 = store.select('df_mixed')
```

```
In [402]: df_mixed1
```

```
Out[402]:
```

	A	B	C	string	int	bool	datetime64
0	0.894171	-1.452159	-0.105646	string	1	True	2001-01-02

```

Storing MultiIndex DataFrames

Storing MultiIndex DataFrames as tables is very similar to storing/selecting from homogeneous index DataFrames.

```
In [405]: index = pd.MultiIndex(levels=[['foo', 'bar', 'baz', 'qux'],
.....:                               ['one', 'two', 'three']],
.....:                          codes=[[0, 0, 0, 1, 1, 2, 2, 3, 3, 3],
.....:                                [0, 1, 2, 0, 1, 1, 2, 0, 1, 2]],
.....:                          names=['foo', 'bar'])
.....:
```

```
In [406]: df_mi = pd.DataFrame(np.random.randn(10, 3), index=index,
.....:                          columns=['A', 'B', 'C'])
.....:
```

```
In [407]: df_mi
```

```
Out[407]:
```

		A	B	C
foo	bar			
foo	one	0.072648	-0.851494	0.140402
	two	-0.568937	0.439050	2.531582
	three	0.539277	-1.398668	0.740635
bar	one	-1.892064	-0.830925	1.775692

```
Out[410]:
```

```
           A         B         C
foo bar
bar one -1.892064 -0.830925  1.775692
      two  2.183350 -1.565258  1.016985
```

Querying

Querying a table

`select` and `delete` operations have an optional criterion that can be specified to select/delete only a subset of the data. This allows one to have a very large on-disk table and retrieve only a portion of the data.

A query is specified using the `Term` class under the hood, as a boolean expression.

- `index` and `columns` are supported indexers of a `DataFrames`.
- if `data_columns` are specified, these can be used as additional indexers.

Valid comparison operators are:

`=`, `==`, `!=`, `>`, `>=`, `<`, `<=`

Valid boolean expressions are combined with:

- `|` : or
- `&` : and
- `(and)` : for grouping

These rules are similar to how boolean expressions are used in pandas for indexing.

Note:

- `=` will be automatically expanded to the comparison operator `==`
 - `~` is the not operator, but can only be used in very limited circumstances
 - If a list/tuple of expressions is passed they will be combined via `&`
-

The following are valid expressions:

- `'index >= date'`
- `"columns = ['A', 'D']"`
- `"columns in ['A', 'D']"`
- `'columns = A'`
- `'columns == A'`
- `"~(columns = ['A', 'B'])"`
- `'index > df.index[3] & string = "bar"'`
- `'(index > df.index[3] & index <= df.index[6]) | string = "bar"'`
- `"ts >= Timestamp('2012-02-01')"`
- `"major_axis>=20130101"`

The `indexers` are on the left-hand side of the sub-expression:

`columns, major_axis, ts`

The right-hand side of the sub-expression (after a comparison operator) can be:

- functions that will be evaluated, e.g. `Timestamp('2012-02-01')`
- strings, e.g. `"bar"`
- date-like, e.g. `20130101`, or `"20130101"`
- lists, e.g. `"['A', 'B']"`
- variables that are defined in the local names space, e.g. `date`

Note: Passing a string to a query by interpolating it into the query expression is not recommended. Simply assign the string of interest to a variable and use that variable in an expression. For example, do this

```
string = "HolyMoly"
store.select('df', 'index == string')
```

instead of this

```
string = "HolyMoly"
store.select('df', 'index == %s' % string)
```

The latter will **not** work and will raise a `SyntaxError`. Note that there's a single quote followed by a double quote in the `string` variable.

If you *must* interpolate, use the `'%r'` format specifier

```
store.select('df', 'index == %r' % string)
```

which will quote `string`.

Here are some examples:

```
In [411]: dfq = pd.DataFrame(np.random.randn(10, 4), columns=list('ABCD'),
.....:                      index=pd.date_range('20130101', periods=10))
.....:
In [412]: store.append('dfq', dfq, format='table', data_columns=True)
```

Use boolean expressions, with in-line function evaluation.

```
In [413]: store.select('dfq', "index>pd.Timestamp('20130104') & columns=['A', 'B']")
Out[413]:
```

	A	B
2013-01-05	0.141437	-0.757467
2013-01-06	0.428370	0.281642
2013-01-07	-0.122746	0.909453
2013-01-08	0.319459	0.828792
2013-01-09	-0.446442	0.030712
2013-01-10	-0.627425	0.599256

Use and inline column reference

```
In [414]: store.select('dfq', where="A>0 or C>0")
```

```
Out [414]:
```

	A	B	C	D
2013-01-03	0.099259	-0.456319	0.079027	1.367963
2013-01-04	1.339489	1.086947	-0.918047	0.552759
2013-01-05	0.141437	-0.757467	-1.536944	-0.641387
2013-01-06	0.428370	0.281642	2.297828	-1.406053
2013-01-07	-0.122746	0.909453	1.434186	2.485565
2013-01-08	0.319459	0.828792	-0.221890	0.693093
2013-01-09	-0.446442	0.030712	1.330275	1.509187

The `columns` keyword can be supplied to select a list of columns to be returned, this is equivalent to passing a `'columns=list_of_columns_to_filter'`:

```
In [415]: store.select('df', "columns=['A', 'B']")
```

```
Out [415]:
```

	A	B
2000-01-01	0.263806	1.913465
2000-01-02	0.283334	1.798001
2000-01-03	0.799684	-0.733715
2000-01-04	0.131478	0.100995
2000-01-05	1.891112	-1.410251
2000-01-06	-0.274852	-0.667027
2000-01-07	0.621607	-1.300199
2000-01-08	-0.999591	-0.320658

`start` and `stop` parameters can be specified to limit the total search space. These are in terms of the total number of rows in a table.

Note: `select` will raise a `ValueError` if the query expression has an unknown variable reference. Usually this means that you are trying to select on a column that is **not** a `data_column`.

`select` will raise a `SyntaxError` if the query expression is not valid.

Using `timedelta64[ns]`

You can store and query using the `timedelta64[ns]` type. Terms can be specified in the format: `<float><unit>`, where float may be signed (and fractional), and unit can be `D,s,ms,us,ns` for the `timedelta`. Here's an example:

```
In [416]: from datetime import timedelta
```

```
In [417]: dftd = pd.DataFrame({'A': pd.Timestamp('20130101'),
.....:                        'B': [pd.Timestamp('20130101') + timedelta(days=i,
.....:                                                                    seconds=10)
.....:                                for i in range(10)]})
```

```
In [418]: dftd['C'] = dftd['A'] - dftd['B']
```

```
In [419]: dftd
```

Indexing

You can create/modify an index for a table with `create_table_index` after data is already in the table (after and `append/put` operation). Creating a table index is **highly** encouraged. This will speed your queries a great deal when you use a `select` with the indexed dimension as the `where`.

Note: Indexes are automatically created on the indexables and any data columns you specify. This behavior can be turned off by passing `index=False` to `append`.

```
# we have automatically already created an index (in the first section)
```

In [422]: i = store.root.df.table.cols.index.index**In [423]:** i.optlevel, i.kind**Out [423]:** (6, 'medium')

```
# change an index by passing new parameters
```

In [424]: store.create_table_index('df', optlevel=9, kind='full')**In [425]:** i = store.root.df.table.cols.index.index**In [426]:** i.optlevel, i.kind**Out [426]:** (9, 'full')

Oftentimes when appending large amounts of data to a store, it is useful to turn off index creation for each `append`, then recreate at the end.

```

In [427]: df_1 = pd.DataFrame(np.random.randn(10, 2), columns=list('AB'))
In [428]: df_2 = pd.DataFrame(np.random.randn(10, 2), columns=list('AB'))
In [429]: st = pd.HDFStore('appends.h5', mode='w')
In [430]: st.append('df', df_1, data_columns=['B'], index=False)
In [431]: st.append('df', df_2, data_columns=['B'], index=False)
In [432]: st.get_storer('df').table
Out[432]:
/df/table (Table(20,)) ''
description := {
  "index": Int64Col(shape=(), dflt=0, pos=0),
  "values_block_0": Float64Col(shape=(1,), dflt=0.0, pos=1),
  "B": Float64Col(shape=(), dflt=0.0, pos=2)}
byteorder := 'little'
chunkshape := (2730,)

```

Then create the index when finished appending.

```

In [433]: st.create_table_index('df', columns=['B'], optlevel=9, kind='full')
In [434]: st.get_storer('df').table
Out[434]:

In [435]: st.close()

```

See [here](#) for how to create a completely-sorted-index (CSI) on an existing store.

Query via data columns

You can designate (and index) certain columns that you want to be able to perform queries (other than the *indexable* columns, which you can always query). For instance say you want to perform this common operation, on-disk, and return just the frame that matches this query. You can specify `data_columns = True` to force all columns to be `data_columns`.

```
In [436]: df_dc = df.copy()
```

```
In [437]: df_dc['string'] = 'foo'
```

```
In [438]: df_dc.loc[df_dc.index[4:6], 'string'] = np.nan
```

```
In [439]: df_dc.loc[df_dc.index[7:9], 'string'] = 'bar'
```

```
In [440]: df_dc['string2'] = 'cool'
```

```
In [441]: df_dc.loc[df_dc.index[1:3], ['B', 'C']] = 1.0
```

```
In [442]: df_dc
```

```
Out[442]:
```

	A	B	C	string	string2

```
# we have automagically created this index and the B/C/string/string2
```

```
# columns are stored separately as ``PyTables`` columns
```

```
In [447]: store.root.df_dc.table
```

```
Out[447]:
/df_dc/table (Table(8,)) ''
  description := {
    "index": Int64Col(shape=(), dflt=0, pos=0),
    "values_block_0": Float64Col(shape=(1,), dflt=0.0, pos=1),
    "B": Float64Col(shape=(), dflt=0.0, pos=2),
    "C": Float64Col(shape=(), dflt=0.0, pos=3),
```

```

"string": StringCol(itemsized=3, shape=(), dflt=b'', pos=4),
"string2": StringCol(itemsized=4, shape=(), dflt=b'', pos=5)}
byteorder := 'little'
chunkshape := (1680,)
autoindex := True
colindexes := {
  "index": Index(6, medium, shuffle, zlib(1)).is_csi=False,
  "B": Index(6, medium, shuffle, zlib(1)).is_csi=False,
  "C": Index(6, medium, shuffle, zlib(1)).is_csi=False,
  "string": Index(6, medium, shuffle, zlib(1)).is_csi=False,
  "string2": Index(6, medium, shuffle, zlib(1)).is_csi=False}

```

There is some performance degradation by making lots of columns into *data columns*, so it is up to the user to designate these. In addition, you cannot change data columns (nor indexables) after the first append/put operation (Of course you can simply read in the data and create a new table!).

Iterator

You can pass `iterator=True` or `chunksize=number_in_a_chunk` to `select` and `select_as_multiple` to return an iterator on the results. The default is 50,000 rows returned in a chunk.

```

In [448]: for df in store.select('df', chunksize=3):
.....:     print(df)
.....:
           A          B          C
2000-01-01  0.263806  1.913465 -0.274536
2000-01-02  0.283334  1.798001 -0.053258
2000-01-03  0.799684 -0.733715  1.205089
           A          B          C
2000-01-04  0.131478  0.100995 -0.764260
2000-01-05  1.891112 -1.410251  0.752883
2000-01-06 -0.274852 -0.667027 -0.688782
           A          B          C
2000-01-07  0.621607 -1.300199  0.050119
2000-01-08 -0.999591 -0.320658 -1.922640

```

Note: You can also use the iterator with `read_hdf` which will open, then automatically close the store when finished iterating.

```

for df in pd.read_hdf('store.h5', 'df', chunksize=3):
    print(df)

```

Note, that the `chunksize` keyword applies to the **source** rows. So if you are doing a query, then the `chunksize` will subdivide the total rows in the table and the query applied, returning an iterator on potentially unequal sized chunks.

Here is a recipe for generating a query and using it to create equal sized return chunks.

```

In [449]: dfeq = pd.DataFrame({'number': np.arange(1, 11)})

In [450]: dfeq
Out[450]:

```

(continues on next page)

(continued from previous page)

```

number
0      1
1      2
2      3
3      4
4      5
5      6
6      7
7      8
8      9
9     10

In [451]: store.append('dfeq', dfeq, data_columns=['number'])

In [452]: def chunks(l, n):
.....:     return [l[i:i + n] for i in range(0, len(l), n)]
.....:

In [453]: evens = [2, 4, 6, 8, 10]

In [454]: coordinates = store.select_as_coordinates('dfeq', 'number=evens')

In [455]: for c in chunks(coordinates, 2):
.....:     print(store.select('dfeq', where=c))
.....:
number
1      2
3      4
number
5      6
7      8
number
9     10

```

Advanced queries

Select a single column

To retrieve a single indexable or data column, use the method `select_column`. This will, for example, enable you to get the index very quickly. These return a `Series` of the result, indexed by the row number. These do not currently accept the `where` selector.

```

In [456]: store.select_column('df_dc', 'index')
Out[456]:
0    2000-01-01
1    2000-01-02
2    2000-01-03
3    2000-01-04
4    2000-01-05
5    2000-01-06
6    2000-01-07

```

```
7 2000-01-08
Name: index, dtype: datetime64[ns]

In [457]: store.select_column('df_dc', 'string')
Out[457]:
0    foo
1    foo
2    foo
3    foo
4    NaN
5    NaN
6    foo
7    bar
Name: string, dtype: object
```

Selecting coordinates

Sometimes you want to get the coordinates (a.k.a the index locations) of your query. This returns an `Int64Index` of the resulting locations. These coordinates can also be passed to subsequent `where` operations.

```
In [458]: df_coord = pd.DataFrame(np.random.randn(1000, 2),
.....:                          index=pd.date_range('20000101', periods=1000))
.....:
```

```
In [459]: store.append('df_coord', df_coord)
```

```
In [460]: c = store.select_as_coordinates('df_coord', 'index > 20020101')
```

```
In [461]: c
Out[461]:
Int64Index([732, 733, 734, 735, 736, 737, 738, 739, 740, 741,
.....:
          ...
          990, 991, 992, 993, 994, 995, 996, 997, 998, 999],
          dtype='int64', length=268)
```

```
In [462]: store.select('df_coord', where=c)
```

```
Out[462]:
           0          1
2002-01-02 -0.479047 -1.957543
2002-01-03  1.254799  1.315447
2002-01-04 -0.233731 -1.630779
2002-01-05 -1.098851 -1.299909
2002-01-06  0.667606  0.143470
...
2002-09-22 -1.066208 -0.894186
2002-09-23  2.079421 -0.266075
2002-09-24  1.496228 -0.668430
2002-09-25  0.402749 -0.187683
2002-09-26  0.350581  1.152795
```

```
[268 rows x 2 columns]
```

Selecting using a where mask

Sometime your query can involve creating a list of rows to select. Usually this `mask` would be a resulting `index` from an indexing operation. This example selects the months of a `datetimeindex` which are 5.

```
In [463]: df_mask = pd.DataFrame(np.random.randn(1000, 2),
.....:                          index=pd.date_range('20000101', periods=1000))
.....:

In [464]: store.append('df_mask', df_mask)

In [465]: c = store.select_column('df_mask', 'index')

In [466]: where = c[pd.DatetimeIndex(c).month == 5].index

In [467]: store.select('df_mask', where=where)
Out[467]:
```

	0	1
2000-05-01	0.673172	0.388669
2000-05-02	0.761613	-0.368644
2000-05-03	0.435121	-0.062180
2000-05-04	1.677448	-0.019684
2000-05-05	0.562315	1.464591
...
2002-05-27	0.437853	1.315529
2002-05-28	0.931011	0.532589
2002-05-29	0.349402	-0.138098
2002-05-30	0.752838	0.254404
2002-05-31	0.013580	1.078755

```
[93 rows x 2 columns]
```

Storer object

If you want to inspect the stored object, retrieve via `get_storer`. You could use this programmatically to say get the number of rows in an object.

```
In [468]: store.get_storer('df_dc').nrows
Out[468]: 8
```

Multiple table queries

The methods `append_to_multiple` and `select_as_multiple` can perform appending/selecting from multiple tables at once. The idea is to have one table (call it the selector table) that you index most/all of the columns, and perform your queries. The other table(s) are data tables with an index matching the selector table's index. You can then perform a very fast query on the selector table, yet get lots of data back. This method is similar to having a very wide table, but enables more efficient queries.

The `append_to_multiple` method splits a given single `DataFrame` into multiple tables according to `d`, a dictionary that maps the table names to a list of 'columns' you want in that table. If `None` is used in place of a list, that table will have the remaining unspecified columns of the given `DataFrame`. The argument `selector` defines which table is the selector table (which you can make queries from). The argument `dropna`

will drop rows from the input DataFrame to ensure tables are synchronized. This means that if a row for one of the tables being written to is entirely `np.NaN`, that row will be dropped from all tables.

If `dropna` is `False`, **THE USER IS RESPONSIBLE FOR SYNCHRONIZING THE TABLES**. Remember that entirely `np.NaN` rows are not written to the HDFStore, so if you choose to call `dropna=False`, some tables may have more rows than others, and therefore `select_as_multiple` may not work or it may return unexpected results.

```
In [469]: df_mt = pd.DataFrame(np.random.randn(8, 6),
.....:                        index=pd.date_range('1/1/2000', periods=8),
.....:                        columns=['A', 'B', 'C', 'D', 'E', 'F'])
.....:
```

```
In [470]: df_mt['foo'] = 'bar'
```

```
In [471]: df_mt.loc[df_mt.index[1], ('A', 'B')] = np.nan
```

```
# you can also create the tables individually
```

```
In [472]: store.append_to_multiple({'df1_mt': ['A', 'B'], 'df2_mt': None},
.....:                             df_mt, selector='df1_mt')
.....:
```

```
In [473]: store
```

```
Out[473]:
```

```
<class 'pandas.io.pytables.HDFStore'>
```

```

Delete from a table

You can delete from a table selectively by specifying a **where**. In deleting rows, it is important to understand the PyTables deletes rows by erasing the rows, then **moving** the following data. Thus deleting can potentially be a very expensive operation depending on the orientation of your data. To get optimal performance, it's worthwhile to have the dimension you are deleting be the first of the **indexables**.

Data is ordered (on the disk) in terms of the **indexables**. Here's a simple use case. You store panel-type data, with dates in the **major_axis** and ids in the **minor_axis**. The data is then interleaved like this:

- **date_1**
 - id_1
 - id_2
 - .
 - id_n
- **date_2**
 - id_1
 - .
 - id_n

It should be clear that a delete operation on the **major_axis** will be fairly quick, as one chunk is removed, then the following data moved. On the other hand a delete operation on the **minor_axis** will be very expensive. In this case it would almost certainly be faster to rewrite the table using a **where** that selects all but the missing data.

Warning: Please note that HDF5 **DOES NOT RECLAIM SPACE** in the h5 files automatically. Thus, repeatedly deleting (or removing nodes) and adding again, **WILL TEND TO INCREASE THE FILE SIZE**.

To *repack and clean* the file, use *ptrepack*.

Notes & caveats

Compression

PyTables allows the stored data to be compressed. This applies to all kinds of stores, not just tables. Two parameters are used to control compression: **complevel** and **complib**.

complevel specifies **if and how hard data is to be compressed**. **complevel=0** and **complevel=None** disables compression and $0 < \text{complevel} < 10$ enables compression.

complib specifies **which compression library to use**. If **nothing is** specified the default library **zlib** is used. A compression library usually optimizes for either good compression rates or speed and the

results will depend on the type of data. Which type of compression to choose depends on your specific needs and data. The list of supported compression libraries:

- `zlib`: The default compression library. A classic in terms of compression, achieves good compression rates but is somewhat slow.
- `lzo`: Fast compression and decompression.
- `bzip2`: Good compression rates.
- `blosc`: Fast compression and decompression.

New in version 0.20.2: Support for alternative `blosc` compressors:

- `blosc:blosclz` This is the default compressor for `blosc`
- `blosc:lz4`: A compact, very popular and fast compressor.
- `blosc:lz4hc`: A tweaked version of LZ4, produces better compression ratios at the expense of speed.
- `blosc:snappy`: A popular compressor used in many places.
- `blosc:zlib`: A classic; somewhat slower than the previous ones, but achieving better compression ratios.
- `blosc:zstd`: An extremely well balanced codec; it provides the best compression ratios among the others above, and at reasonably fast speed.

If `complib` is defined as something other than the listed libraries a `ValueError` exception is issued.

Note: If the library specified with the `complib` option is missing on your platform, compression defaults to `zlib` without further ado.

Enable compression for all objects within the file:

```
store_compressed = pd.HDFStore('store_compressed.h5', complevel=9,
                               complib='blosc:blosclz')
```

Or on-the-fly compression (this only applies to tables) in stores where compression is not enabled:

```
store.append('df', df, complib='zlib', complevel=5)
```

ptrepack

`PyTables` offers better write performance when tables are compressed after they are written, as opposed to turning on compression at the very beginning. You can use the supplied `PyTables` utility `ptrepack`. In addition, `ptrepack` can change compression levels after the fact.

```
ptrepack --chunkshape=auto --propindexes --complevel=9 --complib=blosc in.h5 out.h5
```

Furthermore `ptrepack in.h5 out.h5` will *repack* the file to allow you to reuse previously deleted space. Alternatively, one can simply remove the file and write again, or use the copy method.

Caveats

Warning: `HDFStore` is **not-threadsafe for writing**. The underlying `PyTables` only supports concurrent reads (via threading or processes). If you need reading and writing *at the same time*, you need to serialize these operations in a single thread in a single process. You will corrupt your data otherwise. See the (GH2397) for more information.

- If you use locks to manage write access between multiple processes, you may want to use `fsync()` before releasing write locks. For convenience you can use `store.flush(fsyntax=True)` to do this for you.
- Once a `table` is created columns (`DataFrame`) are fixed; only exactly the same columns can be appended
- Be aware that timezones (e.g., `pytz.timezone('US/Eastern')`) are not necessarily equal across timezone versions. So if data is localized to a specific timezone in the `HDFStore` using one version of a timezone library and that data is updated with another version, the data will be converted to UTC since these timezones are not considered equal. Either use the same version of timezone library or use `tz_convert` with the updated timezone definition.

Warning: `PyTables` will show a `NaturalNameWarning` if a column name cannot be used as an attribute selector. *Natural* identifiers contain only letters, numbers, and underscores, and may not begin with a number. Other identifiers cannot be used in a `where` clause and are generally a bad idea.

DataTypes

`HDFStore` will map an object dtype to the `PyTables` underlying dtype. This means the following types are known to work:

Type	Represents missing values
floating : float64, float32, float16	<code>np.nan</code>
integer : int64, int32, int8, uint64, uint32, uint8	
boolean	
<code>datetime64[ns]</code>	<code>NaT</code>
<code>timedelta64[ns]</code>	<code>NaT</code>
categorical : see the section below	
object : strings	<code>np.nan</code>

unicode columns are not supported, and **WILL FAIL**.

Categorical data

You can write data that contains `category` dtypes to a `HDFStore`. Queries work the same as if it was an object array. However, the `category` dtyped data is stored in a more efficient manner.

```
In [477]: dfcat = pd.DataFrame({'A': pd.Series(list('aabbcdab')).astype('category'),
.....:                        'B': np.random.randn(8)})
.....:
```

```
In [478]: dfcat
```

```
Out[478]:
   A      B
0  a -0.182915
1  a -1.740077
2  b -0.227312
3  b -0.351706
4  c -0.484542
5  d  1.150367
6  b -1.223195
7  a  1.022514
```

```
In [479]: dfcat.dtypes
```

```
Out[479]:
A    category
B    float64
dtype: object
```

```
In [480]: cstore = pd.HDFStore('cats.h5', mode='w')
```

```
In [481]: cstore.append('dfcat', dfcat, format='table', data_columns=['A'])
```

```
In [482]: result = cstore.select('dfcat', where="A in ['b', 'c']")
```

```
In [483]: result
```

```
Out[483]:
   A      B
2  b -0.227312
3  b -0.351706
4  c -0.484542
6  b -1.223195
```

```
In [484]: result.dtypes
```

```
Out[484]:
A    category
B    float64
dtype: object
```

String columns

`min_itemsize`

The underlying implementation of `HDFStore` uses a fixed column width (`itemsize`) for string columns. A string column `itemsize` is calculated as the maximum of the length of data (for that column) that is passed to the `HDFStore`, **in the first `append`**. Subsequent appends, may introduce a string for a column **larger** than the column can hold, an `Exception` will be raised (otherwise you could have a silent truncation of these columns, leading to loss of information). In the future we may relax this and allow a user-specified truncation to occur.

Pass `min_itemsize` on the first table creation to a-priori specify the minimum length of a particular string column. `min_itemsize` can be an integer, or a dict mapping a column name to an integer. You can pass `values` as a key to allow all *indexables* or *data_columns* to have this `min_itemsize`.

Passing a `min_itemsize` dict will cause all passed columns to be created as *data_columns* automatically.

Note: If you are not passing any `data_columns`, then the `min_itemsize` will be the maximum of the length of any string passed

```
In [485]: dfs = pd.DataFrame({'A': 'foo', 'B': 'bar'}, index=list(range(5)))
```

```
In [486]: dfs
```

```
Out[486]:
```

```
   A  B
0  foo bar
1  foo bar
2  foo bar
3  foo bar
4  foo bar
```

```
# A and B have a size of 30
```

```
In [487]: store.append('dfs', dfs, min_itemsize=30)
```

```
In [488]: store.get_storer('dfs').table
```

```
Out[488]:
```

```
/dfs/table (Table(5,)) ''
description := {
  "index": Int64Col(shape=(), dflt=0, pos=0),
  "values_block_0": StringCol(itemsize=30, shape=(2,), dflt=b'', pos=1)}
byteorder := 'little'
chunkshape := (963,)
autoindex := True
colindexes := {
  "index": Index(6, medium, shuffle, zlib(1)).is_csi=False}
```

```
# A is created as a data_column with a size of 30
```

```
# B is size is calculated
```

```
In [489]: store.append('dfs2', dfs, min_itemsize={'A': 30})
```

```
In [490]: store.get_storer('dfs2').table
```

```
Out[490]:
```

```
/dfs2/table (Table(5,)) ''
description := {
  "index": Int64Col(shape=(), dflt=0, pos=0),
  "values_block_0": StringCol(itemsize=3, shape=(1,), dflt=b'', pos=1),
  "A": StringCol(itemsize=30, shape=(), dflt=b'', pos=2)}
byteorder := 'little'
chunkshape := (1598,)
autoindex := True
colindexes := {
  "index": Index(6, medium, shuffle, zlib(1)).is_csi=False,
  "A": Index(6, medium, shuffle, zlib(1)).is_csi=False}
```

nan_rep

String columns will serialize a `np.nan` (a missing value) with the `nan_rep` string representation. This defaults to the string value `nan`. You could inadvertently turn an actual `nan` value into a missing value.

```
In [491]: dfss = pd.DataFrame({'A': ['foo', 'bar', 'nan']})
```

```
In [492]: dfss
```

```
Out[492]:
```

```
   A
0  foo
1  bar
2  nan
```

```
In [493]: store.append('dfss', dfss)
```

```
In [494]: store.select('dfss')
```

```
Out[494]:
```

```
   A
0  foo
1  bar
2  NaN
```

```
# here you need to specify a different nan rep
```

```
In [495]: store.append('dfss2', dfss, nan_rep='_nan_')
```

```
In [496]: store.select('dfss2')
```

```
Out[496]:
```

```
   A
0  foo
1  bar
2  nan
```

External compatibility

HDFStore writes table format objects in specific formats suitable for producing loss-less round trips to pandas objects. For external compatibility, HDFStore can read native PyTables format tables.

It is possible to write an HDFStore object that can easily be imported into R using the `rhd5` library ([Package website](#)). Create a table format store like this:

```
In [497]: df_for_r = pd.DataFrame({"first": np.random.rand(100),
.....:                            "second": np.random.rand(100),
.....:                            "class": np.random.randint(0, 2, (100, ))},
.....:                            index=range(100))
.....:
```

```
In [498]: df_for_r.head()
```

```
Out[498]:
```

```
   first  second  class
0  0.253517  0.473526    0
1  0.232906  0.331008    0
2  0.069221  0.532945    1
3  0.290835  0.069538    1
4  0.912722  0.346792    0
```

```
In [499]: store_export = pd.HDFStore('export.h5')
```

(continues on next page)

(continued from previous page)

```
In [500]: store_export.append('df_for_r', df_for_r, data_columns=df_dc.columns)

In [501]: store_export
Out[501]:
<class 'pandas.io.pytables.HDFStore'>
File path: export.h5
```

In R this file can be read into a `data.frame` object using the `rhdf5` library. The following example function reads the corresponding column names and data values from the values and assembles them into a `data.frame`:

```
# Load values and column names for all datasets from corresponding nodes and
# insert them into one data.frame object.

library(rhdf5)

loadhdf5data <- function(h5File) {

  listing <- h5ls(h5File)
  # Find all data nodes, values are stored in *_values and corresponding column
# titles in *_items
  data_nodes <- grep("_values", listing$name)
  name_nodes <- grep("_items", listing$name)
  data_paths = paste(listing$group[data_nodes], listing$name[data_nodes], sep = "/")
  name_paths = paste(listing$group[name_nodes], listing$name[name_nodes], sep = "/")
  columns = list()
  for (idx in seq(data_paths)) {
    # NOTE: matrices returned by h5read have to be transposed to obtain
    # required Fortran order!
    data <- data.frame(t(h5read(h5File, data_paths[idx])))
    names <- t(h5read(h5File, name_paths[idx]))
    entry <- data.frame(data)
    colnames(entry) <- names
    columns <- append(columns, entry)
  }

  data <- data.frame(columns)

  return(data)
}
```

Now you can import the `DataFrame` into R:

```
> data = loadhdf5data("transfer.hdf5")
> head(data)
      first  second class
1 0.4170220047 0.3266449    0
2 0.7203244934 0.5270581    0
3 0.0001143748 0.8859421    1
4 0.3023325726 0.3572698    1
5 0.1467558908 0.9085352    1
6 0.0923385948 0.6233601    1
```

Note: The R function lists the entire HDF5 file's contents and assembles the `data.frame` object from all matching nodes, so use this only as a starting point if you have stored multiple `DataFrame` objects to a single HDF5 file.

Performance

- `tables` format come with a writing performance penalty as compared to `fixed` stores. The benefit is the ability to append/delete and query (potentially very large amounts of data). Write times are generally longer as compared with regular stores. Query times can be quite fast, especially on an indexed axis.
- You can pass `chunksize=<int>` to `append`, specifying the write chunksize (default is 50000). This will significantly lower your memory usage on writing.
- You can pass `expectedrows=<int>` to the first `append`, to set the TOTAL number of expected rows that `PyTables` will expect. This will optimize read/write performance.
- Duplicate rows can be written to tables, but are filtered out in selection (with the last items being selected; thus a table is unique on major, minor pairs)
- A `PerformanceWarning` will be raised if you are attempting to store types that will be pickled by `PyTables` (rather than stored as endemic types). See [Here](#) for more information and some solutions.

4.1.10 Feather

New in version 0.20.0.

Feather provides binary columnar serialization for data frames. It is designed to make reading and writing data frames efficient, and to make sharing data across data analysis languages easy.

Feather is designed to faithfully serialize and de-serialize `DataFrames`, supporting all of the pandas dtypes, including extension dtypes such as categorical and datetime with tz.

Several caveats.

- This is a newer library, and the format, though stable, is not guaranteed to be backward compatible to the earlier versions.
- The format will NOT write an `Index`, or `MultiIndex` for the `DataFrame` and will raise an error if a non-default one is provided. You can `.reset_index()` to store the index or `.reset_index(drop=True)` to ignore it.
- Duplicate column names and non-string columns names are not supported
- Non supported types include `Period` and actual Python object types. These will raise a helpful error message on an attempt at serialization.

See the [Full Documentation](#).

```
In [502]: df = pd.DataFrame({'a': list('abc'),
.....:                      'b': list(range(1, 4)),
.....:                      'c': np.arange(3, 6).astype('u1'),
.....:                      'd': np.arange(4.0, 7.0, dtype='float64'),
.....:                      'e': [True, False, True],
.....:                      'f': pd.Categorical(list('abc')),
.....:                      'g': pd.date_range('20130101', periods=3),
.....:                      'h': pd.date_range('20130101', periods=3, tz='US/Eastern'),
```

```
.....:          'i': pd.date_range('20130101', periods=3, freq='ns')}}
.....:
```

```
In [503]: df
```

```

4.1.11 Parquet

New in version 0.21.0.

[Apache Parquet](#) provides a partitioned binary columnar serialization for data frames. It is designed to make reading and writing data frames efficient, and to make sharing data across data analysis languages easy. Parquet can use a variety of compression techniques to shrink the file size as much as possible while still maintaining good read performance.

Parquet is designed to faithfully serialize and de-serialize `DataFrame`s, supporting all of the pandas dtypes, including extension dtypes such as datetime with tz.

Several caveats.

- Duplicate column names and non-string column names are not supported.
- The `pyarrow` engine always writes the index to the output, but `fastparquet` only writes non-default indexes. This extra column can cause problems for non-Pandas consumers that are not expecting it. You can force including or omitting indexes with the `index` argument, regardless of the underlying engine.
- Index level names, if specified, must be strings.
- Categorical dtypes can be serialized to parquet, but will de-serialize as `object` dtype.
- Non supported types include `Period` and actual Python object types. These will raise a helpful error message on an attempt at serialization.

You can specify an `engine` to direct the serialization. This can be one of `pyarrow`, or `fastparquet`, or `auto`. If the engine is NOT specified, then the `pd.options.io.parquet.engine` option is checked; if this is also `auto`, then `pyarrow` is tried, and falling back to `fastparquet`.

See the documentation for [pyarrow](#) and [fastparquet](#).

Note: These engines are very similar and should read/write nearly identical parquet format files. Currently `pyarrow` does not support timedelta data, `fastparquet` $\geq 0.1.4$ supports timezone aware datetimes. These libraries differ by having different underlying dependencies (`fastparquet` by using `numba`, while `pyarrow` uses a c-library).

```
In [509]: df = pd.DataFrame({'a': list('abc'),
.....:                      'b': list(range(1, 4)),
.....:                      'c': np.arange(3, 6).astype('u1'),
.....:                      'd': np.arange(4.0, 7.0, dtype='float64'),
.....:                      'e': [True, False, True],
.....:                      'f': pd.date_range('20130101', periods=3),
.....:                      'g': pd.date_range('20130101', periods=3, tz='US/Eastern')})
.....:
```

```
In [510]: df
```

```
Out[510]:
```

```

Handling indexes

Serializing a `DataFrame` to parquet may include the implicit index as one or more columns in the output file. Thus, this code:

```
In [520]: df = pd.DataFrame({'a': [1, 2], 'b': [3, 4]})
```

```
In [521]: df.to_parquet('test.parquet', engine='pyarrow')
```

creates a parquet file with *three* columns if you use `pyarrow` for serialization: `a`, `b`, and `__index_level_0__`. If you're using `fastparquet`, the index may or may not be written to the file.

This unexpected extra column causes some databases like Amazon Redshift to reject the file, because that column doesn't exist in the target table.

If you want to omit a dataframe's indexes when writing, pass `index=False` to `to_parquet()`:

```
In [522]: df.to_parquet('test.parquet', index=False)
```

This creates a parquet file with just the two expected columns, `a` and `b`. If your `DataFrame` has a custom index, you won't get it back when you load this file into a `DataFrame`.

Passing `index=True` will *always* write the index, even if that's not the underlying engine's default behavior.

Partitioning Parquet files

New in version 0.24.0.

Parquet supports partitioning of data based on the values of one or more columns.

```
In [523]: df = pd.DataFrame({'a': [0, 0, 1, 1], 'b': [0, 1, 0, 1]})
```

```
In [524]: df.to_parquet(fname='test', engine='pyarrow',
.....:                  partition_cols=['a'], compression=None)
.....:
```

The `fname` specifies the parent directory to which data will be saved. The `partition_cols` are the column names by which the dataset will be partitioned. Columns are partitioned in the order they are given. The partition splits are determined by the unique values in the partition columns. The above example creates a partitioned dataset that may look like:

```
test
  a=0
    0bac803e32dc42ae83fddfd029cbdebc.parquet
    ...
  a=1
    e6ab24a4f45147b49b54a662f0c412a3.parquet
    ...
```

4.1.12 SQL queries

The `pandas.io.sql` module provides a collection of query wrappers to both facilitate data retrieval and to reduce dependency on DB-specific API. Database abstraction is provided by SQLAlchemy if installed. In addition you will need a driver library for your database. Examples of such drivers are `psycopg2` for PostgreSQL or `pymysql` for MySQL. For `SQLite` this is included in Python's standard library by default. You can find an overview of supported drivers for each SQL dialect in the [SQLAlchemy docs](#).

If SQLAlchemy is not installed, a fallback is only provided for `sqlite` (and for `mysql` for backwards compatibility, but this is deprecated and will be removed in a future version). This mode requires a Python database adapter which respect the [Python DB-API](#).

See also some *cookbook examples* for some advanced strategies.

The key functions are:

<code>read_sql_table(table_name, con[, schema, ...])</code>	Read SQL database table into a DataFrame.
<code>read_sql_query(sql, con[, index_col, ...])</code>	Read SQL query into a DataFrame.
<code>read_sql(sql, con[, index_col, ...])</code>	Read SQL query or database table into a DataFrame.
<code>DataFrame.to_sql(self, name, con[, schema, ...])</code>	Write records stored in a DataFrame to a SQL database.

`pandas.read_sql_table`

```
pandas.read_sql_table(table_name, con, schema=None, index_col=None, coerce_float=True,
                      parse_dates=None, columns=None, chunksize=None)
```

Read SQL database table into a DataFrame.

Given a table name and a SQLAlchemy connectable, returns a DataFrame. This function does not support DBAPI connections.

Parameters

- table_name** [str] Name of SQL table in database.
- con** [SQLAlchemy connectable or str] A database URI could be provided as as str. SQLite DBAPI connection mode not supported.
- schema** [str, default None] Name of SQL schema in database to query (if database flavor supports this). Uses default schema if None (default).
- index_col** [str or list of str, optional, default: None] Column(s) to set as index(MultiIndex).
- coerce_float** [bool, default True] Attempts to convert values of non-string, non-numeric objects (like decimal.Decimal) to floating point. Can result in loss of Precision.

parse_dates [list or dict, default None]

- List of column names to parse as dates.
- Dict of {`column_name`: `format string`} where format string is strftime compatible in case of parsing string times or is one of (D, s, ns, ms, us) in case of parsing integer timestamps.
- Dict of {`column_name`: `arg dict`}, where the arg dict corresponds to the keyword arguments of `pandas.to_datetime()` Especially useful with databases without native Datetime support, such as SQLite.

columns [list, default None] List of column names to select from SQL table.

chunksize [int, default None] If specified, returns an iterator where `chunksize` is the number of rows to include in each chunk.

Returns

DataFrame A SQL table is returned as two-dimensional data structure with labeled axes.

See also:

`read_sql_query` Read SQL query into a DataFrame.

`read_sql` Read SQL query or database table into a DataFrame.

Notes

Any datetime values with time zone information will be converted to UTC.

Examples

```
>>> pd.read_sql_table('table_name', 'postgres:///db_name') # doctest:+SKIP
```

pandas.read_sql_query

`pandas.read_sql_query(sql, con, index_col=None, coerce_float=True, params=None, parse_dates=None, chunksize=None)`

Read SQL query into a DataFrame.

Returns a DataFrame corresponding to the result set of the query string. Optionally provide an `index_col` parameter to use one of the columns as the index, otherwise default integer index will be used.

Parameters

sql [string SQL query or SQLAlchemy Selectable (select or text object)] SQL query to be executed.

con [SQLAlchemy connectable(engine/connection), database string URI,] or sqlite3 DBAPI2 connection Using SQLAlchemy makes it possible to use any DB supported by that library. If a DBAPI2 object, only sqlite3 is supported.

index_col [string or list of strings, optional, default: None] Column(s) to set as index(MultiIndex).

coerce_float [boolean, default True] Attempts to convert values of non-string, non-numeric objects (like decimal.Decimal) to floating point. Useful for SQL result sets.

params [list, tuple or dict, optional, default: None] List of parameters to pass to execute method. The syntax used to pass parameters is database driver dependent. Check your database driver documentation for which of the five syntax styles, described in PEP 249's paramstyle, is supported. Eg. for pycopg2, uses %(name)s so use `params={'name': 'value'}`

parse_dates [list or dict, default: None]

- List of column names to parse as dates.
- Dict of {`column_name`: `format string`} where format string is strftime compatible in case of parsing string times, or is one of (D, s, ns, ms, us) in case of parsing integer timestamps.
- Dict of {`column_name`: `arg dict`}, where the arg dict corresponds to the keyword arguments of `pandas.to_datetime()` Especially useful with databases without native Datetime support, such as SQLite.

chunksize [int, default None] If specified, return an iterator where `chunksize` is the number of rows to include in each chunk.

Returns

DataFrame

See also:

`read_sql_table` Read SQL database table into a DataFrame.

`read_sql`

Notes

Any datetime values with time zone information parsed via the `parse_dates` parameter will be converted to UTC.

pandas.read_sql

`pandas.read_sql(sql, con, index_col=None, coerce_float=True, params=None, parse_dates=None, columns=None, chunksize=None)`

Read SQL query or database table into a DataFrame.

This function is a convenience wrapper around `read_sql_table` and `read_sql_query` (for backward compatibility). It will delegate to the specific function depending on the provided input. A SQL query will be routed to `read_sql_query`, while a database table name will be routed to `read_sql_table`. Note that the delegated function might have more specific notes about their functionality not listed here.

Parameters

sql [string or SQLAlchemy Selectable (select or text object)] SQL query to be executed or a table name.

con [SQLAlchemy connectable (engine/connection) or database string URI] or DBAPI2 connection (fallback mode)

Using SQLAlchemy makes it possible to use any DB supported by that library. If a DBAPI2 object, only sqlite3 is supported.

index_col [string or list of strings, optional, default: None] Column(s) to set as index(MultiIndex).

coerce_float [boolean, default True] Attempts to convert values of non-string, non-numeric objects (like decimal.Decimal) to floating point, useful for SQL result sets.

params [list, tuple or dict, optional, default: None] List of parameters to pass to execute method. The syntax used to pass parameters is database driver dependent. Check your database driver documentation for which of the five syntax styles, described in PEP 249's paramstyle, is supported. Eg. for pycogp2, uses %(name)s so use `params={'name': 'value'}`

parse_dates [list or dict, default: None]

- List of column names to parse as dates.
- Dict of {`column_name`: `format string`} where format string is strftime compatible in case of parsing string times, or is one of (D, s, ns, ms, us) in case of parsing integer timestamps.
- Dict of {`column_name`: `arg dict`}, where the arg dict corresponds to the keyword arguments of `pandas.to_datetime()` Especially useful with databases without native Datetime support, such as SQLite.

columns [list, default: None] List of column names to select from SQL table (only used when reading a table).

chunksize [int, default None] If specified, return an iterator where `chunksize` is the number of rows to include in each chunk.

Returns

DataFrame

See also:

`read_sql_table` Read SQL database table into a DataFrame.

`read_sql_query` Read SQL query into a DataFrame.

pandas.DataFrame.to_sql

`DataFrame.to_sql(self, name, con, schema=None, if_exists='fail', index=True, index_label=None, chunksize=None, dtype=None, method=None)`

Write records stored in a DataFrame to a SQL database.

Databases supported by SQLAlchemy [?] are supported. Tables can be newly created, appended to, or overwritten.

Parameters

name [string] Name of SQL table.

con [sqlalchemy.engine.Engine or sqlite3.Connection] Using SQLAlchemy makes it possible to use any DB supported by that library. Legacy support is provided for sqlite3.Connection objects.

schema [string, optional] Specify the schema (if database flavor supports this). If None, use default schema.

if_exists [{'fail', 'replace', 'append'}, default 'fail'] How to behave if the table already exists.

- fail: Raise a ValueError.
- replace: Drop the table before inserting new values.
- append: Insert new values to the existing table.

index [bool, default True] Write DataFrame index as a column. Uses *index_label* as the column name in the table.

index_label [string or sequence, default None] Column label for index column(s). If None is given (default) and *index* is True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.

chunksize [int, optional] Rows will be written in batches of this size at a time. By default, all rows will be written at once.

dtype [dict, optional] Specifying the datatype for columns. The keys should be the column names and the values should be the SQLAlchemy types or strings for the sqlite3 legacy mode.

method [{None, 'multi', callable}, default None] Controls the SQL insertion clause used:

- None : Uses standard SQL INSERT clause (one per row).
- 'multi': Pass multiple values in a single INSERT clause.
- callable with signature (*pd_table*, *conn*, *keys*, *data_iter*).

Details and a sample callable implementation can be found in the section *insert method*.

New in version 0.24.0.

Raises

ValueError When the table already exists and *if_exists* is 'fail' (the default).

See also:

[*read_sql*](#) Read a DataFrame from a table.

Notes

Timezone aware datetime columns will be written as `Timestamp with timezone` type with SQLAlchemy if supported by the database. Otherwise, the datetimes will be stored as timezone unaware timestamps local to the original timezone.

New in version 0.24.0.

References

[?], [?]

Examples

Create an in-memory SQLite database.

```
>>> from sqlalchemy import create_engine
>>> engine = create_engine('sqlite://', echo=False)
```

Create a table from scratch with 3 rows.

```
>>> df = pd.DataFrame({'name' : ['User 1', 'User 2', 'User 3']})
>>> df
   name
0  User 1
1  User 2
2  User 3
```

```
>>> df.to_sql('users', con=engine)
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 1'), (1, 'User 2'), (2, 'User 3')]
```

```
>>> df1 = pd.DataFrame({'name' : ['User 4', 'User 5']})
>>> df1.to_sql('users', con=engine, if_exists='append')
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 1'), (1, 'User 2'), (2, 'User 3'),
 (0, 'User 4'), (1, 'User 5')]
```

Overwrite the table with just df1.

```
>>> df1.to_sql('users', con=engine, if_exists='replace',
...           index_label='id')
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 4'), (1, 'User 5')]
```

Specify the dtype (especially useful for integers with missing values). Notice that while pandas is forced to store the data as floating point, the database supports nullable integers. When fetching the data with Python, we get back integer scalars.

```
>>> df = pd.DataFrame({"A": [1, None, 2]})
>>> df
   A
0  1.0
1  NaN
2  2.0
```

```
>>> from sqlalchemy.types import Integer
>>> df.to_sql('integers', con=engine, index=False,
...         dtype={"A": Integer()})
```

```
>>> engine.execute("SELECT * FROM integers").fetchall()
[(1,), (None,), (2,)]
```

Note: The function `read_sql()` is a convenience wrapper around `read_sql_table()` and `read_sql_query()` (and for backward compatibility) and will delegate to specific function depending on

the provided input (database table name or sql query). Table names do not need to be quoted if they have special characters.

In the following example, we use the `SQLite` SQL database engine. You can use a temporary SQLite database where data are stored in “memory”.

To connect with SQLAlchemy you use the `create_engine()` function to create an engine object from database URI. You only need to create the engine once per database you are connecting to. For more information on `create_engine()` and the URI formatting, see the examples below and the SQLAlchemy [documentation](#)

```
In [525]: from sqlalchemy import create_engine

# Create your engine.
In [526]: engine = create_engine('sqlite:///memory:')
```

If you want to manage your own connections you can pass one of those instead:

```
with engine.connect() as conn, conn.begin():
    data = pd.read_sql_table('data', conn)
```

Writing DataFrames

Assuming the following data is in a DataFrame `data`, we can insert it into the database using `to_sql()`.

id	Date	Col_1	Col_2	Col_3
26	2012-10-18	X	25.7	True
42	2012-10-19	Y	-12.4	False
63	2012-10-20	Z	5.73	True

```
In [527]: data
Out[527]:
   id  Date  Col_1  Col_2  Col_3
0  26 2010-10-18    X  27.50   True
1  42 2010-10-19    Y -12.50  False
2  63 2010-10-20    Z   5.73   True

In [528]: data.to_sql('data', engine)
```

With some databases, writing large DataFrames can result in errors due to packet size limitations being exceeded. This can be avoided by setting the `chunksize` parameter when calling `to_sql`. For example, the following writes `data` to the database in batches of 1000 rows at a time:

```
In [529]: data.to_sql('data_chunked', engine, chunksize=1000)
```

SQL data types

`to_sql()` will try to map your data to an appropriate SQL data type based on the dtype of the data. When you have columns of dtype `object`, pandas will try to infer the data type.

You can always override the default type by specifying the desired SQL type of any of the columns by using the `dtype` argument. This argument needs a dictionary mapping column names to SQLAlchemy types (or

strings for the sqlite3 fallback mode). For example, specifying to use the sqlalchemy `String` type instead of the default `Text` type for string columns:

```
In [530]: from sqlalchemy.types import String
In [531]: data.to_sql('data_dtype', engine, dtype={'Col_1': String})
```

Note: Due to the limited support for `timedelta`'s in the different database flavors, columns with type `timedelta64` will be written as integer values as nanoseconds to the database and a warning will be raised.

Note: Columns of `category` dtype will be converted to the dense representation as you would get with `np.asarray(categorical)` (e.g. for string categories this gives an array of strings). Because of this, reading the database table back in does **not** generate a categorical.

Datetime data types

Using SQLAlchemy, `to_sql()` is capable of writing datetime data that is timezone naive or timezone aware. However, the resulting data stored in the database ultimately depends on the supported data type for datetime data of the database system being used.

The following table lists supported data types for datetime data for some common databases. Other database dialects may have different data types for datetime data.

Database	SQL Datetime Types	Timezone Support
SQLite	TEXT	No
MySQL	TIMESTAMP or DATETIME	No
PostgreSQL	TIMESTAMP or TIMESTAMP WITH TIME ZONE	Yes

When writing timezone aware data to databases that do not support timezones, the data will be written as timezone naive timestamps that are in local time with respect to the timezone.

`read_sql_table()` is also capable of reading datetime data that is timezone aware or naive. When reading `TIMESTAMP WITH TIME ZONE` types, pandas will convert the data to UTC.

Insertion method

New in version 0.24.0.

The parameter `method` controls the SQL insertion clause used. Possible values are:

- `None`: Uses standard SQL `INSERT` clause (one per row).
- `'multi'`: Pass multiple values in a single `INSERT` clause. It uses a *special* SQL syntax not supported by all backends. This usually provides better performance for analytic databases like *Presto* and *Redshift*, but has worse performance for traditional SQL backend if the table contains many columns. For more information check the SQLAlchemy [documentation](#).
- callable with signature `(pd_table, conn, keys, data_iter)`: This can be used to implement a more performant insertion method based on specific backend dialect features.

Example of a callable using PostgreSQL `COPY` clause:

```

# Alternative to_sql() *method* for DBs that support COPY FROM
import csv
from io import StringIO

def psql_insert_copy(table, conn, keys, data_iter):
    # gets a DBAPI connection that can provide a cursor
    dbapi_conn = conn.connection
    with dbapi_conn.cursor() as cur:
        s_buf = StringIO()
        writer = csv.writer(s_buf)
        writer.writerows(data_iter)
        s_buf.seek(0)

        columns = ', '.join("{} {}".format(k) for k in keys)
        if table.schema:
            table_name = '{}.{}'.format(table.schema, table.name)
        else:
            table_name = table.name

        sql = 'COPY {} ({} FROM STDIN WITH CSV'.format(
            table_name, columns)
        cur.copy_expert(sql=sql, file=s_buf)

```

Reading tables

`read_sql_table()` will read a database table given the table name and optionally a subset of columns to read.

Note: In order to use `read_sql_table()`, you **must** have the SQLAlchemy optional dependency installed.

```
In [532]: pd.read_sql_table('data', engine)
```

```
Out[532]:
```

	index	id	Date	Col_1	Col_2	Col_3
0	0	26	2010-10-18	X	27.50	True
1	1	42	2010-10-19	Y	-12.50	False
2	2	63	2010-10-20	Z	5.73	True

You can also specify the name of the column as the DataFrame index, and specify a subset of columns to be read.

```
In [533]: pd.read_sql_table('data', engine, index_col='id')
```

```
Out[533]:
```

	index	Date	Col_1	Col_2	Col_3
id					
26	0	2010-10-18	X	27.50	True
42	1	2010-10-19	Y	-12.50	False
63	2	2010-10-20	Z	5.73	True

```
In [534]: pd.read_sql_table('data', engine, columns=['Col_1', 'Col_2'])
```

```
Out[534]:
```

Col_1	Col_2
-------	-------

```
0    X  27.50
1    Y -12.50
2    Z   5.73
```

And you can explicitly force columns to be parsed as dates:

```
In [535]: pd.read_sql_table('data', engine, parse_dates=['Date'])
```

```
Out [535]:
```

```
   index  id      Date Col_1  Col_2  Col_3
0      0  26 2010-10-18     X  27.50   True
1      1  42 2010-10-19     Y -12.50  False
2      2  63 2010-10-20     Z   5.73   True
```

If needed you can explicitly specify a format string, or a dict of arguments to pass to `pandas.to_datetime()`:

```
pd.read_sql_table('data', engine, parse_dates={'Date': '%Y-%m-%d'})
pd.read_sql_table('data', engine,
                  parse_dates={'Date': {'format': '%Y-%m-%d %H:%M:%S'}})
```

You can check if a table exists using `has_table()`

Schema support

Reading from and writing to different schema's is supported through the `schema` keyword in the `read_sql_table()` and `to_sql()` functions. Note however that this depends on the database flavor (sqlite does not have schema's). For example:

```
df.to_sql('table', engine, schema='other_schema')
pd.read_sql_table('table', engine, schema='other_schema')
```

Querying

You can query using raw SQL in the `read_sql_query()` function. In this case you must use the SQL variant appropriate for your database. When using SQLAlchemy, you can also pass SQLAlchemy Expression language constructs, which are database-agnostic.

```
In [536]: pd.read_sql_query('SELECT * FROM data', engine)
```

```
Out [536]:
```

```
   index  id      Date Col_1  Col_2  Col_3
0      0  26 2010-10-18 00:00:00.000000     X  27.50    1
1      1  42 2010-10-19 00:00:00.000000     Y -12.50    0
2      2  63 2010-10-20 00:00:00.000000     Z   5.73    1
```

Of course, you can specify a more “complex” query.

```
In [537]: pd.read_sql_query("SELECT id, Col_1, Col_2 FROM data WHERE id = 42;", engine)
```

```
Out [537]:
```

```
   id Col_1  Col_2
0  42     Y -12.5
```

The `read_sql_query()` function supports a `chunksize` argument. Specifying this will return an iterator through chunks of the query result:

```
In [538]: df = pd.DataFrame(np.random.randn(20, 3), columns=list('abc'))
```

```
In [539]: df.to_sql('data_chunks', engine, index=False)
```

```
In [540]: for chunk in pd.read_sql_query("SELECT * FROM data_chunks",
.....:                                 engine, chunksize=5):
.....:     print(chunk)
.....:
```

	a	b	c
0	1.305880	1.962862	-0.365194
1	0.193323	2.602824	-0.896993
2	-2.389181	-1.261600	0.868444
3	0.393496	0.609451	-0.845067
4	-0.322214	-0.447158	0.284659
	a	b	c
0	0.201085	-0.048657	0.720448
1	-0.137165	-0.684949	-0.519145
2	1.271559	-0.861960	0.105051
3	-0.541846	-0.103767	-1.095443
4	-1.361663	1.684795	-0.891315
	a	b	c
0	-0.539063	-0.544872	1.480449
1	0.613611	0.709609	-0.599927
2	0.100530	0.380645	-1.272573
3	-0.868754	0.111400	-1.851400
4	-0.034434	0.323798	-0.247849
	a	b	c
0	1.900594	-0.746429	-0.317105
1	-0.095588	-0.781659	0.205437
2	-0.407292	-0.007602	-0.257895
3	2.356896	-0.650727	0.813023
4	1.094871	0.784225	-0.217173

You can also run a plain query without creating a `DataFrame` with `execute()`. This is useful for queries that don't return values, such as `INSERT`. This is functionally equivalent to calling `execute` on the `SQLAlchemy` engine or `db` connection object. Again, you must use the `SQL` syntax variant appropriate for your database.

```
from pandas.io import sql
sql.execute('SELECT * FROM table_name', engine)
sql.execute('INSERT INTO table_name VALUES(?, ?, ?)', engine,
           params=[('id', 1, 12.2, True)])
```

Engine connection examples

To connect with `SQLAlchemy` you use the `create_engine()` function to create an engine object from database URI. You only need to create the engine once per database you are connecting to.

```
from sqlalchemy import create_engine

engine = create_engine('postgresql://scott:tiger@localhost:5432/mydatabase')
```

(continues on next page)

(continued from previous page)

```

engine = create_engine('mysql+mysqldb://scott:tiger@localhost/foo')

engine = create_engine('oracle://scott:tiger@127.0.0.1:1521/sidname')

engine = create_engine('mssql+pyodbc://mydsn')

# sqlite://<nohostname>/<path>
# where <path> is relative:
engine = create_engine('sqlite:///foo.db')

# or absolute, starting with a slash:
engine = create_engine('sqlite:///absolute/path/to/foo.db')

```

For more information see the examples the SQLAlchemy documentation

Advanced SQLAlchemy queries

You can use SQLAlchemy constructs to describe your query.

Use `sqlalchemy.text()` to specify query parameters in a backend-neutral way

```

In [541]: import sqlalchemy as sa

In [542]: pd.read_sql(sa.text('SELECT * FROM data where Col_1=:col1'),
.....:                engine, params={'col1': 'X'})
.....:
Out[542]:
   index  id          Date Col_1  Col_2  Col_3
0      0  26  2010-10-18 00:00:00.000000    X   27.5    1

```

If you have an SQLAlchemy description of your database you can express where conditions using SQLAlchemy expressions

```

In [543]: metadata = sa.MetaData()

In [544]: data_table = sa.Table('data', metadata,
.....:                          sa.Column('index', sa.Integer),
.....:                          sa.Column('Date', sa.DateTime),
.....:                          sa.Column('Col_1', sa.String),
.....:                          sa.Column('Col_2', sa.Float),
.....:                          sa.Column('Col_3', sa.Boolean),
.....:                          )
.....:

In [545]: pd.read_sql(sa.select([data_table]).where(data_table.c.Col_3 is True), engine)
Out[545]:
Empty DataFrame
Columns: [index, Date, Col_1, Col_2, Col_3]
Index: []

```

You can combine SQLAlchemy expressions with parameters passed to `read_sql()` using `sqlalchemy.bindparam()`

```
In [546]: import datetime as dt

In [547]: expr = sa.select([data_table]).where(data_table.c.Date > sa.bindparam('date'))

In [548]: pd.read_sql(expr, engine, params={'date': dt.datetime(2010, 10, 18)})
Out[548]:
```

	index	Date	Col_1	Col_2	Col_3
0	1	2010-10-19	Y	-12.50	False
1	2	2010-10-20	Z	5.73	True

SQLite fallback

The use of sqlite is supported without using SQLAlchemy. This mode requires a Python database adapter which respect the [Python DB-API](#).

You can create connections like so:

```
import sqlite3
con = sqlite3.connect(':memory:')
```

And then issue the following queries:

```
data.to_sql('data', con)
pd.read_sql_query("SELECT * FROM data", con)
```

4.1.13 Google BigQuery

Warning: Starting in 0.20.0, pandas has split off Google BigQuery support into the separate package `pandas-gbq`. You can `pip install pandas-gbq` to get it.

The `pandas-gbq` package provides functionality to read/write from Google BigQuery.

pandas integrates with this external package. if `pandas-gbq` is installed, you can use the pandas methods `pd.read_gbq` and `DataFrame.to_gbq`, which will call the respective functions from `pandas-gbq`.

Full documentation can be found [here](#).

4.1.14 Stata format

Writing to stata format

The method `to_stata()` will write a `DataFrame` into a `.dta` file. The format version of this file is always 115 (Stata 12).

```
In [549]: df = pd.DataFrame(np.random.randn(10, 2), columns=list('AB'))

In [550]: df.to_stata('stata.dta')
```

Stata data files have limited data type support; only strings with 244 or fewer characters, `int8`, `int16`, `int32`, `float32` and `float64` can be stored in `.dta` files. Additionally, *Stata* reserves certain values to represent missing data. Exporting a non-missing value that is outside of the permitted range in *Stata* for a particular data type will retype the variable to the next larger size. For example, `int8` values are restricted to lie between -127 and 100 in *Stata*, and so variables with values above 100 will trigger a conversion to `int16`. `nan` values in floating points data types are stored as the basic missing data type (`.` in *Stata*).

Note: It is not possible to export missing data values for integer data types.

The *Stata* writer gracefully handles other data types including `int64`, `bool`, `uint8`, `uint16`, `uint32` by casting to the smallest supported type that can represent the data. For example, data with a type of `uint8` will be cast to `int8` if all values are less than 100 (the upper bound for non-missing `int8` data in *Stata*), or, if values are outside of this range, the variable is cast to `int16`.

Warning: Conversion from `int64` to `float64` may result in a loss of precision if `int64` values are larger than $2^{*}53$.

Warning: `StataWriter` and `to_stata()` only support fixed width strings containing up to 244 characters, a limitation imposed by the version 115 *dta* file format. Attempting to write *Stata* *dta* files with strings longer than 244 characters raises a `ValueError`.

Reading from *Stata* format

The top-level function `read_stata` will read a *dta* file and return either a `DataFrame` or a `StataReader` that can be used to read the file incrementally.

```
In [551]: pd.read_stata('stata.dta')
```

```
Out [551]:
```

	index	A	B
0	0	-2.802620	-1.031153
1	1	-0.471722	-1.004288
2	2	-0.809833	1.537958
3	3	-0.833349	2.502008
4	4	-1.016559	-0.583782
5	5	-0.369422	0.146956
6	6	-0.815559	-1.032447
7	7	0.676818	-0.410341
8	8	1.171674	2.227913
9	9	0.764637	1.540163

Specifying a `chunksize` yields a `StataReader` instance that can be used to read `chunksize` lines from the file at a time. The `StataReader` object can be used as an iterator.

```
In [552]: reader = pd.read_stata('stata.dta', chunksize=3)
```

```
In [553]: for df in reader:
.....:     print(df.shape)
.....:
(3, 3)
```

(continues on next page)

(continued from previous page)

```
(3, 3)
(3, 3)
(1, 3)
```

For more fine-grained control, use `iterator=True` and specify `chunksize` with each call to `read()`.

```
In [554]: reader = pd.read_stata('stata.dta', iterator=True)
In [555]: chunk1 = reader.read(5)
In [556]: chunk2 = reader.read(5)
```

Currently the `index` is retrieved as a column.

The parameter `convert_categoricals` indicates whether value labels should be read and used to create a `Categorical` variable from them. Value labels can also be retrieved by the function `value_labels`, which requires `read()` to be called before use.

The parameter `convert_missing` indicates whether missing value representations in Stata should be preserved. If `False` (the default), missing values are represented as `np.nan`. If `True`, missing values are represented using `StataMissingValue` objects, and columns containing missing values will have `object` data type.

Note: `read_stata()` and `StataReader` support `.dta` formats 113-115 (Stata 10-12), 117 (Stata 13), and 118 (Stata 14).

Note: Setting `preserve_dtypes=False` will upcast to the standard pandas data types: `int64` for all integer types and `float64` for floating point data. By default, the Stata data types are preserved when importing.

Categorical data

`Categorical` data can be exported to *Stata* data files as value labeled data. The exported data consists of the underlying category codes as integer data values and the categories as value labels. *Stata* does not have an explicit equivalent to a `Categorical` and information about *whether* the variable is ordered is lost when exporting.

Warning: *Stata* only supports string value labels, and so `str` is called on the categories when exporting data. Exporting `Categorical` variables with non-string categories produces a warning, and can result a loss of information if the `str` representations of the categories are not unique.

Labeled data can similarly be imported from *Stata* data files as `Categorical` variables using the keyword argument `convert_categoricals` (`True` by default). The keyword argument `order_categoricals` (`True` by default) determines whether imported `Categorical` variables are ordered.

Note: When importing categorical data, the values of the variables in the *Stata* data file are not preserved since `Categorical` variables always use integer data types between `-1` and `n-1` where `n` is the number of categories. If the original values in the *Stata* data file are required, these can be imported by setting

`convert_categoricals=False`, which will import original data (but not the variable labels). The original values can be matched to the imported categorical data since there is a simple mapping between the original *Stata* data values and the category codes of imported Categorical variables: missing values are assigned code -1, and the smallest original value is assigned 0, the second smallest is assigned 1 and so on until the largest original value is assigned the code `n-1`.

Note: *Stata* supports partially labeled series. These series have value labels for some but not all data values. Importing a partially labeled series will produce a Categorical with string categories for the values that are labeled and numeric categories for values with no label.

4.1.15 SAS formats

The top-level function `read_sas()` can read (but not write) SAS *xport* (.XPT) and (since *v0.18.0*) *SAS7BDAT* (.sas7bdat) format files.

SAS files only contain two value types: ASCII text and floating point values (usually 8 bytes but sometimes truncated). For *xport* files, there is no automatic type conversion to integers, dates, or categoricals. For *SAS7BDAT* files, the format codes may allow date variables to be automatically converted to dates. By default the whole file is read and returned as a **DataFrame**.

Specify a `chunksize` or use `iterator=True` to obtain reader objects (**XportReader** or **SAS7BDATReader**) for incrementally reading the file. The reader objects also have attributes that contain additional information about the file and its variables.

Read a *SAS7BDAT* file:

```
df = pd.read_sas('sas_data.sas7bdat')
```

Obtain an iterator and read an *XPORT* file 100,000 lines at a time:

```
def do_something(chunk):
    pass

rdr = pd.read_sas('sas_xport.xpt', chunk=100000)
for chunk in rdr:
    do_something(chunk)
```

The [specification](#) for the *xport* file format is available from the SAS web site.

No official documentation is available for the *SAS7BDAT* format.

4.1.16 Other file formats

pandas itself only supports IO with a limited set of file formats that map cleanly to its tabular data model. For reading and writing other file formats into and from *pandas*, we recommend these packages from the broader community.

netCDF

xarray provides data structures inspired by the *pandas* **DataFrame** for working with multi-dimensional datasets, with a focus on the *netCDF* file format and easy conversion to and from *pandas*.

4.1.17 Performance considerations

This is an informal comparison of various IO methods, using pandas 0.20.3. Timings are machine dependent and small differences should be ignored.

```
In [1]: sz = 1000000
In [2]: df = pd.DataFrame({'A': np.random.randn(sz), 'B': [1] * sz})

In [3]: df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 1000000 entries, 0 to 999999
Data columns (total 2 columns):
A      1000000 non-null float64
B      1000000 non-null int64
dtypes: float64(1), int64(1)
memory usage: 15.3 MB
```

Given the next test set:

```
from numpy.random import randn

sz = 1000000
df = pd.DataFrame({'A': randn(sz), 'B': [1] * sz})

def test_sql_write(df):
    if os.path.exists('test.sql'):
        os.remove('test.sql')
    sql_db = sqlite3.connect('test.sql')
    df.to_sql(name='test_table', con=sql_db)
    sql_db.close()

def test_sql_read():
    sql_db = sqlite3.connect('test.sql')
    pd.read_sql_query("select * from test_table", sql_db)
    sql_db.close()

def test_hdf_fixed_write(df):
    df.to_hdf('test_fixed.hdf', 'test', mode='w')

def test_hdf_fixed_read():
    pd.read_hdf('test_fixed.hdf', 'test')

def test_hdf_fixed_write_compress(df):
    df.to_hdf('test_fixed_compress.hdf', 'test', mode='w', complib='blosc')

def test_hdf_fixed_read_compress():
    pd.read_hdf('test_fixed_compress.hdf', 'test')
```

(continues on next page)

(continued from previous page)

```
def test_hdf_table_write(df):
    df.to_hdf('test_table.hdf', 'test', mode='w', format='table')

def test_hdf_table_read():
    pd.read_hdf('test_table.hdf', 'test')

def test_hdf_table_write_compress(df):
    df.to_hdf('test_table_compress.hdf', 'test', mode='w',
              complib='blosc', format='table')

def test_hdf_table_read_compress():
    pd.read_hdf('test_table_compress.hdf', 'test')

def test_csv_write(df):
    df.to_csv('test.csv', mode='w')

def test_csv_read():
    pd.read_csv('test.csv', index_col=0)

def test_feather_write(df):
    df.to_feather('test.feather')

def test_feather_read():
    pd.read_feather('test.feather')

def test_pickle_write(df):
    df.to_pickle('test.pkl')

def test_pickle_read():
    pd.read_pickle('test.pkl')

def test_pickle_write_compress(df):
    df.to_pickle('test.pkl.compress', compression='xz')

def test_pickle_read_compress():
    pd.read_pickle('test.pkl.compress', compression='xz')
```

When writing, the top-three functions in terms of speed are `test_pickle_write`, `test_feather_write` and `test_hdf_fixed_write_compress`.

```
In [14]: %timeit test_sql_write(df)
2.37 s ± 36.6 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [15]: %timeit test_hdf_fixed_write(df)
194 ms ± 65.9 ms per loop (mean ± std. dev. of 7 runs, 10 loops each)

In [26]: %timeit test_hdf_fixed_write_compress(df)
119 ms ± 2.15 ms per loop (mean ± std. dev. of 7 runs, 10 loops each)

In [16]: %timeit test_hdf_table_write(df)
623 ms ± 125 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [27]: %timeit test_hdf_table_write_compress(df)
563 ms ± 23.7 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [17]: %timeit test_csv_write(df)
3.13 s ± 49.9 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [30]: %timeit test_feather_write(df)
103 ms ± 5.88 ms per loop (mean ± std. dev. of 7 runs, 10 loops each)

In [31]: %timeit test_pickle_write(df)
109 ms ± 3.72 ms per loop (mean ± std. dev. of 7 runs, 10 loops each)

In [32]: %timeit test_pickle_write_compress(df)
3.33 s ± 55.2 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)
```

When reading, the top three are `test_feather_read`, `test_pickle_read` and `test_hdf_fixed_read`.

```
In [18]: %timeit test_sql_read()
1.35 s ± 14.7 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [19]: %timeit test_hdf_fixed_read()
14.3 ms ± 438 µs per loop (mean ± std. dev. of 7 runs, 100 loops each)

In [28]: %timeit test_hdf_fixed_read_compress()
23.5 ms ± 672 µs per loop (mean ± std. dev. of 7 runs, 10 loops each)

In [20]: %timeit test_hdf_table_read()
35.4 ms ± 314 µs per loop (mean ± std. dev. of 7 runs, 10 loops each)

In [29]: %timeit test_hdf_table_read_compress()
42.6 ms ± 2.1 ms per loop (mean ± std. dev. of 7 runs, 10 loops each)

In [22]: %timeit test_csv_read()
516 ms ± 27.1 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [33]: %timeit test_feather_read()
4.06 ms ± 115 µs per loop (mean ± std. dev. of 7 runs, 100 loops each)

In [34]: %timeit test_pickle_read()
6.5 ms ± 172 µs per loop (mean ± std. dev. of 7 runs, 100 loops each)
```

(continues on next page)

(continued from previous page)

```
In [35]: %timeit test_pickle_read_compress()
588 ms ± 3.57 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)
```

4.2 Indexing and selecting data

The axis labeling information in pandas objects serves many purposes:

- Identifies data (i.e. provides *metadata*) using known indicators, important for analysis, visualization, and interactive console display.
- Enables automatic and explicit data alignment.
- Allows intuitive getting and setting of subsets of the data set.

In this section, we will focus on the final point: namely, how to slice, dice, and generally get and set subsets of pandas objects. The primary focus will be on Series and DataFrame as they have received more development attention in this area.

Note: The Python and NumPy indexing operators `[]` and attribute operator `.` provide quick and easy access to pandas data structures across a wide range of use cases. This makes interactive work intuitive, as there's little new to learn if you already know how to deal with Python dictionaries and NumPy arrays. However, since the type of the data to be accessed isn't known in advance, directly using standard operators has some optimization limits. For production code, we recommended that you take advantage of the optimized pandas data access methods exposed in this chapter.

Warning: Whether a copy or a reference is returned for a setting operation, may depend on the context. This is sometimes called **chained assignment** and should be avoided. See *Returning a View versus Copy*.

Warning: Indexing on an integer-based Index with floats has been clarified in 0.18.0, for a summary of the changes, see *here*.

See the *MultiIndex / Advanced Indexing* for `MultiIndex` and more advanced indexing documentation.

See the *cookbook* for some advanced strategies.

4.2.1 Different choices for indexing

Object selection has had a number of user-requested additions in order to support more explicit location based indexing. Pandas now supports three types of multi-axis indexing.

- `.loc` is primarily label based, but may also be used with a boolean array. `.loc` will raise `KeyError` when the items are not found. Allowed inputs are:
 - A single label, e.g. 5 or 'a' (Note that 5 is interpreted as a *label* of the index. This use is **not** an integer position along the index.).
 - A list or array of labels ['a', 'b', 'c'].
 - A slice object with labels 'a':'f' (Note that contrary to usual python slices, **both** the start and the stop are included, when present in the index! See *Slicing with labels* and *Endpoints are inclusive.*)
 - A boolean array
 - A `callable` function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above).

New in version 0.18.1.

See more at *Selection by Label*.

- `.iloc` is primarily integer position based (from 0 to `length-1` of the axis), but may also be used with a boolean array. `.iloc` will raise `IndexError` if a requested indexer is out-of-bounds, except *slice* indexers which allow out-of-bounds indexing. (this conforms with Python/NumPy *slice* semantics). Allowed inputs are:
 - An integer e.g. 5.
 - A list or array of integers [4, 3, 0].
 - A slice object with ints 1:7.
 - A boolean array.
 - A `callable` function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above).

New in version 0.18.1.

See more at *Selection by Position*, *Advanced Indexing* and *Advanced Hierarchical*.

- `.loc`, `.iloc`, and also `[]` indexing can accept a `callable` as indexer. See more at *Selection By Callable*.

Getting values from an object with multi-axes selection uses the following notation (using `.loc` as an example, but the following applies to `.iloc` as well). Any of the axes accessors may be the null slice `:`. Axes left out of the specification are assumed to be `:`, e.g. `p.loc['a']` is equivalent to `p.loc['a', :, :]`.

Object Type	Indexers
Series	<code>s.loc[indexer]</code>
DataFrame	<code>df.loc[row_indexer, column_indexer]</code>

4.2.2 Basics

As mentioned when introducing the data structures in the *last section*, the primary function of indexing with `[]` (a.k.a. `__getitem__` for those familiar with implementing class behavior in Python) is selecting out

lower-dimensional slices. The following table shows return type values when indexing pandas objects with []:

Object Type	Selection	Return Value Type
Series	series[label]	scalar value
DataFrame	frame[colname]	Series corresponding to colname

Here we construct a simple time series data set to use for illustrating the indexing functionality:

```
In [1]: dates = pd.date_range('1/1/2000', periods=8)
In [2]: df = pd.DataFrame(np.random.randn(8, 4),
...:                      index=dates, columns=['A', 'B', 'C', 'D'])
...:
In [3]: df
Out[3]:
```

	A	B	C	D
2000-01-01	-1.157426	-0.096491	0.999344	-1.482012
2000-01-02	0.189291	0.926828	-0.029095	1.776600
2000-01-03	-1.334294	2.085399	-0.633036	0.208208
2000-01-04	-1.723333	-0.355486	-0.143959	0.177635
2000-01-05	1.071746	-0.516876	-0.382709	0.888600
2000-01-06	-0.156260	-0.720254	-0.837161	-0.426902
2000-01-07	-0.354174	0.510804	0.156535	0.294767
2000-01-08	-1.448608	-1.191084	-0.128338	-0.687717

Note: None of the indexing functionality is time series specific unless specifically stated.

Thus, as per above, we have the most basic indexing using []:

```
In [4]: s = df['A']
In [5]: s[dates[5]]
Out[5]: -0.15625969875302725
```

You can pass a list of columns to [] to select columns in that order. If a column is not contained in the DataFrame, an exception will be raised. Multiple columns can also be set in this manner:

```
In [6]: df
Out[6]:
```

	A	B	C	D
2000-01-01	-1.157426	-0.096491	0.999344	-1.482012
2000-01-02	0.189291	0.926828	-0.029095	1.776600
2000-01-03	-1.334294	2.085399	-0.633036	0.208208
2000-01-04	-1.723333	-0.355486	-0.143959	0.177635
2000-01-05	1.071746	-0.516876	-0.382709	0.888600
2000-01-06	-0.156260	-0.720254	-0.837161	-0.426902
2000-01-07	-0.354174	0.510804	0.156535	0.294767
2000-01-08	-1.448608	-1.191084	-0.128338	-0.687717

```
In [7]: df[['B', 'A']] = df[['A', 'B']]
```

(continues on next page)

(continued from previous page)

```
In [8]: df
Out[8]:
```

	A	B	C	D
2000-01-01	-0.096491	-1.157426	0.999344	-1.482012
2000-01-02	0.926828	0.189291	-0.029095	1.776600
2000-01-03	2.085399	-1.334294	-0.633036	0.208208
2000-01-04	-0.355486	-1.723333	-0.143959	0.177635
2000-01-05	-0.516876	1.071746	-0.382709	0.888600
2000-01-06	-0.720254	-0.156260	-0.837161	-0.426902
2000-01-07	0.510804	-0.354174	0.156535	0.294767
2000-01-08	-1.191084	-1.448608	-0.128338	-0.687717

You may find this useful for applying a transform (in-place) to a subset of the columns.

Warning: pandas aligns all AXES when setting `Series` and `DataFrame` from `.loc`, and `.iloc`.

This will **not** modify `df` because the column alignment is before value assignment.

```
In [9]: df[['A', 'B']]
Out[9]:
```

	A	B
2000-01-01	-0.096491	-1.157426
2000-01-02	0.926828	0.189291
2000-01-03	2.085399	-1.334294
2000-01-04	-0.355486	-1.723333
2000-01-05	-0.516876	1.071746
2000-01-06	-0.720254	-0.156260
2000-01-07	0.510804	-0.354174
2000-01-08	-1.191084	-1.448608

```
In [10]: df.loc[:, ['B', 'A']] = df[['A', 'B']]
```

```
In [11]: df[['A', 'B']]
Out[11]:
```

	A	B
2000-01-01	-0.096491	-1.157426
2000-01-02	0.926828	0.189291
2000-01-03	2.085399	-1.334294
2000-01-04	-0.355486	-1.723333
2000-01-05	-0.516876	1.071746
2000-01-06	-0.720254	-0.156260
2000-01-07	0.510804	-0.354174
2000-01-08	-1.191084	-1.448608

The correct way to swap column values is by using raw values:

```
In [12]: df.loc[:, ['B', 'A']] = df[['A', 'B']].to_numpy()
```

```
In [13]: df[['A', 'B']]
```

```
Out[13]:
```

	A	B
2000-01-01	-1.157426	-0.096491
2000-01-02	0.189291	0.926828
2000-01-03	-1.334294	2.085399
2000-01-04	-1.723333	-0.355486
2000-01-05	1.071746	-0.516876
2000-01-06	-0.156260	-0.720254
2000-01-07	-0.354174	0.510804
2000-01-08	-1.448608	-1.191084

4.2.3 Attribute access

You may access an index on a `Series` or column on a `DataFrame` directly as an attribute:

```
In [14]: sa = pd.Series([1, 2, 3], index=list('abc'))
```

```
In [15]: dfa = df.copy()
```

```
In [16]: sa.b
```

```
Out[16]: 2
```

```
In [17]: dfa.A
```

```
Out[17]:
```

2000-01-01	-1.157426
2000-01-02	0.189291
2000-01-03	-1.334294
2000-01-04	-1.723333
2000-01-05	1.071746
2000-01-06	-0.156260
2000-01-07	-0.354174
2000-01-08	-1.448608

```
Freq: D, Name: A, dtype: float64
```

```
In [18]: sa.a = 5
```

```
In [19]: sa
```

```
Out[19]:
```

a	5
b	2
c	3

```
dtype: int64
```

```
In [20]: dfa.A = list(range(len(dfa.index))) # ok if A already exists
```

```
In [21]: dfa
```

```
Out[21]:
```

(continues on next page)

(continued from previous page)

```

      A      B      C      D
2000-01-01  0 -0.096491  0.999344 -1.482012
2000-01-02  1  0.926828 -0.029095  1.776600
2000-01-03  2  2.085399 -0.633036  0.208208
2000-01-04  3 -0.355486 -0.143959  0.177635
2000-01-05  4 -0.516876 -0.382709  0.888600
2000-01-06  5 -0.720254 -0.837161 -0.426902
2000-01-07  6  0.510804  0.156535  0.294767
2000-01-08  7 -1.191084 -0.128338 -0.687717

```

```
In [22]: dfa['A'] = list(range(len(dfa.index))) # use this form to create a new column
```

```
In [23]: dfa
```

```
Out [23]:
```

```

      A      B      C      D
2000-01-01  0 -0.096491  0.999344 -1.482012
2000-01-02  1  0.926828 -0.029095  1.776600
2000-01-03  2  2.085399 -0.633036  0.208208
2000-01-04  3 -0.355486 -0.143959  0.177635
2000-01-05  4 -0.516876 -0.382709  0.888600
2000-01-06  5 -0.720254 -0.837161 -0.426902
2000-01-07  6  0.510804  0.156535  0.294767
2000-01-08  7 -1.191084 -0.128338 -0.687717

```

Warning:

- You can use this access only if the index element is a valid Python identifier, e.g. `s.1` is not allowed. See [here](#) for an explanation of valid identifiers.
- The attribute will not be available if it conflicts with an existing method name, e.g. `s.min` is not allowed.
- Similarly, the attribute will not be available if it conflicts with any of the following list: `index`, `major_axis`, `minor_axis`, `items`.
- In any of these cases, standard indexing will still work, e.g. `s['1']`, `s['min']`, and `s['index']` will access the corresponding element or column.

If you are using the IPython environment, you may also use tab-completion to see these accessible attributes.

You can also assign a dict to a row of a DataFrame:

```
In [24]: x = pd.DataFrame({'x': [1, 2, 3], 'y': [3, 4, 5]})
```

```
In [25]: x.iloc[1] = {'x': 9, 'y': 99}
```

```
In [26]: x
```

```
Out [26]:
```

```

   x  y
0  1  3
1  9 99
2  3  5

```

You can use attribute access to modify an existing element of a Series or column of a DataFrame, but be careful; if you try to use attribute access to create a new column, it creates a new attribute rather than a new column. In 0.21.0 and later, this will raise a `UserWarning`:

```
In [1]: df = pd.DataFrame({'one': [1., 2., 3.]})
In [2]: df.two = [4, 5, 6]
UserWarning: Pandas doesn't allow Series to be assigned into nonexistent columns - see
↳ https://pandas.pydata.org/pandas-docs/stable/indexing.html#attribute_access
In [3]: df
Out[3]:
   one
0  1.0
1  2.0
2  3.0
```

4.2.4 Slicing ranges

The most robust and consistent way of slicing ranges along arbitrary axes is described in the *Selection by Position* section detailing the `.iloc` method. For now, we explain the semantics of slicing using the `[]` operator.

With Series, the syntax works exactly as with an ndarray, returning a slice of the values and the corresponding labels:

```
In [27]: s[:5]
Out[27]:
2000-01-01    -1.157426
2000-01-02     0.189291
2000-01-03    -1.334294
2000-01-04    -1.723333
2000-01-05     1.071746
Freq: D, Name: A, dtype: float64
```

```
In [28]: s[::2]
Out[28]:
2000-01-01    -1.157426
2000-01-03    -1.334294
2000-01-05     1.071746
2000-01-07    -0.354174
Freq: 2D, Name: A, dtype: float64
```

```
In [29]: s[::-1]
Out[29]:
2000-01-08    -1.448608
2000-01-07    -0.354174
2000-01-06    -0.156260
2000-01-05     1.071746
2000-01-04    -1.723333
2000-01-03    -1.334294
2000-01-02     0.189291
2000-01-01    -1.157426
Freq: -1D, Name: A, dtype: float64
```

Note that setting works as well:

```
In [30]: s2 = s.copy()
```

```
In [31]: s2[:5] = 0
```

```
In [32]: s2
```

```
Out [32]:
```

```
2000-01-01    0.000000
2000-01-02    0.000000
2000-01-03    0.000000
2000-01-04    0.000000
2000-01-05    0.000000
2000-01-06   -0.156260
2000-01-07   -0.354174
2000-01-08   -1.448608
Freq: D, Name: A, dtype: float64
```

With DataFrame, slicing inside of `[]` **slices the rows**. This is provided largely as a convenience since it is such a common operation.

```
In [33]: df[:3]
```

```
Out [33]:
```

```
          A          B          C          D
2000-01-01 -1.157426 -0.096491  0.999344 -1.482012
2000-01-02  0.189291  0.926828 -0.029095  1.776600
2000-01-03 -1.334294  2.085399 -0.633036  0.208208
```

```
In [34]: df[::-1]
```

```
Out [34]:
```

```
          A          B          C          D
2000-01-08 -1.448608 -1.191084 -0.128338 -0.687717
2000-01-07 -0.354174  0.510804  0.156535  0.294767
2000-01-06 -0.156260 -0.720254 -0.837161 -0.426902
2000-01-05  1.071746 -0.516876 -0.382709  0.888600
2000-01-04 -1.723333 -0.355486 -0.143959  0.177635
2000-01-03 -1.334294  2.085399 -0.633036  0.208208
2000-01-02  0.189291  0.926828 -0.029095  1.776600
2000-01-01 -1.157426 -0.096491  0.999344 -1.482012
```

4.2.5 Selection by label

Warning: Whether a copy or a reference is returned for a setting operation, may depend on the context. This is sometimes called **chained assignment** and should be avoided. See *Returning a View versus Copy*.

Warning:

`.loc` is strict when you present slicers that are not compatible (or convertible) with the index type. For example using integers in a `DatetimeIndex`. These will raise a `TypeError`.

```
In [35]: df1 = pd.DataFrame(np.random.randn(5, 4),
.....:                      columns=list('ABCD'),
.....:                      index=pd.date_range('20130101', periods=5))
.....:
```

```
In [36]: df1
```

```
Out[36]:
```

	A	B	C	D
2013-01-01	-2.100928	1.025928	-0.007973	-1.336035
2013-01-02	0.915382	-0.130655	0.022627	-1.425459
2013-01-03	0.271939	0.169543	0.692513	-1.231139
2013-01-04	1.692870	0.783855	-0.721626	1.698994
2013-01-05	-0.349882	1.586451	1.454199	0.149458

```
In [4]: df1.loc[2:3]
```

```
TypeError: cannot do slice indexing on <class 'pandas.tseries.index.DatetimeIndex'>
↳with these indexers [2] of <type 'int'>
```

String likes in slicing *can* be convertible to the type of the index and lead to natural slicing.

```
In [37]: df1.loc['20130102':'20130104']
```

```
Out[37]:
```

	A	B	C	D
2013-01-02	0.915382	-0.130655	0.022627	-1.425459
2013-01-03	0.271939	0.169543	0.692513	-1.231139
2013-01-04	1.692870	0.783855	-0.721626	1.698994

Warning: Starting in 0.21.0, pandas will show a `FutureWarning` if indexing with a list with missing labels. In the future this will raise a `KeyError`. See *list-like Using loc with missing keys in a list is Deprecated*.

pandas provides a suite of methods in order to have **purely label based indexing**. This is a strict inclusion based protocol. Every label asked for must be in the index, or a `KeyError` will be raised. When slicing, both the start bound **AND** the stop bound are *included*, if present in the index. Integers are valid labels, but they refer to the label **and not the position**.

The `.loc` attribute is the primary access method. The following are valid inputs:

- A single label, e.g. 5 or 'a' (Note that 5 is interpreted as a *label* of the index. This use is **not** an integer position along the index.).
- A list or array of labels ['a', 'b', 'c'].
- A slice object with labels 'a':'f' (Note that contrary to usual python slices, **both** the start and the stop are included, when present in the index! See *Slicing with labels*).
- A boolean array.
- A callable, see *Selection By Callable*.

```
In [38]: s1 = pd.Series(np.random.randn(6), index=list('abcdef'))
```

```
In [39]: s1
```

```
Out[39]:
```

```
a    1.018393
b   -0.565651
c   -1.590951
d   -0.651777
e    0.456407
f    1.134054
dtype: float64
```

```
In [40]: s1.loc['c:']
Out[40]:
c   -1.590951
d   -0.651777
e    0.456407
f    1.134054
dtype: float64
```

```
In [41]: s1.loc['b']
Out[41]: -0.5656513106035832
```

Note that setting works as well:

```
In [42]: s1.loc['c:'] = 0
```

```
In [43]: s1
Out[43]:
a    1.018393
b   -0.565651
c    0.000000
d    0.000000
e    0.000000
f    0.000000
dtype: float64
```

With a DataFrame:

```
In [44]: df1 = pd.DataFrame(np.random.randn(6, 4),
.....:                      index=list('abcdef'),
.....:                      columns=list('ABCD'))
.....:
```

```
In [45]: df1
Out[45]:
```

	A	B	C	D
a	1.695493	1.632303	-1.726092	0.486227
b	-0.625187	0.386616	-0.048112	-2.598355
c	-0.871135	-0.209156	0.004590	0.449006
d	0.573428	0.697186	-2.442512	-1.423556
e	-0.304997	0.672794	0.954090	1.323584
f	0.015720	-0.815293	0.164562	0.576599

```
In [46]: df1.loc[['a', 'b', 'd'], :]
Out[46]:
```

	A	B	C	D
a	1.695493	1.632303	-1.726092	0.486227
b	-0.625187	0.386616	-0.048112	-2.598355

```
d 0.573428 0.697186 -2.442512 -1.423556
```

Accessing via label slices:

```
In [47]: df1.loc['d':, 'A':'C']
Out[47]:
```

	A	B	C
d	0.573428	0.697186	-2.442512
e	-0.304997	0.672794	0.954090
f	0.015720	-0.815293	0.164562

For getting a cross section using a label (equivalent to `df.xs('a')`):

```
In [48]: df1.loc['a']
Out[48]:
```

	A	B	C	D
a	1.695493	1.632303	-1.726092	0.486227

Name: a, dtype: float64

For getting values with a boolean array:

```
In [49]: df1.loc['a'] > 0
Out[49]:
```

	A	B	C	D
a	True	True	False	True

Name: a, dtype: bool

```
In [50]: df1.loc[:, df1.loc['a'] > 0]
Out[50]:
```

	A	B	D
a	1.695493	1.632303	0.486227
b	-0.625187	0.386616	-2.598355
c	-0.871135	-0.209156	0.449006
d	0.573428	0.697186	-1.423556
e	-0.304997	0.672794	1.323584
f	0.015720	-0.815293	0.576599

For getting a value explicitly (equivalent to deprecated `df.get_value('a', 'A')`):

```
# this is also equivalent to ``df1.at['a', 'A']``
In [51]: df1.loc['a', 'A']
Out[51]: 1.6954931738440173
```

Slicing with labels

When using `.loc` with slices, if both the start and the stop labels are present in the index, then elements *located* between the two (including them) are returned:

```
In [52]: s = pd.Series(list('abcde'), index=[0, 3, 2, 5, 4])
```

(continues on next page)

(continued from previous page)

```
In [53]: s.loc[3:5]
Out[53]:
3    b
2    c
5    d
dtype: object
```

If at least one of the two is absent, but the index is sorted, and can be compared against start and stop labels, then slicing will still work as expected, by selecting labels which *rank* between the two:

```
In [54]: s.sort_index()
Out[54]:
0    a
2    c
3    b
4    e
5    d
dtype: object
```

```
In [55]: s.sort_index().loc[1:6]
Out[55]:
2    c
3    b
4    e
5    d
dtype: object
```

However, if at least one of the two is absent *and* the index is not sorted, an error will be raised (since doing otherwise would be computationally expensive, as well as potentially ambiguous for mixed type indexes). For instance, in the above example, `s.loc[1:6]` would raise `KeyError`.

For the rationale behind this behavior, see *Endpoints are inclusive*.

4.2.6 Selection by position

Warning: Whether a copy or a reference is returned for a setting operation, may depend on the context. This is sometimes called **chained assignment** and should be avoided. See *Returning a View versus Copy*.

Pandas provides a suite of methods in order to get **purely integer based indexing**. The semantics follow closely Python and NumPy slicing. These are **0-based** indexing. When slicing, the start bound is *included*, while the upper bound is *excluded*. Trying to use a non-integer, even a **valid** label will raise an `IndexError`.

The `.iloc` attribute is the primary access method. The following are valid inputs:

- An integer e.g. 5.
- A list or array of integers [4, 3, 0].
- A slice object with ints 1:7.
- A boolean array.
- A callable, see *Selection By Callable*.

```
In [56]: s1 = pd.Series(np.random.randn(5), index=list(range(0, 10, 2)))
```

```
In [57]: s1
Out[57]:
0   -0.813837
2    1.020094
4   -0.538755
6   -0.273898
8    1.374350
dtype: float64
```

```
In [58]: s1.iloc[:3]
Out[58]:
0   -0.813837
2    1.020094
4   -0.538755
dtype: float64
```

```
In [59]: s1.iloc[3]
Out[59]: -0.2738980637291465
```

Note that setting works as well:

```
In [60]: s1.iloc[:3] = 0

In [61]: s1
Out[61]:
0    0.000000
2    0.000000
4    0.000000
6   -0.273898
8    1.374350
dtype: float64
```

With a DataFrame:

```
In [62]: df1 = pd.DataFrame(np.random.randn(6, 4),
.....:                      index=list(range(0, 12, 2)),
.....:                      columns=list(range(0, 8, 2)))
.....:

In [63]: df1
Out[63]:
      0         2         4         6
0  -0.769208 -0.094955 -0.339642  1.131238
2  -1.165074  0.191823 -0.424832  0.641310
4  -1.389117  0.367491  2.164790  1.126079
6   1.550817  0.826973 -0.677486  2.087563
8   0.117134 -0.855723  0.082120  1.276149
10  0.270969  1.210188 -0.988631 -1.253327
```

Select via integer slicing:

```
In [64]: df1.iloc[:3]
Out[64]:
```

```

      0      2      4      6
0 -0.769208 -0.094955 -0.339642  1.131238
2 -1.165074  0.191823 -0.424832  0.641310
4 -1.389117  0.367491  2.164790  1.126079

```

```
In [65]: df1.iloc[1:5, 2:4]
```

```
Out[65]:
```

```

      4      6
2 -0.424832  0.641310
4  2.164790  1.126079
6 -0.677486  2.087563
8  0.082120  1.276149

```

Select via integer list:

```
In [66]: df1.iloc[[1, 3, 5], [1, 3]]
```

```
Out[66]:
```

```

      2      6
2  0.191823  0.641310
6  0.826973  2.087563
10 1.210188 -1.253327

```

```
In [67]: df1.iloc[1:3, :]
```

```
Out[67]:
```

```

      0      2      4      6
2 -1.165074  0.191823 -0.424832  0.641310
4 -1.389117  0.367491  2.164790  1.126079

```

```
In [68]: df1.iloc[:, 1:3]
```

```
Out[68]:
```

```

      2      4
0 -0.094955 -0.339642
2  0.191823 -0.424832
4  0.367491  2.164790
6  0.826973 -0.677486
8 -0.855723  0.082120
10 1.210188 -0.988631

```

```
# this is also equivalent to ``df1.iat[1,1]``
```

```
In [69]: df1.iloc[1, 1]
```

```
Out[69]: 0.1918230563556888
```

For getting a cross section using an integer position (equiv to `df.xs(1)`):

```
In [70]: df1.iloc[1]
```

```
Out[70]:
```

```

0 -1.165074
2  0.191823
4 -0.424832
6  0.641310
Name: 2, dtype: float64

```

Out of range slice indexes are handled gracefully just as in Python/NumPy.

```
# these are allowed in python/numpy.
```

```
In [71]: x = list('abcdef')
```

```
In [72]: x
```

```
Out[72]: ['a', 'b', 'c', 'd', 'e', 'f']
```

```
In [73]: x[4:10]
```

```
Out[73]: ['e', 'f']
```

```
In [74]: x[8:10]
```

```
Out[74]: []
```

```
In [75]: s = pd.Series(x)
```

```
In [76]: s
```

```
Out[76]:
```

```
0    a
```

```
1    b
```

```
2    c
```

```
3    d
```

```
4    e
```

```
5    f
```

```
dtype: object
```

```
In [77]: s.iloc[4:10]
```

```
Out[77]:
```

```
4    e
```

```
5    f
```

```
dtype: object
```

```
In [78]: s.iloc[8:10]
```

```
Out[78]: Series([], dtype: object)
```

Note that using slices that go out of bounds can result in an empty axis (e.g. an empty DataFrame being returned).

```
In [79]: dfl = pd.DataFrame(np.random.randn(5, 2), columns=list('AB'))
```

```
In [80]: dfl
```

```
Out[80]:
```

```
      A      B
```

```
0 -1.141824  0.487982
```

```
1  1.110710  1.775785
```

```
2 -0.158929  1.256688
```

```
3  0.480722  0.545781
```

```
4 -1.214729  0.259405
```

```
In [81]: dfl.iloc[:, 2:3]
```

```
Out[81]:
```

```
Empty DataFrame
```

```
Columns: []
```

```
Index: [0, 1, 2, 3, 4]
```

```
In [82]: dfl.iloc[:, 1:3]
```

```
Out[82]:
```

```
      B
```

```
0 0.487982
1 1.775785
2 1.256688
3 0.545781
4 0.259405
```

```
In [83]: df1.iloc[4:6]
Out[83]:
```

```
      A      B
4 -1.214729  0.259405
```

A single indexer that is out of bounds will raise an `IndexError`. A list of indexers where any element is out of bounds will raise an `IndexError`.

```
>>> df1.iloc[[4, 5, 6]]
IndexError: positional indexers are out-of-bounds

>>> df1.iloc[:, 4]
IndexError: single positional indexer is out-of-bounds
```

4.2.7 Selection by callable

New in version 0.18.1.

`.loc`, `.iloc`, and also `[]` indexing can accept a callable as indexer. The callable must be a function with one argument (the calling Series or DataFrame) that returns valid output for indexing.

```
In [84]: df1 = pd.DataFrame(np.random.randn(6, 4),
.....:                      index=list('abcdef'),
.....:                      columns=list('ABCD'))
.....:
```

```
In [85]: df1
```

```
Out[85]:
      A      B      C      D
a -1.898204  0.933280  0.410757 -1.209116
b  1.072207 -2.076376 -0.032087 -1.179905
c  0.819041  0.169362  0.395066  1.793339
d  0.620358  0.687095  0.924752 -0.953211
e  0.272744 -0.264613 -0.299304  0.828769
f  1.384847  1.408420 -0.599304  1.455457
```

```
In [86]: df1.loc[lambda df: df.A > 0, :]
```

```
Out[86]:
      A      B      C      D
b  1.072207 -2.076376 -0.032087 -1.179905
c  0.819041  0.169362  0.395066  1.793339
d  0.620358  0.687095  0.924752 -0.953211
e  0.272744 -0.264613 -0.299304  0.828769
f  1.384847  1.408420 -0.599304  1.455457
```

```
In [87]: df1.loc[:, lambda df: ['A', 'B']]
```

```
Out[87]:
      A      B
```

```
a -1.898204  0.933280
b  1.072207 -2.076376
c  0.819041  0.169362
d  0.620358  0.687095
e  0.272744 -0.264613
f  1.384847  1.408420
```

```
In [88]: df1.iloc[:, lambda df: [0, 1]]
Out[88]:
```

```
      A      B
a -1.898204  0.933280
b  1.072207 -2.076376
c  0.819041  0.169362
d  0.620358  0.687095
e  0.272744 -0.264613
f  1.384847  1.408420
```

```
In [89]: df1[lambda df: df.columns[0]]
Out[89]:
```

```
a  -1.898204
b   1.072207
c   0.819041
d   0.620358
e   0.272744
f   1.384847
```

Name: A, dtype: float64

You can use callable indexing in Series.

```
In [90]: df1.A.loc[lambda s: s > 0]
Out[90]:
b    1.072207
c    0.819041
d    0.620358
e    0.272744
f    1.384847
Name: A, dtype: float64
```

Using these methods / indexers, you can chain data selection operations without using a temporary variable.

```
In [91]: bb = pd.read_csv('data/baseball.csv', index_col='id')

In [92]: (bb.groupby(['year', 'team']).sum()
.....:      .loc[lambda df: df.r > 100])
.....:
Out[92]:
```

4.2.8 IX indexer is deprecated

Warning: Starting in 0.20.0, the `.ix` indexer is deprecated, in favor of the more strict `.iloc` and `.loc` indexers.

`.ix` offers a lot of magic on the inference of what the user wants to do. To wit, `.ix` can decide to index *positionally* OR via *labels* depending on the data type of the index. This has caused quite a bit of user confusion over the years.

The recommended methods of indexing are:

- `.loc` if you want to *label* index.
- `.iloc` if you want to *positionally* index.

```
In [93]: dfd = pd.DataFrame({'A': [1, 2, 3],
.....:                      'B': [4, 5, 6]},
.....:                      index=list('abc'))
.....:
```

```
In [94]: dfd
```

```
Out [94]:
   A  B
a  1  4
b  2  5
c  3  6
```

Previous behavior, where you wish to get the 0th and the 2nd elements from the index in the 'A' column.

```
In [3]: dfd.ix[[0, 2], 'A']
```

```
Out [3]:
```

```
a    1
c    3
Name: A, dtype: int64
```

Using `.loc`. Here we will select the appropriate indexes from the index, then use *label* indexing.

```
In [95]: dfd.loc[dfd.index[[0, 2]], 'A']
Out[95]:
a    1
c    3
Name: A, dtype: int64
```

This can also be expressed using `.iloc`, by explicitly getting locations on the indexers, and using *positional* indexing to select things.

```
In [96]: dfd.iloc[[0, 2], dfd.columns.get_loc('A')]
Out[96]:
a    1
c    3
Name: A, dtype: int64
```

For getting *multiple* indexers, using `.get_indexer`:

```
In [97]: dfd.iloc[[0, 2], dfd.columns.get_indexer(['A', 'B'])]
Out[97]:
   A  B
a  1  4
c  3  6
```

4.2.9 Indexing with list with missing labels is deprecated

Warning: Starting in 0.21.0, using `.loc` or `[]` with a list with one or more missing labels, is deprecated, in favor of `.reindex`.

In prior versions, using `.loc[list-of-labels]` would work as long as *at least 1* of the keys was found (otherwise it would raise a `KeyError`). This behavior is deprecated and will show a warning message pointing to this section. The recommended alternative is to use `.reindex()`.

For example.

```
In [98]: s = pd.Series([1, 2, 3])

In [99]: s
Out[99]:
0    1
1    2
2    3
dtype: int64
```

Selection with all keys found is unchanged.

```
In [100]: s.loc[[1, 2]]
Out[100]:
1    2
2    3
dtype: int64
```

Previous behavior

```
In [4]: s.loc[[1, 2, 3]]
```

```
Out[4]:
```

```
1    2.0
2    3.0
3    NaN
dtype: float64
```

Current behavior

```
In [4]: s.loc[[1, 2, 3]]
```

Passing list-likes to `.loc` with any non-matching elements will raise `KeyError` in the future, you can use `.reindex()` as an alternative.

See the documentation here:

<http://pandas.pydata.org/pandas-docs/stable/indexing.html#deprecate-loc-reindex-listlike>

```
Out[4]:
```

```
1    2.0
2    3.0
3    NaN
dtype: float64
```

Reindexing

The idiomatic way to achieve selecting potentially not-found elements is via `.reindex()`. See also the section on *reindexing*.

```
In [101]: s.reindex([1, 2, 3])
```

```
Out[101]:
```

```
1    2.0
2    3.0
3    NaN
dtype: float64
```

Alternatively, if you want to select only *valid* keys, the following is idiomatic and efficient; it is guaranteed to preserve the dtype of the selection.

```
In [102]: labels = [1, 2, 3]
```

```
In [103]: s.loc[s.index.intersection(labels)]
```

```
Out[103]:
```

```
1    2
2    3
dtype: int64
```

Having a duplicated index will raise for a `.reindex()`:

```
In [104]: s = pd.Series(np.arange(4), index=['a', 'a', 'b', 'c'])
```

```
In [105]: labels = ['c', 'd']
```

```
In [17]: s.reindex(labels)
ValueError: cannot reindex from a duplicate axis
```

Generally, you can intersect the desired labels with the current axis, and then reindex.

```
In [106]: s.loc[s.index.intersection(labels)].reindex(labels)
Out[106]:
c    3.0
d    NaN
dtype: float64
```

However, this would *still* raise if your resulting index is duplicated.

```
In [41]: labels = ['a', 'd']

In [42]: s.loc[s.index.intersection(labels)].reindex(labels)
ValueError: cannot reindex from a duplicate axis
```

4.2.10 Selecting random samples

A random selection of rows or columns from a Series or DataFrame with the `sample()` method. The method will sample rows by default, and accepts a specific number of rows/columns to return, or a fraction of rows.

```
In [107]: s = pd.Series([0, 1, 2, 3, 4, 5])

# When no arguments are passed, returns 1 row.
In [108]: s.sample()
Out[108]:
0    0
dtype: int64

# One may specify either a number of rows:
In [109]: s.sample(n=3)
Out[109]:
2    2
1    1
5    5
dtype: int64

# Or a fraction of the rows:
In [110]: s.sample(frac=0.5)
Out[110]:
0    0
2    2
3    3
dtype: int64
```

By default, `sample` will return each row at most once, but one can also sample with replacement using the `replace` option:

```
In [111]: s = pd.Series([0, 1, 2, 3, 4, 5])

# Without replacement (default):
In [112]: s.sample(n=6, replace=False)
```

```
Out[112]:
3    3
2    2
4    4
0    0
5    5
1    1
dtype: int64
```

```
# With replacement:
In [113]: s.sample(n=6, replace=True)
Out[113]:
0    0
2    2
0    0
3    3
1    1
2    2
dtype: int64
```

By default, each row has an equal probability of being selected, but if you want rows to have different probabilities, you can pass the `sample` function sampling weights as `weights`. These weights can be a list, a NumPy array, or a Series, but they must be of the same length as the object you are sampling. Missing values will be treated as a weight of zero, and inf values are not allowed. If weights do not sum to 1, they will be re-normalized by dividing all weights by the sum of the weights. For example:

```
In [114]: s = pd.Series([0, 1, 2, 3, 4, 5])

In [115]: example_weights = [0, 0, 0.2, 0.2, 0.2, 0.4]

In [116]: s.sample(n=3, weights=example_weights)
Out[116]:
5    5
4    4
3    3
dtype: int64

# Weights will be re-normalized automatically
In [117]: example_weights2 = [0.5, 0, 0, 0, 0, 0]

In [118]: s.sample(n=1, weights=example_weights2)
Out[118]:
0    0
dtype: int64
```

When applied to a DataFrame, you can use a column of the DataFrame as sampling weights (provided you are sampling rows and not columns) by simply passing the name of the column as a string.

```
In [119]: df2 = pd.DataFrame({'col1': [9, 8, 7, 6],
.....:                       'weight_column': [0.5, 0.4, 0.1, 0]})
.....:

In [120]: df2.sample(n=3, weights='weight_column')
Out[120]:
```

(continues on next page)

(continued from previous page)

	col1	weight_column
0	9	0.5
2	7	0.1
1	8	0.4

`sample` also allows users to sample columns instead of rows using the `axis` argument.

```
In [121]: df3 = pd.DataFrame({'col1': [1, 2, 3], 'col2': [2, 3, 4]})
```

```
In [122]: df3.sample(n=1, axis=1)
```

```
Out[122]:
```

```
   col1
0     1
1     2
2     3
```

Finally, one can also set a seed for `sample`'s random number generator using the `random_state` argument, which will accept either an integer (as a seed) or a NumPy `RandomState` object.

```
In [123]: df4 = pd.DataFrame({'col1': [1, 2, 3], 'col2': [2, 3, 4]})
```

```
# With a given seed, the sample will always draw the same rows.
```

```
In [124]: df4.sample(n=2, random_state=2)
```

```
Out[124]:
```

```
   col1  col2
2     3     4
1     2     3
```

```
In [125]: df4.sample(n=2, random_state=2)
```

```
Out[125]:
```

```
   col1  col2
2     3     4
1     2     3
```

4.2.11 Setting with enlargement

The `.loc/[]` operations can perform enlargement when setting a non-existent key for that axis.

In the `Series` case this is effectively an appending operation.

```
In [126]: se = pd.Series([1, 2, 3])
```

```
In [127]: se
```

```
Out[127]:
```

```
0    1
1    2
2    3
dtype: int64
```

```
In [128]: se[5] = 5.
```

```
In [129]: se
```

(continues on next page)

(continued from previous page)

```
Out [129]:
0    1.0
1    2.0
2    3.0
5    5.0
dtype: float64
```

A `DataFrame` can be enlarged on either axis via `.loc`.

```
In [130]: dfi = pd.DataFrame(np.arange(6).reshape(3, 2),
.....:                      columns=['A', 'B'])
.....:

In [131]: dfi
Out [131]:
   A  B
0  0  1
1  2  3
2  4  5

In [132]: dfi.loc[:, 'C'] = dfi.loc[:, 'A']

In [133]: dfi
Out [133]:
   A  B  C
0  0  1  0
1  2  3  2
2  4  5  4
```

This is like an `append` operation on the `DataFrame`.

```
In [134]: dfi.loc[3] = 5

In [135]: dfi
Out [135]:
   A  B  C
0  0  1  0
1  2  3  2
2  4  5  4
3  5  5  5
```

4.2.12 Fast scalar value getting and setting

Since indexing with `[]` must handle a lot of cases (single-label access, slicing, boolean indexing, etc.), it has a bit of overhead in order to figure out what you're asking for. If you only want to access a scalar value, the fastest way is to use the `at` and `iat` methods, which are implemented on all of the data structures.

Similarly to `loc`, `at` provides **label** based scalar lookups, while, `iat` provides **integer** based lookups analogously to `iloc`

```
In [136]: s.iat[5]
Out [136]: 5
```

```
In [137]: df.at[dates[5], 'A']
Out[137]: -0.15625969875302725
```

```
In [138]: df.iat[3, 0]
Out[138]: -1.7233332966009836
```

You can also set using these same indexers.

```
In [139]: df.at[dates[5], 'E'] = 7
```

```
In [140]: df.iat[3, 0] = 7
```

at may enlarge the object in-place as above if the indexer is missing.

```
In [141]: df.at[dates[-1] + pd.Timedelta('1 day'), 0] = 7
```

```
In [142]: df
```

```
Out[142]:
```

	A	B	C	D	E	O
2000-01-01	-1.157426	-0.096491	0.999344	-1.482012	NaN	NaN
2000-01-02	0.189291	0.926828	-0.029095	1.776600	NaN	NaN
2000-01-03	-1.334294	2.085399	-0.633036	0.208208	NaN	NaN
2000-01-04	7.000000	-0.355486	-0.143959	0.177635	NaN	NaN
2000-01-05	1.071746	-0.516876	-0.382709	0.888600	NaN	NaN
2000-01-06	-0.156260	-0.720254	-0.837161	-0.426902	7.0	NaN
2000-01-07	-0.354174	0.510804	0.156535	0.294767	NaN	NaN
2000-01-08	-1.448608	-1.191084	-0.128338	-0.687717	NaN	NaN
2000-01-09	NaN	NaN	NaN	NaN	NaN	7.0

4.2.13 Boolean indexing

Another common operation is the use of boolean vectors to filter the data. The operators are: | for **or**, & for **and**, and ~ for **not**. These **must** be grouped by using parentheses, since by default Python will evaluate an expression such as `df.A > 2 & df.B < 3` as `df.A > (2 & df.B) < 3`, while the desired evaluation order is `(df.A > 2) & (df.B < 3)`.

Using a boolean vector to index a Series works exactly as in a NumPy ndarray:

```
In [143]: s = pd.Series(range(-3, 4))
```

```
In [144]: s
```

```
Out[144]:
```

0	-3
1	-2
2	-1
3	0
4	1
5	2
6	3

```
dtype: int64
```

```
In [145]: s[s > 0]
```

```
Out[145]:
```

4	1
---	---

```
5    2
6    3
dtype: int64
```

```
In [146]: s[(s < -1) | (s > 0.5)]
Out[146]:
0    -3
1    -2
4     1
5     2
6     3
dtype: int64
```

```
In [147]: s[~(s < 0)]
Out[147]:
3     0
4     1
5     2
6     3
dtype: int64
```

You may select rows from a DataFrame using a boolean vector the same length as the DataFrame's index (for example, something derived from one of the columns of the DataFrame):

```
In [148]: df[df['A'] > 0]
Out[148]:
```

	A	B	C	D	E	O
2000-01-02	0.189291	0.926828	-0.029095	1.776600	NaN	NaN
2000-01-04	7.000000	-0.355486	-0.143959	0.177635	NaN	NaN
2000-01-05	1.071746	-0.516876	-0.382709	0.888600	NaN	NaN

List comprehensions and the map method of Series can also be used to produce more complex criteria:

```
In [149]: df2 = pd.DataFrame({'a': ['one', 'one', 'two', 'three', 'two', 'one', 'six'],
.....:                       'b': ['x', 'y', 'y', 'x', 'y', 'x', 'x'],
.....:                       'c': np.random.randn(7)})
.....:
```

```
# only want 'two' or 'three'
```

```
In [150]: criterion = df2['a'].map(lambda x: x.startswith('t'))
```

```
In [151]: df2[criterion]
Out[151]:
```

	a	b	c
2	two	y	0.344065
3	three	x	1.275247
4	two	y	1.303763

```
# equivalent but slower
```

```
In [152]: df2[[x.startswith('t') for x in df2['a']]]
Out[152]:
```

	a	b	c
2	two	y	0.344065
3	three	x	1.275247
4	two	y	1.303763

```
# Multiple criteria
In [153]: df2[criterion & (df2['b'] == 'x')]
Out[153]:
      a  b      c
3  three x  1.275247
```

With the choice methods *Selection by Label*, *Selection by Position*, and *Advanced Indexing* you may select along more than one axis using boolean vectors combined with other indexing expressions.

```
In [154]: df2.loc[criterion & (df2['b'] == 'x'), 'b':'c']
Out[154]:
      b      c
3  x  1.275247
```

4.2.14 Indexing with `isin`

Consider the `isin()` method of `Series`, which returns a boolean vector that is true wherever the `Series` elements exist in the passed list. This allows you to select rows where one or more columns have values you want:

```
In [155]: s = pd.Series(np.arange(5), index=np.arange(5)[::-1], dtype='int64')
```

```
In [156]: s
Out[156]:
4      0
3      1
2      2
1      3
0      4
dtype: int64
```

```
In [157]: s.isin([2, 4, 6])
Out[157]:
4      False
3      False
2       True
1      False
0       True
dtype: bool
```

```
In [158]: s[s.isin([2, 4, 6])]
Out[158]:
2      2
0      4
dtype: int64
```

The same method is available for `Index` objects and is useful for the cases when you don't know which of the sought labels are in fact present:

```
In [159]: s[s.index.isin([2, 4, 6])]
Out[159]:
4      0
2      2
dtype: int64
```

```
# compare it to the following
In [160]: s.reindex([2, 4, 6])
Out[160]:
2    2.0
4    0.0
6    NaN
dtype: float64
```

In addition to that, `MultiIndex` allows selecting a separate level to use in the membership check:

```
In [161]: s_mi = pd.Series(np.arange(6),
.....:                    index=pd.MultiIndex.from_product([[0, 1], ['a', 'b', 'c']]))
.....:
```

```
In [162]: s_mi
Out[162]:
0 a    0
  b    1
  c    2
1 a    3
  b    4
  c    5
dtype: int64
```

```
In [163]: s_mi.iloc[s_mi.index.isin([(1, 'a'), (2, 'b'), (0, 'c')])]
Out[163]:
0 c    2
1 a    3
dtype: int64
```

```
In [164]: s_mi.iloc[s_mi.index.isin(['a', 'c', 'e'], level=1)]
Out[164]:
0 a    0
  c    2
1 a    3
  c    5
dtype: int64
```

`DataFrame` also has an `isin()` method. When calling `isin`, pass a set of values as either an array or dict. If values is an array, `isin` returns a `DataFrame` of booleans that is the same shape as the original `DataFrame`, with `True` wherever the element is in the sequence of values.

```
In [165]: df = pd.DataFrame({'vals': [1, 2, 3, 4], 'ids': ['a', 'b', 'f', 'n'],
.....:                    'ids2': ['a', 'n', 'c', 'n']})
.....:

In [166]: values = ['a', 'b', 1, 3]

In [167]: df.isin(values)
Out[167]:
   vals  ids  ids2
0  True  True  True
1 False  True False
2  True False False
```

(continues on next page)

(continued from previous page)

```
3 False False False
```

Oftentimes you'll want to match certain values with certain columns. Just make values a `dict` where the key is the column, and the value is a list of items you want to check for.

```
In [168]: values = {'ids': ['a', 'b'], 'vals': [1, 3]}
```

```
In [169]: df.isin(values)
```

```
Out[169]:
   vals  ids  ids2
0  True  True  False
1  False True  False
2   True False  False
3  False False  False
```

Combine `DataFrame`'s `isin` with the `any()` and `all()` methods to quickly select subsets of your data that meet a given criteria. To select a row where each column meets its own criterion:

```
In [170]: values = {'ids': ['a', 'b'], 'ids2': ['a', 'c'], 'vals': [1, 3]}
```

```
In [171]: row_mask = df.isin(values).all(1)
```

```
In [172]: df[row_mask]
```

```
Out[172]:
   vals ids ids2
0     1  a    a
```

4.2.15 The `where()` Method and Masking

Selecting values from a `Series` with a boolean vector generally returns a subset of the data. To guarantee that selection output has the same shape as the original data, you can use the `where` method in `Series` and `DataFrame`.

To return only the selected rows:

```
In [173]: s[s > 0]
```

```
Out[173]:
3    1
2    2
1    3
0    4
dtype: int64
```

To return a `Series` of the same shape as the original:

```
In [174]: s.where(s > 0)
```

```
Out[174]:
4    NaN
3     1.0
2     2.0
1     3.0
```

(continues on next page)

(continued from previous page)

```
0    4.0
dtype: float64
```

Selecting values from a DataFrame with a boolean criterion now also preserves input data shape. `where` is used under the hood as the implementation. The code below is equivalent to `df.where(df < 0)`.

```
In [175]: df[df < 0]
Out [175]:
```

	A	B	C	D
2000-01-01	-0.986205	-1.719758	-2.230079	-0.439106
2000-01-02	-2.397242	NaN	NaN	-0.237058
2000-01-03	-1.482014	NaN	-0.782186	NaN
2000-01-04	-0.480306	-1.051903	-0.987736	-0.182060
2000-01-05	-0.379467	NaN	-0.138556	NaN
2000-01-06	-0.514897	-0.117796	-0.108906	-1.142649
2000-01-07	-1.349120	NaN	-0.128845	-1.352644
2000-01-08	NaN	NaN	NaN	-1.495080

In addition, `where` takes an optional `other` argument for replacement of values where the condition is False, in the returned copy.

```
In [176]: df.where(df < 0, -df)
Out [176]:
```

	A	B	C	D
2000-01-01	-0.986205	-1.719758	-2.230079	-0.439106
2000-01-02	-2.397242	-0.124508	-1.493995	-0.237058
2000-01-03	-1.482014	-0.429889	-0.782186	-0.389666
2000-01-04	-0.480306	-1.051903	-0.987736	-0.182060
2000-01-05	-0.379467	-0.273248	-0.138556	-0.881904
2000-01-06	-0.514897	-0.117796	-0.108906	-1.142649
2000-01-07	-1.349120	-0.316880	-0.128845	-1.352644
2000-01-08	-0.161458	-0.739064	-0.165377	-1.495080

You may wish to set values based on some boolean criteria. This can be done intuitively like so:

```
In [177]: s2 = s.copy()

In [178]: s2[s2 < 0] = 0

In [179]: s2
Out [179]:
```

4	0
3	1
2	2
1	3
0	4

```
dtype: int64

In [180]: df2 = df.copy()

In [181]: df2[df2 < 0] = 0
```

(continues on next page)

(continued from previous page)

```
In [182]: df2
Out[182]:
```

	A	B	C	D
2000-01-01	0.000000	0.000000	0.000000	0.000000
2000-01-02	0.000000	0.124508	1.493995	0.000000
2000-01-03	0.000000	0.429889	0.000000	0.389666
2000-01-04	0.000000	0.000000	0.000000	0.000000
2000-01-05	0.000000	0.273248	0.000000	0.881904
2000-01-06	0.000000	0.000000	0.000000	0.000000
2000-01-07	0.000000	0.316880	0.000000	0.000000
2000-01-08	0.161458	0.739064	0.165377	0.000000

By default, `where` returns a modified copy of the data. There is an optional parameter `inplace` so that the original data can be modified without creating a copy:

```
In [183]: df_orig = df.copy()
In [184]: df_orig.where(df > 0, -df, inplace=True)
In [185]: df_orig
Out[185]:
```

	A	B	C	D
2000-01-01	0.986205	1.719758	2.230079	0.439106
2000-01-02	2.397242	0.124508	1.493995	0.237058
2000-01-03	1.482014	0.429889	0.782186	0.389666
2000-01-04	0.480306	1.051903	0.987736	0.182060
2000-01-05	0.379467	0.273248	0.138556	0.881904
2000-01-06	0.514897	0.117796	0.108906	1.142649
2000-01-07	1.349120	0.316880	0.128845	1.352644
2000-01-08	0.161458	0.739064	0.165377	1.495080

Note: The signature for `DataFrame.where()` differs from `numpy.where()`. Roughly `df1.where(m, df2)` is equivalent to `np.where(m, df1, df2)`.

```
In [186]: df.where(df < 0, -df) == np.where(df < 0, df, -df)
Out[186]:
```

	A	B	C	D
2000-01-01	True	True	True	True
2000-01-02	True	True	True	True
2000-01-03	True	True	True	True
2000-01-04	True	True	True	True
2000-01-05	True	True	True	True
2000-01-06	True	True	True	True
2000-01-07	True	True	True	True
2000-01-08	True	True	True	True

Alignment

Furthermore, `where` aligns the input boolean condition (ndarray or DataFrame), such that partial selection with setting is possible. This is analogous to partial setting via `.loc` (but on the contents rather than the axis labels).

```
In [187]: df2 = df.copy()
```

```
In [188]: df2[df2[1:4] > 0] = 3
```

```
In [189]: df2
```

```
Out[189]:
```

	A	B	C	D
2000-01-01	-0.986205	-1.719758	-2.230079	-0.439106
2000-01-02	-2.397242	3.000000	3.000000	-0.237058
2000-01-03	-1.482014	3.000000	-0.782186	3.000000
2000-01-04	-0.480306	-1.051903	-0.987736	-0.182060
2000-01-05	-0.379467	0.273248	-0.138556	0.881904
2000-01-06	-0.514897	-0.117796	-0.108906	-1.142649
2000-01-07	-1.349120	0.316880	-0.128845	-1.352644
2000-01-08	0.161458	0.739064	0.165377	-1.495080

Where can also accept `axis` and `level` parameters to align the input when performing the `where`.

```
In [190]: df2 = df.copy()
```

```
In [191]: df2.where(df2 > 0, df2['A'], axis='index')
```

```
Out[191]:
```

	A	B	C	D
2000-01-01	-0.986205	-0.986205	-0.986205	-0.986205
2000-01-02	-2.397242	0.124508	1.493995	-2.397242
2000-01-03	-1.482014	0.429889	-1.482014	0.389666
2000-01-04	-0.480306	-0.480306	-0.480306	-0.480306
2000-01-05	-0.379467	0.273248	-0.379467	0.881904
2000-01-06	-0.514897	-0.514897	-0.514897	-0.514897
2000-01-07	-1.349120	0.316880	-1.349120	-1.349120
2000-01-08	0.161458	0.739064	0.165377	0.161458

This is equivalent to (but faster than) the following.

```
In [192]: df2 = df.copy()
```

```
In [193]: df.apply(lambda x, y: x.where(x > 0, y), y=df['A'])
```

```
Out[193]:
```

	A	B	C	D
2000-01-01	-0.986205	-0.986205	-0.986205	-0.986205
2000-01-02	-2.397242	0.124508	1.493995	-2.397242
2000-01-03	-1.482014	0.429889	-1.482014	0.389666
2000-01-04	-0.480306	-0.480306	-0.480306	-0.480306
2000-01-05	-0.379467	0.273248	-0.379467	0.881904
2000-01-06	-0.514897	-0.514897	-0.514897	-0.514897
2000-01-07	-1.349120	0.316880	-1.349120	-1.349120
2000-01-08	0.161458	0.739064	0.165377	0.161458

New in version 0.18.1.

Where can accept a callable as condition and `other` arguments. The function must be with one argument (the calling Series or DataFrame) and that returns valid output as condition and `other` argument.

```
In [194]: df3 = pd.DataFrame({'A': [1, 2, 3],
.....:                       'B': [4, 5, 6],
.....:                       'C': [7, 8, 9]})
.....:

In [195]: df3.where(lambda x: x > 4, lambda x: x + 10)
Out[195]:
   A  B  C
0  11 14  7
1  12  5  8
2  13  6  9
```

Mask

`mask()` is the inverse boolean operation of `where`.

```
In [196]: s.mask(s >= 0)
Out[196]:
4  NaN
3  NaN
2  NaN
1  NaN
0  NaN
dtype: float64
```

```
In [197]: df.mask(df >= 0)
Out[197]:
           A         B         C         D
2000-01-01 -0.986205 -1.719758 -2.230079 -0.439106
2000-01-02 -2.397242         NaN         NaN -0.237058
2000-01-03 -1.482014         NaN -0.782186         NaN
2000-01-04 -0.480306 -1.051903 -0.987736 -0.182060
2000-01-05 -0.379467         NaN -0.138556         NaN
2000-01-06 -0.514897 -0.117796 -0.108906 -1.142649
2000-01-07 -1.349120         NaN -0.128845 -1.352644
2000-01-08         NaN         NaN         NaN -1.495080
```

4.2.16 The `query()` Method

`DataFrame` objects have a `query()` method that allows selection using an expression.

You can get the value of the frame where column `b` has values between the values of columns `a` and `c`. For example:

```
In [198]: n = 10

In [199]: df = pd.DataFrame(np.random.rand(n, 3), columns=list('abc'))

In [200]: df
Out[200]:
           a         b         c
0  0.564354  0.446221  0.031135
1  0.902823  0.612305  0.538181
```

```

2 0.663245 0.164731 0.782808
3 0.194429 0.253263 0.923684
4 0.698026 0.425477 0.840259
5 0.739830 0.738261 0.105783
6 0.214871 0.824421 0.246428
7 0.821225 0.243330 0.650292
8 0.373653 0.171969 0.479279
9 0.450277 0.365091 0.217416

```

```
# pure python
```

```
In [201]: df[(df.a < df.b) & (df.b < df.c)]
```

```
Out[201]:
```

```

      a      b      c
3 0.194429 0.253263 0.923684

```

```
# query
```

```
In [202]: df.query('(a < b) & (b < c)')
```

```
Out[202]:
```

```

      a      b      c
3 0.194429 0.253263 0.923684

```

Do the same thing but fall back on a named index if there is no column with the name a.

```
In [203]: df = pd.DataFrame(np.random.randint(n / 2, size=(n, 2)), columns=list('bc'))
```

```
In [204]: df.index.name = 'a'
```

```
In [205]: df
```

```
Out[205]:
```

```

      b  c
a
0  4  0
1  3  1
2  4  3
3  0  2
4  1  4
5  4  4
6  4  2
7  2  0
8  0  0
9  1  3

```

```
In [206]: df.query('a < b and b < c')
```

```
Out[206]:
```

```
Empty DataFrame
```

```
Columns: [b, c]
```

```
Index: []
```

If instead you don't want to or cannot name your index, you can use the name `index` in your query expression:

```
In [207]: df = pd.DataFrame(np.random.randint(n, size=(n, 2)), columns=list('bc'))
```

```
In [208]: df
```

```
Out[208]:
```

```

      b  c
0  4  5

```

```
1 4 1
2 0 8
3 4 7
4 0 0
5 8 5
6 1 2
7 4 3
8 1 0
9 6 3
```

```
In [209]: df.query('index < b < c')
```

```
Out[209]:
```

```
   b  c
0  4  5
3  4  7
```

Note: If the name of your index overlaps with a column name, the column name is given precedence. For example,

```
In [210]: df = pd.DataFrame({'a': np.random.randint(5, size=5)})
```

```
In [211]: df.index.name = 'a'
```

```
In [212]: df.query('a > 2') # uses the column 'a', not the index
```

```
Out[212]:
```

```
   a
a
0  4
1  4
2  3
```

You can still use the index in a query expression by using the special identifier 'index':

```
In [213]: df.query('index > 2')
```

```
Out[213]:
```

```
   a
a
3  1
4  1
```

If for some reason you have a column named `index`, then you can refer to the index as `ilevel_0` as well, but at this point you should consider renaming your columns to something less ambiguous.

MultiIndex query() Syntax

You can also use the levels of a `DataFrame` with a *MultiIndex* as if they were columns in the frame:

```
In [214]: n = 10
```

```
In [215]: colors = np.random.choice(['red', 'green'], size=n)
```

```
In [216]: foods = np.random.choice(['eggs', 'ham'], size=n)
```

```

In [217]: colors
Out[217]:
array(['red', 'red', 'green', 'green', 'red', 'red', 'green', 'green',
      'green', 'red'], dtype='<U5')

In [218]: foods
Out[218]:
array(['eggs', 'ham', 'ham', 'ham', 'ham', 'ham', 'eggs', 'eggs', 'ham',
      'eggs'], dtype='<U4')

In [219]: index = pd.MultiIndex.from_arrays([colors, foods], names=['color', 'food'])

In [220]: df = pd.DataFrame(np.random.randn(n, 2), index=index)

In [221]: df
Out[221]:
           0         1
color food
red  eggs  0.397240  1.722883
     ham   0.634589  1.761948
green ham   1.191222 -0.748678
     ham  -0.013401 -0.982325
red   ham   0.272726  1.042615
     ham   0.267082  0.191461
green eggs -0.435659 -0.035917
     eggs  0.194931  0.970348
     ham   2.187055  0.383666
red   eggs -0.812383 -0.497327

In [222]: df.query('color == "red"')
Out[222]:
           0         1
color food
red  eggs  0.397240  1.722883
     ham   0.634589  1.761948
     ham   0.272726  1.042615
     ham   0.267082  0.191461
     eggs -0.812383 -0.497327

If the levels of the MultiIndex are unnamed, you can refer to them using special names:

In [223]: df.index.names = [None, None]

In [224]: df
Out[224]:
           0         1
red  eggs  0.397240  1.722883
     ham   0.634589  1.761948
green ham   1.191222 -0.748678
     ham  -0.013401 -0.982325
red   ham   0.272726  1.042615
     ham   0.267082  0.191461
green eggs -0.435659 -0.035917
     eggs  0.194931  0.970348
     ham   2.187055  0.383666

```

```
red    eggs -0.812383 -0.497327
```

```
In [225]: df.query('ilevel_0 == "red"')
```

```
Out[225]:
```

	0	1
red eggs	0.397240	1.722883
ham	0.634589	1.761948
ham	0.272726	1.042615
ham	0.267082	0.191461
eggs	-0.812383	-0.497327

The convention is `ilevel_0`, which means “index level 0” for the 0th level of the `index`.

query() Use Cases

A use case for `query()` is when you have a collection of `DataFrame` objects that have a subset of column names (or index levels/names) in common. You can pass the same query to both frames *without* having to specify which frame you’re interested in querying

```
In [226]: df = pd.DataFrame(np.random.rand(n, 3), columns=list('abc'))
```

```
In [227]: df
```

```
Out[227]:
```

	a	b	c
0	0.483974	0.645639	0.413412
1	0.611039	0.585546	0.848970
2	0.523271	0.811649	0.517849
3	0.947506	0.143525	0.055154
4	0.934891	0.214973	0.271028
5	0.832143	0.777114	0.572133
6	0.304056	0.712288	0.960006
7	0.965451	0.803696	0.866318
8	0.965355	0.383391	0.647743
9	0.639263	0.218103	0.886788

```
In [228]: df2 = pd.DataFrame(np.random.rand(n + 2, 3), columns=df.columns)
```

```
In [229]: df2
```

```
Out[229]:
```

	a	b	c
0	0.563472	0.298326	0.361543
1	0.021200	0.761846	0.279478
2	0.274321	0.127032	0.025433
3	0.789059	0.154680	0.999703
4	0.195936	0.042450	0.475367
5	0.970329	0.053024	0.293762
6	0.877607	0.352530	0.300746
7	0.259895	0.666779	0.920354
8	0.861035	0.176572	0.638339
9	0.083984	0.834057	0.673247
10	0.190267	0.647251	0.586836
11	0.395322	0.575815	0.184662

(continues on next page)

(continued from previous page)

```
In [230]: expr = '0.0 <= a <= c <= 0.5'
In [231]: map(lambda frame: frame.query(expr), [df, df2])
Out[231]: <map at 0x13af70b10>
```

query() Python versus pandas Syntax Comparison

Full numpy-like syntax:

```
In [232]: df = pd.DataFrame(np.random.randint(n, size=(n, 3)), columns=list('abc'))
```

```
In [233]: df
```

```
Out[233]:
```

```
   a  b  c
0  4  1  0
1  9  3  7
2  6  7  9
3  1  9  4
4  6  9  9
5  1  1  2
6  6  6  6
7  9  6  3
8  0  7  9
9  3  8  3
```

```
In [234]: df.query('(a < b) & (b < c)')
```

```
Out[234]:
```

```
   a  b  c
2  6  7  9
8  0  7  9
```

```
In [235]: df[(df.a < df.b) & (df.b < df.c)]
```

```
Out[235]:
```

```
   a  b  c
2  6  7  9
8  0  7  9
```

Slightly nicer by removing the parentheses (by binding making comparison operators bind tighter than & and |).

```
In [236]: df.query('a < b & b < c')
```

```
Out[236]:
```

```
   a  b  c
2  6  7  9
8  0  7  9
```

Use English instead of symbols:

```
In [237]: df.query('a < b and b < c')
```

```
Out[237]:
```

```
   a  b  c
```

(continues on next page)

(continued from previous page)

```
2 6 7 9
8 0 7 9
```

Pretty close to how you might write it on paper:

```
In [238]: df.query('a < b < c')
Out[238]:
   a  b  c
2  6  7  9
8  0  7  9
```

The `in` and `not in` operators

`query()` also supports special use of Python's `in` and `not in` comparison operators, providing a succinct syntax for calling the `isin` method of a `Series` or `DataFrame`.

```
# get all rows where columns "a" and "b" have overlapping values
In [239]: df = pd.DataFrame({'a': list('aabbccddeeff'), 'b': list('aaaabbbbcccc'),
.....:                      'c': np.random.randint(5, size=12),
.....:                      'd': np.random.randint(9, size=12)})
.....:
```

```
In [240]: df
Out[240]:
   a  b  c  d
0  a  a  1  5
1  a  a  1  1
2  b  a  4  1
3  b  a  4  3
4  c  b  4  5
5  c  b  0  0
6  d  b  0  4
7  d  b  3  3
8  e  c  4  5
9  e  c  2  0
10 f  c  2  2
11 f  c  4  7
```

```
In [241]: df.query('a in b')
Out[241]:
   a  b  c  d
0  a  a  1  5
1  a  a  1  1
2  b  a  4  1
3  b  a  4  3
4  c  b  4  5
5  c  b  0  0
```

How you'd do it in pure Python

```
In [242]: df[df.a.isin(df.b)]
Out[242]:
   a  b  c  d
```

```

0 a a 1 5
1 a a 1 1
2 b a 4 1
3 b a 4 3
4 c b 4 5
5 c b 0 0

```

```
In [243]: df.query('a not in b')
```

```
Out[243]:
   a b c d
6  d b 0 4
7  d b 3 3
8  e c 4 5
9  e c 2 0
10 f c 2 2
11 f c 4 7

```

```
# pure Python
```

```
In [244]: df[~df.a.isin(df.b)]
```

```
Out[244]:
   a b c d
6  d b 0 4
7  d b 3 3
8  e c 4 5
9  e c 2 0
10 f c 2 2
11 f c 4 7

```

You can combine this with other expressions for very succinct queries:

```
# rows where cols a and b have overlapping values
```

```
# and col c's values are less than col d's
```

```
In [245]: df.query('a in b and c < d')
```

```
Out[245]:
   a b c d
0  a a 1 5
4  c b 4 5

```

```
# pure Python
```

```
In [246]: df[df.b.isin(df.a) & (df.c < df.d)]
```

```
Out[246]:
   a b c d
0  a a 1 5
4  c b 4 5
6  d b 0 4
8  e c 4 5
11 f c 4 7

```

Note: Note that `in` and `not in` are evaluated in Python, since `numexpr` has no equivalent of this operation. However, **only the `in/not in` expression itself** is evaluated in vanilla Python. For example, in the expression

```
df.query('a in b + c + d')
```

`(b + c + d)` is evaluated by `numexpr` and *then* the `in` operation is evaluated in plain Python. In general,

any operations that can be evaluated using numexpr will be.

Special use of the == operator with list objects

Comparing a list of values to a column using ==/!= works similarly to in/not in.

```
In [247]: df.query('b == ["a", "b", "c"]')
```

```
Out[247]:
```

	a	b	c	d
0	a	a	1	5
1	a	a	1	1
2	b	a	4	1
3	b	a	4	3
4	c	b	4	5
5	c	b	0	0
6	d	b	0	4
7	d	b	3	3
8	e	c	4	5
9	e	c	2	0
10	f	c	2	2
11	f	c	4	7

```
# pure Python
```

```
In [248]: df[df.b.isin(["a", "b", "c"])]
```

```
Out[248]:
```

	a	b	c	d
0	a	a	1	5
1	a	a	1	1
2	b	a	4	1
3	b	a	4	3
4	c	b	4	5
5	c	b	0	0
6	d	b	0	4
7	d	b	3	3
8	e	c	4	5
9	e	c	2	0
10	f	c	2	2
11	f	c	4	7

```
In [249]: df.query('c == [1, 2]')
```

```
Out[249]:
```

	a	b	c	d
0	a	a	1	5
1	a	a	1	1
9	e	c	2	0
10	f	c	2	2

```
In [250]: df.query('c != [1, 2]')
```

```
Out[250]:
```

	a	b	c	d
2	b	a	4	1
3	b	a	4	3
4	c	b	4	5

```

5  c  b  0  0
6  d  b  0  4
7  d  b  3  3
8  e  c  4  5
11 f  c  4  7

```

```
# using in/not in
```

```
In [251]: df.query('[1, 2] in c')
```

```
Out[251]:
   a  b  c  d
0  a  a  1  5
1  a  a  1  1
9  e  c  2  0
10 f  c  2  2

```

```
In [252]: df.query('[1, 2] not in c')
```

```
Out[252]:
   a  b  c  d
2  b  a  4  1
3  b  a  4  3
4  c  b  4  5
5  c  b  0  0
6  d  b  0  4
7  d  b  3  3
8  e  c  4  5
11 f  c  4  7

```

```
# pure Python
```

```
In [253]: df[df.c.isin([1, 2])]
```

```
Out[253]:
   a  b  c  d
0  a  a  1  5
1  a  a  1  1
9  e  c  2  0
10 f  c  2  2

```

Boolean operators

You can negate boolean expressions with the word `not` or the `~` operator.

```
In [254]: df = pd.DataFrame(np.random.rand(n, 3), columns=list('abc'))
```

```
In [255]: df['bools'] = np.random.rand(len(df)) > 0.5
```

```
In [256]: df.query('~bools')
```

```
Out[256]:
   a         b         c  bools
0  0.499604  0.981560  0.137759  False
4  0.104751  0.782568  0.977198  False
7  0.973197  0.245000  0.977406  False
9  0.805940  0.451425  0.070470  False

```

```
In [257]: df.query('not bools')
```

```
Out[257]:
```

```
      a      b      c  bools
0  0.499604  0.981560  0.137759  False
4  0.104751  0.782568  0.977198  False
7  0.973197  0.245000  0.977406  False
9  0.805940  0.451425  0.070470  False
```

```
In [258]: df.query('not bools') == df[~df.bools]
Out[258]:
```

```
      a      b      c  bools
0  True  True  True   True
4  True  True  True   True
7  True  True  True   True
9  True  True  True   True
```

Of course, expressions can be arbitrarily complex too:

```
# short query syntax
```

```
In [259]: shorter = df.query('a < b < c and (not bools) or bools > 2')
```

```
# equivalent in pure Python
```

```
In [260]: longer = df[(df.a < df.b) & (df.b < df.c) & (~df.bools) | (df.bools > 2)]
```

```
In [261]: shorter
```

```
Out[261]:
      a      b      c  bools
4  0.104751  0.782568  0.977198  False
```

```
In [262]: longer
```

```
Out[262]:
      a      b      c  bools
4  0.104751  0.782568  0.977198  False
```

```
In [263]: shorter == longer
```

```
Out[263]:
      a      b      c  bools
4  True  True  True   True
```

Performance of query()

DataFrame.query() using numexpr is slightly faster than Python for large frames.

Note: You will only see the performance benefits of using the `numexpr` engine with `DataFrame.query()` if your frame has more than approximately 200,000 rows.

This plot was created using a `DataFrame` with 3 columns each containing floating point values generated using `numpy.random.randn()`.

4.2.17 Duplicate data

If you want to identify and remove duplicate rows in a `DataFrame`, there are two methods that will help: `uplicated` and `drop_duplicates`. Each takes as an argument the columns to use to identify duplicated rows.

- `uplicated` returns a boolean vector whose length is the number of rows, and which indicates whether

a row is duplicated.

- `drop_duplicates` removes duplicate rows.

By default, the first observed row of a duplicate set is considered unique, but each method has a `keep` parameter to specify targets to be kept.

- `keep='first'` (default): mark / drop duplicates except for the first occurrence.
- `keep='last'`: mark / drop duplicates except for the last occurrence.
- `keep=False`: mark / drop all duplicates.

```
In [264]: df2 = pd.DataFrame({'a': ['one', 'one', 'two', 'two', 'two', 'three', 'four'],
.....:                      'b': ['x', 'y', 'x', 'y', 'x', 'x', 'x'],
.....:                      'c': np.random.randn(7)})
.....:
```

```
In [265]: df2
```

```
Out[265]:
```

```
   a  b      c
0  one x -0.086643
1  one y -0.862428
2  two x  1.155986
3  two y -0.583644
4  two x -1.416461
5 three x  0.799196
6 four x -2.063856
```

```
In [266]: df2.duplicated('a')
```

```
Out[266]:
```

```
0    False
1     True
2    False
3     True
4     True
5    False
6    False
dtype: bool
```

```
In [267]: df2.duplicated('a', keep='last')
```

```
Out[267]:
```

```
0     True
1    False
2     True
3     True
4    False
5    False
6    False
dtype: bool
```

```
In [268]: df2.duplicated('a', keep=False)
```

```
Out[268]:
```

```
0     True
1     True
2     True
3     True
```

```

4     True
5     False
6     False
dtype: bool

```

```

In [269]: df2.drop_duplicates('a')
Out[269]:

```

```

      a  b      c
0  one  x -0.086643
2  two  x  1.155986
5 three  x  0.799196
6  four  x -2.063856

```

```

In [270]: df2.drop_duplicates('a', keep='last')
Out[270]:

```

```

      a  b      c
1  one  y -0.862428
4  two  x -1.416461
5 three  x  0.799196
6  four  x -2.063856

```

```

In [271]: df2.drop_duplicates('a', keep=False)
Out[271]:

```

```

      a  b      c
5 three  x  0.799196
6  four  x -2.063856

```

Also, you can pass a list of columns to identify duplications.

```

In [272]: df2.duplicated(['a', 'b'])
Out[272]:

```

```

0     False
1     False
2     False
3     False
4     True
5     False
6     False
dtype: bool

```

```

In [273]: df2.drop_duplicates(['a', 'b'])
Out[273]:

```

```

      a  b      c
0  one  x -0.086643
1  one  y -0.862428
2  two  x  1.155986
3  two  y -0.583644
5 three  x  0.799196
6  four  x -2.063856

```

To drop duplicates by index value, use `Index.duplicated` then perform slicing. The same set of options are available for the `keep` parameter.

```

In [274]: df3 = pd.DataFrame({'a': np.arange(6),
.....:                       'b': np.random.randn(6)},
.....:                       index=['a', 'a', 'b', 'c', 'b', 'a'])

```

```
.....:

In [275]: df3
Out[275]:
   a      b
a  0 -0.457673
a  1  0.315795
b  2 -0.013959
c  3 -0.376069
b  4 -0.715356
a  5  1.802760

In [276]: df3.index.duplicated()
Out[276]: array([False,  True,  False,  False,  True,  True])

In [277]: df3[~df3.index.duplicated()]
Out[277]:
   a      b
a  0 -0.457673
b  2 -0.013959
c  3 -0.376069

In [278]: df3[~df3.index.duplicated(keep='last')]
Out[278]:
   a      b
c  3 -0.376069
b  4 -0.715356
a  5  1.802760

In [279]: df3[~df3.index.duplicated(keep=False)]
Out[279]:
   a      b
c  3 -0.376069
```

4.2.18 Dictionary-like `get()` method

Each of Series or DataFrame have a `get` method which can return a default value.

```
In [280]: s = pd.Series([1, 2, 3], index=['a', 'b', 'c'])
```

```
In [281]: s.get('a') # equivalent to s['a']
```

```
Out[281]: 1
```

```
In [282]: s.get('x', default=-1)
```

```
Out[282]: -1
```

4.2.19 The `lookup()` method

Sometimes you want to extract a set of values given a sequence of row labels and column labels, and the `lookup` method allows for this and returns a NumPy array. For instance:

```
In [283]: dflookup = pd.DataFrame(np.random.rand(20, 4), columns = ['A', 'B', 'C', 'D'])
In [284]: dflookup.lookup(list(range(0, 10, 2)), ['B', 'C', 'A', 'B', 'D'])
Out[284]: array([0.85612986, 0.02825952, 0.99403226, 0.02263787, 0.37166623])
```

4.2.20 Index objects

The pandas *Index* class and its subclasses can be viewed as implementing an *ordered multiset*. Duplicates are allowed. However, if you try to convert an *Index* object with duplicate entries into a *set*, an exception will be raised.

Index also provides the infrastructure necessary for lookups, data alignment, and reindexing. The easiest way to create an *Index* directly is to pass a *list* or other sequence to *Index*:

```
In [285]: index = pd.Index(['e', 'd', 'a', 'b'])
```

```
In [286]: index
Out[286]: Index(['e', 'd', 'a', 'b'], dtype='object')
```

```
In [287]: 'd' in index
Out[287]: True
```

You can also pass a *name* to be stored in the index:

```
In [288]: index = pd.Index(['e', 'd', 'a', 'b'], name='something')
In [289]: index.name
Out[289]: 'something'
```

The name, if set, will be shown in the console display:

```
In [290]: index = pd.Index(list(range(5)), name='rows')
```

```
In [291]: columns = pd.Index(['A', 'B', 'C'], name='cols')
```

```
In [292]: df = pd.DataFrame(np.random.randn(5, 3), index=index, columns=columns)
```

```
In [293]: df
Out[293]:
cols      A      B      C
rows
0   -1.539526  0.083551  1.819217
1   -0.556258 -1.013751  0.804958
2    1.138849 -0.913212  2.047493
3   -0.894783  1.059103 -0.605857
4   -1.096832  0.217643  2.122047
```

```
In [294]: df['A']
```

```
Out[294]:
rows
0   -1.539526
1   -0.556258
2    1.138849
3   -0.894783
```

```
4    -1.096832
Name: A, dtype: float64
```

Setting metadata

Indexes are “mostly immutable”, but it is possible to set and change their metadata, like the index `name` (or, for `MultiIndex`, `levels` and `codes`).

You can use the `rename`, `set_names`, `set_levels`, and `set_codes` to set these attributes directly. They default to returning a copy; however, you can specify `inplace=True` to have the data change in place.

See *Advanced Indexing* for usage of `MultiIndexes`.

```
In [295]: ind = pd.Index([1, 2, 3])
```

```
In [296]: ind.rename("apple")
Out[296]: Int64Index([1, 2, 3], dtype='int64', name='apple')
```

```
In [297]: ind
Out[297]: Int64Index([1, 2, 3], dtype='int64')
```

```
In [298]: ind.set_names(["apple"], inplace=True)
```

```
In [299]: ind.name = "bob"
```

```
In [300]: ind
Out[300]: Int64Index([1, 2, 3], dtype='int64', name='bob')
```

`set_names`, `set_levels`, and `set_codes` also take an optional `level` argument

```
In [301]: index = pd.MultiIndex.from_product([range(3), ['one', 'two']], names=['first', 'second'])
```

```
In [302]: index
Out[302]:
MultiIndex([(0, 'one'),
            (0, 'two'),
            (1, 'one'),
            (1, 'two'),
            (2, 'one'),
            (2, 'two')],
           names=['first', 'second'])
```

```
In [303]: index.levels[1]
Out[303]: Index(['one', 'two'], dtype='object', name='second')
```

```
In [304]: index.set_levels(["a", "b"], level=1)
Out[304]:
```

```
MultiIndex([(0, 'a'),
            (0, 'b'),
            (1, 'a'),
            (1, 'b'),
            (2, 'a'),
            (2, 'b')],
           names=['first', 'second'])
```

Set operations on Index objects

The two main operations are `union` (`|`) and `intersection` (`&`). These can be directly called as instance methods or used via overloaded operators. Difference is provided via the `.difference()` method.

```
In [305]: a = pd.Index(['c', 'b', 'a'])
```

```
In [306]: b = pd.Index(['c', 'e', 'd'])
```

```
In [307]: a | b
```

```
Out[307]: Index(['a', 'b', 'c', 'd', 'e'], dtype='object')
```

```
In [308]: a & b
```

```
Out[308]: Index(['c'], dtype='object')
```

```
In [309]: a.difference(b)
```

```
Out[309]: Index(['a', 'b'], dtype='object')
```

Also available is the `symmetric_difference` (`^`) operation, which returns elements that appear in either `idx1` or `idx2`, but not in both. This is equivalent to the Index created by `idx1.difference(idx2).union(idx2.difference(idx1))`, with duplicates dropped.

```
In [310]: idx1 = pd.Index([1, 2, 3, 4])
```

```
In [311]: idx2 = pd.Index([2, 3, 4, 5])
```

```
In [312]: idx1.symmetric_difference(idx2)
```

```
Out[312]: Int64Index([1, 5], dtype='int64')
```

```
In [313]: idx1 ^ idx2
```

```
Out[313]: Int64Index([1, 5], dtype='int64')
```

Note: The resulting index from a set operation will be sorted in ascending order.

When performing `Index.union()` between indexes with different dtypes, the indexes must be cast to a common dtype. Typically, though not always, this is object dtype. The exception is when performing a union between integer and float data. In this case, the integer values are converted to float

```
In [314]: idx1 = pd.Index([0, 1, 2])
```

```
In [315]: idx2 = pd.Index([0.5, 1.5])
```

```
In [316]: idx1 | idx2
```

```
Out[316]: Float64Index([0.0, 0.5, 1.0, 1.5, 2.0], dtype='float64')
```

Missing values

Important: Even though `Index` can hold missing values (`NaN`), it should be avoided if you do not want any unexpected results. For example, some operations exclude missing values implicitly.

`Index.fillna` fills missing values with specified scalar value.

```

In [317]: idx1 = pd.Index([1, np.nan, 3, 4])

In [318]: idx1
Out[318]: Float64Index([1.0, nan, 3.0, 4.0], dtype='float64')

In [319]: idx1.fillna(2)
Out[319]: Float64Index([1.0, 2.0, 3.0, 4.0], dtype='float64')

In [320]: idx2 = pd.DatetimeIndex([pd.Timestamp('2011-01-01'),
.....:                             pd.NaT,
.....:                             pd.Timestamp('2011-01-03')])
.....:

In [321]: idx2
Out[321]: DatetimeIndex(['2011-01-01', 'NaT', '2011-01-03'], dtype='datetime64[ns]',
↳freq=None)

In [322]: idx2.fillna(pd.Timestamp('2011-01-02'))
Out[322]: DatetimeIndex(['2011-01-01', '2011-01-02', '2011-01-03'],
↳dtype='datetime64[ns]', freq=None)

```

4.2.21 Set / reset index

Occasionally you will load or create a data set into a DataFrame and want to add an index after you've already done so. There are a couple of different ways.

Set an index

DataFrame has a `set_index()` method which takes a column name (for a regular Index) or a list of column names (for a MultiIndex). To create a new, re-indexed DataFrame:

```

In [323]: data
Out[323]:
   a  b  c  d
0  bar one z  1.0
1  bar two y  2.0
2  foo one x  3.0
3  foo two w  4.0

In [324]: indexed1 = data.set_index('c')

In [325]: indexed1
Out[325]:
   a  b  d
c
z  bar one  1.0
y  bar two  2.0
x  foo one  3.0
w  foo two  4.0

In [326]: indexed2 = data.set_index(['a', 'b'])

```

(continues on next page)

(continued from previous page)

```
In [327]: indexed2
```

```
Out[327]:
```

```

      c    d
a  b
bar one z  1.0
      two y  2.0
foo one x  3.0
      two w  4.0

```

The `append` keyword option allow you to keep the existing index and append the given columns to a Multi-Index:

```
In [328]: frame = data.set_index('c', drop=False)
```

```
In [329]: frame = frame.set_index(['a', 'b'], append=True)
```

```
In [330]: frame
```

```
Out[330]:
```

```

      c    d
c a  b
z bar one z  1.0
y bar two y  2.0
x foo one x  3.0
w foo two w  4.0

```

Other options in `set_index` allow you not drop the index columns or to add the index in-place (without creating a new object):

```
In [331]: data.set_index('c', drop=False)
```

```
Out[331]:
```

```

      a    b    c    d
c
z bar one z  1.0
y bar two y  2.0
x foo one x  3.0
w foo two w  4.0

```

```
In [332]: data.set_index(['a', 'b'], inplace=True)
```

```
In [333]: data
```

```
Out[333]:
```

```

      c    d
a  b
bar one z  1.0
      two y  2.0
foo one x  3.0
      two w  4.0

```

Reset the index

As a convenience, there is a new function on `DataFrame` called `reset_index()` which transfers the index values into the `DataFrame`'s columns and sets a simple integer index. This is the inverse operation of

```
set_index().
```

```
In [334]: data
```

```
Out[334]:
```

		c	d
a	b		
bar	one	z	1.0
	two	y	2.0
foo	one	x	3.0
	two	w	4.0

```
In [335]: data.reset_index()
```

```
Out[335]:
```

	a	b	c	d
0	bar	one	z	1.0
1	bar	two	y	2.0
2	foo	one	x	3.0
3	foo	two	w	4.0

The output is more similar to a SQL table or a record array. The names for the columns derived from the index are the ones stored in the `names` attribute.

You can use the `level` keyword to remove only a portion of the index:

```
In [336]: frame
```

```
Out[336]:
```

		c	d
c	a	b	
z	bar	one	z 1.0
y	bar	two	y 2.0
x	foo	one	x 3.0
w	foo	two	w 4.0

```
In [337]: frame.reset_index(level=1)
```

```
Out[337]:
```

	a	c	d
c	b		
z	one	bar	z 1.0
y	two	bar	y 2.0
x	one	foo	x 3.0
w	two	foo	w 4.0

`reset_index` takes an optional parameter `drop` which if true simply discards the index, instead of putting index values in the DataFrame's columns.

Adding an ad hoc index

If you create an index yourself, you can just assign it to the `index` field:

```
data.index = index
```

4.2.22 Returning a view versus a copy

When setting values in a pandas object, care must be taken to avoid what is called `chained indexing`. Here is an example.

```
In [338]: dfmi = pd.DataFrame([list('abcd'),
.....:                        list('efgh'),
.....:                        list('ijkl'),
.....:                        list('mnop')],
.....:                        columns=pd.MultiIndex.from_product([[ 'one', 'two'],
.....:                                                                ['first', 'second']]))
.....:
```

```
In [339]: dfmi
```

```
Out [339]:
```

	one		two	
	first	second	first	second
0	a	b	c	d
1	e	f	g	h
2	i	j	k	l
3	m	n	o	p

Compare these two access methods:

```
In [340]: dfmi['one']['second']
```

```
Out [340]:
```

0	b
1	f
2	j
3	n

Name: second, dtype: object

```
In [341]: dfmi.loc[:, ('one', 'second')]
```

```
Out [341]:
```

0	b
1	f
2	j
3	n

Name: (one, second), dtype: object

These both yield the same results, so which should you use? It is instructive to understand the order of operations on these and why method 2 (`.loc`) is much preferred over method 1 (chained `[]`).

`dfmi['one']` selects the first level of the columns and returns a DataFrame that is singly-indexed. Then another Python operation `dfmi_with_one['second']` selects the series indexed by 'second'. This is indicated by the variable `dfmi_with_one` because pandas sees these operations as separate events. e.g. separate calls to `__getitem__`, so it has to treat them as linear operations, they happen one after another.

Contrast this to `df.loc[:, ('one', 'second')]` which passes a nested tuple of (`slice(None)`, ('one', 'second')) to a single call to `__getitem__`. This allows pandas to deal with this as a single entity. Furthermore this order of operations *can* be significantly faster, and allows one to index *both* axes if so desired.

Why does assignment fail when using chained indexing?

The problem in the previous section is just a performance issue. What's up with the `SettingWithCopy` warning? We don't **usually** throw warnings around when you do something that might cost a few extra milliseconds!

But it turns out that assigning to the product of chained indexing has inherently unpredictable results. To see this, think about how the Python interpreter executes this code:

```
dfmi.loc[:, ('one', 'second')] = value
# becomes
dfmi.loc.__setitem__((slice(None), ('one', 'second')), value)
```

But this code is handled differently:

```
dfmi['one']['second'] = value
# becomes
dfmi.__getitem__('one').__setitem__('second', value)
```

See that `__getitem__` in there? Outside of simple cases, it's very hard to predict whether it will return a view or a copy (it depends on the memory layout of the array, about which pandas makes no guarantees), and therefore whether the `__setitem__` will modify `dfmi` or a temporary object that gets thrown out immediately afterward. **That's** what `SettingWithCopy` is warning you about!

Note: You may be wondering whether we should be concerned about the `loc` property in the first example. But `dfmi.loc` is guaranteed to be `dfmi` itself with modified indexing behavior, so `dfmi.loc.__getitem__` / `dfmi.loc.__setitem__` operate on `dfmi` directly. Of course, `dfmi.loc.__getitem__(idx)` may be a view or a copy of `dfmi`.

Sometimes a `SettingWithCopy` warning will arise at times when there's no obvious chained indexing going on. **These** are the bugs that `SettingWithCopy` is designed to catch! Pandas is probably trying to warn you that you've done this:

```
def do_something(df):
    foo = df[['bar', 'baz']] # Is foo a view? A copy? Nobody knows!
    # ... many lines here ...
    # We don't know whether this will modify df or not!
    foo['quux'] = value
    return foo
```

Yikes!

Evaluation order matters

When you use chained indexing, the order and type of the indexing operation partially determine whether the result is a slice into the original object, or a copy of the slice.

Pandas has the `SettingWithCopyWarning` because assigning to a copy of a slice is frequently not intentional, but a mistake caused by chained indexing returning a copy where a slice was expected.

If you would like pandas to be more or less trusting about assignment to a chained indexing expression, you can set the `option mode.chained_assignment` to one of these values:

- 'warn', the default, means a `SettingWithCopyWarning` is printed.
- 'raise' means pandas will raise a `SettingWithCopyException` you have to deal with.
- None will suppress the warnings entirely.

```
In [342]: dfb = pd.DataFrame({'a': ['one', 'one', 'two',
.....:                          'three', 'two', 'one', 'six'],
.....:                      'c': np.arange(7)})
.....:

# This will show the SettingWithCopyWarning
# but the frame values will be set
In [343]: dfb['c'][dfb.a.str.startswith('o')] = 42
```

This however is operating on a copy and will not work.

```
>>> pd.set_option('mode.chained_assignment', 'warn')
>>> dfb[dfb.a.str.startswith('o')] ['c'] = 42
Traceback (most recent call last):
...
SettingWithCopyWarning:
  A value is trying to be set on a copy of a slice from a DataFrame.
  Try using .loc[row_index,col_indexer] = value instead
```

A chained assignment can also crop up in setting in a mixed dtype frame.

Note: These setting rules apply to all of `.loc/.iloc`.

This is the correct access method:

```
In [344]: dfc = pd.DataFrame({'A': ['aaa', 'bbb', 'ccc'], 'B': [1, 2, 3]})

In [345]: dfc.loc[0, 'A'] = 11

In [346]: dfc
Out[346]:
   A  B
0  11  1
1  bbb  2
2  ccc  3
```

This *can* work at times, but it is not guaranteed to, and therefore should be avoided:

```
In [347]: dfc = dfc.copy()

In [348]: dfc['A'][0] = 111

In [349]: dfc
Out[349]:
   A  B
0  111  1
1  bbb  2
2  ccc  3
```

This will **not** work at all, and so should be avoided:

```
>>> pd.set_option('mode.chained_assignment', 'raise')
>>> dfc.loc[0]['A'] = 1111
Traceback (most recent call last)
...
SettingWithCopyException:
  A value is trying to be set on a copy of a slice from a DataFrame.
  Try using .loc[row_index,col_indexer] = value instead
```

Warning: The chained assignment warnings / exceptions are aiming to inform the user of a possibly invalid assignment. There may be false positives; situations where a chained assignment is inadvertently reported.

{{ header }}

4.3 MultiIndex / advanced indexing

This section covers *indexing with a MultiIndex* and *other advanced indexing features*.

See the *Indexing and Selecting Data* for general indexing documentation.

Warning: Whether a copy or a reference is returned for a setting operation may depend on the context. This is sometimes called **chained assignment** and should be avoided. See *Returning a View versus Copy*.

See the *cookbook* for some advanced strategies.

4.3.1 Hierarchical indexing (MultiIndex)

Hierarchical / Multi-level indexing is very exciting as it opens the door to some quite sophisticated data analysis and manipulation, especially for working with higher dimensional data. In essence, it enables you to store and manipulate data with an arbitrary number of dimensions in lower dimensional data structures like **Series** (1d) and **DataFrame** (2d).

In this section, we will show what exactly we mean by “hierarchical” indexing and how it integrates with all of the pandas indexing functionality described above and in prior sections. Later, when discussing *group by* and *pivoting and reshaping data*, we’ll show non-trivial applications to illustrate how it aids in structuring data for analysis.

See the *cookbook* for some advanced strategies.

Changed in version 0.24.0: `MultiIndex.labels` has been renamed to `MultiIndex.codes` and `MultiIndex.set_labels` to `MultiIndex.set_codes`.

Creating a MultiIndex (hierarchical index) object

The `MultiIndex` object is the hierarchical analogue of the standard `Index` object which typically stores the axis labels in pandas objects. You can think of `MultiIndex` as an array of tuples where each tuple is unique. A `MultiIndex` can be created from a list of arrays (using `MultiIndex.from_arrays()`), an array of tuples (using `MultiIndex.from_tuples()`), a crossed set of iterables (using `MultiIndex.from_product()`), or a `DataFrame` (using `MultiIndex.from_frame()`). The `Index` constructor will attempt to return a `MultiIndex`

when it is passed a list of tuples. The following examples demonstrate different ways to initialize MultiIndexes.

```
In [1]: arrays = [['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'],
...:             ['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two']]
...:

In [2]: tuples = list(zip(*arrays))

In [3]: tuples
Out[3]:
[('bar', 'one'),
 ('bar', 'two'),
 ('baz', 'one'),
 ('baz', 'two'),
 ('foo', 'one'),
 ('foo', 'two'),
 ('qux', 'one'),
 ('qux', 'two')]

In [4]: index = pd.MultiIndex.from_tuples(tuples, names=['first', 'second'])

In [5]: index
Out[5]:
MultiIndex([('bar', 'one'),
            ('bar', 'two'),
            ('baz', 'one'),
            ('baz', 'two'),
            ('foo', 'one'),
            ('foo', 'two'),
            ('qux', 'one'),
            ('qux', 'two')],
           names=['first', 'second'])

In [6]: s = pd.Series(np.random.randn(8), index=index)

In [7]: s
Out[7]:
first second
bar    one    0.941492
      two   -0.234130
baz    one   -0.796227
      two   -0.058695
foo    one    0.090387
      two   -0.543332
qux    one   -0.619806
      two   -0.570133
dtype: float64
```

When you want every pairing of the elements in two iterables, it can be easier to use the `MultiIndex.from_product()` method:

```
In [8]: iterables = [['bar', 'baz', 'foo', 'qux'], ['one', 'two']]
```

(continues on next page)

(continued from previous page)

```
In [9]: pd.MultiIndex.from_product(iterables, names=['first', 'second'])
Out[9]:
MultiIndex([(bar', 'one'),
            (bar', 'two'),
            (baz', 'one'),
            (baz', 'two'),
            (foo', 'one'),
            (foo', 'two'),
            (qux', 'one'),
            (qux', 'two')],
           names=['first', 'second'])
```

You can also construct a `MultiIndex` from a `DataFrame` directly, using the method `MultiIndex.from_frame()`. This is a complementary method to `MultiIndex.to_frame()`.

New in version 0.24.0.

```
In [10]: df = pd.DataFrame(['bar', 'one'], ['bar', 'two'],
.....:                    ['foo', 'one'], ['foo', 'two']),
.....:                    columns=['first', 'second'])
.....:

In [11]: pd.MultiIndex.from_frame(df)
Out[11]:
MultiIndex([(bar', 'one'),
            (bar', 'two'),
            (foo', 'one'),
            (foo', 'two')],
           names=['first', 'second'])
```

As a convenience, you can pass a list of arrays directly into `Series` or `DataFrame` to construct a `MultiIndex` automatically:

```
In [12]: arrays = [np.array(['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux']),
.....:              np.array(['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two'])]
.....:

In [13]: s = pd.Series(np.random.randn(8), index=arrays)

In [14]: s
Out[14]:
bar one    0.245235
     two    0.016378
baz one   -0.347328
     two    0.600062
foo one   -1.300454
     two   -0.813428
qux one    1.462932
     two   -1.206173
dtype: float64

In [15]: df = pd.DataFrame(np.random.randn(8, 4), index=arrays)
```

(continues on next page)

(continued from previous page)

```
In [16]: df
Out[16]:
```

		0	1	2	3
bar	one	0.123843	0.095315	0.299627	-0.565273
	two	-0.479344	-1.049915	1.325264	-0.663394
baz	one	-0.600478	0.162980	-2.392424	0.132758
	two	-1.943984	-0.301217	-0.671959	0.564671
foo	one	-2.047025	-1.518559	0.334093	0.706845
	two	0.300651	0.808573	-0.287338	0.100844
qux	one	0.143827	0.096856	-0.289420	2.127983
	two	0.378318	0.072987	1.407529	-1.555841

All of the `MultiIndex` constructors accept a `names` argument which stores string names for the levels themselves. If no names are provided, `None` will be assigned:

```
In [17]: df.index.names
Out[17]: FrozenList([None, None])
```

This index can back any axis of a pandas object, and the number of **levels** of the index is up to you:

```
In [18]: df = pd.DataFrame(np.random.randn(3, 8), index=['A', 'B', 'C'], columns=index)
```

```
In [19]: df
Out[19]:
```

	first	bar		baz		foo		qux	
		one	two	one	two	one	two	one	two
A	0.771686	-1.515175	0.803511	-1.127083	-0.597308	-0.605145	0.556247	-0.632974	
B	1.802824	-1.471259	0.326461	1.536432	-0.081085	-0.147244	0.101228	0.450182	
C	1.319947	0.675934	2.202010	-0.521456	0.021556	0.789515	-0.895903	1.202173	

```
In [20]: pd.DataFrame(np.random.randn(6, 6), index=index[:6], columns=index[:6])
```

```
Out[20]:
```

	first	bar		baz		foo	
		one	two	one	two	one	two
first	second	bar	baz	foo	two	two	two
bar	one	-1.161584	-0.419912	-0.613777	-0.695241	2.148015	0.032020
	two	-0.123496	-0.337502	1.618203	-0.583729	-0.615066	0.313786
baz	one	0.222633	-0.749983	0.323488	-2.235814	-0.579346	0.996912
	two	-0.861425	1.584781	0.216983	-0.579921	-0.493260	-0.495810
foo	one	0.435279	0.023408	-1.037650	-0.218663	-0.957795	0.280667
	two	0.156257	0.239904	1.060152	1.306596	0.204804	0.399874

We’ve “sparsified” the higher levels of the indexes to make the console output a bit easier on the eyes. Note that how the index is displayed can be controlled using the `multi_sparse` option in `pandas.set_options()`:

```
In [21]: with pd.option_context('display.multi_sparse', False):
.....:     df
.....:
```

It’s worth keeping in mind that there’s nothing preventing you from using tuples as atomic labels on an axis:

```
In [22]: pd.Series(np.random.randn(8), index=tuples)
Out[22]:
```

(continues on next page)

(continued from previous page)

```
(bar, one)    0.298744
(bar, two)    1.214079
(baz, one)    0.328033
(baz, two)   -0.672244
(foo, one)    0.001022
(foo, two)   -0.269680
(qux, one)   -1.508557
(qux, two)   -0.018842
dtype: float64
```

The reason that the `MultiIndex` matters is that it can allow you to do grouping, selection, and reshaping operations as we will describe below and in subsequent areas of the documentation. As you will see in later sections, you can find yourself working with hierarchically-indexed data without creating a `MultiIndex` explicitly yourself. However, when loading data from a file, you may wish to generate your own `MultiIndex` when preparing the data set.

Reconstructing the level labels

The method `get_level_values()` will return a vector of the labels for each location at a particular level:

```
In [23]: index.get_level_values(0)
Out[23]: Index(['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'], dtype='object',
↳name='first')
```

```
In [24]: index.get_level_values('second')
Out[24]: Index(['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two'], dtype='object',
↳name='second')
```

Basic indexing on axis with `MultiIndex`

One of the important features of hierarchical indexing is that you can select data by a “partial” label identifying a subgroup in the data. **Partial** selection “drops” levels of the hierarchical index in the result in a completely analogous way to selecting a column in a regular `DataFrame`:

```
In [25]: df['bar']
Out[25]:
second      one      two
A      0.771686 -1.515175
B      1.802824 -1.471259
C      1.319947  0.675934
```

```
In [26]: df['bar', 'one']
Out[26]:
A      0.771686
B      1.802824
C      1.319947
Name: (bar, one), dtype: float64
```

```
In [27]: df['bar']['one']
Out[27]:
A      0.771686
B      1.802824
```

```
C      1.319947
Name: one, dtype: float64
```

```
In [28]: s['qux']
Out[28]:
one      1.462932
two     -1.206173
dtype: float64
```

See *Cross-section with hierarchical index* for how to select on a deeper level.

Defined levels

The `MultiIndex` keeps all the defined levels of an index, even if they are not actually used. When slicing an index, you may notice this. For example:

```
In [29]: df.columns.levels # original MultiIndex
Out[29]: FrozenList(['bar', 'baz', 'foo', 'qux'], ['one', 'two'])
```

```
In [30]: df[['foo', 'qux']].columns.levels # sliced
Out[30]: FrozenList(['bar', 'baz', 'foo', 'qux'], ['one', 'two'])
```

This is done to avoid a recomputation of the levels in order to make slicing highly performant. If you want to see only the used levels, you can use the `get_level_values()` method.

```
In [31]: df[['foo', 'qux']].columns.to_numpy()
Out[31]:
array([('foo', 'one'), ('foo', 'two'), ('qux', 'one'), ('qux', 'two')],
      dtype=object)
```

for a specific level

```
In [32]: df[['foo', 'qux']].columns.get_level_values(0)
Out[32]: Index(['foo', 'foo', 'qux', 'qux'], dtype='object', name='first')
```

To reconstruct the `MultiIndex` with only the used levels, the `remove_unused_levels()` method may be used.

New in version 0.20.0.

```
In [33]: new_mi = df[['foo', 'qux']].columns.remove_unused_levels()
```

```
In [34]: new_mi.levels
Out[34]: FrozenList(['foo', 'qux'], ['one', 'two'])
```

Data alignment and using `reindex`

Operations between differently-indexed objects having `MultiIndex` on the axes will work as you expect; data alignment will work the same as an `Index` of tuples:

```
In [35]: s + s[:-2]
Out[35]:
bar one    0.490471
     two    0.032756
baz one   -0.694656
     two    1.200123
foo one   -2.600908
```

```
two -1.626856
qux one      NaN
two      NaN
dtype: float64
```

```
In [36]: s + s[:,2]
```

```
Out[36]:
bar one    0.490471
      two     NaN
baz one   -0.694656
      two     NaN
foo one   -2.600908
      two     NaN
qux one    2.925863
      two     NaN
dtype: float64
```

The `reindex()` method of `Series/DataFrames` can be called with another `MultiIndex`, or even a list or array of tuples:

```
In [37]: s.reindex(index[:3])
```

```
Out[37]:
first second
bar   one    0.245235
      two    0.016378
baz   one   -0.347328
dtype: float64
```

```
In [38]: s.reindex([('foo', 'two'), ('bar', 'one'), ('qux', 'one'), ('baz', 'one')])
```

```
Out[38]:
foo two   -0.813428
bar one    0.245235
qux one    1.462932
baz one   -0.347328
dtype: float64
```

4.3.2 Advanced indexing with hierarchical index

Syntactically integrating `MultiIndex` in advanced indexing with `.loc` is a bit challenging, but we've made every effort to do so. In general, `MultiIndex` keys take the form of tuples. For example, the following works as you would expect:

```
In [39]: df = df.T
```

```
In [40]: df
```

```
Out[40]:
```

		A	B	C
first	second			
bar	one	0.771686	1.802824	1.319947
	two	-1.515175	-1.471259	0.675934
baz	one	0.803511	0.326461	2.202010
	two	-1.127083	1.536432	-0.521456
foo	one	-0.597308	-0.081085	0.021556
	two	-0.605145	-0.147244	0.789515
qux	one	0.556247	0.101228	-0.895903

```
two    -0.632974  0.450182  1.202173
```

```
In [41]: df.loc[('bar', 'two')]
```

```
Out[41]:
```

```
A    -1.515175
```

```
B    -1.471259
```

```
C     0.675934
```

```
Name: (bar, two), dtype: float64
```

Note that `df.loc['bar', 'two']` would also work in this example, but this shorthand notation can lead to ambiguity in general.

If you also want to index a specific column with `.loc`, you must use a tuple like this:

```
In [42]: df.loc[('bar', 'two'), 'A']
```

```
Out[42]: -1.5151745976123117
```

You don't have to specify all levels of the `MultiIndex` by passing only the first elements of the tuple. For example, you can use “partial” indexing to get all elements with `bar` in the first level as follows:

```
df.loc['bar']
```

This is a shortcut for the slightly more verbose notation `df.loc[('bar',),]` (equivalent to `df.loc['bar',]` in this example).

“Partial” slicing also works quite nicely.

```
In [43]: df.loc['baz':'foo']
```

```
Out[43]:
```

```

           A         B         C
first second
baz  one    0.803511  0.326461  2.202010
     two   -1.127083  1.536432 -0.521456
foo  one   -0.597308 -0.081085  0.021556
     two   -0.605145 -0.147244  0.789515
```

You can slice with a ‘range’ of values, by providing a slice of tuples.

```
In [44]: df.loc[('baz', 'two'):(('qux', 'one'))]
```

```
Out[44]:
```

```

           A         B         C
first second
baz  two   -1.127083  1.536432 -0.521456
foo  one   -0.597308 -0.081085  0.021556
     two   -0.605145 -0.147244  0.789515
qux  one    0.556247  0.101228 -0.895903
```

```
In [45]: df.loc[('baz', 'two'):'foo']
```

```
Out[45]:
```

```

           A         B         C
first second
baz  two   -1.127083  1.536432 -0.521456
foo  one   -0.597308 -0.081085  0.021556
     two   -0.605145 -0.147244  0.789515
```

Passing a list of labels or tuples works similar to reindexing:

```
In [46]: df.loc[ [('bar', 'two'), ('qux', 'one') ]]
```

```
Out [46]:
```

```

           A          B          C
first second
bar  two   -1.515175 -1.471259  0.675934
qux  one    0.556247  0.101228 -0.895903
```

Note: It is important to note that tuples and lists are not treated identically in pandas when it comes to indexing. Whereas a tuple is interpreted as one multi-level key, a list is used to specify several keys. Or in other words, tuples go horizontally (traversing levels), lists go vertically (scanning levels).

Importantly, a list of tuples indexes several complete `MultiIndex` keys, whereas a tuple of lists refer to several values within a level:

```
In [47]: s = pd.Series([1, 2, 3, 4, 5, 6],
....:                  index=pd.MultiIndex.from_product([["A", "B"], ["c", "d", "e"]]))
....:
```

```
In [48]: s.loc[ [("A", "c"), ("B", "d") ] ] # list of tuples
```

```
Out [48]:
```

```

A  c    1
B  d    5
dtype: int64
```

```
In [49]: s.loc[ (["A", "B"], ["c", "d"]) ] # tuple of lists
```

```
Out [49]:
```

```

A  c    1
   d    2
B  c    4
   d    5
dtype: int64
```

Using slicers

You can slice a `MultiIndex` by providing multiple indexers.

You can provide any of the selectors as if you are indexing by label, see *Selection by Label*, including slices, lists of labels, labels, and boolean indexers.

You can use `slice(None)` to select all the contents of *that* level. You do not need to specify all the *deeper* levels, they will be implied as `slice(None)`.

As usual, **both sides** of the slicers are included as this is label indexing.

Warning: You should specify all axes in the `.loc` specifier, meaning the indexer for the **index** and for the **columns**. There are some ambiguous cases where the passed indexer could be mis-interpreted as indexing *both* axes, rather than into say the `MultiIndex` for the rows.

You should do this:

```
df.loc[(slice('A1', 'A3'), ...), :] # noqa: E999
```

You should **not** do this:

```
df.loc[(slice('A1', 'A3'), ...)] # noqa: E999
```

```
In [50]: def mklbl(prefix, n):
....:     return ["%s%s" % (prefix, i) for i in range(n)]
....:

In [51]: miindex = pd.MultiIndex.from_product([mklbl('A', 4),
....:                                         mklbl('B', 2),
....:                                         mklbl('C', 4),
....:                                         mklbl('D', 2)])
....:

In [52]: micolumns = pd.MultiIndex.from_tuples([('a', 'foo'), ('a', 'bar'),
....:                                         ('b', 'foo'), ('b', 'bah')],
....:                                         names=['lv10', 'lv11'])
....:

In [53]: dfmi = pd.DataFrame(np.arange(len(miindex) * len(micolumns))
....:                          .reshape((len(miindex), len(micolumns))),
....:                          index=miindex,
....:                          columns=micolumns).sort_index().sort_index(axis=1)
....:

In [54]: dfmi
Out[54]:
```

lv10				a		b	
lv11				bar	foo	bah	foo
A0	B0	C0	D0	1	0	3	2
			D1	5	4	7	6
		C1	D0	9	8	11	10
			D1	13	12	15	14
		C2	D0	17	16	19	18
...		
A3	B1	C1	D1	237	236	239	238
		C2	D0	241	240	243	242
			D1	245	244	247	246
		C3	D0	249	248	251	250
			D1	253	252	255	254

```
[64 rows x 4 columns]
```

Basic MultiIndex slicing using slices, lists, and labels.

```
In [55]: dfmi.loc[(slice('A1', 'A3'), slice(None), ['C1', 'C3']), :]
Out[55]:
```

lv10				a		b	
lv11				bar	foo	bah	foo
A1	B0	C1	D0	73	72	75	74
			D1	77	76	79	78
		C3	D0	89	88	91	90
			D1	93	92	95	94

(continues on next page)

(continued from previous page)

```

    B1 C1 D0 105 104 107 106
        D1 109 108 111 110
        C3 D0 121 120 123 122
        D1 125 124 127 126
A2 BO C1 D0 137 136 139 138
        D1 141 140 143 142
        C3 D0 153 152 155 154
        D1 157 156 159 158
    B1 C1 D0 169 168 171 170
        D1 173 172 175 174
        C3 D0 185 184 187 186

        D1 253 252 255 254

```

You can use `pandas.IndexSlice` to facilitate a more natural syntax using `:`, rather than using `slice(None)`.

```
In [56]: idx = pd.IndexSlice
```

```
In [57]: dfmi.loc[idx[:, :, ['C1', 'C3']], idx[:, 'foo']]
```

```
Out[57]:
```

```

lvl0      a      b
lvl1      foo  foo
A0 BO C1 D0    8   10
        D1   12   14
        C3 D0   24   26
        D1   28   30
    B1 C1 D0   40   42
        D1   44   46
        C3 D0   56   58
        D1   60   62
A1 BO C1 D0   72   74
        D1   76   78
        C3 D0   88   90
        D1   92   94
    B1 C1 D0  104  106
        D1  108  110
        C3 D0  120  122
        D1  124  126
A2 BO C1 D0  136  138
        D1  140  142
        C3 D0  152  154
        D1  156  158
    B1 C1 D0  168  170
        D1  172  174
        C3 D0  184  186

```

(continues on next page)

(continued from previous page)

			D1	188	190
A3	B0	C1	D0	200	202
			D1	204	206
		C3	D0	216	218
			D1	220	222
B1	C1	D0	232	234	
			D1	236	238
		C3	D0	248	250
			D1	252	254

It is possible to perform quite complicated selections using this method on multiple axes at the same time.

```
In [58]: dfmi.loc['A1', (slice(None), 'foo')]
```

```
Out[58]:
```

```
lvl0      a      b
lvl1      foo  foo
B0 C0 D0   64   66
      D1   68   70

      D1  100  102
      C1 D0  104  106
      D1  108  110
      C2 D0  112  114
      D1  116  118
      C3 D0  120  122
      D1  124  126
```

```
In [59]: dfmi.loc[idx[:, :, ['C1', 'C3']], idx[:, 'foo']]
```

```
Out[59]:
```

```
lvl0      a      b
lvl1      foo  foo
A0 B0 C1 D0    8   10
      D1   12   14
      C3 D0   24   26
      D1   28   30
      B1 C1 D0   40   42
      D1   44   46
      C3 D0   56   58
      D1   60   62
A1 B0 C1 D0   72   74
      D1   76   78
      C3 D0   88   90
      D1   92   94
      B1 C1 D0  104  106
      D1  108  110
      C3 D0  120  122
      D1  124  126
```

```

A2 B0 C1 D0 136 138
      D1 140 142
      C3 D0 152 154
      D1 156 158
  B1 C1 D0 168 170
      D1 172 174
      C3 D0 184 186
      D1 188 190
A3 B0 C1 D0 200 202
      D1 204 206
      C3 D0 216 218
      D1 220 222
  B1 C1 D0 232 234
      D1 236 238
      C3 D0 248 250
      D1 252 254

```

Using a boolean indexer you can provide selection related to the *values*.

```

In [60]: mask = dfmi[('a', 'foo')] > 200

In [61]: dfmi.loc[idx[mask, :], ['C1', 'C3']], idx[:, 'foo']]
Out[61]:
lvl0      a      b
lvl1      foo  foo
A3 B0 C1 D1 204 206
      C3 D0 216 218
      D1 220 222
  B1 C1 D0 232 234
      D1 236 238
      C3 D0 248 250
      D1 252 254

```

You can also specify the axis argument to `.loc` to interpret the passed slicers on a single axis.

```

In [62]: dfmi.loc(axis=0)[:, :, ['C1', 'C3']]
Out[62]:
lvl0      a      b
lvl1      bar  foo  bah  foo
A0 B0 C1 D0   9   8  11  10
      D1  13  12  15  14
      C3 D0  25  24  27  26
      D1  29  28  31  30
  B1 C1 D0  41  40  43  42
      D1  45  44  47  46
      C3 D0  57  56  59  58
      D1  61  60  63  62
A1 B0 C1 D0  73  72  75  74
      D1  77  76  79  78
      C3 D0  89  88  91  90
      D1  93  92  95  94
  B1 C1 D0 105 104 107 106
      D1 109 108 111 110
      C3 D0 121 120 123 122

```

(continues on next page)

(continued from previous page)

```

      D1 125 124 127 126
A2 BO C1 D0 137 136 139 138
      D1 141 140 143 142
      C3 D0 153 152 155 154
      D1 157 156 159 158
      B1 C1 D0 169 168 171 170
      D1 173 172 175 174
      C3 D0 185 184 187 186
      D1 189 188 191 190
A3 BO C1 D0 201 200 203 202
      D1 205 204 207 206
      C3 D0 217 216 219 218
      D1 221 220 223 222
      B1 C1 D0 233 232 235 234
      D1 237 236 239 238
      C3 D0 249 248 251 250
      D1 253 252 255 254

```

Furthermore, you can *set* the values using the following methods.

```

In [63]: df2 = dfmi.copy()

In [64]: df2.loc(axis=0)[:, :, ['C1', 'C3']] = -10

In [65]: df2
Out[65]:
lv10      a      b
lv11      bar  foo  bah  foo
A0 BO C0 D0    1    0    3    2
      D1    5    4    7    6
      C1 D0 -10 -10 -10 -10
      D1 -10 -10 -10 -10
      C2 D0  17  16  19  18
...

Cross-section

The `xs()` method of `DataFrame` additionally takes a level argument to make selecting data at a particular level of a `MultiIndex` easier.

In [69]: df

Out[69]:

```

              A      B      C
first second
bar  one    0.771686  1.802824  1.319947
     two   -1.515175 -1.471259  0.675934
baz  one    0.803511  0.326461  2.202010
     two   -1.127083  1.536432 -0.521456
foo  one   -0.597308 -0.081085  0.021556
     two   -0.605145 -0.147244  0.789515
qux  one    0.556247  0.101228 -0.895903
     two   -0.632974  0.450182  1.202173

```

In [70]: df.xs('one', level='second')

Out[70]:

```

              A      B      C
first
bar    0.771686  1.802824  1.319947
baz    0.803511  0.326461  2.202010
foo   -0.597308 -0.081085  0.021556
qux    0.556247  0.101228 -0.895903

```

using the slicers

In [71]: df.loc[(slice(None), 'one'), :]

Out[71]:

```

              A      B      C
first second
bar  one    0.771686  1.802824  1.319947
baz  one    0.803511  0.326461  2.202010
foo  one   -0.597308 -0.081085  0.021556
qux  one    0.556247  0.101228 -0.895903

```

You can also select on the columns with `xs`, by providing the axis argument.

```
In [72]: df = df.T
```

```
In [73]: df.xs('one', level='second', axis=1)
```

```
Out[73]:
```

first	bar	baz	foo	qux
A	0.771686	0.803511	-0.597308	0.556247
B	1.802824	0.326461	-0.081085	0.101228
C	1.319947	2.202010	0.021556	-0.895903

```
# using the slicers
```

```
In [74]: df.loc[:, (slice(None), 'one')]
```

```
Out[74]:
```

first	bar	baz	foo	qux
second	one	one	one	one
A	0.771686	0.803511	-0.597308	0.556247
B	1.802824	0.326461	-0.081085	0.101228
C	1.319947	2.202010	0.021556	-0.895903

xs also allows selection with multiple keys.

```
In [75]: df.xs(('one', 'bar'), level=('second', 'first'), axis=1)
```

```
Out[75]:
```

first	bar
second	one
A	0.771686
B	1.802824
C	1.319947

```
# using the slicers
```

```
In [76]: df.loc[:, ('bar', 'one')]
```

```
Out[76]:
```

A	0.771686
B	1.802824
C	1.319947

Name: (bar, one), dtype: float64

You can pass `drop_level=False` to `xs` to retain the level that was selected.

```
In [77]: df.xs('one', level='second', axis=1, drop_level=False)
```

```
Out[77]:
```

first	bar	baz	foo	qux
second	one	one	one	one
A	0.771686	0.803511	-0.597308	0.556247
B	1.802824	0.326461	-0.081085	0.101228
C	1.319947	2.202010	0.021556	-0.895903

Compare the above with the result using `drop_level=True` (the default value).

```
In [78]: df.xs('one', level='second', axis=1, drop_level=True)
```

```
Out[78]:
```

first	bar	baz	foo	qux
A	0.771686	0.803511	-0.597308	0.556247

(continues on next page)

(continued from previous page)

B	1.802824	0.326461	-0.081085	0.101228
C	1.319947	2.202010	0.021556	-0.895903

Advanced reindexing and alignment

Using the parameter `level` in the `reindex()` and `align()` methods of pandas objects is useful to broadcast values across a level. For instance:

```
In [79]: midx = pd.MultiIndex(levels=[['zero', 'one'], ['x', 'y']],
....:                          codes=[[1, 1, 0, 0], [1, 0, 1, 0]])
....:
```

```
In [80]: df = pd.DataFrame(np.random.randn(4, 2), index=midx)
```

```
In [81]: df
Out[81]:
```

		0	1
one	y	-0.346466	0.214630
	x	-1.468255	1.365136
zero	y	-0.092330	-0.395188
	x	-0.998030	0.017783

```
In [82]: df2 = df.mean(level=0)
```

```
In [83]: df2
Out[83]:
```

		0	1
one		-0.907361	0.789883
zero		-0.545180	-0.188703

```
In [84]: df2.reindex(df.index, level=0)
Out[84]:
```

		0	1
one	y	-0.907361	0.789883
	x	-0.907361	0.789883
zero	y	-0.545180	-0.188703
	x	-0.545180	-0.188703

```
# aligning
```

```
In [85]: df_aligned, df2_aligned = df.align(df2, level=0)
```

```
In [86]: df_aligned
Out[86]:
```

		0	1
one	y	-0.346466	0.214630
	x	-1.468255	1.365136
zero	y	-0.092330	-0.395188
	x	-0.998030	0.017783

```
In [87]: df2_aligned
Out[87]:
```

		0	1

```

one y -0.907361  0.789883
   x -0.907361  0.789883
zero y -0.545180 -0.188703
   x -0.545180 -0.188703

```

Swapping levels with `swaplevel`

The `swaplevel()` method can switch the order of two levels:

```
In [88]: df[:5]
```

```
Out[88]:
```

```

           0          1
one  y -0.346466  0.214630
     x -1.468255  1.365136
zero y -0.092330 -0.395188
     x -0.998030  0.017783

```

```
In [89]: df[:5].swaplevel(0, 1, axis=0)
```

```
Out[89]:
```

```

           0          1
y one  -0.346466  0.214630
x one  -1.468255  1.365136
y zero -0.092330 -0.395188
x zero -0.998030  0.017783

```

Reordering levels with `reorder_levels`

The `reorder_levels()` method generalizes the `swaplevel` method, allowing you to permute the hierarchical index levels in one step:

```
In [90]: df[:5].reorder_levels([1, 0], axis=0)
```

```
Out[90]:
```

```

           0          1
y one  -0.346466  0.214630
x one  -1.468255  1.365136
y zero -0.092330 -0.395188
x zero -0.998030  0.017783

```

Renaming names of an Index or MultiIndex

The `rename()` method is used to rename the labels of a `MultiIndex`, and is typically used to rename the columns of a `DataFrame`. The `columns` argument of `rename` allows a dictionary to be specified that includes only the columns you wish to rename.

```
In [91]: df.rename(columns={0: "col0", 1: "col1"})
```

```
Out[91]:
```

```

           col0      col1
one  y -0.346466  0.214630
     x -1.468255  1.365136
zero y -0.092330 -0.395188
     x -0.998030  0.017783

```

This method can also be used to rename specific labels of the main index of the `DataFrame`.

```
In [92]: df.rename(index={"one": "two", "y": "z"})
```

```
Out[92]:
```

```

           0         1
two  z -0.346466  0.214630
     x -1.468255  1.365136
zero z -0.092330 -0.395188
     x -0.998030  0.017783
```

The `rename_axis()` method is used to rename the name of a `Index` or `MultiIndex`. In particular, the names of the levels of a `MultiIndex` can be specified, which is useful if `reset_index()` is later used to move the values from the `MultiIndex` to a column.

```
In [93]: df.rename_axis(index=['abc', 'def'])
```

```
Out[93]:
```

```

           0         1
abc  def
one  y  -0.346466  0.214630
     x  -1.468255  1.365136
zero y  -0.092330 -0.395188
     x  -0.998030  0.017783
```

Note that the columns of a `DataFrame` are an index, so that using `rename_axis` with the `columns` argument will change the name of that index.

```
In [94]: df.rename_axis(columns="Cols").columns
```

```
Out[94]: RangeIndex(start=0, stop=2, step=1, name='Cols')
```

Both `rename` and `rename_axis` support specifying a dictionary, `Series` or a mapping function to map labels/names to new values.

4.3.3 Sorting a `MultiIndex`

For `MultiIndex`-ed objects to be indexed and sliced effectively, they need to be sorted. As with any index, you can use `sort_index()`.

```
In [95]: import random
```

```
In [96]: random.shuffle(tuples)
```

```
In [97]: s = pd.Series(np.random.randn(8), index=pd.MultiIndex.from_tuples(tuples))
```

```
In [98]: s
```

```
Out[98]:
```

```

baz  one  -1.164671
qux  one  -0.923714
foo  one  -0.936684
baz  two  -0.850529
qux  two   0.371209
foo  two   0.662579
bar  two   1.537426
     one  -0.899351
dtype: float64
```

```
In [99]: s.sort_index()
Out[99]:
bar one    -0.899351
     two     1.537426
baz one    -1.164671
     two    -0.850529
foo one    -0.936684
     two     0.662579
qux one    -0.923714
     two     0.371209
dtype: float64
```

```
In [100]: s.sort_index(level=0)
Out[100]:
bar one    -0.899351
     two     1.537426
baz one    -1.164671
     two    -0.850529
foo one    -0.936684
     two     0.662579
qux one    -0.923714
     two     0.371209
dtype: float64
```

```
In [101]: s.sort_index(level=1)
Out[101]:
bar one    -0.899351
baz one    -1.164671
foo one    -0.936684
qux one    -0.923714
bar two     1.537426
baz two    -0.850529
foo two     0.662579
qux two     0.371209
dtype: float64
```

You may also pass a level name to `sort_index` if the `MultiIndex` levels are named.

```
In [102]: s.index.set_names(['L1', 'L2'], inplace=True)
```

```
In [103]: s.sort_index(level='L1')
Out[103]:
L1  L2
bar one    -0.899351
     two     1.537426
baz one    -1.164671
     two    -0.850529
foo one    -0.936684
     two     0.662579
qux one    -0.923714
     two     0.371209
dtype: float64
```

```
In [104]: s.sort_index(level='L2')
```

```
Out[104]:
L1  L2
bar one   -0.899351
baz one   -1.164671
foo one   -0.936684
qux one   -0.923714
bar two    1.537426
baz two   -0.850529
foo two    0.662579
qux two    0.371209
dtype: float64
```

On higher dimensional objects, you can sort any of the other axes by level if they have a `MultiIndex`:

```
In [105]: df.T.sort_index(level=1, axis=1)
Out[105]:
      one      zero      one      zero
      x      x      y      y
0 -1.468255 -0.998030 -0.346466 -0.092330
1  1.365136  0.017783  0.214630 -0.395188
```

Indexing will work even if the data are not sorted, but will be rather inefficient (and show a `PerformanceWarning`). It will also return a copy of the data rather than a view:

```
In [106]: dfm = pd.DataFrame({'jim': [0, 0, 1, 1],
.....:                       'joe': ['x', 'x', 'z', 'y'],
.....:                       'jolie': np.random.rand(4)})
.....:

In [107]: dfm = dfm.set_index(['jim', 'joe'])

In [108]: dfm
Out[108]:
      jolie
jim joe
0  x  0.468958
   x  0.330760
1  z  0.394711
   y  0.247768
```

```
In [4]: dfm.loc[(1, 'z')]
PerformanceWarning: indexing past lexsort depth may impact performance.
```

```
Out[4]:
      jolie
jim joe
1  z  0.64094
```

Furthermore, if you try to index something that is not fully lexsorted, this can raise:

```
In [5]: dfm.loc[(0, 'y'):(1, 'z')]
UnsortedIndexError: 'Key length (2) was greater than MultiIndex lexsort depth (1)'
```

The `is_lexsorted()` method on a `MultiIndex` shows if the index is sorted, and the `lexsort_depth` property returns the sort depth:

```
In [109]: dfm.index.is_lexsorted()
Out[109]: False
```

```
In [110]: dfm.index.lexsort_depth
Out[110]: 1
```

```
In [111]: dfm = dfm.sort_index()
```

```
In [112]: dfm
Out[112]:
```

```
           jolie
jim joe
0    x    0.468958
   x    0.330760
1    y    0.247768
   z    0.394711
```

```
In [113]: dfm.index.is_lexsorted()
Out[113]: True
```

```
In [114]: dfm.index.lexsort_depth
Out[114]: 2
```

And now selection works as expected.

```
In [115]: dfm.loc[(0, 'y'):(1, 'z')]
Out[115]:
```

```
           jolie
jim joe
1    y    0.247768
   z    0.394711
```

4.3.4 Take methods

Similar to NumPy ndarrays, pandas `Index`, `Series`, and `DataFrame` also provides the `take()` method that retrieves elements along a given axis at the given indices. The given indices must be either a list or an ndarray of integer index positions. `take` will also accept negative integers as relative positions to the end of the object.

```
In [116]: index = pd.Index(np.random.randint(0, 1000, 10))
```

```
In [117]: index
Out[117]: Int64Index([680, 761, 606, 142, 515, 764, 803, 789, 939, 518], dtype='int64')
```

```
In [118]: positions = [0, 9, 3]
```

```
In [119]: index[positions]
Out[119]: Int64Index([680, 518, 142], dtype='int64')
```

```
In [120]: index.take(positions)
Out[120]: Int64Index([680, 518, 142], dtype='int64')
```

```
In [121]: ser = pd.Series(np.random.randn(10))
```

```
In [122]: ser.iloc[positions]
Out[122]:
0    2.280385
9    0.956264
3    2.762272
dtype: float64
```

```
In [123]: ser.take(positions)
Out[123]:
0    2.280385
9    0.956264
3    2.762272
dtype: float64
```

For DataFrames, the given indices should be a 1d list or ndarray that specifies row or column positions.

```
In [124]: frm = pd.DataFrame(np.random.randn(5, 3))
```

```
In [125]: frm.take([1, 4, 3])
Out[125]:
```

	0	1	2
1	0.738768	0.993067	-0.168278
4	1.435509	1.156972	-1.894376
3	0.856561	0.613109	0.623521

```
In [126]: frm.take([0, 2], axis=1)
Out[126]:
```

	0	2
0	-0.502004	-1.293411
1	0.738768	-0.168278
2	0.990542	0.565096
3	0.856561	0.623521
4	1.435509	-1.894376

It is important to note that the `take` method on pandas objects are not intended to work on boolean indices and may return unexpected results.

```
In [127]: arr = np.random.randn(10)
```

```
In [128]: arr.take([False, False, True, True])
Out[128]: array([0.53782366, 0.53782366, 0.02173914, 0.02173914])
```

```
In [129]: arr[[0, 1]]
Out[129]: array([0.53782366, 0.02173914])
```

```
In [130]: ser = pd.Series(np.random.randn(10))
```

```
In [131]: ser.take([False, False, True, True])
Out[131]:
0    2.007833
0    2.007833
1   -0.768178
1   -0.768178
dtype: float64
```

```
In [132]: ser.iloc[[0, 1]]
```

```
Out[132]:
0    2.007833
1   -0.768178
dtype: float64
```

Finally, as a small note on performance, because the `take` method handles a narrower range of inputs, it can offer performance that is a good deal faster than fancy indexing.

```
In [133]: arr = np.random.randn(10000, 5)

In [134]: indexer = np.arange(10000)

In [135]: random.shuffle(indexer)

In [136]: %timeit arr[indexer]
.....: %timeit arr.take(indexer, axis=0)
.....:
212 us +- 3.34 us per loop (mean +- std. dev. of 7 runs, 1000 loops each)
77.6 us +- 1.48 us per loop (mean +- std. dev. of 7 runs, 10000 loops each)
```

```
In [137]: ser = pd.Series(arr[:, 0])

In [138]: %timeit ser.iloc[indexer]
.....: %timeit ser.take(indexer)
.....:
124 us +- 1.29 us per loop (mean +- std. dev. of 7 runs, 10000 loops each)
113 us +- 2.7 us per loop (mean +- std. dev. of 7 runs, 10000 loops each)
```

4.3.5 Index types

We have discussed `MultiIndex` in the previous sections pretty extensively. Documentation about `DatetimeIndex` and `PeriodIndex` are shown [here](#), and documentation about `TimedeltaIndex` is found [here](#).

In the following sub-sections we will highlight some other index types.

CategoricalIndex

`CategoricalIndex` is a type of index that is useful for supporting indexing with duplicates. This is a container around a `Categorical` and allows efficient indexing and storage of an index with a large number of duplicated elements.

```
In [139]: from pandas.api.types import CategoricalDtype

In [140]: df = pd.DataFrame({'A': np.arange(6),
.....:                       'B': list('aabbca')})
.....:

In [141]: df['B'] = df['B'].astype(CategoricalDtype(list('cab')))

In [142]: df
Out[142]:
   A  B
```

```
0 0 a
1 1 a
2 2 b
3 3 b
4 4 c
5 5 a
```

```
In [143]: df.dtypes
Out[143]:
A      int64
B      category
dtype: object
```

```
In [144]: df.B.cat.categories
Out[144]: Index(['c', 'a', 'b'], dtype='object')
```

Setting the index will create a `CategoricalIndex`.

```
In [145]: df2 = df.set_index('B')

In [146]: df2.index
Out[146]: CategoricalIndex(['a', 'a', 'b', 'b', 'c', 'a'], categories=['c', 'a', 'b'],
↳ordered=False, name='B', dtype='category')
```

Indexing with `__getitem__`/`.iloc`/`.loc` works similarly to an `Index` with duplicates. The indexers **must** be in the category or the operation will raise a `KeyError`.

```
In [147]: df2.loc['a']
Out[147]:
A
B
a 0
a 1
a 5
```

The `CategoricalIndex` is **preserved** after indexing:

```
In [148]: df2.loc['a'].index
Out[148]: CategoricalIndex(['a', 'a', 'a'], categories=['c', 'a', 'b'], ordered=False,
↳name='B', dtype='category')
```

Sorting the index will sort by the order of the categories (recall that we created the index with `CategoricalDtype(list('cab'))`), so the sorted order is `cab`).

```
In [149]: df2.sort_index()
Out[149]:
A
B
c 4
a 0
a 1
a 5
b 2
b 3
```

Groupby operations on the index will preserve the index nature as well.

```
In [150]: df2.groupby(level=0).sum()
```

```
Out[150]:
```

```
  A
  B
  c  4
  a  6
  b  5
```

```
In [151]: df2.groupby(level=0).sum().index
```

```
Out[151]: CategoricalIndex(['c', 'a', 'b'], categories=['c', 'a', 'b'], ordered=False,
↳ name='B', dtype='category')
```

Reindexing operations will return a resulting index based on the type of the passed indexer. Passing a list will return a plain-old `Index`; indexing with a `Categorical` will return a `CategoricalIndex`, indexed according to the categories of the **passed** `Categorical` dtype. This allows one to arbitrarily index these even with values **not** in the categories, similarly to how you can reindex **any** pandas index.

```
In [152]: df2.reindex(['a', 'e'])
```

```
Out[152]:
```

```
  A
  B
  a  0.0
  a  1.0
  a  5.0
  e  NaN
```

```
In [153]: df2.reindex(['a', 'e']).index
```

```
Out[153]: Index(['a', 'a', 'a', 'e'], dtype='object', name='B')
```

```
In [154]: df2.reindex(pd.Categorical(['a', 'e'], categories=list('abcde')))
```

```
Out[154]:
```

```
  A
  B
  a  0.0
  a  1.0
  a  5.0
  e  NaN
```

```
In [155]: df2.reindex(pd.Categorical(['a', 'e'], categories=list('abcde'))).index
```

```
Out[155]: CategoricalIndex(['a', 'a', 'a', 'e'], categories=['a', 'b', 'c', 'd', 'e'],
↳ ordered=False, name='B', dtype='category')
```

Warning: Reshaping and Comparison operations on a `CategoricalIndex` must have the same categories or a `TypeError` will be raised.

```
In [9]: df3 = pd.DataFrame({'A': np.arange(6), 'B': pd.Series(list('aabbca')).astype(
↳ 'category')})
```

```
In [11]: df3 = df3.set_index('B')
```

```
In [11]: df3.index
```

```
Out[11]: CategoricalIndex(['a', 'a', 'b', 'b', 'c', 'a'], categories=['a', 'b', 'c'],
↳ ordered=False, name='B', dtype='category')
```

```
In [12]: pd.concat([df2, df3])
```

4.3. MultiIndex / advanced indexing `TypeError: categories must match existing categories when appending`

Int64Index and RangeIndex

Warning: Indexing on an integer-based Index with floats has been clarified in 0.18.0, for a summary of the changes, see *here*.

`Int64Index` is a fundamental basic index in pandas. This is an immutable array implementing an ordered, sliceable set. Prior to 0.18.0, the `Int64Index` would provide the default index for all `NDFrame` objects.

`RangeIndex` is a sub-class of `Int64Index` added in version 0.18.0, now providing the default index for all `NDFrame` objects. `RangeIndex` is an optimized version of `Int64Index` that can represent a monotonic ordered set. These are analogous to Python [range types](#).

Float64Index

By default a `Float64Index` will be automatically created when passing floating, or mixed-integer-floating values in index creation. This enables a pure label-based slicing paradigm that makes `[], ix, loc` for scalar indexing and slicing work exactly the same.

```
In [156]: indexf = pd.Index([1.5, 2, 3, 4.5, 5])
In [157]: indexf
Out[157]: Float64Index([1.5, 2.0, 3.0, 4.5, 5.0], dtype='float64')
In [158]: sf = pd.Series(range(5), index=indexf)
In [159]: sf
Out[159]:
1.5    0
2.0    1
3.0    2
4.5    3
5.0    4
dtype: int64
```

Scalar selection for `[], .loc` will always be label based. An integer will match an equal float index (e.g. 3 is equivalent to 3.0).

```
In [160]: sf[3]
Out[160]: 2
```

```
In [161]: sf[3.0]
Out[161]: 2
```

```
In [162]: sf.loc[3]
Out[162]: 2
```

```
In [163]: sf.loc[3.0]
Out[163]: 2
```

The only positional indexing is via `iloc`.

```
In [164]: sf.iloc[3]
Out[164]: 3
```

A scalar index that is not found will raise a `KeyError`. Slicing is primarily on the values of the index when using `[]`, `ix`, `loc`, and **always** positional when using `iloc`. The exception is when the slice is boolean, in which case it will always be positional.

```
In [165]: sf[2:4]
Out[165]:
2.0    1
3.0    2
dtype: int64
```

```
In [166]: sf.loc[2:4]
Out[166]:
2.0    1
3.0    2
dtype: int64
```

```
In [167]: sf.iloc[2:4]
Out[167]:
3.0    2
4.5    3
dtype: int64
```

In float indexes, slicing using floats is allowed.

```
In [168]: sf[2.1:4.6]
Out[168]:
3.0    2
4.5    3
dtype: int64
```

```
In [169]: sf.loc[2.1:4.6]
Out[169]:
3.0    2
4.5    3
dtype: int64
```

In non-float indexes, slicing using floats will raise a `TypeError`.

```
In [1]: pd.Series(range(5))[3.5]
TypeError: the label [3.5] is not a proper indexer for this index type (Int64Index)

In [1]: pd.Series(range(5))[3.5:4.5]
TypeError: the slice start [3.5] is not a proper indexer for this index type (Int64Index)
```

Warning: Using a scalar float indexer for `.iloc` has been removed in 0.18.0, so the following will raise a `TypeError`:

```
In [3]: pd.Series(range(5)).iloc[3.0]
TypeError: cannot do positional indexing on <class 'pandas.indexes.range.RangeIndex'>
↪with these indexers [3.0] of <type 'float'>
```

Here is a typical use-case for using this type of indexing. Imagine that you have a somewhat irregular timedelta-like indexing scheme, but the data is recorded as floats. This could, for example, be millisecond offsets.

```
In [170]: dfir = pd.concat([pd.DataFrame(np.random.randn(5, 2),
.....:                                index=np.arange(5) * 250.0,
.....:                                columns=list('AB')),
.....:                    pd.DataFrame(np.random.randn(6, 2),
.....:                                index=np.arange(4, 10) * 250.1,
.....:                                columns=list('AB'))])

In [171]: dfir
Out[171]:
```

	A	B
0.0	-0.242414	2.329011
250.0	0.764004	0.234595
500.0	2.148210	-0.555984
750.0	-1.494413	-1.635996
1000.0	0.806457	-0.952539
1000.4	0.671243	1.005818
1250.5	-0.658081	0.439328
1500.6	-1.203373	0.245992
1750.7	1.498864	-0.599532
2000.8	-0.985225	-1.469645
2250.9	-0.364937	0.107360

Selection operations then will always work on a value basis, for all selection operators.

```
In [172]: dfir[0:1000.4]
Out[172]:
```

	A	B
0.0	-0.242414	2.329011
250.0	0.764004	0.234595
500.0	2.148210	-0.555984
750.0	-1.494413	-1.635996
1000.0	0.806457	-0.952539
1000.4	0.671243	1.005818

```
In [173]: dfir.loc[0:1001, 'A']
Out[173]:
```

0.0	-0.242414
250.0	0.764004
500.0	2.148210
750.0	-1.494413
1000.0	0.806457
1000.4	0.671243

```
Name: A, dtype: float64

In [174]: dfir.loc[1000.4]
Out[174]:
```

A	0.671243
B	1.005818

```
Name: 1000.4, dtype: float64
```

You could retrieve the first 1 second (1000 ms) of data as such:

```
In [175]: dfir[0:1000]
Out[175]:
```

	A	B
0.0	-0.242414	2.329011
250.0	0.764004	0.234595
500.0	2.148210	-0.555984
750.0	-1.494413	-1.635996
1000.0	0.806457	-0.952539

If you need integer based selection, you should use `iloc`:

```
In [176]: dfir.iloc[0:5]
Out[176]:
```

	A	B
0.0	-0.242414	2.329011
250.0	0.764004	0.234595
500.0	2.148210	-0.555984
750.0	-1.494413	-1.635996
1000.0	0.806457	-0.952539

IntervalIndex

New in version 0.20.0.

`IntervalIndex` together with its own dtype, `IntervalDtype` as well as the `Interval` scalar type, allow first-class support in pandas for interval notation.

The `IntervalIndex` allows some unique indexing and is also used as a return type for the categories in `cut()` and `qcut()`.

Indexing with an IntervalIndex

An `IntervalIndex` can be used in `Series` and in `DataFrame` as the index.

```
In [177]: df = pd.DataFrame({'A': [1, 2, 3, 4]},
.....:                      index=pd.IntervalIndex.from_breaks([0, 1, 2, 3, 4]))
.....:

In [178]: df
Out[178]:
```

A	
(0, 1]	1
(1, 2]	2
(2, 3]	3
(3, 4]	4

Label based indexing via `.loc` along the edges of an interval works as you would expect, selecting that particular interval.

```
In [179]: df.loc[2]
Out[179]:
```

A
2

```
Name: (1, 2], dtype: int64
```

```
In [180]: df.loc[[2, 3]]
```

```
Out[180]:
```

```
      A
(1, 2] 2
(2, 3] 3
```

If you select a label *contained* within an interval, this will also select the interval.

```
In [181]: df.loc[2.5]
```

```
Out[181]:
```

```
A      3
```

```
Name: (2, 3], dtype: int64
```

```
In [182]: df.loc[[2.5, 3.5]]
```

```
Out[182]:
```

```
      A
(2, 3] 3
(3, 4] 4
```

Selecting using an `Interval` will only return exact matches (starting from pandas 0.25.0).

```
In [183]: df.loc[pd.Interval(1, 2)]
```

```
Out[183]:
```

```
A      2
```

```
Name: (1, 2], dtype: int64
```

Trying to select an `Interval` that is not exactly contained in the `IntervalIndex` will raise a `KeyError`.

```
In [7]: df.loc[pd.Interval(0.5, 2.5)]
```

```
-----
KeyError: Interval(0.5, 2.5, closed='right')
```

Selecting all `Intervals` that overlap a given `Interval` can be performed using the `overlaps()` method to create a boolean indexer.

```
In [184]: idxr = df.index.overlaps(pd.Interval(0.5, 2.5))
```

```
In [185]: idxr
```

```
Out[185]: array([ True,  True,  True, False])
```

```
In [186]: df[idxr]
```

```
Out[186]:
```

```
      A
(0, 1] 1
(1, 2] 2
(2, 3] 3
```

Binning data with `cut` and `qcut`

`cut()` and `qcut()` both return a `Categorical` object, and the bins they create are stored as an `IntervalIndex` in its `.categories` attribute.

```
In [187]: c = pd.cut(range(4), bins=2)
```

```
In [188]: c
Out[188]:
[(-0.003, 1.5], (-0.003, 1.5], (1.5, 3.0], (1.5, 3.0]]
Categories (2, interval[float64]): [(-0.003, 1.5] < (1.5, 3.0]]
```

```
In [189]: c.categories
Out[189]:
IntervalIndex([(-0.003, 1.5], (1.5, 3.0]],
              closed='right',
              dtype='interval[float64]')
```

`cut()` also accepts an `IntervalIndex` for its `bins` argument, which enables a useful pandas idiom. First, we call `cut()` with some data and `bins` set to a fixed number, to generate the bins. Then, we pass the values of `.categories` as the `bins` argument in subsequent calls to `cut()`, supplying new data which will be binned into the same bins.

```
In [190]: pd.cut([0, 3, 5, 1], bins=c.categories)
Out[190]:
[(-0.003, 1.5], (1.5, 3.0], NaN, (-0.003, 1.5]]
Categories (2, interval[float64]): [(-0.003, 1.5] < (1.5, 3.0]]
```

Any value which falls outside all bins will be assigned a NaN value.

Generating ranges of intervals

If we need intervals on a regular frequency, we can use the `interval_range()` function to create an `IntervalIndex` using various combinations of `start`, `end`, and `periods`. The default frequency for `interval_range` is a 1 for numeric intervals, and calendar day for datetime-like intervals:

```
In [191]: pd.interval_range(start=0, end=5)
Out[191]:
IntervalIndex([(0, 1], (1, 2], (2, 3], (3, 4], (4, 5]],
              closed='right',
              dtype='interval[int64]')
```

```
In [192]: pd.interval_range(start=pd.Timestamp('2017-01-01'), periods=4)
Out[192]:
IntervalIndex([(2017-01-01, 2017-01-02], (2017-01-02, 2017-01-03], (2017-01-03, 2017-01-
↳ 04], (2017-01-04, 2017-01-05]],
              closed='right',
              dtype='interval[datetime64[ns]]')
```

```
In [193]: pd.interval_range(end=pd.Timedelta('3 days'), periods=3)
Out[193]:
IntervalIndex([(0 days 00:00:00, 1 days 00:00:00], (1 days 00:00:00, 2 days 00:00:00],
↳ (2 days 00:00:00, 3 days 00:00:00]],
              closed='right',
              dtype='interval[timedelta64[ns]]')
```

The `freq` parameter can be used to specify non-default frequencies, and can utilize a variety of *frequency aliases* with datetime-like intervals:

```
In [194]: pd.interval_range(start=0, periods=5, freq=1.5)
Out[194]:
IntervalIndex([(0.0, 1.5], (1.5, 3.0], (3.0, 4.5], (4.5, 6.0], (6.0, 7.5]],
```

```
closed='right',
dtype='interval[float64]')
```

```
In [195]: pd.interval_range(start=pd.Timestamp('2017-01-01'), periods=4, freq='W')
Out[195]:
IntervalIndex([(2017-01-01, 2017-01-08], (2017-01-08, 2017-01-15], (2017-01-15, 2017-01-
↳ 22], (2017-01-22, 2017-01-29]],
              closed='right',
              dtype='interval[datetime64[ns]]')
```

```
In [196]: pd.interval_range(start=pd.Timedelta('0 days'), periods=3, freq='9H')
Out[196]:
IntervalIndex([(0 days 00:00:00, 0 days 09:00:00], (0 days 09:00:00, 0 days 18:00:00],
↳ (0 days 18:00:00, 1 days 03:00:00]],
              closed='right',
              dtype='interval[timedelta64[ns]]')
```

Additionally, the `closed` parameter can be used to specify which side(s) the intervals are closed on. Intervals are closed on the right side by default.

```
In [197]: pd.interval_range(start=0, end=4, closed='both')
Out[197]:
IntervalIndex([[0, 1], [1, 2], [2, 3], [3, 4]],
              closed='both',
              dtype='interval[int64]')
```

```
In [198]: pd.interval_range(start=0, end=4, closed='neither')
Out[198]:
IntervalIndex([(0, 1), (1, 2), (2, 3), (3, 4)],
              closed='neither',
              dtype='interval[int64]')
```

New in version 0.23.0.

Specifying `start`, `end`, and `periods` will generate a range of evenly spaced intervals from `start` to `end` inclusively, with `periods` number of elements in the resulting `IntervalIndex`:

```
In [199]: pd.interval_range(start=0, end=6, periods=4)
Out[199]:
IntervalIndex([(0.0, 1.5], (1.5, 3.0], (3.0, 4.5], (4.5, 6.0]],
              closed='right',
              dtype='interval[float64]')
```

```
In [200]: pd.interval_range(pd.Timestamp('2018-01-01'),
.....:                      pd.Timestamp('2018-02-28'), periods=3)
.....:
Out[200]:
IntervalIndex([(2018-01-01, 2018-01-20 08:00:00], (2018-01-20 08:00:00, 2018-02-08
↳ 16:00:00], (2018-02-08 16:00:00, 2018-02-28]],
              closed='right',
              dtype='interval[datetime64[ns]]')
```

4.3.6 Miscellaneous indexing FAQ

Integer indexing

Label-based indexing with integer axis labels is a thorny topic. It has been discussed heavily on mailing lists and among various members of the scientific Python community. In pandas, our general viewpoint is that labels matter more than integer locations. Therefore, with an integer axis index *only* label-based indexing is possible with the standard tools like `.loc`. The following code will generate exceptions:

```
In [201]: s = pd.Series(range(5))

In [202]: s[-1]
-----
KeyError                                Traceback (most recent call last)

KeyError: -1

In [203]: df = pd.DataFrame(np.random.randn(5, 4))

In [204]: df
Out[204]:
```

	0	1	2	3
0	-1.133558	-0.029021	-0.694313	0.001625
1	0.603428	2.165940	-0.484352	-0.005155
2	1.473773	0.636391	0.557850	-0.894238
3	-0.805963	-1.781931	1.888285	-0.953362
4	-0.112449	1.227497	-0.567709	2.458089

```
In [205]: df.loc[-2:]
Out[205]:
```

	0	1	2	3
0	-1.133558	-0.029021	-0.694313	0.001625
1	0.603428	2.165940	-0.484352	-0.005155
2	1.473773	0.636391	0.557850	-0.894238
3	-0.805963	-1.781931	1.888285	-0.953362
4	-0.112449	1.227497	-0.567709	2.458089

This deliberate decision was made to prevent ambiguities and subtle bugs (many users reported finding bugs when the API change was made to stop “falling back” on position-based indexing).

Non-monotonic indexes require exact matches

If the index of a `Series` or `DataFrame` is monotonically increasing or decreasing, then the bounds of a label-based slice can be outside the range of the index, much like slice indexing a normal Python `list`. Monotonicity of an index can be tested with the `is_monotonic_increasing()` and `is_monotonic_decreasing()` attributes.

```
In [206]: df = pd.DataFrame(index=[2, 3, 3, 4, 5], columns=['data'], data=list(range(5)))
```

```
In [207]: df.index.is_monotonic_increasing
Out[207]: True
```

```
# no rows 0 or 1, but still returns rows 2, 3 (both of them), and 4:
```

```
In [208]: df.loc[0:4, :]
Out[208]:
```

	data
2	0
3	1
3	2
4	3

```
# slice is are outside the index, so empty DataFrame is returned
```

```
In [209]: df.loc[13:15, :]
Out[209]:
Empty DataFrame
Columns: [data]
Index: []
```

On the other hand, if the index is not monotonic, then both slice bounds must be *unique* members of the index.

```
In [210]: df = pd.DataFrame(index=[2, 3, 1, 4, 3, 5],
.....:                       columns=['data'], data=list(range(6)))
.....:
```

```
In [211]: df.index.is_monotonic_increasing
Out[211]: False
```

```
# OK because 2 and 4 are in the index
```

```
In [212]: df.loc[2:4, :]
Out[212]:
```

	data
--	------

```
2    0
3    1
1    2
4    3
```

```
# 0 is not in the index
In [9]: df.loc[0:4, :]
KeyError: 0

# 3 is not a unique label
In [11]: df.loc[2:3, :]
KeyError: 'Cannot get right slice bound for non-unique label: 3'
```

`Index.is_monotonic_increasing` and `Index.is_monotonic_decreasing` only check that an index is weakly monotonic. To check for strict monotonicity, you can combine one of those with the `is_unique()` attribute.

```
In [213]: weakly_monotonic = pd.Index(['a', 'b', 'c', 'c'])
```

```
In [214]: weakly_monotonic
Out[214]: Index(['a', 'b', 'c', 'c'], dtype='object')
```

```
In [215]: weakly_monotonic.is_monotonic_increasing
Out[215]: True
```

```
In [216]: weakly_monotonic.is_monotonic_increasing & weakly_monotonic.is_unique
Out[216]: False
```

Endpoints are inclusive

Compared with standard Python sequence slicing in which the slice endpoint is not inclusive, label-based slicing in pandas **is inclusive**. The primary reason for this is that it is often not possible to easily determine the “successor” or next element after a particular label in an index. For example, consider the following Series:

```
In [217]: s = pd.Series(np.random.randn(6), index=list('abcdef'))

In [218]: s
Out[218]:
a    0.580640
b    0.138820
c   -1.068494
d    1.649395
e   -0.598832
f   -0.322914
dtype: float64
```

Suppose we wished to slice from `c` to `e`, using integers this would be accomplished as such:

```
In [219]: s[2:5]
Out[219]:
c   -1.068494
d    1.649395
```

(continues on next page)

(continued from previous page)

```
e    -0.598832
dtype: float64
```

However, if you only had `c` and `e`, determining the next element in the index can be somewhat complicated. For example, the following does not work:

```
s.loc['c':'e' + 1]
```

A very common use case is to limit a time series to start and end at two specific dates. To enable this, we made the design choice to make label-based slicing include both endpoints:

```
In [220]: s.loc['c':'e']
Out[220]:
c    -1.068494
d     1.649395
e    -0.598832
dtype: float64
```

This is most definitely a “practicality beats purity” sort of thing, but it is something to watch out for if you expect label-based slicing to behave exactly in the way that standard Python integer slicing works.

Indexing potentially changes underlying Series dtype

The different indexing operation can potentially change the dtype of a `Series`.

```
In [221]: series1 = pd.Series([1, 2, 3])
```

```
In [222]: series1.dtype
Out[222]: dtype('int64')
```

```
In [223]: res = series1.reindex([0, 4])
```

```
In [224]: res.dtype
Out[224]: dtype('float64')
```

```
In [225]: res
Out[225]:
0     1.0
4     NaN
dtype: float64
```

```
In [226]: series2 = pd.Series([True])
```

```
In [227]: series2.dtype
Out[227]: dtype('bool')
```

```
In [228]: res = series2.reindex_like(series1)
```

```
In [229]: res.dtype
Out[229]: dtype('O')
```

```
In [230]: res
Out[230]:
```

```
0    True
1    NaN
2    NaN
dtype: object
```

This is because the (re)indexing operations above silently inserts NaNs and the `dtype` changes accordingly. This can cause some issues when using `numpy ufuncs` such as `numpy.logical_and`.

See the [this old issue](#) for a more detailed discussion. `{{ header }}`

4.4 Merge, join, and concatenate

pandas provides various facilities for easily combining together Series or DataFrame with various kinds of set logic for the indexes and relational algebra functionality in the case of join / merge-type operations.

4.4.1 Concatenating objects

The `concat()` function (in the main pandas namespace) does all of the heavy lifting of performing concatenation operations along an axis while performing optional set logic (union or intersection) of the indexes (if any) on the other axes. Note that I say “if any” because there is only a single possible axis of concatenation for Series.

Before diving into all of the details of `concat` and what it can do, here is a simple example:

```
In [1]: df1 = pd.DataFrame({'A': ['A0', 'A1', 'A2', 'A3'],
...:                      'B': ['B0', 'B1', 'B2', 'B3'],
...:                      'C': ['C0', 'C1', 'C2', 'C3'],
...:                      'D': ['D0', 'D1', 'D2', 'D3']},
...:                      index=[0, 1, 2, 3])
...:

In [2]: df2 = pd.DataFrame({'A': ['A4', 'A5', 'A6', 'A7'],
...:                      'B': ['B4', 'B5', 'B6', 'B7'],
...:                      'C': ['C4', 'C5', 'C6', 'C7'],
...:                      'D': ['D4', 'D5', 'D6', 'D7']},
...:                      index=[4, 5, 6, 7])
...:

In [3]: df3 = pd.DataFrame({'A': ['A8', 'A9', 'A10', 'A11'],
...:                      'B': ['B8', 'B9', 'B10', 'B11'],
...:                      'C': ['C8', 'C9', 'C10', 'C11'],
...:                      'D': ['D8', 'D9', 'D10', 'D11']},
...:                      index=[8, 9, 10, 11])
...:

In [4]: frames = [df1, df2, df3]

In [5]: result = pd.concat(frames)
```

df1				
	A	B	C	D
0	A0	B0	C0	D0
1	A1	B1	C1	D1
2	A2	B2	C2	D2
3	A3	B3	C3	D3

df2				
	A	B	C	D
4	A4	B4	C4	D4
5	A5	B5	C5	D5
6	A6	B6	C6	D6
7	A7	B7	C7	D7

df3				
	A	B	C	D
8	A8	B8	C8	D8
9	A9	B9	C9	D9
10	A10	B10	C10	D10
11	A11	B11	C11	D11

Result				
	A	B	C	D
0	A0	B0	C0	D0
1	A1	B1	C1	D1
2	A2	B2	C2	D2
3	A3	B3	C3	D3
4	A4	B4	C4	D4
5	A5	B5	C5	D5
6	A6	B6	C6	D6
7	A7	B7	C7	D7
8	A8	B8	C8	D8
9	A9	B9	C9	D9
10	A10	B10	C10	D10
11	A11	B11	C11	D11

Like its sibling function on ndarrays, `numpy.concatenate`, `pandas.concat` takes a list or dict of homogeneously-typed objects and concatenates them with some configurable handling of “what to do with the other axes”:

```
pd.concat(objs, axis=0, join='outer', ignore_index=False, keys=None,
          levels=None, names=None, verify_integrity=False, copy=True)
```

- `objs` : a sequence or mapping of Series or DataFrame objects. If a dict is passed, the sorted keys will be used as the `keys` argument, unless it is passed, in which case the values will be selected (see below). Any None objects will be dropped silently unless they are all None in which case a `ValueError` will be raised.
- `axis` : {0, 1, ...}, default 0. The axis to concatenate along.
- `join` : {'inner', 'outer'}, default 'outer'. How to handle indexes on other axis(es). Outer for union and inner for intersection.
- `ignore_index` : boolean, default False. If True, do not use the index values on the concatenation axis. The resulting axis will be labeled 0, ..., n - 1. This is useful if you are concatenating objects where the concatenation axis does not have meaningful indexing information. Note the index values on the other axes are still respected in the join.
- `keys` : sequence, default None. Construct hierarchical index using the passed keys as the outermost level. If multiple levels passed, should contain tuples.
- `levels` : list of sequences, default None. Specific levels (unique values) to use for constructing a MultiIndex. Otherwise they will be inferred from the keys.
- `names` : list, default None. Names for the levels in the resulting hierarchical index.
- `verify_integrity` : boolean, default False. Check whether the new concatenated axis contains duplicates. This can be very expensive relative to the actual data concatenation.
- `copy` : boolean, default True. If False, do not copy data unnecessarily.

Without a little bit of context many of these arguments don't make much sense. Let's revisit the above example. Suppose we wanted to associate specific keys with each of the pieces of the chopped up DataFrame. We can do this using the `keys` argument:

```
In [6]: result = pd.concat(frames, keys=['x', 'y', 'z'])
```

df1					Result					
	A	B	C	D			A	B	C	D
0	A0	B0	C0	D0	x	0	A0	B0	C0	D0
1	A1	B1	C1	D1	x	1	A1	B1	C1	D1
2	A2	B2	C2	D2	x	2	A2	B2	C2	D2
3	A3	B3	C3	D3	x	3	A3	B3	C3	D3
df2					y	4	A4	B4	C4	D4
	A	B	C	D	y	5	A5	B5	C5	D5
4	A4	B4	C4	D4	y	6	A6	B6	C6	D6
5	A5	B5	C5	D5	y	7	A7	B7	C7	D7
6	A6	B6	C6	D6	df3					
7	A7	B7	C7	D7		A	B	C	D	
df3					z	8	A8	B8	C8	D8
	A	B	C	D	z	9	A9	B9	C9	D9
8	A8	B8	C8	D8	z	10	A10	B10	C10	D10
9	A9	B9	C9	D9	z	11	A11	B11	C11	D11
10	A10	B10	C10	D10						
11	A11	B11	C11	D11						

As you can see (if you've read the rest of the documentation), the resulting object's index has a *hierarchical index*. This means that we can now select out each chunk by key:

```
In [7]: result.loc['y']
```

```
Out[7]:
```

```
   A  B  C  D
4  A4 B4 C4 D4
5  A5 B5 C5 D5
6  A6 B6 C6 D6
7  A7 B7 C7 D7
```

It's not a stretch to see how this can be very useful. More detail on this functionality below.

Note: It is worth noting that `concat()` (and therefore `append()`) makes a full copy of the data, and that constantly reusing this function can create a significant performance hit. If you need to use the operation over several datasets, use a list comprehension.

```
frames = [ process_your_file(f) for f in files ]
result = pd.concat(frames)
```

Set logic on the other axes

When gluing together multiple DataFrames, you have a choice of how to handle the other axes (other than the one being concatenated). This can be done in the following two ways:

- Take the union of them all, `join='outer'`. This is the default option as it results in zero information loss.
- Take the intersection, `join='inner'`.

Here is an example of each of these methods. First, the default `join='outer'` behavior:

```
In [8]: df4 = pd.DataFrame({'B': ['B2', 'B3', 'B6', 'B7'],
...:                      'D': ['D2', 'D3', 'D6', 'D7'],
...:                      'F': ['F2', 'F3', 'F6', 'F7']},
...:                      index=[2, 3, 6, 7])
...:

In [9]: result = pd.concat([df1, df4], axis=1, sort=False)
```

df1					df4				Result							
	A	B	C	D		B	D	F		A	B	C	D	B	D	F
0	A0	B0	C0	D0	2	B2	D2	F2	0	A0	B0	C0	D0	NaN	NaN	NaN
1	A1	B1	C1	D1	3	B3	D3	F3	1	A1	B1	C1	D1	NaN	NaN	NaN
2	A2	B2	C2	D2	6	B6	D6	F6	2	A2	B2	C2	D2	B2	D2	F2
3	A3	B3	C3	D3	7	B7	D7	F7	3	A3	B3	C3	D3	B3	D3	F3
									6	NaN	NaN	NaN	NaN	B6	D6	F6
									7	NaN	NaN	NaN	NaN	B7	D7	F7

Warning: Changed in version 0.23.0.

The default behavior with `join='outer'` is to sort the other axis (columns in this case). In a future version of pandas, the default will be to not sort. We specified `sort=False` to opt in to the new behavior now.

Here is the same thing with `join='inner'`:

```
In [10]: result = pd.concat([df1, df4], axis=1, join='inner')
```

df1					df4				Result							
	A	B	C	D		B	D	F		A	B	C	D	B	D	F
0	A0	B0	C0	D0	2	B2	D2	F2	2	A2	B2	C2	D2	B2	D2	F2
1	A1	B1	C1	D1	3	B3	D3	F3	3	A3	B3	C3	D3	B3	D3	F3
2	A2	B2	C2	D2	6	B6	D6	F6								
3	A3	B3	C3	D3	7	B7	D7	F7								

Lastly, suppose we just wanted to reuse the *exact index* from the original DataFrame:

```
In [11]: result = pd.concat([df1, df4], axis=1).reindex(df1.index)
```

Similarly, we could index before the concatenation:

```
In [12]: pd.concat([df1, df4.reindex(df1.index)], axis=1)
```

```
Out [12]:
```

	A	B	C	D	B	D	F
0	A0	B0	C0	D0	NaN	NaN	NaN
1	A1	B1	C1	D1	NaN	NaN	NaN
2	A2	B2	C2	D2	B2	D2	F2
3	A3	B3	C3	D3	B3	D3	F3

df1					df4				Result							
	A	B	C	D		B	D	F		A	B	C	D	B	D	F
0	A0	B0	C0	D0	2	B2	D2	F2	0	A0	B0	C0	D0	NaN	NaN	NaN
1	A1	B1	C1	D1	3	B3	D3	F3	1	A1	B1	C1	D1	NaN	NaN	NaN
2	A2	B2	C2	D2	6	B6	D6	F6	2	A2	B2	C2	D2	B2	D2	F2
3	A3	B3	C3	D3	7	B7	D7	F7	3	A3	B3	C3	D3	B3	D3	F3

Concatenating using append

A useful shortcut to `concat()` are the `append()` instance methods on `Series` and `DataFrame`. These methods actually predated `concat`. They concatenate along `axis=0`, namely the index:

```
In [13]: result = df1.append(df2)
```

df1					df2					Result				
	A	B	C	D		A	B	C	D		A	B	C	D
0	A0	B0	C0	D0	4	A4	B4	C4	D4	0	A0	B0	C0	D0
1	A1	B1	C1	D1	5	A5	B5	C5	D5	1	A1	B1	C1	D1
2	A2	B2	C2	D2	6	A6	B6	C6	D6	2	A2	B2	C2	D2
3	A3	B3	C3	D3	7	A7	B7	C7	D7	3	A3	B3	C3	D3

In the case of `DataFrame`, the indexes must be disjoint but the columns do not need to be:

```
In [14]: result = df1.append(df4, sort=False)
```

df1					Result					
	A	B	C	D		A	B	C	D	F
0	A0	B0	C0	D0	0	A0	B0	C0	D0	NaN
1	A1	B1	C1	D1	1	A1	B1	C1	D1	NaN
2	A2	B2	C2	D2	2	A2	B2	C2	D2	NaN
3	A3	B3	C3	D3	3	A3	B3	C3	D3	NaN
df4					2	NaN	B2	NaN	D2	F2
	B	D	F	3	NaN	B3	NaN	D3	F3	
2	B2	D2	F2	6	NaN	B6	NaN	D6	F6	
3	B3	D3	F3	7	NaN	B7	NaN	D7	F7	
6	B6	D6	F6							
7	B7	D7	F7							

append may take multiple objects to concatenate:

```
In [15]: result = df1.append([df2, df3])
```

df1					Result				
	A	B	C	D		A	B	C	D
0	A0	B0	C0	D0	0	A0	B0	C0	D0
1	A1	B1	C1	D1	1	A1	B1	C1	D1
2	A2	B2	C2	D2	2	A2	B2	C2	D2
3	A3	B3	C3	D3	3	A3	B3	C3	D3
df2					4	A4	B4	C4	D4
	A	B	C	D	5	A5	B5	C5	D5
4	A4	B4	C4	D4	6	A6	B6	C6	D6
5	A5	B5	C5	D5	7	A7	B7	C7	D7
6	A6	B6	C6	D6	8	A8	B8	C8	D8
7	A7	B7	C7	D7	9	A9	B9	C9	D9
df3					10	A10	B10	C10	D10
	A	B	C	D	11	A11	B11	C11	D11
8	A8	B8	C8	D8					
9	A9	B9	C9	D9					
10	A10	B10	C10	D10					
11	A11	B11	C11	D11					

Note: Unlike the `append()` method, which appends to the original list and returns `None`, `append()` here

does not modify df1 and returns its copy with df2 appended.

Ignoring indexes on the concatenation axis

For DataFrame objects which don't have a meaningful index, you may wish to append them and ignore the fact that they may have overlapping indexes. To do this, use the `ignore_index` argument:

```
In [16]: result = pd.concat([df1, df4], ignore_index=True, sort=False)
```

df1					Result					
	A	B	C	D		A	B	C	D	F
0	A0	B0	C0	D0	0	A0	B0	C0	D0	NaN
1	A1	B1	C1	D1	1	A1	B1	C1	D1	NaN
2	A2	B2	C2	D2	2	A2	B2	C2	D2	NaN
3	A3	B3	C3	D3	3	A3	B3	C3	D3	NaN
df4					4	NaN	B2	NaN	D2	F2
	B	D	F		5	NaN	B3	NaN	D3	F3
2	B2	D2	F2	6	NaN	B6	NaN	D6	F6	
3	B3	D3	F3	7	NaN	B7	NaN	D7	F7	
6	B6	D6	F6							
7	B7	D7	F7							

This is also a valid argument to `DataFrame.append()`:

```
In [17]: result = df1.append(df4, ignore_index=True, sort=False)
```

df1					Result					
	A	B	C	D		A	B	C	D	F
0	A0	B0	C0	D0	0	A0	B0	C0	D0	NaN
1	A1	B1	C1	D1	1	A1	B1	C1	D1	NaN
2	A2	B2	C2	D2	2	A2	B2	C2	D2	NaN
3	A3	B3	C3	D3	3	A3	B3	C3	D3	NaN
df4					4	NaN	B2	NaN	D2	F2
	B	D	F		5	NaN	B3	NaN	D3	F3
2	B2	D2	F2	6	NaN	B6	NaN	D6	F6	
3	B3	D3	F3	7	NaN	B7	NaN	D7	F7	
6	B6	D6	F6							
7	B7	D7	F7							

Concatenating with mixed ndims

You can concatenate a mix of `Series` and `DataFrame` objects. The `Series` will be transformed to `DataFrame` with the column name as the name of the `Series`.

```
In [18]: s1 = pd.Series(['X0', 'X1', 'X2', 'X3'], name='X')
```

```
In [19]: result = pd.concat([df1, s1], axis=1)
```

df1					s1		Result					
	A	B	C	D		X		A	B	C	D	X
0	A0	B0	C0	D0	0	X0	0	A0	B0	C0	D0	X0
1	A1	B1	C1	D1	1	X1	1	A1	B1	C1	D1	X1
2	A2	B2	C2	D2	2	X2	2	A2	B2	C2	D2	X2
3	A3	B3	C3	D3	3	X3	3	A3	B3	C3	D3	X3

Note: Since we're concatenating a `Series` to a `DataFrame`, we could have achieved the same result with `DataFrame.assign()`. To concatenate an arbitrary number of pandas objects (`DataFrame` or `Series`), use `concat`.

If unnamed `Series` are passed they will be numbered consecutively.

```
In [20]: s2 = pd.Series(['_0', '_1', '_2', '_3'])
```

```
In [21]: result = pd.concat([df1, s2, s2, s2], axis=1)
```

df1					s2		Result								
	A	B	C	D				A	B	C	D	0	1	2	
0	A0	B0	C0	D0	0	_0	0	A0	B0	C0	D0	_0	_0	_0	
1	A1	B1	C1	D1	1	_1	1	A1	B1	C1	D1	_1	_1	_1	
2	A2	B2	C2	D2	2	_2	2	A2	B2	C2	D2	_2	_2	_2	
3	A3	B3	C3	D3	3	_3	3	A3	B3	C3	D3	_3	_3	_3	

Passing `ignore_index=True` will drop all name references.

```
In [22]: result = pd.concat([df1, s1], axis=1, ignore_index=True)
```

df1					s1		Result					
	A	B	C	D		X	0	1	2	3	4	
0	A0	B0	C0	D0	0	X0	0	A0	B0	C0	D0	X0
1	A1	B1	C1	D1	1	X1	1	A1	B1	C1	D1	X1
2	A2	B2	C2	D2	2	X2	2	A2	B2	C2	D2	X2
3	A3	B3	C3	D3	3	X3	3	A3	B3	C3	D3	X3

More concatenating with group keys

A fairly common use of the `keys` argument is to override the column names when creating a new `DataFrame` based on existing `Series`. Notice how the default behaviour consists on letting the resulting `DataFrame` inherit the parent `Series`' name, when these existed.

```
In [23]: s3 = pd.Series([0, 1, 2, 3], name='foo')
```

```
In [24]: s4 = pd.Series([0, 1, 2, 3])
```

```
In [25]: s5 = pd.Series([0, 1, 4, 5])
```

```
In [26]: pd.concat([s3, s4, s5], axis=1)
```

```
Out[26]:
   foo 0 1
0    0 0 0
1    1 1 1
2    2 2 4
3    3 3 5
```

Through the `keys` argument we can override the existing column names.

```
In [27]: pd.concat([s3, s4, s5], axis=1, keys=['red', 'blue', 'yellow'])
```

```
Out[27]:
   red blue yellow
0    0    0      0
1    1    1      1
2    2    2      4
3    3    3      5
```

Let's consider a variation of the very first example presented:

```
In [28]: result = pd.concat(frames, keys=['x', 'y', 'z'])
```

df1					Result					
	A	B	C	D			A	B	C	D
0	A0	B0	C0	D0	x	0	A0	B0	C0	D0
1	A1	B1	C1	D1	x	1	A1	B1	C1	D1
2	A2	B2	C2	D2	x	2	A2	B2	C2	D2
3	A3	B3	C3	D3	x	3	A3	B3	C3	D3
df2										
	A	B	C	D	y <td>4</td> <td>A4</td> <td>B4</td> <td>C4</td> <td>D4</td>	4	A4	B4	C4	D4
4	A4	B4	C4	D4	y	5	A5	B5	C5	D5
5	A5	B5	C5	D5	y	6	A6	B6	C6	D6
6	A6	B6	C6	D6	y	7	A7	B7	C7	D7
7	A7	B7	C7	D7	df3					
	A	B	C	D	z	8	A8	B8	C8	D8
8	A8	B8	C8	D8	z	9	A9	B9	C9	D9
9	A9	B9	C9	D9	z	10	A10	B10	C10	D10
10	A10	B10	C10	D10	z	11	A11	B11	C11	D11
11	A11	B11	C11	D11						

You can also pass a dict to `concat` in which case the dict keys will be used for the `keys` argument (unless other keys are specified):

```
In [29]: pieces = {'x': df1, 'y': df2, 'z': df3}
```

```
In [30]: result = pd.concat(pieces)
```

df1				
	A	B	C	D
0	A0	B0	C0	D0
1	A1	B1	C1	D1
2	A2	B2	C2	D2
3	A3	B3	C3	D3

df2				
	A	B	C	D
4	A4	B4	C4	D4
5	A5	B5	C5	D5
6	A6	B6	C6	D6
7	A7	B7	C7	D7

df3				
	A	B	C	D
8	A8	B8	C8	D8
9	A9	B9	C9	D9
10	A10	B10	C10	D10
11	A11	B11	C11	D11

Result					
		A	B	C	D
x	0	A0	B0	C0	D0
x	1	A1	B1	C1	D1
x	2	A2	B2	C2	D2
x	3	A3	B3	C3	D3
y	4	A4	B4	C4	D4
y	5	A5	B5	C5	D5
y	6	A6	B6	C6	D6
y	7	A7	B7	C7	D7
z	8	A8	B8	C8	D8
z	9	A9	B9	C9	D9
z	10	A10	B10	C10	D10
z	11	A11	B11	C11	D11

```
In [31]: result = pd.concat(pieces, keys=['z', 'y'])
```

df1				
	A	B	C	D
0	A0	B0	C0	D0
1	A1	B1	C1	D1
2	A2	B2	C2	D2
3	A3	B3	C3	D3

df2				
	A	B	C	D
4	A4	B4	C4	D4
5	A5	B5	C5	D5
6	A6	B6	C6	D6
7	A7	B7	C7	D7

df3				
	A	B	C	D
8	A8	B8	C8	D8
9	A9	B9	C9	D9
10	A10	B10	C10	D10
11	A11	B11	C11	D11

Result					
		A	B	C	D
z	8	A8	B8	C8	D8
z	9	A9	B9	C9	D9
z	10	A10	B10	C10	D10
z	11	A11	B11	C11	D11
y	4	A4	B4	C4	D4
y	5	A5	B5	C5	D5
y	6	A6	B6	C6	D6
y	7	A7	B7	C7	D7

The MultiIndex created has levels that are constructed from the passed keys and the index of the DataFrame

pieces:

```
In [32]: result.index.levels
Out[32]: FrozenList([[ 'z', 'y'], [4, 5, 6, 7, 8, 9, 10, 11]])
```

If you wish to specify other levels (as will occasionally be the case), you can do so using the `levels` argument:

```
In [33]: result = pd.concat(pieces, keys=['x', 'y', 'z'],
.....:                      levels=[['z', 'y', 'x', 'w']],
.....:                      names=['group_key'])
.....:
```

df1					Result					
	A	B	C	D			A	B	C	D
0	A0	B0	C0	D0	x	0	A0	B0	C0	D0
1	A1	B1	C1	D1	x	1	A1	B1	C1	D1
2	A2	B2	C2	D2	x	2	A2	B2	C2	D2
3	A3	B3	C3	D3	x	3	A3	B3	C3	D3
df2					y	4	A4	B4	C4	D4
	A	B	C	D	y	5	A5	B5	C5	D5
4	A4	B4	C4	D4	y	6	A6	B6	C6	D6
5	A5	B5	C5	D5	y	7	A7	B7	C7	D7
6	A6	B6	C6	D6	y	8	A8	B8	C8	D8
7	A7	B7	C7	D7	z	9	A9	B9	C9	D9
df3					z	10	A10	B10	C10	D10
	A	B	C	D	z	11	A11	B11	C11	D11
8	A8	B8	C8	D8						
9	A9	B9	C9	D9						
10	A10	B10	C10	D10						
11	A11	B11	C11	D11						

```
In [34]: result.index.levels
Out[34]: FrozenList([[ 'z', 'y', 'x', 'w'], [0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11]])
```

This is fairly esoteric, but it is actually necessary for implementing things like `GroupBy` where the order of a categorical variable is meaningful.

Appending rows to a DataFrame

While not especially efficient (since a new object must be created), you can append a single row to a `DataFrame` by passing a `Series` or dict to `append`, which returns a new `DataFrame` as above.

```
In [35]: s2 = pd.Series(['X0', 'X1', 'X2', 'X3'], index=['A', 'B', 'C', 'D'])
```

```
In [36]: result = df1.append(s2, ignore_index=True)
```

df1					Result				
	A	B	C	D		A	B	C	D
0	A0	B0	C0	D0	0	A0	B0	C0	D0
1	A1	B1	C1	D1	1	A1	B1	C1	D1
2	A2	B2	C2	D2	2	A2	B2	C2	D2
3	A3	B3	C3	D3	3	A3	B3	C3	D3
s2					4	X0	X1	X2	X3
	A			X0					
	B			X1					
	C			X2					
	D			X3					

You should use `ignore_index` with this method to instruct `DataFrame` to discard its index. If you wish to preserve the index, you should construct an appropriately-indexed `DataFrame` and append or concatenate those objects.

You can also pass a list of dicts or `Series`:

```
In [37]: dicts = [{'A': 1, 'B': 2, 'C': 3, 'X': 4},
.....:             {'A': 5, 'B': 6, 'C': 7, 'Y': 8}]
.....:
```

```
In [38]: result = df1.append(dicts, ignore_index=True, sort=False)
```

df1					Result						
	A	B	C	D		A	B	C	D	X	Y
0	A0	B0	C0	D0	0	A0	B0	C0	D0	NaN	NaN
1	A1	B1	C1	D1	1	A1	B1	C1	D1	NaN	NaN
2	A2	B2	C2	D2	2	A2	B2	C2	D2	NaN	NaN
3	A3	B3	C3	D3	3	A3	B3	C3	D3	NaN	NaN
dicts					4	1	2	3	NaN	4.0	NaN
	A	B	C	X	Y	5	5	6	7	NaN	NaN
0	1	2	3	4.0	NaN						
1	5	6	7	NaN	8.0						

4.4.2 Database-style `DataFrame` or named `Series` joining/merging

pandas has full-featured, **high performance** in-memory join operations idiomatically very similar to relational databases like SQL. These methods perform significantly better (in some cases well over an order of magnitude better) than other open source implementations (like `base::merge.data.frame` in R). The reason for this is careful algorithmic design and the internal layout of the data in `DataFrame`.

See the *cookbook* for some advanced strategies.

Users who are familiar with SQL but new to pandas might be interested in a *comparison with SQL*.

pandas provides a single function, `merge()`, as the entry point for all standard database join operations between `DataFrame` or named `Series` objects:

```
pd.merge(left, right, how='inner', on=None, left_on=None, right_on=None,
         left_index=False, right_index=False, sort=True,
         suffixes=('_x', '_y'), copy=True, indicator=False,
         validate=None)
```

- `left`: A `DataFrame` or named `Series` object.
- `right`: Another `DataFrame` or named `Series` object.
- `on`: Column or index level names to join on. Must be found in both the left and right `DataFrame` and/or `Series` objects. If not passed and `left_index` and `right_index` are `False`, the intersection of the columns in the `DataFrames` and/or `Series` will be inferred to be the join keys.
- `left_on`: Columns or index levels from the left `DataFrame` or `Series` to use as keys. Can either be column names, index level names, or arrays with length equal to the length of the `DataFrame` or `Series`.
- `right_on`: Columns or index levels from the right `DataFrame` or `Series` to use as keys. Can either be column names, index level names, or arrays with length equal to the length of the `DataFrame` or `Series`.
- `left_index`: If `True`, use the index (row labels) from the left `DataFrame` or `Series` as its join key(s). In the case of a `DataFrame` or `Series` with a `MultiIndex` (hierarchical), the number of levels must match the number of join keys from the right `DataFrame` or `Series`.
- `right_index`: Same usage as `left_index` for the right `DataFrame` or `Series`
- `how`: One of 'left', 'right', 'outer', 'inner'. Defaults to `inner`. See below for more detailed description of each method.
- `sort`: Sort the result `DataFrame` by the join keys in lexicographical order. Defaults to `True`, setting to `False` will improve performance substantially in many cases.
- `suffixes`: A tuple of string suffixes to apply to overlapping columns. Defaults to ('_x', '_y').
- `copy`: Always copy data (default `True`) from the passed `DataFrame` or named `Series` objects, even when reindexing is not necessary. Cannot be avoided in many cases but may improve performance / memory usage. The cases where copying can be avoided are somewhat pathological but this option is provided nonetheless.
- `indicator`: Add a column to the output `DataFrame` called `_merge` with information on the source of each row. `_merge` is Categorical-type and takes on a value of `left_only` for observations whose merge key only appears in 'left' `DataFrame` or `Series`, `right_only` for observations whose merge key only appears in 'right' `DataFrame` or `Series`, and `both` if the observation's merge key is found in both.
- `validate`: string, default `None`. If specified, checks if merge is of specified type.
 - “one_to_one” or “1:1”: checks if merge keys are unique in both left and right datasets.
 - “one_to_many” or “1:m”: checks if merge keys are unique in left dataset.
 - “many_to_one” or “m:1”: checks if merge keys are unique in right dataset.
 - “many_to_many” or “m:m”: allowed, but does not result in checks.

New in version 0.21.0.

Note: Support for specifying index levels as the `on`, `left_on`, and `right_on` parameters was added in version 0.23.0. Support for merging named `Series` objects was added in version 0.24.0.

The return type will be the same as `left`. If `left` is a `DataFrame` or named `Series` and `right` is a subclass of `DataFrame`, the return type will still be `DataFrame`.

`merge` is a function in the pandas namespace, and it is also available as a `DataFrame` instance method `merge()`, with the calling `DataFrame` being implicitly considered the left object in the join.

The related `join()` method, uses `merge` internally for the index-on-index (by default) and column(s)-on-index join. If you are joining on index only, you may wish to use `DataFrame.join` to save yourself some typing.

Brief primer on merge methods (relational algebra)

Experienced users of relational databases like SQL will be familiar with the terminology used to describe join operations between two SQL-table like structures (`DataFrame` objects). There are several cases to consider which are very important to understand:

- **one-to-one** joins: for example when joining two `DataFrame` objects on their indexes (which must contain unique values).
- **many-to-one** joins: for example when joining an index (unique) to one or more columns in a different `DataFrame`.
- **many-to-many** joins: joining columns on columns.

Note: When joining columns on columns (potentially a many-to-many join), any indexes on the passed `DataFrame` objects **will be discarded**.

It is worth spending some time understanding the result of the **many-to-many** join case. In SQL / standard relational algebra, if a key combination appears more than once in both tables, the resulting table will have the **Cartesian product** of the associated data. Here is a very basic example with one unique key combination:

```
In [39]: left = pd.DataFrame({'key': ['K0', 'K1', 'K2', 'K3'],
.....:                       'A': ['A0', 'A1', 'A2', 'A3'],
.....:                       'B': ['B0', 'B1', 'B2', 'B3']})
.....:

In [40]: right = pd.DataFrame({'key': ['K0', 'K1', 'K2', 'K3'],
.....:                        'C': ['C0', 'C1', 'C2', 'C3'],
.....:                        'D': ['D0', 'D1', 'D2', 'D3']})
.....:

In [41]: result = pd.merge(left, right, on='key')
```

left				right				Result					
	key	A	B		key	C	D		key	A	B	C	D
0	K0	A0	B0	0	K0	C0	D0	0	K0	A0	B0	C0	D0
1	K1	A1	B1	1	K1	C1	D1	1	K1	A1	B1	C1	D1
2	K2	A2	B2	2	K2	C2	D2	2	K2	A2	B2	C2	D2
3	K3	A3	B3	3	K3	C3	D3	3	K3	A3	B3	C3	D3

Here is a more complicated example with multiple join keys. Only the keys appearing in left and right are present (the intersection), since `how='inner'` by default.

```
In [42]: left = pd.DataFrame({'key1': ['K0', 'K0', 'K1', 'K2'],
.....:                       'key2': ['K0', 'K1', 'K0', 'K1'],
.....:                       'A': ['A0', 'A1', 'A2', 'A3'],
.....:                       'B': ['B0', 'B1', 'B2', 'B3']})
.....:

In [43]: right = pd.DataFrame({'key1': ['K0', 'K1', 'K1', 'K2'],
.....:                         'key2': ['K0', 'K0', 'K0', 'K0'],
.....:                         'C': ['C0', 'C1', 'C2', 'C3'],
.....:                         'D': ['D0', 'D1', 'D2', 'D3']})
.....:

In [44]: result = pd.merge(left, right, on=['key1', 'key2'])
```

left					right				Result							
	key1	key2	A	B		key1	key2	C	D		key1	key2	A	B	C	D
0	K0	K0	A0	B0	0	K0	K0	C0	D0	0	K0	K0	A0	B0	C0	D0
1	K0	K1	A1	B1	1	K1	K0	C1	D1	1	K1	K0	A2	B2	C1	D1
2	K1	K0	A2	B2	2	K1	K0	C2	D2	2	K1	K0	A2	B2	C2	D2
3	K2	K1	A3	B3	3	K2	K0	C3	D3							

The `how` argument to `merge` specifies how to determine which keys are to be included in the resulting table. If a key combination **does not appear** in either the left or right tables, the values in the joined table will be NA. Here is a summary of the `how` options and their SQL equivalent names:

Merge method	SQL Join Name	Description
<code>left</code>	LEFT OUTER JOIN	Use keys from left frame only
<code>right</code>	RIGHT OUTER JOIN	Use keys from right frame only
<code>outer</code>	FULL OUTER JOIN	Use union of keys from both frames
<code>inner</code>	INNER JOIN	Use intersection of keys from both frames

```
In [45]: result = pd.merge(left, right, how='left', on=['key1', 'key2'])
```

left					right				Result							
	key1	key2	A	B		key1	key2	C	D		key1	key2	A	B	C	D
0	K0	K0	A0	B0	0	K0	K0	C0	D0	0	K0	K0	A0	B0	C0	D0
1	K0	K1	A1	B1	1	K1	K0	C1	D1	1	K0	K1	A1	B1	NaN	NaN
2	K1	K0	A2	B2	2	K1	K0	C2	D2	2	K1	K0	A2	B2	C1	D1
3	K2	K1	A3	B3	3	K2	K0	C3	D3	3	K1	K0	A2	B2	C2	D2
					4	K2	K1	A3	B3	4	K2	K1	A3	B3	NaN	NaN

```
In [46]: result = pd.merge(left, right, how='right', on=['key1', 'key2'])
```

left					right					Result						
	key1	key2	A	B		key1	key2	C	D		key1	key2	A	B	C	D

3	K2	K1	A3	B3	3	K2	K0	C3	D3							

Here is another example with duplicate join keys in DataFrames:

```
In [49]: left = pd.DataFrame({'A': [1, 2], 'B': [2, 2]})
```

```
In [50]: right = pd.DataFrame({'A': [4, 5, 6], 'B': [2, 2, 2]})
```

```
In [51]: result = pd.merge(left, right, on='B', how='outer')
```

left			right			Result			
	A	B		A	B	A_x	B	A_y	
0	1	2	0	4	2	0	1	2	4
1	2	2	1	5	2	1	1	2	5
			2	6	2	2	1	2	6
						3	2	2	4
						4	2	2	5
						5	2	2	6

Warning: Joining / merging on duplicate keys can cause a returned frame that is the multiplication of the row dimensions, which may result in memory overflow. It is the user's responsibility to manage duplicate values in keys before joining large DataFrames.

Checking for duplicate keys

New in version 0.21.0.

Users can use the `validate` argument to automatically check whether there are unexpected duplicates in their merge keys. Key uniqueness is checked before merge operations and so should protect against memory overflows. Checking key uniqueness is also a good way to ensure user data structures are as expected.

In the following example, there are duplicate values of `B` in the right `DataFrame`. As this is not a one-to-one merge – as specified in the `validate` argument – an exception will be raised.

```
In [52]: left = pd.DataFrame({'A' : [1,2], 'B' : [1, 2]})
```

```
In [53]: right = pd.DataFrame({'A' : [4,5,6], 'B': [2, 2, 2]})
```

```
In [53]: result = pd.merge(left, right, on='B', how='outer', validate="one_to_one")
...
MergeError: Merge keys are not unique in right dataset; not a one-to-one merge
```

If the user is aware of the duplicates in the right `DataFrame` but wants to ensure there are no duplicates in the left `DataFrame`, one can use the `validate='one_to_many'` argument instead, which will not raise an exception.

```
In [54]: pd.merge(left, right, on='B', how='outer', validate="one_to_many")
```

```
Out[54]:
   A_x  B  A_y
0     1  1  NaN
1     2  2  4.0
2     2  2  5.0
3     2  2  6.0
```

The merge indicator

`merge()` accepts the argument `indicator`. If `True`, a Categorical-type column called `_merge` will be added to the output object that takes on values:

Observation Origin	_merge value
Merge key only in 'left' frame	left_only
Merge key only in 'right' frame	right_only
Merge key in both frames	both

```
In [55]: df1 = pd.DataFrame({'col1': [0, 1], 'col_left': ['a', 'b']})
In [56]: df2 = pd.DataFrame({'col1': [1, 2, 2], 'col_right': [2, 2, 2]})
In [57]: pd.merge(df1, df2, on='col1', how='outer', indicator=True)
Out[57]:
```

	col1	col_left	col_right	_merge
0	0	a	NaN	left_only
1	1	b	2.0	both
2	2	NaN	2.0	right_only
3	2	NaN	2.0	right_only

The `indicator` argument will also accept string arguments, in which case the indicator function will use the value of the passed string as the name for the indicator column.

```
In [58]: pd.merge(df1, df2, on='col1', how='outer', indicator='indicator_column')
Out[58]:
```

	col1	col_left	col_right	indicator_column
0	0	a	NaN	left_only
1	1	b	2.0	both
2	2	NaN	2.0	right_only
3	2	NaN	2.0	right_only

Merge dtypes

New in version 0.19.0.

Merging will preserve the dtype of the join keys.

```
In [59]: left = pd.DataFrame({'key': [1], 'v1': [10]})
In [60]: left
Out[60]:
```

	key	v1
0	1	10

```
In [61]: right = pd.DataFrame({'key': [1, 2], 'v1': [20, 30]})
In [62]: right
Out[62]:
```

	key	v1
0	1	20
1	2	30

We are able to preserve the join keys:

```
In [63]: pd.merge(left, right, how='outer')
Out[63]:
```

```
   key  v1
0    1  10
1    1  20
2    2  30
```

```
In [64]: pd.merge(left, right, how='outer').dtypes
Out[64]:
key      int64
v1      int64
dtype: object
```

Of course if you have missing values that are introduced, then the resulting dtype will be upcast.

```
In [65]: pd.merge(left, right, how='outer', on='key')
Out[65]:
   key  v1_x  v1_y
0    1  10.0   20
1    2   NaN   30
```

```
In [66]: pd.merge(left, right, how='outer', on='key').dtypes
Out[66]:
key      int64
v1_x    float64
v1_y    int64
dtype: object
```

New in version 0.20.0.

Merging will preserve `category` dtypes of the mergands. See also the section on *categoricals*.

The left frame.

```
In [67]: from pandas.api.types import CategoricalDtype
```

```
In [68]: X = pd.Series(np.random.choice(['foo', 'bar'], size=(10,)))
```

```
In [69]: X = X.astype(CategoricalDtype(categories=['foo', 'bar']))
```

```
In [70]: left = pd.DataFrame({'X': X,
....:                        'Y': np.random.choice(['one', 'two', 'three'],
....:                                                size=(10,))})
....:
```

```
In [71]: left
Out[71]:
   X      Y
0  foo  three
1  bar  three
2  foo   two
3  foo  three
4  foo   one
5  foo   one
6  bar   one
7  foo   two
8  foo   one
9  bar   two
```

```
In [72]: left.dtypes
```

```
Out[72]:
```

```
X    category
```

```
Y      object
```

```
dtype: object
```

The right frame.

```
In [73]: right = pd.DataFrame({'X': pd.Series(['foo', 'bar'],
.....:                                     dtype=CategoricalDtype(['foo', 'bar'])),
.....:                        'Z': [1, 2]})
.....:
```

```
In [74]: right
```

```
Out[74]:
```

```
   X  Z
```

```
0  foo  1
```

```
1  bar  2
```

```
In [75]: right.dtypes
```

```
Out[75]:
```

```
X    category
```

```
Z      int64
```

```
dtype: object
```

The merged result:

```
In [76]: result = pd.merge(left, right, how='outer')
```

```
In [77]: result
```

```
Out[77]:
```

```
   X      Y  Z
```

```
0  foo  three  1
```

```
1  foo   two  1
```

```
2  foo  three  1
```

```
3  foo   one  1
```

```
4  foo   one  1
```

```
5  foo   two  1
```

```
6  foo   one  1
```

```
7  bar  three  2
```

```
8  bar   one  2
```

```
9  bar   two  2
```

```
In [78]: result.dtypes
```

```
Out[78]:
```

```
X    category
```

```
Y      object
```

```
Z      int64
```

```
dtype: object
```

Note: The category dtypes must be *exactly* the same, meaning the same categories and the ordered attribute. Otherwise the result will coerce to `object` dtype.

Note: Merging on `category` dtypes that are the same can be quite performant compared to `object` dtype

merging.

Joining on index

`DataFrame.join()` is a convenient method for combining the columns of two potentially differently-indexed `DataFrames` into a single result `DataFrame`. Here is a very basic example:

```
In [79]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2'],
.....:                       'B': ['B0', 'B1', 'B2']},
.....:                       index=['K0', 'K1', 'K2'])
.....:

In [80]: right = pd.DataFrame({'C': ['C0', 'C2', 'C3'],
.....:                        'D': ['D0', 'D2', 'D3']},
.....:                        index=['K0', 'K2', 'K3'])
.....:

In [81]: result = left.join(right)
```

left			right			Result				
	A	B		C	D		A	B	C	D
K0	A0	B0	K0	C0	D0	K0	A0	B0	C0	D0
K1	A1	B1	K2	C2	D2	K1	A1	B1	NaN	NaN
K2	A2	B2	K3	C3	D3	K2	A2	B2	C2	D2

```
In [82]: result = left.join(right, how='outer')
```

left			right			Result				
	A	B		C	D		A	B	C	D
K0	A0	B0	K0	C0	D0	K0	A0	B0	C0	D0
K1	A1	B1	K2	C2	D2	K1	A1	B1	NaN	NaN
K2	A2	B2	K3	C3	D3	K2	A2	B2	C2	D2
						K3	NaN	NaN	C3	D3

The same as above, but with `how='inner'`.

```
In [83]: result = left.join(right, how='inner')
```

left			right			Result				
	A	B		C	D		A	B	C	D
K0	A0	B0	K0	C0	D0	K0	A0	B0	C0	D0
K1	A1	B1	K2	C2	D2					
K2	A2	B2	K3	C3	D3	K2	A2	B2	C2	D2

The data alignment here is on the indexes (row labels). This same behavior can be achieved using `merge` plus additional arguments instructing it to use the indexes:

```
In [84]: result = pd.merge(left, right, left_index=True, right_index=True, how='outer')
```

left			right			Result				
	A	B		C	D		A	B	C	D
K0	A0	B0	K0	C0	D0	K0	A0	B0	C0	D0
K1	A1	B1	K2	C2	D2	K1	A1	B1	NaN	NaN
K2	A2	B2	K3	C3	D3	K2	A2	B2	C2	D2
						K3	NaN	NaN	C3	D3

```
In [85]: result = pd.merge(left, right, left_index=True, right_index=True, how='inner');
```

left			right			Result				
	A	B		C	D		A	B	C	D
K0	A0	B0	K0	C0	D0	K0	A0	B0	C0	D0
K1	A1	B1	K2	C2	D2					
K2	A2	B2	K3	C3	D3	K2	A2	B2	C2	D2

Joining key columns on an index

`join()` takes an optional `on` argument which may be a column or multiple column names, which specifies that the passed `DataFrame` is to be aligned on that column in the `DataFrame`. These two function calls are completely equivalent:

```
left.join(right, on=key_or_keys)
pd.merge(left, right, left_on=key_or_keys, right_index=True,
         how='left', sort=False)
```

Obviously you can choose whichever form you find more convenient. For many-to-one joins (where one of the `DataFrame`'s is already indexed by the join key), using `join` may be more convenient. Here is a simple example:

```
In [86]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2', 'A3'],
.....:                       'B': ['B0', 'B1', 'B2', 'B3'],
.....:                       'key': ['K0', 'K1', 'K0', 'K1']})
.....:
```

(continues on next page)

(continued from previous page)

```
In [87]: right = pd.DataFrame({'C': ['C0', 'C1'],
.....:                       'D': ['D0', 'D1']},
.....:                       index=['K0', 'K1'])
.....:
```

```
In [88]: result = left.join(right, on='key')
```

left				right			Result					
	A	B	key		C	D		A	B	key	C	D
0	A0	B0	K0				0	A0	B0	K0	C0	D0
1	A1	B1	K1	K0	C0	D0	1	A1	B1	K1	C1	D1
2	A2	B2	K0	K1	C1	D1	2	A2	B2	K0	C0	D0
3	A3	B3	K1				3	A3	B3	K1	C1	D1

```
In [89]: result = pd.merge(left, right, left_on='key', right_index=True,
.....:                      how='left', sort=False);
.....:
```

left				right			Result					
	A	B	key		C	D		A	B	key	C	D
0	A0	B0	K0				0	A0	B0	K0	C0	D0
1	A1	B1	K1	K0	C0	D0	1	A1	B1	K1	C1	D1
2	A2	B2	K0	K1	C1	D1	2	A2	B2	K0	C0	D0
3	A3	B3	K1				3	A3	B3	K1	C1	D1

To join on multiple

keys, the passed DataFrame must have a MultiIndex:

```
In [90]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2', 'A3'],
.....:                       'B': ['B0', 'B1', 'B2', 'B3'],
.....:                       'key1': ['K0', 'K0', 'K1', 'K2'],
.....:                       'key2': ['K0', 'K1', 'K0', 'K1']})
.....:
```

```
In [91]: index = pd.MultiIndex.from_tuples([('K0', 'K0'), ('K1', 'K0'),
.....:                                     ('K2', 'K0'), ('K2', 'K1')])
.....:
```

```
In [92]: right = pd.DataFrame({'C': ['C0', 'C1', 'C2', 'C3'],
.....:                       'D': ['D0', 'D1', 'D2', 'D3']},
.....:                       index=index)
.....:
```

Now this can be joined by passing the two key column names:

```
In [93]: result = left.join(right, on=['key1', 'key2'])
```

left					right				Result						
	A	B	key1	key2			C	D		A	B	key1	key2	C	D
0	A0	B0	K0	K0	K0	K0	C0	D0	0	A0	B0	K0	K0	C0	D0
1	A1	B1	K0	K1	K1	K1	C1	D1	1	A1	B1	K0	K1	NaN	NaN
2	A2	B2	K1	K0	K2	K2	C2	D2	2	A2	B2	K1	K0	C1	D1
3	A3	B3	K2	K1	K2	K1	C3	D3	3	A3	B3	K2	K1	C3	D3

The default for `DataFrame.join` is to perform a left join (essentially a “VLOOKUP” operation, for Excel users), which uses only the keys found in the calling `DataFrame`. Other join types, for example inner join, can be just as easily performed:

```
In [94]: result = left.join(right, on=['key1', 'key2'], how='inner')
```

left					right				Result						
	A	B	key1	key2			C	D		A	B	key1	key2	C	D
0	A0	B0	K0	K0	K0	K0	C0	D0	0	A0	B0	K0	K0	C0	D0
1	A1	B1	K0	K1	K1	K1	C1	D1							
2	A2	B2	K1	K0	K2	K2	C2	D2	2	A2	B2	K1	K0	C1	D1
3	A3	B3	K2	K1	K2	K1	C3	D3	3	A3	B3	K2	K1	C3	D3

As you can see, this drops any rows where there was no match.

Joining a single Index to a MultiIndex

You can join a singly-indexed `DataFrame` with a level of a MultiIndexed `DataFrame`. The level will match on the name of the index of the singly-indexed frame against a level name of the MultiIndexed frame.

```
In [95]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2'],
.....:                       'B': ['B0', 'B1', 'B2']},
.....:                       index=pd.Index(['K0', 'K1', 'K2'], name='key'))
.....:
```

```
In [96]: index = pd.MultiIndex.from_tuples([('K0', 'Y0'), ('K1', 'Y1'),
.....:                                     ('K2', 'Y2'), ('K2', 'Y3')],
.....:                                     names=['key', 'Y'])
.....:
```

```
In [97]: right = pd.DataFrame({'C': ['C0', 'C1', 'C2', 'C3'],
.....:                        'D': ['D0', 'D1', 'D2', 'D3']},
.....:                        index=index)
.....:
```

```
In [98]: result = left.join(right, how='inner')
```

left			right				Result					
	A	B			C	D			A	B	C	D
K0	A0	B0	K0	Y0	C0	D0	K0	Y0	A0	B0	C0	D0
K1	A1	B1	K1	Y1	C1	D1	K1	Y1	A1	B1	C1	D1
K2	A2	B2	K2	Y2	C2	D2	K2	Y2	A2	B2	C2	D2
			K2	Y3	C3	D3	K2	Y3	A2	B2	C3	D3

This is equivalent but less verbose and more memory efficient / faster than this.

```
In [99]: result = pd.merge(left.reset_index(), right.reset_index(),
.....:     on=['key'], how='inner').set_index(['key', 'Y'])
.....:
```

left			right				Result					
	A	B			C	D			A	B	C	D
K0	A0	B0	K0	Y0	C0	D0	K0	Y0	A0	B0	C0	D0
K1	A1	B1	K1	Y1	C1	D1	K1	Y1	A1	B1	C1	D1
K2	A2	B2	K2	Y2	C2	D2	K2	Y2	A2	B2	C2	D2
			K2	Y3	C3	D3	K2	Y3	A2	B2	C3	D3

Joining with two MultiIndexes

This is supported in a limited way, provided that the index for the right argument is completely used in the join, and is a subset of the indices in the left argument, as in this example:

```
In [100]: leftindex = pd.MultiIndex.from_product([list('abc'), list('xy'), [1, 2]],
.....:     names=['abc', 'xy', 'num'])
.....:
```

```
In [101]: left = pd.DataFrame({'v1': range(12)}, index=leftindex)
```

```
In [102]: left
Out[102]:
```

			v1
abc	xy	num	
a	x	1	0
		2	1
	y	1	2
		2	3
b	x	1	4
		2	5
	y	1	6
		2	7
c	x	1	8
		2	9
	y	1	10

2 11

```
In [103]: rightindex = pd.MultiIndex.from_product([list('abc'), list('xy')],
.....:                                           names=['abc', 'xy'])
.....:
```

```
In [104]: right = pd.DataFrame({'v2': [100 * i for i in range(1, 7)]}, index=rightindex)
```

```
In [105]: right
Out[105]:
```

```
      v2
abc xy
a  x  100
   y  200
b  x  300
   y  400
c  x  500
   y  600
```

```
In [106]: left.join(right, on=['abc', 'xy'], how='inner')
```

```
Out[106]:
```

```
      v1  v2
abc xy num
a  x  1    0  100
   2    1  100
   y  1    2  200
   2    3  200
b  x  1    4  300
   2    5  300
   y  1    6  400
   2    7  400
c  x  1    8  500
   2    9  500
   y  1   10  600
   2   11  600
```

If that condition is not satisfied, a join with two multi-indexes can be done using the following code.

```
In [107]: leftindex = pd.MultiIndex.from_tuples([('K0', 'X0'), ('K0', 'X1'),
.....:                                         ('K1', 'X2')],
.....:                                         names=['key', 'X'])
.....:

In [108]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2'],
.....:                        'B': ['B0', 'B1', 'B2']},
.....:                        index=leftindex)
.....:

In [109]: rightindex = pd.MultiIndex.from_tuples([('K0', 'Y0'), ('K1', 'Y1'),
.....:                                         ('K2', 'Y2'), ('K2', 'Y3')],
.....:                                         names=['key', 'Y'])
.....:

In [110]: right = pd.DataFrame({'C': ['C0', 'C1', 'C2', 'C3'],
```

(continues on next page)

(continued from previous page)

```

.....:         'D': ['D0', 'D1', 'D2', 'D3']},
.....:         index=rightindex)
.....:
In [111]: result = pd.merge(left.reset_index(), right.reset_index(),
.....:                        on='key', how='inner').set_index(['key', 'X', 'Y'])
.....:

```

left				right				Result							
		A	B			C	D			A	B	C	D		
K0	X0	A0	B0	K0	Y0	C0	D0	K0	X0	Y0	A0	B0	C0	D0	
K0	X1	A1	B1	K1	Y1	C1	D1	K0	X1	Y0	A1	B1	C0	D0	
K1	X2	A2	B2	K2	Y2	C2	D2	K1	X2	Y1	A2	B2	C1	D1	
				K2	Y3	C3	D3								

Merging on a combination of columns and index levels

New in version 0.23.

Strings passed as the `on`, `left_on`, and `right_on` parameters may refer to either column names or index level names. This enables merging `DataFrame` instances on a combination of index levels and columns without resetting indexes.

```

In [112]: left_index = pd.Index(['K0', 'K0', 'K1', 'K2'], name='key1')

In [113]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2', 'A3'],
.....:                        'B': ['B0', 'B1', 'B2', 'B3'],
.....:                        'key2': ['K0', 'K1', 'K0', 'K1']},
.....:                        index=left_index)
.....:

In [114]: right_index = pd.Index(['K0', 'K1', 'K2', 'K2'], name='key1')

In [115]: right = pd.DataFrame({'C': ['C0', 'C1', 'C2', 'C3'],
.....:                          'D': ['D0', 'D1', 'D2', 'D3'],
.....:                          'key2': ['K0', 'K0', 'K0', 'K1']},
.....:                          index=right_index)
.....:

In [116]: result = left.merge(right, on=['key1', 'key2'])

```

left				right				Result					
	A	B	key2		C	D	key2		A	B	key2	C	D
K0	A0	B0	K0	K0	C0	D0	K0	K0	A0	B0	K0	C0	D0
K0	A1	B1	K1	K1	C1	D1	K0	K1	A2	B2	K0	C1	D1
K1	A2	B2	K0	K2	C2	D2	K0	K2	A3	B3	K1	C3	D3
K2	A3	B3	K1	K2	C3	D3	K1						

Note: When DataFrames are merged on a string that matches an index level in both frames, the index level is preserved as an index level in the resulting DataFrame.

Note: When DataFrames are merged using only some of the levels of a *MultiIndex*, the extra levels will be dropped from the resulting merge. In order to preserve those levels, use `reset_index` on those level names to move those levels to columns prior to doing the merge.

Note: If a string matches both a column name and an index level name, then a warning is issued and the column takes precedence. This will result in an ambiguity error in a future version.

Overlapping value columns

The merge `suffixes` argument takes a tuple of list of strings to append to overlapping column names in the input DataFrames to disambiguate the result columns:

```
In [117]: left = pd.DataFrame({'k': ['K0', 'K1', 'K2'], 'v': [1, 2, 3]})
```

```
In [118]: right = pd.DataFrame({'k': ['K0', 'K0', 'K3'], 'v': [4, 5, 6]})
```

```
In [119]: result = pd.merge(left, right, on='k')
```

left			right			Result			
	k	v		k	v		k	v_x	v_y
0	K0	1	0	K0	4	0	K0	1	4
1	K1	2	1	K0	5	1	K0	1	5
2	K2	3	2	K3	6				

```
In [120]: result = pd.merge(left, right, on='k', suffixes=['_l', '_r'])
```

left			right			Result			
	k	v		k	v		k	v_l	v_r
0	K0	1	0	K0	4	0	K0	1	4
1	K1	2	1	K0	5	1	K0	1	5
2	K2	3	2	K3	6				

`DataFrame.join()` has `lsuffix` and `rsuffix` arguments which behave similarly.

```
In [121]: left = left.set_index('k')
```

```
In [122]: right = right.set_index('k')
```

```
In [123]: result = left.join(right, lsuffix='_l', rsuffix='_r')
```

left		right		Result		
	v		v		v_l	v_r
K0	1	K0	4	K0	1	4.0
K1	2	K0	5	K0	1	5.0
K2	3	K3	6	K1	2	NaN
				K2	3	NaN

Joining multiple DataFrames

A list or tuple of DataFrames can also be passed to `join()` to join them together on their indexes.

```
In [124]: right2 = pd.DataFrame({'v': [7, 8, 9]}, index=['K1', 'K1', 'K2'])
```

```
In [125]: result = left.join([right, right2])
```

left		right		right2		Result			
	v		v		v		v_x	v_y	v
K0	1	K0	4	K1	7	K0	1	4.0	NaN
K1	2	K0	5	K1	8	K0	1	5.0	NaN
K2	3	K3	6	K2	9	K1	2	NaN	7.0
						K1	2	NaN	8.0
						K2	3	NaN	9.0

Merging together values within Series or DataFrame columns

Another fairly common situation is to have two like-indexed (or similarly indexed) `Series` or `DataFrame` objects and wanting to “patch” values in one object from values for matching indices in the other. Here is an example:

```
In [126]: df1 = pd.DataFrame([[np.nan, 3., 5.], [-4.6, np.nan, np.nan],
.....:                       [np.nan, 7., np.nan]])
.....:
.....:

In [127]: df2 = pd.DataFrame([[-42.6, np.nan, -8.2], [-5., 1.6, 4]],
.....:                       index=[1, 2])
.....:
.....:
```

For this, use the `combine_first()` method:

```
In [128]: result = df1.combine_first(df2)
```

df1				df2				Result			
	0	1	2		0	1	2		0	1	2
0	NaN	3.0	5.0					0	NaN	3.0	5.0
1	-4.6	NaN	NaN	1	-42.6	NaN	-8.2	1	-4.6	NaN	-8.2
2	NaN	7.0	NaN	2	-5.0	1.6	4.0	2	-5.0	7.0	4.0

Note that this method only takes values from the right `DataFrame` if they are missing in the left `DataFrame`. A related method, `update()`, alters non-NA values in place:

```
In [129]: df1.update(df2)
```

df1				df2				Result			
	0	1	2		0	1	2		0	1	2
0	NaN	3.0	5.0					0	NaN	3.0	5.0
1	-4.6	NaN	NaN	1	-42.6	NaN	-8.2	1	-42.6	NaN	-8.2
2	NaN	7.0	NaN	2	-5.0	1.6	4.0	2	-5.0	1.6	4.0

4.4.3 Timeseries friendly merging

Merging ordered data

A `merge_ordered()` function allows combining time series and other ordered data. In particular it has an optional `fill_method` keyword to fill/interpolate missing data:

```
In [130]: left = pd.DataFrame({'k': ['K0', 'K1', 'K1', 'K2'],
.....:                       'lv': [1, 2, 3, 4],
.....:                       's': ['a', 'b', 'c', 'd']})
.....:
.....:

In [131]: right = pd.DataFrame({'k': ['K1', 'K2', 'K4'],
.....:                          'rv': [1, 2, 3]})
.....:
.....:
```

(continues on next page)

(continued from previous page)

```
In [132]: pd.merge_ordered(left, right, fill_method='ffill', left_by='s')
```

```
Out[132]:
```

```

   k  lv s  rv
0  K0  1.0 a NaN
1  K1  1.0 a  1.0
2  K2  1.0 a  2.0
3  K4  1.0 a  3.0
4  K1  2.0 b  1.0
5  K2  2.0 b  2.0
6  K4  2.0 b  3.0
7  K1  3.0 c  1.0
8  K2  3.0 c  2.0
9  K4  3.0 c  3.0
10 K1 NaN d  1.0
11 K2  4.0 d  2.0
12 K4  4.0 d  3.0

```

Merging asof

New in version 0.19.0.

A `merge_asof()` is similar to an ordered left-join except that we match on nearest key rather than equal keys. For each row in the `left DataFrame`, we select the last row in the `right DataFrame` whose `on` key is less than the left's key. Both `DataFrames` must be sorted by the key.

Optionally an asof merge can perform a group-wise merge. This matches the `by` key equally, in addition to the nearest match on the `on` key.

For example; we might have `trades` and `quotes` and we want to `asof` merge them.

```
In [133]: trades = pd.DataFrame({
.....:     'time': pd.to_datetime(['20160525 13:30:00.023',
.....:                             '20160525 13:30:00.038',
.....:                             '20160525 13:30:00.048',
.....:                             '20160525 13:30:00.048',
.....:                             '20160525 13:30:00.048']),
.....:     'ticker': ['MSFT', 'MSFT',
.....:                 'GOOG', 'GOOG', 'AAPL'],
.....:     'price': [51.95, 51.95,
.....:               720.77, 720.92, 98.00],
.....:     'quantity': [75, 155,
.....:                  100, 100, 100]},
.....:     columns=['time', 'ticker', 'price', 'quantity'])
.....:
```

```
In [134]: quotes = pd.DataFrame({
.....:     'time': pd.to_datetime(['20160525 13:30:00.023',
.....:                             '20160525 13:30:00.023',
.....:                             '20160525 13:30:00.030',
.....:                             '20160525 13:30:00.041',
.....:                             '20160525 13:30:00.048',
.....:                             '20160525 13:30:00.049'],
.....:     'price': [0.01, 0.01, 0.01, 0.01, 0.01, 0.01],
.....:     'quantity': [100, 100, 100, 100, 100, 100]},
.....:     columns=['time', 'price', 'quantity'])
.....:
```

(continues on next page)

(continued from previous page)

```

.....:         '20160525 13:30:00.072',
.....:         '20160525 13:30:00.075']]),
.....:     'ticker': ['GOOG', 'MSFT', 'MSFT',
.....:              'MSFT', 'GOOG', 'AAPL', 'GOOG',
.....:              'MSFT'],
.....:     'bid': [720.50, 51.95, 51.97, 51.99,
.....:           720.50, 97.99, 720.50, 52.01],
.....:     'ask': [720.93, 51.96, 51.98, 52.00,
.....:           720.93, 98.01, 720.88, 52.03]},
.....:     columns=['time', 'ticker', 'bid', 'ask'])
.....:

```

In [135]: trades

Out[135]:

	time	ticker	price	quantity
0	2016-05-25 13:30:00.023	MSFT	51.95	75
1	2016-05-25 13:30:00.038	MSFT	51.95	155
2	2016-05-25 13:30:00.048	GOOG	720.77	100
3	2016-05-25 13:30:00.048	GOOG	720.92	100
4	2016-05-25 13:30:00.048	AAPL	98.00	100

In [136]: quotes

Out[136]:

	time	ticker	bid	ask
0	2016-05-25 13:30:00.023	GOOG	720.50	720.93
1	2016-05-25 13:30:00.023	MSFT	51.95	51.96
2	2016-05-25 13:30:00.030	MSFT	51.97	51.98
3	2016-05-25 13:30:00.041	MSFT	51.99	52.00
4	2016-05-25 13:30:00.048	GOOG	720.50	720.93
5	2016-05-25 13:30:00.049	AAPL	97.99	98.01
6	2016-05-25 13:30:00.072	GOOG	720.50	720.88
7	2016-05-25 13:30:00.075	MSFT	52.01	52.03

By default we are taking the asof of the quotes.

```

In [137]: pd.merge_asof(trades, quotes,
.....:                  on='time',
.....:                  by='ticker')
.....:

```

Out[137]:

	time	ticker	price	quantity	bid	ask
0	2016-05-25 13:30:00.023	MSFT	51.95	75	51.95	51.96
1	2016-05-25 13:30:00.038	MSFT	51.95	155	51.97	51.98
2	2016-05-25 13:30:00.048	GOOG	720.77	100	720.50	720.93
3	2016-05-25 13:30:00.048	GOOG	720.92	100	720.50	720.93
4	2016-05-25 13:30:00.048	AAPL	98.00	100	NaN	NaN

We only asof within 2ms between the quote time and the trade time.

```

In [138]: pd.merge_asof(trades, quotes,
.....:                  on='time',
.....:                  by='ticker',
.....:                  tolerance=pd.Timedelta('2ms'))

```

(continues on next page)

(continued from previous page)

```

.....:
Out [138]:
           time ticker  price  quantity  bid  ask
0 2016-05-25 13:30:00.023  MSFT   51.95     75  51.95  51.96
1 2016-05-25 13:30:00.038  MSFT   51.95    155   NaN   NaN
2 2016-05-25 13:30:00.048  GOOG  720.77    100  720.50  720.93
3 2016-05-25 13:30:00.048  GOOG  720.92    100  720.50  720.93
4 2016-05-25 13:30:00.048  AAPL   98.00    100   NaN   NaN

```

We only asof within 10ms between the quote time and the trade time and we exclude exact matches on time. Note that though we exclude the exact matches (of the quotes), prior quotes **do** propagate to that point in time.

```

In [139]: pd.merge_asof(trades, quotes,
.....:                  on='time',
.....:                  by='ticker',
.....:                  tolerance=pd.Timedelta('10ms'),
.....:                  allow_exact_matches=False)
.....:
Out [139]:
           time ticker  price  quantity  bid  ask
0 2016-05-25 13:30:00.023  MSFT   51.95     75   NaN   NaN
1 2016-05-25 13:30:00.038  MSFT   51.95    155  51.97  51.98

4.5 Reshaping and pivot tables

4.5.1 Reshaping by pivoting DataFrame objects

Pivot

	foo	bar	baz	zoo
0	one	A	1	x
1	one	B	2	y
2	one	C	3	z
3	two	A	4	q
4	two	B	5	w
5	two	C	6	t

df

df.pivot(index=
column=
value=)

bar	A
foo	
one	1
two	4

Data is often stored in so-called “stacked” or “record” format:

```
In [1]: df
Out[1]:
```

	date	variable	value
0	2000-01-03	A	0.259126
1	2000-01-04	A	0.774683
2	2000-01-05	A	0.713390
3	2000-01-03	B	-0.837638
4	2000-01-04	B	0.064089
5	2000-01-05	B	-0.034934
6	2000-01-03	C	-0.452395
7	2000-01-04	C	2.488398
8	2000-01-05	C	1.429389
9	2000-01-03	D	0.547623
10	2000-01-04	D	0.008959
11	2000-01-05	D	1.097237

For the curious here is how the above DataFrame was created:

```
import pandas.util.testing as tm

tm.N = 3

def unpivot(frame):
    N, K = frame.shape
    data = {'value': frame.to_numpy().ravel('F'),
           'variable': np.asarray(frame.columns).repeat(N),
           'date': np.tile(np.asarray(frame.index), K)}
    return pd.DataFrame(data, columns=['date', 'variable', 'value'])

df = unpivot(tm.makeTimeDataFrame())
```

To select out everything for variable A we could do:

```
In [2]: df[df['variable'] == 'A']
Out[2]:
```

	date	variable	value
0	2000-01-03	A	0.259126
1	2000-01-04	A	0.774683
2	2000-01-05	A	0.713390

But suppose we wish to do time series operations with the variables. A better representation would be where the `columns` are the unique variables and an `index` of dates identifies individual observations. To reshape the data into this form, we use the `DataFrame.pivot()` method (also implemented as a top level function `pivot()`):

```
In [3]: df.pivot(index='date', columns='variable', values='value')
Out[3]:
```

variable	A	B	C	D
date				
2000-01-03	0.259126	-0.837638	-0.452395	0.547623
2000-01-04	0.774683	0.064089	2.488398	0.008959
2000-01-05	0.713390	-0.034934	1.429389	1.097237

If the `values` argument is omitted, and the input `DataFrame` has more than one column of values which are not used as column or index inputs to `pivot`, then the resulting “pivoted” `DataFrame` will have *hierarchical columns* whose topmost level indicates the respective value column:

```
In [4]: df['value2'] = df['value'] * 2

In [5]: pivoted = df.pivot(index='date', columns='variable')

In [6]: pivoted
Out[6]:
```

	value				value2			
↪	↪	↪	↪	↪	↪	↪	↪	↪
variable	A	B	C	D	A	B	C	D
↪date								
↪								

(continues on next page)

(continued from previous page)

```

2000-01-03  0.259126 -0.837638 -0.452395  0.547623  0.518252 -1.675276 -0.904790  1.
↪095246
2000-01-04  0.774683  0.064089  2.488398  0.008959  1.549366  0.128178  4.976796  0.
↪017919
2000-01-05  0.713390 -0.034934  1.429389  1.097237  1.426780 -0.069868  2.858779  2.
↪194473

```

You can then select subsets from the pivoted DataFrame:

```

In [7]: pivoted['value2']
Out[7]:
variable      A      B      C      D
date
2000-01-03  0.518252 -1.675276 -0.904790  1.095246
2000-01-04  1.549366  0.128178  4.976796  0.017919
2000-01-05  1.426780 -0.069868  2.858779  2.194473

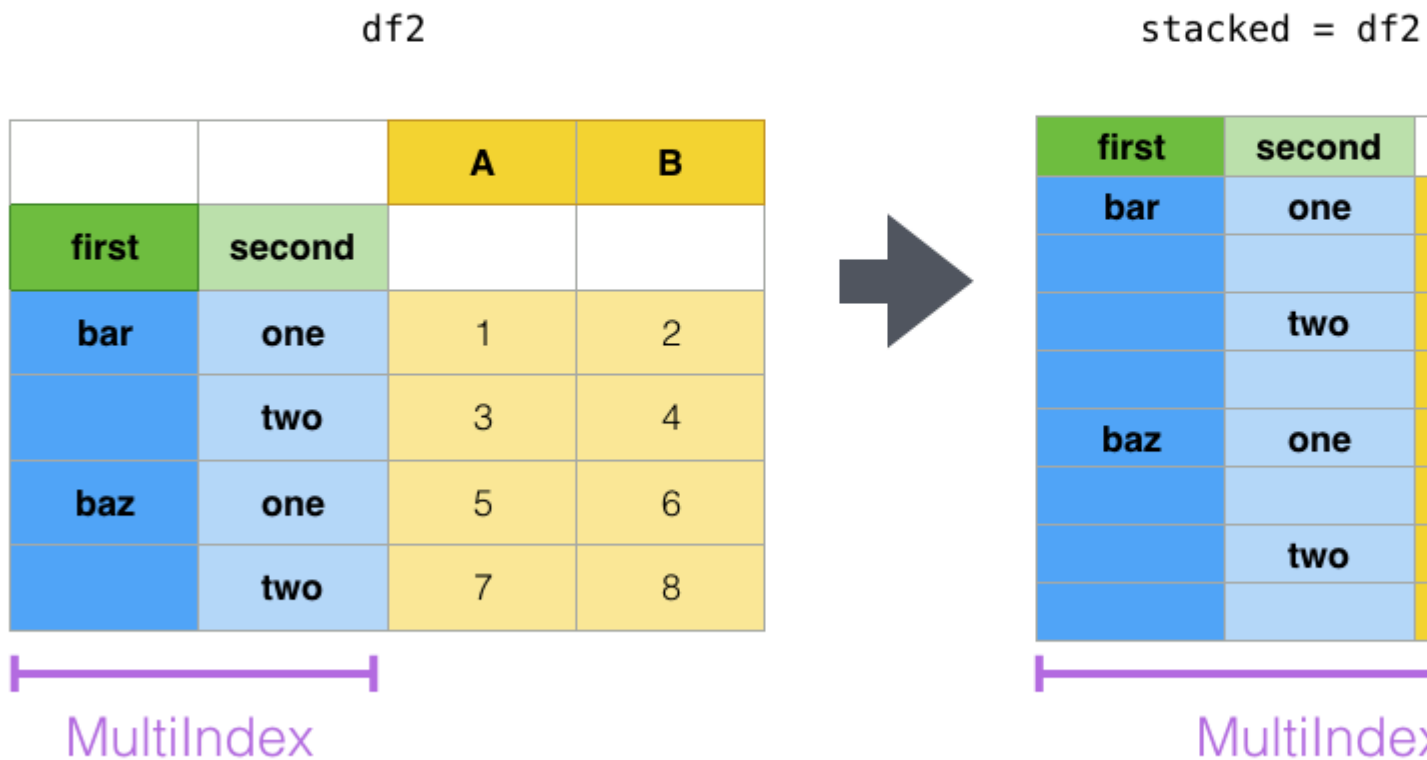

```

Note that this returns a view on the underlying data in the case where the data are homogeneously-typed.

Note: `pivot()` will error with a `ValueError: Index contains duplicate entries, cannot reshape` if the index/column pair is not unique. In this case, consider using `pivot_table()` which is a generalization of `pivot` that can handle duplicate values for one index/column pair.

4.5.2 Reshaping by stacking and unstacking

Stack

Closely related to the `pivot()` method are the related `stack()` and `unstack()` methods available on `Series` and `DataFrame`. These methods are designed to work together with `MultiIndex` objects (see the section on *hierarchical indexing*). Here are essentially what these methods do:

- **stack**: “pivot” a level of the (possibly hierarchical) column labels, returning a `DataFrame` with an index with a new inner-most level of row labels.
- **unstack**: (inverse operation of **stack**) “pivot” a level of the (possibly hierarchical) row index to the column axis, producing a reshaped `DataFrame` with a new inner-most level of column labels.

Unstack

The clearest way to explain is by example. Let's take a prior example data set from the hierarchical indexing section:

```
In [8]: tuples = list(zip(*[['bar', 'bar', 'baz', 'baz',
...:                        'foo', 'foo', 'qux', 'qux'],
...:                        ['one', 'two', 'one', 'two',
...:                        'one', 'two', 'one', 'two']]))
...:

In [9]: index = pd.MultiIndex.from_tuples(tuples, names=['first', 'second'])

In [10]: df = pd.DataFrame(np.random.randn(8, 2), index=index, columns=['A', 'B'])

In [11]: df2 = df[:4]

In [12]: df2
Out[12]:
```

	A	B
first second		

(continues on next page)

(continued from previous page)

```
bar  one  -1.427767  1.011174
     two  -0.227837  0.260297
baz  one  -0.664499 -1.085553
     two  -1.392521 -0.426500
```

The `stack` function “compresses” a level in the `DataFrame`’s columns to produce either:

- A `Series`, in the case of a simple column `Index`.
- A `DataFrame`, in the case of a `MultiIndex` in the columns.

If the columns have a `MultiIndex`, you can choose which level to stack. The stacked level becomes the new lowest level in a `MultiIndex` on the columns:

```
In [13]: stacked = df2.stack()
```

```
In [14]: stacked
```

```
Out[14]:
```

```
first second
bar   one    A   -1.427767
      two    B    1.011174
      two    A   -0.227837
      two    B    0.260297
baz   one    A   -0.664499
      two    B   -1.085553
      two    A   -1.392521
      two    B   -0.426500
```

```
dtype: float64
```

With a “stacked” `DataFrame` or `Series` (having a `MultiIndex` as the index), the inverse operation of `stack` is `unstack`, which by default unstacks the **last level**:

```
In [15]: stacked.unstack()
```

```
Out[15]:
```

```
              A          B
first second
bar   one  -1.427767  1.011174
      two  -0.227837  0.260297
baz   one  -0.664499 -1.085553
      two  -1.392521 -0.426500
```

```
In [16]: stacked.unstack(1)
```

```
Out[16]:
```

```
second      one      two
first
bar   A -1.427767 -0.227837
      B  1.011174  0.260297
baz   A -0.664499 -1.392521
      B -1.085553 -0.426500
```

```
In [17]: stacked.unstack(0)
```

```
Out[17]:
```

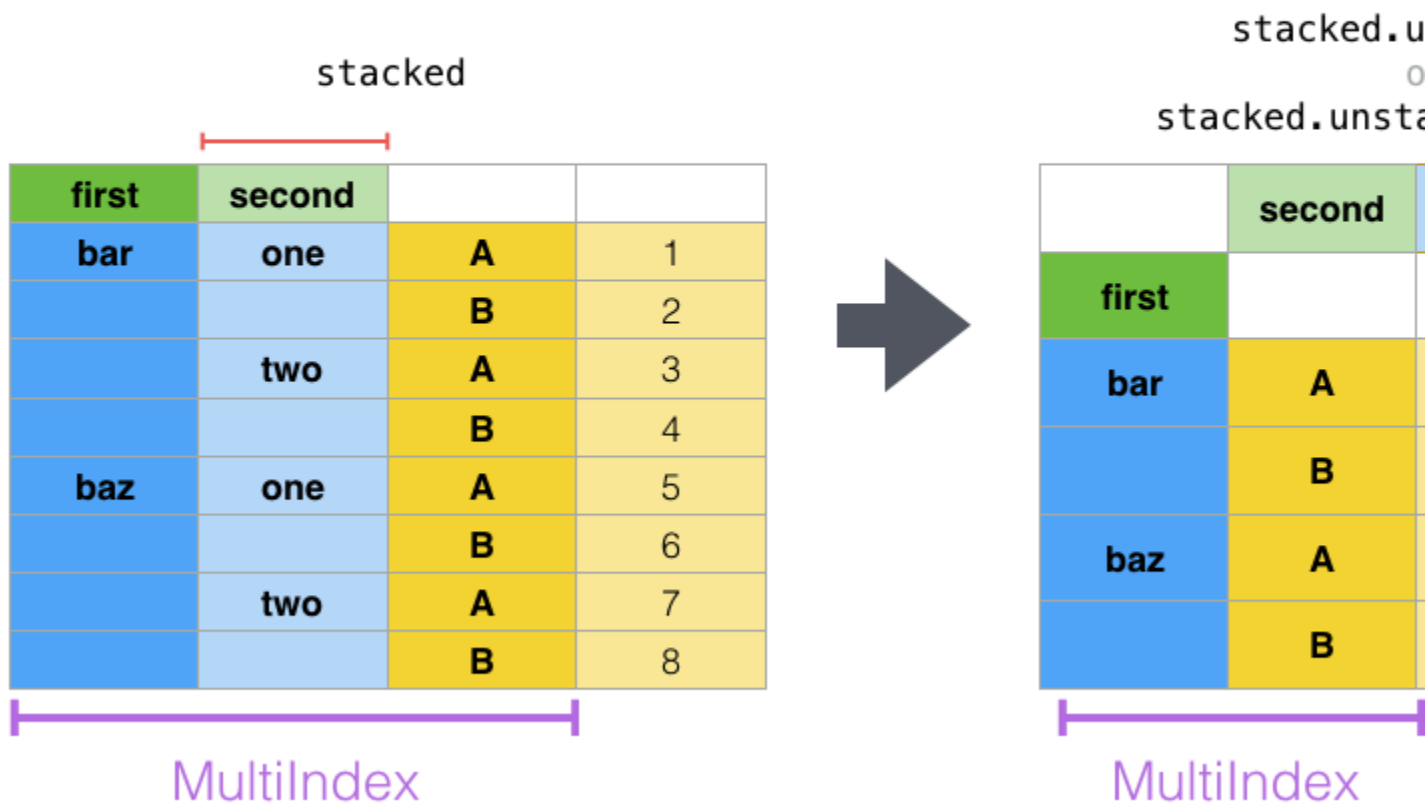

```
first      bar      baz
second
one   A -1.427767 -0.664499
```

```

two      B  1.011174 -1.085553
        A -0.227837 -1.392521
        B  0.260297 -0.426500

```

Unstack(1)

If the indexes have names, you can use the level names instead of specifying the level numbers:

```

In [18]: stacked.unstack('second')
Out[18]:
second      one      two
first
bar   A -1.427767 -0.227837
      B  1.011174  0.260297
baz   A -0.664499 -1.392521
      B -1.085553 -0.426500

```

Unstack(0)

Notice that the `stack` and `unstack` methods implicitly sort the index levels involved. Hence a call to `stack` and then `unstack`, or vice versa, will result in a **sorted** copy of the original `DataFrame` or `Series`:

```
In [19]: index = pd.MultiIndex.from_product([[2, 1], ['a', 'b']])
```

```
In [20]: df = pd.DataFrame(np.random.randn(4), index=index, columns=['A'])
```

```
In [21]: df
```

```
Out[21]:
```

```

      A
2 a -1.727109
  b -1.966122
1 a -0.004308
  b  0.627249
```

```
In [22]: all(df.unstack().stack() == df.sort_index())
```

```
Out[22]: True
```

The above code will raise a `TypeError` if the call to `sort_index` is removed.

Multiple levels

You may also stack or unstack more than one level at a time by passing a list of levels, in which case the end result is as if each level in the list were processed individually.

```
In [23]: columns = pd.MultiIndex.from_tuples([
....:     ('A', 'cat', 'long'), ('B', 'cat', 'long'),
....:     ('A', 'dog', 'short'), ('B', 'dog', 'short')],
....:     names=['exp', 'animal', 'hair_length']
....: )
....:
```

```
In [24]: df = pd.DataFrame(np.random.randn(4, 4), columns=columns)
```

```
In [25]: df
```

```
Out[25]:
```

exp	A		B	
animal	cat	cat	dog	dog
hair_length	long	long	short	short
0	-2.260817	0.023953	-1.328037	-0.091360
1	-0.063483	0.691641	1.062240	-1.912934
2	-0.967661	1.438160	1.796396	0.364482
3	0.384514	0.774313	-1.215737	1.533214

```
In [26]: df.stack(level=['animal', 'hair_length'])
```

```
Out[26]:
```

exp			A	B
animal	hair_length			
0	cat	long	-2.260817	0.023953
	dog	short	-1.328037	-0.091360
1	cat	long	-0.063483	0.691641
	dog	short	1.062240	-1.912934
2	cat	long	-0.967661	1.438160
	dog	short	1.796396	0.364482
3	cat	long	0.384514	0.774313
	dog	short	-1.215737	1.533214

The list of levels can contain either level names or level numbers (but not a mixture of the two).

```
# df.stack(level=['animal', 'hair_length'])
# from above is equivalent to:
In [27]: df.stack(level=[1, 2])
Out[27]:
```

exp			A	B
animal	hair_length			
0	cat	long	-2.260817	0.023953
	dog	short	-1.328037	-0.091360
1	cat	long	-0.063483	0.691641
	dog	short	1.062240	-1.912934
2	cat	long	-0.967661	1.438160
	dog	short	1.796396	0.364482
3	cat	long	0.384514	0.774313
	dog	short	-1.215737	1.533214

Missing data

These functions are intelligent about handling missing data and do not expect each subgroup within the hierarchical index to have the same set of labels. They also can handle the index being unsorted (but you can make it sorted by calling `sort_index`, of course). Here is a more complex example:

```
In [28]: columns = pd.MultiIndex.from_tuples([('A', 'cat'), ('B', 'dog'),
.....:                                     ('B', 'cat'), ('A', 'dog')],
.....:                                     names=['exp', 'animal'])
.....:

In [29]: index = pd.MultiIndex.from_product([('bar', 'baz', 'foo', 'qux'),
.....:                                     ('one', 'two')],
.....:                                     names=['first', 'second'])
.....:

In [30]: df = pd.DataFrame(np.random.randn(8, 4), index=index, columns=columns)

In [31]: df2 = df.iloc[[0, 1, 2, 4, 5, 7]]

In [32]: df2
Out[32]:
exp          A          B          A
animal       cat       dog       cat       dog
first second
bar  one  -1.436953  0.561814 -0.346880 -0.546060
     two  -1.993054 -0.689365 -0.877031  1.507935
baz  one  -1.866380  0.043384  0.252683 -0.479004
foo  one  -1.613149 -0.622599  0.291003  0.792238
     two   0.807151 -0.758613 -2.393856  1.098272
qux  two  -0.411186  1.584705 -1.042868 -0.295906
```

As mentioned above, `stack` can be called with a `level` argument to select which level in the columns to stack:

```
In [33]: df2.stack('exp')
Out[33]:
animal          cat          dog
first second exp
bar  one  A  -1.436953 -0.546060
     two  B  -0.346880  0.561814
     two  A  -1.993054  1.507935
     two  B  -0.877031 -0.689365
baz  one  A  -1.866380 -0.479004
     one  B   0.252683  0.043384
foo  one  A  -1.613149  0.792238
     two  B   0.291003 -0.622599
     two  A   0.807151  1.098272
     two  B  -2.393856 -0.758613
qux  two  A  -0.411186 -0.295906
     two  B  -1.042868  1.584705
```

```
In [34]: df2.stack('animal')
Out[34]:
exp          A          B
```

```

first second animal
bar  one   cat   -1.436953 -0.346880
      dog   -0.546060  0.561814
      two   cat   -1.993054 -0.877031
      dog   1.507935 -0.689365
baz  one   cat   -1.866380  0.252683
      dog   -0.479004  0.043384
foo  one   cat   -1.613149  0.291003
      dog   0.792238 -0.622599
      two   cat   0.807151 -2.393856
      dog   1.098272 -0.758613
qux  two   cat   -0.411186 -1.042868
      dog   -0.295906  1.584705

```

Unstacking can result in missing values if subgroups do not have the same set of labels. By default, missing values will be replaced with the default fill value for that data type, NaN for float, NaT for datetimelike, etc. For integer types, by default data will be converted to float and missing values will be set to NaN.

```
In [35]: df3 = df.iloc[[0, 1, 4, 7], [1, 2]]
```

```
In [36]: df3
```

```

Out[36]:
exp          B
animal      dog      cat
first second
bar  one    0.561814 -0.346880
      two   -0.689365 -0.877031
foo  one   -0.622599  0.291003
qux  two    1.584705 -1.042868

```

```
In [37]: df3.unstack()
```

```

Out[37]:
exp          B
animal      dog      cat
second      one      two      one      two
first
bar    0.561814 -0.689365 -0.346880 -0.877031
foo   -0.622599      NaN  0.291003      NaN
qux          NaN  1.584705      NaN -1.042868

```

New in version 0.18.0.

Alternatively, unstack takes an optional `fill_value` argument, for specifying the value of missing data.

```

In [38]: df3.unstack(fill_value=-1e9)
Out[38]:
exp          B
animal      dog      cat
second      one      two      one      two
first
bar    5.618142e-01 -6.893650e-01 -3.468802e-01 -8.770315e-01
foo   -6.225992e-01 -1.000000e+09  2.910029e-01 -1.000000e+09
qux   -1.000000e+09  1.584705e+00 -1.000000e+09 -1.042868e+00

```

With a MultiIndex

Unstacking when the columns are a MultiIndex is also careful about doing the right thing:

```
In [39]: df[:3].unstack(0)
```

```
Out[39]:
```

```
exp          A          B          A
animal      cat          dog          dog
first      bar      baz      bar      baz      bar      baz      bar      baz
second
one      -1.436953 -1.86638  0.561814  0.043384 -0.346880  0.252683 -0.546060 -0.479004
two      -1.993054      NaN -0.689365      NaN -0.877031      NaN  1.507935      NaN
```

```
In [40]: df2.unstack(1)
```

```
Out[40]:
```

```
exp          A          B          A
animal      cat          dog          dog
second      one      two      one      two      one      two      one      two
first
bar      -1.436953 -1.993054  0.561814 -0.689365 -0.346880 -0.877031 -0.546060  1.507935
baz      -1.866380      NaN  0.043384      NaN  0.252683      NaN -0.479004      NaN
foo      -1.613149  0.807151 -0.622599 -0.758613  0.291003 -2.393856  0.792238  1.098272
qux          NaN -0.411186      NaN  1.584705      NaN -1.042868      NaN -0.295906
```

4.5.3 Reshaping by Melt

Melt

The top-level `melt()` function and the corresponding `DataFrame.melt()` are useful to massage a `DataFrame` into a format where one or more columns are *identifier variables*, while all other columns, considered *measured variables*, are “unpivoted” to the row axis, leaving just two non-identifier columns, “variable” and “value”. The names of those columns can be customized by supplying the `var_name` and `value_name` parameters.

For instance,

```
In [41]: cheese = pd.DataFrame({'first': ['John', 'Mary'],
.....:                        'last': ['Doe', 'Bo'],
.....:                        'height': [5.5, 6.0],
.....:                        'weight': [130, 150]})
.....:
```

```
In [42]: cheese
Out[42]:
   first last  height  weight
0  John  Doe     5.5     130
1  Mary  Bo     6.0     150
```

```
In [43]: cheese.melt(id_vars=['first', 'last'])
Out[43]:
   first last variable  value
```

```
0 John Doe height 5.5
1 Mary Bo height 6.0
2 John Doe weight 130.0
3 Mary Bo weight 150.0
```

```
In [44]: cheese.melt(id_vars=['first', 'last'], var_name='quantity')
```

```
Out[44]:
  first last quantity value
0 John Doe height 5.5
1 Mary Bo height 6.0
2 John Doe weight 130.0
3 Mary Bo weight 150.0
```

Another way to transform is to use the `wide_to_long()` panel data convenience function. It is less flexible than `melt()`, but more user-friendly.

```
In [45]: dft = pd.DataFrame({"A1970": {0: "a", 1: "b", 2: "c"},
.....:                      "A1980": {0: "d", 1: "e", 2: "f"},
.....:                      "B1970": {0: 2.5, 1: 1.2, 2: .7},
.....:                      "B1980": {0: 3.2, 1: 1.3, 2: .1},
.....:                      "X": dict(zip(range(3), np.random.randn(3)))
.....:                      })
.....:
```

```
In [46]: dft["id"] = dft.index
```

```
In [47]: dft
```

```
Out[47]:
  A1970 A1980 B1970 B1980      X id
0     a     d   2.5   3.2 -2.013095  0
1     b     e   1.2   1.3 -1.711797  1
2     c     f   0.7   0.1  0.975018  2
```

```
In [48]: pd.wide_to_long(dft, ["A", "B"], i="id", j="year")
```

```
Out[48]:
      X A  B
id year
0 1970 -2.013095 a 2.5
1 1970 -1.711797 b 1.2
2 1970  0.975018 c 0.7
0 1980 -2.013095 d 3.2
1 1980 -1.711797 e 1.3
2 1980  0.975018 f 0.1
```

4.5.4 Combining with stats and GroupBy

It should be no shock that combining `pivot / stack / unstack` with `GroupBy` and the basic `Series` and `DataFrame` statistical functions can produce some very expressive and fast data manipulations.

```
In [49]: df
```

```
Out[49]:
exp          A      B      A
animal      cat   dog   cat   dog
first second
bar  one   -1.436953  0.561814 -0.346880 -0.546060

4.5.5 Pivot tables

While `pivot()` provides general purpose pivoting with various data types (strings, numerics, etc.), pandas also provides `pivot_table()` for pivoting with aggregation of numeric data.

The function `pivot_table()` can be used to create spreadsheet-style pivot tables. See the *cookbook* for some advanced strategies.

It takes a number of arguments:

- **data:** a DataFrame object.
- **values:** a column or a list of columns to aggregate.
- **index:** a column, Grouper, array which has the same length as data, or list of them. Keys to group by on the pivot table index. If an array is passed, it is being used as the same manner as column values.
- **columns:** a column, Grouper, array which has the same length as data, or list of them. Keys to group by on the pivot table column. If an array is passed, it is being used as the same manner as column values.
- **aggfunc:** function to use for aggregation, defaulting to `numpy.mean`.

Consider a data set like this:

```
In [54]: import datetime

In [55]: df = pd.DataFrame({'A': ['one', 'one', 'two', 'three'] * 6,
.....:                    'B': ['A', 'B', 'C'] * 8,
.....:                    'C': ['foo', 'foo', 'foo', 'bar', 'bar', 'bar'] * 4,
.....:                    'D': np.random.randn(24),
.....:                    'E': np.random.randn(24),
.....:                    'F': [datetime.datetime(2013, i, 1) for i in range(1, 13)]
.....:                    + [datetime.datetime(2013, i, 15) for i in range(1, 13)]})
.....:
```

```
In [56]: df
```

```
Out[56]:
```

	A	B	C	D	E	F
0	one	A	foo	1.772891	-1.594231	2013-01-01
1	one	B	foo	0.498050	-1.165583	2013-02-01
2	two	C	foo	0.476510	0.451407	2013-03-01
3	three	A	bar	0.877022	-1.724523	2013-04-01
4	one	B	bar	-0.301831	2.097509	2013-05-01
5	one	C	bar	-0.733711	1.078343	2013-06-01
6	two	A	foo	0.826360	-0.394125	2013-07-01
7	three	B	foo	0.466766	-0.726083	2013-08-01
8	one	C	foo	1.634589	0.490827	2013-09-01
9	one	A	bar	0.958132	-0.559443	2013-10-01
10	two	B	bar	-0.970543	-0.395876	2013-11-01
11	three	C	bar	-0.932172	-0.927091	2013-12-01
12	one	A	foo	-1.273567	-0.417776	2013-01-15
13	one	B	foo	0.270030	-0.708679	2013-02-15
14	two	C	foo	-1.388749	-1.557855	2013-03-15
15	three	A	bar	2.090035	-1.742504	2013-04-15
16	one	B	bar	-0.815984	-0.201498	2013-05-15
17	one	C	bar	-0.020855	0.070382	2013-06-15
18	two	A	foo	-0.108292	-0.749683	2013-07-15
19	three	B	foo	0.093700	1.434318	2013-08-15
20	one	C	foo	-0.851281	1.226799	2013-09-15
21	one	A	bar	-2.154727	-0.706492	2013-10-15

(continues on next page)

(continued from previous page)

```
22 two B bar -0.120914 0.299114 2013-11-15
23 three C bar -0.976377 -0.081937 2013-12-15
```

We can produce pivot tables from this data very easily:

```
In [57]: pd.pivot_table(df, values='D', index=['A', 'B'], columns=['C'])
```

```
Out[57]:
```

```
C          bar          foo
A  B
one A -0.598297  0.249662
    B -0.558907  0.384040
    C -0.377283  0.391654
three A  1.483528         NaN
     B         NaN  0.280233
     C -0.954274         NaN
two  A         NaN  0.359034
     B -0.545728         NaN
     C         NaN -0.456119
```

```
In [58]: pd.pivot_table(df, values='D', index=['B'], columns=['A', 'C'], aggfunc=np.sum)
```

```
Out[58]:
```

```
A      one          three          two
C      bar      foo      bar      foo      bar      foo
B
A -1.196595  0.499324  2.967057         NaN         NaN  0.718067
B -1.117815  0.768081         NaN  0.560466 -1.091457         NaN
C -0.754566  0.783308 -1.908549         NaN         NaN -0.912238
```

```
In [59]: pd.pivot_table(df, values=['D', 'E'], index=['B'], columns=['A', 'C'],
```

```
.....:          aggfunc=np.sum)
```

```
.....:
```

```
Out[59]:
```

```
          D          E
A      one          three          two          one
↪three          two
C      bar      foo      bar      foo      bar      foo      bar      foo
↪bar      foo      bar      foo
B
A -1.196595  0.499324  2.967057         NaN         NaN  0.718067 -1.265936 -2.012007 -3.
↪467026         NaN         NaN -1.143807
B -1.117815  0.768081         NaN  0.560466 -1.091457         NaN  1.896010 -1.874262
↪NaN  0.708235 -0.096762         NaN
C -0.754566  0.783308 -1.908549         NaN         NaN -0.912238  1.148725  1.717626 -1.
↪009028         NaN         NaN -1.106447
```

The result object is a `DataFrame` having potentially hierarchical indexes on the rows and columns. If the `values` column name is not given, the pivot table will include all of the data that can be aggregated in an additional level of hierarchy in the columns:

```
In [60]: pd.pivot_table(df, index=['A', 'B'], columns=['C'])
```

```
Out[60]:
```

```
C          D          E
          bar      foo      bar      foo
```

(continues on next page)

(continued from previous page)

	A	B			
one	A	-0.598297	0.249662	-0.632968	-1.006004
	B	-0.558907	0.384040	0.948005	-0.937131
	C	-0.377283	0.391654	0.574362	0.858813
three	A	1.483528	NaN	-1.733513	NaN
	B	NaN	0.280233	NaN	0.354117
	C	-0.954274	NaN	-0.504514	NaN
two	A	NaN	0.359034	NaN	-0.571904
	B	-0.545728	NaN	-0.048381	NaN
	C	NaN	-0.456119	NaN	-0.553224

Also, you can use `Grouper` for index and columns keywords. For detail of `Grouper`, see [Grouping with a Grouper specification](#).

```
In [61]: pd.pivot_table(df, values='D', index=pd.Grouper(freq='M', key='F'),
.....:                  columns='C')
```

```
Out [61]:
C          bar      foo
F
2013-01-31    NaN  0.249662
2013-02-28    NaN  0.384040
2013-03-31    NaN -0.456119
2013-04-30  1.483528     NaN
2013-05-31 -0.558907     NaN
2013-06-30 -0.377283     NaN
2013-07-31     NaN  0.359034
2013-08-31     NaN  0.280233
2013-09-30     NaN  0.391654
2013-10-31 -0.598297     NaN
2013-11-30 -0.545728     NaN
2013-12-31 -0.954274     NaN
```

You can render a nice output of the table omitting the missing values by calling `to_string` if you wish:

```
In [62]: table = pd.pivot_table(df, index=['A', 'B'], columns=['C'])
```

```
In [63]: print(table.to_string(na_rep=''))
          D          E
C      bar      foo      bar      foo
A      B
one   A -0.598297  0.249662 -0.632968 -1.006004
      B -0.558907  0.384040  0.948005 -0.937131
      C -0.377283  0.391654  0.574362  0.858813
three A  1.483528          -1.733513
      B          0.280233          0.354117
      C -0.954274          -0.504514
two   A          0.359034          -0.571904
      B -0.545728          -0.048381
      C          -0.456119          -0.553224
```

Note that `pivot_table` is also available as an instance method on `DataFrame`, i.e. `DataFrame.pivot_table()`.

Adding margins

If you pass `margins=True` to `pivot_table`, special All columns and rows will be added with partial group aggregates across the categories on the rows and columns:

```
In [64]: df.pivot_table(index=['A', 'B'], columns='C', margins=True, aggfunc=np.std)
Out [64]:
```

		D			E		
		bar	foo	All	bar	foo	All
A	B						
one	A	2.201124	2.154171	1.844310	0.103979	0.831880	0.529777
	B	0.363561	0.161235	0.590854	1.625643	0.323080	1.449234
	C	0.504065	1.757775	1.145298	0.712737	0.520411	0.535329
three	A	0.857730	NaN	0.857730	0.012714	NaN	0.012714
	B	NaN	0.263797	0.263797	NaN	1.527634	1.527634
	C	0.031258	NaN	0.031258	0.597614	NaN	0.597614
two	A	NaN	0.660899	0.660899	NaN	0.251417	0.251417
	B	0.600778	NaN	0.600778	0.491432	NaN	0.491432
	C	NaN	1.318937	1.318937	NaN	1.420763	1.420763
All		1.126982	1.003301	1.047076	1.082597	1.004895	1.000732

4.5.6 Cross tabulations

Use `crosstab()` to compute a cross-tabulation of two (or more) factors. By default `crosstab` computes a frequency table of the factors unless an array of values and an aggregation function are passed.

It takes a number of arguments

- `index`: array-like, values to group by in the rows.
- `columns`: array-like, values to group by in the columns.
- `values`: array-like, optional, array of values to aggregate according to the factors.
- `aggfunc`: function, optional, If no values array is passed, computes a frequency table.
- `rownames`: sequence, default `None`, must match number of row arrays passed.
- `colnames`: sequence, default `None`, if passed, must match number of column arrays passed.
- `margins`: boolean, default `False`, Add row/column margins (subtotals)
- `normalize`: boolean, {'all', 'index', 'columns'}, or {0,1}, default `False`. Normalize by dividing all values by the sum of values.

Any `Series` passed will have their name attributes used unless row or column names for the cross-tabulation are specified

For example:

```
In [65]: foo, bar, dull, shiny, one, two = 'foo', 'bar', 'dull', 'shiny', 'one', 'two'
```

```
In [66]: a = np.array([foo, foo, bar, bar, foo, foo], dtype=object)
```

```
In [67]: b = np.array([one, one, two, one, two, one], dtype=object)
```

```
In [68]: c = np.array([dull, dull, shiny, dull, dull, shiny], dtype=object)
```

(continues on next page)

(continued from previous page)

```
In [69]: pd.crosstab(a, [b, c], rownames=['a'], colnames=['b', 'c'])
Out[69]:
b      one      two
c  dull shiny dull shiny
a
bar    1     0     0     1
foo    2     1     1     0
```

If `crosstab` receives only two Series, it will provide a frequency table.

```
In [70]: df = pd.DataFrame({'A': [1, 2, 2, 2, 2], 'B': [3, 3, 4, 4, 4],
.....:                      'C': [1, 1, np.nan, 1, 1]})
.....:
```

```
In [71]: df
Out[71]:
   A  B   C
0  1  3  1.0
1  2  3  1.0
2  2  4  NaN
3  2  4  1.0
4  2  4  1.0
```

```
In [72]: pd.crosstab(df.A, df.B)
Out[72]:
B  3  4
A
1  1  0
2  1  3
```

Any input passed containing `Categorical` data will have **all** of its categories included in the cross-tabulation, even if the actual data does not contain any instances of a particular category.

```
In [73]: foo = pd.Categorical(['a', 'b'], categories=['a', 'b', 'c'])
In [74]: bar = pd.Categorical(['d', 'e'], categories=['d', 'e', 'f'])
In [75]: pd.crosstab(foo, bar)
Out[75]:
col_0  d  e
row_0
a      1  0
b      0  1
```

Normalization

New in version 0.18.1.

Frequency tables can also be normalized to show percentages rather than counts using the `normalize` argument:

```
In [76]: pd.crosstab(df.A, df.B, normalize=True)
Out[76]:
```

(continues on next page)

(continued from previous page)

```
B    3    4
A
1  0.2  0.0
2  0.2  0.6
```

`normalize` can also normalize values within each row or within each column:

```
In [77]: pd.crosstab(df.A, df.B, normalize='columns')
Out [77]:
B    3    4
A
1  0.5  0.0
2  0.5  1.0
```

`crosstab` can also be passed a third `Series` and an aggregation function (`aggfunc`) that will be applied to the values of the third `Series` within each group defined by the first two `Series`:

```
In [78]: pd.crosstab(df.A, df.B, values=df.C, aggfunc=np.sum)
Out [78]:
B    3    4
A
1  1.0  NaN
2  1.0  2.0
```

Adding margins

Finally, one can also add margins or normalize this output.

```
In [79]: pd.crosstab(df.A, df.B, values=df.C, aggfunc=np.sum, normalize=True,
.....:                margins=True)
.....:
Out [79]:
B      3    4  All
A
1    0.25  0.0  0.25
2    0.25  0.5  0.75
All  0.50  0.5  1.00
```

4.5.7 Tiling

The `cut()` function computes groupings for the values of the input array and is often used to transform continuous variables to discrete or categorical variables:

```
In [80]: ages = np.array([10, 15, 13, 12, 23, 25, 28, 59, 60])

In [81]: pd.cut(ages, bins=3)
Out [81]:
[(9.95, 26.667], (9.95, 26.667], (9.95, 26.667], (9.95, 26.667], (9.95, 26.667], (9.95,
→26.667], (26.667, 43.333], (43.333, 60.0], (43.333, 60.0]]
Categories (3, interval[float64]): [(9.95, 26.667] < (26.667, 43.333] < (43.333, 60.0]]
```

If the `bins` keyword is an integer, then equal-width bins are formed. Alternatively we can specify custom bin-edges:

```
In [82]: c = pd.cut(ages, bins=[0, 18, 35, 70])

In [83]: c
Out[83]:
[(0, 18], (0, 18], (0, 18], (0, 18], (18, 35], (18, 35], (18, 35], (35, 70], (35, 70]]
Categories (3, interval[int64]): [(0, 18] < (18, 35] < (35, 70]]
```

New in version 0.20.0.

If the `bins` keyword is an `IntervalIndex`, then these will be used to bin the passed data.:

```
pd.cut([25, 20, 50], bins=c.categories)
```

4.5.8 Computing indicator / dummy variables

To convert a categorical variable into a “dummy” or “indicator” `DataFrame`, for example a column in a `DataFrame` (a `Series`) which has `k` distinct values, can derive a `DataFrame` containing `k` columns of 1s and 0s using `get_dummies()`:

```
In [84]: df = pd.DataFrame({'key': list('bbacab'), 'data1': range(6)})

In [85]: pd.get_dummies(df['key'])
Out[85]:
   a  b  c
0  0  1  0
1  0  1  0
2  1  0  0
3  0  0  1
4  1  0  0
5  0  1  0
```

Sometimes it’s useful to prefix the column names, for example when merging the result with the original `DataFrame`:

```
In [86]: dummies = pd.get_dummies(df['key'], prefix='key')
```

```
In [87]: dummies
Out[87]:
   key_a  key_b  key_c
0      0      1      0
1      0      1      0
2      1      0      0
3      0      0      1
4      1      0      0
5      0      1      0
```

```
In [88]: df[['data1']].join(dummies)
Out[88]:
   data1  key_a  key_b  key_c
0      0      0      1      0
1      1      0      1      0
```

```

2     2     1     0     0
3     3     0     0     1
4     4     1     0     0
5     5     0     1     0

```

This function is often used along with discretization functions like `cut`:

```

In [89]: values = np.random.randn(10)

In [90]: values
Out[90]:
array([-0.7350435 ,  1.42920375, -1.11519984, -0.97015174, -1.19270064,
        0.02125661, -0.20556342, -0.66677255,  2.12277401, -0.10814128])

In [91]: bins = [0, 0.2, 0.4, 0.6, 0.8, 1]

In [92]: pd.get_dummies(pd.cut(values, bins))
Out[92]:
   (0.0, 0.2]  (0.2, 0.4]  (0.4, 0.6]  (0.6, 0.8]  (0.8, 1.0]
0             0             0             0             0             0
1             0             0             0             0             0
2             0             0             0             0             0
3             0             0             0             0             0
4             0             0             0             0             0
5             1             0             0             0             0
6             0             0             0             0             0
7             0             0             0             0             0
8             0             0             0             0             0
9             0             0             0             0             0

```

See also `Series.str.get_dummies`.

`get_dummies()` also accepts a `DataFrame`. By default all categorical variables (categorical in the statistical sense, those with `object` or `categorical` dtype) are encoded as dummy variables.

```

In [93]: df = pd.DataFrame({'A': ['a', 'b', 'a'], 'B': ['c', 'c', 'b'],
.....:                      'C': [1, 2, 3]})
.....:

In [94]: pd.get_dummies(df)
Out[94]:
   C  A_a  A_b  B_b  B_c
0  1    1    0    0    1
1  2    0    1    0    1
2  3    1    0    1    0

```

All non-object columns are included untouched in the output. You can control the columns that are encoded with the `columns` keyword.

```

In [95]: pd.get_dummies(df, columns=['A'])
Out[95]:
   B  C  A_a  A_b
0  c  1    1    0
1  c  2    0    1
2  b  3    1    0

```

Notice that the B column is still included in the output, it just hasn't been encoded. You can drop B before calling `get_dummies` if you don't want to include it in the output.

As with the `Series` version, you can pass values for the `prefix` and `prefix_sep`. By default the column name is used as the prefix, and `'_'` as the prefix separator. You can specify `prefix` and `prefix_sep` in 3 ways:

- string: Use the same value for `prefix` or `prefix_sep` for each column to be encoded.
- list: Must be the same length as the number of columns being encoded.
- dict: Mapping column name to prefix.

```
In [96]: simple = pd.get_dummies(df, prefix='new_prefix')
```

```
In [97]: simple
```

```
Out[97]:
```

	C	new_prefix_a	new_prefix_b	new_prefix_b	new_prefix_c
0	1	1	0	0	1
1	2	0	1	0	1
2	3	1	0	1	0

```
In [98]: from_list = pd.get_dummies(df, prefix=['from_A', 'from_B'])
```

```
In [99]: from_list
```

```
Out[99]:
```

	C	from_A_a	from_A_b	from_B_b	from_B_c
0	1	1	0	0	1
1	2	0	1	0	1
2	3	1	0	1	0

```
In [100]: from_dict = pd.get_dummies(df, prefix={'B': 'from_B', 'A': 'from_A'})
```

```
In [101]: from_dict
```

```
Out[101]:
```

	C	from_A_a	from_A_b	from_B_b	from_B_c
0	1	1	0	0	1
1	2	0	1	0	1
2	3	1	0	1	0

New in version 0.18.0.

Sometimes it will be useful to only keep $k-1$ levels of a categorical variable to avoid collinearity when feeding the result to statistical models. You can switch to this mode by turn on `drop_first`.

```
In [102]: s = pd.Series(list('abca'))
```

```
In [103]: pd.get_dummies(s)
```

```
Out[103]:
```

	a	b	c
0	1	0	0
1	0	1	0
2	0	0	1
3	1	0	0
4	1	0	0

```
In [104]: pd.get_dummies(s, drop_first=True)
```

```
Out[104]:
```

```
   b  c
0  0  0
1  1  0
2  0  1
3  0  0
4  0  0
```

When a column contains only one level, it will be omitted in the result.

```
In [105]: df = pd.DataFrame({'A': list('aaaaa'), 'B': list('ababc')})
```

```
In [106]: pd.get_dummies(df)
```

```
Out[106]:
```

```
   A_a  B_a  B_b  B_c
0     1    1    0    0
1     1    0    1    0
2     1    1    0    0
3     1    0    1    0
4     1    0    0    1
```

```
In [107]: pd.get_dummies(df, drop_first=True)
```

```
Out[107]:
```

```
   B_b  B_c
0     0    0
1     1    0
2     0    0
3     1    0
4     0    1
```

By default new columns will have `np.uint8` dtype. To choose another dtype, use the `dtype` argument:

```
In [108]: df = pd.DataFrame({'A': list('abc'), 'B': [1.1, 2.2, 3.3]})
```

```
In [109]: pd.get_dummies(df, dtype=bool).dtypes
```

```
Out[109]:
```

```
B          float64
A_a         bool
A_b         bool
A_c         bool
dtype: object
```

New in version 0.23.0.

4.5.9 Factorizing values

To encode 1-d values as an enumerated type use `factorize()`:

```
In [110]: x = pd.Series(['A', 'A', np.nan, 'B', 3.14, np.inf])
```

```
In [111]: x
```

```
Out[111]:
```

```
0      A
1      A
2     NaN
```

```
3      B
4    3.14
5     inf
dtype: object
```

```
In [112]: labels, uniques = pd.factorize(x)
```

```
In [113]: labels
Out[113]: array([ 0,  0, -1,  1,  2,  3])
```

```
In [114]: uniques
Out[114]: Index(['A', 'B', 3.14, inf], dtype='object')
```

Note that `factorize` is similar to `numpy.unique`, but differs in its handling of NaN:

Note: The following `numpy.unique` will fail under Python 3 with a `TypeError` because of an ordering bug. See also [here](#).

```
In [1]: x = pd.Series(['A', 'A', np.nan, 'B', 3.14, np.inf])
In [2]: pd.factorize(x, sort=True)
Out[2]:
(array([ 2,  2, -1,  3,  0,  1]),
 Index([3.14, inf, 'A', 'B'], dtype='object'))

In [3]: np.unique(x, return_inverse=True)[::-1]
Out[3]: (array([3, 3, 0, 4, 1, 2]), array([nan, 3.14, inf, 'A', 'B'], dtype=object))
```

Note: If you just want to handle one column as a categorical variable (like R's `factor`), you can use `df["cat_col"] = pd.Categorical(df["col"])` or `df["cat_col"] = df["col"].astype("category")`. For full docs on *Categorical*, see the *Categorical introduction* and the *API documentation*.

4.5.10 Examples

In this section, we will review frequently asked questions and examples. The column names and relevant column values are named to correspond with how this DataFrame will be pivoted in the answers below.

```
In [115]: np.random.seed([3, 1415])

In [116]: n = 20

In [117]: cols = np.array(['key', 'row', 'item', 'col'])

In [118]: df = cols + pd.DataFrame((np.random.randint(5, size=(n, 4))
.....:                               // [2, 1, 2, 1]).astype(str))
.....:

In [119]: df.columns = cols

In [120]: df = df.join(pd.DataFrame(np.random.rand(n, 2).round(2)).add_prefix('val'))
```

(continues on next page)

(continued from previous page)

```
In [121]: df
Out[121]:
   key  row  item  col  val0  val1
0  key0 row3  item1 col3  0.81  0.04
1  key1 row2  item1 col2  0.44  0.07
2  key1 row0  item1 col0  0.77  0.01
3  key0 row4  item0 col2  0.15  0.59
4  key1 row0  item2 col1  0.81  0.64
5  key1 row2  item2 col4  0.13  0.88
6  key2 row4  item1 col3  0.88  0.39
7  key1 row4  item1 col1  0.10  0.07
8  key1 row0  item2 col4  0.65  0.02
9  key1 row2  item0 col2  0.35  0.61
10 key2 row0  item2 col1  0.40  0.85
11 key2 row4  item1 col2  0.64  0.25
12 key0 row2  item2 col3  0.50  0.44
13 key0 row4  item1 col4  0.24  0.46
14 key1 row3  item2 col3  0.28  0.11
15 key0 row3  item1 col1  0.31  0.23
16 key0 row0  item2 col3  0.86  0.01
17 key0 row4  item0 col3  0.64  0.21
18 key2 row2  item2 col0  0.13  0.45
19 key0 row2  item0 col4  0.37  0.70
```

Pivoting with single aggregations

Suppose we wanted to pivot `df` such that the `col` values are columns, `row` values are the index, and the mean of `val0` are the values? In particular, the resulting DataFrame should look like:

Note: col col0 col1 col2 col3 col4 row row0 0.77 0.605 NaN 0.860 0.65 row2 0.13 NaN 0.395 0.500 0.25 row3 NaN 0.310 NaN 0.545 NaN row4 NaN 0.100 0.395 0.760 0.24

This solution uses `pivot_table()`. Also note that `aggfunc='mean'` is the default. It is included here to be explicit.

```
In [122]: df.pivot_table(
.....:     values='val0', index='row', columns='col', aggfunc='mean')
.....:
Out[122]:
col  col0  col1  col2  col3  col4
row
row0  0.77  0.605   NaN  0.860  0.65
row2  0.13   NaN  0.395  0.500  0.25
row3   NaN  0.310   NaN  0.545   NaN
row4   NaN  0.100  0.395  0.760  0.24
```

Note that we can also replace the missing values by using the `fill_value` parameter.

```
In [123]: df.pivot_table(
.....:     values='val0', index='row', columns='col', aggfunc='mean', fill_value=0)
```

(continues on next page)

(continued from previous page)

```

.....:
Out [123]:
col  col0  col1  col2  col3  col4
row
row0  0.77  0.605  0.000  0.860  0.65
row2  0.13  0.000  0.395  0.500  0.25
row3  0.00  0.310  0.000  0.545  0.00
row4  0.00  0.100  0.395  0.760  0.24

```

Also note that we can pass in other aggregation functions as well. For example, we can also pass in `sum`.

```

In [124]: df.pivot_table(
.....:     values='val0', index='row', columns='col', aggfunc='sum', fill_value=0)
.....:
Out [124]:
col  col0  col1  col2  col3  col4
row
row0  0.77  1.21  0.00  0.86  0.65
row2  0.13  0.00  0.79  0.50  0.50
row3  0.00  0.31  0.00  1.09  0.00
row4  0.00  0.10  0.79  1.52  0.24

```

Another aggregation we can do is calculate the frequency in which the columns and rows occur together a.k.a. “cross tabulation”. To do this, we can pass `size` to the `aggfunc` parameter.

```

In [125]: df.pivot_table(index='row', columns='col', fill_value=0, aggfunc='size')
Out [125]:
col  col0  col1  col2  col3  col4
row
row0     1     2     0     1     1
row2     1     0     2     1     2
row3     0     1     0     2     0
row4     0     1     2     2     1

```

Pivoting with multiple aggregations

We can also perform multiple aggregations. For example, to perform both a `sum` and `mean`, we can pass in a list to the `aggfunc` argument.

```

In [126]: df.pivot_table(
.....:     values='val0', index='row', columns='col', aggfunc=['mean', 'sum'])
.....:
Out [126]:
      mean
col  col0  col1  col2  col3  col4  col0  col1  col2  col3  col4
row
row0  0.77  0.605  NaN  0.860  0.65  0.77  1.21  NaN  0.86  0.65
row2  0.13  NaN  0.395  0.500  0.25  0.13  NaN  0.79  0.50  0.50
row3  NaN  0.310  NaN  0.545  NaN  NaN  0.31  NaN  1.09  NaN
row4  NaN  0.100  0.395  0.760  0.24  NaN  0.10  0.79  1.52  0.24

```

Note to aggregate over multiple value columns, we can pass in a list to the `values` parameter.

```
In [127]: df.pivot_table(
.....:     values=['val0', 'val1'], index='row', columns='col', aggfunc=['mean'])
.....:
Out[127]:
```

	mean					mean					
	val0					val1					
col	col0	col1	col2	col3	col4	col0	col1	col2	col3	col4	
row	row0	0.77	0.605	NaN	0.860	0.65	0.01	0.745	NaN	0.010	0.02
row2	0.13	NaN	0.395	0.500	0.25	0.45	NaN	0.34	0.440	0.79	
row3	NaN	0.310	NaN	0.545	NaN	NaN	0.230	NaN	0.075	NaN	
row4	NaN	0.100	0.395	0.760	0.24	NaN	0.070	0.42	0.300	0.46	

Note to subdivide over multiple columns we can pass in a list to the `columns` parameter.

```
In [128]: df.pivot_table(
.....:     values=['val0'], index='row', columns=['item', 'col'], aggfunc=['mean'])
.....:
Out[128]:
```

	mean				mean				mean				
	val0				val0				val0				
item	item0		item1		item1		item2		item2		item2		
col	col2	col3	col4	col0	col1	col2	col3	col4	col0	col1	col3	col4	
row	row0	NaN	NaN	NaN	0.77	NaN	NaN	NaN	NaN	NaN	0.605	0.86	0.65
row2	0.35	NaN	0.37	NaN	NaN	0.44	NaN	NaN	0.13	NaN	0.50	0.13	
row3	NaN	NaN	NaN	NaN	0.31	NaN	0.81	NaN	NaN	NaN	0.28	NaN	
row4	0.15	0.64	NaN	NaN	0.10	0.64	0.88	0.24	NaN	NaN	NaN	NaN	

4.5.11 Exploding a list-like column

New in version 0.25.0.

Sometimes the values in a column are list-like.

```
In [129]: keys = ['panda1', 'panda2', 'panda3']
In [130]: values = [['eats', 'shoots'], ['shoots', 'leaves'], ['eats', 'leaves']]
In [131]: df = pd.DataFrame({'keys': keys, 'values': values})
In [132]: df
Out[132]:
```

	keys	values
0	panda1	[eats, shoots]
1	panda2	[shoots, leaves]
2	panda3	[eats, leaves]

We can ‘explode’ the `values` column, transforming each list-like to a separate row, by using `explode()`. This will replicate the index values from the original row:

```
In [133]: df['values'].explode()
Out[133]:
0      eats
0     shoots
1     shoots
1     leaves
2      eats
2     leaves
Name: values, dtype: object
```

You can also explode the column in the DataFrame.

```
In [134]: df.explode('values')
Out[134]:
   keys  values
0  panda1  eats
0  panda1  shoots
1  panda2  shoots
1  panda2  leaves
2  panda3  eats
2  panda3  leaves
```

`Series.explode()` will replace empty lists with `np.nan` and preserve scalar entries. The dtype of the resulting `Series` is always `object`.

```
In [135]: s = pd.Series([[1, 2, 3], 'foo', [], ['a', 'b']])
```

```
In [136]: s
Out[136]:
0    [1, 2, 3]
1         foo
2          []
3    [a, b]
dtype: object
```

```
In [137]: s.explode()
Out[137]:
0      1
0      2
0      3
1     foo
2     NaN
3      a
3      b
dtype: object
```

Here is a typical usecase. You have comma separated strings in a column and want to expand this.

```
In [138]: df = pd.DataFrame([{'var1': 'a,b,c', 'var2': 1},
.....:                      {'var1': 'd,e,f', 'var2': 2}])
.....:

In [139]: df
Out[139]:
```

(continues on next page)

(continued from previous page)

	var1	var2
0	a,b,c	1
1	d,e,f	2

Creating a long form DataFrame is now straightforward using explode and chained operations

```
In [140]: df.assign(var1=df.var1.str.split(',')).explode('var1')
```

```
Out[140]:
```

	var1	var2
0	a	1
0	b	1
0	c	1
1	d	2
1	e	2
1	f	2

```
{{ header }}
```

4.6 Working with text data

Series and Index are equipped with a set of string processing methods that make it easy to operate on each element of the array. Perhaps most importantly, these methods exclude missing/NA values automatically. These are accessed via the `str` attribute and generally have names matching the equivalent (scalar) built-in string methods:

```
In [1]: s = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca', np.nan, 'CABA', 'dog', 'cat'])
```

```
In [2]: s.str.lower()
```

```
Out[2]:
```

0	a
1	b
2	c
3	aaba
4	baca
5	NaN
6	caba
7	dog
8	cat

```
dtype: object
```

```
In [3]: s.str.upper()
```

```
Out[3]:
```

0	A
1	B
2	C
3	AABA
4	BACA
5	NaN
6	CABA
7	DOG
8	CAT

```
dtype: object
```

```
In [4]: s.str.len()
```

```
Out[4]:
```

```
0    1.0
1    1.0
2    1.0
3    4.0
4    4.0
5    NaN
6    4.0
7    3.0
8    3.0
```

```
dtype: float64
```

```
In [5]: idx = pd.Index([' jack', 'jill ', ' jesse ', 'frank'])
```

```
In [6]: idx.str.strip()
```

```
Out[6]: Index(['jack', 'jill', 'jesse', 'frank'], dtype='object')
```

```
In [7]: idx.str.lstrip()
```

```
Out[7]: Index(['jack', 'jill ', 'jesse ', 'frank'], dtype='object')
```

```
In [8]: idx.str.rstrip()
```

```
Out[8]: Index([' jack', 'jill', ' jesse', 'frank'], dtype='object')
```

The string methods on Index are especially useful for cleaning up or transforming DataFrame columns. For instance, you may have columns with leading or trailing whitespace:

```
In [9]: df = pd.DataFrame(np.random.randn(3, 2),
...:                      columns=[' Column A ', ' Column B '], index=range(3))
...:
```

```
In [10]: df
```

```
Out[10]:
```

	Column A	Column B
0	-0.061542	0.528296
1	-0.952849	2.392803
2	-1.524186	2.642204

Since `df.columns` is an Index object, we can use the `.str` accessor

```
In [11]: df.columns.str.strip()
```

```
Out[11]: Index(['Column A', 'Column B'], dtype='object')
```

```
In [12]: df.columns.str.lower()
```

```
Out[12]: Index([' column a ', ' column b '], dtype='object')
```

These string methods can then be used to clean up the columns as needed. Here we are removing leading and trailing whitespaces, lower casing all names, and replacing any remaining whitespaces with underscores:

```
In [13]: df.columns = df.columns.str.strip().str.lower().str.replace(' ', '_')
```

```
In [14]: df
```

```
Out[14]:
```

	column_a	column_b
--	----------	----------

(continues on next page)

(continued from previous page)

```
0 -0.061542  0.528296
1 -0.952849  2.392803
2 -1.524186  2.642204
```

Note: If you have a `Series` where lots of elements are repeated (i.e. the number of unique elements in the `Series` is a lot smaller than the length of the `Series`), it can be faster to convert the original `Series` to one of type `category` and then use `.str.<method>` or `.dt.<property>` on that. The performance difference comes from the fact that, for `Series` of type `category`, the string operations are done on the `.categories` and not on each element of the `Series`.

Please note that a `Series` of type `category` with string `.categories` has some limitations in comparison to `Series` of type `string` (e.g. you can't add strings to each other: `s + " " + s` won't work if `s` is a `Series` of type `category`). Also, `.str` methods which operate on elements of type `list` are not available on such a `Series`.

Warning: Before v.0.25.0, the `.str`-accessor did only the most rudimentary type checks. Starting with v.0.25.0, the type of the `Series` is inferred and the allowed types (i.e. strings) are enforced more rigorously.

Generally speaking, the `.str` accessor is intended to work only on strings. With very few exceptions, other uses are not supported, and may be disabled at a later point.

4.6.1 Splitting and replacing strings

Methods like `split` return a `Series` of lists:

```
In [15]: s2 = pd.Series(['a_b_c', 'c_d_e', np.nan, 'f_g_h'])
In [16]: s2.str.split('_')
Out[16]:
0    [a, b, c]
1    [c, d, e]
2         NaN
3    [f, g, h]
dtype: object
```

Elements in the split lists can be accessed using `get` or `[]` notation:

```
In [17]: s2.str.split('_').str.get(1)
Out[17]:
0     b
1     d
2    NaN
3     g
dtype: object
```

```
In [18]: s2.str.split('_').str[1]
Out[18]:
0     b
1     d
2    NaN
```

```
3      g
dtype: object
```

It is easy to expand this to return a DataFrame using `expand`.

```
In [19]: s2.str.split('_', expand=True)
```

```
Out[19]:
   0  1  2
0  a  b  c
1  c  d  e
2 NaN NaN NaN
3  f  g  h
```

It is also possible to limit the number of splits:

```
In [20]: s2.str.split('_', expand=True, n=1)
```

```
Out[20]:
   0  1
0  a b_c
1  c d_e
2 NaN NaN
3  f g_h
```

`rsplit` is similar to `split` except it works in the reverse direction, i.e., from the end of the string to the beginning of the string:

```
In [21]: s2.str.rsplit('_', expand=True, n=1)
```

```
Out[21]:
   0  1
0 a_b  c
1 c_d  e
2 NaN NaN
3 f_g  h
```

`replace` by default replaces [regular expressions](#):

```
In [22]: s3 = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca',
.....:                  '', np.nan, 'CABA', 'dog', 'cat'])
.....:
```

```
In [23]: s3
```

```
Out[23]:
0      A
1      B
2      C
3  Aaba
4  Baca
5
6     NaN
7  CABA
8   dog
9   cat
dtype: object
```

```
In [24]: s3.str.replace('^.a|dog', 'XX-XX ', case=False)
```

```
Out[24]:
```

```

0          A
1          B
2          C
3   XX-XX  ba
4   XX-XX  ca
5
6          NaN
7   XX-XX  BA
8       XX-XX
9   XX-XX  t
dtype: object

```

Some caution must be taken to keep regular expressions in mind! For example, the following code will cause trouble because of the regular expression meaning of `$`:

```

# Consider the following badly formatted financial data
In [25]: dollars = pd.Series(['12', '-$10', '$10,000'])

```

```

# This does what you'd naively expect:

```

```

In [26]: dollars.str.replace('$', '')
Out[26]:
0          12
1         -10
2    10,000
dtype: object

```

```

# But this doesn't:

```

```

In [27]: dollars.str.replace('-$', '-')
Out[27]:
0          12
1         -$10
2    $10,000
dtype: object

```

```

# We need to escape the special character (for >1 len patterns)

```

```

In [28]: dollars.str.replace(r'\-$', '-')
Out[28]:
0          12
1         -10
2    $10,000
dtype: object

```

New in version 0.23.0.

If you do want literal replacement of a string (equivalent to `str.replace()`), you can set the optional `regex` parameter to `False`, rather than escaping each character. In this case both `pat` and `repl` must be strings:

```

# These lines are equivalent

```

```

In [29]: dollars.str.replace(r'\-$', '-')
Out[29]:
0          12
1         -10
2    $10,000
dtype: object

```

```

In [30]: dollars.str.replace('-$', '-', regex=False)

```

```
Out[30]:
0      12
1     -10
2   $10,000
dtype: object
```

New in version 0.20.0.

The `replace` method can also take a callable as replacement. It is called on every `pat` using `re.sub()`. The callable should expect one positional argument (a regex object) and return a string.

```
# Reverse every lowercase alphabetic word
In [31]: pat = r'[a-z]+'

In [32]: def repl(m):
....:     return m.group(0)[::-1]
....:

In [33]: pd.Series(['foo 123', 'bar baz', np.nan]).str.replace(pat, repl)
Out[33]:
0    oof 123
1    rab zab
2         NaN
dtype: object

# Using regex groups
In [34]: pat = r"(?P<one>\w+) (?P<two>\w+) (?P<three>\w+)"

In [35]: def repl(m):
....:     return m.group('two').swapcase()
....:

In [36]: pd.Series(['Foo Bar Baz', np.nan]).str.replace(pat, repl)
Out[36]:
0    bAR
1    NaN
dtype: object
```

New in version 0.20.0.

The `replace` method also accepts a compiled regular expression object from `re.compile()` as a pattern. All flags should be included in the compiled regular expression object.

```
In [37]: import re

In [38]: regex_pat = re.compile(r'^.a|dog', flags=re.IGNORECASE)

In [39]: s3.str.replace(regex_pat, 'XX-XX ')
Out[39]:
0      A
1      B
2      C
3  XX-XX ba
4  XX-XX ca
5
```

(continues on next page)

(continued from previous page)

```
6      NaN
7    XX-XX BA
8      XX-XX
9    XX-XX t
dtype: object
```

Including a `flags` argument when calling `replace` with a compiled regular expression object will raise a `ValueError`.

```
In [40]: s3.str.replace(regex_pat, 'XX-XX ', flags=re.IGNORECASE)
-----
ValueError: case and flags cannot be set when pat is a compiled regex
```

4.6.2 Concatenation

There are several ways to concatenate a `Series` or `Index`, either with itself or others, all based on `cat()`, resp. `Index.str.cat`.

Concatenating a single Series into a string

The content of a `Series` (or `Index`) can be concatenated:

```
In [41]: s = pd.Series(['a', 'b', 'c', 'd'])
In [42]: s.str.cat(sep=',')
Out[42]: 'a,b,c,d'
```

If not specified, the keyword `sep` for the separator defaults to the empty string, `sep=''`:

```
In [43]: s.str.cat()
Out[43]: 'abcd'
```

By default, missing values are ignored. Using `na_rep`, they can be given a representation:

```
In [44]: t = pd.Series(['a', 'b', np.nan, 'd'])
In [45]: t.str.cat(sep=',')
Out[45]: 'a,b,d'
In [46]: t.str.cat(sep=',', na_rep='-')
Out[46]: 'a,b-,d'
```

Concatenating a Series and something list-like into a Series

The first argument to `cat()` can be a list-like object, provided that it matches the length of the calling `Series` (or `Index`).

```
In [47]: s.str.cat(['A', 'B', 'C', 'D'])
Out[47]:
0      aA
```

(continues on next page)

(continued from previous page)

```
1    bB
2    cC
3    dD
dtype: object
```

Missing values on either side will result in missing values in the result as well, *unless* `na_rep` is specified:

```
In [48]: s.str.cat(t)
Out[48]:
0      aa
1      bb
2      NaN
3      dd
dtype: object
```

```
In [49]: s.str.cat(t, na_rep='-')
Out[49]:
0      aa
1      bb
2      c-
3      dd
dtype: object
```

Concatenating a Series and something array-like into a Series

New in version 0.23.0.

The parameter `others` can also be two-dimensional. In this case, the number or rows must match the lengths of the calling `Series` (or `Index`).

```
In [50]: d = pd.concat([t, s], axis=1)
```

```
In [51]: s
Out[51]:
0      a
1      b
2      c
3      d
dtype: object
```

```
In [52]: d
Out[52]:
   0 1
0  a a
1  b b
2 NaN c
3  d d
```

```
In [53]: s.str.cat(d, na_rep='-')
Out[53]:
0  aaa
1  bbb
2  c-c
```

```
3    ddd
dtype: object
```

Concatenating a Series and an indexed object into a Series, with alignment

New in version 0.23.0.

For concatenation with a `Series` or `DataFrame`, it is possible to align the indexes before concatenation by setting the `join`-keyword.

```
In [54]: u = pd.Series(['b', 'd', 'a', 'c'], index=[1, 3, 0, 2])
```

```
In [55]: s
Out[55]:
0    a
1    b
2    c
3    d
dtype: object
```

```
In [56]: u
Out[56]:
1    b
3    d
0    a
2    c
dtype: object
```

```
In [57]: s.str.cat(u)
Out[57]:
0    ab
1    bd
2    ca
3    dc
dtype: object
```

```
In [58]: s.str.cat(u, join='left')
Out[58]:
0    aa
1    bb
2    cc
3    dd
dtype: object
```

Warning: If the `join` keyword is not passed, the method `cat()` will currently fall back to the behavior before version 0.23.0 (i.e. no alignment), but a `FutureWarning` will be raised if any of the involved indexes differ, since this default will change to `join='left'` in a future version.

The usual options are available for `join` (one of `'left'`, `'outer'`, `'inner'`, `'right'`). In particular, alignment also means that the different lengths do not need to coincide anymore.

```
In [59]: v = pd.Series(['z', 'a', 'b', 'd', 'e'], index=[-1, 0, 1, 3, 4])
```

```
In [60]: s
Out[60]:
0    a
1    b
2    c
3    d
dtype: object
```

```
In [61]: v
Out[61]:
-1    z
0     a
1     b
3     d
4     e
dtype: object
```

```
In [62]: s.str.cat(v, join='left', na_rep='-')
Out[62]:
0    aa
1    bb
2    c-
3    dd
dtype: object
```

```
In [63]: s.str.cat(v, join='outer', na_rep='-')
Out[63]:
-1    -z
0     aa
1     bb
2     c-
3     dd
4     -e
dtype: object
```

The same alignment can be used when `others` is a `DataFrame`:

```
In [64]: f = d.loc[[3, 2, 1, 0], :]
```

```
In [65]: s
Out[65]:
0    a
1    b
2    c
3    d
dtype: object
```

```
In [66]: f
Out[66]:
   0 1
3  d d
2 NaN c
1  b b
0  a a
```

```
In [67]: s.str.cat(f, join='left', na_rep='-')
Out[67]:
0    aaa
1    bbb
2    c-c
3    ddd
dtype: object
```

Concatenating a Series and many objects into a Series

Several array-like items (specifically: `Series`, `Index`, and 1-dimensional variants of `np.ndarray`) can be combined in a list-like container (including iterators, `dict`-views, etc.).

```
In [68]: s
Out[68]:
0    a
1    b
2    c
3    d
dtype: object
```

```
In [69]: u
Out[69]:
1    b
3    d
0    a
2    c
dtype: object
```

```
In [70]: s.str.cat([u, u.to_numpy()], join='left')
Out[70]:
0    aab
1    bbd
2    cca
3    ddc
dtype: object
```

All elements without an index (e.g. `np.ndarray`) within the passed list-like must match in length to the calling `Series` (or `Index`), but `Series` and `Index` may have arbitrary length (as long as alignment is not disabled with `join=None`):

```
In [71]: v
Out[71]:
-1    z
0     a
1     b
3     d
4     e
dtype: object
```

```
In [72]: s.str.cat([v, u, u.to_numpy()], join='outer', na_rep='-')
Out[72]:
-1    -z--
0     aaab
1     bbbd
```

```
2    c-ca
3    dddc
4    -e--
dtype: object
```

If using `join='right'` on a list-like of `others` that contains different indexes, the union of these indexes will be used as the basis for the final concatenation:

```
In [73]: u.loc[[3]]
Out[73]:
3    d
dtype: object
```

```
In [74]: v.loc[[-1, 0]]
Out[74]:
-1    z
0     a
dtype: object
```

```
In [75]: s.str.cat([u.loc[[3]], v.loc[[-1, 0]]], join='right', na_rep='-')
Out[75]:
-1    --z
0     a-a
3     dd-
dtype: object
```

4.6.3 Indexing with `.str`

You can use `[]` notation to directly index by position locations. If you index past the end of the string, the result will be a `NaN`.

```
In [76]: s = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca', np.nan,
.....:                  'CABA', 'dog', 'cat'])
.....:
```

```
In [77]: s.str[0]
Out[77]:
0    A
1    B
2    C
3    A
4    B
5    NaN
6    C
7    d
8    c
dtype: object
```

```
In [78]: s.str[1]
Out[78]:
0    NaN
1    NaN
2    NaN
3    a
4    a
```

```

5    NaN
6     A
7     o
8     a
dtype: object

```

4.6.4 Extracting substrings

Extract first match in each subject (`extract`)

Warning: In version 0.18.0, `extract` gained the `expand` argument. When `expand=False` it returns a `Series`, `Index`, or `DataFrame`, depending on the subject and regular expression pattern (same behavior as pre-0.18.0). When `expand=True` it always returns a `DataFrame`, which is more consistent and less confusing from the perspective of a user. `expand=True` is the default since version 0.23.0.

The `extract` method accepts a [regular expression](#) with at least one capture group.

Extracting a regular expression with more than one group returns a `DataFrame` with one column per group.

```

In [79]: pd.Series(['a1', 'b2', 'c3']).str.extract(r'([ab])(\d)', expand=False)
Out [79]:
   0  1
0  a  1
1  b  2
2 NaN NaN

```

Elements that do not match return a row filled with `NaN`. Thus, a `Series` of messy strings can be “converted” into a like-indexed `Series` or `DataFrame` of cleaned-up or more useful strings, without necessitating `get()` to access tuples or `re.match` objects. The `dtype` of the result is always `object`, even if no match is found and the result only contains `NaN`.

Named groups like

```

In [80]: pd.Series(['a1', 'b2', 'c3']).str.extract(r'(?P<letter>[ab])(?P<digit>\d)',
.....:                                           expand=False)
.....:
Out [80]:
   letter digit
0      a      1
1      b      2
2    NaN    NaN

```

and optional groups like

```

In [81]: pd.Series(['a1', 'b2', '3']).str.extract(r'([ab])?(\d)', expand=False)
Out [81]:
   0  1
0  a  1
1  b  2
2 NaN 3

```

can also be used. Note that any capture group names in the regular expression will be used for column names; otherwise capture group numbers will be used.

Extracting a regular expression with one group returns a DataFrame with one column if `expand=True`.

```
In [82]: pd.Series(['a1', 'b2', 'c3']).str.extract(r'[ab](\d)', expand=True)
Out[82]:
   0
0  1
1  2
2 NaN
```

It returns a Series if `expand=False`.

```
In [83]: pd.Series(['a1', 'b2', 'c3']).str.extract(r'[ab](\d)', expand=False)
Out[83]:
0    1
1    2
2   NaN
dtype: object
```

Calling on an Index with a regex with exactly one capture group returns a DataFrame with one column if `expand=True`.

```
In [84]: s = pd.Series(["a1", "b2", "c3"], ["A11", "B22", "C33"])
```

```
In [85]: s
Out[85]:
A11    a1
B22    b2
C33    c3
dtype: object
```

```
In [86]: s.index.str.extract("(?P<letter>[a-zA-Z])", expand=True)
Out[86]:
   letter
0      A
1      B
2      C
```

It returns an Index if `expand=False`.

```
In [87]: s.index.str.extract("(?P<letter>[a-zA-Z])", expand=False)
Out[87]: Index(['A', 'B', 'C'], dtype='object', name='letter')
```

Calling on an Index with a regex with more than one capture group returns a DataFrame if `expand=True`.

```
In [88]: s.index.str.extract("(?P<letter>[a-zA-Z])([0-9]+)", expand=True)
Out[88]:
   letter  1
0      A  11
1      B  22
2      C  33
```

It raises `ValueError` if `expand=False`.

```
>>> s.index.str.extract("(?P<letter>[a-zA-Z])([0-9]+)", expand=False)
ValueError: only one regex group is supported with Index
```

The table below summarizes the behavior of `extract(expand=False)` (input subject in first column, number of groups in regex in first row)

	1 group	>1 group
Index	Index	ValueError
Series	Series	DataFrame

Extract all matches in each subject (`extractall`)

New in version 0.18.0.

Unlike `extract` (which returns only the first match),

```
In [89]: s = pd.Series(["a1a2", "b1", "c1"], index=["A", "B", "C"])
```

```
In [90]: s
```

```
Out[90]:
```

```
A    a1a2
B     b1
C     c1
dtype: object
```

```
In [91]: two_groups = '(?P<letter>[a-z])(?P<digit>[0-9])'
```

```
In [92]: s.str.extract(two_groups, expand=True)
```

```
Out[92]:
```

```
   letter digit
A      a      1
B      b      1
C      c      1
```

the `extractall` method returns every match. The result of `extractall` is always a `DataFrame` with a `MultiIndex` on its rows. The last level of the `MultiIndex` is named `match` and indicates the order in the subject.

```
In [93]: s.str.extractall(two_groups)
```

```
Out[93]:
```

```
   letter digit
match
A 0          a      1
  1          a      2
B 0          b      1
C 0          c      1
```

When each subject string in the Series has exactly one match,

```
In [94]: s = pd.Series(['a3', 'b3', 'c2'])
```

```
In [95]: s
```

```
Out[95]:
```

```
0    a3
1    b3
```

(continues on next page)

(continued from previous page)

```
2    c2
dtype: object
```

then `extractall(pat).xs(0, level='match')` gives the same result as `extract(pat)`.

```
In [96]: extract_result = s.str.extract(two_groups, expand=True)
```

```
In [97]: extract_result
```

```
Out[97]:
  letter digit
0      a      3
1      b      3
2      c      2
```

```
In [98]: extractall_result = s.str.extractall(two_groups)
```

```
In [99]: extractall_result
```

```
Out[99]:
      letter digit
match
0 0      a      3
1 0      b      3
2 0      c      2
```

```
In [100]: extractall_result.xs(0, level="match")
```

```
Out[100]:
  letter digit
0      a      3
1      b      3
2      c      2
```

Index also supports `.str.extractall`. It returns a `DataFrame` which has the same result as a `Series.str.extractall` with a default index (starts from 0).

New in version 0.19.0.

```
In [101]: pd.Index(["a1a2", "b1", "c1"]).str.extractall(two_groups)
```

```
Out[101]:
      letter digit
match
0 0      a      1
  1      a      2
1 0      b      1
2 0      c      1
```

```
In [102]: pd.Series(["a1a2", "b1", "c1"]).str.extractall(two_groups)
```

```
Out[102]:
      letter digit
match
0 0      a      1
  1      a      2
1 0      b      1
2 0      c      1
```

4.6.5 Testing for Strings that match or contain a pattern

You can check whether elements contain a pattern:

```
In [103]: pattern = r'[0-9][a-z]'

In [104]: pd.Series(['1', '2', '3a', '3b', '03c']).str.contains(pattern)
Out[104]:
0    False
1    False
2     True
3     True
4     True
dtype: bool
```

Or whether elements match a pattern:

```
In [105]: pd.Series(['1', '2', '3a', '3b', '03c']).str.match(pattern)
Out[105]:
0    False
1    False
2     True
3     True
4    False
dtype: bool
```

The distinction between `match` and `contains` is strictness: `match` relies on strict `re.match`, while `contains` relies on `re.search`.

Methods like `match`, `contains`, `startswith`, and `endswith` take an extra `na` argument so missing values can be considered `True` or `False`:

```
In [106]: s4 = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca', np.nan, 'CABA', 'dog', 'cat'])

In [107]: s4.str.contains('A', na=False)
Out[107]:
0     True
1    False
2    False
3     True
4    False
5    False
6     True
7    False
8    False
dtype: bool
```

4.6.6 Creating indicator variables

You can extract dummy variables from string columns. For example if they are separated by a '|':

```
In [108]: s = pd.Series(['a', 'a|b', np.nan, 'a|c'])
```

(continues on next page)

(continued from previous page)

```
In [109]: s.str.get_dummies(sep='|')
Out[109]:
   a  b  c
0  1  0  0
1  1  1  0
2  0  0  0
3  1  0  1
```

String Index also supports `get_dummies` which returns a `MultiIndex`.

New in version 0.18.1.

```
In [110]: idx = pd.Index(['a', 'a|b', np.nan, 'a|c'])

In [111]: idx.str.get_dummies(sep='|')
Out[111]:
MultiIndex([(1, 0, 0),
            (1, 1, 0),
            (0, 0, 0),
            (1, 0, 1)],
           names=['a', 'b', 'c'])
```

See also `get_dummies()`.

4.6.7 Method summary

Method	Description
<code>cat()</code>	Concatenate strings
<code>split()</code>	Split strings on delimiter
<code>rsplit()</code>	Split strings on delimiter working from the end of the string
<code>get()</code>	Index into each element (retrieve i-th element)
<code>join()</code>	Join strings in each element of the Series with passed separator
<code>get_dummies()</code>	Split strings on the delimiter returning DataFrame of dummy variables
<code>contains()</code>	Return boolean array if each string contains pattern/regex
<code>replace()</code>	Replace occurrences of pattern/regex/string with some other string or the return value of a callable given the occurrence
<code>repeat()</code>	Duplicate values (<code>s.str.repeat(3)</code> equivalent to <code>x * 3</code>)
<code>pad()</code>	Add whitespace to left, right, or both sides of strings
<code>center()</code>	Equivalent to <code>str.center</code>
<code>ljust()</code>	Equivalent to <code>str.ljust</code>
<code>rjust()</code>	Equivalent to <code>str.rjust</code>
<code>zfill()</code>	Equivalent to <code>str.zfill</code>
<code>wrap()</code>	Split long strings into lines with length less than a given width
<code>slice()</code>	Slice each string in the Series
<code>slice_replace()</code>	Replace slice in each string with passed value
<code>count()</code>	Count occurrences of pattern
<code>startswith()</code>	Equivalent to <code>str.startswith(pat)</code> for each element
<code>endswith()</code>	Equivalent to <code>str.endswith(pat)</code> for each element
<code>findall()</code>	Compute list of all occurrences of pattern/regex for each string
<code>match()</code>	Call <code>re.match</code> on each element, returning matched groups as list

Continued on next page

Table 2 – continued from previous page

Method	Description
<code>extract()</code>	Call <code>re.search</code> on each element, returning DataFrame with one row for each element and one column for each regex capture group
<code>extractall()</code>	Call <code>re.findall</code> on each element, returning DataFrame with one row for each match and one column for each regex capture group
<code>len()</code>	Compute string lengths
<code>strip()</code>	Equivalent to <code>str.strip</code>
<code>rstrip()</code>	Equivalent to <code>str.rstrip</code>
<code>lstrip()</code>	Equivalent to <code>str.lstrip</code>
<code>partition()</code>	Equivalent to <code>str.partition</code>
<code>rpartition()</code>	Equivalent to <code>str.rpartition</code>
<code>lower()</code>	Equivalent to <code>str.lower</code>
<code>casefold()</code>	Equivalent to <code>str.casefold</code>
<code>upper()</code>	Equivalent to <code>str.upper</code>
<code>find()</code>	Equivalent to <code>str.find</code>
<code>rfind()</code>	Equivalent to <code>str.rfind</code>
<code>index()</code>	Equivalent to <code>str.index</code>
<code>rindex()</code>	Equivalent to <code>str.rindex</code>
<code>capitalize()</code>	Equivalent to <code>str.capitalize</code>
<code>swapcase()</code>	Equivalent to <code>str.swapcase</code>
<code>normalize()</code>	Return Unicode normal form. Equivalent to <code>unicodedata.normalize</code>
<code>translate()</code>	Equivalent to <code>str.translate</code>
<code>isalnum()</code>	Equivalent to <code>str.isalnum</code>
<code>isalpha()</code>	Equivalent to <code>str.isalpha</code>
<code>isdigit()</code>	Equivalent to <code>str.isdigit</code>
<code>isspace()</code>	Equivalent to <code>str.isspace</code>
<code>islower()</code>	Equivalent to <code>str.islower</code>
<code>isupper()</code>	Equivalent to <code>str.isupper</code>
<code>istitle()</code>	Equivalent to <code>str.istitle</code>
<code>isnumeric()</code>	Equivalent to <code>str.isnumeric</code>
<code>isdecimal()</code>	Equivalent to <code>str.isdecimal</code>

{{ header }}

4.7 Working with missing data

In this section, we will discuss missing (also referred to as NA) values in pandas.

Note: The choice of using `NaN` internally to denote missing data was largely for simplicity and performance reasons. It differs from the `MaskedArray` approach of, for example, `scikits.timeseries`. We are hopeful that NumPy will soon be able to provide a native NA type solution (similar to R) performant enough to be used in pandas.

See the *cookbook* for some advanced strategies.

4.7.1 Values considered “missing”

As data comes in many shapes and forms, pandas aims to be flexible with regard to handling missing data. While `NaN` is the default missing value marker for reasons of computational speed and convenience, we need to be able to easily detect this value with data of different types: floating point, integer, boolean, and general object. In many cases, however, the Python `None` will arise and we wish to also consider that “missing” or “not available” or “NA”.

Note: If you want to consider `inf` and `-inf` to be “NA” in computations, you can set `pandas.options.mode.use_inf_as_na = True`.

```
In [1]: df = pd.DataFrame(np.random.randn(5, 3), index=['a', 'c', 'e', 'f', 'h'],
...:                      columns=['one', 'two', 'three'])
...:
...:
```

```
In [2]: df['four'] = 'bar'
```

```
In [3]: df['five'] = df['one'] > 0
```

```
In [4]: df
```

```
Out[4]:
```

	one	two	three	four	five
a	0.070821	-0.093641	0.014099	bar	True
c	0.702961	0.870484	-1.521966	bar	True
e	0.219802	1.546457	-0.174262	bar	True
f	0.831417	1.332054	0.438532	bar	True
h	0.786117	-0.304618	0.956171	bar	True

```
In [5]: df2 = df.reindex(['a', 'b', 'c', 'd', 'e', 'f', 'g', 'h'])
```

```
In [6]: df2
```

```
Out[6]:
```

	one	two	three	four	five
a	0.070821	-0.093641	0.014099	bar	True
b	NaN	NaN	NaN	NaN	NaN
c	0.702961	0.870484	-1.521966	bar	True
d	NaN	NaN	NaN	NaN	NaN
e	0.219802	1.546457	-0.174262	bar	True
f	0.831417	1.332054	0.438532	bar	True
g	NaN	NaN	NaN	NaN	NaN
h	0.786117	-0.304618	0.956171	bar	True

To make detecting missing values easier (and across different array dtypes), pandas provides the `isna()` and `notna()` functions, which are also methods on Series and DataFrame objects:

```
In [7]: df2['one']
```

```
Out[7]:
```

a	0.070821
b	NaN
c	0.702961
d	NaN
e	0.219802
f	0.831417

```
g      NaN
h      0.786117
Name: one, dtype: float64
```

```
In [8]: pd.isna(df2['one'])
```

```
Out[8]:
a      False
b      True
c      False
d      True
e      False
f      False
g      True
h      False
```

```
Name: one, dtype: bool
```

```
In [9]: df2['four'].notna()
```

```
Out[9]:
a      True
b      False
c      True
d      False
e      True
f      True
g      False
h      True
```

```
Name: four, dtype: bool
```

```
In [10]: df2.isna()
```

```
Out[10]:
   one  two  three  four  five
a  False False False False False
b   True  True  True  True  True
c  False False False False False
d   True  True  True  True  True
e  False False False False False
f  False False False False False
g   True  True  True  True  True
h  False False False False False
```

Warning: One has to be mindful that in Python (and NumPy), the `nan`'s don't compare equal, but `None`'s do. Note that pandas/NumPy uses the fact that `np.nan != np.nan`, and treats `None` like `np.nan`.

```
In [11]: None == None                                     # noqa: E711
Out[11]: True
```

```
In [12]: np.nan == np.nan
Out[12]: False
```

So as compared to above, a scalar equality comparison versus a `None/np.nan` doesn't provide useful information.

```
In [13]: df2['one'] == np.nan
Out[13]:
a    False
b    False
c    False
d    False
e    False
f    False
g    False
h    False
Name: one, dtype: bool
```

Integer dtypes and missing data

Because NaN is a float, a column of integers with even one missing values is cast to floating-point dtype (see *Support for integer NA* for more). Pandas provides a nullable integer array, which can be used by explicitly requesting the dtype:

```
In [14]: pd.Series([1, 2, np.nan, 4], dtype=pd.Int64Dtype())
Out[14]:
0     1
1     2
2    NaN
3     4
dtype: Int64
```

Alternatively, the string alias `dtype='Int64'` (note the capital "I") can be used.

See *Nullable integer data type* for more.

Datetimes

For `datetime64[ns]` types, NaT represents missing values. This is a pseudo-native sentinel value that can be represented by NumPy in a singular dtype (`datetime64[ns]`). pandas objects provide compatibility between NaT and NaN.

```
In [15]: df2 = df.copy()
```

```
In [16]: df2['timestamp'] = pd.Timestamp('20120101')
```

```
In [17]: df2
```

```
Out[17]:
   one      two      three four  five  timestamp
a  0.070821 -0.093641  0.014099  bar  True  2012-01-01
c  0.702961  0.870484 -1.521966  bar  True  2012-01-01
e  0.219802  1.546457 -0.174262  bar  True  2012-01-01
f  0.831417  1.332054  0.438532  bar  True  2012-01-01
h  0.786117 -0.304618  0.956171  bar  True  2012-01-01
```

```
In [18]: df2.loc[['a', 'c', 'h'], ['one', 'timestamp']] = np.nan
```

```
In [19]: df2
Out[19]:
```

	one	two	three	four	five	timestamp
a	NaN	-0.093641	0.014099	bar	True	NaT
c	NaN	0.870484	-1.521966	bar	True	NaT
e	0.219802	1.546457	-0.174262	bar	True	2012-01-01
f	0.831417	1.332054	0.438532	bar	True	2012-01-01
h	NaN	-0.304618	0.956171	bar	True	NaT

```
In [20]: df2.dtypes.value_counts()
Out[20]:
float64          3
datetime64[ns]   1
object           1
bool             1
dtype: int64
```

Inserting missing data

You can insert missing values by simply assigning to containers. The actual missing value used will be chosen based on the dtype.

For example, numeric containers will always use NaN regardless of the missing value type chosen:

```
In [21]: s = pd.Series([1, 2, 3])
In [22]: s.loc[0] = None
In [23]: s
Out[23]:
0    NaN
1     2.0
2     3.0
dtype: float64
```

Likewise, datetime containers will always use NaT.

For object containers, pandas will use the value given:

```
In [24]: s = pd.Series(["a", "b", "c"])
In [25]: s.loc[0] = None
In [26]: s.loc[1] = np.nan
In [27]: s
Out[27]:
0    None
1     NaN
2      c
dtype: object
```

Calculations with missing data

Missing values propagate naturally through arithmetic operations between pandas objects.

```
In [28]: a
```

```
Out[28]:
```

```
      one      two
a      NaN -0.093641
c      NaN  0.870484
e  0.219802  1.546457
f  0.831417  1.332054
h  0.831417 -0.304618
```

```
In [29]: b
```

```
Out[29]:
```

```
      one      two      three
a      NaN -0.093641  0.014099
c      NaN  0.870484 -1.521966
e  0.219802  1.546457 -0.174262
f  0.831417  1.332054  0.438532
h      NaN -0.304618  0.956171
```

```
In [30]: a + b
```

```
Out[30]:
```

```
      one  three      two
a      NaN   NaN -0.187283
c      NaN   NaN  1.740968
e  0.439605   NaN  3.092914
f  1.662833   NaN  2.664108
h      NaN   NaN -0.609235
```

The descriptive statistics and computational methods discussed in the [data structure overview](#) (and listed [here](#) and [here](#)) are all written to account for missing data. For example:

- When summing data, NA (missing) values will be treated as zero.
- If the data are all NA, the result will be 0.
- Cumulative methods like `cumsum()` and `cumprod()` ignore NA values by default, but preserve them in the resulting arrays. To override this behaviour and include NA values, use `skipna=False`.

```
In [31]: df
```

```
Out[31]:
```

```
      one      two      three
a      NaN -0.093641  0.014099
c      NaN  0.870484 -1.521966
e  0.219802  1.546457 -0.174262
f  0.831417  1.332054  0.438532
h      NaN -0.304618  0.956171
```

```
In [32]: df['one'].sum()
```

```
Out[32]: 1.0512188858617544
```

```

f  1.051219  3.655354 -1.243596
h     NaN  3.350736 -0.287425
```

```
In [35]: df.cumsum(skipna=False)
```

```
Out[35]:
```

```
      one      two      three
a  NaN -0.093641  0.014099
c  NaN  0.776843 -1.507866
e  NaN  2.323300 -1.682128
f  NaN  3.655354 -1.243596
h  NaN  3.350736 -0.287425
```

4.7.2 Sum/prod of empties/nans

Warning: This behavior is now standard as of v0.22.0 and is consistent with the default in `numpy`; previously sum/prod of all-NA or empty Series/DataFrames would return NaN. See *v0.22.0 whatsnew* for more.

The sum of an empty or all-NA Series or column of a DataFrame is 0.

```
In [36]: pd.Series([np.nan]).sum()
```

```
Out[36]: 0.0
```

```
In [37]: pd.Series([]).sum()
```

```
Out[37]: 0.0
```

The product of an empty or all-NA Series or column of a DataFrame is 1.

```
In [38]: pd.Series([np.nan]).prod()
```

```
Out[38]: 1.0
```

```
In [39]: pd.Series([]).prod()
```

```
Out[39]: 1.0
```

4.7.3 NA values in GroupBy

NA groups in GroupBy are automatically excluded. This behavior is consistent with R, for example:

```
In [40]: df
```

```
Out[40]:
```

```
      one      two      three
```

```
a      NaN -0.093641  0.014099
c      NaN  0.870484 -1.521966
e  0.219802  1.546457 -0.174262
f  0.831417  1.332054  0.438532
h      NaN -0.304618  0.956171
```

```
In [41]: df.groupby('one').mean()
Out[41]:
```

```
          two      three
one
0.219802  1.546457 -0.174262
0.831417  1.332054  0.438532
```

See the `groupby` section [here](#) for more information.

Cleaning / filling missing data

pandas objects are equipped with various data manipulation methods for dealing with missing data.

4.7.4 Filling missing values: `fillna`

`fillna()` can “fill in” NA values with non-NA data in a couple of ways, which we illustrate:

Replace NA with a scalar value

```
In [42]: df2
```

```
Out[42]:
```

	one	two	three	four	five	timestamp
a	NaN	-0.093641	0.014099	bar	True	NaT
c	NaN	0.870484	-1.521966	bar	True	NaT
e	0.219802	1.546457	-0.174262	bar	True	2012-01-01
f	0.831417	1.332054	0.438532	bar	True	2012-01-01
h	NaN	-0.304618	0.956171	bar	True	NaT

```
In [43]: df2.fillna(0)
```

```
Out[43]:
```

	one	two	three	four	five	timestamp
a	0.000000	-0.093641	0.014099	bar	True	0
c	0.000000	0.870484	-1.521966	bar	True	0
e	0.219802	1.546457	-0.174262	bar	True	2012-01-01 00:00:00
f	0.831417	1.332054	0.438532	bar	True	2012-01-01 00:00:00
h	0.000000	-0.304618	0.956171	bar	True	0

```
In [44]: df2['one'].fillna('missing')
```

```
Out[44]:
```

a	missing
c	missing
e	0.219802
f	0.831417
h	missing

```
Name: one, dtype: object
```

Fill gaps forward or backward

Using the same filling arguments as [reindexing](#), we can propagate non-NA values forward or backward:

```
In [45]: df
Out[45]:
```

	one	two	three
a	NaN	-0.093641	0.014099
c	NaN	0.870484	-1.521966
e	0.219802	1.546457	-0.174262
f	0.831417	1.332054	0.438532
h	NaN	-0.304618	0.956171

```
In [46]: df.fillna(method='pad')
Out[46]:
```

	one	two	three
a	NaN	-0.093641	0.014099
c	NaN	0.870484	-1.521966
e	0.219802	1.546457	-0.174262
f	0.831417	1.332054	0.438532
h	0.831417	-0.304618	0.956171

Limit the amount of filling

If we only want consecutive gaps filled up to a certain number of data points, we can use the *limit* keyword:

```
In [47]: df
Out[47]:
```

	one	two	three
a	NaN	-0.093641	0.014099
c	NaN	0.870484	-1.521966
e	NaN	NaN	NaN
f	NaN	NaN	NaN
h	NaN	-0.304618	0.956171

```
In [48]: df.fillna(method='pad', limit=1)
Out[48]:
```

	one	two	three
a	NaN	-0.093641	0.014099
c	NaN	0.870484	-1.521966
e	NaN	0.870484	-1.521966
f	NaN	NaN	NaN
h	NaN	-0.304618	0.956171

To remind you, these are the available filling methods:

Method	Action
pad / ffill	Fill values forward
bfill / backfill	Fill values backward

With time series data, using pad/ffill is extremely common so that the “last known value” is available at every time point.

`ffill()` is equivalent to `fillna(method='ffill')` and `bfill()` is equivalent to `fillna(method='bfill')`

4.7.5 Filling with a PandasObject

You can also fillna using a dict or Series that is alignable. The labels of the dict or index of the Series must match the columns of the frame you wish to fill. The use case of this is to fill a DataFrame with the mean

of that column.

```
In [49]: dff = pd.DataFrame(np.random.randn(10, 3), columns=list('ABC'))
```

```
In [50]: dff.iloc[3:5, 0] = np.nan
```

```
In [51]: dff.iloc[4:6, 1] = np.nan
```

```
In [52]: dff.iloc[5:8, 2] = np.nan
```

```
In [53]: dff
```

```
Out[53]:
```

	A	B	C
0	0.632107	-0.123200	0.579811
1	-0.617833	0.730289	-1.930809
2	-1.795903	-2.012672	-0.884042
3	NaN	0.809658	0.727889
4	NaN	NaN	1.683552
5	-1.134942	NaN	NaN
6	-1.654372	-0.175245	NaN
7	0.332654	-1.208013	NaN
8	0.028692	0.139178	0.877023
9	0.780292	0.682156	0.993475

```
In [54]: dff.fillna(dff.mean())
```

```
Out[54]:
```

	A	B	C
0	0.632107	-0.123200	0.579811
1	-0.617833	0.730289	-1.930809
2	-1.795903	-2.012672	-0.884042
3	-0.428663	0.809658	0.727889
4	-0.428663	-0.144731	1.683552
5	-1.134942	-0.144731	0.292414
6	-1.654372	-0.175245	0.292414
7	0.332654	-1.208013	0.292414
8	0.028692	0.139178	0.877023
9	0.780292	0.682156	0.993475

```
In [55]: dff.fillna(dff.mean()['B':'C'])
```

```
Out[55]:
```

	A	B	C
0	0.632107	-0.123200	0.579811
1	-0.617833	0.730289	-1.930809
2	-1.795903	-2.012672	-0.884042
3	NaN	0.809658	0.727889
4	NaN	-0.144731	1.683552
5	-1.134942	-0.144731	0.292414
6	-1.654372	-0.175245	0.292414
7	0.332654	-1.208013	0.292414
8	0.028692	0.139178	0.877023
9	0.780292	0.682156	0.993475

Same result as above, but is aligning the 'fill' value which is a Series in this case.

```
In [56]: dff.where(pd.notna(dff), dff.mean(), axis='columns')
Out[56]:
```

	A	B	C
0	0.632107	-0.123200	0.579811
1	-0.617833	0.730289	-1.930809
2	-1.795903	-2.012672	-0.884042
3	-0.428663	0.809658	0.727889
4	-0.428663	-0.144731	1.683552
5	-1.134942	-0.144731	0.292414
6	-1.654372	-0.175245	0.292414
7	0.332654	-1.208013	0.292414
8	0.028692	0.139178	0.877023
9	0.780292	0.682156	0.993475

4.7.6 Dropping axis labels with missing data: dropna

You may wish to simply exclude labels from a data set which refer to missing data. To do this, use `dropna()`:

```
In [57]: df
Out[57]:
```

	one	two	three
a	NaN	-0.093641	0.014099
c	NaN	0.870484	-1.521966
e	NaN	0.000000	0.000000
f	NaN	0.000000	0.000000
h	NaN	-0.304618	0.956171

```
In [58]: df.dropna(axis=0)
Out[58]:
Empty DataFrame
Columns: [one, two, three]
Index: []
```

```
In [59]: df.dropna(axis=1)
Out[59]:
```

	two	three
a	-0.093641	0.014099
c	0.870484	-1.521966
e	0.000000	0.000000
f	0.000000	0.000000
h	-0.304618	0.956171

```
In [60]: df['one'].dropna()
Out[60]: Series([], Name: one, dtype: float64)
```

An equivalent `dropna()` is available for Series. `DataFrame.dropna` has considerably more options than `Series.dropna`, which can be examined *in the API*.

4.7.7 Interpolation

New in version 0.23.0: The `limit_area` keyword argument was added.

Both Series and DataFrame objects have `interpolate()` that, by default, performs linear interpolation at missing data points.

```
In [61]: ts
Out[61]:
2000-01-31    0.469112
2000-02-29         NaN
2000-03-31         NaN
2000-04-28         NaN
2000-05-31         NaN
...
2007-12-31   -6.950267
2008-01-31   -7.904475
2008-02-29   -6.441779
2008-03-31   -8.184940
2008-04-30   -9.011531
Freq: BM, Length: 100, dtype: float64

In [62]: ts.count()
Out[62]: 66

In [63]: ts.plot()
Out[63]: <matplotlib.axes._subplots.AxesSubplot at 0x14bbd5690>
```

```
In [64]: ts.interpolate()
Out[64]:
2000-01-31    0.469112
2000-02-29    0.434469
2000-03-31    0.399826
2000-04-28    0.365184
2000-05-31    0.330541
...
2007-12-31   -6.950267
2008-01-31   -7.904475
2008-02-29   -6.441779
2008-03-31   -8.184940
2008-04-30   -9.011531
Freq: BM, Length: 100, dtype: float64

In [65]: ts.interpolate().count()
Out[65]: 100

In [66]: ts.interpolate().plot()
Out[66]: <matplotlib.axes._subplots.AxesSubplot at 0x14a829590>
```

Index aware interpolation is available via the `method` keyword:

```
In [67]: ts2
```

```
Out [67]:
2000-01-31    0.469112
2000-02-29         NaN
2002-07-31   -5.785037
2005-01-31         NaN
2008-04-30   -9.011531
dtype: float64
```

```
In [68]: ts2.interpolate()
Out [68]:
2000-01-31    0.469112
2000-02-29   -2.657962
2002-07-31   -5.785037
2005-01-31   -7.398284
2008-04-30   -9.011531
dtype: float64
```

```
In [69]: ts2.interpolate(method='time')
Out [69]:
2000-01-31    0.469112
2000-02-29    0.270241
2002-07-31   -5.785037
2005-01-31   -7.190866
2008-04-30   -9.011531
dtype: float64
```

For a floating-point index, use `method='values'`:

```
In [70]: ser
Out [70]:
0.0      0.0
1.0      NaN
10.0     10.0
dtype: float64
```

```
In [71]: ser.interpolate()
Out [71]:
0.0      0.0
1.0      5.0
10.0     10.0
dtype: float64
```

```
In [72]: ser.interpolate(method='values')
Out [72]:
0.0      0.0
1.0      1.0
10.0     10.0
dtype: float64
```

You can also interpolate with a DataFrame:

```
In [73]: df = pd.DataFrame({'A': [1, 2.1, np.nan, 4.7, 5.6, 6.8],
.....:                    'B': [.25, np.nan, np.nan, 4, 12.2, 14.4]})
.....:
```

```
In [74]: df
```

```
Out[74]:
```

```

      A      B
0  1.0  0.25
1  2.1   NaN
2  NaN   NaN
3  4.7  4.00
4  5.6 12.20
5  6.8 14.40

```

```
In [75]: df.interpolate()
```

```
Out[75]:
```

```

      A      B
0  1.0  0.25
1  2.1  1.50
2  3.4  2.75
3  4.7  4.00
4  5.6 12.20
5  6.8 14.40

```

The `method` argument gives access to fancier interpolation methods. If you have `scipy` installed, you can pass the name of a 1-d interpolation routine to `method`. You'll want to consult the full [scipy interpolation documentation](#) and reference [guide](#) for details. The appropriate interpolation method will depend on the type of data you are working with.

- If you are dealing with a time series that is growing at an increasing rate, `method='quadratic'` may be appropriate.
- If you have values approximating a cumulative distribution function, then `method='pchip'` should work well.
- To fill missing values with goal of smooth plotting, consider `method='akima'`.

Warning: These methods require `scipy`.

```
In [76]: df.interpolate(method='barycentric')
```

```
Out[76]:
```

```

      A      B
0  1.00  0.250
1  2.10 -7.660
2  3.53 -4.515
3  4.70  4.000
4  5.60 12.200
5  6.80 14.400

```

```
In [77]: df.interpolate(method='pchip')
```

```
Out[77]:
```

```

      A      B
0  1.00000  0.250000
1  2.10000  0.672808
2  3.43454  1.928950
3  4.70000  4.000000
4  5.60000 12.200000
5  6.80000 14.400000

```

```
In [78]: df.interpolate(method='akima')
```

Out [78]:

	A	B
0	1.000000	0.250000
1	2.100000	-0.873316
2	3.406667	0.320034
3	4.700000	4.000000
4	5.600000	12.200000
5	6.800000	14.400000

When interpolating via a polynomial or spline approximation, you must also specify the degree or order of the approximation:

```
In [79]: df.interpolate(method='spline', order=2)
```

Out [79]:

	A	B
0	1.000000	0.250000
1	2.100000	-0.428598
2	3.404545	1.206900
3	4.700000	4.000000
4	5.600000	12.200000
5	6.800000	14.400000

```
In [80]: df.interpolate(method='polynomial', order=2)
```

Out [80]:

	A	B
0	1.000000	0.250000
1	2.100000	-2.703846
2	3.451351	-1.453846
3	4.700000	4.000000
4	5.600000	12.200000
5	6.800000	14.400000

Compare several methods:

```
In [81]: np.random.seed(2)
```

```
In [82]: ser = pd.Series(np.arange(1, 10.1, .25) ** 2 + np.random.randn(37))
```

```
In [83]: missing = np.array([4, 13, 14, 15, 16, 17, 18, 20, 29])
```

```
In [84]: ser[missing] = np.nan
```

```
In [85]: methods = ['linear', 'quadratic', 'cubic']
```

```
In [86]: df = pd.DataFrame({m: ser.interpolate(method=m) for m in methods})
```

```
In [87]: df.plot()
```

```
Out [87]: <matplotlib.axes._subplots.AxesSubplot at 0x14a517d90>
```

Another use case is interpolation at *new* values. Suppose you have 100 observations from some distribution. And let's suppose that you're particularly interested in what's happening around the middle. You can mix pandas' `reindex` and `interpolate` methods to interpolate at the new values.

```
In [88]: ser = pd.Series(np.sort(np.random.uniform(size=100)))

# interpolate at new_index
In [89]: new_index = ser.index | pd.Index([49.25, 49.5, 49.75, 50.25, 50.5, 50.75])

In [90]: interp_s = ser.reindex(new_index).interpolate(method='pchip')

In [91]: interp_s[49:51]
Out[91]:
49.00    0.471410
49.25    0.476841
49.50    0.481780
49.75    0.485998
50.00    0.489266
50.25    0.491814
50.50    0.493995
50.75    0.495763
51.00    0.497074
dtype: float64
```

Interpolation limits

Like other pandas fill methods, `interpolate()` accepts a `limit` keyword argument. Use this argument to limit the number of consecutive NaN values filled since the last valid observation:

```
In [92]: ser = pd.Series([np.nan, np.nan, 5, np.nan, np.nan,
....:                    np.nan, 13, np.nan, np.nan])
....:
```

```
In [93]: ser
```

```
Out[93]:
```

```
0    NaN
1    NaN
2    5.0
3    NaN
4    NaN
5    NaN
6    13.0
7    NaN
8    NaN
dtype: float64
```

```
# fill all consecutive values in a forward direction
```

```
In [94]: ser.interpolate()
```

```
Out[94]:
```

```
0    NaN
1    NaN
2    5.0
3    7.0
4    9.0
5    11.0
6    13.0
7    13.0
8    13.0
dtype: float64
```

```
# fill one consecutive value in a forward direction
```

```
In [95]: ser.interpolate(limit=1)
```

```
Out[95]:
```

```
0    NaN
1    NaN
2    5.0
3    7.0
4    NaN
5    NaN
6    13.0
7    13.0
8    NaN
dtype: float64
```

By default, NaN values are filled in a forward direction. Use `limit_direction` parameter to fill backward or from both directions.

```
# fill one consecutive value backwards
```

```
In [96]: ser.interpolate(limit=1, limit_direction='backward')
```

```
Out[96]:
0      NaN
1      5.0
2      5.0
3      NaN
4      NaN
5     11.0
6     13.0
7      NaN
8      NaN
dtype: float64

# fill one consecutive value in both directions
In [97]: ser.interpolate(limit=1, limit_direction='both')
Out[97]:
0      NaN
1      5.0
2      5.0
3      7.0
4      NaN
5     11.0
6     13.0
7     13.0
8      NaN
dtype: float64
```

```
# fill all consecutive values in both directions
In [98]: ser.interpolate(limit_direction='both')
Out[98]:
0      5.0
1      5.0
2      5.0
3      7.0
4      9.0
5     11.0
6     13.0
7     13.0
8     13.0
dtype: float64
```

By default, NaN values are filled whether they are inside (surrounded by) existing valid values, or outside existing valid values. Introduced in v0.23 the `limit_area` parameter restricts filling to either inside or outside values.

```
# fill one consecutive inside value in both directions
In [99]: ser.interpolate(limit_direction='both', limit_area='inside', limit=1)
Out[99]:
0      NaN
1      NaN
2      5.0
3      7.0
4      NaN
5     11.0
6     13.0
7      NaN
```

```
8      NaN
dtype: float64

# fill all consecutive outside values backward
In [100]: ser.interpolate(limit_direction='backward', limit_area='outside')
Out[100]:
0      5.0
1      5.0
2      5.0
3      NaN
4      NaN
5      NaN
6     13.0
7      NaN
8      NaN
dtype: float64

# fill all consecutive outside values in both directions
In [101]: ser.interpolate(limit_direction='both', limit_area='outside')
Out[101]:
0      5.0
1      5.0
2      5.0
3      NaN
4      NaN
5      NaN
6     13.0
7     13.0
8     13.0
dtype: float64
```

4.7.8 Replacing generic values

Often times we want to replace arbitrary values with other values.

`replace()` in Series and `replace()` in DataFrame provides an efficient yet flexible way to perform such replacements.

For a Series, you can replace a single value or a list of values by another value:

```
In [102]: ser = pd.Series([0., 1., 2., 3., 4.])

In [103]: ser.replace(0, 5)
Out[103]:
0      5.0
1      1.0
2      2.0
3      3.0
4      4.0
dtype: float64
```

You can replace a list of values by a list of other values:

```
In [104]: ser.replace([0, 1, 2, 3, 4], [4, 3, 2, 1, 0])
Out[104]:
0    4.0
1    3.0
2    2.0
3    1.0
4    0.0
dtype: float64
```

You can also specify a mapping dict:

```
In [105]: ser.replace({0: 10, 1: 100})
Out[105]:
0    10.0
1   100.0
2     2.0
3     3.0
4     4.0
dtype: float64
```

For a DataFrame, you can specify individual values by column:

```
In [106]: df = pd.DataFrame({'a': [0, 1, 2, 3, 4], 'b': [5, 6, 7, 8, 9]})
In [107]: df.replace({'a': 0, 'b': 5}, 100)
Out[107]:
   a  b
0 100 100
1   1   6
2   2   7
3   3   8
4   4   9
```

Instead of replacing with specified values, you can treat all given values as missing and interpolate over them:

```
In [108]: ser.replace([1, 2, 3], method='pad')
Out[108]:
0    0.0
1    0.0
2    0.0
3    0.0
4    4.0
dtype: float64
```

4.7.9 String/regular expression replacement

Note: Python strings prefixed with the `r` character such as `r'hello world'` are so-called “raw” strings. They have different semantics regarding backslashes than strings without this prefix. Backslashes in raw strings will be interpreted as an escaped backslash, e.g., `r'\'` == `'\'`. You should read about them if this is unclear.

Replace the '.' with NaN (str -> str):

```
In [109]: d = {'a': list(range(4)), 'b': list('ab..'), 'c': ['a', 'b', np.nan, 'd']}
In [110]: df = pd.DataFrame(d)
In [111]: df.replace('.', np.nan)
Out[111]:
   a  b  c
0  0  a  a
1  1  b  b
2  2 NaN NaN
3  3 NaN  d
```

Now do it with a regular expression that removes surrounding whitespace (regex -> regex):

```
In [112]: df.replace(r'\s*\.\s*', np.nan, regex=True)
Out[112]:
   a  b  c
0  0  a  a
1  1  b  b
2  2 NaN NaN
3  3 NaN  d
```

Replace a few different values (list -> list):

```
In [113]: df.replace(['a', '.'], ['b', np.nan])
Out[113]:
   a  b  c
0  0  b  b
1  1  b  b
2  2 NaN NaN
3  3 NaN  d
```

list of regex -> list of regex:

```
In [114]: df.replace([r'\.', r'(a)'], ['dot', r'\1stuff'], regex=True)
Out[114]:
   a      b      c
0  0 astuff astuff
1  1      b      b
2  2     dot     NaN
3  3     dot      d
```

Only search in column 'b' (dict -> dict):

```
In [115]: df.replace({'b': '.'}, {'b': np.nan})
Out[115]:
   a  b  c
0  0  a  a
1  1  b  b
2  2 NaN NaN
3  3 NaN  d
```

Same as the previous example, but use a regular expression for searching instead (dict of regex -> dict):

```
In [116]: df.replace({'b': r'\s*\.\s*'}, {'b': np.nan}, regex=True)
Out[116]:
   a  b  c
0  0  a  a
1  1  b  b
2  2 NaN NaN
3  3 NaN  d
```

You can pass nested dictionaries of regular expressions that use `regex=True`:

```
In [117]: df.replace({'b': {'b': r''}}, regex=True)
Out[117]:
   a  b  c
0  0  a  a
1  1   b
2  2  . NaN
3  3  .  d
```

Alternatively, you can pass the nested dictionary like so:

```
In [118]: df.replace(regex={'b': {r'\s*\.\s*': np.nan}})
Out[118]:
   a  b  c
0  0  a  a
1  1  b  b
2  2 NaN NaN
3  3 NaN  d
```

You can also use the group of a regular expression match when replacing (dict of regex -> dict of regex), this works for lists as well.

```
In [119]: df.replace({'b': r'\s*(\.)\s*'}, {'b': r'\1ty'}, regex=True)
Out[119]:
   a  b  c
0  0  a  a
1  1  b  b
2  2 .ty NaN
3  3 .ty  d
```

You can pass a list of regular expressions, of which those that match will be replaced with a scalar (list of regex -> regex).

```
In [120]: df.replace([r'\s*\.\s*', r'a|b'], np.nan, regex=True)
Out[120]:
   a  b  c
0  0 NaN NaN
1  1 NaN NaN
2  2 NaN NaN
3  3 NaN  d
```

All of the regular expression examples can also be passed with the `to_replace` argument as the `regex` argument. In this case the `value` argument must be passed explicitly by name or `regex` must be a nested dictionary. The previous example, in this case, would then be:

```
In [121]: df.replace(regex=[r'\s*\.\s*', r'a|b'], value=np.nan)
Out[121]:
   a  b  c
0  0 NaN NaN
1  1 NaN NaN
2  2 NaN NaN
3  3 NaN  d
```

This can be convenient if you do not want to pass `regex=True` every time you want to use a regular expression.

Note: Anywhere in the above `replace` examples that you see a regular expression a compiled regular expression is valid as well.

4.7.10 Numeric replacement

`replace()` is similar to `fillna()`.

```
In [122]: df = pd.DataFrame(np.random.randn(10, 2))
In [123]: df[np.random.rand(df.shape[0]) > 0.5] = 1.5
In [124]: df.replace(1.5, np.nan)
Out[124]:
      0      1
0 -0.844214 -1.021415
1  0.432396 -0.323580
2  0.423825  0.799180
3  1.262614  0.751965
4      NaN      NaN
5      NaN      NaN
6 -0.498174 -1.060799
7  0.591667 -0.183257
8  1.019855 -1.482465
9      NaN      NaN
```

Replacing more than one value is possible by passing a list.

```
In [125]: df00 = df.iloc[0, 0]
In [126]: df.replace([1.5, df00], [np.nan, 'a'])
Out[126]:
      0      1
0      a -1.02141
1  0.432396 -0.32358
2  0.423825  0.79918
3  1.26261  0.751965
4      NaN      NaN
5      NaN      NaN
6 -0.498174 -1.0608
7  0.591667 -0.183257
8  1.01985 -1.48247
9      NaN      NaN
```

```
In [127]: df[1].dtype
Out[127]: dtype('float64')
```

You can also operate on the DataFrame in place:

```
In [128]: df.replace(1.5, np.nan, inplace=True)
```

Warning: When replacing multiple `bool` or `datetime64` objects, the first argument to `replace` (`to_replace`) must match the type of the value being replaced. For example,

```
>>> s = pd.Series([True, False, True])
>>> s.replace({'a string': 'new value', True: False}) # raises
TypeError: Cannot compare types 'ndarray(dtype=bool)' and 'str'
```

will raise a `TypeError` because one of the dict keys is not of the correct type for replacement.

However, when replacing a *single* object such as,

```
In [129]: s = pd.Series([True, False, True])

In [130]: s.replace('a string', 'another string')
Out[130]:
0      True
1     False
2      True
dtype: bool
```

the original `NDFrame` object will be returned untouched. We’re working on unifying this API, but for backwards compatibility reasons we cannot break the latter behavior. See [GH6354](#) for more details.

Missing data casting rules and indexing

While pandas supports storing arrays of integer and boolean type, these types are not capable of storing missing data. Until we can switch to using a native NA type in NumPy, we’ve established some “casting rules”. When a reindexing operation introduces missing data, the Series will be cast according to the rules introduced in the table below.

data type	Cast to
integer	float
boolean	object
float	no cast
object	no cast

For example:

```
In [131]: s = pd.Series(np.random.randn(5), index=[0, 2, 4, 6, 7])
```

```
In [132]: s > 0
Out[132]:
0      True
2      True
4      True
6      True
```

```
7    True
dtype: bool
```

```
In [133]: (s > 0).dtype
Out[133]: dtype('bool')
```

```
In [134]: crit = (s > 0).reindex(list(range(8)))
```

```
In [135]: crit
Out[135]:
0    True
1    NaN
2    True
3    NaN
4    True
5    NaN
6    True
7    True
dtype: object
```

```
In [136]: crit.dtype
Out[136]: dtype('O')
```

Ordinarily NumPy will complain if you try to use an object array (even if it contains boolean values) instead of a boolean array to get or set values from an ndarray (e.g. selecting values based on some criteria). If a boolean vector contains NAs, an exception will be generated:

```
In [137]: reindexed = s.reindex(list(range(8))).fillna(0)

In [138]: reindexed[crit]
-----
ValueError                                Traceback (most recent call last)
<ipython-input-138-0dac417a4890> in <module>
----> 1 reindexed[crit]

~/sandbox/pandas-doc/pandas/core/series.py in __getitem__(self, key)
    1108         key = list(key)
    1109
-> 1110         if com.is_bool_indexer(key):
    1111             key = check_bool_indexer(self.index, key)
    1112

~/sandbox/pandas-doc/pandas/core/common.py in is_bool_indexer(key)
    128         if not lib.is_bool_array(key):
    129             if isna(key).any():
--> 130                 raise ValueError(na_msg)
    131             return False
    132         return True

ValueError: cannot index with vector containing NA / NaN values
```

However, these can be filled in using `fillna()` and it will work fine:

```
In [139]: reindexed[crit.fillna(False)]
Out[139]:
```

```

0    0.126504
2    0.696198
4    0.697416
6    0.601516
7    0.003659
dtype: float64

```

```

In [140]: reindexed[crit.fillna(True)]
Out[140]:
0    0.126504
1    0.000000
2    0.696198
3    0.000000
4    0.697416
5    0.000000
6    0.601516
7    0.003659
dtype: float64

```

Pandas provides a nullable integer dtype, but you must explicitly request it when creating the series or column. Notice that we use a capital “I” in the `dtype="Int64"`.

```

In [141]: s = pd.Series([0, 1, np.nan, 3, 4], dtype="Int64")

In [142]: s
Out[142]:
0      0
1      1
2     NaN
3      3
4      4
dtype: Int64

```

See *Nullable integer data type* for more. `{{ header }}`

4.8 Categorical data

This is an introduction to pandas categorical data type, including a short comparison with R’s `factor`.

Categoricals are a pandas data type corresponding to categorical variables in statistics. A categorical variable takes on a limited, and usually fixed, number of possible values (*categories*; *levels* in R). Examples are gender, social class, blood type, country affiliation, observation time or rating via Likert scales.

In contrast to statistical categorical variables, categorical data might have an order (e.g. ‘strongly agree’ vs ‘agree’ or ‘first observation’ vs. ‘second observation’), but numerical operations (additions, divisions, ...) are not possible.

All values of categorical data are either in *categories* or *np.nan*. Order is defined by the order of *categories*, not lexical order of the values. Internally, the data structure consists of a *categories* array and an integer array of *codes* which point to the real value in the *categories* array.

The categorical data type is useful in the following cases:

- A string variable consisting of only a few different values. Converting such a string variable to a categorical variable will save some memory, see [here](#).

- The lexical order of a variable is not the same as the logical order (“one”, “two”, “three”). By converting to a categorical and specifying an order on the categories, sorting and min/max will use the logical order instead of the lexical order, see [here](#).
- As a signal to other Python libraries that this column should be treated as a categorical variable (e.g. to use suitable statistical methods or plot types).

See also the *API docs on categoricals*.

4.8.1 Object creation

Series creation

Categorical `Series` or columns in a `DataFrame` can be created in several ways:

By specifying `dtype="category"` when constructing a `Series`:

```
In [1]: s = pd.Series(["a", "b", "c", "a"], dtype="category")

In [2]: s
Out[2]:
0    a
1    b
2    c
3    a
dtype: category
Categories (3, object): [a, b, c]
```

By converting an existing `Series` or column to a `category` dtype:

```
In [3]: df = pd.DataFrame({"A": ["a", "b", "c", "a"]})

In [4]: df["B"] = df["A"].astype('category')

In [5]: df
Out[5]:
   A B
0  a a
1  b b
2  c c
3  a a
```

By using special functions, such as `cut()`, which groups data into discrete bins. See the *example on tiling* in the docs.

```
In [6]: df = pd.DataFrame({'value': np.random.randint(0, 100, 20)})

In [7]: labels = ["{0} - {1}".format(i, i + 9) for i in range(0, 100, 10)]

In [8]: df['group'] = pd.cut(df.value, range(0, 105, 10), right=False, labels=labels)

In [9]: df.head(10)
Out[9]:
   value  group
```

(continues on next page)

(continued from previous page)

```

0    59  50 - 59
1    81  80 - 89
2    62  60 - 69
3    82  80 - 89
4    63  60 - 69
5    90  90 - 99
6    73  70 - 79
7     5   0 - 9
8    15  10 - 19
9    40  40 - 49

```

By passing a `pandas.Categorical` object to a `Series` or assigning it to a `DataFrame`.

```

In [10]: raw_cat = pd.Categorical(["a", "b", "c", "a"], categories=["b", "c", "d"],
.....:                          ordered=False)
.....:

In [11]: s = pd.Series(raw_cat)

In [12]: s
Out[12]:
0    NaN
1     b
2     c
3    NaN
dtype: category
Categories (3, object): [b, c, d]

In [13]: df = pd.DataFrame({"A": ["a", "b", "c", "a"]})

In [14]: df["B"] = raw_cat

In [15]: df
Out[15]:
   A  B
0  a NaN
1  b  b
2  c  c
3  a NaN

```

Categorical data has a specific `category dtype`:

```

In [16]: df.dtypes
Out[16]:
A    object
B    category
dtype: object

```

DataFrame creation

Similar to the previous section where a single column was converted to categorical, all columns in a `DataFrame` can be batch converted to categorical either during or after construction.

This can be done during construction by specifying `dtype="category"` in the `DataFrame` constructor:

```
In [17]: df = pd.DataFrame({'A': list('abca'), 'B': list('bccd')}, dtype="category")
In [18]: df.dtypes
Out[18]:
A    category
B    category
dtype: object
```

Note that the categories present in each column differ; the conversion is done column by column, so only labels present in a given column are categories:

```
In [19]: df['A']
Out[19]:
0    a
1    b
2    c
3    a
Name: A, dtype: category
Categories (3, object): [a, b, c]
```

```
In [20]: df['B']
Out[20]:
0    b
1    c
2    c
3    d
Name: B, dtype: category
Categories (3, object): [b, c, d]
```

New in version 0.23.0.

Analogously, all columns in an existing `DataFrame` can be batch converted using `DataFrame.astype()`:

```
In [21]: df = pd.DataFrame({'A': list('abca'), 'B': list('bccd')})
In [22]: df_cat = df.astype('category')
In [23]: df_cat.dtypes
Out[23]:
A    category
B    category
dtype: object
```

This conversion is likewise done column by column:

```
In [24]: df_cat['A']
Out[24]:
0    a
1    b
2    c
3    a
Name: A, dtype: category
Categories (3, object): [a, b, c]
```

```
In [25]: df_cat['B']
Out[25]:
0    b
1    c
2    c
3    d
Name: B, dtype: category
Categories (3, object): [b, c, d]
```

Controlling behavior

In the examples above where we passed `dtype='category'`, we used the default behavior:

1. Categories are inferred from the data.
2. Categories are unordered.

To control those behaviors, instead of passing `'category'`, use an instance of `CategoricalDtype`.

```
In [26]: from pandas.api.types import CategoricalDtype

In [27]: s = pd.Series(["a", "b", "c", "a"])

In [28]: cat_type = CategoricalDtype(categories=["b", "c", "d"],
....:                                     ordered=True)
....:

In [29]: s_cat = s.astype(cat_type)

In [30]: s_cat
Out[30]:
0    NaN
1     b
2     c
3    NaN
dtype: category
Categories (3, object): [b < c < d]
```

Similarly, a `CategoricalDtype` can be used with a `DataFrame` to ensure that categories are consistent among all columns.

```
In [31]: from pandas.api.types import CategoricalDtype

In [32]: df = pd.DataFrame({'A': list('abca'), 'B': list('bccd')})

In [33]: cat_type = CategoricalDtype(categories=list('abcd'),
....:                                     ordered=True)
....:

In [34]: df_cat = df.astype(cat_type)

In [35]: df_cat['A']
Out[35]:
0    a
1    b
```

```
2    c
3    a
Name: A, dtype: category
Categories (4, object): [a < b < c < d]
```

```
In [36]: df_cat['B']
Out[36]:
0    b
1    c
2    c
3    d
Name: B, dtype: category
Categories (4, object): [a < b < c < d]
```

Note: To perform table-wise conversion, where all labels in the entire `DataFrame` are used as categories for each column, the `categories` parameter can be determined programmatically by `categories = pd.unique(df.to_numpy().ravel())`.

If you already have `codes` and `categories`, you can use the `from_codes()` constructor to save the factorize step during normal constructor mode:

```
In [37]: splitter = np.random.choice([0, 1], 5, p=[0.5, 0.5])
In [38]: s = pd.Series(pd.Categorical.from_codes(splitter,
.....:                                         categories=["train", "test"]))
.....:
```

Regaining original data

To get back to the original `Series` or NumPy array, use `Series.astype(original_dtype)` or `np.asarray(categorical)`:

```
In [39]: s = pd.Series(["a", "b", "c", "a"])
```

```
In [40]: s
Out[40]:
0    a
1    b
2    c
3    a
dtype: object
```

```
In [41]: s2 = s.astype('category')
```

```
In [42]: s2
Out[42]:
0    a
1    b
2    c
3    a
dtype: category
Categories (3, object): [a, b, c]
```

```
In [43]: s2.astype(str)
Out[43]:
0    a
1    b
2    c
3    a
dtype: object

In [44]: np.asarray(s2)
Out[44]: array(['a', 'b', 'c', 'a'], dtype=object)
```

Note: In contrast to R's *factor* function, categorical data is not converting input values to strings; categories will end up the same data type as the original values.

Note: In contrast to R's *factor* function, there is currently no way to assign/change labels at creation time. Use *categories* to change the categories after creation time.

4.8.2 CategoricalDtype

Changed in version 0.21.0.

A categorical's type is fully described by

1. **categories:** a sequence of unique values and no missing values
2. **ordered:** a boolean

This information can be stored in a `CategoricalDtype`. The `categories` argument is optional, which implies that the actual categories should be inferred from whatever is present in the data when the `pandas.Categorical` is created. The categories are assumed to be unordered by default.

```
In [45]: from pandas.api.types import CategoricalDtype

In [46]: CategoricalDtype(['a', 'b', 'c'])
Out[46]: CategoricalDtype(categories=['a', 'b', 'c'], ordered=None)

In [47]: CategoricalDtype(['a', 'b', 'c'], ordered=True)
Out[47]: CategoricalDtype(categories=['a', 'b', 'c'], ordered=True)

In [48]: CategoricalDtype()
Out[48]: CategoricalDtype(categories=None, ordered=None)
```

A `CategoricalDtype` can be used in any place pandas expects a *dtype*. For example `pandas.read_csv()`, `pandas.DataFrame.astype()`, or in the `Series` constructor.

Note: As a convenience, you can use the string `'category'` in place of a `CategoricalDtype` when you want the default behavior of the categories being unordered, and equal to the set values present in the array. In other words, `dtype='category'` is equivalent to `dtype=CategoricalDtype()`.

Equality semantics

Two instances of `CategoricalDtype` compare equal whenever they have the same categories and order. When comparing two unordered categoricals, the order of the `categories` is not considered.

```
In [49]: c1 = CategoricalDtype(['a', 'b', 'c'], ordered=False)
```

```
# Equal, since order is not considered when ordered=False
```

```
In [50]: c1 == CategoricalDtype(['b', 'c', 'a'], ordered=False)
```

```
Out[50]: True
```

```
# Unequal, since the second CategoricalDtype is ordered
```

```
In [51]: c1 == CategoricalDtype(['a', 'b', 'c'], ordered=True)
```

```
Out[51]: False
```

All instances of `CategoricalDtype` compare equal to the string `'category'`.

```
In [52]: c1 == 'category'
```

```
Out[52]: True
```

Warning: Since `dtype='category'` is essentially `CategoricalDtype(None, False)`, and since all instances `CategoricalDtype` compare equal to `'category'`, all instances of `CategoricalDtype` compare equal to a `CategoricalDtype(None, False)`, regardless of `categories` or `ordered`.

4.8.3 Description

Using `describe()` on categorical data will produce similar output to a `Series` or `DataFrame` of type `string`.

```
In [53]: cat = pd.Categorical(["a", "c", "c", np.nan], categories=["b", "a", "c"])
```

```
In [54]: df = pd.DataFrame({"cat": cat, "s": ["a", "c", "c", np.nan]})
```

```
In [55]: df.describe()
```

```
Out[55]:
```

```
      cat  s
count    3  3
unique    2  2
top       c  c
freq     2  2
```

```
In [56]: df["cat"].describe()
```

```
Out[56]:
```

```
count    3
unique    2
top       c
freq     2
Name: cat, dtype: object
```

4.8.4 Working with categories

Categorical data has a `categories` and a `ordered` property, which list their possible values and whether the ordering matters or not. These properties are exposed as `s.cat.categories` and `s.cat.ordered`. If you

don't manually specify categories and ordering, they are inferred from the passed arguments.

```
In [57]: s = pd.Series(["a", "b", "c", "a"], dtype="category")
```

```
In [58]: s.cat.categories
```

```
Out[58]: Index(['a', 'b', 'c'], dtype='object')
```

```
In [59]: s.cat.ordered
```

```
Out[59]: False
```

It's also possible to pass in the categories in a specific order:

```
In [60]: s = pd.Series(pd.Categorical(["a", "b", "c", "a"],
....:                               categories=["c", "b", "a"]))
....:
....:
```

```
In [61]: s.cat.categories
```

```
Out[61]: Index(['c', 'b', 'a'], dtype='object')
```

```
In [62]: s.cat.ordered
```

```
Out[62]: False
```

Note: New categorical data are **not** automatically ordered. You must explicitly pass `ordered=True` to indicate an ordered `Categorical`.

Note: The result of `unique()` is not always the same as `Series.cat.categories`, because `Series.unique()` has a couple of guarantees, namely that it returns categories in the order of appearance, and it only includes values that are actually present.

```
In [63]: s = pd.Series(list('babc')).astype(CategoricalDtype(list('abcd')))
```

```
In [64]: s
```

```
Out[64]:
```

```
0    b
```

```
1    a
```

```
2    b
```

```
3    c
```

```
dtype: category
```

```
Categories (4, object): [a, b, c, d]
```

```
# categories
```

```
In [65]: s.cat.categories
```

```
Out[65]: Index(['a', 'b', 'c', 'd'], dtype='object')
```

```
# uniques
```

```
In [66]: s.unique()
```

```
Out[66]:
```

```
[b, a, c]
```

```
Categories (3, object): [b, a, c]
```

Renaming categories

Renaming categories is done by assigning new values to the `Series.cat.categories` property or by using the `rename_categories()` method:

```
In [67]: s = pd.Series(["a", "b", "c", "a"], dtype="category")

In [68]: s
Out[68]:
0    a
1    b
2    c
3    a
dtype: category
Categories (3, object): [a, b, c]

In [69]: s.cat.categories = ["Group %s" % g for g in s.cat.categories]

In [70]: s
Out[70]:
0    Group a
1    Group b
2    Group c
3    Group a
dtype: category
Categories (3, object): [Group a, Group b, Group c]

In [71]: s = s.cat.rename_categories([1, 2, 3])

In [72]: s
Out[72]:
0    1
1    2
2    3
3    1
dtype: category
Categories (3, int64): [1, 2, 3]

# You can also pass a dict-like object to map the renaming
In [73]: s = s.cat.rename_categories({1: 'x', 2: 'y', 3: 'z'})

In [74]: s
Out[74]:
0    x
1    y
2    z
3    x
dtype: category
Categories (3, object): [x, y, z]
```

Note: In contrast to R's *factor*, categorical data can have categories of other types than string.

Note: Be aware that assigning new categories is an inplace operation, while most other operations under `Series.cat` per default return a new `Series` of dtype `category`.

Categories must be unique or a `ValueError` is raised:

```
In [75]: try:
.....:     s.cat.categories = [1, 1, 1]
.....: except ValueError as e:
.....:     print("ValueError:", str(e))
.....:
ValueError: Categorical categories must be unique
```

Categories must also not be NaN or a `ValueError` is raised:

```
In [76]: try:
.....:     s.cat.categories = [1, 2, np.nan]
.....: except ValueError as e:
.....:     print("ValueError:", str(e))
.....:
ValueError: Categorical categories cannot be null
```

Appending new categories

Appending categories can be done by using the `add_categories()` method:

```
In [77]: s = s.cat.add_categories([4])

In [78]: s.cat.categories
Out[78]: Index(['x', 'y', 'z', 4], dtype='object')

In [79]: s
Out[79]:
0    x
1    y
2    z
3    x
dtype: category
Categories (4, object): [x, y, z, 4]
```

Removing categories

Removing categories can be done by using the `remove_categories()` method. Values which are removed are replaced by `np.nan`:

```
In [80]: s = s.cat.remove_categories([4])

In [81]: s
Out[81]:
0    x
1    y
2    z
```

(continues on next page)

(continued from previous page)

```
3    x
dtype: category
Categories (3, object): [x, y, z]
```

Removing unused categories

Removing unused categories can also be done:

```
In [82]: s = pd.Series(pd.Categorical(["a", "b", "a"],
....:                               categories=["a", "b", "c", "d"]))
....:
```

```
In [83]: s
Out[83]:
0    a
1    b
2    a
dtype: category
Categories (4, object): [a, b, c, d]
```

```
In [84]: s.cat.remove_unused_categories()
Out[84]:
0    a
1    b
2    a
dtype: category
Categories (2, object): [a, b]
```

Setting categories

If you want to do remove and add new categories in one step (which has some speed advantage), or simply set the categories to a predefined scale, use `set_categories()`.

```
In [85]: s = pd.Series(["one", "two", "four", "-"], dtype="category")
```

```
In [86]: s
Out[86]:
0    one
1    two
2    four
3     -
dtype: category
Categories (4, object): [-, four, one, two]
```

```
In [87]: s = s.cat.set_categories(["one", "two", "three", "four"])
```

```
In [88]: s
Out[88]:
0    one
1    two
2    four
```

(continues on next page)

(continued from previous page)

```
3      NaN
dtype: category
Categories (4, object): [one, two, three, four]
```

Note: Be aware that `Categorical.set_categories()` cannot know whether some category is omitted intentionally or because it is misspelled or (under Python3) due to a type difference (e.g., NumPy S1 dtype and Python strings). This can result in surprising behaviour!

4.8.5 Sorting and order

If categorical data is ordered (`s.cat.ordered == True`), then the order of the categories has a meaning and certain operations are possible. If the categorical is unordered, `.min()/max()` will raise a `TypeError`.

```
In [89]: s = pd.Series(pd.Categorical(["a", "b", "c", "a"], ordered=False))
```

```
In [90]: s.sort_values(inplace=True)
```

```
In [91]: s = pd.Series(["a", "b", "c", "a"]).astype(
....:     CategoricalDtype(ordered=True)
....: )
....:
```

```
In [92]: s.sort_values(inplace=True)
```

```
In [93]: s
Out[93]:
0      a
3      a
1      b
2      c
dtype: category
Categories (3, object): [a < b < c]
```

```
In [94]: s.min(), s.max()
Out[94]: ('a', 'c')
```

You can set categorical data to be ordered by using `as_ordered()` or unordered by using `as_unordered()`. These will by default return a *new* object.

```
In [95]: s.cat.as_ordered()
Out[95]:
0      a
3      a
1      b
2      c
dtype: category
Categories (3, object): [a < b < c]
```

```
In [96]: s.cat.as_unordered()
Out[96]:
0      a
```

```
3    a
1    b
2    c
dtype: category
Categories (3, object): [a, b, c]
```

Sorting will use the order defined by categories, not any lexical order present on the data type. This is even true for strings and numeric data:

```
In [97]: s = pd.Series([1, 2, 3, 1], dtype="category")
```

```
In [98]: s = s.cat.set_categories([2, 3, 1], ordered=True)
```

```
In [99]: s
Out[99]:
0    1
1    2
2    3
3    1
dtype: category
Categories (3, int64): [2 < 3 < 1]
```

```
In [100]: s.sort_values(inplace=True)
```

```
In [101]: s
Out[101]:
1    2
2    3
0    1
3    1
dtype: category
Categories (3, int64): [2 < 3 < 1]
```

```
In [102]: s.min(), s.max()
Out[102]: (2, 1)
```

Reordering

Reordering the categories is possible via the `Categorical.reorder_categories()` and the `Categorical.set_categories()` methods. For `Categorical.reorder_categories()`, all old categories must be included in the new categories and no new categories are allowed. This will necessarily make the sort order the same as the categories order.

```
In [103]: s = pd.Series([1, 2, 3, 1], dtype="category")
```

```
In [104]: s = s.cat.reorder_categories([2, 3, 1], ordered=True)
```

```
In [105]: s
Out[105]:
0    1
1    2
2    3
3    1
dtype: category
Categories (3, int64): [2 < 3 < 1]
```

```
In [106]: s.sort_values(inplace=True)
```

```
In [107]: s
```

```
Out[107]:
```

```
1    2
2    3
0    1
3    1
dtype: category
Categories (3, int64): [2 < 3 < 1]
```

```
In [108]: s.min(), s.max()
```

```
Out[108]: (2, 1)
```

Note: Note the difference between assigning new categories and reordering the categories: the first renames categories and therefore the individual values in the `Series`, but if the first position was sorted last, the renamed value will still be sorted last. Reordering means that the way values are sorted is different afterwards, but not that individual values in the `Series` are changed.

Note: If the `Categorical` is not ordered, `Series.min()` and `Series.max()` will raise `TypeError`. Numeric operations like `+`, `-`, `*`, `/` and operations based on them (e.g. `Series.median()`, which would need to compute the mean between two values if the length of an array is even) do not work and raise a `TypeError`.

Multi column sorting

A categorical dtyped column will participate in a multi-column sort in a similar manner to other columns. The ordering of the categorical is determined by the `categories` of that column.

```
In [109]: dfs = pd.DataFrame({'A': pd.Categorical(list('bbeebbaa'),
.....:                                     categories=['e', 'a', 'b'],
.....:                                     ordered=True),
.....:                       'B': [1, 2, 1, 2, 2, 1, 2, 1]})
.....:
```

```
In [110]: dfs.sort_values(by=['A', 'B'])
```

```
Out[110]:
```

```
  A  B
2  e  1
3  e  2
7  a  1
6  a  2
0  b  1
5  b  1
1  b  2
4  b  2
```

Reordering the `categories` changes a future sort.

```
In [111]: dfs['A'] = dfs['A'].cat.reorder_categories(['a', 'b', 'e'])
```

```
In [112]: dfs.sort_values(by=['A', 'B'])
```

```
Out[112]:
```

```
   A B
7  a  1
6  a  2
0  b  1
5  b  1
1  b  2
4  b  2
2  e  1
3  e  2
```

4.8.6 Comparisons

Comparing categorical data with other objects is possible in three cases:

- Comparing equality (`==` and `!=`) to a list-like object (list, Series, array, ...) of the same length as the categorical data.
- All comparisons (`==`, `!=`, `>`, `>=`, `<`, and `<=`) of categorical data to another categorical Series, when `ordered=True` and the *categories* are the same.
- All comparisons of a categorical data to a scalar.

All other comparisons, especially “non-equality” comparisons of two categoricals with different categories or a categorical with any list-like object, will raise a `TypeError`.

Note: Any “non-equality” comparisons of categorical data with a `Series`, `np.array`, `list` or categorical data with different categories or ordering will raise a `TypeError` because custom categories ordering could be interpreted in two ways: one with taking into account the ordering and one without.

```
In [113]: cat = pd.Series([1, 2, 3]).astype(
.....:     CategoricalDtype([3, 2, 1], ordered=True)
.....: )
.....:
```

```
In [114]: cat_base = pd.Series([2, 2, 2]).astype(
.....:     CategoricalDtype([3, 2, 1], ordered=True)
.....: )
.....:
```

```
In [115]: cat_base2 = pd.Series([2, 2, 2]).astype(
.....:     CategoricalDtype(ordered=True)
.....: )
.....:
```

```
In [116]: cat
```

```
Out[116]:
```

```
0    1
1    2
2    3
```

```
dtype: category
Categories (3, int64): [3 < 2 < 1]
```

```
In [117]: cat_base
Out[117]:
0    2
1    2
2    2
dtype: category
Categories (3, int64): [3 < 2 < 1]
```

```
In [118]: cat_base2
Out[118]:
0    2
1    2
2    2
dtype: category
Categories (1, int64): [2]
```

Comparing to a categorical with the same categories and ordering or to a scalar works:

```
In [119]: cat > cat_base
Out[119]:
0    True
1   False
2   False
dtype: bool
```

```
In [120]: cat > 2
Out[120]:
0    True
1   False
2   False
dtype: bool
```

Equality comparisons work with any list-like object of same length and scalars:

```
In [121]: cat == cat_base
Out[121]:
0   False
1    True
2   False
dtype: bool
```

```
In [122]: cat == np.array([1, 2, 3])
Out[122]:
0    True
1    True
2    True
dtype: bool
```

```
In [123]: cat == 2
Out[123]:
0   False
1    True
2   False
```

dtype: bool

This doesn't work because the categories are not the same:

```
In [124]: try:
.....:     cat > cat_base2
.....: except TypeError as e:
.....:     print("TypeError:", str(e))
.....:
TypeError: Categoricals can only be compared if 'categories' are the same. Categories
↪are different lengths
```

If you want to do a “non-equality” comparison of a categorical series with a list-like object which is not categorical data, you need to be explicit and convert the categorical data back to the original values:

```
In [125]: base = np.array([1, 2, 3])
```

```
In [126]: try:
.....:     cat > base
.....: except TypeError as e:
.....:     print("TypeError:", str(e))
.....:
TypeError: Cannot compare a Categorical for op __gt__ with type <class 'numpy.ndarray'>.
If you want to compare values, use 'np.asarray(cat) <op> other'.
```

```
In [127]: np.asarray(cat) > base
Out[127]: array([False, False, False])
```

When you compare two unordered categoricals with the same categories, the order is not considered:

```
In [128]: c1 = pd.Categorical(['a', 'b'], categories=['a', 'b'], ordered=False)
In [129]: c2 = pd.Categorical(['a', 'b'], categories=['b', 'a'], ordered=False)
In [130]: c1 == c2
Out[130]: array([ True,  True])
```

4.8.7 Operations

Apart from `Series.min()`, `Series.max()` and `Series.mode()`, the following operations are possible with categorical data:

`Series` methods like `Series.value_counts()` will use all categories, even if some categories are not present in the data:

```
In [131]: s = pd.Series(pd.Categorical(["a", "b", "c", "c"],
.....:                                 categories=["c", "a", "b", "d"]))
.....:
.....:
In [132]: s.value_counts()
Out[132]:
c    2
b    1
a    1
```

(continues on next page)

(continued from previous page)

```
d      0
dtype: int64
```

Groupby will also show “unused” categories:

```
In [133]: cats = pd.Categorical(["a", "b", "b", "b", "c", "c", "c"],
.....:                        categories=["a", "b", "c", "d"])
.....:

In [134]: df = pd.DataFrame({"cats": cats, "values": [1, 2, 2, 2, 3, 4, 5]})

In [135]: df.groupby("cats").mean()
Out[135]:
      values
cats
a         1.0
b         2.0
c         4.0
d         NaN

In [136]: cats2 = pd.Categorical(["a", "a", "b", "b"], categories=["a", "b", "c"])

In [137]: df2 = pd.DataFrame({"cats": cats2,
.....:                       "B": ["c", "d", "c", "d"],
.....:                       "values": [1, 2, 3, 4]})
.....:

In [138]: df2.groupby(["cats", "B"]).mean()
Out[138]:
      values
cats B
a   c     1.0
   d     2.0
b   c     3.0
   d     4.0
c   c     NaN
   d     NaN
```

Pivot tables:

```
In [139]: raw_cat = pd.Categorical(["a", "a", "b", "b"], categories=["a", "b", "c"])

In [140]: df = pd.DataFrame({"A": raw_cat,
.....:                      "B": ["c", "d", "c", "d"],
.....:                      "values": [1, 2, 3, 4]})
.....:

In [141]: pd.pivot_table(df, values='values', index=['A', 'B'])
Out[141]:
      values
A B
a c         1
```

4.8.8 Data munging

The optimized pandas data access methods `.loc`, `.iloc`, `.at`, and `.iat`, work as normal. The only difference is the return type (for getting) and that only values already in *categories* can be assigned.

Getting

If the slicing operation returns either a `DataFrame` or a column of type `Series`, the `category` dtype is preserved.

```
In [142]: idx = pd.Index(["h", "i", "j", "k", "l", "m", "n"])
```

```
In [143]: cats = pd.Series(["a", "b", "b", "b", "c", "c", "c"],
.....:                      dtype="category", index=idx)
.....:
```

```
In [144]: values = [1, 2, 2, 2, 3, 4, 5]
```

```
In [145]: df = pd.DataFrame({"cats": cats, "values": values}, index=idx)
```

```
In [146]: df.iloc[2:4, :]
```

```
Out[146]:
   cats  values
j     b        2
k     b        2
```

```
In [147]: df.iloc[2:4, :].dtypes
```

```
Out[147]:
cats      category
values    int64
dtype: object
```

```
In [148]: df.loc["h":"j", "cats"]
```

```
Out[148]:
h     a
i     b
j     b
Name: cats, dtype: category
Categories (3, object): [a, b, c]
```

```
In [149]: df[df["cats"] == "b"]
```

```
Out[149]:
   cats  values
i     b        2
j     b        2
k     b        2
```

An example where the category type is not preserved is if you take one single row: the resulting Series is of dtype object:

```
# get the complete "h" row as a Series
In [150]: df.loc["h", :]
Out[150]:
cats      a
values    1
Name: h, dtype: object
```

Returning a single item from categorical data will also return the value, not a categorical of length “1”.

```
In [151]: df.iat[0, 0]
Out[151]: 'a'

In [152]: df["cats"].cat.categories = ["x", "y", "z"]

In [153]: df.at["h", "cats"] # returns a string
Out[153]: 'x'
```

Note: This is in contrast to R’s *factor* function, where `factor(c(1,2,3))[1]` returns a single value *factor*.

To get a single value Series of type category, you pass in a list with a single value:

```
In [154]: df.loc[["h"], "cats"]
Out[154]:
h      x
Name: cats, dtype: category
Categories (3, object): [x, y, z]
```

String and datetime accessors

The accessors `.dt` and `.str` will work if the `s.cat.categories` are of an appropriate type:

```
In [155]: str_s = pd.Series(list('aabb'))
```

```
In [156]: str_cat = str_s.astype('category')
```

```
In [157]: str_cat
Out[157]:
0      a
1      a
2      b
3      b
dtype: category
Categories (2, object): [a, b]
```

```
In [158]: str_cat.str.contains("a")
Out[158]:
0      True
1      True
2     False
```

```
3    False
dtype: bool
```

```
In [159]: date_s = pd.Series(pd.date_range('1/1/2015', periods=5))
```

```
In [160]: date_cat = date_s.astype('category')
```

```
In [161]: date_cat
```

```
Out[161]:
```

```
0    2015-01-01
1    2015-01-02
2    2015-01-03
3    2015-01-04
4    2015-01-05
```

```
dtype: category
```

```
Categories (5, datetime64[ns]): [2015-01-01, 2015-01-02, 2015-01-03, 2015-01-04, 2015-01-05]
```

```
In [162]: date_cat.dt.day
```

```
Out[162]:
```

```
0     1
1     2
2     3
3     4
4     5
```

```
dtype: int64
```

Note: The returned `Series` (or `DataFrame`) is of the same type as if you used the `.str.<method>` / `.dt.<method>` on a `Series` of that type (and not of type `category`!).

That means, that the returned values from methods and properties on the accessors of a `Series` and the returned values from methods and properties on the accessors of this `Series` transformed to one of type `category` will be equal:

```
In [163]: ret_s = str_s.str.contains("a")
```

```
In [164]: ret_cat = str_cat.str.contains("a")
```

```
In [165]: ret_s.dtype == ret_cat.dtype
```

```
Out[165]: True
```

```
In [166]: ret_s == ret_cat
```

```
Out[166]:
```

```
0     True
1     True
2     True
3     True
```

```
dtype: bool
```

Note: The work is done on the `categories` and then a new `Series` is constructed. This has some performance implication if you have a `Series` of type string, where lots of elements are repeated (i.e. the number of unique elements in the `Series` is a lot smaller than the length of the `Series`). In this case it can be faster to convert the original `Series` to one of type `category` and use `.str.<method>` or `.dt.<property>`

on that.

Setting

Setting values in a categorical column (or `Series`) works as long as the value is included in the *categories*:

```
In [167]: idx = pd.Index(["h", "i", "j", "k", "l", "m", "n"])
```

```
In [168]: cats = pd.Categorical(["a", "a", "a", "a", "a", "a", "a"],
.....:                          categories=["a", "b"])
.....:
```

```
In [169]: values = [1, 1, 1, 1, 1, 1, 1]
```

```
In [170]: df = pd.DataFrame({"cats": cats, "values": values}, index=idx)
```

```
In [171]: df.iloc[2:4, :] = [["b", 2], ["b", 2]]
```

```
In [172]: df
```

```
Out[172]:
   cats  values
h     a      1
i     a      1
j     b      2
k     b      2
l     a      1
m     a      1
n     a      1
```

```
In [173]: try:
.....:     df.iloc[2:4, :] = [["c", 3], ["c", 3]]
.....: except ValueError as e:
.....:     print("ValueError:", str(e))
.....:
```

ValueError: Cannot setitem on a Categorical with a new category, set the categories first

Setting values by assigning categorical data will also check that the *categories* match:

```
In [174]: df.loc["j":"k", "cats"] = pd.Categorical(["a", "a"], categories=["a", "b"])
```

```
In [175]: df
```

```
Out[175]:
   cats  values
h     a      1
i     a      1
j     a      2
k     a      2
l     a      1
m     a      1
n     a      1
```

```
In [176]: try:
.....:     df.loc["j":"k", "cats"] = pd.Categorical(["b", "b"],
.....:                                               categories=["a", "b", "c"])
```

```
.....: except ValueError as e:
.....:     print("ValueError:", str(e))
.....:
ValueError: Cannot set a Categorical with another, without identical categories
Assigning a Categorical to parts of a column of other types will use the values:
In [177]: df = pd.DataFrame({"a": [1, 1, 1, 1, 1], "b": ["a", "a", "a", "a", "a"]})
In [178]: df.loc[1:2, "a"] = pd.Categorical(["b", "b"], categories=["a", "b"])
In [179]: df.loc[2:3, "b"] = pd.Categorical(["b", "b"], categories=["a", "b"])

In [180]: df
Out[180]:
   a  b
0  1  a
1  b  a
2  b  b
3  1  b
4  1  a

In [181]: df.dtypes
Out[181]:
a    object
b    object
dtype: object
```

Merging

You can concat two `DataFrames` containing categorical data together, but the categories of these categoricals need to be the same:

```
In [182]: cat = pd.Series(["a", "b"], dtype="category")
In [183]: vals = [1, 2]
In [184]: df = pd.DataFrame({"cats": cat, "vals": vals})
In [185]: res = pd.concat([df, df])

In [186]: res
Out[186]:
   cats  vals
0    a     1
1    b     2
0    a     1
1    b     2

In [187]: res.dtypes
Out[187]:
cats    category
vals      int64
dtype: object
```

In this case the categories are not the same, and therefore an error is raised:

```
In [188]: df_different = df.copy()

In [189]: df_different["cats"].cat.categories = ["c", "d"]

In [190]: try:
.....:     pd.concat([df, df_different])
.....: except ValueError as e:
.....:     print("ValueError:", str(e))
.....:
```

The same applies to `df.append(df_different)`.

See also the section on *merge dtypes* for notes about preserving merge dtypes and performance.

Unioning

New in version 0.19.0.

If you want to combine categoricals that do not necessarily have the same categories, the `union_categoricals()` function will combine a list-like of categoricals. The new categories will be the union of the categories being combined.

```
In [191]: from pandas.api.types import union_categoricals

In [192]: a = pd.Categorical(["b", "c"])

In [193]: b = pd.Categorical(["a", "b"])

In [194]: union_categoricals([a, b])
Out[194]:
[b, c, a, b]
Categories (3, object): [b, c, a]
```

By default, the resulting categories will be ordered as they appear in the data. If you want the categories to be lexsorted, use `sort_categories=True` argument.

```
In [195]: union_categoricals([a, b], sort_categories=True)
Out[195]:
[b, c, a, b]
Categories (3, object): [a, b, c]
```

`union_categoricals` also works with the “easy” case of combining two categoricals of the same categories and order information (e.g. what you could also `append` for).

```
In [196]: a = pd.Categorical(["a", "b"], ordered=True)

In [197]: b = pd.Categorical(["a", "b", "a"], ordered=True)

In [198]: union_categoricals([a, b])
Out[198]:
[a, b, a, b, a]
Categories (2, object): [a < b]
```

The below raises `TypeError` because the categories are ordered and not identical.

```
In [1]: a = pd.Categorical(["a", "b"], ordered=True)
In [2]: b = pd.Categorical(["a", "b", "c"], ordered=True)
In [3]: union_categoricals([a, b])
Out[3]:
TypeError: to union ordered Categoricals, all categories must be the same
```

New in version 0.20.0.

Ordered categoricals with different categories or orderings can be combined by using the `ignore_ordered=True` argument.

```
In [199]: a = pd.Categorical(["a", "b", "c"], ordered=True)
In [200]: b = pd.Categorical(["c", "b", "a"], ordered=True)
In [201]: union_categoricals([a, b], ignore_order=True)
Out[201]:
[a, b, c, c, b, a]
Categories (3, object): [a, b, c]
```

`union_categoricals()` also works with a `CategoricalIndex`, or `Series` containing categorical data, but note that the resulting array will always be a plain `Categorical`:

```
In [202]: a = pd.Series(["b", "c"], dtype='category')
In [203]: b = pd.Series(["a", "b"], dtype='category')
In [204]: union_categoricals([a, b])
Out[204]:
[b, c, a, b]
Categories (3, object): [b, c, a]
```

Note: `union_categoricals` may recode the integer codes for categories when combining categoricals. This is likely what you want, but if you are relying on the exact numbering of the categories, be aware.

```
In [205]: c1 = pd.Categorical(["b", "c"])
```

```
In [206]: c2 = pd.Categorical(["a", "b"])
```

```
In [207]: c1
Out[207]:
[b, c]
Categories (2, object): [b, c]
```

```
# "b" is coded to 0
In [208]: c1.codes
Out[208]: array([0, 1], dtype=int8)
```

```
In [209]: c2
Out[209]:
[a, b]
Categories (2, object): [a, b]
```

```

# "b" is coded to 1
In [210]: c2.codes
Out[210]: array([0, 1], dtype=int8)

In [211]: c = union_categoricals([c1, c2])

In [212]: c
Out[212]:
[b, c, a, b]
Categories (3, object): [b, c, a]

# "b" is coded to 0 throughout, same as c1, different from c2
In [213]: c.codes
Out[213]: array([0, 1, 2, 0], dtype=int8)

```

Concatenation

This section describes concatenations specific to `category` dtype. See *Concatenating objects* for general description.

By default, `Series` or `DataFrame` concatenation which contains the same categories results in `category` dtype, otherwise results in `object` dtype. Use `.astype` or `union_categoricals` to get `category` result.

```

# same categories
In [214]: s1 = pd.Series(['a', 'b'], dtype='category')

In [215]: s2 = pd.Series(['a', 'b', 'a'], dtype='category')

In [216]: pd.concat([s1, s2])
Out[216]:
0    a
1    b
0    a
1    b
2    a
dtype: category
Categories (2, object): [a, b]

# different categories
In [217]: s3 = pd.Series(['b', 'c'], dtype='category')

In [218]: pd.concat([s1, s3])
Out[218]:
0    a
1    b
0    b
1    c
dtype: object

In [219]: pd.concat([s1, s3]).astype('category')
Out[219]:
0    a
1    b

```

```
0    b
1    c
dtype: category
Categories (3, object): [a, b, c]
```

```
In [220]: union_categoricals([s1.array, s3.array])
Out[220]:
[a, b, b, c]
Categories (3, object): [a, b, c]
```

Following table summarizes the results of `Categoricals` related concatenations.

arg1	arg2	result
category	category (identical categories)	category
category	category (different categories, both not ordered)	object (dtype is inferred)
category	category (different categories, either one is ordered)	object (dtype is inferred)
category	not category	object (dtype is inferred)

4.8.9 Getting data in/out

You can write data that contains `category` dtypes to a `HDFStore`. See [here](#) for an example and caveats.

It is also possible to write data to and reading data from *Stata* format files. See [here](#) for an example and caveats.

Writing to a CSV file will convert the data, effectively removing any information about the categorical (categories and ordering). So if you read back the CSV file you have to convert the relevant columns back to `category` and assign the right categories and categories ordering.

```
In [221]: import io
```

```
In [222]: s = pd.Series(pd.Categorical(['a', 'b', 'b', 'a', 'a', 'd']))
```

```
# rename the categories
```

```
In [223]: s.cat.categories = ["very good", "good", "bad"]
```

```
# reorder the categories and add missing categories
```

```
In [224]: s = s.cat.set_categories(["very bad", "bad", "medium", "good", "very good"])
```

```
In [225]: df = pd.DataFrame({"cats": s, "vals": [1, 2, 3, 4, 5, 6]})
```

```
In [226]: csv = io.StringIO()
```

```
In [227]: df.to_csv(csv)
```

```
In [228]: df2 = pd.read_csv(io.StringIO(csv.getvalue()))
```

```
In [229]: df2.dtypes
```

```
Out[229]:
Unnamed: 0    int64
cats         object
vals         int64
dtype: object
```

```

In [230]: df2["cats"]
Out[230]:
0    very good
1         good
2         good
3    very good
4    very good
5         bad
Name: cats, dtype: object

# Redo the category
In [231]: df2["cats"] = df2["cats"].astype("category")

In [232]: df2["cats"].cat.set_categories(["very bad", "bad", "medium",
.....:                                "good", "very good"],
.....:                                inplace=True)
.....:

In [233]: df2.dtypes
Out[233]:
Unnamed: 0    int64
cats         category
vals         int64
dtype: object

In [234]: df2["cats"]
Out[234]:
0    very good
1         good
2         good
3    very good
4    very good
5         bad
Name: cats, dtype: category
Categories (5, object): [very bad, bad, medium, good, very good]

The same holds for writing to a SQL database with to_sql.

```

4.8.10 Missing data

pandas primarily uses the value `np.nan` to represent missing data. It is by default not included in computations. See the *Missing Data section*.

Missing values should **not** be included in the Categorical's `categories`, only in the `values`. Instead, it is understood that NaN is different, and is always a possibility. When working with the Categorical's `codes`, missing values will always have a code of `-1`.

```

In [235]: s = pd.Series(["a", "b", np.nan, "a"], dtype="category")

# only two categories
In [236]: s
Out[236]:
0    a
1    b
2  NaN

```

```
3      a
dtype: category
Categories (2, object): [a, b]
```

```
In [237]: s.cat.codes
Out[237]:
0      0
1      1
2     -1
3      0
dtype: int8
```

Methods for working with missing data, e.g. `isna()`, `fillna()`, `dropna()`, all work normally:

```
In [238]: s = pd.Series(["a", "b", np.nan], dtype="category")
```

```
In [239]: s
Out[239]:
0      a
1      b
2     NaN
dtype: category
Categories (2, object): [a, b]
```

```
In [240]: pd.isna(s)
Out[240]:
0    False
1    False
2     True
dtype: bool
```

```
In [241]: s.fillna("a")
Out[241]:
0      a
1      b
2      a
dtype: category
Categories (2, object): [a, b]
```

4.8.11 Differences to R's *factor*

The following differences to R's factor functions can be observed:

- R's *levels* are named *categories*.
- R's *levels* are always of type string, while *categories* in pandas can be of any dtype.
- It's not possible to specify labels at creation time. Use `s.cat.rename_categories(new_labels)` afterwards.
- In contrast to R's *factor* function, using categorical data as the sole input to create a new categorical series will *not* remove unused categories but create a new categorical series which is equal to the passed in one!
- R allows for missing values to be included in its *levels* (pandas' *categories*). Pandas does not allow *NaN* categories, but missing values can still be in the *values*.

4.8.12 Gotchas

Memory usage

The memory usage of a `Categorical` is proportional to the number of categories plus the length of the data. In contrast, an `object` dtype is a constant times the length of the data.

```
In [242]: s = pd.Series(['foo', 'bar'] * 1000)
```

```
# object dtype
```

```
In [243]: s.nbytes
```

```
Out[243]: 16000
```

```
# category dtype
```

```
In [244]: s.astype('category').nbytes
```

```
Out[244]: 2016
```

Note: If the number of categories approaches the length of the data, the `Categorical` will use nearly the same or more memory than an equivalent `object` dtype representation.

```
In [245]: s = pd.Series(['foo%04d' % i for i in range(2000)])
```

```
# object dtype
```

```
In [246]: s.nbytes
```

```
Out[246]: 16000
```

```
# category dtype
```

```
In [247]: s.astype('category').nbytes
```

```
Out[247]: 20000
```

Categorical is not a numpy array

Currently, categorical data and the underlying `Categorical` is implemented as a Python object and not as a low-level NumPy array dtype. This leads to some problems.

NumPy itself doesn't know about the new *dtype*:

```
In [248]: try:
.....:     np.dtype("category")
.....: except TypeError as e:
.....:     print("TypeError:", str(e))
.....:
TypeError: data type "category" not understood
```

```
In [249]: dtype = pd.Categorical(["a"]).dtype
```

```
In [250]: try:
.....:     np.dtype(dtype)
.....: except TypeError as e:
.....:     print("TypeError:", str(e))
.....:
TypeError: data type not understood
```

Dtype comparisons work:

```
In [251]: dtype == np.str_
Out[251]: False
```

```
In [252]: np.str_ == dtype
Out[252]: False
```

To check if a Series contains Categorical data, use `hasattr(s, 'cat')`:

```
In [253]: hasattr(pd.Series(['a']), dtype='category'), 'cat')
Out[253]: True
```

```
In [254]: hasattr(pd.Series(['a']), 'cat')
Out[254]: False
```

Using NumPy functions on a Series of type `category` should not work as *Categoricals* are not numeric data (even in the case that `.categories` is numeric).

```
In [255]: s = pd.Series(pd.Categorical([1, 2, 3, 4]))

In [256]: try:
.....:     np.sum(s)
.....: except TypeError as e:
.....:     print("TypeError:", str(e))
.....:
TypeError: Categorical cannot perform the operation sum
```

Note: If such a function works, please file a bug at <https://github.com/pandas-dev/pandas!>

dtype in apply

Pandas currently does not preserve the dtype in apply functions: If you apply along rows you get a *Series* of object *dtype* (same as getting a row -> getting one element will return a basic type) and applying along columns will also convert to object. NaN values are unaffected. You can use `fillna` to handle missing values before applying a function.

```
In [257]: df = pd.DataFrame({"a": [1, 2, 3, 4],
.....:                      "b": ["a", "b", "c", "d"],
.....:                      "cats": pd.Categorical([1, 2, 3, 2])})
.....:
```

```
In [258]: df.apply(lambda row: type(row["cats"]), axis=1)
Out[258]:
0    <class 'int'>
1    <class 'int'>
2    <class 'int'>
3    <class 'int'>
dtype: object
```

```
In [259]: df.apply(lambda col: col.dtype, axis=0)
Out[259]:
a      int64
b      object
```

```
cats    category
dtype: object
```

Categorical index

`CategoricalIndex` is a type of index that is useful for supporting indexing with duplicates. This is a container around a `Categorical` and allows efficient indexing and storage of an index with a large number of duplicated elements. See the [advanced indexing docs](#) for a more detailed explanation.

Setting the index will create a `CategoricalIndex`:

```
In [260]: cats = pd.Categorical([1, 2, 3, 4], categories=[4, 2, 3, 1])
```

```
In [261]: strings = ["a", "b", "c", "d"]
```

```
In [262]: values = [4, 2, 3, 1]
```

```
In [263]: df = pd.DataFrame({"strings": strings, "values": values}, index=cats)
```

```
In [264]: df.index
```

```
Out[264]: CategoricalIndex([1, 2, 3, 4], categories=[4, 2, 3, 1], ordered=False,
↳ dtype='category')
```

```
# This now sorts by the categories order
```

```
In [265]: df.sort_index()
```

```
Out[265]:
```

```
   strings  values
4        d         1
2        b         2
3        c         3
1        a         4
```

Side effects

Constructing a `Series` from a `Categorical` will not copy the input `Categorical`. This means that changes to the `Series` will in most cases change the original `Categorical`:

```
In [266]: cat = pd.Categorical([1, 2, 3, 10], categories=[1, 2, 3, 4, 10])
```

```
In [267]: s = pd.Series(cat, name="cat")
```

```
In [268]: cat
```

```
Out[268]:
```

```
[1, 2, 3, 10]
```

```
Categories (5, int64): [1, 2, 3, 4, 10]
```

```
In [269]: s.iloc[0:2] = 10
```

```
In [270]: cat
```

```
Out[270]:
```

```
[10, 10, 3, 10]
```

```
Categories (5, int64): [1, 2, 3, 4, 10]
```

(continues on next page)

(continued from previous page)

```
In [271]: df = pd.DataFrame(s)

In [272]: df["cat"].cat.categories = [1, 2, 3, 4, 5]

In [273]: cat
Out[273]:
[5, 5, 3, 5]
Categories (5, int64): [1, 2, 3, 4, 5]
```

Use `copy=True` to prevent such a behaviour or simply don't reuse `Categoricals`:

```
In [274]: cat = pd.Categorical([1, 2, 3, 10], categories=[1, 2, 3, 4, 10])

In [275]: s = pd.Series(cat, name="cat", copy=True)

In [276]: cat
Out[276]:
[1, 2, 3, 10]
Categories (5, int64): [1, 2, 3, 4, 10]

In [277]: s.iloc[0:2] = 10

In [278]: cat
Out[278]:
[1, 2, 3, 10]
Categories (5, int64): [1, 2, 3, 4, 10]
```

Note: This also happens in some cases when you supply a NumPy array instead of a `Categorical`: using an int array (e.g. `np.array([1,2,3,4])`) will exhibit the same behavior, while using a string array (e.g. `np.array(["a","b","c","a"])`) will not.

{{ header }}

4.9 Nullable integer data type

New in version 0.24.0.

Note: `IntegerArray` is currently experimental. Its API or implementation may change without warning.

In [Missing Data](#), we saw that pandas primarily uses `NaN` to represent missing data. Because `NaN` is a float, this forces an array of integers with any missing values to become floating point. In some cases, this may not matter much. But if your integer column is, say, an identifier, casting to float can be problematic. Some integers cannot even be represented as floating point numbers.

Pandas can represent integer data with possibly missing values using `arrays.IntegerArray`. This is an *extension types* implemented within pandas. It is not the default dtype for integers, and will not be inferred; you must explicitly pass the dtype into `array()` or `Series`:

```
In [1]: arr = pd.array([1, 2, np.nan], dtype=pd.Int64Dtype())
```

```
In [2]: arr
```

```
Out[2]:
```

```
<IntegerArray>
```

```
[1, 2, NaN]
```

```
Length: 3, dtype: Int64
```

Or the string alias "Int64" (note the capital "I", to differentiate from NumPy's 'int64' dtype):

```
In [3]: pd.array([1, 2, np.nan], dtype="Int64")
```

```
Out[3]:
```

```
<IntegerArray>
```

```
[1, 2, NaN]
```

```
Length: 3, dtype: Int64
```

This array can be stored in a *DataFrame* or *Series* like any NumPy array.

```
In [4]: pd.Series(arr)
```

```
Out[4]:
```

```
0      1
```

```
1      2
```

```
2     NaN
```

```
dtype: Int64
```

You can also pass the list-like object to the *Series* constructor with the dtype.

```
In [5]: s = pd.Series([1, 2, np.nan], dtype="Int64")
```

```
In [6]: s
```

```
Out[6]:
```

```
0      1
```

```
1      2
```

```
2     NaN
```

```
dtype: Int64
```

By default (if you don't specify dtype), NumPy is used, and you'll end up with a `float64` dtype Series:

```
In [7]: pd.Series([1, 2, np.nan])
```

```
Out[7]:
```

```
0     1.0
```

```
1     2.0
```

```
2     NaN
```

```
dtype: float64
```

Operations involving an integer array will behave similar to NumPy arrays. Missing values will be propagated, and the data will be coerced to another dtype if needed.

```
# arithmetic
```

```
In [8]: s + 1
```

```
Out[8]:
```

```
0      2
```

```
1      3
```

```
2     NaN
```

```
dtype: Int64
```

```
# comparison
In [9]: s == 1
Out[9]:
0    True
1   False
2   False
dtype: bool

# indexing
In [10]: s.iloc[1:3]
Out[10]:
1     2
2   NaN
dtype: Int64

# operate with other dtypes
In [11]: s + s.iloc[1:3].astype('Int8')
Out[11]:
0   NaN
1     4
2   NaN
dtype: Int64
```

```
# coerce when needed
In [12]: s + 0.01
Out[12]:
0    1.01
1    2.01
2     NaN
dtype: float64
```

These dtypes can operate as part of of DataFrame.

```
In [13]: df = pd.DataFrame({'A': s, 'B': [1, 1, 3], 'C': list('aab')})
```

```
In [14]: df
Out[14]:
   A  B  C
0   1  1  a
1   2  1  a
2  NaN  3  b
```

```
In [15]: df.dtypes
Out[15]:
A    Int64
B    int64
C    object
dtype: object
```

These dtypes can be merged & reshaped & casted.

```
In [16]: pd.concat([df[['A']], df[['B', 'C']], axis=1).dtypes
Out[16]:
A    Int64
B    int64
```

```
C    object
dtype: object
```

```
In [17]: df['A'].astype(float)
Out[17]:
0    1.0
1    2.0
2    NaN
Name: A, dtype: float64
```

Reduction and groupby operations such as ‘sum’ work as well.

```
In [18]: df.sum()
Out[18]:
A      3
B      5
C    aab
dtype: object
```

```
In [19]: df.groupby('B').A.sum()
Out[19]:
B
1      3
3      0
Name: A, dtype: Int64
{{ header }}
```

4.10 Visualization

We use the standard convention for referencing the matplotlib API:

```
In [1]: import matplotlib.pyplot as plt
In [2]: plt.close('all')
```

We provide the basics in pandas to easily create decent looking plots. See the *ecosystem* section for visualization libraries that go beyond the basics documented here.

Note: All calls to `np.random` are seeded with 123456.

4.10.1 Basic plotting: plot

We will demonstrate the basics, see the *cookbook* for some advanced strategies.

The `plot` method on Series and DataFrame is just a simple wrapper around `plt.plot()`:

```
In [3]: ts = pd.Series(np.random.randn(1000),
...:                  index=pd.date_range('1/1/2000', periods=1000))
...:
...:
```

(continues on next page)

(continued from previous page)

```
In [4]: ts = ts.cumsum()
```

```
In [5]: ts.plot()
```

```
Out[5]: <matplotlib.axes._subplots.AxesSubplot at 0x13fc51490>
```

If the index consists of dates, it calls `gcf().autofmt_xdate()` to try to format the x-axis nicely as per above.

On `DataFrame`, `plot()` is a convenience to plot all of the columns with labels:

```
In [6]: df = pd.DataFrame(np.random.randn(1000, 4),
...:                      index=ts.index, columns=list('ABCD'))
...:
```

```
In [7]: df = df.cumsum()
```

```
In [8]: plt.figure();
```

```
In [9]: df.plot();
```

You can plot one column versus another using the *x* and *y* keywords in `plot()`:

```
In [10]: df3 = pd.DataFrame(np.random.randn(1000, 2), columns=['B', 'C']).cumsum()
```

```
In [11]: df3['A'] = pd.Series(list(range(len(df))))
```

```
In [12]: df3.plot(x='A', y='B')
```

```
Out[12]: <matplotlib.axes._subplots.AxesSubplot at 0x14e8e3b90>
```

Note: For more formatting and styling options, see *formatting* below.

4.10.2 Other plots

Plotting methods allow for a handful of plot styles other than the default line plot. These methods can be provided as the `kind` keyword argument to `plot()`, and include:

- `'bar'` or `'barh'` for bar plots
- `'hist'` for histogram
- `'box'` for boxplot
- `'kde'` or `'density'` for density plots
- `'area'` for area plots
- `'scatter'` for scatter plots
- `'hexbin'` for hexagonal bin plots
- `'pie'` for pie plots

For example, a bar plot can be created the following way:

```
In [13]: plt.figure();
```

```
In [14]: df.iloc[5].plot(kind='bar');
```

You can also create these other plots using the methods `DataFrame.plot.<kind>` instead of providing the `kind` keyword argument. This makes it easier to discover plot methods and the specific arguments they use:

```
In [15]: df = pd.DataFrame()
```

```
In [16]: df.plot.<TAB> # noqa: E225, E999
```

```
df.plot.area      df.plot.barh      df.plot.density  df.plot.hist      df.plot.line      df.
↳plot.scatter
df.plot.bar       df.plot.box        df.plot.hexbin   df.plot.kde       df.plot.pie
```

In addition to these `kind`s, there are the `DataFrame.hist()`, and `DataFrame.boxplot()` methods, which use a separate interface.

Finally, there are several *plotting functions* in `pandas.plotting` that take a `Series` or `DataFrame` as an argument. These include:

- *Scatter Matrix*
- *Andrews Curves*
- *Parallel Coordinates*

- *Lag Plot*
- *Autocorrelation Plot*
- *Bootstrap Plot*
- *RadViz*

Plots may also be adorned with *errorbars* or *tables*.

Bar plots

For labeled, non-time series data, you may wish to produce a bar plot:

```
In [17]: plt.figure();  
  
In [18]: df.iloc[5].plot.bar()  
Out[18]: <matplotlib.axes._subplots.AxesSubplot at 0x14eadd910>  
  
In [19]: plt.axhline(0, color='k');
```

Calling a DataFrame's `plot.bar()` method produces a multiple bar plot:

```
In [20]: df2 = pd.DataFrame(np.random.rand(10, 4), columns=['a', 'b', 'c', 'd'])  
In [21]: df2.plot.bar();
```

To produce a stacked bar plot, pass `stacked=True`:

```
In [22]: df2.plot.bar(stacked=True);
```

To get horizontal bar plots, use the `barh` method:

```
In [23]: df2.plot.barh(stacked=True);
```

Histograms

Histograms can be drawn by using the `DataFrame.plot.hist()` and `Series.plot.hist()` methods.

```
In [24]: df4 = pd.DataFrame({'a': np.random.randn(1000) + 1, 'b': np.random.randn(1000),
.....:                      'c': np.random.randn(1000) - 1}, columns=['a', 'b', 'c'])
.....:
```

```
In [25]: plt.figure();
```

```
In [26]: df4.plot.hist(alpha=0.5)
```

```
Out[26]: <matplotlib.axes._subplots.AxesSubplot at 0x14f3e8ad0>
```

A histogram can be stacked using `stacked=True`. Bin size can be changed using the `bins` keyword.

```
In [27]: plt.figure();
```

```
In [28]: df4.plot.hist(stacked=True, bins=20)
```

```
Out[28]: <matplotlib.axes._subplots.AxesSubplot at 0x14f226990>
```

You can pass other keywords supported by matplotlib `hist`. For example, horizontal and cumulative histograms can be drawn by `orientation='horizontal'` and `cumulative=True`.

```
In [29]: plt.figure();
```

```
In [30]: df4['a'].plot.hist(orientation='horizontal', cumulative=True)
```

```
Out[30]: <matplotlib.axes._subplots.AxesSubplot at 0x14f7b2610>
```

See the `hist` method and the [matplotlib hist documentation](#) for more.

The existing interface `DataFrame.hist` to plot histogram still can be used.

```
In [31]: plt.figure();
```

```
In [32]: df['A'].diff().hist()
```

```
Out[32]: <matplotlib.axes._subplots.AxesSubplot at 0x14f986890>
```

`DataFrame.hist()` plots the histograms of the columns on multiple subplots:

```
In [33]: plt.figure()
```

```
Out[33]: <Figure size 640x480 with 0 Axes>
```

```
In [34]: df.diff().hist(color='k', alpha=0.5, bins=50)
```

```
Out[34]:
```

```
array([[<matplotlib.axes._subplots.AxesSubplot object at 0x14fb5ff10>,  
       <matplotlib.axes._subplots.AxesSubplot object at 0x14fbbd850>],  
       [<matplotlib.axes._subplots.AxesSubplot object at 0x14fbf4b50>,  
       <matplotlib.axes._subplots.AxesSubplot object at 0x14fc2ce50>]],  
      dtype=object)
```

The `by` keyword can be specified to plot grouped histograms:

```
In [35]: data = pd.Series(np.random.randn(1000))
```

```
In [36]: data.hist(by=np.random.randint(0, 4, 1000), figsize=(6, 4))
```

```
Out[36]:
```

```
array([[<matplotlib.axes._subplots.AxesSubplot object at 0x1500475d0>,
        <matplotlib.axes._subplots.AxesSubplot object at 0x15007fe90>],
        [<matplotlib.axes._subplots.AxesSubplot object at 0x1500e3c50>,
         <matplotlib.axes._subplots.AxesSubplot object at 0x15011df50>]],
        dtype=object)
```

Box plots

Boxplot can be drawn calling `Series.plot.box()` and `DataFrame.plot.box()`, or `DataFrame.boxplot()` to visualize the distribution of values within each column.

For instance, here is a boxplot representing five trials of 10 observations of a uniform random variable on $[0,1)$.

```
In [37]: df = pd.DataFrame(np.random.rand(10, 5), columns=['A', 'B', 'C', 'D', 'E'])
```

```
In [38]: df.plot.box()
```

```
Out[38]: <matplotlib.axes._subplots.AxesSubplot at 0x15022c950>
```

Boxplot can be colored by passing `color` keyword. You can pass a `dict` whose keys are `boxes`, `whiskers`, `medians` and `caps`. If some keys are missing in the `dict`, default colors are used for the corresponding artists. Also, boxplot has `sym` keyword to specify fliers style.

When you pass other type of arguments via `color` keyword, it will be directly passed to `matplotlib` for all the `boxes`, `whiskers`, `medians` and `caps` colorization.

The colors are applied to every boxes to be drawn. If you want more complicated colorization, you can get each drawn artists by passing `return_type`.

```
In [39]: color = {'boxes': 'DarkGreen', 'whiskers': 'DarkOrange',
.....:           'medians': 'DarkBlue', 'caps': 'Gray'}
.....:
```

```
In [40]: df.plot.box(color=color, sym='r+')
```

```
Out[40]: <matplotlib.axes._subplots.AxesSubplot at 0x1503ec310>
```

Also, you can pass other keywords supported by matplotlib `boxplot`. For example, horizontal and custom-positioned boxplot can be drawn by `vert=False` and `positions` keywords.

```
In [41]: df.plot.box(vert=False, positions=[1, 4, 5, 6, 8])
Out[41]: <matplotlib.axes._subplots.AxesSubplot at 0x1505b69d0>
```

See the `boxplot` method and the `matplotlib` `boxplot` documentation for more.

The existing interface `DataFrame.boxplot` to plot boxplot still can be used.

```
In [42]: df = pd.DataFrame(np.random.rand(10, 5))
```

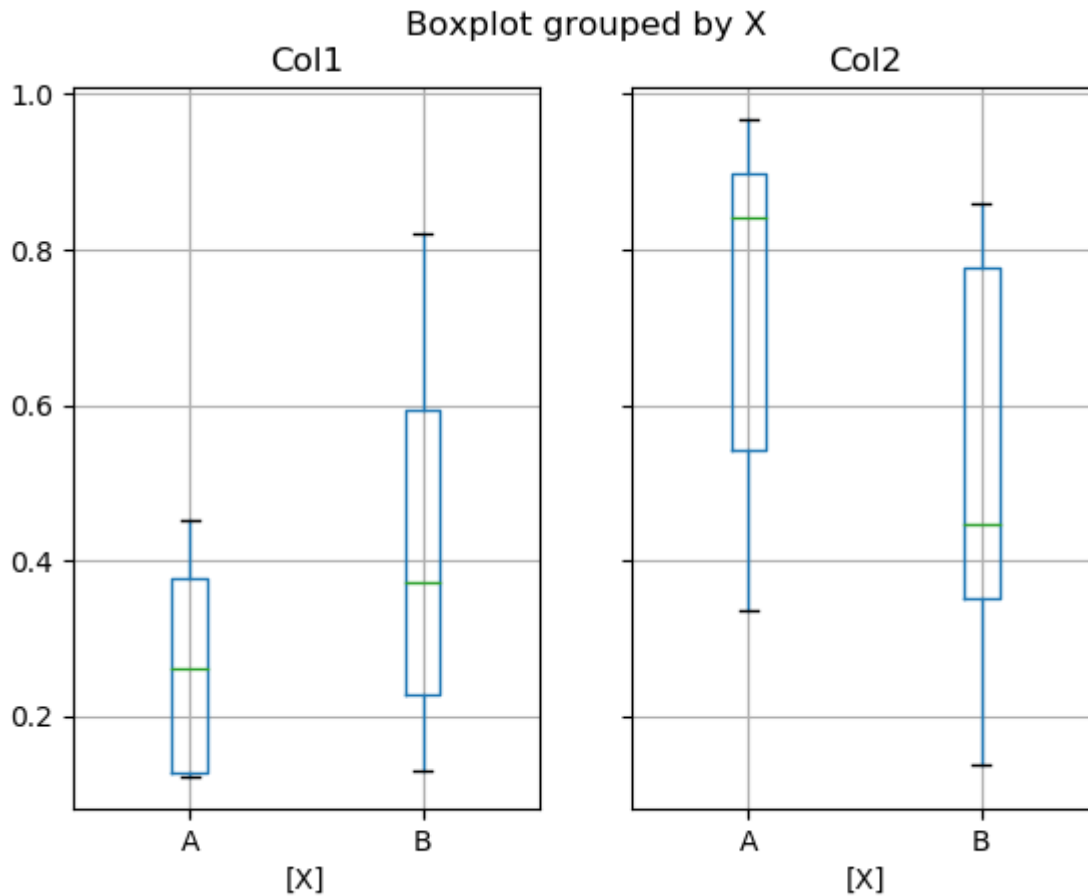

```
In [43]: plt.figure();
```

```
In [44]: bp = df.boxplot()
```

You can create a stratified boxplot using the `by` keyword argument to create groupings. For instance,

```
In [45]: df = pd.DataFrame(np.random.rand(10, 2), columns=['Col1', 'Col2'])
In [46]: df['X'] = pd.Series(['A', 'A', 'A', 'A', 'A', 'B', 'B', 'B', 'B', 'B'])
In [47]: plt.figure();
In [48]: bp = df.boxplot(by='X')
```

You can also pass a subset of columns to plot, as well as group by multiple columns:

```
In [49]: df = pd.DataFrame(np.random.rand(10, 3), columns=['Col1', 'Col2', 'Col3'])
In [50]: df['X'] = pd.Series(['A', 'A', 'A', 'A', 'A', 'B', 'B', 'B', 'B', 'B'])
In [51]: df['Y'] = pd.Series(['A', 'B', 'A', 'B', 'A', 'B', 'A', 'B', 'A', 'B'])
In [52]: plt.figure();
In [53]: bp = df.boxplot(column=['Col1', 'Col2'], by=['X', 'Y'])
```

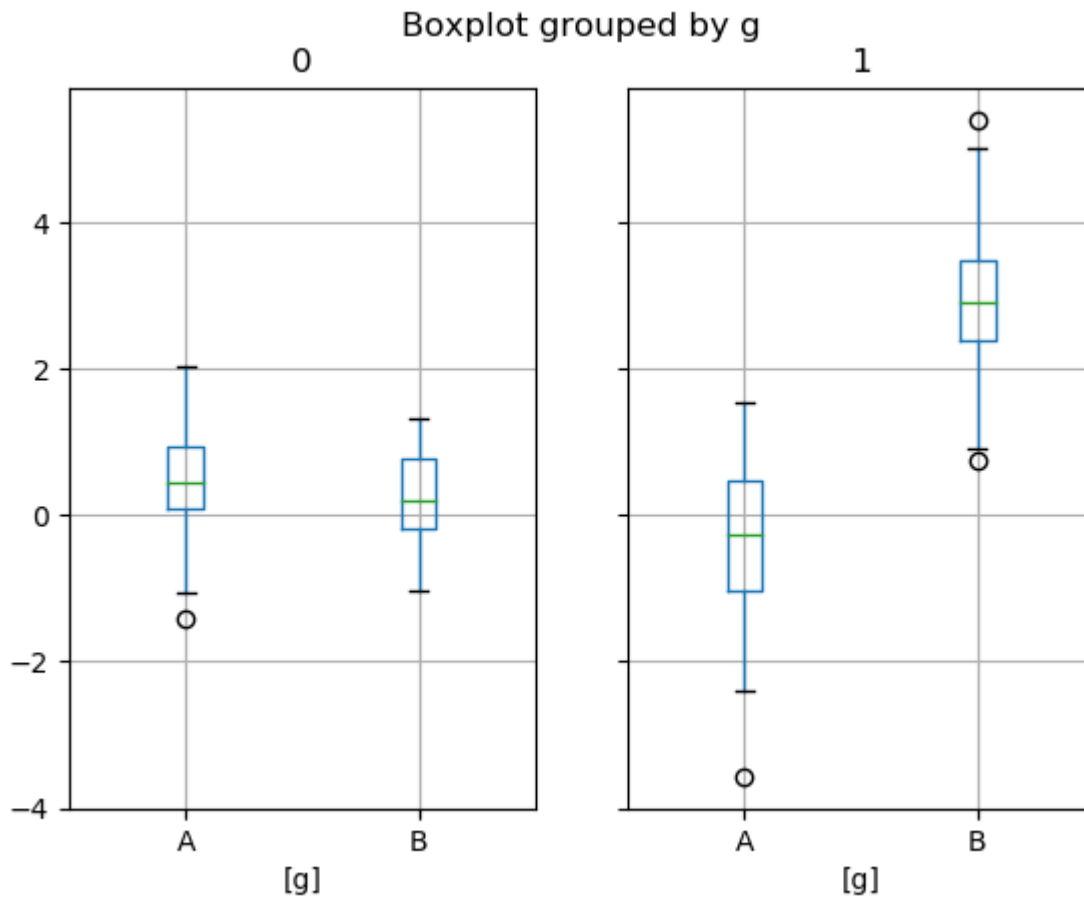

Warning: The default changed from 'dict' to 'axes' in version 0.19.0.

In `boxplot`, the return type can be controlled by the `return_type` keyword. The valid choices are {"axes", "dict", "both", None}. Faceting, created by `DataFrame.boxplot` with the `by` keyword, will affect the output type as well:

<code>return_type=</code>	Faceted	Output type
None	No	axes
None	Yes	2-D ndarray of axes
'axes'	No	axes
'axes'	Yes	Series of axes
'dict'	No	dict of artists
'dict'	Yes	Series of dicts of artists
'both'	No	namedtuple
'both'	Yes	Series of namedtuples

`Groupby.boxplot` always returns a `Series` of `return_type`.

```
In [54]: np.random.seed(1234)
In [55]: df_box = pd.DataFrame(np.random.randn(50, 2))
In [56]: df_box['g'] = np.random.choice(['A', 'B'], size=50)
In [57]: df_box.loc[df_box['g'] == 'B', 1] += 3
In [58]: bp = df_box.boxplot(by='g')
```

The subplots above are split by the numeric columns first, then the value of the g column. Below the subplots are first split by the value of g, then by the numeric columns.

```
In [59]: bp = df_box.groupby('g').boxplot()
```

Area plot

You can create area plots with `Series.plot.area()` and `DataFrame.plot.area()`. Area plots are stacked by default. To produce stacked area plot, each column must be either all positive or all negative values.

When input data contains *NaN*, it will be automatically filled by 0. If you want to drop or fill by different values, use `dataframe.dropna()` or `dataframe.fillna()` before calling `plot`.

```
In [60]: df = pd.DataFrame(np.random.rand(10, 4), columns=['a', 'b', 'c', 'd'])
```

```
In [61]: df.plot.area();
```

To produce an unstacked plot, pass `stacked=False`. Alpha value is set to 0.5 unless otherwise specified:

```
In [62]: df.plot.area(stacked=False);
```

Scatter plot

Scatter plot can be drawn by using the `DataFrame.plot.scatter()` method. Scatter plot requires numeric columns for the x and y axes. These can be specified by the `x` and `y` keywords.

```
In [63]: df = pd.DataFrame(np.random.rand(50, 4), columns=['a', 'b', 'c', 'd'])
```

```
In [64]: df.plot.scatter(x='a', y='b');
```

To plot multiple column groups in a single axes, repeat `plot` method specifying target `ax`. It is recommended to specify `color` and `label` keywords to distinguish each groups.

```
In [65]: ax = df.plot.scatter(x='a', y='b', color='DarkBlue', label='Group 1');
```

```
In [66]: df.plot.scatter(x='c', y='d', color='DarkGreen', label='Group 2', ax=ax);
```

The keyword `c` may be given as the name of a column to provide colors for each point:

```
In [67]: df.plot.scatter(x='a', y='b', c='c', s=50);
```

You can pass other keywords supported by matplotlib `scatter`. The example below shows a bubble chart using a column of the `DataFrame` as the bubble size.

```
In [68]: df.plot.scatter(x='a', y='b', s=df['c'] * 200);
```

See the `scatter` method and the `matplotlib scatter` documentation for more.

Hexagonal bin plot

You can create hexagonal bin plots with `DataFrame.plot.hexbin()`. Hexbin plots can be a useful alternative to scatter plots if your data are too dense to plot each point individually.

```
In [69]: df = pd.DataFrame(np.random.randn(1000, 2), columns=['a', 'b'])
```

```
In [70]: df['b'] = df['b'] + np.arange(1000)
```

```
In [71]: df.plot.hexbin(x='a', y='b', gridsize=25)
```

```
Out[71]: <matplotlib.axes._subplots.AxesSubplot at 0x14a067090>
```

A useful keyword argument is `gridsize`; it controls the number of hexagons in the x-direction, and defaults to 100. A larger `gridsize` means more, smaller bins.

By default, a histogram of the counts around each (x, y) point is computed. You can specify alternative aggregations by passing values to the `C` and `reduce_C_function` arguments. `C` specifies the value at each (x, y) point and `reduce_C_function` is a function of one argument that reduces all the values in a bin to a single number (e.g. `mean`, `max`, `sum`, `std`). In this example the positions are given by columns `a` and `b`, while the value is given by column `z`. The bins are aggregated with NumPy's `max` function.

```
In [72]: df = pd.DataFrame(np.random.randn(1000, 2), columns=['a', 'b'])
In [73]: df['b'] = df['b'] + np.arange(1000)
In [74]: df['z'] = np.random.uniform(0, 3, 1000)
In [75]: df.plot.hexbin(x='a', y='b', C='z', reduce_C_function=np.max, gridsize=25)
Out[75]: <matplotlib.axes._subplots.AxesSubplot at 0x149d68f90>
```

See the `hexbin` method and the `matplotlib hexbin` documentation for more.

Pie plot

You can create a pie plot with `DataFrame.plot.pie()` or `Series.plot.pie()`. If your data includes any `NaN`, they will be automatically filled with 0. A `ValueError` will be raised if there are any negative values in your data.

```
In [76]: series = pd.Series(3 * np.random.rand(4),
.....:                      index=['a', 'b', 'c', 'd'], name='series')
.....:

In [77]: series.plot.pie(figsize=(6, 6))
Out[77]: <matplotlib.axes._subplots.AxesSubplot at 0x13fd5bc90>
```

For pie plots it's best to use square figures, i.e. a figure aspect ratio 1. You can create the figure with equal width and height, or force the aspect ratio to be equal after plotting by calling `ax.set_aspect('equal')` on the returned `axes` object.

Note that pie plot with `DataFrame` requires that you either specify a target column by the `y` argument or `subplots=True`. When `y` is specified, pie plot of selected column will be drawn. If `subplots=True` is specified, pie plots for each column are drawn as subplots. A legend will be drawn in each pie plots by default; specify `legend=False` to hide it.

```
In [78]: df = pd.DataFrame(3 * np.random.rand(4, 2),
.....:                    index=['a', 'b', 'c', 'd'], columns=['x', 'y'])
.....:

In [79]: df.plot.pie(subplots=True, figsize=(8, 4))
Out[79]:
```

(continues on next page)

(continued from previous page)

```
array([<matplotlib.axes._subplots.AxesSubplot object at 0x1499e5b10>,
      <matplotlib.axes._subplots.AxesSubplot object at 0x14838c8d0>],
      dtype=object)
```

You can use the `labels` and `colors` keywords to specify the labels and colors of each wedge.

Warning: Most pandas plots use the `label` and `color` arguments (note the lack of “s” on those). To be consistent with `matplotlib.pyplot.pie()` you must use `labels` and `colors`.

If you want to hide wedge labels, specify `labels=None`. If `fontsize` is specified, the value will be applied to wedge labels. Also, other keywords supported by `matplotlib.pyplot.pie()` can be used.

```
In [80]: series.plot.pie(labels=['AA', 'BB', 'CC', 'DD'], colors=['r', 'g', 'b', 'c'],
.....:                  autopct='%.2f', fontsize=20, figsize=(6, 6))
.....:
Out [80]: <matplotlib.axes._subplots.AxesSubplot at 0x146b127d0>
```

If you pass values whose sum total is less than 1.0, matplotlib draws a semicircle.

```
In [81]: series = pd.Series([0.1] * 4, index=['a', 'b', 'c', 'd'], name='series2')
```

```
In [82]: series.plot.pie(figsize=(6, 6))
```

```
Out[82]: <matplotlib.axes._subplots.AxesSubplot at 0x145c79e90>
```

See the [matplotlib pie](#) documentation for more.

4.10.3 Plotting with missing data

Pandas tries to be pragmatic about plotting `DataFrames` or `Series` that contain missing data. Missing values are dropped, left out, or filled depending on the plot type.

Plot Type	NaN Handling
Line	Leave gaps at NaNs
Line (stacked)	Fill 0's
Bar	Fill 0's
Scatter	Drop NaNs
Histogram	Drop NaNs (column-wise)
Box	Drop NaNs (column-wise)
Area	Fill 0's
KDE	Drop NaNs (column-wise)
Hexbin	Drop NaNs
Pie	Fill 0's

If any of these defaults are not what you want, or if you want to be explicit about how missing values are handled, consider using `fillna()` or `dropna()` before plotting.

4.10.4 Plotting Tools

These functions can be imported from `pandas.plotting` and take a `Series` or `DataFrame` as an argument.

Scatter matrix plot

You can create a scatter plot matrix using the `scatter_matrix` method in `pandas.plotting`:

```
In [83]: from pandas.plotting import scatter_matrix

In [84]: df = pd.DataFrame(np.random.randn(1000, 4), columns=['a', 'b', 'c', 'd'])

In [85]: scatter_matrix(df, alpha=0.2, figsize=(6, 6), diagonal='kde')
Out[85]:
array([[<matplotlib.axes._subplots.AxesSubplot object at 0x147a9b6d0>,
      <matplotlib.axes._subplots.AxesSubplot object at 0x1470b3950>,
      <matplotlib.axes._subplots.AxesSubplot object at 0x146a313d0>,
      <matplotlib.axes._subplots.AxesSubplot object at 0x149c012d0>],
      [<matplotlib.axes._subplots.AxesSubplot object at 0x149631310>,
      <matplotlib.axes._subplots.AxesSubplot object at 0x1482b4b10>,
      <matplotlib.axes._subplots.AxesSubplot object at 0x1479d9a90>,
      <matplotlib.axes._subplots.AxesSubplot object at 0x14647fe50>],
      [<matplotlib.axes._subplots.AxesSubplot object at 0x1464cb890>,
      <matplotlib.axes._subplots.AxesSubplot object at 0x123525dd0>,
      <matplotlib.axes._subplots.AxesSubplot object at 0x12348ee10>,
      <matplotlib.axes._subplots.AxesSubplot object at 0x14aa3bc50>],
      [<matplotlib.axes._subplots.AxesSubplot object at 0x14b586c90>,
      <matplotlib.axes._subplots.AxesSubplot object at 0x149c11e90>,
      <matplotlib.axes._subplots.AxesSubplot object at 0x14ad68b50>,
      <matplotlib.axes._subplots.AxesSubplot object at 0x14b39aed0>]],
      dtype=object)
```

Density plot

You can create density plots using the `Series.plot.kde()` and `DataFrame.plot.kde()` methods.

```
In [86]: ser = pd.Series(np.random.randn(1000))
```

```
In [87]: ser.plot.kde()
```

```
Out[87]: <matplotlib.axes._subplots.AxesSubplot at 0x1471045d0>
```

Andrews curves

Andrews curves allow one to plot multivariate data as a large number of curves that are created using the attributes of samples as coefficients for Fourier series, see the [Wikipedia entry](#) for more information. By coloring these curves differently for each class it is possible to visualize data clustering. Curves belonging to samples of the same class will usually be closer together and form larger structures.

Note: The “Iris” dataset is available [here](#).

```
In [88]: from pandas.plotting import andrews_curves
```

```
In [89]: data = pd.read_csv('data/iris.data')
```

```
In [90]: plt.figure()
```

```
Out[90]: <Figure size 640x480 with 0 Axes>
```

```
In [91]: andrews_curves(data, 'Name')
```

```
Out[91]: <matplotlib.axes._subplots.AxesSubplot at 0x146afe590>
```

Parallel coordinates

Parallel coordinates is a plotting technique for plotting multivariate data, see the [Wikipedia entry](#) for an introduction. Parallel coordinates allows one to see clusters in data and to estimate other statistics visually. Using parallel coordinates points are represented as connected line segments. Each vertical line represents one attribute. One set of connected line segments represents one data point. Points that tend to cluster will appear closer together.

```
In [92]: from pandas.plotting import parallel_coordinates
```

```
In [93]: data = pd.read_csv('data/iris.data')
```

```
In [94]: plt.figure()
```

```
Out[94]: <Figure size 640x480 with 0 Axes>
```

```
In [95]: parallel_coordinates(data, 'Name')
```

```
Out[95]: <matplotlib.axes._subplots.AxesSubplot at 0x14aeb2190>
```

Lag plot

Lag plots are used to check if a data set or time series is random. Random data should not exhibit any structure in the lag plot. Non-random structure implies that the underlying data are not random. The `lag` argument may be passed, and when `lag=1` the plot is essentially `data[:-1]` vs. `data[1:]`.

```
In [96]: from pandas.plotting import lag_plot

In [97]: plt.figure()
Out[97]: <Figure size 640x480 with 0 Axes>

In [98]: spacing = np.linspace(-99 * np.pi, 99 * np.pi, num=1000)

In [99]: data = pd.Series(0.1 * np.random.rand(1000) + 0.9 * np.sin(spacing))

In [100]: lag_plot(data)
Out[100]: <matplotlib.axes._subplots.AxesSubplot at 0x14aeb2710>
```

Autocorrelation plot

Autocorrelation plots are often used for checking randomness in time series. This is done by computing autocorrelations for data values at varying time lags. If time series is random, such autocorrelations should be near zero for any and all time-lag separations. If time series is non-random then one or more of the autocorrelations will be significantly non-zero. The horizontal lines displayed in the plot correspond to 95% and 99% confidence bands. The dashed line is 99% confidence band. See the [Wikipedia entry](#) for more about autocorrelation plots.

```
In [101]: from pandas.plotting import autocorrelation_plot
```

```
In [102]: plt.figure()
```

```
Out[102]: <Figure size 640x480 with 0 Axes>
```

```
In [103]: spacing = np.linspace(-9 * np.pi, 9 * np.pi, num=1000)
```

```
In [104]: data = pd.Series(0.7 * np.random.rand(1000) + 0.3 * np.sin(spacing))
```

```
In [105]: autocorrelation_plot(data)
```

```
Out[105]: <matplotlib.axes._subplots.AxesSubplot at 0x145c97590>
```

Bootstrap plot

Bootstrap plots are used to visually assess the uncertainty of a statistic, such as mean, median, midrange, etc. A random subset of a specified size is selected from a data set, the statistic in question is computed for this subset and the process is repeated a specified number of times. Resulting plots and histograms are what constitutes the bootstrap plot.

```
In [106]: from pandas.plotting import bootstrap_plot
In [107]: data = pd.Series(np.random.rand(1000))
In [108]: bootstrap_plot(data, size=50, samples=500, color='grey')
Out[108]: <Figure size 640x480 with 6 Axes>
```

RadViz

RadViz is a way of visualizing multi-variate data. It is based on a simple spring tension minimization algorithm. Basically you set up a bunch of points in a plane. In our case they are equally spaced on a unit circle. Each point represents a single attribute. You then pretend that each sample in the data set is attached to each of these points by a spring, the stiffness of which is proportional to the numerical value of that attribute (they are normalized to unit interval). The point in the plane, where our sample settles to (where the forces acting on our sample are at an equilibrium) is where a dot representing our sample will be drawn. Depending on which class that sample belongs it will be colored differently. See the R package [Radviz](#) for more information.

Note: The “Iris” dataset is available [here](#).

```
In [109]: from pandas.plotting import radviz

In [110]: data = pd.read_csv('data/iris.data')

In [111]: plt.figure()
Out[111]: <Figure size 640x480 with 0 Axes>

In [112]: radviz(data, 'Name')
Out[112]: <matplotlib.axes._subplots.AxesSubplot at 0x14b31fc50>
```

4.10.5 Plot Formatting

Setting the plot style

From version 1.5 and up, matplotlib offers a range of pre-configured plotting styles. Setting the style can be used to easily give plots the general look that you want. Setting the style is as easy as calling `matplotlib.style.use(my_plot_style)` before creating your plot. For example you could write `matplotlib.style.use('ggplot')` for ggplot-style plots.

You can see the various available style names at `matplotlib.style.available` and it's very easy to try them out.

General plot style arguments

Most plotting methods have a set of keyword arguments that control the layout and formatting of the returned plot:

```
In [113]: plt.figure();  
In [114]: ts.plot(style='k--', label='Series');
```

For each kind of plot (e.g. *line*, *bar*, *scatter*) any additional arguments keywords are passed along to the corresponding matplotlib function (`ax.plot()`, `ax.bar()`, `ax.scatter()`). These can be used to control additional styling, beyond what pandas provides.

Controlling the legend

You may set the `legend` argument to `False` to hide the legend, which is shown by default.

```
In [115]: df = pd.DataFrame(np.random.randn(1000, 4),
.....:                      index=ts.index, columns=list('ABCD'))
.....:

In [116]: df = df.cumsum()

In [117]: df.plot(legend=False)
Out[117]: <matplotlib.axes._subplots.AxesSubplot at 0x14a278510>
```

Scales

You may pass `logy` to get a log-scale Y axis.

```
In [118]: ts = pd.Series(np.random.randn(1000),
.....:                  index=pd.date_range('1/1/2000', periods=1000))
.....:
```

```
In [119]: ts = np.exp(ts.cumsum())
```

```
In [120]: ts.plot(logy=True)
```

```
Out[120]: <matplotlib.axes._subplots.AxesSubplot at 0x14a63f0d0>
```

See also the `logx` and `loglog` keyword arguments.

Plotting on a secondary y-axis

To plot data on a secondary y-axis, use the `secondary_y` keyword:

```
In [121]: df.A.plot()
Out[121]: <matplotlib.axes._subplots.AxesSubplot at 0x14a181b90>
```

```
In [122]: df.B.plot(secondary_y=True, style='g')
Out[122]: <matplotlib.axes._subplots.AxesSubplot at 0x14ab1a590>
```

To plot some columns in a DataFrame, give the column names to the `secondary_y` keyword:

```
In [123]: plt.figure()
```

```
Out[123]: <Figure size 640x480 with 0 Axes>
```

```
In [124]: ax = df.plot(secondary_y=['A', 'B'])
```

```
In [125]: ax.set_ylabel('CD scale')
```

```
Out[125]: Text(0, 0.5, 'CD scale')
```

```
In [126]: ax.right_ax.set_ylabel('AB scale')
```

```
Out[126]: Text(0, 0.5, 'AB scale')
```

Note that the columns plotted on the secondary y-axis is automatically marked with “(right)” in the legend. To turn off the automatic marking, use the `mark_right=False` keyword:

```
In [127]: plt.figure()
Out[127]: <Figure size 640x480 with 0 Axes>
```

```
In [128]: df.plot(secondary_y=['A', 'B'], mark_right=False)
Out[128]: <matplotlib.axes._subplots.AxesSubplot at 0x14a5fff10>
```

Suppressing tick resolution adjustment

pandas includes automatic tick resolution adjustment for regular frequency time-series data. For limited cases where pandas cannot infer the frequency information (e.g., in an externally created `twinx`), you can choose to suppress this behavior for alignment purposes.

Here is the default behavior, notice how the x-axis tick labeling is performed:

```
In [129]: plt.figure()
Out[129]: <Figure size 640x480 with 0 Axes>
```

```
In [130]: df.A.plot()
Out[130]: <matplotlib.axes._subplots.AxesSubplot at 0x149b267d0>
```

Using the `x_compat` parameter, you can suppress this behavior:

```
In [131]: plt.figure()
```

```
Out[131]: <Figure size 640x480 with 0 Axes>
```

```
In [132]: df.A.plot(x_compat=True)
```

```
Out[132]: <matplotlib.axes._subplots.AxesSubplot at 0x13c3baed0>
```

If you have more than one plot that needs to be suppressed, the use method in `pandas.plotting.plot_params` can be used in a *with statement*:

```
In [133]: plt.figure()
Out[133]: <Figure size 640x480 with 0 Axes>

In [134]: with pd.plotting.plot_params.use('x_compat', True):
.....:     df.A.plot(color='r')
.....:     df.B.plot(color='g')
.....:     df.C.plot(color='b')
.....:
```

Automatic date tick adjustment

New in version 0.20.0.

`TimedeltaIndex` now uses the native matplotlib tick locator methods, it is useful to call the automatic date tick adjustment from matplotlib for figures whose ticklabels overlap.

See the `autofmt_xdate` method and the [matplotlib documentation](#) for more.

Subplots

Each `Series` in a `DataFrame` can be plotted on a different axis with the `subplots` keyword:

```
In [135]: df.plot(subplots=True, figsize=(6, 6));
```

Using layout and targeting multiple axes

The layout of subplots can be specified by the `layout` keyword. It can accept `(rows, columns)`. The `layout` keyword can be used in `hist` and `boxplot` also. If the input is invalid, a `ValueError` will be raised.

The number of axes which can be contained by rows x columns specified by `layout` must be larger than the number of required subplots. If layout can contain more axes than required, blank axes are not drawn. Similar to a NumPy array's `reshape` method, you can use `-1` for one dimension to automatically calculate the number of rows or columns needed, given the other.

```
In [136]: df.plot(subplots=True, layout=(2, 3), figsize=(6, 6), sharex=False);
```

The above example is identical to using:

```
In [137]: df.plot(subplots=True, layout=(2, -1), figsize=(6, 6), sharex=False);
```

The required number of columns (3) is inferred from the number of series to plot and the given number of rows (2).

You can pass multiple axes created beforehand as list-like via `ax` keyword. This allows more complicated layouts. The passed axes must be the same number as the subplots being drawn.

When multiple axes are passed via the `ax` keyword, `layout`, `sharex` and `sharey` keywords don't affect to the output. You should explicitly pass `sharex=False` and `sharey=False`, otherwise you will see a warning.

```
In [138]: fig, axes = plt.subplots(4, 4, figsize=(6, 6))
```

```
In [139]: plt.subplots_adjust(wspace=0.5, hspace=0.5)
```

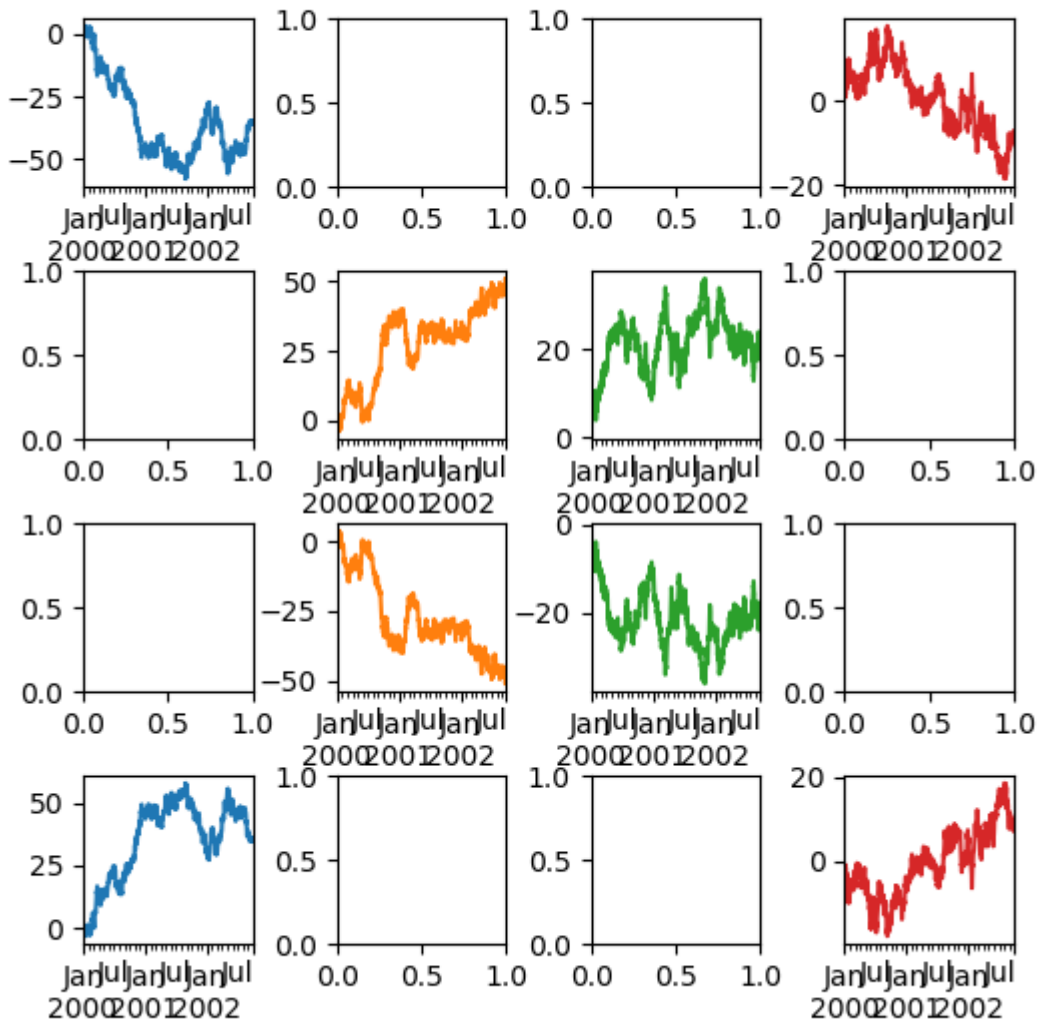

(continues on next page)

(continued from previous page)

```

In [140]: target1 = [axes[0][0], axes[1][1], axes[2][2], axes[3][3]]
In [141]: target2 = [axes[3][0], axes[2][1], axes[1][2], axes[0][3]]
In [142]: df.plot(subplots=True, ax=target1, legend=False, sharex=False, sharey=False);
In [143]: (-df).plot(subplots=True, ax=target2, legend=False,
.....:                sharex=False, sharey=False);
.....:

```

Another option is passing an `ax` argument to `Series.plot()` to plot on a particular axis:

```

In [144]: fig, axes = plt.subplots(nrows=2, ncols=2)
In [145]: df['A'].plot(ax=axes[0, 0]);
In [146]: axes[0, 0].set_title('A');
In [147]: df['B'].plot(ax=axes[0, 1]);
In [148]: axes[0, 1].set_title('B');
In [149]: df['C'].plot(ax=axes[1, 0]);
In [150]: axes[1, 0].set_title('C');
In [151]: df['D'].plot(ax=axes[1, 1]);
In [152]: axes[1, 1].set_title('D');

```

Plotting with error bars

Plotting with error bars is supported in `DataFrame.plot()` and `Series.plot()`.

Horizontal and vertical error bars can be supplied to the `xerr` and `yerr` keyword arguments to `plot()`. The error values can be specified using a variety of formats:

- As a `DataFrame` or `dict` of errors with column names matching the `columns` attribute of the plotting `DataFrame` or matching the `name` attribute of the `Series`.
- As a `str` indicating which of the columns of plotting `DataFrame` contain the error values.
- As raw values (`list`, `tuple`, or `np.ndarray`). Must be the same length as the plotting `DataFrame/Series`.

Asymmetrical error bars are also supported, however raw error values must be provided in this case. For a `M` length `Series`, a `Mx2` array should be provided indicating lower and upper (or left and right) errors. For a `MxN DataFrame`, asymmetrical errors should be in a `Mx2xN` array.

Here is an example of one way to easily plot group means with standard deviations from the raw data.

```
# Generate the data
In [153]: ix3 = pd.MultiIndex.from_arrays([
.....:     ['a', 'a', 'a', 'a', 'b', 'b', 'b', 'b'],
.....:     ['foo', 'foo', 'bar', 'bar', 'foo', 'foo', 'bar', 'bar']],
.....:     names=['letter', 'word'])
.....:

In [154]: df3 = pd.DataFrame({'data1': [3, 2, 4, 3, 2, 4, 3, 2],
.....:                        'data2': [6, 5, 7, 5, 4, 5, 6, 5]}, index=ix3)
.....:

# Group by index labels and take the means and standard deviations
# for each group
In [155]: gp3 = df3.groupby(level=('letter', 'word'))

In [156]: means = gp3.mean()

In [157]: errors = gp3.std()

In [158]: means
Out[158]:
      data1  data2
letter word
a      bar    3.5    6.0
      foo    2.5    5.5
b      bar    2.5    5.5
      foo    3.0    4.5

In [159]: errors
Out[159]:
      data1  data2
letter word
a      bar  0.707107  1.414214
      foo  0.707107  0.707107
b      bar  0.707107  0.707107
      foo  1.414214  0.707107

# Plot
In [160]: fig, ax = plt.subplots()
```

```
In [161]: means.plot.bar(yerr=errors, ax=ax, capsize=4)
Out[161]: <matplotlib.axes._subplots.AxesSubplot at 0x14992de10>
```

Plotting tables

Plotting with matplotlib table is now supported in `DataFrame.plot()` and `Series.plot()` with a `table` keyword. The `table` keyword can accept `bool`, `DataFrame` or `Series`. The simple way to draw a table is to specify `table=True`. Data will be transposed to meet matplotlib's default layout.

```
In [162]: fig, ax = plt.subplots(1, 1)
In [163]: df = pd.DataFrame(np.random.rand(5, 3), columns=['a', 'b', 'c'])
In [164]: ax.get_xaxis().set_visible(False) # Hide Ticks
In [165]: df.plot(table=True, ax=ax)
Out[165]: <matplotlib.axes._subplots.AxesSubplot at 0x149da98d0>
```

Also, you can pass a different DataFrame or Series to the `table` keyword. The data will be drawn as displayed in print method (not transposed automatically). If required, it should be transposed manually as seen in the example below.

```
In [166]: fig, ax = plt.subplots(1, 1)

In [167]: ax.get_xaxis().set_visible(False) # Hide Ticks

In [168]: df.plot(table=np.round(df.T, 2), ax=ax)
Out[168]: <matplotlib.axes._subplots.AxesSubplot at 0x14aad6b10>
```

There also exists a helper function `pandas.plotting.table`, which creates a table from `DataFrame` or `Series`, and adds it to an `matplotlib.Axes` instance. This function can accept keywords which the `matplotlib table` has.

```
In [169]: from pandas.plotting import table
```

```
In [170]: fig, ax = plt.subplots(1, 1)
```

```
In [171]: table(ax, np.round(df.describe(), 2),
.....:         loc='upper right', colWidths=[0.2, 0.2, 0.2])
.....:
```

```
Out[171]: <matplotlib.table.Table at 0x14b2164d0>
```

```
In [172]: df.plot(ax=ax, ylim=(0, 2), legend=None)
```

```
Out[172]: <matplotlib.axes._subplots.AxesSubplot at 0x14b0e9050>
```

Note: You can get table instances on the axes using `axes.tables` property for further decorations. See the [matplotlib table documentation](#) for more.

Colormaps

A potential issue when plotting a large number of columns is that it can be difficult to distinguish some series due to repetition in the default colors. To remedy this, `DataFrame` plotting supports the use of the `colormap` argument, which accepts either a Matplotlib [colormap](#) or a string that is a name of a colormap registered with Matplotlib. A visualization of the default matplotlib colormaps is available [here](#).

As matplotlib does not directly support colormaps for line-based plots, the colors are selected based on an even spacing determined by the number of columns in the `DataFrame`. There is no consideration made for background color, so some colormaps will produce lines that are not easily visible.

To use the cubehelix colormap, we can pass `colormap='cubehelix'`.

```
In [173]: df = pd.DataFrame(np.random.randn(1000, 10), index=ts.index)
```

```
In [174]: df = df.cumsum()
```

```
In [175]: plt.figure()
```

```
Out[175]: <Figure size 640x480 with 0 Axes>
```

```
In [176]: df.plot(colormap='cubehelix')
```

```
Out[176]: <matplotlib.axes._subplots.AxesSubplot at 0x14b63c490>
```

Alternatively, we can pass the colormap itself:

```
In [177]: from matplotlib import cm
```

```
In [178]: plt.figure()
```

```
Out[178]: <Figure size 640x480 with 0 Axes>
```

```
In [179]: df.plot(colormap=cm.cubehelix)
```

```
Out[179]: <matplotlib.axes._subplots.AxesSubplot at 0x152a997d0>
```

Colormaps can also be used other plot types, like bar charts:

```
In [180]: dd = pd.DataFrame(np.random.randn(10, 10)).applymap(abs)
```

```
In [181]: dd = dd.cumsum()
```

```
In [182]: plt.figure()
```

```
Out[182]: <Figure size 640x480 with 0 Axes>
```

```
In [183]: dd.plot.bar(colormap='Greens')
```

```
Out[183]: <matplotlib.axes._subplots.AxesSubplot at 0x152d6fdd0>
```

Parallel coordinates charts:

```
In [184]: plt.figure()
```

```
Out[184]: <Figure size 640x480 with 0 Axes>
```

```
In [185]: parallel_coordinates(data, 'Name', colormap='gist_rainbow')
```

```
Out[185]: <matplotlib.axes._subplots.AxesSubplot at 0x152f62c50>
```

Andrews curves charts:

```
In [186]: plt.figure()
```

```
Out[186]: <Figure size 640x480 with 0 Axes>
```

```
In [187]: andrews_curves(data, 'Name', colormap='winter')
```

```
Out[187]: <matplotlib.axes._subplots.AxesSubplot at 0x15344c510>
```

4.10.6 Plotting directly with matplotlib

In some situations it may still be preferable or necessary to prepare plots directly with matplotlib, for instance when a certain type of plot or customization is not (yet) supported by pandas. `Series` and `DataFrame` objects behave like arrays and can therefore be passed directly to matplotlib functions without explicit casts.

pandas also automatically registers formatters and locators that recognize date indices, thereby extending date and time support to practically all plot types available in matplotlib. Although this formatting does not provide the same level of refinement you would get when plotting via pandas, it can be faster when plotting a large number of points.

```
In [188]: price = pd.Series(np.random.randn(150).cumsum(),
.....:                      index=pd.date_range('2000-1-1', periods=150, freq='B'))
.....:
```

```
In [189]: ma = price.rolling(20).mean()
```

```
In [190]: mstd = price.rolling(20).std()
```

```
In [191]: plt.figure()
Out[191]: <Figure size 640x480 with 0 Axes>
```

```
In [192]: plt.plot(price.index, price, 'k')
```

```
Out[192]: [<matplotlib.lines.Line2D at 0x1537fb490>]
```

```
In [193]: plt.plot(ma.index, ma, 'b')
```

```
Out[193]: [<matplotlib.lines.Line2D at 0x15382bd10>]
```

```
In [194]: plt.fill_between(mstd.index, ma - 2 * mstd, ma + 2 * mstd,  
.....:                    color='b', alpha=0.2)  
.....:
```

```
Out[194]: <matplotlib.collections.PolyCollection at 0x15383b990>
```

4.10.7 Trellis plotting interface

Warning: The `rplot` trellis plotting interface has been **removed**. Please use external packages like [seaborn](#) for similar but more refined functionality and refer to our 0.18.1 documentation [here](#) for how to convert to using it.

```
{{ header }}
```

4.11 Computational tools

4.11.1 Statistical functions

Percent change

`Series` and `DataFrame` have a method `pct_change()` to compute the percent change over a given number of periods (using `fill_method` to fill NA/null values *before* computing the percent change).

```
In [1]: ser = pd.Series(np.random.randn(8))
```

```
In [2]: ser.pct_change()
```

```
Out[2]:
```

```
0         NaN
1    -3.499440
2    -1.209115
3     0.755930
4    -1.107920
5    -8.278259
6     4.389155
7    -1.588397
dtype: float64
```

```
In [3]: df = pd.DataFrame(np.random.randn(10, 4))
```

```
In [4]: df.pct_change(periods=3)
```

```
Out[4]:
```

```
      0      1      2      3
0     NaN   NaN   NaN   NaN
1     NaN   NaN   NaN   NaN
2     NaN   NaN   NaN   NaN
3  -1.032320 -0.144445  0.009776 -1.063561
4   0.262689  2.337771 -0.795219 -0.475762
5  -1.922600 -0.225164 -0.450228 -1.658606
6 -16.918561 -1.257664  2.236560 -17.931375
7  -1.660564 -1.197864 -8.654122 -0.311955
8  -2.167621 -1.274100 -2.128553 -0.511969
9   0.152402 -5.672460 -1.180728 -1.336598
```

Covariance

`Series.cov()` can be used to compute covariance between series (excluding missing values).

```
In [5]: s1 = pd.Series(np.random.randn(1000))
```

```
In [6]: s2 = pd.Series(np.random.randn(1000))
```

```
In [7]: s1.cov(s2)
```

```
Out[7]: -0.01982050306978479
```

Analogously, `DataFrame.cov()` to compute pairwise covariances among the series in the `DataFrame`, also excluding NA/null values.

Note: Assuming the missing data are missing at random this results in an estimate for the covariance matrix which is unbiased. However, for many applications this estimate may not be acceptable because the estimated covariance matrix is not guaranteed to be positive semi-definite. This could lead to estimated correlations having absolute values which are greater than one, and/or a non-invertible covariance matrix. See [Estimation of covariance matrices](#) for more details.

```
In [8]: frame = pd.DataFrame(np.random.randn(1000, 5),
...:                         columns=['a', 'b', 'c', 'd', 'e'])
...:
```

```
In [9]: frame.cov()
```

```
Out[9]:
```

	a	b	c	d	e
a	0.993079	-0.041165	-0.000453	-0.034713	0.015692
b	-0.041165	1.003421	-0.012468	-0.004746	-0.039112
c	-0.000453	-0.012468	1.016472	-0.032166	-0.021802
d	-0.034713	-0.004746	-0.032166	1.074440	0.022702
e	0.015692	-0.039112	-0.021802	0.022702	1.001368

`DataFrame.cov` also supports an optional `min_periods` keyword that specifies the required minimum number of observations for each column pair in order to have a valid result.

```
In [10]: frame = pd.DataFrame(np.random.randn(20, 3), columns=['a', 'b', 'c'])
```

```
In [11]: frame.loc[frame.index[:5], 'a'] = np.nan
```

```
In [12]: frame.loc[frame.index[5:10], 'b'] = np.nan
```

```
In [13]: frame.cov()
```

```
Out[13]:
```

	a	b	c
a	1.246580	0.142555	-0.347796
b	0.142555	0.395455	-0.093032
c	-0.347796	-0.093032	1.303810

```
In [14]: frame.cov(min_periods=12)
```

```
Out[14]:
```

	a	b	c
a	1.246580	NaN	-0.347796
b	NaN	0.395455	-0.093032
c	-0.347796	-0.093032	1.303810

Correlation

Correlation may be computed using the `corr()` method. Using the `method` parameter, several methods for computing correlations are provided:

Method name	Description
pearson (default)	Standard correlation coefficient
kendall	Kendall Tau correlation coefficient
spearman	Spearman rank correlation coefficient

All of these are currently computed using pairwise complete observations. Wikipedia has articles covering the above correlation coefficients:

- Pearson correlation coefficient
- Kendall rank correlation coefficient
- Spearman's rank correlation coefficient

Note: Please see the *caveats* associated with this method of calculating correlation matrices in the *covariance section*.

```
In [15]: frame = pd.DataFrame(np.random.randn(1000, 5),
....:                          columns=['a', 'b', 'c', 'd', 'e'])
....:
```

```
In [16]: frame.iloc[:,2] = np.nan
```

```
# Series with Series
```

```
In [17]: frame['a'].corr(frame['b'])
```

```
Out[17]: -0.08822605915478045
```

```
In [18]: frame['a'].corr(frame['b'], method='spearman')
```

```
Out[18]: -0.09523247692990772
```

```
# Pairwise correlation of DataFrame columns
```

```
In [19]: frame.corr()
```

```
Out[19]:
```

	a	b	c	d	e
a	1.000000	-0.088226	-0.022193	-0.041645	0.037615
b	-0.088226	1.000000	-0.054368	0.000873	0.035809
c	-0.022193	-0.054368	1.000000	-0.032274	0.071477
d	-0.041645	0.000873	-0.032274	1.000000	-0.040517
e	0.037615	0.035809	0.071477	-0.040517	1.000000

Note that non-numeric columns will be automatically excluded from the correlation calculation.

Like `cov`, `corr` also supports the optional `min_periods` keyword:

```
In [20]: frame = pd.DataFrame(np.random.randn(20, 3), columns=['a', 'b', 'c'])
```

```
In [21]: frame.loc[frame.index[:5], 'a'] = np.nan
```

```
In [22]: frame.loc[frame.index[5:10], 'b'] = np.nan
```

```
In [23]: frame.corr()
```

```
Out[23]:
```

	a	b	c
a	1.000000	0.199704	0.057058
b	0.199704	1.000000	0.087441
c	0.057058	0.087441	1.000000

```
In [24]: frame.corr(min_periods=12)
```

```
Out[24]:
```

	a	b	c
a	1.000000	NaN	0.057058

```
b      NaN  1.000000  0.087441
c  0.057058  0.087441  1.000000
```

New in version 0.24.0.

The `method` argument can also be a callable for a generic correlation calculation. In this case, it should be a single function that produces a single value from two ndarray inputs. Suppose we wanted to compute the correlation based on histogram intersection:

```
# histogram intersection
In [25]: def histogram_intersection(a, b):
.....:     return np.minimum(np.true_divide(a, a.sum()),
.....:                       np.true_divide(b, b.sum())).sum()
.....:

In [26]: frame.corr(method=histogram_intersection)
Out[26]:
```

	a	b	c
a	1.000000	-0.837485	-4.851772
b	-0.837485	1.000000	-36.602246
c	-4.851772	-36.602246	1.000000

A related method `corrwith()` is implemented on `DataFrame` to compute the correlation between like-labeled Series contained in different `DataFrame` objects.

```
In [27]: index = ['a', 'b', 'c', 'd', 'e']
```

```
In [28]: columns = ['one', 'two', 'three', 'four']
```

```
In [29]: df1 = pd.DataFrame(np.random.randn(5, 4), index=index, columns=columns)
```

```
In [30]: df2 = pd.DataFrame(np.random.randn(4, 4), index=index[:4], columns=columns)
```

```
In [31]: df1.corrwith(df2)
```

```
Out[31]:
one    -0.445528
two     -0.351807
three  -0.905237
four     0.351228
dtype: float64
```

```
In [32]: df2.corrwith(df1, axis=1)
```

```
Out[32]:
a    -0.912687
b     0.356132
c    -0.588100
d     0.581389
e         NaN
dtype: float64
```

Data ranking

The `rank()` method produces a data ranking with ties being assigned the mean of the ranks (by default) for the group:

```
In [33]: s = pd.Series(np.random.randn(5), index=list('abcde'))
```

```
In [34]: s['d'] = s['b'] # so there's a tie
```

```
In [35]: s.rank()
```

```
Out[35]:
```

```
a    1.0
b    2.5
c    4.0
d    2.5
e    5.0
dtype: float64
```

`rank()` is also a DataFrame method and can rank either the rows (`axis=0`) or the columns (`axis=1`). NaN values are excluded from the ranking.

```
In [36]: df = pd.DataFrame(np.random.randn(10, 6))
```

```
In [37]: df[4] = df[2][:5] # some ties
```

```
In [38]: df
```

```
Out[38]:
```

	0	1	2	3	4	5
0	-0.706923	-0.165747	3.230001	0.251850	3.230001	-1.656365
1	1.049660	0.183541	0.966606	-0.193403	0.966606	2.218584
2	-0.505413	1.414760	0.898012	0.984841	0.898012	1.808877
3	1.836020	-1.449018	0.123195	1.262849	0.123195	0.120509
4	-3.715824	0.277952	-0.101871	0.019478	-0.101871	0.456955
5	-1.013384	-0.966352	-0.525177	-0.873757	NaN	-1.858289
6	-0.313772	-1.143538	1.034543	0.569028	NaN	-0.083523
7	-1.009067	0.825404	0.122760	0.911427	NaN	1.128538
8	-0.335681	0.722818	0.102682	-1.701922	NaN	-1.660909
9	1.571059	1.169795	-0.988364	0.586451	NaN	-0.999830

```
In [39]: df.rank(1)
```

```
Out[39]:
```

	0	1	2	3	4	5
0	2.0	3.0	5.5	4.0	5.5	1.0
1	5.0	2.0	3.5	1.0	3.5	6.0
2	1.0	5.0	2.5	4.0	2.5	6.0
3	6.0	1.0	3.5	5.0	3.5	2.0
4	1.0	5.0	2.5	4.0	2.5	6.0
5	2.0	3.0	5.0	4.0	NaN	1.0
6	2.0	1.0	5.0	4.0	NaN	3.0
7	1.0	3.0	2.0	4.0	NaN	5.0
8	3.0	5.0	4.0	1.0	NaN	2.0
9	5.0	4.0	2.0	3.0	NaN	1.0

`rank` optionally takes a parameter `ascending` which by default is true; when false, data is reverse-ranked, with larger values assigned a smaller rank.

`rank` supports different tie-breaking methods, specified with the `method` parameter:

- `average` : average rank of tied group
- `min` : lowest rank in the group

- `max` : highest rank in the group
- `first` : ranks assigned in the order they appear in the array

4.11.2 Window Functions

For working with data, a number of window functions are provided for computing common *window* or *rolling* statistics. Among these are count, sum, mean, median, correlation, variance, covariance, standard deviation, skewness, and kurtosis.

The `rolling()` and `expanding()` functions can be used directly from `DataFrameGroupBy` objects, see the [groupby docs](#).

Note: The API for window statistics is quite similar to the way one works with `GroupBy` objects, see the documentation [here](#).

We work with `rolling`, `expanding` and `exponentially weighted` data through the corresponding objects, `Rolling`, `Expanding` and `EWM`.

```
In [40]: s = pd.Series(np.random.randn(1000),
.....:                 index=pd.date_range('1/1/2000', periods=1000))
.....:

In [41]: s = s.cumsum()

In [42]: s
Out[42]:
2000-01-01    -0.976840
2000-01-02    -1.301961
2000-01-03    -1.621681
2000-01-04    -1.526089
2000-01-05    -1.816793
...
2002-09-22     0.175963
2002-09-23    -0.049734
2002-09-24     1.187367
2002-09-25     1.189690
2002-09-26     1.045869
Freq: D, Length: 1000, dtype: float64
```

These are created from methods on `Series` and `DataFrame`.

```
In [43]: r = s.rolling(window=60)

In [44]: r
Out[44]: Rolling [window=60,center=False,axis=0]
```

These object provide tab-completion of the available methods and properties.

```
In [14]: r.<TAB>                                     # noqa: E225, E999
r.agg          r.apply          r.count          r.exclusions  r.max          r.median        r.
↪name          r.skew            r.sum
r.aggregate    r.corr            r.cov            r.kurt        r.mean         r.min           r.
↪quantile     r.std             r.var
                                                    (continues on next page)
```

(continued from previous page)

Generally these methods all have the same interface. They all accept the following arguments:

- **window**: size of moving window
- **min_periods**: threshold of non-null data points to require (otherwise result is NA)
- **center**: boolean, whether to set the labels at the center (default is False)

We can then call methods on these **rolling** objects. These return like-indexed objects:

```
In [45]: r.mean()
Out[45]:
2000-01-01      NaN
2000-01-02      NaN
2000-01-03      NaN
2000-01-04      NaN
2000-01-05      NaN
...
2002-09-22  -1.233792
2002-09-23  -1.193738
2002-09-24  -1.133761
2002-09-25  -1.079222
2002-09-26  -1.001532
Freq: D, Length: 1000, dtype: float64
```

```
In [46]: s.plot(style='k--')
Out[46]: <matplotlib.axes._subplots.AxesSubplot at 0x127785a50>
```

```
In [47]: r.mean().plot(style='k')
Out[47]: <matplotlib.axes._subplots.AxesSubplot at 0x127785a50>
```

They can also be applied to DataFrame objects. This is really just syntactic sugar for applying the moving window operator to all of the DataFrame's columns:

```
In [48]: df = pd.DataFrame(np.random.randn(1000, 4),
.....:                    index=pd.date_range('1/1/2000', periods=1000),
.....:                    columns=['A', 'B', 'C', 'D'])
.....:

In [49]: df = df.cumsum()

In [50]: df.rolling(window=60).sum().plot(subplots=True)
Out[50]:
array([<matplotlib.axes._subplots.AxesSubplot object at 0x13b785110>,
       <matplotlib.axes._subplots.AxesSubplot object at 0x1228a5e50>,
       <matplotlib.axes._subplots.AxesSubplot object at 0x122939510>,
       <matplotlib.axes._subplots.AxesSubplot object at 0x122992690>],
      dtype=object)
```

Method summary

We provide a number of common statistical functions:

Method	Description
<i>count()</i>	Number of non-null observations
<i>sum()</i>	Sum of values
<i>mean()</i>	Mean of values
<i>median()</i>	Arithmetic median of values
<i>min()</i>	Minimum
<i>max()</i>	Maximum
<i>std()</i>	Bessel-corrected sample standard deviation
<i>var()</i>	Unbiased variance
<i>skew()</i>	Sample skewness (3rd moment)
<i>kurt()</i>	Sample kurtosis (4th moment)
<i>quantile()</i>	Sample quantile (value at %)
<i>apply()</i>	Generic apply
<i>cov()</i>	Unbiased covariance (binary)
<i>corr()</i>	Correlation (binary)

The *apply()* function takes an extra *func* argument and performs generic rolling computations. The *func*

argument should be a single function that produces a single value from an ndarray input. Suppose we wanted to compute the mean absolute deviation on a rolling basis:

```
In [51]: def mad(x):
...:     return np.fabs(x - x.mean()).mean()
...:

In [52]: s.rolling(window=60).apply(mad, raw=True).plot(style='k')
Out[52]: <matplotlib.axes._subplots.AxesSubplot at 0x122d5a1d0>
```

Rolling windows

Passing `win_type` to `.rolling` generates a generic rolling window computation, that is weighted according to the `win_type`. The following methods are available:

Method	Description
<code>sum()</code>	Sum of values
<code>mean()</code>	Mean of values

The weights used in the window are specified by the `win_type` keyword. The list of recognized types are the `scipy.signal` window functions:

- boxcar
- triang
- blackman
- hamming
- bartlett
- parzen
- bohman
- blackmanharris
- nuttall
- barthann
- kaiser (needs beta)
- gaussian (needs std)
- general_gaussian (needs power, width)
- slepian (needs width)
- exponential (needs tau).

```
In [53]: ser = pd.Series(np.random.randn(10),
.....:                  index=pd.date_range('1/1/2000', periods=10))
.....:
```

```
In [54]: ser.rolling(window=5, win_type='triang').mean()
```

```
Out[54]:
```

```
2000-01-01      NaN
2000-01-02      NaN
2000-01-03      NaN

2000-01-10     -0.358661
```

```
Freq: D, dtype: float64
```

For some windowing functions, additional parameters must be specified:

```
In [57]: ser.rolling(window=5, win_type='gaussian').mean(std=0.1)
```

```
Out[57]:
```

```
2000-01-01      NaN
2000-01-02      NaN
2000-01-03      NaN
2000-01-04      NaN
2000-01-05      0.192276
2000-01-06      0.004481
2000-01-07     -0.156407
2000-01-08      1.572132
2000-01-09     -1.682813
2000-01-10      0.729975
```

```
Freq: D, dtype: float64
```

Note: For `.sum()` with a `win_type`, there is no normalization done to the weights for the window. Passing custom weights of `[1, 1, 1]` will yield a different result than passing weights of `[2, 2, 2]`, for example. When passing a `win_type` instead of explicitly specifying the weights, the weights are already normalized so that the largest weight is 1.

In contrast, the nature of the `.mean()` calculation is such that the weights are normalized with respect to each other. Weights of `[1, 1, 1]` and `[2, 2, 2]` yield the same result.

Time-aware rolling

New in version 0.19.0.

New in version 0.19.0 are the ability to pass an offset (or convertible) to a `.rolling()` method and have it produce variable sized windows based on the passed time window. For each time point, this includes all preceding values occurring within the indicated time delta.

This can be particularly useful for a non-regular time frequency index.

```
In [58]: dft = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]},
.....:                      index=pd.date_range('20130101 09:00:00',
.....:                      periods=5,
```

(continues on next page)

(continued from previous page)

```

.....:                                     freq='s'))
.....:
In [59]: dft
Out[59]:
          B
2013-01-01 09:00:00  0.0
2013-01-01 09:00:01  1.0
2013-01-01 09:00:02  2.0
2013-01-01 09:00:03  NaN
2013-01-01 09:00:04  4.0

```

This is a regular frequency index. Using an integer window parameter works to roll along the window frequency.

```
In [60]: dft.rolling(2).sum()
```

```
Out[60]:
          B
2013-01-01 09:00:00  NaN
2013-01-01 09:00:01  1.0
2013-01-01 09:00:02  3.0
2013-01-01 09:00:03  NaN
2013-01-01 09:00:04  NaN

```

```
In [61]: dft.rolling(2, min_periods=1).sum()
```

```
Out[61]:
          B
2013-01-01 09:00:00  0.0
2013-01-01 09:00:01  1.0
2013-01-01 09:00:02  3.0
2013-01-01 09:00:03  2.0
2013-01-01 09:00:04  4.0

```

Specifying an offset allows a more intuitive specification of the rolling frequency.

```
In [62]: dft.rolling('2s').sum()
```

```
Out[62]:
          B
2013-01-01 09:00:00  0.0
2013-01-01 09:00:01  1.0
2013-01-01 09:00:02  3.0
2013-01-01 09:00:03  2.0
2013-01-01 09:00:04  4.0

```

Using a non-regular, but still monotonic index, rolling with an integer window does not impart any special calculation.

```
In [63]: dft = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]},
.....:                       index=pd.Index([pd.Timestamp('20130101 09:00:00'),
.....:                                       pd.Timestamp('20130101 09:00:02'),
.....:                                       pd.Timestamp('20130101 09:00:03'),
.....:                                       pd.Timestamp('20130101 09:00:05'),
.....:                                       pd.Timestamp('20130101 09:00:06')]),
.....:                       name='foo'))

```

```
....:
```

```
In [64]: dft
```

```
Out[64]:
```

```
          B
foo
2013-01-01 09:00:00  0.0
2013-01-01 09:00:02  1.0
2013-01-01 09:00:03  2.0
2013-01-01 09:00:05  NaN
2013-01-01 09:00:06  4.0
```

```
In [65]: dft.rolling(2).sum()
```

```
Out[65]:
```

```
          B
foo
2013-01-01 09:00:00  NaN
2013-01-01 09:00:02  1.0
2013-01-01 09:00:03  3.0
2013-01-01 09:00:05  NaN
2013-01-01 09:00:06  NaN
```

Using the time-specification generates variable windows for this sparse data.

```
In [66]: dft.rolling('2s').sum()
```

```
Out[66]:
```

```
          B
foo
2013-01-01 09:00:00  0.0
2013-01-01 09:00:02  1.0
2013-01-01 09:00:03  3.0
2013-01-01 09:00:05  NaN
2013-01-01 09:00:06  4.0
```

Furthermore, we now allow an optional `on` parameter to specify a column (rather than the default of the index) in a DataFrame.

```
In [67]: dft = dft.reset_index()
```

```
In [68]: dft
```

```
Out[68]:
```

```
   foo      B
0 2013-01-01 09:00:00  0.0
1 2013-01-01 09:00:02  1.0
2 2013-01-01 09:00:03  2.0
3 2013-01-01 09:00:05  NaN
4 2013-01-01 09:00:06  4.0
```

```
In [69]: dft.rolling('2s', on='foo').sum()
```

```
Out[69]:
```

```
   foo      B
0 2013-01-01 09:00:00  0.0
1 2013-01-01 09:00:02  1.0
2 2013-01-01 09:00:03  3.0
3 2013-01-01 09:00:05  NaN
```

4 2013-01-01 09:00:06 4.0

Rolling window endpoints

New in version 0.20.0.

The inclusion of the interval endpoints in rolling window calculations can be specified with the `closed` parameter:

closed	Description	Default for
right	close right endpoint	time-based windows
left	close left endpoint	
both	close both endpoints	fixed windows
neither	open endpoints	

For example, having the right endpoint open is useful in many problems that require that there is no contamination from present information back to past information. This allows the rolling window to compute statistics “up to that point in time”, but not including that point in time.

```
In [70]: df = pd.DataFrame({'x': 1},
.....:                      index=[pd.Timestamp('20130101 09:00:01'),
.....:                               pd.Timestamp('20130101 09:00:02'),
.....:                               pd.Timestamp('20130101 09:00:03'),
.....:                               pd.Timestamp('20130101 09:00:04'),
.....:                               pd.Timestamp('20130101 09:00:06')])
.....:

In [71]: df["right"] = df.rolling('2s', closed='right').x.sum() # default

In [72]: df["both"] = df.rolling('2s', closed='both').x.sum()

In [73]: df["left"] = df.rolling('2s', closed='left').x.sum()

In [74]: df["neither"] = df.rolling('2s', closed='neither').x.sum()

In [75]: df
Out[75]:
```

	x	right	both	left	neither
2013-01-01 09:00:01	1	1.0	1.0	NaN	NaN
2013-01-01 09:00:02	1	2.0	2.0	1.0	1.0
2013-01-01 09:00:03	1	2.0	3.0	2.0	1.0
2013-01-01 09:00:04	1	2.0	3.0	2.0	1.0
2013-01-01 09:00:06	1	1.0	2.0	1.0	NaN

Currently, this feature is only implemented for time-based windows. For fixed windows, the `closed` parameter cannot be set and the rolling window will always have both endpoints closed.

Time-aware rolling vs. resampling

Using `.rolling()` with a time-based index is quite similar to *resampling*. They both operate and perform reductive operations on time-indexed pandas objects.

When using `.rolling()` with an offset. The offset is a time-delta. Take a backwards-in-time looking window, and aggregate all of the values in that window (including the end-point, but not the start-point). This is the new value at that point in the result. These are variable sized windows in time-space for each point of the input. You will get a same sized result as the input.

When using `.resample()` with an offset. Construct a new index that is the frequency of the offset. For each frequency bin, aggregate points from the input within a backwards-in-time looking window that fall in that bin. The result of this aggregation is the output for that frequency point. The windows are fixed size in the frequency space. Your result will have the shape of a regular frequency between the min and the max of the original input object.

To summarize, `.rolling()` is a time-based window operation, while `.resample()` is a frequency-based window operation.

Centering windows

By default the labels are set to the right edge of the window, but a `center` keyword is available so the labels can be set at the center.

```
In [76]: ser.rolling(window=5).mean()

```

Binary window functions

`cov()` and `corr()` can compute moving window statistics about two `Series` or any combination of `DataFrame/Series` or `DataFrame/DataFrame`. Here is the behavior in each case:

- two `Series`: compute the statistic for the pairing.

- `DataFrame/Series`: compute the statistics for each column of the `DataFrame` with the passed `Series`, thus returning a `DataFrame`.
- `DataFrame/DataFrame`: by default compute the statistic for matching column names, returning a `DataFrame`. If the keyword argument `pairwise=True` is passed then computes the statistic for each pair of columns, returning a `MultiIndexed DataFrame` whose `index` are the dates in question (see [the next section](#)).

For example:

```
In [78]: df = pd.DataFrame(np.random.randn(1000, 4),
.....:                    index=pd.date_range('1/1/2000', periods=1000),
.....:                    columns=['A', 'B', 'C', 'D'])
.....:
```

```
In [79]: df = df.cumsum()
```

```
In [80]: df2 = df[:20]
```

```
In [81]: df2.rolling(window=5).corr(df2['B'])
```

```
Out[81]:
```

Computing rolling pairwise covariances and correlations

In financial data analysis and other fields it's common to compute covariance and correlation matrices for a collection of time series. Often one is also interested in moving-window covariance and correlation matrices. This can be done by passing the `pairwise` keyword argument, which in the case of `DataFrame` inputs will yield a `MultiIndexed DataFrame` whose `index` are the dates in question. In the case of a single `DataFrame` argument the `pairwise` argument can even be omitted:

Note: Missing values are ignored and each entry is computed using the pairwise complete observations. Please see the [covariance section](#) for *caveats* associated with this method of calculating covariance and

correlation matrices.

```
In [82]: covs = (df[['B', 'C', 'D']].rolling(window=50)
.....:             .cov(df[['A', 'B', 'C']], pairwise=True))
.....:
```

```
In [83]: covs.loc['2002-09-22:']
```

```
Out[83]:
```

	C	-0.773133	0.441891	1.000000	-0.356259
	D	0.510224	-0.645289	-0.356259	1.000000
2002-09-26	A	1.000000	-0.802958	-0.791964	0.560321
	B	-0.802958	1.000000	0.518293	-0.667628
	C	-0.791964	0.518293	1.000000	-0.414793
	D	0.560321	-0.667628	-0.414793	1.000000

You can efficiently retrieve the time series of correlations between two columns by reshaping and indexing:

```
In [86]: correls.unstack(1)[('A', 'C')].plot()
Out[86]: <matplotlib.axes._subplots.AxesSubplot at 0x121a1db90>
```

4.11.3 Aggregation

Once the `Rolling`, `Expanding` or `EWM` objects have been created, several methods are available to perform multiple computations on the data. These operations are similar to the *aggregating API*, *groupby API*, and *resample API*.

```
In [87]: dfa = pd.DataFrame(np.random.randn(1000, 3),
.....:                      index=pd.date_range('1/1/2000', periods=1000),
.....:                      columns=['A', 'B', 'C'])
.....:

In [88]: r = dfa.rolling(window=60, min_periods=1)

In [89]: r
Out[89]: Rolling [window=60,min_periods=1,center=False,axis=0]
```

We can aggregate by passing a function to the entire `DataFrame`, or select a `Series` (or multiple `Series`) via standard `__getitem__`.

```
In [90]: r.aggregate(np.sum)
Out[90]:
```

	A	B	C
2000-01-01	1.697962	0.139101	-0.658131
2000-01-02	1.956254	0.333698	-3.074300
2000-01-03	2.226001	-0.657883	-6.222614
2000-01-04	1.882546	-1.518917	-6.271144
2000-01-05	2.049197	-2.031094	-6.393307
...
2002-09-22	5.024121	8.047617	12.955634
2002-09-23	3.556230	8.547739	13.261263
2002-09-24	2.352943	9.139912	12.724014
2002-09-25	1.206819	7.741372	11.936045
2002-09-26	-0.064820	5.847811	11.188268

[1000 rows x 3 columns]

```
In [91]: r['A'].aggregate(np.sum)
Out[91]:
```

2000-01-01	1.697962
2000-01-02	1.956254
2000-01-03	2.226001
2000-01-04	1.882546
2000-01-05	2.049197
...	...
2002-09-22	5.024121
2002-09-23	3.556230
2002-09-24	2.352943
2002-09-25	1.206819
2002-09-26	-0.064820

Freq: D, Name: A, Length: 1000, dtype: float64

```
In [92]: r[['A', 'B']].aggregate(np.sum)
Out[92]:
```

	A	B
2000-01-01	1.697962	0.139101
2000-01-02	1.956254	0.333698
2000-01-03	2.226001	-0.657883
2000-01-04	1.882546	-1.518917
2000-01-05	2.049197	-2.031094
...
2002-09-22	5.024121	8.047617
2002-09-23	3.556230	8.547739
2002-09-24	2.352943	9.139912
2002-09-25	1.206819	7.741372
2002-09-26	-0.064820	5.847811

[1000 rows x 2 columns]

As you can see, the result of the aggregation will have the selected columns, or all columns if none are selected.

Applying multiple functions

With windowed `Series` you can also pass a list of functions to do aggregation with, outputting a `DataFrame`:

```
In [93]: r['A'].agg([np.sum, np.mean, np.std])
```

```
Out [93]:
```

	sum	mean	std
2000-01-01	1.697962	1.697962	NaN
2000-01-02	1.956254	0.978127	1.018000
2000-01-03	2.226001	0.742000	0.827907
2000-01-04	1.882546	0.470637	0.866895
2000-01-05	2.049197	0.409839	0.762962
...
2002-09-22	5.024121	0.083735	0.988084
2002-09-23	3.556230	0.059271	0.990491
2002-09-24	2.352943	0.039216	0.983297
2002-09-25	1.206819	0.020114	0.987603
2002-09-26	-0.064820	-0.001080	0.976379

```
[1000 rows x 3 columns]
```

On a windowed `DataFrame`, you can pass a list of functions to apply to each column, which produces an aggregated result with a hierarchical index:

```
In [94]: r.agg([np.sum, np.mean])
```

```
Out [94]:
```

	A		B		C	
	sum	mean	sum	mean	sum	mean
2000-01-01	1.697962	1.697962	0.139101	0.139101	-0.658131	-0.658131
2000-01-02	1.956254	0.978127	0.333698	0.166849	-3.074300	-1.537150
2000-01-03	2.226001	0.742000	-0.657883	-0.219294	-6.222614	-2.074205
2000-01-04	1.882546	0.470637	-1.518917	-0.379729	-6.271144	-1.567786
2000-01-05	2.049197	0.409839	-2.031094	-0.406219	-6.393307	-1.278661
...
2002-09-22	5.024121	0.083735	8.047617	0.134127	12.955634	0.215927
2002-09-23	3.556230	0.059271	8.547739	0.142462	13.261263	0.221021
2002-09-24	2.352943	0.039216	9.139912	0.152332	12.724014	0.212067
2002-09-25	1.206819	0.020114	7.741372	0.129023	11.936045	0.198934
2002-09-26	-0.064820	-0.001080	5.847811	0.097464	11.188268	0.186471

```
[1000 rows x 6 columns]
```

Passing a dict of functions has different behavior by default, see the next section.

Applying different functions to DataFrame columns

By passing a dict to `aggregate` you can apply a different aggregation to the columns of a `DataFrame`:

```
In [95]: r.agg({'A': np.sum, 'B': lambda x: np.std(x, ddof=1)})
```

```
Out [95]:
```

	A	B
2000-01-01	1.697962	NaN
2000-01-02	1.956254	0.039242

(continues on next page)

(continued from previous page)

```

2000-01-03  2.226001  0.669395
2000-01-04  1.882546  0.633786
2000-01-05  2.049197  0.552061
...
2002-09-22  5.024121  0.872681
2002-09-23  3.556230  0.872378
2002-09-24  2.352943  0.877968
2002-09-25  1.206819  0.866026
2002-09-26 -0.064820  0.896717

```

```
[1000 rows x 2 columns]
```

The function names can also be strings. In order for a string to be valid it must be implemented on the windowed object

```
In [96]: r.agg({'A': 'sum', 'B': 'std'})
```

```
Out [96]:
```

	A	B
2000-01-01	1.697962	NaN
2000-01-02	1.956254	0.039242
2000-01-03	2.226001	0.669395
2000-01-04	1.882546	0.633786
2000-01-05	2.049197	0.552061
...
2002-09-22	5.024121	0.872681
2002-09-23	3.556230	0.872378
2002-09-24	2.352943	0.877968
2002-09-25	1.206819	0.866026
2002-09-26	-0.064820	0.896717

```
[1000 rows x 2 columns]
```

Furthermore you can pass a nested dict to indicate different aggregations on different columns.

```
In [97]: r.agg({'A': ['sum', 'std'], 'B': ['mean', 'std']})
```

```
Out [97]:
```

	A		B	
	sum	std	mean	std
2000-01-01	1.697962	NaN	0.139101	NaN
2000-01-02	1.956254	1.018000	0.166849	0.039242
2000-01-03	2.226001	0.827907	-0.219294	0.669395
2000-01-04	1.882546	0.866895	-0.379729	0.633786
2000-01-05	2.049197	0.762962	-0.406219	0.552061
...
2002-09-22	5.024121	0.988084	0.134127	0.872681
2002-09-23	3.556230	0.990491	0.142462	0.872378
2002-09-24	2.352943	0.983297	0.152332	0.877968
2002-09-25	1.206819	0.987603	0.129023	0.866026
2002-09-26	-0.064820	0.976379	0.097464	0.896717

```
[1000 rows x 4 columns]
```

4.11.4 Expanding windows

A common alternative to rolling statistics is to use an *expanding* window, which yields the value of the statistic with all the data available up to that point in time.

These follow a similar interface to `.rolling`, with the `.expanding` method returning an `Expanding` object.

As these calculations are a special case of rolling statistics, they are implemented in pandas such that the following two calls are equivalent:

```
In [98]: df.rolling(window=len(df), min_periods=1).mean()[:5]
Out[98]:
```

	A	B	C	D
2000-01-01	-1.294374	0.554789	-0.493573	-1.044350
2000-01-02	-1.685776	0.306997	-0.491494	-1.785642
2000-01-03	-1.896213	0.797296	-0.378842	-2.447085
2000-01-04	-1.894460	1.091742	-0.467363	-2.590780
2000-01-05	-1.788451	1.095136	-0.690874	-2.647958

```
In [99]: df.expanding(min_periods=1).mean()[:5]
Out[99]:
```

	A	B	C	D
2000-01-01	-1.294374	0.554789	-0.493573	-1.044350
2000-01-02	-1.685776	0.306997	-0.491494	-1.785642
2000-01-03	-1.896213	0.797296	-0.378842	-2.447085
2000-01-04	-1.894460	1.091742	-0.467363	-2.590780
2000-01-05	-1.788451	1.095136	-0.690874	-2.647958

These have a similar set of methods to `.rolling` methods.

Method summary

Function	Description
<code>count()</code>	Number of non-null observations
<code>sum()</code>	Sum of values
<code>mean()</code>	Mean of values
<code>median()</code>	Arithmetic median of values
<code>min()</code>	Minimum
<code>max()</code>	Maximum
<code>std()</code>	Unbiased standard deviation
<code>var()</code>	Unbiased variance
<code>skew()</code>	Unbiased skewness (3rd moment)
<code>kurt()</code>	Unbiased kurtosis (4th moment)
<code>quantile()</code>	Sample quantile (value at %)
<code>apply()</code>	Generic apply
<code>cov()</code>	Unbiased covariance (binary)
<code>corr()</code>	Correlation (binary)

Aside from not having a `window` parameter, these functions have the same interfaces as their `.rolling` counterparts. Like above, the parameters they all accept are:

- `min_periods`: threshold of non-null data points to require. Defaults to minimum needed to compute statistic. No NaNs will be output once `min_periods` non-null data points have been seen.
- `center`: boolean, whether to set the labels at the center (default is False).

Note: The output of the `.rolling` and `.expanding` methods do not return a NaN if there are at least `min_periods` non-null values in the current window. For example:

```
In [100]: sn = pd.Series([1, 2, np.nan, 3, np.nan, 4])
```

```
In [101]: sn
```

```
Out[101]:
```

```
0    1.0
1    2.0
2    NaN
3    3.0
4    NaN
5    4.0
```

```
dtype: float64
```

```
In [102]: sn.rolling(2).max()
```

```
Out[102]:
```

```
0    NaN
1    2.0
2    NaN
3    NaN
4    NaN
5    NaN
```

```
dtype: float64
```

```
In [103]: sn.rolling(2, min_periods=1).max()
```

```
Out[103]:
```

```
0    1.0
1    2.0
2    2.0
3    3.0
4    3.0
5    4.0
```

```
dtype: float64
```

In case of expanding functions, this differs from `cumsum()`, `cumprod()`, `cummax()`, and `cummin()`, which return NaN in the output wherever a NaN is encountered in the input. In order to match the output of `cumsum` with `expanding`, use `fillna()`:

```
In [104]: sn.expanding().sum()
```

```
Out[104]:
```

```
0    1.0
1    3.0
2    3.0
3    6.0
4    6.0
5   10.0
```

```
dtype: float64
```

```
In [105]: sn.cumsum()
```

```
Out[105]:
```

```
0    1.0
1    3.0
2    NaN
```

```
3    6.0
4    NaN
5    10.0
dtype: float64
```

```
In [106]: sn.cumsum().fillna(method='ffill')
```

```
Out[106]:
0    1.0
1    3.0
2    3.0
3    6.0
4    6.0
5    10.0
dtype: float64
```

An expanding window statistic will be more stable (and less responsive) than its rolling window counterpart as the increasing window size decreases the relative impact of an individual data point. As an example, here is the `mean()` output for the previous time series dataset:

```
In [107]: s.plot(style='k--')
```

```
Out[107]: <matplotlib.axes._subplots.AxesSubplot at 0x13c6ca050>
```

```
In [108]: s.expanding().mean().plot(style='k')
```

```
Out[108]: <matplotlib.axes._subplots.AxesSubplot at 0x13c6ca050>
```

4.11.5 Exponentially weighted windows

A related set of functions are exponentially weighted versions of several of the above statistics. A similar interface to `.rolling` and `.expanding` is accessed through the `.ewm` method to receive an EWM object. A number of expanding EW (exponentially weighted) methods are provided:

Function	Description
<code>mean()</code>	EW moving average
<code>var()</code>	EW moving variance
<code>std()</code>	EW moving standard deviation
<code>corr()</code>	EW moving correlation
<code>cov()</code>	EW moving covariance

In general, a weighted moving average is calculated as

$$y_t = \frac{\sum_{i=0}^t w_i x_{t-i}}{\sum_{i=0}^t w_i},$$

where x_t is the input, y_t is the result and the w_i are the weights.

The EW functions support two variants of exponential weights. The default, `adjust=True`, uses the weights

$w_i = (1 - \alpha)^i$ which gives

$$y_t = \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \dots + (1 - \alpha)^t x_0}{1 + (1 - \alpha) + (1 - \alpha)^2 + \dots + (1 - \alpha)^t}$$

When `adjust=False` is specified, moving averages are calculated as

$$\begin{aligned} y_0 &= x_0 \\ y_t &= (1 - \alpha)y_{t-1} + \alpha x_t, \end{aligned}$$

which is equivalent to using weights

$$w_i = \begin{cases} \alpha(1 - \alpha)^i & \text{if } i < t \\ (1 - \alpha)^i & \text{if } i = t. \end{cases}$$

Note: These equations are sometimes written in terms of $\alpha' = 1 - \alpha$, e.g.

$$y_t = \alpha' y_{t-1} + (1 - \alpha') x_t.$$

The difference between the above two variants arises because we are dealing with series which have finite history. Consider a series of infinite history, with `adjust=True`:

$$y_t = \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \dots}{1 + (1 - \alpha) + (1 - \alpha)^2 + \dots}$$

Noting that the denominator is a geometric series with initial term equal to 1 and a ratio of $1 - \alpha$ we have

$$\begin{aligned} y_t &= \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \dots}{\frac{1}{1 - (1 - \alpha)}} \\ &= [x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \dots]\alpha \\ &= \alpha x_t + [(1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \dots]\alpha \\ &= \alpha x_t + (1 - \alpha)[x_{t-1} + (1 - \alpha)x_{t-2} + \dots]\alpha \\ &= \alpha x_t + (1 - \alpha)y_{t-1} \end{aligned}$$

which is the same expression as `adjust=False` above and therefore shows the equivalence of the two variants for infinite series. When `adjust=False`, we have $y_0 = x_0$ and $y_t = \alpha x_t + (1 - \alpha)y_{t-1}$. Therefore, there is an assumption that x_0 is not an ordinary value but rather an exponentially weighted moment of the infinite series up to that point.

One must have $0 < \alpha \leq 1$, and while since version 0.18.0 it has been possible to pass α directly, it's often easier to think about either the **span**, **center of mass (com)** or **half-life** of an EW moment:

$$\alpha = \begin{cases} \frac{2}{s+1}, & \text{for span } s \geq 1 \\ \frac{1}{1+c}, & \text{for center of mass } c \geq 0 \\ 1 - \exp^{-\frac{\log 0.5}{h}}, & \text{for half-life } h > 0 \end{cases}$$

One must specify precisely one of **span**, **center of mass**, **half-life** and **alpha** to the EW functions:

- **Span** corresponds to what is commonly called an “N-day EW moving average”.
- **Center of mass** has a more physical interpretation and can be thought of in terms of span: $c = (s - 1)/2$.
- **Half-life** is the period of time for the exponential weight to reduce to one half.

- **Alpha** specifies the smoothing factor directly.

Here is an example for a univariate time series:

```
In [109]: s.plot(style='k--')
Out[109]: <matplotlib.axes._subplots.AxesSubplot at 0x13c6e4c50>

In [110]: s.ewm(span=20).mean().plot(style='k')
Out[110]: <matplotlib.axes._subplots.AxesSubplot at 0x13c6e4c50>
```

EWM has a `min_periods` argument, which has the same meaning it does for all the `.expanding` and `.rolling` methods: no output values will be set until at least `min_periods` non-null values are encountered in the (expanding) window.

EWM also has an `ignore_na` argument, which determines how intermediate null values affect the calculation of the weights. When `ignore_na=False` (the default), weights are calculated based on absolute positions, so that intermediate null values affect the result. When `ignore_na=True`, weights are calculated by ignoring intermediate null values. For example, assuming `adjust=True`, if `ignore_na=False`, the weighted average of 3, NaN, 5 would be calculated as

$$\frac{(1 - \alpha)^2 \cdot 3 + 1 \cdot 5}{(1 - \alpha)^2 + 1}.$$

Whereas if `ignore_na=True`, the weighted average would be calculated as

$$\frac{(1 - \alpha) \cdot 3 + 1 \cdot 5}{(1 - \alpha) + 1}.$$

The `var()`, `std()`, and `cov()` functions have a `bias` argument, specifying whether the result should contain biased or unbiased statistics. For example, if `bias=True`, `ewmvar(x)` is calculated as `ewmvar(x) = ewma(x**2) - ewma(x)**2`; whereas if `bias=False` (the default), the biased variance statistics are scaled by debiasing factors

$$\frac{\left(\sum_{i=0}^t w_i\right)^2}{\left(\sum_{i=0}^t w_i\right)^2 - \sum_{i=0}^t w_i^2}$$

(For $w_i = 1$, this reduces to the usual $N/(N - 1)$ factor, with $N = t + 1$.) See [Weighted Sample Variance](#) on Wikipedia for further details. `{{ header }}`

4.12 Group By: split-apply-combine

By “group by” we are referring to a process involving one or more of the following steps:

- **Splitting** the data into groups based on some criteria.
- **Applying** a function to each group independently.
- **Combining** the results into a data structure.

Out of these, the split step is the most straightforward. In fact, in many situations we may wish to split the data set into groups and do something with those groups. In the apply step, we might wish to do one of the following:

- **Aggregation:** compute a summary statistic (or statistics) for each group. Some examples:
 - Compute group sums or means.
 - Compute group sizes / counts.
- **Transformation:** perform some group-specific computations and return a like-indexed object. Some examples:
 - Standardize data (zscore) within a group.
 - Filling NAs within groups with a value derived from each group.
- **Filtration:** discard some groups, according to a group-wise computation that evaluates True or False. Some examples:
 - Discard data that belongs to groups with only a few members.
 - Filter out data based on the group sum or mean.
- Some combination of the above: `GroupBy` will examine the results of the apply step and try to return a sensibly combined result if it doesn’t fit into either of the above two categories.

Since the set of object instance methods on pandas data structures are generally rich and expressive, we often simply want to invoke, say, a `DataFrame` function on each group. The name `GroupBy` should be quite familiar to those who have used a SQL-based tool (or `itertools`), in which you can write code like:

```
SELECT Column1, Column2, mean(Column3), sum(Column4)
FROM SomeTable
GROUP BY Column1, Column2
```

We aim to make operations like this natural and easy to express using pandas. We’ll address each area of `GroupBy` functionality then provide some non-trivial examples / use cases.

See the *cookbook* for some advanced strategies.

4.12.1 Splitting an object into groups

pandas objects can be split on any of their axes. The abstract definition of grouping is to provide a mapping of labels to group names. To create a GroupBy object (more on what the GroupBy object is later), you may do the following:

```
In [1]: df = pd.DataFrame([('bird', 'Falconiformes', 389.0),
...:                      ('bird', 'Psittaciformes', 24.0),
...:                      ('mammal', 'Carnivora', 80.2),
...:                      ('mammal', 'Primates', np.nan),
...:                      ('mammal', 'Carnivora', 58)],
...:                      index=['falcon', 'parrot', 'lion', 'monkey', 'leopard'],
...:                      columns=('class', 'order', 'max_speed'))
...:

In [2]: df
Out[2]:
   class      order  max_speed
falcon  bird  Falconiformes    389.0
parrot  bird  Psittaciformes     24.0
lion    mammal   Carnivora     80.2
monkey  mammal   Primates       NaN
leopard mammal   Carnivora     58.0

# default is axis=0
In [3]: grouped = df.groupby('class')

In [4]: grouped = df.groupby('order', axis='columns')

In [5]: grouped = df.groupby(['class', 'order'])
```

The mapping can be specified many different ways:

- A Python function, to be called on each of the axis labels.
- A list or NumPy array of the same length as the selected axis.
- A dict or Series, providing a label → group name mapping.
- For DataFrame objects, a string indicating a column to be used to group. Of course `df.groupby('A')` is just syntactic sugar for `df.groupby(df['A'])`, but it makes life simpler.
- For DataFrame objects, a string indicating an index level to be used to group.
- A list of any of the above things.

Collectively we refer to the grouping objects as the **keys**. For example, consider the following DataFrame:

Note: A string passed to `groupby` may refer to either a column or an index level. If a string matches both a column name and an index level name, a `ValueError` will be raised.

```
In [6]: df = pd.DataFrame({'A': ['foo', 'bar', 'foo', 'bar',
...:                            'foo', 'bar', 'foo', 'foo'],
...:                      'B': ['one', 'one', 'two', 'three',
...:                            'two', 'two', 'one', 'three'],
```

(continues on next page)

(continued from previous page)

```

...:         'C': np.random.randn(8),
...:         'D': np.random.randn(8)}
...:
In [7]: df
Out[7]:
   A      B      C      D
0  foo  one  0.359465 -1.079191
1  bar  one -1.554635  0.249527
2  foo  two  0.266660  0.810474
3  bar three  0.982955  0.093005
4  foo  two  1.619710  0.809906
5  bar  two -1.090548 -0.713776
6  foo  one -1.058445  0.737929
7  foo three  0.565722  0.323839

```

On a DataFrame, we obtain a GroupBy object by calling `groupby()`. We could naturally group by either the A or B columns, or both:

```

In [8]: grouped = df.groupby('A')
In [9]: grouped = df.groupby(['A', 'B'])

```

New in version 0.24.

If we also have a MultiIndex on columns A and B, we can group by all but the specified columns

```

In [10]: df2 = df.set_index(['A', 'B'])
In [11]: grouped = df2.groupby(level=df2.index.names.difference(['B']))
In [12]: grouped.sum()
Out[12]:
      C      D
A
bar -1.662228 -0.371244
foo  1.753112  1.602958

```

These will split the DataFrame on its index (rows). We could also split by the columns:

```

In [13]: def get_letter_type(letter):
...:     if letter.lower() in 'aeiou':
...:         return 'vowel'
...:     else:
...:         return 'consonant'
...:
In [14]: grouped = df.groupby(get_letter_type, axis=1)

```

pandas *Index* objects support duplicate values. If a non-unique index is used as the group key in a groupby operation, all values for the same index value will be considered to be in one group and thus the output of aggregation functions will only contain unique index values:

```

In [15]: lst = [1, 2, 3, 1, 2, 3]

```

```
In [16]: s = pd.Series([1, 2, 3, 10, 20, 30], lst)
```

```
In [17]: grouped = s.groupby(level=0)
```

```
In [18]: grouped.first()
```

```
Out[18]:
1    1
2    2
3    3
dtype: int64
```

```
In [19]: grouped.last()
```

```
Out[19]:
1    10
2    20
3    30
dtype: int64
```

```
In [20]: grouped.sum()
```

```
Out[20]:
1    11
2    22
3    33
dtype: int64
```

Note that **no splitting occurs** until it's needed. Creating the GroupBy object only verifies that you've passed a valid mapping.

Note: Many kinds of complicated data manipulations can be expressed in terms of GroupBy operations (though can't be guaranteed to be the most efficient). You can get quite creative with the label mapping functions.

GroupBy sorting

By default the group keys are sorted during the `groupby` operation. You may however pass `sort=False` for potential speedups:

```
In [21]: df2 = pd.DataFrame({'X': ['B', 'B', 'A', 'A'], 'Y': [1, 2, 3, 4]})
```

```
In [22]: df2.groupby(['X']).sum()
```

```
Out[22]:
   Y
X
A   7
B   3
```

```
In [23]: df2.groupby(['X'], sort=False).sum()
```

```
Out[23]:
   Y
X
B   3
A   7
```

Note that `groupby` will preserve the order in which *observations* are sorted *within* each group. For example, the groups created by `groupby()` below are in the order they appeared in the original `DataFrame`:

```
In [24]: df3 = pd.DataFrame({'X': ['A', 'B', 'A', 'B'], 'Y': [1, 4, 3, 2]})
```

```
In [25]: df3.groupby(['X']).get_group('A')
```

```
Out[25]:
   X  Y
0  A  1
2  A  3
```

```
In [26]: df3.groupby(['X']).get_group('B')
```

```
Out[26]:
   X  Y
1  B  4
3  B  2
```

GroupBy object attributes

The `groups` attribute is a dict whose keys are the computed unique groups and corresponding values being the axis labels belonging to each group. In the above example we have:

```
In [27]: df.groupby('A').groups
```

```
Out[27]:
{'bar': Int64Index([1, 3, 5], dtype='int64'),
 'foo': Int64Index([0, 2, 4, 6, 7], dtype='int64')}
```

```
In [28]: df.groupby(get_letter_type, axis=1).groups
```

```
Out[28]:
{'consonant': Index(['B', 'C', 'D'], dtype='object'),
 'vowel': Index(['A'], dtype='object')}
```

Calling the standard Python `len` function on the `GroupBy` object just returns the length of the `groups` dict, so it is largely just a convenience:

```
In [29]: grouped = df.groupby(['A', 'B'])
```

```
In [30]: grouped.groups
```

```
Out[30]:
{('bar', 'one'): Int64Index([1], dtype='int64'),
 ('bar', 'three'): Int64Index([3], dtype='int64'),
 ('bar', 'two'): Int64Index([5], dtype='int64'),
 ('foo', 'one'): Int64Index([0, 6], dtype='int64'),
 ('foo', 'three'): Int64Index([7], dtype='int64'),
 ('foo', 'two'): Int64Index([2, 4], dtype='int64')}
```

```
In [31]: len(grouped)
```

```
Out[31]: 6
```

`GroupBy` will tab complete column names (and other attributes):

```
In [32]: df
Out[32]:
           height      weight  gender
2000-01-01  67.539208  153.593088   male
```

(continues on next page)

(continued from previous page)

```

2000-01-02  62.989840  178.848509  female
2000-01-03  61.287909  179.717656   male
2000-01-04  50.455174  166.099746   male
2000-01-05  46.985801  169.133885  female
2000-01-06  57.198503  166.582830   male
2000-01-07  68.953009  161.630518  female
2000-01-08  71.651298  161.978666  female
2000-01-09  60.524136  176.080671   male
2000-01-10  60.397859  177.704182   male

```

```
In [33]: gb = df.groupby('gender')
```

```
In [34]: gb.<TAB> # noqa: E225, E999
```

```

gb.agg      gb.boxplot      gb.cummin      gb.describe    gb.filter      gb.get_group  gb.
↳height    gb.last         gb.median      gb.ngroups     gb.plot        gb.rank       gb.
↳std       gb.transform
gb.aggregate gb.count        gb.cumprod     gb.dtype       gb.first       gb.groups     gb.
↳hist      gb.max          gb.min         gb.nth         gb.prod        gb.resample   gb.
↳sum       gb.var
gb.apply     gb.cummax       gb.cumsum      gb.fillna      gb.gender      gb.head       gb.
↳indices   gb.mean         gb.name        gb.ohlc        gb.quantile    gb.size       gb.
↳tail     gb.weight

```

GroupBy with MultiIndex

With *hierarchically-indexed data*, it's quite natural to group by one of the levels of the hierarchy.

Let's create a Series with a two-level MultiIndex.

```
In [35]: arrays = [['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'],
.....:             ['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two']]
.....:
```

```
In [36]: index = pd.MultiIndex.from_arrays(arrays, names=['first', 'second'])
```

```
In [37]: s = pd.Series(np.random.randn(8), index=index)
```

```
In [38]: s
```

```
Out[38]:
```

```

first second
bar    one    0.994442
      two   -1.007082
baz    one    0.541666
      two    1.649827
foo    one   -0.218738
      two    1.589639
qux    one   -0.811123
      two    0.299770
dtype: float64

```

We can then group by one of the levels in `s`.

```
In [39]: grouped = s.groupby(level=0)
```

```
In [40]: grouped.sum()
```

```
Out [40]:
first
bar    -0.012640
baz     2.191493
foo     1.370901
qux    -0.511354
dtype: float64
```

If the MultiIndex has names specified, these can be passed instead of the level number:

```
In [41]: s.groupby(level='second').sum()
```

```
Out [41]:
second
one     0.506247
two     2.532153
dtype: float64
```

The aggregation functions such as `sum` will take the level parameter directly. Additionally, the resulting index will be named according to the chosen level:

```
In [42]: s.sum(level='second')
```

```
Out [42]:
second
one     0.506247
two     2.532153
dtype: float64
```

Grouping with multiple levels is supported.

```
In [43]: s
```

```
Out [43]:
first second third
bar   doo   one    1.672060
      doo   two   -0.141621
baz   bee   one   -0.584087
      bee   two   -1.725987
foo   bop   one   -1.262896
      bop   two    1.017510
qux   bop   one   -0.429949
      bop   two   -1.226542
dtype: float64
```

```
In [44]: s.groupby(level=['first', 'second']).sum()
```

```
Out [44]:
first second
bar   doo    1.530439
baz   bee   -2.310073
foo   bop   -0.245385
qux   bop   -1.656491
dtype: float64
```

New in version 0.20.

Index level names may be supplied as keys.

```
In [45]: s.groupby(['first', 'second']).sum()
Out[45]:
first second
bar   doo      1.530439
baz   bee     -2.310073
foo   bop     -0.245385
qux   bop     -1.656491
dtype: float64
```

More on the `sum` function and aggregation later.

Grouping DataFrame with Index levels and columns

A DataFrame may be grouped by a combination of columns and index levels by specifying the column names as strings and the index levels as `pd.Grouper` objects.

```
In [46]: arrays = [['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'],
.....:              ['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two']]
.....:

In [47]: index = pd.MultiIndex.from_arrays(arrays, names=['first', 'second'])

In [48]: df = pd.DataFrame({'A': [1, 1, 1, 1, 2, 2, 3, 3],
.....:                      'B': np.arange(8)},
.....:                      index=index)
.....:

In [49]: df
Out[49]:
           A  B
first second
bar   one    1  0
      two    1  1
baz   one    1  2
      two    1  3
foo   one    2  4
      two    2  5
qux   one    3  6
      two    3  7
```

The following example groups `df` by the `second` index level and the `A` column.

```
In [50]: df.groupby([pd.Grouper(level=1), 'A']).sum()
Out[50]:
           B
second A
one     1  2
        2  4
        3  6
two     1  4
```

(continues on next page)

(continued from previous page)

```
2  5
3  7
```

Index levels may also be specified by name.

```
In [51]: df.groupby([pd.Grouper(level='second'), 'A']).sum()
Out[51]:
```

		B	
second	A		
one	1	2	
	2	4	
	3	6	
two	1	4	
	2	5	
	3	7	

New in version 0.20.

Index level names may be specified as keys directly to `groupby`.

```
In [52]: df.groupby(['second', 'A']).sum()
Out[52]:
```

		B	
second	A		
one	1	2	
	2	4	
	3	6	
two	1	4	
	2	5	
	3	7	

DataFrame column selection in GroupBy

Once you have created the `GroupBy` object from a `DataFrame`, you might want to do something different for each of the columns. Thus, using `[]` similar to getting a column from a `DataFrame`, you can do:

```
In [53]: grouped = df.groupby(['A'])
In [54]: grouped_C = grouped['C']
In [55]: grouped_D = grouped['D']
```

This is mainly syntactic sugar for the alternative and much more verbose:

```
In [56]: df['C'].groupby(df['A'])
Out[56]: <pandas.core.groupby.generic.SeriesGroupBy object at 0x14280af90>
```

Additionally this method avoids recomputing the internal grouping information derived from the passed key.

4.12.2 Iterating through groups

With the GroupBy object in hand, iterating through the grouped data is very natural and functions similarly to `itertools.groupby()`:

```
In [57]: grouped = df.groupby('A')

In [58]: for name, group in grouped:
.....:     print(name)
.....:     print(group)
.....:
bar
   A      B      C      D
1 bar  one  0.288024 -1.467627
3 bar  three 0.745006  0.788612
5 bar  two  2.621557  0.125725
foo
   A      B      C      D
0 foo  one -0.297872  0.630951
2 foo  two  0.049068  0.077597
4 foo  two  1.256393  1.628982
6 foo  one  1.368453  1.456025
7 foo  three 0.362188 -0.068011
```

In the case of grouping by multiple keys, the group name will be a tuple:

```
In [59]: for name, group in df.groupby(['A', 'B']):
.....:     print(name)
.....:     print(group)
.....:
('bar', 'one')
   A      B      C      D
1 bar  one  0.288024 -1.467627
('bar', 'three')
   A      B      C      D
3 bar  three 0.745006  0.788612
('bar', 'two')
   A      B      C      D
5 bar  two  2.621557  0.125725
('foo', 'one')
   A      B      C      D
0 foo  one -0.297872  0.630951
6 foo  one  1.368453  1.456025
('foo', 'three')
   A      B      C      D
7 foo  three 0.362188 -0.068011
('foo', 'two')
   A      B      C      D
2 foo  two  0.049068  0.077597
4 foo  two  1.256393  1.628982
```

See *Iterating through groups*.

4.12.3 Selecting a group

A single group can be selected using `get_group()`:

```
In [60]: grouped.get_group('bar')
Out[60]:
   A      B      C      D
1 bar  one  0.288024 -1.467627
3 bar three 0.745006  0.788612
5 bar  two  2.621557  0.125725
```

Or for an object grouped on multiple columns:

```
In [61]: df.groupby(['A', 'B']).get_group(('bar', 'one'))
Out[61]:
   A      B      C      D
1 bar  one  0.288024 -1.467627
```

4.12.4 Aggregation

Once the `GroupBy` object has been created, several methods are available to perform a computation on the grouped data. These operations are similar to the *aggregating API*, *window functions API*, and *resample API*.

An obvious one is aggregation via the `aggregate()` or equivalently `agg()` method:

```
In [62]: grouped = df.groupby('A')

In [63]: grouped.aggregate(np.sum)
Out[63]:
      C      D
A
bar  3.654587 -0.553289
foo  2.738230  3.725545

In [64]: grouped = df.groupby(['A', 'B'])

In [65]: grouped.aggregate(np.sum)
Out[65]:
      C      D
A  B
bar one  0.288024 -1.467627
   three 0.745006  0.788612
   two  2.621557  0.125725
foo one  1.070581  2.086976
   three 0.362188 -0.068011
   two  1.305461  1.706580
```

As you can see, the result of the aggregation will have the group names as the new index along the grouped axis. In the case of multiple keys, the result is a *MultiIndex* by default, though this can be changed by using the `as_index` option:

```
In [66]: grouped = df.groupby(['A', 'B'], as_index=False)
```

```
In [67]: grouped.aggregate(np.sum)
Out[67]:
```

	A	B	C	D
0	bar	one	0.288024	-1.467627
1	bar	three	0.745006	0.788612
2	bar	two	2.621557	0.125725
3	foo	one	1.070581	2.086976
4	foo	three	0.362188	-0.068011
5	foo	two	1.305461	1.706580

```
In [68]: df.groupby('A', as_index=False).sum()
Out[68]:
```

	A	C	D
0	bar	3.654587	-0.553289
1	foo	2.738230	3.725545

Note that you could use the `reset_index` DataFrame function to achieve the same result as the column names are stored in the resulting MultiIndex:

```
In [69]: df.groupby(['A', 'B']).sum().reset_index()
```

```
Out[69]:
```

	A	B	C	D
0	bar	one	0.288024	-1.467627
1	bar	three	0.745006	0.788612
2	bar	two	2.621557	0.125725
3	foo	one	1.070581	2.086976
4	foo	three	0.362188	-0.068011
5	foo	two	1.305461	1.706580

Another simple aggregation example is to compute the size of each group. This is included in GroupBy as the `size` method. It returns a Series whose index are the group names and whose values are the sizes of each group.

```
In [70]: grouped.size()
```

```
Out[70]:
```

A	B	
bar	one	1
	three	1
	two	1
foo	one	2
	three	1
	two	2

dtype: int64

```
In [71]: grouped.describe()
```

```
Out[71]:
```

	C							D	
↪	count	mean	std	min	25%	50%	75%	max	count
↪	mean	std	min	25%	50%	75%	max

↳853290  1.096995  0.077597  0.465444  0.853290  1.241136  1.628982

```

Note: Aggregation functions **will not** return the groups that you are aggregating over if they are named *columns*, when `as_index=True`, the default. The grouped columns will be the **indices** of the returned object. Passing `as_index=False` **will** return the groups that you are aggregating over, if they are named *columns*.

Aggregating functions are the ones that reduce the dimension of the returned objects. Some common aggregating functions are tabulated below:

Function	Description
<code>mean()</code>	Compute mean of groups
<code>sum()</code>	Compute sum of group values
<code>size()</code>	Compute group sizes
<code>count()</code>	Compute count of group
<code>std()</code>	Standard deviation of groups
<code>var()</code>	Compute variance of groups
<code>sem()</code>	Standard error of the mean of groups
<code>describe()</code>	Generates descriptive statistics
<code>first()</code>	Compute first of group values
<code>last()</code>	Compute last of group values
<code>nth()</code>	Take <i>n</i> th value, or a subset if <i>n</i> is a list
<code>min()</code>	Compute min of group values
<code>max()</code>	Compute max of group values

The aggregating functions above will exclude NA values. Any function which reduces a `Series` to a scalar value is an aggregation function and will work, a trivial example is `df.groupby('A').agg(lambda ser: 1)`. Note that `nth()` can act as a reducer *or* a filter, see [here](#).

Applying multiple functions at once

With grouped `Series` you can also pass a list or dict of functions to do aggregation with, outputting a `DataFrame`:

```

In [72]: grouped = df.groupby('A')

In [73]: grouped['C'].agg([np.sum, np.mean, np.std])
Out [73]:
           sum      mean      std
A
bar  3.654587  1.218196  1.236638
foo  2.738230  0.547646  0.737211

```

On a grouped DataFrame, you can pass a list of functions to apply to each column, which produces an aggregated result with a hierarchical index:

```
In [74]: grouped.agg([np.sum, np.mean, np.std])
Out[74]:
```

	C			D		
	sum	mean	std	sum	mean	std
A						
bar	3.654587	1.218196	1.236638	-0.553289	-0.184430	1.159655
foo	2.738230	0.547646	0.737211	3.725545	0.745109	0.775629

The resulting aggregations are named for the functions themselves. If you need to rename, then you can add in a chained operation for a Series like this:

```
In [75]: (grouped['C'].agg([np.sum, np.mean, np.std])
.....:                .rename(columns={'sum': 'foo',
.....:                                'mean': 'bar',
.....:                                'std': 'baz'}))
.....:
Out[75]:
```

	foo	bar	baz
A			
bar	3.654587	1.218196	1.236638
foo	2.738230	0.547646	0.737211

For a grouped DataFrame, you can rename in a similar manner:

```
In [76]: (grouped.agg([np.sum, np.mean, np.std])
.....:                .rename(columns={'sum': 'foo',
.....:                                'mean': 'bar',
.....:                                'std': 'baz'}))
.....:
Out[76]:
```

	C			D		
	foo	bar	baz	foo	bar	baz
A						
bar	3.654587	1.218196	1.236638	-0.553289	-0.184430	1.159655
foo	2.738230	0.547646	0.737211	3.725545	0.745109	0.775629

Note: In general, the output column names should be unique. You can't apply the same function (or two functions with the same name) to the same column.

```
In [77]: grouped['C'].agg(['sum', 'sum'])

922             )
923

SpecificationError: Function names must be unique, found multiple named sum

```

Pandas *does* allow you to provide multiple lambdas. In this case, pandas will mangle the name of the (nameless) lambda functions, appending `<i>` to each subsequent lambda.

```

In [78]: grouped['C'].agg([lambda x: x.max() - x.min(),
.....:                    lambda x: x.median() - x.mean()])
.....:
Out[78]:
   <lambda_0>  <lambda_1>
A
bar    2.333533  -0.473189
foo    1.666325  -0.185458

```

Named aggregation

New in version 0.25.0.

To support column-specific aggregation *with control over the output column names*, pandas accepts the special syntax in `GroupBy.agg()`, known as “named aggregation”, where

- The keywords are the *output* column names
- The values are tuples whose first element is the column to select and the second element is the aggregation to apply to that column. Pandas provides the `pandas.NamedAgg` namedtuple with the fields `['column', 'aggfunc']` to make it clearer what the arguments are. As usual, the aggregation can be a callable or a string alias.

```

In [79]: animals = pd.DataFrame({'kind': ['cat', 'dog', 'cat', 'dog'],
.....:                          'height': [9.1, 6.0, 9.5, 34.0],
.....:                          'weight': [7.9, 7.5, 9.9, 198.0]})
.....:

```

```

In [80]: animals
Out[80]:
   kind  height  weight
0  cat     9.1     7.9
1  dog     6.0     7.5
2  cat     9.5     9.9
3  dog    34.0   198.0

```

```

In [81]: animals.groupby("kind").agg(

```

```

.....: min_height=pd.NamedAgg(column='height', aggfunc='min'),
.....: max_height=pd.NamedAgg(column='height', aggfunc='max'),
.....: average_weight=pd.NamedAgg(column='weight', aggfunc=np.mean),
.....: )
.....:
Out[81]:

```

	min_height	max_height	average_weight
kind			
cat	9.1	9.5	8.90
dog	6.0	34.0	102.75

pandas.NamedAgg is just a namedtuple. Plain tuples are allowed as well.

```

In [82]: animals.groupby("kind").agg(
.....:     min_height=('height', 'min'),
.....:     max_height=('height', 'max'),
.....:     average_weight=('weight', np.mean),
.....: )
.....:

```

```

Out[82]:

```

	min_height	max_height	average_weight
kind			
cat	9.1	9.5	8.90
dog	6.0	34.0	102.75

If your desired output column names are not valid python keywords, construct a dictionary and unpack the keyword arguments

```

In [83]: animals.groupby("kind").agg(**{
.....:     'total_weight': pd.NamedAgg(column='weight', aggfunc=sum),
.....: })
.....:

```

```

Out[83]:

```

	total_weight
kind	
cat	17.8
dog	205.5

Additional keyword arguments are not passed through to the aggregation functions. Only pairs of (column, aggfunc) should be passed as ****kwargs**. If your aggregation functions requires additional arguments, partially apply them with `functools.partial()`.

Note: For Python 3.5 and earlier, the order of ****kwargs** in a functions was not preserved. This means that the output column ordering would not be consistent. To ensure consistent ordering, the keys (and so output columns) will always be sorted for Python 3.5.

Named aggregation is also valid for Series groupby aggregations. In this case there's no column selection, so the values are just the functions.

```

In [84]: animals.groupby("kind").height.agg(
.....:     min_height='min',
.....:     max_height='max',
.....: )

```

(continues on next page)

(continued from previous page)

```

.....:
Out [84]:
      min_height  max_height
kind
cat           9.1          9.5
dog           6.0         34.0

```

Applying different functions to DataFrame columns

By passing a dict to `aggregate` you can apply a different aggregation to the columns of a DataFrame:

```

In [85]: grouped.agg({'C': np.sum,
.....:                'D': lambda x: np.std(x, ddof=1)})
.....:
Out [85]:
      C      D
A
bar  3.654587  1.159655
foo  2.738230  0.775629

```

The function names can also be strings. In order for a string to be valid it must be either implemented on `GroupBy` or available via *dispatching*:

```

In [86]: grouped.agg({'C': 'sum', 'D': 'std'})
Out [86]:
      C      D
A
bar  3.654587  1.159655
foo  2.738230  0.775629

```

Cython-optimized aggregation functions

Some common aggregations, currently only `sum`, `mean`, `std`, and `sem`, have optimized Cython implementations:

```

In [87]: df.groupby('A').sum()
Out [87]:

```

```

      C      D
A
bar  3.654587 -0.553289
foo  2.738230  3.725545

```

```

In [88]: df.groupby(['A', 'B']).mean()
Out [88]:

```

```

      C      D
A  B
bar one  0.288024 -1.467627
   three 0.745006  0.788612
   two   2.621557  0.125725
foo one  0.535291  1.043488
   three 0.362188 -0.068011

```

```
two    0.652731  0.853290
```

Of course `sum` and `mean` are implemented on pandas objects, so the above code would work even without the special versions via dispatching (see below).

4.12.5 Transformation

The `transform` method returns an object that is indexed the same (same size) as the one being grouped. The transform function must:

- Return a result that is either the same size as the group chunk or broadcastable to the size of the group chunk (e.g., a scalar, `grouped.transform(lambda x: x.iloc[-1])`).
- Operate column-by-column on the group chunk. The transform is applied to the first group chunk using `chunk.apply`.
- Not perform in-place operations on the group chunk. Group chunks should be treated as immutable, and changes to a group chunk may produce unexpected results. For example, when using `fillna`, `inplace` must be `False` (`grouped.transform(lambda x: x.fillna(inplace=False))`).
- (Optionally) operates on the entire group chunk. If this is supported, a fast path is used starting from the *second* chunk.

For example, suppose we wished to standardize the data within each group:

```
In [89]: index = pd.date_range('10/1/1999', periods=1100)

In [90]: ts = pd.Series(np.random.normal(0.5, 2, 1100), index)

In [91]: ts = ts.rolling(window=100, min_periods=100).mean().dropna()

In [92]: ts.head()
Out[92]:
2000-01-08    0.865232
2000-01-09    0.835242
2000-01-10    0.801536
2000-01-11    0.786370
2000-01-12    0.777867
Freq: D, dtype: float64

In [93]: ts.tail()
Out[93]:
2002-09-30    0.360614
2002-10-01    0.382288
2002-10-02    0.383086
2002-10-03    0.365846
2002-10-04    0.374030
Freq: D, dtype: float64

In [94]: transformed = (ts.groupby(lambda x: x.year)
....:                      .transform(lambda x: (x - x.mean()) / x.std()))
....:
```

We would expect the result to now have mean 0 and standard deviation 1 within each group, which we can easily check:

```
# Original Data
In [95]: grouped = ts.groupby(lambda x: x.year)
```

```
In [96]: grouped.mean()
```

```
Out[96]:
```

```
2000    0.460436
```

```
2001    0.477878
```

```
2002    0.440377
```

```
dtype: float64
```

```
In [97]: grouped.std()
```

```
Out[97]:
```

```
2000    0.215566
```

```
2001    0.111128
```

```
2002    0.130943
```

```
dtype: float64
```

```
# Transformed Data
```

```
In [98]: grouped_trans = transformed.groupby(lambda x: x.year)
```

```
In [99]: grouped_trans.mean()
```

```
Out[99]:
```

```
2000    2.368656e-15
```

```
2001    3.565451e-16
```

```
2002   -2.629265e-16
```

```
dtype: float64
```

```
In [100]: grouped_trans.std()
```

```
Out[100]:
```

```
2000    1.0
```

```
2001    1.0
```

```
2002    1.0
```

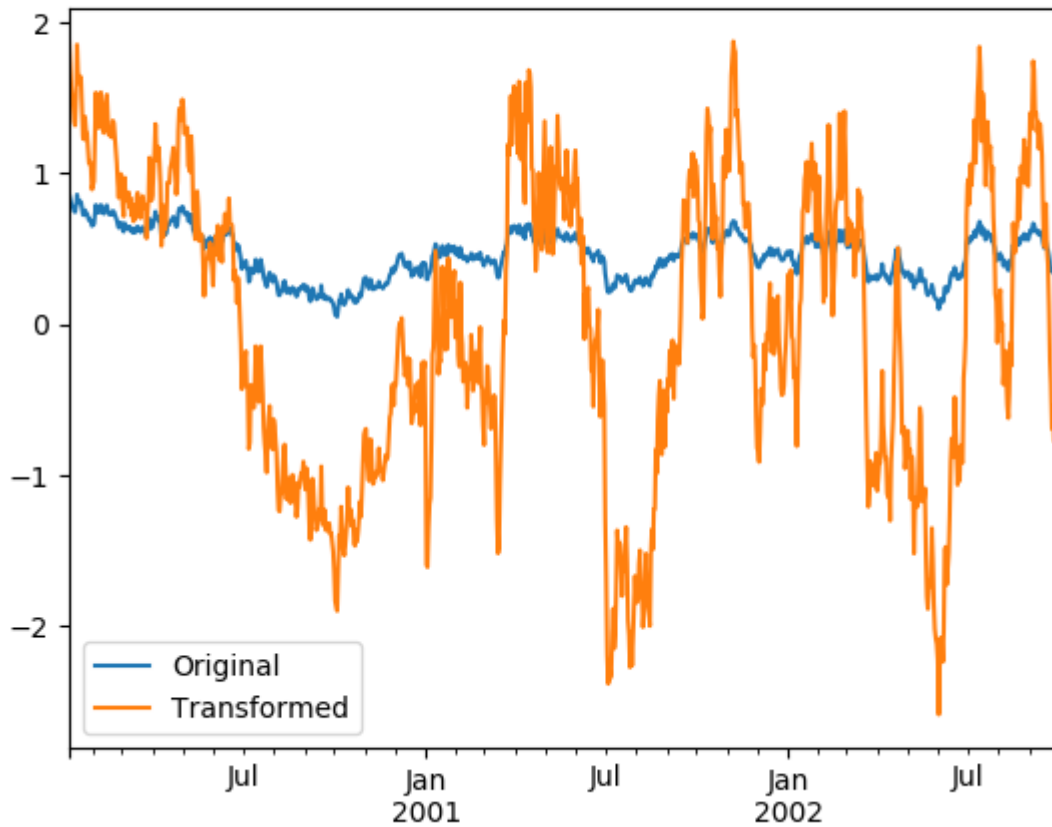

```
dtype: float64
```

We can also visually compare the original and transformed data sets.

```
In [101]: compare = pd.DataFrame({'Original': ts, 'Transformed': transformed})
```

```
In [102]: compare.plot()
```

```
Out[102]: <matplotlib.axes._subplots.AxesSubplot at 0x13c6d1250>
```

Transformation functions that have lower dimension outputs are broadcast to match the shape of the input array.

```
In [103]: ts.groupby(lambda x: x.year).transform(lambda x: x.max() - x.min())
Out[103]:
2000-01-08    0.814101
2000-01-09    0.814101
2000-01-10    0.814101
2000-01-11    0.814101
2000-01-12    0.814101
...
2002-09-30    0.579454
2002-10-01    0.579454
2002-10-02    0.579454
2002-10-03    0.579454
2002-10-04    0.579454
Freq: D, Length: 1001, dtype: float64
```

Alternatively, the built-in methods could be used to produce the same outputs.

```
In [104]: max = ts.groupby(lambda x: x.year).transform('max')
In [105]: min = ts.groupby(lambda x: x.year).transform('min')
```

(continues on next page)

(continued from previous page)

```

New syntax to window and resample operations

New in version 0.18.1.

Working with the resample, expanding or rolling operations on the groupby level used to require the application of helper functions. However, now it is possible to use `resample()`, `expanding()` and `rolling()` as methods on groupbys.

The example below will apply the `rolling()` method on the samples of the column B based on the groups of column A.

```
In [120]: df_re = pd.DataFrame({'A': [1] * 10 + [5] * 10,
.....:                        'B': np.arange(20)})
.....:
```

```
In [121]: df_re
```

```
Out[121]:
```

```

   A  B
0  1  0
1  1  1
2  1  2
3  1  3
4  1  4
5  1  5
6  1  6
7  1  7
8  1  8
9  1  9
10 5 10
11 5 11
12 5 12
13 5 13
14 5 14
15 5 15
16 5 16
17 5 17
18 5 18
19 5 19

```

```
In [122]: df_re.groupby('A').rolling(4).B.mean()
```

```
Out[122]:
```

```
A
1  0      NaN
   1      NaN
   2      NaN
   3      1.5
   4      2.5
   5      3.5
   6      4.5
   7      5.5
   8      6.5
   9      7.5
5 10      NaN
   11     NaN
   12     NaN
   13     11.5
   14     12.5
   15     13.5
   16     14.5
   17     15.5
   18     16.5
   19     17.5
```

```
Name: B, dtype: float64
```

The `expanding()` method will accumulate a given operation (`sum()` in the example) for all the members of each particular group.

```
In [123]: df_re.groupby('A').expanding().sum()
```

```
Out[123]:
```

```
      A      B
A
1  0   1.0   0.0
   1   2.0   1.0
   2   3.0   3.0
   3   4.0   6.0
   4   5.0  10.0
   5   6.0  15.0
   6   7.0  21.0
   7   8.0  28.0
   8   9.0  36.0
   9  10.0  45.0
5 10   5.0  10.0
   11  10.0  21.0
   12  15.0  33.0
   13  20.0  46.0
   14  25.0  60.0
   15  30.0  75.0
   16  35.0  91.0
   17  40.0 108.0
   18  45.0 126.0
   19  50.0 145.0
```

Suppose you want to use the `resample()` method to get a daily frequency in each group of your dataframe and wish to complete the missing values with the `ffill()` method.

```
In [124]: df_re = pd.DataFrame({'date': pd.date_range(start='2016-01-01', periods=4,
.....:                                     freq='W'),
.....:                        'group': [1, 1, 2, 2],
.....:                        'val': [5, 6, 7, 8]}).set_index('date')
.....:
```

```
In [125]: df_re
```

```
Out[125]:
```

date	group	val
2016-01-03	1	5
2016-01-10	1	6
2016-01-17	2	7
2016-01-24	2	8

```
In [126]: df_re.groupby('group').resample('1D').ffill()
```

```
Out[126]:
```

group	date	group	val	
1	2016-01-03	1	5	
	2016-01-04	1	5	
	2016-01-05	1	5	
	2016-01-06	1	5	
	2016-01-07	1	5	
	2016-01-08	1	5	
	2016-01-09	1	5	
	2016-01-10	1	6	
	2	2016-01-17	2	7
		2016-01-18	2	7
2016-01-19		2	7	
2016-01-20		2	7	
2016-01-21		2	7	
2016-01-22		2	7	
2016-01-23		2	7	
2016-01-24		2	8	

4.12.6 Filtration

The `filter` method returns a subset of the original object. Suppose we want to take only elements that belong to groups with a group sum greater than 2.

```
In [127]: sf = pd.Series([1, 1, 2, 3, 3, 3])

In [128]: sf.groupby(sf).filter(lambda x: x.sum() > 2)
Out[128]:
3    3
4    3
5    3
dtype: int64
```

The argument of `filter` must be a function that, applied to the group as a whole, returns `True` or `False`. Another useful operation is filtering out elements that belong to groups with only a couple members.

```
In [129]: dff = pd.DataFrame({'A': np.arange(8), 'B': list('aabbbbcc')})
```

```
In [130]: dff.groupby('B').filter(lambda x: len(x) > 2)
```

```
Out[130]:
```

	A	B
2	2	b
3	3	b
4	4	b
5	5	b

Alternatively, instead of dropping the offending groups, we can return a like-indexed objects where the groups that do not pass the filter are filled with NaNs.

```
In [131]: dff.groupby('B').filter(lambda x: len(x) > 2, dropna=False)
```

```
Out[131]:
```

	A	B
0	NaN	NaN
1	NaN	NaN
2	2.0	b
3	3.0	b
4	4.0	b
5	5.0	b
6	NaN	NaN
7	NaN	NaN

For DataFrames with multiple columns, filters should explicitly specify a column as the filter criterion.

```
In [132]: dff['C'] = np.arange(8)
```

```
In [133]: dff.groupby('B').filter(lambda x: len(x['C']) > 2)
```

```
Out[133]:
```

	A	B	C
2	2	b	2
3	3	b	3
4	4	b	4
5	5	b	5

Note: Some functions when applied to a groupby object will act as a **filter** on the input, returning a reduced shape of the original (and potentially eliminating groups), but with the index unchanged. Passing `as_index=False` will not affect these transformation methods.

For example: `head`, `tail`.

```
In [134]: dff.groupby('B').head(2)
```

```
Out[134]:
```

	A	B	C
0	0	a	0
1	1	a	1
2	2	b	2
3	3	b	3
6	6	c	6
7	7	c	7

4.12.7 Dispatching to instance methods

When doing an aggregation or transformation, you might just want to call an instance method on each data group. This is pretty easy to do by passing lambda functions:

```
In [135]: grouped = df.groupby('A')

In [136]: grouped.agg(lambda x: x.std())
Out[136]:
```

	C	D
A		
bar	1.236638	1.159655
foo	0.737211	0.775629

But, it's rather verbose and can be untidy if you need to pass additional arguments. Using a bit of metaprogramming cleverness, GroupBy now has the ability to “dispatch” method calls to the groups:

```
In [137]: grouped.std()
Out[137]:
```

	C	D
A		
bar	1.236638	1.159655
foo	0.737211	0.775629

What is actually happening here is that a function wrapper is being generated. When invoked, it takes any passed arguments and invokes the function with any arguments on each group (in the above example, the `std` function). The results are then combined together much in the style of `agg` and `transform` (it actually uses `apply` to infer the gluing, documented next). This enables some operations to be carried out rather succinctly:

```
In [138]: tsdf = pd.DataFrame(np.random.randn(1000, 3),
.....:                        index=pd.date_range('1/1/2000', periods=1000),
.....:                        columns=['A', 'B', 'C'])
.....:

In [139]: tsdf.iloc[:,2] = np.nan

In [140]: grouped = tsdf.groupby(lambda x: x.year)

In [141]: grouped.fillna(method='pad')
Out[141]:
```

	A	B	C
2000-01-01	NaN	NaN	NaN
2000-01-02	1.125163	-0.383261	0.284227
2000-01-03	1.125163	-0.383261	0.284227
2000-01-04	0.606730	-0.880692	-0.944393
2000-01-05	0.606730	-0.880692	-0.944393
...
2002-09-22	-1.409950	-0.444110	-0.553993
2002-09-23	-1.409950	-0.444110	-0.553993
2002-09-24	-1.158956	0.108182	3.050277
2002-09-25	-1.158956	0.108182	3.050277
2002-09-26	0.061621	0.301882	-1.085504

(continues on next page)

(continued from previous page)

[1000 rows x 3 columns]

In this example, we chopped the collection of time series into yearly chunks then independently called *fillna* on the groups.

The `nlargest` and `nsmallest` methods work on `Series` style groupbys:

```
In [142]: s = pd.Series([9, 8, 7, 5, 19, 1, 4.2, 3.3])
```

```
In [143]: g = pd.Series(list('abababab'))
```

```
In [144]: gb = s.groupby(g)
```

```
In [145]: gb.nlargest(3)
```

```
Out[145]:
```

```
a 4    19.0
   0     9.0
   2     7.0
b 1     8.0
   3     5.0
   7     3.3
```

```
dtype: float64
```

```
In [146]: gb.nsmallest(3)
```

```
Out[146]:
```

```
a 6     4.2
   2     7.0
   0     9.0
b 5     1.0
   7     3.3
   3     5.0
```

```
dtype: float64
```

4.12.8 Flexible apply

Some operations on the grouped data might not fit into either the aggregate or transform categories. Or, you may simply want `GroupBy` to infer how to combine the results. For these, use the `apply` function, which can be substituted for both `aggregate` and `transform` in many standard use cases. However, `apply` can handle some exceptional use cases, for example:

```
In [147]: df
```

```
Out[147]:
```

	A	B	C	D
0	foo	one	-0.297872	0.630951
1	bar	one	0.288024	-1.467627
2	foo	two	0.049068	0.077597
3	bar	three	0.745006	0.788612
4	foo	two	1.256393	1.628982
5	bar	two	2.621557	0.125725
6	foo	one	1.368453	1.456025
7	foo	three	0.362188	-0.068011

(continues on next page)

(continued from previous page)

```
In [148]: grouped = df.groupby('A')

# could also just call .describe()
In [149]: grouped['C'].apply(lambda x: x.describe())
Out[149]:
A
bar  count    3.000000
     mean    1.218196
     std     1.236638
     min     0.288024
     25%     0.516515
     50%     0.745006
     75%     1.683281
     max     2.621557
foo  count    5.000000
     mean     0.547646
     std     0.737211
     min    -0.297872
     25%     0.049068
     50%     0.362188
     75%     1.256393
     max     1.368453
Name: C, dtype: float64
```

The dimension of the returned result can also change:

```
In [150]: grouped = df.groupby('A')['C']

In [151]: def f(group):
.....:     return pd.DataFrame({'original': group,
.....:                          'demeaned': group - group.mean()})
.....:

In [152]: grouped.apply(f)
Out[152]:
   original  demeaned
0 -0.297872 -0.845518
1  0.288024 -0.930172
2  0.049068 -0.498578
3  0.745006 -0.473189
4  1.256393  0.708747
5  2.621557  1.403361
6  1.368453  0.820807
7  0.362188 -0.185458
```

`apply` on a Series can operate on a returned value from the applied function, that is itself a series, and possibly upcast the result to a DataFrame:

```
In [153]: def f(x):
.....:     return pd.Series([x, x ** 2], index=['x', 'x^2'])
.....:
```

```
In [154]: s = pd.Series(np.random.rand(5))
```

```
In [155]: s
Out[155]:
0    0.798954
1    0.191223
2    0.584617
3    0.692853
4    0.064370
dtype: float64
```

```
In [156]: s.apply(f)
Out[156]:
      x      x^2
0  0.798954  0.638328
1  0.191223  0.036566
2  0.584617  0.341777
3  0.692853  0.480045
4  0.064370  0.004144
```

Note: `apply` can act as a reducer, transformer, *or* filter function, depending on exactly what is passed to it. So depending on the path taken, and exactly what you are grouping. Thus the grouped columns(s) may be included in the output as well as set the indices.

4.12.9 Other useful features

Automatic exclusion of “nuisance” columns

Again consider the example DataFrame we’ve been looking at:

```
In [157]: df
Out[157]:
   A      B      C      D
0  foo  one -0.297872  0.630951
1  bar  one  0.288024 -1.467627
2  foo  two  0.049068  0.077597
3  bar three  0.745006  0.788612
4  foo  two  1.256393  1.628982
5  bar  two  2.621557  0.125725
6  foo  one  1.368453  1.456025
7  foo three  0.362188 -0.068011
```

Suppose we wish to compute the standard deviation grouped by the A column. There is a slight problem, namely that we don’t care about the data in column B. We refer to this as a “nuisance” column. If the passed aggregation function can’t be applied to some columns, the troublesome columns will be (silently) dropped. Thus, this does not pose any problems:

```
In [158]: df.groupby('A').std()
Out[158]:
      C      D
A
```

(continues on next page)

(continued from previous page)

```
bar 1.236638 1.159655
foo 0.737211 0.775629
```

Note that `df.groupby('A').colname.std()` is more efficient than `df.groupby('A').std().colname`, so if the result of an aggregation function is only interesting over one column (here `colname`), it may be filtered *before* applying the aggregation function.

Note: Any object column, also if it contains numerical values such as `Decimal` objects, is considered as a “nuisance” columns. They are excluded from aggregate functions automatically in `groupby`.

If you do wish to include decimal or object columns in an aggregation with other non-nuisance data types, you must do so explicitly.

```
In [159]: from decimal import Decimal
```

```
In [160]: df_dec = pd.DataFrame(
.....:     {'id': [1, 2, 1, 2],
.....:      'int_column': [1, 2, 3, 4],
.....:      'dec_column': [Decimal('0.50'), Decimal('0.15'),
.....:                   Decimal('0.25'), Decimal('0.40')]
.....:     }
.....: )
.....:
```

Decimal columns can be sum'd explicitly by themselves...

```
In [161]: df_dec.groupby(['id'])[['dec_column']].sum()
```

```
Out[161]:
   dec_column
id
1          0.75
2          0.55
```

...but cannot be combined with standard data types or they will be excluded

```
In [162]: df_dec.groupby(['id'])[['int_column', 'dec_column']].sum()
```

```
Out[162]:
   int_column
id
1            4
2            6
```

Use `.agg` function to aggregate over standard and “nuisance” data types
at the same time

```
In [163]: df_dec.groupby(['id']).agg({'int_column': 'sum', 'dec_column': 'sum'})
```

```
Out[163]:
   int_column dec_column
id
1            4          0.75
2            6          0.55
```

Handling of (un)observed Categorical values

When using a `Categorical` grouper (as a single grouper, or as part of multiple groupers), the `observed` keyword controls whether to return a cartesian product of all possible groupers values (`observed=False`) or only those that are observed groupers (`observed=True`).

Show all values:

```
In [164]: pd.Series([1, 1, 1]).groupby(pd.Categorical(['a', 'a', 'a'],
.....:                                           categories=['a', 'b']),
.....:                                observed=False).count()
.....:
Out[164]:
a    3
b    0
dtype: int64
```

Show only the observed values:

```
In [165]: pd.Series([1, 1, 1]).groupby(pd.Categorical(['a', 'a', 'a'],
.....:                                           categories=['a', 'b']),
.....:                                observed=True).count()
.....:
Out[165]:
a    3
dtype: int64
```

The returned dtype of the grouped will *always* include *all* of the categories that were grouped.

```
In [166]: s = pd.Series([1, 1, 1]).groupby(pd.Categorical(['a', 'a', 'a'],
.....:                                           categories=['a', 'b']),
.....:                                observed=False).count()
.....:

In [167]: s.index.dtype
Out[167]: CategoricalDtype(categories=['a', 'b'], ordered=False)
```

NA and NaT group handling

If there are any NaN or NaT values in the grouping key, these will be automatically excluded. In other words, there will never be an “NA group” or “NaT group”. This was not the case in older versions of pandas, but users were generally discarding the NA group anyway (and supporting it was an implementation headache).

Grouping with ordered factors

Categorical variables represented as instance of pandas’s `Categorical` class can be used as group keys. If so, the order of the levels will be preserved:

```
In [168]: data = pd.Series(np.random.randn(100))

In [169]: factor = pd.qcut(data, [0, .25, .5, .75, 1.])
```

(continues on next page)

(continued from previous page)

```
In [170]: data.groupby(factor).mean()
Out[170]:
(-2.407, -0.818]    -1.390271
(-0.818, -0.0898] -0.463751
(-0.0898, 0.6]    0.216895
(0.6, 3.554]      1.338414
dtype: float64
```

Grouping with a grouper specification

You may need to specify a bit more data to properly group. You can use the `pd.Grouper` to provide this local control.

```
In [171]: import datetime

In [172]: df = pd.DataFrame({'Branch': 'A A A A A A A B'.split(),
.....:                      'Buyer': 'Carl Mark Carl Carl Joe Joe Joe Carl'.split(),
.....:                      'Quantity': [1, 3, 5, 1, 8, 1, 9, 3],
.....:                      'Date': [
.....:                          datetime.datetime(2013, 1, 1, 13, 0),
.....:                          datetime.datetime(2013, 1, 1, 13, 5),
.....:                          datetime.datetime(2013, 10, 1, 20, 0),
.....:                          datetime.datetime(2013, 10, 2, 10, 0),
.....:                          datetime.datetime(2013, 10, 1, 20, 0),
.....:                          datetime.datetime(2013, 10, 2, 10, 0),
.....:                          datetime.datetime(2013, 12, 2, 12, 0),
.....:                          datetime.datetime(2013, 12, 2, 14, 0)]
.....:                      })
.....:
```

```
In [173]: df
```

```
Out[173]:
```

	Branch	Buyer	Quantity	Date
0	A	Carl	1	2013-01-01 13:00:00
1	A	Mark	3	2013-01-01 13:05:00
2	A	Carl	5	2013-10-01 20:00:00
3	A	Carl	1	2013-10-02 10:00:00
4	A	Joe	8	2013-10-01 20:00:00
5	A	Joe	1	2013-10-02 10:00:00
6	A	Joe	9	2013-12-02 12:00:00
7	B	Carl	3	2013-12-02 14:00:00

Groupby a specific column with the desired frequency. This is like resampling.

```
In [174]: df.groupby([pd.Grouper(freq='1M', key='Date'), 'Buyer']).sum()
Out[174]:
```

Date	Buyer	Quantity
2013-01-31	Carl	1
	Mark	3
2013-10-31	Carl	6

(continues on next page)

(continued from previous page)

	Joe	9
2013-12-31	Carl	3
	Joe	9

You have an ambiguous specification in that you have a named index and a column that could be potential groupers.

```
In [175]: df = df.set_index('Date')
```

```
In [176]: df['Date'] = df.index + pd.offsets.MonthEnd(2)
```

```
In [177]: df.groupby([pd.Grouper(freq='6M', key='Date'), 'Buyer']).sum()
```

```
Out[177]:
```

Date	Buyer	Quantity
2013-02-28	Carl	1
	Mark	3
2014-02-28	Carl	9
	Joe	18

```
In [178]: df.groupby([pd.Grouper(freq='6M', level='Date'), 'Buyer']).sum()
```

```
Out[178]:
```

Date	Buyer	Quantity
2013-01-31	Carl	1
	Mark	3
2014-01-31	Carl	9
	Joe	18

Taking the first rows of each group

Just like for a DataFrame or Series you can call head and tail on a groupby:

```
In [179]: df = pd.DataFrame([[1, 2], [1, 4], [5, 6]], columns=['A', 'B'])
```

```
In [180]: df
```

```
Out[180]:
```

	A	B
0	1	2
1	1	4
2	5	6

```
In [181]: g = df.groupby('A')
```

```
In [182]: g.head(1)
```

```
Out[182]:
```

	A	B
0	1	2
2	5	6

```
In [183]: g.tail(1)
```

```
Out[183]:
```

	A	B
2	5	6

```
1 1 4
2 5 6
```

This shows the first or last n rows from each group.

Taking the nth row of each group

To select from a DataFrame or Series the nth item, use `nth()`. This is a reduction method, and will return a single row (or no row) per group if you pass an int for n:

```
In [184]: df = pd.DataFrame([[1, np.nan], [1, 4], [5, 6]], columns=['A', 'B'])
```

```
In [185]: g = df.groupby('A')
```

```
In [186]: g.nth(0)
```

```
Out[186]:
```

```
      B
A
1  NaN
5  6.0
```

```
In [187]: g.nth(-1)
```

```
Out[187]:
```

```
      B
A
1  4.0
5  6.0
```

```
In [188]: g.nth(1)
```

```
Out[188]:
```

```
      B
A
1  4.0
```

If you want to select the nth not-null item, use the `dropna` kwarg. For a DataFrame this should be either `'any'` or `'all'` just like you would pass to `dropna`:

```
# nth(0) is the same as g.first()
```

```
In [189]: g.nth(0, dropna='any')
```

```
Out[189]:
```

```
      B
A
1  4.0
5  6.0
```

```
In [190]: g.first()
```

```
Out[190]:
```

```
      B
A
1  4.0
5  6.0
```

```
# nth(-1) is the same as g.last()
```

```
In [191]: g.nth(-1, dropna='any') # NaNs denote group exhausted when using dropna
```

```
Out[191]:
```

```

      B
A
1  4.0
5  6.0

```

```
In [192]: g.last()
```

```
Out[192]:
```

```

      B
A
1  4.0
5  6.0

```

```
In [193]: g.B.nth(0, dropna='all')
```

```
Out[193]:
```

```

A
1    4.0
5    6.0

```

```
Name: B, dtype: float64
```

As with other methods, passing `as_index=False`, will achieve a filtration, which returns the grouped row.

```
In [194]: df = pd.DataFrame([[1, np.nan], [1, 4], [5, 6]], columns=['A', 'B'])
```

```
In [195]: g = df.groupby('A', as_index=False)
```

```
In [196]: g.nth(0)
```

```
Out[196]:
```

```

   A   B
0  1 NaN
2  5  6.0

```

```
In [197]: g.nth(-1)
```

```
Out[197]:
```

```

   A   B
1  1  4.0
2  5  6.0

```

You can also select multiple rows from each group by specifying multiple `nth` values as a list of ints.

```
In [198]: business_dates = pd.date_range(start='4/1/2014', end='6/30/2014', freq='B')
```

```
In [199]: df = pd.DataFrame(1, index=business_dates, columns=['a', 'b'])
```

```
# get the first, 4th, and last date index for each month
```

```
In [200]: df.groupby([df.index.year, df.index.month]).nth([0, 3, -1])
```

```
Out[200]:
```

```

      a  b
2014 4  1  1
      4  1  1
      4  1  1
      5  1  1
      5  1  1
      5  1  1
      6  1  1
      6  1  1

```

(continues on next page)

(continued from previous page)

6 1 1

Enumerate group items

To see the order in which each row appears within its group, use the `cumcount` method:

```
In [201]: dfg = pd.DataFrame(list('aaabba'), columns=['A'])
```

```
In [202]: dfg
```

```
Out[202]:
```

```

  A
0  a
1  a
2  a
3  b
4  b
5  a

```

```
In [203]: dfg.groupby('A').cumcount()
```

```
Out[203]:
```

```

0    0
1    1
2    2
3    0
4    1
5    3

```

```
dtype: int64
```

```
In [204]: dfg.groupby('A').cumcount(ascending=False)
```

```
Out[204]:
```

```

0    3
1    2
2    1
3    1
4    0
5    0

```

```
dtype: int64
```

Enumerate groups

New in version 0.20.2.

To see the ordering of the groups (as opposed to the order of rows within a group given by `cumcount`) you can use `ngroup()`.

Note that the numbers given to the groups match the order in which the groups would be seen when iterating over the `groupby` object, not the order they are first observed.

```
In [205]: dfg = pd.DataFrame(list('aaabba'), columns=['A'])
```

```
In [206]: dfg
```

```
Out[206]:
```

```

  A

```

```
0 a
1 a
2 a
3 b
4 b
5 a
```

```
In [207]: dfg.groupby('A').ngroup()
```

```
Out[207]:
```

```
0 0
1 0
2 0
3 1
4 1
5 0
```

```
dtype: int64
```

```
In [208]: dfg.groupby('A').ngroup(ascending=False)
```

```
Out[208]:
```

```
0 1
1 1
2 1
3 0
4 0
5 1
```

```
dtype: int64
```

Plotting

Groupby also works with some plotting methods. For example, suppose we suspect that some features in a DataFrame may differ by group, in this case, the values in column 1 where the group is “B” are 3 higher on average.

```
In [209]: np.random.seed(1234)
```

```
In [210]: df = pd.DataFrame(np.random.randn(50, 2))
```

```
In [211]: df['g'] = np.random.choice(['A', 'B'], size=50)
```

```
In [212]: df.loc[df['g'] == 'B', 1] += 3
```

We can easily visualize this with a boxplot:

```
In [213]: df.groupby('g').boxplot()
```

```
Out[213]:
```

```
A      AxesSubplot(0.1,0.15;0.363636x0.75)
B      AxesSubplot(0.536364,0.15;0.363636x0.75)
dtype: object
```

The result of calling `boxplot` is a dictionary whose keys are the values of our grouping column `g` (“A” and “B”). The values of the resulting dictionary can be controlled by the `return_type` keyword of `boxplot`. See the [visualization documentation](#) for more.

Warning: For historical reasons, `df.groupby("g").boxplot()` is not equivalent to `df.boxplot(by="g")`. See [here](#) for an explanation.

Piping function calls

New in version 0.21.0.

Similar to the functionality provided by `DataFrame` and `Series`, functions that take `GroupBy` objects can be chained together using a `pipe` method to allow for a cleaner, more readable syntax. To read about `.pipe` in general terms, see [here](#).

Combining `.groupby` and `.pipe` is often useful when you need to reuse `GroupBy` objects.

As an example, imagine having a `DataFrame` with columns for stores, products, revenue and quantity sold. We’d like to do a groupwise calculation of *prices* (i.e. revenue/quantity) per store and per product. We could do this in a multi-step operation, but expressing it in terms of piping can make the code more readable. First we set the data:

```
In [214]: n = 1000

In [215]: df = pd.DataFrame({'Store': np.random.choice(['Store_1', 'Store_2'], n),
.....:                      'Product': np.random.choice(['Product_1',
.....:                                                    'Product_2'], n),
.....:                      'Revenue': (np.random.random(n) * 50 + 10).round(2),
.....:                      'Quantity': np.random.randint(1, 10, size=n)})
.....:
```

```
In [216]: df.head(2)
Out[216]:
```

	Store	Product	Revenue	Quantity
0	Store_2	Product_1	26.12	1
1	Store_2	Product_1	28.86	1

Now, to find prices per store/product, we can simply do:

```
In [217]: (df.groupby(['Store', 'Product'])
.....:       .pipe(lambda grp: grp.Revenue.sum() / grp.Quantity.sum())
.....:       .unstack().round(2))
.....:
```

```
Out[217]:
```

Product	Product_1	Product_2
Store		
Store_1	6.82	7.05
Store_2	6.30	6.64

Piping can also be expressive when you want to deliver a grouped object to some arbitrary function, for example:

```
In [218]: def mean(groupby):
.....:     return groupby.mean()
.....:
```

```
In [219]: df.groupby(['Store', 'Product']).pipe(mean)
Out[219]:
```

Store	Product	Revenue	Quantity
Store_1	Product_1	34.622727	5.075758
	Product_2	35.482815	5.029630
Store_2	Product_1	32.972837	5.237589
	Product_2	34.684360	5.224000

where `mean` takes a `GroupBy` object and finds the mean of the `Revenue` and `Quantity` columns respectively for each `Store-Product` combination. The `mean` function can be any function that takes in a `GroupBy` object; the `.pipe` will pass the `GroupBy` object as a parameter into the function you specify.

4.12.10 Examples

Regrouping by factor

Regroup columns of a `DataFrame` according to their sum, and sum the aggregated ones.

```
In [220]: df = pd.DataFrame({'a': [1, 0, 0], 'b': [0, 1, 0],
.....:                      'c': [1, 0, 0], 'd': [2, 3, 4]})
.....:
```

```
In [221]: df
Out[221]:
   a  b  c  d
0  1  0  1  2
1  0  1  0  3
2  0  0  0  4
```

```
In [222]: df.groupby(df.sum(), axis=1).sum()
Out[222]:
   1  9
0  2  2
1  1  3
2  0  4
```

Multi-column factorization

By using `ngroup()`, we can extract information about the groups in a way similar to `factorize()` (as described further in the *reshaping API*) but which applies naturally to multiple columns of mixed type and different sources. This can be useful as an intermediate categorical-like step in processing, when the relationships between the group rows are more important than their content, or as input to an algorithm which only accepts the integer encoding. (For more information about support in pandas for full categorical data, see the *Categorical introduction* and the *API documentation*.)

```
In [223]: dfg = pd.DataFrame({"A": [1, 1, 2, 3, 2], "B": list("aaaba")})
```

```
In [224]: dfg
Out[224]:
   A  B
0  1  a
1  1  a
2  2  a
3  3  b
4  2  a
```

```
In [225]: dfg.groupby(["A", "B"]).ngroup()
Out[225]:
0    0
1    0
2    1
3    2
4    1
dtype: int64
```

```
In [226]: dfg.groupby(["A", [0, 0, 0, 1, 1]]).ngroup()
Out[226]:
0    0
1    0
2    1
3    3
4    2
```

```
dtype: int64
```

Groupby by indexer to 'resample' data

Resampling produces new hypothetical samples (resamples) from already existing observed data or from a model that generates data. These new samples are similar to the pre-existing samples.

In order to resample to work on indices that are non-datetimelike, the following procedure can be utilized.

In the following examples, `df.index // 5` returns a binary array which is used to determine what gets selected for the groupby operation.

Note: The below example shows how we can downsample by consolidation of samples into fewer samples. Here by using `df.index // 5`, we are aggregating the samples in bins. By applying `std()` function, we aggregate the information contained in many samples into a small subset of values which is their standard deviation thereby reducing the number of samples.

```
In [227]: df = pd.DataFrame(np.random.randn(10, 2))
```

```
In [228]: df
```

```
Out[228]:
```

	0	1
0	-0.793893	0.321153
1	0.342250	1.618906
2	-0.975807	1.918201

```
In [229]: df.index // 5
```

```
Out[229]: Int64Index([0, 0, 0, 0, 0, 1, 1, 1, 1, 1], dtype='int64')
```

```
In [230]: df.groupby(df.index // 5).std()
```

```
Out[230]:
```

	0	1
0	0.823647	1.312912
1	0.760109	0.942941

Returning a Series to propagate names

Group DataFrame columns, compute a set of metrics and return a named Series. The Series name is used as the name for the column index. This is especially useful in conjunction with reshaping operations such as stacking in which the column index name will be used as the name of the inserted column:

```
In [231]: df = pd.DataFrame({'a': [0, 0, 0, 0, 1, 1, 1, 1, 2, 2, 2, 2],
.....:                      'b': [0, 0, 1, 1, 0, 0, 1, 1, 0, 0, 1, 1],
.....:                      'c': [1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, 0],
.....:                      'd': [0, 0, 0, 1, 0, 0, 0, 1, 0, 0, 0, 1]})
.....:
```

```
In [232]: def compute_metrics(x):
.....:     result = {'b_sum': x['b'].sum(), 'c_mean': x['c'].mean()}
.....:     return pd.Series(result, name='metrics')
.....:
```

```
In [233]: result = df.groupby('a').apply(compute_metrics)
```

```
In [234]: result
Out[234]:
metrics  b_sum  c_mean
a
0         2.0    0.5
1         2.0    0.5
2         2.0    0.5
```

```
In [235]: result.stack()
Out[235]:
a metrics
0  b_sum      2.0
   c_mean      0.5
1  b_sum      2.0
   c_mean      0.5
2  b_sum      2.0
   c_mean      0.5
dtype: float64
{{ header }}
```

4.13 Time series / date functionality

pandas contains extensive capabilities and features for working with time series data for all domains. Using the NumPy `datetime64` and `timedelta64` dtypes, pandas has consolidated a large number of features from other Python libraries like `scikits.timeseries` as well as created a tremendous amount of new functionality for manipulating time series data.

For example, pandas supports:

Parsing time series information from various sources and formats

```
In [1]: import datetime

In [2]: dti = pd.to_datetime(['1/1/2018', np.datetime64('2018-01-01'),
...:                        datetime.datetime(2018, 1, 1)])
...:

In [3]: dti
Out[3]: DatetimeIndex(['2018-01-01', '2018-01-01', '2018-01-01'], dtype='datetime64[ns]',
→ freq=None)
```

Generate sequences of fixed-frequency dates and time spans

```
In [4]: dti = pd.date_range('2018-01-01', periods=3, freq='H')
```

```
In [5]: dti
```

```
Out[5]:
```

```
DatetimeIndex(['2018-01-01 00:00:00', '2018-01-01 01:00:00',
               '2018-01-01 02:00:00'],
              dtype='datetime64[ns]', freq='H')
```

Manipulating and converting date times with timezone information

```
In [6]: dti = dti.tz_localize('UTC')
```

```
In [7]: dti
```

```
Out[7]:
```

```
DatetimeIndex(['2018-01-01 00:00:00+00:00', '2018-01-01 01:00:00+00:00',
               '2018-01-01 02:00:00+00:00'],
              dtype='datetime64[ns, UTC]', freq='H')
```

```
In [8]: dti.tz_convert('US/Pacific')
```

```
Out[8]:
```

```
DatetimeIndex(['2017-12-31 16:00:00-08:00', '2017-12-31 17:00:00-08:00',
               '2017-12-31 18:00:00-08:00'],
              dtype='datetime64[ns, US/Pacific]', freq='H')
```

Resampling or converting a time series to a particular frequency

```
In [9]: idx = pd.date_range('2018-01-01', periods=5, freq='H')
```

```
In [10]: ts = pd.Series(range(len(idx)), index=idx)
```

```
In [11]: ts
```

```
Out[11]:
```

```
2018-01-01 00:00:00    0
2018-01-01 01:00:00    1
2018-01-01 02:00:00    2
2018-01-01 03:00:00    3
2018-01-01 04:00:00    4
Freq: H, dtype: int64
```

```
In [12]: ts.resample('2H').mean()
```

```
Out[12]:
```

```
2018-01-01 00:00:00    0.5
2018-01-01 02:00:00    2.5
2018-01-01 04:00:00    4.0
Freq: 2H, dtype: float64
```

Performing date and time arithmetic with absolute or relative time increments

```
In [13]: friday = pd.Timestamp('2018-01-05')
```

```
In [14]: friday.day_name()
```

```
Out[14]: 'Friday'
```

```
# Add 1 day
```

```
In [15]: saturday = friday + pd.Timedelta('1 day')
```

(continues on next page)

(continued from previous page)

```

In [16]: saturday.day_name()
Out[16]: 'Saturday'

# Add 1 business day (Friday --> Monday)
In [17]: monday = friday + pd.offsets.BDay()

In [18]: monday.day_name()
Out[18]: 'Monday'

```

pandas provides a relatively compact and self-contained set of tools for performing the above tasks and more.

4.13.1 Overview

pandas captures 4 general time related concepts:

1. Date times: A specific date and time with timezone support. Similar to `datetime.datetime` from the standard library.
2. Time deltas: An absolute time duration. Similar to `datetime.timedelta` from the standard library.
3. Time spans: A span of time defined by a point in time and its associated frequency.
4. Date offsets: A relative time duration that respects calendar arithmetic. Similar to `dateutil.relativedelta.relativedelta` from the `dateutil` package.

Concept	Scalar Class	Array Class	pandas Data Type	Primary Creation Method
Date times	Timestamp	DatetimeIndex	<code>datetime64[ns]</code> or <code>datetime64[ns, tz]</code>	<code>to_datetime</code> or <code>date_range</code>
Time deltas	Timedelta	TimedeltaIndex	<code>timedelta64[ns]</code>	<code>to_timedelta</code> or <code>timedelta_range</code>
Time spans	Period	PeriodIndex	<code>period[freq]</code>	<code>Period</code> or <code>period_range</code>
Date offsets	DateOffset	None	None	<code>DateOffset</code>

For time series data, it's conventional to represent the time component in the index of a `Series` or `DataFrame` so manipulations can be performed with respect to the time element.

```

In [19]: pd.Series(range(3), index=pd.date_range('2000', freq='D', periods=3))
Out[19]:
2000-01-01    0
2000-01-02    1
2000-01-03    2
Freq: D, dtype: int64

```

However, `Series` and `DataFrame` can directly also support the time component as data itself.

```

In [20]: pd.Series(pd.date_range('2000', freq='D', periods=3))
Out[20]:
0    2000-01-01
1    2000-01-02

```

(continues on next page)

(continued from previous page)

```
2    2000-01-03
dtype: datetime64[ns]
```

Series and DataFrame have extended data type support and functionality for `datetime`, `timedelta` and `Period` data when passed into those constructors. `DateOffset` data however will be stored as `object` data.

```
In [21]: pd.Series(pd.period_range('1/1/2011', freq='M', periods=3))
Out[21]:
0    2011-01
1    2011-02
2    2011-03
dtype: period[M]
```

```
In [22]: pd.Series([pd.DateOffset(1), pd.DateOffset(2)])
Out[22]:
0    <DateOffset>
1    <2 * DateOffsets>
dtype: object
```

```
In [23]: pd.Series(pd.date_range('1/1/2011', freq='M', periods=3))
Out[23]:
0    2011-01-31
1    2011-02-28
2    2011-03-31
dtype: datetime64[ns]
```

Lastly, pandas represents null date times, time deltas, and time spans as `NaT` which is useful for representing missing or null date like values and behaves similar as `np.nan` does for float data.

```
In [24]: pd.Timestamp(pd.NaT)
Out[24]: NaT
```

```
In [25]: pd.Timedelta(pd.NaT)
Out[25]: NaT
```

```
In [26]: pd.Period(pd.NaT)
Out[26]: NaT
```

```
# Equality acts as np.nan would
In [27]: pd.NaT == pd.NaT
Out[27]: False
```

4.13.2 Timestamps vs. Time Spans

Timestamped data is the most basic type of time series data that associates values with points in time. For pandas objects it means using the points in time.

```
In [28]: pd.Timestamp(datetime.datetime(2012, 5, 1))
Out[28]: Timestamp('2012-05-01 00:00:00')
```

```
In [29]: pd.Timestamp('2012-05-01')
Out[29]: Timestamp('2012-05-01 00:00:00')
```

```
In [30]: pd.Timestamp(2012, 5, 1)
```

```
Out[30]: Timestamp('2012-05-01 00:00:00')
```

However, in many cases it is more natural to associate things like change variables with a time span instead. The span represented by `Period` can be specified explicitly, or inferred from datetime string format.

For example:

```
In [31]: pd.Period('2011-01')
Out[31]: Period('2011-01', 'M')
```

```
In [32]: pd.Period('2012-05', freq='D')
Out[32]: Period('2012-05-01', 'D')
```

`Timestamp` and `Period` can serve as an index. Lists of `Timestamp` and `Period` are automatically coerced to `DatetimeIndex` and `PeriodIndex` respectively.

```
In [33]: dates = [pd.Timestamp('2012-05-01'),
....:             pd.Timestamp('2012-05-02'),
....:             pd.Timestamp('2012-05-03')]
....:
```

```
In [34]: ts = pd.Series(np.random.randn(3), dates)
```

```
In [35]: type(ts.index)
Out[35]: pandas.core.indexes.datetimes.DatetimeIndex
```

```
In [36]: ts.index
Out[36]: DatetimeIndex(['2012-05-01', '2012-05-02', '2012-05-03'],
↳ dtype='datetime64[ns]', freq=None)
```

```
In [37]: ts
Out[37]:
2012-05-01    1.212707
2012-05-02   -2.219105
2012-05-03    0.930394
dtype: float64
```

```
In [38]: periods = [pd.Period('2012-01'), pd.Period('2012-02'), pd.Period('2012-03')]
```

```
In [39]: ts = pd.Series(np.random.randn(3), periods)
```

```
In [40]: type(ts.index)
Out[40]: pandas.core.indexes.period.PeriodIndex
```

```
In [41]: ts.index
Out[41]: PeriodIndex(['2012-01', '2012-02', '2012-03'], dtype='period[M]', freq='M')
```

```
In [42]: ts
Out[42]:
2012-01    0.703754
2012-02    0.580511
2012-03   -0.135776
Freq: M, dtype: float64
```

pandas allows you to capture both representations and convert between them. Under the hood, pandas represents timestamps using instances of `Timestamp` and sequences of timestamps using instances of `DatetimeIndex`. For regular time spans, pandas uses `Period` objects for scalar values and `PeriodIndex` for

sequences of spans. Better support for irregular intervals with arbitrary start and end points are forth-coming in future releases.

4.13.3 Converting to timestamps

To convert a `Series` or list-like object of date-like objects e.g. strings, epochs, or a mixture, you can use the `to_datetime` function. When passed a `Series`, this returns a `Series` (with the same index), while a list-like is converted to a `DatetimeIndex`:

```
In [43]: pd.to_datetime(pd.Series(['Jul 31, 2009', '2010-01-10', None]))
Out[43]:
0    2009-07-31
1    2010-01-10
2             NaT
dtype: datetime64[ns]
```

```
In [44]: pd.to_datetime(['2005/11/23', '2010.12.31'])
Out[44]: DatetimeIndex(['2005-11-23', '2010-12-31'], dtype='datetime64[ns]', freq=None)
```

If you use dates which start with the day first (i.e. European style), you can pass the `dayfirst` flag:

```
In [45]: pd.to_datetime(['04-01-2012 10:00'], dayfirst=True)
Out[45]: DatetimeIndex(['2012-01-04 10:00:00'], dtype='datetime64[ns]', freq=None)
```

```
In [46]: pd.to_datetime(['14-01-2012', '01-14-2012'], dayfirst=True)
Out[46]: DatetimeIndex(['2012-01-14', '2012-01-14'], dtype='datetime64[ns]', freq=None)
```

Warning: You see in the above example that `dayfirst` isn't strict, so if a date can't be parsed with the day being first it will be parsed as if `dayfirst` were `False`.

If you pass a single string to `to_datetime`, it returns a single `Timestamp`. `Timestamp` can also accept string input, but it doesn't accept string parsing options like `dayfirst` or `format`, so use `to_datetime` if these are required.

```
In [47]: pd.to_datetime('2010/11/12')
Out[47]: Timestamp('2010-11-12 00:00:00')
```

```
In [48]: pd.Timestamp('2010/11/12')
Out[48]: Timestamp('2010-11-12 00:00:00')
```

You can also use the `DatetimeIndex` constructor directly:

```
In [49]: pd.DatetimeIndex(['2018-01-01', '2018-01-03', '2018-01-05'])
Out[49]: DatetimeIndex(['2018-01-01', '2018-01-03', '2018-01-05'], dtype='datetime64[ns]
↳', freq=None)
```

The string 'infer' can be passed in order to set the frequency of the index as the inferred frequency upon creation:

```
In [50]: pd.DatetimeIndex(['2018-01-01', '2018-01-03', '2018-01-05'], freq='infer')
Out[50]: DatetimeIndex(['2018-01-01', '2018-01-03', '2018-01-05'], dtype='datetime64[ns]
↳', freq='2D')
```

Providing a format argument

In addition to the required datetime string, a `format` argument can be passed to ensure specific parsing. This could also potentially speed up the conversion considerably.

```
In [51]: pd.to_datetime('2010/11/12', format='%Y/%m/%d')
Out[51]: Timestamp('2010-11-12 00:00:00')
```

```
In [52]: pd.to_datetime('12-11-2010 00:00', format='%d-%m-%Y %H:%M')
Out[52]: Timestamp('2010-11-12 00:00:00')
```

For more information on the choices available when specifying the `format` option, see the [Python datetime documentation](#).

Assembling datetime from multiple DataFrame columns

New in version 0.18.1.

You can also pass a `DataFrame` of integer or string columns to assemble into a `Series` of `Timestamps`.

```
In [53]: df = pd.DataFrame({'year': [2015, 2016],
.....:                    'month': [2, 3],
.....:                    'day': [4, 5],
.....:                    'hour': [2, 3]})
.....:
```

```
In [54]: pd.to_datetime(df)
```

```
Out[54]:
0    2015-02-04 02:00:00
1    2016-03-05 03:00:00
dtype: datetime64[ns]
```

You can pass only the columns that you need to assemble.

```
In [55]: pd.to_datetime(df[['year', 'month', 'day']])
```

```
Out[55]:
0    2015-02-04
1    2016-03-05
dtype: datetime64[ns]
```

`pd.to_datetime` looks for standard designations of the datetime component in the column names, including:

- required: year, month, day
- optional: hour, minute, second, millisecond, microsecond, nanosecond

Invalid data

The default behavior, `errors='raise'`, is to raise when unparseable:

```
In [2]: pd.to_datetime(['2009/07/31', 'asd'], errors='raise')
ValueError: Unknown string format
```

Pass `errors='ignore'` to return the original input when unparseable:

```
In [56]: pd.to_datetime(['2009/07/31', 'asd'], errors='ignore')
Out[56]: Index(['2009/07/31', 'asd'], dtype='object')
```

Pass `errors='coerce'` to convert unparseable data to NaT (not a time):

```
In [57]: pd.to_datetime(['2009/07/31', 'asd'], errors='coerce')
Out[57]: DatetimeIndex(['2009-07-31', 'NaT'], dtype='datetime64[ns]', freq=None)
```

Epoch timestamps

pandas supports converting integer or float epoch times to `Timestamp` and `DatetimeIndex`. The default unit is nanoseconds, since that is how `Timestamp` objects are stored internally. However, epochs are often stored in another unit which can be specified. These are computed from the starting point specified by the `origin` parameter.

```
In [58]: pd.to_datetime([1349720105, 1349806505, 1349892905,
....:                  1349979305, 1350065705], unit='s')
....:
Out[58]:
DatetimeIndex(['2012-10-08 18:15:05', '2012-10-09 18:15:05',
              '2012-10-10 18:15:05', '2012-10-11 18:15:05',
              '2012-10-12 18:15:05'],
              dtype='datetime64[ns]', freq=None)
```

```
In [59]: pd.to_datetime([1349720105100, 1349720105200, 1349720105300,
....:                  1349720105400, 1349720105500], unit='ms')
....:
Out[59]:
DatetimeIndex(['2012-10-08 18:15:05.100000', '2012-10-08 18:15:05.200000',
              '2012-10-08 18:15:05.300000', '2012-10-08 18:15:05.400000',
              '2012-10-08 18:15:05.500000'],
              dtype='datetime64[ns]', freq=None)
```

Constructing a `Timestamp` or `DatetimeIndex` with an epoch timestamp with the `tz` argument specified will currently localize the epoch timestamps to UTC first then convert the result to the specified time zone. However, this behavior is *deprecated*, and if you have epochs in wall time in another timezone, it is recommended to read the epochs as timezone-naive timestamps and then localize to the appropriate timezone:

```
In [60]: pd.Timestamp(1262347200000000000).tz_localize('US/Pacific')
Out[60]: Timestamp('2010-01-01 12:00:00-0800', tz='US/Pacific')

In [61]: pd.DatetimeIndex([1262347200000000000]).tz_localize('US/Pacific')
Out[61]: DatetimeIndex(['2010-01-01 12:00:00-08:00'], dtype='datetime64[ns, US/Pacific]',
↪ freq=None)
```

Note: Epoch times will be rounded to the nearest nanosecond.

Warning: Conversion of float epoch times can lead to inaccurate and unexpected results. Python floats have about 15 digits precision in decimal. Rounding during conversion from float to high precision

Timestamp is unavoidable. The only way to achieve exact precision is to use a fixed-width types (e.g. an int64).

```
In [62]: pd.to_datetime([1490195805.433, 1490195805.433502912], unit='s')
Out[62]: DatetimeIndex(['2017-03-22 15:16:45.433000088', '2017-03-22 15:16:45.
↪433502913'], dtype='datetime64[ns]', freq=None)

In [63]: pd.to_datetime(1490195805433502912, unit='ns')
Out[63]: Timestamp('2017-03-22 15:16:45.433502912')
```

See also:

Using the origin Parameter

From timestamps to epoch

To invert the operation from above, namely, to convert from a `Timestamp` to a ‘unix’ epoch:

```
In [64]: stamps = pd.date_range('2012-10-08 18:15:05', periods=4, freq='D')

In [65]: stamps
Out[65]:
DatetimeIndex(['2012-10-08 18:15:05', '2012-10-09 18:15:05',
              '2012-10-10 18:15:05', '2012-10-11 18:15:05'],
              dtype='datetime64[ns]', freq='D')
```

We subtract the epoch (midnight at January 1, 1970 UTC) and then floor divide by the “unit” (1 second).

```
In [66]: (stamps - pd.Timestamp("1970-01-01")) // pd.Timedelta('1s')
Out[66]: Int64Index([1349720105, 1349806505, 1349892905, 1349979305], dtype='int64')
```

Using the origin Parameter

New in version 0.20.0.

Using the `origin` parameter, one can specify an alternative starting point for creation of a `DatetimeIndex`. For example, to use 1960-01-01 as the starting date:

```
In [67]: pd.to_datetime([1, 2, 3], unit='D', origin=pd.Timestamp('1960-01-01'))
Out[67]: DatetimeIndex(['1960-01-02', '1960-01-03', '1960-01-04'], dtype='datetime64[ns]
↪', freq=None)
```

The default is set at `origin='unix'`, which defaults to 1970-01-01 00:00:00. Commonly called ‘unix epoch’ or POSIX time.

```
In [68]: pd.to_datetime([1, 2, 3], unit='D')
Out[68]: DatetimeIndex(['1970-01-02', '1970-01-03', '1970-01-04'], dtype='datetime64[ns]
↪', freq=None)
```

4.13.4 Generating ranges of timestamps

To generate an index with timestamps, you can use either the `DatetimeIndex` or `Index` constructor and pass in a list of datetime objects:

```
In [69]: dates = [datetime.datetime(2012, 5, 1),
.....:             datetime.datetime(2012, 5, 2),
.....:             datetime.datetime(2012, 5, 3)]
.....:

# Note the frequency information
In [70]: index = pd.DatetimeIndex(dates)

In [71]: index
Out[71]: DatetimeIndex(['2012-05-01', '2012-05-02', '2012-05-03'], dtype='datetime64[ns]
↪', freq=None)

# Automatically converted to DatetimeIndex
In [72]: index = pd.Index(dates)

In [73]: index
Out[73]: DatetimeIndex(['2012-05-01', '2012-05-02', '2012-05-03'], dtype='datetime64[ns]
↪', freq=None)
```

In practice this becomes very cumbersome because we often need a very long index with a large number of timestamps. If we need timestamps on a regular frequency, we can use the `date_range()` and `bdate_range()` functions to create a `DatetimeIndex`. The default frequency for `date_range` is a **calendar day** while the default for `bdate_range` is a **business day**:

```
In [74]: start = datetime.datetime(2011, 1, 1)

In [75]: end = datetime.datetime(2012, 1, 1)

In [76]: index = pd.date_range(start, end)

In [77]: index
Out[77]:
DatetimeIndex(['2011-01-01', '2011-01-02', '2011-01-03', '2011-01-04',
              '2011-01-05', '2011-01-06', '2011-01-07', '2011-01-08',
              '2011-01-09', '2011-01-10',
              ...
              '2011-12-23', '2011-12-24', '2011-12-25', '2011-12-26',
              '2011-12-27', '2011-12-28', '2011-12-29', '2011-12-30',
              '2011-12-31', '2012-01-01'],
              dtype='datetime64[ns]', length=366, freq='D')

In [78]: index = pd.bdate_range(start, end)

In [79]: index
Out[79]:
DatetimeIndex(['2011-01-03', '2011-01-04', '2011-01-05', '2011-01-06',
              '2011-01-07', '2011-01-10', '2011-01-11', '2011-01-12',
              '2011-01-13', '2011-01-14',
```

(continues on next page)

(continued from previous page)

```

...
'2011-12-19', '2011-12-20', '2011-12-21', '2011-12-22',
'2011-12-23', '2011-12-26', '2011-12-27', '2011-12-28',
'2011-12-29', '2011-12-30'],
dtype='datetime64[ns]', length=260, freq='B')

```

Convenience functions like `date_range` and `bdate_range` can utilize a variety of *frequency aliases*:

```

In [80]: pd.date_range(start, periods=1000, freq='M')
Out[80]:
DatetimeIndex(['2011-01-31', '2011-02-28', '2011-03-31', '2011-04-30',
              '2011-05-31', '2011-06-30', '2011-07-31', '2011-08-31',
              '2011-09-30', '2011-10-31',
              ...
              '2093-07-31', '2093-08-31', '2093-09-30', '2093-10-31',
              '2093-11-30', '2093-12-31', '2094-01-31', '2094-02-28',
              '2094-03-31', '2094-04-30'],
              dtype='datetime64[ns]', length=1000, freq='M')

```

```

In [81]: pd.bdate_range(start, periods=250, freq='BQS')
Out[81]:
DatetimeIndex(['2011-01-03', '2011-04-01', '2011-07-01', '2011-10-03',
              '2012-01-02', '2012-04-02', '2012-07-02', '2012-10-01',
              '2013-01-01', '2013-04-01',
              ...
              '2071-01-01', '2071-04-01', '2071-07-01', '2071-10-01',
              '2072-01-01', '2072-04-01', '2072-07-01', '2072-10-03',
              '2073-01-02', '2073-04-03'],
              dtype='datetime64[ns]', length=250, freq='BQS-JAN')

```

`date_range` and `bdate_range` make it easy to generate a range of dates using various combinations of parameters like `start`, `end`, `periods`, and `freq`. The start and end dates are strictly inclusive, so dates outside of those specified will not be generated:

```

In [82]: pd.date_range(start, end, freq='BM')
Out[82]:
DatetimeIndex(['2011-01-31', '2011-02-28', '2011-03-31', '2011-04-29',
              '2011-05-31', '2011-06-30', '2011-07-29', '2011-08-31',
              '2011-09-30', '2011-10-31', '2011-11-30', '2011-12-30'],
              dtype='datetime64[ns]', freq='BM')

```

```

In [83]: pd.date_range(start, end, freq='W')
Out[83]:
DatetimeIndex(['2011-01-02', '2011-01-09', '2011-01-16', '2011-01-23',
              '2011-01-30', '2011-02-06', '2011-02-13', '2011-02-20',
              '2011-02-27', '2011-03-06', '2011-03-13', '2011-03-20',
              '2011-03-27', '2011-04-03', '2011-04-10', '2011-04-17',
              '2011-04-24', '2011-05-01', '2011-05-08', '2011-05-15',
              '2011-05-22', '2011-05-29', '2011-06-05', '2011-06-12',
              '2011-06-19', '2011-06-26', '2011-07-03', '2011-07-10',
              '2011-07-17', '2011-07-24', '2011-07-31', '2011-08-07',
              '2011-08-14', '2011-08-21', '2011-08-28', '2011-09-04',
              '2011-09-11', '2011-09-18', '2011-09-25', '2011-10-02',
              '2011-10-09', '2011-10-16', '2011-10-23', '2011-10-30'],
              dtype='datetime64[ns]', freq='W')

```

```
'2011-11-06', '2011-11-13', '2011-11-20', '2011-11-27',  
'2011-12-04', '2011-12-11', '2011-12-18', '2011-12-25',  
'2012-01-01'],  
dtype='datetime64[ns]', freq='W-SUN')
```

```
In [84]: pd.bdate_range(end=end, periods=20)
```

```
Out[84]:
```

```
DatetimeIndex(['2011-12-05', '2011-12-06', '2011-12-07', '2011-12-08',  
'2011-12-09', '2011-12-12', '2011-12-13', '2011-12-14',  
'2011-12-15', '2011-12-16', '2011-12-19', '2011-12-20',  
'2011-12-21', '2011-12-22', '2011-12-23', '2011-12-26',  
'2011-12-27', '2011-12-28', '2011-12-29', '2011-12-30'],  
dtype='datetime64[ns]', freq='B')
```

```
In [85]: pd.bdate_range(start=start, periods=20)
```

```
Out[85]:
```

```
DatetimeIndex(['2011-01-03', '2011-01-04', '2011-01-05', '2011-01-06',  
'2011-01-07', '2011-01-10', '2011-01-11', '2011-01-12',  
'2011-01-13', '2011-01-14', '2011-01-17', '2011-01-18',  
'2011-01-19', '2011-01-20', '2011-01-21', '2011-01-24',  
'2011-01-25', '2011-01-26', '2011-01-27', '2011-01-28'],  
dtype='datetime64[ns]', freq='B')
```

New in version 0.23.0.

Specifying `start`, `end`, and `periods` will generate a range of evenly spaced dates from `start` to `end` inclusively, with `periods` number of elements in the resulting `DatetimeIndex`:

```
In [86]: pd.date_range('2018-01-01', '2018-01-05', periods=5)
```

```
Out[86]:
```

```
DatetimeIndex(['2018-01-01', '2018-01-02', '2018-01-03', '2018-01-04',  
'2018-01-05'],  
dtype='datetime64[ns]', freq=None)
```

```
In [87]: pd.date_range('2018-01-01', '2018-01-05', periods=10)
```

```
Out[87]:
```

```
DatetimeIndex(['2018-01-01 00:00:00', '2018-01-01 10:40:00',  
'2018-01-01 21:20:00', '2018-01-02 08:00:00',  
'2018-01-02 18:40:00', '2018-01-03 05:20:00',  
'2018-01-03 16:00:00', '2018-01-04 02:40:00',  
'2018-01-04 13:20:00', '2018-01-05 00:00:00'],  
dtype='datetime64[ns]', freq=None)
```

Custom frequency ranges

`bdate_range` can also generate a range of custom frequency dates by using the `weekmask` and `holidays` parameters. These parameters will only be used if a custom frequency string is passed.

```
In [88]: weekmask = 'Mon Wed Fri'
```

```
In [89]: holidays = [datetime.datetime(2011, 1, 5), datetime.datetime(2011, 3, 14)]
```

```
In [90]: pd.bdate_range(start, end, freq='C', weekmask=weekmask, holidays=holidays)
```

```
Out[90]:
```

```
DatetimeIndex(['2011-01-03', '2011-01-07', '2011-01-10', '2011-01-12',
```

```
'2011-01-14', '2011-01-17', '2011-01-19', '2011-01-21',
'2011-01-24', '2011-01-26',
...
'2011-12-09', '2011-12-12', '2011-12-14', '2011-12-16',
'2011-12-19', '2011-12-21', '2011-12-23', '2011-12-26',
'2011-12-28', '2011-12-30'],
dtype='datetime64[ns]', length=154, freq='C')
```

```
In [91]: pd.bdate_range(start, end, freq='CBMS', weekmask=weekmask)
```

```
Out[91]:
```

```
DatetimeIndex(['2011-01-03', '2011-02-02', '2011-03-02', '2011-04-01',
               '2011-05-02', '2011-06-01', '2011-07-01', '2011-08-01',
               '2011-09-02', '2011-10-03', '2011-11-02', '2011-12-02'],
              dtype='datetime64[ns]', freq='CBMS')
```

Custom business days

4.13.5 Timestamp limitations

Since pandas represents timestamps in nanosecond resolution, the time span that can be represented using a 64-bit integer is limited to approximately 584 years:

```
In [92]: pd.Timestamp.min
```

```
Out[92]: Timestamp('1677-09-21 00:12:43.145225')
```

```
In [93]: pd.Timestamp.max
```

```
Out[93]: Timestamp('2262-04-11 23:47:16.854775807')
```

See also:

Representing out-of-bounds spans

4.13.6 Indexing

One of the main uses for `DatetimeIndex` is as an index for pandas objects. The `DatetimeIndex` class contains many time series related optimizations:

- A large range of dates for various offsets are pre-computed and cached under the hood in order to make generating subsequent date ranges very fast (just have to grab a slice).
- Fast shifting using the `shift` and `tshift` method on pandas objects.
- Unioning of overlapping `DatetimeIndex` objects with the same frequency is very fast (important for fast data alignment).
- Quick access to date fields via properties such as `year`, `month`, etc.
- Regularization functions like `snap` and very fast `asof` logic.

`DatetimeIndex` objects have all the basic functionality of regular `Index` objects, and a smorgasbord of advanced time series specific methods for easy frequency processing.

See also:

Reindexing methods

Note: While pandas does not force you to have a sorted date index, some of these methods may have unexpected or incorrect behavior if the dates are unsorted.

`DatetimeIndex` can be used like a regular index and offers all of its intelligent functionality like selection, slicing, etc.

```
In [94]: rng = pd.date_range(start, end, freq='BM')
```

```
In [95]: ts = pd.Series(np.random.randn(len(rng)), index=rng)
```

```
In [96]: ts.index
```

```
Out[96]:
```

```
DatetimeIndex(['2011-01-31', '2011-02-28', '2011-03-31', '2011-04-29',
               '2011-05-31', '2011-06-30', '2011-07-29', '2011-08-31',
               '2011-09-30', '2011-10-31', '2011-11-30', '2011-12-30'],
              dtype='datetime64[ns]', freq='BM')
```

```
In [97]: ts[:5].index
```

```
Out[97]:
```

```
DatetimeIndex(['2011-01-31', '2011-02-28', '2011-03-31', '2011-04-29',
               '2011-05-31'],
              dtype='datetime64[ns]', freq='BM')
```

```
In [98]: ts[::2].index
```

```
Out[98]:
```

```
DatetimeIndex(['2011-01-31', '2011-03-31', '2011-05-31', '2011-07-29',
               '2011-09-30', '2011-11-30'],
              dtype='datetime64[ns]', freq='2BM')
```

Partial string indexing

Dates and strings that parse to timestamps can be passed as indexing parameters:

```
In [99]: ts['1/31/2011']
```

```
Out[99]: 0.3135034497740378
```

```
In [100]: ts[datetime.datetime(2011, 12, 25):]
```

```
Out[100]:
```

```
2011-12-30    -0.62564
Freq: BM, dtype: float64
```

```
In [101]: ts['10/31/2011':'12/31/2011']
```

```
Out[101]:
```

```
2011-10-31    -0.042894
2011-11-30     1.321441
2011-12-30    -0.625640
Freq: BM, dtype: float64
```

To provide convenience for accessing longer time series, you can also pass in the year or year and month as strings:

```
In [102]: ts['2011']
```

```
Out[102]:
```

```
2011-01-31     0.313503
```

```

2011-02-28    1.055889
2011-03-31    0.714651
2011-04-29    0.612442
2011-05-31   -0.170038
2011-06-30   -0.828809
2011-07-29    0.458806
2011-08-31    0.764740
2011-09-30    1.917429
2011-10-31   -0.042894
2011-11-30    1.321441
2011-12-30   -0.625640
Freq: BM, dtype: float64

```

```

In [103]: ts['2011-6']
Out[103]:
2011-06-30   -0.828809
Freq: BM, dtype: float64

```

This type of slicing will work on a `DataFrame` with a `DatetimeIndex` as well. Since the partial string selection is a form of label slicing, the endpoints **will be** included. This would include matching times on an included date:

```

In [104]: dft = pd.DataFrame(np.random.randn(100000, 1), columns=['A'],
.....:                       index=pd.date_range('20130101', periods=100000, freq='T'))
.....:

```

```

In [105]: dft
Out[105]:

```

	A
2013-01-01 00:00:00	0.480217
2013-01-01 00:01:00	0.791875

```

```
[751 rows x 1 columns]
```

New in version 0.18.0.

DatetimeIndex partial string indexing also works on a DataFrame with a MultiIndex:

```
In [111]: dft2 = pd.DataFrame(np.random.randn(20, 1),
.....:                        columns=['A'],
.....:                        index=pd.MultiIndex.from_product(
.....:                            [pd.date_range('20130101', periods=10, freq='12H'),
.....:                             ['a', 'b']]))
.....:
```

```
In [112]: dft2
```

```
Out [112]:
```

```

                A
2013-01-01 00:00:00 a  0.030508
                b  0.201088
2013-01-01 12:00:00 a -0.822650
                b -0.159673
2013-01-02 00:00:00 a  0.715939
                b  0.635435
2013-01-02 12:00:00 a  0.071542
                b  0.539646

                b  0.651751
```

```
In [113]: dft2.loc['2013-01-05']
Out[113]:
```

```
                A
2013-01-05 00:00:00 a  0.048871
                b -0.400048
2013-01-05 12:00:00 a  1.325801
                b  0.651751
```

```
In [114]: idx = pd.IndexSlice
```

```
In [115]: dft2 = dft2.swaplevel(0, 1).sort_index()
```

```
In [116]: dft2.loc[idx[:, '2013-01-05'], :]
Out[116]:
```

```
                A
a 2013-01-05 00:00:00  0.048871
   2013-01-05 12:00:00  1.325801
b 2013-01-05 00:00:00 -0.400048
   2013-01-05 12:00:00  0.651751
```

New in version 0.25.0.

Slicing with string indexing also honors UTC offset.

```
In [117]: df = pd.DataFrame([0], index=pd.DatetimeIndex(['2019-01-01'], tz='US/Pacific'))
```

```
In [118]: df
Out[118]:
```

```
                0
2019-01-01 00:00:00-08:00  0
```

```
In [119]: df['2019-01-01 12:00:00+04:00':'2019-01-01 13:00:00+04:00']
Out[119]:
```

```
                0
2019-01-01 00:00:00-08:00  0
```

Slice vs. exact match

Changed in version 0.20.0.

The same string used as an indexing parameter can be treated either as a slice or as an exact match depending on the resolution of the index. If the string is less accurate than the index, it will be treated as a slice, otherwise as an exact match.

Consider a `Series` object with a minute resolution index:

```
In [120]: series_minute = pd.Series([1, 2, 3],
.....:                             pd.DatetimeIndex(['2011-12-31 23:59:00',
.....:                                                '2012-01-01 00:00:00',
.....:                                                '2012-01-01 00:02:00']))
.....:

In [121]: series_minute.index.resolution
Out[121]: 'minute'
```

A timestamp string less accurate than a minute gives a `Series` object.

```
In [122]: series_minute['2011-12-31 23']
Out[122]:
2011-12-31 23:59:00    1
dtype: int64
```

A timestamp string with minute resolution (or more accurate), gives a scalar instead, i.e. it is not casted to a slice.

```
In [123]: series_minute['2011-12-31 23:59']
Out[123]: 1
```

```
In [124]: series_minute['2011-12-31 23:59:00']
Out[124]: 1
```

If index resolution is second, then the minute-accurate timestamp gives a `Series`.

```
In [125]: series_second = pd.Series([1, 2, 3],
.....:                             pd.DatetimeIndex(['2011-12-31 23:59:59',
.....:                                                '2012-01-01 00:00:00',
.....:                                                '2012-01-01 00:00:01']))
.....:
```

```
In [126]: series_second.index.resolution
Out[126]: 'second'
```

```
In [127]: series_second['2011-12-31 23:59']
Out[127]:
2011-12-31 23:59:59    1
dtype: int64
```

If the timestamp string is treated as a slice, it can be used to index `DataFrame` with `[]` as well.

```
In [128]: dft_minute = pd.DataFrame({'a': [1, 2, 3], 'b': [4, 5, 6]},
.....:                             index=series_minute.index)
.....:

In [129]: dft_minute['2011-12-31 23']
Out[129]:
           a  b
2011-12-31 23:59:00  1  4
```

Warning: However, if the string is treated as an exact match, the selection in `DataFrame`'s `[]` will be column-wise and not row-wise, see *Indexing Basics*. For example `dft_minute['2011-12-31 23:59']`

will raise `KeyError` as '2012-12-31 23:59' has the same resolution as the index and there is no column with such name:

To *always* have unambiguous selection, whether the row is treated as a slice or a single selection, use `.loc`.

```
In [130]: dft_minute.loc['2011-12-31 23:59']
```

```
Out[130]:
```

```
a    1
b    4
```

```
Name: 2011-12-31 23:59:00, dtype: int64
```

Note also that `DatetimeIndex` resolution cannot be less precise than day.

```
In [131]: series_monthly = pd.Series([1, 2, 3],
.....:                               pd.DatetimeIndex(['2011-12', '2012-01', '2012-02']))
.....:
```

```
In [132]: series_monthly.index.resolution
```

```
Out[132]: 'day'
```

```
In [133]: series_monthly['2011-12'] # returns Series
```

```
Out[133]:
```

```
2011-12-01    1
```

```
dtype: int64
```

Exact indexing

As discussed in previous section, indexing a `DatetimeIndex` with a partial string depends on the “accuracy” of the period, in other words how specific the interval is in relation to the resolution of the index. In contrast, indexing with `Timestamp` or `datetime` objects is exact, because the objects have exact meaning. These also follow the semantics of *including both endpoints*.

These `Timestamp` and `datetime` objects have exact hours, minutes, and seconds, even though they were not explicitly specified (they are 0).

```
In [134]: dft[datetime.datetime(2013, 1, 1):datetime.datetime(2013, 2, 28)]
```

```
Out[134]:
```

```

                A
2013-01-01 00:00:00  0.480217

2013-02-28 10:11:00 -1.521579
2013-02-28 10:12:00 -0.318755
```

```
[83521 rows x 1 columns]
```

Truncating & fancy indexing

A `truncate()` convenience function is provided that is similar to slicing. Note that `truncate` assumes a 0 value for any unspecified date component in a `DatetimeIndex` in contrast to slicing which returns any partially matching dates:

```
In [136]: rng2 = pd.date_range('2011-01-01', '2012-01-01', freq='W')
```

```
In [137]: ts2 = pd.Series(np.random.randn(len(rng2)), index=rng2)
```

```
In [138]: ts2.truncate(before='2011-11', after='2011-12')
```

```
Out [138]:
2011-11-06    0.524645
2011-11-13    0.027878
2011-11-20   -0.914186
2011-11-27    0.672453
Freq: W-SUN, dtype: float64
```

```
In [139]: ts2['2011-11':'2011-12']
```

```
Out [139]:
2011-11-06    0.524645
2011-11-13    0.027878
2011-11-20   -0.914186
2011-11-27    0.672453
2011-12-04   -0.698538
2011-12-11    1.048716
2011-12-18    0.158099
2011-12-25    1.605115
Freq: W-SUN, dtype: float64
```

Even complicated fancy indexing that breaks the `DatetimeIndex` frequency regularity will result in a `DatetimeIndex`, although frequency is lost:

```
In [140]: ts2[[0, 2, 6]].index
Out [140]: DatetimeIndex(['2011-01-02', '2011-01-16', '2011-02-13'], dtype='datetime64[ns]
↳', freq=None)
```

4.13.7 Time/date components

There are several time/date properties that one can access from `Timestamp` or a collection of timestamps like a `DatetimeIndex`.

Property	Description
<code>year</code>	The year of the datetime
<code>month</code>	The month of the datetime
<code>day</code>	The days of the datetime
<code>hour</code>	The hour of the datetime
<code>minute</code>	The minutes of the datetime
<code>second</code>	The seconds of the datetime
<code>microsecond</code>	The microseconds of the datetime
<code>nanosecond</code>	The nanoseconds of the datetime
<code>date</code>	Returns <code>datetime.date</code> (does not contain timezone information)
<code>time</code>	Returns <code>datetime.time</code> (does not contain timezone information)
<code>timetz</code>	Returns <code>datetime.time</code> as local time with timezone information
<code>dayofyear</code>	The ordinal day of year
<code>weekofyear</code>	The week ordinal of the year
<code>week</code>	The week ordinal of the year
<code>dayofweek</code>	The number of the day of the week with Monday=0, Sunday=6
<code>weekday</code>	The number of the day of the week with Monday=0, Sunday=6
<code>weekday_name</code>	The name of the day in a week (ex: Friday)
<code>quarter</code>	Quarter of the date: Jan-Mar = 1, Apr-Jun = 2, etc.
<code>days_in_month</code>	The number of days in the month of the datetime
<code>is_month_start</code>	Logical indicating if first day of month (defined by frequency)
<code>is_month_end</code>	Logical indicating if last day of month (defined by frequency)
<code>is_quarter_start</code>	Logical indicating if first day of quarter (defined by frequency)
<code>is_quarter_end</code>	Logical indicating if last day of quarter (defined by frequency)
<code>is_year_start</code>	Logical indicating if first day of year (defined by frequency)
<code>is_year_end</code>	Logical indicating if last day of year (defined by frequency)
<code>is_leap_year</code>	Logical indicating if the date belongs to a leap year

Furthermore, if you have a `Series` with datetimelike values, then you can access these properties via the `.dt` accessor, as detailed in the section on *.dt accessors*.

4.13.8 DateOffset objects

In the preceding examples, frequency strings (e.g. 'D') were used to specify a frequency that defined:

- how the date times in `DatetimeIndex` were spaced when using `date_range()`
- the frequency of a `Period` or `PeriodIndex`

These frequency strings map to a `DateOffset` object and its subclasses. A `DateOffset` is similar to a `Timedelta` that represents a duration of time but follows specific calendar duration rules. For example, a `Timedelta` day will always increment `datetimes` by 24 hours, while a `DateOffset` day will increment

`datetimes` to the same time the next day whether a day represents 23, 24 or 25 hours due to daylight savings time. However, all `DateOffset` subclasses that are an hour or smaller (`Hour`, `Minute`, `Second`, `Milli`, `Micro`, `Nano`) behave like `Timedelta` and respect absolute time.

The basic `DateOffset` acts similar to `dateutil.relativedelta` ([relativedelta documentation](#)) that shifts a date time by the corresponding calendar duration specified. The arithmetic operator (+) or the `apply` method can be used to perform the shift.

```
# This particular day contains a day light savings time transition
In [141]: ts = pd.Timestamp('2016-10-30 00:00:00', tz='Europe/Helsinki')
```

```
# Respects absolute time
In [142]: ts + pd.Timedelta(days=1)
Out[142]: Timestamp('2016-10-30 23:00:00+0200', tz='Europe/Helsinki')
```

```
# Respects calendar time
In [143]: ts + pd.DateOffset(days=1)
Out[143]: Timestamp('2016-10-31 00:00:00+0200', tz='Europe/Helsinki')
```

```
In [144]: friday = pd.Timestamp('2018-01-05')
```

```
In [145]: friday.day_name()
Out[145]: 'Friday'
```

```
# Add 2 business days (Friday --> Tuesday)
In [146]: two_business_days = 2 * pd.offsets.BDay()
```

```
In [147]: two_business_days.apply(friday)
Out[147]: Timestamp('2018-01-09 00:00:00')
```

```
In [148]: friday + two_business_days
Out[148]: Timestamp('2018-01-09 00:00:00')
```

```
In [149]: (friday + two_business_days).day_name()
Out[149]: 'Tuesday'
```

Most `DateOffsets` have associated frequencies strings, or offset aliases, that can be passed into `freq` keyword arguments. The available date offsets and associated frequency strings can be found below:

Date Offset	Frequency String	Description
<i>DateOffset</i>	None	Generic offset class, defaults to 1 calendar day
<i>BDay</i> or <i>BusinessDay</i>	'B'	business day (weekday)
<i>CDay</i> or <i>CustomBusinessDay</i>	'C'	custom business day
<i>Week</i>	'W'	one week, optionally anchored on a day of the week
<i>WeekOfMonth</i>	'WOM'	the x-th day of the y-th week of each month
<i>LastWeekOfMonth</i>	'LWOM'	the x-th day of the last week of each month
<i>MonthEnd</i>	'M'	calendar month end
<i>MonthBegin</i>	'MS'	calendar month begin
<i>BMonthEnd</i> or <i>BusinessMonthEnd</i>	'BM'	business month end

Continued on next page

Table 3 – continued from previous page

Date Offset	Frequency String	Description
<i>BMonthBegin</i> or <i>BusinessMonthBegin</i>	'BMS'	business month begin
<i>CBMonthEnd</i> or <i>CustomBusinessMonthEnd</i>	'CBM'	custom business month end
<i>CBMonthBegin</i> or <i>CustomBusinessMonthBegin</i>	'CBMS'	custom business month begin
<i>SemiMonthEnd</i>	'SM'	15th (or other day_of_month) and calendar month end
<i>SemiMonthBegin</i>	'SMS'	15th (or other day_of_month) and calendar month begin
<i>QuarterEnd</i>	'Q'	calendar quarter end
<i>QuarterBegin</i>	'QS'	calendar quarter begin
<i>BQuarterEnd</i>	'BQ'	business quarter end
<i>BQuarterBegin</i>	'BQS'	business quarter begin
<i>FY5253Quarter</i>	'REQ'	retail (aka 52-53 week) quarter
<i>YearEnd</i>	'A'	calendar year end
<i>YearBegin</i>	'AS' or 'BYS'	calendar year begin
<i>BYearEnd</i>	'BA'	business year end
<i>BYearBegin</i>	'BAS'	business year begin
<i>FY5253</i>	'RE'	retail (aka 52-53 week) year
<i>Easter</i>	None	Easter holiday
<i>BusinessHour</i>	'BH'	business hour
<i>CustomBusinessHour</i>	'CBH'	custom business hour
<i>Day</i>	'D'	one absolute day
<i>Hour</i>	'H'	one hour
<i>Minute</i>	'T' or 'min'	one minute
<i>Second</i>	'S'	one second
<i>Milli</i>	'L' or 'ms'	one millisecond
<i>Micro</i>	'U' or 'us'	one microsecond
<i>Nano</i>	'N'	one nanosecond

`DateOffsets` additionally have `rollforward()` and `rollback()` methods for moving a date forward or backward respectively to a valid offset date relative to the offset. For example, business offsets will roll dates that land on the weekends (Saturday and Sunday) forward to Monday since business offsets operate on the weekdays.

```
In [150]: ts = pd.Timestamp('2018-01-06 00:00:00')
```

```
In [151]: ts.day_name()
Out[151]: 'Saturday'
```

```
# BusinessHour's valid offset dates are Monday through Friday
```

```
In [152]: offset = pd.offsets.BusinessHour(start='09:00')
```

```
# Bring the date to the closest offset date (Monday)
```

```
In [153]: offset.rollforward(ts)
Out[153]: Timestamp('2018-01-08 09:00:00')
```

```
# Date is brought to the closest offset date first and then the hour is added
```

```
In [154]: ts + offset
Out[154]: Timestamp('2018-01-08 10:00:00')
```

These operations preserve time (hour, minute, etc) information by default. To reset time to midnight, use `normalize()` before or after applying the operation (depending on whether you want the time information included in the operation).

```
In [155]: ts = pd.Timestamp('2014-01-01 09:00')
```

```
In [156]: day = pd.offsets.Day()
```

```
In [157]: day.apply(ts)
Out[157]: Timestamp('2014-01-02 09:00:00')
```

```
In [158]: day.apply(ts).normalize()
Out[158]: Timestamp('2014-01-02 00:00:00')
```

```
In [159]: ts = pd.Timestamp('2014-01-01 22:00')
```

```
In [160]: hour = pd.offsets.Hour()
```

```
In [161]: hour.apply(ts)
Out[161]: Timestamp('2014-01-01 23:00:00')
```

```
In [162]: hour.apply(ts).normalize()
Out[162]: Timestamp('2014-01-01 00:00:00')
```

```
In [163]: hour.apply(pd.Timestamp("2014-01-01 23:30")).normalize()
Out[163]: Timestamp('2014-01-02 00:00:00')
```

Parametric offsets

Some of the offsets can be “parameterized” when created to result in different behaviors. For example, the `Week` offset for generating weekly data accepts a `weekday` parameter which results in the generated dates always lying on a particular day of the week:

```
In [164]: d = datetime.datetime(2008, 8, 18, 9, 0)
```

```
In [165]: d
Out[165]: datetime.datetime(2008, 8, 18, 9, 0)
```

```
In [166]: d + pd.offsets.Week()
Out[166]: Timestamp('2008-08-25 09:00:00')
```

```
In [167]: d + pd.offsets.Week(weekday=4)
Out[167]: Timestamp('2008-08-22 09:00:00')
```

```
In [168]: (d + pd.offsets.Week(weekday=4)).weekday()
Out[168]: 4
```

```
In [169]: d - pd.offsets.Week()
Out[169]: Timestamp('2008-08-11 09:00:00')
```

The `normalize` option will be effective for addition and subtraction.

```
In [170]: d + pd.offsets.Week(normalize=True)
```

```
Out[170]: Timestamp('2008-08-25 00:00:00')
```

```
In [171]: d - pd.offsets.Week(normalize=True)
```

```
Out[171]: Timestamp('2008-08-11 00:00:00')
```

Another example is parameterizing `YearEnd` with the specific ending month:

```
In [172]: d + pd.offsets.YearEnd()
```

```
Out[172]: Timestamp('2008-12-31 09:00:00')
```

```
In [173]: d + pd.offsets.YearEnd(month=6)
```

```
Out[173]: Timestamp('2009-06-30 09:00:00')
```

Using offsets with Series / DatetimeIndex

Offsets can be used with either a `Series` or `DatetimeIndex` to apply the offset to each element.

```
In [174]: rng = pd.date_range('2012-01-01', '2012-01-03')
```

```
In [175]: s = pd.Series(rng)
```

```
In [176]: rng
```

```
Out[176]: DatetimeIndex(['2012-01-01', '2012-01-02', '2012-01-03'],  
↳ dtype='datetime64[ns]', freq='D')
```

```
In [177]: rng + pd.DateOffset(months=2)
```

```
Out[177]: DatetimeIndex(['2012-03-01', '2012-03-02', '2012-03-03'],  
↳ dtype='datetime64[ns]', freq='D')
```

```
In [178]: s + pd.DateOffset(months=2)
```

```
Out[178]:  
0    2012-03-01  
1    2012-03-02  
2    2012-03-03  
dtype: datetime64[ns]
```

```
In [179]: s - pd.DateOffset(months=2)
```

```
Out[179]:  
0    2011-11-01  
1    2011-11-02  
2    2011-11-03  
dtype: datetime64[ns]
```

If the offset class maps directly to a `Timedelta` (`Day`, `Hour`, `Minute`, `Second`, `Micro`, `Milli`, `Nano`) it can be used exactly like a `Timedelta` - see the *Timedelta section* for more examples.

```
In [180]: s - pd.offsets.Day(2)
```

```
Out[180]:  
0    2011-12-30  
1    2011-12-31  
2    2012-01-01  
dtype: datetime64[ns]
```

```
In [181]: td = s - pd.Series(pd.date_range('2011-12-29', '2011-12-31'))
```

```
In [182]: td
```

```
Out[182]:
0    3 days
1    3 days
2    3 days
dtype: timedelta64[ns]
```

```
In [183]: td + pd.offsets.Minute(15)
Out[183]:
0    3 days 00:15:00
1    3 days 00:15:00
2    3 days 00:15:00
dtype: timedelta64[ns]
```

Note that some offsets (such as `BQuarterEnd`) do not have a vectorized implementation. They can still be used but may calculate significantly slower and will show a `PerformanceWarning`

```
In [184]: rng + pd.offsets.BQuarterEnd()
Out[184]: DatetimeIndex(['2012-03-30', '2012-03-30', '2012-03-30'], dtype='datetime64[ns]
↳', freq='D')
```

Custom business days

The `CDay` or `CustomBusinessDay` class provides a parametric `BusinessDay` class which can be used to create customized business day calendars which account for local holidays and local weekend conventions.

As an interesting example, let's look at Egypt where a Friday-Saturday weekend is observed.

```
In [185]: weekmask_egypt = 'Sun Mon Tue Wed Thu'

# They also observe International Workers' Day so let's
# add that for a couple of years
In [186]: holidays = ['2012-05-01',
.....:                 datetime.datetime(2013, 5, 1),
.....:                 np.datetime64('2014-05-01')]
.....:

In [187]: bday_egypt = pd.offsets.CustomBusinessDay(holidays=holidays,
.....:                                              weekmask=weekmask_egypt)
.....:

In [188]: dt = datetime.datetime(2013, 4, 30)

In [189]: dt + 2 * bday_egypt
Out[189]: Timestamp('2013-05-05 00:00:00')
```

Let's map to the weekday names:

```
In [190]: dts = pd.date_range(dt, periods=5, freq=bday_egypt)

In [191]: pd.Series(dts.weekday, dts).map(
.....:     pd.Series('Mon Tue Wed Thu Fri Sat Sun'.split()))
.....:
Out[191]:
```

(continues on next page)

(continued from previous page)

```

2013-04-30    Tue
2013-05-02    Thu
2013-05-05    Sun
2013-05-06    Mon
2013-05-07    Tue
Freq: C, dtype: object

```

Holiday calendars can be used to provide the list of holidays. See the *holiday calendar* section for more information.

```

In [192]: from pandas.tseries.holiday import USFederalHolidayCalendar

In [193]: bday_us = pd.offsets.CustomBusinessDay(calendar=USFederalHolidayCalendar())

# Friday before MLK Day
In [194]: dt = datetime.datetime(2014, 1, 17)

# Tuesday after MLK Day (Monday is skipped because it's a holiday)
In [195]: dt + bday_us
Out[195]: Timestamp('2014-01-21 00:00:00')

```

Monthly offsets that respect a certain holiday calendar can be defined in the usual way.

```

In [196]: bmth_us = pd.offsets.CustomBusinessMonthBegin(
.....:     calendar=USFederalHolidayCalendar())
.....:

# Skip new years
In [197]: dt = datetime.datetime(2013, 12, 17)

In [198]: dt + bmth_us
Out[198]: Timestamp('2014-01-02 00:00:00')

# Define date index with custom offset
In [199]: pd.date_range(start='20100101', end='20120101', freq=bmth_us)
Out[199]:
DatetimeIndex(['2010-01-04', '2010-02-01', '2010-03-01', '2010-04-01',
              '2010-05-03', '2010-06-01', '2010-07-01', '2010-08-02',
              '2010-09-01', '2010-10-01', '2010-11-01', '2010-12-01',
              '2011-01-03', '2011-02-01', '2011-03-01', '2011-04-01',
              '2011-05-02', '2011-06-01', '2011-07-01', '2011-08-01',
              '2011-09-01', '2011-10-03', '2011-11-01', '2011-12-01'],
              dtype='datetime64[ns]', freq='CBMS')

```

Note: The frequency string ‘C’ is used to indicate that a CustomBusinessDay DateOffset is used, it is important to note that since CustomBusinessDay is a parameterised type, instances of CustomBusinessDay may differ and this is not detectable from the ‘C’ frequency string. The user therefore needs to ensure that the ‘C’ frequency string is used consistently within the user’s application.

Business hour

The `BusinessHour` class provides a business hour representation on `BusinessDay`, allowing to use specific start and end times.

By default, `BusinessHour` uses 9:00 - 17:00 as business hours. Adding `BusinessHour` will increment `Timestamp` by hourly frequency. If target `Timestamp` is out of business hours, move to the next business hour then increment it. If the result exceeds the business hours end, the remaining hours are added to the next business day.

```
In [200]: bh = pd.offsets.BusinessHour()

In [201]: bh
Out[201]: <BusinessHour: BH=09:00-17:00>

# 2014-08-01 is Friday
In [202]: pd.Timestamp('2014-08-01 10:00').weekday()
Out[202]: 4

In [203]: pd.Timestamp('2014-08-01 10:00') + bh
Out[203]: Timestamp('2014-08-01 11:00:00')

# Below example is the same as: pd.Timestamp('2014-08-01 09:00') + bh
In [204]: pd.Timestamp('2014-08-01 08:00') + bh
Out[204]: Timestamp('2014-08-01 10:00:00')

# If the results is on the end time, move to the next business day
In [205]: pd.Timestamp('2014-08-01 16:00') + bh
Out[205]: Timestamp('2014-08-04 09:00:00')

# Remainings are added to the next day
In [206]: pd.Timestamp('2014-08-01 16:30') + bh
Out[206]: Timestamp('2014-08-04 09:30:00')

# Adding 2 business hours
In [207]: pd.Timestamp('2014-08-01 10:00') + pd.offsets.BusinessHour(2)
Out[207]: Timestamp('2014-08-01 12:00:00')

# Subtracting 3 business hours
In [208]: pd.Timestamp('2014-08-01 10:00') + pd.offsets.BusinessHour(-3)
Out[208]: Timestamp('2014-07-31 15:00:00')
```

You can also specify `start` and `end` time by keywords. The argument must be a `str` with an `hour:minute` representation or a `datetime.time` instance. Specifying seconds, microseconds and nanoseconds as business hour results in `ValueError`.

```
In [209]: bh = pd.offsets.BusinessHour(start='11:00', end=datetime.time(20, 0))

In [210]: bh
Out[210]: <BusinessHour: BH=11:00-20:00>

In [211]: pd.Timestamp('2014-08-01 13:00') + bh
Out[211]: Timestamp('2014-08-01 14:00:00')

In [212]: pd.Timestamp('2014-08-01 09:00') + bh
Out[212]: Timestamp('2014-08-01 12:00:00')
```

```
In [213]: pd.Timestamp('2014-08-01 18:00') + bh
Out[213]: Timestamp('2014-08-01 19:00:00')
```

Passing start time later than end represents midnight business hour. In this case, business hour exceeds midnight and overlap to the next day. Valid business hours are distinguished by whether it started from valid `BusinessDay`.

```
In [214]: bh = pd.offsets.BusinessHour(start='17:00', end='09:00')
```

```
In [215]: bh
Out[215]: <BusinessHour: BH=17:00-09:00>
```

```
In [216]: pd.Timestamp('2014-08-01 17:00') + bh
Out[216]: Timestamp('2014-08-01 18:00:00')
```

```
In [217]: pd.Timestamp('2014-08-01 23:00') + bh
Out[217]: Timestamp('2014-08-02 00:00:00')
```

```
# Although 2014-08-02 is Saturday,
# it is valid because it starts from 08-01 (Friday).
In [218]: pd.Timestamp('2014-08-02 04:00') + bh
Out[218]: Timestamp('2014-08-02 05:00:00')
```

```
# Although 2014-08-04 is Monday,
# it is out of business hours because it starts from 08-03 (Sunday).
In [219]: pd.Timestamp('2014-08-04 04:00') + bh
Out[219]: Timestamp('2014-08-04 18:00:00')
```

Applying `BusinessHour.rollforward` and `rollback` to out of business hours results in the next business hour start or previous day's end. Different from other offsets, `BusinessHour.rollforward` may output different results from `apply` by definition.

This is because one day's business hour end is equal to next day's business hour start. For example, under the default business hours (9:00 - 17:00), there is no gap (0 minutes) between 2014-08-01 17:00 and 2014-08-04 09:00.

```
# This adjusts a Timestamp to business hour edge
In [220]: pd.offsets.BusinessHour().rollback(pd.Timestamp('2014-08-02 15:00'))
Out[220]: Timestamp('2014-08-01 17:00:00')
```

```
In [221]: pd.offsets.BusinessHour().rollforward(pd.Timestamp('2014-08-02 15:00'))
Out[221]: Timestamp('2014-08-04 09:00:00')
```

```
# It is the same as BusinessHour().apply(pd.Timestamp('2014-08-01 17:00')).
# And it is the same as BusinessHour().apply(pd.Timestamp('2014-08-04 09:00'))
In [222]: pd.offsets.BusinessHour().apply(pd.Timestamp('2014-08-02 15:00'))
Out[222]: Timestamp('2014-08-04 10:00:00')
```

```
# BusinessDay results (for reference)
In [223]: pd.offsets.BusinessHour().rollforward(pd.Timestamp('2014-08-02'))
Out[223]: Timestamp('2014-08-04 09:00:00')
```

```
# It is the same as BusinessDay().apply(pd.Timestamp('2014-08-01'))
# The result is the same as rollforward because BusinessDay never overlap.
In [224]: pd.offsets.BusinessHour().apply(pd.Timestamp('2014-08-02'))
```

```
Out[224]: Timestamp('2014-08-04 10:00:00')
```

`BusinessHour` regards Saturday and Sunday as holidays. To use arbitrary holidays, you can use `CustomBusinessHour` offset, as explained in the following subsection.

Custom business hour

New in version 0.18.1.

The `CustomBusinessHour` is a mixture of `BusinessHour` and `CustomBusinessDay` which allows you to specify arbitrary holidays. `CustomBusinessHour` works as the same as `BusinessHour` except that it skips specified custom holidays.

```
In [225]: from pandas.tseries.holiday import USFederalHolidayCalendar
```

```
In [226]: bhour_us = pd.offsets.CustomBusinessHour(calendar=USFederalHolidayCalendar())
```

```
# Friday before MLK Day
```

```
In [227]: dt = datetime.datetime(2014, 1, 17, 15)
```

```
In [228]: dt + bhour_us
```

```
Out[228]: Timestamp('2014-01-17 16:00:00')
```

```
# Tuesday after MLK Day (Monday is skipped because it's a holiday)
```

```
In [229]: dt + bhour_us * 2
```

```
Out[229]: Timestamp('2014-01-21 09:00:00')
```

You can use keyword arguments supported by either `BusinessHour` and `CustomBusinessDay`.

```
In [230]: bhour_mon = pd.offsets.CustomBusinessHour(start='10:00',
.....:                                             weekmask='Tue Wed Thu Fri')
.....:
```

```
# Monday is skipped because it's a holiday, business hour starts from 10:00
```

```
In [231]: dt + bhour_mon * 2
```

```
Out[231]: Timestamp('2014-01-21 10:00:00')
```

Offset aliases

A number of string aliases are given to useful common time series frequencies. We will refer to these aliases as *offset aliases*.

Alias	Description
B	business day frequency
C	custom business day frequency
D	calendar day frequency
W	weekly frequency
M	month end frequency
SM	semi-month end frequency (15th and end of month)
BM	business month end frequency
CBM	custom business month end frequency
MS	month start frequency
SMS	semi-month start frequency (1st and 15th)
BMS	business month start frequency
CBMS	custom business month start frequency
Q	quarter end frequency
BQ	business quarter end frequency
QS	quarter start frequency
BQS	business quarter start frequency
A, Y	year end frequency
BA, BY	business year end frequency
AS, YS	year start frequency
BAS, BYS	business year start frequency
BH	business hour frequency
H	hourly frequency
T, min	minutely frequency
S	secondly frequency
L, ms	milliseconds
U, us	microseconds
N	nanoseconds

Combining aliases

As we have seen previously, the alias and the offset instance are fungible in most functions:

```
In [232]: pd.date_range(start, periods=5, freq='B')
Out[232]:
DatetimeIndex(['2011-01-03', '2011-01-04', '2011-01-05', '2011-01-06',
              '2011-01-07'],
              dtype='datetime64[ns]', freq='B')
```

```
In [233]: pd.date_range(start, periods=5, freq=pd.offsets.BDay())
Out[233]:
DatetimeIndex(['2011-01-03', '2011-01-04', '2011-01-05', '2011-01-06',
              '2011-01-07'],
              dtype='datetime64[ns]', freq='B')
```

You can combine together day and intraday offsets:

```
In [234]: pd.date_range(start, periods=10, freq='2h20min')
Out[234]:
DatetimeIndex(['2011-01-01 00:00:00', '2011-01-01 02:20:00',
              '2011-01-01 04:40:00', '2011-01-01 07:00:00',
              '2011-01-01 09:20:00', '2011-01-01 11:40:00',
              '2011-01-01 14:00:00', '2011-01-01 16:20:00',
```

```
'2011-01-01 18:40:00', '2011-01-01 21:00:00'],
dtype='datetime64[ns]', freq='140T')
```

```
In [235]: pd.date_range(start, periods=10, freq='1D10U')
```

```
Out [235]:
```

```
DatetimeIndex([      '2011-01-01 00:00:00', '2011-01-02 00:00:00.000010',
      '2011-01-03 00:00:00.000020', '2011-01-04 00:00:00.000030',
      '2011-01-05 00:00:00.000040', '2011-01-06 00:00:00.000050',
      '2011-01-07 00:00:00.000060', '2011-01-08 00:00:00.000070',
      '2011-01-09 00:00:00.000080', '2011-01-10 00:00:00.000090'],
dtype='datetime64[ns]', freq='86400000010U')
```

Anchored offsets

For some frequencies you can specify an anchoring suffix:

Alias	Description
W-SUN	weekly frequency (Sundays). Same as 'W'
W-MON	weekly frequency (Mondays)
W-TUE	weekly frequency (Tuesdays)
W-WED	weekly frequency (Wednesdays)
W-THU	weekly frequency (Thursdays)
W-FRI	weekly frequency (Fridays)
W-SAT	weekly frequency (Saturdays)
(B)Q(S)-DEC	quarterly frequency, year ends in December. Same as 'Q'
(B)Q(S)-JAN	quarterly frequency, year ends in January
(B)Q(S)-FEB	quarterly frequency, year ends in February
(B)Q(S)-MAR	quarterly frequency, year ends in March
(B)Q(S)-APR	quarterly frequency, year ends in April
(B)Q(S)-MAY	quarterly frequency, year ends in May
(B)Q(S)-JUN	quarterly frequency, year ends in June
(B)Q(S)-JUL	quarterly frequency, year ends in July
(B)Q(S)-AUG	quarterly frequency, year ends in August
(B)Q(S)-SEP	quarterly frequency, year ends in September
(B)Q(S)-OCT	quarterly frequency, year ends in October
(B)Q(S)-NOV	quarterly frequency, year ends in November
(B)A(S)-DEC	annual frequency, anchored end of December. Same as 'A'

Continued on next page

Table 4 – continued from previous page

Alias	Description
(B)A(S)-JAN	annual frequency, anchored end of January
(B)A(S)-FEB	annual frequency, anchored end of February
(B)A(S)-MAR	annual frequency, anchored end of March
(B)A(S)-APR	annual frequency, anchored end of April
(B)A(S)-MAY	annual frequency, anchored end of May
(B)A(S)-JUN	annual frequency, anchored end of June
(B)A(S)-JUL	annual frequency, anchored end of July
(B)A(S)-AUG	annual frequency, anchored end of August
(B)A(S)-SEP	annual frequency, anchored end of September
(B)A(S)-OCT	annual frequency, anchored end of October
(B)A(S)-NOV	annual frequency, anchored end of November

These can be used as arguments to `date_range`, `bdate_range`, constructors for `DatetimeIndex`, as well as various other timeseries-related functions in pandas.

Anchored offset semantics

For those offsets that are anchored to the start or end of specific frequency (`MonthEnd`, `MonthBegin`, `WeekEnd`, etc), the following rules apply to rolling forward and backwards.

When `n` is not 0, if the given date is not on an anchor point, it snapped to the next(previous) anchor point, and moved `|n|-1` additional steps forwards or backwards.

```
In [236]: pd.Timestamp('2014-01-02') + pd.offsets.MonthBegin(n=1)
Out[236]: Timestamp('2014-02-01 00:00:00')
```

```
In [237]: pd.Timestamp('2014-01-02') + pd.offsets.MonthEnd(n=1)
Out[237]: Timestamp('2014-01-31 00:00:00')
```

```
In [238]: pd.Timestamp('2014-01-02') - pd.offsets.MonthBegin(n=1)
Out[238]: Timestamp('2014-01-01 00:00:00')
```

```
In [239]: pd.Timestamp('2014-01-02') - pd.offsets.MonthEnd(n=1)
Out[239]: Timestamp('2013-12-31 00:00:00')
```

```
In [240]: pd.Timestamp('2014-01-02') + pd.offsets.MonthBegin(n=4)
Out[240]: Timestamp('2014-05-01 00:00:00')
```

```
In [241]: pd.Timestamp('2014-01-02') - pd.offsets.MonthBegin(n=4)
Out[241]: Timestamp('2013-10-01 00:00:00')
```

If the given date *is* on an anchor point, it is moved `|n|` points forwards or backwards.

```
In [242]: pd.Timestamp('2014-01-01') + pd.offsets.MonthBegin(n=1)
Out[242]: Timestamp('2014-02-01 00:00:00')
```

```
In [243]: pd.Timestamp('2014-01-31') + pd.offsets.MonthEnd(n=1)
Out[243]: Timestamp('2014-02-28 00:00:00')
```

```
In [244]: pd.Timestamp('2014-01-01') - pd.offsets.MonthBegin(n=1)
Out[244]: Timestamp('2013-12-01 00:00:00')
```

```
In [245]: pd.Timestamp('2014-01-31') - pd.offsets.MonthEnd(n=1)
Out[245]: Timestamp('2013-12-31 00:00:00')
```

```
In [246]: pd.Timestamp('2014-01-01') + pd.offsets.MonthBegin(n=4)
Out[246]: Timestamp('2014-05-01 00:00:00')
```

```
In [247]: pd.Timestamp('2014-01-31') - pd.offsets.MonthBegin(n=4)
Out[247]: Timestamp('2013-10-01 00:00:00')
```

For the case when `n=0`, the date is not moved if on an anchor point, otherwise it is rolled forward to the next anchor point.

```
In [248]: pd.Timestamp('2014-01-02') + pd.offsets.MonthBegin(n=0)
Out[248]: Timestamp('2014-02-01 00:00:00')
```

```
In [249]: pd.Timestamp('2014-01-02') + pd.offsets.MonthEnd(n=0)
Out[249]: Timestamp('2014-01-31 00:00:00')
```

```
In [250]: pd.Timestamp('2014-01-01') + pd.offsets.MonthBegin(n=0)
Out[250]: Timestamp('2014-01-01 00:00:00')
```

```
In [251]: pd.Timestamp('2014-01-31') + pd.offsets.MonthEnd(n=0)
Out[251]: Timestamp('2014-01-31 00:00:00')
```

Holidays / holiday calendars

Holidays and calendars provide a simple way to define holiday rules to be used with `CustomBusinessDay` or in other analysis that requires a predefined set of holidays. The `AbstractHolidayCalendar` class provides all the necessary methods to return a list of holidays and only `rules` need to be defined in a specific holiday calendar class. Furthermore, the `start_date` and `end_date` class attributes determine over what date range holidays are generated. These should be overwritten on the `AbstractHolidayCalendar` class to have the range apply to all calendar subclasses. `USFederalHolidayCalendar` is the only calendar that exists and primarily serves as an example for developing other calendars.

For holidays that occur on fixed dates (e.g., US Memorial Day or July 4th) an observance rule determines when that holiday is observed if it falls on a weekend or some other non-observed day. Defined observance rules are:

Rule	Description
<code>nearest_workday</code>	move Saturday to Friday and Sunday to Monday
<code>sunday_to_monday</code>	move Sunday to following Monday
<code>next_monday_or_monday</code>	move Saturday to Monday and Sunday/Monday to Tuesday
<code>previous_friday</code>	move Saturday and Sunday to previous Friday"
<code>next_monday</code>	move Saturday and Sunday to following Monday

An example of how holidays and holiday calendars are defined:

```
In [252]: from pandas.tseries.holiday import Holiday, USMemorialDay,\
.....:      AbstractHolidayCalendar, nearest_workday, MO
.....:

In [253]: class ExampleCalendar(AbstractHolidayCalendar):
.....:     rules = [
.....:         USMemorialDay,
.....:         Holiday('July 4th', month=7, day=4, observance=nearest_workday),
.....:         Holiday('Columbus Day', month=10, day=1,
.....:             offset=pd.DateOffset(weekday=MO(2)))]
.....:

In [254]: cal = ExampleCalendar()

In [255]: cal.holidays(datetime.datetime(2012, 1, 1), datetime.datetime(2012, 12, 31))
Out[255]: DatetimeIndex(['2012-05-28', '2012-07-04', '2012-10-08'], dtype='datetime64[ns]
↪', freq=None)
```

hint weekday=MO(2) is same as 2 * Week(weekday=2)

Using this calendar, creating an index or doing offset arithmetic skips weekends and holidays (i.e., Memorial Day/July 4th). For example, the below defines a custom business day offset using the `ExampleCalendar`. Like any other offset, it can be used to create a `DatetimeIndex` or added to `datetime` or `Timestamp` objects.

```
In [256]: pd.date_range(start='7/1/2012', end='7/10/2012',
.....:                   freq=pd.offsets.CDay(calendar=cal)).to_pydatetime()
.....:
Out[256]:
array([datetime.datetime(2012, 7, 2, 0, 0),
       datetime.datetime(2012, 7, 3, 0, 0),
       datetime.datetime(2012, 7, 5, 0, 0),
       datetime.datetime(2012, 7, 6, 0, 0),
       datetime.datetime(2012, 7, 9, 0, 0),
       datetime.datetime(2012, 7, 10, 0, 0)], dtype=object)
```

```
In [257]: offset = pd.offsets.CustomBusinessDay(calendar=cal)
```

```
In [258]: datetime.datetime(2012, 5, 25) + offset
Out[258]: Timestamp('2012-05-29 00:00:00')
```

```
In [259]: datetime.datetime(2012, 7, 3) + offset
Out[259]: Timestamp('2012-07-05 00:00:00')
```

```
In [260]: datetime.datetime(2012, 7, 3) + 2 * offset
Out[260]: Timestamp('2012-07-06 00:00:00')
```

```
In [261]: datetime.datetime(2012, 7, 6) + offset
Out[261]: Timestamp('2012-07-09 00:00:00')
```

Ranges are defined by the `start_date` and `end_date` class attributes of `AbstractHolidayCalendar`. The defaults are shown below.

```
In [262]: AbstractHolidayCalendar.start_date
Out[262]: Timestamp('1970-01-01 00:00:00')
```

```
In [263]: AbstractHolidayCalendar.end_date
Out[263]: Timestamp('2030-12-31 00:00:00')
```

These dates can be overwritten by setting the attributes as datetime/Timestamp/string.

```
In [264]: AbstractHolidayCalendar.start_date = datetime.datetime(2012, 1, 1)
In [265]: AbstractHolidayCalendar.end_date = datetime.datetime(2012, 12, 31)
In [266]: cal.holidays()
Out[266]: DatetimeIndex(['2012-05-28', '2012-07-04', '2012-10-08'], dtype='datetime64[ns]
↳', freq=None)
```

Every calendar class is accessible by name using the `get_calendar` function which returns a holiday class instance. Any imported calendar class will automatically be available by this function. Also, `HolidayCalendarFactory` provides an easy interface to create calendars that are combinations of calendars or calendars with additional rules.

```
In [267]: from pandas.tseries.holiday import get_calendar, HolidayCalendarFactory,\
.....:      USLaborDay
.....:

In [268]: cal = get_calendar('ExampleCalendar')

In [269]: cal.rules
Out[269]:
[Holiday: Memorial Day (month=5, day=31, offset=<DateOffset: weekday=MO(-1)>),
 Holiday: July 4th (month=7, day=4, observance=<function nearest_workday at 0x144b099e0>
↳),
 Holiday: Columbus Day (month=10, day=1, offset=<DateOffset: weekday=MO(+2)>)]

In [270]: new_cal = HolidayCalendarFactory('NewExampleCalendar', cal, USLaborDay)

In [271]: new_cal.rules
Out[271]:
[Holiday: Labor Day (month=9, day=1, offset=<DateOffset: weekday=MO(+1)>),
 Holiday: Memorial Day (month=5, day=31, offset=<DateOffset: weekday=MO(-1)>),
 Holiday: July 4th (month=7, day=4, observance=<function nearest_workday at 0x144b099e0>
↳),
 Holiday: Columbus Day (month=10, day=1, offset=<DateOffset: weekday=MO(+2)>)]
```

4.13.9 Time Series-Related Instance Methods

Shifting / lagging

One may want to *shift* or *lag* the values in a time series back and forward in time. The method for this is `shift()`, which is available on all of the pandas objects.

```
In [272]: ts = pd.Series(range(len(rng)), index=rng)
In [273]: ts = ts[:5]
```

(continues on next page)

(continued from previous page)

```
In [274]: ts.shift(1)
Out[274]:
2012-01-01    NaN
2012-01-02    0.0
2012-01-03    1.0
Freq: D, dtype: float64
```

The `shift` method accepts an `freq` argument which can accept a `DateOffset` class or other `timedelta`-like object or also an *offset alias*:

```
In [275]: ts.shift(5, freq=pd.offsets.BDay())
Out[275]:
2012-01-06    0
2012-01-09    1
2012-01-10    2
Freq: B, dtype: int64
```

```
In [276]: ts.shift(5, freq='BM')
Out[276]:
2012-05-31    0
2012-05-31    1
2012-05-31    2
Freq: D, dtype: int64
```

Rather than changing the alignment of the data and the index, `DataFrame` and `Series` objects also have a `tshift()` convenience method that changes all the dates in the index by a specified number of offsets:

```
In [277]: ts.tshift(5, freq='D')
Out[277]:
2012-01-06    0
2012-01-07    1
2012-01-08    2
Freq: D, dtype: int64
```

Note that with `tshift`, the leading entry is no longer `NaN` because the data is not being realigned.

Frequency conversion

The primary function for changing frequencies is the `asfreq()` method. For a `DatetimeIndex`, this is basically just a thin, but convenient wrapper around `reindex()` which generates a `date_range` and calls `reindex`.

```
In [278]: dr = pd.date_range('1/1/2010', periods=3, freq=3 * pd.offsets.BDay())
```

```
In [279]: ts = pd.Series(np.random.randn(3), index=dr)
```

```
In [280]: ts
Out[280]:
2010-01-01   -0.014261
2010-01-06   -0.760069
2010-01-11    0.028879
Freq: 3B, dtype: float64
```

```
In [281]: ts.asfreq(pd.offsets.BDay())
```

```

Out [281]:
2010-01-01    -0.014261
2010-01-04         NaN
2010-01-05         NaN
2010-01-06    -0.760069
2010-01-07         NaN
2010-01-08         NaN
2010-01-11     0.028879
Freq: B, dtype: float64

```

`asfreq` provides a further convenience so you can specify an interpolation method for any gaps that may appear after the frequency conversion.

```
In [282]: ts.asfreq(pd.offsets.BDay(), method='pad')
```

```

Out [282]:
2010-01-01    -0.014261
2010-01-04    -0.014261
2010-01-05    -0.014261
2010-01-06    -0.760069
2010-01-07    -0.760069
2010-01-08    -0.760069
2010-01-11     0.028879
Freq: B, dtype: float64

```

Filling forward / backward

Related to `asfreq` and `reindex` is `fillna()`, which is documented in the *missing data section*.

Converting to Python datetimes

`DatetimeIndex` can be converted to an array of Python native `datetime.datetime` objects using the `to_pydatetime` method.

4.13.10 Resampling

Warning: The interface to `.resample` has changed in 0.18.0 to be more groupby-like and hence more flexible. See the *whatsnew docs* for a comparison with prior versions.

Pandas has a simple, powerful, and efficient functionality for performing resampling operations during frequency conversion (e.g., converting secondly data into 5-minutely data). This is extremely common in, but not limited to, financial applications.

`resample()` is a time-based groupby, followed by a reduction method on each of its groups. See some *cookbook examples* for some advanced strategies.

Starting in version 0.18.1, the `resample()` function can be used directly from `DataFrameGroupBy` objects, see the *groupby docs*.

Note: `.resample()` is similar to using a `rolling()` operation with a time-based offset, see a discussion *here*.

Basics

```
In [283]: rng = pd.date_range('1/1/2012', periods=100, freq='S')
In [284]: ts = pd.Series(np.random.randint(0, 500, len(rng)), index=rng)
In [285]: ts.resample('5Min').sum()
Out[285]:
2012-01-01    25003
Freq: 5T, dtype: int64
```

The `resample` function is very flexible and allows you to specify many different parameters to control the frequency conversion and resampling operation.

Any function available via *dispatching* is available as a method of the returned object, including `sum`, `mean`, `std`, `sem`, `max`, `min`, `median`, `first`, `last`, `ohlc`:

```
In [286]: ts.resample('5Min').mean()
Out[286]:
2012-01-01    250.03
Freq: 5T, dtype: float64
```

```
In [287]: ts.resample('5Min').ohlc()
Out[287]:
           open  high  low  close
2012-01-01   114   499    0   381
```

```
In [288]: ts.resample('5Min').max()
Out[288]:
2012-01-01    499
Freq: 5T, dtype: int64
```

For downsampling, `closed` can be set to `'left'` or `'right'` to specify which end of the interval is closed:

```
In [289]: ts.resample('5Min', closed='right').mean()
Out[289]:
2011-12-31 23:55:00    114.00000
2012-01-01 00:00:00    251.40404
Freq: 5T, dtype: float64
```

```
In [290]: ts.resample('5Min', closed='left').mean()
Out[290]:
2012-01-01    250.03
Freq: 5T, dtype: float64
```

Parameters like `label` and `loffset` are used to manipulate the resulting labels. `label` specifies whether the result is labeled with the beginning or the end of the interval. `loffset` performs a time adjustment on the output labels.

```
In [291]: ts.resample('5Min').mean() # by default label='left'
Out[291]:
2012-01-01    250.03
Freq: 5T, dtype: float64
```

```
In [292]: ts.resample('5Min', label='left').mean()
Out[292]:
2012-01-01    250.03
```

```
Freq: 5T, dtype: float64
```

```
In [293]: ts.resample('5Min', label='left', loffset='1s').mean()
Out[293]:
2012-01-01 00:00:01    250.03
dtype: float64
```

Warning: The default values for `label` and `closed` is `'left'` for all frequency offsets except for `'M'`, `'A'`, `'Q'`, `'BM'`, `'BA'`, `'BQ'`, and `'W'` which all have a default of `'right'`.

This might unintendedly lead to looking ahead, where the value for a later time is pulled back to a previous time as in the following example with the `BusinessDay` frequency:

```
In [294]: s = pd.date_range('2000-01-01', '2000-01-05').to_series()
```

```
In [295]: s.iloc[2] = pd.NaT
```

```
In [296]: s.dt.weekday_name
```

```
Out[296]:
2000-01-01    Saturday
2000-01-02     Sunday
2000-01-03         NaN
2000-01-04    Tuesday
2000-01-05    Wednesday
Freq: D, dtype: object
```

```
# default: label='left', closed='left'
```

```
In [297]: s.resample('B').last().dt.weekday_name
```

```
Out[297]:
1999-12-31     Sunday
2000-01-03         NaN
2000-01-04    Tuesday
2000-01-05    Wednesday
Freq: B, dtype: object
```

Notice how the value for Sunday got pulled back to the previous Friday. To get the behavior where the value for Sunday is pushed to Monday, use instead

```
In [298]: s.resample('B', label='right', closed='right').last().dt.weekday_name
```

```
Out[298]:
2000-01-03     Sunday
2000-01-04    Tuesday
2000-01-05    Wednesday
Freq: B, dtype: object
```

The `axis` parameter can be set to 0 or 1 and allows you to resample the specified axis for a `DataFrame`.

`kind` can be set to `'timestamp'` or `'period'` to convert the resulting index to/from timestamp and time span representations. By default `resample` retains the input representation.

`convention` can be set to `'start'` or `'end'` when resampling period data (detail below). It specifies how low frequency periods are converted to higher frequency periods.

Upsampling

For upsampling, you can specify a way to upsample and the `limit` parameter to interpolate over the gaps that are created:

```
# from secondly to every 250 milliseconds
In [299]: ts[:2].resample('250L').asfreq()
Out[299]:
2012-01-01 00:00:00.000    114.0
2012-01-01 00:00:00.250      NaN
2012-01-01 00:00:00.500      NaN
2012-01-01 00:00:00.750      NaN
2012-01-01 00:00:01.000    119.0
Freq: 250L, dtype: float64
```

```
In [300]: ts[:2].resample('250L').ffill()
Out[300]:
2012-01-01 00:00:00.000    114
2012-01-01 00:00:00.250    114
2012-01-01 00:00:00.500    114
2012-01-01 00:00:00.750    114
2012-01-01 00:00:01.000    119
Freq: 250L, dtype: int64
```

```
In [301]: ts[:2].resample('250L').ffill(limit=2)
Out[301]:
2012-01-01 00:00:00.000    114.0
2012-01-01 00:00:00.250    114.0
2012-01-01 00:00:00.500    114.0
2012-01-01 00:00:00.750      NaN
2012-01-01 00:00:01.000    119.0
Freq: 250L, dtype: float64
```

Sparse resampling

Sparse timeseries are the ones where you have a lot fewer points relative to the amount of time you are looking to resample. Naively upsampling a sparse series can potentially generate lots of intermediate values. When you don't want to use a method to fill these values, e.g. `fill_method` is `None`, then intermediate values will be filled with `NaN`.

Since `resample` is a time-based groupby, the following is a method to efficiently resample only the groups that are not all `NaN`.

```
In [302]: rng = pd.date_range('2014-1-1', periods=100, freq='D') + pd.Timedelta('1s')
In [303]: ts = pd.Series(range(100), index=rng)
```

If we want to resample to the full range of the series:

```
In [304]: ts.resample('3T').sum()
Out[304]:
2014-01-01 00:00:00    0
2014-01-01 00:03:00    0
2014-01-01 00:06:00    0
```

(continues on next page)

(continued from previous page)

```

2014-01-01 00:09:00    0
2014-01-01 00:12:00    0
...
2014-04-09 23:48:00    0
2014-04-09 23:51:00    0
2014-04-09 23:54:00    0
2014-04-09 23:57:00    0
2014-04-10 00:00:00   99
Freq: 3T, Length: 47521, dtype: int64

```

We can instead only resample those groups where we have points as follows:

```

In [305]: from functools import partial

In [306]: from pandas.tseries.frequencies import to_offset

In [307]: def round(t, freq):
.....:     freq = to_offset(freq)
.....:     return pd.Timestamp((t.value // freq.delta.value) * freq.delta.value)
.....:

In [308]: ts.groupby(partial(round, freq='3T')).sum()
Out[308]:
2014-01-01    0
2014-01-02    1
2014-01-03    2
2014-01-04    3
2014-01-05    4
...
2014-04-06   95
2014-04-07   96
2014-04-08   97
2014-04-09   98
2014-04-10   99
Length: 100, dtype: int64

```

Aggregation

Similar to the *aggregating API*, *groupby API*, and the *window functions API*, a `Resampler` can be selectively resampled.

Resampling a `DataFrame`, the default will be to act on all columns with the same function.

```

In [309]: df = pd.DataFrame(np.random.randn(1000, 3),
.....:                       index=pd.date_range('1/1/2012', freq='S', periods=1000),
.....:                       columns=['A', 'B', 'C'])
.....:

In [310]: r = df.resample('3T')

In [311]: r.mean()

```

(continues on next page)

(continued from previous page)

```
Out [311]:
```

	A	B	C
2012-01-01 00:00:00	-0.033781	-0.032439	0.024324
2012-01-01 00:03:00	-0.023499	0.121188	0.013790
2012-01-01 00:06:00	-0.038522	0.061784	0.022712
2012-01-01 00:09:00	0.015962	0.076245	0.028317
2012-01-01 00:12:00	-0.011113	-0.044745	-0.086097
2012-01-01 00:15:00	-0.008164	-0.148956	-0.025592

We can select a specific column or columns using standard `getitem`.

```
In [312]: r['A'].mean()
Out [312]:
```

2012-01-01 00:00:00	-0.033781
2012-01-01 00:03:00	-0.023499
2012-01-01 00:06:00	-0.038522
2012-01-01 00:09:00	0.015962
2012-01-01 00:12:00	-0.011113
2012-01-01 00:15:00	-0.008164

```
Freq: 3T, Name: A, dtype: float64
```

```
In [313]: r[['A', 'B']].mean()
Out [313]:
```

	A	B
2012-01-01 00:00:00	-0.033781	-0.032439
2012-01-01 00:03:00	-0.023499	0.121188
2012-01-01 00:06:00	-0.038522	0.061784
2012-01-01 00:09:00	0.015962	0.076245
2012-01-01 00:12:00	-0.011113	-0.044745
2012-01-01 00:15:00	-0.008164	-0.148956

You can pass a list or dict of functions to do aggregation with, outputting a `DataFrame`:

```
In [314]: r['A'].agg([np.sum, np.mean, np.std])
Out [314]:
```

	sum	mean	std
2012-01-01 00:00:00	-6.080538	-0.033781	1.063125
2012-01-01 00:03:00	-4.229885	-0.023499	0.967564
2012-01-01 00:06:00	-6.934007	-0.038522	1.026984
2012-01-01 00:09:00	2.873238	0.015962	0.961662
2012-01-01 00:12:00	-2.000302	-0.011113	0.951884
2012-01-01 00:15:00	-0.816366	-0.008164	0.879981

On a resampled `DataFrame`, you can pass a list of functions to apply to each column, which produces an aggregated result with a hierarchical index:

```
In [315]: r.agg([np.sum, np.mean])
Out [315]:
```

	A		B		C	
	sum	mean	sum	mean	sum	mean
2012-01-01 00:00:00	-6.080538	-0.033781	-5.838938	-0.032439	4.378241	0.024324
2012-01-01 00:03:00	-4.229885	-0.023499	21.813827	0.121188	2.482252	0.013790
2012-01-01 00:06:00	-6.934007	-0.038522	11.121162	0.061784	4.088109	0.022712

(continues on next page)

(continued from previous page)

```

2012-01-01 00:09:00  2.873238  0.015962  13.724028  0.076245  5.097129  0.028317
2012-01-01 00:12:00 -2.000302 -0.011113  -8.054085 -0.044745 -15.497435 -0.086097
2012-01-01 00:15:00 -0.816366 -0.008164 -14.895550 -0.148956  -2.559218 -0.025592

```

By passing a dict to `aggregate` you can apply a different aggregation to the columns of a `DataFrame`:

```

In [316]: r.agg({'A': np.sum,
.....:         'B': lambda x: np.std(x, ddof=1)})
.....:
Out [316]:

```

	A	B
2012-01-01 00:00:00	-6.080538	0.929504
2012-01-01 00:03:00	-4.229885	0.945142
2012-01-01 00:06:00	-6.934007	0.992286
2012-01-01 00:09:00	2.873238	0.990177
2012-01-01 00:12:00	-2.000302	0.976255
2012-01-01 00:15:00	-0.816366	1.037785

The function names can also be strings. In order for a string to be valid it must be implemented on the resampled object:

```

In [317]: r.agg({'A': 'sum', 'B': 'std'})
Out [317]:

```

	A	B
2012-01-01 00:00:00	-6.080538	0.929504
2012-01-01 00:03:00	-4.229885	0.945142
2012-01-01 00:06:00	-6.934007	0.992286
2012-01-01 00:09:00	2.873238	0.990177
2012-01-01 00:12:00	-2.000302	0.976255
2012-01-01 00:15:00	-0.816366	1.037785

Furthermore, you can also specify multiple aggregation functions for each column separately.

```

In [318]: r.agg({'A': ['sum', 'std'], 'B': ['mean', 'std']})
Out [318]:

```

	A		B	
	sum	std	mean	std
2012-01-01 00:00:00	-6.080538	1.063125	-0.032439	0.929504
2012-01-01 00:03:00	-4.229885	0.967564	0.121188	0.945142
2012-01-01 00:06:00	-6.934007	1.026984	0.061784	0.992286
2012-01-01 00:09:00	2.873238	0.961662	0.076245	0.990177
2012-01-01 00:12:00	-2.000302	0.951884	-0.044745	0.976255
2012-01-01 00:15:00	-0.816366	0.879981	-0.148956	1.037785

If a `DataFrame` does not have a datetimelike index, but instead you want to resample based on datetimelike column in the frame, it can be passed to the `on` keyword.

```

In [319]: df = pd.DataFrame({'date': pd.date_range('2015-01-01', freq='W', periods=5),
.....:                      'a': np.arange(5)},
.....:                      index=pd.MultiIndex.from_arrays([
.....:                          [1, 2, 3, 4, 5],
.....:                          pd.date_range('2015-01-01', freq='W', periods=5)],
.....:                      names=['v', 'd']))
.....:

```

```
In [320]: df
```

```
Out[320]:
```

		date	a
v	d		
1	2015-01-04	2015-01-04	0
2	2015-01-11	2015-01-11	1
3	2015-01-18	2015-01-18	2
4	2015-01-25	2015-01-25	3
5	2015-02-01	2015-02-01	4

```
In [321]: df.resample('M', on='date').sum()
```

```
Out[321]:
```

	a
date	
2015-01-31	6
2015-02-28	4

Similarly, if you instead want to resample by a datetimelike level of `MultiIndex`, its name or location can be passed to the `level` keyword.

```
In [322]: df.resample('M', level='d').sum()
```

```
Out[322]:
```

	a
d	
2015-01-31	6
2015-02-28	4

Iterating through groups

With the `Resampler` object in hand, iterating through the grouped data is very natural and functions similarly to `itertools.groupby()`:

```
In [323]: small = pd.Series(
.....:     range(6),
.....:     index=pd.to_datetime(['2017-01-01T00:00:00',
.....:                          '2017-01-01T00:30:00',
.....:                          '2017-01-01T00:31:00',
.....:                          '2017-01-01T01:00:00',
.....:                          '2017-01-01T03:00:00',
.....:                          '2017-01-01T03:05:00']))
.....: )
.....:
```

```
In [324]: resampled = small.resample('H')
```

```
In [325]: for name, group in resampled:
```

```
.....:     print("Group: ", name)
.....:     print("-" * 27)
.....:     print(group, end="\n\n")
.....:
```

```
Group: 2017-01-01 00:00:00
-----
```

(continues on next page)

(continued from previous page)

```

2017-01-01 00:00:00    0
2017-01-01 00:30:00    1
2017-01-01 00:31:00    2
dtype: int64

-----
2017-01-01 01:00:00    3
dtype: int64

Group: 2017-01-01 02:00:00
-----
Series([], dtype: int64)

Group: 2017-01-01 03:00:00
-----
2017-01-01 03:00:00    4
2017-01-01 03:05:00    5
dtype: int64

```

See *Iterating through groups* or `Resampler.__iter__` for more.

4.13.11 Time span representation

Regular intervals of time are represented by `Period` objects in pandas while sequences of `Period` objects are collected in a `PeriodIndex`, which can be created with the convenience function `period_range`.

Period

A `Period` represents a span of time (e.g., a day, a month, a quarter, etc). You can specify the span via `freq` keyword using a frequency alias like below. Because `freq` represents a span of `Period`, it cannot be negative like “-3D”.

```
In [326]: pd.Period('2012', freq='A-DEC')
Out[326]: Period('2012', 'A-DEC')
```

```
In [327]: pd.Period('2012-1-1', freq='D')
Out[327]: Period('2012-01-01', 'D')
```

```
In [328]: pd.Period('2012-1-1 19:00', freq='H')
Out[328]: Period('2012-01-01 19:00', 'H')
```

```
In [329]: pd.Period('2012-1-1 19:00', freq='5H')
Out[329]: Period('2012-01-01 19:00', '5H')
```

Adding and subtracting integers from periods shifts the period by its own frequency. Arithmetic is not allowed between `Period` with different `freq` (span).

```
In [330]: p = pd.Period('2012', freq='A-DEC')
```

```
In [331]: p + 1
Out[331]: Period('2013', 'A-DEC')
```

```
In [332]: p - 3
Out[332]: Period('2009', 'A-DEC')

In [333]: p = pd.Period('2012-01', freq='2M')
```

```
In [334]: p + 2
Out[334]: Period('2012-05', '2M')
```

```
In [335]: p - 1
Out[335]: Period('2011-11', '2M')
```

```
In [336]: p == pd.Period('2012-01', freq='3M')
```

```
-----
IncompatibleFrequency                                Traceback (most recent call last)
<ipython-input-336-4b67dc0b596c> in <module>
----> 1 p == pd.Period('2012-01', freq='3M')

~/sandbox/pandas-doc/pandas/_libs/tslibs/period.pyx in pandas._libs.tslibs.period._
↳Period.__richcmp__()
```

IncompatibleFrequency: Input has different freq=3M from Period(freq=2M)

If `Period` freq is daily or higher (D, H, T, S, L, U, N), `offsets` and `timedelta`-like can be added if the result can have the same freq. Otherwise, `ValueError` will be raised.

```
In [337]: p = pd.Period('2014-07-01 09:00', freq='H')
```

```
In [338]: p + pd.offsets.Hour(2)
Out[338]: Period('2014-07-01 11:00', 'H')
```

```
In [339]: p + datetime.timedelta(minutes=120)
Out[339]: Period('2014-07-01 11:00', 'H')
```

```
In [340]: p + np.timedelta64(7200, 's')
Out[340]: Period('2014-07-01 11:00', 'H')
```

```
In [1]: p + pd.offsets.Minute(5)
Traceback
...
ValueError: Input has different freq from Period(freq=H)
```

If `Period` has other frequencies, only the same `offsets` can be added. Otherwise, `ValueError` will be raised.

```
In [341]: p = pd.Period('2014-07', freq='M')
```

```
In [342]: p + pd.offsets.MonthEnd(3)
Out[342]: Period('2014-10', 'M')
```

```
In [1]: p + pd.offsets.MonthBegin(3)
Traceback
...
ValueError: Input has different freq from Period(freq=M)
```

Taking the difference of `Period` instances with the same frequency will return the number of frequency units between them:

```
In [343]: pd.Period('2012', freq='A-DEC') - pd.Period('2002', freq='A-DEC')
Out[343]: <10 * YearEnds: month=12>
```

PeriodIndex and period_range

Regular sequences of `Period` objects can be collected in a `PeriodIndex`, which can be constructed using the `period_range` convenience function:

```
In [344]: prng = pd.period_range('1/1/2011', '1/1/2012', freq='M')

In [345]: prng
Out[345]:
PeriodIndex(['2011-01', '2011-02', '2011-03', '2011-04', '2011-05', '2011-06',
            '2011-07', '2011-08', '2011-09', '2011-10', '2011-11', '2011-12',
            '2012-01'],
            dtype='period[M]', freq='M')
```

The `PeriodIndex` constructor can also be used directly:

```
In [346]: pd.PeriodIndex(['2011-1', '2011-2', '2011-3'], freq='M')
Out[346]: PeriodIndex(['2011-01', '2011-02', '2011-03'], dtype='period[M]', freq='M')
```

Passing multiplied frequency outputs a sequence of `Period` which has multiplied span.

```
In [347]: pd.period_range(start='2014-01', freq='3M', periods=4)
Out[347]: PeriodIndex(['2014-01', '2014-04', '2014-07', '2014-10'], dtype='period[3M]',
                    ↪freq='3M')
```

If `start` or `end` are `Period` objects, they will be used as anchor endpoints for a `PeriodIndex` with frequency matching that of the `PeriodIndex` constructor.

```
In [348]: pd.period_range(start=pd.Period('2017Q1', freq='Q'),
    .....:                  end=pd.Period('2017Q2', freq='Q'), freq='M')
    .....:
Out[348]: PeriodIndex(['2017-03', '2017-04', '2017-05', '2017-06'], dtype='period[M]',
                    ↪freq='M')
```

Just like `DatetimeIndex`, a `PeriodIndex` can also be used to index pandas objects:

```
In [349]: ps = pd.Series(np.random.randn(len(prng)), prng)

In [350]: ps
Out[350]:
2011-01    0.818145
2011-02    0.267439
2011-03   -0.133309
2011-04    0.662254
2011-05   -0.688393
2011-06   -0.731718
2011-07   -1.190946
2011-08   -1.889384
2011-09    0.171033
```

(continues on next page)

(continued from previous page)

```

2011-10    0.368582
2011-11    0.356459
2011-12    0.556248
2012-01   -0.148709
Freq: M, dtype: float64

```

PeriodIndex supports addition and subtraction with the same rule as Period.

```
In [351]: idx = pd.period_range('2014-07-01 09:00', periods=5, freq='H')
```

```
In [352]: idx
```

```
Out[352]:
```

```

PeriodIndex(['2014-07-01 09:00', '2014-07-01 10:00', '2014-07-01 11:00',
            '2014-07-01 12:00', '2014-07-01 13:00'],
            dtype='period[H]', freq='H')

```

```
In [353]: idx + pd.offsets.Hour(2)
```

```
Out[353]:
```

```

PeriodIndex(['2014-07-01 11:00', '2014-07-01 12:00', '2014-07-01 13:00',
            '2014-07-01 14:00', '2014-07-01 15:00'],
            dtype='period[H]', freq='H')

```

```
In [354]: idx = pd.period_range('2014-07', periods=5, freq='M')
```

```
In [355]: idx
```

```

Out[355]: PeriodIndex(['2014-07', '2014-08', '2014-09', '2014-10', '2014-11'],
                    dtype='period[M]', freq='M')

```

```
In [356]: idx + pd.offsets.MonthEnd(3)
```

```

Out[356]: PeriodIndex(['2014-10', '2014-11', '2014-12', '2015-01', '2015-02'],
                    dtype='period[M]', freq='M')

```

PeriodIndex has its own dtype named `period`, refer to *Period Dtypes*.

Period dtypes

New in version 0.19.0.

PeriodIndex has a custom `period` dtype. This is a pandas extension dtype similar to the *timezone aware dtype* (`datetime64[ns, tz]`).

The `period` dtype holds the `freq` attribute and is represented with `period[freq]` like `period[D]` or `period[M]`, using *frequency strings*.

```
In [357]: pi = pd.period_range('2016-01-01', periods=3, freq='M')
```

```
In [358]: pi
```

```
Out[358]: PeriodIndex(['2016-01', '2016-02', '2016-03'], dtype='period[M]', freq='M')
```

```
In [359]: pi.dtype
```

```
Out[359]: period[M]
```

The `period` dtype can be used in `.astype(...)`. It allows one to change the `freq` of a `PeriodIndex` like `.asfreq()` and convert a `DatetimeIndex` to `PeriodIndex` like `to_period()`:

```

# change monthly freq to daily freq
In [360]: pi.astype('period[D]')
Out[360]: PeriodIndex(['2016-01-31', '2016-02-29', '2016-03-31'], dtype='period[D]',
↳freq='D')

# convert to DatetimeIndex
In [361]: pi.astype('datetime64[ns]')
Out[361]: DatetimeIndex(['2016-01-01', '2016-02-01', '2016-03-01'],
↳dtype='datetime64[ns]', freq='MS')

# convert to PeriodIndex
In [362]: dti = pd.date_range('2011-01-01', freq='M', periods=3)

In [363]: dti
Out[363]: DatetimeIndex(['2011-01-31', '2011-02-28', '2011-03-31'],
↳dtype='datetime64[ns]', freq='M')

In [364]: dti.astype('period[M]')
Out[364]: PeriodIndex(['2011-01', '2011-02', '2011-03'], dtype='period[M]', freq='M')

```

PeriodIndex partial string indexing

You can pass in dates and strings to `Series` and `DataFrame` with `PeriodIndex`, in the same manner as `DatetimeIndex`. For details, refer to *DatetimeIndex Partial String Indexing*.

```

In [365]: ps['2011-01']
Out[365]: 0.8181454127659131

In [366]: ps[datetime.datetime(2011, 12, 25):]
Out[366]:
2011-12    0.556248
2012-01   -0.148709
Freq: M, dtype: float64

In [367]: ps['10/31/2011':'12/31/2011']
Out[367]:
2011-10    0.368582
2011-11    0.356459
2011-12    0.556248
Freq: M, dtype: float64

```

Passing a string representing a lower frequency than `PeriodIndex` returns partial sliced data.

```

In [368]: ps['2011']
Out[368]:
2011-01    0.818145
2011-02    0.267439

Frequency conversion and resampling with PeriodIndex

The frequency of `Period` and `PeriodIndex` can be converted via the `asfreq` method. Let's start with the fiscal year 2011, ending in December:

```
In [373]: p = pd.Period('2011', freq='A-DEC')
```

```
In [374]: p
```

```
Out[374]: Period('2011', 'A-DEC')
```

We can convert it to a monthly frequency. Using the `how` parameter, we can specify whether to return the starting or ending month:

```
In [375]: p.asfreq('M', how='start')
```

```
Out[375]: Period('2011-01', 'M')
```

```
In [376]: p.asfreq('M', how='end')
```

```
Out[376]: Period('2011-12', 'M')
```

The shorthands `'s'` and `'e'` are provided for convenience:

```
In [377]: p.asfreq('M', 's')
```

```
Out[377]: Period('2011-01', 'M')
```

```
In [378]: p.asfreq('M', 'e')
```

```
Out[378]: Period('2011-12', 'M')
```

Converting to a “super-period” (e.g., annual frequency is a super-period of quarterly frequency) automatically returns the super-period that includes the input period:

```
In [379]: p = pd.Period('2011-12', freq='M')
```

```
In [380]: p.asfreq('A-NOV')
```

```
Out[380]: Period('2012', 'A-NOV')
```

Note that since we converted to an annual frequency that ends the year in November, the monthly period of December 2011 is actually in the 2012 A-NOV period.

Period conversions with anchored frequencies are particularly useful for working with various quarterly data common to economics, business, and other fields. Many organizations define quarters relative to the month in which their fiscal year starts and ends. Thus, first quarter of 2011 could start in 2010 or a few months into 2011. Via anchored frequencies, pandas works for all quarterly frequencies Q-JAN through Q-DEC.

Q-DEC define regular calendar quarters:

```
In [381]: p = pd.Period('2012Q1', freq='Q-DEC')
```

```
In [382]: p.asfreq('D', 's')
```

```
Out[382]: Period('2012-01-01', 'D')
```

```
In [383]: p.asfreq('D', 'e')
```

```

Out[383]: Period('2012-03-31', 'D')
Q-MAR defines fiscal year end in March:
In [384]: p = pd.Period('2011Q4', freq='Q-MAR')

In [385]: p.asfreq('D', 's')
Out[385]: Period('2011-01-01', 'D')

In [386]: p.asfreq('D', 'e')
Out[386]: Period('2011-03-31', 'D')

```

4.13.12 Converting between representations

Timestamped data can be converted to PeriodIndex-ed data using `to_period` and vice-versa using `to_timestamp`:

```
In [387]: rng = pd.date_range('1/1/2012', periods=5, freq='M')
```

```
In [388]: ts = pd.Series(np.random.randn(len(rng)), index=rng)
```

```

In [389]: ts
Out[389]:
2012-01-31    0.886762
2012-02-29    0.034219
2012-03-31   -0.120191
2012-04-30   -1.448144
2012-05-31   -0.316413
Freq: M, dtype: float64

```

```
In [390]: ps = ts.to_period()
```

```

In [391]: ps
Out[391]:
2012-01    0.886762
2012-02    0.034219
2012-03   -0.120191
2012-04   -1.448144
2012-05   -0.316413
Freq: M, dtype: float64

```

```

In [392]: ps.to_timestamp()
Out[392]:
2012-01-01    0.886762
2012-02-01    0.034219
2012-03-01   -0.120191
2012-04-01   -1.448144
2012-05-01   -0.316413
Freq: MS, dtype: float64

```

Remember that 's' and 'e' can be used to return the timestamps at the start or end of the period:

```

In [393]: ps.to_timestamp('D', how='s')
Out[393]:

```

(continues on next page)

(continued from previous page)

```

2012-01-01    0.886762
2012-02-01    0.034219
2012-03-01   -0.120191
2012-04-01   -1.448144
2012-05-01   -0.316413
Freq: MS, dtype: float64

```

Converting between period and timestamp enables some convenient arithmetic functions to be used. In the following example, we convert a quarterly frequency with year ending in November to 9am of the end of the month following the quarter end:

```

In [394]: prng = pd.period_range('1990Q1', '2000Q4', freq='Q-NOV')
In [395]: ts = pd.Series(np.random.randn(len(prng)), prng)
In [396]: ts.index = (prng.asfreq('M', 'e') + 1).asfreq('H', 's') + 9
In [397]: ts.head()
Out [397]:
1990-03-01 09:00    1.136089
1990-06-01 09:00    0.413044
1990-09-01 09:00   -0.815750
1990-12-01 09:00    0.473114
1991-03-01 09:00   -0.242094
Freq: H, dtype: float64

```

4.13.13 Representing out-of-bounds spans

If you have data that is outside of the `Timestamp` bounds, see *Timestamp limitations*, then you can use a `PeriodIndex` and/or `Series` of `Periods` to do computations.

```

In [398]: span = pd.period_range('1215-01-01', '1381-01-01', freq='D')
In [399]: span
Out [399]:
PeriodIndex(['1215-01-01', '1215-01-02', '1215-01-03', '1215-01-04',
            '1215-01-05', '1215-01-06', '1215-01-07', '1215-01-08',
            '1215-01-09', '1215-01-10',
            ...,
            '1380-12-23', '1380-12-24', '1380-12-25', '1380-12-26',
            '1380-12-27', '1380-12-28', '1380-12-29', '1380-12-30',
            '1380-12-31', '1381-01-01'],
            dtype='period[D]', length=60632, freq='D')

```

To convert from an `int64` based `YYYYMMDD` representation.

```
In [400]: s = pd.Series([20121231, 20141130, 99991231])
```

```

In [401]: s
Out [401]:
0    20121231
1    20141130

```

```
2    99991231
dtype: int64
```

```
In [402]: def conv(x):
.....:     return pd.Period(year=x // 10000, month=x // 100 % 100,
.....:                     day=x % 100, freq='D')
.....:
```

```
In [403]: s.apply(conv)
Out[403]:
0    2012-12-31
1    2014-11-30
2    9999-12-31
dtype: period[D]
```

```
In [404]: s.apply(conv)[2]
Out[404]: Period('9999-12-31', 'D')
```

These can easily be converted to a `PeriodIndex`:

```
In [405]: span = pd.PeriodIndex(s.apply(conv))

In [406]: span
Out[406]: PeriodIndex(['2012-12-31', '2014-11-30', '9999-12-31'], dtype='period[D]',
↳freq='D')
```

4.13.14 Time zone handling

pandas provides rich support for working with timestamps in different time zones using the `pytz` and `dateutil` libraries or class: `datetime.timezone` objects from the standard library.

Working with time zones

By default, pandas objects are time zone unaware:

```
In [407]: rng = pd.date_range('3/6/2012 00:00', periods=15, freq='D')

In [408]: rng.tz is None
Out[408]: True
```

To localize these dates to a time zone (assign a particular time zone to a naive date), you can use the `tz_localize` method or the `tz` keyword argument in `date_range()`, `Timestamp`, or `DatetimeIndex`. You can either pass `pytz` or `dateutil` time zone objects or Olson time zone database strings. Olson time zone strings will return `pytz` time zone objects by default. To return `dateutil` time zone objects, append `dateutil/` before the string.

- In `pytz` you can find a list of common (and less common) time zones using `from pytz import common_timezones, all_timezones`.
- `dateutil` uses the OS time zones so there isn't a fixed list available. For common zones, the names are the same as `pytz`.

```

In [409]: import dateutil

# pytz
In [410]: rng_pytz = pd.date_range('3/6/2012 00:00', periods=3, freq='D',
.....:                             tz='Europe/London')
.....:

In [411]: rng_pytz.tz
Out[411]: <DstTzInfo 'Europe/London' LMT-1 day, 23:59:00 STD>

# dateutil
In [412]: rng_dateutil = pd.date_range('3/6/2012 00:00', periods=3, freq='D')

In [413]: rng_dateutil = rng_dateutil.tz_localize('dateutil/Europe/London')

In [414]: rng_dateutil.tz
Out[414]: tzfile('/usr/share/zoneinfo/Europe/London')

# dateutil - utc special case
In [415]: rng_utc = pd.date_range('3/6/2012 00:00', periods=3, freq='D',
.....:                             tz=dateutil.tz.tzutc())
.....:

In [416]: rng_utc.tz
Out[416]: tzutc()

```

New in version 0.25.0.

```

# datetime.timezone
In [417]: rng_utc = pd.date_range('3/6/2012 00:00', periods=3, freq='D',
.....:                             tz=datetime.timezone.utc)
.....:

In [418]: rng_utc.tz
Out[418]: datetime.timezone.utc

```

Note that the UTC time zone is a special case in `dateutil` and should be constructed explicitly as an instance of `dateutil.tz.tzutc`. You can also construct other time zones objects explicitly first.

```

In [419]: import pytz

# pytz
In [420]: tz_pytz = pytz.timezone('Europe/London')

In [421]: rng_pytz = pd.date_range('3/6/2012 00:00', periods=3, freq='D')

In [422]: rng_pytz = rng_pytz.tz_localize(tz_pytz)

In [423]: rng_pytz.tz == tz_pytz
Out[423]: True

# dateutil
In [424]: tz_dateutil = dateutil.tz.gettz('Europe/London')

```

(continues on next page)

(continued from previous page)

```
In [425]: rng_dateutil = pd.date_range('3/6/2012 00:00', periods=3, freq='D',
.....:                               tz=tz_dateutil)
.....:
```

```
In [426]: rng_dateutil.tz == tz_dateutil
Out[426]: True
```

To convert a time zone aware pandas object from one time zone to another, you can use the `tz_convert` method.

```
In [427]: rng_pytz.tz_convert('US/Eastern')
Out[427]:
DatetimeIndex(['2012-03-05 19:00:00-05:00', '2012-03-06 19:00:00-05:00',
              '2012-03-07 19:00:00-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq='D')
```

Note: When using `pytz` time zones, `DatetimeIndex` will construct a different time zone object than a `Timestamp` for the same time zone input. A `DatetimeIndex` can hold a collection of `Timestamp` objects that may have different UTC offsets and cannot be succinctly represented by one `pytz` time zone instance while one `Timestamp` represents one point in time with a specific UTC offset.

```
In [428]: dti = pd.date_range('2019-01-01', periods=3, freq='D', tz='US/Pacific')
```

```
In [429]: dti.tz
```

```
Out[429]: <DstTzInfo 'US/Pacific' LMT-1 day, 16:07:00 STD>
```

```
In [430]: ts = pd.Timestamp('2019-01-01', tz='US/Pacific')
```

```
In [431]: ts.tz
```

```
Out[431]: <DstTzInfo 'US/Pacific' PST-1 day, 16:00:00 STD>
```

Warning: Be wary of conversions between libraries. For some time zones, `pytz` and `dateutil` have different definitions of the zone. This is more of a problem for unusual time zones than for ‘standard’ zones like `US/Eastern`.

Warning: Be aware that a time zone definition across versions of time zone libraries may not be considered equal. This may cause problems when working with stored data that is localized using one version and operated on with a different version. See [here](#) for how to handle such a situation.

Warning: For `pytz` time zones, it is incorrect to pass a time zone object directly into the `datetime.datetime` constructor (e.g., `datetime.datetime(2011, 1, 1, tz=pytz.timezone('US/Eastern'))`). Instead, the `datetime` needs to be localized using the `localize` method on the `pytz` time zone object.

Under the hood, all timestamps are stored in UTC. Values from a time zone aware `DatetimeIndex` or `Timestamp` will have their fields (day, hour, minute, etc.) localized to the time zone. However, timestamps

with the same UTC value are still considered to be equal even if they are in different time zones:

```
In [432]: rng_eastern = rng_utc.tz_convert('US/Eastern')
```

```
In [433]: rng_berlin = rng_utc.tz_convert('Europe/Berlin')
```

```
In [434]: rng_eastern[2]
```

```
Out[434]: Timestamp('2012-03-07 19:00:00-0500', tz='US/Eastern', freq='D')
```

```
In [435]: rng_berlin[2]
```

```
Out[435]: Timestamp('2012-03-08 01:00:00+0100', tz='Europe/Berlin', freq='D')
```

```
In [436]: rng_eastern[2] == rng_berlin[2]
```

```
Out[436]: True
```

Operations between `Series` in different time zones will yield `UTC Series`, aligning the data on the `UTC` timestamps:

```
In [437]: ts_utc = pd.Series(range(3), pd.date_range('20130101', periods=3, tz='UTC'))
```

```
In [438]: eastern = ts_utc.tz_convert('US/Eastern')
```

```
In [439]: berlin = ts_utc.tz_convert('Europe/Berlin')
```

```
In [440]: result = eastern + berlin
```

```
In [441]: result
```

```
Out[441]:
```

```
2013-01-01 00:00:00+00:00    0
```

```
2013-01-02 00:00:00+00:00    2
```

```
2013-01-03 00:00:00+00:00    4
```

```
Freq: D, dtype: int64
```

```
In [442]: result.index
```

```
Out[442]:
```

```
DatetimeIndex(['2013-01-01 00:00:00+00:00', '2013-01-02 00:00:00+00:00',  
              '2013-01-03 00:00:00+00:00'],  
              dtype='datetime64[ns, UTC]', freq='D')
```

To remove time zone information, use `tz_localize(None)` or `tz_convert(None)`. `tz_localize(None)` will remove the time zone yielding the local time representation. `tz_convert(None)` will remove the time zone after converting to `UTC` time.

```
In [443]: didx = pd.date_range(start='2014-08-01 09:00', freq='H',  
.....:                        periods=3, tz='US/Eastern')  
.....:
```

```
In [444]: didx
```

```
Out[444]:
```

```
DatetimeIndex(['2014-08-01 09:00:00-04:00', '2014-08-01 10:00:00-04:00',  
              '2014-08-01 11:00:00-04:00'],  
              dtype='datetime64[ns, US/Eastern]', freq='H')
```

```
In [445]: didx.tz_localize(None)
```

```
Out[445]:
```

```
DatetimeIndex(['2014-08-01 09:00:00', '2014-08-01 10:00:00',
```

```
'2014-08-01 11:00:00'],
dtype='datetime64[ns]', freq='H')
```

```
In [446]: didx.tz_convert(None)
```

```
Out[446]:
```

```
DatetimeIndex(['2014-08-01 13:00:00', '2014-08-01 14:00:00',
               '2014-08-01 15:00:00'],
              dtype='datetime64[ns]', freq='H')
```

```
# tz_convert(None) is identical to tz_convert('UTC').tz_localize(None)
```

```
In [447]: didx.tz_convert('UTC').tz_localize(None)
```

```
Out[447]:
```

```
DatetimeIndex(['2014-08-01 13:00:00', '2014-08-01 14:00:00',
               '2014-08-01 15:00:00'],
              dtype='datetime64[ns]', freq='H')
```

Ambiguous times when localizing

`tz_localize` may not be able to determine the UTC offset of a timestamp because daylight savings time (DST) in a local time zone causes some times to occur twice within one day (“clocks fall back”). The following options are available:

- `'raise'`: Raises a `pytz.AmbiguousTimeError` (the default behavior)
- `'infer'`: Attempt to determine the correct offset base on the monotonicity of the timestamps
- `'NaT'`: Replaces ambiguous times with `NaT`
- `bool`: `True` represents a DST time, `False` represents non-DST time. An array-like of `bool` values is supported for a sequence of times.

```
In [448]: rng_hourly = pd.DatetimeIndex(['11/06/2011 00:00', '11/06/2011 01:00',
.....:                                '11/06/2011 01:00', '11/06/2011 02:00'])
.....:
```

This will fail as there are ambiguous times ('11/06/2011 01:00')

```
In [2]: rng_hourly.tz_localize('US/Eastern')
AmbiguousTimeError: Cannot infer dst time from Timestamp('2011-11-06 01:00:00'), try
↳ using the 'ambiguous' argument
```

Handle these ambiguous times by specifying the following.

```
In [449]: rng_hourly.tz_localize('US/Eastern', ambiguous='infer')
```

```
Out[449]:
```

```
DatetimeIndex(['2011-11-06 00:00:00-04:00', '2011-11-06 01:00:00-04:00',
               '2011-11-06 01:00:00-05:00', '2011-11-06 02:00:00-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq=None)
```

```
In [450]: rng_hourly.tz_localize('US/Eastern', ambiguous='NaT')
```

```
Out[450]:
```

```
DatetimeIndex(['2011-11-06 00:00:00-04:00', 'NaT', 'NaT',
               '2011-11-06 02:00:00-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq=None)
```

```
In [451]: rng_hourly.tz_localize('US/Eastern', ambiguous=[True, True, False, False])
```

```
Out [451]:
DatetimeIndex(['2011-11-06 00:00:00-04:00', '2011-11-06 01:00:00-04:00',
              '2011-11-06 01:00:00-05:00', '2011-11-06 02:00:00-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq=None)
```

Nonexistent times when localizing

A DST transition may also shift the local time ahead by 1 hour creating nonexistent local times (“clocks spring forward”). The behavior of localizing a timeseries with nonexistent times can be controlled by the `nonexistent` argument. The following options are available:

- 'raise': Raises a `pytz.NonExistentTimeError` (the default behavior)
- 'NaT': Replaces nonexistent times with `NaT`
- 'shift_forward': Shifts nonexistent times forward to the closest real time
- 'shift_backward': Shifts nonexistent times backward to the closest real time
- `timedelta` object: Shifts nonexistent times by the `timedelta` duration

```
In [452]: dti = pd.date_range(start='2015-03-29 02:30:00', periods=3, freq='H')
# 2:30 is a nonexistent time
```

Localization of nonexistent times will raise an error by default.

```
In [2]: dti.tz_localize('Europe/Warsaw')
NonExistentTimeError: 2015-03-29 02:30:00
```

Transform nonexistent times to `NaT` or shift the times.

```
In [453]: dti
Out[453]:
DatetimeIndex(['2015-03-29 02:30:00', '2015-03-29 03:30:00',
              '2015-03-29 04:30:00'],
              dtype='datetime64[ns]', freq='H')
```

```
In [454]: dti.tz_localize('Europe/Warsaw', nonexistent='shift_forward')
Out[454]:
DatetimeIndex(['2015-03-29 03:00:00+02:00', '2015-03-29 03:30:00+02:00',
              '2015-03-29 04:30:00+02:00'],
              dtype='datetime64[ns, Europe/Warsaw]', freq='H')
```

```
In [455]: dti.tz_localize('Europe/Warsaw', nonexistent='shift_backward')
Out[455]:
DatetimeIndex(['2015-03-29 01:59:59.999999999+01:00',
              '2015-03-29 03:30:00+02:00',
              '2015-03-29 04:30:00+02:00'],
              dtype='datetime64[ns, Europe/Warsaw]', freq='H')
```

```
In [456]: dti.tz_localize('Europe/Warsaw', nonexistent=pd.Timedelta(1, unit='H'))
Out[456]:
DatetimeIndex(['2015-03-29 03:30:00+02:00', '2015-03-29 03:30:00+02:00',
              '2015-03-29 04:30:00+02:00'],
              dtype='datetime64[ns, Europe/Warsaw]', freq='H')
```

```
In [457]: dti.tz_localize('Europe/Warsaw', nonexistent='NaT')
Out[457]:
DatetimeIndex(['NaT', '2015-03-29 03:30:00+02:00',
              '2015-03-29 04:30:00+02:00'],
              dtype='datetime64[ns, Europe/Warsaw]', freq='H')
```

Time zone series operations

A Series with time zone **naive** values is represented with a dtype of `datetime64[ns]`.

```
In [458]: s_naive = pd.Series(pd.date_range('20130101', periods=3))

In [459]: s_naive
Out[459]:
0    2013-01-01
1    2013-01-02
2    2013-01-03
dtype: datetime64[ns]
```

A Series with a time zone **aware** values is represented with a dtype of `datetime64[ns, tz]` where `tz` is the time zone

```
In [460]: s_aware = pd.Series(pd.date_range('20130101', periods=3, tz='US/Eastern'))

In [461]: s_aware
Out[461]:
0    2013-01-01 00:00:00-05:00
1    2013-01-02 00:00:00-05:00
2    2013-01-03 00:00:00-05:00
dtype: datetime64[ns, US/Eastern]
```

Both of these Series time zone information can be manipulated via the `.dt` accessor, see [the dt accessor section](#).

For example, to localize and convert a naive stamp to time zone aware.

```
In [462]: s_naive.dt.tz_localize('UTC').dt.tz_convert('US/Eastern')
Out[462]:
0    2012-12-31 19:00:00-05:00
1    2013-01-01 19:00:00-05:00
2    2013-01-02 19:00:00-05:00
dtype: datetime64[ns, US/Eastern]
```

Time zone information can also be manipulated using the `astype` method. This method can localize and convert time zone naive timestamps or convert time zone aware timestamps.

```
# localize and convert a naive time zone
In [463]: s_naive.astype('datetime64[ns, US/Eastern]')
Out[463]:
0    2012-12-31 19:00:00-05:00
1    2013-01-01 19:00:00-05:00
2    2013-01-02 19:00:00-05:00
dtype: datetime64[ns, US/Eastern]

# make an aware tz naive
```

```
In [464]: s_aware.astype('datetime64[ns]')
Out[464]:
0    2013-01-01 05:00:00
1    2013-01-02 05:00:00
2    2013-01-03 05:00:00
dtype: datetime64[ns]

# convert to a new time zone
In [465]: s_aware.astype('datetime64[ns, CET]')
Out[465]:
0    2013-01-01 06:00:00+01:00
1    2013-01-02 06:00:00+01:00
2    2013-01-03 06:00:00+01:00
dtype: datetime64[ns, CET]
```

Note: Using `Series.to_numpy()` on a `Series`, returns a NumPy array of the data. NumPy does not currently support time zones (even though it is *printing* in the local time zone!), therefore an object array of Timestamps is returned for time zone aware data:

```
In [466]: s_naive.to_numpy()
Out[466]:
array(['2013-01-01T00:00:00.000000000', '2013-01-02T00:00:00.000000000',
      '2013-01-03T00:00:00.000000000'], dtype='datetime64[ns]')

In [467]: s_aware.to_numpy()
Out[467]:
array([Timestamp('2013-01-01 00:00:00-0500', tz='US/Eastern', freq='D'),
      Timestamp('2013-01-02 00:00:00-0500', tz='US/Eastern', freq='D'),
      Timestamp('2013-01-03 00:00:00-0500', tz='US/Eastern', freq='D')],
      dtype=object)
```

By converting to an object array of Timestamps, it preserves the time zone information. For example, when converting back to a `Series`:

```
In [468]: pd.Series(s_aware.to_numpy())
Out[468]:
0    2013-01-01 00:00:00-05:00
1    2013-01-02 00:00:00-05:00
2    2013-01-03 00:00:00-05:00
dtype: datetime64[ns, US/Eastern]
```

However, if you want an actual NumPy `datetime64[ns]` array (with the values converted to UTC) instead of an array of objects, you can specify the `dtype` argument:

```
In [469]: s_aware.to_numpy(dtype='datetime64[ns]')
Out[469]:
array(['2013-01-01T05:00:00.000000000', '2013-01-02T05:00:00.000000000',
      '2013-01-03T05:00:00.000000000'], dtype='datetime64[ns]')
```

{{ header }}

4.14 Time deltas

Timedeltas are differences in times, expressed in difference units, e.g. days, hours, minutes, seconds. They can be both positive and negative.

`Timedelta` is a subclass of `datetime.timedelta`, and behaves in a similar manner, but allows compatibility with `np.timedelta64` types as well as a host of custom representation, parsing, and attributes.

4.14.1 Parsing

You can construct a `Timedelta` scalar through various arguments:

```
In [1]: import datetime

# strings
In [2]: pd.Timedelta('1 days')
Out[2]: Timedelta('1 days 00:00:00')

In [3]: pd.Timedelta('1 days 00:00:00')
Out[3]: Timedelta('1 days 00:00:00')

In [4]: pd.Timedelta('1 days 2 hours')
Out[4]: Timedelta('1 days 02:00:00')

In [5]: pd.Timedelta('-1 days 2 min 3us')
Out[5]: Timedelta('-2 days +23:57:59.999997')

# like datetime.timedelta
# note: these MUST be specified as keyword arguments
In [6]: pd.Timedelta(days=1, seconds=1)
Out[6]: Timedelta('1 days 00:00:01')

# integers with a unit
In [7]: pd.Timedelta(1, unit='d')
Out[7]: Timedelta('1 days 00:00:00')

# from a datetime.timedelta/np.timedelta64
In [8]: pd.Timedelta(datetime.timedelta(days=1, seconds=1))
Out[8]: Timedelta('1 days 00:00:01')

In [9]: pd.Timedelta(np.timedelta64(1, 'ms'))
Out[9]: Timedelta('0 days 00:00:00.001000')

# negative Timedeltas have this string repr
# to be more consistent with datetime.timedelta conventions
In [10]: pd.Timedelta('-1us')
Out[10]: Timedelta('-1 days +23:59:59.999999')

# a NaT
In [11]: pd.Timedelta('nan')
Out[11]: NaT

In [12]: pd.Timedelta('nat')
```

```
Out[12]: NaT
```

```
# ISO 8601 Duration strings
```

```
In [13]: pd.Timedelta('PODTH1MOS')
```

```
Out[13]: Timedelta('0 days 00:01:00')
```

```
In [14]: pd.Timedelta('PODTHOM0.000000123S')
```

```
Out[14]: Timedelta('0 days 00:00:00.000000')
```

New in version 0.23.0: Added constructor for [ISO 8601 Duration](#) strings

DateOffsets (Day, Hour, Minute, Second, Milli, Micro, Nano) can also be used in construction.

```
In [15]: pd.Timedelta(pd.offsets.Second(2))
```

```
Out[15]: Timedelta('0 days 00:00:02')
```

Further, operations among the scalars yield another scalar `Timedelta`.

```
In [16]: pd.Timedelta(pd.offsets.Day(2)) + pd.Timedelta(pd.offsets.Second(2)) + \
.....:      pd.Timedelta('00:00:00.000123')
```

```
.....:
Out[16]: Timedelta('2 days 00:00:02.000123')
```

to_timedelta

Using the top-level `pd.to_timedelta`, you can convert a scalar, array, list, or Series from a recognized timedelta format / value into a `Timedelta` type. It will construct Series if the input is a Series, a scalar if the input is scalar-like, otherwise it will output a `TimedeltaIndex`.

You can parse a single string to a `Timedelta`:

```
In [17]: pd.to_timedelta('1 days 06:05:01.00003')
```

```
Out[17]: Timedelta('1 days 06:05:01.000030')
```

```
In [18]: pd.to_timedelta('15.5us')
```

```
Out[18]: Timedelta('0 days 00:00:00.000015')
```

or a list/array of strings:

```
In [19]: pd.to_timedelta(['1 days 06:05:01.00003', '15.5us', 'nan'])
```

```
Out[19]: TimedeltaIndex(['1 days 06:05:01.000030', '0 days 00:00:00.000015', NaT], dtype=
↳ 'timedelta64[ns]', freq=None)
```

The `unit` keyword argument specifies the unit of the `Timedelta`:

```
In [20]: pd.to_timedelta(np.arange(5), unit='s')
```

```
Out[20]: TimedeltaIndex(['00:00:00', '00:00:01', '00:00:02', '00:00:03', '00:00:04'],
↳ dtype='timedelta64[ns]', freq=None)
```

```
In [21]: pd.to_timedelta(np.arange(5), unit='d')
```

```
Out[21]: TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'],
↳ dtype='timedelta64[ns]', freq=None)
```

Timedelta limitations

Pandas represents `Timedeltas` in nanosecond resolution using 64 bit integers. As such, the 64 bit integer limits determine the `Timedelta` limits.

```
In [22]: pd.Timedelta.min
Out[22]: Timedelta('-106752 days +00:12:43.145224')
```

```
In [23]: pd.Timedelta.max
Out[23]: Timedelta('106751 days 23:47:16.854775')
```

4.14.2 Operations

You can operate on `Series/DataFrames` and construct `timedelta64[ns]` `Series` through subtraction operations on `datetime64[ns]` `Series`, or `Timestamps`.

```
In [24]: s = pd.Series(pd.date_range('2012-1-1', periods=3, freq='D'))
```

```
In [25]: td = pd.Series([pd.Timedelta(days=i) for i in range(3)])
```

```
In [26]: df = pd.DataFrame({'A': s, 'B': td})
```

```
In [27]: df
Out[27]:
           A          B
0 2012-01-01 0 days
1 2012-01-02 1 days
2 2012-01-03 2 days
```

```
In [28]: df['C'] = df['A'] + df['B']
```

```
In [29]: df
Out[29]:
           A          B          C
0 2012-01-01 0 days 2012-01-01
1 2012-01-02 1 days 2012-01-03
2 2012-01-03 2 days 2012-01-05
```

```
In [30]: df.dtypes
Out[30]:
A    datetime64[ns]
B    timedelta64[ns]
C    datetime64[ns]
dtype: object
```

```
In [31]: s - s.max()
Out[31]:
0    -2 days
1    -1 days
2     0 days
dtype: timedelta64[ns]
```

```
In [32]: s - datetime.datetime(2011, 1, 1, 3, 5)
Out[32]:
```

```
0    364 days 20:55:00
1    365 days 20:55:00
2    366 days 20:55:00
dtype: timedelta64[ns]
```

```
In [33]: s + datetime.timedelta(minutes=5)
Out[33]:
0    2012-01-01 00:05:00
1    2012-01-02 00:05:00
2    2012-01-03 00:05:00
dtype: datetime64[ns]
```

```
In [34]: s + pd.offsets.Minute(5)
Out[34]:
0    2012-01-01 00:05:00
1    2012-01-02 00:05:00
2    2012-01-03 00:05:00
dtype: datetime64[ns]
```

```
In [35]: s + pd.offsets.Minute(5) + pd.offsets.Milli(5)
Out[35]:
0    2012-01-01 00:05:00.005
1    2012-01-02 00:05:00.005
2    2012-01-03 00:05:00.005
dtype: datetime64[ns]
```

Operations with scalars from a `timedelta64[ns]` series:

```
In [36]: y = s - s[0]
In [37]: y
Out[37]:
0    0 days
1    1 days
2    2 days
dtype: timedelta64[ns]
```

Series of `timedeltas` with `NaT` values are supported:

```
In [38]: y = s - s.shift()
In [39]: y
Out[39]:
0     NaT
1    1 days
2    1 days
dtype: timedelta64[ns]
```

Elements can be set to `NaT` using `np.nan` analogously to datetimes:

```
In [40]: y[1] = np.nan
In [41]: y
Out[41]:
```

(continues on next page)

(continued from previous page)

```

0      NaT
1      NaT
2    1 days
dtype: timedelta64[ns]

```

Operands can also appear in a reversed order (a singular object operated with a Series):

```

In [42]: s.max() - s
Out[42]:
0    2 days
1    1 days
2    0 days
dtype: timedelta64[ns]

```

```

In [43]: datetime.datetime(2011, 1, 1, 3, 5) - s
Out[43]:
0   -365 days +03:05:00
1   -366 days +03:05:00
2   -367 days +03:05:00
dtype: timedelta64[ns]

```

```

In [44]: datetime.timedelta(minutes=5) + s
Out[44]:
0   2012-01-01 00:05:00
1   2012-01-02 00:05:00
2   2012-01-03 00:05:00
dtype: datetime64[ns]

```

min, max and the corresponding idxmin, idxmax operations are supported on frames:

```

In [45]: A = s - pd.Timestamp('20120101') - pd.Timedelta('00:05:05')

In [46]: B = s - pd.Series(pd.date_range('2012-1-2', periods=3, freq='D'))

In [47]: df = pd.DataFrame({'A': A, 'B': B})

```

```

In [48]: df
Out[48]:
           A          B
0 -1 days +23:54:55 -1 days
1    0 days 23:54:55 -1 days
2    1 days 23:54:55 -1 days

```

```

In [49]: df.min()
Out[49]:
A   -1 days +23:54:55
B   -1 days +00:00:00
dtype: timedelta64[ns]

```

```

In [50]: df.min(axis=1)
Out[50]:
0   -1 days
1   -1 days
2   -1 days

```

```
dtype: timedelta64[ns]
```

```
In [51]: df.idxmin()
```

```
Out[51]:
```

```
A    0
```

```
B    0
```

```
dtype: int64
```

```
In [52]: df.idxmax()
```

```
Out[52]:
```

```
A    2
```

```
B    0
```

```
dtype: int64
```

min, max, idxmin, idxmax operations are supported on Series as well. A scalar result will be a Timedelta.

```
In [53]: df.min().max()
```

```
Out[53]: Timedelta('-1 days +23:54:55')
```

```
In [54]: df.min(axis=1).min()
```

```
Out[54]: Timedelta('-1 days +00:00:00')
```

```
In [55]: df.min().idxmax()
```

```
Out[55]: 'A'
```

```
In [56]: df.min(axis=1).idxmin()
```

```
Out[56]: 0
```

You can fillna on timedeltas, passing a timedelta to get a particular value.

```
In [57]: y.fillna(pd.Timedelta(0))
```

```
Out[57]:
```

```
0    0 days
```

```
1    0 days
```

```
2    1 days
```

```
dtype: timedelta64[ns]
```

```
In [58]: y.fillna(pd.Timedelta(10, unit='s'))
```

```
Out[58]:
```

```
0    0 days 00:00:10
```

```
1    0 days 00:00:10
```

```
2    1 days 00:00:00
```

```
dtype: timedelta64[ns]
```

```
In [59]: y.fillna(pd.Timedelta('-1 days, 00:00:05'))
```

```
Out[59]:
```

```
0   -1 days +00:00:05
```

```
1   -1 days +00:00:05
```

```
2     1 days 00:00:00
```

```
dtype: timedelta64[ns]
```

You can also negate, multiply and use abs on Timedeltas:

```
In [60]: td1 = pd.Timedelta('-1 days 2 hours 3 seconds')
```

```
In [61]: td1
```

```
Out[61]: Timedelta('-2 days +21:59:57')
```

```
In [62]: -1 * td1
Out[62]: Timedelta('1 days 02:00:03')
```

```
In [63]: - td1
Out[63]: Timedelta('1 days 02:00:03')
```

```
In [64]: abs(td1)
Out[64]: Timedelta('1 days 02:00:03')
```

4.14.3 Reductions

Numeric reduction operation for `timedelta64[ns]` will return `Timedelta` objects. As usual `NaT` are skipped during evaluation.

```
In [65]: y2 = pd.Series(pd.to_timedelta(['-1 days +00:00:05', 'nat',
.....:                                '-1 days +00:00:05', '1 days']))
.....:
```

```
In [66]: y2
Out[66]:
0   -1 days +00:00:05
1                NaT
2   -1 days +00:00:05
3    1 days 00:00:00
dtype: timedelta64[ns]
```

```
In [67]: y2.mean()
Out[67]: Timedelta('-1 days +16:00:03.333333')
```

```
In [68]: y2.median()
Out[68]: Timedelta('-1 days +00:00:05')
```

```
In [69]: y2.quantile(.1)
Out[69]: Timedelta('-1 days +00:00:05')
```

```
In [70]: y2.sum()
Out[70]: Timedelta('-1 days +00:00:10')
```

4.14.4 Frequency conversion

`Timedelta Series`, `TimedeltaIndex`, and `Timedelta` scalars can be converted to other ‘frequencies’ by dividing by another `timedelta`, or by astyping to a specific `timedelta` type. These operations yield `Series` and propagate `NaT` -> `nan`. Note that division by the NumPy scalar is true division, while astyping is equivalent of floor division.

```
In [71]: december = pd.Series(pd.date_range('20121201', periods=4))
```

```
In [72]: january = pd.Series(pd.date_range('20130101', periods=4))
```

```
In [73]: td = january - december
```

```
In [74]: td[2] += datetime.timedelta(minutes=5, seconds=3)
```

```
In [75]: td[3] = np.nan

In [76]: td
Out[76]:
0    31 days 00:00:00
1    31 days 00:00:00
2    31 days 00:05:03
3                NaT
dtype: timedelta64[ns]

# to days
In [77]: td / np.timedelta64(1, 'D')
Out[77]:
0    31.000000
1    31.000000
2    31.003507
3                NaN
dtype: float64

In [78]: td.astype('timedelta64[D]')
Out[78]:
0    31.0
1    31.0
2    31.0
3     NaN
dtype: float64

# to seconds
In [79]: td / np.timedelta64(1, 's')
Out[79]:
0    2678400.0
1    2678400.0
2    2678703.0
3                NaN
dtype: float64

In [80]: td.astype('timedelta64[s]')
Out[80]:
0    2678400.0
1    2678400.0
2    2678703.0
3                NaN
dtype: float64

# to months (these are constant months)
In [81]: td / np.timedelta64(1, 'M')
Out[81]:
0    1.018501
1    1.018501
2    1.018617
3                NaN
dtype: float64
```

Dividing or multiplying a `timedelta64[ns]` Series by an integer or integer Series yields another `timedelta64[ns]` dtypes Series.

```
In [82]: td * -1
Out[82]:
0    -31 days +00:00:00
1    -31 days +00:00:00
2    -32 days +23:54:57
3                NaT
dtype: timedelta64[ns]
```

```
In [83]: td * pd.Series([1, 2, 3, 4])
Out[83]:
0    31 days 00:00:00
1    62 days 00:00:00
2    93 days 00:15:09
3                NaT
dtype: timedelta64[ns]
```

Rounded division (floor-division) of a `timedelta64[ns]` Series by a scalar `Timedelta` gives a series of integers.

```
In [84]: td // pd.Timedelta(days=3, hours=4)
Out[84]:
0     9.0
1     9.0
2     9.0
3     NaN
dtype: float64
```

```
In [85]: pd.Timedelta(days=3, hours=4) // td
Out[85]:
0     0.0
1     0.0
2     0.0
3     NaN
dtype: float64
```

The mod (%) and divmod operations are defined for `Timedelta` when operating with another `timedelta`-like or with a numeric argument.

```
In [86]: pd.Timedelta(hours=37) % datetime.timedelta(hours=2)
Out[86]: Timedelta('0 days 01:00:00')
```

```
# divmod against a timedelta-like returns a pair (int, Timedelta)
In [87]: divmod(datetime.timedelta(hours=2), pd.Timedelta(minutes=11))
Out[87]: (10, Timedelta('0 days 00:10:00'))
```

```
# divmod against a numeric returns a pair (Timedelta, Timedelta)
In [88]: divmod(pd.Timedelta(hours=25), 8640000000000)
Out[88]: (Timedelta('0 days 00:00:00.000000'), Timedelta('0 days 01:00:00'))
```

4.14.5 Attributes

You can access various components of the `Timedelta` or `TimedeltaIndex` directly using the attributes `days`, `seconds`, `microseconds`, `nanoseconds`. These are identical to the values returned by `datetime.timedelta`,

in that, for example, the `.seconds` attribute represents the number of seconds ≥ 0 and < 1 day. These are signed according to whether the `Timedelta` is signed.

These operations can also be directly accessed via the `.dt` property of the `Series` as well.

Note: Note that the attributes are NOT the displayed values of the `Timedelta`. Use `.components` to retrieve the displayed values.

For a `Series`:

```
In [89]: td.dt.days
```

```
Out[89]:
```

```
0    31.0
```

```
1    31.0
```

```
2    31.0
```

```
3     NaN
```

```
dtype: float64
```

```
In [90]: td.dt.seconds
```

```
Out[90]:
```

```
0     0.0
```

```
1     0.0
```

```
2    303.0
```

```
3     NaN
```

```
dtype: float64
```

You can access the value of the fields for a scalar `Timedelta` directly.

```
In [91]: tds = pd.Timedelta('31 days 5 min 3 sec')
```

```
In [92]: tds.days
```

```
Out[92]: 31
```

```
In [93]: tds.seconds
```

```
Out[93]: 303
```

```
In [94]: (-tds).seconds
```

```
Out[94]: 86097
```

You can use the `.components` property to access a reduced form of the `timedelta`. This returns a `DataFrame` indexed similarly to the `Series`. These are the *displayed* values of the `Timedelta`.

```
In [95]: td.dt.components
```

```
Out[95]:
```

```
   days  hours  minutes  seconds  milliseconds  microseconds  nanoseconds
```

```
0  31.0   0.0     0.0     0.0           0.0             0.0             0.0
```

```
1  31.0   0.0     0.0     0.0           0.0             0.0             0.0
```

```
2  31.0   0.0     5.0     3.0           0.0             0.0             0.0
```

```
3   NaN   NaN     NaN     NaN           NaN             NaN             NaN
```

```
In [96]: td.dt.components.seconds
```

```
Out[96]:
```

```
0     0.0
```

```
1     0.0
```

```
2     3.0
```

```
3     NaN
```

Name: seconds, dtype: float64

You can convert a Timedelta to an ISO 8601 Duration string with the `.isoformat` method

New in version 0.20.0.

```
In [97]: pd.Timedelta(days=6, minutes=50, seconds=3,
.....:                milliseconds=10, microseconds=10,
.....:                nanoseconds=12).isoformat()
.....:
Out [97]: 'P6DT0H50M3.010010012S'
```

4.14.6 TimedeltaIndex

To generate an index with time delta, you can use either the `TimedeltaIndex` or the `timedelta_range()` constructor.

Using `TimedeltaIndex` you can pass string-like, `Timedelta`, `timedelta`, or `np.timedelta64` objects. Passing `np.nan`/`pd.NaT`/`nat` will represent missing values.

```
In [98]: pd.TimedeltaIndex(['1 days', '1 days, 00:00:05', np.timedelta64(2, 'D'),
.....:                    datetime.timedelta(days=2, seconds=2)])
.....:
Out [98]:
TimedeltaIndex(['1 days 00:00:00', '1 days 00:00:05', '2 days 00:00:00',
                '2 days 00:00:02'],
              dtype='timedelta64[ns]', freq=None)
```

The string ‘infer’ can be passed in order to set the frequency of the index as the inferred frequency upon creation:

```
In [99]: pd.TimedeltaIndex(['0 days', '10 days', '20 days'], freq='infer')
Out [99]: TimedeltaIndex(['0 days', '10 days', '20 days'], dtype='timedelta64[ns]', freq=
↳ '10D')
```

Generating ranges of time deltas

Similar to `date_range()`, you can construct regular ranges of a `TimedeltaIndex` using `timedelta_range()`. The default frequency for `timedelta_range` is calendar day:

```
In [100]: pd.timedelta_range(start='1 days', periods=5)
Out [100]: TimedeltaIndex(['1 days', '2 days', '3 days', '4 days', '5 days'], dtype=
↳ 'timedelta64[ns]', freq='D')
```

Various combinations of `start`, `end`, and `periods` can be used with `timedelta_range`:

```
In [101]: pd.timedelta_range(start='1 days', end='5 days')
Out [101]: TimedeltaIndex(['1 days', '2 days', '3 days', '4 days', '5 days'],
↳ dtype='timedelta64[ns]', freq='D')
```

```
In [102]: pd.timedelta_range(end='10 days', periods=4)
Out [102]: TimedeltaIndex(['7 days', '8 days', '9 days', '10 days'],
↳ dtype='timedelta64[ns]', freq='D')
```

The `freq` parameter can be passed a variety of *frequency aliases*:

```
In [103]: pd.timedelta_range(start='1 days', end='2 days', freq='30T')
Out[103]:
TimedeltaIndex(['1 days 00:00:00', '1 days 00:30:00', '1 days 01:00:00',
                '1 days 01:30:00', '1 days 02:00:00', '1 days 02:30:00',
                '1 days 03:00:00', '1 days 03:30:00', '1 days 04:00:00',
                '1 days 04:30:00', '1 days 05:00:00', '1 days 05:30:00',
                '1 days 06:00:00', '1 days 06:30:00', '1 days 07:00:00',
                '1 days 07:30:00', '1 days 08:00:00', '1 days 08:30:00',
                '1 days 09:00:00', '1 days 09:30:00', '1 days 10:00:00',
                '1 days 10:30:00', '1 days 11:00:00', '1 days 11:30:00',
                '1 days 12:00:00', '1 days 12:30:00', '1 days 13:00:00',
                '1 days 13:30:00', '1 days 14:00:00', '1 days 14:30:00',
                '1 days 15:00:00', '1 days 15:30:00', '1 days 16:00:00',
                '1 days 16:30:00', '1 days 17:00:00', '1 days 17:30:00',
                '1 days 18:00:00', '1 days 18:30:00', '1 days 19:00:00',
                '1 days 19:30:00', '1 days 20:00:00', '1 days 20:30:00',
                '1 days 21:00:00', '1 days 21:30:00', '1 days 22:00:00',
                '1 days 22:30:00', '1 days 23:00:00', '1 days 23:30:00',
                '2 days 00:00:00'],
                dtype='timedelta64[ns]', freq='30T')
```

```
In [104]: pd.timedelta_range(start='1 days', periods=5, freq='2D5H')
Out[104]:
TimedeltaIndex(['1 days 00:00:00', '3 days 05:00:00', '5 days 10:00:00',
                '7 days 15:00:00', '9 days 20:00:00'],
                dtype='timedelta64[ns]', freq='53H')
```

New in version 0.23.0.

Specifying `start`, `end`, and `periods` will generate a range of evenly spaced timesteps from `start` to `end` inclusively, with `periods` number of elements in the resulting `TimedeltaIndex`:

```
In [105]: pd.timedelta_range('0 days', '4 days', periods=5)
Out[105]: TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'],
                          dtype='timedelta64[ns]', freq=None)
```

```
In [106]: pd.timedelta_range('0 days', '4 days', periods=10)
Out[106]:
TimedeltaIndex(['0 days 00:00:00', '0 days 10:40:00', '0 days 21:20:00',
                '1 days 08:00:00', '1 days 18:40:00', '2 days 05:20:00',
                '2 days 16:00:00', '3 days 02:40:00', '3 days 13:20:00',
                '4 days 00:00:00'],
                dtype='timedelta64[ns]', freq=None)
```

Using the `TimedeltaIndex`

Similarly to other of the datetime-like indices, `DatetimeIndex` and `PeriodIndex`, you can use `TimedeltaIndex` as the index of pandas objects.

```
In [107]: s = pd.Series(np.arange(100),
.....:                  index=pd.timedelta_range('1 days', periods=100, freq='h'))
.....:

In [108]: s
```

(continues on next page)

(continued from previous page)

```
Out [108]:
1 days 00:00:00    0
1 days 01:00:00    1
1 days 02:00:00    2
1 days 03:00:00    3
1 days 04:00:00    4
..
4 days 23:00:00   95
5 days 00:00:00   96
5 days 01:00:00   97
5 days 02:00:00   98
5 days 03:00:00   99
Freq: H, Length: 100, dtype: int64
```

Selections work similarly, with coercion on string-likes and slices:

```
In [109]: s['1 day':'2 day']
```

```
Out [109]:
1 days 00:00:00    0
1 days 01:00:00    1
1 days 02:00:00    2
1 days 03:00:00    3
1 days 04:00:00    4
1 days 05:00:00    5
1 days 06:00:00    6
1 days 07:00:00    7
1 days 08:00:00    8
1 days 09:00:00    9
1 days 10:00:00   10
1 days 11:00:00   11
1 days 12:00:00   12
1 days 13:00:00   13
1 days 14:00:00   14
1 days 15:00:00   15
1 days 16:00:00   16
1 days 17:00:00   17
1 days 18:00:00   18
1 days 19:00:00   19
1 days 20:00:00   20
1 days 21:00:00   21
1 days 22:00:00   22
1 days 23:00:00   23
2 days 00:00:00   24
2 days 01:00:00   25
2 days 02:00:00   26
2 days 03:00:00   27
2 days 04:00:00   28
2 days 05:00:00   29
2 days 06:00:00   30
2 days 07:00:00   31
2 days 08:00:00   32
2 days 09:00:00   33
2 days 10:00:00   34
```

```
2 days 11:00:00    35
2 days 12:00:00    36
2 days 13:00:00    37
2 days 14:00:00    38
2 days 15:00:00    39
2 days 16:00:00    40
2 days 17:00:00    41
2 days 18:00:00    42
2 days 19:00:00    43
2 days 20:00:00    44
2 days 21:00:00    45
2 days 22:00:00    46
2 days 23:00:00    47
Freq: H, dtype: int64
```

```
In [110]: s['1 day 01:00:00']
Out[110]: 1
```

```
In [111]: s[pd.Timedelta('1 day 1h')]
Out[111]: 1
```

Furthermore you can use partial string selection and the range will be inferred:

```
In [112]: s['1 day':'1 day 5 hours']
Out[112]:
1 days 00:00:00    0
1 days 01:00:00    1
1 days 02:00:00    2
1 days 03:00:00    3
1 days 04:00:00    4
1 days 05:00:00    5
Freq: H, dtype: int64
```

Operations

Finally, the combination of `TimedeltaIndex` with `DatetimeIndex` allow certain combination operations that are NaT preserving:

```
In [113]: tdi = pd.TimedeltaIndex(['1 days', pd.NaT, '2 days'])
```

```
In [114]: tdi.to_list()
Out[114]: [Timedelta('1 days 00:00:00'), NaT, Timedelta('2 days 00:00:00')]
```

```
In [115]: dti = pd.date_range('20130101', periods=3)
```

```
In [116]: dti.to_list()
Out[116]:
[Timestamp('2013-01-01 00:00:00', freq='D'),
 Timestamp('2013-01-02 00:00:00', freq='D'),
 Timestamp('2013-01-03 00:00:00', freq='D')]
```

```
In [117]: (dti + tdi).to_list()
Out[117]: [Timestamp('2013-01-02 00:00:00'), NaT, Timestamp('2013-01-05 00:00:00')]
```

```
In [118]: (dti - tdi).to_list()
Out[118]: [Timestamp('2012-12-31 00:00:00'), NaT, Timestamp('2013-01-01 00:00:00')]
```

Conversions

Similarly to frequency conversion on a `Series` above, you can convert these indices to yield another `Index`.

```
In [119]: tdi / np.timedelta64(1, 's')
Out[119]: Float64Index([86400.0, nan, 172800.0], dtype='float64')
```

```
In [120]: tdi.astype('timedelta64[s]')
Out[120]: Float64Index([86400.0, nan, 172800.0], dtype='float64')
```

Scalars type ops work as well. These can potentially return a *different* type of index.

```
# adding or timedelta and date -> datelike
```

```
In [121]: tdi + pd.Timestamp('20130101')
Out[121]: DatetimeIndex(['2013-01-02', 'NaT', '2013-01-03'], dtype='datetime64[ns]',
↳freq=None)
```

```
# subtraction of a date and a timedelta -> datelike
```

```
# note that trying to subtract a date from a Timedelta will raise an exception
```

```
In [122]: (pd.Timestamp('20130101') - tdi).to_list()
Out[122]: [Timestamp('2012-12-31 00:00:00'), NaT, Timestamp('2012-12-30 00:00:00')]
```

```
# timedelta + timedelta -> timedelta
```

```
In [123]: tdi + pd.Timedelta('10 days')
Out[123]: TimedeltaIndex(['11 days', NaT, '12 days'], dtype='timedelta64[ns]', freq=None)
```

```
# division can result in a Timedelta if the divisor is an integer
```

```
In [124]: tdi / 2
Out[124]: TimedeltaIndex(['0 days 12:00:00', NaT, '1 days 00:00:00'],
↳dtype='timedelta64[ns]', freq=None)
```

```
# or a Float64Index if the divisor is a Timedelta
```

```
In [125]: tdi / tdi[0]
Out[125]: Float64Index([1.0, nan, 2.0], dtype='float64')
```

4.14.7 Resampling

Similar to *timeseries resampling*, we can resample with a `TimedeltaIndex`.

```
In [126]: s.resample('D').mean()
Out[126]:
1 days    11.5
2 days    35.5
3 days    59.5
4 days    83.5
5 days    97.5
Freq: D, dtype: float64
```

4.15 Styling

New in version 0.17.1

Provisional: This is a new feature and still under development. We'll be adding features and possibly making breaking changes in future releases. We'd love to hear your feedback.

This document is written as a Jupyter Notebook, and can be viewed or downloaded [here](#).

You can apply **conditional formatting**, the visual styling of a DataFrame depending on the data within, by using the `DataFrame.style` property. This is a property that returns a `Styler` object, which has useful methods for formatting and displaying DataFrames.

The styling is accomplished using CSS. You write “style functions” that take scalars, DataFrames or Series, and return *like-indexed* DataFrames or Series with CSS “attribute: value” pairs for the values. These functions can be incrementally passed to the `Styler` which collects the styles before rendering.

4.15.1 Building styles

Pass your style functions into one of the following methods:

- `Styler.applymap`: elementwise
- `Styler.apply`: column-/row-/table-wise

Both of those methods take a function (and some other keyword arguments) and applies your function to the DataFrame in a certain way. `Styler.applymap` works through the DataFrame elementwise. `Styler.apply` passes each column or row into your DataFrame one-at-a-time or the entire table at once, depending on the `axis` keyword argument. For columnwise use `axis=0`, rowwise use `axis=1`, and for the entire table at once use `axis=None`.

For `Styler.applymap` your function should take a scalar and return a single string with the CSS attribute-value pair.

For `Styler.apply` your function should take a Series or DataFrame (depending on the axis parameter), and return a Series or DataFrame with an identical shape where each value is a string with a CSS attribute-value pair.

Let's see some examples.

```
[2]: import pandas as pd
import numpy as np

np.random.seed(24)
df = pd.DataFrame({'A': np.linspace(1, 10, 10)})
df = pd.concat([df, pd.DataFrame(np.random.randn(10, 4), columns=list('BCDE'))],
              axis=1)
df.iloc[0, 2] = np.nan
```

Here's a boring example of rendering a DataFrame, without any (visible) styles:

```
[3]: df.style
[3]: <pandas.io.formats.style.Styler at 0x119f9e710>
```

Note: The `DataFrame.style` attribute is a property that returns a `Styler` object. `Styler` has a `_repr_html_` method defined on it so they are rendered automatically. If you want the actual HTML back for further processing or for writing to file call the `.render()` method which returns a string.

The above output looks very similar to the standard DataFrame HTML representation. But we've done some work behind the scenes to attach CSS classes to each cell. We can view these by calling the `.render` method.

```
[4]: df.style.highlight_null().render().split('\n')[:10]
[4]: ['<style type="text/css" >',
      '#T_d2a38a0c_f5cb_11e9_af35_186590cd1c87row0_col2 {' ,
      '    background-color: red;',
      '    }</style><table id="T_d2a38a0c_f5cb_11e9_af35_186590cd1c87" ><thead> <tr>
      ↪ <th class="blank level0" ></th> <th class="col_heading level0 col0" >A</th>
      ↪ <th class="col_heading level0 col1" >B</th> <th class="col_heading
      ↪ level0 col2" >C</th> <th class="col_heading level0 col3" >D</th> <th
      ↪ class="col_heading level0 col4" >E</th> </tr></thead><tbody>',
      '    <tr>',
      '        <th id="T_d2a38a0c_f5cb_11e9_af35_186590cd1c87level0_row0"
      ↪ class="row_heading level0 row0" >0</th>',
      '        <td id="T_d2a38a0c_f5cb_11e9_af35_186590cd1c87row0_col0" class=
      ↪ "data row0 col0" >1</td>',
      '        <td id="T_d2a38a0c_f5cb_11e9_af35_186590cd1c87row0_col1" class=
      ↪ "data row0 col1" >1.32921</td>',
      '        <td id="T_d2a38a0c_f5cb_11e9_af35_186590cd1c87row0_col2" class=
      ↪ "data row0 col2" >nan</td>',
      '        <td id="T_d2a38a0c_f5cb_11e9_af35_186590cd1c87row0_col3" class=
      ↪ "data row0 col3" >-0.31628</td>']
```

The `row0_col2` is the identifier for that particular cell. We've also prepended each row/column identifier with a UUID unique to each DataFrame so that the style from one doesn't collide with the styling from another within the same notebook or page (you can set the `uuid` if you'd like to tie together the styling of two DataFrames).

When writing style functions, you take care of producing the CSS attribute / value pairs you want. Pandas matches those up with the CSS classes that identify each cell.

Let's write a simple style function that will color negative numbers red and positive numbers black.

```
[5]: def color_negative_red(val):
      """
      Takes a scalar and returns a string with
      the css property `color: red` for negative
      strings, black otherwise.
      """
      color = 'red' if val < 0 else 'black'
      return 'color: %s' % color
```

In this case, the cell's style depends only on it's own value. That means we should use the `Styler.applymap` method which works elementwise.

```
[6]: s = df.style.applymap(color_negative_red)
      s
[6]: <pandas.io.formats.style.Styler at 0x11a5b9790>
```

Notice the similarity with the standard `df.applymap`, which operates on DataFrames elementwise. We want you to be able to reuse your existing knowledge of how to interact with DataFrames.

Notice also that our function returned a string containing the CSS attribute and value, separated by a colon

just like in a `<style>` tag. This will be a common theme.

Finally, the input shapes matched. `Styler.applymap` calls the function on each scalar input, and the function returns a scalar output.

Now suppose you wanted to highlight the maximum value in each column. We can't use `.applymap` anymore since that operated elementwise. Instead, we'll turn to `.apply` which operates columnwise (or rowwise using the `axis` keyword). Later on we'll see that something like `highlight_max` is already defined on `Styler` so you wouldn't need to write this yourself.

```
[7]: def highlight_max(s):
      '''
      highlight the maximum in a Series yellow.
      '''
      is_max = s == s.max()
      return ['background-color: yellow' if v else '' for v in is_max]
```

```
[8]: df.style.apply(highlight_max)
```

```
[8]: <pandas.io.formats.style.Styler at 0x11a5e4a50>
```

In this case the input is a `Series`, one column at a time. Notice that the output shape of `highlight_max` matches the input shape, an array with `len(s)` items.

We encourage you to use method chains to build up a style piecewise, before finally rendering at the end of the chain.

```
[9]: df.style.\
      applymap(color_negative_red).\
      apply(highlight_max)
```

```
[9]: <pandas.io.formats.style.Styler at 0x11a5edd50>
```

Above we used `Styler.apply` to pass in each column one at a time.

Debugging Tip: If you're having trouble writing your style function, try just passing it into `DataFrame.apply`. Internally, `Styler.apply` uses `DataFrame.apply` so the result should be the same.

What if you wanted to highlight just the maximum value in the entire table? Use `.apply(function, axis=None)` to indicate that your function wants the entire table, not one column or row at a time. Let's try that next.

We'll rewrite our `highlight_max` to handle either `Series` (from `.apply(axis=0 or 1)`) or `DataFrames` (from `.apply(axis=None)`). We'll also allow the color to be adjustable, to demonstrate that `.apply`, and `.applymap` pass along keyword arguments.

```
[10]: def highlight_max(data, color='yellow'):
       '''
       highlight the maximum in a Series or DataFrame
       '''
       attr = 'background-color: {}'.format(color)
       if data.ndim == 1: # Series from .apply(axis=0) or axis=1
           is_max = data == data.max()
           return [attr if v else '' for v in is_max]
       else: # from .apply(axis=None)
           is_max = data == data.max().max()
           return pd.DataFrame(np.where(is_max, attr, ''),
                               index=data.index, columns=data.columns)
```

When using `Styler.apply(func, axis=None)`, the function must return a `DataFrame` with the same index and column labels.

```
[11]: df.style.apply(highlight_max, color='darkorange', axis=None)
[11]: <pandas.io.formats.style.Styler at 0x11a5e4490>
```

Building Styles Summary

Style functions should return strings with one or more CSS `attribute: value` delimited by semicolons. Use

- `Styler.applymap(func)` for elementwise styles
- `Styler.apply(func, axis=0)` for columnwise styles
- `Styler.apply(func, axis=1)` for rowwise styles
- `Styler.apply(func, axis=None)` for tablewise styles

And crucially the input and output shapes of `func` must match. If `x` is the input then `func(x).shape == x.shape`.

4.15.2 Finer control: slicing

Both `Styler.apply`, and `Styler.applymap` accept a `subset` keyword. This allows you to apply styles to specific rows or columns, without having to code that logic into your `style` function.

The value passed to `subset` behaves similar to slicing a `DataFrame`.

- A scalar is treated as a column label
- A list (or series or numpy array)
- A tuple is treated as `(row_indexer, column_indexer)`

Consider using `pd.IndexSlice` to construct the tuple for the last one.

```
[12]: df.style.apply(highlight_max, subset=['B', 'C', 'D'])
[12]: <pandas.io.formats.style.Styler at 0x11a5e4d10>
```

For row and column slicing, any valid indexer to `.loc` will work.

```
[13]: df.style.applymap(color_negative_red,
                        subset=pd.IndexSlice[2:5, ['B', 'D']])
[13]: <pandas.io.formats.style.Styler at 0x11a61ad10>
```

Only label-based slicing is supported right now, not positional.

If your style function uses a `subset` or `axis` keyword argument, consider wrapping your function in a `functools.partial`, partialing out that keyword.

```
my_func2 = functools.partial(my_func, subset=42)
```

4.15.3 Finer Control: Display Values

We distinguish the *display* value from the *actual* value in `Styler`. To control the display value, the text is printed in each cell, use `Styler.format`. Cells can be formatted according to a `format spec string` or a callable that takes a single value and returns a string.

```
[14]: df.style.format("{:.2%}")
[14]: <pandas.io.formats.style.Styler at 0x11a61a510>
```

Use a dictionary to format specific columns.

```
[15]: df.style.format({'B': "{:0<4.0f}", 'D': '{:+.2f}'})
[15]: <pandas.io.formats.style.Styler at 0x11a630290>
```

Or pass in a callable (or dictionary of callables) for more flexible handling.

```
[16]: df.style.format({"B": lambda x: "±{:.2f}".format(abs(x))})
[16]: <pandas.io.formats.style.Styler at 0x11a630d90>
```

4.15.4 Builtin styles

Finally, we expect certain styling functions to be common enough that we've included a few “built-in” to the `Styler`, so you don't have to write them yourself.

```
[17]: df.style.highlight_null(null_color='red')
[17]: <pandas.io.formats.style.Styler at 0x11a630110>
```

You can create “heatmaps” with the `background_gradient` method. These require `matplotlib`, and we'll use `Seaborn` to get a nice colormap.

```
[18]: import seaborn as sns

cm = sns.light_palette("green", as_cmap=True)

s = df.style.background_gradient(cmap=cm)
s

/Users/taugspurger/miniconda3/envs/pandas-doc/lib/python3.7/site-packages/matplotlib/
↳ colors.py:527: RuntimeWarning: invalid value encountered in less
  xa[xa < 0] = -1
[18]: <pandas.io.formats.style.Styler at 0x1a1c4d2fd0>
```

`Styler.background_gradient` takes the keyword arguments `low` and `high`. Roughly speaking these extend the range of your data by `low` and `high` percent so that when we convert the colors, the colormap's entire range isn't used. This is useful so that you can actually read the text still.

```
[19]: # Uses the full color range
df.loc[:4].style.background_gradient(cmap='viridis')
[19]: <pandas.io.formats.style.Styler at 0x1a1c63c850>
```

```
[20]: # Compress the color range
(df.loc[:4]
 .style
 .background_gradient(cmap='viridis', low=.5, high=0)
 .highlight_null('red'))
```

```
[20]: <pandas.io.formats.style.Styler at 0x1a1c641350>
```

There's also `.highlight_min` and `.highlight_max`.

```
[21]: df.style.highlight_max(axis=0)
```

```
[21]: <pandas.io.formats.style.Styler at 0x1a1c64c290>
```

Use `Styler.set_properties` when the style doesn't actually depend on the values.

```
[22]: df.style.set_properties(**{'background-color': 'black',
                               'color': 'lawngreen',
                               'border-color': 'white'})
```

```
[22]: <pandas.io.formats.style.Styler at 0x1a1c64cf10>
```

Bar charts

You can include “bar charts” in your DataFrame.

```
[23]: df.style.bar(subset=['A', 'B'], color='#d65f5f')
```

```
[23]: <pandas.io.formats.style.Styler at 0x1a1c64cad0>
```

New in version 0.20.0 is the ability to customize further the bar chart: You can now have the `df.style.bar` be centered on zero or midpoint value (in addition to the already existing way of having the min value at the left side of the cell), and you can pass a list of `[color_negative, color_positive]`.

Here's how you can change the above with the new `align='mid'` option:

```
[24]: df.style.bar(subset=['A', 'B'], align='mid', color=['#d65f5f', '#5fba7d'])
```

```
[24]: <pandas.io.formats.style.Styler at 0x1a1c660450>
```

The following example aims to give a highlight of the behavior of the new align options:

```
[25]: import pandas as pd
from IPython.display import HTML

# Test series
test1 = pd.Series([-100,-60,-30,-20], name='All Negative')
test2 = pd.Series([10,20,50,100], name='All Positive')
test3 = pd.Series([-10,-5,0,90], name='Both Pos and Neg')

head = """
<table>
  <thead>
    <th>Align</th>
    <th>All Negative</th>
```

(continues on next page)

(continued from previous page)

```

        <th>All Positive</th>
        <th>Both Neg and Pos</th>
    </thead>
</tbody>

"""

aligns = ['left','zero','mid']
for align in aligns:
    row = "<tr><th>{}</th>".format(align)
    for serie in [test1,test2,test3]:
        s = serie.copy()
        s.name=' '
        row += "<td>{}</td>".format(s.to_frame().style.bar(align=align,
                                                                color=['#d65f5f', '#5fba7d'],
                                                                width=100).render()) #testn[
↪ 'width']
    row += '</tr>'
    head += row

head+= """
</tbody>
</table>"""

```

HTML(head)

[25]: <IPython.core.display.HTML object>

4.15.5 Sharing styles

Say you have a lovely style built up for a DataFrame, and now you want to apply the same style to a second DataFrame. Export the style with `df1.style.export`, and import it on the second DataFrame with `df1.style.set`

```
[26]: df2 = -df
      style1 = df.style.applymap(color_negative_red)
      style1
```

[26]: <pandas.io.formats.style.Styler at 0x1a1c674b10>

```
[27]: style2 = df2.style
      style2.use(style1.export())
      style2
```

[27]: <pandas.io.formats.style.Styler at 0x1a1c644750>

Notice that you're able share the styles even though they're data aware. The styles are re-evaluated on the new DataFrame they've been used upon.

4.15.6 Other Options

You've seen a few methods for data-driven styling. `Styler` also provides a few other options for styles that don't depend on the data.

- precision
- captions
- table-wide styles
- hiding the index or columns

Each of these can be specified in two ways:

- A keyword argument to `Styler.__init__`
- A call to one of the `.set_` or `.hide_` methods, e.g. `.set_caption` or `.hide_columns`

The best method to use depends on the context. Use the `Styler` constructor when building many styled DataFrames that should all share the same properties. For interactive use, the `.set_` and `.hide_` methods are more convenient.

Precision

You can control the precision of floats using pandas' regular `display.precision` option.

```
[28]: with pd.option_context('display.precision', 2):
      html = (df.style
              .applymap(color_negative_red)
              .apply(highlight_max))
      html
```

```
[28]: <pandas.io.formats.style.Styler at 0x1a1c684210>
```

Or through a `set_precision` method.

```
[29]: df.style\
      .applymap(color_negative_red)\
      .apply(highlight_max)\
      .set_precision(2)
```

```
[29]: <pandas.io.formats.style.Styler at 0x1a1c68b990>
```

Setting the precision only affects the printed number; the full-precision values are always passed to your style functions. You can always use `df.round(2).style` if you'd prefer to round from the start.

Captions

Regular table captions can be added in a few ways.

```
[30]: df.style.set_caption('Colormaps, with a caption.')\
      .background_gradient(cmap=cm)
```

```
[30]: <pandas.io.formats.style.Styler at 0x1a1c68b450>
```

Table styles

The next option you have are “table styles”. These are styles that apply to the table as a whole, but don’t look at the data. Certain sytlings, including pseudo-selectors like `:hover` can only be used this way.

```
[31]: from IPython.display import HTML

def hover(hover_color="#ffff99"):
    return dict(selector="tr:hover",
                props=[("background-color", "%s" % hover_color)])

styles = [
    hover(),
    dict(selector="th", props=[("font-size", "150%"),
                              ("text-align", "center")]),
    dict(selector="caption", props=[("caption-side", "bottom")])
]
html = (df.style.set_table_styles(styles)
        .set_caption("Hover to highlight. "))
html
```

```
[31]: <pandas.io.formats.style.Styler at 0x1a1c684190>
```

`table_styles` should be a list of dictionaries. Each dictionary should have the `selector` and `props` keys. The value for `selector` should be a valid CSS selector. Recall that all the styles are already attached to an id, unique to each `Styler`. This selector is in addition to that id. The value for `props` should be a list of tuples of ('attribute', 'value').

`table_styles` are extremely flexible, but not as fun to type out by hand. We hope to collect some useful ones either in pandas, or preferable in a new package that *builds on top* the tools here.

Hiding the Index or Columns

The index can be hidden from rendering by calling `Styler.hide_index`. Columns can be hidden from rendering by calling `Styler.hide_columns` and passing in the name of a column, or a slice of columns.

```
[32]: df.style.hide_index()
```

```
[32]: <pandas.io.formats.style.Styler at 0x1a1c68b550>
```

```
[33]: df.style.hide_columns(['C', 'D'])
```

```
[33]: <pandas.io.formats.style.Styler at 0x1a1c674710>
```

CSS classes

Certain CSS classes are attached to cells.

- Index and Column names include `index_name` and `level<k>` where `k` is its level in a `MultiIndex`
- Index label cells include
 - `row_heading`
 - `row<n>` where `n` is the numeric position of the row
 - `level<k>` where `k` is the level in a `MultiIndex`

- Column label cells include
 - `col_heading`
 - `col<n>` where `n` is the numeric position of the column
 - `level<k>` where `k` is the level in a MultiIndex
- Blank cells include `blank`
- Data cells include `data`

Limitations

- DataFrame only (use `Series.to_frame().style`)
- The index and columns must be unique
- No large repr, and performance isn't great; this is intended for summary DataFrames
- You can only style the *values*, not the index or columns
- You can only apply styles, you can't insert new HTML entities

Some of these will be addressed in the future.

Terms

- Style function: a function that's passed into `Styler.apply` or `Styler.applymap` and returns values like `'css attribute: value'`
- Builtin style functions: style functions that are methods on `Styler`
- table style: a dictionary with the two keys `selector` and `props`. `selector` is the CSS selector that `props` will apply to. `props` is a list of `(attribute, value)` tuples. A list of table styles passed into `Styler`.

4.15.7 Fun stuff

Here are a few interesting examples.

`Styler` interacts pretty well with widgets. If you're viewing this online instead of running the notebook yourself, you're missing out on interactively adjusting the color palette.

```
[34]: from IPython.html import widgets
@widgets.interact
def f(h_neg=(0, 359, 1), h_pos=(0, 359), s=(0., 99.9), l=(0., 99.9)):
    return df.style.background_gradient(
        cmap=sns.palettes.diverging_palette(h_neg=h_neg, h_pos=h_pos, s=s, l=1,
                                           as_cmap=True)
    )
```

<pandas.io.formats.style.Styler at 0x1a1c68d3d0>

```
[35]: def magnify():
    return [dict(selector="th",
                props=[("font-size", "4pt")]),
            dict(selector="td",
```

(continues on next page)

(continued from previous page)

```

        props=[('padding', "0em 0em")]),
    dict(selector="th:hover",
        props=[("font-size", "12pt")]),
    dict(selector="tr:hover td:hover",
        props=[('max-width', '200px'),
                ('font-size', '12pt')])
]

```

```

[36]: np.random.seed(25)
      cmap = sns.diverging_palette(5, 250, as_cmap=True)
      bigdf = pd.DataFrame(np.random.randn(20, 25)).cumsum()

      bigdf.style.background_gradient(cmap, axis=1)\
        .set_properties(**{'max-width': '80px', 'font-size': '1pt'})\
        .set_caption("Hover to magnify")\
        .set_precision(2)\
        .set_table_styles(magnify())

```

```

[36]: <pandas.io.formats.style.Styler at 0x1a1c641890>

```

4.15.8 Export to Excel

New in version 0.20.0

Experimental: This is a new feature and still under development. We'll be adding features and possibly making breaking changes in future releases. We'd love to hear your feedback.

Some support is available for exporting styled `DataFrames` to Excel worksheets using the `OpenPyXL` or `XlsxWriter` engines. CSS2.2 properties handled include:

- background-color
- border-style, border-width, border-color and their {top, right, bottom, left variants}
- color
- font-family
- font-style
- font-weight
- text-align
- text-decoration
- vertical-align
- white-space: nowrap
- Only CSS2 named colors and hex colors of the form `#rgb` or `#rrggbb` are currently supported.
- The following pseudo CSS properties are also available to set excel specific style properties:
 - number-format

```
[37]: df.style.\
      applymap(color_negative_red).\
      apply(highlight_max).\
      to_excel('styled.xlsx', engine='openpyxl')
```

A screenshot of the output:

	A	B	C	D	E	F
1		A	B	C	D	E
2	0	1	1.329212		-0.31628	-0.99081
3	1	2	-1.070816	-1.438713	0.564417	0.295722
4	2	3	-1.626404	0.219565	0.678805	1.889273
5	3	4	0.961538	0.104011	-0.481165	0.850229
6	4	5	1.453425	1.057737	0.165562	0.515018
7	5	6	-1.336936	0.562861	1.392855	-0.063328
8	6	7	0.121668	1.207603	-0.00204	1.627796
9	7	8	0.354493	1.037528	-0.385684	0.519818
10	8	9	1.686583	-1.325963	1.428984	-2.089354
11	9	10	-0.12982	0.631523	-0.586538	0.29072

4.15.9 Extensibility

The core of pandas is, and will remain, its “high-performance, easy-to-use data structures”. With that in mind, we hope that `DataFrame.style` accomplishes two goals

- Provide an API that is pleasing to use interactively and is “good enough” for many tasks
- Provide the foundations for dedicated libraries to build on

If you build a great library on top of this, let us know and we’ll link to it.

Subclassing

If the default template doesn’t quite suit your needs, you can subclass `Styler` and extend or override the template. We’ll show an example of extending the default template to insert a custom header before each table.

```
[38]: from jinja2 import Environment, ChoiceLoader, FileSystemLoader
      from IPython.display import HTML
      from pandas.io.formats.style import Styler
```

We’ll use the following template:

```
[39]: with open("templates/myhtml.tpl") as f:
      print(f.read())

{% extends "html.tpl" %}
{% block table %}
<h1>{{ table_title|default("My Table") }}</h1>
{{ super() }}
```

(continues on next page)

(continued from previous page)

```
{% endblock table %}
```

Now that we've created a template, we need to set up a subclass of `Styler` that knows about it.

```
[40]: class MyStyler(Styler):
      env = Environment(
          loader=ChoiceLoader([
              FileSystemLoader("templates"), # contains ours
              Styler.loader, # the default
          ])
      )
      template = env.get_template("myhtml.tpl")
```

Notice that we include the original loader in our environment's loader. That's because we extend the original template, so the Jinja environment needs to be able to find it.

Now we can use that custom styler. Its `__init__` takes a `DataFrame`.

```
[41]: MyStyler(df)
```

```
[41]: <__main__.MyStyler at 0x1a1d3b0e10>
```

Our custom template accepts a `table_title` keyword. We can provide the value in the `.render` method.

```
[42]: HTML(MyStyler(df).render(table_title="Extending Example"))
```

```
[42]: <IPython.core.display.HTML object>
```

For convenience, we provide the `Styler.from_custom_template` method that does the same as the custom subclass.

```
[43]: EasyStyler = Styler.from_custom_template("templates", "myhtml.tpl")
      EasyStyler(df)
```

```
[43]: <pandas.io.formats.style.Styler.from_custom_template.<locals>.MyStyler at 0x1a1c6ef090>
```

Here's the template structure:

```
[44]: with open("templates/template_structure.html") as f:
      structure = f.read()
```

```
HTML(structure)
```

```
[44]: <IPython.core.display.HTML object>
```

See the template in the [GitHub repo](#) for more details.

```
{{ header }}
```

4.16 Options and settings

4.16.1 Overview

pandas has an options system that lets you customize some aspects of its behaviour, display-related options being those the user is most likely to adjust.

Options have a full “dotted-style”, case-insensitive name (e.g. `display.max_rows`). You can get/set options directly as attributes of the top-level `options` attribute:

```
In [1]: import pandas as pd

In [2]: pd.options.display.max_rows
Out[2]: 60

In [3]: pd.options.display.max_rows = 999

In [4]: pd.options.display.max_rows
Out[4]: 999
```

The API is composed of 5 relevant functions, available directly from the `pandas` namespace:

- `get_option()` / `set_option()` - get/set the value of a single option.
- `reset_option()` - reset one or more options to their default value.
- `describe_option()` - print the descriptions of one or more options.
- `option_context()` - execute a codeblock with a set of options that revert to prior settings after execution.

Note: Developers can check out [pandas/core/config.py](#) for more information.

All of the functions above accept a regexp pattern (`re.search` style) as an argument, and so passing in a substring will work - as long as it is unambiguous:

```
In [5]: pd.get_option("display.max_rows")
Out[5]: 999

In [6]: pd.set_option("display.max_rows", 101)

In [7]: pd.get_option("display.max_rows")
Out[7]: 101

In [8]: pd.set_option("max_r", 102)

In [9]: pd.get_option("display.max_rows")
Out[9]: 102
```

The following will **not work** because it matches multiple option names, e.g. `display.max_colwidth`, `display.max_rows`, `display.max_columns`:

```
In [10]: try:
...:     pd.get_option("column")
...: except KeyError as e:
...:     print(e)
```

(continues on next page)

(continued from previous page)

```
.....:
'Pattern matched multiple keys'
```

Note: Using this form of shorthand may cause your code to break if new options with similar names are added in future versions.

You can get a list of available options and their descriptions with `describe_option`. When called with no argument `describe_option` will print out the descriptions for all available options.

4.16.2 Getting and setting options

As described above, `get_option()` and `set_option()` are available from the pandas namespace. To change an option, call `set_option('option regex', new_value)`.

```
In [11]: pd.get_option('mode.sim_interactive')
Out[11]: False

In [12]: pd.set_option('mode.sim_interactive', True)

In [13]: pd.get_option('mode.sim_interactive')
Out[13]: True
```

Note: The option `'mode.sim_interactive'` is mostly used for debugging purposes.

All options also have a default value, and you can use `reset_option` to do just that:

```
In [14]: pd.get_option("display.max_rows")
Out[14]: 60

In [15]: pd.set_option("display.max_rows", 999)

In [16]: pd.get_option("display.max_rows")
Out[16]: 999

In [17]: pd.reset_option("display.max_rows")

In [18]: pd.get_option("display.max_rows")
Out[18]: 60
```

It's also possible to reset multiple options at once (using a regex):

```
In [19]: pd.reset_option("^display")
```

`option_context` context manager has been exposed through the top-level API, allowing you to execute code with given option values. Option values are restored automatically when you exit the *with* block:

```
In [20]: with pd.option_context("display.max_rows", 10, "display.max_columns", 5):
.....:     print(pd.get_option("display.max_rows"))
.....:     print(pd.get_option("display.max_columns"))
.....:
10
5

In [21]: print(pd.get_option("display.max_rows"))
```

60

```
In [22]: print(pd.get_option("display.max_columns"))
0
```

4.16.3 Setting startup options in Python/IPython environment

Using startup scripts for the Python/IPython environment to import pandas and set options makes working with pandas more efficient. To do this, create a .py or .ipy script in the startup directory of the desired profile. An example where the startup folder is in a default ipython profile can be found at:

```
$IPYTHONDIR/profile_default/startup
```

More information can be found in the [ipython documentation](#). An example startup script for pandas is displayed below:

```
import pandas as pd
pd.set_option('display.max_rows', 999)
pd.set_option('precision', 5)
```

4.16.4 Frequently Used Options

The following is a walk-through of the more frequently used display options.

`display.max_rows` and `display.max_columns` sets the maximum number of rows and columns displayed when a frame is pretty-printed. Truncated lines are replaced by an ellipsis.

```
In [23]: df = pd.DataFrame(np.random.randn(7, 2))
```

```
In [24]: pd.set_option('max_rows', 7)
```

```
In [25]: df
```

```
Out[25]:
```

```
      0      1
0 -0.228248 -2.069612
1  0.610144  0.423497
2  1.117887 -0.274242
3  1.741812 -0.447501
4 -1.255427  0.938164
5 -0.468346 -1.254720
6  0.124824  0.756502
```

```
In [26]: pd.set_option('max_rows', 5)
```

```
In [27]: df
```

```
Out[27]:
```

```
      0      1
0 -0.228248 -2.069612
1  0.610144  0.423497
..     ...     ...
5 -0.468346 -1.254720
6  0.124824  0.756502
```

(continues on next page)

(continued from previous page)

```
[7 rows x 2 columns]
```

```
In [28]: pd.reset_option('max_rows')
```

Once the `display.max_rows` is exceeded, the `display.min_rows` options determines how many rows are shown in the truncated repr.

```
In [29]: pd.set_option('max_rows', 8)
```

```
In [30]: pd.set_option('max_rows', 4)
```

```
# below max_rows -> all rows shown
```

```
In [31]: df = pd.DataFrame(np.random.randn(7, 2))
```

```
In [32]: df
```

```
Out[32]:
```

```

      0         1
0  0.241440  0.497426
1  4.108693  0.821121
..     ...     ...
5  0.396520 -0.314617
6 -0.593756  1.149501
```

```
[7 rows x 2 columns]
```

```
# above max_rows -> only min_rows (4) rows shown
```

```
In [33]: df = pd.DataFrame(np.random.randn(9, 2))
```

```
In [34]: df
```

```
Out[34]:
```

```

      0         1
0  1.335566  0.302629
1 -0.454228  0.514371
..     ...     ...
7 -1.221429  1.804477
8  0.180410  0.553164
```

```
[9 rows x 2 columns]
```

```
In [35]: pd.reset_option('max_rows')
```

```
In [36]: pd.reset_option('min_rows')
```

`display.expand_frame_repr` allows for the representation of dataframes to stretch across pages, wrapped over the full column vs row-wise.

```
In [37]: df = pd.DataFrame(np.random.randn(5, 10))
```

```
In [38]: pd.set_option('expand_frame_repr', True)
```

```
In [39]: df
```

(continues on next page)

(continued from previous page)

```

Out [39]:

`display.max_info_rows: df.info()` will usually show null-counts for each column. For large frames this can be quite slow. `max_info_rows` and `max_info_cols` limit this null check only to frames with smaller dimensions than specified. Note that you can specify the option `df.info(null_counts=True)` to override on showing a particular frame.

```

4.16.5 Available options

	Option	Default	Function
display.chop_threshold	None		If set to a float value, all float values smaller than the given threshold will be chopped.
display.colheader_justify	right		Controls the justification of column headers. used by DataFrameFormatter.
display.column_space	12		No description available.
display.date_dayfirst	False		When True, prints and parses dates with the day first, eg 20/01/2005
display.date_yearfirst	False		When True, prints and parses dates with the year first, eg 2005/01/20
display.encoding	UTF-8		Defaults to the detected encoding of the console. Specifies the encoding to use for printing and parsing.
display.expand_frame_repr	True		Whether to print out the full DataFrame repr for wide DataFrames across multiple lines.
display.float_format	None		The callable should accept a floating point number and return a string with the desired format.
display.large_repr	truncate		For DataFrames exceeding max_rows/max_cols, the repr (and HTML repr) will be truncated.
display.latex_repr	False		Whether to produce a latex DataFrame representation for jupyter frontend.
display.latex.escape	True		Escapes special characters in DataFrames, when using the to_latex method.
display.latex.longtable	False		Specifies if the to_latex method of a DataFrame uses the longtable format.
display.latex.multipage	True		Combines columns when using a MultiIndex.
display.latex.multipage_format	'l'		Alignment of multipage labels.
display.latex.multirow	False		Combines rows when using a MultiIndex. Centered instead of top-aligned.

4.16.6 Number formatting

pandas also allows you to set how numbers are displayed in the console. This option is not set through the `set_options` API.

Use the `set_eng_float_format` function to alter the floating-point formatting of pandas objects to produce a particular format.

For instance:

```
In [87]: import numpy as np
```

```
In [88]: pd.set_eng_float_format(accuracy=3, use_eng_prefix=True)
```

```
In [89]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])
```

```
In [90]: s / 1.e3
```

```
Out[90]:
```

```
a      1.615m
b     -104.292u
c     -1.455m
```

```
d    927.500u
e   -17.229u
dtype: float64
```

```
In [91]: s / 1.e6
Out[91]:
a     1.615u
b   -104.292n
c    -1.455u
d    927.500n
e   -17.229n
dtype: float64
```

To round floats on a case-by-case basis, you can also use `round()` and `round()`.

4.16.7 Unicode formatting

Warning: Enabling this option will affect the performance for printing of DataFrame and Series (about 2 times slower). Use only when it is actually required.

Some East Asian countries use Unicode characters whose width corresponds to two Latin characters. If a DataFrame or Series contains these characters, the default output mode may not align them properly.

Note: Screen captures are attached for each output to show the actual results.

```
In [92]: df = pd.DataFrame({' ': ['UK', ' '], ' ': ['Alice', ' ']}))
```

```
In [93]: df
Out[93]:
```

```
0  UK  Alice
1
```

```
>>> df = pd.DataFrame({'国籍': ['UK', u'日本'], u'名前': ['Alice', u'しのぶ']})
```

```
>>> df
```

```
   名前  国籍
0  Alice  UK
1   のぶ  日本
```

Enabling `display.unicode.east_asian_width` allows pandas to check each character’s “East Asian Width” property. These characters can be aligned properly by setting this option to `True`. However, this will result in longer render times than the standard `len` function.

```
In [94]: pd.set_option('display.unicode.east_asian_width', True)
```

```
In [95]: df
Out[95]:
```

```
0    UK  Alice
1
```

```
>>> pd.set_option('display.unicode.east_asian_width', True)
>>> df
   名前  国籍
0  Alice  UK
1  し の ぶ  日本
```

In addition, Unicode characters whose width is “Ambiguous” can either be 1 or 2 characters wide depending on the terminal setting or encoding. The option `display.unicode.ambiguous_as_wide` can be used to handle the ambiguity.

By default, an “Ambiguous” character’s width, such as “¡” (inverted exclamation) in the example below, is taken to be 1.

```
In [96]: df = pd.DataFrame({'a': ['xxx', '¡¡'], 'b': ['yyy', '¡¡']})
```

```
In [97]: df
```

```
Out[97]:
```

```
   a  b
0 xxx yyy
1  ¡¡ ¡¡
```

```
>>> df = pd.DataFrame({'a': ['xxx', u'¡¡'], 'b': ['yyy', u'¡¡']})
```

```
>>> df
```

```
   a  b
0 xxx yyy
1  ¡¡ ¡¡
```

Enabling `display.unicode.ambiguous_as_wide` makes pandas interpret these characters’ widths to be 2. (Note that this option will only be effective when `display.unicode.east_asian_width` is enabled.)

However, setting this option incorrectly for your terminal will cause these characters to be aligned incorrectly:

```
In [98]: pd.set_option('display.unicode.ambiguous_as_wide', True)
```

```
In [99]: df
```

```
Out[99]:
```

```
   a  b
0 xxx yyy
1  ¡¡ ¡¡
```

```
>>> pd.set_option('display.unicode.ambiguous_as_wide', True)
```

```
>>> df
```

```
   a  b
0 xxx yyy
1  ¡¡ ¡¡
```

4.16.8 Table schema display

New in version 0.20.0.

`DataFrame` and `Series` will publish a Table Schema representation by default. False by default, this can be enabled globally with the `display.html.table_schema` option:

```
In [100]: pd.set_option('display.html.table_schema', True)
```

Only `'display.max_rows'` are serialized and published. `{{ header }}`

4.17 Enhancing performance

In this part of the tutorial, we will investigate how to speed up certain functions operating on pandas `DataFrames` using three different techniques: Cython, Numba and `pandas.eval()`. We will see a speed improvement of ~200 when we use Cython and Numba on a test function operating row-wise on the `DataFrame`. Using `pandas.eval()` we will speed up a sum by an order of ~2.

4.17.1 Cython (writing C extensions for pandas)

For many use cases writing pandas in pure Python and NumPy is sufficient. In some computationally heavy applications however, it can be possible to achieve sizable speed-ups by offloading work to `cython`.

This tutorial assumes you have refactored as much as possible in Python, for example by trying to remove for-loops and making use of NumPy vectorization. It's always worth optimising in Python first.

This tutorial walks through a “typical” process of cythonizing a slow computation. We use an [example from the Cython documentation](#) but in the context of pandas. Our final cythonized solution is around 100 times faster than the pure Python solution.

Pure Python

We have a `DataFrame` to which we want to apply a function row-wise.

```
In [1]: df = pd.DataFrame({'a': np.random.randn(1000),
...:                      'b': np.random.randn(1000),
...:                      'N': np.random.randint(100, 1000, (1000)),
...:                      'x': 'x'})
...:

In [2]: df
Out[2]:
```

	a	b	N	x
0	0.286932	-1.108820	468	x
1	0.816278	-0.591357	796	x
2	-0.555291	0.240515	941	x
3	0.819424	-0.555205	760	x
4	1.179587	-0.379999	519	x
..
995	0.498704	0.962552	352	x
996	0.376858	2.123431	543	x
997	-1.407083	1.844740	687	x
998	0.304963	0.234843	925	x
999	1.679794	-0.947443	291	x

```
[1000 rows x 4 columns]
```

Here's the function in pure Python:

```
In [3]: def f(x):
...:     return x * (x - 1)
...:
```

(continues on next page)

(continued from previous page)

```
In [4]: def integrate_f(a, b, N):
...:     s = 0
...:     dx = (b - a) / N
...:     for i in range(N):
...:         s += f(a + i * dx)
...:     return s * dx
...:
```

We achieve our result by using `apply` (row-wise):

```
In [7]: %timeit df.apply(lambda x: integrate_f(x['a'], x['b'], x['N']), axis=1)
10 loops, best of 3: 174 ms per loop
```

But clearly this isn't fast enough for us. Let's take a look and see where the time is spent during this operation (limited to the most time consuming four calls) using the `prun` `ipython` magic function:

```
In [5]: %prun -l 4 df.apply(lambda x: integrate_f(x['a'], x['b'], x['N']), axis=1) #L
↳noqa E999
      668169 function calls (663143 primitive calls) in 0.212 seconds

Ordered by: internal time
List reduced from 221 to 4 due to restriction <4>

ncalls  tottime  percall  cumtime  percall  filename:lineno(function)
   1000    0.108    0.000    0.158    0.000  <ipython-input-4-c2a74e076cf0>:1(integrate_
↳f)
 548260    0.050    0.000    0.050    0.000  <ipython-input-3-c138bdd570e3>:1(f)
   3000    0.006    0.000    0.035    0.000  base.py:4702(get_value)
   3000    0.004    0.000    0.041    0.000  series.py:1068(__getitem__)
```

By far the majority of time is spent inside either `integrate_f` or `f`, hence we'll concentrate our efforts cythonizing these two functions.

Note: In Python 2 replacing the `range` with its generator counterpart (`xrange`) would mean the `range` line would vanish. In Python 3 `range` is already a generator.

Plain Cython

First we're going to need to import the Cython magic function to `ipython`:

```
In [6]: %load_ext Cython
```

Now, let's simply copy our functions over to Cython as is (the suffix is here to distinguish between function versions):

```
In [7]: %%cython
...: def f_plain(x):
...:     return x * (x - 1)
...: def integrate_f_plain(a, b, N):
...:     s = 0
```

(continues on next page)

(continued from previous page)

```

...:     dx = (b - a) / N
...:     for i in range(N):
...:         s += f_plain(a + i * dx)
...:     return s * dx
...:

```

Note: If you're having trouble pasting the above into your ipython, you may need to be using bleeding edge ipython for paste to play well with cell magics.

```

In [4]: %%timeit df.apply(lambda x: integrate_f_plain(x['a'], x['b'], x['N']), axis=1)
10 loops, best of 3: 85.5 ms per loop

```

Already this has shaved a third off, not too bad for a simple copy and paste.

Adding type

We get another huge improvement simply by providing type information:

```

In [8]: %%cython
...: cdef double f_typed(double x) except? -2:
...:     return x * (x - 1)
...: cpdef double integrate_f_typed(double a, double b, int N):
...:     cdef int i
...:     cdef double s, dx
...:     s = 0
...:     dx = (b - a) / N
...:     for i in range(N):
...:         s += f_typed(a + i * dx)
...:     return s * dx
...:

```

```

In [4]: %%timeit df.apply(lambda x: integrate_f_typed(x['a'], x['b'], x['N']), axis=1)
10 loops, best of 3: 20.3 ms per loop

```

Now, we're talking! It's now over ten times faster than the original python implementation, and we haven't *really* modified the code. Let's have another look at what's eating up time:

```

In [9]: %prun -l 4 df.apply(lambda x: integrate_f_typed(x['a'], x['b'], x['N']), axis=1)
119905 function calls (114879 primitive calls) in 0.050 seconds

```

Ordered by: internal time

List reduced from 216 to 4 due to restriction <4>

ncalls	totttime	percall	cumtime	percall	filename:lineno(function)
3000	0.006	0.000	0.033	0.000	base.py:4702(get_value)
3000	0.003	0.000	0.038	0.000	series.py:1068(__getitem__)
6001	0.003	0.000	0.009	0.000	{pandas._libs.lib.values_from_object}
1	0.003	0.003	0.048	0.048	{pandas._libs.reduction.reduce}

Using ndarray

It's calling series... a lot! It's creating a Series from each row, and getting from both the index and the series (three times for each row). Function calls are expensive in Python, so maybe we could minimize these by cythonizing the apply part.

Note: We are now passing ndarrays into the Cython function, fortunately Cython plays very nicely with NumPy.

```
In [10]: %%cython
...: cimport numpy as np
...: import numpy as np
...: cdef double f_typed(double x) except? -2:
...:     return x * (x - 1)
...: cpdef double integrate_f_typed(double a, double b, int N):
...:     cdef int i
...:     cdef double s, dx
...:     s = 0
...:     dx = (b - a) / N
...:     for i in range(N):
...:         s += f_typed(a + i * dx)
...:     return s * dx
...: cpdef np.ndarray[double] apply_integrate_f(np.ndarray col_a, np.ndarray col_b,
...:                                           np.ndarray col_N):
...:     assert (col_a.dtype == np.float
...:           and col_b.dtype == np.float and col_N.dtype == np.int)
...:     cdef Py_ssize_t i, n = len(col_N)
...:     assert (len(col_a) == len(col_b) == n)
...:     cdef np.ndarray[double] res = np.empty(n)
...:     for i in range(len(col_a)):
...:         res[i] = integrate_f_typed(col_a[i], col_b[i], col_N[i])
...:     return res
...:
```

The implementation is simple, it creates an array of zeros and loops over the rows, applying our `integrate_f_typed`, and putting this in the zeros array.

Warning: You can **not** pass a Series directly as a ndarray typed parameter to a Cython function. Instead pass the actual ndarray using the `Series.to_numpy()`. The reason is that the Cython definition is specific to an ndarray and not the passed Series.

So, do not do this:

```
apply_integrate_f(df['a'], df['b'], df['N'])
```

But rather, use `Series.to_numpy()` to get the underlying ndarray:

```
apply_integrate_f(df['a'].to_numpy(),
                  df['b'].to_numpy(),
                  df['N'].to_numpy())
```

Note: Loops like this would be *extremely* slow in Python, but in Cython looping over NumPy arrays is

fast.

```
In [4]: %timeit apply_integrate_f(df['a'].to_numpy(),
                                df['b'].to_numpy(),
                                df['N'].to_numpy())
1000 loops, best of 3: 1.25 ms per loop
```

We've gotten another big improvement. Let's check again where the time is spent:

```
In [11]: %%prun -l 4 apply_integrate_f(df['a'].to_numpy(),
.....:                                df['b'].to_numpy(),
.....:                                df['N'].to_numpy())
.....:
269 function calls in 0.001 seconds

Ordered by: internal time
List reduced from 64 to 4 due to restriction <4>

ncalls  tottime  percall  cumtime  percall  filename:lineno(function)
  1      0.001    0.001    0.001    0.001  {built-in method _cython_magic_
↪13e5f90f678dd113b7239601d072756f.apply_integrate_f}
  1      0.000    0.000    0.001    0.001  {built-in method builtins.exec}
  3      0.000    0.000    0.000    0.000  frame.py:2964(__getitem__)
  3      0.000    0.000    0.000    0.000  managers.py:971(iget)
```

As one might expect, the majority of the time is now spent in `apply_integrate_f`, so if we wanted to make anymore efficiencies we must continue to concentrate our efforts here.

More advanced techniques

There is still hope for improvement. Here's an example of using some more advanced Cython techniques:

```
In [12]: %%cython
.....: cimport cython
.....: cimport numpy as np
.....: import numpy as np
.....: cdef double f_typed(double x) except? -2:
.....:     return x * (x - 1)
.....: cpdef double integrate_f_typed(double a, double b, int N):
.....:     cdef int i
.....:     cdef double s, dx
.....:     s = 0
.....:     dx = (b - a) / N
.....:     for i in range(N):
.....:         s += f_typed(a + i * dx)
.....:     return s * dx
.....: @cython.boundscheck(False)
.....: @cython.wraparound(False)
.....: cpdef np.ndarray[double] apply_integrate_f_wrap(np.ndarray[double] col_a,
.....:                                             np.ndarray[double] col_b,
.....:                                             np.ndarray[int] col_N):
.....:     cdef int i, n = len(col_N)
```

(continues on next page)

(continued from previous page)

```

.....:     assert len(col_a) == len(col_b) == n
.....:     cdef np.ndarray[double] res = np.empty(n)
.....:     for i in range(n):
.....:         res[i] = integrate_f_typed(col_a[i], col_b[i], col_N[i])
.....:     return res
.....:

```

```

In [4]: %timeit apply_integrate_f_wrap(df['a'].to_numpy(),
                                       df['b'].to_numpy(),
                                       df['N'].to_numpy())
1000 loops, best of 3: 987 us per loop

```

Even faster, with the caveat that a bug in our Cython code (an off-by-one error, for example) might cause a segfault because memory access isn't checked. For more about `boundscheck` and `wraparound`, see the Cython docs on [compiler directives](#).

4.17.2 Using Numba

A recent alternative to statically compiling Cython code, is to use a *dynamic jit-compiler*, Numba.

Numba gives you the power to speed up your applications with high performance functions written directly in Python. With a few annotations, array-oriented and math-heavy Python code can be just-in-time compiled to native machine instructions, similar in performance to C, C++ and Fortran, without having to switch languages or Python interpreters.

Numba works by generating optimized machine code using the LLVM compiler infrastructure at import time, runtime, or statically (using the included `pycc` tool). Numba supports compilation of Python to run on either CPU or GPU hardware, and is designed to integrate with the Python scientific software stack.

Note: You will need to install Numba. This is easy with `conda`, by using: `conda install numba`, see [installing using miniconda](#).

Note: As of Numba version 0.20, pandas objects cannot be passed directly to Numba-compiled functions. Instead, one must pass the NumPy array underlying the pandas object to the Numba-compiled function as demonstrated below.

Jit

We demonstrate how to use Numba to just-in-time compile our code. We simply take the plain Python code from above and annotate with the `@jit` decorator.

```

import numba

@numba.jit
def f_plain(x):
    return x * (x - 1)

```

(continues on next page)

(continued from previous page)

```

@numba.jit
def integrate_f_numba(a, b, N):
    s = 0
    dx = (b - a) / N
    for i in range(N):
        s += f_plain(a + i * dx)
    return s * dx

@numba.jit
def apply_integrate_f_numba(col_a, col_b, col_N):
    n = len(col_N)
    result = np.empty(n, dtype='float64')
    assert len(col_a) == len(col_b) == n
    for i in range(n):
        result[i] = integrate_f_numba(col_a[i], col_b[i], col_N[i])
    return result

def compute_numba(df):
    result = apply_integrate_f_numba(df['a'].to_numpy(),
                                     df['b'].to_numpy(),
                                     df['N'].to_numpy())
    return pd.Series(result, index=df.index, name='result')

```

Note that we directly pass NumPy arrays to the Numba function. `compute_numba` is just a wrapper that provides a nicer interface by passing/returning pandas objects.

```

In [4]: %timeit compute_numba(df)
1000 loops, best of 3: 798 us per loop

```

In this example, using Numba was faster than Cython.

Vectorize

Numba can also be used to write vectorized functions that do not require the user to explicitly loop over the observations of a vector; a vectorized function will be applied to each row automatically. Consider the following toy example of doubling each observation:

```

import numba

def double_every_value_nonumba(x):
    return x * 2

@numba.vectorize
def double_every_value_withnumba(x): # noqa E501
    return x * 2

```

```

# Custom function without numba
In [5]: %timeit df['col1_doubled'] = df.a.apply(double_every_value_nonumba) # noqa E501
1000 loops, best of 3: 797 us per loop

# Standard implementation (faster than a custom function)
In [6]: %timeit df['col1_doubled'] = df.a * 2
1000 loops, best of 3: 233 us per loop

# Custom function with numba
In [7]: %timeit (df['col1_doubled'] = double_every_value_withnumba(df.a.to_numpy()))
1000 loops, best of 3: 145 us per loop

```

Caveats

Note: Numba will execute on any function, but can only accelerate certain classes of functions.

Numba is best at accelerating functions that apply numerical functions to NumPy arrays. When passed a function that only uses operations it knows how to accelerate, it will execute in `nopython` mode.

If Numba is passed a function that includes something it doesn't know how to work with – a category that currently includes sets, lists, dictionaries, or string functions – it will revert to `object` mode. In `object` mode, Numba will execute but your code will not speed up significantly. If you would prefer that Numba throw an error if it cannot compile a function in a way that speeds up your code, pass Numba the argument `nopython=True` (e.g. `@numba.jit(nopython=True)`). For more on troubleshooting Numba modes, see the [Numba troubleshooting page](#).

Read more in the [Numba docs](#).

4.17.3 Expression evaluation via `eval()`

The top-level function `pandas.eval()` implements expression evaluation of *Series* and *DataFrame* objects.

Note: To benefit from using `eval()` you need to install `numexpr`. See the [recommended dependencies section](#) for more details.

The point of using `eval()` for expression evaluation rather than plain Python is two-fold: 1) large *DataFrame* objects are evaluated more efficiently and 2) large arithmetic and boolean expressions are evaluated all at once by the underlying engine (by default `numexpr` is used for evaluation).

Note: You should not use `eval()` for simple expressions or for expressions involving small *DataFrames*. In fact, `eval()` is many orders of magnitude slower for smaller expressions/objects than plain ol' Python. A good rule of thumb is to only use `eval()` when you have a *DataFrame* with more than 10,000 rows.

`eval()` supports all arithmetic expressions supported by the engine in addition to some extensions available only in pandas.

Note: The larger the frame and the larger the expression the more speedup you will see from using `eval()`.

Supported syntax

These operations are supported by `pandas.eval()`:

- Arithmetic operations except for the left shift (`<<`) and right shift (`>>`) operators, e.g., `df + 2 * pi / s ** 4 % 42 - the_golden_ratio`
- Comparison operations, including chained comparisons, e.g., `2 < df < df2`
- Boolean operations, e.g., `df < df2 and df3 < df4 or not df_bool`
- list and tuple literals, e.g., `[1, 2]` or `(1, 2)`
- Attribute access, e.g., `df.a`
- Subscript expressions, e.g., `df[0]`
- Simple variable evaluation, e.g., `pd.eval('df')` (this is not very useful)
- Math functions: `sin`, `cos`, `exp`, `log`, `expm1`, `log1p`, `sqrt`, `sinh`, `cosh`, `tanh`, `arcsin`, `arccos`, `arctan`, `arccosh`, `arcsinh`, `arctanh`, `abs`, `arctan2` and `log10`.

This Python syntax is **not** allowed:

- Expressions
 - Function calls other than math functions.
 - `is/is not` operations
 - `if` expressions
 - `lambda` expressions
 - `list/set/dict` comprehensions
 - Literal `dict` and `set` expressions
 - `yield` expressions
 - Generator expressions
 - Boolean expressions consisting of only scalar values
- Statements
 - Neither `simple` nor `compound` statements are allowed. This includes things like `for`, `while`, and `if`.

`eval()` examples

`pandas.eval()` works well with expressions containing large arrays.

First let's create a few decent-sized arrays to play with:

```
In [13]: nrows, ncols = 20000, 100
In [14]: df1, df2, df3, df4 = [pd.DataFrame(np.random.randn(nrows, ncols)) for _ in
↳ range(4)]
```

Now let's compare adding them together using plain ol' Python versus `eval()`:

```
In [15]: %timeit df1 + df2 + df3 + df4
10.1 ms +- 472 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

```
In [16]: %timeit pd.eval('df1 + df2 + df3 + df4')
7.1 ms +- 315 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

Now let's do the same thing but with comparisons:

```
In [17]: %timeit (df1 > 0) & (df2 > 0) & (df3 > 0) & (df4 > 0)
148 ms +- 5.16 ms per loop (mean +- std. dev. of 7 runs, 10 loops each)
```

```
In [18]: %timeit pd.eval('(df1 > 0) & (df2 > 0) & (df3 > 0) & (df4 > 0)')
10.4 ms +- 463 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

`eval()` also works with unaligned pandas objects:

```
In [19]: s = pd.Series(np.random.randn(50))
```

```
In [20]: %timeit df1 + df2 + df3 + df4 + s
66.3 ms +- 2.76 ms per loop (mean +- std. dev. of 7 runs, 10 loops each)
```

```
In [21]: %timeit pd.eval('df1 + df2 + df3 + df4 + s')
8.26 ms +- 558 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

Note: Operations such as

```
1 and 2 # would parse to 1 & 2, but should evaluate to 2
3 or 4 # would parse to 3 | 4, but should evaluate to 3
~1 # this is okay, but slower when using eval
```

should be performed in Python. An exception will be raised if you try to perform any boolean/bitwise operations with scalar operands that are not of type `bool` or `np.bool_`. Again, you should perform these kinds of operations in plain Python.

The `DataFrame.eval` method

In addition to the top level `pandas.eval()` function you can also evaluate an expression in the “context” of a `DataFrame`.

```
In [22]: df = pd.DataFrame(np.random.randn(5, 2), columns=['a', 'b'])
```

```
In [23]: df.eval('a + b')
```

```
Out[23]:
0    -1.247618
1     0.530103
2    -1.965325
3    -0.746692
4     0.816589
dtype: float64
```

Any expression that is a valid `pandas.eval()` expression is also a valid `DataFrame.eval()` expression, with the added benefit that you don't have to prefix the name of the `DataFrame` to the column(s) you're interested in evaluating.

In addition, you can perform assignment of columns within an expression. This allows for *formulaic evaluation*. The assignment target can be a new column name or an existing column name, and it must be a valid Python identifier.

New in version 0.18.0.

The `inplace` keyword determines whether this assignment will be performed on the original `DataFrame` or return a copy with the new column.

Warning: For backwards compatibility, `inplace` defaults to `True` if not specified. This will change in a future version of pandas - if your code depends on an `inplace` assignment you should update to explicitly set `inplace=True`.

```
In [24]: df = pd.DataFrame(dict(a=range(5), b=range(5, 10)))
```

```
In [25]: df.eval('c = a + b', inplace=True)
```

```
In [26]: df.eval('d = a + b + c', inplace=True)
```

```
In [27]: df.eval('a = 1', inplace=True)
```

```
In [28]: df
```

```
Out[28]:
```

```
   a  b  c  d
0  1  5  5  10
1  1  6  7  14
2  1  7  9  18
3  1  8  11 22
4  1  9  13 26
```

When `inplace` is set to `False`, a copy of the `DataFrame` with the new or modified columns is returned and the original frame is unchanged.

```
In [29]: df
```

```
Out[29]:
```

```
   a  b  c  d
0  1  5  5  10
1  1  6  7  14
2  1  7  9  18
3  1  8  11 22
4  1  9  13 26
```

```
In [30]: df.eval('e = a - c', inplace=False)
```

```
Out[30]:
```

```
   a  b  c  d  e
0  1  5  5  10 -4
1  1  6  7  14 -6
2  1  7  9  18 -8
3  1  8  11 22 -10
4  1  9  13 26 -12
```

```
In [31]: df
```

```
Out[31]:
```

```
   a  b  c  d
```

```

0 1 5 5 10
1 1 6 7 14
2 1 7 9 18
3 1 8 11 22
4 1 9 13 26

```

New in version 0.18.0.

As a convenience, multiple assignments can be performed by using a multi-line string.

```

In [32]: df.eval("""
.....: c = a + b
.....: d = a + b + c
.....: a = 1""", inplace=False)
.....:
Out[32]:
   a  b  c  d
0  1  5  6 12
1  1  6  7 14
2  1  7  8 16
3  1  8  9 18
4  1  9 10 20

```

The equivalent in standard Python would be

```

In [33]: df = pd.DataFrame(dict(a=range(5), b=range(5, 10)))

In [34]: df['c'] = df.a + df.b

In [35]: df['d'] = df.a + df.b + df.c

In [36]: df['a'] = 1

In [37]: df
Out[37]:
   a  b  c  d
0  1  5  5 10
1  1  6  7 14
2  1  7  9 18
3  1  8 11 22
4  1  9 13 26

```

New in version 0.18.0.

The `query` method gained the `inplace` keyword which determines whether the query modifies the original frame.

```

In [38]: df = pd.DataFrame(dict(a=range(5), b=range(5, 10)))

In [39]: df.query('a > 2')
Out[39]:
   a  b
3  3  8
4  4  9

```

(continues on next page)

(continued from previous page)

```
In [40]: df.query('a > 2', inplace=True)
```

```
In [41]: df
```

```
Out[41]:
```

```
   a  b
3  3  8
4  4  9
```

Warning: Unlike with `eval`, the default value for `inplace` for `query` is `False`. This is consistent with prior versions of pandas.

Local variables

You must *explicitly reference* any local variable that you want to use in an expression by placing the `@` character in front of the name. For example,

```
In [42]: df = pd.DataFrame(np.random.randn(5, 2), columns=list('ab'))
```

```
In [43]: newcol = np.random.randn(len(df))
```

```
In [44]: df.eval('b + @newcol')
```

```
Out[44]:
```

```
0   -1.572444
1   -0.314155
2    1.148114
3    0.490933
4   -1.572458
dtype: float64
```

```
In [45]: df.query('b < @newcol')
```

```
Out[45]:
```

```
   a      b
3 -0.078677  0.05597
```

If you don't prefix the local variable with `@`, pandas will raise an exception telling you the variable is undefined.

When using `DataFrame.eval()` and `DataFrame.query()`, this allows you to have a local variable and a `DataFrame` column with the same name in an expression.

```
In [46]: a = np.random.randn()
```

```
In [47]: df.query('@a < a')
```

```
Out[47]:
```

```
   a      b
1  1.07967  0.596787
```

```
In [48]: df.loc[a < df.a] # same as the previous expression
```

```
Out[48]:
```

```
   a      b
1  1.07967  0.596787
```

With `pandas.eval()` you cannot use the `@` prefix *at all*, because it isn't defined in that context. `pandas` will let you know this if you try to use `@` in a top-level call to `pandas.eval()`. For example,

```
In [49]: a, b = 1, 2

In [50]: pd.eval('@a + b')
Traceback (most recent call last):

  File "/Users/taugspurger/miniconda3/envs/pandas-doc/lib/python3.7/site-packages/
↳ IPython/core/interactiveshell.py", line 3326, in run_code
    exec(code_obj, self.user_global_ns, self.user_ns)

  File "<ipython-input-50-af17947a194f>", line 1, in <module>
    pd.eval('@a + b')

  File "/Users/taugspurger/sandbox/pandas-doc/pandas/core/computation/eval.py", line 311,
↳ in eval
    _check_for_locals(expr, level, parser)

  File "/Users/taugspurger/sandbox/pandas-doc/pandas/core/computation/eval.py", line 166,
↳ in _check_for_locals
    raise SyntaxError(msg)

  File "<string>", line unknown
SyntaxError: The '@' prefix is not allowed in top-level eval calls,
please refer to your variables by name without the '@' prefix
```

In this case, you should simply refer to the variables like you would in standard Python.

```
In [51]: pd.eval('a + b')
Out[51]: 3
```

`pandas.eval()` parsers

There are two different parsers and two different engines you can use as the backend.

The default `'pandas'` parser allows a more intuitive syntax for expressing query-like operations (comparisons, conjunctions and disjunctions). In particular, the precedence of the `&` and `|` operators is made equal to the precedence of the corresponding boolean operations `and` and `or`.

For example, the above conjunction can be written without parentheses. Alternatively, you can use the `'python'` parser to enforce strict Python semantics.

```
In [52]: expr = '(df1 > 0) & (df2 > 0) & (df3 > 0) & (df4 > 0)'
```

```
In [53]: x = pd.eval(expr, parser='python')
```

```
In [54]: expr_no_parens = 'df1 > 0 & df2 > 0 & df3 > 0 & df4 > 0'
```

```
In [55]: y = pd.eval(expr_no_parens, parser='pandas')
```

```
In [56]: np.all(x == y)
Out[56]: True
```

The same expression can be “anded” together with the word `and` as well:

```
In [57]: expr = '(df1 > 0) & (df2 > 0) & (df3 > 0) & (df4 > 0)'\nIn [58]: x = pd.eval(expr, parser='python')\nIn [59]: expr_with_and = 'df1 > 0 and df2 > 0 and df3 > 0 and df4 > 0'\nIn [60]: y = pd.eval(expr_with_and, parser='pandas')\nIn [61]: np.all(x == y)\nOut[61]: True
```

The `and` and `or` operators here have the same precedence that they would in vanilla Python.

`pandas.eval()` backends

There’s also the option to make `eval()` operate identical to plain ol’ Python.

Note: Using the `'python'` engine is generally *not* useful, except for testing other evaluation engines against it. You will achieve **no** performance benefits using `eval()` with `engine='python'` and in fact may incur a performance hit.

You can see this by using `pandas.eval()` with the `'python'` engine. It is a bit slower (not by much) than evaluating the same expression in Python

```
In [62]: %timeit df1 + df2 + df3 + df4\n10.7 ms +- 374 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

```
In [63]: %timeit pd.eval('df1 + df2 + df3 + df4', engine='python')\n11.8 ms +- 811 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

`pandas.eval()` performance

`eval()` is intended to speed up certain kinds of operations. In particular, those operations involving complex expressions with large `DataFrame/Series` objects should see a significant performance benefit. Here is a plot showing the running time of `pandas.eval()` as function of the size of the frame involved in the computation. The two lines are two different engines.

Note: Operations with smallish objects (around 15k-20k rows) are faster using plain Python:

This plot was created using a `DataFrame` with 3 columns each containing floating point values generated using `numpy.random.randn()`.

Technical minutia regarding expression evaluation

Expressions that would result in an object dtype or involve datetime operations (because of `NaT`) must be evaluated in Python space. The main reason for this behavior is to maintain backwards compatibility with versions of NumPy < 1.7. In those versions of NumPy a call to `ndarray.astype(str)` will truncate any strings that are more than 60 characters in length. Second, we can't pass object arrays to `numexpr` thus string comparisons must be evaluated in Python space.

The upshot is that this *only* applies to object-dtype expressions. So, if you have an expression—for example

```
In [64]: df = pd.DataFrame({'strings': np.repeat(list('cba'), 3),
.....:                    'nums': np.repeat(range(3), 3)})
.....:
```

```
In [65]: df
```

```
Out[65]:
  strings  nums
0        c     0
1        c     0
2        c     0
3        b     1
4        b     1
5        b     1
6        a     2
7        a     2
8        a     2
```

```
In [66]: df.query('strings == "a" and nums == 1')
```

```
Out[66]:
Empty DataFrame
Columns: [strings, nums]
Index: []
```

the numeric part of the comparison (`nums == 1`) will be evaluated by `numexpr`.

In general, `DataFrame.query()`/`pandas.eval()` will evaluate the subexpressions that *can* be evaluated by `numexpr` and those that must be evaluated in Python space transparently to the user. This is done by inferring the result type of an expression from its arguments and operators. `{{ header }}`

4.18 Sparse data structures

Note: `SparseSeries` and `SparseDataFrame` have been deprecated. Their purpose is served equally well by a `Series` or `DataFrame` with sparse values. See *Migrating* for tips on migrating.

Pandas provides data structures for efficiently storing sparse data. These are not necessarily sparse in the typical “mostly 0”. Rather, you can view these objects as being “compressed” where any data matching a specific value (NaN / missing value, though any value can be chosen, including 0) is omitted. The compressed values are not actually stored in the array.

```
In [1]: arr = np.random.randn(10)

In [2]: arr[2:-2] = np.nan

In [3]: ts = pd.Series(pd.SparseArray(arr))

In [4]: ts
Out[4]:
0    1.485629
1    0.328995
2         NaN
```

(continues on next page)

(continued from previous page)

```

3      NaN
4      NaN
5      NaN
6      NaN
7      NaN
8    -0.305795
9     0.163245
dtype: Sparse[float64, nan]

```

Notice the dtype, `Sparse[float64, nan]`. The `nan` means that elements in the array that are `nan` aren't actually stored, only the non-`nan` elements are. Those non-`nan` elements have a `float64` dtype.

The sparse objects exist for memory efficiency reasons. Suppose you had a large, mostly NA `DataFrame`:

```
In [5]: df = pd.DataFrame(np.random.randn(10000, 4))
```

```
In [6]: df.iloc[:9998] = np.nan
```

```
In [7]: sdf = df.astype(pd.SparseDtype("float", np.nan))
```

```
In [8]: sdf.head()
```

```
Out[8]:
```

```

   0  1  2  3
0 NaN NaN NaN NaN
1 NaN NaN NaN NaN
2 NaN NaN NaN NaN
3 NaN NaN NaN NaN
4 NaN NaN NaN NaN

```

```
In [9]: sdf.dtypes
```

```
Out[9]:
```

```

0    Sparse[float64, nan]
1    Sparse[float64, nan]
2    Sparse[float64, nan]
3    Sparse[float64, nan]
dtype: object

```

```
In [10]: sdf.sparse.density
```

```
Out[10]: 0.0002
```

As you can see, the density (% of values that have not been “compressed”) is extremely low. This sparse object takes up much less memory on disk (pickled) and in the Python interpreter.

```
In [11]: 'dense : {:.2f} bytes'.format(df.memory_usage().sum() / 1e3)
```

```
Out[11]: 'dense : 320.13 bytes'
```

```
In [12]: 'sparse: {:.2f} bytes'.format(sdf.memory_usage().sum() / 1e3)
```

```
Out[12]: 'sparse: 0.22 bytes'
```

Functionally, their behavior should be nearly identical to their dense counterparts.

4.18.1 SparseArray

`SparseArray` is a *ExtensionArray* for storing an array of sparse values (see *dtypes* for more on extension arrays). It is a 1-dimensional ndarray-like object storing only values distinct from the `fill_value`:

```
In [13]: arr = np.random.randn(10)
In [14]: arr[2:5] = np.nan
In [15]: arr[7:8] = np.nan
In [16]: sparr = pd.SparseArray(arr)
In [17]: sparr
Out[17]:
[0.6814937596731665, -0.3936934801139613, nan, nan, nan, 1.1656790567319866, -0.
↪4627293996578389, nan, -0.12411975873999016, 1.979438803899594]
Fill: nan
IntIndex
Indices: array([0, 1, 5, 6, 8, 9], dtype=int32)
```

A sparse array can be converted to a regular (dense) ndarray with `numpy.asarray()`

```
In [18]: np.asarray(sparr)
Out[18]:
array([ 0.68149376, -0.39369348,          nan,          nan,          nan,
        1.16567906, -0.4627294 ,          nan, -0.12411976,  1.9794388 ])
```

4.18.2 SparseDtype

The `SparseArray.dtype` property stores two pieces of information

1. The dtype of the non-sparse values
2. The scalar fill value

```
In [19]: sparr.dtype
Out[19]: Sparse[float64, nan]
```

A `SparseDtype` may be constructed by passing each of these

```
In [20]: pd.SparseDtype(np.dtype('datetime64[ns]'))
Out[20]: Sparse[datetime64[ns], NaT]
```

The default fill value for a given NumPy dtype is the “missing” value for that dtype, though it may be overridden.

```
In [21]: pd.SparseDtype(np.dtype('datetime64[ns]'),
.....:                   fill_value=pd.Timestamp('2017-01-01'))
.....:
Out[21]: Sparse[datetime64[ns], 2017-01-01 00:00:00]
```

Finally, the string alias `'Sparse[dtype]'` may be used to specify a sparse dtype in many places

```
In [22]: pd.array([1, 0, 0, 2], dtype='Sparse[int]')
Out[22]:
[1, 0, 0, 2]
Fill: 0
IntIndex
Indices: array([0, 3], dtype=int32)
```

4.18.3 Sparse accessor

New in version 0.24.0.

Pandas provides a `.sparse` accessor, similar to `.str` for string data, `.cat` for categorical data, and `.dt` for datetime-like data. This namespace provides attributes and methods that are specific to sparse data.

```
In [23]: s = pd.Series([0, 0, 1, 2], dtype="Sparse[int]")
```

```
In [24]: s.sparse.density
Out[24]: 0.5
```

```
In [25]: s.sparse.fill_value
Out[25]: 0
```

This accessor is available only on data with `SparseDtype`, and on the `Series` class itself for creating a `Series` with sparse data from a scipy COO matrix with.

New in version 0.25.0.

A `.sparse` accessor has been added for `DataFrame` as well. See *Sparse accessor* for more.

4.18.4 Sparse calculation

You can apply NumPy `ufuncs` to `SparseArray` and get a `SparseArray` as a result.

```
In [26]: arr = pd.SparseArray([1., np.nan, np.nan, -2., np.nan])
In [27]: np.abs(arr)
Out[27]:
[1.0, nan, nan, 2.0, nan]
Fill: nan
IntIndex
Indices: array([0, 3], dtype=int32)
```

The `ufunc` is also applied to `fill_value`. This is needed to get the correct dense result.

```
In [28]: arr = pd.SparseArray([1., -1, -1, -2., -1], fill_value=-1)
```

```
In [29]: np.abs(arr)
Out[29]:
[1.0, 1, 1, 2.0, 1]
Fill: 1
IntIndex
Indices: array([0, 3], dtype=int32)
```

```
In [30]: np.abs(arr).to_dense()
```

```
Out[30]: array([1., 1., 1., 2., 1.])
```

4.18.5 Migrating

In older versions of pandas, the `SparseSeries` and `SparseDataFrame` classes (documented below) were the preferred way to work with sparse data. With the advent of extension arrays, these subclasses are no longer needed. Their purpose is better served by using a regular `Series` or `DataFrame` with sparse values instead.

Note: There's no performance or memory penalty to using a `Series` or `DataFrame` with sparse values, rather than a `SparseSeries` or `SparseDataFrame`.

This section provides some guidance on migrating your code to the new style. As a reminder, you can use the `python warnings` module to control warnings. But we recommend modifying your code, rather than ignoring the warning.

Construction

From an array-like, use the regular `Series` or `DataFrame` constructors with `SparseArray` values.

```
# Previous way
>>> pd.SparseDataFrame({"A": [0, 1]})
```

```
# New way
In [31]: pd.DataFrame({"A": pd.SparseArray([0, 1])})
Out[31]:
   A
0  0
1  1
```

From a SciPy sparse matrix, use `DataFrame.sparse.from_spmatrix()`,

```
# Previous way
>>> from scipy import sparse
>>> mat = sparse.eye(3)
>>> df = pd.SparseDataFrame(mat, columns=['A', 'B', 'C'])
```

```
# New way
In [32]: from scipy import sparse

In [33]: mat = sparse.eye(3)

In [34]: df = pd.DataFrame.sparse.from_spmatrix(mat, columns=['A', 'B', 'C'])

In [35]: df.dtypes
Out[35]:
A    Sparse[float64, 0.0]
B    Sparse[float64, 0.0]
C    Sparse[float64, 0.0]
dtype: object
```

Conversion

From sparse to dense, use the `.sparse` accessors

```
In [36]: df.sparse.to_dense()
Out[36]:
```

```
   A   B   C
0  1.0  0.0  0.0
1  0.0  1.0  0.0
2  0.0  0.0  1.0
```

```
In [37]: df.sparse.to_coo()
Out[37]:
```

```
<3x3 sparse matrix of type '<class 'numpy.float64''
with 3 stored elements in COOrdinate format>
```

From dense to sparse, use `DataFrame.astype()` with a `SparseDtype`.

```
In [38]: dense = pd.DataFrame({"A": [1, 0, 0, 1]})
```

```
In [39]: dtype = pd.SparseDtype(int, fill_value=0)
```

```
In [40]: dense.astype(dtype)
```

```
Out[40]:
```

```
   A
0  1
1  0
2  0
3  1
```

Sparse Properties

Sparse-specific properties, like `density`, are available on the `.sparse` accessor.

```
In [41]: df.sparse.density
```

```
Out[41]: 0.3333333333333333
```

General differences

In a `SparseDataFrame`, *all* columns were sparse. A `DataFrame` can have a mixture of sparse and dense columns. As a consequence, assigning new columns to a `DataFrame` with sparse values will not automatically convert the input to be sparse.

```
# Previous Way
>>> df = pd.SparseDataFrame({"A": [0, 1]})
>>> df['B'] = [0, 0] # implicitly becomes Sparse
>>> df['B'].dtype
Sparse[int64, nan]
```

Instead, you'll need to ensure that the values being assigned are sparse

```
In [42]: df = pd.DataFrame({"A": pd.SparseArray([0, 1])})
```

```
In [43]: df['B'] = [0, 0] # remains dense
```

```
In [44]: df['B'].dtype
```

```
Out[44]: dtype('int64')
```

```
In [45]: df['B'] = pd.SparseArray([0, 0])
```

(continues on next page)

(continued from previous page)

```
In [46]: df['B'].dtype
Out[46]: Sparse[int64, 0]
```

The `SparseDataFrame.default_kind` and `SparseDataFrame.default_fill_value` attributes have no replacement.

4.18.6 Interaction with `scipy.sparse`

Use `DataFrame.sparse.from_spmatrix()` to create a `DataFrame` with sparse values from a sparse matrix. New in version 0.25.0.

```
In [47]: from scipy.sparse import csr_matrix

In [48]: arr = np.random.random(size=(1000, 5))

In [49]: arr[arr < .9] = 0

In [50]: sp_arr = csr_matrix(arr)

In [51]: sp_arr
Out[51]:
<1000x5 sparse matrix of type '<class 'numpy.float64''>'
with 464 stored elements in Compressed Sparse Row format>

In [52]: sdf = pd.DataFrame.sparse.from_spmatrix(sp_arr)

In [53]: sdf.head()
Out[53]:
   0      1      2      3      4
0  0.0  0.921245  0.0  0.000000  0.000000
1  0.0  0.000000  0.0  0.000000  0.000000
2  0.0  0.000000  0.0  0.000000  0.000000
3  0.0  0.000000  0.0  0.000000  0.000000
4  0.0  0.000000  0.0  0.936826  0.918174

In [54]: sdf.dtypes
Out[54]:
0    Sparse[float64, 0.0]
1    Sparse[float64, 0.0]
2    Sparse[float64, 0.0]
3    Sparse[float64, 0.0]
4    Sparse[float64, 0.0]
dtype: object
```

All sparse formats are supported, but matrices that are not in `COOrdinate` format will be converted, copying data as needed. To convert back to sparse SciPy matrix in `COO` format, you can use the `DataFrame.sparse.to_coo()` method:

```
In [55]: sdf.sparse.to_coo()
Out[55]:
```

(continues on next page)

(continued from previous page)

```
<1000x5 sparse matrix of type '<class 'numpy.float64'>'
  with 464 stored elements in COOrdinate format>
```

meth:*Series.sparse.to_coo* is implemented for transforming a *Series* with sparse values indexed by a *MultiIndex* to a *scipy.sparse.coo_matrix*.

The method requires a *MultiIndex* with two or more levels.

```
In [56]: s = pd.Series([3.0, np.nan, 1.0, 3.0, np.nan, np.nan])

In [57]: s.index = pd.MultiIndex.from_tuples([(1, 2, 'a', 0),
.....:                                     (1, 2, 'a', 1),
.....:                                     (1, 1, 'b', 0),
.....:                                     (1, 1, 'b', 1),
.....:                                     (2, 1, 'b', 0),
.....:                                     (2, 1, 'b', 1)],
.....:                                     names=['A', 'B', 'C', 'D'])

In [58]: s
Out[58]:
A B C D
1 2 a 0 3.0
   1 NaN
   1 b 0 1.0
   1 3.0
2 1 b 0 NaN
   1 NaN
dtype: float64

In [59]: ss = s.astype('Sparse')

In [60]: ss
Out[60]:
A B C D
1 2 a 0 3.0
   1 NaN
   1 b 0 1.0
   1 3.0
2 1 b 0 NaN
   1 NaN
dtype: Sparse[float64, nan]
```

In the example below, we transform the *Series* to a sparse representation of a 2-d array by specifying that the first and second *MultiIndex* levels define labels for the rows and the third and fourth levels define labels for the columns. We also specify that the column and row labels should be sorted in the final sparse representation.

```
In [61]: A, rows, columns = ss.sparse.to_coo(row_levels=['A', 'B'],
.....:                                     column_levels=['C', 'D'],
.....:                                     sort_labels=True)
.....:
```

```
In [62]: A
```

```
Out[62]:
<3x4 sparse matrix of type '<class 'numpy.float64''>'
with 3 stored elements in COOrdinate format>
```

```
In [63]: A.todense()
Out[63]:
matrix([[0., 0., 1., 3.],
        [3., 0., 0., 0.],
        [0., 0., 0., 0.]])
```

```
In [64]: rows
Out[64]: [(1, 1), (1, 2), (2, 1)]
```

```
In [65]: columns
Out[65]: [('a', 0), ('a', 1), ('b', 0), ('b', 1)]
```

Specifying different row and column labels (and not sorting them) yields a different sparse matrix:

```
In [66]: A, rows, columns = ss.sparse.to_coo(row_levels=['A', 'B', 'C'],
.....:                                     column_levels=['D'],
.....:                                     sort_labels=False)
.....:
```

```
In [67]: A
Out[67]:
<3x2 sparse matrix of type '<class 'numpy.float64''>'
with 3 stored elements in COOrdinate format>
```

```
In [68]: A.todense()
Out[68]:
matrix([[3., 0.],
        [1., 3.],
        [0., 0.]])
```

```
In [69]: rows
Out[69]: [(1, 2, 'a'), (1, 1, 'b'), (2, 1, 'b')]
```

```
In [70]: columns
Out[70]: [0, 1]
```

A convenience method `Series.sparse.from_coo()` is implemented for creating a `Series` with sparse values from a `scipy.sparse.coo_matrix`.

```
In [71]: from scipy import sparse
```

```
In [72]: A = sparse.coo_matrix(([3.0, 1.0, 2.0], ([1, 0, 0], [0, 2, 3])),
.....:                         shape=(3, 4))
.....:
```

```
In [73]: A
Out[73]:
<3x4 sparse matrix of type '<class 'numpy.float64''>'
with 3 stored elements in COOrdinate format>
```

```
In [74]: A.todense()
Out[74]:
```

```
matrix([[0., 0., 1., 2.],
        [3., 0., 0., 0.],
        [0., 0., 0., 0.]])
```

The default behaviour (with `dense_index=False`) simply returns a `Series` containing only the non-null entries.

```
In [75]: ss = pd.Series.sparse.from_coo(A)
```

```
In [76]: ss
```

```
Out[76]:
```

```
0 2 1.0
  3 2.0
1 0 3.0
dtype: Sparse[float64, nan]
```

Specifying `dense_index=True` will result in an index that is the Cartesian product of the row and columns coordinates of the matrix. Note that this will consume a significant amount of memory (relative to `dense_index=False`) if the sparse matrix is large (and sparse) enough.

```
In [77]: ss_dense = pd.Series.sparse.from_coo(A, dense_index=True)
```

```
In [78]: ss_dense
```

```
Out[78]:
```

```
0 0 NaN
  1 NaN
  2 1.0
  3 2.0
1 0 3.0
  1 NaN
  2 NaN
  3 NaN
2 0 NaN
  1 NaN
  2 NaN
  3 NaN
dtype: Sparse[float64, nan]
```

4.18.7 Sparse subclasses

The `SparseSeries` and `SparseDataFrame` classes are deprecated. Visit their API pages for usage. `{{ header }}`

4.19 Frequently Asked Questions (FAQ)

4.19.1 DataFrame memory usage

The memory usage of a `DataFrame` (including the index) is shown when calling the `info()`. A configuration option, `display.memory_usage` (see *the list of options*), specifies if the `DataFrame`'s memory usage will be displayed when invoking the `df.info()` method.

For example, the memory usage of the `DataFrame` below is shown when calling `info()`:

```

In [1]: dtypes = ['int64', 'float64', 'datetime64[ns]', 'timedelta64[ns]',
...:             'complex128', 'object', 'bool']
...:

In [2]: n = 5000

In [3]: data = {t: np.random.randint(100, size=n).astype(t) for t in dtypes}

In [4]: df = pd.DataFrame(data)

In [5]: df['categorical'] = df['object'].astype('category')

In [6]: df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5000 entries, 0 to 4999
Data columns (total 8 columns):
int64          5000 non-null int64
float64        5000 non-null float64
datetime64[ns] 5000 non-null datetime64[ns]
timedelta64[ns] 5000 non-null timedelta64[ns]
complex128     5000 non-null complex128
object         5000 non-null object
bool           5000 non-null bool
categorical    5000 non-null category
dtypes: bool(1), category(1), complex128(1), datetime64[ns](1), float64(1), int64(1),
↳object(1), timedelta64[ns](1)
memory usage: 289.1+ KB

```

The + symbol indicates that the true memory usage could be higher, because pandas does not count the memory used by values in columns with `dtype=object`.

Passing `memory_usage='deep'` will enable a more accurate memory usage report, accounting for the full usage of the contained objects. This is optional as it can be expensive to do this deeper introspection.

```

In [7]: df.info(memory_usage='deep')
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5000 entries, 0 to 4999
Data columns (total 8 columns):
int64          5000 non-null int64
float64        5000 non-null float64
datetime64[ns] 5000 non-null datetime64[ns]
timedelta64[ns] 5000 non-null timedelta64[ns]
complex128     5000 non-null complex128
object         5000 non-null object
bool           5000 non-null bool
categorical    5000 non-null category
dtypes: bool(1), category(1), complex128(1), datetime64[ns](1), float64(1), int64(1),
↳object(1), timedelta64[ns](1)
memory usage: 425.6 KB

```

By default the display option is set to `True` but can be explicitly overridden by passing the `memory_usage` argument when invoking `df.info()`.

The memory usage of each column can be found by calling the `memory_usage()` method. This returns a `Series` with an index represented by column names and memory usage of each column shown in bytes. For

the `DataFrame` above, the memory usage of each column and the total memory usage can be found with the `memory_usage` method:

```
In [8]: df.memory_usage()
Out[8]:
Index          128
int64          40000
float64        40000
datetime64[ns] 40000
timedelta64[ns] 40000
complex128     80000
object         40000
bool           5000
categorical    10920
dtype: int64
```

total memory usage of dataframe

```
In [9]: df.memory_usage().sum()
Out[9]: 296048
```

By default the memory usage of the `DataFrame`'s index is shown in the returned `Series`, the memory usage of the index can be suppressed by passing the `index=False` argument:

```
In [10]: df.memory_usage(index=False)
Out[10]:
int64          40000
float64        40000
datetime64[ns] 40000
timedelta64[ns] 40000
complex128     80000
object         40000
bool           5000
categorical    10920
dtype: int64
```

The memory usage displayed by the `info()` method utilizes the `memory_usage()` method to determine the memory usage of a `DataFrame` while also formatting the output in human-readable units (base-2 representation; i.e. 1KB = 1024 bytes).

See also *Categorical Memory Usage*.

4.19.2 Using if/truth statements with pandas

pandas follows the NumPy convention of raising an error when you try to convert something to a `bool`. This happens in an `if`-statement or when using the boolean operations: `and`, `or`, and `not`. It is not clear what the result of the following code should be:

```
>>> if pd.Series([False, True, False]):
...     pass
```

Should it be `True` because it's not zero-length, or `False` because there are `False` values? It is unclear, so instead, pandas raises a `ValueError`:

```
>>> if pd.Series([False, True, False]):
...     print("I was true")
Traceback
...
ValueError: The truth value of an array is ambiguous. Use a.empty, a.any() or a.all().
```

You need to explicitly choose what you want to do with the `DataFrame`, e.g. use `any()`, `all()` or `empty()`. Alternatively, you might want to compare if the pandas object is `None`:

```
>>> if pd.Series([False, True, False]) is not None:
...     print("I was not None")
I was not None
```

Below is how to check if any of the values are `True`:

```
>>> if pd.Series([False, True, False]).any():
...     print("I am any")
I am any
```

To evaluate single-element pandas objects in a boolean context, use the method `bool()`:

```
In [11]: pd.Series([True]).bool()
Out[11]: True
```

```
In [12]: pd.Series([False]).bool()
Out[12]: False
```

```
In [13]: pd.DataFrame([[True]]).bool()
Out[13]: True
```

```
In [14]: pd.DataFrame([[False]]).bool()
Out[14]: False
```

Bitwise boolean

Bitwise boolean operators like `==` and `!=` return a boolean `Series`, which is almost always what you want anyways.

```
>>> s = pd.Series(range(5))
>>> s == 4
0    False
1    False
2    False
3    False
4     True
dtype: bool
```

See *boolean comparisons* for more examples.

Using the `in` operator

Using the Python `in` operator on a `Series` tests for membership in the index, not membership among the values.

```
In [15]: s = pd.Series(range(5), index=list('abcde'))
```

```
In [16]: 2 in s
Out[16]: False
```

```
In [17]: 'b' in s
Out[17]: True
```

If this behavior is surprising, keep in mind that using `in` on a Python dictionary tests keys, not values, and `Series` are dict-like. To test for membership in the values, use the method `isin()`:

```
In [18]: s.isin([2])
Out[18]:
a    False
b    False
c     True
d    False
e    False
dtype: bool
```

```
In [19]: s.isin([2]).any()
Out[19]: True
```

For `DataFrames`, likewise, `in` applies to the column axis, testing for membership in the list of column names.

4.19.3 NaN, Integer NA values and NA type promotions

Choice of NA representation

For lack of NA (missing) support from the ground up in NumPy and Python in general, we were given the difficult choice between either:

- A *masked array* solution: an array of data and an array of boolean values indicating whether a value is there or is missing.
- Using a special sentinel value, bit pattern, or set of sentinel values to denote NA across the dtypes.

For many reasons we chose the latter. After years of production use it has proven, at least in my opinion, to be the best decision given the state of affairs in NumPy and Python in general. The special value NaN (Not-A-Number) is used everywhere as the NA value, and there are API functions `isna` and `notna` which can be used across the dtypes to detect NA values.

However, it comes with it a couple of trade-offs which I most certainly have not ignored.

Support for integer NA

In the absence of high performance NA support being built into NumPy from the ground up, the primary casualty is the ability to represent NAs in integer arrays. For example:

```
In [20]: s = pd.Series([1, 2, 3, 4, 5], index=list('abcde'))
```

```
In [21]: s
Out[21]:
a     1
b     2
c     3
```

```
d    4
e    5
dtype: int64
```

```
In [22]: s.dtype
Out[22]: dtype('int64')
```

```
In [23]: s2 = s.reindex(['a', 'b', 'c', 'f', 'u'])
```

```
In [24]: s2
Out[24]:
a    1.0
b    2.0
c    3.0
f    NaN
u    NaN
dtype: float64
```

```
In [25]: s2.dtype
Out[25]: dtype('float64')
```

This trade-off is made largely for memory and performance reasons, and also so that the resulting `Series` continues to be “numeric”.

If you need to represent integers with possibly missing values, use one of the nullable-integer extension dtypes provided by pandas

- `Int8Dtype`
- `Int16Dtype`
- `Int32Dtype`
- `Int64Dtype`

```
In [26]: s_int = pd.Series([1, 2, 3, 4, 5], index=list('abcde'),
.....:                    dtype=pd.Int64Dtype())
.....:
```

```
In [27]: s_int
Out[27]:
a    1
b    2
c    3
d    4
e    5
dtype: Int64
```

```
In [28]: s_int.dtype
Out[28]: Int64Dtype()
```

```
In [29]: s2_int = s_int.reindex(['a', 'b', 'c', 'f', 'u'])
```

```
In [30]: s2_int
Out[30]:
a    1
b    2
```

```
c      3
f     NaN
u     NaN
dtype: Int64
```

```
In [31]: s2_int.dtype
Out[31]: Int64Dtype()
```

See *Nullable integer data type* for more.

NA type promotions

When introducing NAs into an existing `Series` or `DataFrame` via `reindex()` or some other means, boolean and integer types will be promoted to a different dtype in order to store the NAs. The promotions are summarized in this table:

Typeclass	Promotion dtype for storing NAs
<code>floating</code>	no change
<code>object</code>	no change
<code>integer</code>	cast to <code>float64</code>
<code>boolean</code>	cast to <code>object</code>

While this may seem like a heavy trade-off, I have found very few cases where this is an issue in practice i.e. storing values greater than 2^{53} . Some explanation for the motivation is in the next section.

Why not make NumPy like R?

Many people have suggested that NumPy should simply emulate the NA support present in the more domain-specific statistical programming language R. Part of the reason is the NumPy type hierarchy:

Typeclass	Dtypes
<code>numpy.floating</code>	<code>float16</code> , <code>float32</code> , <code>float64</code> , <code>float128</code>
<code>numpy.integer</code>	<code>int8</code> , <code>int16</code> , <code>int32</code> , <code>int64</code>
<code>numpy.unsignedinteger</code>	<code>uint8</code> , <code>uint16</code> , <code>uint32</code> , <code>uint64</code>
<code>numpy.object_</code>	<code>object_</code>
<code>numpy.bool_</code>	<code>bool_</code>
<code>numpy.character</code>	<code>string_</code> , <code>unicode_</code>

The R language, by contrast, only has a handful of built-in data types: `integer`, `numeric` (floating-point), `character`, and `boolean`. NA types are implemented by reserving special bit patterns for each type to be used as the missing value. While doing this with the full NumPy type hierarchy would be possible, it would be a more substantial trade-off (especially for the 8- and 16-bit data types) and implementation undertaking.

An alternate approach is that of using masked arrays. A masked array is an array of data with an associated boolean *mask* denoting whether each value should be considered NA or not. I am personally not in love with this approach as I feel that overall it places a fairly heavy burden on the user and the library implementer. Additionally, it exacts a fairly high performance cost when working with numerical data compared with the simple approach of using NaN. Thus, I have chosen the Pythonic “practicality beats purity” approach and traded integer NA capability for a much simpler approach of using a special value in float and object arrays to denote NA, and promoting integer arrays to floating when NAs must be introduced.

4.19.4 Differences with NumPy

For `Series` and `DataFrame` objects, `var()` normalizes by $N-1$ to produce unbiased estimates of the sample variance, while NumPy's `var` normalizes by N , which measures the variance of the sample. Note that `cov()` normalizes by $N-1$ in both pandas and NumPy.

4.19.5 Thread-safety

As of pandas 0.11, pandas is not 100% thread safe. The known issues relate to the `copy()` method. If you are doing a lot of copying of `DataFrame` objects shared among threads, we recommend holding locks inside the threads where the data copying occurs.

See [this link](#) for more information.

4.19.6 Byte-Ordering issues

Occasionally you may have to deal with data that were created on a machine with a different byte order than the one on which you are running Python. A common symptom of this issue is an error like::

```
Traceback
...
ValueError: Big-endian buffer not supported on little-endian compiler
```

To deal with this issue you should convert the underlying NumPy array to the native system byte order *before* passing it to `Series` or `DataFrame` constructors using something similar to the following:

```
In [32]: x = np.array(list(range(10)), '>i4') # big endian
In [33]: newx = x.byteswap().newbyteorder() # force native byteorder
In [34]: s = pd.Series(newx)
```

See the NumPy documentation on byte order for more details. {{ header }}

4.20 Cookbook

This is a repository for *short and sweet* examples and links for useful pandas recipes. We encourage users to add to this documentation.

Adding interesting links and/or inline examples to this section is a great *First Pull Request*.

Simplified, condensed, new-user friendly, in-line examples have been inserted where possible to augment the Stack-Overflow and GitHub links. Many of the links contain expanded information, above what the in-line examples offer.

Pandas (pd) and Numpy (np) are the only two abbreviated imported modules. The rest are kept explicitly imported for newer users.

These examples are written for Python 3. Minor tweaks might be necessary for earlier python versions.

4.20.1 Idioms

These are some neat pandas idioms

if-then/if-then-else on one column, and assignment to another one or more columns:

```
In [1]: df = pd.DataFrame({'AAA': [4, 5, 6, 7],
...:                      'BBB': [10, 20, 30, 40],
...:                      'CCC': [100, 50, -30, -50]})
...:
```

```
In [2]: df
```

```
Out[2]:
   AAA  BBB  CCC
0    4   10  100
1    5   20   50
2    6   30  -30
3    7   40  -50
```

if-then...

An if-then on one column

```
In [3]: df.loc[df.AAA >= 5, 'BBB'] = -1
```

```
In [4]: df
```

```
Out[4]:
   AAA  BBB  CCC
0    4   10  100
1    5   -1   50
2    6   -1  -30
3    7   -1  -50
```

An if-then with assignment to 2 columns:

```
In [5]: df.loc[df.AAA >= 5, ['BBB', 'CCC']] = 555
```

```
In [6]: df
```

```
Out[6]:
   AAA  BBB  CCC
0    4   10  100
1    5  555  555
2    6  555  555
3    7  555  555
```

Add another line with different logic, to do the -else

```
In [7]: df.loc[df.AAA < 5, ['BBB', 'CCC']] = 2000
```

```
In [8]: df
```

```
Out[8]:
   AAA  BBB  CCC
0    4  2000  2000
```

(continues on next page)

(continued from previous page)

1	5	555	555
2	6	555	555
3	7	555	555

Or use pandas where after you've set up a mask

```
In [9]: df_mask = pd.DataFrame({'AAA': [True] * 4,
...:                          'BBB': [False] * 4,
...:                          'CCC': [True, False] * 2})
...:

In [10]: df.where(df_mask, -1000)
Out[10]:
   AAA  BBB  CCC
0    4 -1000 2000
1    5 -1000 -1000
2    6 -1000  555
3    7 -1000 -1000
```

if-then-else using numpy's where()

```
In [11]: df = pd.DataFrame({'AAA': [4, 5, 6, 7],
...:                       'BBB': [10, 20, 30, 40],
...:                       'CCC': [100, 50, -30, -50]})
...:

In [12]: df
Out[12]:
   AAA  BBB  CCC
0    4   10  100
1    5   20   50
2    6   30  -30
3    7   40  -50

In [13]: df['logic'] = np.where(df['AAA'] > 5, 'high', 'low')

In [14]: df
Out[14]:
   AAA  BBB  CCC logic
0    4   10  100  low
1    5   20   50  low
2    6   30  -30  high
3    7   40  -50  high
```

Splitting

Split a frame with a boolean criterion

```
In [15]: df = pd.DataFrame({'AAA': [4, 5, 6, 7],
...:                       'BBB': [10, 20, 30, 40],
...:                       'CCC': [100, 50, -30, -50]})
...:
```

```
In [16]: df
```

```
Out[16]:
```

```
   AAA  BBB  CCC
0    4   10  100
1    5   20   50
2    6   30  -30
3    7   40  -50
```

```
In [17]: df[df.AAA <= 5]
```

```
Out[17]:
```

```
   AAA  BBB  CCC
0    4   10  100
1    5   20   50
```

```
In [18]: df[df.AAA > 5]
```

```
Out[18]:
```

```
   AAA  BBB  CCC
2    6   30  -30
3    7   40  -50
```

Building criteria

Select with multi-column criteria

```
In [19]: df = pd.DataFrame({'AAA': [4, 5, 6, 7],
.....:                    'BBB': [10, 20, 30, 40],
.....:                    'CCC': [100, 50, -30, -50]})
.....:
```

```
In [20]: df
```

```
Out[20]:
```

```
   AAA  BBB  CCC
0    4   10  100
1    5   20   50
2    6   30  -30
3    7   40  -50
```

...and (without assignment returns a Series)

```
In [21]: df.loc[(df['BBB'] < 25) & (df['CCC'] >= -40), 'AAA']
```

```
Out[21]:
```

```
0    4
1    5
Name: AAA, dtype: int64
```

...or (without assignment returns a Series)

```
In [22]: df.loc[(df['BBB'] > 25) | (df['CCC'] >= -40), 'AAA']
```

```
Out[22]:
```

```
0    4
1    5
2    6
```

(continues on next page)

(continued from previous page)

```
3      7
Name: AAA, dtype: int64
```

...or (with assignment modifies the DataFrame.)

```
In [23]: df.loc[(df['BBB'] > 25) | (df['CCC'] >= 75), 'AAA'] = 0.1

In [24]: df
Out[24]:
```

	AAA	BBB	CCC
0	0.1	10	100
1	5.0	20	50
2	0.1	30	-30
3	0.1	40	-50

Select rows with data closest to certain value using argsort

```
In [25]: df = pd.DataFrame({'AAA': [4, 5, 6, 7],
.....:                    'BBB': [10, 20, 30, 40],
.....:                    'CCC': [100, 50, -30, -50]})
.....:

In [26]: df
Out[26]:
```

	AAA	BBB	CCC
0	4	10	100
1	5	20	50
2	6	30	-30
3	7	40	-50

```
In [27]: aValue = 43.0

In [28]: df.loc[(df.CCC - aValue).abs().argsort()]
Out[28]:
```

	AAA	BBB	CCC
1	5	20	50
0	4	10	100
2	6	30	-30
3	7	40	-50

Dynamically reduce a list of criteria using a binary operators

```
In [29]: df = pd.DataFrame({'AAA': [4, 5, 6, 7],
.....:                    'BBB': [10, 20, 30, 40],
.....:                    'CCC': [100, 50, -30, -50]})
.....:

In [30]: df
Out[30]:
```

	AAA	BBB	CCC
0	4	10	100
1	5	20	50

(continues on next page)

(continued from previous page)

```
2    6    30   -30
3    7    40   -50
```

```
In [31]: Crit1 = df.AAA <= 5.5
```

```
In [32]: Crit2 = df.BBB == 10.0
```

```
In [33]: Crit3 = df.CCC > -40.0
```

One could hard code:

```
In [34]: AllCrit = Crit1 & Crit2 & Crit3
```

...Or it can be done with a list of dynamically built criteria

```
In [35]: import functools
```

```
In [36]: CritList = [Crit1, Crit2, Crit3]
```

```
In [37]: AllCrit = functools.reduce(lambda x, y: x & y, CritList)
```

```
In [38]: df[AllCrit]
```

```
Out[38]:
```

```
   AAA  BBB  CCC
0     4   10  100
```

4.20.2 Selection

DataFrames

The *indexing* docs.

Using both row labels and value conditionals

```
In [39]: df = pd.DataFrame({'AAA': [4, 5, 6, 7],
.....:                    'BBB': [10, 20, 30, 40],
.....:                    'CCC': [100, 50, -30, -50]})
.....:
```

```
In [40]: df
```

```
Out[40]:
```

```
   AAA  BBB  CCC
0     4   10  100
1     5   20   50
2     6   30  -30
3     7   40  -50
```

```
In [41]: df[(df.AAA <= 6) & (df.index.isin([0, 2, 4]))]
```

```
Out[41]:
```

```
   AAA  BBB  CCC
0     4   10  100
2     6   30  -30
```

Use loc for label-oriented slicing and iloc positional slicing

```
In [42]: df = pd.DataFrame({'AAA': [4, 5, 6, 7],
.....:                    'BBB': [10, 20, 30, 40],
.....:                    'CCC': [100, 50, -30, -50]},
.....:                    index=['foo', 'bar', 'boo', 'kar'])
.....:
```

There are 2 explicit slicing methods, with a third general case

1. Positional-oriented (Python slicing style : exclusive of end)
2. Label-oriented (Non-Python slicing style : inclusive of end)
3. General (Either slicing style : depends on if the slice contains labels or positions)

```
In [43]: df.loc['bar':'kar'] # Label
```

```
Out[43]:
   AAA  BBB  CCC
bar   5   20   50
boo   6   30  -30
kar   7   40  -50
```

Generic

```
In [44]: df.iloc[0:3]
```

```
Out[44]:
   AAA  BBB  CCC
foo   4   10  100
bar   5   20   50
boo   6   30  -30
```

```
In [45]: df.loc['bar':'kar']
```

```
Out[45]:
   AAA  BBB  CCC
bar   5   20   50
boo   6   30  -30
kar   7   40  -50
```

Ambiguity arises when an index consists of integers with a non-zero start or non-unit increment.

```
In [46]: data = {'AAA': [4, 5, 6, 7],
.....:           'BBB': [10, 20, 30, 40],
.....:           'CCC': [100, 50, -30, -50]}
.....:
```

```
In [47]: df2 = pd.DataFrame(data=data, index=[1, 2, 3, 4]) # Note index starts at 1.
```

```
In [48]: df2.iloc[1:3] # Position-oriented
```

```
Out[48]:
   AAA  BBB  CCC
2    5   20   50
3    6   30  -30
```

```
In [49]: df2.loc[1:3] # Label-oriented
```

```
Out[49]:
   AAA  BBB  CCC
1    4   10  100
```

```
2    5    20    50
3    6    30   -30
```

Using inverse operator (~) to take the complement of a mask

```
In [50]: df = pd.DataFrame({'AAA': [4, 5, 6, 7],
.....:                    'BBB': [10, 20, 30, 40],
.....:                    'CCC': [100, 50, -30, -50]})
.....:
```

```
In [51]: df
Out[51]:
   AAA  BBB  CCC
0     4   10  100
1     5   20   50
2     6   30  -30
3     7   40  -50
```

```
In [52]: df[~((df.AAA <= 6) & (df.index.isin([0, 2, 4])))]
Out[52]:
   AAA  BBB  CCC
1     5   20   50
3     7   40  -50
```

New columns

Efficiently and dynamically creating new columns using applymap

```
In [53]: df = pd.DataFrame({'AAA': [1, 2, 1, 3],
.....:                    'BBB': [1, 1, 2, 2],
.....:                    'CCC': [2, 1, 3, 1]})
.....:

In [54]: df
Out[54]:
   AAA  BBB  CCC
0     1    1    2
1     2    1    1
2     1    2    3
3     3    2    1

In [55]: source_cols = df.columns    # Or some subset would work too

In [56]: new_cols = [str(x) + "_cat" for x in source_cols]

In [57]: categories = {1: 'Alpha', 2: 'Beta', 3: 'Charlie'}

In [58]: df[new_cols] = df[source_cols].applymap(categories.get)

In [59]: df
Out[59]:
   AAA  BBB  CCC  AAA_cat  BBB_cat  CCC_cat
0     1    1    2   Alpha   Alpha   Beta
1     2    1    1   Beta   Alpha   Alpha
```

(continues on next page)

(continued from previous page)

2	1	2	3	Alpha	Beta	Charlie
3	3	2	1	Charlie	Beta	Alpha

Keep other columns when using `min()` with `groupby`

```
In [60]: df = pd.DataFrame({'AAA': [1, 1, 1, 2, 2, 2, 3, 3],
.....:                    'BBB': [2, 1, 3, 4, 5, 1, 2, 3]})
.....:

In [61]: df
Out[61]:
   AAA  BBB
0    1    2
1    1    1
2    1    3
3    2    4
4    2    5
5    2    1
6    3    2
7    3    3
```

Method 1 : `idxmin()` to get the index of the minimums

```
In [62]: df.loc[df.groupby("AAA")["BBB"].idxmin()]
Out[62]:
   AAA  BBB
1    1    1
5    2    1
6    3    2
```

Method 2 : sort then take first of each

```
In [63]: df.sort_values(by="BBB").groupby("AAA", as_index=False).first()
Out[63]:
   AAA  BBB
0    1    1
1    2    1
2    3    2
```

Notice the same results, with the exception of the index.

4.20.3 MultiIndexing

The *multiindexing* docs.

Creating a MultiIndex from a labeled frame

```
In [64]: df = pd.DataFrame({'row': [0, 1, 2],
.....:                    'One_X': [1.1, 1.1, 1.1],
.....:                    'One_Y': [1.2, 1.2, 1.2],
.....:                    'Two_X': [1.11, 1.11, 1.11],
.....:                    'Two_Y': [1.22, 1.22, 1.22]})
```

(continues on next page)

(continued from previous page)

```

.....:

In [65]: df
Out[65]:
   row  One_X  One_Y  Two_X  Two_Y
0    0    1.1    1.2    1.11  1.22
1    1    1.1    1.2    1.11  1.22
2    2    1.1    1.2    1.11  1.22

# As Labelled Index
In [66]: df = df.set_index('row')

In [67]: df
Out[67]:
      One_X  One_Y  Two_X  Two_Y
row
0        1.1    1.2    1.11  1.22
1        1.1    1.2    1.11  1.22
2        1.1    1.2    1.11  1.22

# With Hierarchical Columns
In [68]: df.columns = pd.MultiIndex.from_tuples([tuple(c.split('_'))
.....:                                          for c in df.columns])
.....:

In [69]: df
Out[69]:
      One      Two
      X  Y    X  Y
row
0    1.1  1.2  1.11  1.22
1    1.1  1.2  1.11  1.22
2    1.1  1.2  1.11  1.22

# Now stack & Reset
In [70]: df = df.stack(0).reset_index(1)

In [71]: df
Out[71]:
   level_1  X  Y
row
0        One  1.10  1.20
0        Two  1.11  1.22
1        One  1.10  1.20
1        Two  1.11  1.22
2        One  1.10  1.20
2        Two  1.11  1.22

# And fix the labels (Notice the label 'level_1' got added automatically)
In [72]: df.columns = ['Sample', 'All_X', 'All_Y']

In [73]: df

```

(continues on next page)

(continued from previous page)

```

Out [73]:
      Sample  All_X  All_Y
row
0      One    1.10   1.20
0      Two    1.11   1.22
1      One    1.10   1.20
1      Two    1.11   1.22
2      One    1.10   1.20
2      Two    1.11   1.22

```

Arithmetic

Performing arithmetic with a MultiIndex that needs broadcasting

```

In [74]: cols = pd.MultiIndex.from_tuples([(x, y) for x in ['A', 'B', 'C']
.....:                                     for y in ['O', 'I']])
.....:

In [75]: df = pd.DataFrame(np.random.randn(2, 6), index=['n', 'm'], columns=cols)

In [76]: df
Out [76]:
      A          I          B          I          C          I
n  1.891290  0.239601  0.271233 -3.008824 -1.061154 -0.772010
m -0.046401  1.346871  0.489157  0.354291 -0.537453 -1.290894

In [77]: df = df.div(df['C'], level=1)

In [78]: df
Out [78]:
      A          I          B          I          C          I
n -1.782296 -0.310360 -0.255602  3.897391  1.0  1.0
m  0.086335 -1.043363 -0.910138 -0.274454  1.0  1.0

```

Slicing

Slicing a MultiIndex with xs

```

In [79]: coords = [('AA', 'one'), ('AA', 'six'), ('BB', 'one'), ('BB', 'two'),
.....:               ('BB', 'six')]
.....:

In [80]: index = pd.MultiIndex.from_tuples(coords)

In [81]: df = pd.DataFrame([11, 22, 33, 44, 55], index, ['MyData'])

In [82]: df
Out [82]:

```

(continues on next page)

(continued from previous page)

```

MyData
AA one    11
   six    22
BB one    33
   two    44
   six    55

```

To take the cross section of the 1st level and 1st axis the index:

```

# Note : level and axis are optional, and default to zero
In [83]: df.xs('BB', level=0, axis=0)
Out[83]:
   MyData
one     33
two     44
six     55

```

...and now the 2nd level of the 1st axis.

```

In [84]: df.xs('six', level=1, axis=0)
Out[84]:
   MyData
AA      22
BB      55

```

Slicing a MultiIndex with xs, method #2

```
In [85]: import itertools
```

```
In [86]: index = list(itertools.product(['Ada', 'Quinn', 'Violet'],
....:                                   ['Comp', 'Math', 'Sci']))
....:
```

```
In [87]: headr = list(itertools.product(['Exams', 'Labs'], ['I', 'II']))
```

```
In [88]: indx = pd.MultiIndex.from_tuples(index, names=['Student', 'Course'])
```

```
In [89]: cols = pd.MultiIndex.from_tuples(headr) # Notice these are un-named
```

```
In [90]: data = [[70 + x + y + (x * y) % 3 for x in range(4)] for y in range(9)]
```

```
In [91]: df = pd.DataFrame(data, indx, cols)
```

```
In [92]: df
```

```

Out[92]:

Partial selection, the need for sortedness;

Levels

Prepending a level to a multiindex

Flatten Hierarchical columns

4.20.4 Missing data

The *missing data* docs.

Fill forward a reversed timeseries

```
In [100]: df = pd.DataFrame(np.random.randn(6, 1),
.....:                      index=pd.date_range('2013-08-01', periods=6, freq='B'),
.....:                      columns=list('A'))
.....:
```

```
In [101]: df.loc[df.index[3], 'A'] = np.nan
```

```
In [102]: df

cumsum reset at NaN values

Replace

Using `replace` with backrefs

4.20.5 Grouping

The *grouping* docs.

Basic grouping with `apply`

Unlike `agg`, `apply`'s callable is passed a sub-DataFrame which gives you access to all the columns

```
In [104]: df = pd.DataFrame({'animal': 'cat dog cat fish dog cat cat'.split(),
.....:                      'size': list('SSMMMLL'),
.....:                      'weight': [8, 10, 11, 1, 20, 12, 12],
.....:                      'adult': [False] * 5 + [True] * 2})
.....:
```

```
In [105]: df
```

```
Out[105]:
   animal size  weight  adult
0    cat   S      8   False
1    dog   S     10   False
2    cat   M     11   False
3  fish   M      1   False
4    dog   M     20   False
5    cat   L     12    True
6    cat   L     12    True
```

List the size of the animals with the highest weight.

```
In [106]: df.groupby('animal').apply(lambda subf: subf['size'][subf['weight'].idxmax()])
```

```
Out[106]:
animal
cat    L
dog    M
fish   M
dtype: object
```

Using `get_group`

```
In [107]: gb = df.groupby(['animal'])
```

```
In [108]: gb.get_group('cat')
```

```
Out[108]:
   animal size  weight  adult
0    cat   S      8   False
2    cat   M     11   False
5    cat   L     12    True
6    cat   L     12    True
```

Apply to different items in a group

```
In [109]: def GrowUp(x):
.....:     avg_weight = sum(x[x['size'] == 'S'].weight * 1.5)
.....:     avg_weight += sum(x[x['size'] == 'M'].weight * 1.25)
.....:     avg_weight += sum(x[x['size'] == 'L'].weight)
.....:     avg_weight /= len(x)
.....:     return pd.Series(['L', avg_weight, True],
.....:                     index=['size', 'weight', 'adult'])
.....:
```

```
In [110]: expected_df = gb.apply(GrowUp)
```

```
In [111]: expected_df
```

```
Out[111]:
      size  weight  adult
animal
cat      L  12.4375  True
dog      L  20.0000  True
fish     L   1.2500  True
```

Expanding apply

```
In [112]: S = pd.Series([i / 100.0 for i in range(1, 11)])
```

```
In [113]: def cum_ret(x, y):
.....:     return x * (1 + y)
.....:
```

```
In [114]: def red(x):
.....:     return functools.reduce(cum_ret, x, 1.0)
.....:
```

```
In [115]: S.expanding().apply(red, raw=True)
```

```
Out[115]:
0    1.010000
1    1.030200
2    1.061106
3    1.103550
4    1.158728
5    1.228251
6    1.314229
7    1.419367
8    1.547110
9    1.701821
dtype: float64
```

Replacing some values with mean of the rest of a group

```
In [116]: df = pd.DataFrame({'A': [1, 1, 2, 2], 'B': [1, -1, 1, 2]})
```

```
In [117]: gb = df.groupby('A')
```

```
In [118]: def replace(g):
```

(continues on next page)

(continued from previous page)

```

.....:     mask = g < 0
.....:     return g.where(mask, g[~mask].mean())
.....:
In [119]: gb.transform(replace)
Out[119]:
      B
0  1.0
1 -1.0
2  1.5
3  1.5

```

Sort groups by aggregated data

```

In [120]: df = pd.DataFrame({'code': ['foo', 'bar', 'baz'] * 2,
.....:                      'data': [0.16, -0.21, 0.33, 0.45, -0.59, 0.62],
.....:                      'flag': [False, True] * 3})
.....:

In [121]: code_groups = df.groupby('code')

In [122]: agg_n_sort_order = code_groups[['data']].transform(sum).sort_values(by='data')

In [123]: sorted_df = df.loc[agg_n_sort_order.index]

In [124]: sorted_df
Out[124]:
   code  data  flag
1  bar -0.21  True
4  bar -0.59 False
0  foo  0.16 False
3  foo  0.45  True
2  baz  0.33 False
5  baz  0.62  True

```

Create multiple aggregated columns

```
In [125]: rng = pd.date_range(start="2014-10-07", periods=10, freq='2min')
```

```
In [126]: ts = pd.Series(data=list(range(10)), index=rng)
```

```

In [127]: def MyCust(x):
.....:     if len(x) > 2:
.....:         return x[1] * 1.234
.....:     return pd.NaT
.....:

```

```
In [128]: mhc = {'Mean': np.mean, 'Max': np.max, 'Custom': MyCust}
```

```
In [129]: ts.resample("5min").apply(mhc)
```

```

12	-0.229201	1.473266	0.236527

Apply

Rolling apply to organize - Turning embedded lists into a MultiIndex frame

```
In [159]: df = pd.DataFrame(data={'A': [[2, 4, 8, 16], [100, 200], [10, 20, 30]],
.....:                          'B': [['a', 'b', 'c'], ['jj', 'kk'], ['ccc']]},
.....:                          index=['I', 'II', 'III'])
.....:

In [160]: def SeriesFromSubList(aList):
.....:     return pd.Series(aList)
.....:

In [161]: df_orgz = pd.concat({ind: row.apply(SeriesFromSubList)
.....:                          for ind, row in df.iterrows()})
.....:

In [162]: df_orgz
Out[162]:
```

		0	1	2	3
I	A	2	4	8	16.0
	B	a	b	c	NaN
II	A	100	200	NaN	NaN
	B	jj	kk	NaN	NaN
III	A	10	20	30	NaN
	B	ccc	NaN	NaN	NaN

Rolling apply with a DataFrame returning a Series

Rolling Apply to multiple columns where function calculates a Series before a Scalar from the Series is returned

```
In [163]: df = pd.DataFrame(data=np.random.randn(2000, 2) / 10000,
.....:                       index=pd.date_range('2001-01-01', periods=2000),
.....:                       columns=['A', 'B'])
.....:

In [164]: df
Out[164]:
```

4.20.9 Data In/Out

Performance comparison of SQL vs HDF5

CSV

The *CSV* docs

`read_csv` in action

appending to a csv

Reading a csv chunk-by-chunk

Reading only certain rows of a csv chunk-by-chunk

Reading the first few lines of a frame

Reading a file that is compressed but not by `gzip/bz2` (the native compressed formats which `read_csv` understands). This example shows a `WinZipped` file, but is a general application of opening the file within a context manager and using that handle to read. [See here](#)

Inferring dtypes from a file

Dealing with bad lines

Dealing with bad lines II

Reading CSV with Unix timestamps and converting to local timezone

Write a multi-row index CSV without writing duplicates

Reading multiple files to create a single DataFrame

The best way to combine multiple files into a single DataFrame is to read the individual frames one by one, put all of the individual frames into a list, and then combine the frames in the list using `pd.concat()`:

```
In [189]: for i in range(3):
.....:     data = pd.DataFrame(np.random.randn(10, 4))
.....:     data.to_csv('file_{}.csv'.format(i))
.....:

In [190]: files = ['file_0.csv', 'file_1.csv', 'file_2.csv']

In [191]: result = pd.concat([pd.read_csv(f) for f in files], ignore_index=True)
```

You can use the same approach to read all files matching a pattern. Here is an example using `glob`:

```
In [192]: import glob

In [193]: import os

In [194]: files = glob.glob('file_*.csv')

In [195]: result = pd.concat([pd.read_csv(f) for f in files], ignore_index=True)
```

Finally, this strategy will work with the other `pd.read_*`(...) functions described in the *io docs*.

Parsing date components in multi-columns

Parsing date components in multi-columns is faster with a format

```
In [201]: from io import StringIO

In [202]: pd.read_csv(StringIO(data), sep=';', skiprows=[11, 12],
.....:                 index_col=0, parse_dates=True, header=10)
.....:
Out[202]:
```

	Param1	Param2	Param4	Param5
date				
1990-01-01 00:00:00	1	1	2	3
1990-01-01 01:00:00	5	3	4	5
1990-01-01 02:00:00	9	5	6	7
1990-01-01 03:00:00	13	7	8	9
1990-01-01 04:00:00	17	9	10	11
1990-01-01 05:00:00	21	11	12	13

Option 2: read column names and then data

```
In [203]: pd.read_csv(StringIO(data), sep=';', header=10, nrows=10).columns
Out[203]: Index(['date', 'Param1', 'Param2', 'Param4', 'Param5'], dtype='object')

In [204]: columns = pd.read_csv(StringIO(data), sep=';', header=10, nrows=10).columns

In [205]: pd.read_csv(StringIO(data), sep=';', index_col=0,
.....:                 header=12, parse_dates=True, names=columns)
.....:
Out[205]:
```

	Param1	Param2	Param4	Param5
date				
1990-01-01 00:00:00	1	1	2	3
1990-01-01 01:00:00	5	3	4	5
1990-01-01 02:00:00	9	5	6	7
1990-01-01 03:00:00	13	7	8	9
1990-01-01 04:00:00	17	9	10	11
1990-01-01 05:00:00	21	11	12	13

SQL

The *SQL* docs

Reading from databases with SQL

Excel

The *Excel* docs

Reading from a filelike handle

Modifying formatting in XlsxWriter output

HTML

Reading HTML tables from a server that cannot handle the default request header

HDFStore

The *HDFStores* docs

Simple queries with a Timestamp Index

Managing heterogeneous data using a linked multiple table hierarchy

Merging on-disk tables with millions of rows

Avoiding inconsistencies when writing to a store from multiple processes/threads

De-duplicating a large store by chunks, essentially a recursive reduction operation. Shows a function for taking in data from csv file and creating a store by chunks, with date parsing as well. See [here](#)

Creating a store chunk-by-chunk from a csv file

Appending to a store, while creating a unique index

Large Data work flows

Reading in a sequence of files, then providing a global unique index to a store while appending

Groupby on a HDFStore with low group density

Groupby on a HDFStore with high group density

Hierarchical queries on a HDFStore

Counting with a HDFStore

Troubleshoot HDFStore exceptions

Setting `min_itemsize` with strings

Using `ptrepack` to create a completely-sorted-index on a store

Storing Attributes to a group node

```

In [206]: df = pd.DataFrame(np.random.randn(8, 3))

In [207]: store = pd.HDFStore('test.h5')

In [208]: store.put('df', df)

# you can store an arbitrary Python object via pickle
In [209]: store.get_storer('df').attrs.my_attribute = {'A': 10}

In [210]: store.get_storer('df').attrs.my_attribute
Out[210]: {'A': 10}

```

Binary files

pandas readily accepts NumPy record arrays, if you need to read in a binary file consisting of an array of C structs. For example, given this C program in a file called `main.c` compiled with `gcc main.c -std=gnu99` on a 64-bit machine,

```

#include <stdio.h>
#include <stdint.h>

typedef struct _Data
{
    int32_t count;
    double avg;
    float scale;
} Data;

int main(int argc, const char *argv[])
{
    size_t n = 10;
    Data d[n];

    for (int i = 0; i < n; ++i)
    {
        d[i].count = i;
        d[i].avg = i + 1.0;
        d[i].scale = (float) i + 2.0f;
    }

    FILE *file = fopen("binary.dat", "wb");
    fwrite(&d, sizeof(Data), n, file);
    fclose(file);

    return 0;
}

```

the following Python code will read the binary file 'binary.dat' into a pandas DataFrame, where each element of the struct corresponds to a column in the frame:

```

names = 'count', 'avg', 'scale'

# note that the offsets are larger than the size of the type because of
# struct padding
offsets = 0, 8, 16
formats = 'i4', 'f8', 'f4'
dt = np.dtype({'names': names, 'offsets': offsets, 'formats': formats},
              align=True)
df = pd.DataFrame(np.fromfile('binary.dat', dt))

```

Note: The offsets of the structure elements may be different depending on the architecture of the machine on which the file was created. Using a raw binary file format like this for general data storage is not recommended, as it is not cross platform. We recommended either HDF5 or msgpack, both of which are supported by pandas' IO facilities.

4.20.10 Computation

Numerical integration (sample-based) of a time series

Correlation

Often it's useful to obtain the lower (or upper) triangular form of a correlation matrix calculated from `DataFrame.corr()`. This can be achieved by passing a boolean mask to `where` as follows:

```
In [211]: df = pd.DataFrame(np.random.random(size=(100, 5)))

In [212]: corr_mat = df.corr()

In [213]: mask = np.tril(np.ones_like(corr_mat, dtype=np.bool), k=-1)

In [214]: corr_mat.where(mask)
Out[214]:
```

	0	1	2	3	4
0	NaN	NaN	NaN	NaN	NaN
1	0.058568	NaN	NaN	NaN	NaN
2	-0.036451	-0.014375	NaN	NaN	NaN
3	-0.141872	-0.069392	0.015754	NaN	NaN
4	0.173949	0.087820	-0.124553	0.100906	NaN

The `method` argument within `DataFrame.corr` can accept a callable in addition to the named correlation types. Here we compute the [distance correlation](#) matrix for a `DataFrame` object.

```
In [215]: def distcorr(x, y):
.....:     n = len(x)
.....:     a = np.zeros(shape=(n, n))
.....:     b = np.zeros(shape=(n, n))
.....:     for i in range(n):
.....:         for j in range(i + 1, n):
.....:             a[i, j] = abs(x[i] - x[j])
.....:             b[i, j] = abs(y[i] - y[j])
.....:     a += a.T
.....:     b += b.T
.....:     a_bar = np.vstack([np.nanmean(a, axis=0)] * n)
.....:     b_bar = np.vstack([np.nanmean(b, axis=0)] * n)
.....:     A = a - a_bar - a_bar.T + np.full(shape=(n, n), fill_value=a_bar.mean())
.....:     B = b - b_bar - b_bar.T + np.full(shape=(n, n), fill_value=b_bar.mean())
.....:     cov_ab = np.sqrt(np.nansum(A * B)) / n
.....:     std_a = np.sqrt(np.sqrt(np.nansum(A**2)) / n)
.....:     std_b = np.sqrt(np.sqrt(np.nansum(B**2)) / n)
.....:     return cov_ab / std_a / std_b
.....:

In [216]: df = pd.DataFrame(np.random.normal(size=(100, 3)))

In [217]: df.corr(method=distcorr)
Out[217]:
```

	0	1	2
0	1.000000	0.169628	0.202669
1	0.169628	1.000000	0.208482
2	0.202669	0.208482	1.000000

4.20.11 Timedeltas

The *Timedeltas* docs.

Using `timedeltas`

```
In [218]: import datetime
```

```
In [219]: s = pd.Series(pd.date_range('2012-1-1', periods=3, freq='D'))
```

```
In [220]: s - s.max()
```

```
Out[220]:
0    -2 days
1    -1 days
2     0 days
dtype: timedelta64[ns]
```

```
In [221]: s.max() - s
```

```
Out[221]:
0     2 days
1     1 days
2     0 days
dtype: timedelta64[ns]
```

```
In [222]: s - datetime.datetime(2011, 1, 1, 3, 5)
```

```
Out[222]:
0    364 days 20:55:00
1    365 days 20:55:00
2    366 days 20:55:00
dtype: timedelta64[ns]
```

```
In [223]: s + datetime.timedelta(minutes=5)
```

```
Out[223]:
0    2012-01-01 00:05:00
1    2012-01-02 00:05:00
2    2012-01-03 00:05:00
dtype: datetime64[ns]
```

```
In [224]: datetime.datetime(2011, 1, 1, 3, 5) - s
```

```
Out[224]:
0    -365 days +03:05:00
1    -366 days +03:05:00
2    -367 days +03:05:00
dtype: timedelta64[ns]
```

```
In [225]: datetime.timedelta(minutes=5) + s
```

```
Out[225]:
0    2012-01-01 00:05:00
1    2012-01-02 00:05:00
2    2012-01-03 00:05:00
dtype: datetime64[ns]
```

Adding and subtracting deltas and dates

```
In [226]: deltas = pd.Series([datetime.timedelta(days=i) for i in range(3)])
```

```
In [227]: df = pd.DataFrame({'A': s, 'B': deltas})
```

```
In [228]: df
```

```
Out[228]:
   A      B
0 2012-01-01 0 days
1 2012-01-02 1 days
2 2012-01-03 2 days
```

```
In [229]: df['New Dates'] = df['A'] + df['B']
```

```
In [230]: df['Delta'] = df['A'] - df['New Dates']
```

```
In [231]: df
```

```
Out[231]:
   A      B  New Dates  Delta
0 2012-01-01 0 days 2012-01-01  0 days
1 2012-01-02 1 days 2012-01-03 -1 days
2 2012-01-03 2 days 2012-01-05 -2 days
```

```
In [232]: df.dtypes
```

```
Out[232]:
A          datetime64[ns]
B          timedelta64[ns]
New Dates  datetime64[ns]
Delta      timedelta64[ns]
dtype: object
```

Another example

Values can be set to NaT using `np.nan`, similar to `datetime`

```
In [233]: y = s - s.shift()
```

```
In [234]: y
```

```
Out[234]:
0      NaT
1    1 days
2    1 days
dtype: timedelta64[ns]
```

```
In [235]: y[1] = np.nan
```

```
In [236]: y
```

```
Out[236]:
0      NaT
1      NaT
2    1 days
dtype: timedelta64[ns]
```

4.20.12 Aliasing axis names

To globally provide aliases for axis names, one can define these 2 functions:

```
In [237]: def set_axis_alias(cls, axis, alias):
.....:     if axis not in cls._AXIS_NUMBERS:
.....:         raise Exception("invalid axis [%s] for alias [%s]" % (axis, alias))
.....:     cls._AXIS_ALIASES[axis] = alias
.....:
```

```
In [238]: def clear_axis_alias(cls, axis, alias):
.....:     if axis not in cls._AXIS_NUMBERS:
.....:         raise Exception("invalid axis [%s] for alias [%s]" % (axis, alias))
.....:     cls._AXIS_ALIASES.pop(alias, None)
.....:
```

```
In [239]: set_axis_alias(pd.DataFrame, 'columns', 'myaxis2')
```

```
In [240]: df2 = pd.DataFrame(np.random.randn(3, 2), columns=['c1', 'c2'],
.....:                        index=['i1', 'i2', 'i3'])
.....:
```

```
In [241]: df2.sum(axis='myaxis2')
```

```
Out[241]:
i1    -2.646263
i2    -1.737358
i3    -0.200793
dtype: float64
```

```
In [242]: clear_axis_alias(pd.DataFrame, 'columns', 'myaxis2')
```

4.20.13 Creating example data

To create a dataframe from every combination of some given values, like R's `expand.grid()` function, we can create a dict where the keys are column names and the values are lists of the data values:

```
In [243]: def expand_grid(data_dict):
.....:     rows = itertools.product(*data_dict.values())
.....:     return pd.DataFrame.from_records(rows, columns=data_dict.keys())
.....:
```

```
In [244]: df = expand_grid({'height': [60, 70],
.....:                     'weight': [100, 140, 180],
.....:                     'sex': ['Male', 'Female']})
.....:
```

```
In [245]: df
```

```
Out[245]:
   height  weight  sex
0      60    100  Male
1      60    100 Female
2      60    140  Male
3      60    140 Female
4      60    180  Male
5      60    180 Female
```

(continues on next page)

(continued from previous page)

6	70	100	Male
7	70	100	Female
8	70	140	Male
9	70	140	Female
10	70	180	Male
11	70	180	Female

{{ header }}

PANDAS ECOSYSTEM

Increasingly, packages are being built on top of pandas to address specific needs in data preparation, analysis and visualization. This is encouraging because it means pandas is not only helping users to handle their data tasks but also that it provides a better starting point for developers to build powerful and more focused data tools. The creation of libraries that complement pandas' functionality also allows pandas development to remain focused around its original requirements.

This is an inexhaustive list of projects that build on pandas in order to provide tools in the PyData space. For a list of projects that depend on pandas, see the [libraries.io usage page for pandas](#) or [search pypi for pandas](#).

We'd like to make it easier for users to find these projects, if you know of other substantial projects that you feel should be on this list, please let us know.

5.1 Statistics and machine learning

5.1.1 Statsmodels

Statsmodels is the prominent Python “statistics and econometrics library” and it has a long-standing special relationship with pandas. Statsmodels provides powerful statistics, econometrics, analysis and modeling functionality that is out of pandas' scope. Statsmodels leverages pandas objects as the underlying data container for computation.

5.1.2 sklearn-pandas

Use pandas DataFrames in your [scikit-learn](#) ML pipeline.

5.1.3 Featuretools

Featuretools is a Python library for automated feature engineering built on top of pandas. It excels at transforming temporal and relational datasets into feature matrices for machine learning using reusable feature engineering “primitives”. Users can contribute their own primitives in Python and share them with the rest of the community.

5.2 Visualization

5.2.1 Altair

Altair is a declarative statistical visualization library for Python. With Altair, you can spend more time understanding your data and its meaning. Altair’s API is simple, friendly and consistent and built on top of the powerful Vega-Lite JSON specification. This elegant simplicity produces beautiful and effective visualizations with a minimal amount of code. Altair works with Pandas DataFrames.

5.2.2 Bokeh

Bokeh is a Python interactive visualization library for large datasets that natively uses the latest web technologies. Its goal is to provide elegant, concise construction of novel graphics in the style of Protovis/D3, while delivering high-performance interactivity over large data to thin clients.

5.2.3 seaborn

Seaborn is a Python visualization library based on `matplotlib`. It provides a high-level, dataset-oriented interface for creating attractive statistical graphics. The plotting functions in seaborn understand pandas objects and leverage pandas grouping operations internally to support concise specification of complex visualizations. Seaborn also goes beyond matplotlib and pandas with the option to perform statistical estimation while plotting, aggregating across observations and visualizing the fit of statistical models to emphasize patterns in a dataset.

5.2.4 yhat/ggpy

Hadley Wickham’s `ggplot2` is a foundational exploratory visualization package for the R language. Based on “The Grammar of Graphics” it provides a powerful, declarative and extremely general way to generate bespoke plots of any kind of data. It’s really quite incredible. Various implementations to other languages are available, but a faithful implementation for Python users has long been missing. Although still young (as of Jan-2014), the `yhat/ggpy` project has been progressing quickly in that direction.

5.2.5 IPython Vega

IPython Vega leverages Vega to create plots within Jupyter Notebook.

5.2.6 Plotly

Plotly’s Python API enables interactive figures and web shareability. Maps, 2D, 3D, and live-streaming graphs are rendered with WebGL and D3.js. The library supports plotting directly from a pandas DataFrame and cloud-based collaboration. Users of `matplotlib`, `ggplot for Python`, and `Seaborn` can convert figures into interactive web-based plots. Plots can be drawn in IPython Notebooks, edited with R or MATLAB, modified in a GUI, or embedded in apps and dashboards. Plotly is free for unlimited sharing, and has cloud, offline, or on-premise accounts for private use.

5.2.7 QtPandas

Spun off from the main pandas library, the `qtpandas` library enables DataFrame visualization and manipulation in PyQt4 and PySide applications.

5.3 IDE

5.3.1 IPython

IPython is an interactive command shell and distributed computing environment. IPython tab completion works with Pandas methods and also attributes like DataFrame columns.

5.3.2 Jupyter Notebook / Jupyter Lab

Jupyter Notebook is a web application for creating Jupyter notebooks. A Jupyter notebook is a JSON document containing an ordered list of input/output cells which can contain code, text, mathematics, plots and rich media. Jupyter notebooks can be converted to a number of open standard output formats (HTML, HTML presentation slides, LaTeX, PDF, ReStructuredText, Markdown, Python) through ‘Download As’ in the web interface and `jupyter convert` in a shell.

Pandas DataFrames implement `_repr_html_` and `_repr_latex` methods which are utilized by Jupyter Notebook for displaying (abbreviated) HTML or LaTeX tables. LaTeX output is properly escaped. (Note: HTML tables may or may not be compatible with non-HTML Jupyter output formats.)

See *Options and Settings* and *Available Options* for pandas `display`. settings.

5.3.3 quantopian/qgrid

qgrid is “an interactive grid for sorting and filtering DataFrames in IPython Notebook” built with SlickGrid.

5.3.4 Spyder

Spyder is a cross-platform PyQt-based IDE combining the editing, analysis, debugging and profiling functionality of a software development tool with the data exploration, interactive execution, deep inspection and rich visualization capabilities of a scientific environment like MATLAB or Rstudio.

Its *Variable Explorer* allows users to view, manipulate and edit pandas `Index`, `Series`, and `DataFrame` objects like a “spreadsheet”, including copying and modifying values, sorting, displaying a “heatmap”, converting data types and more. Pandas objects can also be renamed, duplicated, new columns added, copied/pasted to/from the clipboard (as TSV), and saved/loaded to/from a file. Spyder can also import data from a variety of plain text and binary files or the clipboard into a new pandas DataFrame via a sophisticated import wizard.

Most pandas classes, methods and data attributes can be autocompleted in Spyder’s *Editor* and *IPython Console*, and Spyder’s *Help pane* can retrieve and render Numpydoc documentation on pandas objects in rich text with Sphinx both automatically and on-demand.

5.4 API

5.4.1 pandas-datareader

`pandas-datareader` is a remote data access library for pandas (PyPI:`pandas-datareader`). It is based on functionality that was located in `pandas.io.data` and `pandas.io.wb` but was split off in v0.19. See more in the [pandas-datareader docs](#):

The following data feeds are available:

- Google Finance
- Tiingo
- Morningstar
- IEX
- Robinhood
- Enigma
- Quandl
- FRED
- Fama/French
- World Bank
- OECD
- Eurostat
- TSP Fund Data
- Nasdaq Trader Symbol Definitions
- Stooq Index Data
- MOEX Data

5.4.2 quandl/Python

Quandl API for Python wraps the Quandl REST API to return Pandas DataFrames with timeseries indexes.

5.4.3 pydatastream

PyDatastream is a Python interface to the Thomson Dataworks Enterprise (DWE/Datastream) SOAP API to return indexed Pandas DataFrames with financial data. This package requires valid credentials for this API (non free).

5.4.4 pandaSDMX

pandaSDMX is a library to retrieve and acquire statistical data and metadata disseminated in SDMX 2.1, an ISO-standard widely used by institutions such as statistics offices, central banks, and international organisations. pandaSDMX can expose datasets and related structural metadata including data flows, code-lists, and data structure definitions as pandas Series or MultiIndexed DataFrames.

5.4.5 fredapi

fredapi is a Python interface to the [Federal Reserve Economic Data \(FRED\)](#) provided by the Federal Reserve Bank of St. Louis. It works with both the FRED database and ALFRED database that contains point-in-time data (i.e. historic data revisions). fredapi provides a wrapper in Python to the FRED HTTP API, and also provides several convenient methods for parsing and analyzing point-in-time data from ALFRED. fredapi makes use of pandas and returns data in a Series or DataFrame. This module requires a FRED API key that you can obtain for free on the FRED website.

5.5 Domain specific

5.5.1 Geopandas

Geopandas extends pandas data objects to include geographic information which support geometric operations. If your work entails maps and geographical coordinates, and you love pandas, you should take a close look at Geopandas.

5.5.2 xarray

xarray brings the labeled data power of pandas to the physical sciences by providing N-dimensional variants of the core pandas data structures. It aims to provide a pandas-like and pandas-compatible toolkit for analytics on multi-dimensional arrays, rather than the tabular data for which pandas excels.

5.6 Out-of-core

5.6.1 Blaze

Blaze provides a standard API for doing computations with various in-memory and on-disk backends: NumPy, Pandas, SQLAlchemy, MongoDB, PyTables, PySpark.

5.6.2 Dask

Dask is a flexible parallel computing library for analytics. Dask provides a familiar `DataFrame` interface for out-of-core, parallel and distributed computing.

5.6.3 Dask-ML

Dask-ML enables parallel and distributed machine learning using Dask alongside existing machine learning libraries like Scikit-Learn, XGBoost, and TensorFlow.

5.6.4 Koalas

Koalas provides a familiar pandas `DataFrame` interface on top of Apache Spark. It enables users to leverage multi-cores on one machine or a cluster of machines to speed up or scale their `DataFrame` code.

5.6.5 Odo

Odo provides a uniform API for moving data between different formats. It uses pandas own `read_csv` for CSV IO and leverages many existing packages such as PyTables, h5py, and pymongo to move data between non pandas formats. Its graph based approach is also extensible by end users for custom formats that may be too specific for the core of odo.

5.6.6 Ray

Pandas on Ray is an early stage DataFrame library that wraps Pandas and transparently distributes the data and computation. The user does not need to know how many cores their system has, nor do they need to specify how to distribute the data. In fact, users can continue using their previous Pandas notebooks while experiencing a considerable speedup from Pandas on Ray, even on a single machine. Only a modification of the import statement is needed, as we demonstrate below. Once you've changed your import statement, you're ready to use Pandas on Ray just like you would Pandas.

```
# import pandas as pd
import ray.dataframe as pd
```

5.6.7 Vaex

Increasingly, packages are being built on top of pandas to address specific needs in data preparation, analysis and visualization. Vaex is a python library for Out-of-Core DataFrames (similar to Pandas), to visualize and explore big tabular datasets. It can calculate statistics such as mean, sum, count, standard deviation etc, on an N-dimensional grid up to a billion (10^9) objects/rows per second. Visualization is done using histograms, density plots and 3d volume rendering, allowing interactive exploration of big data. Vaex uses memory mapping, zero memory copy policy and lazy computations for best performance (no memory wasted).

- `vaex.from_pandas`
- `vaex.to_pandas_df`

5.7 Data validation

5.7.1 Engarde

Engarde is a lightweight library used to explicitly state your assumptions about your datasets and check that they're *actually* true.

5.8 Extension data types

Pandas provides an interface for defining *extension types* to extend NumPy's type system. The following libraries implement that interface to provide types not found in NumPy or pandas, which work well with pandas' data containers.

5.8.1 cyberpandas

Cyberpandas provides an extension type for storing arrays of IP Addresses. These arrays can be stored inside pandas' Series and DataFrame.

5.9 Accessors

A directory of projects providing *extension accessors*. This is for users to discover new accessors and for library authors to coordinate on the namespace.

Library	Accessor	Classes
cyberpandas	<code>ip</code>	<code>Series</code>
pdvega	<code>vgplot</code>	<code>Series</code> , <code>DataFrame</code>

{{ header }}

API REFERENCE

This page gives an overview of all public pandas objects, functions and methods. All classes and functions exposed in `pandas.*` namespace are public.

Some subpackages are public which include `pandas.errors`, `pandas.plotting`, and `pandas.testing`. Public functions in `pandas.io` and `pandas.tseries` submodules are mentioned in the documentation. `pandas.api.types` subpackage holds some public functions related to data types in pandas.

Warning: The `pandas.core`, `pandas.compat`, and `pandas.util` top-level modules are PRIVATE. Stable functionality in such modules is not guaranteed.

{{ header }}

6.1 Input/output

6.1.1 Pickling

<code>read_pickle(path[, compression])</code>	Load pickled pandas object (or any object) from file.
---	---

`pandas.read_pickle`

`pandas.read_pickle(path, compression='infer')`
Load pickled pandas object (or any object) from file.

Warning: Loading pickled data received from untrusted sources can be unsafe. See [here](#).

Parameters

path [str] File path where the pickled object will be loaded.

compression [{'infer', 'gzip', 'bz2', 'zip', 'xz', None}, default 'infer'] For on-the-fly decompression of on-disk data. If 'infer', then use gzip, bz2, xz or zip if path ends in 'gz', 'bz2', 'xz', or 'zip' respectively, and no decompression otherwise. Set to None for no decompression.

New in version 0.20.0.

Returns

`unpickled` [same type as object stored in file]

See also:

`DataFrame.to_pickle` Pickle (serialize) DataFrame object to file.

`Series.to_pickle` Pickle (serialize) Series object to file.

`read_hdf` Read HDF5 file into a DataFrame.

`read_sql` Read SQL query or database table into a DataFrame.

`read_parquet` Load a parquet object, returning a DataFrame.

Notes

`read_pickle` is only guaranteed to be backwards compatible to pandas 0.20.3.

Examples

```
>>> original_df = pd.DataFrame({"foo": range(5), "bar": range(5, 10)})
>>> original_df
   foo  bar
0    0    5
1    1    6
2    2    7
3    3    8
4    4    9
>>> pd.to_pickle(original_df, "./dummy.pkl")
```

```
>>> unpickled_df = pd.read_pickle("./dummy.pkl")
>>> unpickled_df
   foo  bar
0    0    5
1    1    6
2    2    7
3    3    8
4    4    9
```

```
>>> import os
>>> os.remove("./dummy.pkl")
```

6.1.2 Flat file

<code>read_table(filepath_or_buffer, pathlib.Path, ...)</code>	Read general delimited file into DataFrame.
<code>read_csv(filepath_or_buffer, pathlib.Path, ...)</code>	Read a comma-separated values (csv) file into DataFrame.
<code>read_fwf(filepath_or_buffer, pathlib.Path, ...)</code>	Read a table of fixed-width formatted lines into DataFrame.
<code>read_msgpack(path_or_buf[, encoding, iterator])</code>	(DEPRECATED) Load msgpack pandas object from the specified file path.

pandas.read_table

```
pandas.read_table(filepath_or_buffer: Union[str, pathlib.Path, IO[AnyStr]], sep='t', delimiter=None, header='infer', names=None, index_col=None, usecols=None, squeeze=False, prefix=None, mangle_dupe_cols=True, dtype=None, engine=None, converters=None, true_values=None, false_values=None, skipinitialspace=False, skiprows=None, skipfooter=0, nrows=None, na_values=None, keep_default_na=True, na_filter=True, verbose=False, skip_blank_lines=True, parse_dates=False, infer_datetime_format=False, keep_date_col=False, date_parser=None, dayfirst=False, cache_dates=True, iterator=False, chunksize=None, compression='infer', thousands=None, decimal=b',', lineterminator=None, quotechar='"', quoting=0, doublequote=True, escapechar=None, comment=None, encoding=None, dialect=None, error_bad_lines=True, warn_bad_lines=True, delim_whitespace=False, low_memory=True, memory_map=False, float_precision=None)
```

Read general delimited file into DataFrame.

Also supports optionally iterating or breaking of the file into chunks.

Additional help can be found in the online docs for [IO Tools](#).

Parameters

filepath_or_buffer [str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file://localhost/path/to/table.csv`.

If you want to pass in a path object, pandas accepts any `os.PathLike`.

By file-like object, we refer to objects with a `read()` method, such as a file handler (e.g. via builtin `open` function) or `StringIO`.

sep [str, default '\t' (tab-stop)] Delimiter to use. If sep is None, the C engine cannot automatically detect the separator, but the Python parsing engine can, meaning the latter will be used and automatically detect the separator by Python's builtin sniffer tool, `csv.Sniffer`. In addition, separators longer than 1 character and different from '\s+' will be interpreted as regular expressions and will also force the use of the Python parsing engine. Note that regex delimiters are prone to ignoring quoted data. Regex example: '\r\t'.

delimiter [str, default None] Alias for sep.

header [int, list of int, default 'infer'] Row number(s) to use as the column names, and the start of the data. Default behavior is to infer the column names: if no names are passed the behavior is identical to `header=0` and column names are inferred from the first line of the file, if column names are passed explicitly then the behavior is identical to `header=None`. Explicitly pass `header=0` to be able to replace existing names. The header can be a list of integers that specify row locations for a multi-index on the columns e.g. [0,1,3]. Intervening rows that are not specified will be skipped (e.g. 2 in this example is skipped). Note that this parameter ignores commented lines and empty lines if `skip_blank_lines=True`, so `header=0` denotes the first line of data rather than the first line of the file.

names [array-like, optional] List of column names to use. If file contains no header row, then you should explicitly pass `header=None`. Duplicates in this list are not allowed.

index_col [int, str, sequence of int / str, or False, default None] Column(s) to use as the row labels of the DataFrame, either given as string name or column index. If a

sequence of int / str is given, a MultiIndex is used.

Note: `index_col=False` can be used to force pandas to *not* use the first column as the index, e.g. when you have a malformed file with delimiters at the end of each line.

usecols [list-like or callable, optional] Return a subset of the columns. If list-like, all elements must either be positional (i.e. integer indices into the document columns) or strings that correspond to column names provided either by the user in *names* or inferred from the document header row(s). For example, a valid list-like *usecols* parameter would be `[0, 1, 2]` or `['foo', 'bar', 'baz']`. Element order is ignored, so `usecols=[0, 1]` is the same as `[1, 0]`. To instantiate a DataFrame from *data* with element order preserved use `pd.read_csv(data, usecols=['foo', 'bar'])[['foo', 'bar']]` for columns in `['foo', 'bar']` order or `pd.read_csv(data, usecols=['foo', 'bar'])[['bar', 'foo']]` for `['bar', 'foo']` order.

If callable, the callable function will be evaluated against the column names, returning names where the callable function evaluates to True. An example of a valid callable argument would be `lambda x: x.upper() in ['AAA', 'BBB', 'DDD']`. Using this parameter results in much faster parsing time and lower memory usage.

squeeze [bool, default False] If the parsed data only contains one column then return a Series.

prefix [str, optional] Prefix to add to column numbers when no header, e.g. 'X' for X0, X1, ...

mangle_dupe_cols [bool, default True] Duplicate columns will be specified as 'X', 'X.1', ...'X.N', rather than 'X'...'X'. Passing in False will cause data to be overwritten if there are duplicate names in the columns.

dtype [Type name or dict of column -> type, optional] Data type for data or columns. E.g. `{'a': np.float64, 'b': np.int32, 'c': 'Int64'}` Use *str* or *object* together with suitable *na_values* settings to preserve and not interpret dtype. If converters are specified, they will be applied INSTEAD of dtype conversion.

engine [{'c', 'python'}, optional] Parser engine to use. The C engine is faster while the python engine is currently more feature-complete.

converters [dict, optional] Dict of functions for converting values in certain columns. Keys can either be integers or column labels.

true_values [list, optional] Values to consider as True.

false_values [list, optional] Values to consider as False.

skipinitialspace [bool, default False] Skip spaces after delimiter.

skiprows [list-like, int or callable, optional] Line numbers to skip (0-indexed) or number of lines to skip (int) at the start of the file.

If callable, the callable function will be evaluated against the row indices, returning True if the row should be skipped and False otherwise. An example of a valid callable argument would be `lambda x: x in [0, 2]`.

skipfooter [int, default 0] Number of lines at bottom of file to skip (Unsupported with `engine='c'`).

nrows [int, optional] Number of rows of file to read. Useful for reading pieces of large files.

na_values [scalar, str, list-like, or dict, optional] Additional strings to recognize as NA/NaN. If dict passed, specific per-column NA values. By default the following values are interpreted as NaN: ‘’, ‘#N/A’, ‘#N/A N/A’, ‘#NA’, ‘-1.#IND’, ‘-1.#QNAN’, ‘-NaN’, ‘-nan’, ‘1.#IND’, ‘1.#QNAN’, ‘N/A’, ‘NA’, ‘NULL’, ‘NaN’, ‘n/a’, ‘nan’, ‘null’.

keep_default_na [bool, default True] Whether or not to include the default NaN values when parsing the data. Depending on whether *na_values* is passed in, the behavior is as follows:

- If *keep_default_na* is True, and *na_values* are specified, *na_values* is appended to the default NaN values used for parsing.
- If *keep_default_na* is True, and *na_values* are not specified, only the default NaN values are used for parsing.
- If *keep_default_na* is False, and *na_values* are specified, only the NaN values specified *na_values* are used for parsing.
- If *keep_default_na* is False, and *na_values* are not specified, no strings will be parsed as NaN.

Note that if *na_filter* is passed in as False, the *keep_default_na* and *na_values* parameters will be ignored.

na_filter [bool, default True] Detect missing value markers (empty strings and the value of *na_values*). In data without any NAs, passing *na_filter*=False can improve the performance of reading a large file.

verbose [bool, default False] Indicate number of NA values placed in non-numeric columns.

skip_blank_lines [bool, default True] If True, skip over blank lines rather than interpreting as NaN values.

parse_dates [bool or list of int or names or list of lists or dict, default False] The behavior is as follows:

- boolean. If True -> try parsing the index.
- list of int or names. e.g. If [1, 2, 3] -> try parsing columns 1, 2, 3 each as a separate date column.
- list of lists. e.g. If [[1, 3]] -> combine columns 1 and 3 and parse as a single date column.
- dict, e.g. {'foo' : [1, 3]} -> parse columns 1, 3 as date and call result 'foo'

If a column or index cannot be represented as an array of datetimes, say because of an unparseable value or a mixture of timezones, the column or index will be returned unaltered as an object data type. For non-standard datetime parsing, use `pd.to_datetime` after `pd.read_csv`. To parse an index or column with a mixture of timezones, specify `date_parser` to be a partially-applied `pandas.to_datetime()` with `utc=True`. See *Parsing a CSV with mixed timezones* for more.

Note: A fast-path exists for iso8601-formatted dates.

infer_datetime_format [bool, default False] If True and *parse_dates* is enabled, pandas will attempt to infer the format of the datetime strings in the columns, and if it can be inferred, switch to a faster method of parsing them. In some cases this can increase the parsing speed by 5-10x.

keep_date_col [bool, default False] If True and *parse_dates* specifies combining multiple columns then keep the original columns.

date_parser [function, optional] Function to use for converting a sequence of string columns to an array of datetime instances. The default uses `dateutil.parser.parser` to do the conversion. Pandas will try to call *date_parser* in three different ways, advancing to the next if an exception occurs: 1) Pass one or more arrays (as defined by *parse_dates*) as arguments; 2) concatenate (row-wise) the string values from the columns defined by *parse_dates* into a single array and pass that; and 3) call *date_parser* once for each row using one or more strings (corresponding to the columns defined by *parse_dates*) as arguments.

dayfirst [bool, default False] DD/MM format dates, international and European format.

cache_dates [boolean, default True] If True, use a cache of unique, converted dates to apply the datetime conversion. May produce significant speed-up when parsing duplicate date strings, especially ones with timezone offsets.

New in version 0.25.0.

iterator [bool, default False] Return TextFileReader object for iteration or getting chunks with `get_chunk()`.

chunksize [int, optional] Return TextFileReader object for iteration. See the [IO Tools docs](#) for more information on **iterator** and **chunksize**.

compression [{‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}, default ‘infer’] For on-the-fly decompression of on-disk data. If ‘infer’ and *filepath_or_buffer* is path-like, then detect compression from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’, or ‘.xz’ (otherwise no decompression). If using ‘zip’, the ZIP file must contain only one data file to be read in. Set to None for no decompression.

New in version 0.18.1: support for ‘zip’ and ‘xz’ compression.

thousands [str, optional] Thousands separator.

decimal [str, default ‘.’] Character to recognize as decimal point (e.g. use ‘,’ for European data).

lineterminator [str (length 1), optional] Character to break file into lines. Only valid with C parser.

quotechar [str (length 1), optional] The character used to denote the start and end of a quoted item. Quoted items can include the delimiter and it will be ignored.

quoting [int or csv.QUOTE_* instance, default 0] Control field quoting behavior per `csv.QUOTE_*` constants. Use one of QUOTE_MINIMAL (0), QUOTE_ALL (1), QUOTE_NONNUMERIC (2) or QUOTE_NONE (3).

doublequote [bool, default True] When quotechar is specified and quoting is not QUOTE_NONE, indicate whether or not to interpret two consecutive quotechar elements INSIDE a field as a single quotechar element.

escapechar [str (length 1), optional] One-character string used to escape other characters.

comment [str, optional] Indicates remainder of line should not be parsed. If found at the beginning of a line, the line will be ignored altogether. This parameter must be a single character. Like empty lines (as long as `skip_blank_lines=True`), fully commented lines are ignored by the parameter *header* but not by *skiprows*. For

example, if `comment='#'`, parsing `#empty\na,b,c\n1,2,3` with `header=0` will result in `'a,b,c'` being treated as the header.

encoding [str, optional] Encoding to use for UTF when reading/writing (ex. `'utf-8'`). [List of Python standard encodings](#) .

dialect [str or `csv.Dialect`, optional] If provided, this parameter will override values (default or not) for the following parameters: *delimiter*, *doublequote*, *escapechar*, *skipinitialspace*, *quotechar*, and *quoting*. If it is necessary to override values, a `ParserWarning` will be issued. See `csv.Dialect` documentation for more details.

error_bad_lines [bool, default `True`] Lines with too many fields (e.g. a csv line with too many commas) will by default cause an exception to be raised, and no `DataFrame` will be returned. If `False`, then these “bad lines” will be dropped from the `DataFrame` that is returned.

warn_bad_lines [bool, default `True`] If `error_bad_lines` is `False`, and `warn_bad_lines` is `True`, a warning for each “bad line” will be output.

delim_whitespace [bool, default `False`] Specifies whether or not whitespace (e.g. `' '` or `'\s'`) will be used as the sep. Equivalent to setting `sep='\s+'`. If this option is set to `True`, nothing should be passed in for the `delimiter` parameter.

New in version 0.18.1: support for the Python parser.

low_memory [bool, default `True`] Internally process the file in chunks, resulting in lower memory use while parsing, but possibly mixed type inference. To ensure no mixed types either set `False`, or specify the type with the `dtype` parameter. Note that the entire file is read into a single `DataFrame` regardless, use the `chunksize` or `iterator` parameter to return the data in chunks. (Only valid with C parser).

memory_map [bool, default `False`] If a filepath is provided for `filepath_or_buffer`, map the file object directly onto memory and access the data directly from there. Using this option can improve performance because there is no longer any I/O overhead.

float_precision [str, optional] Specifies which converter the C engine should use for floating-point values. The options are *None* for the ordinary converter, *high* for the high-precision converter, and *round_trip* for the round-trip converter.

Returns

DataFrame or TextParser A comma-separated values (csv) file is returned as two-dimensional data structure with labeled axes.

See also:

to_csv Write `DataFrame` to a comma-separated values (csv) file.

read_csv Read a comma-separated values (csv) file into `DataFrame`.

read_fwf Read a table of fixed-width formatted lines into `DataFrame`.

Examples

```
>>> pd.read_table('data.csv') # doctest: +SKIP
```

pandas.read_csv

```
pandas.read_csv(filepath_or_buffer: Union[str, pathlib.Path, IO[~AnyStr]], sep=',', delimiter=None, header='infer', names=None, index_col=None, usecols=None, squeeze=False, prefix=None, mangle_dupe_cols=True, dtype=None, engine=None, converters=None, true_values=None, false_values=None, skip_initialspace=False, skiprows=None, skipfooter=0, nrows=None, na_values=None, keep_default_na=True, na_filter=True, verbose=False, skip_blank_lines=True, parse_dates=False, infer_datetime_format=False, keep_date_col=False, date_parser=None, dayfirst=False, cache_dates=True, iterator=False, chunksize=None, compression='infer', thousands=None, decimal=b'.', lineterminator=None, quotechar='"', quoting=0, doublequote=True, escapechar=None, comment=None, encoding=None, dialect=None, error_bad_lines=True, warn_bad_lines=True, delim_whitespace=False, low_memory=True, memory_map=False, float_precision=None)
```

Read a comma-separated values (csv) file into DataFrame.

Also supports optionally iterating or breaking of the file into chunks.

Additional help can be found in the online docs for [IO Tools](#).

Parameters

filepath_or_buffer [str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file://localhost/path/to/table.csv`.

If you want to pass in a path object, pandas accepts any `os.PathLike`.

By file-like object, we refer to objects with a `read()` method, such as a file handler (e.g. via builtin `open` function) or `StringIO`.

sep [str, default ','] Delimiter to use. If sep is None, the C engine cannot automatically detect the separator, but the Python parsing engine can, meaning the latter will be used and automatically detect the separator by Python's builtin sniffer tool, `csv.Sniffer`. In addition, separators longer than 1 character and different from `'\s+'` will be interpreted as regular expressions and will also force the use of the Python parsing engine. Note that regex delimiters are prone to ignoring quoted data. Regex example: `'\r\t'`.

delimiter [str, default None] Alias for sep.

header [int, list of int, default 'infer'] Row number(s) to use as the column names, and the start of the data. Default behavior is to infer the column names: if no names are passed the behavior is identical to `header=0` and column names are inferred from the first line of the file, if column names are passed explicitly then the behavior is identical to `header=None`. Explicitly pass `header=0` to be able to replace existing names. The header can be a list of integers that specify row locations for a multi-index on the columns e.g. `[0,1,3]`. Intervening rows that are not specified will be skipped (e.g. 2 in this example is skipped). Note that this parameter ignores commented lines and empty lines if `skip_blank_lines=True`, so `header=0` denotes the first line of data rather than the first line of the file.

names [array-like, optional] List of column names to use. If file contains no header row, then you should explicitly pass `header=None`. Duplicates in this list are not allowed.

index_col [int, str, sequence of int / str, or False, default None] Column(s) to use as the row labels of the DataFrame, either given as string name or column index. If a

sequence of int / str is given, a MultiIndex is used.

Note: `index_col=False` can be used to force pandas to *not* use the first column as the index, e.g. when you have a malformed file with delimiters at the end of each line.

usecols [list-like or callable, optional] Return a subset of the columns. If list-like, all elements must either be positional (i.e. integer indices into the document columns) or strings that correspond to column names provided either by the user in *names* or inferred from the document header row(s). For example, a valid list-like *usecols* parameter would be `[0, 1, 2]` or `['foo', 'bar', 'baz']`. Element order is ignored, so `usecols=[0, 1]` is the same as `[1, 0]`. To instantiate a DataFrame from *data* with element order preserved use `pd.read_csv(data, usecols=['foo', 'bar'])[['foo', 'bar']]` for columns in `['foo', 'bar']` order or `pd.read_csv(data, usecols=['foo', 'bar'])[['bar', 'foo']]` for `['bar', 'foo']` order.

If callable, the callable function will be evaluated against the column names, returning names where the callable function evaluates to True. An example of a valid callable argument would be `lambda x: x.upper() in ['AAA', 'BBB', 'DDD']`. Using this parameter results in much faster parsing time and lower memory usage.

squeeze [bool, default False] If the parsed data only contains one column then return a Series.

prefix [str, optional] Prefix to add to column numbers when no header, e.g. 'X' for X0, X1, ...

mangle_dupe_cols [bool, default True] Duplicate columns will be specified as 'X', 'X.1', ...'X.N', rather than 'X'...'X'. Passing in False will cause data to be overwritten if there are duplicate names in the columns.

dtype [Type name or dict of column -> type, optional] Data type for data or columns. E.g. `{'a': np.float64, 'b': np.int32, 'c': 'Int64'}` Use *str* or *object* together with suitable *na_values* settings to preserve and not interpret dtype. If converters are specified, they will be applied INSTEAD of dtype conversion.

engine [{'c', 'python'}, optional] Parser engine to use. The C engine is faster while the python engine is currently more feature-complete.

converters [dict, optional] Dict of functions for converting values in certain columns. Keys can either be integers or column labels.

true_values [list, optional] Values to consider as True.

false_values [list, optional] Values to consider as False.

skipinitialspace [bool, default False] Skip spaces after delimiter.

skiprows [list-like, int or callable, optional] Line numbers to skip (0-indexed) or number of lines to skip (int) at the start of the file.

If callable, the callable function will be evaluated against the row indices, returning True if the row should be skipped and False otherwise. An example of a valid callable argument would be `lambda x: x in [0, 2]`.

skipfooter [int, default 0] Number of lines at bottom of file to skip (Unsupported with `engine='c'`).

nrows [int, optional] Number of rows of file to read. Useful for reading pieces of large files.

na_values [scalar, str, list-like, or dict, optional] Additional strings to recognize as NA/NaN. If dict passed, specific per-column NA values. By default the following values are interpreted as NaN: ‘’, ‘#N/A’, ‘#N/A N/A’, ‘#NA’, ‘-1.#IND’, ‘-1.#QNAN’, ‘-NaN’, ‘-nan’, ‘1.#IND’, ‘1.#QNAN’, ‘N/A’, ‘NA’, ‘NULL’, ‘NaN’, ‘n/a’, ‘nan’, ‘null’.

keep_default_na [bool, default True] Whether or not to include the default NaN values when parsing the data. Depending on whether *na_values* is passed in, the behavior is as follows:

- If *keep_default_na* is True, and *na_values* are specified, *na_values* is appended to the default NaN values used for parsing.
- If *keep_default_na* is True, and *na_values* are not specified, only the default NaN values are used for parsing.
- If *keep_default_na* is False, and *na_values* are specified, only the NaN values specified *na_values* are used for parsing.
- If *keep_default_na* is False, and *na_values* are not specified, no strings will be parsed as NaN.

Note that if *na_filter* is passed in as False, the *keep_default_na* and *na_values* parameters will be ignored.

na_filter [bool, default True] Detect missing value markers (empty strings and the value of *na_values*). In data without any NAs, passing *na_filter*=False can improve the performance of reading a large file.

verbose [bool, default False] Indicate number of NA values placed in non-numeric columns.

skip_blank_lines [bool, default True] If True, skip over blank lines rather than interpreting as NaN values.

parse_dates [bool or list of int or names or list of lists or dict, default False] The behavior is as follows:

- boolean. If True -> try parsing the index.
- list of int or names. e.g. If [1, 2, 3] -> try parsing columns 1, 2, 3 each as a separate date column.
- list of lists. e.g. If [[1, 3]] -> combine columns 1 and 3 and parse as a single date column.
- dict, e.g. {'foo' : [1, 3]} -> parse columns 1, 3 as date and call result 'foo'

If a column or index cannot be represented as an array of datetimes, say because of an unparseable value or a mixture of timezones, the column or index will be returned unaltered as an object data type. For non-standard datetime parsing, use `pd.to_datetime` after `pd.read_csv`. To parse an index or column with a mixture of timezones, specify `date_parser` to be a partially-applied `pandas.to_datetime()` with `utc=True`. See *Parsing a CSV with mixed timezones* for more.

Note: A fast-path exists for iso8601-formatted dates.

infer_datetime_format [bool, default False] If True and *parse_dates* is enabled, pandas will attempt to infer the format of the datetime strings in the columns, and if it can be inferred, switch to a faster method of parsing them. In some cases this can increase the parsing speed by 5-10x.

keep_date_col [bool, default False] If True and *parse_dates* specifies combining multiple columns then keep the original columns.

date_parser [function, optional] Function to use for converting a sequence of string columns to an array of datetime instances. The default uses `dateutil.parser.parser` to do the conversion. Pandas will try to call *date_parser* in three different ways, advancing to the next if an exception occurs: 1) Pass one or more arrays (as defined by *parse_dates*) as arguments; 2) concatenate (row-wise) the string values from the columns defined by *parse_dates* into a single array and pass that; and 3) call *date_parser* once for each row using one or more strings (corresponding to the columns defined by *parse_dates*) as arguments.

dayfirst [bool, default False] DD/MM format dates, international and European format.

cache_dates [boolean, default True] If True, use a cache of unique, converted dates to apply the datetime conversion. May produce significant speed-up when parsing duplicate date strings, especially ones with timezone offsets.

New in version 0.25.0.

iterator [bool, default False] Return TextFileReader object for iteration or getting chunks with `get_chunk()`.

chunksize [int, optional] Return TextFileReader object for iteration. See the [IO Tools docs](#) for more information on **iterator** and **chunksize**.

compression [{‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}, default ‘infer’] For on-the-fly decompression of on-disk data. If ‘infer’ and *filepath_or_buffer* is path-like, then detect compression from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’, or ‘.xz’ (otherwise no decompression). If using ‘zip’, the ZIP file must contain only one data file to be read in. Set to None for no decompression.

New in version 0.18.1: support for ‘zip’ and ‘xz’ compression.

thousands [str, optional] Thousands separator.

decimal [str, default ‘.’] Character to recognize as decimal point (e.g. use ‘,’ for European data).

lineterminator [str (length 1), optional] Character to break file into lines. Only valid with C parser.

quotechar [str (length 1), optional] The character used to denote the start and end of a quoted item. Quoted items can include the delimiter and it will be ignored.

quoting [int or csv.QUOTE_* instance, default 0] Control field quoting behavior per `csv.QUOTE_*` constants. Use one of QUOTE_MINIMAL (0), QUOTE_ALL (1), QUOTE_NONNUMERIC (2) or QUOTE_NONE (3).

doublequote [bool, default True] When quotechar is specified and quoting is not QUOTE_NONE, indicate whether or not to interpret two consecutive quotechar elements INSIDE a field as a single quotechar element.

escapechar [str (length 1), optional] One-character string used to escape other characters.

comment [str, optional] Indicates remainder of line should not be parsed. If found at the beginning of a line, the line will be ignored altogether. This parameter must be a single character. Like empty lines (as long as `skip_blank_lines=True`), fully commented lines are ignored by the parameter *header* but not by *skiprows*. For

example, if `comment='#'`, parsing `#empty\na,b,c\n1,2,3` with `header=0` will result in `'a,b,c'` being treated as the header.

encoding [str, optional] Encoding to use for UTF when reading/writing (ex. `'utf-8'`). [List of Python standard encodings](#) .

dialect [str or `csv.Dialect`, optional] If provided, this parameter will override values (default or not) for the following parameters: *delimiter*, *doublequote*, *escapechar*, *skipinitialspace*, *quotechar*, and *quoting*. If it is necessary to override values, a `ParserWarning` will be issued. See `csv.Dialect` documentation for more details.

error_bad_lines [bool, default `True`] Lines with too many fields (e.g. a csv line with too many commas) will by default cause an exception to be raised, and no `DataFrame` will be returned. If `False`, then these “bad lines” will dropped from the `DataFrame` that is returned.

warn_bad_lines [bool, default `True`] If `error_bad_lines` is `False`, and `warn_bad_lines` is `True`, a warning for each “bad line” will be output.

delim_whitespace [bool, default `False`] Specifies whether or not whitespace (e.g. `' '` or `'\s'`) will be used as the sep. Equivalent to setting `sep='\s+'`. If this option is set to `True`, nothing should be passed in for the `delimiter` parameter.

New in version 0.18.1: support for the Python parser.

low_memory [bool, default `True`] Internally process the file in chunks, resulting in lower memory use while parsing, but possibly mixed type inference. To ensure no mixed types either set `False`, or specify the type with the `dtype` parameter. Note that the entire file is read into a single `DataFrame` regardless, use the `chunksize` or `iterator` parameter to return the data in chunks. (Only valid with C parser).

memory_map [bool, default `False`] If a filepath is provided for `filepath_or_buffer`, map the file object directly onto memory and access the data directly from there. Using this option can improve performance because there is no longer any I/O overhead.

float_precision [str, optional] Specifies which converter the C engine should use for floating-point values. The options are *None* for the ordinary converter, *high* for the high-precision converter, and *round_trip* for the round-trip converter.

Returns

DataFrame or TextParser A comma-separated values (csv) file is returned as two-dimensional data structure with labeled axes.

See also:

to_csv Write `DataFrame` to a comma-separated values (csv) file.

read_csv Read a comma-separated values (csv) file into `DataFrame`.

read_fwf Read a table of fixed-width formatted lines into `DataFrame`.

Examples

```
>>> pd.read_csv('data.csv') # doctest: +SKIP
```

pandas.read_fwf

```
pandas.read_fwf(filepath_or_buffer: Union[str, pathlib.Path, IO[~AnyStr]], colspecs='infer',
                widths=None, infer_nrows=100, **kwargs)
```

Read a table of fixed-width formatted lines into DataFrame.

Also supports optionally iterating or breaking of the file into chunks.

Additional help can be found in the [online docs for IO Tools](#).

Parameters

filepath_or_buffer [str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file://localhost/path/to/table.csv`.

If you want to pass in a path object, pandas accepts any `os.PathLike`.

By file-like object, we refer to objects with a `read()` method, such as a file handler (e.g. via builtin `open` function) or `StringIO`.

colspecs [list of tuple (int, int) or 'infer'. optional] A list of tuples giving the extents of the fixed-width fields of each line as half-open intervals (i.e., [from, to[). String value 'infer' can be used to instruct the parser to try detecting the column specifications from the first 100 rows of the data which are not being skipped via `skiprows` (default='infer').

widths [list of int, optional] A list of field widths which can be used instead of 'colspecs' if the intervals are contiguous.

infer_nrows [int, default 100] The number of rows to consider when letting the parser determine the `colspecs`.

New in version 0.24.0.

****kwargs** [optional] Optional keyword arguments can be passed to `TextFileReader`.

Returns

DataFrame or TextParser A comma-separated values (csv) file is returned as two-dimensional data structure with labeled axes.

See also:

to_csv Write DataFrame to a comma-separated values (csv) file.

read_csv Read a comma-separated values (csv) file into DataFrame.

Examples

```
>>> pd.read_fwf('data.csv') # doctest: +SKIP
```

pandas.read_msgpack

```
pandas.read_msgpack(path_or_buf, encoding='utf-8', iterator=False, **kwargs)
```

Load msgpack pandas object from the specified file path.

Deprecated since version 0.25.0.

`read_msgpack` is deprecated and will be removed in a future version. It is recommended to use `pyarrow` for on-the-wire transmission of pandas objects.

Parameters

path_or_buf [str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include `http`, `ftp`, `s3`, and `file`. For file URLs, a host is expected.

If you want to pass in a path object, pandas accepts any `os.PathLike`.

By file-like object, we refer to objects with a `read()` method, such as a file handler (e.g. via builtin `open` function) or `StringIO`.

encoding [Encoding for decoding msgpack str type]

iterator [boolean, if True, return an iterator to the unpacker] (default is False)

Returns

obj [same type as object stored in file]

Notes

`read_msgpack` is only guaranteed to be backwards compatible to pandas 0.20.3.

6.1.3 Clipboard

<code>read_clipboard([sep])</code>	Read text from clipboard and pass to <code>read_csv</code> .
------------------------------------	--

`pandas.read_clipboard`

`pandas.read_clipboard(sep='|s+', **kwargs)`

Read text from clipboard and pass to `read_csv`. See `read_csv` for the full argument list

Parameters

sep [str, default 's+'] A string or regex delimiter. The default of 's+' denotes one or more whitespace characters.

Returns

parsed [DataFrame]

6.1.4 Excel

<code>read_excel(io[, sheet_name, header, names, ...])</code>	Read an Excel file into a pandas DataFrame.
---	---

<code>ExcelFile.parse(self[, sheet_name, header, ...])</code>	Parse specified sheet(s) into a DataFrame
---	---

pandas.read_excel

```
pandas.read_excel(io, sheet_name=0, header=0, names=None, index_col=None, usecols=None, squeeze=False, dtype=None, engine=None, converters=None, true_values=None, false_values=None, skiprows=None, nrows=None, na_values=None, keep_default_na=True, verbose=False, parse_dates=False, date_parser=None, thousands=None, comment=None, skip_footer=0, skip_header=0, convert_float=True, mangle_dupe_cols=True, **kwargs)
```

Read an Excel file into a pandas DataFrame.

Support both *xls* and *xlsx* file extensions from a local filesystem or URL. Support an option to read a single sheet or a list of sheets.

Parameters

io [str, ExcelFile, xlrd.Book, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file://localhost/path/to/table.xlsx`.

If you want to pass in a path object, pandas accepts any `os.PathLike`.

By file-like object, we refer to objects with a `read()` method, such as a file handler (e.g. via builtin `open` function) or `StringIO`.

sheet_name [str, int, list, or None, default 0] Strings are used for sheet names. Integers are used in zero-indexed sheet positions. Lists of strings/integers are used to request multiple sheets. Specify None to get all sheets.

Available cases:

- Defaults to 0: 1st sheet as a *DataFrame*
- 1: 2nd sheet as a *DataFrame*
- "Sheet1": Load sheet with name "Sheet1"
- [0, 1, "Sheet5"]: Load first, second and sheet named "Sheet5" as a dict of *DataFrame*
- None: All sheets.

header [int, list of int, default 0] Row (0-indexed) to use for the column labels of the parsed DataFrame. If a list of integers is passed those row positions will be combined into a `MultiIndex`. Use None if there is no header.

names [array-like, default None] List of column names to use. If file contains no header row, then you should explicitly pass `header=None`.

index_col [int, list of int, default None] Column (0-indexed) to use as the row labels of the DataFrame. Pass None if there is no such column. If a list is passed, those columns will be combined into a `MultiIndex`. If a subset of data is selected with `usecols`, `index_col` is based on the subset.

usecols [int, str, list-like, or callable default None] Return a subset of the columns.

- If None, then parse all columns.
- If int, then indicates last column to be parsed.

Deprecated since version 0.24.0: Pass in a list of int instead from 0 to `usecols` inclusive.

- If `str`, then indicates comma separated list of Excel column letters and column ranges (e.g. “A:E” or “A,C,E:F”). Ranges are inclusive of both sides.
- If list of int, then indicates list of column numbers to be parsed.
- If list of string, then indicates list of column names to be parsed.

New in version 0.24.0.

- If callable, then evaluate each column name against it and parse the column if the callable returns `True`.

New in version 0.24.0.

squeeze [bool, default False] If the parsed data only contains one column then return a Series.

dtype [Type name or dict of column -> type, default None] Data type for data or columns. E.g. {'a': np.float64, 'b': np.int32} Use *object* to preserve data as stored in Excel and not interpret dtype. If converters are specified, they will be applied INSTEAD of dtype conversion.

New in version 0.20.0.

engine [str, default None] If io is not a buffer or path, this must be set to identify io. Acceptable values are None or xldr.

converters [dict, default None] Dict of functions for converting values in certain columns. Keys can either be integers or column labels, values are functions that take one input argument, the Excel cell content, and return the transformed content.

true_values [list, default None] Values to consider as True.

New in version 0.19.0.

false_values [list, default None] Values to consider as False.

New in version 0.19.0.

skiprows [list-like] Rows to skip at the beginning (0-indexed).

nrows [int, default None] Number of rows to parse.

New in version 0.23.0.

na_values [scalar, str, list-like, or dict, default None] Additional strings to recognize as NA/NaN. If dict passed, specific per-column NA values. By default the following values are interpreted as NaN: ‘’, ‘#N/A’, ‘#N/A N/A’, ‘#NA’, ‘-1.#IND’, ‘-1.#QNAN’, ‘-NaN’, ‘-nan’, ‘1.#IND’, ‘1.#QNAN’, ‘N/A’, ‘NA’, ‘NULL’, ‘NaN’, ‘n/a’, ‘nan’, ‘null’.

keep_default_na [bool, default True] If `na_values` are specified and `keep_default_na` is False the default NaN values are overridden, otherwise they're appended to.

verbose [bool, default False] Indicate number of NA values placed in non-numeric columns.

parse_dates [bool, list-like, or dict, default False] The behavior is as follows:

- bool. If True -> try parsing the index.
- list of int or names. e.g. If [1, 2, 3] -> try parsing columns 1, 2, 3 each as a separate date column.

- list of lists. e.g. If `[[1, 3]]` -> combine columns 1 and 3 and parse as a single date column.
- dict, e.g. `{'foo' : [1, 3]}` -> parse columns 1, 3 as date and call result 'foo'

If a column or index contains an unparseable date, the entire column or index will be returned unaltered as an object data type. For non-standard datetime parsing, use `pd.to_datetime` after `pd.read_excel`.

Note: A fast-path exists for iso8601-formatted dates.

date_parser [function, optional] Function to use for converting a sequence of string columns to an array of datetime instances. The default uses `dateutil.parser.parser` to do the conversion. Pandas will try to call `date_parser` in three different ways, advancing to the next if an exception occurs: 1) Pass one or more arrays (as defined by `parse_dates`) as arguments; 2) concatenate (row-wise) the string values from the columns defined by `parse_dates` into a single array and pass that; and 3) call `date_parser` once for each row using one or more strings (corresponding to the columns defined by `parse_dates`) as arguments.

thousands [str, default None] Thousands separator for parsing string columns to numeric. Note that this parameter is only necessary for columns stored as TEXT in Excel, any numeric columns will automatically be parsed, regardless of display format.

comment [str, default None] Comments out remainder of line. Pass a character or characters to this argument to indicate comments in the input file. Any data between the comment string and the end of the current line is ignored.

skip_footer [int, default 0] Alias of `skipfooter`.

Deprecated since version 0.23.0: Use `skipfooter` instead.

skipfooter [int, default 0] Rows at the end to skip (0-indexed).

convert_float [bool, default True] Convert integral floats to int (i.e., 1.0 -> 1). If False, all numeric data will be read in as floats: Excel stores all numbers as floats internally.

mangle_dupe_cols [bool, default True] Duplicate columns will be specified as 'X', 'X.1', ...'X.N', rather than 'X...'X'. Passing in False will cause data to be overwritten if there are duplicate names in the columns.

****kwargs** [optional] Optional keyword arguments can be passed to `TextFileReader`.

Returns

DataFrame or dict of DataFrames DataFrame from the passed in Excel file. See notes in `sheet_name` argument for more information on when a dict of DataFrames is returned.

See also:

to_excel Write DataFrame to an Excel file.

to_csv Write DataFrame to a comma-separated values (csv) file.

read_csv Read a comma-separated values (csv) file into DataFrame.

read_fwf Read a table of fixed-width formatted lines into DataFrame.

Examples

The file can be read using the file name as string or an open file object:

```
>>> pd.read_excel('tmp.xlsx', index_col=0) # doctest: +SKIP
   Name  Value
0  string1    1
1  string2    2
2  #Comment    3
```

```
>>> pd.read_excel(open('tmp.xlsx', 'rb'),
...               sheet_name='Sheet3') # doctest: +SKIP
   Unnamed: 0  Name  Value
0           0  string1    1
1           1  string2    2
2           2  #Comment    3
```

Index and header can be specified via the *index_col* and *header* arguments

```
>>> pd.read_excel('tmp.xlsx', index_col=None, header=None) # doctest: +SKIP
   0      1      2
0 NaN      Name  Value
1 0.0  string1    1
2 1.0  string2    2
3 2.0  #Comment    3
```

Column types are inferred but can be explicitly specified

```
>>> pd.read_excel('tmp.xlsx', index_col=0,
...               dtype={'Name': str, 'Value': float}) # doctest: +SKIP
   Name  Value
0  string1  1.0
1  string2  2.0
2  #Comment  3.0
```

True, False, and NA values, and thousands separators have defaults, but can be explicitly specified, too. Supply the values you would like as strings or lists of strings!

```
>>> pd.read_excel('tmp.xlsx', index_col=0,
...               na_values=['string1', 'string2']) # doctest: +SKIP
   Name  Value
0     NaN    1
1     NaN    2
2  #Comment    3
```

Comment lines in the excel input file can be skipped using the *comment* kwarg

```
>>> pd.read_excel('tmp.xlsx', index_col=0, comment='#') # doctest: +SKIP
   Name  Value
0  string1  1.0
1  string2  2.0
2     None  NaN
```

pandas.ExcelFile.parse

```
ExcelFile.parse(self, sheet_name=0, header=0, names=None, index_col=None, usecols=None,
                squeeze=False, converters=None, true_values=None, false_values=None,
                skiprows=None, nrows=None, na_values=None, parse_dates=False,
                date_parser=None, thousands=None, comment=None, skipfooter=0,
                vert_float=True, mangle_dupe_cols=True, **kwds)
```

Parse specified sheet(s) into a DataFrame

Equivalent to `read_excel(ExcelFile, ...)` See the `read_excel` docstring for more info on accepted parameters

Returns

DataFrame or dict of DataFrames DataFrame from the passed in Excel file.

ExcelWriter(path[, engine, date_format, ...]) Class for writing DataFrame objects into excel sheets, default is to use xlwt for xls, openpyxl for xlsx.

pandas.ExcelWriter

```
class pandas.ExcelWriter(path, engine=None, date_format=None, datetime_format=None,
                        mode='w', **engine_kwargs)
```

Class for writing DataFrame objects into excel sheets, default is to use xlwt for xls, openpyxl for xlsx. See `DataFrame.to_excel` for typical usage.

Parameters

path [string] Path to xls or xlsx file.

engine [string (optional)] Engine to use for writing. If None, defaults to `io.excel.<extension>.writer`. NOTE: can only be passed as a keyword argument.

date_format [string, default None] Format string for dates written into Excel files (e.g. 'YYYY-MM-DD')

datetime_format [string, default None] Format string for datetime objects written into Excel files (e.g. 'YYYY-MM-DD HH:MM:SS')

mode [{ 'w', 'a' }, default 'w'] File mode to use (write or append).

New in version 0.24.0.

Notes

None of the methods and properties are considered public.

For compatibility with CSV writers, `ExcelWriter` serializes lists and dicts to strings before writing.

Examples

Default usage:

```
>>> with ExcelWriter('path_to_file.xlsx') as writer:
...     df.to_excel(writer)
```

To write to separate sheets in a single file:

```
>>> with ExcelWriter('path_to_file.xlsx') as writer:
...     df1.to_excel(writer, sheet_name='Sheet1')
...     df2.to_excel(writer, sheet_name='Sheet2')
```

You can set the date format or datetime format:

```
>>> with ExcelWriter('path_to_file.xlsx',
...                 date_format='YYYY-MM-DD',
...                 datetime_format='YYYY-MM-DD HH:MM:SS') as writer:
...     df.to_excel(writer)
```

You can also append to an existing Excel file:

```
>>> with ExcelWriter('path_to_file.xlsx', mode='a') as writer:
...     df.to_excel(writer, sheet_name='Sheet3')
```

Attributes

None	
------	--

Methods

None	
------	--

6.1.5 JSON

`read_json([path_or_buf, orient, typ, dtype, ...])` Convert a JSON string to pandas object.

pandas.read_json

`pandas.read_json(path_or_buf=None, orient=None, typ='frame', dtype=None, convert_axes=None, convert_dates=True, keep_default_dates=True, numpy=False, precise_float=False, date_unit=None, encoding=None, lines=False, chunksize=None, compression='infer')`

Convert a JSON string to pandas object.

Parameters

path_or_buf [a valid JSON str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file://localhost/path/to/table.json`.

If you want to pass in a path object, pandas accepts any `os.PathLike`.

By file-like object, we refer to objects with a `read()` method, such as a file handler (e.g. via builtin `open` function) or `StringIO`.

orient [string,] Indication of expected JSON string format. Compatible JSON strings

can be produced by `to_json()` with a corresponding `orient` value. The set of possible `orient`s is:

- `'split'` : dict like `{index -> [index], columns -> [columns], data -> [values]}`
- `'records'` : list like `[{column -> value}, ... , {column -> value}]`
- `'index'` : dict like `{index -> {column -> value}}`
- `'columns'` : dict like `{column -> {index -> value}}`
- `'values'` : just the values array

The allowed and default values depend on the value of the `typ` parameter.

- when `typ == 'series'`,
 - allowed `orient`s are `{'split', 'records', 'index'}`
 - default is `'index'`
 - The Series index must be unique for `orient 'index'`.
- when `typ == 'frame'`,
 - allowed `orient`s are `{'split', 'records', 'index', 'columns', 'values', 'table'}`
 - default is `'columns'`
 - The DataFrame index must be unique for `orient 'index'` and `'columns'`.
 - The DataFrame columns must be unique for `orient 'index', 'columns', and 'records'`.

New in version 0.23.0: `'table'` as an allowed value for the `orient` argument

typ [`{'frame', 'series'}`, default `'frame'`] The type of object to recover.

dtype [`bool` or `dict`, default `None`] If `True`, infer dtypes; if a `dict` of column to `dtype`, then use those; if `False`, then don't infer dtypes at all, applies only to the data.

For all `orient` values except `'table'`, default is `True`.

Changed in version 0.25.0: Not applicable for `orient='table'`.

convert_axes [`bool`, default `None`] Try to convert the axes to the proper dtypes.

For all `orient` values except `'table'`, default is `True`.

Changed in version 0.25.0: Not applicable for `orient='table'`.

convert_dates [`bool` or list of `str`, default `True`] List of columns to parse for dates. If `True`, then try to parse datelike columns. A column label is datelike if

- it ends with `'_at'`,
- it ends with `'_time'`,
- it begins with `'timestamp'`,
- it is `'modified'`, or
- it is `'date'`.

keep_default_dates [`bool`, default `True`] If parsing dates, then parse the default date-like columns.

numpy [bool, default False] Direct decoding to numpy arrays. Supports numeric data only, but non-numeric column and index labels are supported. Note also that the JSON ordering MUST be the same for each term if `numpy=True`.

precise_float [bool, default False] Set to enable usage of higher precision (`strtod`) function when decoding string to double values. Default (False) is to use fast but less precise builtin functionality.

date_unit [str, default None] The timestamp unit to detect if converting dates. The default behaviour is to try and detect the correct precision, but if this is not desired then pass one of 's', 'ms', 'us' or 'ns' to force parsing only seconds, milliseconds, microseconds or nanoseconds respectively.

encoding [str, default is 'utf-8'] The encoding to use to decode py3 bytes.

New in version 0.19.0.

lines [bool, default False] Read the file as a json object per line.

New in version 0.19.0.

chunksize [int, optional] Return `JsonReader` object for iteration. See the [line-delimited json docs](#) for more information on `chunksize`. This can only be passed if `lines=True`. If this is None, the file will be read into memory all at once.

New in version 0.21.0.

compression [{ 'infer', 'gzip', 'bz2', 'zip', 'xz', None }, default 'infer'] For on-the-fly decompression of on-disk data. If 'infer', then use gzip, bz2, zip or xz if `path_or_buf` is a string ending in '.gz', '.bz2', '.zip', or '.xz', respectively, and no decompression otherwise. If using 'zip', the ZIP file must contain only one data file to be read in. Set to None for no decompression.

New in version 0.21.0.

Returns

Series or DataFrame The type returned depends on the value of `typ`.

See also:

`DataFrame.to_json` Convert a DataFrame to a JSON string.

`Series.to_json` Convert a Series to a JSON string.

Notes

Specific to `orient='table'`, if a `DataFrame` with a literal `Index` name of `index` gets written with `to_json()`, the subsequent read operation will incorrectly set the `Index` name to `None`. This is because `index` is also used by `DataFrame.to_json()` to denote a missing `Index` name, and the subsequent `read_json()` operation cannot distinguish between the two. The same limitation is encountered with a `MultiIndex` and any names beginning with `'level_'`.

Examples

```
>>> df = pd.DataFrame([[ 'a', 'b'], [ 'c', 'd']],
...                   index=[ 'row 1', 'row 2'],
...                   columns=[ 'col 1', 'col 2'])
```

Encoding/decoding a Dataframe using 'split' formatted JSON:

```
>>> df.to_json(orient='split')
'{"columns":["col 1","col 2"],
  "index":["row 1","row 2"],
  "data":[["a","b"],["c","d"]}]'
>>> pd.read_json(_, orient='split')
   col 1 col 2
row 1    a    b
row 2    c    d
```

Encoding/decoding a Dataframe using 'index' formatted JSON:

```
>>> df.to_json(orient='index')
'{"row 1":{"col 1":"a","col 2":"b"},"row 2":{"col 1":"c","col 2":"d"}}'
>>> pd.read_json(_, orient='index')
   col 1 col 2
row 1    a    b
row 2    c    d
```

Encoding/decoding a Dataframe using 'records' formatted JSON. Note that index labels are not preserved with this encoding.

```
>>> df.to_json(orient='records')
'[{"col 1":"a","col 2":"b"}, {"col 1":"c","col 2":"d"}]'
>>> pd.read_json(_, orient='records')
   col 1 col 2
0      a    b
1      c    d
```

Encoding with Table Schema

```
>>> df.to_json(orient='table')
'{"schema": {"fields": [{"name": "index", "type": "string"},
                       {"name": "col 1", "type": "string"},
                       {"name": "col 2", "type": "string"}],
  "primaryKey": "index",
  "pandas_version": "0.20.0"},
  "data": [{"index": "row 1", "col 1": "a", "col 2": "b"},
           {"index": "row 2", "col 1": "c", "col 2": "d"}]}'
```

<code>json_normalize(data, List[Dict], ...)</code>	Normalize semi-structured JSON data into a flat table.
<code>build_table_schema(data[, index, ...])</code>	Create a Table schema from <code>data</code> .

pandas.io.json.json_normalize

```
pandas.io.json.json_normalize(data: Union[Dict, List[Dict]], record_path: Union[str, List, NoneType] = None, meta: Union[str, List, NoneType] = None, meta_prefix: Union[str, NoneType] = None, record_prefix: Union[str, NoneType] = None, errors: Union[str, NoneType] = 'raise', sep: str = '.', max_level: Union[int, NoneType] = None)
```

Normalize semi-structured JSON data into a flat table.

Parameters

- data** [dict or list of dicts] Unserialized JSON objects.
- record_path** [str or list of str, default None] Path in each object to list of records. If not passed, data will be assumed to be an array of records.
- meta** [list of paths (str or list of str), default None] Fields to use as metadata for each record in resulting table.
- meta_prefix** [str, default None] If True, prefix records with dotted (?) path, e.g. foo.bar.field if meta is ['foo', 'bar'].
- record_prefix** [str, default None] If True, prefix records with dotted (?) path, e.g. foo.bar.field if path to records is ['foo', 'bar'].
- errors** [{'raise', 'ignore'}, default 'raise'] Configures error handling.
- 'ignore': will ignore KeyError if keys listed in meta are not always present.
 - 'raise': will raise KeyError if keys listed in meta are not always present.
- New in version 0.20.0.
- sep** [str, default ']'] Nested records will generate names separated by sep. e.g., for sep=".", {'foo': {'bar': 0}} -> foo.bar.
- New in version 0.20.0.
- max_level** [int, default None] Max number of levels(depth of dict) to normalize. if None, normalizes all levels.
- New in version 0.25.0.

Returns

frame [DataFrame]

Normalize semi-structured JSON data into a flat table.

Examples

```
>>> from pandas.io.json import json_normalize
>>> data = [{ 'id': 1, 'name': { 'first': 'Coleen', 'last': 'Volk' } },
...         { 'name': { 'given': 'Mose', 'family': 'Regner' } },
...         { 'id': 2, 'name': 'Faye Raker' } ]
>>> json_normalize(data)
   id  name  name.family  name.first  name.given  name.last
0  1.0    NaN          NaN    Coleen         NaN         Volk
1  NaN    NaN        Regner         NaN         Mose         NaN
2  2.0  Faye Raker         NaN         NaN         NaN         NaN
```

```
>>> data = [{ 'id': 1,
...           'name': "Cole Volk",
...           'fitness': { 'height': 130, 'weight': 60 } },
...         { 'name': "Mose Reg",
...           'fitness': { 'height': 130, 'weight': 60 } },
...         { 'id': 2, 'name': 'Faye Raker',
...           'fitness': { 'height': 130, 'weight': 60 } } ]
>>> json_normalize(data, max_level=0)
```

(continues on next page)

(continued from previous page)

	fitness	id	name
0	{'height': 130, 'weight': 60}	1.0	Cole Volk
1	{'height': 130, 'weight': 60}	NaN	Mose Reg
2	{'height': 130, 'weight': 60}	2.0	Faye Raker

Normalizes nested data upto level 1.

```
>>> data = [{'id': 1,
...         'name': "Cole Volk",
...         'fitness': {'height': 130, 'weight': 60}},
...         {'name': "Mose Reg",
...         'fitness': {'height': 130, 'weight': 60}},
...         {'id': 2, 'name': 'Faye Raker',
...         'fitness': {'height': 130, 'weight': 60}}]
>>> json_normalize(data, max_level=1)
  fitness.height  fitness.weight  id  name
0      130             60      1.0  Cole Volk
1      130             60      NaN  Mose Reg
2      130             60      2.0  Faye Raker
```

```
>>> data = [{'state': 'Florida',
...         'shortname': 'FL',
...         'info': {'governor': 'Rick Scott'},
...         'counties': [{'name': 'Dade', 'population': 12345},
...                       {'name': 'Broward', 'population': 40000},
...                       {'name': 'Palm Beach', 'population': 60000}]},
...         {'state': 'Ohio',
...         'shortname': 'OH',
...         'info': {'governor': 'John Kasich'},
...         'counties': [{'name': 'Summit', 'population': 1234},
...                       {'name': 'Cuyahoga', 'population': 1337}]}]
>>> result = json_normalize(data, 'counties', ['state', 'shortname',
...                                             ['info', 'governor']])
>>> result
   name  population  state shortname  info.governor
0    Dade    12345  Florida      FL    Rick Scott
1  Broward    40000  Florida      FL    Rick Scott
2  Palm Beach  60000  Florida      FL    Rick Scott
3    Summit    1234   Ohio      OH    John Kasich
4  Cuyahoga    1337   Ohio      OH    John Kasich
```

```
>>> data = {'A': [1, 2]}
>>> json_normalize(data, 'A', record_prefix='Prefix.')
  Prefix.0
0         1
1         2
```

Returns normalized data with columns prefixed with the given string.

pandas.io.json.build_table_schema

`pandas.io.json.build_table_schema(data, index=True, primary_key=None, version=True)`
Create a Table schema from data.

Parameters

data [Series, DataFrame]

index [bool, default True] Whether to include `data.index` in the schema.

primary_key [bool or None, default True] column names to designate as the primary key. The default *None* will set *'primaryKey'* to the index level or levels if the index is unique.

version [bool, default True] Whether to include a field *pandas_version* with the version of pandas that generated the schema.

Returns

schema [dict]

Notes

See *_as_json_table_type* for conversion types. Timedeltas as converted to ISO8601 duration format with 9 decimal places after the seconds field for nanosecond precision.

Categoricals are converted to the *any* dtype, and use the *enum* field constraint to list the allowed values. The *ordered* attribute is included in an *ordered* field.

Examples

```
>>> df = pd.DataFrame(
...     {'A': [1, 2, 3],
...      'B': ['a', 'b', 'c'],
...      'C': pd.date_range('2016-01-01', freq='d', periods=3),
...     }, index=pd.Index(range(3), name='idx'))
>>> build_table_schema(df)
{'fields': [{'name': 'idx', 'type': 'integer'},
{'name': 'A', 'type': 'integer'},
{'name': 'B', 'type': 'string'},
{'name': 'C', 'type': 'datetime'}],
'pandas_version': '0.20.0',
'primaryKey': ['idx']}
```

6.1.6 HTML

`read_html(io[, match, flavor, header, ...])`

Read HTML tables into a list of DataFrame objects.

pandas.read_html

`pandas.read_html(io, match='.+', flavor=None, header=None, index_col=None, skiprows=None, attrs=None, parse_dates=False, thousands=', ', encoding=None, decimal='.', converters=None, na_values=None, keep_default_na=True, displayed_only=True)`
 Read HTML tables into a list of `DataFrame` objects.

Parameters

io [str, path object or file-like object] A URL, a file-like object, or a raw string containing HTML. Note that `lxml` only accepts the `http`, `ftp` and `file` url protocols. If you have a URL that starts with `'https'` you might try removing the `'s'`.

match [str or compiled regular expression, optional] The set of tables containing text matching this regex or string will be returned. Unless the HTML is extremely simple you will probably need to pass a non-empty string here. Defaults to `‘.+’` (match any non-empty string). The default value will return all tables contained on a page. This value is converted to a regular expression so that there is consistent behavior between `Beautiful Soup` and `lxml`.

flavor [str or None, container of strings] The parsing engine to use. `‘bs4’` and `‘html5lib’` are synonymous with each other, they are both there for backwards compatibility. The default of `None` tries to use `lxml` to parse and if that fails it falls back on `bs4 + html5lib`.

header [int or list-like or None, optional] The row (or list of rows for a *MultiIndex*) to use to make the columns headers.

index_col [int or list-like or None, optional] The column (or list of columns) to use to create the index.

skiprows [int or list-like or slice or None, optional] 0-based. Number of rows to skip after parsing the column integer. If a sequence of integers or a slice is given, will skip the rows indexed by that sequence. Note that a single element sequence means ‘skip the nth row’ whereas an integer means ‘skip n rows’.

attrs [dict or None, optional] This is a dictionary of attributes that you can pass to use to identify the table in the HTML. These are not checked for validity before being passed to `lxml` or `Beautiful Soup`. However, these attributes must be valid HTML table attributes to work correctly. For example,

```
attrs = {'id': 'table'}
```

is a valid attribute dictionary because the `‘id’` HTML tag attribute is a valid HTML attribute for *any* HTML tag as per [this document](#).

```
attrs = {'asdf': 'table'}
```

is *not* a valid attribute dictionary because `‘asdf’` is not a valid HTML attribute even if it is a valid XML attribute. Valid HTML 4.01 table attributes can be found [here](#). A working draft of the HTML 5 spec can be found [here](#). It contains the latest information on table attributes for the modern web.

parse_dates [bool, optional] See `read_csv()` for more details.

thousands [str, optional] Separator to use to parse thousands. Defaults to `‘,’`.

encoding [str or None, optional] The encoding used to decode the web page. Defaults to `None`:`‘None’` preserves the previous encoding behavior, which depends on the

underlying parser library (e.g., the parser library will try to use the encoding provided by the document).

decimal [str, default ':'] Character to recognize as decimal point (e.g. use ',' for European data).

New in version 0.19.0.

converters [dict, default None] Dict of functions for converting values in certain columns. Keys can either be integers or column labels, values are functions that take one input argument, the cell (not column) content, and return the transformed content.

New in version 0.19.0.

na_values [iterable, default None] Custom NA values

New in version 0.19.0.

keep_default_na [bool, default True] If na_values are specified and keep_default_na is False the default NaN values are overridden, otherwise they're appended to

New in version 0.19.0.

displayed_only [bool, default True] Whether elements with "display: none" should be parsed

New in version 0.23.0.

Returns

dfs [list of DataFrames]

See also:

read_csv

Notes

Before using this function you should read the *gotchas about the HTML parsing libraries*.

Expect to do some cleanup after you call this function. For example, you might need to manually assign column names if the column names are converted to NaN when you pass the *header=0* argument. We try to assume as little as possible about the structure of the table and push the idiosyncrasies of the HTML contained in the table to the user.

This function searches for `<table>` elements and only for `<tr>` and `<th>` rows and `<td>` elements within each `<tr>` or `<th>` element in the table. `<td>` stands for "table data". This function attempts to properly handle `colspan` and `rowspan` attributes. If the function has a `<thead>` argument, it is used to construct the header, otherwise the function attempts to find the header within the body (by putting rows with only `<th>` elements into the header).

New in version 0.21.0.

Similar to *read_csv()* the *header* argument is applied **after** *skiprows* is applied.

This function will *always* return a list of *DataFrame* or it will fail, e.g., it will *not* return an empty list.

Examples

See the *read_html documentation in the IO section of the docs* for some examples of reading in HTML tables.

6.1.7 HDFStore: PyTables (HDF5)

<code>read_hdf(path_or_buf[, key, mode])</code>	Read from the store, close it if we opened it.
<code>HDFStore.put(self, key, value[, format, append])</code>	Store object in HDFStore
<code>HDFStore.append(self, key, value[, format, ...])</code>	Append to Table in file.
<code>HDFStore.get(self, key)</code>	Retrieve pandas object stored in file
<code>HDFStore.select(self, key[, where, start, ...])</code>	Retrieve pandas object stored in file, optionally based on where criteria
<code>HDFStore.info(self)</code>	Print detailed information on the store.
<code>HDFStore.keys(self)</code>	Return a (potentially unordered) list of the keys corresponding to the objects stored in the HDFStore.
<code>HDFStore.groups(self)</code>	return a list of all the top-level nodes (that are not themselves a pandas storage object)
<code>HDFStore.walk(self[, where])</code>	Walk the pytables group hierarchy for pandas objects

pandas.read_hdf

`pandas.read_hdf(path_or_buf, key=None, mode='r', **kwargs)`

Read from the store, close it if we opened it.

Retrieve pandas object stored in file, optionally based on where criteria

Parameters

path_or_buf [str, path object, pandas.HDFStore or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file://localhost/path/to/table.h5`.

If you want to pass in a path object, pandas accepts any `os.PathLike`.

Alternatively, pandas accepts an open `pandas.HDFStore` object.

By file-like object, we refer to objects with a `read()` method, such as a file handler (e.g. via builtin `open` function) or `StringIO`.

New in version 0.19.0: support for `pathlib`, `py.path`.

New in version 0.21.0: support for `__fspath__` protocol.

key [object, optional] The group identifier in the store. Can be omitted if the HDF file contains a single pandas object.

mode [{‘r’, ‘r+’, ‘a’}, optional] Mode to use when opening the file. Ignored if `path_or_buf` is a `pandas.HDFStore`. Default is ‘r’.

where [list, optional] A list of Term (or convertible) objects.

start [int, optional] Row number to start selection.

stop [int, optional] Row number to stop selection.

columns [list, optional] A list of columns names to return.

iterator [bool, optional] Return an iterator object.

chunksize [int, optional] Number of rows to include in an iteration when using an iterator.

errors [str, default 'strict'] Specifies how encoding and decoding errors are to be handled. See the errors argument for `open()` for a full list of options.

****kwargs** Additional keyword arguments passed to HDFStore.

Returns

item [object] The selected object. Return type depends on the object stored.

See also:

DataFrame.to_hdf Write a HDF file from a DataFrame.

HDFStore Low-level access to HDF files.

Examples

```
>>> df = pd.DataFrame([[1, 1.0, 'a']], columns=['x', 'y', 'z'])
>>> df.to_hdf('./store.h5', 'data')
>>> reread = pd.read_hdf('./store.h5')
```

pandas.HDFStore.put

`HDFStore.put(self, key, value, format=None, append=False, **kwargs)`
Store object in HDFStore

Parameters

key [object]

value [{Series, DataFrame}]

format ['fixed(f)|table(t)', default is 'fixed']

fixed(f) [Fixed format] Fast writing/reading. Not-appendable, nor searchable

table(t) [Table format] Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data

append [boolean, default False] This will force Table format, append the input data to the existing.

data_columns [list of columns to create as data columns, or True to] use all columns. See [here](#).

encoding [default None, provide an encoding for strings]

dropna [boolean, default False, do not write an ALL nan row to] the store settable by the option 'io.hdf.dropna_table'

pandas.HDFStore.append

`HDFStore.append(self, key, value, format=None, append=True, columns=None, dropna=None, **kwargs)`

Append to Table in file. Node must already exist and be Table format.

Parameters

key [object]

value [{Series, DataFrame}]

format ['table' is the default]

table(t) [table format] Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data

append [boolean, default True, append the input data to the] existing

data_columns [list of columns, or True, default None] List of columns to create as indexed data columns for on-disk queries, or True to use all columns. By default only the axes of the object are indexed. See [here](#).

min_itemsize [dict of columns that specify minimum string sizes]

nan_rep [string to use as string nan representation]

chunksize [size to chunk the writing]

expectedrows [expected TOTAL row size of this table]

encoding [default None, provide an encoding for strings]

dropna [boolean, default False, do not write an ALL nan row to] the store settable by the option 'io.hdf.dropna_table'

Notes

Does *not* check if data being appended overlaps with existing data in the table, so be careful

pandas.HDFStore.get

`HDFStore.get(self, key)`
Retrieve pandas object stored in file

Parameters

key [object]

Returns

obj [same type as object stored in file]

pandas.HDFStore.select

`HDFStore.select(self, key, where=None, start=None, stop=None, columns=None, iterator=False, chunksize=None, auto_close=False, **kwargs)`
Retrieve pandas object stored in file, optionally based on where criteria

Parameters

key [object]

where [list of Term (or convertible) objects, optional]

start [integer (defaults to None), row number to start selection]

stop [integer (defaults to None), row number to stop selection]

columns [a list of columns that if not None, will limit the return] columns

iterator [boolean, return an iterator, default False]

chunksize [nrows to include in iteration, return an iterator]

auto_close [boolean, should automatically close the store when] finished, default is False

Returns

The selected object

pandas.HDFStore.info

`HDFStore.info(self)`

Print detailed information on the store.

New in version 0.21.0.

Returns

str

pandas.HDFStore.keys

`HDFStore.keys(self)`

Return a (potentially unordered) list of the keys corresponding to the objects stored in the HDFStore. These are ABSOLUTE path-names (e.g. have the leading '/')

Returns

list

pandas.HDFStore.groups

`HDFStore.groups(self)`

return a list of all the top-level nodes (that are not themselves a pandas storage object)

Returns

list

pandas.HDFStore.walk

`HDFStore.walk(self, where='/')`

Walk the pytables group hierarchy for pandas objects

This generator will yield the group path, subgroups and pandas object names for each group. Any non-pandas PyTables objects that are not a group will be ignored.

The *where* group itself is listed first (preorder), then each of its child groups (following an alphanumeric order) is also traversed, following the same procedure.

New in version 0.24.0.

Parameters

where [str, optional] Group where to start walking. If not supplied, the root group is used.

Yields

path [str] Full path to a group (without trailing '/')
groups [list of str] names of the groups contained in *path*
leaves [list of str] names of the pandas objects contained in *path*

6.1.8 Feather

`read_feather(path[, columns, use_threads])` Load a feather-format object from the file path.

pandas.read_feather

`pandas.read_feather(path, columns=None, use_threads=True)`
Load a feather-format object from the file path.

Parameters

path [str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file://localhost/path/to/table.feather`.

If you want to pass in a path object, pandas accepts any `os.PathLike`.

By file-like object, we refer to objects with a `read()` method, such as a file handler (e.g. via builtin `open` function) or `StringIO`.

columns [sequence, default None] If not provided, all columns are read.

nthreads [int, default 1]

Number of CPU threads to use when reading to `pandas.DataFrame`.

use_threads [bool, default True]

Whether to parallelize reading using multiple threads.

Returns

type of object stored in file

6.1.9 Parquet

`read_parquet(path[, engine, columns])` Load a parquet object from the file path, returning a `DataFrame`.

pandas.read_parquet

`pandas.read_parquet(path, engine='auto', columns=None, **kwargs)`
Load a parquet object from the file path, returning a `DataFrame`.

Parameters

path [str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file://localhost/path/to/table.parquet`.

If you want to pass in a path object, pandas accepts any `os.PathLike`.

By file-like object, we refer to objects with a `read()` method, such as a file handler (e.g. via builtin `open` function) or `StringIO`.

engine [`{'auto', 'pyarrow', 'fastparquet'}`, default `'auto'`] Parquet library to use. If `'auto'`, then the option `io.parquet.engine` is used. The default `io.parquet.engine` behavior is to try `'pyarrow'`, falling back to `'fastparquet'` if `'pyarrow'` is unavailable.

columns [list, default=`None`] If not `None`, only these columns will be read from the file.

****kwargs** Any additional kwargs are passed to the engine.

Returns

DataFrame

6.1.10 SAS

<code>read_sas</code> (<i>filepath_or_buffer</i> [, <i>format</i> , ...])	Read SAS files stored as either XPORT or SAS7BDAT format files.
--	---

pandas.read_sas

`pandas.read_sas`(*filepath_or_buffer*, *format=None*, *index=None*, *encoding=None*, *chunksize=None*, *iterator=False*)

Read SAS files stored as either XPORT or SAS7BDAT format files.

Parameters

filepath_or_buffer [str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include `http`, `ftp`, `s3`, and `file`. For file URLs, a host is expected. A local file could be: `file://localhost/path/to/table.sas`.

If you want to pass in a path object, pandas accepts any `os.PathLike`.

By file-like object, we refer to objects with a `read()` method, such as a file handler (e.g. via builtin `open` function) or `StringIO`.

format [string `{'xport', 'sas7bdat'}` or `None`] If `None`, file format is inferred from file extension. If `'xport'` or `'sas7bdat'`, uses the corresponding format.

index [identifier of index column, defaults to `None`] Identifier of column that should be used as index of the `DataFrame`.

encoding [string, default is `None`] Encoding for text data. If `None`, text data are stored as raw bytes.

chunksize [int] Read file *chunksize* lines at a time, returns iterator.

iterator [bool, defaults to `False`] If `True`, returns an iterator for reading the file incrementally.

Returns

DataFrame if `iterator=False` and `chunksize=None`, else **SAS7BDATReader** or **XportReader**

6.1.11 SQL

<code>read_sql_table(table_name, con[, schema, ...])</code>	Read SQL database table into a DataFrame.
<code>read_sql_query(sql, con[, index_col, ...])</code>	Read SQL query into a DataFrame.
<code>read_sql(sql, con[, index_col, ...])</code>	Read SQL query or database table into a DataFrame.

6.1.12 Google BigQuery

<code>read_gbq(query[, project_id, index_col, ...])</code>	Load data from Google BigQuery.
--	---------------------------------

pandas.read_gbq

`pandas.read_gbq(query, project_id=None, index_col=None, col_order=None, reauth=False, auth_local_webserver=False, dialect=None, location=None, configuration=None, credentials=None, use_bqstorage_api=None, private_key=None, verbose=None)`
Load data from Google BigQuery.

This function requires the `pandas-gbq` package.

See the [How to authenticate with Google BigQuery](#) guide for authentication instructions.

Parameters

query [str] SQL-Like Query to return data values.

project_id [str, optional] Google BigQuery Account project ID. Optional when available from the environment.

index_col [str, optional] Name of result column to use for index in results DataFrame.

col_order [list(str), optional] List of BigQuery column names in the desired order for results DataFrame.

reauth [boolean, default False] Force Google BigQuery to re-authenticate the user. This is useful if multiple accounts are used.

auth_local_webserver [boolean, default False] Use the [local webserver flow](#) instead of the [console flow](#) when getting user credentials.

New in version 0.2.0 of pandas-gbq.

dialect [str, default 'legacy'] Note: The default value is changing to 'standard' in a future version.

SQL syntax dialect to use. Value can be one of:

'**legacy**' Use BigQuery's legacy SQL dialect. For more information see [BigQuery Legacy SQL Reference](#).

'**standard**' Use BigQuery's standard SQL, which is compliant with the SQL 2011 standard. For more information see [BigQuery Standard SQL Reference](#).

Changed in version 0.24.0.

location [str, optional] Location where the query job should run. See the [BigQuery locations documentation](#) for a list of available locations. The location must match that of any datasets used in the query.

New in version 0.5.0 of pandas-gbq.

configuration [dict, optional] Query config parameters for job processing. For example:

```
configuration = {'query': {'useQueryCache': False}}
```

For more information see [BigQuery REST API Reference](#).

credentials [google.auth.credentials.Credentials, optional] Credentials for accessing Google APIs. Use this parameter to override default credentials, such as to use Compute Engine `google.auth.compute_engine.Credentials` or Service Account `google.oauth2.service_account.Credentials` directly.

New in version 0.8.0 of pandas-gbq.

New in version 0.24.0.

use_bqstorage_api [bool, default False] Use the [BigQuery Storage API](#) to download query results quickly, but at an increased cost. To use this API, first [enable it in the Cloud Console](#). You must also have the `bigquery.readsessions.create` permission on the project you are billing queries to.

This feature requires version 0.10.0 or later of the `pandas-gbq` package. It also requires the `google-cloud-bigquery-storage` and `fastavro` packages.

New in version 0.25.0.

private_key [str, deprecated] Deprecated in pandas-gbq version 0.8.0. Use the `credentials` parameter and `google.oauth2.service_account.Credentials.from_service_account_info()` or `google.oauth2.service_account.Credentials.from_service_account_file()` instead.

Service account private key in JSON format. Can be file path or string contents. This is useful for remote server authentication (eg. Jupyter/IPython notebook on remote host).

verbose [None, deprecated] Deprecated in pandas-gbq version 0.4.0. Use the [logging module to adjust verbosity instead](#).

Returns

df: DataFrame DataFrame representing results of query.

See also:

`pandas_gbq.read_gbq` This function in the pandas-gbq library.

`DataFrame.to_gbq` Write a DataFrame to Google BigQuery.

6.1.13 STATA

`read_stata(filepath_or_buffer[, ...])` Read Stata file into DataFrame.

pandas.read_stata

```
pandas.read_stata(filepath_or_buffer, convert_dates=True, convert_categoricals=True, encoding=None, index_col=None, convert_missing=False, preserve_dtypes=True, columns=None, order_categoricals=True, chunksize=None, iterator=False)
```

Read Stata file into DataFrame.

Parameters

filepath_or_buffer [str, path object or file-like object] Any valid string path is ac-

ceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file://localhost/path/to/table.dta`.

If you want to pass in a path object, pandas accepts any `os.PathLike`.

By file-like object, we refer to objects with a `read()` method, such as a file handler (e.g. via builtin `open` function) or `StringIO`.

convert_dates [boolean, defaults to True] Convert date variables to DataFrame time values.

convert_categoricals [boolean, defaults to True] Read value labels and convert columns to Categorical/Factor variables.

encoding [string, None or encoding] Encoding used to parse the files. None defaults to latin-1.

index_col [string, optional, default: None] Column to set as index.

convert_missing [boolean, defaults to False] Flag indicating whether to convert missing values to their Stata representations. If False, missing values are replaced with nan. If True, columns containing missing values are returned with object data types and missing values are represented by StataMissingValue objects.

preserve_dtypes [boolean, defaults to True] Preserve Stata datatypes. If False, numeric data are upcast to pandas default types for foreign data (float64 or int64).

columns [list or None] Columns to retain. Columns will be returned in the given order. None returns all columns.

order_categoricals [boolean, defaults to True] Flag indicating whether converted categorical data are ordered.

chunksize [int, default None] Return StataReader object for iterations, returns chunks with given number of lines.

iterator [boolean, default False] Return StataReader object.

Returns

DataFrame or StataReader

See also:

`io.stata.StataReader` Low-level reader for Stata data files.

`DataFrame.to_stata` Export Stata data files.

Examples

Read a Stata dta file:

```
>>> df = pd.read_stata('filename.dta')
```

Read a Stata dta file in 10,000 line chunks:

```
>>> itr = pd.read_stata('filename.dta', chunksize=10000)
>>> for chunk in itr:
...     do_something(chunk)
```

<code>StataReader.data(self, *\kwargs)</code>	(DEPRECATED) Read observations from Stata file, converting them into a dataframe
<code>StataReader.data_label</code>	Return data label of Stata file.
<code>StataReader.value_labels(self)</code>	Return a dict, associating each variable name a dict, associating each value its corresponding label.
<code>StataReader.variable_labels(self)</code>	Return variable labels as a dict, associating each variable name with corresponding label.
<code>StataWriter.write_file(self)</code>	

pandas.io.stata.StataReader.data

`StataReader.data(self, **kwargs)`

Read observations from Stata file, converting them into a dataframe

Deprecated since version This: is a legacy method. Use `read` in new code.

Parameters

convert_dates [boolean, defaults to True] Convert date variables to DataFrame time values.

convert_categoricals [boolean, defaults to True] Read value labels and convert columns to Categorical/Factor variables.

index_col [string, optional, default: None] Column to set as index.

convert_missing [boolean, defaults to False] Flag indicating whether to convert missing values to their Stata representations. If False, missing values are replaced with nan. If True, columns containing missing values are returned with object data types and missing values are represented by StataMissingValue objects.

preserve_dtypes [boolean, defaults to True] Preserve Stata datatypes. If False, numeric data are upcast to pandas default types for foreign data (float64 or int64).

columns [list or None] Columns to retain. Columns will be returned in the given order. None returns all columns.

order_categoricals [boolean, defaults to True] Flag indicating whether converted categorical data are ordered.

Returns

DataFrame

pandas.io.stata.StataReader.data_label

`StataReader.data_label`

Return data label of Stata file.

pandas.io.stata.StataReader.value_labels

`StataReader.value_labels(self)`

Return a dict, associating each variable name a dict, associating each value its corresponding label.

Returns

dict

pandas.io.stata.StataReader.variable_labels`StataReader.variable_labels(self)`

Return variable labels as a dict, associating each variable name with corresponding label.

Returns

dict

pandas.io.stata.StataWriter.write_file`StataWriter.write_file(self)`

{{ header }}

6.2 General functions

6.2.1 Data manipulations

<code>melt(frame[, id_vars, value_vars, var_name, ...])</code>	Unpivot a DataFrame from wide format to long format, optionally leaving identifier variables set.
<code>pivot(data[, index, columns, values])</code>	Return reshaped DataFrame organized by given index / column values.
<code>pivot_table(data[, values, index, columns, ...])</code>	Create a spreadsheet-style pivot table as a DataFrame.
<code>crosstab(index, columns[, values, rownames, ...])</code>	Compute a simple cross tabulation of two (or more) factors.
<code>cut(x, bins[, right, labels, retbins, ...])</code>	Bin values into discrete intervals.
<code>qcut(x, q[, labels, retbins, precision, ...])</code>	Quantile-based discretization function.
<code>merge(left, right[, how, on, left_on, ...])</code>	Merge DataFrame or named Series objects with a database-style join.
<code>merge_ordered(left, right[, on, left_on, ...])</code>	Perform merge with optional filling/interpolation designed for ordered data like time series data.
<code>merge_asof(left, right[, on, left_on, ...])</code>	Perform an asof merge.
<code>concat(objs[, axis, join, join_axes, ...])</code>	Concatenate pandas objects along a particular axis with optional set logic along the other axes.
<code>get_dummies(data[, prefix, prefix_sep, ...])</code>	Convert categorical variable into dummy/indicator variables.
<code>factorize(values[, sort, order, ...])</code>	Encode the object as an enumerated type or categorical variable.
<code>unique(values)</code>	Hash table-based unique.
<code>wide_to_long(df, stubnames, i, j[, sep, suffix])</code>	Wide panel to long format.

pandas.melt`pandas.melt(frame, id_vars=None, value_vars=None, var_name=None, value_name='value', col_level=None)`

Unpivot a DataFrame from wide format to long format, optionally leaving identifier variables set.

This function is useful to massage a DataFrame into a format where one or more columns are identifier variables (*id_vars*), while all other columns, considered measured variables (*value_vars*), are “unpivoted” to the row axis, leaving just two non-identifier columns, ‘variable’ and ‘value’.

Parameters

- frame** [DataFrame]
- id_vars** [tuple, list, or ndarray, optional] Column(s) to use as identifier variables.
- value_vars** [tuple, list, or ndarray, optional] Column(s) to unpivot. If not specified, uses all columns that are not set as *id_vars*.
- var_name** [scalar] Name to use for the ‘variable’ column. If None it uses `frame.columns.name` or ‘variable’.
- value_name** [scalar, default ‘value’] Name to use for the ‘value’ column.
- col_level** [int or string, optional] If columns are a MultiIndex then use this level to melt.

Returns

DataFrame Unpivoted DataFrame.

See also:

`DataFrame.melt`

`pivot_table`

`DataFrame.pivot`

`Series.explode`

Examples

```
>>> df = pd.DataFrame({'A': {0: 'a', 1: 'b', 2: 'c'},
...                   'B': {0: 1, 1: 3, 2: 5},
...                   'C': {0: 2, 1: 4, 2: 6}})
>>> df
   A  B  C
0  a  1  2
1  b  3  4
2  c  5  6
```

```
>>> pd.melt(df, id_vars=['A'], value_vars=['B'])
   A variable  value
0  a         B      1
1  b         B      3
2  c         B      5
```

```
>>> pd.melt(df, id_vars=['A'], value_vars=['B', 'C'])
   A variable  value
0  a         B      1
1  b         B      3
2  c         B      5
3  a         C      2
4  b         C      4
5  c         C      6
```

The names of ‘variable’ and ‘value’ columns can be customized:

```
>>> pd.melt(df, id_vars=['A'], value_vars=['B'],
...         var_name='myVarname', value_name='myValname')
   A myVarname  myValname
0  a          B           1
1  b          B           3
2  c          B           5
```

If you have multi-index columns:

```
>>> df.columns = [list('ABC'), list('DEF')]
>>> df
   A B C
   D E F
0  a 1 2
1  b 3 4
2  c 5 6
```

```
>>> pd.melt(df, col_level=0, id_vars=['A'], value_vars=['B'])
   A variable  value
0  a          B       1
1  b          B       3
2  c          B       5
```

```
>>> pd.melt(df, id_vars=[('A', 'D')], value_vars=[('B', 'E')])
   (A, D) variable_0 variable_1  value
0      a           B           E       1
1      b           B           E       3
2      c           B           E       5
```

pandas.pivot

`pandas.pivot(data, index=None, columns=None, values=None)`

Return reshaped DataFrame organized by given index / column values.

Reshape data (produce a “pivot” table) based on column values. Uses unique values from specified *index* / *columns* to form axes of the resulting DataFrame. This function does not support data aggregation, multiple values will result in a MultiIndex in the columns. See the *User Guide* for more on reshaping.

Parameters

data [DataFrame]

index [string or object, optional] Column to use to make new frame’s index. If None, uses existing index.

columns [string or object] Column to use to make new frame’s columns.

values [string, object or a list of the previous, optional] Column(s) to use for populating new frame’s values. If not specified, all remaining columns will be used and the result will have hierarchically indexed columns.

Changed in version 0.23.0: Also accept list of column names.

Returns

DataFrame Returns reshaped DataFrame.

Raises

ValueError: When there are any *index*, *columns* combinations with multiple values.
DataFrame.pivot_table when you need to aggregate.

See also:

DataFrame.pivot_table Generalization of *pivot* that can handle duplicate values for one index/column pair.

DataFrame.unstack Pivot based on the index values instead of a column.

Notes

For finer-tuned control, see hierarchical indexing documentation along with the related *stack/unstack* methods.

Examples

```
>>> df = pd.DataFrame({'foo': ['one', 'one', 'one', 'two', 'two',
...                             'two'],
...                    'bar': ['A', 'B', 'C', 'A', 'B', 'C'],
...                    'baz': [1, 2, 3, 4, 5, 6],
...                    'zoo': ['x', 'y', 'z', 'q', 'w', 't']})
>>> df
   foo  bar  baz  zoo
0  one   A    1    x
1  one   B    2    y
2  one   C    3    z
3  two   A    4    q
4  two   B    5    w
5  two   C    6    t
```

```
>>> df.pivot(index='foo', columns='bar', values='baz')
bar A  B  C
foo
one 1  2  3
two 4  5  6
```

```
>>> df.pivot(index='foo', columns='bar')['baz']
bar A  B  C
foo
one 1  2  3
two 4  5  6
```

```
>>> df.pivot(index='foo', columns='bar', values=['baz', 'zoo'])
      baz      zoo
bar  A B C  A B C
foo
one  1 2 3  x y z
two  4 5 6  q w t
```

A *ValueError* is raised if there are any duplicates.

```
>>> df = pd.DataFrame({"foo": ['one', 'one', 'two', 'two'],
...                    "bar": ['A', 'A', 'B', 'C'],
...                    "baz": [1, 2, 3, 4]})
>>> df
   foo bar  baz
0  one  A    1
1  one  A    2
2  two  B    3
3  two  C    4
```

Notice that the first two rows are the same for our *index* and *columns* arguments.

```
>>> df.pivot(index='foo', columns='bar', values='baz')
Traceback (most recent call last):
...
ValueError: Index contains duplicate entries, cannot reshape
```

pandas.pivot_table

```
pandas.pivot_table(data, values=None, index=None, columns=None, aggfunc='mean',
                   fill_value=None, margins=False, dropna=True, margins_name='All',
                   observed=False)
```

Create a spreadsheet-style pivot table as a DataFrame. The levels in the pivot table will be stored in MultiIndex objects (hierarchical indexes) on the index and columns of the result DataFrame.

Parameters

data [DataFrame]

values [column to aggregate, optional]

index [column, Grouper, array, or list of the previous] If an array is passed, it must be the same length as the data. The list can contain any of the other types (except list). Keys to group by on the pivot table index. If an array is passed, it is being used as the same manner as column values.

columns [column, Grouper, array, or list of the previous] If an array is passed, it must be the same length as the data. The list can contain any of the other types (except list). Keys to group by on the pivot table column. If an array is passed, it is being used as the same manner as column values.

aggfunc [function, list of functions, dict, default numpy.mean] If list of functions passed, the resulting pivot table will have hierarchical columns whose top level are the function names (inferred from the function objects themselves) If dict is passed, the key is column to aggregate and value is function or list of functions

fill_value [scalar, default None] Value to replace missing values with

margins [boolean, default False] Add all row / columns (e.g. for subtotal / grand totals)

dropna [boolean, default True] Do not include columns whose entries are all NaN

margins_name [string, default 'All'] Name of the row / column that will contain the totals when margins is True.

observed [boolean, default False] This only applies if any of the groupers are Categoricals. If True: only show observed values for categorical groupers. If False: show all values for categorical groupers.

Changed in version 0.25.0.

Returns

DataFrame

See also:

`DataFrame.pivot` Pivot without aggregation that can handle non-numeric data.

Examples

```
>>> df = pd.DataFrame({"A": ["foo", "foo", "foo", "foo", "foo",
...                          "bar", "bar", "bar", "bar"],
...                   "B": ["one", "one", "one", "two", "two",
...                          "one", "one", "two", "two"],
...                   "C": ["small", "large", "large", "small",
...                          "small", "large", "small", "small",
...                          "large"],
...                   "D": [1, 2, 2, 3, 3, 4, 5, 6, 7],
...                   "E": [2, 4, 5, 5, 6, 6, 8, 9, 9]})
>>> df
   A  B  C  D  E
0  foo one small  1  2
1  foo one large  2  4
2  foo one large  2  5
3  foo two small  3  5
4  foo two small  3  6
5  bar one large  4  6
6  bar one small  5  8
7  bar two small  6  9
8  bar two large  7  9
```

This first example aggregates values by taking the sum.

```
>>> table = pd.pivot_table(df, values='D', index=['A', 'B'],
...                          columns=['C'], aggfunc=np.sum)
>>> table
C      large  small
A  B
bar one    4.0    5.0
   two    7.0    6.0
foo one    4.0    1.0
   two    NaN    6.0
```

We can also fill missing values using the `fill_value` parameter.

```
>>> table = pd.pivot_table(df, values='D', index=['A', 'B'],
...                          columns=['C'], aggfunc=np.sum, fill_value=0)
>>> table
```

(continues on next page)

(continued from previous page)

C		large	small
A	B		
bar	one	4	5
	two	7	6
foo	one	4	1
	two	0	6

The next example aggregates by taking the mean across multiple columns.

```
>>> table = pd.pivot_table(df, values=['D', 'E'], index=['A', 'C'],
...                          aggfunc={'D': np.mean,
...                                    'E': np.mean})
>>> table
```

		D	E
A	C		
bar	large	5.500000	7.500000
	small	5.500000	8.500000
foo	large	2.000000	4.500000
	small	2.333333	4.333333

We can also calculate multiple types of aggregations for any given value column.

```
>>> table = pd.pivot_table(df, values=['D', 'E'], index=['A', 'C'],
...                          aggfunc={'D': np.mean,
...                                    'E': [min, max, np.mean]})
>>> table
```

		D		E	
		mean	max	mean	min
A	C				
bar	large	5.500000	9.0	7.500000	6.0
	small	5.500000	9.0	8.500000	8.0
foo	large	2.000000	5.0	4.500000	4.0
	small	2.333333	6.0	4.333333	2.0

pandas.crosstab

`pandas.crosstab(index, columns, values=None, rownames=None, colnames=None, aggfunc=None, margins=False, margins_name='All', dropna=True, normalize=False)`

Compute a simple cross tabulation of two (or more) factors. By default computes a frequency table of the factors unless an array of values and an aggregation function are passed.

Parameters

index [array-like, Series, or list of arrays/Series] Values to group by in the rows.

columns [array-like, Series, or list of arrays/Series] Values to group by in the columns.

values [array-like, optional] Array of values to aggregate according to the factors. Requires `aggfunc` be specified.

rownames [sequence, default None] If passed, must match number of row arrays passed.

colnames [sequence, default None] If passed, must match number of column arrays passed.

aggfunc [function, optional] If specified, requires *values* be specified as well.

margins [bool, default False] Add row/column margins (subtotals).

margins_name [str, default 'All'] Name of the row/column that will contain the totals when margins is True.

New in version 0.21.0.

dropna [bool, default True] Do not include columns whose entries are all NaN.

normalize [bool, {'all', 'index', 'columns'}, or {0,1}, default False] Normalize by dividing all values by the sum of values.

- If passed 'all' or *True*, will normalize over all values.
- If passed 'index' will normalize over each row.
- If passed 'columns' will normalize over each column.
- If margins is *True*, will also normalize margin values.

New in version 0.18.1.

Returns

DataFrame Cross tabulation of the data.

See also:

DataFrame.pivot Reshape data based on column values.

pivot_table Create a pivot table as a DataFrame.

Notes

Any Series passed will have their name attributes used unless row or column names for the cross-tabulation are specified.

Any input passed containing Categorical data will have **all** of its categories included in the cross-tabulation, even if the actual data does not contain any instances of a particular category.

In the event that there aren't overlapping indexes an empty DataFrame will be returned.

Examples

```
>>> a = np.array(["foo", "foo", "foo", "foo", "bar", "bar",
...              "bar", "bar", "foo", "foo", "foo"], dtype=object)
>>> b = np.array(["one", "one", "one", "two", "one", "one",
...              "one", "two", "two", "two", "one"], dtype=object)
>>> c = np.array(["dull", "dull", "shiny", "dull", "dull", "shiny",
...              "shiny", "dull", "shiny", "shiny", "shiny"],
...              dtype=object)
>>> pd.crosstab(a, [b, c], rownames=['a'], colnames=['b', 'c'])
b   one      two
c   dull shiny dull shiny
a
bar    1     2    1     0
foo    2     2    1     2
```

Here 'c' and 'f' are not represented in the data and will not be shown in the output because `dropna` is `True` by default. Set `dropna=False` to preserve categories with no data.

```
>>> foo = pd.Categorical(['a', 'b'], categories=['a', 'b', 'c'])
>>> bar = pd.Categorical(['d', 'e'], categories=['d', 'e', 'f'])
>>> pd.crosstab(foo, bar)
col_0  d  e
row_0
a      1  0
b      0  1
>>> pd.crosstab(foo, bar, dropna=False)
col_0  d  e  f
row_0
a      1  0  0
b      0  1  0
c      0  0  0
```

pandas.cut

`pandas.cut(x, bins, right=True, labels=None, rebins=False, precision=3, include_lowest=False, duplicates='raise')`

Bin values into discrete intervals.

Use `cut` when you need to segment and sort data values into bins. This function is also useful for going from a continuous variable to a categorical variable. For example, `cut` could convert ages to groups of age ranges. Supports binning into an equal number of bins, or a pre-specified array of bins.

Parameters

x [array-like] The input array to be binned. Must be 1-dimensional.

bins [int, sequence of scalars, or IntervalIndex] The criteria to bin by.

- `int` : Defines the number of equal-width bins in the range of `x`. The range of `x` is extended by `.1%` on each side to include the minimum and maximum values of `x`.
- `sequence of scalars` : Defines the bin edges allowing for non-uniform width. No extension of the range of `x` is done.
- `IntervalIndex` : Defines the exact bins to be used. Note that `IntervalIndex` for `bins` must be non-overlapping.

right [bool, default `True`] Indicates whether `bins` includes the rightmost edge or not. If `right == True` (the default), then the `bins` `[1, 2, 3, 4]` indicate `(1,2]`, `(2,3]`, `(3,4]`. This argument is ignored when `bins` is an `IntervalIndex`.

labels [array or bool, optional] Specifies the labels for the returned bins. Must be the same length as the resulting bins. If `False`, returns only integer indicators of the bins. This affects the type of the output container (see below). This argument is ignored when `bins` is an `IntervalIndex`.

rebins [bool, default `False`] Whether to return the bins or not. Useful when bins is provided as a scalar.

precision [int, default `3`] The precision at which to store and display the bins labels.

include_lowest [bool, default `False`] Whether the first interval should be left-inclusive or not.

duplicates [{default 'raise', 'drop'}, optional] If bin edges are not unique, raise ValueError or drop non-uniques.

New in version 0.23.0.

Returns

out [Categorical, Series, or ndarray] An array-like object representing the respective bin for each value of *x*. The type depends on the value of *labels*.

- True (default) : returns a Series for Series *x* or a Categorical for all other inputs. The values stored within are Interval dtype.
- sequence of scalars : returns a Series for Series *x* or a Categorical for all other inputs. The values stored within are whatever the type in the sequence is.
- False : returns an ndarray of integers.

bins [numpy.ndarray or IntervalIndex.] The computed or specified bins. Only returned when *retbins=True*. For scalar or sequence *bins*, this is an ndarray with the computed bins. If set *duplicates=drop*, *bins* will drop non-unique bin. For an IntervalIndex *bins*, this is equal to *bins*.

See also:

qcut Discretize variable into equal-sized buckets based on rank or based on sample quantiles.

Categorical Array type for storing data that come from a fixed set of values.

Series One-dimensional array with axis labels (including time series).

IntervalIndex Immutable Index implementing an ordered, sliceable set.

Notes

Any NA values will be NA in the result. Out of bounds values will be NA in the resulting Series or Categorical object.

Examples

Discretize into three equal-sized bins.

```
>>> pd.cut(np.array([1, 7, 5, 4, 6, 3]), 3)
... # doctest: +ELLIPSIS
[(0.994, 3.0], (5.0, 7.0], (3.0, 5.0], (3.0, 5.0], (5.0, 7.0], ...
Categories (3, interval[float64]): [(0.994, 3.0] < (3.0, 5.0] ...
```

```
>>> pd.cut(np.array([1, 7, 5, 4, 6, 3]), 3, retbins=True)
... # doctest: +ELLIPSIS
([(0.994, 3.0], (5.0, 7.0], (3.0, 5.0], (3.0, 5.0], (5.0, 7.0], ...
Categories (3, interval[float64]): [(0.994, 3.0] < (3.0, 5.0] ...
array([0.994, 3.    , 5.    , 7.    ]))
```

Discovers the same bins, but assign them specific labels. Notice that the returned Categorical's categories are *labels* and is ordered.

```
>>> pd.cut(np.array([1, 7, 5, 4, 6, 3]),
...         3, labels=["bad", "medium", "good"])
[bad, good, medium, medium, good, bad]
Categories (3, object): [bad < medium < good]
```

labels=False implies you just want the bins back.

```
>>> pd.cut([0, 1, 1, 2], bins=4, labels=False)
array([0, 1, 1, 3])
```

Passing a Series as an input returns a Series with categorical dtype:

```
>>> s = pd.Series(np.array([2, 4, 6, 8, 10]),
...               index=['a', 'b', 'c', 'd', 'e'])
>>> pd.cut(s, 3)
... # doctest: +ELLIPSIS
a    (1.992, 4.667]
b    (1.992, 4.667]
c    (4.667, 7.333]
d    (7.333, 10.0]
e    (7.333, 10.0]
dtype: category
Categories (3, interval[float64]): [(1.992, 4.667] < (4.667, ...]
```

Passing a Series as an input returns a Series with mapping value. It is used to map numerically to intervals based on bins.

```
>>> s = pd.Series(np.array([2, 4, 6, 8, 10]),
...               index=['a', 'b', 'c', 'd', 'e'])
>>> pd.cut(s, [0, 2, 4, 6, 8, 10], labels=False, retbins=True, right=False)
... # doctest: +ELLIPSIS
(a)  0.0
(b)  1.0
(c)  2.0
(d)  3.0
(e)  4.0
dtype: float64, array([0, 2, 4, 6, 8])
```

Use *drop* optional when bins is not unique

```
>>> pd.cut(s, [0, 2, 4, 6, 10, 10], labels=False, retbins=True,
...         right=False, duplicates='drop')
... # doctest: +ELLIPSIS
(a)  0.0
(b)  1.0
(c)  2.0
(d)  3.0
(e)  3.0
dtype: float64, array([0, 2, 4, 6, 8])
```

Passing an IntervalIndex for *bins* results in those categories exactly. Notice that values not covered by the IntervalIndex are set to NaN. 0 is to the left of the first bin (which is closed on the right), and 1.5 falls between two bins.

```
>>> bins = pd.IntervalIndex.from_tuples([(0, 1), (2, 3), (4, 5)])
>>> pd.cut([0, 0.5, 1.5, 2.5, 4.5], bins)
[NaN, (0, 1], NaN, (2, 3], (4, 5]]
Categories (3, interval[int64]): [(0, 1] < (2, 3] < (4, 5]]
```

pandas.qcut

`pandas.qcut(x, q, labels=None, retbins=False, precision=3, duplicates='raise')`

Quantile-based discretization function. Discretize variable into equal-sized buckets based on rank or based on sample quantiles. For example 1000 values for 10 quantiles would produce a Categorical object indicating quantile membership for each data point.

Parameters

- x** [1d ndarray or Series]
- q** [integer or array of quantiles] Number of quantiles. 10 for deciles, 4 for quartiles, etc. Alternately array of quantiles, e.g. [0, .25, .5, .75, 1.] for quartiles
- labels** [array or boolean, default None] Used as labels for the resulting bins. Must be of the same length as the resulting bins. If False, return only integer indicators of the bins.
- retbins** [bool, optional] Whether to return the (bins, labels) or not. Can be useful if bins is given as a scalar.
- precision** [int, optional] The precision at which to store and display the bins labels
- duplicates** [{default 'raise', 'drop'}, optional] If bin edges are not unique, raise ValueError or drop non-uniques.

New in version 0.20.0.

Returns

- out** [Categorical or Series or array of integers if labels is False] The return type (Categorical or Series) depends on the input: a Series of type category if input is a Series else Categorical. Bins are represented as categories when categorical data is returned.
- bins** [ndarray of floats] Returned only if `retbins` is True.

Notes

Out of bounds values will be NA in the resulting Categorical object

Examples

```
>>> pd.qcut(range(5), 4)
... # doctest: +ELLIPSIS
[(-0.001, 1.0], (-0.001, 1.0], (1.0, 2.0], (2.0, 3.0], (3.0, 4.0]]
Categories (4, interval[float64]): [(-0.001, 1.0] < (1.0, 2.0] ...
```

```
>>> pd.qcut(range(5), 3, labels=["good", "medium", "bad"])
... # doctest: +SKIP
[good, good, medium, bad, bad]
Categories (3, object): [good < medium < bad]
```

```
>>> pd.qcut(range(5), 4, labels=False)
array([0, 0, 1, 2, 3])
```

pandas.merge

`pandas.merge(left, right, how='inner', on=None, left_on=None, right_on=None, left_index=False, right_index=False, sort=False, suffixes=('_x', '_y'), copy=True, indicator=False, validate=None)`

Merge DataFrame or named Series objects with a database-style join.

The join is done on columns or indexes. If joining columns on columns, the DataFrame indexes *will be ignored*. Otherwise if joining indexes on indexes or indexes on a column or columns, the index will be passed on.

Parameters

left [DataFrame]

right [DataFrame or named Series] Object to merge with.

how [{'left', 'right', 'outer', 'inner'}, default 'inner'] Type of merge to be performed.

- left: use only keys from left frame, similar to a SQL left outer join; preserve key order.
- right: use only keys from right frame, similar to a SQL right outer join; preserve key order.
- outer: use union of keys from both frames, similar to a SQL full outer join; sort keys lexicographically.
- inner: use intersection of keys from both frames, similar to a SQL inner join; preserve the order of the left keys.

on [label or list] Column or index level names to join on. These must be found in both DataFrames. If *on* is None and not merging on indexes then this defaults to the intersection of the columns in both DataFrames.

left_on [label or list, or array-like] Column or index level names to join on in the left DataFrame. Can also be an array or list of arrays of the length of the left DataFrame. These arrays are treated as if they are columns.

right_on [label or list, or array-like] Column or index level names to join on in the right DataFrame. Can also be an array or list of arrays of the length of the right DataFrame. These arrays are treated as if they are columns.

left_index [bool, default False] Use the index from the left DataFrame as the join key(s). If it is a MultiIndex, the number of keys in the other DataFrame (either the index or a number of columns) must match the number of levels.

right_index [bool, default False] Use the index from the right DataFrame as the join key. Same caveats as `left_index`.

sort [bool, default False] Sort the join keys lexicographically in the result DataFrame. If False, the order of the join keys depends on the join type (`how` keyword).

suffixes [tuple of (str, str), default ('_x', '_y')] Suffix to apply to overlapping column names in the left and right side, respectively. To raise an exception on overlapping columns use (False, False).

copy [bool, default True] If False, avoid copy if possible.

indicator [bool or str, default False] If True, adds a column to output DataFrame called “_merge” with information on the source of each row. If string, column with information on source of each row will be added to output DataFrame, and column will be named value of string. Information column is Categorical-type and takes on a value of “left_only” for observations whose merge key only appears in ‘left’ DataFrame, “right_only” for observations whose merge key only appears in ‘right’ DataFrame, and “both” if the observation’s merge key is found in both.

validate [str, optional] If specified, checks if merge is of specified type.

- “one_to_one” or “1:1”: check if merge keys are unique in both left and right datasets.
- “one_to_many” or “1:m”: check if merge keys are unique in left dataset.
- “many_to_one” or “m:1”: check if merge keys are unique in right dataset.
- “many_to_many” or “m:m”: allowed, but does not result in checks.

New in version 0.21.0.

Returns

DataFrame A DataFrame of the two merged objects.

See also:

merge_ordered Merge with optional filling/interpolation.

merge_asof Merge on nearest keys.

DataFrame.join Similar method using indices.

Notes

Support for specifying index levels as the *on*, *left_on*, and *right_on* parameters was added in version 0.23.0 Support for merging named Series objects was added in version 0.24.0

Examples

```
>>> df1 = pd.DataFrame({'lkey': ['foo', 'bar', 'baz', 'foo'],
...                    'value': [1, 2, 3, 5]})
>>> df2 = pd.DataFrame({'rkey': ['foo', 'bar', 'baz', 'foo'],
...                    'value': [5, 6, 7, 8]})
>>> df1
   lkey  value
0   foo     1
1   bar     2
2   baz     3
3   foo     5
>>> df2
   rkey  value
```

(continues on next page)

(continued from previous page)

0	foo	5
1	bar	6
2	baz	7
3	foo	8

Merge df1 and df2 on the lkey and rkey columns. The value columns have the default suffixes, `_x` and `_y`, appended.

```
>>> df1.merge(df2, left_on='lkey', right_on='rkey')
   lkey  value_x rkey  value_y
0  foo         1  foo         5
1  foo         1  foo         8
2  foo         5  foo         5
3  foo         5  foo         8
4  bar         2  bar         6
5  baz         3  baz         7
```

Merge DataFrames df1 and df2 with specified left and right suffixes appended to any overlapping columns.

```
>>> df1.merge(df2, left_on='lkey', right_on='rkey',
...           suffixes=('_left', '_right'))
   lkey  value_left rkey  value_right
0  foo           1  foo           5
1  foo           1  foo           8
2  foo           5  foo           5
3  foo           5  foo           8
4  bar           2  bar           6
5  baz           3  baz           7
```

Merge DataFrames df1 and df2, but raise an exception if the DataFrames have any overlapping columns.

```
>>> df1.merge(df2, left_on='lkey', right_on='rkey', suffixes=(False, False))
Traceback (most recent call last):
...
ValueError: columns overlap but no suffix specified:
   Index(['value'], dtype='object')
```

pandas.merge_ordered

`pandas.merge_ordered(left, right, on=None, left_on=None, right_on=None, left_by=None, right_by=None, fill_method=None, suffixes=('_x', '_y'), how='outer')`

Perform merge with optional filling/interpolation designed for ordered data like time series data. Optionally perform group-wise merge (see examples)

Parameters

left [DataFrame]

right [DataFrame]

on [label or list] Field names to join on. Must be found in both DataFrames.

left_on [label or list, or array-like] Field names to join on in left DataFrame. Can be a vector or list of vectors of the length of the DataFrame to use a particular vector as the join key instead of columns

right_on [label or list, or array-like] Field names to join on in right DataFrame or vector/list of vectors per left_on docs

left_by [column name or list of column names] Group left DataFrame by group columns and merge piece by piece with right DataFrame

right_by [column name or list of column names] Group right DataFrame by group columns and merge piece by piece with left DataFrame

fill_method [{'ffill', None}, default None] Interpolation method for data

suffixes [Sequence, default is (“_x”, “_y”)] A length-2 sequence where each element is optionally a string indicating the suffix to add to overlapping column names in *left* and *right* respectively. Pass a value of *None* instead of a string to indicate that the column name from *left* or *right* should be left as-is, with no suffix. At least one of the values must not be None.

Changed in version 0.25.0.

how [{'left', 'right', 'outer', 'inner'}, default 'outer']

- left: use only keys from left frame (SQL: left outer join)
- right: use only keys from right frame (SQL: right outer join)
- outer: use union of keys from both frames (SQL: full outer join)
- inner: use intersection of keys from both frames (SQL: inner join)

New in version 0.19.0.

Returns

merged [DataFrame] The output type will be the same as 'left', if it is a subclass of DataFrame.

Examples

```
>>> A
   key  lvalue group
0  a      1      a
1  c      2      a
2  e      3      a
3  a      1      b
4  c      2      b
5  e      3      b

>>> B
   key  rvalue
0  b      1
1  c      2
2  d      3
```

```
>>> merge_ordered(A, B, fill_method='ffill', left_by='group')
   group key  lvalue  rvalue
0     a  a      1      NaN
```

(continues on next page)

(continued from previous page)

1	a	b	1	1.0
2	a	c	2	2.0
3	a	d	2	3.0
4	a	e	3	3.0
5	b	a	1	NaN
6	b	b	1	1.0
7	b	c	2	2.0
8	b	d	2	3.0
9	b	e	3	3.0

pandas.merge_asof

`pandas.merge_asof(left, right, on=None, left_on=None, right_on=None, left_index=False, right_index=False, by=None, left_by=None, right_by=None, suffixes=('_x', '_y'), tolerance=None, allow_exact_matches=True, direction='backward')`

Perform an asof merge. This is similar to a left-join except that we match on nearest key rather than equal keys.

Both DataFrames must be sorted by the key.

For each row in the left DataFrame:

- A “backward” search selects the last row in the right DataFrame whose ‘on’ key is less than or equal to the left’s key.
- A “forward” search selects the first row in the right DataFrame whose ‘on’ key is greater than or equal to the left’s key.
- A “nearest” search selects the row in the right DataFrame whose ‘on’ key is closest in absolute distance to the left’s key.

The default is “backward” and is compatible in versions below 0.20.0. The direction parameter was added in version 0.20.0 and introduces “forward” and “nearest”.

Optionally match on equivalent keys with ‘by’ before searching with ‘on’.

New in version 0.19.0.

Parameters

left [DataFrame]

right [DataFrame]

on [label] Field name to join on. Must be found in both DataFrames. The data MUST be ordered. Furthermore this must be a numeric column, such as datetimelike, integer, or float. On or left_on/right_on must be given.

left_on [label] Field name to join on in left DataFrame.

right_on [label] Field name to join on in right DataFrame.

left_index [boolean] Use the index of the left DataFrame as the join key.

New in version 0.19.2.

right_index [boolean] Use the index of the right DataFrame as the join key.

New in version 0.19.2.

by [column name or list of column names] Match on these columns before performing merge operation.

left_by [column name] Field names to match on in the left DataFrame.

New in version 0.19.2.

right_by [column name] Field names to match on in the right DataFrame.

New in version 0.19.2.

suffixes [2-length sequence (tuple, list, ...)] Suffix to apply to overlapping column names in the left and right side, respectively.

tolerance [integer or Timedelta, optional, default None] Select asof tolerance within this range; must be compatible with the merge index.

allow_exact_matches [boolean, default True]

- If True, allow matching with the same ‘on’ value (i.e. less-than-or-equal-to / greater-than-or-equal-to)
- If False, don’t match the same ‘on’ value (i.e., strictly less-than / strictly greater-than)

direction [‘backward’ (default), ‘forward’, or ‘nearest’] Whether to search for prior, subsequent, or closest matches.

New in version 0.20.0.

Returns

merged [DataFrame]

Examples

```
>>> left = pd.DataFrame({'a': [1, 5, 10], 'left_val': ['a', 'b', 'c']})
>>> left
   a left_val
0  1         a
1  5         b
2 10         c
```

```
>>> right = pd.DataFrame({'a': [1, 2, 3, 6, 7],
...                       'right_val': [1, 2, 3, 6, 7]})
>>> right
   a right_val
0  1          1
1  2          2
2  3          3
3  6          6
4  7          7
```

```
>>> pd.merge_asof(left, right, on='a')
  a left_val right_val
0  1         a         1
1  5         b         3
2 10         c         7
```

```
>>> pd.merge_asof(left, right, on='a', allow_exact_matches=False)
  a left_val right_val
0  1         a        NaN
1  5         b         3.0
2 10         c         7.0
```

```
>>> pd.merge_asof(left, right, on='a', direction='forward')
  a left_val right_val
0  1         a         1.0
1  5         b         6.0
2 10         c         NaN
```

```
>>> pd.merge_asof(left, right, on='a', direction='nearest')
  a left_val right_val
0  1         a         1
1  5         b         6
2 10         c         7
```

We can use indexed DataFrames as well.

```
>>> left = pd.DataFrame({'left_val': ['a', 'b', 'c']}, index=[1, 5, 10])
>>> left
  left_val
1         a
5         b
10        c
```

```
>>> right = pd.DataFrame({'right_val': [1, 2, 3, 6, 7]},
...                       index=[1, 2, 3, 6, 7])
>>> right
  right_val
1          1
2          2
3          3
6          6
7          7
```

```
>>> pd.merge_asof(left, right, left_index=True, right_index=True)
  left_val right_val
1         a         1
5         b         3
10        c         7
```

Here is a real-world times-series example

```
>>> quotes
      time ticker    bid    ask
0 2016-05-25 13:30:00.023  GOOG 720.50 720.93
1 2016-05-25 13:30:00.023  MSFT  51.95  51.96
2 2016-05-25 13:30:00.030  MSFT  51.97  51.98
3 2016-05-25 13:30:00.041  MSFT  51.99  52.00
4 2016-05-25 13:30:00.048  GOOG 720.50 720.93
5 2016-05-25 13:30:00.049  AAPL  97.99  98.01
6 2016-05-25 13:30:00.072  GOOG 720.50 720.88
7 2016-05-25 13:30:00.075  MSFT  52.01  52.03
```

```
>>> trades
      time ticker  price  quantity
0 2016-05-25 13:30:00.023  MSFT   51.95     75
1 2016-05-25 13:30:00.038  MSFT   51.95    155
2 2016-05-25 13:30:00.048  GOOG  720.77    100
3 2016-05-25 13:30:00.048  GOOG  720.92    100
4 2016-05-25 13:30:00.048  AAPL   98.00    100
```

By default we are taking the asof of the quotes

```
>>> pd.merge_asof(trades, quotes,
...               on='time',
...               by='ticker')
      time ticker  price  quantity  bid  ask
0 2016-05-25 13:30:00.023  MSFT   51.95     75  51.95  51.96
1 2016-05-25 13:30:00.038  MSFT   51.95    155  51.97  51.98
2 2016-05-25 13:30:00.048  GOOG  720.77    100  720.50  720.93
3 2016-05-25 13:30:00.048  GOOG  720.92    100  720.50  720.93
4 2016-05-25 13:30:00.048  AAPL   98.00    100    NaN    NaN
```

We only asof within 2ms between the quote time and the trade time

```
>>> pd.merge_asof(trades, quotes,
...               on='time',
...               by='ticker',
...               tolerance=pd.Timedelta('2ms'))
      time ticker  price  quantity  bid  ask
0 2016-05-25 13:30:00.023  MSFT   51.95     75  51.95  51.96
1 2016-05-25 13:30:00.038  MSFT   51.95    155    NaN    NaN
2 2016-05-25 13:30:00.048  GOOG  720.77    100  720.50  720.93
3 2016-05-25 13:30:00.048  GOOG  720.92    100  720.50  720.93
4 2016-05-25 13:30:00.048  AAPL   98.00    100    NaN    NaN
```

We only asof within 10ms between the quote time and the trade time and we exclude exact matches on time. However *prior* data will propagate forward

```
>>> pd.merge_asof(trades, quotes,
...               on='time',
...               by='ticker',
...               tolerance=pd.Timedelta('10ms'),
...               allow_exact_matches=False)
      time ticker  price  quantity  bid  ask
```

pandas.concat

`pandas.concat(objs, axis=0, join='outer', join_axes=None, ignore_index=False, keys=None, levels=None, names=None, verify_integrity=False, sort=None, copy=True)`

Concatenate pandas objects along a particular axis with optional set logic along the other axes.

Can also add a layer of hierarchical indexing on the concatenation axis, which may be useful if the labels are the same (or overlapping) on the passed axis number.

Parameters

objs [a sequence or mapping of Series or DataFrame objects] If a dict is passed, the sorted keys will be used as the *keys* argument, unless it is passed, in which case the values will be selected (see below). Any None objects will be dropped silently unless they are all None in which case a `ValueError` will be raised.

axis [{0/'index', 1/'columns'}, default 0] The axis to concatenate along.

join [{'inner', 'outer'}, default 'outer'] How to handle indexes on other axis (or axes).

join_axes [list of Index objects] Deprecated since version 0.25.0.

Specific indexes to use for the other $n - 1$ axes instead of performing inner/outer set logic. Use `.reindex()` before or after concatenation as a replacement.

ignore_index [bool, default False] If True, do not use the index values along the concatenation axis. The resulting axis will be labeled 0, ..., $n - 1$. This is useful if you are concatenating objects where the concatenation axis does not have meaningful indexing information. Note the index values on the other axes are still respected in the join.

keys [sequence, default None] If multiple levels passed, should contain tuples. Construct hierarchical index using the passed keys as the outermost level.

levels [list of sequences, default None] Specific levels (unique values) to use for constructing a MultiIndex. Otherwise they will be inferred from the keys.

names [list, default None] Names for the levels in the resulting hierarchical index.

verify_integrity [bool, default False] Check whether the new concatenated axis contains duplicates. This can be very expensive relative to the actual data concatenation.

sort [bool, default None] Sort non-concatenation axis if it is not already aligned when *join* is 'outer'. The current default of sorting is deprecated and will change to not-sorting in a future version of pandas.

Explicitly pass `sort=True` to silence the warning and sort. Explicitly pass `sort=False` to silence the warning and not sort.

This has no effect when `join='inner'`, which already preserves the order of the non-concatenation axis.

New in version 0.23.0.

`copy` [bool, default True] If False, do not copy data unnecessarily.

Returns

object, type of objs When concatenating all `Series` along the index (`axis=0`), a `Series` is returned. When `objs` contains at least one `DataFrame`, a `DataFrame` is returned. When concatenating along the columns (`axis=1`), a `DataFrame` is returned.

See also:

`Series.append` Concatenate Series.

`DataFrame.append` Concatenate DataFrames.

`DataFrame.join` Join DataFrames using indexes.

`DataFrame.merge` Merge DataFrames by indexes or columns.

Notes

The keys, levels, and names arguments are all optional.

A walkthrough of how this method fits in with other tools for combining pandas objects can be found [here](#).

Examples

Combine two `Series`.

```
>>> s1 = pd.Series(['a', 'b'])
>>> s2 = pd.Series(['c', 'd'])
>>> pd.concat([s1, s2])
0    a
1    b
0    c
1    d
dtype: object
```

Clear the existing index and reset it in the result by setting the `ignore_index` option to `True`.

```
>>> pd.concat([s1, s2], ignore_index=True)
0    a
1    b
2    c
3    d
dtype: object
```

Add a hierarchical index at the outermost level of the data with the `keys` option.

```
>>> pd.concat([s1, s2], keys=['s1', 's2'])
s1 0    a
   1    b
s2 0    c
   1    d
dtype: object
```

Label the index keys you create with the `names` option.

```
>>> pd.concat([s1, s2], keys=['s1', 's2'],
...           names=['Series name', 'Row ID'])
Series name  Row ID
s1           0      a
             1      b
s2           0      c
             1      d
dtype: object
```

Combine two `DataFrame` objects with identical columns.

```
>>> df1 = pd.DataFrame([[ 'a', 1], [ 'b', 2]],
...                   columns=['letter', 'number'])
>>> df1
   letter  number
0      a      1
1      b      2
>>> df2 = pd.DataFrame([[ 'c', 3], [ 'd', 4]],
...                   columns=['letter', 'number'])
>>> df2
   letter  number
0      c      3
1      d      4
>>> pd.concat([df1, df2])
   letter  number
0      a      1
1      b      2
0      c      3
1      d      4
```

Combine `DataFrame` objects with overlapping columns and return everything. Columns outside the intersection will be filled with `NaN` values.

```
>>> df3 = pd.DataFrame([[ 'c', 3, 'cat'], [ 'd', 4, 'dog']],
...                   columns=['letter', 'number', 'animal'])
>>> df3
   letter  number  animal
0      c      3     cat
1      d      4     dog
>>> pd.concat([df1, df3], sort=False)
   letter  number  animal
0      a      1     NaN
1      b      2     NaN
0      c      3     cat
1      d      4     dog
```

Combine `DataFrame` objects with overlapping columns and return only those that are shared by passing `inner` to the `join` keyword argument.

```
>>> pd.concat([df1, df3], join="inner")
   letter  number
0      a      1
1      b      2
```

(continues on next page)

(continued from previous page)

0	c	3
1	d	4

Combine DataFrame objects horizontally along the x axis by passing in `axis=1`.

```
>>> df4 = pd.DataFrame(['bird', 'polly'], ['monkey', 'george'],
...                      columns=['animal', 'name'])
>>> pd.concat([df1, df4], axis=1)
  letter number animal  name
0     a      1   bird  polly
1     b      2  monkey  george
```

Prevent the result from including duplicate index values with the `verify_integrity` option.

```
>>> df5 = pd.DataFrame([1], index=['a'])
>>> df5
  0
a  1
>>> df6 = pd.DataFrame([2], index=['a'])
>>> df6
  0
a  2
>>> pd.concat([df5, df6], verify_integrity=True)
Traceback (most recent call last):
...
ValueError: Indexes have overlapping values: ['a']
```

pandas.get_dummies

`pandas.get_dummies(data, prefix=None, prefix_sep='_', dummy_na=False, columns=None, sparse=False, drop_first=False, dtype=None)`

Convert categorical variable into dummy/indicator variables.

Parameters

- data** [array-like, Series, or DataFrame] Data of which to get dummy indicators.
- prefix** [str, list of str, or dict of str, default None] String to append DataFrame column names. Pass a list with length equal to the number of columns when calling `get_dummies` on a DataFrame. Alternatively, `prefix` can be a dictionary mapping column names to prefixes.
- prefix_sep** [str, default '_'] If appending prefix, separator/delimiter to use. Or pass a list or dictionary as with `prefix`.
- dummy_na** [bool, default False] Add a column to indicate NaNs, if False NaNs are ignored.
- columns** [list-like, default None] Column names in the DataFrame to be encoded. If `columns` is None then all the columns with `object` or `category` dtype will be converted.
- sparse** [bool, default False] Whether the dummy-encoded columns should be backed by a `SparseArray` (True) or a regular NumPy array (False).
- drop_first** [bool, default False] Whether to get k-1 dummies out of k categorical levels by removing the first level.

New in version 0.18.0.

dtype [dtype, default np.uint8] Data type for new columns. Only a single dtype is allowed.

New in version 0.23.0.

Returns

DataFrame Dummy-coded data.

See also:

Series.str.get_dummies Convert Series to dummy codes.

Examples

```
>>> s = pd.Series(list('abca'))
```

```
>>> pd.get_dummies(s)
   a  b  c
0  1  0  0
1  0  1  0
2  0  0  1
3  1  0  0
```

```
>>> s1 = ['a', 'b', np.nan]
```

```
>>> pd.get_dummies(s1)
   a  b
0  1  0
1  0  1
2  0  0
```

```
>>> pd.get_dummies(s1, dummy_na=True)
   a  b  NaN
0  1  0    0
1  0  1    0
2  0  0    1
```

```
>>> df = pd.DataFrame({'A': ['a', 'b', 'a'], 'B': ['b', 'a', 'c'],
...                    'C': [1, 2, 3]})
```

```
>>> pd.get_dummies(df, prefix=['col1', 'col2'])
   C  col1_a  col1_b  col2_a  col2_b  col2_c
0  1         1         0         0         1         0
1  2         0         1         1         0         0

2  0.0  0.0  1.0

```

pandas.factorize

`pandas.factorize(values, sort=False, order=None, na_sentinel=-1, size_hint=None)`

Encode the object as an enumerated type or categorical variable.

This method is useful for obtaining a numeric representation of an array when all that matters is identifying distinct values. `factorize` is available as both a top-level function `pandas.factorize()`, and as a method `Series.factorize()` and `Index.factorize()`.

Parameters

- values** [sequence] A 1-D sequence. Sequences that aren't pandas objects are coerced to ndarrays before factorization.
- sort** [bool, default False] Sort *uniques* and shuffle *labels* to maintain the relationship.
- order** [None] Deprecated since version 0.23.0: This parameter has no effect and is deprecated.
- na_sentinel** [int, default -1] Value to mark “not found”.
- size_hint** [int, optional] Hint to the hashtable sizer.

Returns

- labels** [ndarray] An integer ndarray that's an indexer into *uniques*. `uniques.take(labels)` will have the same values as *values*.
- uniques** [ndarray, Index, or Categorical] The unique valid values. When *values* is Categorical, *uniques* is a Categorical. When *values* is some other pandas object, an *Index* is returned. Otherwise, a 1-D ndarray is returned.

Note: Even if there's a missing value in *values*, *uniques* will *not* contain an entry for it.

See also:

cut Discretize continuous-valued array.

unique Find the unique value in an array.

Examples

These examples all show `factorize` as a top-level method like `pd.factorize(values)`. The results are identical for methods like `Series.factorize()`.

```
>>> labels, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'])
>>> labels
array([0, 0, 1, 2, 0])
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

With `sort=True`, the `uniques` will be sorted, and `labels` will be shuffled so that the relationship is the maintained.

```
>>> labels, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'], sort=True)
>>> labels
array([1, 1, 0, 2, 1])
>>> uniques
array(['a', 'b', 'c'], dtype=object)
```

Missing values are indicated in `labels` with `na_sentinel` (-1 by default). Note that missing values are never included in `uniques`.

```
>>> labels, uniques = pd.factorize(['b', None, 'a', 'c', 'b'])
>>> labels
array([ 0, -1,  1,  2,  0])
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

Thus far, we've only factorized lists (which are internally coerced to NumPy arrays). When factorizing pandas objects, the type of `uniques` will differ. For Categoricals, a `Categorical` is returned.

```
>>> cat = pd.Categorical(['a', 'a', 'c'], categories=['a', 'b', 'c'])
>>> labels, uniques = pd.factorize(cat)
>>> labels
array([0, 0, 1])
>>> uniques
[a, c]
Categories (3, object): [a, b, c]
```

Notice that 'b' is in `uniques.categories`, despite not being present in `cat.values`.

For all other pandas objects, an `Index` of the appropriate type is returned.

```
>>> cat = pd.Series(['a', 'a', 'c'])
>>> labels, uniques = pd.factorize(cat)
>>> labels
array([0, 0, 1])
>>> uniques
Index(['a', 'c'], dtype='object')
```

pandas.unique**pandas.unique**(*values*)

Hash table-based unique. Uniques are returned in order of appearance. This does NOT sort.

Significantly faster than `numpy.unique`. Includes NA values.**Parameters****values** [1d array-like]**Returns****numpy.ndarray or ExtensionArray** The return can be:

- Index : when the input is an Index
- Categorical : when the input is a Categorical dtype
- ndarray : when the input is a Series/ndarray

Return `numpy.ndarray` or `ExtensionArray`.**See also:***Index.unique**Series.unique***Examples**

```
>>> pd.unique(pd.Series([2, 1, 3, 3]))
array([2, 1, 3])
```

```
>>> pd.unique(pd.Series([2] + [1] * 5))
array([2, 1])
```

```
>>> pd.unique(pd.Series([pd.Timestamp('20160101'),
...                       pd.Timestamp('20160101')]))
array(['2016-01-01T00:00:00.000000000'], dtype='datetime64[ns]')
```

```
>>> pd.unique(pd.Series([pd.Timestamp('20160101', tz='US/Eastern'),
...                       pd.Timestamp('20160101', tz='US/Eastern')]))
array([Timestamp('2016-01-01 00:00:00-0500', tz='US/Eastern')],
      dtype=object)
```

```
>>> pd.unique(pd.Index([pd.Timestamp('20160101', tz='US/Eastern'),
...                      pd.Timestamp('20160101', tz='US/Eastern')]))
DatetimeIndex(['2016-01-01 00:00:00-05:00'],
...           dtype='datetime64[ns, US/Eastern]', freq=None)
```

```
>>> pd.unique(list('baabc'))
array(['b', 'a', 'c'], dtype=object)
```

An unordered Categorical will return categories in the order of appearance.

```
>>> pd.unique(pd.Series(pd.Categorical(list('baabc'))))
[b, a, c]
Categories (3, object): [b, a, c]
```

```
>>> pd.unique(pd.Series(pd.Categorical(list('baabc'),
...                               categories=list('abc'))))
[b, a, c]
Categories (3, object): [b, a, c]
```

An ordered Categorical preserves the category ordering.

```
>>> pd.unique(pd.Series(pd.Categorical(list('baabc'),
...                               categories=list('abc'),
...                               ordered=True)))
[b, a, c]
Categories (3, object): [a < b < c]
```

An array of tuples

```
>>> pd.unique([('a', 'b'), ('b', 'a'), ('a', 'c'), ('b', 'a')])
array([('a', 'b'), ('b', 'a'), ('a', 'c')], dtype=object)
```

pandas.wide_to_long

`pandas.wide_to_long(df, stubnames, i, j, sep=" ", suffix='\d+')`

Wide panel to long format. Less flexible but more user-friendly than melt.

With `stubnames` ['A', 'B'], this function expects to find one or more group of columns with format A-suffix1, A-suffix2,..., B-suffix1, B-suffix2,... You specify what you want to call this suffix in the resulting long format with `j` (for example `j='year'`)

Each row of these wide variables are assumed to be uniquely identified by `i` (can be a single column name or a list of column names)

All remaining variables in the data frame are left intact.

Parameters

df [DataFrame] The wide-format DataFrame

stubnames [str or list-like] The stub name(s). The wide format variables are assumed to start with the stub names.

i [str or list-like] Column(s) to use as id variable(s)

j [str] The name of the sub-observation variable. What you wish to name your suffix in the long format.

sep [str, default " "] A character indicating the separation of the variable names in the wide format, to be stripped from the names in the long format. For example, if your column names are A-suffix1, A-suffix2, you can strip the hyphen by specifying `sep='-'`

New in version 0.20.0.

suffix [str, default '\d+'] A regular expression capturing the wanted suffixes. '\d+' captures numeric suffixes. Suffixes with no numbers could be specified with the

negated character class `\D+`. You can also further disambiguate suffixes, for example, if your wide variables are of the form A-one, B-two,..., and you have an unrelated column A-rating, you can ignore the last one by specifying `suffix='(!?one/two)'`

New in version 0.20.0.

Changed in version 0.23.0: When all suffixes are numeric, they are cast to `int64/float64`.

Returns

DataFrame A DataFrame that contains each stub name as a variable, with new index (i, j).

Notes

All extra variables are left untouched. This simply uses `pandas.melt` under the hood, but is hard-coded to “do the right thing” in a typical case.

Examples

```
>>> np.random.seed(123)
>>> df = pd.DataFrame({"A1970" : {0 : "a", 1 : "b", 2 : "c"},
...                   "A1980" : {0 : "d", 1 : "e", 2 : "f"},
...                   "B1970" : {0 : 2.5, 1 : 1.2, 2 : .7},
...                   "B1980" : {0 : 3.2, 1 : 1.3, 2 : .1},
...                   "X"      : dict(zip(range(3), np.random.randn(3)))
...                   })
>>> df["id"] = df.index
>>> df
   A1970 A1980 B1970 B1980      X id
0     a     d   2.5   3.2 -1.085631  0
1     b     e   1.2   1.3  0.997345  1
2     c     f   0.7   0.1  0.282978  2
>>> pd.wide_to_long(df, ["A", "B"], i="id", j="year")
... # doctest: +NORMALIZE_WHITESPACE
      X A    B
id year
0 1970 -1.085631 a  2.5
1 1970  0.997345 b  1.2
2 1970  0.282978 c  0.7
0 1980 -1.085631 d  3.2
1 1980  0.997345 e  1.3
2 1980  0.282978 f  0.1
```

With multiple id columns

```
>>> df = pd.DataFrame({
...     'famid': [1, 1, 1, 2, 2, 2, 3, 3, 3],
...     'birth': [1, 2, 3, 1, 2, 3, 1, 2, 3],
...     'ht1': [2.8, 2.9, 2.2, 2, 1.8, 1.9, 2.2, 2.3, 2.1],
...     'ht2': [3.4, 3.8, 2.9, 3.2, 2.8, 2.4, 3.3, 3.4, 2.9]
... })
>>> df
```

(continues on next page)

(continued from previous page)

```

    famid  birth  ht1  ht2
0         1      1  2.8  3.4
1         1      2  2.9  3.8
2         1      3  2.2  2.9
3         2      1  2.0  3.2
4         2      2  1.8  2.8
5         2      3  1.9  2.4
6         3      1  2.2  3.3
7         3      2  2.3  3.4
8         3      3  2.1  2.9
>>> l = pd.wide_to_long(df, stubnames='ht', i=['famid', 'birth'], j='age')
>>> l
... # doctest: +NORMALIZE_WHITESPACE
           ht
famid birth age
1         1      1  2.8
           2      3.4
           2      1  2.9
           2      3.8
           3      1  2.2
           2      2.9
2         1      1  2.0
           2      3.2
           2      1  1.8
           2      2.8
           3      1  1.9
           2      2.4
3         1      1  2.2
           2      3.3
           2      1  2.3
           2      3.4
           3      1  2.1
           2      2.9

```

Going from long back to wide just takes some creative use of *unstack*

```

>>> w = l.unstack()
>>> w.columns = w.columns.map('{0[0]}{0[1]}'.format)
>>> w.reset_index()
    famid  birth  ht1  ht2
0         1      1  2.8  3.4
1         1      2  2.9  3.8
2         1      3  2.2  2.9
3         2      1  2.0  3.2
4         2      2  1.8  2.8
5         2      3  1.9  2.4
6         3      1  2.2  3.3
7         3      2  2.3  3.4
8         3      3  2.1  2.9

```

Less wieldy column names are also handled

```
>>> np.random.seed(0)
>>> df = pd.DataFrame({'A(weekly)-2010': np.random.rand(3),
...                   'A(weekly)-2011': np.random.rand(3),
...                   'B(weekly)-2010': np.random.rand(3),
...                   'B(weekly)-2011': np.random.rand(3),
...                   'X' : np.random.randint(3, size=3)})
>>> df['id'] = df.index
>>> df # doctest: +NORMALIZE_WHITESPACE, +ELLIPSIS
   A(weekly)-2010  A(weekly)-2011  B(weekly)-2010  B(weekly)-2011  X  id
0      0.548814      0.544883      0.437587      0.383442  0  0
1      0.715189      0.423655      0.891773      0.791725  1  1
2      0.602763      0.645894      0.963663      0.528895  1  2
```

```
>>> pd.wide_to_long(df, ['A(weekly)', 'B(weekly)'], i='id',
...                j='year', sep='-')
... # doctest: +NORMALIZE_WHITESPACE
   X  A(weekly)  B(weekly)
id year
0  2010  0      0.548814  0.437587
1  2010  1      0.715189  0.891773
2  2010  1      0.602763  0.963663
0  2011  0      0.544883  0.383442
1  2011  1      0.423655  0.791725
2  2011  1      0.645894  0.528895
```

If we have many columns, we could also use a regex to find our stubnames and pass that list on to `wide_to_long`

```
>>> stubnames = sorted(
...     set([match[0] for match in df.columns.str.findall(
...         r'[A-B]\(.*\)').values if match != [] ]))
... )
>>> list(stubnames)
['A(weekly)', 'B(weekly)']
```

All of the above examples have integers as suffixes. It is possible to have non-integers as suffixes.

```
>>> df = pd.DataFrame({
...     'famid': [1, 1, 1, 2, 2, 2, 3, 3, 3],
...     'birth': [1, 2, 3, 1, 2, 3, 1, 2, 3],
...     'ht_one': [2.8, 2.9, 2.2, 2, 1.8, 1.9, 2.2, 2.3, 2.1],
...     'ht_two': [3.4, 3.8, 2.9, 3.2, 2.8, 2.4, 3.3, 3.4, 2.9]
... })
>>> df
   famid  birth  ht_one  ht_two
0      1      1      2.8      3.4
1      1      2      2.9      3.8
2      1      3      2.2      2.9
3      2      1      2.0      3.2
4      2      2      1.8      2.8
5      2      3      1.9      2.4
6      3      1      2.2      3.3
7      3      2      2.3      3.4
```

(continues on next page)

(continued from previous page)

```

8      3      3      2.1      2.9

```

```

>>> l = pd.wide_to_long(df, stubnames='ht', i=['famid', 'birth'], j='age',
...                      sep='_', suffix='\w+')
>>> l
... # doctest: +NORMALIZE_WHITESPACE
              ht

```

6.2.2 Top-level missing data

<code>isna(obj)</code>	Detect missing values for an array-like object.
<code>isnull(obj)</code>	Detect missing values for an array-like object.
<code>notna(obj)</code>	Detect non-missing values for an array-like object.
<code>notnull(obj)</code>	Detect non-missing values for an array-like object.

pandas.isna

`pandas.isna(obj)`

Detect missing values for an array-like object.

This function takes a scalar or array-like object and indicates whether values are missing (NaN in numeric arrays, None or NaN in object arrays, NaT in datetimelike).

Parameters

obj [scalar or array-like] Object to check for null or missing values.

Returns

bool or array-like of bool For scalar input, returns a scalar boolean. For array input, returns an array of boolean indicating whether each corresponding element is missing.

See also:

notna Boolean inverse of pandas.isna.

Series.isna Detect missing values in a Series.

DataFrame.isna Detect missing values in a DataFrame.

Index.isna Detect missing values in an Index.

Examples

Scalar arguments (including strings) result in a scalar boolean.

```
>>> pd.isna('dog')
False
```

```
>>> pd.isna(np.nan)
True
```

ndarrays result in an ndarray of booleans.

```
>>> array = np.array([[1, np.nan, 3], [4, 5, np.nan]])
>>> array
array([[ 1., nan,  3.],
       [ 4.,  5., nan]])
>>> pd.isna(array)
array([[False,  True, False],
       [False, False,  True]])
```

For indexes, an ndarray of booleans is returned.

```
>>> index = pd.DatetimeIndex(["2017-07-05", "2017-07-06", None,
...                           "2017-07-08"])
>>> index
DatetimeIndex(['2017-07-05', '2017-07-06', 'NaT', '2017-07-08'],
              dtype='datetime64[ns]', freq=None)
>>> pd.isna(index)
array([False, False,  True, False])
```

For Series and DataFrame, the same type is returned, containing booleans.

```
>>> df = pd.DataFrame(['ant', 'bee', 'cat'], ['dog', None, 'fly'])
>>> df
   0    1    2
0  ant  bee  cat
1  dog None fly
>>> pd.isna(df)
   0    1    2
0  False False False
1  False  True False
```

```
>>> pd.isna(df[1])
0    False
1     True
Name: 1, dtype: bool
```

pandas.isnull`pandas.isnull(obj)`

Detect missing values for an array-like object.

This function takes a scalar or array-like object and indicates whether values are missing (NaN in numeric arrays, None or NaN in object arrays, NaT in datetimelike).

Parameters

obj [scalar or array-like] Object to check for null or missing values.

Returns

bool or array-like of bool For scalar input, returns a scalar boolean. For array input, returns an array of boolean indicating whether each corresponding element is missing.

See also:

notna Boolean inverse of pandas.isna.

Series.isna Detect missing values in a Series.

DataFrame.isna Detect missing values in a DataFrame.

Index.isna Detect missing values in an Index.

Examples

Scalar arguments (including strings) result in a scalar boolean.

```
>>> pd.isna('dog')
False
```

```
>>> pd.isna(np.nan)
True
```

ndarrays result in an ndarray of booleans.

```
>>> array = np.array([[1, np.nan, 3], [4, 5, np.nan]])
>>> array
array([[ 1., nan,  3.],
       [ 4.,  5., nan]])
>>> pd.isna(array)
array([[False,  True, False],
       [False, False,  True]])
```

For indexes, an ndarray of booleans is returned.

```
>>> index = pd.DatetimeIndex(["2017-07-05", "2017-07-06", None,
...                           "2017-07-08"])
>>> index
DatetimeIndex(['2017-07-05', '2017-07-06', 'NaT', '2017-07-08'],
              dtype='datetime64[ns]', freq=None)
>>> pd.isna(index)
array([False, False,  True, False])
```

For Series and DataFrame, the same type is returned, containing booleans.

```
>>> df = pd.DataFrame([[ 'ant', 'bee', 'cat'], ['dog', None, 'fly']])
>>> df
   0    1    2
0  ant  bee  cat
1  dog None  fly
>>> pd.isna(df)
   0    1    2
0  False False False
1  False  True  False
```

```
>>> pd.isna(df[1])
0    False
1     True
Name: 1, dtype: bool
```

pandas.notna

`pandas.notna(obj)`

Detect non-missing values for an array-like object.

This function takes a scalar or array-like object and indicates whether values are valid (not missing, which is NaN in numeric arrays, None or NaN in object arrays, NaT in datetimelike).

Parameters

obj [array-like or object value] Object to check for *not* null or *non*-missing values.

Returns

bool or array-like of bool For scalar input, returns a scalar boolean. For array input, returns an array of boolean indicating whether each corresponding element is valid.

See also:

isna Boolean inverse of `pandas.notna`.

Series.notna Detect valid values in a Series.

DataFrame.notna Detect valid values in a DataFrame.

Index.notna Detect valid values in an Index.

Examples

Scalar arguments (including strings) result in a scalar boolean.

```
>>> pd.notna('dog')
True
```

```
>>> pd.notna(np.nan)
False
```

ndarrays result in an ndarray of booleans.

```

>>> array = np.array([[1, np.nan, 3], [4, 5, np.nan]])
>>> array
array([[ 1., nan,  3.],
       [ 4.,  5., nan]])
>>> pd.notna(array)
array([[ True, False,  True],
       [ True,  True, False]])

```

For indexes, an ndarray of booleans is returned.

```

>>> index = pd.DatetimeIndex(["2017-07-05", "2017-07-06", None,
...                           "2017-07-08"])
>>> index
DatetimeIndex(['2017-07-05', '2017-07-06', 'NaT', '2017-07-08'],
              dtype='datetime64[ns]', freq=None)
>>> pd.notna(index)
array([ True,  True, False,  True])

```

For Series and DataFrame, the same type is returned, containing booleans.

```

>>> df = pd.DataFrame(['ant', 'bee', 'cat'], ['dog', None, 'fly'])
>>> df
   0    1    2
0  ant  bee  cat
1  dog None  fly
>>> pd.notna(df)
   0    1    2
0  True  True  True
1  True False  True

```

```

>>> pd.notna(df[1])
0    True
1   False
Name: 1, dtype: bool

```

pandas.notnull

`pandas.notnull(obj)`

Detect non-missing values for an array-like object.

This function takes a scalar or array-like object and indicates whether values are valid (not missing, which is NaN in numeric arrays, None or NaT in object arrays, NaT in datetimelike).

Parameters

obj [array-like or object value] Object to check for *not* null or *non*-missing values.

Returns

bool or array-like of bool For scalar input, returns a scalar boolean. For array input, returns an array of boolean indicating whether each corresponding element is valid.

See also:

isna Boolean inverse of pandas.notna.

Series.notna Detect valid values in a Series.

DataFrame.notna Detect valid values in a DataFrame.

Index.notna Detect valid values in an Index.

Examples

Scalar arguments (including strings) result in a scalar boolean.

```
>>> pd.notna('dog')
True
```

```
>>> pd.notna(np.nan)
False
```

ndarrays result in an ndarray of booleans.

```
>>> array = np.array([[1, np.nan, 3], [4, 5, np.nan]])
>>> array
array([[ 1., nan,  3.],
       [ 4.,  5., nan]])
>>> pd.notna(array)
array([[ True, False,  True],
       [ True,  True, False]])
```

For indexes, an ndarray of booleans is returned.

```
>>> index = pd.DatetimeIndex(["2017-07-05", "2017-07-06", None,
...                           "2017-07-08"])
>>> index
DatetimeIndex(['2017-07-05', '2017-07-06', 'NaT', '2017-07-08'],
              dtype='datetime64[ns]', freq=None)
>>> pd.notna(index)
array([ True,  True, False,  True])
```

For Series and DataFrame, the same type is returned, containing booleans.

```
>>> df = pd.DataFrame(['ant', 'bee', 'cat'], ['dog', None, 'fly'])
>>> df
   0    1    2
0 ant  bee cat
1 dog None fly
>>> pd.notna(df)
   0    1    2
0 True  True  True
1 True False  True
```

```
>>> pd.notna(df[1])
0    True
1    False
Name: 1, dtype: bool
```

6.2.3 Top-level conversions

`to_numeric(arg[, errors, downcast])` Convert argument to a numeric type.

`pandas.to_numeric`

`pandas.to_numeric(arg, errors='raise', downcast=None)`

Convert argument to a numeric type.

The default return dtype is `float64` or `int64` depending on the data supplied. Use the `downcast` parameter to obtain other dtypes.

Please note that precision loss may occur if really large numbers are passed in. Due to the internal limitations of `ndarray`, if numbers smaller than `-9223372036854775808` (`np.iinfo(np.int64).min`) or larger than `18446744073709551615` (`np.iinfo(np.uint64).max`) are passed in, it is very likely they will be converted to float so that they can be stored in an `ndarray`. These warnings apply similarly to `Series` since it internally leverages `ndarray`.

Parameters

arg [scalar, list, tuple, 1-d array, or Series]

errors [{'ignore', 'raise', 'coerce'}, default 'raise']

- If 'raise', then invalid parsing will raise an exception
- If 'coerce', then invalid parsing will be set as NaN
- If 'ignore', then invalid parsing will return the input

downcast [{'integer', 'signed', 'unsigned', 'float'} , default None] If not None, and if the data has been successfully cast to a numerical dtype (or if the data was numeric to begin with), downcast that resulting data to the smallest numerical dtype possible according to the following rules:

- 'integer' or 'signed': smallest signed int dtype (min.: `np.int8`)
- 'unsigned': smallest unsigned int dtype (min.: `np.uint8`)
- 'float': smallest float dtype (min.: `np.float32`)

As this behaviour is separate from the core conversion to numeric values, any errors raised during the downcasting will be surfaced regardless of the value of the 'errors' input.

In addition, downcasting will only occur if the size of the resulting data's dtype is strictly larger than the dtype it is to be cast to, so if none of the dtypes checked satisfy that specification, no downcasting will be performed on the data.

New in version 0.19.0.

Returns

ret [numeric if parsing succeeded.] Return type depends on input. Series if Series, otherwise ndarray.

See also:

`DataFrame.astype` Cast argument to a specified dtype.

`to_datetime` Convert argument to datetime.

`to_timedelta` Convert argument to timedelta.

`numpy.ndarray.astype` Cast a numpy array to a specified type.

Examples

Take separate series and convert to numeric, coercing when told to

```
>>> s = pd.Series(['1.0', '2', -3])
>>> pd.to_numeric(s)
0    1.0
1    2.0
2   -3.0
dtype: float64
>>> pd.to_numeric(s, downcast='float')
0    1.0
1    2.0
2   -3.0
dtype: float32
>>> pd.to_numeric(s, downcast='signed')
0    1
1    2
2   -3
dtype: int8
>>> s = pd.Series(['apple', '1.0', '2', -3])
>>> pd.to_numeric(s, errors='ignore')
0    apple
1     1.0
2     2
3    -3
dtype: object
>>> pd.to_numeric(s, errors='coerce')
0    NaN
1     1.0
2     2.0
3    -3.0
dtype: float64
```

6.2.4 Top-level dealing with datetimelike

<code>to_datetime</code> (arg[, errors, dayfirst, ...])	Convert argument to datetime.
<code>to_timedelta</code> (arg[, unit, box, errors])	Convert argument to timedelta.
<code>date_range</code> ([start, end, periods, freq, tz, ...])	Return a fixed frequency DatetimeIndex.
<code>bdate_range</code> ([start, end, periods, freq, tz, ...])	Return a fixed frequency DatetimeIndex, with business day as the default frequency
<code>period_range</code> ([start, end, periods, freq, name])	Return a fixed frequency PeriodIndex, with day (calendar) as the default frequency
<code>timedelta_range</code> ([start, end, periods, freq, ...])	Return a fixed frequency TimedeltaIndex, with day as the default frequency
<code>infer_freq</code> (index[, warn])	Infer the most likely frequency given the input index.

pandas.to_datetime

```
pandas.to_datetime(arg, errors='raise', dayfirst=False, yearfirst=False, utc=None, box=True,
                  format=None, exact=True, unit=None, infer_datetime_format=False, origin='unix', cache=True)
```

Convert argument to datetime.

Parameters

arg [integer, float, string, datetime, list, tuple, 1-d array, Series] New in version 0.18.1: or DataFrame/dict-like

errors [{'ignore', 'raise', 'coerce'}, default 'raise']

- If 'raise', then invalid parsing will raise an exception
- If 'coerce', then invalid parsing will be set as NaT
- If 'ignore', then invalid parsing will return the input

dayfirst [boolean, default False] Specify a date parse order if *arg* is str or its list-likes. If True, parses dates with the day first, eg 10/11/12 is parsed as 2012-11-10. Warning: dayfirst=True is not strict, but will prefer to parse with day first (this is a known bug, based on dateutil behavior).

yearfirst [boolean, default False] Specify a date parse order if *arg* is str or its list-likes.

- If True parses dates with the year first, eg 10/11/12 is parsed as 2010-11-12.
- If both dayfirst and yearfirst are True, yearfirst is preceded (same as dateutil).

Warning: yearfirst=True is not strict, but will prefer to parse with year first (this is a known bug, based on dateutil behavior).

New in version 0.16.1.

utc [boolean, default None] Return UTC DatetimeIndex if True (converting any tz-aware datetime.datetime objects as well).

box [boolean, default True]

- If True returns a DatetimeIndex or Index-like object
- If False returns ndarray of values.

Deprecated since version 0.25.0: Use *Series.to_numpy()* or *Timestamp.to_datetime64()* instead to get an ndarray of values or numpy.datetime64, respectively.

format [string, default None] strftime to parse time, eg “%d/%m/%Y”, note that “%f” will parse all the way up to nanoseconds. See strftime documentation for more information on choices: <https://docs.python.org/3/library/datetime.html#strftime-and-strptime-behavior>

exact [boolean, True by default]

- If True, require an exact format match.
- If False, allow the format to match anywhere in the target string.

unit [string, default 'ns'] unit of the arg (D,s,ms,us,ns) denote the unit, which is an integer or float number. This will be based off the origin. Example, with unit='ms' and origin='unix' (the default), this would calculate the number of milliseconds to the unix epoch start.

infer_datetime_format [boolean, default False] If True and no *format* is given, attempt to infer the format of the datetime strings, and if it can be inferred, switch to a faster method of parsing them. In some cases this can increase the parsing speed by ~5-10x.

origin [scalar, default is 'unix'] Define the reference date. The numeric values would be parsed as number of units (defined by *unit*) since this reference date.

- If 'unix' (or POSIX) time; origin is set to 1970-01-01.
- If 'julian', unit must be 'D', and origin is set to beginning of Julian Calendar. Julian day number 0 is assigned to the day starting at noon on January 1, 4713 BC.
- If Timestamp convertible, origin is set to Timestamp identified by origin.

New in version 0.20.0.

cache [boolean, default True] If True, use a cache of unique, converted dates to apply the datetime conversion. May produce significant speed-up when parsing duplicate date strings, especially ones with timezone offsets.

New in version 0.23.0.

Changed in version 0.25.0: - changed default value from False to True

Returns

ret [datetime if parsing succeeded.] Return type depends on input:

- list-like: DatetimeIndex
- Series: Series of datetime64 dtype
- scalar: Timestamp

In case when it is not possible to return designated types (e.g. when any element of input is before Timestamp.min or after Timestamp.max) return will have datetime.datetime type (or corresponding array/Series).

See also:

DataFrame.astype Cast argument to a specified dtype.

to_timedelta Convert argument to timedelta.

Examples

Assembling a datetime from multiple columns of a DataFrame. The keys can be common abbreviations like ['year', 'month', 'day', 'minute', 'second', 'ms', 'us', 'ns']) or plurals of the same

```
>>> df = pd.DataFrame({'year': [2015, 2016],
...                    'month': [2, 3],
...                    'day': [4, 5]})
>>> pd.to_datetime(df)
0    2015-02-04
1    2016-03-05
dtype: datetime64[ns]
```

If a date does not meet the [timestamp limitations](#), passing `errors='ignore'` will return the original input instead of raising any exception.

Passing `errors='coerce'` will force an out-of-bounds date to NaT, in addition to forcing non-dates (or non-parseable dates) to NaT.

```
>>> pd.to_datetime('13000101', format='%Y%m%d', errors='ignore')
datetime.datetime(1300, 1, 1, 0, 0)
>>> pd.to_datetime('13000101', format='%Y%m%d', errors='coerce')
NaT
```

Passing `infer_datetime_format=True` can often-times speedup a parsing if its not an ISO8601 format exactly, but in a regular format.

```
>>> s = pd.Series(['3/11/2000', '3/12/2000', '3/13/2000'] * 1000)
>>> s.head()
0    3/11/2000
1    3/12/2000
2    3/13/2000
3    3/11/2000
4    3/12/2000
dtype: object
```

```
>>> %timeit pd.to_datetime(s,infer_datetime_format=True) # doctest: +SKIP
100 loops, best of 3: 10.4 ms per loop
```

```
>>> %timeit pd.to_datetime(s,infer_datetime_format=False) # doctest: +SKIP
1 loop, best of 3: 471 ms per loop
```

Using a unix epoch time

```
>>> pd.to_datetime(1490195805, unit='s')
Timestamp('2017-03-22 15:16:45')
>>> pd.to_datetime(1490195805433502912, unit='ns')
Timestamp('2017-03-22 15:16:45.433502912')
```

Warning: For float arg, precision rounding might happen. To prevent unexpected behavior use a fixed-width exact type.

Using a non-unix epoch origin

```
>>> pd.to_datetime([1, 2, 3], unit='D',
...                origin=pd.Timestamp('1960-01-01'))
DatetimeIndex(['1960-01-02', '1960-01-03', '1960-01-04'], dtype='datetime64[ns]',
              ↪ freq=None)
```

pandas.to_timedelta

`pandas.to_timedelta(arg, unit='ns', box=True, errors='raise')`
Convert argument to timedelta.

Timedeltas are absolute differences in times, expressed in difference units (e.g. days, hours, minutes, seconds). This method converts an argument from a recognized timedelta format / value into a Timedelta type.

Parameters

arg [str, timedelta, list-like or Series] The data to be converted to timedelta.

unit [str, default 'ns'] Denotes the unit of the arg. Possible values: ('Y', 'M', 'W', 'D', 'days', 'day', 'hours', 'hour', 'hr', 'h', 'm', 'minute', 'min', 'minutes', 'T', 'S', 'seconds', 'sec', 'second', 'ms', 'milliseconds', 'millisecond', 'milli', 'millis', 'L', 'us', 'microseconds', 'microsecond', 'micro', 'micros', 'U', 'ns', 'nanoseconds', 'nano', 'nanos', 'nanosecond', 'N').

box [bool, default True]

- If True returns a Timedelta/TimedeltaIndex of the results.
- If False returns a numpy.timedelta64 or numpy.darray of values of dtype timedelta64[ns].

Deprecated since version 0.25.0: Use `Series.to_numpy()` or `Timedelta.to_timedelta64()` instead to get an ndarray of values or numpy.timedelta64, respectively.

errors [{'ignore', 'raise', 'coerce'}, default 'raise']

- If 'raise', then invalid parsing will raise an exception.
- If 'coerce', then invalid parsing will be set as NaT.
- If 'ignore', then invalid parsing will return the input.

Returns

timedelta64 or numpy.array of timedelta64 Output type returned if parsing succeeded.

See also:

DataFrame.astype Cast argument to a specified dtype.

to_datetime Convert argument to datetime.

Examples

Parsing a single string to a Timedelta:

```
>>> pd.to_timedelta('1 days 06:05:01.000030')
Timedelta('1 days 06:05:01.000030')
>>> pd.to_timedelta('15.5us')
Timedelta('0 days 00:00:00.000015')
```

Parsing a list or array of strings:

```
>>> pd.to_timedelta(['1 days 06:05:01.000030', '15.5us', 'nan'])
TimedeltaIndex(['1 days 06:05:01.000030', '0 days 00:00:00.000015', NaT],
                dtype='timedelta64[ns]', freq=None)
```

Converting numbers by specifying the *unit* keyword argument:

```
>>> pd.to_timedelta(np.arange(5), unit='s')
TimedeltaIndex(['00:00:00', '00:00:01', '00:00:02',
                '00:00:03', '00:00:04'],
```

(continues on next page)

(continued from previous page)

```

dtype='timedelta64[ns]', freq=None)
>>> pd.to_timedelta(np.arange(5), unit='d')
TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'],
                dtype='timedelta64[ns]', freq=None)

```

Returning an ndarray by using the 'box' keyword argument:

```

>>> pd.to_timedelta(np.arange(5), box=False)
array([0, 1, 2, 3, 4], dtype='timedelta64[ns]')

```

pandas.date_range

`pandas.date_range`(*start=None, end=None, periods=None, freq=None, tz=None, normalize=False, name=None, closed=None, **kwargs*)

Return a fixed frequency DatetimeIndex.

Parameters

start [str or datetime-like, optional] Left bound for generating dates.

end [str or datetime-like, optional] Right bound for generating dates.

periods [integer, optional] Number of periods to generate.

freq [str or DateOffset, default 'D'] Frequency strings can have multiples, e.g. '5H'. See [here](#) for a list of frequency aliases.

tz [str or tzinfo, optional] Time zone name for returning localized DatetimeIndex, for example 'Asia/Hong_Kong'. By default, the resulting DatetimeIndex is timezone-naive.

normalize [bool, default False] Normalize start/end dates to midnight before generating date range.

name [str, default None] Name of the resulting DatetimeIndex.

closed [{None, 'left', 'right'}, optional] Make the interval closed with respect to the given frequency to the 'left', 'right', or both sides (None, the default).

****kwargs** For compatibility. Has no effect on the result.

Returns

rng [DatetimeIndex]

See also:

DatetimeIndex An immutable container for datetimes.

timedelta_range Return a fixed frequency TimedeltaIndex.

period_range Return a fixed frequency PeriodIndex.

interval_range Return a fixed frequency IntervalIndex.

Notes

Of the four parameters `start`, `end`, `periods`, and `freq`, exactly three must be specified. If `freq` is omitted, the resulting `DatetimeIndex` will have `periods` linearly spaced elements between `start` and `end` (closed on both sides).

To learn more about the frequency strings, please see [this link](#).

Examples

Specifying the values

The next four examples generate the same `DatetimeIndex`, but vary the combination of `start`, `end` and `periods`.

Specify `start` and `end`, with the default daily frequency.

```
>>> pd.date_range(start='1/1/2018', end='1/08/2018')
DatetimeIndex(['2018-01-01', '2018-01-02', '2018-01-03', '2018-01-04',
              '2018-01-05', '2018-01-06', '2018-01-07', '2018-01-08'],
              dtype='datetime64[ns]', freq='D')
```

Specify `start` and `periods`, the number of periods (days).

```
>>> pd.date_range(start='1/1/2018', periods=8)
DatetimeIndex(['2018-01-01', '2018-01-02', '2018-01-03', '2018-01-04',
              '2018-01-05', '2018-01-06', '2018-01-07', '2018-01-08'],
              dtype='datetime64[ns]', freq='D')
```

Specify `end` and `periods`, the number of periods (days).

```
>>> pd.date_range(end='1/1/2018', periods=8)
DatetimeIndex(['2017-12-25', '2017-12-26', '2017-12-27', '2017-12-28',
              '2017-12-29', '2017-12-30', '2017-12-31', '2018-01-01'],
              dtype='datetime64[ns]', freq='D')
```

Specify `start`, `end`, and `periods`; the frequency is generated automatically (linearly spaced).

```
>>> pd.date_range(start='2018-04-24', end='2018-04-27', periods=3)
DatetimeIndex(['2018-04-24 00:00:00', '2018-04-25 12:00:00',
              '2018-04-27 00:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Other Parameters

Changed the `freq` (frequency) to 'M' (month end frequency).

```
>>> pd.date_range(start='1/1/2018', periods=5, freq='M')
DatetimeIndex(['2018-01-31', '2018-02-28', '2018-03-31', '2018-04-30',
              '2018-05-31'],
              dtype='datetime64[ns]', freq='M')
```

Multiples are allowed

```
>>> pd.date_range(start='1/1/2018', periods=5, freq='3M')
DatetimeIndex(['2018-01-31', '2018-04-30', '2018-07-31', '2018-10-31',
              '2019-01-31'],
              dtype='datetime64[ns]', freq='3M')
```

freq can also be specified as an Offset object.

```
>>> pd.date_range(start='1/1/2018', periods=5, freq=pd.offsets.MonthEnd(3))
DatetimeIndex(['2018-01-31', '2018-04-30', '2018-07-31', '2018-10-31',
              '2019-01-31'],
              dtype='datetime64[ns]', freq='3M')
```

Specify *tz* to set the timezone.

```
>>> pd.date_range(start='1/1/2018', periods=5, tz='Asia/Tokyo')
DatetimeIndex(['2018-01-01 00:00:00+09:00', '2018-01-02 00:00:00+09:00',
              '2018-01-03 00:00:00+09:00', '2018-01-04 00:00:00+09:00',
              '2018-01-05 00:00:00+09:00'],
              dtype='datetime64[ns, Asia/Tokyo]', freq='D')
```

closed controls whether to include *start* and *end* that are on the boundary. The default includes boundary points on either end.

```
>>> pd.date_range(start='2017-01-01', end='2017-01-04', closed=None)
DatetimeIndex(['2017-01-01', '2017-01-02', '2017-01-03', '2017-01-04'],
              dtype='datetime64[ns]', freq='D')
```

Use *closed='left'* to exclude *end* if it falls on the boundary.

```
>>> pd.date_range(start='2017-01-01', end='2017-01-04', closed='left')
DatetimeIndex(['2017-01-01', '2017-01-02', '2017-01-03'],
              dtype='datetime64[ns]', freq='D')
```

Use *closed='right'* to exclude *start* if it falls on the boundary.

```
>>> pd.date_range(start='2017-01-01', end='2017-01-04', closed='right')
DatetimeIndex(['2017-01-02', '2017-01-03', '2017-01-04'],
              dtype='datetime64[ns]', freq='D')
```

pandas.bdate_range

`pandas.bdate_range(start=None, end=None, periods=None, freq='B', tz=None, normalize=True, name=None, weekmask=None, holidays=None, closed=None, **kwargs)`

Return a fixed frequency DatetimeIndex, with business day as the default frequency

Parameters

start [string or datetime-like, default None] Left bound for generating dates.

end [string or datetime-like, default None] Right bound for generating dates.

periods [integer, default None] Number of periods to generate.

freq [string or DateOffset, default 'B' (business daily)] Frequency strings can have multiples, e.g. '5H'.

tz [string or None] Time zone name for returning localized DatetimeIndex, for example Asia/Beijing.

normalize [bool, default False] Normalize start/end dates to midnight before generating date range.

name [string, default None] Name of the resulting DatetimeIndex.

weekmask [string or None, default None] Weekmask of valid business days, passed to `numpy.busdaycalendar`, only used when custom frequency strings are passed. The default value None is equivalent to 'Mon Tue Wed Thu Fri'.

New in version 0.21.0.

holidays [list-like or None, default None] Dates to exclude from the set of valid business days, passed to `numpy.busdaycalendar`, only used when custom frequency strings are passed.

New in version 0.21.0.

closed [string, default None] Make the interval closed with respect to the given frequency to the 'left', 'right', or both sides (None).

****kwargs** For compatibility. Has no effect on the result.

Returns

DatetimeIndex

Notes

Of the four parameters: `start`, `end`, `periods`, and `freq`, exactly three must be specified. Specifying `freq` is a requirement for `bdate_range`. Use `date_range` if specifying `freq` is not desired.

To learn more about the frequency strings, please see [this link](#).

Examples

Note how the two weekend days are skipped in the result.

```
>>> pd.bdate_range(start='1/1/2018', end='1/08/2018')
DatetimeIndex(['2018-01-01', '2018-01-02', '2018-01-03', '2018-01-04',
              '2018-01-05', '2018-01-08'],
              dtype='datetime64[ns]', freq='B')
```

pandas.period_range

`pandas.period_range(start=None, end=None, periods=None, freq=None, name=None)`
Return a fixed frequency PeriodIndex, with day (calendar) as the default frequency

Parameters

start [string or period-like, default None] Left bound for generating periods

end [string or period-like, default None] Right bound for generating periods

periods [integer, default None] Number of periods to generate

freq [string or DateOffset, optional] Frequency alias. By default the freq is taken from *start* or *end* if those are Period objects. Otherwise, the default is "D" for daily frequency.

name [string, default None] Name of the resulting PeriodIndex

Returns

prng [PeriodIndex]

Notes

Of the three parameters: *start*, *end*, and *periods*, exactly two must be specified.

To learn more about the frequency strings, please see [this link](#).

Examples

```
>>> pd.period_range(start='2017-01-01', end='2018-01-01', freq='M')
PeriodIndex(['2017-01', '2017-02', '2017-03', '2017-04', '2017-05',
            '2017-06', '2017-06', '2017-07', '2017-08', '2017-09',
            '2017-10', '2017-11', '2017-12', '2018-01'],
            dtype='period[M]', freq='M')
```

If *start* or *end* are Period objects, they will be used as anchor endpoints for a PeriodIndex with frequency matching that of the `period_range` constructor.

```
>>> pd.period_range(start=pd.Period('2017Q1', freq='Q'),
...                 end=pd.Period('2017Q2', freq='Q'), freq='M')
PeriodIndex(['2017-03', '2017-04', '2017-05', '2017-06'],
            dtype='period[M]', freq='M')
```

pandas.timedelta_range

`pandas.timedelta_range(start=None, end=None, periods=None, freq=None, name=None, closed=None)`

Return a fixed frequency TimedeltaIndex, with day as the default frequency

Parameters

start [string or timedelta-like, default None] Left bound for generating timesteps

end [string or timedelta-like, default None] Right bound for generating timesteps

periods [integer, default None] Number of periods to generate

freq [string or DateOffset, default 'D'] Frequency strings can have multiples, e.g. '5H'

name [string, default None] Name of the resulting TimedeltaIndex

closed [string, default None] Make the interval closed with respect to the given frequency to the 'left', 'right', or both sides (None)

Returns

rng [TimedeltaIndex]

Notes

Of the four parameters `start`, `end`, `periods`, and `freq`, exactly three must be specified. If `freq` is omitted, the resulting `TimedeltaIndex` will have `periods` linearly spaced elements between `start` and `end` (closed on both sides).

To learn more about the frequency strings, please see [this link](#).

Examples

```
>>> pd.timedelta_range(start='1 day', periods=4)
TimedeltaIndex(['1 days', '2 days', '3 days', '4 days'],
                dtype='timedelta64[ns]', freq='D')
```

The `closed` parameter specifies which endpoint is included. The default behavior is to include both endpoints.

```
>>> pd.timedelta_range(start='1 day', periods=4, closed='right')
TimedeltaIndex(['2 days', '3 days', '4 days'],
                dtype='timedelta64[ns]', freq='D')
```

The `freq` parameter specifies the frequency of the `TimedeltaIndex`. Only fixed frequencies can be passed, non-fixed frequencies such as 'M' (month end) will raise.

```
>>> pd.timedelta_range(start='1 day', end='2 days', freq='6H')
TimedeltaIndex(['1 days 00:00:00', '1 days 06:00:00', '1 days 12:00:00',
                '1 days 18:00:00', '2 days 00:00:00'],
                dtype='timedelta64[ns]', freq='6H')
```

Specify `start`, `end`, and `periods`; the frequency is generated automatically (linearly spaced).

```
>>> pd.timedelta_range(start='1 day', end='5 days', periods=4)
TimedeltaIndex(['1 days 00:00:00', '2 days 08:00:00', '3 days 16:00:00',
                '5 days 00:00:00'],
                dtype='timedelta64[ns]', freq=None)
```

pandas.infer_freq

`pandas.infer_freq(index, warn=True)`

Infer the most likely frequency given the input index. If the frequency is uncertain, a warning will be printed.

Parameters

index [DatetimeIndex or TimedeltaIndex] if passed a Series will use the values of the series (NOT THE INDEX)

warn [boolean, default True]

Returns

str or None None if no discernible frequency `TypeError` if the index is not datetime-like `ValueError` if there are less than three values.

6.2.5 Top-level dealing with intervals

`interval_range`([start, end, periods, freq, ...]) Return a fixed frequency `IntervalIndex`

`pandas.interval_range`

`pandas.interval_range`(*start=None, end=None, periods=None, freq=None, name=None, closed='right'*)

Return a fixed frequency `IntervalIndex`

Parameters

start [numeric or datetime-like, default None] Left bound for generating intervals

end [numeric or datetime-like, default None] Right bound for generating intervals

periods [integer, default None] Number of periods to generate

freq [numeric, string, or `DateOffset`, default None] The length of each interval. Must be consistent with the type of `start` and `end`, e.g. 2 for numeric, or '5H' for datetime-like. Default is 1 for numeric and 'D' for datetime-like.

name [string, default None] Name of the resulting `IntervalIndex`

closed [{'left', 'right', 'both', 'neither'}, default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.

Returns

`rng` [`IntervalIndex`]

See also:

`IntervalIndex` An Index of intervals that are all closed on the same side.

Notes

Of the four parameters `start`, `end`, `periods`, and `freq`, exactly three must be specified. If `freq` is omitted, the resulting `IntervalIndex` will have `periods` linearly spaced elements between `start` and `end`, inclusively.

To learn more about datetime-like frequency strings, please see [this link](#).

Examples

Numeric `start` and `end` is supported.

```
>>> pd.interval_range(start=0, end=5)
IntervalIndex([(0, 1], (1, 2], (2, 3], (3, 4], (4, 5]],
              closed='right', dtype='interval[int64]')
```

Additionally, datetime-like input is also supported.

```
>>> pd.interval_range(start=pd.Timestamp('2017-01-01'),
...                  end=pd.Timestamp('2017-01-04'))
IntervalIndex([(2017-01-01, 2017-01-02], (2017-01-02, 2017-01-03]),
```

(continues on next page)

(continued from previous page)

```
(2017-01-03, 2017-01-04]],
closed='right', dtype='interval[datetime64[ns]]')
```

The `freq` parameter specifies the frequency between the left and right endpoints of the individual intervals within the `IntervalIndex`. For numeric `start` and `end`, the frequency must also be numeric.

```
>>> pd.interval_range(start=0, periods=4, freq=1.5)
IntervalIndex([(0.0, 1.5], (1.5, 3.0], (3.0, 4.5], (4.5, 6.0]],
              closed='right', dtype='interval[float64]')
```

Similarly, for datetime-like `start` and `end`, the frequency must be convertible to a `DateOffset`.

```
>>> pd.interval_range(start=pd.Timestamp('2017-01-01'),
...                  periods=3, freq='MS')
IntervalIndex([(2017-01-01, 2017-02-01], (2017-02-01, 2017-03-01],
              (2017-03-01, 2017-04-01]],
              closed='right', dtype='interval[datetime64[ns]]')
```

Specify `start`, `end`, and `periods`; the frequency is generated automatically (linearly spaced).

```
>>> pd.interval_range(start=0, end=6, periods=4)
IntervalIndex([(0.0, 1.5], (1.5, 3.0], (3.0, 4.5], (4.5, 6.0]],
              closed='right',
              dtype='interval[float64]')
```

The `closed` parameter specifies which endpoints of the individual intervals within the `IntervalIndex` are closed.

```
>>> pd.interval_range(end=5, periods=4, closed='both')
IntervalIndex([[1, 2], [2, 3], [3, 4], [4, 5]],
              closed='both', dtype='interval[int64]')
```

6.2.6 Top-level evaluation

`eval(expr[, parser, engine, truediv, ...])`

Evaluate a Python expression as a string using various backends.

pandas.eval

`pandas.eval(expr, parser='pandas', engine=None, truediv=True, local_dict=None, global_dict=None, resolvers=(), level=0, target=None, inplace=False)`

Evaluate a Python expression as a string using various backends.

The following arithmetic operations are supported: `+`, `-`, `*`, `/`, `**`, `%`, `//` (python engine only) along with the following boolean operations: `|` (or), `&` (and), and `~` (not). Additionally, the 'pandas' parser allows the use of `and`, `or`, and `not` with the same semantics as the corresponding bitwise operators. *Series* and *DataFrame* objects are supported and behave as they would with plain ol' Python evaluation.

Parameters

`expr` [str or unicode] The expression to evaluate. This string cannot contain any Python statements, only Python expressions.

parser [string, default 'pandas', {'pandas', 'python'}] The parser to use to construct the syntax tree from the expression. The default of 'pandas' parses code slightly different than standard Python. Alternatively, you can parse an expression using the 'python' parser to retain strict Python semantics. See the *enhancing performance* documentation for more details.

engine [string or None, default 'numexpr', {'python', 'numexpr'}] The engine used to evaluate the expression. Supported engines are

- None : tries to use numexpr, falls back to python
- 'numexpr': This default engine evaluates pandas objects using numexpr for large speed ups in complex expressions with large frames.
- 'python': Performs operations as if you had eval'd in top level python. This engine is generally not that useful.

More backends may be available in the future.

truediv [bool, optional] Whether to use true division, like in Python ≥ 3

local_dict [dict or None, optional] A dictionary of local variables, taken from locals() by default.

global_dict [dict or None, optional] A dictionary of global variables, taken from globals() by default.

resolvers [list of dict-like or None, optional] A list of objects implementing the `__getitem__` special method that you can use to inject an additional collection of namespaces to use for variable lookup. For example, this is used in the `query()` method to inject the `DataFrame.index` and `DataFrame.columns` variables that refer to their respective `DataFrame` instance attributes.

level [int, optional] The number of prior stack frames to traverse and add to the current scope. Most users will **not** need to change this parameter.

target [object, optional, default None] This is the target object for assignment. It is used when there is variable assignment in the expression. If so, then *target* must support item assignment with string keys, and if a copy is being returned, it must also support `.copy()`.

inplace [bool, default False] If *target* is provided, and the expression mutates *target*, whether to modify *target* inplace. Otherwise, return a copy of *target* with the mutation.

Returns

ndarray, numeric scalar, DataFrame, Series

Raises

ValueError There are many instances where such an error can be raised:

- *target=None*, but the expression is multiline.
- The expression is multiline, but not all them have item assignment. An example of such an arrangement is this:

```
a = b + 1 a + 2
```

Here, there are expressions on different lines, making it multiline, but the last line has no variable assigned to the output of `a + 2`.

- *inplace=True*, but the expression is missing item assignment.

- Item assignment is provided, but the *target* does not support string item assignment.
- Item assignment is provided and *inplace=False*, but the *target* does not support the *.copy()* method

See also:

`DataFrame.query`

`DataFrame.eval`

Notes

The dtype of any objects involved in an arithmetic % operation are recursively cast to `float64`.

See the *enhancing performance* documentation for more details.

6.2.7 Hashing

<code>util.hash_array(vals[, encoding, hash_key, ...])</code>	Given a 1d array, return an array of deterministic integers.
<code>util.hash_pandas_object(obj[, index, ...])</code>	Return a data hash of the Index/Series/DataFrame

`pandas.util.hash_array`

`pandas.util.hash_array(vals, encoding='utf8', hash_key=None, categorize=True)`

Given a 1d array, return an array of deterministic integers.

New in version 0.19.2.

Parameters

vals [ndarray, Categorical]

encoding [string, default 'utf8'] encoding for data & key when strings

hash_key [string key to encode, default to `_default_hash_key`]

categorize [bool, default True] Whether to first categorize object arrays before hashing. This is more efficient when the array contains duplicate values.

New in version 0.20.0.

Returns

1d uint64 numpy array of hash values, same length as the vals

`pandas.util.hash_pandas_object`

`pandas.util.hash_pandas_object(obj, index=True, encoding='utf8', hash_key=None, categorize=True)`

Return a data hash of the Index/Series/DataFrame

New in version 0.19.2.

Parameters

index [boolean, default True] include the index in the hash (if Series/DataFrame)

encoding [string, default 'utf8'] encoding for data & key when strings

hash_key [string key to encode, default to `__default_hash_key`]

categorize [bool, default True] Whether to first categorize object arrays before hashing. This is more efficient when the array contains duplicate values.

New in version 0.20.0.

Returns

Series of `uint64`, same length as the object

6.2.8 Testing

```
test([extra_args])
```

pandas.test

```
pandas.test(extra_args=None)
```

```
{{ header }}
```

6.3 Series

6.3.1 Constructor

<code>Series([data, index, dtype, name, copy, ...])</code>	One-dimensional ndarray with axis labels (including time series).
--	---

pandas.Series

```
class pandas.Series(data=None, index=None, dtype=None, name=None, copy=False, fast-path=False)
```

One-dimensional ndarray with axis labels (including time series).

Labels need not be unique but must be a hashable type. The object supports both integer- and label-based indexing and provides a host of methods for performing operations involving the index. Statistical methods from ndarray have been overridden to automatically exclude missing data (currently represented as NaN).

Operations between Series (+, -, /, *, **) align values based on their associated index values– they need not be the same length. The result index will be the sorted union of the two indexes.

Parameters

data [array-like, Iterable, dict, or scalar value] Contains data stored in Series.

Changed in version 0.23.0: If data is a dict, argument order is maintained for Python 3.6 and later.

index [array-like or Index (1d)] Values must be hashable and have the same length as `data`. Non-unique index values are allowed. Will default to `RangeIndex(0, 1, 2, ..., n)` if not provided. If both a dict and index sequence are used, the index will override the keys found in the dict.

dtype [str, numpy.dtype, or ExtensionDtype, optional] Data type for the output Series. If not specified, this will be inferred from *data*. See the *user guide* for more usages.

copy [bool, default False] Copy input data.

Attributes

<i>T</i>	Return the transpose, which is by
<i>array</i>	The ExtensionArray of the data backing this Series or Index.
<i>asobject</i>	Return object Series which contains boxed values.
<i>at</i>	Access a single value for a row/column label pair.
<i>axes</i>	Return a list of the row axis labels.
<i>base</i>	(DEPRECATED) Return the base object if the memory of the underlying data is shared.
<i>blocks</i>	(DEPRECATED) Internal property, property synonym for <i>as_blocks()</i> .
<i>data</i>	(DEPRECATED) Return the data pointer of the underlying data.
<i>dtype</i>	Return the dtype object of the underlying data.
<i>dtypes</i>	Return the dtype object of the underlying data.
<i>flags</i>	(DEPRECATED)
<i>ftype</i>	(DEPRECATED) Return if the data is sparse dense.
<i>ftypes</i>	(DEPRECATED) Return if the data is sparse dense.
<i>hasnans</i>	Return if I have any nans; enables various perf speedups.
<i>iat</i>	Access a single value for a row/column pair by integer position.
<i>iloc</i>	Purely integer-location based indexing for selection by position.
<i>imag</i>	Return imag value of vector.
<i>index</i>	The index (axis labels) of the Series.
<i>is_copy</i>	Return the copy.
<i>is_monotonic</i>	Return boolean if values in the object are monotonic_increasing.
<i>is_monotonic_decreasing</i>	Return boolean if values in the object are monotonic_decreasing.
<i>is_monotonic_increasing</i>	Return boolean if values in the object are monotonic_increasing.
<i>is_unique</i>	Return boolean if values in the object are unique.
<i>itemsizes</i>	(DEPRECATED) Return the size of the dtype of the item of the underlying data.
<i>ix</i>	A primarily label-location based indexer, with integer position fallback.
<i>loc</i>	Access a group of rows and columns by label(s) or a boolean array.
<i>name</i>	Return name of the Series.

Continued on next page

Table 26 – continued from previous page

<i>nbytes</i>	Return the number of bytes in the underlying data.
<i>ndim</i>	Number of dimensions of the underlying data, by definition 1.
<i>real</i>	Return the real value of vector.
<i>shape</i>	Return a tuple of the shape of the underlying data.
<i>size</i>	Return the number of elements in the underlying data.
<i>strides</i>	(DEPRECATED) Return the strides of the underlying data.
<i>values</i>	Return Series as ndarray or ndarray-like depending on the dtype.

pandas.Series.T**Series.T**

Return the transpose, which is by definition self.

pandas.Series.array**Series.array**

The ExtensionArray of the data backing this Series or Index.

New in version 0.24.0.

Returns**ExtensionArray** An ExtensionArray of the values stored within. For extension types, this is the actual array. For NumPy native types, this is a thin (no copy) wrapper around `numpy.ndarray`.`.array` differs `.values` which may require converting the data to a different form.

See also:

Index.to_numpy Similar method that always returns a NumPy array.**Series.to_numpy** Similar method that always returns a NumPy array.**Notes**

This table lays out the different array types for each extension dtype within pandas.

dtype	array type
category	Categorical
period	PeriodArray
interval	IntervalArray
IntegerNA	IntegerArray
datetime64[ns, tz]	DatetimeArray

For any 3rd-party extension types, the array type will be an ExtensionArray.

For all remaining dtypes `.array` will be a `arrays.NumpyExtensionArray` wrapping the actual ndarray stored within. If you absolutely need a NumPy array (possibly with copying / coercing data), then use `Series.to_numpy()` instead.

Examples

For regular NumPy types like int, and float, a PandasArray is returned.

```
>>> pd.Series([1, 2, 3]).array
<PandasArray>
[1, 2, 3]
Length: 3, dtype: int64
```

For extension types, like Categorical, the actual ExtensionArray is returned

```
>>> ser = pd.Series(pd.Categorical(['a', 'b', 'a']))
>>> ser.array
[a, b, a]
Categories (2, object): [a, b]
```

pandas.Series.asobject

Series.asobject

Return object Series which contains boxed values.

Deprecated since version 0.23.0: Use `astype(object)` instead.

this is an internal non-public method

pandas.Series.at

Series.at

Access a single value for a row/column label pair.

Similar to `loc`, in that both provide label-based lookups. Use `at` if you only need to get or set a single value in a DataFrame or Series.

Raises

KeyError When label does not exist in DataFrame

See also:

DataFrame.iat Access a single value for a row/column pair by integer position.

DataFrame.loc Access a group of rows and columns by label(s).

Series.at Access a single value using a label.

Examples

```
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
...                    index=[4, 5, 6], columns=['A', 'B', 'C'])
>>> df
   A  B  C
4  0  2  3
5  0  4  1
6 10 20 30
```

Get value at specified row/column pair

```
>>> df.at[4, 'B']
2
```

Set value at specified row/column pair

```
>>> df.at[4, 'B'] = 10
>>> df.at[4, 'B']
10
```

Get value within a Series

```
>>> df.loc[5].at['B']
4
```

pandas.Series.axes

Series.axes

Return a list of the row axis labels.

pandas.Series.base

Series.base

Return the base object if the memory of the underlying data is shared.

Deprecated since version 0.23.0.

pandas.Series.blocks

Series.blocks

Internal property, property synonym for `as_blocks()`.

Deprecated since version 0.21.0.

pandas.Series.data

Series.data

Return the data pointer of the underlying data.

Deprecated since version 0.23.0.

pandas.Series.dtype

Series.dtype

Return the dtype object of the underlying data.

pandas.Series.dtypes

Series.dtypes

Return the dtype object of the underlying data.

pandas.Series.flags

Series.flags

pandas.Series.ftype

Series.ftype

Return if the data is sparse|dense.

Deprecated since version 0.25.0: Use *dtype()* instead.

pandas.Series.ftypes

Series.ftypes

Return if the data is sparse|dense.

Deprecated since version 0.25.0: Use *dtypes()* instead.

pandas.Series.hasnans

Series.hasnans

Return if I have any nans; enables various perf speedups.

pandas.Series.iat

Series.iat

Access a single value for a row/column pair by integer position.

Similar to *iloc*, in that both provide integer-based lookups. Use *iat* if you only need to get or set a single value in a DataFrame or Series.

Raises

IndexError When integer position is out of bounds

See also:

DataFrame.at Access a single value for a row/column label pair.

DataFrame.loc Access a group of rows and columns by label(s).

DataFrame.iloc Access a group of rows and columns by integer position(s).

Examples

```
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
...                    columns=['A', 'B', 'C'])
>>> df
   A  B  C
0  0  2  3
1  0  4  1
2 10 20 30
```

Get value at specified row/column pair

```
>>> df.iat[1, 2]
1
```

Set value at specified row/column pair

```
>>> df.iat[1, 2] = 10
>>> df.iat[1, 2]
10
```

Get value within a series

```
>>> df.loc[0].iat[1]
2
```

pandas.Series.iloc

Series.iloc

Purely integer-location based indexing for selection by position.

`.iloc[]` is primarily integer position based (from 0 to `length-1` of the axis), but may also be used with a boolean array.

Allowed inputs are:

- An integer, e.g. 5.
- A list or array of integers, e.g. [4, 3, 0].
- A slice object with ints, e.g. 1:7.
- A boolean array.
- A callable function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above). This is useful in method chains, when you don't have a reference to the calling object, but would like to base your selection on some value.

`.iloc` will raise `IndexError` if a requested indexer is out-of-bounds, except *slice* indexers which allow out-of-bounds indexing (this conforms with python/numpy *slice* semantics).

See more at [Selection by Position](#).

See also:

DataFrame.iat Fast integer location scalar accessor.

DataFrame.loc Purely label-location based indexer for selection by label.

`Series.iloc` Purely integer-location based indexing for selection by position.

Examples

```
>>> mydict = [{'a': 1, 'b': 2, 'c': 3, 'd': 4},
...           {'a': 100, 'b': 200, 'c': 300, 'd': 400},
...           {'a': 1000, 'b': 2000, 'c': 3000, 'd': 4000}]
>>> df = pd.DataFrame(mydict)
>>> df
   a    b    c    d
0   1    2    3    4
1 100  200 300 400
2 1000 2000 3000 4000
```

Indexing just the rows

With a scalar integer.

```
>>> type(df.iloc[0])
<class 'pandas.core.series.Series'>
>>> df.iloc[0]
a    1
b    2
c    3
d    4
Name: 0, dtype: int64
```

With a list of integers.

```
>>> df.iloc[[0]]
   a  b  c  d
0  1  2  3  4
>>> type(df.iloc[[0]])
<class 'pandas.core.frame.DataFrame'>
```

```
>>> df.iloc[[0, 1]]
   a  b  c  d
0  1  2  3  4
1 100 200 300 400
```

With a *slice* object.

```
>>> df.iloc[:3]
   a    b    c    d
0   1    2    3    4
1  100  200  300  400
2 1000 2000 3000 4000
```

With a boolean mask the same length as the index.

```
>>> df.iloc[[True, False, True]]
   a    b    c    d
0   1    2    3    4
2 1000 2000 3000 4000
```

With a callable, useful in method chains. The x passed to the `lambda` is the DataFrame being sliced. This selects the rows whose index label even.

```
>>> df.iloc[lambda x: x.index % 2 == 0]
   a    b    c    d
0   1    2    3    4
2 1000 2000 3000 4000
```

Indexing both axes

You can mix the indexer types for the index and columns. Use `:` to select the entire axis.

With scalar integers.

```
>>> df.iloc[0, 1]
2
```

With lists of integers.

```
>>> df.iloc[[0, 2], [1, 3]]
   b    d
0   2    4
2 2000 4000
```

With *slice* objects.

```
>>> df.iloc[1:3, 0:3]
   a    b    c
1  100  200  300
2 1000 2000 3000
```

With a boolean array whose length matches the columns.

```
>>> df.iloc[:, [True, False, True, False]]
   a    c
0   1    3
1  100  300
2 1000 3000
```

With a callable function that expects the Series or DataFrame.

```
>>> df.iloc[:, lambda df: [0, 2]]
   a    c
0   1    3
1  100  300
2 1000 3000
```

pandas.Series.imag

Series.imag

Return imag value of vector.

pandas.Series.index

Series.index

The index (axis labels) of the Series.

pandas.Series.is_copy

Series.is_copy

Return the copy.

pandas.Series.is_monotonic

Series.is_monotonic

Return boolean if values in the object are monotonic_increasing.

New in version 0.19.0.

Returns

bool

pandas.Series.is_monotonic_decreasing

Series.is_monotonic_decreasing

Return boolean if values in the object are monotonic_decreasing.

New in version 0.19.0.

Returns

bool

pandas.Series.is_monotonic_increasing

Series.is_monotonic_increasing

Return boolean if values in the object are monotonic_increasing.

New in version 0.19.0.

Returns

bool

pandas.Series.is_unique

Series.is_unique

Return boolean if values in the object are unique.

Returns

bool

pandas.Series.itemsize

Series.itemsize

Return the size of the dtype of the item of the underlying data.

Deprecated since version 0.23.0.

pandas.Series.ix

Series.ix

A primarily label-location based indexer, with integer position fallback.

Warning: Starting in 0.20.0, the `.ix` indexer is deprecated, in favor of the more strict `.iloc` and `.loc` indexers.

`.ix[]` supports mixed integer and label based access. It is primarily label based, but will fall back to integer positional access unless the corresponding axis is of integer type.

`.ix` is the most general indexer and will support any of the inputs in `.loc` and `.iloc`. `.ix` also supports floating point label schemes. `.ix` is exceptionally useful when dealing with mixed positional and label based hierarchical indexes.

However, when an axis is integer based, **ONLY** label based access and not positional access is supported. Thus, in such cases, it's usually better to be explicit and use `.iloc` or `.loc`.

See more at *Advanced Indexing*.

pandas.Series.loc

Series.loc

Access a group of rows and columns by label(s) or a boolean array.

`.loc[]` is primarily label based, but may also be used with a boolean array.

Allowed inputs are:

- A single label, e.g. 5 or 'a', (note that 5 is interpreted as a *label* of the index, and **never** as an integer position along the index).
- A list or array of labels, e.g. ['a', 'b', 'c'].
- A slice object with labels, e.g. 'a':'f'.

Warning: Note that contrary to usual python slices, **both** the start and the stop are included

- A boolean array of the same length as the axis being sliced, e.g. [True, False, True].
- A **callable** function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above)

See more at *Selection by Label*

Raises

KeyError: when any items are not found

See also:

DataFrame.at Access a single value for a row/column label pair.

DataFrame.iloc Access group of rows and columns by integer position(s).

DataFrame.xs Returns a cross-section (row(s) or column(s)) from the Series/DataFrame.

Series.loc Access group of values using labels.

Examples

Getting values

```
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
...                    index=['cobra', 'viper', 'sidewinder'],
...                    columns=['max_speed', 'shield'])
>>> df
```

	max_speed	shield
cobra	1	2
viper	4	5
sidewinder	7	8

Single label. Note this returns the row as a Series.

```
>>> df.loc['viper']
max_speed    4
shield       5
Name: viper, dtype: int64
```

List of labels. Note using `[[]]` returns a DataFrame.

```
>>> df.loc[['viper', 'sidewinder']]
```

	max_speed	shield
viper	4	5
sidewinder	7	8

Single label for row and column

```
>>> df.loc['cobra', 'shield']
2
```

Slice with labels for row and single label for column. As mentioned above, note that both the start and stop of the slice are included.

```
>>> df.loc['cobra':'viper', 'max_speed']
cobra    1
viper    4
Name: max_speed, dtype: int64
```

Boolean list with the same length as the row axis

```
>>> df.loc[[False, False, True]]
```

	max_speed	shield
sidewinder	7	8

Conditional that returns a boolean Series

```
>>> df.loc[df['shield'] > 6]
           max_speed  shield
sidewinder           7      8
```

Conditional that returns a boolean Series with column labels specified

```
>>> df.loc[df['shield'] > 6, ['max_speed']]
           max_speed
sidewinder           7
```

Callable that returns a boolean Series

```
>>> df.loc[lambda df: df['shield'] == 8]
           max_speed  shield
sidewinder           7      8
```

Setting values

Set value for all items matching the list of labels

```
>>> df.loc[['viper', 'sidewinder'], ['shield']] = 50
>>> df
           max_speed  shield
cobra              1      2
viper              4      50
sidewinder         7      50
```

Set value for an entire row

```
>>> df.loc['cobra'] = 10
>>> df
           max_speed  shield
cobra            10      10
viper             4      50
sidewinder        7      50
```

Set value for an entire column

```
>>> df.loc[:, 'max_speed'] = 30
>>> df
           max_speed  shield
cobra             30      10
viper             30      50
sidewinder        30      50
```

Set value for rows matching callable condition

```
>>> df.loc[df['shield'] > 35] = 0
>>> df
           max_speed  shield
cobra             30      10
viper              0      0
sidewinder         0      0
```

Getting values on a DataFrame with an index that has integer labels

Another example using integers for the index

```
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
...                    index=[7, 8, 9], columns=['max_speed', 'shield'])
>>> df
   max_speed  shield
7          1       2
8          4       5
9          7       8
```

Slice with integer labels for rows. As mentioned above, note that both the start and stop of the slice are included.

```
>>> df.loc[7:9]
   max_speed  shield
7          1       2
8          4       5
9          7       8
```

Getting values with a MultiIndex

A number of examples using a DataFrame with a MultiIndex

```
>>> tuples = [
...     ('cobra', 'mark i'), ('cobra', 'mark ii'),
...     ('sidewinder', 'mark i'), ('sidewinder', 'mark ii'),
...     ('viper', 'mark ii'), ('viper', 'mark iii')
... ]
>>> index = pd.MultiIndex.from_tuples(tuples)
>>> values = [[12, 2], [0, 4], [10, 20],
...           [1, 4], [7, 1], [16, 36]]
>>> df = pd.DataFrame(values, columns=['max_speed', 'shield'], index=index)
>>> df
                max_speed  shield
cobra  mark i             12       2
        mark ii            0       4
sidewinder mark i          10      20
          mark ii           1       4
viper   mark ii           7        1
        mark iii          16      36
```

Single label. Note this returns a DataFrame with a single index.

```
>>> df.loc['cobra']
   max_speed  shield
mark i         12       2
mark ii         0       4
```

Single index tuple. Note this returns a Series.

```
>>> df.loc[('cobra', 'mark ii')]
max_speed    0
shield       4
Name: (cobra, mark ii), dtype: int64
```

Single label for row and column. Similar to passing in a tuple, this returns a Series.

```
>>> df.loc['cobra', 'mark i']
max_speed    12
shield        2
Name: (cobra, mark i), dtype: int64
```

Single tuple. Note using `[[]]` returns a DataFrame.

```
>>> df.loc[['cobra', 'mark ii']]
           max_speed  shield
cobra mark ii         0     4
```

Single tuple for the index with a single label for the column

```
>>> df.loc[('cobra', 'mark i'), 'shield']
2
```

Slice from index tuple to single label

```
>>> df.loc[('cobra', 'mark i'):'viper']
           max_speed  shield
cobra      mark i      12     2
           mark ii      0     4
sidewinder mark i      10    20
           mark ii       1     4
viper      mark ii       7     1
           mark iii     16    36
```

Slice from index tuple to index tuple

```
>>> df.loc[('cobra', 'mark i'):(('viper', 'mark ii'))]
           max_speed  shield
cobra      mark i      12     2
           mark ii      0     4
sidewinder mark i      10    20
           mark ii       1     4
viper      mark ii       7     1
```

pandas.Series.name

Series.name

Return name of the Series.

pandas.Series.nbytes

Series.nbytes

Return the number of bytes in the underlying data.

pandas.Series.ndim

Series.ndim

Number of dimensions of the underlying data, by definition 1.

pandas.Series.real

Series.real

Return the real value of vector.

pandas.Series.shape

Series.shape

Return a tuple of the shape of the underlying data.

pandas.Series.size

Series.size

Return the number of elements in the underlying data.

pandas.Series.strides

Series.strides

Return the strides of the underlying data.

Deprecated since version 0.23.0.

pandas.Series.values

Series.values

Return Series as ndarray or ndarray-like depending on the dtype.

Warning: We recommend using *Series.array* or *Series.to_numpy()*, depending on whether you need a reference to the underlying data or a NumPy array.

Returns

numpy.ndarray or ndarray-like

See also:

Series.array Reference to the underlying data.

Series.to_numpy A NumPy array representing the underlying data.

Examples

```
>>> pd.Series([1, 2, 3]).values
array([1, 2, 3])
```

```
>>> pd.Series(list('abc')).values
array(['a', 'a', 'b', 'c'], dtype=object)
```

```
>>> pd.Series(list('aabc')).astype('category').values
[a, a, b, c]
Categories (3, object): [a, b, c]
```

Timezone aware datetime data is converted to UTC:

```
>>> pd.Series(pd.date_range('20130101', periods=3,
...                          tz='US/Eastern')).values
array(['2013-01-01T05:00:00.000000000',
       '2013-01-02T05:00:00.000000000',
       '2013-01-03T05:00:00.000000000'], dtype='datetime64[ns]')
```

empty

Methods

<i>abs</i> (self)	Return a Series/DataFrame with absolute numeric value of each element.
<i>add</i> (self, other[, level, fill_value, axis])	Return Addition of series and other, element-wise (binary operator <i>add</i>).
<i>add_prefix</i> (self, prefix)	Prefix labels with string <i>prefix</i> .
<i>add_suffix</i> (self, suffix)	Suffix labels with string <i>suffix</i> .
<i>agg</i> (self, func[, axis])	Aggregate using one or more operations over the specified axis.
<i>aggregate</i> (self, func[, axis])	Aggregate using one or more operations over the specified axis.
<i>align</i> (self, other[, join, axis, level, ...])	Align two objects on their axes with the specified join method for each axis Index.
<i>all</i> (self[, axis, bool_only, skipna, level])	Return whether all elements are True, potentially over an axis.
<i>any</i> (self[, axis, bool_only, skipna, level])	Return whether any element is True, potentially over an axis.
<i>append</i> (self, to_append[, ignore_index, ...])	Concatenate two or more Series.
<i>apply</i> (self, func[, convert_dtype, args])	Invoke function on values of Series.
<i>argmax</i> (self[, axis, skipna])	(DEPRECATED) Return the row label of the maximum value.
<i>argmin</i> (self[, axis, skipna])	(DEPRECATED) Return the row label of the minimum value.
<i>argsort</i> (self[, axis, kind, order])	Override ndarray.argsort.
<i>as_blocks</i> (self[, copy])	(DEPRECATED) Convert the frame to a dict of dtype -> Constructor Types that each has a homogeneous dtype.
<i>as_matrix</i> (self[, columns])	(DEPRECATED) Convert the frame to its Numpy-array representation.
<i>asfreq</i> (self, freq[, method, how, normalize, ...])	Convert TimeSeries to specified frequency.
<i>asof</i> (self, where[, subset])	Return the last row(s) without any NaNs before <i>where</i> .
<i>astype</i> (self, dtype[, copy, errors])	Cast a pandas object to a specified dtype <i>dtype</i> .
<i>at_time</i> (self, time[, asof, axis])	Select values at particular time of day (e.g.

Continued on next page

Table 27 – continued from previous page

<code>autocorr(self[, lag])</code>	Compute the lag-N autocorrelation.
<code>between(self, left, right[, inclusive])</code>	Return boolean Series equivalent to <code>left <= series <= right</code> .
<code>between_time(self, start_time, end_time[, ...])</code>	Select values between particular times of the day (e.g., 9:00-9:30 AM).
<code>bfill(self[, axis, inplace, limit, downcast])</code>	Synonym for <code>DataFrame.fillna()</code> with <code>method='bfill'</code> .
<code>bool(self)</code>	Return the bool of a single element PandasObject.
<code>cat</code>	alias of <code>pandas.core.arrays.categorical.CategoricalAccessor</code>
<code>clip(self[, lower, upper, axis, inplace])</code>	Trim values at input threshold(s).
<code>clip_lower(self, threshold[, axis, inplace])</code>	(DEPRECATED) Trim values below a given threshold.
<code>clip_upper(self, threshold[, axis, inplace])</code>	(DEPRECATED) Trim values above a given threshold.
<code>combine(self, other, func[, fill_value])</code>	Combine the Series with a Series or scalar according to <code>func</code> .
<code>combine_first(self, other)</code>	Combine Series values, choosing the calling Series's values first.
<code>compound(self[, axis, skipna, level])</code>	(DEPRECATED) Return the compound percentage of the values for the requested axis.
<code>compress(self, condition, *args, **kwargs)</code>	(DEPRECATED) Return selected slices of an array along given axis as a Series.
<code>copy(self[, deep])</code>	Make a copy of this object's indices and data.
<code>corr(self, other[, method, min_periods])</code>	Compute correlation with <code>other</code> Series, excluding missing values.
<code>count(self[, level])</code>	Return number of non-NA/null observations in the Series.
<code>cov(self, other[, min_periods])</code>	Compute covariance with Series, excluding missing values.
<code>cummax(self[, axis, skipna])</code>	Return cumulative maximum over a DataFrame or Series axis.
<code>cummin(self[, axis, skipna])</code>	Return cumulative minimum over a DataFrame or Series axis.
<code>cumprod(self[, axis, skipna])</code>	Return cumulative product over a DataFrame or Series axis.
<code>cumsum(self[, axis, skipna])</code>	Return cumulative sum over a DataFrame or Series axis.
<code>describe(self[, percentiles, include, exclude])</code>	Generate descriptive statistics that summarize the central tendency, dispersion and shape of a dataset's distribution, excluding NaN values.
<code>diff(self[, periods])</code>	First discrete difference of element.
<code>div(self, other[, level, fill_value, axis])</code>	Return Floating division of series and other, element-wise (binary operator <code>truediv</code>).
<code>divide(self, other[, level, fill_value, axis])</code>	Return Floating division of series and other, element-wise (binary operator <code>truediv</code>).
<code>divmod(self, other[, level, fill_value, axis])</code>	Return Integer division and modulo of series and other, element-wise (binary operator <code>divmod</code>).
<code>dot(self, other)</code>	Compute the dot product between the Series and the columns of other.

Continued on next page

Table 27 – continued from previous page

<code>drop(self[, labels, axis, index, columns, ...])</code>	Return Series with specified index labels removed.
<code>drop_duplicates(self[, keep, inplace])</code>	Return Series with duplicate values removed.
<code>droplevel(self, level[, axis])</code>	Return DataFrame with requested index / column level(s) removed.
<code>dropna(self[, axis, inplace])</code>	Return a new Series with missing values removed.
<code>dt</code>	alias of <code>pandas.core.indexes.accessors.CombinedDatetimelikeProperties</code>
<code>duplicated(self[, keep])</code>	Indicate duplicate Series values.
<code>eq(self, other[, level, fill_value, axis])</code>	Return Equal to of series and other, element-wise (binary operator <code>eq</code>).
<code>equals(self, other)</code>	Test whether two objects contain the same elements.
<code>ewm(self[, com, span, halflife, alpha, ...])</code>	Provide exponential weighted functions.
<code>expanding(self[, min_periods, center, axis])</code>	Provide expanding transformations.
<code>explode(self)</code>	Transform each element of a list-like to a row, replicating the index values.
<code>factorize(self[, sort, na_sentinel])</code>	Encode the object as an enumerated type or categorical variable.
<code>ffill(self[, axis, inplace, limit, downcast])</code>	Synonym for <code>DataFrame.fillna()</code> with <code>method='ffill'</code> .
<code>fillna(self[, value, method, axis, inplace, ...])</code>	Fill NA/NaN values using the specified method.
<code>filter(self[, items, like, regex, axis])</code>	Subset rows or columns of dataframe according to labels in the specified index.
<code>first(self, offset)</code>	Convenience method for subsetting initial periods of time series data based on a date offset.
<code>first_valid_index(self)</code>	Return index for first non-NA/null value.
<code>floordiv(self, other[, level, fill_value, axis])</code>	Return Integer division of series and other, element-wise (binary operator <code>floordiv</code>).
<code>from_array(arr[, index, name, dtype, copy, ...])</code>	Construct Series from array.
<code>ge(self, other[, level, fill_value, axis])</code>	Return Greater than or equal to of series and other, element-wise (binary operator <code>ge</code>).
<code>get(self, key[, default])</code>	Get item from object for given key (ex: DataFrame column).
<code>get_dtype_counts(self)</code>	(DEPRECATED) Return counts of unique dtypes in this object.
<code>get_ftype_counts(self)</code>	(DEPRECATED) Return counts of unique ftypes in this object.
<code>get_value(self, label[, takeable])</code>	(DEPRECATED) Quickly retrieve single value at passed index label.
<code>get_values(self)</code>	(DEPRECATED) Same as <code>values</code> (but handles sparseness conversions); is a view.
<code>groupby(self[, by, axis, level, as_index, ...])</code>	Group DataFrame or Series using a mapper or by a Series of columns.
<code>gt(self, other[, level, fill_value, axis])</code>	Return Greater than of series and other, element-wise (binary operator <code>gt</code>).
<code>head(self[, n])</code>	Return the first <code>n</code> rows.
<code>hist(self[, by, ax, grid, xlabelsize, xrot, ...])</code>	Draw histogram of the input series using matplotlib.
<code>iidxmax(self[, axis, skipna])</code>	Return the row label of the maximum value.

Continued on next page

Table 27 – continued from previous page

<code>idxmin(self[, axis, skipna])</code>	Return the row label of the minimum value.
<code>infer_objects(self)</code>	Attempt to infer better dtypes for object columns.
<code>interpolate(self[, method, axis, limit, ...])</code>	Interpolate values according to different methods.
<code>isin(self, values)</code>	Check whether <i>values</i> are contained in Series.
<code>isna(self)</code>	Detect missing values.
<code>isnull(self)</code>	Detect missing values.
<code>item(self)</code>	Return the first element of the underlying data as a python scalar.
<code>items(self)</code>	Lazily iterate over (index, value) tuples.
<code>iteritems(self)</code>	Lazily iterate over (index, value) tuples.
<code>keys(self)</code>	Return alias for index.
<code>kurt(self[, axis, skipna, level, numeric_only])</code>	Return unbiased kurtosis over requested axis using Fisher's definition of kurtosis (kurtosis of normal == 0.0).
<code>kurtosis(self[, axis, skipna, level, ...])</code>	Return unbiased kurtosis over requested axis using Fisher's definition of kurtosis (kurtosis of normal == 0.0).
<code>last(self, offset)</code>	Convenience method for subsetting final periods of time series data based on a date offset.
<code>last_valid_index(self)</code>	Return index for last non-NA/null value.
<code>le(self, other[, level, fill_value, axis])</code>	Return Less than or equal to of series and other, element-wise (binary operator <i>le</i>).
<code>lt(self, other[, level, fill_value, axis])</code>	Return Less than of series and other, element-wise (binary operator <i>lt</i>).
<code>mad(self[, axis, skipna, level])</code>	Return the mean absolute deviation of the values for the requested axis.
<code>map(self, arg[, na_action])</code>	Map values of Series according to input correspondence.
<code>mask(self, cond[, other, inplace, axis, ...])</code>	Replace values where the condition is True.
<code>max(self[, axis, skipna, level, numeric_only])</code>	Return the maximum of the values for the requested axis.
<code>mean(self[, axis, skipna, level, numeric_only])</code>	Return the mean of the values for the requested axis.
<code>median(self[, axis, skipna, level, numeric_only])</code>	Return the median of the values for the requested axis.
<code>memory_usage(self[, index, deep])</code>	Return the memory usage of the Series.
<code>min(self[, axis, skipna, level, numeric_only])</code>	Return the minimum of the values for the requested axis.
<code>mod(self, other[, level, fill_value, axis])</code>	Return Modulo of series and other, element-wise (binary operator <i>mod</i>).
<code>mode(self[, dropna])</code>	Return the mode(s) of the dataset.
<code>mul(self, other[, level, fill_value, axis])</code>	Return Multiplication of series and other, element-wise (binary operator <i>mul</i>).
<code>multiply(self, other[, level, fill_value, axis])</code>	Return Multiplication of series and other, element-wise (binary operator <i>mul</i>).
<code>ne(self, other[, level, fill_value, axis])</code>	Return Not equal to of series and other, element-wise (binary operator <i>ne</i>).
<code>nlargest(self[, n, keep])</code>	Return the largest <i>n</i> elements.

Continued on next page

Table 27 – continued from previous page

<code>nonzero(self)</code>	(DEPRECATED) Return the <i>integer</i> indices of the elements that are non-zero.
<code>notna(self)</code>	Detect existing (non-missing) values.
<code>notnull(self)</code>	Detect existing (non-missing) values.
<code>nsmallest(self[, n, keep])</code>	Return the smallest <i>n</i> elements.
<code>nunique(self[, dropna])</code>	Return number of unique elements in the object.
<code>pct_change(self[, periods, fill_method, ...])</code>	Percentage change between the current and a prior element.
<code>pipe(self, func, <code>\</code>*args, <code>\</code>*<code>\</code>*kwargs)</code>	Apply <code>func(self, *args, **kwargs)</code> .
<code>plot</code>	alias of <code>pandas.plotting._core.PlotAccessor</code>
<code>pop(self, item)</code>	Return item and drop from frame.
<code>pow(self, other[, level, fill_value, axis])</code>	Return Exponential power of series and other, element-wise (binary operator <i>pow</i>).
<code>prod(self[, axis, skipna, level, ...])</code>	Return the product of the values for the requested axis.
<code>product(self[, axis, skipna, level, ...])</code>	Return the product of the values for the requested axis.
<code>ptp(self[, axis, skipna, level, numeric_only])</code>	(DEPRECATED) Return the difference between the maximum value and the
<code>put(self, <code>\</code>*args, <code>\</code>*<code>\</code>*kwargs)</code>	(DEPRECATED) Apply the <i>put</i> method to its <i>values</i> attribute if it has one.
<code>quantile(self[, q, interpolation])</code>	Return value at the given quantile.
<code>radd(self, other[, level, fill_value, axis])</code>	Return Addition of series and other, element-wise (binary operator <i>radd</i>).
<code>rank(self[, axis, method, numeric_only, ...])</code>	Compute numerical data ranks (1 through <i>n</i>) along axis.
<code>ravel(self[, order])</code>	Return the flattened underlying data as an ndarray.
<code>rdiv(self, other[, level, fill_value, axis])</code>	Return Floating division of series and other, element-wise (binary operator <i>rtruediv</i>).
<code>rdivmod(self, other[, level, fill_value, axis])</code>	Return Integer division and modulo of series and other, element-wise (binary operator <i>rdivmod</i>).
<code>reindex(self[, index])</code>	Conform Series to new index with optional filling logic, placing NA/NaN in locations having no value in the previous index.
<code>reindex_like(self, other[, method, copy, ...])</code>	Return an object with matching indices as other object.
<code>rename(self[, index])</code>	Alter Series index labels or name.
<code>rename_axis(self[, mapper, index, columns, ...])</code>	Set the name of the axis for the index or columns.
<code>reorder_levels(self, order)</code>	Rearrange index levels using input order.
<code>repeat(self, repeats[, axis])</code>	Repeat elements of a Series.
<code>replace(self[, to_replace, value, inplace, ...])</code>	Replace values given in <i>to_replace</i> with <i>value</i> .
<code>resample(self, rule[, how, axis, ...])</code>	Resample time-series data.
<code>reset_index(self[, level, drop, name, inplace])</code>	Generate a new DataFrame or Series with the index reset.
<code>rfloordiv(self, other[, level, fill_value, axis])</code>	Return Integer division of series and other, element-wise (binary operator <i>rfloordiv</i>).
<code>rmod(self, other[, level, fill_value, axis])</code>	Return Modulo of series and other, element-wise (binary operator <i>rmod</i>).

Continued on next page

Table 27 – continued from previous page

<code>rmul</code> (self, other[, level, fill_value, axis])	Return Multiplication of series and other, element-wise (binary operator <code>rmul</code>).
<code>rolling</code> (self, window[, min_periods, center, ...])	Provide rolling window calculations.
<code>round</code> (self[, decimals])	Round each value in a Series to the given number of decimals.
<code>rpow</code> (self, other[, level, fill_value, axis])	Return Exponential power of series and other, element-wise (binary operator <code>rpow</code>).
<code>rsub</code> (self, other[, level, fill_value, axis])	Return Subtraction of series and other, element-wise (binary operator <code>rsub</code>).
<code>rtruediv</code> (self, other[, level, fill_value, axis])	Return Floating division of series and other, element-wise (binary operator <code>rtruediv</code>).
<code>sample</code> (self[, n, frac, replace, weights, ...])	Return a random sample of items from an axis of object.
<code>searchsorted</code> (self, value[, side, sorter])	Find indices where elements should be inserted to maintain order.
<code>sem</code> (self[, axis, skipna, level, ddof, ...])	Return unbiased standard error of the mean over requested axis.
<code>set_axis</code> (self, labels[, axis, inplace])	Assign desired index to given axis.
<code>set_value</code> (self, label, value[, takeable])	(DEPRECATED) Quickly set single value at passed label.
<code>shift</code> (self[, periods, freq, axis, fill_value])	Shift index by desired number of periods with an optional time <code>freq</code> .
<code>skew</code> (self[, axis, skipna, level, numeric_only])	Return unbiased skew over requested axis Normalized by N-1.
<code>slice_shift</code> (self[, periods, axis])	Equivalent to <code>shift</code> without copying data.
<code>sort_index</code> (self[, axis, level, ascending, ...])	Sort Series by index labels.
<code>sort_values</code> (self[, axis, ascending, ...])	Sort by the values.
<code>sparse</code>	alias of <code>pandas.core.arrays.sparse.SparseAccessor</code>
<code>squeeze</code> (self[, axis])	Squeeze 1 dimensional axis objects into scalars.
<code>std</code> (self[, axis, skipna, level, ddof, ...])	Return sample standard deviation over requested axis.
<code>str</code>	alias of <code>pandas.core.strings.StringMethods</code>
<code>sub</code> (self, other[, level, fill_value, axis])	Return Subtraction of series and other, element-wise (binary operator <code>sub</code>).
<code>subtract</code> (self, other[, level, fill_value, axis])	Return Subtraction of series and other, element-wise (binary operator <code>sub</code>).
<code>sum</code> (self[, axis, skipna, level, ...])	Return the sum of the values for the requested axis.
<code>swapaxes</code> (self, axis1, axis2[, copy])	Interchange axes and swap values axes appropriately.
<code>swaplevel</code> (self[, i, j, copy])	Swap levels i and j in a MultiIndex.
<code>tail</code> (self[, n])	Return the last <code>n</code> rows.
<code>take</code> (self, indices[, axis, is_copy])	Return the elements in the given <i>positional</i> indices along an axis.
<code>to_clipboard</code> (self[, excel, sep])	Copy object to the system clipboard.
<code>to_csv</code> (self, *args, **kwargs)	Write object to a comma-separated values (csv) file.
<code>to_dense</code> (self)	(DEPRECATED) Return dense representation of Series/DataFrame (as opposed to sparse).

Continued on next page

Table 27 – continued from previous page

<code>to_dict(self[, into])</code>	Convert Series to {label -> value} dict or dict-like object.
<code>to_excel(self, excel_writer[, sheet_name, ...])</code>	Write object to an Excel sheet.
<code>to_frame(self[, name])</code>	Convert Series to DataFrame.
<code>to_hdf(self, path_or_buf, key, <i>**kwargs</i>)</code>	Write the contained data to an HDF5 file using HDFStore.
<code>to_json(self[, path_or_buf, orient, ...])</code>	Convert the object to a JSON string.
<code>to_latex(self[, buf, columns, col_space, ...])</code>	Render an object to a LaTeX tabular environment table.
<code>to_list(self)</code>	Return a list of the values.
<code>to_msgpack(self[, path_or_buf, encoding])</code>	(DEPRECATED) Serialize object to input file path using msgpack format.
<code>to_numpy(self[, dtype, copy])</code>	A NumPy ndarray representing the values in this Series or Index.
<code>to_period(self[, freq, copy])</code>	Convert Series from DatetimeIndex to PeriodIndex with desired frequency (inferred from index if not passed).
<code>to_pickle(self, path[, compression, protocol])</code>	Pickle (serialize) object to file.
<code>to_sparse(self[, kind, fill_value])</code>	(DEPRECATED) Convert Series to SparseSeries.
<code>to_sql(self, name, con[, schema, if_exists, ...])</code>	Write records stored in a DataFrame to a SQL database.
<code>to_string(self[, buf, na_rep, float_format, ...])</code>	Render a string representation of the Series.
<code>to_timestamp(self[, freq, how, copy])</code>	Cast to DatetimeIndex of Timestamps, at <i>beginning</i> of period.
<code>to_xarray(self)</code>	Return an xarray object from the pandas object.
<code>tolist(self)</code>	Return a list of the values.
<code>transform(self, func[, axis])</code>	Call <code>func</code> on self producing a Series with transformed values and that has the same axis length as self.
<code>transpose(self, <i>*args</i>, <i>**kwargs</i>)</code>	Return the transpose, which is by definition self.
<code>truediv(self, other[, level, fill_value, axis])</code>	Return Floating division of series and other, element-wise (binary operator <i>truediv</i>).
<code>truncate(self[, before, after, axis, copy])</code>	Truncate a Series or DataFrame before and after some index value.
<code>tshift(self[, periods, freq, axis])</code>	Shift the time index, using the index's frequency if available.
<code>tz_convert(self, tz[, axis, level, copy])</code>	Convert tz-aware axis to target time zone.
<code>tz_localize(self, tz[, axis, level, copy, ...])</code>	Localize tz-naive index of a Series or DataFrame to target time zone.
<code>unique(self)</code>	Return unique values of Series object.
<code>unstack(self[, level, fill_value])</code>	Unstack, a.k.a.
<code>update(self, other)</code>	Modify Series in place using non-NA values from passed Series.
<code>valid(self[, inplace])</code>	(DEPRECATED) Return Series without null values.
<code>value_counts(self[, normalize, sort, ...])</code>	Return a Series containing counts of unique values.
<code>var(self[, axis, skipna, level, ddof, ...])</code>	Return unbiased variance over requested axis.
<code>view(self[, dtype])</code>	Create a new view of the Series.
<code>where(self, cond[, other, inplace, axis, ...])</code>	Replace values where the condition is False.

Continued on next page

Table 27 – continued from previous page

<code>xs(self, key[, axis, level, drop_level])</code>	Return cross-section from the Series/DataFrame.
---	---

pandas.Series.abs**Series.abs(self)**

Return a Series/DataFrame with absolute numeric value of each element.

This function only applies to elements that are all numeric.

Returns

abs Series/DataFrame containing the absolute value of each element.

See also:

`numpy.absolute` Calculate the absolute value element-wise.

Notes

For complex inputs, $1.2 + 1j$, the absolute value is $\sqrt{a^2 + b^2}$.

Examples

Absolute numeric values in a Series.

```
>>> s = pd.Series([-1.10, 2, -3.33, 4])
>>> s.abs()
0    1.10
1    2.00
2    3.33
3    4.00
dtype: float64
```

Absolute numeric values in a Series with complex numbers.

```
>>> s = pd.Series([1.2 + 1j])
>>> s.abs()
0    1.56205
dtype: float64
```

Absolute numeric values in a Series with a Timedelta element.

```
>>> s = pd.Series([pd.Timedelta('1 days')])
>>> s.abs()
0    1 days
dtype: timedelta64[ns]
```

Select rows with data closest to certain value using `argsort` (from [StackOverflow](#)).

```
>>> df = pd.DataFrame({
...     'a': [4, 5, 6, 7],
...     'b': [10, 20, 30, 40],
```

(continues on next page)

(continued from previous page)

```

...     'c': [100, 50, -30, -50]
... })
>>> df
   a    b    c
0   4   10  100
1   5   20   50
2   6   30  -30
3   7   40  -50
>>> df.loc[(df.c - 43).abs().argsort()]
   a    b    c
1   5   20   50
0   4   10  100
2   6   30  -30
3   7   40  -50

```

pandas.Series.add

Series.add(*self*, *other*, *level=None*, *fill_value=None*, *axis=0*)

Return Addition of series and other, element-wise (binary operator *add*).

Equivalent to `series + other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

Series.radd

Examples

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])

```

(continues on next page)

(continued from previous page)

```
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64
```

pandas.Series.add_prefix

`Series.add_prefix(self, prefix)`

Prefix labels with string *prefix*.

For Series, the row labels are prefixed. For DataFrame, the column labels are prefixed.

Parameters

prefix [str] The string to add before each label.

Returns

Series or DataFrame New Series or DataFrame with updated labels.

See also:

Series.add_suffix Suffix row labels with string *suffix*.

DataFrame.add_suffix Suffix column labels with string *suffix*.

Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64
```

```
>>> s.add_prefix('item_')
item_0    1
item_1    2
item_2    3
item_3    4
dtype: int64
```

```
>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
>>> df
   A  B
0  1  3
1  2  4
2  3  5
3  4  6
```

```
>>> df.add_prefix('col_')
   col_A  col_B
0      1     3
1      2     4
2      3     5
3      4     6
```

pandas.Series.add_suffix

Series.add_suffix(*self*, *suffix*)
Suffix labels with string *suffix*.

For Series, the row labels are suffixed. For DataFrame, the column labels are suffixed.

Parameters

suffix [str] The string to add after each label.

Returns

Series or DataFrame New Series or DataFrame with updated labels.

See also:

Series.add_prefix Prefix row labels with string *prefix*.

DataFrame.add_prefix Prefix column labels with string *prefix*.

Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64
```

```
>>> s.add_suffix('_item')
0_item    1
1_item    2
2_item    3
3_item    4
dtype: int64
```

```
>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
>>> df
   A  B
0  1  3
1  2  4
2  3  5
3  4  6
```

```
>>> df.add_suffix('_col')
   A_col  B_col
0      1      3
1      2      4
2      3      5
3      4      6
```

pandas.Series.agg

`Series.agg(self, func, axis=0, *args, **kwargs)`

Aggregate using one or more operations over the specified axis.

New in version 0.20.0.

Parameters

func [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a Series or when passed to Series.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. `[np.sum, 'mean']`
- dict of axis labels -> functions, function names or list of such.

axis [{0 or 'index'}] Parameter needed for compatibility with DataFrame.

***args** Positional arguments to pass to *func*.

****kwargs** Keyword arguments to pass to *func*.

Returns

scalar, Series or DataFrame The return can be:

- scalar : when Series.agg is called with single function
- Series : when DataFrame.agg is called with a single function
- DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

See also:

Series.apply Invoke function on a Series.

Series.transform Transform function producing a Series with like indexes.

Notes

agg is an alias for *aggregate*. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64
```

```
>>> s.agg('min')
1
```

```
>>> s.agg(['min', 'max'])
min    1
max    4
dtype: int64
```

pandas.Series.aggregate

Series.aggregate(*self*, *func*, *axis=0*, **args*, ***kwargs*)

Aggregate using one or more operations over the specified axis.

New in version 0.20.0.

Parameters

func [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a Series or when passed to Series.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. `[np.sum, 'mean']`
- dict of axis labels -> functions, function names or list of such.

axis [{0 or 'index'}] Parameter needed for compatibility with DataFrame.

***args** Positional arguments to pass to *func*.

****kwargs** Keyword arguments to pass to *func*.

Returns

scalar, Series or DataFrame The return can be:

- scalar : when Series.agg is called with single function
- Series : when DataFrame.agg is called with a single function

- `DataFrame` : when `DataFrame.agg` is called with several functions

Return scalar, `Series` or `DataFrame`.

See also:

`Series.apply` Invoke function on a `Series`.

`Series.transform` Transform function producing a `Series` with like indexes.

Notes

`agg` is an alias for *aggregate*. Use the alias.

A passed user-defined-function will be passed a `Series` for evaluation.

Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64
```

```
>>> s.agg('min')
1
```

```
>>> s.agg(['min', 'max'])
min    1
max    4
dtype: int64
```

`pandas.Series.align`

`Series.align(self, other, join='outer', axis=None, level=None, copy=True, fill_value=None, method=None, limit=None, fill_axis=0, broadcast_axis=None)`

Align two objects on their axes with the specified join method for each axis `Index`.

Parameters

other [`DataFrame` or `Series`]

join [{'outer', 'inner', 'left', 'right'}, default 'outer']

axis [allowed axis of the other object, default `None`] Align on index (0), columns (1), or both (`None`)

level [int or level name, default `None`] Broadcast across a level, matching `Index` values on the passed `MultiIndex` level

copy [boolean, default `True`] Always returns new objects. If `copy=False` and no reindexing is required then original objects are returned.

fill_value [scalar, default np.NaN] Value to use for missing values. Defaults to NaN, but can be any “compatible” value

method [{‘backfill’, ‘bfill’, ‘pad’, ‘ffill’, None}, default None] Method to use for filling holes in reindexed Series pad / ffill: propagate last valid observation forward to next valid backfill / bfill: use NEXT valid observation to fill gap

limit [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

fill_axis [{0 or ‘index’}, default 0] Filling axis, method and limit

broadcast_axis [{0 or ‘index’}, default None] Broadcast values along this axis, if aligning two objects of different dimensions

Returns

(left, right) [(Series, type of other)] Aligned objects.

pandas.Series.all

`Series.all(self, axis=0, bool_only=None, skipna=True, level=None, **kwargs)`

Return whether all elements are True, potentially over an axis.

Returns True unless there at least one element within a series or along a Dataframe axis that is False or equivalent (e.g. zero or empty).

Parameters

axis [{0 or ‘index’, 1 or ‘columns’, None}, default 0] Indicate which axis or axes should be reduced.

- 0 / ‘index’ : reduce the index, return a Series whose index is the original column labels.
- 1 / ‘columns’ : reduce the columns, return a Series whose index is the original index.
- None : reduce all axes, return a scalar.

bool_only [bool, default None] Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.

skipna [bool, default True] Exclude NA/null values. If the entire row/column is NA and skipna is True, then the result will be True, as for an empty row/column. If skipna is False, then NA are treated as True, because these are not equal to zero.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

****kwargs** [any, default None] Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

scalar or Series If level is specified, then, Series is returned; otherwise, scalar is returned.

See also:

Series.all Return True if all elements are True.

DataFrame.any Return True if one (or more) elements are True.

Examples

Series

```
>>> pd.Series([True, True]).all()
True
>>> pd.Series([True, False]).all()
False
>>> pd.Series([]).all()
True
>>> pd.Series([np.nan]).all()
True
>>> pd.Series([np.nan]).all(skipna=False)
True
```

DataFrames

Create a dataframe from a dictionary.

```
>>> df = pd.DataFrame({'col1': [True, True], 'col2': [True, False]})
>>> df
   col1  col2
0  True  True
1  True False
```

Default behaviour checks if column-wise values all return True.

```
>>> df.all()
col1    True
col2   False
dtype: bool
```

Specify `axis='columns'` to check if row-wise values all return True.

```
>>> df.all(axis='columns')
0    True
1   False
dtype: bool
```

Or `axis=None` for whether every value is True.

```
>>> df.all(axis=None)
False
```

pandas.Series.any

Series.any(*self*, *axis=0*, *bool_only=None*, *skipna=True*, *level=None*, ***kwargs*)

Return whether any element is True, potentially over an axis.

Returns False unless there at least one element within a series or along a Dataframe axis that is True or equivalent (e.g. non-zero or non-empty).

Parameters

axis [{0 or 'index', 1 or 'columns', None}, default 0] Indicate which axis or axes should be reduced.

- 0 / 'index' : reduce the index, return a Series whose index is the original column labels.
- 1 / 'columns' : reduce the columns, return a Series whose index is the original index.
- None : reduce all axes, return a scalar.

bool_only [bool, default None] Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.

skipna [bool, default True] Exclude NA/null values. If the entire row/column is NA and skipna is True, then the result will be False, as for an empty row/column. If skipna is False, then NA are treated as True, because these are not equal to zero.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

****kwargs** [any, default None] Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

scalar or Series If level is specified, then, Series is returned; otherwise, scalar is returned.

See also:

`numpy.any` Numpy version of this method.

`Series.any` Return whether any element is True.

`Series.all` Return whether all elements are True.

`DataFrame.any` Return whether any element is True over requested axis.

`DataFrame.all` Return whether all elements are True over requested axis.

Examples

Series

For Series input, the output is a scalar indicating whether any element is True.

```
>>> pd.Series([False, False]).any()
False
>>> pd.Series([True, False]).any()
True
>>> pd.Series([]).any()
False
>>> pd.Series([np.nan]).any()
False
>>> pd.Series([np.nan]).any(skipna=False)
True
```

DataFrame

Whether each column contains at least one True element (the default).

```
>>> df = pd.DataFrame({"A": [1, 2], "B": [0, 2], "C": [0, 0]})
>>> df
   A  B  C
0  1  0  0
1  2  2  0
```

```
>>> df.any()
A     True
B     True
C    False
dtype: bool
```

Aggregating over the columns.

```
>>> df = pd.DataFrame({"A": [True, False], "B": [1, 2]})
>>> df
   A  B
0  True  1
1  False  2
```

```
>>> df.any(axis='columns')
0     True
1     True
dtype: bool
```

```
>>> df = pd.DataFrame({"A": [True, False], "B": [1, 0]})
>>> df
   A  B
0  True  1
1  False  0
```

```
>>> df.any(axis='columns')
0     True
1    False
dtype: bool
```

Aggregating over the entire DataFrame with `axis=None`.

```
>>> df.any(axis=None)
True
```

any for an empty DataFrame is an empty Series.

```
>>> pd.DataFrame([]).any()
Series([], dtype: bool)
```

pandas.Series.append

`Series.append(self, to_append, ignore_index=False, verify_integrity=False)`

Concatenate two or more Series.

Parameters

to_append [Series or list/tuple of Series] Series to append with self.

ignore_index [bool, default False] If True, do not use the index labels.

New in version 0.19.0.

verify_integrity [bool, default False] If True, raise Exception on creating index with duplicates.

Returns

Series Concatenated Series.

See also:

concat General function to concatenate DataFrame or Series objects.

Notes

Iteratively appending to a Series can be more computationally intensive than a single concatenate. A better solution is to append values to a list and then concatenate the list with the original Series all at once.

Examples

```
>>> s1 = pd.Series([1, 2, 3])
>>> s2 = pd.Series([4, 5, 6])
>>> s3 = pd.Series([4, 5, 6], index=[3, 4, 5])
>>> s1.append(s2)
0    1
1    2
2    3
0    4
1    5
2    6
dtype: int64
```

```
>>> s1.append(s3)
0    1
1    2
2    3
3    4
4    5
5    6
dtype: int64
```

With `ignore_index` set to True:

```
>>> s1.append(s2, ignore_index=True)
0    1
1    2
2    3
3    4
4    5
5    6
dtype: int64
```

With `verify_integrity` set to `True`:

```
>>> s1.append(s2, verify_integrity=True)
Traceback (most recent call last):
...
ValueError: Indexes have overlapping values: [0, 1, 2]
```

pandas.Series.apply

`Series.apply(self, func, convert_dtype=True, args=(), **kwargs)`

Invoke function on values of Series.

Can be ufunc (a NumPy function that applies to the entire Series) or a Python function that only works on single values.

Parameters

func [function] Python function or NumPy ufunc to apply.

convert_dtype [bool, default True] Try to find better dtype for elementwise function results. If False, leave as dtype=object.

args [tuple] Positional arguments passed to func after the series value.

****kwargs** Additional keyword arguments passed to func.

Returns

Series or DataFrame If func returns a Series object the result will be a DataFrame.

See also:

Series.map For element-wise operations.

Series.agg Only perform aggregating type operations.

Series.transform Only perform transforming type operations.

Examples

Create a series with typical summer temperatures for each city.

```
>>> s = pd.Series([20, 21, 12],
...               index=['London', 'New York', 'Helsinki'])
>>> s
London      20
New York    21
```

(continues on next page)

(continued from previous page)

```
Helsinki    12
dtype: int64
```

Square the values by defining a function and passing it as an argument to `apply()`.

```
>>> def square(x):
...     return x ** 2
>>> s.apply(square)
London      400
New York    441
Helsinki    144
dtype: int64
```

Square the values by passing an anonymous function as an argument to `apply()`.

```
>>> s.apply(lambda x: x ** 2)
London      400
New York    441
Helsinki    144
dtype: int64
```

Define a custom function that needs additional positional arguments and pass these additional arguments using the `args` keyword.

```
>>> def subtract_custom_value(x, custom_value):
...     return x - custom_value
```

```
>>> s.apply(subtract_custom_value, args=(5,))
London      15
New York    16
Helsinki     7
dtype: int64
```

Define a custom function that takes keyword arguments and pass these arguments to `apply`.

```
>>> def add_custom_values(x, **kwargs):
...     for month in kwargs:
...         x += kwargs[month]
...     return x
```

```
>>> s.apply(add_custom_values, june=30, july=20, august=25)
London      95
New York    96
Helsinki    87
dtype: int64
```

Use a function from the Numpy library.

```
>>> s.apply(np.log)
London      2.995732
New York    3.044522
Helsinki    2.484907
dtype: float64
```

pandas.Series.argmax

`Series.argmax(self, axis=0, skipna=True, *args, **kwargs)`

Return the row label of the maximum value.

Deprecated since version 0.21.0.

The current behaviour of ‘Series.argmax’ is deprecated, use ‘idxmax’ instead. The behavior of ‘argmax’ will be corrected to return the positional maximum in the future. For now, use ‘series.values.argmax’ or ‘np.argmax(np.array(values))’ to get the position of the maximum row.

If multiple values equal the maximum, the first row label with that value is returned.

Parameters

skipna [bool, default True] Exclude NA/null values. If the entire Series is NA, the result will be NA.

axis [int, default 0] For compatibility with DataFrame.idxmax. Redundant for application on Series.

***args, **kwargs** Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

Index Label of the maximum value.

Raises

ValueError If the Series is empty.

See also:

`numpy.argmax` Return indices of the maximum values along the given axis.

`DataFrame.idxmax` Return index of first occurrence of maximum over requested axis.

`Series.idxmin` Return index *label* of the first occurrence of minimum of values.

Notes

This method is the Series version of `ndarray.argmax`. This method returns the label of the maximum, while `ndarray.argmax` returns the position. To get the position, use `series.values.argmax()`.

Examples

```
>>> s = pd.Series(data=[1, None, 4, 3, 4],
...                index=['A', 'B', 'C', 'D', 'E'])
>>> s
A    1.0
B    NaN
C    4.0
D    3.0
E    4.0
dtype: float64
```

```
>>> s.idxmax()
'C'
```

If *skipna* is False and there is an NA value in the data, the function returns `nan`.

```
>>> s.idxmax(skipna=False)
nan
```

pandas.Series.argmax

`Series.argmax(self, axis=0, skipna=True, *args, **kwargs)`

Return the row label of the minimum value.

Deprecated since version 0.21.0.

The current behaviour of ‘Series.argmax’ is deprecated, use ‘idxmin’ instead. The behavior of ‘argmin’ will be corrected to return the positional minimum in the future. For now, use ‘series.values.argmaxin’ or ‘np.argmaxin(np.array(values))’ to get the position of the minimum row.

If multiple values equal the minimum, the first row label with that value is returned.

Parameters

skipna [bool, default True] Exclude NA/null values. If the entire Series is NA, the result will be NA.

axis [int, default 0] For compatibility with DataFrame.idxmin. Redundant for application on Series.

***args, **kwargs** Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

Index Label of the minimum value.

Raises

ValueError If the Series is empty.

See also:

`numpy.argmaxin` Return indices of the minimum values along the given axis.

`DataFrame.idxmin` Return index of first occurrence of minimum over requested axis.

`Series.idxmax` Return index *label* of the first occurrence of maximum of values.

Notes

This method is the Series version of `ndarray.argmaxin`. This method returns the label of the minimum, while `ndarray.argmaxin` returns the position. To get the position, use `series.values.argmaxin()`.

Examples

```
>>> s = pd.Series(data=[1, None, 4, 1],
...                index=['A', 'B', 'C', 'D'])
>>> s
A    1.0
B    NaN
C    4.0
D    1.0
dtype: float64
```

```
>>> s.idxmin()
'A'
```

If *skipna* is False and there is an NA value in the data, the function returns `nan`.

```
>>> s.idxmin(skipna=False)
nan
```

pandas.Series.argsort

`Series.argsort(self, axis=0, kind='quicksort', order=None)`

Override ndarray.argsort. Argsorts the value, omitting NA/null values, and places the result in the same locations as the non-NA values.

Parameters

axis [int] Has no effect but is accepted for compatibility with numpy.

kind [{‘mergesort’, ‘quicksort’, ‘heapsort’}, default ‘quicksort’] Choice of sorting algorithm. See `np.sort` for more information. ‘mergesort’ is the only stable algorithm

order [None] Has no effect but is accepted for compatibility with numpy.

Returns

Series Positions of values within the sort order with -1 indicating nan values.

See also:

`numpy.ndarray.argsort`

pandas.Series.as_blocks

`Series.as_blocks(self, copy=True)`

Convert the frame to a dict of dtype -> Constructor Types that each has a homogeneous dtype.

Deprecated since version 0.21.0.

NOTE: the dtypes of the blocks WILL BE PRESERVED HERE (unlike in `as_matrix`)

Parameters

copy [boolean, default True]

Returns

values [a dict of dtype -> Constructor Types]

pandas.Series.as_matrix

`Series.as_matrix(self, columns=None)`

Convert the frame to its Numpy-array representation.

Deprecated since version 0.23.0: Use `DataFrame.values()` instead.

Parameters

columns [list, optional, default:None] If None, return all columns, otherwise, returns specified columns.

Returns

values [ndarray] If the caller is heterogeneous and contains booleans or objects, the result will be of dtype=object. See Notes.

See also:

`DataFrame.values`

Notes

Return is NOT a Numpy-matrix, rather, a Numpy-array.

The dtype will be a lower-common-denominator dtype (implicit upcasting); that is to say if the dtypes (even of numeric types) are mixed, the one that accommodates all will be chosen. Use this with care if you are not dealing with the blocks.

e.g. If the dtypes are float16 and float32, dtype will be upcast to float32. If dtypes are int32 and uint8, dtype will be upcase to int32. By `numpy.find_common_type` convention, mixing int64 and uint64 will result in a float64 dtype.

This method is provided for backwards compatibility. Generally, it is recommended to use `'values'`.

pandas.Series.asfreq

`Series.asfreq(self, freq, method=None, how=None, normalize=False, fill_value=None)`

Convert TimeSeries to specified frequency.

Optionally provide filling method to pad/backfill missing values.

Returns the original data conformed to a new index with the specified frequency. `resample` is more appropriate if an operation, such as summarization, is necessary to represent the data at the new frequency.

Parameters

freq [DateOffset object, or string]

method [{'backfill'/'bfill', 'pad'/'ffill'}, default None] Method to use for filling holes in reindexed Series (note this does not fill NaNs that already were present):

- 'pad' / 'ffill': propagate last valid observation forward to next valid
- 'backfill' / 'bfill': use NEXT valid observation to fill

how [{‘start’, ‘end’}, default end] For PeriodIndex only, see PeriodIndex.asfreq

normalize [bool, default False] Whether to reset output index to midnight

fill_value [scalar, optional] Value to use for missing values, applied during upsampling (note this does not fill NaNs that already were present).

New in version 0.20.0.

Returns

converted [same type as caller]

See also:

reindex

Notes

To learn more about the frequency strings, please see [this link](#).

Examples

Start by creating a series with 4 one minute timestamps.

```
>>> index = pd.date_range('1/1/2000', periods=4, freq='T')
>>> series = pd.Series([0.0, None, 2.0, 3.0], index=index)
>>> df = pd.DataFrame({'s':series})
>>> df
```

	s
2000-01-01 00:00:00	0.0
2000-01-01 00:01:00	NaN
2000-01-01 00:02:00	2.0
2000-01-01 00:03:00	3.0

Upsample the series into 30 second bins.

```
>>> df.asfreq(freq='30S')
```

	s
2000-01-01 00:00:00	0.0
2000-01-01 00:00:30	NaN
2000-01-01 00:01:00	NaN
2000-01-01 00:01:30	NaN
2000-01-01 00:02:00	2.0
2000-01-01 00:02:30	NaN
2000-01-01 00:03:00	3.0

Upsample again, providing a fill value.

```
>>> df.asfreq(freq='30S', fill_value=9.0)
```

	s
2000-01-01 00:00:00	0.0
2000-01-01 00:00:30	9.0
2000-01-01 00:01:00	NaN
2000-01-01 00:01:30	9.0

(continues on next page)

(continued from previous page)

```
2000-01-01 00:02:00    2.0
2000-01-01 00:02:30    9.0
2000-01-01 00:03:00    3.0
```

Upsample again, providing a `method`.

```
>>> df.asfreq(freq='30S', method='bfill')
           s
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30   NaN
2000-01-01 00:01:00   NaN
2000-01-01 00:01:30    2.0
2000-01-01 00:02:00    2.0
2000-01-01 00:02:30    3.0
2000-01-01 00:03:00    3.0
```

pandas.Series.asof

`Series.asof(self, where, subset=None)`

Return the last row(s) without any NaNs before *where*.

The last row (for each element in *where*, if list) without any NaN is taken. In case of a *DataFrame*, the last row without NaN considering only the subset of columns (if not *None*)

New in version 0.19.0: For *DataFrame*

If there is no good value, NaN is returned for a *Series* or a *Series* of NaN values for a *DataFrame*

Parameters

where [date or array-like of dates] Date(s) before which the last row(s) are returned.

subset [str or array-like of str, default *None*] For *DataFrame*, if not *None*, only use these columns to check for NaNs.

Returns

scalar, Series, or DataFrame The return can be:

- scalar : when *self* is a *Series* and *where* is a scalar
- Series: when *self* is a *Series* and *where* is an array-like, or when *self* is a *DataFrame* and *where* is a scalar
- DataFrame : when *self* is a *DataFrame* and *where* is an array-like

Return scalar, *Series*, or *DataFrame*.

See also:

merge_asof Perform an asof merge. Similar to left join.

Notes

Dates are assumed to be sorted. Raises if this is not the case.

Examples

A Series and a scalar *where*.

```
>>> s = pd.Series([1, 2, np.nan, 4], index=[10, 20, 30, 40])
>>> s
10    1.0
20    2.0
30    NaN
40    4.0
dtype: float64
```

```
>>> s.asof(20)
2.0
```

For a sequence *where*, a Series is returned. The first value is NaN, because the first element of *where* is before the first index value.

```
>>> s.asof([5, 20])
5     NaN
20    2.0
dtype: float64
```

Missing values are not considered. The following is 2.0, not NaN, even though NaN is at the index location for 30.

```
>>> s.asof(30)
2.0
```

Take all columns into consideration

```
>>> df = pd.DataFrame({'a': [10, 20, 30, 40, 50],
...                    'b': [None, None, None, None, 500]},
...                    index=pd.DatetimeIndex(['2018-02-27 09:01:00',
...                                             '2018-02-27 09:02:00',
...                                             '2018-02-27 09:03:00',
...                                             '2018-02-27 09:04:00',
...                                             '2018-02-27 09:05:00']))
>>> df.asof(pd.DatetimeIndex(['2018-02-27 09:03:30',
...                           '2018-02-27 09:04:30']))
...                a    b
2018-02-27 09:03:30 NaN NaN
2018-02-27 09:04:30 NaN NaN
```

Take a single column into consideration

```
>>> df.asof(pd.DatetimeIndex(['2018-02-27 09:03:30',
...                           '2018-02-27 09:04:30']),
...         subset=['a'])
...                a    b
2018-02-27 09:03:30 30.0 NaN
2018-02-27 09:04:30 40.0 NaN
```

pandas.Series.astype

`Series.astype(self, dtype, copy=True, errors='raise', **kwargs)`

Cast a pandas object to a specified dtype.

Parameters

dtype [data type, or dict of column name -> data type] Use a `numpy.dtype` or Python type to cast entire pandas object to the same type. Alternatively, use `{col: dtype, ...}`, where `col` is a column label and `dtype` is a `numpy.dtype` or Python type to cast one or more of the DataFrame's columns to column-specific types.

copy [bool, default True] Return a copy when `copy=True` (be very careful setting `copy=False` as changes to values then may propagate to other pandas objects).

errors [{'raise', 'ignore'}, default 'raise'] Control raising of exceptions on invalid data for provided dtype.

- `raise` : allow exceptions to be raised
- `ignore` : suppress exceptions. On error return original object

New in version 0.20.0.

kwargs [keyword arguments to pass on to the constructor]

Returns

casted [same type as caller]

See also:

`to_datetime` Convert argument to datetime.

`to_timedelta` Convert argument to timedelta.

`to_numeric` Convert argument to a numeric type.

`numpy.ndarray.astype` Cast a numpy array to a specified type.

Examples

Create a DataFrame:

```
>>> d = {'col1': [1, 2], 'col2': [3, 4]}
>>> df = pd.DataFrame(data=d)
>>> df.dtypes
col1    int64
col2    int64
dtype: object
```

Cast all columns to int32:

```
>>> df.astype('int32').dtypes
col1    int32
col2    int32
dtype: object
```

Cast col1 to int32 using a dictionary:

```
>>> df.astype({'col1': 'int32'}).dtypes
col1    int32
col2    int64
dtype: object
```

Create a series:

```
>>> ser = pd.Series([1, 2], dtype='int32')
>>> ser
0    1
1    2
dtype: int32
>>> ser.astype('int64')
0    1
1    2
dtype: int64
```

Convert to categorical type:

```
>>> ser.astype('category')
0    1
1    2
dtype: category
Categories (2, int64): [1, 2]
```

Convert to ordered categorical type with custom ordering:

```
>>> cat_dtype = pd.api.types.CategoricalDtype(
...     categories=[2, 1], ordered=True)
>>> ser.astype(cat_dtype)
0    1
1    2
dtype: category
Categories (2, int64): [2 < 1]
```

Note that using `copy=False` and changing data on a new pandas object may propagate changes:

```
>>> s1 = pd.Series([1,2])
>>> s2 = s1.astype('int64', copy=False)
>>> s2[0] = 10
>>> s1 # note that s1[0] has changed too
0    10
1     2
dtype: int64
```

pandas.Series.at_time

`Series.at_time(self, time, asof=False, axis=None)`
 Select values at particular time of day (e.g. 9:30AM).

Parameters

time [datetime.time or str]

axis [{0 or 'index', 1 or 'columns'}, default 0] New in version 0.24.0.

Returns

Series or DataFrame

Raises

TypeError If the index is not a *DatetimeIndex*

See also:

between_time Select values between particular times of the day.

first Select initial periods of time series based on a date offset.

last Select final periods of time series based on a date offset.

DatetimeIndex.indexer_at_time Get just the index locations for values at particular time of the day.

Examples

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='12H')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
              A
2018-04-09 00:00:00  1
2018-04-09 12:00:00  2
2018-04-10 00:00:00  3
2018-04-10 12:00:00  4
```

```
>>> ts.at_time('12:00')
              A
2018-04-09 12:00:00  2
2018-04-10 12:00:00  4
```

pandas.Series.autocorr

Series.autocorr(*self*, *lag=1*)

Compute the lag-N autocorrelation.

This method computes the Pearson correlation between the Series and its shifted self.

Parameters

lag [int, default 1] Number of lags to apply before performing autocorrelation.

Returns

float The Pearson correlation between self and self.shift(lag).

See also:

Series.corr Compute the correlation between two Series.

Series.shift Shift index by desired number of periods.

DataFrame.corr Compute pairwise correlation of columns.

DataFrame.corrwith Compute pairwise correlation between rows or columns of two DataFrame objects.

Notes

If the Pearson correlation is not well defined return 'NaN'.

Examples

```
>>> s = pd.Series([0.25, 0.5, 0.2, -0.05])
>>> s.autocorr() # doctest: +ELLIPSIS
0.10355...
>>> s.autocorr(lag=2) # doctest: +ELLIPSIS
-0.99999...
```

If the Pearson correlation is not well defined, then 'NaN' is returned.

```
>>> s = pd.Series([1, 0, 0, 0])
>>> s.autocorr()
nan
```

pandas.Series.between

Series.between(*self*, *left*, *right*, *inclusive=True*)

Return boolean Series equivalent to $\text{left} \leq \text{series} \leq \text{right}$.

This function returns a boolean vector containing *True* wherever the corresponding Series element is between the boundary values *left* and *right*. NA values are treated as *False*.

Parameters

left [scalar] Left boundary.

right [scalar] Right boundary.

inclusive [bool, default True] Include boundaries.

Returns

Series Series representing whether each element is between left and right (inclusive).

See also:

Series.gt Greater than of series and other.

Series.lt Less than of series and other.

Notes

This function is equivalent to $(\text{left} \leq \text{ser}) \ \& \ (\text{ser} \leq \text{right})$

Examples

```
>>> s = pd.Series([2, 0, 4, 8, np.nan])
```

Boundary values are included by default:

```
>>> s.between(1, 4)
0     True
1    False
2     True
3    False
4    False
dtype: bool
```

With *inclusive* set to `False` boundary values are excluded:

```
>>> s.between(1, 4, inclusive=False)
0     True
1    False
2    False
3    False
4    False
dtype: bool
```

left and *right* can be any scalar value:

```
>>> s = pd.Series(['Alice', 'Bob', 'Carol', 'Eve'])
>>> s.between('Anna', 'Daniel')
0    False
1     True
2     True
3    False
dtype: bool
```

pandas.Series.between_time

`Series.between_time(self, start_time, end_time, include_start=True, include_end=True, axis=None)`

Select values between particular times of the day (e.g., 9:00-9:30 AM).

By setting `start_time` to be later than `end_time`, you can get the times that are *not* between the two times.

Parameters

start_time [datetime.time or str]

end_time [datetime.time or str]

include_start [bool, default True]

include_end [bool, default True]

axis [{0 or 'index', 1 or 'columns'}, default 0] New in version 0.24.0.

Returns

Series or DataFrame

Raises

TypeError If the index is not a *DatetimeIndex*

See also:

at_time Select values at a particular time of the day.

first Select initial periods of time series based on a date offset.

last Select final periods of time series based on a date offset.

DatetimeIndex.indexer_between_time Get just the index locations for values between particular times of the day.

Examples

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='1D20min')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
```

	A
2018-04-09 00:00:00	1
2018-04-10 00:20:00	2
2018-04-11 00:40:00	3
2018-04-12 01:00:00	4

```
>>> ts.between_time('0:15', '0:45')
```

	A
2018-04-10 00:20:00	2
2018-04-11 00:40:00	3

You get the times that are *not* between two times by setting **start_time** later than **end_time**:

```
>>> ts.between_time('0:45', '0:15')
```

	A
2018-04-09 00:00:00	1
2018-04-12 01:00:00	4

pandas.Series.bfill

Series.bfill(*self*, *axis=None*, *inplace=False*, *limit=None*, *downcast=None*)

Synonym for *DataFrame.fillna()* with method='bfill'.

Returns

%(klass)s Object with missing values filled.

pandas.Series.bool

Series.bool(*self*)

Return the bool of a single element PandasObject.

This must be a boolean scalar value, either True or False. Raise a ValueError if the PandasObject does not have exactly 1 element, or that element is not boolean

Returns

bool Same single boolean value converted to bool type.

pandas.Series.cat

Series.cat()

Accessor object for categorical properties of the Series values.

Be aware that assigning to *categories* is a inplace operation, while all methods return new categorical data per default (but can be called with *inplace=True*).

Parameters

data [Series or CategoricalIndex]

Examples

```
>>> s.cat.categories
>>> s.cat.categories = list('abc')
>>> s.cat.rename_categories(list('cab'))
>>> s.cat.reorder_categories(list('cab'))
>>> s.cat.add_categories(['d', 'e'])
>>> s.cat.remove_categories(['d'])
>>> s.cat.remove_unused_categories()
>>> s.cat.set_categories(list('abcde'))
>>> s.cat.as_ordered()
>>> s.cat.as_unordered()
```

pandas.Series.clip

Series.clip(*self*, *lower=None*, *upper=None*, *axis=None*, *inplace=False*, **args*, ***kwargs*)

Trim values at input threshold(s).

Assigns values outside boundary to boundary values. Thresholds can be singular values or array like, and in the latter case the clipping is performed element-wise in the specified axis.

Parameters

lower [float or array_like, default None] Minimum threshold value. All values below this threshold will be set to it.

upper [float or array_like, default None] Maximum threshold value. All values above this threshold will be set to it.

axis [int or str axis name, optional] Align object with lower and upper along the given axis.

inplace [bool, default False] Whether to perform the operation in place on the data.

New in version 0.21.0.

***args, **kwargs** Additional keywords have no effect but might be accepted for compatibility with numpy.

Returns

Series or DataFrame Same type as calling object with the values outside the clip boundaries replaced.

Examples

```
>>> data = {'col_0': [9, -3, 0, -1, 5], 'col_1': [-2, -7, 6, 8, -5]}
>>> df = pd.DataFrame(data)
>>> df
   col_0  col_1
0      9    -2
1     -3    -7
2      0     6
3     -1     8
4      5    -5
```

Clips per column using lower and upper thresholds:

```
>>> df.clip(-4, 6)
   col_0  col_1
0      6    -2
1     -3    -4
2      0     6
3     -1     6
4      5    -4
```

Clips using specific lower and upper thresholds per column element:

```
>>> t = pd.Series([2, -4, -1, 6, 3])
>>> t
0     2
1    -4
2    -1
3     6
4     3
dtype: int64
```

```
>>> df.clip(t, t + 4, axis=0)
   col_0  col_1
0      6     2
1     -3    -4
2      0     3
3      6     8
4      5     3
```

pandas.Series.clip_lower

Series.clip_lower(*self*, *threshold*, *axis=None*, *inplace=False*)

Trim values below a given threshold.

Deprecated since version 0.24.0: Use clip(lower=threshold) instead.

Elements below the *threshold* will be changed to match the *threshold* value(s). Threshold can be a single value or an array, in the latter case it performs the truncation element-wise.

Parameters

threshold [numeric or array-like] Minimum value allowed. All values below threshold will be set to this value.

- float : every value is compared to *threshold*.
- array-like : The shape of *threshold* should match the object it's compared to. When *self* is a Series, *threshold* should be the length. When *self* is a DataFrame, *threshold* should 2-D and the same shape as *self* for `axis=None`, or 1-D and the same length as the axis being compared.

axis [{0 or 'index', 1 or 'columns'}, default 0] Align *self* with *threshold* along the given axis.

inplace [bool, default False] Whether to perform the operation in place on the data.

New in version 0.21.0.

Returns

Series or DataFrame Original data with values trimmed.

See also:

Series.clip General purpose method to trim Series values to given threshold(s).

DataFrame.clip General purpose method to trim DataFrame values to given threshold(s).

Examples

Series single threshold clipping:

```
>>> s = pd.Series([5, 6, 7, 8, 9])
>>> s.clip(lower=8)
0    8
1    8
2    8
3    8
4    9
dtype: int64
```

Series clipping element-wise using an array of thresholds. *threshold* should be the same length as the Series.

```
>>> elemwise_thresholds = [4, 8, 7, 2, 5]
>>> s.clip(lower=elemwise_thresholds)
0    5
1    8
2    7
3    8
4    9
dtype: int64
```

DataFrames can be compared to a scalar.

```
>>> df = pd.DataFrame({"A": [1, 3, 5], "B": [2, 4, 6]})
>>> df
   A  B
0  1  2
1  3  4
2  5  6
```

```
>>> df.clip(lower=3)
   A  B
0  3  3
1  3  4
2  5  6
```

Or to an array of values. By default, *threshold* should be the same shape as the DataFrame.

```
>>> df.clip(lower=np.array([[3, 4], [2, 2], [6, 2]]))
   A  B
0  3  4
1  3  4
2  6  6
```

Control how *threshold* is broadcast with *axis*. In this case *threshold* should be the same length as the axis specified by *axis*.

```
>>> df.clip(lower=[3, 3, 5], axis='index')
   A  B
0  3  3
1  3  4
2  5  6
```

```
>>> df.clip(lower=[4, 5], axis='columns')
   A  B
0  4  5
1  4  5
2  5  6
```

pandas.Series.clip_upper

`Series.clip_upper(self, threshold, axis=None, inplace=False)`

Trim values above a given threshold.

Deprecated since version 0.24.0: Use `clip(upper=threshold)` instead.

Elements above the *threshold* will be changed to match the *threshold* value(s). Threshold can be a single value or an array, in the latter case it performs the truncation element-wise.

Parameters

threshold [numeric or array-like] Maximum value allowed. All values above threshold will be set to this value.

- float : every value is compared to *threshold*.
- array-like : The shape of *threshold* should match the object it's compared to. When *self* is a Series, *threshold* should be the length. When *self* is a DataFrame,

threshold should 2-D and the same shape as *self* for *axis=None*, or 1-D and the same length as the axis being compared.

axis [{0 or 'index', 1 or 'columns'}, default 0] Align object with *threshold* along the given axis.

inplace [bool, default False] Whether to perform the operation in place on the data.

New in version 0.21.0.

Returns

Series or DataFrame Original data with values trimmed.

See also:

Series.clip General purpose method to trim Series values to given threshold(s).

DataFrame.clip General purpose method to trim DataFrame values to given threshold(s).

Examples

```
>>> s = pd.Series([1, 2, 3, 4, 5])
>>> s
0    1
1    2
2    3
3    4
4    5
dtype: int64
```

```
>>> s.clip(upper=3)
0    1
1    2
2    3
3    3
4    3
dtype: int64
```

```
>>> elemwise_thresholds = [5, 4, 3, 2, 1]
>>> elemwise_thresholds
[5, 4, 3, 2, 1]
```

```
>>> s.clip(upper=elemwise_thresholds)
0    1
1    2
2    3
3    2
4    1
dtype: int64
```

pandas.Series.combine

`Series.combine(self, other, func, fill_value=None)`

Combine the Series with a Series or scalar according to *func*.

Combine the Series and *other* using *func* to perform elementwise selection for combined Series. *fill_value* is assumed when value is missing at some index from one of the two objects being combined.

Parameters

other [Series or scalar] The value(s) to be combined with the *Series*.

func [function] Function that takes two scalars as inputs and returns an element.

fill_value [scalar, optional] The value to assume when an index is missing from one Series or the other. The default specifies to use the appropriate NaN value for the underlying dtype of the Series.

Returns

Series The result of combining the Series with the other object.

See also:

Series.combine_first Combine Series values, choosing the calling Series' values first.

Examples

Consider 2 Datasets `s1` and `s2` containing highest clocked speeds of different birds.

```
>>> s1 = pd.Series({'falcon': 330.0, 'eagle': 160.0})
>>> s1
falcon    330.0
eagle     160.0
dtype: float64
>>> s2 = pd.Series({'falcon': 345.0, 'eagle': 200.0, 'duck': 30.0})
>>> s2
falcon    345.0
eagle     200.0
duck       30.0
dtype: float64
```

Now, to combine the two datasets and view the highest speeds of the birds across the two datasets

```
>>> s1.combine(s2, max)
duck      NaN
eagle     200.0
falcon    345.0
dtype: float64
```

In the previous example, the resulting value for duck is missing, because the maximum of a NaN and a float is a NaN. So, in the example, we set `fill_value=0`, so the maximum value returned will be the value from some dataset.

```
>>> s1.combine(s2, max, fill_value=0)
duck      30.0
eagle     200.0
falcon    345.0
dtype: float64
```

pandas.Series.combine_first

`Series.combine_first(self, other)`

Combine Series values, choosing the calling Series's values first.

Parameters

other [Series] The value(s) to be combined with the *Series*.

Returns

Series The result of combining the Series with the other object.

See also:

Series.combine Perform elementwise operation on two Series using a given function.

Notes

Result index will be the union of the two indexes.

Examples

```
>>> s1 = pd.Series([1, np.nan])
>>> s2 = pd.Series([3, 4])
>>> s1.combine_first(s2)
0    1.0
1    4.0
dtype: float64
```

pandas.Series.compound

`Series.compound(self, axis=None, skipna=None, level=None)`

Return the compound percentage of the values for the requested axis.

Deprecated since version 0.25.0.

Parameters

axis [{index (0)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

scalar or Series (if level specified)

pandas.Series.compress

`Series.compress(self, condition, *args, **kwargs)`

Return selected slices of an array along given axis as a Series.

Deprecated since version 0.24.0.

Returns

Series Series without the slices for which condition is false.

See also:

[numpy.ndarray.compress](#)

pandas.Series.copy

`Series.copy(self, deep=True)`

Make a copy of this object's indices and data.

When **deep=True** (default), a new object will be created with a copy of the calling object's data and indices. Modifications to the data or indices of the copy will not be reflected in the original object (see notes below).

When **deep=False**, a new object will be created without copying the calling object's data or index (only references to the data and index are copied). Any changes to the data of the original will be reflected in the shallow copy (and vice versa).

Parameters

deep [bool, default True] Make a deep copy, including a copy of the data and the indices. With **deep=False** neither the indices nor the data are copied.

Returns

copy [Series or DataFrame] Object type matches caller.

Notes

When **deep=True**, data is copied but actual Python objects will not be copied recursively, only the reference to the object. This is in contrast to `copy.deepcopy` in the Standard Library, which recursively copies object data (see examples below).

While **Index** objects are copied when **deep=True**, the underlying numpy array is not copied for performance reasons. Since **Index** is immutable, the underlying data can be safely shared and a copy is not needed.

Examples

```
>>> s = pd.Series([1, 2], index=["a", "b"])
>>> s
a    1
b    2
dtype: int64
```

```
>>> s_copy = s.copy()
>>> s_copy
a    1
b    2
dtype: int64
```

Shallow copy versus default (deep) copy:

```
>>> s = pd.Series([1, 2], index=["a", "b"])
>>> deep = s.copy()
>>> shallow = s.copy(deep=False)
```

Shallow copy shares data and index with original.

```
>>> s is shallow
False
>>> s.values is shallow.values and s.index is shallow.index
True
```

Deep copy has own copy of data and index.

```
>>> s is deep
False
>>> s.values is deep.values or s.index is deep.index
False
```

Updates to the data shared by shallow copy and original is reflected in both; deep copy remains unchanged.

```
>>> s[0] = 3
>>> shallow[1] = 4
>>> s
a    3
b    4
dtype: int64
>>> shallow
a    3
b    4
dtype: int64
>>> deep
a    1
b    2
dtype: int64
```

Note that when copying an object containing Python objects, a deep copy will copy the data, but will not do so recursively. Updating a nested data object will be reflected in the deep copy.

```

>>> s = pd.Series([[1, 2], [3, 4]])
>>> deep = s.copy()
>>> s[0][0] = 10
>>> s
0    [10, 2]
1     [3, 4]
dtype: object
>>> deep
0    [10, 2]
1     [3, 4]
dtype: object

```

pandas.Series.corr

`Series.corr(self, other, method='pearson', min_periods=None)`
 Compute correlation with *other* Series, excluding missing values.

Parameters

other [Series] Series with which to compute the correlation.

method [{'pearson', 'kendall', 'spearman'} or callable]

- **pearson** : standard correlation coefficient
- **kendall** : Kendall Tau correlation coefficient
- **spearman** : Spearman rank correlation
- **callable**: callable with input two 1d ndarrays and returning a float. Note that the returned matrix from corr will have 1 along the diagonals and will be symmetric regardless of the callable's behavior .. versionadded:: 0.24.0

min_periods [int, optional] Minimum number of observations needed to have a valid result.

Returns

float Correlation with other.

Examples

```

>>> def histogram_intersection(a, b):
...     v = np.minimum(a, b).sum().round(decimals=1)
...     return v
>>> s1 = pd.Series([.2, .0, .6, .2])
>>> s2 = pd.Series([.3, .6, .0, .1])
>>> s1.corr(s2, method=histogram_intersection)
0.3

```

pandas.Series.count

`Series.count(self, level=None)`
 Return number of non-NA/null observations in the Series.

Parameters

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a smaller Series.

Returns

int or Series (if level specified) Number of non-null values in the Series.

Examples

```
>>> s = pd.Series([0.0, 1.0, np.nan])
>>> s.count()
2
```

pandas.Series.cov

Series.cov(*self*, *other*, *min_periods=None*)

Compute covariance with Series, excluding missing values.

Parameters

other [Series] Series with which to compute the covariance.

min_periods [int, optional] Minimum number of observations needed to have a valid result.

Returns

float Covariance between Series and other normalized by N-1 (unbiased estimator).

Examples

```
>>> s1 = pd.Series([0.90010907, 0.13484424, 0.62036035])
>>> s2 = pd.Series([0.12528585, 0.26962463, 0.51111198])
>>> s1.cov(s2)
-0.01685762652715874
```

pandas.Series.cummax

Series.cummax(*self*, *axis=None*, *skipna=True*, **args*, ***kwargs*)

Return cumulative maximum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative maximum.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

skipna [boolean, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

***args, **kwargs** : Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

scalar or Series

See also:

core.window.Expanding.max Similar functionality but ignores NaN values.

Series.max Return the maximum over Series axis.

Series.cummax Return cumulative maximum over Series axis.

Series.cummin Return cumulative minimum over Series axis.

Series.cumsum Return cumulative sum over Series axis.

Series.cumprod Return cumulative product over Series axis.

Examples

Series

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cummax()
0    2.0
1    NaN
2    5.0
3    5.0
4    5.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cummax(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                    [3.0, np.nan],
...                    [1.0, 0.0]],
...                    columns=list('AB'))
```

(continues on next page)

(continued from previous page)

```
>>> df
   A    B
0  2.0  1.0
1  3.0 NaN
2  1.0  0.0
```

By default, iterates over rows and finds the maximum in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cummax()
   A    B
0  2.0  1.0
1  3.0 NaN
2  3.0  1.0
```

To iterate over columns and find the maximum in each row, use `axis=1`

```
>>> df.cummax(axis=1)
   A    B
0  2.0  2.0
1  3.0 NaN
2  1.0  1.0
```

pandas.Series.cummin

`Series.cummin(self, axis=None, skipna=True, *args, **kwargs)`

Return cumulative minimum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative minimum.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

skipna [boolean, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

***args, **kwargs** : Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

scalar or Series

See also:

`core.window.Expanding.min` Similar functionality but ignores NaN values.

`Series.min` Return the minimum over Series axis.

`Series.cummax` Return cumulative maximum over Series axis.

`Series.cummin` Return cumulative minimum over Series axis.

`Series.cumsum` Return cumulative sum over Series axis.

`Series.cumprod` Return cumulative product over Series axis.

Examples

Series

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cummin()
0    2.0
1    NaN
2    2.0
3   -1.0
4   -1.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cummin(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                    [3.0, np.nan],
...                    [1.0, 0.0]],
...                    columns=list('AB'))
>>> df
   A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the minimum in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cummin()
   A    B
0  2.0  1.0
1  2.0  NaN
2  1.0  0.0
```

To iterate over columns and find the minimum in each row, use `axis=1`

```
>>> df.cummin(axis=1)
   A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

pandas.Series.cumprod

`Series.cumprod(self, axis=None, skipna=True, *args, **kwargs)`

Return cumulative product over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative product.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

skipna [boolean, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

***args, **kwargs** : Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

scalar or Series

See also:

`core.window.Expanding.prod` Similar functionality but ignores NaN values.

`Series.prod` Return the product over Series axis.

`Series.cummax` Return cumulative maximum over Series axis.

`Series.cummin` Return cumulative minimum over Series axis.

`Series.cumsum` Return cumulative sum over Series axis.

`Series.cumprod` Return cumulative product over Series axis.

Examples

Series

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cumprod()
0    2.0
1    NaN
2    10.0
3   -10.0
4    -0.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cumprod(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                   [3.0, np.nan],
...                   [1.0, 0.0]],
...                   columns=list('AB'))
>>> df
   A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the product in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cumprod()
   A    B
0  2.0  1.0
1  6.0  NaN
2  6.0  0.0
```

To iterate over columns and find the product in each row, use `axis=1`

```
>>> df.cumprod(axis=1)
   A    B
0  2.0  2.0
1  3.0  NaN
2  1.0  0.0
```

pandas.Series.cumsum

`Series.cumsum(self, axis=None, skipna=True, *args, **kwargs)`

Return cumulative sum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative sum.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

skipna [boolean, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

***args, **kwargs** : Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

scalar or Series

See also:

core.window.Expanding.sum Similar functionality but ignores NaN values.

Series.sum Return the sum over Series axis.

Series.cummax Return cumulative maximum over Series axis.

Series.cummin Return cumulative minimum over Series axis.

Series.cumsum Return cumulative sum over Series axis.

Series.cumprod Return cumulative product over Series axis.

Examples

Series

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cumsum()
0    2.0
1    NaN
2    7.0
3    6.0
4    6.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cumsum(skipna=False)
0    2.0
1    NaN
2    NaN
```

(continues on next page)

(continued from previous page)

```
3    NaN
4    NaN
dtype: float64
```

DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                    [3.0, np.nan],
...                    [1.0, 0.0]],
...                    columns=list('AB'))
>>> df
   A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the sum in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cumsum()
   A    B
0  2.0  1.0
1  5.0  NaN
2  6.0  1.0
```

To iterate over columns and find the sum in each row, use `axis=1`

```
>>> df.cumsum(axis=1)
   A    B
0  2.0  3.0
1  3.0  NaN
2  1.0  1.0
```

pandas.Series.describe

`Series.describe(self, percentiles=None, include=None, exclude=None)`

Generate descriptive statistics that summarize the central tendency, dispersion and shape of a dataset's distribution, excluding NaN values.

Analyzes both numeric and object series, as well as `DataFrame` column sets of mixed data types. The output will vary depending on what is provided. Refer to the notes below for more detail.

Parameters

percentiles [list-like of numbers, optional] The percentiles to include in the output. All should fall between 0 and 1. The default is `[.25, .5, .75]`, which returns the 25th, 50th, and 75th percentiles.

include ['all', list-like of dtypes or None (default), optional] A white list of data types to include in the result. Ignored for `Series`. Here are the options:

- 'all': All columns of the input will be included in the output.
- A list-like of dtypes: Limits the results to the provided data types. To limit the result to numeric types submit `numpy.number`. To limit it instead

to object columns submit the `numpy.object` data type. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(include=['O'])`). To select pandas categorical columns, use `'category'`

- None (default) : The result will include all numeric columns.

exclude [list-like of dtypes or None (default), optional,] A black list of data types to omit from the result. Ignored for **Series**. Here are the options:

- A list-like of dtypes : Excludes the provided data types from the result. To exclude numeric types submit `numpy.number`. To exclude object columns submit the data type `numpy.object`. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(include=['O'])`). To exclude pandas categorical columns, use `'category'`
- None (default) : The result will exclude nothing.

Returns

Series or DataFrame Summary statistics of the Series or Dataframe provided.

See also:

DataFrame.count Count number of non-NA/null observations.

DataFrame.max Maximum of the values in the object.

DataFrame.min Minimum of the values in the object.

DataFrame.mean Mean of the values.

DataFrame.std Standard deviation of the observations.

DataFrame.select_dtypes Subset of a DataFrame including/excluding columns based on their dtype.

Notes

For numeric data, the result's index will include `count`, `mean`, `std`, `min`, `max` as well as lower, 50 and upper percentiles. By default the lower percentile is 25 and the upper percentile is 75. The 50 percentile is the same as the median.

For object data (e.g. strings or timestamps), the result's index will include `count`, `unique`, `top`, and `freq`. The `top` is the most common value. The `freq` is the most common value's frequency. Timestamps also include the `first` and `last` items.

If multiple object values have the highest count, then the `count` and `top` results will be arbitrarily chosen from among those with the highest count.

For mixed data types provided via a **DataFrame**, the default is to return only an analysis of numeric columns. If the dataframe consists only of object and categorical data without any numeric columns, the default is to return an analysis of both the object and categorical columns. If `include='all'` is provided as an option, the result will include a union of attributes of each type.

The `include` and `exclude` parameters can be used to limit which columns in a **DataFrame** are analyzed for the output. The parameters are ignored when analyzing a **Series**.

Examples

Describing a numeric Series.

```
>>> s = pd.Series([1, 2, 3])
>>> s.describe()
count      3.0
mean       2.0
std        1.0
min        1.0
25%        1.5
50%        2.0
75%        2.5
max        3.0
dtype: float64
```

Describing a categorical Series.

```
>>> s = pd.Series(['a', 'a', 'b', 'c'])
>>> s.describe()
count      4
unique     3
top        a
freq       2
dtype: object
```

Describing a timestamp Series.

```
>>> s = pd.Series([
...     np.datetime64("2000-01-01"),
...     np.datetime64("2010-01-01"),
...     np.datetime64("2010-01-01")
... ])
>>> s.describe()
count                3
unique                2
top      2010-01-01 00:00:00
freq                2
first    2000-01-01 00:00:00
last     2010-01-01 00:00:00
dtype: object
```

Describing a DataFrame. By default only numeric fields are returned.

```
>>> df = pd.DataFrame({'categorical': pd.Categorical(['d', 'e', 'f']),
...                   'numeric': [1, 2, 3],
...                   'object': ['a', 'b', 'c']}
... )
>>> df.describe()
           numeric
count          3.0
mean           2.0
std            1.0
min            1.0
```

(continues on next page)

(continued from previous page)

25%	1.5
50%	2.0
75%	2.5
max	3.0

Describing all columns of a `DataFrame` regardless of data type.

```
>>> df.describe(include='all')
      categorical  numeric  object
count           3        3.0      3
unique           3        NaN      3
top              f        NaN      c
freq             1        NaN      1
mean            NaN        2.0     NaN
std             NaN        1.0     NaN
min            NaN        1.0     NaN
25%            NaN        1.5     NaN
50%            NaN        2.0     NaN
75%            NaN        2.5     NaN
max            NaN        3.0     NaN
```

Describing a column from a `DataFrame` by accessing it as an attribute.

```
>>> df.numeric.describe()
count    3.0
mean     2.0
std      1.0
min      1.0
25%     1.5
50%     2.0
75%     2.5
max      3.0
Name: numeric, dtype: float64
```

Including only numeric columns in a `DataFrame` description.

```
>>> df.describe(include=[np.number])
      numeric
count      3.0
mean       2.0
std        1.0
min        1.0
25%        1.5
50%        2.0
75%        2.5
max        3.0
```

Including only string columns in a `DataFrame` description.

```
>>> df.describe(include=[np.object])
      object
count      3
unique      3
```

(continues on next page)

(continued from previous page)

top	c
freq	1

Including only categorical columns from a DataFrame description.

```
>>> df.describe(include=['category'])
      categorical
count          3
unique          3
top            f
freq           1
```

Excluding numeric columns from a DataFrame description.

```
>>> df.describe(exclude=[np.number])
      categorical  object
count           3      3
unique          3      3
top            f      c
freq           1      1
```

Excluding object columns from a DataFrame description.

```
>>> df.describe(exclude=[np.object])
      categorical  numeric
count           3      3.0
unique          3      NaN
top            f      NaN
freq           1      NaN
mean           NaN      2.0
std            NaN      1.0
min            NaN      1.0
25%            NaN      1.5
50%            NaN      2.0
75%            NaN      2.5
max            NaN      3.0
```

pandas.Series.diff

`Series.diff(self, periods=1)`

First discrete difference of element.

Calculates the difference of a Series element compared with another element in the Series (default is element in previous row).

Parameters

periods [int, default 1] Periods to shift for calculating difference, accepts negative values.

Returns

Series First differences of the Series.

See also:

Series.pct_change Percent change over given number of periods.

Series.shift Shift index by desired number of periods with an optional time freq.

DataFrame.diff First discrete difference of object.

Examples

Difference with previous row

```
>>> s = pd.Series([1, 1, 2, 3, 5, 8])
>>> s.diff()
0    NaN
1    0.0
2    1.0
3    1.0
4    2.0
5    3.0
dtype: float64
```

Difference with 3rd previous row

```
>>> s.diff( periods=3)
0    NaN
1    NaN
2    NaN
3    2.0
4    4.0
5    6.0
dtype: float64
```

Difference with following row

```
>>> s.diff( periods=-1)
0    0.0
1   -1.0
2   -1.0
3   -2.0
4   -3.0
5    NaN
dtype: float64
```

pandas.Series.div

Series.div(*self*, *other*, *level=None*, *fill_value=None*, *axis=0*)

Return Floating division of series and other, element-wise (binary operator *truediv*).

Equivalent to `series / other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

Series.rtruediv

Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.divide(b, fill_value=0)
a    1.0
b    inf
c    inf
d    0.0
e    NaN
dtype: float64
```

pandas.Series.divide

Series.divide(*self*, *other*, *level=None*, *fill_value=None*, *axis=0*)

Return Floating division of series and other, element-wise (binary operator *truediv*).

Equivalent to `series / other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

`Series.rtruediv`

Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.divide(b, fill_value=0)
a    1.0
b    inf
c    inf
d    0.0
e    NaN
dtype: float64
```

pandas.Series.divmod

`Series.divmod(self, other, level=None, fill_value=None, axis=0)`

Return Integer division and modulo of series and other, element-wise (binary operator *divmod*).

Equivalent to `series divmod other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

Series.rdivmod

pandas.Series.dot

Series.dot(*self*, *other*)

Compute the dot product between the Series and the columns of other.

This method computes the dot product between the Series and another one, or the Series and each columns of a DataFrame, or the Series and each columns of an array.

It can also be called using *self @ other* in Python ≥ 3.5 .

Parameters

other [Series, DataFrame or array-like] The other object to compute the dot product with its columns.

Returns

scalar, Series or numpy.ndarray Return the dot product of the Series and other if other is a Series, the Series of the dot product of Series and each rows of other if other is a DataFrame or a numpy.ndarray between the Series and each columns of the numpy array.

See also:

DataFrame.dot Compute the matrix product with the DataFrame.

Series.mul Multiplication of series and other, element-wise.

Notes

The Series and other has to share the same index if other is a Series or a DataFrame.

Examples

```
>>> s = pd.Series([0, 1, 2, 3])
>>> other = pd.Series([-1, 2, -3, 4])
>>> s.dot(other)
8
>>> s @ other
8
>>> df = pd.DataFrame([[0, 1], [-2, 3], [4, -5], [6, 7]])
>>> s.dot(df)
0    24
1    14
dtype: int64
>>> arr = np.array([[0, 1], [-2, 3], [4, -5], [6, 7]])
>>> s.dot(arr)
array([24, 14])
```

pandas.Series.drop

`Series.drop(self, labels=None, axis=0, index=None, columns=None, level=None, inplace=False, errors='raise')`

Return Series with specified index labels removed.

Remove elements of a Series based on specifying the index labels. When using a multi-index, labels on different levels can be removed by specifying the level.

Parameters

labels [single label or list-like] Index labels to drop.

axis [0, default 0] Redundant for application on Series.

index, columns [None] Redundant for application on Series, but index can be used instead of labels.

New in version 0.21.0.

level [int or level name, optional] For MultiIndex, level for which the labels will be removed.

inplace [bool, default False] If True, do operation inplace and return None.

errors [{'ignore', 'raise'}, default 'raise'] If 'ignore', suppress error and only existing labels are dropped.

Returns

Series Series with specified index labels removed.

Raises

KeyError If none of the labels are found in the index.

See also:

Series.reindex Return only specified index labels of Series.

Series.dropna Return series without null values.

Series.drop_duplicates Return Series with duplicate values removed.

DataFrame.drop Drop specified labels from rows or columns.

Examples

```
>>> s = pd.Series(data=np.arange(3), index=['A', 'B', 'C'])
>>> s
A    0
B    1
C    2
dtype: int64
```

Drop labels B en C

```
>>> s.drop(labels=['B', 'C'])
A    0
dtype: int64
```

Drop 2nd level label in MultiIndex Series

```
>>> midx = pd.MultiIndex(levels=[['lama', 'cow', 'falcon'],
...                             ['speed', 'weight', 'length']],
...                       codes=[[0, 0, 0, 1, 1, 1, 2, 2, 2],
...                              [0, 1, 2, 0, 1, 2, 0, 1, 2]])
>>> s = pd.Series([45, 200, 1.2, 30, 250, 1.5, 320, 1, 0.3],
...               index=midx)
>>> s
lama    speed    45.0
        weight   200.0
        length    1.2
cow     speed    30.0
        weight   250.0
        length    1.5
falcon  speed   320.0
        weight    1.0
        length    0.3
dtype: float64
```

```
>>> s.drop(labels='weight', level=1)
lama    speed    45.0
        length    1.2
cow     speed    30.0
        length    1.5
falcon  speed   320.0
        length    0.3
dtype: float64
```

pandas.Series.drop_duplicates

`Series.drop_duplicates(self, keep='first', inplace=False)`

Return Series with duplicate values removed.

Parameters

keep [{'first', 'last', False}, default 'first']

- 'first' : Drop duplicates except for the first occurrence.
- 'last' : Drop duplicates except for the last occurrence.
- False : Drop all duplicates.

inplace [bool, default False] If True, performs operation inplace and returns None.

Returns

Series Series with duplicates dropped.

See also:

Index.drop_duplicates Equivalent method on Index.

DataFrame.drop_duplicates Equivalent method on DataFrame.

Series.duplicated Related method on Series, indicating duplicate Series values.

Examples

Generate a Series with duplicated entries.

```
>>> s = pd.Series(['lama', 'cow', 'lama', 'beetle', 'lama', 'hippo'],
...                 name='animal')
>>> s
0      lama
1       cow
2      lama
3    beetle
4      lama
5     hippo
Name: animal, dtype: object
```

With the ‘keep’ parameter, the selection behaviour of duplicated values can be changed. The value ‘first’ keeps the first occurrence for each set of duplicated entries. The default value of keep is ‘first’.

```
>>> s.drop_duplicates()
0      lama
1       cow
3    beetle
5     hippo
Name: animal, dtype: object
```

The value ‘last’ for parameter ‘keep’ keeps the last occurrence for each set of duplicated entries.

```
>>> s.drop_duplicates(keep='last')
1       cow
3    beetle
4      lama
5     hippo
Name: animal, dtype: object
```

The value `False` for parameter ‘keep’ discards all sets of duplicated entries. Setting the value of ‘inplace’ to `True` performs the operation inplace and returns `None`.

```
>>> s.drop_duplicates(keep=False, inplace=True)
>>> s
1       cow
3    beetle
5     hippo
Name: animal, dtype: object
```

pandas.Series.droplevel

`Series.droplevel(self, level, axis=0)`

Return DataFrame with requested index / column level(s) removed.

New in version 0.24.0.

Parameters

level [int, str, or list-like] If a string is given, must be the name of a level. If list-like, elements must be names or positional indexes of levels.

axis [{0 or 'index', 1 or 'columns'}, default 0]

Returns

DataFrame.droplevel()

Examples

```
>>> df = pd.DataFrame([
...     [1, 2, 3, 4],
...     [5, 6, 7, 8],
...     [9, 10, 11, 12]
... ]).set_index([0, 1]).rename_axis(['a', 'b'])
```

```
>>> df.columns = pd.MultiIndex.from_tuples([
...     ('c', 'e'), ('d', 'f')
... ], names=['level_1', 'level_2'])
```

```
>>> df
level_1  c  d
level_2  e  f
a b
1 2      3  4
5 6      7  8
9 10     11 12
```

```
>>> df.droplevel('a')
level_1  c  d
level_2  e  f
b
2      3  4
6      7  8
10     11 12
```

```
>>> df.droplevel('level2', axis=1)
level_1  c  d
a b
1 2      3  4
5 6      7  8
9 10     11 12
```

pandas.Series.dropna

Series.dropna(*self*, *axis=0*, *inplace=False*, ***kwargs*)

Return a new Series with missing values removed.

See the *User Guide* for more on which values are considered missing, and how to work with missing data.

Parameters

axis [{0 or 'index'}, default 0] There is only one axis to drop values from.

inplace [bool, default False] If True, do operation inplace and return None.

****kwargs** Not in use.

Returns

Series Series with NA entries dropped from it.

See also:

Series.isna Indicate missing values.

Series.notna Indicate existing (non-missing) values.

Series.fillna Replace missing values.

DataFrame.dropna Drop rows or columns which contain NA values.

Index.dropna Drop missing indices.

Examples

```
>>> ser = pd.Series([1., 2., np.nan])
>>> ser
0    1.0
1    2.0
2     NaN
dtype: float64
```

Drop NA values from a Series.

```
>>> ser.dropna()
0    1.0
1    2.0
dtype: float64
```

Keep the Series with valid entries in the same variable.

```
>>> ser.dropna(inplace=True)
>>> ser
0    1.0
1    2.0
dtype: float64
```

Empty strings are not considered NA values. None is considered an NA value.

```
>>> ser = pd.Series([np.NaN, 2, pd.NaT, '', None, 'I stay'])
>>> ser
0     NaN
1      2
2     NaT
3
4     None
5    I stay
dtype: object
```

(continues on next page)

(continued from previous page)

```
>>> ser.dropna()
1      2
3
5      I stay
dtype: object
```

pandas.Series.dt

Series.dt()

Accessor object for datetimelike properties of the Series values.

Examples

```
>>> s.dt.hour
>>> s.dt.second
>>> s.dt.quarter
```

Returns a Series indexed like the original Series. Raises `TypeError` if the Series does not contain datetimelike values.

pandas.Series.duplicated

Series.duplicated(*self*, *keep='first'*)

Indicate duplicate Series values.

Duplicated values are indicated as `True` values in the resulting Series. Either all duplicates, all except the first or all except the last occurrence of duplicates can be indicated.

Parameters

keep [({'first', 'last', False}, default 'first')]

- 'first' : Mark duplicates as `True` except for the first occurrence.
- 'last' : Mark duplicates as `True` except for the last occurrence.
- `False` : Mark all duplicates as `True`.

Returns

Series Series indicating whether each value has occurred in the preceding values.

See also:

Index.duplicated Equivalent method on `pandas.Index`.

DataFrame.duplicated Equivalent method on `pandas.DataFrame`.

Series.drop_duplicates Remove duplicate values from Series.

Examples

By default, for each set of duplicated values, the first occurrence is set on `False` and all others on `True`:

```
>>> animals = pd.Series(['lama', 'cow', 'lama', 'beetle', 'lama'])
>>> animals.duplicated()
0    False
1    False
2     True
3    False
4     True
dtype: bool
```

which is equivalent to

```
>>> animals.duplicated(keep='first')
0    False
1    False
2     True
3    False
4     True
dtype: bool
```

By using 'last', the last occurrence of each set of duplicated values is set on False and all others on True:

```
>>> animals.duplicated(keep='last')
0     True
1    False
2     True
3    False
4    False
dtype: bool
```

By setting keep on False, all duplicates are True:

```
>>> animals.duplicated(keep=False)
0     True
1    False
2     True
3    False
4     True
dtype: bool
```

pandas.Series.eq

`Series.eq(self, other, level=None, fill_value=None, axis=0)`

Return Equal to of series and other, element-wise (binary operator *eq*).

Equivalent to `series == other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this

value before computation. If data in both corresponding Series locations is missing the result will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

Series.None

pandas.Series.equals

Series.equals(*self*, *other*)

Test whether two objects contain the same elements.

This function allows two Series or DataFrames to be compared against each other to see if they have the same shape and elements. NaNs in the same location are considered equal. The column headers do not need to have the same type, but the elements within the columns must be the same dtype.

Parameters

other [Series or DataFrame] The other Series or DataFrame to be compared with the first.

Returns

bool True if all elements are the same in both objects, False otherwise.

See also:

Series.eq Compare two Series objects of the same length and return a Series where each element is True if the element in each Series is equal, False otherwise.

DataFrame.eq Compare two DataFrame objects of the same shape and return a DataFrame where each element is True if the respective element in each DataFrame is equal, False otherwise.

assert_series_equal Return True if left and right Series are equal, False otherwise.

assert_frame_equal Return True if left and right DataFrames are equal, False otherwise.

numpy.array_equal Return True if two arrays have the same shape and elements, False otherwise.

Notes

This function requires that the elements have the same dtype as their respective elements in the other Series or DataFrame. However, the column labels do not need to have the same type, as long as they are still considered equal.

Examples

```
>>> df = pd.DataFrame({'1': [10], 2: [20]})
>>> df
   1  2
0 10 20
```

DataFrames `df` and `exactly_equal` have the same types and values for their elements and column labels, which will return `True`.

```
>>> exactly_equal = pd.DataFrame({'1': [10], 2: [20]})
>>> exactly_equal
   1  2
0 10 20
>>> df.equals(exactly_equal)
True
```

DataFrames `df` and `different_column_type` have the same element types and values, but have different types for the column labels, which will still return `True`.

```
>>> different_column_type = pd.DataFrame({'1.0': [10], 2.0: [20]})
>>> different_column_type
   1.0  2.0
0   10   20
>>> df.equals(different_column_type)
True
```

DataFrames `df` and `different_data_type` have different types for the same values for their elements, and will return `False` even though their column labels are the same values and types.

```
>>> different_data_type = pd.DataFrame({'1': [10.0], 2: [20.0]})
>>> different_data_type
   1    2
0 10.0 20.0
>>> df.equals(different_data_type)
False
```

pandas.Series.ewm

`Series.ewm(self, com=None, span=None, halflife=None, alpha=None, min_periods=0, adjust=True, ignore_na=False, axis=0)`

Provide exponential weighted functions.

New in version 0.18.0.

Parameters

com [float, optional] Specify decay in terms of center of mass, $\alpha = 1/(1 + com)$, for $com \geq 0$.

span [float, optional] Specify decay in terms of span, $\alpha = 2/(span+1)$, for $span \geq 1$.

halflife [float, optional] Specify decay in terms of half-life, $\alpha = 1 - \exp(\log(0.5)/halflife)$, for $halflife > 0$.

alpha [float, optional] Specify smoothing factor α directly, $0 < \alpha \leq 1$.

New in version 0.18.0.

min_periods [int, default 0] Minimum number of observations in window required to have a value (otherwise result is NA).

adjust [bool, default True] Divide by decaying adjustment factor in beginning periods to account for imbalance in relative weightings (viewing EWMA as a moving average).

ignore_na [bool, default False] Ignore missing values when calculating weights; specify True to reproduce pre-0.15.0 behavior.

axis [{0 or 'index', 1 or 'columns'}, default 0] The axis to use. The value 0 identifies the rows, and 1 identifies the columns.

Returns

DataFrame A Window sub-classed for the particular operation.

See also:

rolling Provides rolling window calculations.

expanding Provides expanding transformations.

Notes

Exactly one of center of mass, span, half-life, and alpha must be provided. Allowed values and relationship between the parameters are specified in the parameter descriptions above; see the link at the end of this section for a detailed explanation.

When adjust is True (default), weighted averages are calculated using weights $(1-\alpha)^{(n-1)}$, $(1-\alpha)^{(n-2)}$, ..., $1-\alpha$, 1.

When adjust is False, weighted averages are calculated recursively as:

$$\text{weighted_average}[0] = \text{arg}[0]; \text{weighted_average}[i] = (1-\alpha)*\text{weighted_average}[i-1] + \alpha*\text{arg}[i].$$

When ignore_na is False (default), weights are based on absolute positions. For example, the weights of x and y used in calculating the final weighted average of [x, None, y] are $(1-\alpha)^{**2}$ and 1 (if adjust is True), and $(1-\alpha)^{**2}$ and alpha (if adjust is False).

When ignore_na is True (reproducing pre-0.15.0 behavior), weights are based on relative positions. For example, the weights of x and y used in calculating the final weighted average of [x, None, y] are 1-alpha and 1 (if adjust is True), and 1-alpha and alpha (if adjust is False).

More details can be found at http://pandas.pydata.org/pandas-docs/stable/user_guide/computation.html#exponentially-weighted-windows

Examples

```
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
>>> df
   B
0  0.0
1  1.0
```

(continues on next page)

(continued from previous page)

```
2  2.0
3  NaN
4  4.0
```

```
>>> df.ewm(com=0.5).mean()
      B
0  0.000000
1  0.750000
2  1.615385
3  1.615385
4  3.670213
```

pandas.Series.expanding

`Series.expanding(self, min_periods=1, center=False, axis=0)`

Provide expanding transformations.

New in version 0.18.0.

Parameters

min_periods [int, default 1] Minimum number of observations in window required to have a value (otherwise result is NA).

center [bool, default False] Set the labels at the center of the window.

axis [int or str, default 0]

Returns

a **Window** sub-classed for the particular operation

See also:

rolling Provides rolling window calculations.

ewm Provides exponential weighted functions.

Notes

By default, the result is set to the right edge of the window. This can be changed to the center of the window by setting `center=True`.

Examples

```
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
      B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0
```

```
>>> df.expanding(2).sum()
      B
0  NaN
1  1.0
2  3.0
3  3.0
4  7.0
```

pandas.Series.explode

`Series.explode(self)` → 'Series'

Transform each element of a list-like to a row, replicating the index values.

New in version 0.25.0.

Returns

Series Exploded lists to rows; index will be duplicated for these rows.

See also:

Series.str.split Split string values on specified separator.

Series.unstack Unstack, a.k.a. pivot, Series with MultiIndex to produce DataFrame.

DataFrame.melt Unpivot a DataFrame from wide format to long format

DataFrame.explode Explode a DataFrame from list-like columns to long format.

Notes

This routine will explode list-likes including lists, tuples, Series, and np.ndarray. The result dtype of the subset rows will be object. Scalars will be returned unchanged. Empty list-likes will result in a np.nan for that row.

Examples

```
>>> s = pd.Series([[1, 2, 3], 'foo', [], [3, 4]])
>>> s
0    [1, 2, 3]
1         foo
2          []
3     [3, 4]
dtype: object
```

```
>>> s.explode()
0     1
0     2
0     3
1    foo
2    NaN
3     3
```

(continues on next page)

(continued from previous page)

```
3      4
dtype: object
```

pandas.Series.factorize**Series.factorize**(*self*, *sort=False*, *na_sentinel=-1*)

Encode the object as an enumerated type or categorical variable.

This method is useful for obtaining a numeric representation of an array when all that matters is identifying distinct values. *factorize* is available as both a top-level function *pandas.factorize()*, and as a method *Series.factorize()* and *Index.factorize()*.

Parameters

sort [boolean, default False] Sort *uniques* and shuffle *labels* to maintain the relationship.

na_sentinel [int, default -1] Value to mark “not found”.

Returns

labels [ndarray] An integer ndarray that’s an indexer into *uniques*. *uniques.take(labels)* will have the same values as *values*.

uniques [ndarray, Index, or Categorical] The unique valid values. When *values* is Categorical, *uniques* is a Categorical. When *values* is some other pandas object, an *Index* is returned. Otherwise, a 1-D ndarray is returned.

Note: Even if there’s a missing value in *values*, *uniques* will *not* contain an entry for it.

See also:

cut Discretize continuous-valued array.

unique Find the unique value in an array.

Examples

These examples all show *factorize* as a top-level method like *pd.factorize(values)*. The results are identical for methods like *Series.factorize()*.

```
>>> labels, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'])
>>> labels
array([0, 0, 1, 2, 0])
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

With *sort=True*, the *uniques* will be sorted, and *labels* will be shuffled so that the relationship is the maintained.

```
>>> labels, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'], sort=True)
>>> labels
array([1, 1, 0, 2, 1])
>>> uniques
array(['a', 'b', 'c'], dtype=object)
```

Missing values are indicated in *labels* with *na_sentinel* (-1 by default). Note that missing values are never included in *uniques*.

```
>>> labels, uniques = pd.factorize(['b', None, 'a', 'c', 'b'])
>>> labels
array([ 0, -1,  1,  2,  0])
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

Thus far, we've only factorized lists (which are internally coerced to NumPy arrays). When factorizing pandas objects, the type of *uniques* will differ. For Categoricals, a *Categorical* is returned.

```
>>> cat = pd.Categorical(['a', 'a', 'c'], categories=['a', 'b', 'c'])
>>> labels, uniques = pd.factorize(cat)
>>> labels
array([0, 0, 1])
>>> uniques
[a, c]
Categories (3, object): [a, b, c]
```

Notice that 'b' is in *uniques.categories*, despite not being present in *cat.values*.

For all other pandas objects, an Index of the appropriate type is returned.

```
>>> cat = pd.Series(['a', 'a', 'c'])
>>> labels, uniques = pd.factorize(cat)
>>> labels
array([0, 0, 1])
>>> uniques
Index(['a', 'c'], dtype='object')
```

pandas.Series.ffill

`Series.fffll(self, axis=None, inplace=False, limit=None, downcast=None)`

Synonym for `DataFrame.fillna()` with `method='ffill'`.

Returns

`%(klass)s` Object with missing values filled.

pandas.Series.fillna

`Series.fillna(self, value=None, method=None, axis=None, inplace=False, limit=None, downcast=None, **kwargs)`

Fill NA/NaN values using the specified method.

Parameters

value [scalar, dict, Series, or DataFrame] Value to use to fill holes (e.g. 0), alternately a dict/Series/DataFrame of values specifying which value to use for each index (for a Series) or column (for a DataFrame). Values not in the dict/Series/DataFrame will not be filled. This value cannot be a list.

method [{‘backfill’, ‘bfill’, ‘pad’, ‘ffill’, None}, default None] Method to use for filling holes in reindexed Series pad / ffill: propagate last valid observation forward to next valid backfill / bfill: use next valid observation to fill gap.

axis [{0 or ‘index’}] Axis along which to fill missing values.

inplace [bool, default False] If True, fill in-place. Note: this will modify any other views on this object (e.g., a no-copy slice for a column in a DataFrame).

limit [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

downcast [dict, default is None] A dict of item->dtype of what to downcast if possible, or the string ‘infer’ which will try to downcast to an appropriate equal type (e.g. float64 to int64 if possible).

Returns

Series Object with missing values filled.

See also:

interpolate Fill NaN values using interpolation.

reindex Conform object to new index.

asfreq Convert TimeSeries to specified frequency.

Examples

```
>>> df = pd.DataFrame([[np.nan, 2, np.nan, 0],
...                    [3, 4, np.nan, 1],
...                    [np.nan, np.nan, np.nan, 5],
...                    [np.nan, 3, np.nan, 4]],
...                    columns=list('ABCD'))
>>> df
   A    B    C    D
0 NaN  2.0 NaN  0
1  3.0  4.0 NaN  1
2 NaN  NaN NaN  5
3 NaN  3.0 NaN  4
```

Replace all NaN elements with 0s.

```
>>> df.fillna(0)
   A    B    C    D
0  0.0  2.0  0.0  0
1  3.0  4.0  0.0  1
2  0.0  0.0  0.0  5
3  0.0  3.0  0.0  4
```

We can also propagate non-null values forward or backward.

```
>>> df.fillna(method='ffill')
   A    B    C    D
0  NaN  2.0 NaN  0
1  3.0  4.0 NaN  1
2  3.0  4.0 NaN  5
3  3.0  3.0 NaN  4
```

Replace all NaN elements in column 'A', 'B', 'C', and 'D', with 0, 1, 2, and 3 respectively.

```
>>> values = {'A': 0, 'B': 1, 'C': 2, 'D': 3}
>>> df.fillna(value=values)
   A    B    C    D
0  0.0  2.0  2.0  0
1  3.0  4.0  2.0  1
2  0.0  1.0  2.0  5
3  0.0  3.0  2.0  4
```

Only replace the first NaN element.

```
>>> df.fillna(value=values, limit=1)
   A    B    C    D
0  0.0  2.0  2.0  0
1  3.0  4.0 NaN  1
2  NaN  1.0 NaN  5
3  NaN  3.0 NaN  4
```

pandas.Series.filter

`Series.filter(self, items=None, like=None, regex=None, axis=None)`

Subset rows or columns of dataframe according to labels in the specified index.

Note that this routine does not filter a dataframe on its contents. The filter is applied to the labels of the index.

Parameters

items [list-like] Keep labels from axis which are in items.

like [string] Keep labels from axis for which “like in label == True”.

regex [string (regular expression)] Keep labels from axis for which `re.search(regex, label) == True`.

axis [int or string axis name] The axis to filter on. By default this is the info axis, ‘index’ for Series, ‘columns’ for DataFrame.

Returns

same type as input object

See also:

`DataFrame.loc`

Notes

The `items`, `like`, and `regex` parameters are enforced to be mutually exclusive.
`axis` defaults to the info axis that is used when indexing with `[]`.

Examples

```
>>> df = pd.DataFrame(np.array([[1, 2, 3], [4, 5, 6]]),
...                   index=['mouse', 'rabbit'],
...                   columns=['one', 'two', 'three'])
```

```
>>> # select columns by name
>>> df.filter(items=['one', 'three'])
      one  three
mouse   1     3
rabbit  4     6
```

```
>>> # select columns by regular expression
>>> df.filter(regex='e$', axis=1)
      one  three
mouse   1     3
rabbit  4     6
```

```
>>> # select rows containing 'bbi'
>>> df.filter(like='bbi', axis=0)
      one  two  three
rabbit  4   5     6
```

pandas.Series.first

`Series.first(self, offset)`

Convenience method for subsetting initial periods of time series data based on a date offset.

Parameters

offset [string, DateOffset, dateutil.relativedelta]

Returns

subset [same type as caller]

Raises

TypeError If the index is not a *DatetimeIndex*

See also:

last Select final periods of time series based on a date offset.

at_time Select values at a particular time of the day.

between_time Select values between particular times of the day.

Examples

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1,2,3,4]}, index=i)
>>> ts
           A
2018-04-09  1
2018-04-11  2
2018-04-13  3
2018-04-15  4
```

Get the rows for the first 3 days:

```
>>> ts.first('3D')
           A
2018-04-09  1
2018-04-11  2
```

Notice the data for 3 first calendar days were returned, not the first 3 days observed in the dataset, and therefore data for 2018-04-13 was not returned.

pandas.Series.first_valid_index

`Series.first_valid_index(self)`

Return index for first non-NA/null value.

Returns

scalar [type of index]

Notes

If all elements are non-NA/null, returns None. Also returns None for empty Series/DataFrame.

pandas.Series.floordiv

`Series.floordiv(self, other, level=None, fill_value=None, axis=0)`

Return Integer division of series and other, element-wise (binary operator *floordiv*).

Equivalent to `series // other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

Series.rfloordiv

Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.floordiv(b, fill_value=0)
a    1.0
b    NaN
c    NaN
d    0.0
e    NaN
dtype: float64
```

pandas.Series.from_array

classmethod `Series.from_array(arr, index=None, name=None, dtype=None, copy=False, fastpath=False)`

Construct Series from array.

Deprecated since version 0.23.0: Use `pd.Series(..)` constructor instead.

Returns

Series Constructed Series.

pandas.Series.ge

Series.ge(*self*, *other*, *level=None*, *fill_value=None*, *axis=0*)

Return Greater than or equal to of series and other, element-wise (binary operator *ge*).

Equivalent to `series >= other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

`Series.None`

pandas.Series.get

`Series.get(self, key, default=None)`

Get item from object for given key (ex: DataFrame column).

Returns default value if not found.

Parameters

key [object]

Returns

value [same type as items contained in object]

pandas.Series.get_dtype_counts

`Series.get_dtype_counts(self)`

Return counts of unique dtypes in this object.

Deprecated since version 0.25.0.

Use `.dtypes.value_counts()` instead.

Returns

dtype [Series] Series with the count of columns with each dtype.

See also:

dtypes Return the dtypes in this object.

Examples

```
>>> a = [['a', 1, 1.0], ['b', 2, 2.0], ['c', 3, 3.0]]
>>> df = pd.DataFrame(a, columns=['str', 'int', 'float'])
>>> df
   str  int  float
0   a    1   1.0
1   b    2   2.0
2   c    3   3.0
```

```
>>> df.get_dtype_counts()
float64    1
int64      1
object     1
dtype: int64
```

pandas.Series.get_ftype_counts

`Series.get_ftype_counts(self)`

Return counts of unique ftypes in this object.

Deprecated since version 0.23.0.

This is useful for SparseDataFrame or for DataFrames containing sparse arrays.

Returns

dtype [Series] Series with the count of columns with each type and sparsity (dense/sparse).

See also:

ftypes Return ftypes (indication of sparse/dense and dtype) in this object.

Examples

```
>>> a = [['a', 1, 1.0], ['b', 2, 2.0], ['c', 3, 3.0]]
>>> df = pd.DataFrame(a, columns=['str', 'int', 'float'])
>>> df
   str  int  float
0  a    1    1.0
1  b    2    2.0
2  c    3    3.0
```

```
>>> df.get_ftype_counts() # doctest: +SKIP
float64:dense    1
int64:dense      1
object:dense     1
dtype: int64
```

pandas.Series.get_value

`Series.get_value(self, label, takeable=False)`

Quickly retrieve single value at passed index label.

Deprecated since version 0.21.0: Please use `.at[]` or `.iat[]` accessors.

Parameters

label [object]

takeable [interpret the index as indexers, default False]

Returns

scalar value

pandas.Series.get_values

Series.get_values(*self*)

Same as `values` (but handles sparseness conversions); is a view.

Deprecated since version 0.25.0: Use `Series.to_numpy()` or `Series.array` instead.

Returns

numpy.ndarray Data of the Series.

pandas.Series.groupby

Series.groupby(*self*, *by=None*, *axis=0*, *level=None*, *as_index=True*, *sort=True*,
group_keys=True, *squeeze=False*, *observed=False*, ***kwargs*)

Group DataFrame or Series using a mapper or by a Series of columns.

A groupby operation involves some combination of splitting the object, applying a function, and combining the results. This can be used to group large amounts of data and compute operations on these groups.

Parameters

by [mapping, function, label, or list of labels] Used to determine the groups for the groupby. If **by** is a function, it's called on each value of the object's index. If a dict or Series is passed, the Series or dict VALUES will be used to determine the groups (the Series' values are first aligned; see `.align()` method). If an ndarray is passed, the values are used as-is determine the groups. A label or list of labels may be passed to group by the columns in **self**. Notice that a tuple is interpreted as a (single) key.

axis [{0 or 'index', 1 or 'columns'}, default 0] Split along rows (0) or columns (1).

level [int, level name, or sequence of such, default None] If the axis is a MultiIndex (hierarchical), group by a particular level or levels.

as_index [bool, default True] For aggregated output, return object with group labels as the index. Only relevant for DataFrame input. `as_index=False` is effectively "SQL-style" grouped output.

sort [bool, default True] Sort group keys. Get better performance by turning this off. Note this does not influence the order of observations within each group. Groupby preserves the order of rows within each group.

group_keys [bool, default True] When calling `apply`, add group keys to index to identify pieces.

squeeze [bool, default False] Reduce the dimensionality of the return type if possible, otherwise return a consistent type.

observed [bool, default False] This only applies if any of the groupers are Categoricals. If True: only show observed values for categorical groupers. If False: show all values for categorical groupers.

New in version 0.23.0.

****kwargs** Optional, only accepts keyword argument 'mutated' and is passed to `groupby`.

Returns

DataFrameGroupBy or **SeriesGroupBy** Depends on the calling object and returns groupby object that contains information about the groups.

See also:

resample Convenience method for frequency conversion and resampling of time series.

Notes

See the [user guide](#) for more.

Examples

```
>>> df = pd.DataFrame({'Animal': ['Falcon', 'Falcon',
...                               'Parrot', 'Parrot'],
...                   'Max Speed': [380., 370., 24., 26.]})
>>> df
   Animal  Max Speed
0  Falcon    380.0
1  Falcon    370.0
2  Parrot     24.0
3  Parrot     26.0
>>> df.groupby(['Animal']).mean()
   Animal
Falcon    375.0
Parrot     25.0
```

Hierarchical Indexes

We can groupby different levels of a hierarchical index using the *level* parameter:

```
>>> arrays = [['Falcon', 'Falcon', 'Parrot', 'Parrot'],
...           ['Captive', 'Wild', 'Captive', 'Wild']]
>>> index = pd.MultiIndex.from_arrays(arrays, names=('Animal', 'Type'))
>>> df = pd.DataFrame({'Max Speed': [390., 350., 30., 20.]},
...                   index=index)
>>> df
   Animal Type  Max Speed
Falcon Captive    390.0
       Wild      350.0
Parrot Captive     30.0
       Wild      20.0
>>> df.groupby(level=0).mean()
   Animal
Falcon    370.0
Parrot     25.0
>>> df.groupby(level=1).mean()
   Animal
Falcon    370.0
Parrot     25.0
```

(continues on next page)

(continued from previous page)

Type	
Captive	210.0
Wild	185.0

pandas.Series.gt**Series.gt**(*self*, *other*, *level=None*, *fill_value=None*, *axis=0*)Return Greater than of series and other, element-wise (binary operator *gt*).Equivalent to `series > other`, but with support to substitute a `fill_value` for missing data in one of the inputs.**Parameters****other** [Series or scalar value]**fill_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.**level** [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.**Returns****Series** The result of the operation.**See also:****Series.None****pandas.Series.head****Series.head**(*self*, *n=5*)Return the first *n* rows.This function returns the first *n* rows for the object based on position. It is useful for quickly testing if your object has the right type of data in it.**Parameters****n** [int, default 5] Number of rows to select.**Returns****obj_head** [same type as caller] The first *n* rows of the caller object.**See also:****DataFrame.tail** Returns the last *n* rows.**Examples**

```
>>> df = pd.DataFrame({'animal': ['alligator', 'bee', 'falcon', 'lion',
...                               'monkey', 'parrot', 'shark', 'whale', 'zebra']})
>>> df
   animal
0 alligator
1      bee
2   falcon
3     lion
4   monkey
5   parrot
6     shark
7     whale
8     zebra
```

Viewing the first 5 lines

```
>>> df.head()
   animal
0 alligator
1      bee
2   falcon
3     lion
4   monkey
```

Viewing the first *n* lines (three in this case)

```
>>> df.head(3)
   animal
0 alligator
1      bee
2   falcon
```

pandas.Series.hist

`Series.hist(self, by=None, ax=None, grid=True, xlabelsize=None, xrot=None, ylabelsize=None, yrot=None, figsize=None, bins=10, **kwargs)`
 Draw histogram of the input series using matplotlib.

Parameters

by [object, optional] If passed, then used to form histograms for separate groups

ax [matplotlib axis object] If not passed, uses `gca()`

grid [bool, default True] Whether to show axis grid lines

xlabelsize [int, default None] If specified changes the x-axis label size

xrot [float, default None] rotation of x axis labels

ylabelsize [int, default None] If specified changes the y-axis label size

yrot [float, default None] rotation of y axis labels

figsize [tuple, default None] figure size in inches by default

bins [integer or sequence, default 10] Number of histogram bins to be used. If an integer is given, bins + 1 bin edges are calculated and returned. If bins is a sequence, gives bin edges, including left edge of first bin and right edge of last bin. In this case, bins is returned unmodified.

****kwds** [keywords] To be passed to the actual plotting function

Returns

matplotlib.AxesSubplot A histogram plot.

See also:

`matplotlib.axes.Axes.hist` Plot a histogram using matplotlib.

pandas.Series.idxmax

`Series.idxmax(self, axis=0, skipna=True, *args, **kwargs)`

Return the row label of the maximum value.

If multiple values equal the maximum, the first row label with that value is returned.

Parameters

skipna [bool, default True] Exclude NA/null values. If the entire Series is NA, the result will be NA.

axis [int, default 0] For compatibility with DataFrame.idxmax. Redundant for application on Series.

***args, **kwargs** Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

Index Label of the maximum value.

Raises

ValueError If the Series is empty.

See also:

`numpy.argmax` Return indices of the maximum values along the given axis.

`DataFrame.idxmax` Return index of first occurrence of maximum over requested axis.

`Series.idxmin` Return index *label* of the first occurrence of minimum of values.

Notes

This method is the Series version of `ndarray.argmax`. This method returns the label of the maximum, while `ndarray.argmax` returns the position. To get the position, use `series.values.argmax()`.

Examples

```
>>> s = pd.Series(data=[1, None, 4, 3, 4],
...               index=['A', 'B', 'C', 'D', 'E'])
>>> s
A    1.0
B    NaN
C    4.0
D    3.0
E    4.0
dtype: float64
```

```
>>> s.idxmax()
'C'
```

If *skipna* is False and there is an NA value in the data, the function returns `nan`.

```
>>> s.idxmax(skipna=False)
nan
```

pandas.Series.idxmin

`Series.idxmin(self, axis=0, skipna=True, *args, **kwargs)`

Return the row label of the minimum value.

If multiple values equal the minimum, the first row label with that value is returned.

Parameters

skipna [bool, default True] Exclude NA/null values. If the entire Series is NA, the result will be NA.

axis [int, default 0] For compatibility with `DataFrame.idxmin`. Redundant for application on Series.

***args, **kwargs** Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

Index Label of the minimum value.

Raises

ValueError If the Series is empty.

See also:

`numpy.argmax` Return indices of the minimum values along the given axis.

`DataFrame.idxmin` Return index of first occurrence of minimum over requested axis.

`Series.idxmax` Return index *label* of the first occurrence of maximum of values.

Notes

This method is the Series version of `ndarray.argmax`. This method returns the label of the minimum, while `ndarray.argmax` returns the position. To get the position, use `series.values.argmax()`.

Examples

```
>>> s = pd.Series(data=[1, None, 4, 1],
...               index=['A', 'B', 'C', 'D'])
>>> s
A    1.0
B    NaN
C    4.0
D    1.0
dtype: float64
```

```
>>> s.idxmin()
'A'
```

If *skipna* is False and there is an NA value in the data, the function returns nan.

```
>>> s.idxmin(skipna=False)
nan
```

pandas.Series.infer_objects

Series.infer_objects(*self*)

Attempt to infer better dtypes for object columns.

Attempts soft conversion of object-dtyped columns, leaving non-object and unconvertible columns unchanged. The inference rules are the same as during normal Series/DataFrame construction.

New in version 0.21.0.

Returns

converted [same type as input object]

See also:

to_datetime Convert argument to datetime.

to_timedelta Convert argument to timedelta.

to_numeric Convert argument to numeric type.

Examples

```
>>> df = pd.DataFrame({"A": ["a", 1, 2, 3]})
>>> df = df.iloc[1:]
>>> df
   A
1  1
2  2
3  3
```

```
>>> df.dtypes
A    object
dtype: object
```

```
>>> df.infer_objects().dtypes
A    int64
dtype: object
```

pandas.Series.interpolate

`Series.interpolate(self, method='linear', axis=0, limit=None, inplace=False, limit_direction='forward', limit_area=None, downcast=None, **kwargs)`
Interpolate values according to different methods.

Please note that only `method='linear'` is supported for DataFrame/Series with a MultiIndex.

Parameters

method [str, default 'linear'] Interpolation technique to use. One of:

- 'linear': Ignore the index and treat the values as equally spaced. This is the only method supported on MultiIndexes.
- 'time': Works on daily and higher resolution data to interpolate given length of interval.
- 'index', 'values': use the actual numerical values of the index.
- 'pad': Fill in NaNs using existing values.
- 'nearest', 'zero', 'slinear', 'quadratic', 'cubic', 'spline', 'barycentric', 'polynomial': Passed to `scipy.interpolate.interp1d`. These methods use the numerical values of the index. Both 'polynomial' and 'spline' require that you also specify an `order` (int), e.g. `df.interpolate(method='polynomial', order=5)`.
- 'krogh', 'piecewise_polynomial', 'spline', 'pchip', 'akima': Wrappers around the SciPy interpolation methods of similar names. See *Notes*.
- 'from_derivatives': Refers to `scipy.interpolate.BPoly.from_derivatives` which replaces 'piecewise_polynomial' interpolation method in scipy 0.18.

New in version 0.18.1: Added support for the 'akima' method. Added interpolate method 'from_derivatives' which replaces 'piecewise_polynomial' in SciPy 0.18; backwards-compatible with SciPy < 0.18

axis [{0 or 'index', 1 or 'columns', None}, default None] Axis to interpolate along.

limit [int, optional] Maximum number of consecutive NaNs to fill. Must be greater than 0.

inplace [bool, default False] Update the data in place if possible.

limit_direction [{'forward', 'backward', 'both'}, default 'forward'] If limit is specified, consecutive NaNs will be filled in this direction.

limit_area [{None, 'inside', 'outside'}, default None] If limit is specified, consecutive NaNs will be filled with this restriction.

- None: No fill restriction.
- 'inside': Only fill NaNs surrounded by valid values (interpolate).
- 'outside': Only fill NaNs outside valid values (extrapolate).

New in version 0.23.0.

downcast [optional, 'infer' or None, defaults to None] Downcast dtypes if possible.

****kwargs** Keyword arguments to pass on to the interpolating function.

Returns

Series or DataFrame Returns the same object type as the caller, interpolated at some or all NaN values.

See also:

fillna Fill missing values using different methods.

scipy.interpolate.Akima1DInterpolator Piecewise cubic polynomials (Akima interpolator).

scipy.interpolate.BPoly.from_derivatives Piecewise polynomial in the Bernstein basis.

scipy.interpolate.interp1d Interpolate a 1-D function.

scipy.interpolate.KroghInterpolator Interpolate polynomial (Krogh interpolator).

scipy.interpolate.PchipInterpolator PCHIP 1-d monotonic cubic interpolation.

scipy.interpolate.CubicSpline Cubic spline data interpolator.

Notes

The 'krogh', 'piecewise_polynomial', 'spline', 'pchip' and 'akima' methods are wrappers around the respective SciPy implementations of similar names. These use the actual numerical values of the index. For more information on their behavior, see the [SciPy documentation](#) and [SciPy tutorial](#).

Examples

Filling in NaN in a *Series* via linear interpolation.

```
>>> s = pd.Series([0, 1, np.nan, 3])
>>> s
0    0.0
1    1.0
2    NaN
3    3.0
dtype: float64
>>> s.interpolate()
0    0.0
1    1.0
2    2.0
3    3.0
dtype: float64
```

Filling in NaN in a Series by padding, but filling at most two consecutive NaN at a time.

```
>>> s = pd.Series([np.nan, "single_one", np.nan,
...               "fill_two_more", np.nan, np.nan, np.nan,
...               4.71, np.nan])
>>> s
0          NaN
```

(continues on next page)

(continued from previous page)

```

1      single_one
2          NaN
3      fill_two_more
4          NaN
5          NaN
6          NaN
7          4.71
8          NaN
dtype: object
>>> s.interpolate(method='pad', limit=2)
0          NaN
1      single_one
2      single_one
3      fill_two_more
4      fill_two_more
5      fill_two_more
6          NaN
7          4.71
8          4.71
dtype: object

```

Filling in NaN in a Series via polynomial interpolation or splines: Both 'polynomial' and 'spline' methods require that you also specify an order (int).

```

>>> s = pd.Series([0, 2, np.nan, 8])
>>> s.interpolate(method='polynomial', order=2)
0    0.000000
1    2.000000
2    4.666667
3    8.000000
dtype: float64

```

Fill the DataFrame forward (that is, going down) along each column using linear interpolation.

Note how the last entry in column 'a' is interpolated differently, because there is no entry after it to use for interpolation. Note how the first entry in column 'b' remains NaN, because there is no entry before it to use for interpolation.

```

>>> df = pd.DataFrame([(0.0, np.nan, -1.0, 1.0),
...                    (np.nan, 2.0, np.nan, np.nan),
...                    (2.0, 3.0, np.nan, 9.0),
...                    (np.nan, 4.0, -4.0, 16.0)],
...                   columns=list('abcd'))
>>> df
   a    b    c    d
0  0.0 NaN -1.0  1.0
1  NaN  2.0 NaN  NaN
2  2.0  3.0 NaN  9.0
3  NaN  4.0 -4.0 16.0
>>> df.interpolate(method='linear', limit_direction='forward', axis=0)
   a    b    c    d
0  0.0 NaN -1.0  1.0
1  1.0  2.0 -2.0  5.0

```

(continues on next page)

(continued from previous page)

```
2  2.0  3.0 -3.0  9.0
3  2.0  4.0 -4.0 16.0
```

Using polynomial interpolation.

```
>>> df['d'].interpolate(method='polynomial', order=2)
0    1.0
1    4.0
2    9.0
3   16.0
Name: d, dtype: float64
```

pandas.Series.isin

Series.isin(*self*, *values*)

Check whether *values* are contained in Series.

Return a boolean Series showing whether each element in the Series matches an element in the passed sequence of *values* exactly.

Parameters

values [set or list-like] The sequence of values to test. Passing in a single string will raise a `TypeError`. Instead, turn a single string into a list of one element.

New in version 0.18.1: Support for values as a set.

Returns

Series Series of booleans indicating if each element is in values.

Raises

TypeError

- If *values* is a string

See also:

DataFrame.isin Equivalent method on DataFrame.

Examples

```
>>> s = pd.Series(['lama', 'cow', 'lama', 'beetle', 'lama',
...               'hippo'], name='animal')
>>> s.isin(['cow', 'lama'])
0    True
1    True
2    True
3    False
4    True
5    False
Name: animal, dtype: bool
```

Passing a single string as `s.isin('lama')` will raise an error. Use a list of one element instead:

```
>>> s.isin(['lama'])
0     True
1     False
2     True
3     False
4     True
5     False
Name: animal, dtype: bool
```

pandas.Series.isna

Series.isna(*self*)

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as None or numpy.NaN, gets mapped to True values. Everything else gets mapped to False values. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True).

Returns

Series Mask of bool values for each element in Series that indicates whether an element is not an NA value.

See also:

Series.isnull Alias of isna.

Series.notna Boolean inverse of isna.

Series.dropna Omit axes labels with missing values.

isna Top-level isna.

Examples

Show which entries in a DataFrame are NA.

```
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
...                   'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                             pd.Timestamp('1940-04-25')],
...                   'name': ['Alfred', 'Batman', ''],
...                   'toy': [None, 'Batmobile', 'Joker']})
>>> df
   age      born  name      toy
0  5.0      NaT  Alfred    None
1  6.0  1939-05-27  Batman  Batmobile
2  NaN  1940-04-25      Joker
```

```
>>> df.isna()
   age  born  name  toy
0  False  True  False  True
1  False  False  False  False
2   True  False  False  False
```

Show which entries in a Series are NA.

```
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2    NaN
dtype: float64
```

```
>>> ser.isna()
0    False
1    False
2     True
dtype: bool
```

pandas.Series.isnull

`Series.isnull(self)`

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as `None` or `numpy.NaN`, gets mapped to `True` values. Everything else gets mapped to `False` values. Characters such as empty strings `''` or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`).

Returns

Series Mask of bool values for each element in Series that indicates whether an element is not an NA value.

See also:

Series.isnull Alias of `isna`.

Series.notna Boolean inverse of `isna`.

Series.dropna Omit axes labels with missing values.

isna Top-level `isna`.

Examples

Show which entries in a DataFrame are NA.

```
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
...                    'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                              pd.Timestamp('1940-04-25')],
...                    'name': ['Alfred', 'Batman', ''],
...                    'toy': [None, 'Batmobile', 'Joker']})
>>> df
   age      born      name      toy
0  5.0      NaT  Alfred     None
1  6.0  1939-05-27  Batman  Batmobile
2  NaN  1940-04-25           Joker
```

```
>>> df.isna()
   age  born  name  toy
0  False  True  False  True
1  False  False  False  False
2   True  False  False  False
```

Show which entries in a Series are NA.

```
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2    NaN
dtype: float64
```

```
>>> ser.isna()
0    False
1    False
2     True
dtype: bool
```

pandas.Series.item

`Series.item(self)`

Return the first element of the underlying data as a python scalar.

Returns

scalar The first element of %(klass)s.

pandas.Series.items

`Series.items(self)`

Lazily iterate over (index, value) tuples.

This method returns an iterable tuple (index, value). This is convenient if you want to create a lazy iterator.

Returns

iterable Iterable of tuples containing the (index, value) pairs from a Series.

See also:

DataFrame.items Equivalent to Series.items for DataFrame.

Examples

```
>>> s = pd.Series(['A', 'B', 'C'])
>>> for index, value in s.items():
...     print("Index : {}, Value : {}".format(index, value))
Index : 0, Value : A
```

(continues on next page)

(continued from previous page)

```
Index : 1, Value : B
Index : 2, Value : C
```

pandas.Series.iteritems

Series.iteritems(*self*)

Lazily iterate over (index, value) tuples.

This method returns an iterable tuple (index, value). This is convenient if you want to create a lazy iterator.

Returns

iterable Iterable of tuples containing the (index, value) pairs from a Series.

See also:

DataFrame.items Equivalent to Series.items for DataFrame.

Examples

```
>>> s = pd.Series(['A', 'B', 'C'])
>>> for index, value in s.items():
...     print("Index : {}, Value : {}".format(index, value))
Index : 0, Value : A
Index : 1, Value : B
Index : 2, Value : C
```

pandas.Series.keys

Series.keys(*self*)

Return alias for index.

Returns

Index Index of the Series.

pandas.Series.kurt

Series.kurt(*self*, *axis=None*, *skipna=None*, *level=None*, *numeric_only=None*, ***kwargs*)

Return unbiased kurtosis over requested axis using Fisher's definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1.

Parameters

axis [{index (0)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

scalar or Series (if level specified)

pandas.Series.kurtosis

`Series.kurtosis(self, axis=None, skipna=None, level=None, numeric_only=None, **kwargs)`

Return unbiased kurtosis over requested axis using Fisher's definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1.

Parameters

axis [{index (0)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

scalar or Series (if level specified)

pandas.Series.last

`Series.last(self, offset)`

Convenience method for subsetting final periods of time series data based on a date offset.

Parameters

offset [string, DateOffset, dateutil.relativedelta]

Returns

subset [same type as caller]

Raises

TypeError If the index is not a *DatetimeIndex*

See also:

first Select initial periods of time series based on a date offset.

at_time Select values at a particular time of the day.

between_time Select values between particular times of the day.

Examples

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1,2,3,4]}, index=i)
>>> ts
           A
2018-04-09  1
2018-04-11  2
2018-04-13  3
2018-04-15  4
```

Get the rows for the last 3 days:

```
>>> ts.last('3D')
           A
2018-04-13  3
2018-04-15  4
```

Notice the data for 3 last calendar days were returned, not the last 3 observed days in the dataset, and therefore data for 2018-04-11 was not returned.

pandas.Series.last_valid_index

`Series.last_valid_index(self)`

Return index for last non-NA/null value.

Returns

scalar [type of index]

Notes

If all elements are non-NA/null, returns None. Also returns None for empty Series/DataFrame.

pandas.Series.le

`Series.le(self, other, level=None, fill_value=None, axis=0)`

Return Less than or equal to of series and other, element-wise (binary operator *le*).

Equivalent to `series <= other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

`Series.None`

pandas.Series.lt

`Series.lt(self, other, level=None, fill_value=None, axis=0)`

Return Less than of series and other, element-wise (binary operator *lt*).

Equivalent to `series < other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

`Series.None`

pandas.Series.mad

`Series.mad(self, axis=None, skipna=None, level=None)`

Return the mean absolute deviation of the values for the requested axis.

Parameters

axis [{index (0)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

scalar or Series (if level specified)

pandas.Series.map

`Series.map(self, arg, na_action=None)`

Map values of Series according to input correspondence.

Used for substituting each value in a Series with another value, that may be derived from a function, a `dict` or a *Series*.

Parameters

arg [function, dict, or Series] Mapping correspondence.

na_action [{None, 'ignore'}, default None] If 'ignore', propagate NaN values, without passing them to the mapping correspondence.

Returns

Series Same index as caller.

See also:

Series.apply For applying more complex functions on a Series.

DataFrame.apply Apply a function row-/column-wise.

DataFrame.applymap Apply a function elementwise on a whole DataFrame.

Notes

When `arg` is a dictionary, values in Series that are not in the dictionary (as keys) are converted to NaN. However, if the dictionary is a `dict` subclass that defines `__missing__` (i.e. provides a method for default values), then this default is used rather than NaN.

Examples

```
>>> s = pd.Series(['cat', 'dog', np.nan, 'rabbit'])
>>> s
0      cat
1      dog
2      NaN
3  rabbit
dtype: object
```

`map` accepts a `dict` or a *Series*. Values that are not found in the `dict` are converted to NaN, unless the `dict` has a default value (e.g. `defaultdict`):

```
>>> s.map({'cat': 'kitten', 'dog': 'puppy'})
0  kitten
1  puppy
2    NaN
3    NaN
dtype: object
```

It also accepts a function:

```
>>> s.map('I am a {}'.format)
0      I am a cat
1      I am a dog
2      I am a nan
3      I am a rabbit
dtype: object
```

To avoid applying the function to missing values (and keep them as NaN) `na_action='ignore'` can be used:

```
>>> s.map('I am a {}'.format, na_action='ignore')
0      I am a cat
1      I am a dog
2      NaN
3      I am a rabbit
dtype: object
```

pandas.Series.mask

`Series.mask(self, cond, other=nan, inplace=False, axis=None, level=None, errors='raise', try_cast=False)`

Replace values where the condition is True.

Parameters

cond [boolean Series/DataFrame, array-like, or callable] Where *cond* is False, keep the original value. Where True, replace with corresponding value from *other*. If *cond* is callable, it is computed on the Series/DataFrame and should return boolean Series/DataFrame or array. The callable must not change input Series/DataFrame (though pandas doesn't check it).

New in version 0.18.1: A callable can be used as *cond*.

other [scalar, Series/DataFrame, or callable] Entries where *cond* is True are replaced with corresponding value from *other*. If *other* is callable, it is computed on the Series/DataFrame and should return scalar or Series/DataFrame. The callable must not change input Series/DataFrame (though pandas doesn't check it).

New in version 0.18.1: A callable can be used as *other*.

inplace [bool, default False] Whether to perform the operation in place on the data.

axis [int, default None] Alignment axis if needed.

level [int, default None] Alignment level if needed.

errors [str, {'raise', 'ignore'}, default 'raise'] Note that currently this parameter won't affect the results and will always coerce to a suitable dtype.

- 'raise' : allow exceptions to be raised.
- 'ignore' : suppress exceptions. On error return original object.

try_cast [bool, default False] Try to cast the result back to the input type (if possible).

Returns

Same type as caller

See also:

`DataFrame.where()` Return an object of same shape as self.

Notes

The mask method is an application of the if-then idiom. For each element in the calling DataFrame, if `cond` is `False` the element is used; otherwise the corresponding element from the DataFrame `other` is used.

The signature for `DataFrame.where()` differs from `numpy.where()`. Roughly `df1.where(m, df2)` is equivalent to `np.where(m, df1, df2)`.

For further details and examples see the [mask](#) documentation in *indexing*.

Examples

```
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0    NaN
1    1.0
2    2.0
3    3.0
4    4.0
dtype: float64
```

```
>>> s.mask(s > 0)
0    0.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

```
>>> s.where(s > 1, 10)
0    10
1    10
2     2
3     3
4     4
dtype: int64
```

```
>>> df = pd.DataFrame(np.arange(10).reshape(-1, 2), columns=['A', 'B'])
>>> df
   A  B
0  0  1
1  2  3
2  4  5
3  6  7
4  8  9
```

(continues on next page)

(continued from previous page)

```

>>> m = df % 3 == 0
>>> df.where(m, -df)
   A  B
0  0 -1
1 -2  3
2 -4 -5
3  6 -7
4 -8  9
>>> df.where(m, -df) == np.where(m, df, -df)
   A  B
0 True True
1 True True
2 True True
3 True True
4 True True
>>> df.where(m, -df) == df.mask(~m, -df)
   A  B
0 True True
1 True True
2 True True
3 True True
4 True True

```

pandas.Series.max

`Series.max(self, axis=None, skipna=None, level=None, numeric_only=None, **kwargs)`

Return the maximum of the values for the requested axis.

If you want the *index* of the maximum, use `idxmax`. This is the equivalent of the `numpy.ndarray` method `argmax`.

Parameters

axis [{index (0)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

scalar or Series (if level specified)

See also:

`Series.sum` Return the sum.

`Series.min` Return the minimum.

Series.max Return the maximum.

Series.idxmin Return the index of the minimum.

Series.idxmax Return the index of the maximum.

DataFrame.sum Return the sum over the requested axis.

DataFrame.min Return the minimum over the requested axis.

DataFrame.max Return the maximum over the requested axis.

DataFrame.idxmin Return the index of the minimum over the requested axis.

DataFrame.idxmax Return the index of the maximum over the requested axis.

Examples

```
>>> idx = pd.MultiIndex.from_arrays([
...     ['warm', 'warm', 'cold', 'cold'],
...     ['dog', 'falcon', 'fish', 'spider']],
...     names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded animal
warm      dog      4
          falcon   2
cold     fish      0
          spider   8
Name: legs, dtype: int64
```

```
>>> s.max()
8
```

Max using level names, as well as indices.

```
>>> s.max(level='blooded')
blooded
warm      4
cold      8
Name: legs, dtype: int64
```

```
>>> s.max(level=0)
blooded
warm      4
cold      8
Name: legs, dtype: int64
```

pandas.Series.mean

Series.mean(*self*, *axis=None*, *skipna=None*, *level=None*, *numeric_only=None*, ***kwargs*)
Return the mean of the values for the requested axis.

Parameters

axis [{index (0)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

scalar or Series (if level specified)

pandas.Series.median

`Series.median(self, axis=None, skipna=None, level=None, numeric_only=None, **kwargs)`

Return the median of the values for the requested axis.

Parameters

axis [{index (0)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

scalar or Series (if level specified)

pandas.Series.memory_usage

`Series.memory_usage(self, index=True, deep=False)`

Return the memory usage of the Series.

The memory usage can optionally include the contribution of the index and of elements of *object* dtype.

Parameters

index [bool, default True] Specifies whether to include the memory usage of the Series index.

deep [bool, default False] If True, introspect the data deeply by interrogating *object* dtypes for system-level memory consumption, and include it in the returned value.

Returns

int Bytes of memory consumed.

See also:

`numpy.ndarray.nbytes` Total bytes consumed by the elements of the array.

`DataFrame.memory_usage` Bytes consumed by a DataFrame.

Examples

```
>>> s = pd.Series(range(3))
>>> s.memory_usage()
152
```

Not including the index gives the size of the rest of the data, which is necessarily smaller:

```
>>> s.memory_usage(index=False)
24
```

The memory footprint of *object* values is ignored by default:

```
>>> s = pd.Series(["a", "b"])
>>> s.values
array(['a', 'b'], dtype=object)
>>> s.memory_usage()
144
>>> s.memory_usage(deep=True)
260
```

`pandas.Series.min`

`Series.min(self, axis=None, skipna=None, level=None, numeric_only=None, **kwargs)`

Return the minimum of the values for the requested axis.

If you want the *index* of the minimum, use `idxmin`. This is the equivalent of the `numpy.ndarray` method `argmin`.

Parameters

axis [{index (0)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

scalar or `Series` (if level specified)

See also:

`Series.sum` Return the sum.

`Series.min` Return the minimum.

Series.max Return the maximum.

Series.idxmin Return the index of the minimum.

Series.idxmax Return the index of the maximum.

DataFrame.sum Return the sum over the requested axis.

DataFrame.min Return the minimum over the requested axis.

DataFrame.max Return the maximum over the requested axis.

DataFrame.idxmin Return the index of the minimum over the requested axis.

DataFrame.idxmax Return the index of the maximum over the requested axis.

Examples

```
>>> idx = pd.MultiIndex.from_arrays([
...     ['warm', 'warm', 'cold', 'cold'],
...     ['dog', 'falcon', 'fish', 'spider']],
...     names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded animal
warm      dog      4
          falcon   2
cold     fish      0
          spider   8
Name: legs, dtype: int64
```

```
>>> s.min()
0
```

Min using level names, as well as indices.

```
>>> s.min(level='blooded')
blooded
warm      2
cold      0
Name: legs, dtype: int64
```

```
>>> s.min(level=0)
blooded
warm      2
cold      0
Name: legs, dtype: int64
```

pandas.Series.mod

Series.mod(*self*, *other*, *level=None*, *fill_value=None*, *axis=0*)

Return Modulo of series and other, element-wise (binary operator *mod*).

Equivalent to `series % other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters**other** [Series or scalar value]**fill_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.**level** [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.**Returns****Series** The result of the operation.**See also:***Series.rmod***Examples**

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.mod(b, fill_value=0)
a    0.0
b    NaN
c    NaN
d    0.0
e    NaN
dtype: float64

```

pandas.Series.mode**Series.mode**(*self*, *dropna=True*)

Return the mode(s) of the dataset.

Always returns Series even if only one value is returned.

Parameters**dropna** [bool, default True] Don't consider counts of NaN/NaT.

New in version 0.24.0.

Returns

Series Modes of the Series in sorted order.

pandas.Series.mul

Series.mul(*self*, *other*, *level=None*, *fill_value=None*, *axis=0*)

Return Multiplication of series and other, element-wise (binary operator *mul*).

Equivalent to `series * other`, but with support to substitute a *fill_value* for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

Series.rmul

Examples

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.multiply(b, fill_value=0)
a    1.0
b    0.0
c    0.0
d    0.0
e    NaN
dtype: float64

```

pandas.Series.multiply

`Series.multiply(self, other, level=None, fill_value=None, axis=0)`

Return Multiplication of series and other, element-wise (binary operator *mul*).

Equivalent to `series * other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

`Series.rmul`

Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.multiply(b, fill_value=0)
a    1.0
b    0.0
c    0.0
d    0.0
e    NaN
dtype: float64
```

pandas.Series.ne

Series.ne(*self*, *other*, *level=None*, *fill_value=None*, *axis=0*)

Return Not equal to of series and other, element-wise (binary operator *ne*).

Equivalent to `series != other`, but with support to substitute a *fill_value* for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

Series.None

pandas.Series.nlargest

Series.nlargest(*self*, *n=5*, *keep='first'*)

Return the largest *n* elements.

Parameters

n [int, default 5] Return this many descending sorted values.

keep [{'first', 'last', 'all'}, default 'first'] When there are duplicate values that cannot all fit in a Series of *n* elements:

- **first** [return the first *n* occurrences in order] of appearance.
- **last** [return the last *n* occurrences in reverse] order of appearance.
- **all** [keep all occurrences. This can result in a Series of] size larger than *n*.

Returns

Series The *n* largest values in the Series, sorted in decreasing order.

See also:

Series.nsmallest Get the *n* smallest elements.

Series.sort_values Sort Series by values.

Series.head Return the first *n* rows.

Notes

Faster than `.sort_values(ascending=False).head(n)` for small n relative to the size of the Series object.

Examples

```
>>> countries_population = {"Italy": 59000000, "France": 65000000,
...                          "Malta": 434000, "Maldives": 434000,
...                          "Brunei": 434000, "Iceland": 337000,
...                          "Nauru": 11300, "Tuvalu": 11300,
...                          "Anguilla": 11300, "Monserat": 5200}
>>> s = pd.Series(countries_population)
>>> s
Italy          59000000
France         65000000
Malta           434000
Maldives        434000
Brunei          434000
Iceland         337000
Nauru            11300
Tuvalu           11300
Anguilla         11300
Monserat         5200
dtype: int64
```

The n largest elements where $n=5$ by default.

```
>>> s.nlargest()
France         65000000
Italy          59000000
Malta           434000
Maldives        434000
Brunei          434000
dtype: int64
```

The n largest elements where $n=3$. Default *keep* value is 'first' so Malta will be kept.

```
>>> s.nlargest(3)
France         65000000
Italy          59000000
Malta           434000
dtype: int64
```

The n largest elements where $n=3$ and keeping the last duplicates. Brunei will be kept since it is the last with value 434000 based on the index order.

```
>>> s.nlargest(3, keep='last')
France         65000000
Italy          59000000
Brunei          434000
dtype: int64
```

The n largest elements where $n=3$ with all duplicates kept. Note that the returned Series has five elements due to the three duplicates.

```
>>> s.nlargest(3, keep='all')
France      65000000
Italy       59000000
Malta       434000
Maldives    434000
Brunei      434000
dtype: int64
```

pandas.Series.nonzero

Series.nonzero(*self*)

Return the *integer* indices of the elements that are non-zero.

Deprecated since version 0.24.0: Please use `.to_numpy().nonzero()` as a replacement.

This method is equivalent to calling `numpy.nonzero` on the series data. For compatibility with NumPy, the return value is the same (a tuple with an array of indices for each dimension), but it will always be a one-item tuple because series only have one dimension.

Returns

numpy.ndarray Indices of elements that are non-zero.

See also:

`numpy.nonzero`

Examples

```
>>> s = pd.Series([0, 3, 0, 4])
>>> s.nonzero()
(array([1, 3]),)
>>> s.iloc[s.nonzero()[0]]
1    3
3    4
dtype: int64
```

```
>>> s = pd.Series([0, 3, 0, 4], index=['a', 'b', 'c', 'd'])
# same return although index of s is different
>>> s.nonzero()
(array([1, 3]),)
>>> s.iloc[s.nonzero()[0]]
b    3
d    4
dtype: int64
```

pandas.Series.notna

Series.notna(*self*)

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`). NA values, such as None or `numpy.NaN`, get mapped to False values.

Returns

Series Mask of bool values for each element in Series that indicates whether an element is not an NA value.

See also:

Series.notnull Alias of `notna`.

Series.isna Boolean inverse of `notna`.

Series.dropna Omit axes labels with missing values.

notna Top-level `notna`.

Examples

Show which entries in a DataFrame are not NA.

```
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
...                    'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                             pd.Timestamp('1940-04-25')],
...                    'name': ['Alfred', 'Batman', ''],
...                    'toy': [None, 'Batmobile', 'Joker']})
>>> df
   age      born  name  toy
0  5.0      NaT  Alfred  None
1  6.0 1939-05-27  Batman  Batmobile
2  NaN 1940-04-25         Joker
```

```
>>> df.notna()
   age  born  name  toy
0  True False  True False
1  True  True  True  True
2  False  True  True  True
```

Show which entries in a Series are not NA.

```
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2    NaN
dtype: float64
```

```
>>> ser.notna()
0    True
1    True
2    False
dtype: bool
```

pandas.Series.notnull**Series.notnull**(*self*)

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`). NA values, such as None or `numpy.NaN`, get mapped to False values.

Returns

Series Mask of bool values for each element in Series that indicates whether an element is not an NA value.

See also:*Series.notnull* Alias of *notna*.*Series.isna* Boolean inverse of *notna*.*Series.dropna* Omit axes labels with missing values.*notna* Top-level *notna*.**Examples**

Show which entries in a DataFrame are not NA.

```
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
...                    'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                             pd.Timestamp('1940-04-25')],
...                    'name': ['Alfred', 'Batman', ''],
...                    'toy': [None, 'Batmobile', 'Joker']})
>>> df
   age      born  name      toy
0  5.0      NaT  Alfred  None
1  6.0 1939-05-27  Batman  Batmobile
2  NaN 1940-04-25           Joker
```

```
>>> df.notna()
   age  born  name  toy
0  True  False  True  False
1  True   True  True  True
2  False  True  True  True
```

Show which entries in a Series are not NA.

```
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2    NaN
dtype: float64
```

```
>>> ser.notna()
0      True
1      True
2     False
dtype: bool
```

pandas.Series.nsmallest

`Series.nsmallest(self, n=5, keep='first')`

Return the smallest n elements.

Parameters

n [int, default 5] Return this many ascending sorted values.

keep [{'first', 'last', 'all'}, default 'first'] When there are duplicate values that cannot all fit in a Series of n elements:

- **first** [return the first n occurrences in order] of appearance.
- **last** [return the last n occurrences in reverse] order of appearance.
- **all** [keep all occurrences. This can result in a Series of] size larger than n .

Returns

Series The n smallest values in the Series, sorted in increasing order.

See also:

`Series.nlargest` Get the n largest elements.

`Series.sort_values` Sort Series by values.

`Series.head` Return the first n rows.

Notes

Faster than `.sort_values().head(n)` for small n relative to the size of the Series object.

Examples

```
>>> countries_population = {"Italy": 59000000, "France": 65000000,
...                          "Brunei": 434000, "Malta": 434000,
...                          "Maldives": 434000, "Iceland": 337000,
...                          "Nauru": 11300, "Tuvalu": 11300,
...                          "Anguilla": 11300, "Monserat": 5200}
>>> s = pd.Series(countries_population)
>>> s
Italy          59000000
France         65000000
Brunei          434000
Malta           434000
Maldives        434000
Iceland         337000
```

(continues on next page)

(continued from previous page)

```
Nauru          11300
Tuvalu         11300
Anguilla       11300
Monserat       5200
dtype: int64
```

The n smallest elements where $n=5$ by default.

```
>>> s.nsmallest()
Monserat       5200
Nauru          11300
Tuvalu         11300
Anguilla       11300
Iceland       337000
dtype: int64
```

The n smallest elements where $n=3$. Default *keep* value is 'first' so Nauru and Tuvalu will be kept.

```
>>> s.nsmallest(3)
Monserat       5200
Nauru          11300
Tuvalu         11300
dtype: int64
```

The n smallest elements where $n=3$ and keeping the last duplicates. Anguilla and Tuvalu will be kept since they are the last with value 11300 based on the index order.

```
>>> s.nsmallest(3, keep='last')
Monserat       5200
Anguilla       11300
Tuvalu         11300
dtype: int64
```

The n smallest elements where $n=3$ with all duplicates kept. Note that the returned Series has four elements due to the three duplicates.

```
>>> s.nsmallest(3, keep='all')
Monserat       5200
Nauru          11300
Tuvalu         11300
Anguilla       11300
dtype: int64
```

pandas.Series.nunique

`Series.nunique(self, dropna=True)`

Return number of unique elements in the object.

Excludes NA values by default.

Parameters

dropna [bool, default True] Don't include NaN in the count.

Returns

`int`

See also:

`DataFrame.nunique` Method `nunique` for `DataFrame`.

`Series.count` Count non-NA/null observations in the Series.

Examples

```
>>> s = pd.Series([1, 3, 5, 7, 7])
>>> s
0    1
1    3
2    5
3    7
4    7
dtype: int64
```

```
>>> s.nunique()
4
```

`pandas.Series.pct_change`

`Series.pct_change(self, periods=1, fill_method='pad', limit=None, freq=None, **kwargs)`
Percentage change between the current and a prior element.

Computes the percentage change from the immediately previous row by default. This is useful in comparing the percentage of change in a time series of elements.

Parameters

periods [int, default 1] Periods to shift for forming percent change.

fill_method [str, default 'pad'] How to handle NAs before computing percent changes.

limit [int, default None] The number of consecutive NAs to fill before stopping.

freq [DateOffset, timedelta, or offset alias string, optional] Increment to use from time series API (e.g. 'M' or `BDay()`).

****kwargs** Additional keyword arguments are passed into `DataFrame.shift` or `Series.shift`.

Returns

chg [Series or DataFrame] The same type as the calling object.

See also:

`Series.diff` Compute the difference of two elements in a Series.

`DataFrame.diff` Compute the difference of two elements in a DataFrame.

`Series.shift` Shift the index by some number of periods.

`DataFrame.shift` Shift the index by some number of periods.

Examples

Series

```
>>> s = pd.Series([90, 91, 85])
>>> s
0    90
1    91
2    85
dtype: int64
```

```
>>> s.pct_change()
0         NaN
1    0.011111
2   -0.065934
dtype: float64
```

```
>>> s.pct_change(periods=2)
0         NaN
1         NaN
2   -0.055556
dtype: float64
```

See the percentage change in a Series where filling NAs with last valid observation forward to next valid.

```
>>> s = pd.Series([90, 91, None, 85])
>>> s
0    90.0
1    91.0
2     NaN
3    85.0
dtype: float64
```

```
>>> s.pct_change(fill_method='ffill')
0         NaN
1    0.011111
2    0.000000
3   -0.065934
dtype: float64
```

DataFrame

Percentage change in French franc, Deutsche Mark, and Italian lira from 1980-01-01 to 1980-03-01.

```
>>> df = pd.DataFrame({
...     'FR': [4.0405, 4.0963, 4.3149],
...     'GR': [1.7246, 1.7482, 1.8519],
...     'IT': [804.74, 810.01, 860.13]},
...     index=['1980-01-01', '1980-02-01', '1980-03-01'])
```

(continues on next page)

(continued from previous page)

```
>>> df
          FR      GR      IT
1980-01-01  4.0405  1.7246  804.74
1980-02-01  4.0963  1.7482  810.01
1980-03-01  4.3149  1.8519  860.13
```

```
>>> df.pct_change()
          FR      GR      IT
1980-01-01   NaN   NaN   NaN
1980-02-01  0.013810  0.013684  0.006549
1980-03-01  0.053365  0.059318  0.061876
```

Percentage of change in GOOG and APPL stock volume. Shows computing the percentage change between columns.

```
>>> df = pd.DataFrame({
...     '2016': [1769950, 30586265],
...     '2015': [1500923, 40912316],
...     '2014': [1371819, 41403351]},
...     index=['GOOG', 'APPL'])
>>> df
          2016      2015      2014
GOOG  1769950  1500923  1371819
APPL  30586265  40912316  41403351
```

```
>>> df.pct_change(axis='columns')
          2016      2015      2014
GOOG   NaN -0.151997 -0.086016
APPL   NaN  0.337604  0.012002
```

pandas.Series.pipe

`Series.pipe(self, func, *args, **kwargs)`
Apply func(self, *args, **kwargs).

Parameters

func [function] function to apply to the Series/DataFrame. **args**, and **kwargs** are passed into **func**. Alternatively a (callable, data_keyword) tuple where **data_keyword** is a string indicating the keyword of callable that expects the Series/DataFrame.

args [iterable, optional] positional arguments passed into **func**.

kwargs [mapping, optional] a dictionary of keyword arguments passed into **func**.

Returns

object [the return type of **func**.]

See also:

`DataFrame.apply`

`DataFrame.applymap`

Series.map**Notes**

Use `.pipe` when chaining together functions that expect Series, DataFrames or GroupBy objects. Instead of writing

```
>>> f(g(h(df), arg1=a), arg2=b, arg3=c)
```

You can write

```
>>> (df.pipe(h)
...   .pipe(g, arg1=a)
...   .pipe(f, arg2=b, arg3=c)
... )
```

If you have a function that takes the data as (say) the second argument, pass a tuple indicating which keyword expects the data. For example, suppose `f` takes its data as `arg2`:

```
>>> (df.pipe(h)
...   .pipe(g, arg1=a)
...   .pipe((f, 'arg2'), arg1=a, arg3=c)
... )
```

pandas.Series.plot

`Series.plot(self, *args, **kwargs)`

Call self as a function.

pandas.Series.pop

`Series.pop(self, item)`

Return item and drop from frame. Raise `KeyError` if not found.

Parameters

`item` [str] Label of column to be popped.

Returns

Series

Examples

```
>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
...                   ('parrot', 'bird', 24.0),
...                   ('lion', 'mammal', 80.5),
...                   ('monkey', 'mammal', np.nan)],
...                   columns=('name', 'class', 'max_speed'))
>>> df
   name  class  max_speed
0  falcon  bird    389.0
1  parrot  bird     24.0
2  lion   mammal    80.5
3  monkey  mammal    nan
```

(continues on next page)

(continued from previous page)

```

0 falcon bird 389.0
1 parrot bird 24.0
2 lion mammal 80.5
3 monkey mammal NaN

```

```

>>> df.pop('class')
0 bird
1 bird
2 mammal
3 mammal
Name: class, dtype: object

```

```

>>> df
   name  max_speed
0 falcon    389.0
1 parrot    24.0
2 lion     80.5
3 monkey     NaN

```

pandas.Series.pow

`Series.pow(self, other, level=None, fill_value=None, axis=0)`

Return Exponential power of series and other, element-wise (binary operator *pow*).

Equivalent to `series ** other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

Series.rpow

Examples

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0

```

(continues on next page)

(continued from previous page)

```

c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.pow(b, fill_value=0)
a    1.0
b    1.0
c    1.0
d    0.0
e    NaN
dtype: float64

```

pandas.Series.prod

`Series.prod(self, axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs)`

Return the product of the values for the requested axis.

Parameters

axis [{index (0)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

min_count [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

New in version 0.22.0: Added with the default being 0. This means the sum of an all-NA or empty Series is 0, and the product of an all-NA or empty Series is 1.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

scalar or Series (if level specified)

Examples

By default, the product of an empty or all-NA Series is 1

```
>>> pd.Series([]).prod()
1.0
```

This can be controlled with the `min_count` parameter

```
>>> pd.Series([]).prod(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```
>>> pd.Series([np.nan]).prod()
1.0
```

```
>>> pd.Series([np.nan]).prod(min_count=1)
nan
```

pandas.Series.product

```
Series.product(self, axis=None, skipna=None, level=None, numeric_only=None,
               min_count=0, **kwargs)
```

Return the product of the values for the requested axis.

Parameters

axis [{index (0)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

min_count [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

New in version 0.22.0: Added with the default being 0. This means the sum of an all-NA or empty Series is 0, and the product of an all-NA or empty Series is 1.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

scalar or Series (if level specified)

Examples

By default, the product of an empty or all-NA Series is 1

```
>>> pd.Series([]).prod()
1.0
```

This can be controlled with the `min_count` parameter

```
>>> pd.Series([]).prod(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```
>>> pd.Series([np.nan]).prod()
1.0
```

```
>>> pd.Series([np.nan]).prod(min_count=1)
nan
```

pandas.Series.ptp

`Series.ptp(self, axis=None, skipna=None, level=None, numeric_only=None, **kwargs)`

Return the difference between the maximum value and the minimum value in the object. This is the equivalent of the `numpy.ndarray` method `ptp`.

Deprecated since version 0.24.0: Use `numpy.ptp` instead

Parameters

axis [{index (0)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

scalar or Series (if level specified)

pandas.Series.put

`Series.put(self, *args, **kwargs)`

Apply the `put` method to its `values` attribute if it has one.

Deprecated since version 0.25.0.

See also:

`numpy.ndarray.put`

pandas.Series.quantile

`Series.quantile(self, q=0.5, interpolation='linear')`

Return value at the given quantile.

Parameters

q [float or array-like, default 0.5 (50% quantile)] $0 \leq q \leq 1$, the quantile(s) to compute.

interpolation [{'linear', 'lower', 'higher', 'midpoint', 'nearest'}] New in version 0.18.0.

This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points i and j :

- linear: $i + (j - i) * fraction$, where *fraction* is the fractional part of the index surrounded by i and j .
- lower: i .
- higher: j .
- nearest: i or j whichever is nearest.
- midpoint: $(i + j) / 2$.

Returns

float or Series If **q** is an array, a Series will be returned where the index is **q** and the values are the quantiles, otherwise a float will be returned.

See also:

`core.window.Rolling.quantile`

`numpy.percentile`

Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s.quantile(.5)
2.5
>>> s.quantile([.25, .5, .75])
0.25    1.75
0.50    2.50
0.75    3.25
dtype: float64
```

pandas.Series.radd

`Series.radd(self, other, level=None, fill_value=None, axis=0)`

Return Addition of series and other, element-wise (binary operator *radd*).

Equivalent to `other + series`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

`Series.add`

Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64
```

pandas.Series.rank

Series.rank(*self*, *axis=0*, *method='average'*, *numeric_only=None*, *na_option='keep'*, *ascending=True*, *pct=False*)

Compute numerical data ranks (1 through n) along axis.

By default, equal values are assigned a rank that is the average of the ranks of those values.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] Index to direct ranking.

method [{'average', 'min', 'max', 'first', 'dense'}, default 'average'] How to rank the group of records that have the same value (i.e. ties):

- average: average rank of the group
- min: lowest rank in the group
- max: highest rank in the group
- first: ranks assigned in order they appear in the array

- `dense`: like `'min'`, but rank always increases by 1 between groups

numeric_only [bool, optional] For DataFrame objects, rank only numeric columns if set to True.

na_option [{'keep', 'top', 'bottom'}, default 'keep'] How to rank NaN values:

- `keep`: assign NaN rank to NaN values
- `top`: assign smallest rank to NaN values if ascending
- `bottom`: assign highest rank to NaN values if ascending

ascending [bool, default True] Whether or not the elements should be ranked in ascending order.

pct [bool, default False] Whether or not to display the returned rankings in percentile form.

Returns

same type as caller Return a Series or DataFrame with data ranks as values.

See also:

`core.groupby.GroupBy.rank` Rank of values within each group.

Examples

```
>>> df = pd.DataFrame(data={'Animal': ['cat', 'penguin', 'dog',
...                                   'spider', 'snake'],
...                        'Number_legs': [4, 2, 4, 8, np.nan]})
>>> df
   Animal  Number_legs
0    cat             4.0
1  penguin             2.0
2    dog             4.0
3  spider             8.0
4   snake             NaN
```

The following example shows how the method behaves with the above parameters:

- `default_rank`: this is the default behaviour obtained without using any parameter.
- `max_rank`: setting `method = 'max'` the records that have the same values are ranked using the highest rank (e.g.: since `'cat'` and `'dog'` are both in the 2nd and 3rd position, rank 3 is assigned.)
- `NA_bottom`: choosing `na_option = 'bottom'`, if there are records with NaN values they are placed at the bottom of the ranking.
- `pct_rank`: when setting `pct = True`, the ranking is expressed as percentile rank.

```
>>> df['default_rank'] = df['Number_legs'].rank()
>>> df['max_rank'] = df['Number_legs'].rank(method='max')
>>> df['NA_bottom'] = df['Number_legs'].rank(na_option='bottom')
>>> df['pct_rank'] = df['Number_legs'].rank(pct=True)
>>> df
   Animal  Number_legs  default_rank  max_rank  NA_bottom  pct_rank
```

(continues on next page)

(continued from previous page)

0	cat	4.0	2.5	3.0	2.5	0.625
1	penguin	2.0	1.0	1.0	1.0	0.250
2	dog	4.0	2.5	3.0	2.5	0.625
3	spider	8.0	4.0	4.0	4.0	1.000
4	snake	NaN	NaN	NaN	5.0	NaN

pandas.Series.ravel**Series.ravel**(*self*, *order='C'*)

Return the flattened underlying data as an ndarray.

Returns**numpy.ndarray or ndarray-like** Flattened data of the Series.**See also:**[numpy.ndarray.ravel](#)**pandas.Series.rdiv****Series.rdiv**(*self*, *other*, *level=None*, *fill_value=None*, *axis=0*)Return Floating division of series and other, element-wise (binary operator *rtruediv*).Equivalent to `other / series`, but with support to substitute a `fill_value` for missing data in one of the inputs.**Parameters****other** [Series or scalar value]**fill_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.**level** [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.**Returns****Series** The result of the operation.**See also:**[Series.truediv](#)**Examples**

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0

```

(continues on next page)

(continued from previous page)

```

d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.divide(b, fill_value=0)
a    1.0
b    inf
c    inf
d    0.0
e    NaN
dtype: float64

```

pandas.Series.rdivmod

`Series.rdivmod(self, other, level=None, fill_value=None, axis=0)`

Return Integer division and modulo of series and other, element-wise (binary operator *rdivmod*).

Equivalent to `other divmod series`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

Series.divmod

pandas.Series.reindex

`Series.reindex(self, index=None, **kwargs)`

Conform Series to new index with optional filling logic, placing NA/NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and `copy=False`.

Parameters

index [array-like, optional] New labels / index to conform to, should be specified using keywords. Preferably an Index object to avoid duplicating data

method [{None, 'backfill'/'bfill', 'pad'/'ffill', 'nearest'}] Method to use for filling holes in reindexed DataFrame. Please note: this is only applicable to DataFrames/Series with a monotonically increasing/decreasing index.

- None (default): don't fill gaps
- pad / ffill: propagate last valid observation forward to next valid
- backfill / bfill: use next valid observation to fill gap
- nearest: use nearest valid observations to fill gap

copy [bool, default True] Return a new object, even if the passed indexes are the same.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [scalar, default np.NaN] Value to use for missing values. Defaults to NaN, but can be any "compatible" value.

limit [int, default None] Maximum number of consecutive elements to forward or backward fill.

tolerance [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations most satisfy the equation $\text{abs}(\text{index}[\text{indexer}] - \text{target}) \leq \text{tolerance}$.

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index's type.

New in version 0.21.0: (list-like tolerance)

Returns

Series with changed index.

See also:

DataFrame.set_index Set row labels.

DataFrame.reset_index Remove row labels or move them to new columns.

DataFrame.reindex_like Change to same indices as other DataFrame.

Examples

DataFrame.reindex supports two calling conventions

- (index=index_labels, columns=column_labels, ...)
- (labels, axis={'index', 'columns'}, ...)

We *highly* recommend using keyword arguments to clarify your intent.

Create a dataframe with some fictional data.

```

>>> index = ['Firefox', 'Chrome', 'Safari', 'IE10', 'Konqueror']
>>> df = pd.DataFrame({
...     'http_status': [200,200,404,404,301],
...     'response_time': [0.04, 0.02, 0.07, 0.08, 1.0]},
...     index=index)
>>> df

```

	http_status	response_time
Firefox	200	0.04
Chrome	200	0.02
Safari	404	0.07
IE10	404	0.08
Konqueror	301	1.00

Create a new index and reindex the dataframe. By default values in the new index that do not have corresponding records in the dataframe are assigned NaN.

```

>>> new_index= ['Safari', 'Iceweasel', 'Comodo Dragon', 'IE10',
...             'Chrome']
>>> df.reindex(new_index)

```

	http_status	response_time
Safari	404.0	0.07
Iceweasel	NaN	NaN
Comodo Dragon	NaN	NaN
IE10	404.0	0.08
Chrome	200.0	0.02

We can fill in the missing values by passing a value to the keyword `fill_value`. Because the index is not monotonically increasing or decreasing, we cannot use arguments to the keyword method to fill the NaN values.

```

>>> df.reindex(new_index, fill_value=0)

```

	http_status	response_time
Safari	404	0.07
Iceweasel	0	0.00
Comodo Dragon	0	0.00
IE10	404	0.08
Chrome	200	0.02

```

>>> df.reindex(new_index, fill_value='missing')

```

	http_status	response_time
Safari	404	0.07
Iceweasel	missing	missing
Comodo Dragon	missing	missing
IE10	404	0.08
Chrome	200	0.02

We can also reindex the columns.

```

>>> df.reindex(columns=['http_status', 'user_agent'])

```

	http_status	user_agent
Firefox	200	NaN
Chrome	200	NaN
Safari	404	NaN

(continues on next page)

(continued from previous page)

IE10	404	NaN
Konqueror	301	NaN

Or we can use “axis-style” keyword arguments

```
>>> df.reindex(['http_status', 'user_agent'], axis="columns")
      http_status  user_agent
Firefox         200         NaN
Chrome          200         NaN
Safari          404         NaN
IE10             404         NaN
Konqueror       301         NaN
```

To further illustrate the filling functionality in `reindex`, we will create a dataframe with a monotonically increasing index (for example, a sequence of dates).

```
>>> date_index = pd.date_range('1/1/2010', periods=6, freq='D')
>>> df2 = pd.DataFrame({"prices": [100, 101, np.nan, 100, 89, 88]},
...                    index=date_index)
>>> df2
      prices
2010-01-01  100.0
2010-01-02  101.0
2010-01-03    NaN
2010-01-04  100.0
2010-01-05   89.0
2010-01-06   88.0
```

Suppose we decide to expand the dataframe to cover a wider date range.

```
>>> date_index2 = pd.date_range('12/29/2009', periods=10, freq='D')
>>> df2.reindex(date_index2)
      prices
2009-12-29    NaN
2009-12-30    NaN
2009-12-31    NaN
2010-01-01  100.0
2010-01-02  101.0
2010-01-03    NaN
2010-01-04  100.0
2010-01-05   89.0
2010-01-06   88.0
2010-01-07    NaN
```

The index entries that did not have a value in the original data frame (for example, ‘2009-12-29’) are by default filled with NaN. If desired, we can fill in the missing values using one of several options.

For example, to back-propagate the last valid value to fill the NaN values, pass `bfill` as an argument to the `method` keyword.

```
>>> df2.reindex(date_index2, method='bfill')
      prices
```

(continues on next page)

(continued from previous page)

2009-12-29	100.0
2009-12-30	100.0
2009-12-31	100.0
2010-01-01	100.0
2010-01-02	101.0
2010-01-03	NaN
2010-01-04	100.0
2010-01-05	89.0
2010-01-06	88.0
2010-01-07	NaN

Please note that the NaN value present in the original dataframe (at index value 2010-01-03) will not be filled by any of the value propagation schemes. This is because filling while reindexing does not look at dataframe values, but only compares the original and desired indexes. If you do want to fill in the NaN values present in the original dataframe, use the `fillna()` method.

See the *user guide* for more.

pandas.Series.reindex_like

`Series.reindex_like(self, other, method=None, copy=True, limit=None, tolerance=None)`

Return an object with matching indices as other object.

Conform the object to the same index on all axes. Optional filling logic, placing NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and `copy=False`.

Parameters

other [Object of the same data type] Its row and column indices are used to define the new indices of this object.

method [{None, 'backfill'/'bfill', 'pad'/'ffill', 'nearest'}] Method to use for filling holes in reindexed DataFrame. Please note: this is only applicable to DataFrames/Series with a monotonically increasing/decreasing index.

- None (default): don't fill gaps
- pad / ffill: propagate last valid observation forward to next valid
- backfill / bfill: use next valid observation to fill gap
- nearest: use nearest valid observations to fill gap

copy [bool, default True] Return a new object, even if the passed indexes are the same.

limit [int, default None] Maximum number of consecutive labels to fill for inexact matches.

tolerance [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations most satisfy the equation `abs(index[indexer] - target) <= tolerance`.

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index's type.

New in version 0.21.0: (list-like tolerance)

Returns

Series or DataFrame Same type as caller, but with changed indices on each axis.

See also:

DataFrame.set_index Set row labels.

DataFrame.reset_index Remove row labels or move them to new columns.

DataFrame.reindex Change to new indices or expand indices.

Notes

Same as calling `.reindex(index=other.index, columns=other.columns,...)`.

Examples

```
>>> df1 = pd.DataFrame([[24.3, 75.7, 'high'],
...                     [31, 87.8, 'high'],
...                     [22, 71.6, 'medium'],
...                     [35, 95, 'medium']],
...                     columns=['temp_celsius', 'temp_fahrenheit', 'windspeed'],
...                     index=pd.date_range(start='2014-02-12',
...                                         end='2014-02-15', freq='D'))
```

```
>>> df1
           temp_celsius  temp_fahrenheit  windspeed
2014-02-12           24.3             75.7         high
2014-02-13           31.0             87.8          high
2014-02-14           22.0             71.6        medium
2014-02-15           35.0             95.0        medium
```

```
>>> df2 = pd.DataFrame([[28, 'low'],
...                     [30, 'low'],
...                     [35.1, 'medium']],
...                     columns=['temp_celsius', 'windspeed'],
...                     index=pd.DatetimeIndex(['2014-02-12', '2014-02-13',
...                                             '2014-02-15']))
```

```
>>> df2
           temp_celsius  windspeed
2014-02-12           28.0         low
2014-02-13           30.0         low
2014-02-15           35.1        medium
```

```
>>> df2.reindex_like(df1)
           temp_celsius  temp_fahrenheit  windspeed
2014-02-12           28.0             NaN         low
2014-02-13           30.0             NaN         low
```

(continues on next page)

(continued from previous page)

2014-02-14	NaN	NaN	NaN
2014-02-15	35.1	NaN	medium

pandas.Series.rename**Series.rename**(self, index=None, **kwargs)

Alter Series index labels or name.

Function / dict values must be unique (1-to-1). Labels not contained in a dict / Series will be left as-is. Extra labels listed don't throw an error.

Alternatively, change **Series.name** with a scalar value.See the *user guide* for more.**Parameters****index** [scalar, hashable sequence, dict-like or function, optional] dict-like or functions are transformations to apply to the index. Scalar or hashable sequence-like will alter the **Series.name** attribute.**copy** [bool, default True] Whether to copy underlying data.**inplace** [bool, default False] Whether to return a new Series. If True then value of copy is ignored.**level** [int or level name, default None] In case of a MultiIndex, only rename labels in the specified level.**Returns****Series** Series with index labels or name altered.**See also:****Series.rename_axis** Set the name of the axis.**Examples**

```

>>> s = pd.Series([1, 2, 3])
>>> s
0    1
1    2
2    3
dtype: int64
>>> s.rename("my_name") # scalar, changes Series.name
0    1
1    2
2    3
Name: my_name, dtype: int64
>>> s.rename(lambda x: x ** 2) # function, changes labels
0    1
1    2
4    3
dtype: int64

```

(continues on next page)

(continued from previous page)

```
>>> s.rename({1: 3, 2: 5}) # mapping, changes labels
0    1
3    2
5    3
dtype: int64
```

pandas.Series.rename_axis

`Series.rename_axis`(*self*, *mapper=None*, *index=None*, *columns=None*, *axis=None*, *copy=True*, *inplace=False*)

Set the name of the axis for the index or columns.

Parameters

mapper [scalar, list-like, optional] Value to set the axis name attribute.

index, columns [scalar, list-like, dict-like or function, optional] A scalar, list-like, dict-like or functions transformations to apply to that axis' values.

Use either `mapper` and `axis` to specify the axis to target with `mapper`, or `index` and/or `columns`.

Changed in version 0.24.0.

axis [{0 or 'index', 1 or 'columns'}, default 0] The axis to rename.

copy [bool, default True] Also copy underlying data.

inplace [bool, default False] Modifies the object directly, instead of creating a new Series or DataFrame.

Returns

Series, DataFrame, or None The same type as the caller or None if *inplace* is True.

See also:

Series.rename Alter Series index labels or name.

DataFrame.rename Alter DataFrame index labels or name.

Index.rename Set new names on index.

Notes

`DataFrame.rename_axis` supports two calling conventions

- (`index=index_mapper`, `columns=columns_mapper`, ...)
- (`mapper`, `axis={'index', 'columns'}`, ...)

The first calling convention will only modify the names of the index and/or the names of the Index object that is the columns. In this case, the parameter `copy` is ignored.

The second calling convention will modify the names of the the corresponding index if `mapper` is a list or a scalar. However, if `mapper` is dict-like or a function, it will use the deprecated behavior of modifying the axis *labels*.

We *highly* recommend using keyword arguments to clarify your intent.

Examples

Series

```
>>> s = pd.Series(["dog", "cat", "monkey"])
>>> s
0      dog
1      cat
2  monkey
dtype: object
>>> s.rename_axis("animal")
animal
0      dog
1      cat
2  monkey
dtype: object
```

DataFrame

```
>>> df = pd.DataFrame({"num_legs": [4, 4, 2],
...                    "num_arms": [0, 0, 2]},
...                    ["dog", "cat", "monkey"])
>>> df
   num_legs  num_arms
dog         4         0
cat         4         0
monkey      2         2
>>> df = df.rename_axis("animal")
>>> df
   num_legs  num_arms
animal
dog         4         0
cat         4         0
monkey      2         2
>>> df = df.rename_axis("limbs", axis="columns")
>>> df
limbs  num_legs  num_arms
animal
dog         4         0
cat         4         0
monkey      2         2
```

MultiIndex

```
>>> df.index = pd.MultiIndex.from_product([['mammal'],
...                                       ['dog', 'cat', 'monkey']],
...                                       names=['type', 'name'])
>>> df
limbs  num_legs  num_arms
type  name
mammal dog         4         0
      cat         4         0
      monkey      2         2
```

```
>>> df.rename_axis(index={'type': 'class'})
limbs      num_legs  num_arms
class name
mammal dog         4         0
        cat         4         0
        monkey      2         2
```

```
>>> df.rename_axis(columns=str.upper)
LIMBS      num_legs  num_arms
type name
mammal dog         4         0
        cat         4         0
        monkey      2         2
```

pandas.Series.reorder_levels

`Series.reorder_levels(self, order)`

Rearrange index levels using input order.

May not drop or duplicate levels.

Parameters

order [list of int representing new level order] (reference level by number or key)

Returns

type of caller (new object)

pandas.Series.repeat

`Series.repeat(self, repeats, axis=None)`

Repeat elements of a Series.

Returns a new Series where each element of the current Series is repeated consecutively a given number of times.

Parameters

repeats [int or array of ints] The number of repetitions for each element. This should be a non-negative integer. Repeating 0 times will return an empty Series.

axis [None] Must be None. Has no effect but is accepted for compatibility with numpy.

Returns

Series Newly created Series with repeated elements.

See also:

`Index.repeat` Equivalent function for Index.

`numpy.repeat` Similar method for `numpy.ndarray`.

Examples

```

>>> s = pd.Series(['a', 'b', 'c'])
>>> s
0    a
1    b
2    c
dtype: object
>>> s.repeat(2)
0    a
0    a
1    b
1    b
2    c
2    c
dtype: object
>>> s.repeat([1, 2, 3])
0    a
1    b
1    b
2    c
2    c
2    c
dtype: object

```

pandas.Series.replace

`Series.replace(self, to_replace=None, value=None, inplace=False, limit=None, regex=False, method='pad')`

Replace values given in *to_replace* with *value*.

Values of the Series are replaced with other values dynamically. This differs from updating with `.loc` or `.iloc`, which require you to specify a location to update with some value.

Parameters

to_replace [str, regex, list, dict, Series, int, float, or None] How to find the values that will be replaced.

- numeric, str or regex:
 - numeric: numeric values equal to *to_replace* will be replaced with *value*
 - str: string exactly matching *to_replace* will be replaced with *value*
 - regex: regexs matching *to_replace* will be replaced with *value*
- list of str, regex, or numeric:
 - First, if *to_replace* and *value* are both lists, they **must** be the same length.
 - Second, if **regex=True** then all of the strings in **both** lists will be interpreted as regexs otherwise they will match directly. This doesn't matter much for *value* since there are only a few possible substitution regexes you can use.
 - str, regex and numeric rules apply as above.

- **dict:**
 - Dicts can be used to specify different replacement values for different existing values. For example, `{'a': 'b', 'y': 'z'}` replaces the value 'a' with 'b' and 'y' with 'z'. To use a dict in this way the *value* parameter should be *None*.
 - For a DataFrame a dict can specify that different values should be replaced in different columns. For example, `{'a': 1, 'b': 'z'}` looks for the value 1 in column 'a' and the value 'z' in column 'b' and replaces these values with whatever is specified in *value*. The *value* parameter should not be *None* in this case. You can treat this as a special case of passing two lists except that you are specifying the column to search in.
 - For a DataFrame nested dictionaries, e.g., `{'a': {'b': np.nan}}`, are read as follows: look in column 'a' for the value 'b' and replace it with NaN. The *value* parameter should be *None* to use a nested dict in this way. You can nest regular expressions as well. Note that column names (the top-level dictionary keys in a nested dictionary) **cannot** be regular expressions.
- **None:**
 - This means that the *regex* argument must be a string, compiled regular expression, or list, dict, ndarray or Series of such elements. If *value* is also *None* then this **must** be a nested dictionary or Series.

See the examples section for examples of each of these.

value [scalar, dict, list, str, regex, default None] Value to replace any values matching *to_replace* with. For a DataFrame a dict of values can be used to specify which value to use for each column (columns not in the dict will not be filled). Regular expressions, strings and lists or dicts of such objects are also allowed.

inplace [bool, default False] If True, in place. Note: this will modify any other views on this object (e.g. a column from a DataFrame). Returns the caller if this is True.

limit [int, default None] Maximum size gap to forward or backward fill.

regex [bool or same types as *to_replace*, default False] Whether to interpret *to_replace* and/or *value* as regular expressions. If this is *True* then *to_replace* *must* be a string. Alternatively, this could be a regular expression or a list, dict, or array of regular expressions in which case *to_replace* *must* be *None*.

method [{ 'pad', 'ffill', 'bfill', *None*}] The method to use when for replacement, when *to_replace* is a scalar, list or tuple and *value* is *None*.

Changed in version 0.23.0: Added to DataFrame.

Returns

Series Object after replacement.

Raises

AssertionError

- If *regex* is not a bool and *to_replace* is not *None*.

TypeError

- If *to_replace* is a dict and *value* is not a list, dict, ndarray, or Series

- If `to_replace` is `None` and `regex` is not compilable into a regular expression or is a list, dict, ndarray, or Series.
- When replacing multiple `bool` or `datetime64` objects and the arguments to `to_replace` does not match the type of the value being replaced

ValueError

- If a `list` or an `ndarray` is passed to `to_replace` and `value` but they are not the same length.

See also:

`Series.fillna` Fill NA values.

`Series.where` Replace values based on boolean condition.

`Series.str.replace` Simple string replacement.

Notes

- Regex substitution is performed under the hood with `re.sub`. The rules for substitution for `re.sub` are the same.
- Regular expressions will only substitute on strings, meaning you cannot provide, for example, a regular expression matching floating point numbers and expect the columns in your frame that have a numeric dtype to be matched. However, if those floating point numbers *are* strings, then you can do this.
- This method has *a lot* of options. You are encouraged to experiment and play with this method to gain intuition about how it works.
- When dict is used as the `to_replace` value, it is like key(s) in the dict are the `to_replace` part and value(s) in the dict are the value parameter.

Examples

Scalar ‘to_replace’ and ‘value’

```
>>> s = pd.Series([0, 1, 2, 3, 4])
>>> s.replace(0, 5)
0    5
1    1
2    2
3    3
4    4
dtype: int64
```

```
>>> df = pd.DataFrame({'A': [0, 1, 2, 3, 4],
...                   'B': [5, 6, 7, 8, 9],
...                   'C': ['a', 'b', 'c', 'd', 'e']})
>>> df.replace(0, 5)
   A  B  C
0  5  5  a
1  1  6  b
2  2  7  c
```

(continues on next page)

(continued from previous page)

```
3 3 8 d
4 4 9 e
```

List-like ‘to_replace’

```
>>> df.replace([0, 1, 2, 3], 4)
   A  B  C
0  4  5  a
1  4  6  b
2  4  7  c
3  4  8  d
4  4  9  e
```

```
>>> df.replace([0, 1, 2, 3], [4, 3, 2, 1])
   A  B  C
0  4  5  a
1  3  6  b
2  2  7  c
3  1  8  d
4  4  9  e
```

```
>>> s.replace([1, 2], method='bfill')
0    0
1    3
2    3
3    3
4    4
dtype: int64
```

dict-like ‘to_replace’

```
>>> df.replace({0: 10, 1: 100})
   A  B  C
0  10  5  a
1 100  6  b
2   2  7  c
3   3  8  d
4   4  9  e
```

```
>>> df.replace({'A': 0, 'B': 5}, 100)
   A  B  C
0 100 100  a
1   1   6  b
2   2   7  c
3   3   8  d
4   4   9  e
```

```
>>> df.replace({'A': {0: 100, 4: 400}})
   A  B  C
0 100  5  a
1   1   6  b
```

(continues on next page)

(continued from previous page)

```

2    2    7    c
3    3    8    d
4   400    9    e

```

Regular expression 'to_replace'

```

>>> df = pd.DataFrame({'A': ['bat', 'foo', 'bait'],
...                    'B': ['abc', 'bar', 'xyz']})
>>> df.replace(to_replace=r'^ba.$', value='new', regex=True)
   A    B
0  new  abc
1  foo  new
2  bait xyz

```

```

>>> df.replace({'A': r'^ba.$'}, {'A': 'new'}, regex=True)
   A    B
0  new  abc
1  foo  bar
2  bait xyz

```

```

>>> df.replace(regex=r'^ba.$', value='new')
   A    B
0  new  abc
1  foo  new
2  bait xyz

```

```

>>> df.replace(regex={r'^ba.$': 'new', 'foo': 'xyz'})
   A    B
0  new  abc
1  xyz  new
2  bait xyz

```

```

>>> df.replace(regex=[r'^ba.$', 'foo'], value='new')
   A    B
0  new  abc
1  new  new
2  bait xyz

```

Note that when replacing multiple `bool` or `datetime64` objects, the data types in the `to_replace` parameter must match the data type of the value being replaced:

```

>>> df = pd.DataFrame({'A': [True, False, True],
...                    'B': [False, True, False]})
>>> df.replace({'a string': 'new value', True: False}) # raises
Traceback (most recent call last):
...
TypeError: Cannot compare types 'ndarray(dtype=bool)' and 'str'

```

This raises a `TypeError` because one of the dict keys is not of the correct type for replacement.

Compare the behavior of `s.replace({'a': None})` and `s.replace('a', None)` to understand the peculiarities of the `to_replace` parameter:

```
>>> s = pd.Series([10, 'a', 'a', 'b', 'a'])
```

When one uses a dict as the *to_replace* value, it is like the value(s) in the dict are equal to the *value* parameter. `s.replace({'a': None})` is equivalent to `s.replace(to_replace={'a': None}, value=None, method=None)`:

```
>>> s.replace({'a': None})
0      10
1     None
2     None
3        b
4     None
dtype: object
```

When *value=None* and *to_replace* is a scalar, list or tuple, *replace* uses the *method* parameter (default 'pad') to do the replacement. So this is why the 'a' values are being replaced by 10 in rows 1 and 2 and 'b' in row 4 in this case. The command `s.replace('a', None)` is actually equivalent to `s.replace(to_replace='a', value=None, method='pad')`:

```
>>> s.replace('a', None)
0      10
1      10
2      10
3        b
4        b
dtype: object
```

pandas.Series.resample

`Series.resample(self, rule, how=None, axis=0, fill_method=None, closed=None, label=None, convention='start', kind=None, loffset=None, limit=None, base=0, on=None, level=None)`
Resample time-series data.

Convenience method for frequency conversion and resampling of time series. Object must have a datetime-like index (*DatetimeIndex*, *PeriodIndex*, or *TimedeltaIndex*), or pass datetime-like values to the *on* or *level* keyword.

Parameters

rule [DateOffset, Timedelta or str] The offset string or object representing target conversion.

how [str] Method for down/re-sampling, default to 'mean' for downsampling.

Deprecated since version 0.18.0: The new syntax is `.resample(...).mean()`, or `.resample(...).apply(<func>)`

axis [{0 or 'index', 1 or 'columns'}, default 0] Which axis to use for up- or down-sampling. For *Series* this will default to 0, i.e. along the rows. Must be *DatetimeIndex*, *TimedeltaIndex* or *PeriodIndex*.

fill_method [str, default None] Filling method for upsampling.

Deprecated since version 0.18.0: The new syntax is `.resample(...).<func>()`, e.g. `.resample(...).pad()`

closed [{‘right’, ‘left’}, default None] Which side of bin interval is closed. The default is ‘left’ for all frequency offsets except for ‘M’, ‘A’, ‘Q’, ‘BM’, ‘BA’, ‘BQ’, and ‘W’ which all have a default of ‘right’.

label [{‘right’, ‘left’}, default None] Which bin edge label to label bucket with. The default is ‘left’ for all frequency offsets except for ‘M’, ‘A’, ‘Q’, ‘BM’, ‘BA’, ‘BQ’, and ‘W’ which all have a default of ‘right’.

convention [{‘start’, ‘end’, ‘s’, ‘e’}, default ‘start’] For *PeriodIndex* only, controls whether to use the start or end of *rule*.

kind [{‘timestamp’, ‘period’}, optional, default None] Pass ‘timestamp’ to convert the resulting index to a *DateTimeIndex* or ‘period’ to convert it to a *PeriodIndex*. By default the input representation is retained.

loffset [timedelta, default None] Adjust the resampled time labels.

limit [int, default None] Maximum size gap when reindexing with *fill_method*.

Deprecated since version 0.18.0.

base [int, default 0] For frequencies that evenly subdivide 1 day, the “origin” of the aggregated intervals. For example, for ‘5min’ frequency, base could range from 0 through 4. Defaults to 0.

on [str, optional] For a DataFrame, column to use instead of index for resampling. Column must be datetime-like.

New in version 0.19.0.

level [str or int, optional] For a MultiIndex, level (name or number) to use for resampling. *level* must be datetime-like.

New in version 0.19.0.

Returns

Resampler object

See also:

groupby Group by mapping, function, label, or list of labels.

Series.resample Resample a Series.

DataFrame.resample Resample a DataFrame.

Notes

See the [user guide](#) for more.

To learn more about the offset strings, please see [this link](#).

Examples

Start by creating a series with 9 one minute timestamps.

```
>>> index = pd.date_range('1/1/2000', periods=9, freq='T')
>>> series = pd.Series(range(9), index=index)
>>> series
```

(continues on next page)

(continued from previous page)

```

2000-01-01 00:00:00    0
2000-01-01 00:01:00    1
2000-01-01 00:02:00    2
2000-01-01 00:03:00    3
2000-01-01 00:04:00    4
2000-01-01 00:05:00    5
2000-01-01 00:06:00    6
2000-01-01 00:07:00    7
2000-01-01 00:08:00    8
Freq: T, dtype: int64

```

Downsample the series into 3 minute bins and sum the values of the timestamps falling into a bin.

```

>>> series.resample('3T').sum()
2000-01-01 00:00:00    3
2000-01-01 00:03:00   12
2000-01-01 00:06:00   21
Freq: 3T, dtype: int64

```

Downsample the series into 3 minute bins as above, but label each bin using the right edge instead of the left. Please note that the value in the bucket used as the label is not included in the bucket, which it labels. For example, in the original series the bucket 2000-01-01 00:03:00 contains the value 3, but the summed value in the resampled bucket with the label 2000-01-01 00:03:00 does not include 3 (if it did, the summed value would be 6, not 3). To include this value close the right side of the bin interval as illustrated in the example below this one.

```

>>> series.resample('3T', label='right').sum()
2000-01-01 00:03:00    3
2000-01-01 00:06:00   12
2000-01-01 00:09:00   21
Freq: 3T, dtype: int64

```

Downsample the series into 3 minute bins as above, but close the right side of the bin interval.

```

>>> series.resample('3T', label='right', closed='right').sum()
2000-01-01 00:00:00    0
2000-01-01 00:03:00    6
2000-01-01 00:06:00   15
2000-01-01 00:09:00   15
Freq: 3T, dtype: int64

```

Upsample the series into 30 second bins.

```

>>> series.resample('30S').asfreq()[0:5]    # Select first 5 rows
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30    NaN
2000-01-01 00:01:00    1.0
2000-01-01 00:01:30    NaN
2000-01-01 00:02:00    2.0
Freq: 30S, dtype: float64

```

Upsample the series into 30 second bins and fill the NaN values using the `pad` method.

```
>>> series.resample('30S').pad()[0:5]
2000-01-01 00:00:00    0
2000-01-01 00:00:30    0
2000-01-01 00:01:00    1
2000-01-01 00:01:30    1
2000-01-01 00:02:00    2
Freq: 30S, dtype: int64
```

Upsample the series into 30 second bins and fill the NaN values using the `bfill` method.

```
>>> series.resample('30S').bfill()[0:5]
2000-01-01 00:00:00    0
2000-01-01 00:00:30    1
2000-01-01 00:01:00    1
2000-01-01 00:01:30    2
2000-01-01 00:02:00    2
Freq: 30S, dtype: int64
```

Pass a custom function via `apply`

```
>>> def custom_resampler(array_like):
...     return np.sum(array_like) + 5
...
>>> series.resample('3T').apply(custom_resampler)
2000-01-01 00:00:00    8
2000-01-01 00:03:00   17
2000-01-01 00:06:00   26
Freq: 3T, dtype: int64
```

For a Series with a PeriodIndex, the keyword *convention* can be used to control whether to use the start or end of *rule*.

Resample a year by quarter using 'start' *convention*. Values are assigned to the first quarter of the period.

```
>>> s = pd.Series([1, 2], index=pd.period_range('2012-01-01',
...                                           freq='A',
...                                           periods=2))
>>> s
2012    1
2013    2
Freq: A-DEC, dtype: int64
>>> s.resample('Q', convention='start').asfreq()
2012Q1    1.0
2012Q2    NaN
2012Q3    NaN
2012Q4    NaN
2013Q1    2.0
2013Q2    NaN
2013Q3    NaN
2013Q4    NaN
Freq: Q-DEC, dtype: float64
```

Resample quarters by month using 'end' *convention*. Values are assigned to the last month of the period.

(continued from previous page)

```

>>> df2 = pd.DataFrame(d2,
...                     index=pd.MultiIndex.from_product([days,
...                                                       ['morning',
...                                                       'afternoon']])
...                     ))
>>> df2

```

		price	volume
2000-01-01	morning	10	50
	afternoon	11	60
2000-01-02	morning	9	40
	afternoon	13	100
2000-01-03	morning	14	50
	afternoon	18	100
2000-01-04	morning	17	40
	afternoon	19	50

```

>>> df2.resample('D', level=0).sum()

```

	price	volume
2000-01-01	21	110
2000-01-02	22	140
2000-01-03	32	150
2000-01-04	36	90

pandas.Series.reset_index

`Series.reset_index(self, level=None, drop=False, name=None, inplace=False)`

Generate a new DataFrame or Series with the index reset.

This is useful when the index needs to be treated as a column, or when the index is meaningless and needs to be reset to the default before another operation.

Parameters

level [int, str, tuple, or list, default optional] For a Series with a MultiIndex, only remove the specified levels from the index. Removes all levels by default.

drop [bool, default False] Just reset the index, without inserting it as a column in the new DataFrame.

name [object, optional] The name to use for the column containing the original Series values. Uses `self.name` by default. This argument is ignored when `drop` is True.

inplace [bool, default False] Modify the Series in place (do not create a new object).

Returns

Series or DataFrame When `drop` is False (the default), a DataFrame is returned. The newly created columns will come first in the DataFrame, followed by the original Series values. When `drop` is True, a Series is returned. In either case, if `inplace=True`, no value is returned.

See also:

`DataFrame.reset_index` Analogous function for DataFrame.

Examples

```
>>> s = pd.Series([1, 2, 3, 4], name='foo',
...               index=pd.Index(['a', 'b', 'c', 'd'], name='idx'))
```

Generate a DataFrame with default index.

```
>>> s.reset_index()
   idx  foo
0   a    1
1   b    2
2   c    3
3   d    4
```

To specify the name of the new column use *name*.

```
>>> s.reset_index(name='values')
   idx  values
0   a         1
1   b         2
2   c         3
3   d         4
```

To generate a new Series with the default set *drop* to True.

```
>>> s.reset_index(drop=True)
0    1
1    2
2    3
3    4
Name: foo, dtype: int64
```

To update the Series in place, without generating a new one set *inplace* to True. Note that it also requires *drop=True*.

```
>>> s.reset_index(inplace=True, drop=True)
>>> s
0    1
1    2
2    3
3    4
Name: foo, dtype: int64
```

The *level* parameter is interesting for Series with a multi-level index.

```
>>> arrays = [np.array(['bar', 'bar', 'baz', 'baz']),
...           np.array(['one', 'two', 'one', 'two'])]
>>> s2 = pd.Series(
...     range(4), name='foo',
...     index=pd.MultiIndex.from_arrays(arrays,
...                                     names=['a', 'b']))
```

To remove a specific level from the Index, use *level*.

```
>>> s2.reset_index(level='a')
      a  foo
b
one  bar    0
two  bar    1
one  baz    2
two  baz    3
```

If *level* is not set, all levels are removed from the Index.

```
>>> s2.reset_index()
      a  b  foo
0  bar  one    0
1  bar  two    1
2  baz  one    2
3  baz  two    3
```

pandas.Series.rfloordiv

`Series.rfloordiv(self, other, level=None, fill_value=None, axis=0)`

Return Integer division of series and other, element-wise (binary operator *rfloordiv*).

Equivalent to `other // series`, but with support to substitute a *fill_value* for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

Series.floordiv

Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
```

(continues on next page)

(continued from previous page)

```

>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.floordiv(b, fill_value=0)
a    1.0
b    NaN
c    NaN
d    0.0
e    NaN
dtype: float64

```

pandas.Series.rmod

`Series.rmod(self, other, level=None, fill_value=None, axis=0)`

Return Modulo of series and other, element-wise (binary operator *rmod*).

Equivalent to `other % series`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

Series.mod

Examples

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])

```

(continues on next page)

(continued from previous page)

```

>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.mod(b, fill_value=0)
a    0.0
b    NaN
c    NaN
d    0.0
e    NaN
dtype: float64

```

pandas.Series.rmul

`Series.rmul(self, other, level=None, fill_value=None, axis=0)`

Return Multiplication of series and other, element-wise (binary operator *rmul*).

Equivalent to `other * series`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

`Series.mul`

Examples

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b

```

(continues on next page)

(continued from previous page)

```

a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.multiply(b, fill_value=0)
a    1.0
b    0.0
c    0.0
d    0.0
e    NaN
dtype: float64

```

pandas.Series.rolling

`Series.rolling(self, window, min_periods=None, center=False, win_type=None, on=None, axis=0, closed=None)`

Provide rolling window calculations.

New in version 0.18.0.

Parameters

window [int, or offset] Size of the moving window. This is the number of observations used for calculating the statistic. Each window will be a fixed size.

If its an offset then this will be the time period of each window. Each window will be a variable sized based on the observations included in the time-period. This is only valid for datetimelike indexes. This is new in 0.19.0

min_periods [int, default None] Minimum number of observations in window required to have a value (otherwise result is NA). For a window that is specified by an offset, *min_periods* will default to 1. Otherwise, *min_periods* will default to the size of the window.

center [bool, default False] Set the labels at the center of the window.

win_type [str, default None] Provide a window type. If None, all points are evenly weighted. See the notes below for further information.

on [str, optional] For a DataFrame, a datetime-like column on which to calculate the rolling window, rather than the DataFrame's index. Provided integer column is ignored and excluded from result since an integer index is not used to calculate the rolling window.

axis [int or str, default 0]

closed [str, default None] Make the interval closed on the 'right', 'left', 'both' or 'neither' endpoints. For offset-based windows, it defaults to 'right'. For fixed windows, defaults to 'both'. Remaining cases not implemented for fixed windows.

New in version 0.20.0.

Returns

a Window or Rolling sub-classed for the particular operation

See also:

expanding Provides expanding transformations.

ewm Provides exponential weighted functions.

Notes

By default, the result is set to the right edge of the window. This can be changed to the center of the window by setting `center=True`.

To learn more about the offsets & frequency strings, please see [this link](#).

The recognized `win_types` are:

- `boxcar`
- `triang`
- `blackman`
- `hamming`
- `bartlett`
- `parzen`
- `bohman`
- `blackmanharris`
- `nutall`
- `barthann`
- `kaiser` (needs beta)
- `gaussian` (needs std)
- `general_gaussian` (needs power, width)
- `slepian` (needs width)
- `exponential` (needs tau), center is set to None.

If `win_type=None` all points are evenly weighted. To learn more about different window types see [scipy.signal window functions](#).

Examples

```
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
>>> df
   B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0
```

Rolling sum with a window length of 2, using the 'triang' window type.

```
>>> df.rolling(2, win_type='triang').sum()
      B
0  NaN
1  0.5
2  1.5
3  NaN
4  NaN
```

Rolling sum with a window length of 2, `min_periods` defaults to the window length.

```
>>> df.rolling(2).sum()
      B
0  NaN
1  1.0
2  3.0
3  NaN
4  NaN
```

Same as above, but explicitly set the `min_periods`

```
>>> df.rolling(2, min_periods=1).sum()
      B
0  0.0
1  1.0
2  3.0
3  2.0
4  4.0
```

A ragged (meaning not-a-regular frequency), time-indexed DataFrame

```
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]},
...                   index = [pd.Timestamp('20130101 09:00:00'),
...                             pd.Timestamp('20130101 09:00:02'),
...                             pd.Timestamp('20130101 09:00:03'),
...                             pd.Timestamp('20130101 09:00:05'),
...                             pd.Timestamp('20130101 09:00:06')])
```

```
>>> df
                B
2013-01-01 09:00:00  0.0
2013-01-01 09:00:02  1.0
2013-01-01 09:00:03  2.0
2013-01-01 09:00:05  NaN
2013-01-01 09:00:06  4.0
```

Contrasting to an integer rolling window, this will roll a variable length window corresponding to the time period. The default for `min_periods` is 1.

```
>>> df.rolling('2s').sum()
                B
2013-01-01 09:00:00  0.0
2013-01-01 09:00:02  1.0
2013-01-01 09:00:03  3.0
```

(continues on next page)

(continued from previous page)

```
2013-01-01 09:00:05 NaN
2013-01-01 09:00:06 4.0
```

pandas.Series.round**Series.round**(*self*, *decimals=0*, **args*, ***kwargs*)

Round each value in a Series to the given number of decimals.

Parameters**decimals** [int] Number of decimal places to round to (default: 0). If decimals is negative, it specifies the number of positions to the left of the decimal point.**Returns****Series** Rounded values of the Series.**See also:****numpy.around** Round values of an np.array.**DataFrame.round** Round values of a DataFrame.**Examples**

```
>>> s = pd.Series([0.1, 1.3, 2.7])
>>> s.round()
0    0.0
1    1.0
2    3.0
dtype: float64
```

pandas.Series.rpow**Series.rpow**(*self*, *other*, *level=None*, *fill_value=None*, *axis=0*)Return Exponential power of series and other, element-wise (binary operator *rpow*).Equivalent to `other ** series`, but with support to substitute a *fill_value* for missing data in one of the inputs.**Parameters****other** [Series or scalar value]**fill_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.**level** [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.**Returns****Series** The result of the operation.

See also:

Series.pow

Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.pow(b, fill_value=0)
a    1.0
b    1.0
c    1.0
d    0.0
e    NaN
dtype: float64
```

pandas.Series.rsub

Series.rsub(*self*, *other*, *level=None*, *fill_value=None*, *axis=0*)

Return Subtraction of series and other, element-wise (binary operator *rsub*).

Equivalent to `other - series`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

Series.sub

Examples

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.subtract(b, fill_value=0)
a    0.0
b    1.0
c    1.0
d   -1.0
e    NaN
dtype: float64

```

pandas.Series.rtruediv

Series.rtruediv(*self*, *other*, *level=None*, *fill_value=None*, *axis=0*)

Return Floating division of series and other, element-wise (binary operator *rtruediv*).

Equivalent to `other / series`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

Series.truediv

Examples

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.divide(b, fill_value=0)
a    1.0
b    inf
c    inf
d    0.0
e    NaN
dtype: float64

```

pandas.Series.sample

`Series.sample(self, n=None, frac=None, replace=False, weights=None, random_state=None, axis=None)`

Return a random sample of items from an axis of object.

You can use `random_state` for reproducibility.

Parameters

n [int, optional] Number of items from axis to return. Cannot be used with `frac`. Default = 1 if `frac` = None.

frac [float, optional] Fraction of axis items to return. Cannot be used with `n`.

replace [bool, default False] Sample with or without replacement.

weights [str or ndarray-like, optional] Default 'None' results in equal probability weighting. If passed a Series, will align with target object on index. Index values in weights not found in sampled object will be ignored and index values in sampled object not in weights will be assigned weights of zero. If called on a DataFrame, will accept the name of a column when `axis = 0`. Unless weights are a Series, weights must be same length as axis being sampled. If weights do not sum to 1, they will be normalized to sum to 1. Missing values in the weights column will be treated as zero. Infinite values not allowed.

random_state [int or numpy.random.RandomState, optional] Seed for the random number generator (if int), or numpy RandomState object.

axis [int or string, optional] Axis to sample. Accepts axis number or name. Default is stat axis for given data type (0 for Series and DataFrames).

Returns

Series or DataFrame A new object of same type as caller containing n items randomly sampled from the caller object.

See also:

`numpy.random.choice` Generates a random sample from a given 1-D numpy array.

Examples

```
>>> df = pd.DataFrame({'num_legs': [2, 4, 8, 0],
...                    'num_wings': [2, 0, 0, 0],
...                    'num_specimen_seen': [10, 2, 1, 8]},
...                    index=['falcon', 'dog', 'spider', 'fish'])
>>> df
```

	num_legs	num_wings	num_specimen_seen
falcon	2	2	10
dog	4	0	2
spider	8	0	1
fish	0	0	8

Extract 3 random elements from the `Series df['num_legs']`: Note that we use `random_state` to ensure the reproducibility of the examples.

```
>>> df['num_legs'].sample(n=3, random_state=1)
fish      0
spider    8
falcon    2
Name: num_legs, dtype: int64
```

A random 50% sample of the `DataFrame` with replacement:

```
>>> df.sample(frac=0.5, replace=True, random_state=1)
   num_legs  num_wings  num_specimen_seen
dog         4         0                   2
fish        0         0                   8
```

Using a `DataFrame` column as weights. Rows with larger value in the `num_specimen_seen` column are more likely to be sampled.

```
>>> df.sample(n=2, weights='num_specimen_seen', random_state=1)
   num_legs  num_wings  num_specimen_seen
falcon     2         2                   10
fish       0         0                   8
```

pandas.Series.searchsorted

`Series.searchsorted(self, value, side='left', sorter=None)`

Find indices where elements should be inserted to maintain order.

Find the indices into a sorted `Series self` such that, if the corresponding elements in `value` were inserted before the indices, the order of `self` would be preserved.

Parameters

value [array_like] Values to insert into *self*.

side [{'left', 'right'}, optional] If 'left', the index of the first suitable location found is given. If 'right', return the last such index. If there is no suitable index, return either 0 or N (where N is the length of *self*).

sorter [1-D array_like, optional] Optional array of integer indices that sort *self* into ascending order. They are typically the result of `np.argsort`.

Returns

int or array of int A scalar or array of insertion points with the same shape as *value*.

Changed in version 0.24.0: If *value* is a scalar, an int is now always returned. Previously, scalar inputs returned an 1-item array for *Series* and *Categorical*.

See also:

`numpy.searchsorted`

Notes

Binary search is used to find the required insertion points.

Examples

```
>>> x = pd.Series([1, 2, 3])
>>> x
0    1
1    2
2    3
dtype: int64
```

```
>>> x.searchsorted(4)
3
```

```
>>> x.searchsorted([0, 4])
array([0, 3])
```

```
>>> x.searchsorted([1, 3], side='left')
array([0, 2])
```

```
>>> x.searchsorted([1, 3], side='right')
array([1, 3])
```

```
>>> x = pd.Categorical(['apple', 'bread', 'bread',
                       'cheese', 'milk'], ordered=True)
[apple, bread, bread, cheese, milk]
Categories (4, object): [apple < bread < cheese < milk]
```

```
>>> x.searchsorted('bread')
1
```

```
>>> x.searchsorted(['bread'], side='right')
array([3])
```

pandas.Series.sem

`Series.sem`(*self*, *axis=None*, *skipna=None*, *level=None*, *ddof=1*, *numeric_only=None*, ***kwargs*)

Return unbiased standard error of the mean over requested axis.

Normalized by N-1 by default. This can be changed using the `ddof` argument

Parameters

axis [{index (0)}]

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is $N - \text{ddof}$, where N represents the number of elements.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns

scalar or Series (if level specified)

pandas.Series.set_axis

`Series.set_axis`(*self*, *labels*, *axis=0*, *inplace=None*)

Assign desired index to given axis.

Indexes for column or row labels can be changed by assigning a list-like or Index.

Changed in version 0.21.0: The signature is now *labels* and *axis*, consistent with the rest of pandas API. Previously, the *axis* and *labels* arguments were respectively the first and second positional arguments.

Parameters

labels [list-like, Index] The values for the new index.

axis [{0 or 'index', 1 or 'columns'}, default 0] The axis to update. The value 0 identifies the rows, and 1 identifies the columns.

inplace [bool, default None] Whether to return a new %(klass)s instance.

Warning: `inplace=None` currently falls back to `True`, but in a future version, will default to `False`. Use `inplace=True` explicitly rather than relying on the default.

Returns

renamed [%s or None] An object of same type as caller if `inplace=False`, None otherwise.

See also:

`DataFrame.rename_axis` Alter the name of the index or columns.

Examples

Series

```
>>> s = pd.Series([1, 2, 3])
>>> s
0    1
1    2
2    3
dtype: int64
```

```
>>> s.set_axis(['a', 'b', 'c'], axis=0, inplace=False)
a    1
b    2
c    3
dtype: int64
```

The original object is not modified.

```
>>> s
0    1
1    2
2    3
dtype: int64
```

DataFrame

```
>>> df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6]})
```

Change the row labels.

```
>>> df.set_axis(['a', 'b', 'c'], axis='index', inplace=False)
   A  B
a  1  4
b  2  5
c  3  6
```

Change the column labels.

```
>>> df.set_axis(['I', 'II'], axis='columns', inplace=False)
   I  II
0  1   4
1  2   5
2  3   6
```

Now, update the labels inplace.

```
>>> df.set_axis(['i', 'ii'], axis='columns', inplace=True)
>>> df
   i  ii
0  1   4
1  2   5
2  3   6
```

pandas.Series.set_value

Series.set_value(*self*, *label*, *value*, *takeable=False*)

Quickly set single value at passed label.

Deprecated since version 0.21.0: Please use `.at[]` or `.iat[]` accessors.

If label is not contained, a new object is created with the label placed at the end of the result index.

Parameters

label [object] Partial indexing with MultiIndex not allowed

value [object] Scalar value

takeable [interpret the index as indexers, default False]

Returns

Series If label is contained, will be reference to calling Series, otherwise a new object.

pandas.Series.shift

Series.shift(*self*, *periods=1*, *freq=None*, *axis=0*, *fill_value=None*)

Shift index by desired number of periods with an optional time *freq*.

When *freq* is not passed, shift the index without realigning the data. If *freq* is passed (in this case, the index must be date or datetime, or it will raise a `NotImplementedError`), the index will be increased using the periods and the *freq*.

Parameters

periods [int] Number of periods to shift. Can be positive or negative.

freq [DateOffset, tseries.offsets, timedelta, or str, optional] Offset to use from the tseries module or time rule (e.g. 'EOM'). If *freq* is specified then the index values are shifted but the data is not realigned. That is, use *freq* if you would like to extend the index when shifting and preserve the original data.

axis [{0 or 'index', 1 or 'columns', None}, default None] Shift direction.

fill_value [object, optional] The scalar value to use for newly introduced missing values. the default depends on the dtype of *self*. For numeric data, `np.nan` is used. For datetime, timedelta, or period data, etc. `NaT` is used. For extension dtypes, `self.dtype.na_value` is used.

Changed in version 0.24.0.

Returns

Series Copy of input object, shifted.

See also:

Index.shift Shift values of Index.

DatetimeIndex.shift Shift values of DatetimeIndex.

PeriodIndex.shift Shift values of PeriodIndex.

tshift Shift the time index, using the index's frequency if available.

Examples

```
>>> df = pd.DataFrame({'Col1': [10, 20, 15, 30, 45],
...                    'Col2': [13, 23, 18, 33, 48],
...                    'Col3': [17, 27, 22, 37, 52]})
```

```
>>> df.shift(periods=3)
   Col1  Col2  Col3
0   NaN   NaN   NaN
1   NaN   NaN   NaN
2   NaN   NaN   NaN
3  10.0  13.0  17.0
4  20.0  23.0  27.0
```

```
>>> df.shift(periods=1, axis='columns')
   Col1  Col2  Col3
0   NaN  10.0  13.0
1   NaN  20.0  23.0
2   NaN  15.0  18.0
3   NaN  30.0  33.0
4   NaN  45.0  48.0
```

```
>>> df.shift(periods=3, fill_value=0)
   Col1  Col2  Col3
0     0     0     0
1     0     0     0
2     0     0     0
3    10    13    17
4    20    23    27
```

pandas.Series.skew

`Series.skew(self, axis=None, skipna=None, level=None, numeric_only=None, **kwargs)`
Return unbiased skew over requested axis Normalized by N-1.

Parameters

- axis** [int (0)] Axis for the function to be applied on.
- skipna** [bool, default True] Exclude NA/null values when computing the result.
- level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.
- numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- **kwargs** Additional keyword arguments to be passed to the function.

Returns

scalar or Series (if level specified)

pandas.Series.slice_shift

`Series.slice_shift(self, periods=1, axis=0)`
Equivalent to *shift* without copying data. The shifted data will not include the dropped periods and the shifted axis will be smaller than the original.

Parameters

- periods** [int] Number of periods to move, can be positive or negative

Returns

shifted [same type as caller]

Notes

While the *slice_shift* is faster than *shift*, you may pay for it later during alignment.

pandas.Series.sort_index

`Series.sort_index(self, axis=0, level=None, ascending=True, inplace=False, kind='quicksort', na_position='last', sort_remaining=True)`
Sort Series by index labels.

Returns a new Series sorted by label if *inplace* argument is **False**, otherwise updates the original series and returns None.

Parameters

- axis** [int, default 0] Axis to direct sorting. This can only be 0 for Series.
- level** [int, optional] If not None, sort on values in specified index level(s).
- ascending** [bool, default true] Sort ascending vs. descending.
- inplace** [bool, default False] If True, perform operation in-place.

kind [{'quicksort', 'mergesort', 'heapsort'}, default 'quicksort'] Choice of sorting algorithm. See also `numpy.sort()` for more information. 'mergesort' is the only stable algorithm. For DataFrames, this option is only applied when sorting on a single column or label.

na_position [{'first', 'last'}, default 'last'] If 'first' puts NaNs at the beginning, 'last' puts NaNs at the end. Not implemented for MultiIndex.

sort_remaining [bool, default True] If True and sorting by level and index is multilevel, sort by other levels too (in order) after sorting by specified level.

Returns

Series The original Series sorted by the labels.

See also:

`DataFrame.sort_index` Sort DataFrame by the index.

`DataFrame.sort_values` Sort DataFrame by the value.

`Series.sort_values` Sort Series by the value.

Examples

```
>>> s = pd.Series(['a', 'b', 'c', 'd'], index=[3, 2, 1, 4])
>>> s.sort_index()
1    c
2    b
3    a
4    d
dtype: object
```

Sort Descending

```
>>> s.sort_index(ascending=False)
4    d
3    a
2    b
1    c
dtype: object
```

Sort Inplace

```
>>> s.sort_index(inplace=True)
>>> s
1    c
2    b
3    a
4    d
dtype: object
```

By default NaNs are put at the end, but use `na_position` to place them at the beginning

```
>>> s = pd.Series(['a', 'b', 'c', 'd'], index=[3, 2, 1, np.nan])
>>> s.sort_index(na_position='first')
```

(continues on next page)

(continued from previous page)

```
NaN    d
1.0    c
2.0    b
3.0    a
dtype: object
```

Specify index level to sort

```
>>> arrays = [np.array(['qux', 'qux', 'foo', 'foo',
...                    'baz', 'baz', 'bar', 'bar']),
...           np.array(['two', 'one', 'two', 'one',
...                    'two', 'one', 'two', 'one'])]
>>> s = pd.Series([1, 2, 3, 4, 5, 6, 7, 8], index=arrays)
>>> s.sort_index(level=1)
bar one    8
baz one    6
foo one    4
qux one    2
bar two    7
baz two    5
foo two    3
qux two    1
dtype: int64
```

Does not sort by remaining levels when sorting by levels

```
>>> s.sort_index(level=1, sort_remaining=False)
qux one    2
foo one    4
baz one    6
bar one    8
qux two    1
foo two    3
baz two    5
bar two    7
dtype: int64
```

pandas.Series.sort_values

`Series.sort_values(self, axis=0, ascending=True, inplace=False, kind='quicksort', na_position='last')`

Sort by the values.

Sort a Series in ascending or descending order by some criterion.

Parameters

axis [{0 or 'index'}, default 0] Axis to direct sorting. The value 'index' is accepted for compatibility with `DataFrame.sort_values`.

ascending [bool, default True] If True, sort values in ascending order, otherwise descending.

inplace [bool, default False] If True, perform operation in-place.

kind [{'quicksort', 'mergesort' or 'heapsort'}, default 'quicksort'] Choice of sorting algorithm. See also `numpy.sort()` for more information. 'mergesort' is the only stable algorithm.

na_position [{'first' or 'last'}, default 'last'] Argument 'first' puts NaNs at the beginning, 'last' puts NaNs at the end.

Returns

Series Series ordered by values.

See also:

Series.sort_index Sort by the Series indices.

DataFrame.sort_values Sort DataFrame by the values along either axis.

DataFrame.sort_index Sort DataFrame by indices.

Examples

```
>>> s = pd.Series([np.nan, 1, 3, 10, 5])
>>> s
0      NaN
1      1.0
2      3.0
3     10.0
4      5.0
dtype: float64
```

Sort values ascending order (default behaviour)

```
>>> s.sort_values(ascending=True)
1      1.0
2      3.0
4      5.0
3     10.0
0      NaN
dtype: float64
```

Sort values descending order

```
>>> s.sort_values(ascending=False)
3     10.0
4      5.0
2      3.0
1      1.0
0      NaN
dtype: float64
```

Sort values inplace

```
>>> s.sort_values(ascending=False, inplace=True)
>>> s
3     10.0
4      5.0
```

(continues on next page)

(continued from previous page)

```
2    3.0
1    1.0
0    NaN
dtype: float64
```

Sort values putting NAs first

```
>>> s.sort_values(na_position='first')
0    NaN
1    1.0
2    3.0
4    5.0
3   10.0
dtype: float64
```

Sort a series of strings

```
>>> s = pd.Series(['z', 'b', 'd', 'a', 'c'])
>>> s
0    z
1    b
2    d
3    a
4    c
dtype: object
```

```
>>> s.sort_values()
3    a
1    b
4    c
2    d
0    z
dtype: object
```

pandas.Series.sparse

Series.sparse()

Accessor for SparseSparse from other sparse matrix data types.

pandas.Series.squeeze

Series.squeeze(*self*, *axis=None*)

Squeeze 1 dimensional axis objects into scalars.

Series or DataFrames with a single element are squeezed to a scalar. DataFrames with a single column or a single row are squeezed to a Series. Otherwise the object is unchanged.

This method is most useful when you don't know if your object is a Series or DataFrame, but you do know it has just a single column. In that case you can safely call *squeeze* to ensure you have a Series.

Parameters

axis [{0 or 'index', 1 or 'columns', None}, default None] A specific axis to squeeze.
By default, all length-1 axes are squeezed.

New in version 0.20.0.

Returns

DataFrame, Series, or scalar The projection after squeezing *axis* or all the axes.

See also:

Series.iloc Integer-location based indexing for selecting scalars.

DataFrame.iloc Integer-location based indexing for selecting Series.

Series.to_frame Inverse of DataFrame.squeeze for a single-column DataFrame.

Examples

```
>>> primes = pd.Series([2, 3, 5, 7])
```

Slicing might produce a Series with a single value:

```
>>> even_primes = primes[primes % 2 == 0]
>>> even_primes
0    2
dtype: int64
```

```
>>> even_primes.squeeze()
2
```

Squeezing objects with more than one value in every axis does nothing:

```
>>> odd_primes = primes[primes % 2 == 1]
>>> odd_primes
1    3
2    5
3    7
dtype: int64
```

```
>>> odd_primes.squeeze()
1    3
2    5
3    7
dtype: int64
```

Squeezing is even more effective when used with DataFrames.

```
>>> df = pd.DataFrame([[1, 2], [3, 4]], columns=['a', 'b'])
>>> df
   a  b
0  1  2
1  3  4
```

Slicing a single column will produce a DataFrame with the columns having only one value:

```
>>> df_a = df[['a']]
>>> df_a
   a
0  1
1  3
```

So the columns can be squeezed down, resulting in a Series:

```
>>> df_a.squeeze('columns')
0    1
1    3
Name: a, dtype: int64
```

Slicing a single row from a single column will produce a single scalar DataFrame:

```
>>> df_0a = df.loc[df.index < 1, ['a']]
>>> df_0a
   a
0  1
```

Squeezing the rows produces a single scalar Series:

```
>>> df_0a.squeeze('rows')
a    1
Name: 0, dtype: int64
```

Squeezing all axes will project directly into a scalar:

```
>>> df_0a.squeeze()
1
```

pandas.Series.std

`Series.std(self, axis=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs)`

Return sample standard deviation over requested axis.

Normalized by N-1 by default. This can be changed using the `ddof` argument

Parameters

axis [{index (0)}]

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is $N - \text{ddof}$, where N represents the number of elements.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns

scalar or Series (if level specified)

pandas.Series.str

Series.str()

Vectorized string functions for Series and Index. NAs stay NA unless handled otherwise by a particular method. Patterned after Python's string methods, with some inspiration from R's stringr package.

Examples

```
>>> s.str.split('_')
>>> s.str.replace('_', '')
```

pandas.Series.sub

Series.sub(*self*, *other*, *level=None*, *fill_value=None*, *axis=0*)

Return Subtraction of series and other, element-wise (binary operator *sub*).

Equivalent to `series - other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

Series.rsub

Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
```

(continues on next page)

(continued from previous page)

```

a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.subtract(b, fill_value=0)
a    0.0
b    1.0
c    1.0
d   -1.0
e    NaN
dtype: float64

```

pandas.Series.subtract**Series.subtract**(*self*, *other*, *level=None*, *fill_value=None*, *axis=0*)Return Subtraction of series and other, element-wise (binary operator *sub*).Equivalent to `series - other`, but with support to substitute a `fill_value` for missing data in one of the inputs.**Parameters****other** [Series or scalar value]**fill_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.**level** [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.**Returns****Series** The result of the operation.**See also:****Series.rsub****Examples**

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0

```

(continues on next page)

(continued from previous page)

```

b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.subtract(b, fill_value=0)
a    0.0
b    1.0
c    1.0
d   -1.0
e    NaN
dtype: float64

```

pandas.Series.sum

`Series.sum(self, axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs)`

Return the sum of the values for the requested axis.

This is equivalent to the method `numpy.sum`.

Parameters

axis [{index (0)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

min_count [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

New in version 0.22.0: Added with the default being 0. This means the sum of an all-NA or empty Series is 0, and the product of an all-NA or empty Series is 1.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

scalar or Series (if level specified)

See also:

Series.sum Return the sum.

Series.min Return the minimum.

Series.max Return the maximum.

Series.idxmin Return the index of the minimum.

Series.idxmax Return the index of the maximum.

DataFrame.sum Return the sum over the requested axis.

DataFrame.min Return the minimum over the requested axis.

DataFrame.max Return the maximum over the requested axis.

DataFrame.idxmin Return the index of the minimum over the requested axis.

DataFrame.idxmax Return the index of the maximum over the requested axis.

Examples

```
>>> idx = pd.MultiIndex.from_arrays([
...     ['warm', 'warm', 'cold', 'cold'],
...     ['dog', 'falcon', 'fish', 'spider']],
...     names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded  animal
warm     dog      4
         falcon   2
cold     fish     0
         spider   8
Name: legs, dtype: int64
```

```
>>> s.sum()
14
```

Sum using level names, as well as indices.

```
>>> s.sum(level='blooded')
blooded
warm     6
cold     8
Name: legs, dtype: int64
```

```
>>> s.sum(level=0)
blooded
warm     6
cold     8
Name: legs, dtype: int64
```

By default, the sum of an empty or all-NA Series is 0.

```
>>> pd.Series([]).sum() # min_count=0 is the default
0.0
```

This can be controlled with the `min_count` parameter. For example, if you'd like the sum of an empty series to be NaN, pass `min_count=1`.

```
>>> pd.Series([]).sum(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```
>>> pd.Series([np.nan]).sum()
0.0
```

```
>>> pd.Series([np.nan]).sum(min_count=1)
nan
```

pandas.Series.swapaxes

Series.swapaxes(*self*, *axis1*, *axis2*, *copy=True*)
Interchange axes and swap values axes appropriately.

Returns

y [same as input]

pandas.Series.swaplevel

Series.swaplevel(*self*, *i=-2*, *j=-1*, *copy=True*)
Swap levels *i* and *j* in a MultiIndex.

Parameters

i, j [int, str (can be mixed)] Level of index to be swapped. Can pass level name as string.

Returns

Series Series with levels swapped in MultiIndex.

Changed in version 0.18.1: The indexes *i* and *j* are now optional, and default to the two innermost levels of the index.

pandas.Series.tail

Series.tail(*self*, *n=5*)
Return the last *n* rows.

This function returns last *n* rows from the object based on position. It is useful for quickly verifying data, for example, after sorting or appending rows.

Parameters

n [int, default 5] Number of rows to select.

Returns

type of caller The last *n* rows of the caller object.

See also:

DataFrame.head The first *n* rows of the caller object.

Examples

```
>>> df = pd.DataFrame({'animal':['alligator', 'bee', 'falcon', 'lion',
...                               'monkey', 'parrot', 'shark', 'whale', 'zebra']})
>>> df
   animal
0 alligator
1      bee
2   falcon
3     lion
4   monkey
5   parrot
6    shark
7    whale
8    zebra
```

Viewing the last 5 lines

```
>>> df.tail()
   animal
4 monkey
5 parrot
6  shark
7  whale
8  zebra
```

Viewing the last n lines (three in this case)

```
>>> df.tail(3)
   animal
6  shark
7  whale
8  zebra
```

pandas.Series.take

Series.take(*self*, *indices*, *axis=0*, *is_copy=False*, ***kwargs*)

Return the elements in the given *positional* indices along an axis.

This means that we are not indexing according to actual values in the index attribute of the object. We are indexing according to the actual position of the element in the object.

Parameters

indices [array-like] An array of ints indicating which positions to take.

axis [{0 or 'index', 1 or 'columns', None}, default 0] The axis on which to select elements. 0 means that we are selecting rows, 1 means that we are selecting columns.

is_copy [bool, default True] Whether to return a copy of the original object or not.

****kwargs** For compatibility with `numpy.take()`. Has no effect on the output.

Returns

taken [same type as caller] An array-like containing the elements taken from the object.

See also:

DataFrame.loc Select a subset of a DataFrame by labels.

DataFrame.iloc Select a subset of a DataFrame by positions.

numpy.take Take elements from an array along an axis.

Examples

```
>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
...                    ('parrot', 'bird', 24.0),
...                    ('lion', 'mammal', 80.5),
...                    ('monkey', 'mammal', np.nan)],
...                    columns=['name', 'class', 'max_speed'],
...                    index=[0, 2, 3, 1])
>>> df
```

	name	class	max_speed
0	falcon	bird	389.0
2	parrot	bird	24.0
3	lion	mammal	80.5
1	monkey	mammal	NaN

Take elements at positions 0 and 3 along the axis 0 (default).

Note how the actual indices selected (0 and 1) do not correspond to our selected indices 0 and 3. That's because we are selecting the 0th and 3rd rows, not rows whose indices equal 0 and 3.

```
>>> df.take([0, 3])
```

	name	class	max_speed
0	falcon	bird	389.0
1	monkey	mammal	NaN

Take elements at indices 1 and 2 along the axis 1 (column selection).

```
>>> df.take([1, 2], axis=1)
```

	class	max_speed
0	bird	389.0
2	bird	24.0
3	mammal	80.5
1	mammal	NaN

We may take elements using negative integers for positive indices, starting from the end of the object, just like with Python lists.

```
>>> df.take([-1, -2])
```

	name	class	max_speed
1	monkey	mammal	NaN
3	lion	mammal	80.5

pandas.Series.to_clipboard

`Series.to_clipboard(self, excel=True, sep=None, **kwargs)`

Copy object to the system clipboard.

Write a text representation of object to the system clipboard. This can be pasted into Excel, for example.

Parameters

`excel` [bool, default True]

- True, use the provided separator, writing in a csv format for allowing easy pasting into excel.
- False, write a string representation of the object to the clipboard.

`sep` [str, default '\t'] Field delimiter.

`**kwargs` These parameters will be passed to `DataFrame.to_csv`.

See also:

`DataFrame.to_csv` Write a DataFrame to a comma-separated values (csv) file.

`read_clipboard` Read text from clipboard and pass to `read_table`.

Notes

Requirements for your platform.

- Linux : `xclip`, or `xsel` (with `PyQt4` modules)
- Windows : none
- OS X : none

Examples

Copy the contents of a DataFrame to the clipboard.

```
>>> df = pd.DataFrame([[1, 2, 3], [4, 5, 6]], columns=['A', 'B', 'C'])
>>> df.to_clipboard(sep=',')
... # Wrote the following to the system clipboard:
... # ,A,B,C
... # 0,1,2,3
... # 1,4,5,6
```

We can omit the the index by passing the keyword `index` and setting it to false.

```
>>> df.to_clipboard(sep=',', index=False)
... # Wrote the following to the system clipboard:
... # A,B,C
... # 1,2,3
... # 4,5,6
```

pandas.Series.to_csv**Series.to_csv**(*self*, **args*, ***kwargs*)

Write object to a comma-separated values (csv) file.

Changed in version 0.24.0: The order of arguments for Series was changed.

Parameters**path_or_buf** [str or file handle, default None] File path or object, if None is provided the result is returned as a string. If a file object is passed it should be opened with *newline=''*, disabling universal newlines.

Changed in version 0.24.0: Was previously named “path” for Series.

sep [str, default ‘,’] String of length 1. Field delimiter for the output file.**na_rep** [str, default ‘’] Missing data representation.**float_format** [str, default None] Format string for floating point numbers.**columns** [sequence, optional] Columns to write.**header** [bool or list of str, default True] Write out the column names. If a list of strings is given it is assumed to be aliases for the column names.

Changed in version 0.24.0: Previously defaulted to False for Series.

index [bool, default True] Write row names (index).**index_label** [str or sequence, or False, default None] Column label for index column(s) if desired. If None is given, and *header* and *index* are True, then the index names are used. A sequence should be given if the object uses MultiIndex. If False do not print fields for index names. Use *index_label=False* for easier importing in R.**mode** [str] Python write mode, default ‘w’.**encoding** [str, optional] A string representing the encoding to use in the output file, defaults to ‘utf-8’.**compression** [str, default ‘infer’] Compression mode among the following possible values: {‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}. If ‘infer’ and *path_or_buf* is path-like, then detect compression from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’ or ‘.xz’. (otherwise no compression).

Changed in version 0.24.0: ‘infer’ option added and set to default.

quoting [optional constant from csv module] Defaults to *csv.QUOTE_MINIMAL*. If you have set a *float_format* then floats are converted to strings and thus *csv.QUOTE_NONNUMERIC* will treat them as non-numeric.**quotechar** [str, default ‘”’] String of length 1. Character used to quote fields.**line_terminator** [str, optional] The newline character or character sequence to use in the output file. Defaults to *os.linesep*, which depends on the OS in which this method is called (‘\n’ for linux, ‘\r\n’ for Windows, i.e.).

Changed in version 0.24.0.

chunksize [int or None] Rows to write at a time.**date_format** [str, default None] Format string for datetime objects.

doublequote [bool, default True] Control quoting of *quotechar* inside a field.

escapechar [str, default None] String of length 1. Character used to escape *sep* and *quotechar* when appropriate.

decimal [str, default ‘.’] Character recognized as decimal separator. E.g. use ‘,’ for European data.

Returns

None or str If *path_or_buf* is None, returns the resulting csv format as a string. Otherwise returns None.

See also:

read_csv Load a CSV file into a DataFrame.

to_excel Write DataFrame to an Excel file.

Examples

```
>>> df = pd.DataFrame({'name': ['Raphael', 'Donatello'],
...                   'mask': ['red', 'purple'],
...                   'weapon': ['sai', 'bo staff']})
>>> df.to_csv(index=False)
'name,mask,weapon\nRaphael,red,sai\nDonatello,purple,bo staff\n'
```

pandas.Series.to_dense

Series.to_dense(*self*)

Return dense representation of Series/DataFrame (as opposed to sparse).

Deprecated since version 0.25.0.

Returns

%(klass)s Dense %(klass)s.

pandas.Series.to_dict

Series.to_dict(*self*, *into*=<class 'dict'>)

Convert Series to {label -> value} dict or dict-like object.

Parameters

into [class, default dict] The collections.abc.Mapping subclass to use as the return object. Can be the actual class or an empty instance of the mapping type you want. If you want a collections.defaultdict, you must pass it initialized.

New in version 0.21.0.

Returns

collections.abc.Mapping Key-value representation of Series.

Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s.to_dict()
{0: 1, 1: 2, 2: 3, 3: 4}
>>> from collections import OrderedDict, defaultdict
>>> s.to_dict(OrderedDict)
OrderedDict([(0, 1), (1, 2), (2, 3), (3, 4)])
>>> dd = defaultdict(list)
>>> s.to_dict(dd)
defaultdict(<class 'list'>, {0: 1, 1: 2, 2: 3, 3: 4})
```

pandas.Series.to_excel

```
Series.to_excel(self, excel_writer, sheet_name='Sheet1', na_rep="", float_format=None,
                columns=None, header=True, index=True, index_label=None, startrow=0,
                startcol=0, engine=None, merge_cells=True, encoding=None, inf_rep='inf',
                verbose=True, freeze_panes=None)
```

Write object to an Excel sheet.

To write a single object to an Excel .xlsx file it is only necessary to specify a target file name. To write to multiple sheets it is necessary to create an *ExcelWriter* object with a target file name, and specify a sheet in the file to write to.

Multiple sheets may be written to by specifying unique *sheet_name*. With all data written to the file it is necessary to save the changes. Note that creating an *ExcelWriter* object with a file name that already exists will result in the contents of the existing file being erased.

Parameters

excel_writer [str or ExcelWriter object] File path or existing ExcelWriter.

sheet_name [str, default 'Sheet1'] Name of sheet which will contain DataFrame.

na_rep [str, default ''] Missing data representation.

float_format [str, optional] Format string for floating point numbers. For example `float_format="%.2f"` will format 0.1234 to 0.12.

columns [sequence or list of str, optional] Columns to write.

header [bool or list of str, default True] Write out the column names. If a list of string is given it is assumed to be aliases for the column names.

index [bool, default True] Write row names (index).

index_label [str or sequence, optional] Column label for index column(s) if desired. If not specified, and *header* and *index* are True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.

startrow [int, default 0] Upper left cell row to dump data frame.

startcol [int, default 0] Upper left cell column to dump data frame.

engine [str, optional] Write engine to use, 'openpyxl' or 'xlsxwriter'. You can also set this via the options `io.excel.xlsx.writer`, `io.excel.xls.writer`, and `io.excel.xlsm.writer`.

merge_cells [bool, default True] Write MultiIndex and Hierarchical Rows as merged cells.

encoding [str, optional] Encoding of the resulting excel file. Only necessary for xlwt, other writers support unicode natively.

inf_rep [str, default 'inf'] Representation for infinity (there is no native representation for infinity in Excel).

verbose [bool, default True] Display more information in the error logs.

freeze_panes [tuple of int (length 2), optional] Specifies the one-based bottom-most row and rightmost column that is to be frozen.

New in version 0.20.0..

See also:

to_csv Write DataFrame to a comma-separated values (csv) file.

ExcelWriter Class for writing DataFrame objects into excel sheets.

read_excel Read an Excel file into a pandas DataFrame.

read_csv Read a comma-separated values (csv) file into DataFrame.

Notes

For compatibility with `to_csv()`, `to_excel` serializes lists and dicts to strings before writing.

Once a workbook has been saved it is not possible write further data without rewriting the whole workbook.

Examples

Create, write to and save a workbook:

```
>>> df1 = pd.DataFrame([[ 'a', 'b'], [ 'c', 'd']],
...                     index=[ 'row 1', 'row 2'],
...                     columns=[ 'col 1', 'col 2'])
>>> df1.to_excel("output.xlsx") # doctest: +SKIP
```

To specify the sheet name:

```
>>> df1.to_excel("output.xlsx",
...              sheet_name='Sheet_name_1') # doctest: +SKIP
```

If you wish to write to more than one sheet in the workbook, it is necessary to specify an ExcelWriter object:

```
>>> df2 = df1.copy()
>>> with pd.ExcelWriter('output.xlsx') as writer: # doctest: +SKIP
...     df1.to_excel(writer, sheet_name='Sheet_name_1')
...     df2.to_excel(writer, sheet_name='Sheet_name_2')
```

To set the library that is used to write the Excel file, you can pass the `engine` keyword (the default engine is automatically chosen depending on the file extension):

```
>>> df1.to_excel('output1.xlsx', engine='xlsxwriter') # doctest: +SKIP
```

pandas.Series.to_frame**Series.to_frame**(*self*, *name=None*)

Convert Series to DataFrame.

Parameters**name** [object, default None] The passed name should substitute for the series name (if it has one).**Returns****DataFrame** DataFrame representation of Series.**Examples**

```

>>> s = pd.Series(["a", "b", "c"],
...                name="vals")
>>> s.to_frame()
   vals
0     a
1     b
2     c

```

pandas.Series.to_hdf**Series.to_hdf**(*self*, *path_or_buf*, *key*, ***kwargs*)

Write the contained data to an HDF5 file using HDFStore.

Hierarchical Data Format (HDF) is self-describing, allowing an application to interpret the structure and contents of a file with no outside information. One HDF file can hold a mix of related objects which can be accessed as a group or as individual objects.

In order to add another DataFrame or Series to an existing HDF file please use append mode and a different a key.

For more information see the *user guide*.

Parameters**path_or_buf** [str or pandas.HDFStore] File path or HDFStore object.**key** [str] Identifier for the group in the store.**mode** [{‘a’, ‘w’, ‘r+’}, default ‘a’] Mode to open file:

- ‘w’: write, a new file is created (an existing file with the same name would be deleted).
- ‘a’: append, an existing file is opened for reading and writing, and if the file does not exist it is created.
- ‘r+’: similar to ‘a’, but the file must already exist.

format [{‘fixed’, ‘table’}, default ‘fixed’] Possible values:

- ‘fixed’: Fixed format. Fast writing/reading. Not-appendable, nor searchable.

- ‘table’: Table format. Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data.

append [bool, default False] For Table formats, append the input data to the existing.

data_columns [list of columns or True, optional] List of columns to create as indexed data columns for on-disk queries, or True to use all columns. By default only the axes of the object are indexed. See *Query via data columns*. Applicable only to format='table'.

complevel [{0-9}, optional] Specifies a compression level for data. A value of 0 disables compression.

complib [{'zlib', 'lzo', 'bzip2', 'blosc'}, default 'zlib'] Specifies the compression library to be used. As of v0.20.2 these additional compressors for Blosc are supported (default if no compressor specified: 'blosc:blosclz'): {'blosc:blosclz', 'blosc:lz4', 'blosc:lz4hc', 'blosc:snappy', 'blosc:zlib', 'blosc:zstd'}. Specifying a compression library which is not available issues a ValueError.

fletcher32 [bool, default False] If applying compression use the fletcher32 checksum.

dropna [bool, default False] If true, ALL nan rows will not be written to store.

errors [str, default 'strict'] Specifies how encoding and decoding errors are to be handled. See the errors argument for `open()` for a full list of options.

See also:

`DataFrame.read_hdf` Read from HDF file.

`DataFrame.to_parquet` Write a DataFrame to the binary parquet format.

`DataFrame.to_sql` Write to a sql table.

`DataFrame.to_feather` Write out feather-format for DataFrames.

`DataFrame.to_csv` Write out to a csv file.

Examples

```
>>> df = pd.DataFrame({'A': [1, 2, 3], 'B': [4, 5, 6]},
...                   index=['a', 'b', 'c'])
>>> df.to_hdf('data.h5', key='df', mode='w')
```

We can add another object to the same file:

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s.to_hdf('data.h5', key='s')
```

Reading from HDF file:

```
>>> pd.read_hdf('data.h5', 'df')
A  B
a  1  4
b  2  5
```

(continues on next page)

(continued from previous page)

```

c 3 6
>>> pd.read_hdf('data.h5', 's')
0    1
1    2
2    3
3    4
dtype: int64

```

Deleting file with data:

```

>>> import os
>>> os.remove('data.h5')

```

pandas.Series.to_json

`Series.to_json(self, path_or_buf=None, orient=None, date_format=None, double_precision=10, force_ascii=True, date_unit='ms', default_handler=None, lines=False, compression='infer', index=True)`

Convert the object to a JSON string.

Note NaN's and None will be converted to null and datetime objects will be converted to UNIX timestamps.

Parameters

path_or_buf [string or file handle, optional] File path or object. If not specified, the result is returned as a string.

orient [string] Indication of expected JSON string format.

- Series
 - default is 'index'
 - allowed values are: {'split', 'records', 'index', 'table'}
- DataFrame
 - default is 'columns'
 - allowed values are: {'split', 'records', 'index', 'columns', 'values', 'table'}
- The format of the JSON string
 - 'split' : dict like {'index' -> [index], 'columns' -> [columns], 'data' -> [values]}
 - 'records' : list like [{column -> value}, ... , {column -> value}]
 - 'index' : dict like {index -> {column -> value}}
 - 'columns' : dict like {column -> {index -> value}}
 - 'values' : just the values array
 - 'table' : dict like {'schema': {schema}, 'data': {data}} describing the data, and the data component is like `orient='records'`.

Changed in version 0.20.0.

date_format [{None, 'epoch', 'iso'}] Type of date conversion. 'epoch' = epoch milliseconds, 'iso' = ISO8601. The default depends on the *orient*. For *orient*='table', the default is 'iso'. For all other *orient*s, the default is 'epoch'.

double_precision [int, default 10] The number of decimal places to use when encoding floating point values.

force_ascii [bool, default True] Force encoded string to be ASCII.

date_unit [string, default 'ms' (milliseconds)] The time unit to encode to, governs timestamp and ISO8601 precision. One of 's', 'ms', 'us', 'ns' for second, millisecond, microsecond, and nanosecond respectively.

default_handler [callable, default None] Handler to call if object cannot otherwise be converted to a suitable format for JSON. Should receive a single argument which is the object to convert and return a serialisable object.

lines [bool, default False] If 'orient' is 'records' write out line delimited json format. Will throw ValueError if incorrect 'orient' since others are not list like.

New in version 0.19.0.

compression [{ 'infer', 'gzip', 'bz2', 'zip', 'xz', None}] A string representing the compression to use in the output file, only used when the first argument is a filename. By default, the compression is inferred from the filename.

New in version 0.21.0.

Changed in version 0.24.0: 'infer' option added and set to default

index [bool, default True] Whether to include the index values in the JSON string. Not including the index (*index=False*) is only supported when *orient* is 'split' or 'table'.

New in version 0.23.0.

Returns

None or str If *path_or_buf* is None, returns the resulting json format as a string. Otherwise returns None.

See also:

read_json

Examples

```
>>> df = pd.DataFrame([[ 'a', 'b'], [ 'c', 'd']],
...                   index=['row 1', 'row 2'],
...                   columns=['col 1', 'col 2'])
>>> df.to_json(orient='split')
'{"columns":["col 1","col 2"],
  "index":["row 1","row 2"],
  "data":[["a","b"],["c","d"]}]'
```

Encoding/decoding a Dataframe using 'records' formatted JSON. Note that index labels are not preserved with this encoding.

```
>>> df.to_json(orient='records')
'[{ "col 1": "a", "col 2": "b"}, { "col 1": "c", "col 2": "d"}]'
```

Encoding/decoding a Dataframe using 'index' formatted JSON:

```
>>> df.to_json(orient='index')
'{"row 1":{"col 1":"a","col 2":"b"},"row 2":{"col 1":"c","col 2":"d"}}'
```

Encoding/decoding a Dataframe using 'columns' formatted JSON:

```
>>> df.to_json(orient='columns')
'{"col 1":{"row 1":"a","row 2":"c"},"col 2":{"row 1":"b","row 2":"d"}}'
```

Encoding/decoding a Dataframe using 'values' formatted JSON:

```
>>> df.to_json(orient='values')
'[["a","b"],["c","d"]]
```

Encoding with Table Schema

```
>>> df.to_json(orient='table')
'{"schema": {"fields": [{"name": "index", "type": "string"},
                        {"name": "col 1", "type": "string"},
                        {"name": "col 2", "type": "string"}],
  "primaryKey": "index",
  "pandas_version": "0.20.0"},
 "data": [{"index": "row 1", "col 1": "a", "col 2": "b"},
           {"index": "row 2", "col 1": "c", "col 2": "d"}]}'
```

pandas.Series.to_latex

`Series.to_latex(self, buf=None, columns=None, col_space=None, header=True, index=True, na_rep='NaN', formatters=None, float_format=None, sparsify=None, index_names=True, bold_rows=False, column_format=None, longtable=None, escape=None, encoding=None, decimal='.', multicolumn=None, multicolumn_format=None, multirow=None)`

Render an object to a LaTeX tabular environment table.

Render an object to a tabular environment table. You can splice this into a LaTeX document. Requires `usepackage{booktabs}`.

Changed in version 0.20.2: Added to Series

Parameters

- buf** [file descriptor or None] Buffer to write to. If None, the output is returned as a string.
- columns** [list of label, optional] The subset of columns to write. Writes all columns by default.
- col_space** [int, optional] The minimum width of each column.
- header** [bool or list of str, default True] Write out the column names. If a list of strings is given, it is assumed to be aliases for the column names.
- index** [bool, default True] Write row names (index).
- na_rep** [str, default 'NaN'] Missing data representation.

formatters [list of functions or dict of {str: function}, optional] Formatter functions to apply to columns' elements by position or name. The result of each function must be a unicode string. List must be of length equal to the number of columns.

float_format [one-parameter function or str, optional, default None] Formatter for floating point numbers. For example `float_format="%.2f"` and `float_format="{:0.2f}".format` will both result in 0.1234 being formatted as 0.12.

sparsify [bool, optional] Set to False for a DataFrame with a hierarchical index to print every multiindex key at each row. By default, the value will be read from the config module.

index_names [bool, default True] Prints the names of the indexes.

bold_rows [bool, default False] Make the row labels bold in the output.

column_format [str, optional] The columns format as specified in [LaTeX table format](#) e.g. 'rcl' for 3 columns. By default, 'l' will be used for all columns except columns of numbers, which default to 'r'.

longtable [bool, optional] By default, the value will be read from the pandas config module. Use a longtable environment instead of tabular. Requires adding a `usepackage{longtable}` to your LaTeX preamble.

escape [bool, optional] By default, the value will be read from the pandas config module. When set to False prevents from escaping latex special characters in column names.

encoding [str, optional] A string representing the encoding to use in the output file, defaults to 'utf-8'.

decimal [str, default '.'] Character recognized as decimal separator, e.g. ',' in Europe.

New in version 0.18.0.

multicolumn [bool, default True] Use multicolumn to enhance MultiIndex columns. The default will be read from the config module.

New in version 0.20.0.

multicolumn_format [str, default 'l'] The alignment for multicolumns, similar to *column_format* The default will be read from the config module.

New in version 0.20.0.

multirow [bool, default False] Use multirow to enhance MultiIndex rows. Requires adding a `usepackage{multirow}` to your LaTeX preamble. Will print centered labels (instead of top-aligned) across the contained rows, separating groups via clines. The default will be read from the pandas config module.

New in version 0.20.0.

Returns

str or None If buf is None, returns the resulting LaTeX format as a string. Otherwise returns None.

See also:

DataFrame.to_string Render a DataFrame to a console-friendly tabular output.

`DataFrame.to_html` Render a DataFrame as an HTML table.

Examples

```
>>> df = pd.DataFrame({'name': ['Raphael', 'Donatello'],
...                    'mask': ['red', 'purple'],
...                    'weapon': ['sai', 'bo staff']})
>>> df.to_latex(index=False) # doctest: +NORMALIZE_WHITESPACE
'\begin{tabular}{lll}\n\toprule\n    name &    mask &    weapon\n\\\\\n\midrule\n    Raphael &    red &    sai \\\n\n Donatello &    purple &    bo staff \\\n\n\bottomrule\n\n\end{tabular}\n'
```

pandas.Series.to_list

`Series.to_list(self)`

Return a list of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

Returns

list

See also:

`numpy.ndarray.tolist`

pandas.Series.to_msgpack

`Series.to_msgpack(self, path_or_buf=None, encoding='utf-8', **kwargs)`

Serialize object to input file path using msgpack format.

Deprecated since version 0.25.0.

`to_msgpack` is deprecated and will be removed in a future version. It is recommended to use `pyarrow` for on-the-wire transmission of pandas objects.

Parameters

path [string File path, buffer-like, or None] if None, return generated bytes

append [bool whether to append to an existing msgpack] (default is False)

compress [type of compressor (zlib or blosc), default to None (no) compression]

Returns

None or bytes If `path_or_buf` is None, returns the resulting msgpack format as a byte string. Otherwise returns None.

pandas.Series.to_numpy

`Series.to_numpy(self, dtype=None, copy=False)`

A NumPy ndarray representing the values in this Series or Index.

New in version 0.24.0.

Parameters

dtype [str or numpy.dtype, optional] The dtype to pass to `numpy.asarray()`

copy [bool, default False] Whether to ensure that the returned value is a not a view on another array. Note that `copy=False` does not *ensure* that `to_numpy()` is no-copy. Rather, `copy=True` ensure that a copy is made, even if not strictly necessary.

Returns

`numpy.ndarray`

See also:

Series.array Get the actual data stored within.

Index.array Get the actual data stored within.

DataFrame.to_numpy Similar method for DataFrame.

Notes

The returned array will be the same up to equality (values equal in *self* will be equal in the returned array; likewise for values that are not equal). When *self* contains an ExtensionArray, the dtype may be different. For example, for a category-dtype Series, `to_numpy()` will return a NumPy array and the categorical dtype will be lost.

For NumPy dtypes, this will be a reference to the actual data stored in this Series or Index (assuming `copy=False`). Modifying the result in place will modify the data stored in the Series or Index (not that we recommend doing that).

For extension types, `to_numpy()` *may* require copying data and coercing the result to a NumPy type (possibly object), which may be expensive. When you need a no-copy reference to the underlying data, `Series.array` should be used instead.

This table lays out the different dtypes and default return types of `to_numpy()` for various dtypes within pandas.

dtype	array type
category[T]	ndarray[T] (same dtype as input)
period	ndarray[object] (Periods)
interval	ndarray[object] (Intervals)
IntegerNA	ndarray[object]
datetime64[ns]	datetime64[ns]
datetime64[ns, tz]	ndarray[object] (Timestamps)

Examples

```
>>> ser = pd.Series(pd.Categorical(['a', 'b', 'a']))
>>> ser.to_numpy()
array(['a', 'b', 'a'], dtype=object)
```

Specify the *dtype* to control how datetime-aware data is represented. Use `dtype=object` to return an ndarray of pandas *Timestamp* objects, each with the correct *tz*.

```
>>> ser = pd.Series(pd.date_range('2000', periods=2, tz="CET"))
>>> ser.to_numpy(dtype=object)
array([Timestamp('2000-01-01 00:00:00+0100', tz='CET', freq='D'),
       Timestamp('2000-01-02 00:00:00+0100', tz='CET', freq='D')],
      dtype=object)
```

Or `dtype='datetime64[ns]'` to return an ndarray of native datetime64 values. The values are converted to UTC and the timezone info is dropped.

```
>>> ser.to_numpy(dtype="datetime64[ns]")
... # doctest: +ELLIPSIS
array(['1999-12-31T23:00:00.000000000', '2000-01-01T23:00:00...'],
      dtype='datetime64[ns]')
```

pandas.Series.to_period

`Series.to_period(self, freq=None, copy=True)`

Convert Series from DatetimeIndex to PeriodIndex with desired frequency (inferred from index if not passed).

Parameters

freq [str, default None] Frequency associated with the PeriodIndex.

copy [bool, default True] Whether or not to return a copy.

Returns

Series Series with index converted to PeriodIndex.

pandas.Series.to_pickle

`Series.to_pickle(self, path, compression='infer', protocol=4)`

Pickle (serialize) object to file.

Parameters

path [str] File path where the pickled object will be stored.

compression [{‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}, default ‘infer’] A string representing the compression to use in the output file. By default, infers from the file extension in specified path.

New in version 0.20.0.

protocol [int] Int which indicates which protocol should be used by the pickler, default HIGHEST_PROTOCOL (see [?] paragraph 12.1.2). The possible values are 0, 1, 2, 3, 4. A negative value for the protocol parameter is equivalent to setting its value to HIGHEST_PROTOCOL.

New in version 0.21.0.

See also:

`read_pickle` Load pickled pandas object (or any object) from file.

`DataFrame.to_hdf` Write DataFrame to an HDF5 file.

`DataFrame.to_sql` Write DataFrame to a SQL database.

`DataFrame.to_parquet` Write a DataFrame to the binary parquet format.

Examples

```
>>> original_df = pd.DataFrame({"foo": range(5), "bar": range(5, 10)})
>>> original_df
   foo  bar
0    0    5
1    1    6
2    2    7
3    3    8
4    4    9
>>> original_df.to_pickle("./dummy.pkl")
```

```
>>> unpickled_df = pd.read_pickle("./dummy.pkl")
>>> unpickled_df
   foo  bar
0    0    5
1    1    6
2    2    7
3    3    8
4    4    9
```

```
>>> import os
>>> os.remove("./dummy.pkl")
```

`pandas.Series.to_sparse`

`Series.to_sparse(self, kind='block', fill_value=None)`

Convert Series to SparseSeries.

Deprecated since version 0.25.0.

Parameters

kind [{"block", "integer"}], default 'block'

fill_value [float, defaults to NaN (missing)] Value to use for filling NaN values.

Returns

SparseSeries Sparse representation of the Series.

`pandas.Series.to_sql`

`Series.to_sql(self, name, con, schema=None, if_exists='fail', index=True, index_label=None, chunksize=None, dtype=None, method=None)`

Write records stored in a DataFrame to a SQL database.

Databases supported by SQLAlchemy [?] are supported. Tables can be newly created, appended to, or overwritten.

Parameters

- name** [string] Name of SQL table.
- con** [sqlalchemy.engine.Engine or sqlite3.Connection] Using SQLAlchemy makes it possible to use any DB supported by that library. Legacy support is provided for sqlite3.Connection objects.
- schema** [string, optional] Specify the schema (if database flavor supports this). If None, use default schema.
- if_exists** [{'fail', 'replace', 'append'}, default 'fail'] How to behave if the table already exists.
- fail: Raise a ValueError.
 - replace: Drop the table before inserting new values.
 - append: Insert new values to the existing table.
- index** [bool, default True] Write DataFrame index as a column. Uses *index_label* as the column name in the table.
- index_label** [string or sequence, default None] Column label for index column(s). If None is given (default) and *index* is True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.
- chunksize** [int, optional] Rows will be written in batches of this size at a time. By default, all rows will be written at once.
- dtype** [dict, optional] Specifying the datatype for columns. The keys should be the column names and the values should be the SQLAlchemy types or strings for the sqlite3 legacy mode.
- method** [{None, 'multi', callable}, default None] Controls the SQL insertion clause used:
- None : Uses standard SQL INSERT clause (one per row).
 - 'multi': Pass multiple values in a single INSERT clause.
 - callable with signature (*pd_table*, *conn*, *keys*, *data_iter*).
- Details and a sample callable implementation can be found in the section [insert method](#).
- New in version 0.24.0.

Raises

ValueError When the table already exists and *if_exists* is 'fail' (the default).

See also:

[read_sql](#) Read a DataFrame from a table.

Notes

Timezone aware datetime columns will be written as `Timestamp with timezone` type with SQLAlchemy if supported by the database. Otherwise, the datetimes will be stored as timezone unaware timestamps local to the original timezone.

New in version 0.24.0.

References

[?], [?]

Examples

Create an in-memory SQLite database.

```
>>> from sqlalchemy import create_engine
>>> engine = create_engine('sqlite://', echo=False)
```

Create a table from scratch with 3 rows.

```
>>> df = pd.DataFrame({'name' : ['User 1', 'User 2', 'User 3']})
>>> df
   name
0  User 1
1  User 2
2  User 3
```

```
>>> df.to_sql('users', con=engine)
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 1'), (1, 'User 2'), (2, 'User 3')]
```

```
>>> df1 = pd.DataFrame({'name' : ['User 4', 'User 5']})
>>> df1.to_sql('users', con=engine, if_exists='append')
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 1'), (1, 'User 2'), (2, 'User 3'),
 (0, 'User 4'), (1, 'User 5')]
```

Overwrite the table with just df1.

```
>>> df1.to_sql('users', con=engine, if_exists='replace',
...           index_label='id')
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 4'), (1, 'User 5')]
```

Specify the dtype (especially useful for integers with missing values). Notice that while pandas is forced to store the data as floating point, the database supports nullable integers. When fetching the data with Python, we get back integer scalars.

```
>>> df = pd.DataFrame({"A": [1, None, 2]})
>>> df
   A
0  1.0
1  NaN
2  2.0
```

```
>>> from sqlalchemy.types import Integer
>>> df.to_sql('integers', con=engine, index=False,
...         dtype={"A": Integer()})
```

```
>>> engine.execute("SELECT * FROM integers").fetchall()
[(1,), (None,), (2,)]
```

pandas.Series.to_string

`Series.to_string(self, buf=None, na_rep='NaN', float_format=None, header=True, index=True, length=False, dtype=False, name=False, max_rows=None, min_rows=None)`

Render a string representation of the Series.

Parameters

- buf** [StringIO-like, optional] Buffer to write to.
- na_rep** [str, optional] String representation of NaN to use, default 'NaN'.
- float_format** [one-parameter function, optional] Formatter function to apply to columns' elements if they are floats, default None.
- header** [bool, default True] Add the Series header (index name).
- index** [bool, optional] Add index (row) labels, default True.
- length** [bool, default False] Add the Series length.
- dtype** [bool, default False] Add the Series dtype.
- name** [bool, default False] Add the Series name if not None.
- max_rows** [int, optional] Maximum number of rows to show before truncating. If None, show all.
- min_rows** [int, optional] The number of rows to display in a truncated repr (when number of rows is above *max_rows*).

Returns

str or **None** String representation of Series if `buf=None`, otherwise None.

pandas.Series.to_timestamp

`Series.to_timestamp(self, freq=None, how='start', copy=True)`
 Cast to DatetimeIndex of Timestamps, at *beginning* of period.

Parameters

- freq** [str, default frequency of PeriodIndex] Desired frequency.
- how** [{'s', 'e', 'start', 'end'}] Convention for converting period to timestamp; start of period vs. end.
- copy** [bool, default True] Whether or not to return a copy.

Returns

Series with DatetimeIndex

pandas.Series.to_xarray**Series.to_xarray**(*self*)

Return an xarray object from the pandas object.

Returns**xarray.DataArray** or **xarray.Dataset** Data in the pandas structure converted to Dataset if the object is a DataFrame, or a DataArray if the object is a Series.**See also:****DataFrame.to_hdf** Write DataFrame to an HDF5 file.**DataFrame.to_parquet** Write a DataFrame to the binary parquet format.**Notes**See the [xarray docs](#)**Examples**

```
>>> df = pd.DataFrame([('falcon', 'bird', 389.0, 2),
...                    ('parrot', 'bird', 24.0, 2),
...                    ('lion', 'mammal', 80.5, 4),
...                    ('monkey', 'mammal', np.nan, 4)],
...                    columns=['name', 'class', 'max_speed',
...                             'num_legs'])
>>> df
   name  class  max_speed  num_legs
0  falcon  bird     389.0         2
1  parrot  bird     24.0         2
2   lion  mammal     80.5         4
3  monkey  mammal      NaN         4
```

```
>>> df.to_xarray()
<xarray.Dataset>
Dimensions:  (index: 4)
Coordinates:
  * index    (index) int64 0 1 2 3
Data variables:
  name      (index) object 'falcon' 'parrot' 'lion' 'monkey'
  class     (index) object 'bird' 'bird' 'mammal' 'mammal'
  max_speed (index) float64 389.0 24.0 80.5 nan
  num_legs  (index) int64 2 2 4 4
```

```
>>> df['max_speed'].to_xarray()
<xarray.DataArray 'max_speed' (index: 4)>
array([389. , 24. , 80.5,  nan])
Coordinates:
  * index    (index) int64 0 1 2 3
```

```
>>> dates = pd.to_datetime(['2018-01-01', '2018-01-01',
...                          '2018-01-02', '2018-01-02'])
>>> df_multiindex = pd.DataFrame({'date': dates,
...                               'animal': ['falcon', 'parrot', 'falcon',
...                                         'parrot'],
...                               'speed': [350, 18, 361, 15]}).set_index(['date',
...                               'animal'])
>>> df_multiindex
```

date	animal	speed
2018-01-01	falcon	350
	parrot	18
2018-01-02	falcon	361
	parrot	15

```
>>> df_multiindex.to_xarray()
<xarray.Dataset>
Dimensions: (animal: 2, date: 2)
Coordinates:
  * date      (date) datetime64[ns] 2018-01-01 2018-01-02
  * animal    (animal) object 'falcon' 'parrot'
Data variables:
  speed      (date, animal) int64 350 18 361 15
```

pandas.Series.tolist

`Series.tolist(self)`

Return a list of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

Returns

list

See also:

[numpy.ndarray.tolist](#)

pandas.Series.transform

`Series.transform(self, func, axis=0, *args, **kwargs)`

Call `func` on self producing a Series with transformed values and that has the same axis length as self.

New in version 0.20.0.

Parameters

func [function, str, list or dict] Function to use for transforming the data. If a function, must either work when passed a Series or when passed to `Series.apply`.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. `[np.exp, 'sqrt']`
- dict of axis labels -> functions, function names or list of such.

axis `[[0 or 'index']]` Parameter needed for compatibility with DataFrame.

***args** Positional arguments to pass to *func*.

****kwargs** Keyword arguments to pass to *func*.

Returns

Series A Series that must have the same length as self.

Raises

ValueError [If the returned Series has a different length than self.]

See also:

Series.agg Only perform aggregating type operations.

Series.apply Invoke function on a Series.

Examples

```
>>> df = pd.DataFrame({'A': range(3), 'B': range(1, 4)})
>>> df
   A  B
0  0  1
1  1  2
2  2  3
>>> df.transform(lambda x: x + 1)
   A  B
0  1  2
1  2  3
2  3  4
```

Even though the resulting Series must have the same length as the input Series, it is possible to provide several input functions:

```
>>> s = pd.Series(range(3))
>>> s
0    0
1    1
2    2
dtype: int64
>>> s.transform([np.sqrt, np.exp])
      sqrt      exp
0  0.000000  1.000000
1  1.000000  2.718282
2  1.414214  7.389056
```

pandas.Series.transpose`Series.transpose(self, *args, **kwargs)`

Return the transpose, which is by definition self.

Returns%(**klass**)s**pandas.Series.truediv**`Series.truediv(self, other, level=None, fill_value=None, axis=0)`Return Floating division of series and other, element-wise (binary operator *truediv*).Equivalent to `series / other`, but with support to substitute a `fill_value` for missing data in one of the inputs.**Parameters****other** [Series or scalar value]**fill_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.**level** [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.**Returns****Series** The result of the operation.**See also:***Series.rtruediv***Examples**

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.divide(b, fill_value=0)
a    1.0
b    inf

```

(continues on next page)

(continued from previous page)

```
c    inf
d    0.0
e    NaN
dtype: float64
```

pandas.Series.truncate**Series.truncate**(*self*, *before=None*, *after=None*, *axis=None*, *copy=True*)

Truncate a Series or DataFrame before and after some index value.

This is a useful shorthand for boolean indexing based on index values above or below certain thresholds.

Parameters**before** [date, string, int] Truncate all rows before this index value.**after** [date, string, int] Truncate all rows after this index value.**axis** [{0 or 'index', 1 or 'columns'}, optional] Axis to truncate. Truncates the index (rows) by default.**copy** [boolean, default is True,] Return a copy of the truncated section.**Returns****type of caller** The truncated Series or DataFrame.**See also:****DataFrame.loc** Select a subset of a DataFrame by label.**DataFrame.iloc** Select a subset of a DataFrame by position.**Notes**

If the index being truncated contains only datetime values, *before* and *after* may be specified as strings instead of Timestamps.

Examples

```
>>> df = pd.DataFrame({'A': ['a', 'b', 'c', 'd', 'e'],
...                   'B': ['f', 'g', 'h', 'i', 'j'],
...                   'C': ['k', 'l', 'm', 'n', 'o']},
...                   index=[1, 2, 3, 4, 5])
>>> df
   A B C
1  a f k
2  b g l
3  c h m
4  d i n
5  e j o
```

```
>>> df.truncate(before=2, after=4)
   A B C
2  b g l
3  c h m
4  d i n
```

The columns of a DataFrame can be truncated.

```
>>> df.truncate(before="A", after="B", axis="columns")
   A B
1  a f
2  b g
3  c h
4  d i
5  e j
```

For Series, only rows can be truncated.

```
>>> df['A'].truncate(before=2, after=4)
2    b
3    c
4    d
Name: A, dtype: object
```

The index values in `truncate` can be datetimes or string dates.

```
>>> dates = pd.date_range('2016-01-01', '2016-02-01', freq='s')
>>> df = pd.DataFrame(index=dates, data={'A': 1})
>>> df.tail()
                A
2016-01-31 23:59:56  1
2016-01-31 23:59:57  1
2016-01-31 23:59:58  1
2016-01-31 23:59:59  1
2016-02-01 00:00:00  1
```

```
>>> df.truncate(before=pd.Timestamp('2016-01-05'),
...             after=pd.Timestamp('2016-01-10')).tail()
                A
2016-01-09 23:59:56  1
2016-01-09 23:59:57  1
2016-01-09 23:59:58  1
2016-01-09 23:59:59  1
2016-01-10 00:00:00  1
```

Because the index is a `DatetimeIndex` containing only dates, we can specify *before* and *after* as strings. They will be coerced to `Timestamps` before truncation.

```
>>> df.truncate('2016-01-05', '2016-01-10').tail()
                A
2016-01-09 23:59:56  1
2016-01-09 23:59:57  1
2016-01-09 23:59:58  1
```

(continues on next page)

(continued from previous page)

```
2016-01-09 23:59:59 1
2016-01-10 00:00:00 1
```

Note that `truncate` assumes a 0 value for any unspecified time component (midnight). This differs from partial string slicing, which returns any partially matching dates.

```
>>> df.loc['2016-01-05':'2016-01-10', :].tail()
                                     A
2016-01-10 23:59:55 1
2016-01-10 23:59:56 1
2016-01-10 23:59:57 1
2016-01-10 23:59:58 1
2016-01-10 23:59:59 1
```

pandas.Series.tshift

`Series.tshift(self, periods=1, freq=None, axis=0)`

Shift the time index, using the index's frequency if available.

Parameters

- periods** [int] Number of periods to move, can be positive or negative
- freq** [DateOffset, timedelta, or time rule string, default None] Increment to use from the tseries module or time rule (e.g. 'EOM')
- axis** [int or basestring] Corresponds to the axis that contains the Index

Returns

shifted [Series/DataFrame]

Notes

If `freq` is not specified then tries to use the `freq` or `inferred_freq` attributes of the index. If neither of those attributes exist, a `ValueError` is thrown

pandas.Series.tz_convert

`Series.tz_convert(self, tz, axis=0, level=None, copy=True)`

Convert tz-aware axis to target time zone.

Parameters

- tz** [string or pytz.timezone object]
- axis** [the axis to convert]
- level** [int, str, default None] If axis is a MultiIndex, convert a specific level. Otherwise must be None
- copy** [boolean, default True] Also make a copy of the underlying data

Returns

%(klass)s Object with time zone converted axis.

Raises**TypeError** If the axis is tz-naive.**pandas.Series.tz_localize**

```
Series.tz_localize(self, tz, axis=0, level=None, copy=True, ambiguous='raise', nonexistent='raise')
```

Localize tz-naive index of a Series or DataFrame to target time zone.

This operation localizes the Index. To localize the values in a timezone-naive Series, use `Series.dt.tz_localize()`.

Parameters**tz** [string or pytz.timezone object]**axis** [the axis to localize]**level** [int, str, default None] If axis is a MultiIndex, localize a specific level. Otherwise must be None**copy** [boolean, default True] Also make a copy of the underlying data

ambiguous ['infer', bool-ndarray, 'NaT', default 'raise'] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the *ambiguous* parameter dictates how ambiguous times should be handled.

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times

nonexistent [str, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST. Valid values are:

- 'shift_forward' will shift the nonexistent time forward to the closest existing time
- 'shift_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise a NonExistentTimeError if there are nonexistent times

New in version 0.24.0.

Returns**Series or DataFrame** Same type as the input.**Raises****TypeError** If the TimeSeries is tz-aware and tz is not None.

Examples

Localize local times:

```
>>> s = pd.Series([1],
... index=pd.DatetimeIndex(['2018-09-15 01:30:00']))
>>> s.tz_localize('CET')
2018-09-15 01:30:00+02:00    1
dtype: int64
```

Be careful with DST changes. When there is sequential data, pandas can infer the DST time:

```
>>> s = pd.Series(range(7), index=pd.DatetimeIndex([
... '2018-10-28 01:30:00',
... '2018-10-28 02:00:00',
... '2018-10-28 02:30:00',
... '2018-10-28 02:00:00',
... '2018-10-28 02:30:00',
... '2018-10-28 03:00:00',
... '2018-10-28 03:30:00']))
>>> s.tz_localize('CET', ambiguous='infer')
2018-10-28 01:30:00+02:00    0
2018-10-28 02:00:00+02:00    1
2018-10-28 02:30:00+02:00    2
2018-10-28 02:00:00+01:00    3
2018-10-28 02:30:00+01:00    4
2018-10-28 03:00:00+01:00    5
2018-10-28 03:30:00+01:00    6
dtype: int64
```

In some cases, inferring the DST is impossible. In such cases, you can pass an ndarray to the `ambiguous` parameter to set the DST explicitly

```
>>> s = pd.Series(range(3), index=pd.DatetimeIndex([
... '2018-10-28 01:20:00',
... '2018-10-28 02:36:00',
... '2018-10-28 03:46:00']))
>>> s.tz_localize('CET', ambiguous=np.array([True, True, False]))
2018-10-28 01:20:00+02:00    0
2018-10-28 02:36:00+02:00    1
2018-10-28 03:46:00+01:00    2
dtype: int64
```

If the DST transition causes nonexistent times, you can shift these dates forward or backwards with a `timedelta` object or `'shift_forward'` or `'shift_backwards'`. `>>> s = pd.Series(range(2), index=pd.DatetimeIndex(['2015-03-29 02:30:00', '2015-03-29 03:30:00']))`
`>>> s.tz_localize('Europe/Warsaw', nonexistent='shift_forward')` 2015-03-29 03:00:00+02:00
0 2015-03-29 03:30:00+02:00 1 dtype: int64
`>>> s.tz_localize('Europe/Warsaw', nonexistent='shift_backward')` 2015-03-29 01:59:59.999999999+01:00 0 2015-03-29 03:30:00+02:00 1
dtype: int64
`>>> s.tz_localize('Europe/Warsaw', nonexistent=pd.Timedelta('1H'))` 2015-03-29
03:30:00+02:00 0 2015-03-29 03:30:00+02:00 1 dtype: int64

pandas.Series.unique**Series.unique(*self*)**

Return unique values of Series object.

Uniques are returned in order of appearance. Hash table-based unique, therefore does NOT sort.

Returns**ndarray or ExtensionArray** The unique values returned as a NumPy array.
See Notes.**See also:****unique** Top-level unique method for any 1-d array-like object.**Index.unique** Return Index with unique values from an Index object.**Notes**Returns the unique values as a NumPy array. In case of an extension-array backed Series, a new *ExtensionArray* of that type with just the unique values is returned. This includes

- Categorical
- Period
- Datetime with Timezone
- Interval
- Sparse
- IntegerNA

See Examples section.

Examples

```
>>> pd.Series([2, 1, 3, 3], name='A').unique()
array([2, 1, 3])
```

```
>>> pd.Series([pd.Timestamp('2016-01-01') for _ in range(3)]).unique()
array(['2016-01-01T00:00:00.000000000'], dtype='datetime64[ns]')
```

```
>>> pd.Series([pd.Timestamp('2016-01-01', tz='US/Eastern')
...           for _ in range(3)]).unique()
<DatetimeArray>
['2016-01-01 00:00:00-05:00']
Length: 1, dtype: datetime64[ns, US/Eastern]
```

An unordered Categorical will return categories in the order of appearance.

```
>>> pd.Series(pd.Categorical(list('baabc'))).unique()
[b, a, c]
Categories (3, object): [b, a, c]
```

An ordered Categorical preserves the category ordering.

```
>>> pd.Series(pd.Categorical(list('baabc'), categories=list('abc'),
...                          ordered=True)).unique()
[b, a, c]
Categories (3, object): [a < b < c]
```

pandas.Series.unstack

Series.unstack(*self*, *level=-1*, *fill_value=None*)

Unstack, a.k.a. pivot, Series with MultiIndex to produce DataFrame. The level involved will automatically get sorted.

Parameters

level [int, str, or list of these, default last level] Level(s) to unstack, can pass level name.

fill_value [scalar value, default None] Value to use when replacing NaN values.

New in version 0.18.0.

Returns

DataFrame Unstacked Series.

Examples

```
>>> s = pd.Series([1, 2, 3, 4],
...               index=pd.MultiIndex.from_product([['one', 'two'],
...                                                 ['a', 'b']]))
>>> s
one  a    1
     b    2
two  a    3
     b    4
dtype: int64
```

```
>>> s.unstack(level=-1)
   a  b
one 1  2
two 3  4
```

```
>>> s.unstack(level=0)
   one  two
a    1    3
b    2    4
```

pandas.Series.update

Series.update(*self*, *other*)

Modify Series in place using non-NA values from passed Series. Aligns on index.

Parameters

other [Series]

Examples

```
>>> s = pd.Series([1, 2, 3])
>>> s.update(pd.Series([4, 5, 6]))
>>> s
0    4
1    5
2    6
dtype: int64
```

```
>>> s = pd.Series(['a', 'b', 'c'])
>>> s.update(pd.Series(['d', 'e'], index=[0, 2]))
>>> s
0    d
1    b
2    e
dtype: object
```

```
>>> s = pd.Series([1, 2, 3])
>>> s.update(pd.Series([4, 5, 6, 7, 8]))
>>> s
0    4
1    5
2    6
dtype: int64
```

If **other** contains NaNs the corresponding values are not updated in the original Series.

```
>>> s = pd.Series([1, 2, 3])
>>> s.update(pd.Series([4, np.nan, 6]))
>>> s
0    4
1    2
2    6
dtype: int64
```

pandas.Series.valid

Series.valid(*self*, *inplace=False*, ***kwargs*)

Return Series without null values.

Deprecated since version 0.23.0: Use *Series.dropna()* instead.

Returns

Series Series without null values.

pandas.Series.value_counts

```
Series.value_counts(self, normalize=False, sort=True, ascending=False, bins=None, dropna=True)
```

Return a Series containing counts of unique values.

The resulting object will be in descending order so that the first element is the most frequently-occurring element. Excludes NA values by default.

Parameters

normalize [boolean, default False] If True then the object returned will contain the relative frequencies of the unique values.

sort [boolean, default True] Sort by frequencies.

ascending [boolean, default False] Sort in ascending order.

bins [integer, optional] Rather than count values, group them into half-open bins, a convenience for `pd.cut`, only works with numeric data.

dropna [boolean, default True] Don't include counts of NaN.

Returns

Series

See also:

Series.count Number of non-NA elements in a Series.

DataFrame.count Number of non-NA elements in a DataFrame.

Examples

```
>>> index = pd.Index([3, 1, 2, 3, 4, np.nan])
>>> index.value_counts()
3.0    2
4.0    1
2.0    1
1.0    1
dtype: int64
```

With *normalize* set to *True*, returns the relative frequency by dividing all values by the sum of values.

```
>>> s = pd.Series([3, 1, 2, 3, 4, np.nan])
>>> s.value_counts(normalize=True)
3.0    0.4
4.0    0.2
2.0    0.2
1.0    0.2
dtype: float64
```

bins

Bins can be useful for going from a continuous variable to a categorical variable; instead of counting unique apparitions of values, divide the index in the specified number of half-open bins.

```
>>> s.value_counts(bins=3)
(2.0, 3.0]      2
(0.996, 2.0]    2
(3.0, 4.0]      1
dtype: int64
```

dropna

With *dropna* set to *False* we can also see NaN index values.

```
>>> s.value_counts(dropna=False)
3.0      2
NaN      1
4.0      1
2.0      1
1.0      1
dtype: int64
```

pandas.Series.var

`Series.var(self, axis=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs)`

Return unbiased variance over requested axis.

Normalized by N-1 by default. This can be changed using the *ddof* argument

Parameters

axis [{index (0)}]

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is $N - \text{ddof}$, where N represents the number of elements.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns

scalar or Series (if level specified)

pandas.Series.view

`Series.view(self, dtype=None)`

Create a new view of the Series.

This function will return a new Series with a view of the same underlying values in memory, optionally reinterpreted with a new data type. The new data type must preserve the same size in bytes as to not cause index misalignment.

Parameters

dtype [data type] Data type object or one of their string representations.

Returns

Series A new Series object as a view of the same data in memory.

See also:

`numpy.ndarray.view` Equivalent numpy function to create a new view of the same data in memory.

Notes

Series are instantiated with `dtype=float64` by default. While `numpy.ndarray.view()` will return a view with the same data type as the original array, `Series.view()` (without specified dtype) will try using `float64` and may fail if the original data type size in bytes is not the same.

Examples

```
>>> s = pd.Series([-2, -1, 0, 1, 2], dtype='int8')
>>> s
0    -2
1    -1
2     0
3     1
4     2
dtype: int8
```

The 8 bit signed integer representation of `-1` is `0b11111111`, but the same bytes represent 255 if read as an 8 bit unsigned integer:

```
>>> us = s.view('uint8')
>>> us
0    254
1    255
2     0
3     1
4     2
dtype: uint8
```

The views share the same underlying values:

```
>>> us[0] = 128
>>> s
0   -128
1     -1
2      0
3      1
4      2
dtype: int8
```

pandas.Series.where

```
Series.where(self, cond, other=nan, inplace=False, axis=None, level=None, errors='raise',
             try_cast=False)
```

Replace values where the condition is False.

Parameters

cond [boolean Series/DataFrame, array-like, or callable] Where *cond* is True, keep the original value. Where False, replace with corresponding value from *other*. If *cond* is callable, it is computed on the Series/DataFrame and should return boolean Series/DataFrame or array. The callable must not change input Series/DataFrame (though pandas doesn't check it).

New in version 0.18.1: A callable can be used as *cond*.

other [scalar, Series/DataFrame, or callable] Entries where *cond* is False are replaced with corresponding value from *other*. If *other* is callable, it is computed on the Series/DataFrame and should return scalar or Series/DataFrame. The callable must not change input Series/DataFrame (though pandas doesn't check it).

New in version 0.18.1: A callable can be used as *other*.

inplace [bool, default False] Whether to perform the operation in place on the data.

axis [int, default None] Alignment axis if needed.

level [int, default None] Alignment level if needed.

errors [str, {'raise', 'ignore'}, default 'raise'] Note that currently this parameter won't affect the results and will always coerce to a suitable dtype.

- 'raise' : allow exceptions to be raised.
- 'ignore' : suppress exceptions. On error return original object.

try_cast [bool, default False] Try to cast the result back to the input type (if possible).

Returns

Same type as caller

See also:

DataFrame.mask() Return an object of same shape as self.

Notes

The *where* method is an application of the if-then idiom. For each element in the calling DataFrame, if *cond* is True the element is used; otherwise the corresponding element from the DataFrame *other* is used.

The signature for *DataFrame.where()* differs from *numpy.where()*. Roughly *df1.where(m, df2)* is equivalent to *np.where(m, df1, df2)*.

For further details and examples see the *where* documentation in *indexing*.

Examples

```
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0    NaN
1    1.0
2    2.0
3    3.0
4    4.0
dtype: float64
```

```
>>> s.mask(s > 0)
0    0.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

```
>>> s.where(s > 1, 10)
0    10
1    10
2     2
3     3
4     4
dtype: int64
```

```
>>> df = pd.DataFrame(np.arange(10).reshape(-1, 2), columns=['A', 'B'])
>>> df
   A  B
0  0  1
1  2  3
2  4  5
3  6  7
4  8  9
>>> m = df % 3 == 0
>>> df.where(m, -df)
   A  B
0  0 -1
1 -2  3
2 -4 -5
3  6 -7
4 -8  9
>>> df.where(m, -df) == np.where(m, df, -df)
   A    B
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True
>>> df.where(m, -df) == df.mask(~m, -df)
   A    B
```

(continues on next page)

(continued from previous page)

```

0 True True
1 True True
2 True True
3 True True
4 True True

```

pandas.Series.xs**Series.xs**(*self*, *key*, *axis=0*, *level=None*, *drop_level=True*)

Return cross-section from the Series/DataFrame.

This method takes a *key* argument to select data at a particular level of a MultiIndex.**Parameters****key** [label or tuple of label] Label contained in the index, or partially in a Multi-Index.**axis** [{0 or 'index', 1 or 'columns'}, default 0] Axis to retrieve cross-section on.**level** [object, defaults to first n levels (n=1 or len(key))] In case of a key partially contained in a MultiIndex, indicate which levels are used. Levels can be referred by label or position.**drop_level** [bool, default True] If False, returns object with same levels as self.**Returns****Series or DataFrame** Cross-section from the original Series or DataFrame corresponding to the selected index levels.**See also:****DataFrame.loc** Access a group of rows and columns by label(s) or a boolean array.**DataFrame.iloc** Purely integer-location based indexing for selection by position.**Notes***xs* can not be used to set values.MultiIndex Slicers is a generic way to get/set values on any level or levels. It is a superset of *xs* functionality, see *MultiIndex Slicers*.**Examples**

```

>>> d = {'num_legs': [4, 4, 2, 2],
...      'num_wings': [0, 0, 2, 2],
...      'class': ['mammal', 'mammal', 'mammal', 'bird'],
...      'animal': ['cat', 'dog', 'bat', 'penguin'],
...      'locomotion': ['walks', 'walks', 'flies', 'walks']}
>>> df = pd.DataFrame(data=d)
>>> df = df.set_index(['class', 'animal', 'locomotion'])
>>> df

```

(continues on next page)

(continued from previous page)

			num_legs	num_wings
class	animal	locomotion		
mammal	cat	walks	4	0
	dog	walks	4	0
	bat	flies	2	2
bird	penguin	walks	2	2

Get values at specified index

```
>>> df.xs('mammal')
           num_legs  num_wings
animal locomotion
cat     walks      4           0
dog     walks      4           0
bat     flies      2           2
```

Get values at several indexes

```
>>> df.xs(('mammal', 'dog'))
           num_legs  num_wings
locomotion
walks          4           0
```

Get values at specified index and level

```
>>> df.xs('cat', level=1)
           num_legs  num_wings
class locomotion
mammal walks      4           0
```

Get values at several indexes and levels

```
>>> df.xs(('bird', 'walks'),
...       level=[0, 'locomotion'])
           num_legs  num_wings
animal
penguin      2           2
```

Get values at specified column and axis

```
>>> df.xs('num_wings', axis=1)
class  animal  locomotion
mammal  cat    walks      0
         dog    walks      0
         bat    flies      2
bird    penguin walks      2
Name: num_wings, dtype: int64
```

6.3.2 Attributes

Axes

<i>Series.index</i>	The index (axis labels) of the Series.
<i>Series.array</i>	The ExtensionArray of the data backing this Series or Index.
<i>Series.values</i>	Return Series as ndarray or ndarray-like depending on the dtype.
<i>Series.dtype</i>	Return the dtype object of the underlying data.
<i>Series.ftype</i>	(DEPRECATED) Return if the data is sparse dense.
<i>Series.shape</i>	Return a tuple of the shape of the underlying data.
<i>Series.nbytes</i>	Return the number of bytes in the underlying data.
<i>Series.ndim</i>	Number of dimensions of the underlying data, by definition 1.
<i>Series.size</i>	Return the number of elements in the underlying data.
<i>Series.strides</i>	(DEPRECATED) Return the strides of the underlying data.
<i>Series.itemsize</i>	(DEPRECATED) Return the size of the dtype of the item of the underlying data.
<i>Series.base</i>	(DEPRECATED) Return the base object if the memory of the underlying data is shared.
<i>Series.T</i>	Return the transpose, which is by
<i>Series.memory_usage(self[, index, deep])</i>	Return the memory usage of the Series.
<i>Series.hasnans</i>	Return if I have any nans; enables various perf speedups.
<i>Series.flags</i>	(DEPRECATED)
<i>Series.empty</i>	
<i>Series.dtypes</i>	Return the dtype object of the underlying data.
<i>Series.ftypes</i>	(DEPRECATED) Return if the data is sparse dense.
<i>Series.data</i>	(DEPRECATED) Return the data pointer of the underlying data.
<i>Series.is_copy</i>	Return the copy.
<i>Series.name</i>	Return name of the Series.
<i>Series.put(self, *args, **kwargs)</i>	(DEPRECATED) Apply the <i>put</i> method to its <i>values</i> attribute if it has one.

pandas.Series.empty

`Series.empty`

6.3.3 Conversion

<i>Series.astype(self, dtype[, copy, errors])</i>	Cast a pandas object to a specified dtype <code>dtype</code> .
<i>Series.infer_objects(self)</i>	Attempt to infer better dtypes for object columns.
<i>Series.copy(self[, deep])</i>	Make a copy of this object's indices and data.
<i>Series.bool(self)</i>	Return the bool of a single element PandasObject.

Continued on next page

Table 30 – continued from previous page

<code>Series.to_numpy(self[, dtype, copy])</code>	A NumPy ndarray representing the values in this Series or Index.
<code>Series.to_period(self[, freq, copy])</code>	Convert Series from DatetimeIndex to PeriodIndex with desired frequency (inferred from index if not passed).
<code>Series.to_timestamp(self[, freq, how, copy])</code>	Cast to DatetimeIndex of Timestamps, at <i>beginning</i> of period.
<code>Series.to_list(self)</code>	Return a list of the values.
<code>Series.get_values(self)</code>	(DEPRECATED) Same as <code>values</code> (but handles sparseness conversions); is a view.
<code>Series.__array__(self[, dtype])</code>	Return the values as a NumPy array.

pandas.Series.__array__

`Series.__array__(self, dtype=None)`

Return the values as a NumPy array.

Users should not call this directly. Rather, it is invoked by `numpy.array()` and `numpy.asarray()`.

Parameters

dtype [str or `numpy.dtype`, optional] The dtype to use for the resulting NumPy array. By default, the dtype is inferred from the data.

Returns

numpy.ndarray The values in the series converted to a `numpy.ndarray` with the specified *dtype*.

See also:

array Create a new array from data.

Series.array Zero-copy view to the array backing the Series.

Series.to_numpy Series method for similar behavior.

Examples

```
>>> ser = pd.Series([1, 2, 3])
>>> np.asarray(ser)
array([1, 2, 3])
```

For timezone-aware data, the timezones may be retained with `dtype='object'`

```
>>> tzser = pd.Series(pd.date_range('2000', periods=2, tz="CET"))
>>> np.asarray(tzser, dtype="object")
array([Timestamp('2000-01-01 00:00:00+0100', tz='CET', freq='D'),
       Timestamp('2000-01-02 00:00:00+0100', tz='CET', freq='D')],
      dtype=object)
```

Or the values may be localized to UTC and the tzinfo discarded with `dtype='datetime64[ns]'`

```
>>> np.asarray(tzser, dtype="datetime64[ns]") # doctest: +ELLIPSIS
array(['1999-12-31T23:00:00.000000000', ...],
      dtype='datetime64[ns]')
```

6.3.4 Indexing, iteration

<code>Series.get(self, key[, default])</code>	Get item from object for given key (ex: DataFrame column).
<code>Series.at</code>	Access a single value for a row/column label pair.
<code>Series.iat</code>	Access a single value for a row/column pair by integer position.
<code>Series.loc</code>	Access a group of rows and columns by label(s) or a boolean array.
<code>Series.iloc</code>	Purely integer-location based indexing for selection by position.
<code>Series.__iter__(self)</code>	Return an iterator of the values.
<code>Series.items(self)</code>	Lazily iterate over (index, value) tuples.
<code>Series.iteritems(self)</code>	Lazily iterate over (index, value) tuples.
<code>Series.keys(self)</code>	Return alias for index.
<code>Series.pop(self, item)</code>	Return item and drop from frame.
<code>Series.item(self)</code>	Return the first element of the underlying data as a python scalar.
<code>Series.xs(self, key[, axis, level, drop_level])</code>	Return cross-section from the Series/DataFrame.

pandas.Series.__iter__

Series.__iter__(self)

Return an iterator of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

Returns

iterator

For more information on `.at`, `.iat`, `.loc`, and `.iloc`, see the [indexing documentation](#).

6.3.5 Binary operator functions

<code>Series.add(self, other[, level, fill_value, ...])</code>	Return Addition of series and other, element-wise (binary operator <i>add</i>).
<code>Series.sub(self, other[, level, fill_value, ...])</code>	Return Subtraction of series and other, element-wise (binary operator <i>sub</i>).
<code>Series.mul(self, other[, level, fill_value, ...])</code>	Return Multiplication of series and other, element-wise (binary operator <i>mul</i>).
<code>Series.div(self, other[, level, fill_value, ...])</code>	Return Floating division of series and other, element-wise (binary operator <i>truediv</i>).
<code>Series.truediv(self, other[, level, ...])</code>	Return Floating division of series and other, element-wise (binary operator <i>truediv</i>).
<code>Series.floordiv(self, other[, level, ...])</code>	Return Integer division of series and other, element-wise (binary operator <i>floordiv</i>).
<code>Series.mod(self, other[, level, fill_value, ...])</code>	Return Modulo of series and other, element-wise (binary operator <i>mod</i>).
<code>Series.pow(self, other[, level, fill_value, ...])</code>	Return Exponential power of series and other, element-wise (binary operator <i>pow</i>).

Continued on next page

Table 32 – continued from previous page

<code>Series.radd</code> (self, other[, level, ...])	Return Addition of series and other, element-wise (binary operator <i>radd</i>).
<code>Series.rsub</code> (self, other[, level, ...])	Return Subtraction of series and other, element-wise (binary operator <i>rsub</i>).
<code>Series.rmul</code> (self, other[, level, ...])	Return Multiplication of series and other, element-wise (binary operator <i>rmul</i>).
<code>Series.rdiv</code> (self, other[, level, ...])	Return Floating division of series and other, element-wise (binary operator <i>rtruediv</i>).
<code>Series.rtruediv</code> (self, other[, level, ...])	Return Floating division of series and other, element-wise (binary operator <i>rtruediv</i>).
<code>Series.rfloordiv</code> (self, other[, level, ...])	Return Integer division of series and other, element-wise (binary operator <i>rfloordiv</i>).
<code>Series.rmod</code> (self, other[, level, ...])	Return Modulo of series and other, element-wise (binary operator <i>rmod</i>).
<code>Series.rpow</code> (self, other[, level, ...])	Return Exponential power of series and other, element-wise (binary operator <i>rpow</i>).
<code>Series.combine</code> (self, other, func[, fill_value])	Combine the Series with a Series or scalar according to <i>func</i> .
<code>Series.combine_first</code> (self, other)	Combine Series values, choosing the calling Series's values first.
<code>Series.round</code> (self[, decimals])	Round each value in a Series to the given number of decimals.
<code>Series.lt</code> (self, other[, level, fill_value, axis])	Return Less than of series and other, element-wise (binary operator <i>lt</i>).
<code>Series.gt</code> (self, other[, level, fill_value, axis])	Return Greater than of series and other, element-wise (binary operator <i>gt</i>).
<code>Series.le</code> (self, other[, level, fill_value, axis])	Return Less than or equal to of series and other, element-wise (binary operator <i>le</i>).
<code>Series.ge</code> (self, other[, level, fill_value, axis])	Return Greater than or equal to of series and other, element-wise (binary operator <i>ge</i>).
<code>Series.ne</code> (self, other[, level, fill_value, axis])	Return Not equal to of series and other, element-wise (binary operator <i>ne</i>).
<code>Series.eq</code> (self, other[, level, fill_value, axis])	Return Equal to of series and other, element-wise (binary operator <i>eq</i>).
<code>Series.product</code> (self[, axis, skipna, level, ...])	Return the product of the values for the requested axis.
<code>Series.dot</code> (self, other)	Compute the dot product between the Series and the columns of other.

6.3.6 Function application, groupby & window

<code>Series.apply</code> (self, func[, convert_dtype, args])	Invoke function on values of Series.
<code>Series.agg</code> (self, func[, axis])	Aggregate using one or more operations over the specified axis.
<code>Series.aggregate</code> (self, func[, axis])	Aggregate using one or more operations over the specified axis.
<code>Series.transform</code> (self, func[, axis])	Call <i>func</i> on self producing a Series with transformed values and that has the same axis length as self.

Continued on next page

Table 33 – continued from previous page

<code>Series.map(self, arg[, na_action])</code>	Map values of Series according to input correspondence.
<code>Series.groupby(self[, by, axis, level, ...])</code>	Group DataFrame or Series using a mapper or by a Series of columns.
<code>Series.rolling(self, window[, min_periods, ...])</code>	Provide rolling window calculations.
<code>Series.expanding(self[, min_periods, ...])</code>	Provide expanding transformations.
<code>Series.ewm(self[, com, span, halflife, ...])</code>	Provide exponential weighted functions.
<code>Series.pipe(self, func, <i>*args</i>, <i>**kwargs</i>)</code>	Apply <code>func(self, <i>*args</i>, <i>**kwargs</i>)</code> .

6.3.7 Computations / descriptive stats

<code>Series.abs(self)</code>	Return a Series/DataFrame with absolute numeric value of each element.
<code>Series.all(self[, axis, bool_only, skipna, ...])</code>	Return whether all elements are True, potentially over an axis.
<code>Series.any(self[, axis, bool_only, skipna, ...])</code>	Return whether any element is True, potentially over an axis.
<code>Series.autocorr(self[, lag])</code>	Compute the lag-N autocorrelation.
<code>Series.between(self, left, right[, inclusive])</code>	Return boolean Series equivalent to <code>left <= series <= right</code> .
<code>Series.clip(self[, lower, upper, axis, inplace])</code>	Trim values at input threshold(s).
<code>Series.clip_lower(self, threshold[, axis, ...])</code>	(DEPRECATED) Trim values below a given threshold.
<code>Series.clip_upper(self, threshold[, axis, ...])</code>	(DEPRECATED) Trim values above a given threshold.
<code>Series.corr(self, other[, method, min_periods])</code>	Compute correlation with <i>other</i> Series, excluding missing values.
<code>Series.count(self[, level])</code>	Return number of non-NA/null observations in the Series.
<code>Series.cov(self, other[, min_periods])</code>	Compute covariance with Series, excluding missing values.
<code>Series.cummax(self[, axis, skipna])</code>	Return cumulative maximum over a DataFrame or Series axis.
<code>Series.cummin(self[, axis, skipna])</code>	Return cumulative minimum over a DataFrame or Series axis.
<code>Series.cumprod(self[, axis, skipna])</code>	Return cumulative product over a DataFrame or Series axis.
<code>Series.cumsum(self[, axis, skipna])</code>	Return cumulative sum over a DataFrame or Series axis.
<code>Series.describe(self[, percentiles, ...])</code>	Generate descriptive statistics that summarize the central tendency, dispersion and shape of a dataset's distribution, excluding NaN values.
<code>Series.diff(self[, periods])</code>	First discrete difference of element.
<code>Series.factorize(self[, sort, na_sentinel])</code>	Encode the object as an enumerated type or categorical variable.
<code>Series.kurt(self[, axis, skipna, level, ...])</code>	Return unbiased kurtosis over requested axis using Fisher's definition of kurtosis (kurtosis of normal == 0.0).
<code>Series.mad(self[, axis, skipna, level])</code>	Return the mean absolute deviation of the values for the requested axis.

Continued on next page

Table 34 – continued from previous page

<i>Series.max</i> (self[, axis, skipna, level, ...])	Return the maximum of the values for the requested axis.
<i>Series.mean</i> (self[, axis, skipna, level, ...])	Return the mean of the values for the requested axis.
<i>Series.median</i> (self[, axis, skipna, level, ...])	Return the median of the values for the requested axis.
<i>Series.min</i> (self[, axis, skipna, level, ...])	Return the minimum of the values for the requested axis.
<i>Series.mode</i> (self[, dropna])	Return the mode(s) of the dataset.
<i>Series.nlargest</i> (self[, n, keep])	Return the largest <i>n</i> elements.
<i>Series.nsmallest</i> (self[, n, keep])	Return the smallest <i>n</i> elements.
<i>Series.pct_change</i> (self[, periods, ...])	Percentage change between the current and a prior element.
<i>Series.prod</i> (self[, axis, skipna, level, ...])	Return the product of the values for the requested axis.
<i>Series.quantile</i> (self[, q, interpolation])	Return value at the given quantile.
<i>Series.rank</i> (self[, axis, method, ...])	Compute numerical data ranks (1 through n) along axis.
<i>Series.sem</i> (self[, axis, skipna, level, ...])	Return unbiased standard error of the mean over requested axis.
<i>Series.skew</i> (self[, axis, skipna, level, ...])	Return unbiased skew over requested axis Normalized by N-1.
<i>Series.std</i> (self[, axis, skipna, level, ...])	Return sample standard deviation over requested axis.
<i>Series.sum</i> (self[, axis, skipna, level, ...])	Return the sum of the values for the requested axis.
<i>Series.var</i> (self[, axis, skipna, level, ...])	Return unbiased variance over requested axis.
<i>Series.kurtosis</i> (self[, axis, skipna, level, ...])	Return unbiased kurtosis over requested axis using Fisher's definition of kurtosis (kurtosis of normal == 0.0).
<i>Series.unique</i> (self)	Return unique values of Series object.
<i>Series.nunique</i> (self[, dropna])	Return number of unique elements in the object.
<i>Series.is_unique</i>	Return boolean if values in the object are unique.
<i>Series.is_monotonic</i>	Return boolean if values in the object are monotonic_increasing.
<i>Series.is_monotonic_increasing</i>	Return boolean if values in the object are monotonic_increasing.
<i>Series.is_monotonic_decreasing</i>	Return boolean if values in the object are monotonic_decreasing.
<i>Series.value_counts</i> (self[, normalize, sort, ...])	Return a Series containing counts of unique values.
<i>Series.compound</i> (self[, axis, skipna, level])	(DEPRECATED) Return the compound percentage of the values for the requested axis.

6.3.8 Reindexing / selection / label manipulation

<i>Series.align</i> (self, other[, join, axis, ...])	Align two objects on their axes with the specified join method for each axis Index.
<i>Series.drop</i> (self[, labels, axis, index, ...])	Return Series with specified index labels removed.
<i>Series.droplevel</i> (self, level[, axis])	Return DataFrame with requested index / column level(s) removed.
<i>Series.drop_duplicates</i> (self[, keep, inplace])	Return Series with duplicate values removed.

Continued on next page

Table 35 – continued from previous page

<code>Series.duplicated(self[, keep])</code>	Indicate duplicate Series values.
<code>Series.equals(self, other)</code>	Test whether two objects contain the same elements.
<code>Series.first(self, offset)</code>	Convenience method for subsetting initial periods of time series data based on a date offset.
<code>Series.head(self[, n])</code>	Return the first n rows.
<code>Series.idxmax(self[, axis, skipna])</code>	Return the row label of the maximum value.
<code>Series.idxmin(self[, axis, skipna])</code>	Return the row label of the minimum value.
<code>Series.isin(self, values)</code>	Check whether <i>values</i> are contained in Series.
<code>Series.last(self, offset)</code>	Convenience method for subsetting final periods of time series data based on a date offset.
<code>Series.reindex(self[, index])</code>	Conform Series to new index with optional filling logic, placing NA/NaN in locations having no value in the previous index.
<code>Series.reindex_like(self, other[, method, ...])</code>	Return an object with matching indices as other object.
<code>Series.rename(self[, index])</code>	Alter Series index labels or name.
<code>Series.rename_axis(self[, mapper, index, ...])</code>	Set the name of the axis for the index or columns.
<code>Series.reset_index(self[, level, drop, ...])</code>	Generate a new DataFrame or Series with the index reset.
<code>Series.sample(self[, n, frac, replace, ...])</code>	Return a random sample of items from an axis of object.
<code>Series.set_axis(self, labels[, axis, inplace])</code>	Assign desired index to given axis.
<code>Series.take(self, indices[, axis, is_copy])</code>	Return the elements in the given <i>positional</i> indices along an axis.
<code>Series.tail(self[, n])</code>	Return the last n rows.
<code>Series.truncate(self[, before, after, axis, ...])</code>	Truncate a Series or DataFrame before and after some index value.
<code>Series.where(self, cond[, other, inplace, ...])</code>	Replace values where the condition is False.
<code>Series.mask(self, cond[, other, inplace, ...])</code>	Replace values where the condition is True.
<code>Series.add_prefix(self, prefix)</code>	Prefix labels with string <i>prefix</i> .
<code>Series.add_suffix(self, suffix)</code>	Suffix labels with string <i>suffix</i> .
<code>Series.filter(self[, items, like, regex, axis])</code>	Subset rows or columns of dataframe according to labels in the specified index.

6.3.9 Missing data handling

<code>Series.isna(self)</code>	Detect missing values.
<code>Series.notna(self)</code>	Detect existing (non-missing) values.
<code>Series.dropna(self[, axis, inplace])</code>	Return a new Series with missing values removed.
<code>Series.fillna(self[, value, method, axis, ...])</code>	Fill NA/NaN values using the specified method.
<code>Series.interpolate(self[, method, axis, ...])</code>	Interpolate values according to different methods.

6.3.10 Reshaping, sorting

<code>Series.argsort(self[, axis, kind, order])</code>	Override ndarray.argsort.
<code>Series.argmin(self[, axis, skipna])</code>	(DEPRECATED) Return the row label of the minimum value.

Continued on next page

Table 37 – continued from previous page

<code>Series.argmax</code> (self[, axis, skipna])	(DEPRECATED) Return the row label of the maximum value.
<code>Series.reorder_levels</code> (self, order)	Rearrange index levels using input order.
<code>Series.sort_values</code> (self[, axis, ascending, ...])	Sort by the values.
<code>Series.sort_index</code> (self[, axis, level, ...])	Sort Series by index labels.
<code>Series.swaplevel</code> (self[, i, j, copy])	Swap levels i and j in a MultiIndex.
<code>Series.unstack</code> (self[, level, fill_value])	Unstack, a.k.a.
<code>Series.explode</code> (self)	Transform each element of a list-like to a row, replicating the index values.
<code>Series.searchsorted</code> (self, value[, side, sorter])	Find indices where elements should be inserted to maintain order.
<code>Series.ravel</code> (self[, order])	Return the flattened underlying data as an ndarray.
<code>Series.repeat</code> (self, repeats[, axis])	Repeat elements of a Series.
<code>Series.squeeze</code> (self[, axis])	Squeeze 1 dimensional axis objects into scalars.
<code>Series.view</code> (self[, dtype])	Create a new view of the Series.

6.3.11 Combining / joining / merging

<code>Series.append</code> (self, to_append[, ...])	Concatenate two or more Series.
<code>Series.replace</code> (self[, to_replace, value, ...])	Replace values given in <i>to_replace</i> with <i>value</i> .
<code>Series.update</code> (self, other)	Modify Series in place using non-NA values from passed Series.

6.3.12 Time series-related

<code>Series.asfreq</code> (self, freq[, method, how, ...])	Convert TimeSeries to specified frequency.
<code>Series.asof</code> (self, where[, subset])	Return the last row(s) without any NaNs before <i>where</i> .
<code>Series.shift</code> (self[, periods, freq, axis, ...])	Shift index by desired number of periods with an optional time <i>freq</i> .
<code>Series.first_valid_index</code> (self)	Return index for first non-NA/null value.
<code>Series.last_valid_index</code> (self)	Return index for last non-NA/null value.
<code>Series.resample</code> (self, rule[, how, axis, ...])	Resample time-series data.
<code>Series.tz_convert</code> (self, tz[, axis, level, copy])	Convert tz-aware axis to target time zone.
<code>Series.tz_localize</code> (self, tz[, axis, level, ...])	Localize tz-naive index of a Series or DataFrame to target time zone.
<code>Series.at_time</code> (self, time[, asof, axis])	Select values at particular time of day (e.g.
<code>Series.between_time</code> (self, start_time, end_time)	Select values between particular times of the day (e.g., 9:00-9:30 AM).
<code>Series.tshift</code> (self[, periods, freq, axis])	Shift the time index, using the index's frequency if available.
<code>Series.slice_shift</code> (self[, periods, axis])	Equivalent to <i>shift</i> without copying data.

6.3.13 Accessors

Pandas provides dtype-specific methods under various accessors. These are separate namespaces within *Series* that only apply to specific data types.

Data Type	Accessor
Datetime, Timedelta, Period	<i>dt</i>
String	<i>str</i>
Categorical	<i>cat</i>
Sparse	<i>sparse</i>

Datetimelike properties

`Series.dt` can be used to access the values of the series as datetimelike and return several properties. These can be accessed like `Series.dt.<property>`.

Datetime properties

<code>Series.dt.date</code>	Returns numpy array of python datetime.date objects (namely, the date part of Timestamps without timezone information).
<code>Series.dt.time</code>	Returns numpy array of datetime.time.
<code>Series.dt.timetz</code>	Returns numpy array of datetime.time also containing timezone information.
<code>Series.dt.year</code>	The year of the datetime.
<code>Series.dt.month</code>	The month as January=1, December=12.
<code>Series.dt.day</code>	The days of the datetime.
<code>Series.dt.hour</code>	The hours of the datetime.
<code>Series.dt.minute</code>	The minutes of the datetime.
<code>Series.dt.second</code>	The seconds of the datetime.
<code>Series.dt.microsecond</code>	The microseconds of the datetime.
<code>Series.dt.nanosecond</code>	The nanoseconds of the datetime.
<code>Series.dt.week</code>	The week ordinal of the year.
<code>Series.dt.weekofyear</code>	The week ordinal of the year.
<code>Series.dt.dayofweek</code>	The day of the week with Monday=0, Sunday=6.
<code>Series.dt.weekday</code>	The day of the week with Monday=0, Sunday=6.
<code>Series.dt.dayofyear</code>	The ordinal day of the year.
<code>Series.dt.quarter</code>	The quarter of the date.
<code>Series.dt.is_month_start</code>	Indicates whether the date is the first day of the month.
<code>Series.dt.is_month_end</code>	Indicates whether the date is the last day of the month.
<code>Series.dt.is_quarter_start</code>	Indicator for whether the date is the first day of a quarter.
<code>Series.dt.is_quarter_end</code>	Indicator for whether the date is the last day of a quarter.
<code>Series.dt.is_year_start</code>	Indicate whether the date is the first day of a year.
<code>Series.dt.is_year_end</code>	Indicate whether the date is the last day of the year.
<code>Series.dt.is_leap_year</code>	Boolean indicator if the date belongs to a leap year.
<code>Series.dt.daysinmonth</code>	The number of days in the month.
<code>Series.dt.days_in_month</code>	The number of days in the month.
<code>Series.dt.tz</code>	Return timezone, if any.
<code>Series.dt.freq</code>	

pandas.Series.dt.date

Series.dt.date

Returns numpy array of python datetime.date objects (namely, the date part of Timestamps without timezone information).

pandas.Series.dt.time

Series.dt.time

Returns numpy array of datetime.time. The time part of the Timestamps.

pandas.Series.dt.timetz

Series.dt.timetz

Returns numpy array of datetime.time also containing timezone information. The time part of the Timestamps.

pandas.Series.dt.year

Series.dt.year

The year of the datetime.

pandas.Series.dt.month

Series.dt.month

The month as January=1, December=12.

pandas.Series.dt.day

Series.dt.day

The days of the datetime.

pandas.Series.dt.hour

Series.dt.hour

The hours of the datetime.

pandas.Series.dt.minute

Series.dt.minute

The minutes of the datetime.

pandas.Series.dt.second

Series.dt.second

The seconds of the datetime.

pandas.Series.dt.microsecond**Series.dt.microsecond**

The microseconds of the datetime.

pandas.Series.dt.nanosecond**Series.dt.nanosecond**

The nanoseconds of the datetime.

pandas.Series.dt.week**Series.dt.week**

The week ordinal of the year.

pandas.Series.dt.weekofyear**Series.dt.weekofyear**

The week ordinal of the year.

pandas.Series.dt.dayofweek**Series.dt.dayofweek**

The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the *dt* accessor) or DatetimeIndex.

Returns

Series or Index Containing integers indicating the day number.

See also:

Series.dt.dayofweek Alias.

Series.dt.weekday Alias.

Series.dt.day_name Returns the name of the day of the week.

Examples

```
>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31    5
2017-01-01    6
2017-01-02    0
2017-01-03    1
2017-01-04    2
2017-01-05    3
```

(continues on next page)

(continued from previous page)

```
2017-01-06    4
2017-01-07    5
2017-01-08    6
Freq: D, dtype: int64
```

pandas.Series.dt.weekday

Series.dt.weekday

The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the *dt* accessor) or DatetimeIndex.

Returns

Series or Index Containing integers indicating the day number.

See also:

Series.dt.dayofweek Alias.

Series.dt.weekday Alias.

Series.dt.day_name Returns the name of the day of the week.

Examples

```
>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31    5
2017-01-01    6
2017-01-02    0
2017-01-03    1
2017-01-04    2
2017-01-05    3
2017-01-06    4
2017-01-07    5
2017-01-08    6
Freq: D, dtype: int64
```

pandas.Series.dt.dayofyear

Series.dt.dayofyear

The ordinal day of the year.

pandas.Series.dt.quarter

Series.dt.quarter

The quarter of the date.

pandas.Series.dt.is_month_start**Series.dt.is_month_start**

Indicates whether the date is the first day of the month.

Returns

Series or array For Series, returns a Series with boolean values. For DatetimeIndex, returns a boolean array.

See also:

is_month_start Return a boolean indicating whether the date is the first day of the month.

is_month_end Return a boolean indicating whether the date is the last day of the month.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```
>>> s = pd.Series(pd.date_range("2018-02-27", periods=3))
>>> s
0    2018-02-27
1    2018-02-28
2    2018-03-01
dtype: datetime64[ns]
>>> s.dt.is_month_start
0    False
1    False
2     True
dtype: bool
>>> s.dt.is_month_end
0    False
1     True
2    False
dtype: bool
```

```
>>> idx = pd.date_range("2018-02-27", periods=3)
>>> idx.is_month_start
array([False, False,  True])
>>> idx.is_month_end
array([False,  True, False])
```

pandas.Series.dt.is_month_end**Series.dt.is_month_end**

Indicates whether the date is the last day of the month.

Returns

Series or array For Series, returns a Series with boolean values. For DatetimeIndex, returns a boolean array.

See also:

is_month_start Return a boolean indicating whether the date is the first day of the month.

is_month_end Return a boolean indicating whether the date is the last day of the month.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on `DatetimeIndex`.

```
>>> s = pd.Series(pd.date_range("2018-02-27", periods=3))
>>> s
0    2018-02-27
1    2018-02-28
2    2018-03-01
dtype: datetime64[ns]
>>> s.dt.is_month_start
0    False
1    False
2     True
dtype: bool
>>> s.dt.is_month_end
0    False
1     True
2    False
dtype: bool
```

```
>>> idx = pd.date_range("2018-02-27", periods=3)
>>> idx.is_month_start
array([False, False,  True])
>>> idx.is_month_end
array([False,  True, False])
```

`pandas.Series.dt.is_quarter_start`

`Series.dt.is_quarter_start`

Indicator for whether the date is the first day of a quarter.

Returns

is_quarter_start [Series or DatetimeIndex] The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

quarter Return the quarter of the date.

is_quarter_end Similar property for indicating the quarter start.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on `DatetimeIndex`.

```
>>> df = pd.DataFrame({'dates': pd.date_range("2017-03-30",
...                                           periods=4)})
>>> df.assign(quarter=df.dates.dt.quarter,
...           is_quarter_start=df.dates.dt.is_quarter_start)
   dates      quarter  is_quarter_start
0 2017-03-30         1                False
1 2017-03-31         1                False
2 2017-04-01         2                 True
3 2017-04-02         2                False
```

```
>>> idx = pd.date_range('2017-03-30', periods=4)
>>> idx
DatetimeIndex(['2017-03-30', '2017-03-31', '2017-04-01', '2017-04-02'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_quarter_start
array([False, False,  True, False])
```

pandas.Series.dt.is_quarter_end

Series.dt.is_quarter_end

Indicator for whether the date is the last day of a quarter.

Returns

is_quarter_end [Series or DatetimeIndex] The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

quarter Return the quarter of the date.

is_quarter_start Similar property indicating the quarter start.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on `DatetimeIndex`.

```
>>> df = pd.DataFrame({'dates': pd.date_range("2017-03-30",
...                                           periods=4)})
>>> df.assign(quarter=df.dates.dt.quarter,
...           is_quarter_end=df.dates.dt.is_quarter_end)
   dates      quarter  is_quarter_end
0 2017-03-30         1                False
1 2017-03-31         1                 True
2 2017-04-01         2                False
3 2017-04-02         2                False
```

```
>>> idx = pd.date_range('2017-03-30', periods=4)
>>> idx
DatetimeIndex(['2017-03-30', '2017-03-31', '2017-04-01', '2017-04-02'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_quarter_end
array([False,  True,  False,  False])
```

pandas.Series.dt.is_year_start

Series.dt.is_year_start

Indicate whether the date is the first day of a year.

Returns

Series or DatetimeIndex The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

is_year_end Similar property indicating the last day of the year.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on `DatetimeIndex`.

```
>>> dates = pd.Series(pd.date_range("2017-12-30", periods=3))
>>> dates
0    2017-12-30
1    2017-12-31
2    2018-01-01
dtype: datetime64[ns]
```

```
>>> dates.dt.is_year_start
0    False
1    False
2     True
dtype: bool
```

```
>>> idx = pd.date_range("2017-12-30", periods=3)
>>> idx
DatetimeIndex(['2017-12-30', '2017-12-31', '2018-01-01'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_year_start
array([False,  False,  True])
```

pandas.Series.dt.is_year_end

Series.dt.is_year_end

Indicate whether the date is the last day of the year.

Returns

Series or DatetimeIndex The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

is_year_start Similar property indicating the start of the year.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on `DatetimeIndex`.

```
>>> dates = pd.Series(pd.date_range("2017-12-30", periods=3))
>>> dates
0    2017-12-30
1    2017-12-31
2    2018-01-01
dtype: datetime64[ns]
```

```
>>> dates.dt.is_year_end
0    False
1     True
2    False
dtype: bool
```

```
>>> idx = pd.date_range("2017-12-30", periods=3)
>>> idx
DatetimeIndex(['2017-12-30', '2017-12-31', '2018-01-01'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_year_end
array([False,  True,  False])
```

pandas.Series.dt.is_leap_year

Series.dt.is_leap_year

Boolean indicator if the date belongs to a leap year.

A leap year is a year, which has 366 days (instead of 365) including 29th of February as an intercalary day. Leap years are years which are multiples of four with the exception of years divisible by 100 but not by 400.

Returns

Series or ndarray Booleans indicating if dates belong to a leap year.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on `Date-timeIndex`.

```
>>> idx = pd.date_range("2012-01-01", "2015-01-01", freq="Y")
>>> idx
DatetimeIndex(['2012-12-31', '2013-12-31', '2014-12-31'],
              dtype='datetime64[ns]', freq='A-DEC')
>>> idx.is_leap_year
array([ True, False, False], dtype=bool)
```

```
>>> dates = pd.Series(idx)
>>> dates_series
0    2012-12-31
1    2013-12-31
2    2014-12-31
dtype: datetime64[ns]
>>> dates_series.dt.is_leap_year
0     True
1    False
2    False
dtype: bool
```

`pandas.Series.dt.daysinmonth`

`Series.dt.daysinmonth`

The number of days in the month.

`pandas.Series.dt.days_in_month`

`Series.dt.days_in_month`

The number of days in the month.

`pandas.Series.dt.tz`

`Series.dt.tz`

Return timezone, if any.

Returns

`datetime.tzinfo`, `pytz.tzinfo.BaseTZInfo`, `dateutil.tz.tz.tzfile`, or `None`

Returns `None` when the array is tz-naive.

`pandas.Series.dt.freq`

`Series.dt.freq`

Datetime methods

<code>Series.dt.to_period(self, *args, **kwargs)</code>	Cast to PeriodArray/Index at a particular frequency.
<code>Series.dt.to_pydatetime(self)</code>	Return the data as an array of native Python datetime objects.
<code>Series.dt.tz_localize(self, *args, **kwargs)</code>	Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index.
<code>Series.dt.tz_convert(self, *args, **kwargs)</code>	Convert tz-aware Datetime Array/Index from one time zone to another.
<code>Series.dt.normalize(self, *args, **kwargs)</code>	Convert times to midnight.
<code>Series.dt.strftime(self, *args, **kwargs)</code>	Convert to Index using specified <code>date_format</code> .
<code>Series.dt.round(self, *args, **kwargs)</code>	Perform round operation on the data to the specified <i>freq</i> .
<code>Series.dt.floor(self, *args, **kwargs)</code>	Perform floor operation on the data to the specified <i>freq</i> .
<code>Series.dt.ceil(self, *args, **kwargs)</code>	Perform ceil operation on the data to the specified <i>freq</i> .
<code>Series.dt.month_name(self, *args, **kwargs)</code>	Return the month names of the DateTimeIndex with specified locale.
<code>Series.dt.day_name(self, *args, **kwargs)</code>	Return the day names of the DateTimeIndex with specified locale.

pandas.Series.dt.to_period

`Series.dt.to_period(self, *args, **kwargs)`

Cast to PeriodArray/Index at a particular frequency.

Converts DatetimeArray/Index to PeriodArray/Index.

Parameters

freq [str or Offset, optional] One of pandas' *offset strings* or an Offset object. Will be inferred by default.

Returns

PeriodArray/Index

Raises

ValueError When converting a DatetimeArray/Index with non-regular values, so that a frequency cannot be inferred.

See also:

PeriodIndex Immutable ndarray holding ordinal values.

DatetimeIndex.to_pydatetime Return DatetimeIndex as object.

Examples

```
>>> df = pd.DataFrame({"y": [1, 2, 3]},
...                    index=pd.to_datetime(["2000-03-31 00:00:00",
```

(continues on next page)

(continued from previous page)

```

...         "2000-05-31 00:00:00",
...         "2000-08-31 00:00:00"]])
>>> df.index.to_period("M")
PeriodIndex(['2000-03', '2000-05', '2000-08'],
            dtype='period[M]', freq='M')

```

Infer the daily frequency

```

>>> idx = pd.date_range("2017-01-01", periods=2)
>>> idx.to_period()
PeriodIndex(['2017-01-01', '2017-01-02'],
            dtype='period[D]', freq='D')

```

pandas.Series.dt.to_pydatetime

Series.dt.to_pydatetime(*self*)

Return the data as an array of native Python datetime objects.

Timezone information is retained if present.

Warning: Python's datetime uses microsecond resolution, which is lower than pandas (nanosecond). The values are truncated.

Returns

`numpy.ndarray` Object dtype array containing native Python datetime objects.

See also:

`datetime.datetime` Standard library value for a datetime.

Examples

```

>>> s = pd.Series(pd.date_range('20180310', periods=2))
>>> s
0    2018-03-10
1    2018-03-11
dtype: datetime64[ns]

```

```

>>> s.dt.to_pydatetime()
array([datetime.datetime(2018, 3, 10, 0, 0),
       datetime.datetime(2018, 3, 11, 0, 0)], dtype=object)

```

pandas' nanosecond precision is truncated to microseconds.

```

>>> s = pd.Series(pd.date_range('20180310', periods=2, freq='ns'))
>>> s
0    2018-03-10 00:00:00.000000000

```

(continues on next page)

(continued from previous page)

```
1 2018-03-10 00:00:00.000000001
dtype: datetime64[ns]
```

```
>>> s.dt.to_pydatetime()
array([datetime.datetime(2018, 3, 10, 0, 0),
       datetime.datetime(2018, 3, 10, 0, 0)], dtype=object)
```

pandas.Series.dt.tz_localize

`Series.dt.tz_localize(self, *args, **kwargs)`

Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index.

This method takes a time zone (tz) naive Datetime Array/Index object and makes this time zone aware. It does not move the time to another time zone. Time zone localization helps to switch from time zone aware to time zone unaware objects.

Parameters

tz [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone to convert timestamps to. Passing None will remove the time zone information preserving local time.

ambiguous ['infer', 'NaT', bool array, default 'raise'] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the *ambiguous* parameter dictates how ambiguous times should be handled.

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False signifies a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times

nonexistent ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift_forward' will shift the nonexistent time forward to the closest existing time
- 'shift_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise a NonExistentTimeError if there are nonexistent times

New in version 0.24.0.

errors [{'raise', 'coerce'}, default None]

- 'raise' will raise a NonExistentTimeError if a timestamp is not valid in the specified time zone (e.g. due to a transition from or to DST time). Use `nonexistent='raise'` instead.

- 'coerce' will return NaT if the timestamp can not be converted to the specified time zone. Use `nonexistent='NaT'` instead.

Deprecated since version 0.24.0.

Returns

Same type as `self` Array/Index converted to the specified time zone.

Raises

TypeError If the Datetime Array/Index is tz-aware and `tz` is not `None`.

See also:

DatetimeIndex.tz_convert Convert tz-aware DatetimeIndex from one time zone to another.

Examples

```
>>> tz_naive = pd.date_range('2018-03-01 09:00', periods=3)
>>> tz_naive
DatetimeIndex(['2018-03-01 09:00:00', '2018-03-02 09:00:00',
              '2018-03-03 09:00:00'],
              dtype='datetime64[ns]', freq='D')
```

Localize DatetimeIndex in US/Eastern time zone:

```
>>> tz_aware = tz_naive.tz_localize(tz='US/Eastern')
>>> tz_aware
DatetimeIndex(['2018-03-01 09:00:00-05:00',
              '2018-03-02 09:00:00-05:00',
              '2018-03-03 09:00:00-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq='D')
```

With the `tz=None`, we can remove the time zone information while keeping the local time (not converted to UTC):

```
>>> tz_aware.tz_localize(None)
DatetimeIndex(['2018-03-01 09:00:00', '2018-03-02 09:00:00',
              '2018-03-03 09:00:00'],
              dtype='datetime64[ns]', freq='D')
```

Be careful with DST changes. When there is sequential data, pandas can infer the DST time: `>>> s = pd.to_datetime(pd.Series(['2018-10-28 01:30:00', ... '2018-10-28 02:00:00', ... '2018-10-28 02:30:00', ... '2018-10-28 02:00:00', ... '2018-10-28 02:30:00', ... '2018-10-28 03:00:00', ... '2018-10-28 03:30:00'])) >>> s.dt.tz_localize('CET', ambiguous='infer')` 0 2018-10-28 01:30:00+02:00 1 2018-10-28 02:00:00+02:00 2 2018-10-28 02:30:00+02:00 3 2018-10-28 02:00:00+01:00 4 2018-10-28 02:30:00+01:00 5 2018-10-28 03:00:00+01:00 6 2018-10-28 03:30:00+01:00 dtype: datetime64[ns, CET]

In some cases, inferring the DST is impossible. In such cases, you can pass an ndarray to the `ambiguous` parameter to set the DST explicitly

```
>>> s = pd.to_datetime(pd.Series(['2018-10-28 01:20:00',
...                             '2018-10-28 02:36:00',
...                             '2018-10-28 03:46:00']))
>>> s.dt.tz_localize('CET', ambiguous=np.array([True, True, False]))
```

(continues on next page)

(continued from previous page)

```
0    2015-03-29 03:00:00+02:00
1    2015-03-29 03:30:00+02:00
dtype: datetime64[ns, Europe/Warsaw]
```

If the DST transition causes nonexistent times, you can shift these dates forward or backwards with a `timedelta` object or `'shift_forward'` or `'shift_backwards'`. `>>> s = pd.to_datetime(pd.Series(['2015-03-29 02:30:00', ... '2015-03-29 03:30:00'])) >>> s.dt.tz_localize('Europe/Warsaw', nonexistent='shift_forward')` `0 2015-03-29 03:00:00+02:00 1 2015-03-29 03:30:00+02:00 dtype: datetime64[ns, 'Europe/Warsaw']` `>>> s.dt.tz_localize('Europe/Warsaw', nonexistent='shift_backward')` `0 2015-03-29 01:59:59.999999999+01:00 1 2015-03-29 03:30:00+02:00 dtype: datetime64[ns, 'Europe/Warsaw']` `>>> s.dt.tz_localize('Europe/Warsaw', nonexistent=pd.Timedelta('1H'))` `0 2015-03-29 03:30:00+02:00 1 2015-03-29 03:30:00+02:00 dtype: datetime64[ns, 'Europe/Warsaw']`

pandas.Series.dt.tz_convert

`Series.dt.tz_convert(self, *args, **kwargs)`

Convert tz-aware Datetime Array/Index from one time zone to another.

Parameters

tz [str, `pytz.timezone`, `dateutil.tz.tzfile` or `None`] Time zone for time. Corresponding timestamps would be converted to this time zone of the Datetime Array/Index. A `tz` of `None` will convert to UTC and remove the timezone information.

Returns

Array or Index

Raises

TypeError If Datetime Array/Index is tz-naive.

See also:

DatetimeIndex.tz A timezone that has a variable offset from UTC.

DatetimeIndex.tz_localize Localize tz-naive DatetimeIndex to a given time zone, or remove time-zone from a tz-aware DatetimeIndex.

Examples

With the `tz` parameter, we can change the DatetimeIndex to other time zones:

```
>>> dti = pd.date_range(start='2014-08-01 09:00',
...                      freq='H', periods=3, tz='Europe/Berlin')
```

```
>>> dti
DatetimeIndex(['2014-08-01 09:00:00+02:00',
               '2014-08-01 10:00:00+02:00',
               '2014-08-01 11:00:00+02:00'],
              dtype='datetime64[ns, Europe/Berlin]', freq='H')
```

```
>>> dti.tz_convert('US/Central')
DatetimeIndex(['2014-08-01 02:00:00-05:00',
              '2014-08-01 03:00:00-05:00',
              '2014-08-01 04:00:00-05:00'],
              dtype='datetime64[ns, US/Central]', freq='H')
```

With the `tz=None`, we can remove the timezone (after converting to UTC if necessary):

```
>>> dti = pd.date_range(start='2014-08-01 09:00', freq='H',
...                      periods=3, tz='Europe/Berlin')
```

```
>>> dti
DatetimeIndex(['2014-08-01 09:00:00+02:00',
              '2014-08-01 10:00:00+02:00',
              '2014-08-01 11:00:00+02:00'],
              dtype='datetime64[ns, Europe/Berlin]', freq='H')
```

```
>>> dti.tz_convert(None)
DatetimeIndex(['2014-08-01 07:00:00',
              '2014-08-01 08:00:00',
              '2014-08-01 09:00:00'],
              dtype='datetime64[ns]', freq='H')
```

pandas.Series.dt.normalize

`Series.dt.normalize(self, *args, **kwargs)`

Convert times to midnight.

The time component of the date-time is converted to midnight i.e. 00:00:00. This is useful in cases, when the time does not matter. Length is unaltered. The timezones are unaffected.

This method is available on Series with datetime values under the `.dt` accessor, and directly on Date-time Array/Index.

Returns

DatetimeArray, DatetimeIndex or Series The same type as the original data. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

floor Floor the datetimes to the specified freq.

ceil Ceil the datetimes to the specified freq.

round Round the datetimes to the specified freq.

Examples

```
>>> idx = pd.date_range(start='2014-08-01 10:00', freq='H',
...                      periods=3, tz='Asia/Calcutta')
>>> idx
```

(continues on next page)

(continued from previous page)

```
DatetimeIndex(['2014-08-01 10:00:00+05:30',
               '2014-08-01 11:00:00+05:30',
               '2014-08-01 12:00:00+05:30'],
              dtype='datetime64[ns, Asia/Calcutta]', freq='H')
>>> idx.normalize()
DatetimeIndex(['2014-08-01 00:00:00+05:30',
               '2014-08-01 00:00:00+05:30',
               '2014-08-01 00:00:00+05:30'],
              dtype='datetime64[ns, Asia/Calcutta]', freq=None)
```

pandas.Series.dt.strftime

`Series.dt.strftime(self, *args, **kwargs)`

Convert to Index using specified `date_format`.

Return an Index of formatted strings specified by `date_format`, which supports the same string format as the python standard library. Details of the string format can be found in [python string format doc](#).

Parameters

date_format [str] Date format string (e.g. “%Y-%m-%d”).

Returns

Index Index of formatted strings.

See also:

`to_datetime` Convert the given argument to datetime.

`DatetimeIndex.normalize` Return `DatetimeIndex` with times to midnight.

`DatetimeIndex.round` Round the `DatetimeIndex` to the specified `freq`.

`DatetimeIndex.floor` Floor the `DatetimeIndex` to the specified `freq`.

Examples

```
>>> rng = pd.date_range(pd.Timestamp("2018-03-10 09:00"),
...                    periods=3, freq='s')
>>> rng.strftime('%B %d, %Y, %r')
Index(['March 10, 2018, 09:00:00 AM', 'March 10, 2018, 09:00:01 AM',
       'March 10, 2018, 09:00:02 AM'],
      dtype='object')
```

pandas.Series.dt.round

`Series.dt.round(self, *args, **kwargs)`

Perform round operation on the data to the specified `freq`.

Parameters

freq [str or Offset] The frequency level to round the index to. Must be a fixed frequency like 'S' (second) not 'ME' (month end). See *frequency aliases* for a list of possible *freq* values.

ambiguous ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for `DatetimeIndex`:

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an `AmbiguousTimeError` if there are ambiguous times

New in version 0.24.0.

nonexistent ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift_forward' will shift the nonexistent time forward to the closest existing time
- 'shift_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise an `NonExistentTimeError` if there are nonexistent times

New in version 0.24.0.

Returns

DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a `DatetimeIndex` or `TimedeltaIndex`, or a `Series` with the same index for a `Series`.

Raises

ValueError if the *freq* cannot be converted.

Examples

DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
              '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.round('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
              '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Series

```
>>> pd.Series(rng).dt.round("H")
0    2018-01-01 12:00:00
1    2018-01-01 12:00:00
2    2018-01-01 12:00:00
dtype: datetime64[ns]
```

pandas.Series.dt.floor

`Series.dt.floor(self, *args, **kwargs)`

Perform floor operation on the data to the specified *freq*.

Parameters

freq [str or Offset] The frequency level to floor the index to. Must be a fixed frequency like 'S' (second) not 'ME' (month end). See *frequency aliases* for a list of possible *freq* values.

ambiguous ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for DateTimeIndex:

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times

New in version 0.24.0.

nonexistent ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift_forward' will shift the nonexistent time forward to the closest existing time
- 'shift_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise a NonExistentTimeError if there are nonexistent times

New in version 0.24.0.

Returns

DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a DateTimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

ValueError if the *freq* cannot be converted.

Examples

DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
              '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.floor('H')
DatetimeIndex(['2018-01-01 11:00:00', '2018-01-01 12:00:00',
              '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Series

```
>>> pd.Series(rng).dt.floor("H")
0    2018-01-01 11:00:00
1    2018-01-01 12:00:00
2    2018-01-01 12:00:00
dtype: datetime64[ns]
```

pandas.Series.dt.ceil

`Series.dt.ceil(self, *args, **kwargs)`

Perform ceil operation on the data to the specified *freq*.

Parameters

freq [str or Offset] The frequency level to ceil the index to. Must be a fixed frequency like 'S' (second) not 'ME' (month end). See *frequency aliases* for a list of possible *freq* values.

ambiguous ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for `DatetimeIndex`:

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an `AmbiguousTimeError` if there are ambiguous times

New in version 0.24.0.

nonexistent ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift_forward' will shift the nonexistent time forward to the closest existing time
- 'shift_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times

- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise an NonExistentTimeError if there are nonexistent times

New in version 0.24.0.

Returns

DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a DateTimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

ValueError if the *freq* cannot be converted.

Examples

DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
              '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.ceil('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
              '2018-01-01 13:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Series

```
>>> pd.Series(rng).dt.ceil("H")
0    2018-01-01 12:00:00
1    2018-01-01 12:00:00
2    2018-01-01 13:00:00
dtype: datetime64[ns]
```

pandas.Series.dt.month_name

`Series.dt.month_name(self, *args, **kwargs)`

Return the month names of the DateTimeIndex with specified locale.

New in version 0.23.0.

Parameters

locale [str, optional] Locale determining the language in which to return the month name. Default is English locale.

Returns

Index Index of month names.

Examples

```
>>> idx = pd.date_range(start='2018-01', freq='M', periods=3)
>>> idx
DatetimeIndex(['2018-01-31', '2018-02-28', '2018-03-31'],
              dtype='datetime64[ns]', freq='M')
>>> idx.month_name()
Index(['January', 'February', 'March'], dtype='object')
```

pandas.Series.dt.day_name

`Series.dt.day_name(self, *args, **kwargs)`

Return the day names of the DateTimeIndex with specified locale.

New in version 0.23.0.

Parameters

locale [str, optional] Locale determining the language in which to return the day name. Default is English locale.

Returns

Index Index of day names.

Examples

```
>>> idx = pd.date_range(start='2018-01-01', freq='D', periods=3)
>>> idx
DatetimeIndex(['2018-01-01', '2018-01-02', '2018-01-03'],
              dtype='datetime64[ns]', freq='D')
>>> idx.day_name()
Index(['Monday', 'Tuesday', 'Wednesday'], dtype='object')
```

pandas.Series.dt.start_time

`Series.dt.start_time`

pandas.Series.dt.end_time`Series.dt.end_time`**Timedelta properties**

<i>Series.dt.days</i>	Number of days for each element.
<i>Series.dt.seconds</i>	Number of seconds (≥ 0 and less than 1 day) for each element.
<i>Series.dt.microseconds</i>	Number of microseconds (≥ 0 and less than 1 second) for each element.
<i>Series.dt.nanoseconds</i>	Number of nanoseconds (≥ 0 and less than 1 microsecond) for each element.
<i>Series.dt.components</i>	Return a Dataframe of the components of the Timedeltas.

pandas.Series.dt.days`Series.dt.days`

Number of days for each element.

pandas.Series.dt.seconds`Series.dt.seconds`Number of seconds (≥ 0 and less than 1 day) for each element.**pandas.Series.dt.microseconds**`Series.dt.microseconds`Number of microseconds (≥ 0 and less than 1 second) for each element.**pandas.Series.dt.nanoseconds**`Series.dt.nanoseconds`Number of nanoseconds (≥ 0 and less than 1 microsecond) for each element.**pandas.Series.dt.components**`Series.dt.components`

Return a Dataframe of the components of the Timedeltas.

Returns**DataFrame**

Examples

```

>>> s = pd.Series(pd.to_timedelta(np.arange(5), unit='s'))
>>> s
0    00:00:00
1    00:00:01
2    00:00:02
3    00:00:03
4    00:00:04
dtype: timedelta64[ns]
>>> s.dt.components
   days  hours  minutes  seconds  milliseconds  microseconds  nanoseconds
0     0     0         0         0             0             0             0
1     0     0         0          1             0             0             0
2     0     0         0          2             0             0             0
3     0     0         0          3             0             0             0
4     0     0         0          4             0             0             0

```

Timedelta methods

Series.dt.to_pytimedelta(self) Return an array of native *datetime.timedelta* objects.

Series.dt.total_seconds(self, **args*, ***kwargs*) Return total duration of each element expressed in seconds.

pandas.Series.dt.to_pytimedelta

Series.dt.to_pytimedelta(self)
Return an array of native *datetime.timedelta* objects.

Python's standard *datetime* library uses a different representation *timedelta*'s. This method converts a Series of pandas *Timedeltas* to *datetime.timedelta* format with the same length as the original Series.

Returns

a [numpy.ndarray] Array of 1D containing data with *datetime.timedelta* type.

See also:

[`datetime.timedelta`](#)

Examples

```

>>> s = pd.Series(pd.to_timedelta(np.arange(5), unit='d'))
>>> s
0    0 days
1    1 days
2    2 days
3    3 days
4    4 days
dtype: timedelta64[ns]

```

```
>>> s.dt.to_pytimedelta()
array([datetime.timedelta(0), datetime.timedelta(1),
       datetime.timedelta(2), datetime.timedelta(3),
       datetime.timedelta(4)], dtype=object)
```

pandas.Series.dt.total_seconds

`Series.dt.total_seconds(self, *args, **kwargs)`

Return total duration of each element expressed in seconds.

This method is available directly on `TimedeltaArray`, `TimedeltaIndex` and on `Series` containing `timedelta` values under the `.dt` namespace.

Returns

seconds [[ndarray, Float64Index, Series]] When the calling object is a `TimedeltaArray`, the return type is `ndarray`. When the calling object is a `TimedeltaIndex`, the return type is a `Float64Index`. When the calling object is a `Series`, the return type is `Series` of type `float64` whose index is the same as the original.

See also:

`datetime.timedelta.total_seconds` Standard library version of this method.

`TimedeltaIndex.components` Return a `DataFrame` with components of each `Timedelta`.

Examples

Series

```
>>> s = pd.Series(pd.to_timedelta(np.arange(5), unit='d'))
>>> s
0    0 days
1    1 days
2    2 days
3    3 days
4    4 days
dtype: timedelta64[ns]
```

```
>>> s.dt.total_seconds()
0         0.0
1    86400.0
2   172800.0
3   259200.0
4   345600.0
dtype: float64
```

TimedeltaIndex

```
>>> idx = pd.to_timedelta(np.arange(5), unit='d')
>>> idx
TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'],
               dtype='timedelta64[ns]', freq=None)
```

```
>>> idx.total_seconds()
Float64Index([0.0, 86400.0, 172800.0, 259200.00000000003, 345600.0],
              dtype='float64')
```

String handling

`Series.str` can be used to access the values of the series as strings and apply several methods to it. These can be accessed like `Series.str.<function/property>`.

<code>Series.str.capitalize(self)</code>	Convert strings in the Series/Index to be capitalized.
<code>Series.str.casefold(self)</code>	Convert strings in the Series/Index to be casefolded.
<code>Series.str.cat(self[, others, sep, na_rep, join])</code>	Concatenate strings in the Series/Index with given separator.
<code>Series.str.center(self, width[, fillchar])</code>	Filling left and right side of strings in the Series/Index with an additional character.
<code>Series.str.contains(self, pat[, case, ...])</code>	Test if pattern or regex is contained within a string of a Series or Index.
<code>Series.str.count(self, pat[, flags])</code>	Count occurrences of pattern in each string of the Series/Index.
<code>Series.str.decode(self, encoding[, errors])</code>	Decode character string in the Series/Index using indicated encoding.
<code>Series.str.encode(self, encoding[, errors])</code>	Encode character string in the Series/Index using indicated encoding.
<code>Series.str.endswith(self, pat[, na])</code>	Test if the end of each string element matches a pattern.
<code>Series.str.extract(self, pat[, flags, expand])</code>	Extract capture groups in the regex <i>pat</i> as columns in a DataFrame.
<code>Series.str.extractall(self, pat[, flags])</code>	For each subject string in the Series, extract groups from all matches of regular expression <i>pat</i> .
<code>Series.str.find(self, sub[, start, end])</code>	Return lowest indexes in each strings in the Series/Index where the substring is fully contained between [start:end].
<code>Series.str.findall(self, pat[, flags])</code>	Find all occurrences of pattern or regular expression in the Series/Index.
<code>Series.str.get(self, i)</code>	Extract element from each component at specified position.
<code>Series.str.index(self, sub[, start, end])</code>	Return lowest indexes in each strings where the substring is fully contained between [start:end].
<code>Series.str.join(self, sep)</code>	Join lists contained as elements in the Series/Index with passed delimiter.
<code>Series.str.len(self)</code>	Compute the length of each element in the Series/Index.
<code>Series.str.ljust(self, width[, fillchar])</code>	Filling right side of strings in the Series/Index with an additional character.
<code>Series.str.lower(self)</code>	Convert strings in the Series/Index to lowercase.
<code>Series.str.lstrip(self[, to_strip])</code>	Remove leading and trailing characters.
<code>Series.str.match(self, pat[, case, flags, na])</code>	Determine if each string matches a regular expression.

Continued on next page

Table 45 – continued from previous page

<code>Series.str.normalize(self, form)</code>	Return the Unicode normal form for the strings in the Series/Index.
<code>Series.str.pad(self, width[, side, fillchar])</code>	Pad strings in the Series/Index up to width.
<code>Series.str.partition(self[, sep, expand])</code>	Split the string at the first occurrence of <i>sep</i> .
<code>Series.str.repeat(self, repeats)</code>	Duplicate each string in the Series or Index.
<code>Series.str.replace(self, pat, repl[, n, ...])</code>	Replace occurrences of pattern/regex in the Series/Index with some other string.
<code>Series.str.rfind(self, sub[, start, end])</code>	Return highest indexes in each strings in the Series/Index where the substring is fully contained between [start:end].
<code>Series.str.rindex(self, sub[, start, end])</code>	Return highest indexes in each strings where the substring is fully contained between [start:end].
<code>Series.str.rjust(self, width[, fillchar])</code>	Filling left side of strings in the Series/Index with an additional character.
<code>Series.str.rpartition(self[, sep, expand])</code>	Split the string at the last occurrence of <i>sep</i> .
<code>Series.str.rstrip(self[, to_strip])</code>	Remove leading and trailing characters.
<code>Series.str.slice(self[, start, stop, step])</code>	Slice substrings from each element in the Series or Index.
<code>Series.str.slice_replace(self[, start, ...])</code>	Replace a positional slice of a string with another value.
<code>Series.str.split(self[, pat, n, expand])</code>	Split strings around given separator/delimiter.
<code>Series.str.rsplit(self[, pat, n, expand])</code>	Split strings around given separator/delimiter.
<code>Series.str.startswith(self, pat[, na])</code>	Test if the start of each string element matches a pattern.
<code>Series.str.strip(self[, to_strip])</code>	Remove leading and trailing characters.
<code>Series.str.swapcase(self)</code>	Convert strings in the Series/Index to be swapped.
<code>Series.str.title(self)</code>	Convert strings in the Series/Index to titlecase.
<code>Series.str.translate(self, table)</code>	Map all characters in the string through the given mapping table.
<code>Series.str.upper(self)</code>	Convert strings in the Series/Index to uppercase.
<code>Series.str.wrap(self, width, **kwargs)</code>	Wrap long strings in the Series/Index to be formatted in paragraphs with length less than a given width.
<code>Series.str.zfill(self, width)</code>	Pad strings in the Series/Index by prepending '0' characters.
<code>Series.str.isalnum(self)</code>	Check whether all characters in each string are alphanumeric.
<code>Series.str.isalpha(self)</code>	Check whether all characters in each string are alphabetic.
<code>Series.str.isdigit(self)</code>	Check whether all characters in each string are digits.
<code>Series.str.isspace(self)</code>	Check whether all characters in each string are whitespace.
<code>Series.str.islower(self)</code>	Check whether all characters in each string are lowercase.
<code>Series.str.isupper(self)</code>	Check whether all characters in each string are uppercase.
<code>Series.str.istitle(self)</code>	Check whether all characters in each string are titlecase.

Continued on next page

Table 45 – continued from previous page

<code>Series.str.isnumeric(self)</code>	Check whether all characters in each string are numeric.
<code>Series.str.isdecimal(self)</code>	Check whether all characters in each string are decimal.
<code>Series.str.get_dummies(self[, sep])</code>	Split each string in the Series by <code>sep</code> and return a DataFrame of dummy/indicator variables.

pandas.Series.str.capitalize**Series.str.capitalize(self)**

Convert strings in the Series/Index to be capitalized.

Equivalent to `str.capitalize()`.

Returns

Series/Index of objects

See also:

Series.str.lower Converts all characters to lowercase.

Series.str.upper Converts all characters to uppercase.

Series.str.title Converts first character of each word to uppercase and remaining to lowercase.

Series.str.capitalize Converts first character to uppercase and remaining to lowercase.

Series.str.swapcase Converts uppercase to lowercase and lowercase to uppercase.

Series.str.casefold Removes all case distinctions in the string.

Examples

```
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0          lower
1        CAPITALS
2  this is a sentence
3        SwApCaSe
dtype: object
```

```
>>> s.str.lower()
0          lower
1        capitals
2  this is a sentence
3        swapcase
dtype: object
```

```
>>> s.str.upper()
0          LOWER
1        CAPITALS
2  THIS IS A SENTENCE
```

(continues on next page)

(continued from previous page)

```
3          SWAPCASE
dtype: object
```

```
>>> s.str.title()
0          Lower
1        Capitals
2  This Is A Sentence
3        Swapcase
dtype: object
```

```
>>> s.str.capitalize()
0          Lower
1        Capitals
2  This is a sentence
3        Swapcase
dtype: object
```

```
>>> s.str.swapcase()
0          LOWER
1        capitals
2  THIS IS A SENTENCE
3        sWaPcAsE
dtype: object
```

pandas.Series.str.casefold

`Series.str.casefold(self)`

Convert strings in the Series/Index to be casefolded.

New in version 0.25.0.

Equivalent to `str.casefold()`.

Returns

Series/Index of objects

See also:

`Series.str.lower` Converts all characters to lowercase.

`Series.str.upper` Converts all characters to uppercase.

`Series.str.title` Converts first character of each word to uppercase and remaining to lowercase.

`Series.str.capitalize` Converts first character to uppercase and remaining to lowercase.

`Series.str.swapcase` Converts uppercase to lowercase and lowercase to uppercase.

`Series.str.casefold` Removes all case distinctions in the string.

Examples

```
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0          lower
1      CAPITALS
2  this is a sentence
3      SwApCaSe
dtype: object
```

```
>>> s.str.lower()
0          lower
1      capitals
2  this is a sentence
3      swapcase
dtype: object
```

```
>>> s.str.upper()
0          LOWER
1      CAPITALS
2  THIS IS A SENTENCE
3      SWAPCASE
dtype: object
```

```
>>> s.str.title()
0          Lower
1      Capitals
2  This Is A Sentence
3      Swapcase
dtype: object
```

```
>>> s.str.capitalize()
0          Lower
1      Capitals
2  This is a sentence
3      Swapcase
dtype: object
```

```
>>> s.str.swapcase()
0          LOWER
1      capitals
2  THIS IS A SENTENCE
3      sWaPcAsE
dtype: object
```

pandas.Series.str.cat

`Series.str.cat(self, others=None, sep=None, na_rep=None, join=None)`
Concatenate strings in the Series/Index with given separator.

If *others* is specified, this function concatenates the Series/Index and elements of *others* element-wise.

If *others* is not passed, then all values in the Series/Index are concatenated into a single string with a given *sep*.

Parameters

others [Series, Index, DataFrame, np.ndarray or list-like] Series, Index, DataFrame, np.ndarray (one- or two-dimensional) and other list-likes of strings must have the same length as the calling Series/Index, with the exception of indexed objects (i.e. Series/Index/DataFrame) if *join* is not None.

If *others* is a list-like that contains a combination of Series, Index or np.ndarray (1-dim), then all elements will be unpacked and must satisfy the above criteria individually.

If *others* is None, the method returns the concatenation of all strings in the calling Series/Index.

sep [str, default ''] The separator between the different elements/columns. By default the empty string '' is used.

na_rep [str or None, default None] Representation that is inserted for all missing values:

- If *na_rep* is None, and *others* is None, missing values in the Series/Index are omitted from the result.
- If *na_rep* is None, and *others* is not None, a row containing a missing value in any of the columns (before concatenation) will have a missing value in the result.

join [{'left', 'right', 'outer', 'inner'}, default None] Determines the join-style between the calling Series/Index and any Series/Index/DataFrame in *others* (objects without an index need to match the length of the calling Series/Index). If None, alignment is disabled, but this option will be removed in a future version of pandas and replaced with a default of 'left'. To disable alignment, use *.values* on any Series/Index/DataFrame in *others*.

New in version 0.23.0.

Returns

str, Series or Index If *others* is None, *str* is returned, otherwise a *Series/Index* (same type as caller) of objects is returned.

See also:

split Split each string in the Series/Index.

join Join lists contained as elements in the Series/Index.

Examples

When not passing *others*, all values are concatenated into a single string:

```
>>> s = pd.Series(['a', 'b', np.nan, 'd'])
>>> s.str.cat(sep=' ')
'a b d'
```

By default, NA values in the Series are ignored. Using *na_rep*, they can be given a representation:

```
>>> s.str.cat(sep=' ', na_rep='?')
'a b ? d'
```

If *others* is specified, corresponding values are concatenated with the separator. Result will be a Series of strings.

```
>>> s.str.cat(['A', 'B', 'C', 'D'], sep=',')
0    a,A
1    b,B
2    NaN
3    d,D
dtype: object
```

Missing values will remain missing in the result, but can again be represented using *na_rep*

```
>>> s.str.cat(['A', 'B', 'C', 'D'], sep=',', na_rep='-')
0    a,A
1    b,B
2    -,C
3    d,D
dtype: object
```

If *sep* is not specified, the values are concatenated without separation.

```
>>> s.str.cat(['A', 'B', 'C', 'D'], na_rep='-')
0    aA
1    bB
2    -C
3    dD
dtype: object
```

Series with different indexes can be aligned before concatenation. The *join*-keyword works as in other methods.

```
>>> t = pd.Series(['d', 'a', 'e', 'c'], index=[3, 0, 4, 2])
>>> s.str.cat(t, join='left', na_rep='-')
0    aa
1    b-
2    -c
3    dd
dtype: object
>>>
>>> s.str.cat(t, join='outer', na_rep='-')
0    aa
1    b-
2    -c
3    dd
4    -e
dtype: object
>>>
>>> s.str.cat(t, join='inner', na_rep='-')
0    aa
2    -c
```

(continues on next page)

(continued from previous page)

```

3    dd
dtype: object
>>>
>>> s.str.cat(t, join='right', na_rep='-')
3    dd
0    aa
4    -e
2    -c
dtype: object

```

For more examples, see [here](#).

pandas.Series.str.center

`Series.str.center(self, width, fillchar=' ')`

Filling left and right side of strings in the Series/Index with an additional character. Equivalent to `str.center()`.

Parameters

width [int] Minimum width of resulting string; additional characters will be filled with `fillchar`

fillchar [str] Additional character for filling, default is whitespace

Returns

filled [Series/Index of objects]

pandas.Series.str.contains

`Series.str.contains(self, pat, case=True, flags=0, na=nan, regex=True)`

Test if pattern or regex is contained within a string of a Series or Index.

Return boolean Series or Index based on whether a given pattern or regex is contained within a string of a Series or Index.

Parameters

pat [str] Character sequence or regular expression.

case [bool, default True] If True, case sensitive.

flags [int, default 0 (no flags)] Flags to pass through to the re module, e.g. `re.IGNORECASE`.

na [default NaN] Fill value for missing values.

regex [bool, default True] If True, assumes the pat is a regular expression.

If False, treats the pat as a literal string.

Returns

Series or Index of boolean values A Series or Index of boolean values indicating whether the given pattern is contained within the string of each element of the Series or Index.

See also:

match Analogous, but stricter, relying on `re.match` instead of `re.search`.

Series.str.startswith Test if the start of each string element matches a pattern.

Series.str.endswith Same as `startswith`, but tests the end of string.

Examples

Returning a Series of booleans using only a literal pattern.

```
>>> s1 = pd.Series(['Mouse', 'dog', 'house and parrot', '23', np.NaN])
>>> s1.str.contains('og', regex=False)
0    False
1     True
2    False
3    False
4     NaN
dtype: object
```

Returning an Index of booleans using only a literal pattern.

```
>>> ind = pd.Index(['Mouse', 'dog', 'house and parrot', '23.0', np.NaN])
>>> ind.str.contains('23', regex=False)
Index([False, False, False, True, nan], dtype='object')
```

Specifying case sensitivity using *case*.

```
>>> s1.str.contains('oG', case=True, regex=True)
0    False
1    False
2    False
3    False
4     NaN
dtype: object
```

Specifying *na* to be *False* instead of *NaN* replaces *NaN* values with *False*. If Series or Index does not contain *NaN* values the resultant dtype will be *bool*, otherwise, an *object* dtype.

```
>>> s1.str.contains('og', na=False, regex=True)
0    False
1     True
2    False
3    False
4    False
dtype: bool
```

Returning 'house' or 'dog' when either expression occurs in a string.

```
>>> s1.str.contains('house|dog', regex=True)
0    False
1     True
2     True
3    False
4     NaN
dtype: object
```

Ignoring case sensitivity using *flags* with regex.

```
>>> import re
>>> s1.str.contains('PARROT', flags=re.IGNORECASE, regex=True)
0    False
1    False
2     True
3    False
4     NaN
dtype: object
```

Returning any digit using regular expression.

```
>>> s1.str.contains('\d', regex=True)
0    False
1    False
2    False
3     True
4     NaN
dtype: object
```

Ensure *pat* is not a literal pattern when *regex* is set to *True*. Note in the following example one might expect only *s2[1]* and *s2[3]* to return *True*. However, *'0'* as a regex matches any character followed by a 0.

```
>>> s2 = pd.Series(['40', '40.0', '41', '41.0', '35'])
>>> s2.str.contains('.0', regex=True)
0     True
1     True
2    False
3     True
4    False
dtype: bool
```

pandas.Series.str.count

`Series.str.count(self, pat, flags=0, **kwargs)`

Count occurrences of pattern in each string of the Series/Index.

This function is used to count the number of times a particular regex pattern is repeated in each of the string elements of the *Series*.

Parameters

pat [str] Valid regular expression.

flags [int, default 0, meaning no flags] Flags for the *re* module. For a complete list, [see here](#).

****kwargs** For compatibility with other string methods. Not used.

Returns

Series or Index Same type as the calling object containing the integer counts.

See also:

`re` Standard library module for regular expressions.

`str.count` Standard library version, without regular expression support.

Notes

Some characters need to be escaped when passing in *pat*. eg. '\$' has a special meaning in regex and must be escaped when finding this literal character.

Examples

```
>>> s = pd.Series(['A', 'B', 'Aaba', 'Baca', np.nan, 'CABA', 'cat'])
>>> s.str.count('a')
0    0.0
1    0.0
2    2.0
3    2.0
4    NaN
5    0.0
6    1.0
dtype: float64
```

Escape '\$' to find the literal dollar sign.

```
>>> s = pd.Series(['$', 'B', 'Aab$', '$$ca', 'C$B$', 'cat'])
>>> s.str.count('\$')
0    1
1    0
2    1
3    2
4    2
5    0
dtype: int64
```

This is also available on Index

```
>>> pd.Index(['A', 'A', 'Aaba', 'cat']).str.count('a')
Int64Index([0, 0, 2, 1], dtype='int64')
```

pandas.Series.str.decode

`Series.str.decode(self, encoding, errors='strict')`

Decode character string in the Series/Index using indicated encoding. Equivalent to `str.decode()` in python2 and `bytes.decode()` in python3.

Parameters

`encoding` [str]

`errors` [str, optional]

Returns

Series or Index

pandas.Series.str.encode

`Series.str.encode(self, encoding, errors='strict')`

Encode character string in the Series/Index using indicated encoding. Equivalent to `str.encode()`.

Parameters

encoding [str]

errors [str, optional]

Returns

encoded [Series/Index of objects]

pandas.Series.str.endswith

`Series.str.endswith(self, pat, na=nan)`

Test if the end of each string element matches a pattern.

Equivalent to `str.endswith()`.

Parameters

pat [str] Character sequence. Regular expressions are not accepted.

na [object, default NaN] Object shown if element tested is not a string.

Returns

Series or Index of bool A Series of booleans indicating whether the given pattern matches the end of each string element.

See also:

`str.endswith` Python standard library string method.

`Series.str.startswith` Same as `endswith`, but tests the start of string.

`Series.str.contains` Tests if string element contains a pattern.

Examples

```
>>> s = pd.Series(['bat', 'bear', 'caT', np.nan])
>>> s
0    bat
1    bear
2    caT
3    NaN
dtype: object
```

```
>>> s.str.endswith('t')
0    True
1    False
2    False
3    NaN
dtype: object
```

Specifying *na* to be *False* instead of *NaN*.

```
>>> s.str.endswith('t', na=False)
0    True
1    False
2    False
3    False
dtype: bool
```

pandas.Series.str.extract

`Series.str.extract(self, pat, flags=0, expand=True)`

Extract capture groups in the regex *pat* as columns in a DataFrame.

For each subject string in the Series, extract groups from the first match of regular expression *pat*.

Parameters

pat [str] Regular expression pattern with capturing groups.

flags [int, default 0 (no flags)] Flags from the `re` module, e.g. `re.IGNORECASE`, that modify regular expression matching for things like case, spaces, etc. For more details, see `re`.

expand [bool, default True] If True, return DataFrame with one column per capture group. If False, return a Series/Index if there is one capture group or DataFrame if there are multiple capture groups.

New in version 0.18.0.

Returns

DataFrame or Series or Index A DataFrame with one row for each subject string, and one column for each group. Any capture group names in regular expression *pat* will be used for column names; otherwise capture group numbers will be used. The dtype of each result column is always object, even when no match is found. If `expand=False` and *pat* has only one capture group, then return a Series (if subject is a Series) or Index (if subject is an Index).

See also:

`extractall` Returns all matches (not just the first match).

Examples

A pattern with two groups will return a DataFrame with two columns. Non-matches will be NaN.

```
>>> s = pd.Series(['a1', 'b2', 'c3'])
>>> s.str.extract(r'([ab])(\d)')
   0  1
0  a  1
1  b  2
2 NaN NaN
```

A pattern may contain optional groups.

```
>>> s.str.extract(r'([ab])?(\d)')
   0 1
0  a 1
1  b 2
2 NaN 3
```

Named groups will become column names in the result.

```
>>> s.str.extract(r'(?P<letter>[ab])(?P<digit>\d)')
   letter digit
0      a      1
1      b      2
2    NaN    NaN
```

A pattern with one group will return a DataFrame with one column if `expand=True`.

```
>>> s.str.extract(r'[ab](\d)', expand=True)
   0
0  1
1  2
2 NaN
```

A pattern with one group will return a Series if `expand=False`.

```
>>> s.str.extract(r'[ab](\d)', expand=False)
0      1
1      2
2    NaN
dtype: object
```

pandas.Series.str.extractall

`Series.str.extractall(self, pat, flags=0)`

For each subject string in the Series, extract groups from all matches of regular expression `pat`. When each subject string in the Series has exactly one match, `extractall(pat).xs(0, level='match')` is the same as `extract(pat)`.

New in version 0.18.0.

Parameters

pat [str] Regular expression pattern with capturing groups.

flags [int, default 0 (no flags)] A `re` module flag, for example `re.IGNORECASE`. These allow to modify regular expression matching for things like case, spaces, etc. Multiple flags can be combined with the bitwise OR operator, for example `re.IGNORECASE | re.MULTILINE`.

Returns

DataFrame A `DataFrame` with one row for each match, and one column for each group. Its rows have a `MultiIndex` with first levels that come from the subject `Series`. The last level is named 'match' and indexes the matches in each item of the `Series`. Any capture group names in regular expression `pat` will be used for column names; otherwise capture group numbers will be used.

See also:

extract Returns first match only (not all matches).

Examples

A pattern with one group will return a DataFrame with one column. Indices with no matches will not appear in the result.

```
>>> s = pd.Series(["a1a2", "b1", "c1"], index=["A", "B", "C"])
>>> s.str.extractall(r"[ab](\d)")
      0
  match
A 0    1
  1    2
B 0    1
```

Capture group names are used for column names of the result.

```
>>> s.str.extractall(r"[ab](?P<digit>\d)")
      digit
  match
A 0        1
  1        2
B 0        1
```

A pattern with two groups will return a DataFrame with two columns.

```
>>> s.str.extractall(r"(?P<letter>[ab])(?P<digit>\d)")
      letter digit
  match
A 0         a     1
  1         a     2
B 0         b     1
```

Optional groups that do not match are NaN in the result.

```
>>> s.str.extractall(r"(?P<letter>[ab])?(?P<digit>\d)")
      letter digit
  match
A 0         a     1
  1         a     2
B 0         b     1
C 0        NaN     1
```

pandas.Series.str.find

`Series.str.find(self, sub, start=0, end=None)`

Return lowest indexes in each strings in the Series/Index where the substring is fully contained between [start:end]. Return -1 on failure. Equivalent to standard `str.find()`.

Parameters

sub [str] Substring being searched

start [int] Left edge index

end [int] Right edge index

Returns

found [Series/Index of integer values]

See also:

rfind Return highest indexes in each strings.

pandas.Series.str.findall

`Series.str.findall(self, pat, flags=0, **kwargs)`

Find all occurrences of pattern or regular expression in the Series/Index.

Equivalent to applying `re.findall()` to all the elements in the Series/Index.

Parameters

pat [str] Pattern or regular expression.

flags [int, default 0] Flags from `re` module, e.g. `re.IGNORECASE` (default is 0, which means no flags).

Returns

Series/Index of lists of strings All non-overlapping matches of pattern or regular expression in each string of this Series/Index.

See also:

count Count occurrences of pattern or regular expression in each string of the Series/Index.

extractall For each string in the Series, extract groups from all matches of regular expression and return a DataFrame with one row for each match and one column for each group.

re.findall The equivalent `re` function to all non-overlapping matches of pattern or regular expression in string, as a list of strings.

Examples

```
>>> s = pd.Series(['Lion', 'Monkey', 'Rabbit'])
```

The search for the pattern 'Monkey' returns one match:

```
>>> s.str.findall('Monkey')
0      []
1  [Monkey]
2      []
dtype: object
```

On the other hand, the search for the pattern 'MONKEY' doesn't return any match:

```
>>> s.str.findall('MONKEY')
0    []
1    []
2    []
dtype: object
```

Flags can be added to the pattern or regular expression. For instance, to find the pattern 'MONKEY' ignoring the case:

```
>>> import re
>>> s.str.findall('MONKEY', flags=re.IGNORECASE)
0    []
1    [Monkey]
2    []
dtype: object
```

When the pattern matches more than one string in the Series, all matches are returned:

```
>>> s.str.findall('on')
0    [on]
1    [on]
2    []
dtype: object
```

Regular expressions are supported too. For instance, the search for all the strings ending with the word 'on' is shown next:

```
>>> s.str.findall('on$')
0    [on]
1    []
2    []
dtype: object
```

If the pattern is found more than once in the same string, then a list of multiple strings is returned:

```
>>> s.str.findall('b')
0    []
1    []
2    [b, b]
dtype: object
```

pandas.Series.str.get

`Series.str.get(self, i)`

Extract element from each component at specified position.

Extract element from lists, tuples, or strings in each element in the Series/Index.

Parameters

`i` [int] Position of element to extract.

Returns

Series or Index

Examples

```
>>> s = pd.Series(["String",
...                (1, 2, 3),
...                ["a", "b", "c"],
...                123,
...                -456,
...                {1: "Hello", "2": "World"}])
>>> s
0                String
1                (1, 2, 3)
2                [a, b, c]
3                123
4                -456
5    {1: 'Hello', '2': 'World'}
dtype: object
```

```
>>> s.str.get(1)
0         t
1         2
2         b
3        NaN
4        NaN
5    Hello
dtype: object
```

```
>>> s.str.get(-1)
0         g
1         3
2         c
3        NaN
4        NaN
5        None
dtype: object
```

pandas.Series.str.index

Series.str.index(*self*, *sub*, *start=0*, *end=None*)

Return lowest indexes in each strings where the substring is fully contained between [start:end]. This is the same as `str.find` except instead of returning -1, it raises a `ValueError` when the substring is not found. Equivalent to standard `str.index`.

Parameters

sub [str] Substring being searched

start [int] Left edge index

end [int] Right edge index

Returns

found [Series/Index of objects]

See also:

`rindex` Return highest indexes in each strings.

pandas.Series.str.join

`Series.str.join(self, sep)`

Join lists contained as elements in the Series/Index with passed delimiter.

If the elements of a Series are lists themselves, join the content of these lists using the delimiter passed to the function. This function is an equivalent to `str.join()`.

Parameters

`sep` [str] Delimiter to use between list entries.

Returns

Series/Index: object The list entries concatenated by intervening occurrences of the delimiter.

Raises

AttributeError If the supplied Series contains neither strings nor lists.

See also:

`str.join` Standard library version of this method.

`Series.str.split` Split strings around given separator/delimiter.

Notes

If any of the list items is not a string object, the result of the join will be `NaN`.

Examples

Example with a list that contains non-string elements.

```
>>> s = pd.Series(['lion', 'elephant', 'zebra'],
...               [1.1, 2.2, 3.3],
...               ['cat', np.nan, 'dog'],
...               ['cow', 4.5, 'goat'],
...               ['duck', ['swan', 'fish'], 'guppy'])
>>> s
0      [lion, elephant, zebra]
1      [1.1, 2.2, 3.3]
2      [cat, nan, dog]
3      [cow, 4.5, goat]
4      [duck, [swan, fish], guppy]
dtype: object
```

Join all lists using a '-'. The lists containing object(s) of types other than str will produce a NaN.

```
>>> s.str.join('-')
0      lion-elephant-zebra
1      NaN
2      NaN
```

(continues on next page)

(continued from previous page)

```

3           NaN
4           NaN
dtype: object

```

pandas.Series.str.len**Series.str.len(*self*)**

Compute the length of each element in the Series/Index. The element may be a sequence (such as a string, tuple or list) or a collection (such as a dictionary).

Returns

Series or Index of int A Series or Index of integer values indicating the length of each element in the Series or Index.

See also:

str.len Python built-in function returning the length of an object.

Series.size Returns the length of the Series.

Examples

Returns the length (number of characters) in a string. Returns the number of entries for dictionaries, lists or tuples.

```

>>> s = pd.Series(['dog',
...                '',
...                5,
...                {'foo': 'bar'},
...                [2, 3, 5, 7],
...                ('one', 'two', 'three')])
>>> s
0           dog
1
2           5
3    {'foo': 'bar'}
4    [2, 3, 5, 7]
5    (one, two, three)
dtype: object
>>> s.str.len()
0    3.0
1    0.0
2    NaN
3    1.0
4    4.0
5    3.0
dtype: float64

```

pandas.Series.str.ljust

`Series.str.ljust(self, width, fillchar='')`

Filling right side of strings in the Series/Index with an additional character. Equivalent to `str.ljust()`.

Parameters

width [int] Minimum width of resulting string; additional characters will be filled with `fillchar`

fillchar [str] Additional character for filling, default is whitespace

Returns

filled [Series/Index of objects]

pandas.Series.str.lower

`Series.str.lower(self)`

Convert strings in the Series/Index to lowercase.

Equivalent to `str.lower()`.

Returns

Series/Index of objects

See also:

Series.str.lower Converts all characters to lowercase.

Series.str.upper Converts all characters to uppercase.

Series.str.title Converts first character of each word to uppercase and remaining to lowercase.

Series.str.capitalize Converts first character to uppercase and remaining to lowercase.

Series.str.swapcase Converts uppercase to lowercase and lowercase to uppercase.

Series.str.casefold Removes all case distinctions in the string.

Examples

```
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0          lower
1      CAPITALS
2  this is a sentence
3      SwApCaSe
dtype: object
```

```
>>> s.str.lower()
0          lower
1      capitals
2  this is a sentence
3      swapcase
dtype: object
```

```
>>> s.str.upper()
0          LOWER
1      CAPITALS
2  THIS IS A SENTENCE
3      SWAPCASE
dtype: object
```

```
>>> s.str.title()
0          Lower
1      Capitals
2  This Is A Sentence
3      Swapcase
dtype: object
```

```
>>> s.str.capitalize()
0          Lower
1      Capitals
2  This is a sentence
3      Swapcase
dtype: object
```

```
>>> s.str.swapcase()
0          LOWER
1      capitals
2  THIS IS A SENTENCE
3      sWaPcAsE
dtype: object
```

pandas.Series.str.lstrip

Series.str.lstrip(*self*, *to_strip=None*)

Remove leading and trailing characters.

Strip whitespaces (including newlines) or a set of specified characters from each string in the Series/Index from left side. Equivalent to `str.lstrip()`.

Parameters

to_strip [str or None, default None] Specifying the set of characters to be removed. All combinations of this set of characters will be stripped. If None then whitespaces are removed.

Returns

Series/Index of objects

See also:

Series.str.strip Remove leading and trailing characters in Series/Index.

Series.str.lstrip Remove leading characters in Series/Index.

Series.str.rstrip Remove trailing characters in Series/Index.

Examples

```
>>> s = pd.Series(['1. Ant. ', '2. Bee!\n', '3. Cat?\t', np.nan])
>>> s
0    1. Ant.
1    2. Bee!\n
2    3. Cat?\t
3           NaN
dtype: object
```

```
>>> s.str.strip()
0    1. Ant.
1    2. Bee!
2    3. Cat?
3           NaN
dtype: object
```

```
>>> s.str.lstrip('123.')
0    Ant.
1    Bee!\n
2    Cat?\t
3           NaN
dtype: object
```

```
>>> s.str.rstrip('.!? \n\t')
0    1. Ant
1    2. Bee
2    3. Cat
3           NaN
dtype: object
```

```
>>> s.str.strip('123.!? \n\t')
0    Ant
1    Bee
2    Cat
3    NaN
dtype: object
```

pandas.Series.str.match

`Series.str.match(self, pat, case=True, flags=0, na=nan)`
Determine if each string matches a regular expression.

Parameters

- pat** [str] Character sequence or regular expression.
- case** [bool, default True] If True, case sensitive.
- flags** [int, default 0 (no flags)] re module flags, e.g. re.IGNORECASE.
- na** [default NaN] Fill value for missing values.

Returns

Series/array of boolean values**See also:****contains** Analogous, but less strict, relying on `re.search` instead of `re.match`.**extract** Extract matched groups.**pandas.Series.str.normalize**`Series.str.normalize(self, form)`Return the Unicode normal form for the strings in the Series/Index. For more information on the forms, see the `unicodedata.normalize()`.**Parameters****form** [{'NFC', 'NFKC', 'NFD', 'NFKD'}] Unicode form**Returns****normalized** [Series/Index of objects]**pandas.Series.str.pad**`Series.str.pad(self, width, side='left', fillchar=' ')`

Pad strings in the Series/Index up to width.

Parameters**width** [int] Minimum width of resulting string; additional characters will be filled with character defined in *fillchar*.**side** [{'left', 'right', 'both'}, default 'left'] Side from which to fill resulting string.**fillchar** [str, default ' '] Additional character for filling, default is whitespace.**Returns****Series or Index of object** Returns Series or Index with minimum number of char in object.**See also:****Series.str.rjust** Fills the left side of strings with an arbitrary character. Equivalent to `Series.str.pad(side='left')`.**Series.str.ljust** Fills the right side of strings with an arbitrary character. Equivalent to `Series.str.pad(side='right')`.**Series.str.center** Fills boths sides of strings with an arbitrary character. Equivalent to `Series.str.pad(side='both')`.**Series.str.zfill** Pad strings in the Series/Index by prepending '0' character. Equivalent to `Series.str.pad(side='left', fillchar='0')`.**Examples**

```
>>> s = pd.Series(["caribou", "tiger"])
>>> s
0    caribou
1     tiger
dtype: object
```

```
>>> s.str.pad(width=10)
0    caribou
1     tiger
dtype: object
```

```
>>> s.str.pad(width=10, side='right', fillchar='-')
0    caribou---
1    tiger-----
dtype: object
```

```
>>> s.str.pad(width=10, side='both', fillchar='-')
0    -caribou--
1    --tiger---
dtype: object
```

pandas.Series.str.partition

`Series.str.partition(self, sep=' ', expand=True)`

Split the string at the first occurrence of *sep*.

This method splits the string at the first occurrence of *sep*, and returns 3 elements containing the part before the separator, the separator itself, and the part after the separator. If the separator is not found, return 3 elements containing the string itself, followed by two empty strings.

Parameters

sep [str, default whitespace] String to split on.

pat [str, default whitespace] Deprecated since version 0.24.0: Use **sep** instead

expand [bool, default True] If True, return DataFrame/MultiIndex expanding dimensionality. If False, return Series/Index.

Returns

DataFrame/MultiIndex or Series/Index of objects

See also:

rpartition Split the string at the last occurrence of *sep*.

Series.str.split Split strings around given separators.

str.partition Standard library version.

Examples

```
>>> s = pd.Series(['Linda van der Berg', 'George Pitt-Rivers'])
>>> s
0    Linda van der Berg
1    George Pitt-Rivers
dtype: object
```

```
>>> s.str.partition()
      0 1          2
0  Linda  van der Berg
1  George  Pitt-Rivers
```

To partition by the last space instead of the first one:

```
>>> s.str.rpartition()
      0 1          2
0  Linda van der      Berg
1      George  Pitt-Rivers
```

To partition by something different than a space:

```
>>> s.str.partition('-')
      0 1          2
0  Linda van der Berg
1      George Pitt - Rivers
```

To return a Series containing tuples instead of a DataFrame:

```
>>> s.str.partition('-', expand=False)
0    (Linda van der Berg, , )
1    (George Pitt, -, Rivers)
dtype: object
```

Also available on indices:

```
>>> idx = pd.Index(['X 123', 'Y 999'])
>>> idx
Index(['X 123', 'Y 999'], dtype='object')
```

Which will create a MultiIndex:

```
>>> idx.str.partition()
MultiIndex([('X', ' ', '123'),
           ('Y', ' ', '999')],
          dtype='object')
```

Or an index with tuples with `expand=False`:

```
>>> idx.str.partition(expand=False)
Index([('X', ' ', '123'), ('Y', ' ', '999')], dtype='object')
```

pandas.Series.str.repeat

`Series.str.repeat(self, repeats)`

Duplicate each string in the Series or Index.

Parameters

repeats [int or sequence of int] Same value for all (int) or different value per (sequence).

Returns

Series or Index of object Series or Index of repeated string objects specified by input parameter repeats.

Examples

```
>>> s = pd.Series(['a', 'b', 'c'])
>>> s
0    a
1    b
2    c
dtype: object
```

Single int repeats string in Series

```
>>> s.str.repeat(repeats=2)
0    aa
1    bb
2    cc
dtype: object
```

Sequence of int repeats corresponding string in Series

```
>>> s.str.repeat(repeats=[1, 2, 3])
0    a
1    bb
2    ccc
dtype: object
```

pandas.Series.str.replace

`Series.str.replace(self, pat, repl, n=-1, case=None, flags=0, regex=True)`

Replace occurrences of pattern/regex in the Series/Index with some other string. Equivalent to `str.replace()` or `re.sub()`.

Parameters

pat [str or compiled regex] String can be a character sequence or regular expression.

New in version 0.20.0: *pat* also accepts a compiled regex.

repl [str or callable] Replacement string or a callable. The callable is passed the regex match object and must return a replacement string to be used. See `re.sub()`.

New in version 0.20.0: *repl* also accepts a callable.

n [int, default -1 (all)] Number of replacements to make from start.

case [bool, default None]

- If True, case sensitive (the default if *pat* is a string)
- Set to False for case insensitive
- Cannot be set if *pat* is a compiled regex

flags [int, default 0 (no flags)]

- re module flags, e.g. re.IGNORECASE
- Cannot be set if *pat* is a compiled regex

regex [bool, default True]

- If True, assumes the passed-in pattern is a regular expression.
- If False, treats the pattern as a literal string
- Cannot be set to False if *pat* is a compiled regex or *repl* is a callable.

New in version 0.23.0.

Returns

Series or Index of object A copy of the object with all matching occurrences of *pat* replaced by *repl*.

Raises

ValueError

- if *regex* is False and *repl* is a callable or *pat* is a compiled regex
- if *pat* is a compiled regex and *case* or *flags* is set

Notes

When *pat* is a compiled regex, all flags should be included in the compiled regex. Use of *case*, *flags*, or *regex=False* with a compiled regex will raise an error.

Examples

When *pat* is a string and *regex* is True (the default), the given *pat* is compiled as a regex. When *repl* is a string, it replaces matching regex patterns as with `re.sub()`. NaN value(s) in the Series are left as is:

```
>>> pd.Series(['foo', 'fuz', np.nan]).str.replace('f.', 'ba', regex=True)
0    bao
1    baz
2    NaN
dtype: object
```

When *pat* is a string and *regex* is False, every *pat* is replaced with *repl* as with `str.replace()`:

```
>>> pd.Series(['f.o', 'fuz', np.nan]).str.replace('f.', 'ba', regex=False)
0    bao
1    fuz
2    NaN
dtype: object
```

When *repl* is a callable, it is called on every *pat* using `re.sub()`. The callable should expect one positional argument (a regex object) and return a string.

To get the idea:

```
>>> pd.Series(['foo', 'fuz', np.nan]).str.replace('f', repr)
0    <_sre.SRE_Match object; span=(0, 1), match='f'>oo
1    <_sre.SRE_Match object; span=(0, 1), match='f'>uz
2                                     NaN
dtype: object
```

Reverse every lowercase alphabetic word:

```
>>> repl = lambda m: m.group(0)[::-1]
>>> pd.Series(['foo 123', 'bar baz', np.nan]).str.replace(r'[a-z]+', repl)
0    oof 123
1    rab zab
2         NaN
dtype: object
```

Using regex groups (extract second group and swap case):

```
>>> pat = r"(?P<one>\w+) (?P<two>\w+) (?P<three>\w+)"
>>> repl = lambda m: m.group('two').swapcase()
>>> pd.Series(['One Two Three', 'Foo Bar Baz']).str.replace(pat, repl)
0    tW0
1    bAR
dtype: object
```

Using a compiled regex with flags

```
>>> import re
>>> regex_pat = re.compile(r'FUZ', flags=re.IGNORECASE)
>>> pd.Series(['foo', 'fuz', np.nan]).str.replace(regex_pat, 'bar')
0    foo
1    bar
2    NaN
dtype: object
```

pandas.Series.str.rfind

`Series.str.rfind(self, sub, start=0, end=None)`

Return highest indexes in each strings in the Series/Index where the substring is fully contained between [start:end]. Return -1 on failure. Equivalent to standard `str.rfind()`.

Parameters

sub [str] Substring being searched

start [int] Left edge index

end [int] Right edge index

Returns

found [Series/Index of integer values]

See also:

find Return lowest indexes in each strings.

pandas.Series.str.rindex

`Series.str.rindex(self, sub, start=0, end=None)`

Return highest indexes in each strings where the substring is fully contained between [start:end]. This is the same as `str.rfind` except instead of returning -1, it raises a `ValueError` when the substring is not found. Equivalent to standard `str.rindex`.

Parameters

sub [str] Substring being searched

start [int] Left edge index

end [int] Right edge index

Returns

found [Series/Index of objects]

See also:

index Return lowest indexes in each strings.

pandas.Series.str.rjust

`Series.str.rjust(self, width, fillchar='')`

Filling left side of strings in the Series/Index with an additional character. Equivalent to `str.rjust()`.

Parameters

width [int] Minimum width of resulting string; additional characters will be filled with `fillchar`

fillchar [str] Additional character for filling, default is whitespace

Returns

filled [Series/Index of objects]

pandas.Series.str.rpartition

`Series.str.rpartition(self, sep=' ', expand=True)`

Split the string at the last occurrence of `sep`.

This method splits the string at the last occurrence of `sep`, and returns 3 elements containing the part before the separator, the separator itself, and the part after the separator. If the separator is not found, return 3 elements containing two empty strings, followed by the string itself.

Parameters

sep [str, default whitespace] String to split on.

pat [str, default whitespace] Deprecated since version 0.24.0: Use **sep** instead

expand [bool, default True] If True, return DataFrame/MultiIndex expanding dimensionality. If False, return Series/Index.

Returns

DataFrame/MultiIndex or Series/Index of objects

See also:

partition Split the string at the first occurrence of *sep*.

Series.str.split Split strings around given separators.

str.partition Standard library version.

Examples

```
>>> s = pd.Series(['Linda van der Berg', 'George Pitt-Rivers'])
>>> s
0    Linda van der Berg
1    George Pitt-Rivers
dtype: object
```

```
>>> s.str.partition()
      0 1      2
0  Linda  van der Berg
1  George  Pitt-Rivers
```

To partition by the last space instead of the first one:

```
>>> s.str.rpartition()
      0 1      2
0  Linda van der      Berg
1      George  Pitt-Rivers
```

To partition by something different than a space:

```
>>> s.str.partition('-')
      0 1      2
0  Linda van der Berg
1      George Pitt - Rivers
```

To return a Series containing tuples instead of a DataFrame:

```
>>> s.str.partition('-', expand=False)
0    (Linda van der Berg, , )
1    (George Pitt, -, Rivers)
dtype: object
```

Also available on indices:

```
>>> idx = pd.Index(['X 123', 'Y 999'])
>>> idx
Index(['X 123', 'Y 999'], dtype='object')
```

Which will create a MultiIndex:

```
>>> idx.str.partition()
MultiIndex([('X', ' ', '123'),
           ('Y', ' ', '999')],
          dtype='object')
```

Or an index with tuples with `expand=False`:

```
>>> idx.str.partition(expand=False)
Index([('X', ' ', '123'), ('Y', ' ', '999')], dtype='object')
```

pandas.Series.str.rstrip

Series.str.rstrip(*self*, *to_strip=None*)

Remove leading and trailing characters.

Strip whitespaces (including newlines) or a set of specified characters from each string in the Series/Index from right side. Equivalent to `str.rstrip()`.

Parameters

to_strip [str or None, default None] Specifying the set of characters to be removed. All combinations of this set of characters will be stripped. If None then whitespaces are removed.

Returns

Series/Index of objects

See also:

Series.str.strip Remove leading and trailing characters in Series/Index.

Series.str.lstrip Remove leading characters in Series/Index.

Series.str.rstrip Remove trailing characters in Series/Index.

Examples

```
>>> s = pd.Series(['1. Ant. ', '2. Bee!\n', '3. Cat?\t', np.nan])
>>> s
0    1. Ant.
1    2. Bee!\n
2    3. Cat?\t
3         NaN
dtype: object
```

```
>>> s.str.strip()
0    1. Ant.
1    2. Bee!
2    3. Cat?
3         NaN
dtype: object
```

```
>>> s.str.lstrip('123.')
0    Ant.
1    Bee!\n
2    Cat?\t
3         NaN
dtype: object
```

```
>>> s.str.rstrip('.!? \n\t')
0    1. Ant
1    2. Bee
2    3. Cat
3         NaN
dtype: object
```

```
>>> s.str.strip('123.!? \n\t')
0    Ant
1    Bee
2    Cat
3    NaN
dtype: object
```

pandas.Series.str.slice

`Series.str.slice(self, start=None, stop=None, step=None)`
Slice substrings from each element in the Series or Index.

Parameters

start [int, optional] Start position for slice operation.

stop [int, optional] Stop position for slice operation.

step [int, optional] Step size for slice operation.

Returns

Series or Index of object Series or Index from sliced substring from original string object.

See also:

`Series.str.slice_replace` Replace a slice with a string.

`Series.str.get` Return element at position. Equivalent to `Series.str.slice(start=i, stop=i+1)` with *i* being the position.

Examples

```
>>> s = pd.Series(["koala", "fox", "chameleon"])
>>> s
0      koala
1       fox
2  chameleon
dtype: object
```

```
>>> s.str.slice(start=1)
0      oala
1       ox
2  hameleon
dtype: object
```

```
>>> s.str.slice(stop=2)
0   ko
1   fo
2   ch
dtype: object
```

```
>>> s.str.slice(step=2)
0   kaa
1   fx
2  caeen
dtype: object
```

```
>>> s.str.slice(start=0, stop=5, step=3)
0   kl
1   f
2   cm
dtype: object
```

Equivalent behaviour to:

```
>>> s.str[0:5:3]
0   kl
1   f
2   cm
dtype: object
```

pandas.Series.str.slice_replace

`Series.str.slice_replace(self, start=None, stop=None, repl=None)`

Replace a positional slice of a string with another value.

Parameters

start [int, optional] Left index position to use for the slice. If not specified (None), the slice is unbounded on the left, i.e. slice from the start of the string.

stop [int, optional] Right index position to use for the slice. If not specified (None), the slice is unbounded on the right, i.e. slice until the end of the string.

repl [str, optional] String for replacement. If not specified (None), the sliced region is replaced with an empty string.

Returns

Series or Index Same type as the original object.

See also:

`Series.str.slice` Just slicing without replacement.

Examples

```
>>> s = pd.Series(['a', 'ab', 'abc', 'abdc', 'abcde'])
>>> s
0      a
1     ab
2    abc
3   abdc
4  abcde
dtype: object
```

Specify just *start*, meaning replace *start* until the end of the string with *repl*.

```
>>> s.str.slice_replace(1, repl='X')
0    aX
1    aX
2    aX
3    aX
4    aX
dtype: object
```

Specify just *stop*, meaning the start of the string to *stop* is replaced with *repl*, and the rest of the string is included.

```
>>> s.str.slice_replace(stop=2, repl='X')
0      X
1      X
2     Xc
3    Xdc
4   Xcde
dtype: object
```

Specify *start* and *stop*, meaning the slice from *start* to *stop* is replaced with *repl*. Everything before or after *start* and *stop* is included as is.

```
>>> s.str.slice_replace(start=1, stop=3, repl='X')
0    aX
1    aX
2    aX
3   aXc
4  aXde
dtype: object
```

pandas.Series.str.split

`Series.str.split(self, pat=None, n=-1, expand=False)`

Split strings around given separator/delimiter.

Splits the string in the Series/Index from the beginning, at the specified delimiter string. Equivalent to `str.split()`.

Parameters

pat [str, optional] String or regular expression to split on. If not specified, split on whitespace.

n [int, default -1 (all)] Limit number of splits in output. `None`, 0 and -1 will be interpreted as return all splits.

expand [bool, default False] Expand the splitted strings into separate columns.

- If `True`, return DataFrame/MultiIndex expanding dimensionality.
- If `False`, return Series/Index, containing lists of strings.

Returns

Series, Index, DataFrame or MultiIndex Type matches caller unless `expand=True` (see Notes).

See also:

`Series.str.split` Split strings around given separator/delimiter.

`Series.str.rsplit` Splits string around given separator/delimiter, starting from the right.

`Series.str.join` Join lists contained as elements in the Series/Index with passed delimiter.

`str.split` Standard library version for split.

`str.rsplit` Standard library version for rsplit.

Notes

The handling of the `n` keyword depends on the number of found splits:

- If found splits $> n$, make first n splits only
- If found splits $\leq n$, make all splits
- If for a certain row the number of found splits $< n$, append `None` for padding up to n if `expand=True`

If using `expand=True`, Series and Index callers return DataFrame and MultiIndex objects, respectively.

Examples

```
>>> s = pd.Series(["this is a regular sentence",
...               "https://docs.python.org/3/tutorial/index.html",
...               np.nan])
0          this is a regular sentence
1  https://docs.python.org/3/tutorial/index.html
```

(continues on next page)

(continued from previous page)

```
2 NaN
dtype: object
```

In the default setting, the string is split by whitespace.

```
>>> s.str.split()
0 [this, is, a, regular, sentence]
1 [https://docs.python.org/3/tutorial/index.html]
2 NaN
dtype: object
```

Without the *n* parameter, the outputs of *rsplit* and *split* are identical.

```
>>> s.str.rsplit()
0 [this, is, a, regular, sentence]
1 [https://docs.python.org/3/tutorial/index.html]
2 NaN
dtype: object
```

The *n* parameter can be used to limit the number of splits on the delimiter. The outputs of *split* and *rsplit* are different.

```
>>> s.str.split(n=2)
0 [this, is, a regular sentence]
1 [https://docs.python.org/3/tutorial/index.html]
2 NaN
dtype: object
```

```
>>> s.str.rsplit(n=2)
0 [this is a, regular, sentence]
1 [https://docs.python.org/3/tutorial/index.html]
2 NaN
dtype: object
```

The *pat* parameter can be used to split by other characters.

```
>>> s.str.split(pat = "/")
0 [this is a regular sentence]
1 [https:, , docs.python.org, 3, tutorial, index...]
2 NaN
dtype: object
```

When using `expand=True`, the split elements will expand out into separate columns. If NaN is present, it is propagated throughout the columns during the split.

```
>>> s.str.split(expand=True)
0          0      1      2      3
0          this  is   a  regular
1  https://docs.python.org/3/tutorial/index.html  None  None  None
2          NaN  NaN  NaN  NaN \
0          4
0          sentence
```

(continues on next page)

(continued from previous page)

```
1      None
2      NaN
```

For slightly more complex use cases like splitting the html document name from a url, a combination of parameter settings can be used.

```
>>> s.str.rsplit("/", n=1, expand=True)
           0      1
0      this is a regular sentence      None
1  https://docs.python.org/3/tutorial  index.html
2                                 NaN      NaN
```

Remember to escape special characters when explicitly using regular expressions.

```
>>> s = pd.Series(["1+1=2"])
```

```
>>> s.str.split(r"\+|=", expand=True)
   0  1  2
0  1  1  2
```

pandas.Series.str.rsplit

`Series.str.rsplit(self, pat=None, n=-1, expand=False)`

Split strings around given separator/delimiter.

Splits the string in the Series/Index from the end, at the specified delimiter string. Equivalent to `str.rsplit()`.

Parameters

pat [str, optional] String or regular expression to split on. If not specified, split on whitespace.

n [int, default -1 (all)] Limit number of splits in output. `None`, 0 and -1 will be interpreted as return all splits.

expand [bool, default False] Expand the splitted strings into separate columns.

- If `True`, return `DataFrame`/`MultiIndex` expanding dimensionality.
- If `False`, return `Series`/`Index`, containing lists of strings.

Returns

`Series`, `Index`, `DataFrame` or `MultiIndex` Type matches caller unless `expand=True` (see Notes).

See also:

`Series.str.split` Split strings around given separator/delimiter.

`Series.str.rsplit` Splits string around given separator/delimiter, starting from the right.

`Series.str.join` Join lists contained as elements in the Series/Index with passed delimiter.

`str.split` Standard library version for split.

`str.rsplit` Standard library version for rsplit.

Notes

The handling of the n keyword depends on the number of found splits:

- If found splits $> n$, make first n splits only
- If found splits $\leq n$, make all splits
- If for a certain row the number of found splits $< n$, append *None* for padding up to n if `expand=True`

If using `expand=True`, Series and Index callers return DataFrame and MultiIndex objects, respectively.

Examples

```
>>> s = pd.Series(["this is a regular sentence",
...               "https://docs.python.org/3/tutorial/index.html",
...               np.nan])
0          this is a regular sentence
1  https://docs.python.org/3/tutorial/index.html
2                               NaN
dtype: object
```

In the default setting, the string is split by whitespace.

```
>>> s.str.split()
0          [this, is, a, regular, sentence]
1  [https://docs.python.org/3/tutorial/index.html]
2                               NaN
dtype: object
```

Without the n parameter, the outputs of *rsplit* and *split* are identical.

```
>>> s.str.rsplit()
0          [this, is, a, regular, sentence]
1  [https://docs.python.org/3/tutorial/index.html]
2                               NaN
dtype: object
```

The n parameter can be used to limit the number of splits on the delimiter. The outputs of *split* and *rsplit* are different.

```
>>> s.str.split(n=2)
0          [this, is, a regular sentence]
1  [https://docs.python.org/3/tutorial/index.html]
2                               NaN
dtype: object
```

```
>>> s.str.rsplit(n=2)
0          [this is a, regular, sentence]
1  [https://docs.python.org/3/tutorial/index.html]
2                               NaN
dtype: object
```

The *pat* parameter can be used to split by other characters.

```
>>> s.str.split(pat = "/")
0          [this is a regular sentence]
1  [https:, , docs.python.org, 3, tutorial, index...
2                                     NaN
dtype: object
```

When using `expand=True`, the split elements will expand out into separate columns. If NaN is present, it is propagated throughout the columns during the split.

```
>>> s.str.split(expand=True)
           0      1      2      3
0          this  is   a  regular
1  https://docs.python.org/3/tutorial/index.html  None  None  None
2          NaN  NaN  NaN  NaN \
           4
0          sentence
1          None
2          NaN
```

For slightly more complex use cases like splitting the html document name from a url, a combination of parameter settings can be used.

```
>>> s.str.rsplit("/", n=1, expand=True)
           0      1
0          this is a regular sentence  None
1  https://docs.python.org/3/tutorial  index.html
2          NaN  NaN
```

Remember to escape special characters when explicitly using regular expressions.

```
>>> s = pd.Series(["1+1=2"])
```

```
>>> s.str.split(r"\+|=)", expand=True)
   0  1  2
0  1  1  2
```

pandas.Series.str.startswith

`Series.str.startswith(self, pat, na=nan)`

Test if the start of each string element matches a pattern.

Equivalent to `str.startswith()`.

Parameters

pat [str] Character sequence. Regular expressions are not accepted.

na [object, default NaN] Object shown if element tested is not a string.

Returns

Series or Index of bool A Series of booleans indicating whether the given pattern matches the start of each string element.

See also:

`str.startswith` Python standard library string method.

`Series.str.endswith` Same as `startswith`, but tests the end of string.

`Series.str.contains` Tests if string element contains a pattern.

Examples

```
>>> s = pd.Series(['bat', 'Bear', 'cat', np.nan])
>>> s
0    bat
1   Bear
2    cat
3   NaN
dtype: object
```

```
>>> s.str.startswith('b')
0    True
1   False
2   False
3    NaN
dtype: object
```

Specifying `na` to be `False` instead of `NaN`.

```
>>> s.str.startswith('b', na=False)
0    True
1   False
2   False
3   False
dtype: bool
```

pandas.Series.str.strip

`Series.str.strip(self, to_strip=None)`

Remove leading and trailing characters.

Strip whitespaces (including newlines) or a set of specified characters from each string in the Series/Index from left and right sides. Equivalent to `str.strip()`.

Parameters

to_strip [str or None, default None] Specifying the set of characters to be removed. All combinations of this set of characters will be stripped. If None then whitespaces are removed.

Returns

Series/Index of objects

See also:

`Series.str.strip` Remove leading and trailing characters in Series/Index.

`Series.str.lstrip` Remove leading characters in Series/Index.

`Series.str.rstrip` Remove trailing characters in Series/Index.

Examples

```
>>> s = pd.Series(['1. Ant. ', '2. Bee!\n', '3. Cat?\t', np.nan])
>>> s
0    1. Ant.
1    2. Bee!\n
2    3. Cat?\t
3           NaN
dtype: object
```

```
>>> s.str.strip()
0    1. Ant.
1    2. Bee!
2    3. Cat?
3           NaN
dtype: object
```

```
>>> s.str.lstrip('123.')
0    Ant.
1    Bee!\n
2    Cat?\t
3           NaN
dtype: object
```

```
>>> s.str.rstrip('.!? \n\t')
0    1. Ant
1    2. Bee
2    3. Cat
3           NaN
dtype: object
```

```
>>> s.str.strip('123.!? \n\t')
0    Ant
1    Bee
2    Cat
3    NaN
dtype: object
```

pandas.Series.str.swapcase

`Series.str.swapcase(self)`

Convert strings in the Series/Index to be swapcased.

Equivalent to `str.swapcase()`.

Returns

Series/Index of objects

See also:

`Series.str.lower` Converts all characters to lowercase.

`Series.str.upper` Converts all characters to uppercase.

Series.str.title Converts first character of each word to uppercase and remaining to lowercase.

Series.str.capitalize Converts first character to uppercase and remaining to lowercase.

Series.str.swapcase Converts uppercase to lowercase and lowercase to uppercase.

Series.str.casefold Removes all case distinctions in the string.

Examples

```
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0          lower
1        CAPITALS
2  this is a sentence
3        SwApCaSe
dtype: object
```

```
>>> s.str.lower()
0          lower
1        capitals
2  this is a sentence
3        swapcase
dtype: object
```

```
>>> s.str.upper()
0          LOWER
1        CAPITALS
2  THIS IS A SENTENCE
3        SWAPCASE
dtype: object
```

```
>>> s.str.title()
0          Lower
1        Capitals
2  This Is A Sentence
3        Swapcase
dtype: object
```

```
>>> s.str.capitalize()
0          Lower
1        Capitals
2  This is a sentence
3        Swapcase
dtype: object
```

```
>>> s.str.swapcase()
0          LOWER
1        capitals
2  THIS IS A SENTENCE
3        sWaPcAsE
dtype: object
```

pandas.Series.str.title**Series.str.title(*self*)**

Convert strings in the Series/Index to titlecase.

Equivalent to `str.title()`.**Returns****Series/Index of objects****See also:****Series.str.lower** Converts all characters to lowercase.**Series.str.upper** Converts all characters to uppercase.**Series.str.title** Converts first character of each word to uppercase and remaining to lowercase.**Series.str.capitalize** Converts first character to uppercase and remaining to lowercase.**Series.str.swapcase** Converts uppercase to lowercase and lowercase to uppercase.**Series.str.casefold** Removes all case distinctions in the string.**Examples**

```
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0          lower
1        CAPITALS
2  this is a sentence
3        SwApCaSe
dtype: object
```

```
>>> s.str.lower()
0          lower
1        capitals
2  this is a sentence
3        swapcase
dtype: object
```

```
>>> s.str.upper()
0          LOWER
1        CAPITALS
2  THIS IS A SENTENCE
3        SWAPCASE
dtype: object
```

```
>>> s.str.title()
0          Lower
1        Capitals
2  This Is A Sentence
3        Swapcase
dtype: object
```

```
>>> s.str.capitalize()
0          Lower
1        Capitals
2  This is a sentence
3          Swapcase
dtype: object
```

```
>>> s.str.swapcase()
0          LOWER
1        capitals
2  THIS IS A SENTENCE
3          sWaPcAsE
dtype: object
```

pandas.Series.str.translate

`Series.str.translate(self, table)`

Map all characters in the string through the given mapping table. Equivalent to standard `str.translate()`.

Parameters

table [dict] table is a mapping of Unicode ordinals to Unicode ordinals, strings, or None. Unmapped characters are left untouched. Characters mapped to None are deleted. `str.maketrans()` is a helper function for making translation tables.

Returns

Series or Index

pandas.Series.str.upper

`Series.str.upper(self)`

Convert strings in the Series/Index to uppercase.

Equivalent to `str.upper()`.

Returns

Series/Index of objects

See also:

Series.str.lower Converts all characters to lowercase.

Series.str.upper Converts all characters to uppercase.

Series.str.title Converts first character of each word to uppercase and remaining to lowercase.

Series.str.capitalize Converts first character to uppercase and remaining to lowercase.

Series.str.swapcase Converts uppercase to lowercase and lowercase to uppercase.

Series.str.casefold Removes all case distinctions in the string.

Examples

```
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0          lower
1      CAPITALS
2  this is a sentence
3      SwApCaSe
dtype: object
```

```
>>> s.str.lower()
0          lower
1      capitals
2  this is a sentence
3      swapcase
dtype: object
```

```
>>> s.str.upper()
0          LOWER
1      CAPITALS
2  THIS IS A SENTENCE
3      SWAPCASE
dtype: object
```

```
>>> s.str.title()
0          Lower
1      Capitals
2  This Is A Sentence
3      Swapcase
dtype: object
```

```
>>> s.str.capitalize()
0          Lower
1      Capitals
2  This is a sentence
3      Swapcase
dtype: object
```

```
>>> s.str.swapcase()
0          LOWER
1      capitals
2  THIS IS A SENTENCE
3      sWaPcAsE
dtype: object
```

pandas.Series.str.wrap

`Series.str.wrap(self, width, **kwargs)`

Wrap long strings in the Series/Index to be formatted in paragraphs with length less than a given width.

This method has the same keyword parameters and defaults as `textwrap.TextWrapper`.

Parameters

width [int] Maximum line width.

expand_tabs [bool, optional] If True, tab characters will be expanded to spaces (default: True).

replace_whitespace [bool, optional] If True, each whitespace character (as defined by `string.whitespace`) remaining after tab expansion will be replaced by a single space (default: True).

drop_whitespace [bool, optional] If True, whitespace that, after wrapping, happens to end up at the beginning or end of a line is dropped (default: True).

break_long_words [bool, optional] If True, then words longer than width will be broken in order to ensure that no lines are longer than width. If it is false, long words will not be broken, and some lines may be longer than width (default: True).
