>>> df.assign(quarter=df.dates.dt.quarter,
...           is_quarter_start=df.dates.dt.is_quarter_start)
   dates  quarter  is_quarter_start
0 2017-03-30      1                False
1 2017-03-31      1                False
2 2017-04-01      2                 True
3 2017-04-02      2                False
```

```
>>> idx = pd.date_range('2017-03-30', periods=4)
>>> idx
DatetimeIndex(['2017-03-30', '2017-03-31', '2017-04-01', '2017-04-02'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_quarter_start
array([False, False,  True, False])
```

## pandas.Series.dt.is\_quarter\_end

### Series.dt.is\_quarter\_end

Indicator for whether the date is the last day of a quarter.

#### Returns

**is\_quarter\_end** [Series or DatetimeIndex] The same type as the original data with boolean values. Series will have the same name and index. `DatetimeIndex` will have the same name.

#### See also:

**quarter** Return the quarter of the date.

**is\_quarter\_start** Similar property indicating the quarter start.

## Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on `DatetimeIndex`.

```
>>> df = pd.DataFrame({'dates': pd.date_range("2017-03-30",
...                                           periods=4)})
>>> df.assign(quarter=df.dates.dt.quarter,
...           is_quarter_end=df.dates.dt.is_quarter_end)
   dates  quarter  is_quarter_end
0 2017-03-30      1                False
1 2017-03-31      1                 True
2 2017-04-01      2                False
3 2017-04-02      2                False
```

```
>>> idx = pd.date_range('2017-03-30', periods=4)
>>> idx
DatetimeIndex(['2017-03-30', '2017-03-31', '2017-04-01', '2017-04-02'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_quarter_end
array([False,  True,  False,  False])
```

## pandas.Series.dt.is\_year\_start

### Series.dt.is\_year\_start

Indicate whether the date is the first day of a year.

#### Returns

**Series or DatetimeIndex** The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

#### See also:

**is\_year\_end** Similar property indicating the last day of the year.

### Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```
>>> dates = pd.Series(pd.date_range("2017-12-30", periods=3))
>>> dates
0    2017-12-30
1    2017-12-31
2    2018-01-01
dtype: datetime64[ns]
```

```
>>> dates.dt.is_year_start
0    False
1    False
2     True
dtype: bool
```

```
>>> idx = pd.date_range("2017-12-30", periods=3)
>>> idx
DatetimeIndex(['2017-12-30', '2017-12-31', '2018-01-01'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_year_start
array([False,  False,  True])
```

## pandas.Series.dt.is\_year\_end

### Series.dt.is\_year\_end

Indicate whether the date is the last day of the year.

#### Returns

**Series or DatetimeIndex** The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

#### See also:

**is\_year\_start** Similar property indicating the start of the year.

## Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on `DatetimeIndex`.

```
>>> dates = pd.Series(pd.date_range("2017-12-30", periods=3))
>>> dates
0    2017-12-30
1    2017-12-31
2    2018-01-01
dtype: datetime64[ns]
```

```
>>> dates.dt.is_year_end
0    False
1     True
2    False
dtype: bool
```

```
>>> idx = pd.date_range("2017-12-30", periods=3)
>>> idx
DatetimeIndex(['2017-12-30', '2017-12-31', '2018-01-01'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_year_end
array([False,  True,  False])
```

## pandas.Series.dt.is\_leap\_year

### Series.dt.is\_leap\_year

Boolean indicator if the date belongs to a leap year.

A leap year is a year, which has 366 days (instead of 365) including 29th of February as an intercalary day. Leap years are years which are multiples of four with the exception of years divisible by 100 but not by 400.

#### Returns

**Series or ndarray** Booleans indicating if dates belong to a leap year.

## Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on `DatetimeIndex`.

```
>>> idx = pd.date_range("2012-01-01", "2015-01-01", freq="Y")
>>> idx
DatetimeIndex(['2012-12-31', '2013-12-31', '2014-12-31'],
              dtype='datetime64[ns]', freq='A-DEC')
>>> idx.is_leap_year
array([ True,  False,  False], dtype=bool)
```

```
>>> dates = pd.Series(idx)
>>> dates_series
0    2012-12-31
1    2013-12-31
2    2014-12-31
dtype: datetime64[ns]
>>> dates_series.dt.is_leap_year
```

(continues on next page)

(continued from previous page)

```
0    True
1    False
2    False
dtype: bool
```

### pandas.Series.dt.daysinmonth

`Series.dt.daysinmonth`  
The number of days in the month.

### pandas.Series.dt.days\_in\_month

`Series.dt.days_in_month`  
The number of days in the month.

### pandas.Series.dt.tz

`Series.dt.tz`  
Return timezone, if any.

**Returns**

`datetime.tzinfo, pytz.tzinfo.BaseTZInfo, dateutil.tz.tzfile, or None` Returns `None` when the array is tz-naive.

### pandas.Series.dt.freq

`Series.dt.freq`

### Datetime methods

<code>Series.dt.to_period(self, *args, **kwargs)</code>	Cast to PeriodArray/Index at a particular frequency.
<code>Series.dt.to_pydatetime(self)</code>	Return the data as an array of native Python datetime objects.
<code>Series.dt.tz_localize(self, *args, **kwargs)</code>	Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index.
<code>Series.dt.tz_convert(self, *args, **kwargs)</code>	Convert tz-aware Datetime Array/Index from one time zone to another.
<code>Series.dt.normalize(self, *args, **kwargs)</code>	Convert times to midnight.
<code>Series.dt.strftime(self, *args, **kwargs)</code>	Convert to Index using specified <code>date_format</code> .
<code>Series.dt.round(self, *args, **kwargs)</code>	Perform round operation on the data to the specified <code>freq</code> .
<code>Series.dt.floor(self, *args, **kwargs)</code>	Perform floor operation on the data to the specified <code>freq</code> .
<code>Series.dt.ceil(self, *args, **kwargs)</code>	Perform ceil operation on the data to the specified <code>freq</code> .
<code>Series.dt.month_name(self, *args, **kwargs)</code>	Return the month names of the DateTimeIndex with specified locale.

Continued on next page

Table 43 – continued from previous page

<code>Series.dt.day_name(self, \*args, \*\*kwargs)</code>	Return the day names of the DateTimeIndex with specified locale.
-----------------------------------------------------------	------------------------------------------------------------------

### pandas.Series.dt.to\_period

`Series.dt.to_period(self, \*args, \*\*kwargs)`

Cast to PeriodArray/Index at a particular frequency.

Converts DatetimeArray/Index to PeriodArray/Index.

#### Parameters

**freq** [str or Offset, optional] One of pandas' *offset strings* or an Offset object. Will be inferred by default.

#### Returns

**PeriodArray/Index**

#### Raises

**ValueError** When converting a DatetimeArray/Index with non-regular values, so that a frequency cannot be inferred.

#### See also:

**PeriodIndex** Immutable ndarray holding ordinal values.

**DatetimeIndex.to\_pydatetime** Return DateTimeIndex as object.

### Examples

```
>>> df = pd.DataFrame({"y": [1, 2, 3]},
...                    index=pd.to_datetime(["2000-03-31 00:00:00",
...                                          "2000-05-31 00:00:00",
...                                          "2000-08-31 00:00:00"]))
>>> df.index.to_period("M")
PeriodIndex(['2000-03', '2000-05', '2000-08'],
            dtype='period[M]', freq='M')
```

Infer the daily frequency

```
>>> idx = pd.date_range("2017-01-01", periods=2)
>>> idx.to_period()
PeriodIndex(['2017-01-01', '2017-01-02'],
            dtype='period[D]', freq='D')
```

### pandas.Series.dt.to\_pydatetime

`Series.dt.to_pydatetime(self)`

Return the data as an array of native Python datetime objects.

Timezone information is retained if present.

**Warning:** Python's datetime uses microsecond resolution, which is lower than pandas (nanosecond). The values are truncated.

## Returns

`numpy.ndarray` Object dtype array containing native Python datetime objects.

## See also:

`datetime.datetime` Standard library value for a datetime.

## Examples

```
>>> s = pd.Series(pd.date_range('20180310', periods=2))
>>> s
0    2018-03-10
1    2018-03-11
dtype: datetime64[ns]
```

```
>>> s.dt.to_pydatetime()
array([datetime.datetime(2018, 3, 10, 0, 0),
       datetime.datetime(2018, 3, 11, 0, 0)], dtype=object)
```

pandas' nanosecond precision is truncated to microseconds.

```
>>> s = pd.Series(pd.date_range('20180310', periods=2, freq='ns'))
>>> s
0    2018-03-10 00:00:00.000000000
1    2018-03-10 00:00:00.000000001
dtype: datetime64[ns]
```

```
>>> s.dt.to_pydatetime()
array([datetime.datetime(2018, 3, 10, 0, 0),
       datetime.datetime(2018, 3, 10, 0, 0)], dtype=object)
```

## pandas.Series.dt.tz\_localize

`Series.dt.tz_localize` (*self*, \*args, \*\*kwargs)

Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index.

This method takes a time zone (tz) naive Datetime Array/Index object and makes this time zone aware. It does not move the time to another time zone. Time zone localization helps to switch from time zone aware to time zone unaware objects.

### Parameters

**tz** [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone to convert timestamps to. Passing None will remove the time zone information preserving local time.

**ambiguous** ['infer', 'NaT', bool array, default 'raise'] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the *ambiguous* parameter dictates how ambiguous times should be handled.

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False signifies a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times

- 'raise' will raise an `AmbiguousTimeError` if there are ambiguous times.

**nonexistent** ['shift\_forward', 'shift\_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift\_forward' will shift the nonexistent time forward to the closest existing time
- 'shift\_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return `NaT` where there are nonexistent times
- `timedelta` objects will shift nonexistent times by the `timedelta`
- 'raise' will raise an `NonExistentTimeError` if there are nonexistent times.

New in version 0.24.0.

### Returns

**Same type as self** Array/Index converted to the specified time zone.

### Raises

**TypeError** If the `Datetime Array/Index` is tz-aware and `tz` is not `None`.

See also:

**`DatetimeIndex.tz_convert`** Convert tz-aware `DatetimeIndex` from one time zone to another.

### Examples

```
>>> tz_naive = pd.date_range('2018-03-01 09:00', periods=3)
>>> tz_naive
DatetimeIndex(['2018-03-01 09:00:00', '2018-03-02 09:00:00',
              '2018-03-03 09:00:00'],
              dtype='datetime64[ns]', freq='D')
```

Localize `DatetimeIndex` in US/Eastern time zone:

```
>>> tz_aware = tz_naive.tz_localize(tz='US/Eastern')
>>> tz_aware
DatetimeIndex(['2018-03-01 09:00:00-05:00',
              '2018-03-02 09:00:00-05:00',
              '2018-03-03 09:00:00-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq='D')
```

With the `tz=None`, we can remove the time zone information while keeping the local time (not converted to UTC):

```
>>> tz_aware.tz_localize(None)
DatetimeIndex(['2018-03-01 09:00:00', '2018-03-02 09:00:00',
              '2018-03-03 09:00:00'],
              dtype='datetime64[ns]', freq='D')
```

Be careful with DST changes. When there is sequential data, pandas can infer the DST time:

```
>>> s = pd.to_datetime(pd.Series(['2018-10-28 01:30:00',
...                               '2018-10-28 02:00:00',
...                               '2018-10-28 02:30:00',
```

(continues on next page)

(continued from previous page)

```

...         '2018-10-28 02:00:00',
...         '2018-10-28 02:30:00',
...         '2018-10-28 03:00:00',
...         '2018-10-28 03:30:00'])))
>>> s.dt.tz_localize('CET', ambiguous='infer')
0    2018-10-28 01:30:00+02:00
1    2018-10-28 02:00:00+02:00
2    2018-10-28 02:30:00+02:00
3    2018-10-28 02:00:00+01:00
4    2018-10-28 02:30:00+01:00
5    2018-10-28 03:00:00+01:00
6    2018-10-28 03:30:00+01:00
dtype: datetime64[ns, CET]

```

In some cases, inferring the DST is impossible. In such cases, you can pass an ndarray to the `ambiguous` parameter to set the DST explicitly

```

>>> s = pd.to_datetime(pd.Series(['2018-10-28 01:20:00',
...                               '2018-10-28 02:36:00',
...                               '2018-10-28 03:46:00']))
>>> s.dt.tz_localize('CET', ambiguous=np.array([True, True, False]))
0    2015-03-29 03:00:00+02:00
1    2015-03-29 03:30:00+02:00
dtype: datetime64[ns, Europe/Warsaw]

```

If the DST transition causes nonexistent times, you can shift these dates forward or backwards with a `timedelta` object or `'shift_forward'` or `'shift_backwards'`.

```

>>> s = pd.to_datetime(pd.Series(['2015-03-29 02:30:00',
...                               '2015-03-29 03:30:00']))
>>> s.dt.tz_localize('Europe/Warsaw', nonexistent='shift_forward')
0    2015-03-29 03:00:00+02:00
1    2015-03-29 03:30:00+02:00
dtype: datetime64[ns, 'Europe/Warsaw']
>>> s.dt.tz_localize('Europe/Warsaw', nonexistent='shift_backward')
0    2015-03-29 01:59:59.999999999+01:00
1    2015-03-29 03:30:00+02:00
dtype: datetime64[ns, 'Europe/Warsaw']
>>> s.dt.tz_localize('Europe/Warsaw', nonexistent=pd.Timedelta('1H'))
0    2015-03-29 03:30:00+02:00
1    2015-03-29 03:30:00+02:00
dtype: datetime64[ns, 'Europe/Warsaw']

```

## pandas.Series.dt.tz\_convert

`Series.dt.tz_convert` (*self*, \*args, \*\*kwargs)

Convert tz-aware Datetime Array/Index from one time zone to another.

### Parameters

**tz** [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time. Corresponding timestamps would be converted to this time zone of the Datetime Array/Index. A *tz* of None will convert to UTC and remove the timezone information.

### Returns

Array or Index

## Raises

**TypeError** If Datetime Array/Index is tz-naive.

See also:

**DatetimeIndex.tz** A timezone that has a variable offset from UTC.

**DatetimeIndex.tz\_localize** Localize tz-naive DatetimeIndex to a given time zone, or remove time-zone from a tz-aware DatetimeIndex.

## Examples

With the `tz` parameter, we can change the DatetimeIndex to other time zones:

```
>>> dti = pd.date_range(start='2014-08-01 09:00',
...                       freq='H', periods=3, tz='Europe/Berlin')
```

```
>>> dti
DatetimeIndex(['2014-08-01 09:00:00+02:00',
               '2014-08-01 10:00:00+02:00',
               '2014-08-01 11:00:00+02:00'],
              dtype='datetime64[ns, Europe/Berlin]', freq='H')
```

```
>>> dti.tz_convert('US/Central')
DatetimeIndex(['2014-08-01 02:00:00-05:00',
               '2014-08-01 03:00:00-05:00',
               '2014-08-01 04:00:00-05:00'],
              dtype='datetime64[ns, US/Central]', freq='H')
```

With the `tz=None`, we can remove the timezone (after converting to UTC if necessary):

```
>>> dti = pd.date_range(start='2014-08-01 09:00', freq='H',
...                       periods=3, tz='Europe/Berlin')
```

```
>>> dti
DatetimeIndex(['2014-08-01 09:00:00+02:00',
               '2014-08-01 10:00:00+02:00',
               '2014-08-01 11:00:00+02:00'],
              dtype='datetime64[ns, Europe/Berlin]', freq='H')
```

```
>>> dti.tz_convert(None)
DatetimeIndex(['2014-08-01 07:00:00',
               '2014-08-01 08:00:00',
               '2014-08-01 09:00:00'],
              dtype='datetime64[ns]', freq='H')
```

## pandas.Series.dt.normalize

Series.dt.**normalize** (*self*, \*args, \*\*kwargs)

Convert times to midnight.

The time component of the date-time is converted to midnight i.e. 00:00:00. This is useful in cases, when the time does not matter. Length is unaltered. The timezones are unaffected.

This method is available on Series with datetime values under the .dt accessor, and directly on Datetime Array/Index.

### Returns

**DatetimeArray, DatetimeIndex or Series** The same type as the original data. Series will have the same name and index. DatetimeIndex will have the same name.

### See also:

**floor** Floor the datetimes to the specified freq.

**ceil** Ceil the datetimes to the specified freq.

**round** Round the datetimes to the specified freq.

## Examples

```
>>> idx = pd.date_range(start='2014-08-01 10:00', freq='H',
...                     periods=3, tz='Asia/Calcutta')
>>> idx
DatetimeIndex(['2014-08-01 10:00:00+05:30',
              '2014-08-01 11:00:00+05:30',
              '2014-08-01 12:00:00+05:30'],
              dtype='datetime64[ns, Asia/Calcutta]', freq='H')
>>> idx.normalize()
DatetimeIndex(['2014-08-01 00:00:00+05:30',
              '2014-08-01 00:00:00+05:30',
              '2014-08-01 00:00:00+05:30'],
              dtype='datetime64[ns, Asia/Calcutta]', freq=None)
```

## pandas.Series.dt.strftime

Series.dt.**strftime** (*self*, \*args, \*\*kwargs)

Convert to Index using specified date\_format.

Return an Index of formatted strings specified by date\_format, which supports the same string format as the python standard library. Details of the string format can be found in [python string format doc](#).

### Parameters

**date\_format** [str] Date format string (e.g. “%Y-%m-%d”).

### Returns

**ndarray** NumPy ndarray of formatted strings.

### See also:

**to\_datetime** Convert the given argument to datetime.

**DatetimeIndex.normalize** Return DatetimeIndex with times to midnight.

**DatetimeIndex.round** Round the DatetimeIndex to the specified freq.

**DatetimeIndex.floor** Floor the DatetimeIndex to the specified freq.

## Examples

```
>>> rng = pd.date_range(pd.Timestamp("2018-03-10 09:00"),
...                      periods=3, freq='s')
>>> rng.strftime('%B %d, %Y, %r')
Index(['March 10, 2018, 09:00:00 AM', 'March 10, 2018, 09:00:01 AM',
       'March 10, 2018, 09:00:02 AM'],
      dtype='object')
```

## pandas.Series.dt.round

`Series.dt.round` (*self*, \*args, \*\*kwargs)

Perform round operation on the data to the specified *freq*.

### Parameters

**freq** [str or Offset] The frequency level to round the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See *frequency aliases* for a list of possible *freq* values.

**ambiguous** [‘infer’, bool-ndarray, ‘NaT’, default ‘raise’] Only relevant for DatetimeIndex:

- ‘infer’ will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- ‘NaT’ will return NaT where there are ambiguous times
- ‘raise’ will raise an `AmbiguousTimeError` if there are ambiguous times.

New in version 0.24.0.

**nonexistent** [‘shift\_forward’, ‘shift\_backward’, ‘NaT’, timedelta, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- ‘shift\_forward’ will shift the nonexistent time forward to the closest existing time
- ‘shift\_backward’ will shift the nonexistent time backward to the closest existing time
- ‘NaT’ will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- ‘raise’ will raise an `NonExistentTimeError` if there are nonexistent times.

New in version 0.24.0.

### Returns

**DatetimeIndex, TimedeltaIndex, or Series** Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

### Raises

**ValueError** if the *freq* cannot be converted.

## Examples

### DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
              '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.round('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
              '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq=None)
```

### Series

```
>>> pd.Series(rng).dt.round("H")
0    2018-01-01 12:00:00
1    2018-01-01 12:00:00
2    2018-01-01 12:00:00
dtype: datetime64[ns]
```

## pandas.Series.dt.floor

`Series.dt.floor` (*self*, \*args, \*\*kwargs)

Perform floor operation on the data to the specified *freq*.

### Parameters

**freq** [str or Offset] The frequency level to floor the index to. Must be a fixed frequency like 'S' (second) not 'ME' (month end). See *frequency aliases* for a list of possible *freq* values.

**ambiguous** ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for DatetimeIndex:

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an `AmbiguousTimeError` if there are ambiguous times.

New in version 0.24.0.

**nonexistent** ['shift\_forward', 'shift\_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift\_forward' will shift the nonexistent time forward to the closest existing time
- 'shift\_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise a `NonExistentTimeError` if there are nonexistent times.

New in version 0.24.0.

**Returns**

**DatetimeIndex, TimedeltaIndex, or Series** Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

**Raises**

**ValueError** if the *freq* cannot be converted.

**Examples****DatetimeIndex**

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
              '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.floor('H')
DatetimeIndex(['2018-01-01 11:00:00', '2018-01-01 12:00:00',
              '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq=None)
```

**Series**

```
>>> pd.Series(rng).dt.floor("H")
0    2018-01-01 11:00:00
1    2018-01-01 12:00:00
2    2018-01-01 12:00:00
dtype: datetime64[ns]
```

**pandas.Series.dt.ceil**

`Series.dt.ceil` (*self*, \*args, \*\*kwargs)

Perform ceil operation on the data to the specified *freq*.

**Parameters**

**freq** [str or Offset] The frequency level to ceil the index to. Must be a fixed frequency like 'S' (second) not 'ME' (month end). See *frequency aliases* for a list of possible *freq* values.

**ambiguous** ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for DatetimeIndex:

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times.

New in version 0.24.0.

**nonexistent** ['shift\_forward', 'shift\_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift\_forward' will shift the nonexistent time forward to the closest existing time

- 'shift\_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

#### Returns

**DatetimeIndex, TimedeltaIndex, or Series** Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

#### Raises

**ValueError** if the *freq* cannot be converted.

### Examples

#### DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
              '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.ceil('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
              '2018-01-01 13:00:00'],
              dtype='datetime64[ns]', freq=None)
```

#### Series

```
>>> pd.Series(rng).dt.ceil("H")
0    2018-01-01 12:00:00
1    2018-01-01 12:00:00
2    2018-01-01 13:00:00
dtype: datetime64[ns]
```

### pandas.Series.dt.month\_name

`Series.dt.month_name` (*self*, \*args, \*\*kwargs)

Return the month names of the DateTimeIndex with specified locale.

New in version 0.23.0.

#### Parameters

**locale** [str, optional] Locale determining the language in which to return the month name. Default is English locale.

#### Returns

**Index** Index of month names.

## Examples

```
>>> idx = pd.date_range(start='2018-01', freq='M', periods=3)
>>> idx
DatetimeIndex(['2018-01-31', '2018-02-28', '2018-03-31'],
              dtype='datetime64[ns]', freq='M')
>>> idx.month_name()
Index(['January', 'February', 'March'], dtype='object')
```

## pandas.Series.dt.day\_name

`Series.dt.day_name` (*self*, \*args, \*\*kwargs)

Return the day names of the DateTimeIndex with specified locale.

New in version 0.23.0.

### Parameters

**locale** [str, optional] Locale determining the language in which to return the day name. Default is English locale.

### Returns

**Index** Index of day names.

## Examples

```
>>> idx = pd.date_range(start='2018-01-01', freq='D', periods=3)
>>> idx
DatetimeIndex(['2018-01-01', '2018-01-02', '2018-01-03'],
              dtype='datetime64[ns]', freq='D')
>>> idx.day_name()
Index(['Monday', 'Tuesday', 'Wednesday'], dtype='object')
```

## Period properties

*Series.dt.qyear*

*Series.dt.start\_time*

*Series.dt.end\_time*

## pandas.Series.dt.qyear

`Series.dt.qyear`

### **pandas.Series.dt.start\_time**

`Series.dt.start_time`

### **pandas.Series.dt.end\_time**

`Series.dt.end_time`

### **Timedelta properties**

<i>Series.dt.days</i>	Number of days for each element.
<i>Series.dt.seconds</i>	Number of seconds ( $\geq 0$ and less than 1 day) for each element.
<i>Series.dt.microseconds</i>	Number of microseconds ( $\geq 0$ and less than 1 second) for each element.
<i>Series.dt.nanoseconds</i>	Number of nanoseconds ( $\geq 0$ and less than 1 microsecond) for each element.
<i>Series.dt.components</i>	Return a Dataframe of the components of the Timedeltas.

### **pandas.Series.dt.days**

`Series.dt.days`  
Number of days for each element.

### **pandas.Series.dt.seconds**

`Series.dt.seconds`  
Number of seconds ( $\geq 0$  and less than 1 day) for each element.

### **pandas.Series.dt.microseconds**

`Series.dt.microseconds`  
Number of microseconds ( $\geq 0$  and less than 1 second) for each element.

### **pandas.Series.dt.nanoseconds**

`Series.dt.nanoseconds`  
Number of nanoseconds ( $\geq 0$  and less than 1 microsecond) for each element.

## pandas.Series.dt.components

### Series.dt.components

Return a Dataframe of the components of the Timedeltas.

#### Returns

**DataFrame**

#### Examples

```

>>> s = pd.Series(pd.to_timedelta(np.arange(5), unit='s'))
>>> s
0    00:00:00
1    00:00:01
2    00:00:02
3    00:00:03
4    00:00:04
dtype: timedelta64[ns]
>>> s.dt.components
   days  hours  minutes  seconds  milliseconds  microseconds  nanoseconds
0     0     0         0         0             0             0             0
1     0     0         0         1             0             0             0
2     0     0         0         2             0             0             0
3     0     0         0         3             0             0             0
4     0     0         0         4             0             0             0

```

## Timedelta methods

<code>Series.dt.to_pytimedelta(self)</code>		Return an array of native <i>datetime.timedelta</i> objects.
<code>Series.dt.total_seconds(self,   \**kwargs)</code>	<code>\*args,</code>	Return total duration of each element expressed in seconds.

## pandas.Series.dt.to\_pytimedelta

### Series.dt.to\_pytimedelta(self)

Return an array of native *datetime.timedelta* objects.

Python's standard *datetime* library uses a different representation *timedelta*'s. This method converts a Series of pandas *Timedeltas* to *datetime.timedelta* format with the same length as the original Series.

#### Returns

**numpy.ndarray** Array of 1D containing data with *datetime.timedelta* type.

See also:

`datetime.timedelta`

## Examples

```
>>> s = pd.Series(pd.to_timedelta(np.arange(5), unit='d'))
>>> s
0    0 days
1    1 days
2    2 days
3    3 days
4    4 days
dtype: timedelta64[ns]
```

```
>>> s.dt.to_pytimedelta()
array([datetime.timedelta(0), datetime.timedelta(1),
       datetime.timedelta(2), datetime.timedelta(3),
       datetime.timedelta(4)], dtype=object)
```

## pandas.Series.dt.total\_seconds

`Series.dt.total_seconds` (*self*, \*args, \*\*kwargs)

Return total duration of each element expressed in seconds.

This method is available directly on `TimedeltaArray`, `TimedeltaIndex` and on `Series` containing `timedelta` values under the `.dt` namespace.

### Returns

**seconds** `[[ndarray, Float64Index, Series]]` When the calling object is a `TimedeltaArray`, the return type is `ndarray`. When the calling object is a `TimedeltaIndex`, the return type is a `Float64Index`. When the calling object is a `Series`, the return type is `Series` of type `float64` whose index is the same as the original.

### See also:

`datetime.timedelta.total_seconds` Standard library version of this method.

`TimedeltaIndex.components` Return a `DataFrame` with components of each `Timedelta`.

## Examples

### Series

```
>>> s = pd.Series(pd.to_timedelta(np.arange(5), unit='d'))
>>> s
0    0 days
1    1 days
2    2 days
3    3 days
4    4 days
dtype: timedelta64[ns]
```

```
>>> s.dt.total_seconds()
0         0.0
1    86400.0
2   172800.0
3   259200.0
4   345600.0
dtype: float64
```

**TimedeltaIndex**

```
>>> idx = pd.to_timedelta(np.arange(5), unit='d')
>>> idx
TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'],
                dtype='timedelta64[ns]', freq=None)
```

```
>>> idx.total_seconds()
Float64Index([0.0, 86400.0, 172800.0, 259200.000000000003, 345600.0],
              dtype='float64')
```

**String handling**

`Series.str` can be used to access the values of the series as strings and apply several methods to it. These can be accessed like `Series.str.<function/property>`.

<code>Series.str.capitalize(self)</code>	Convert strings in the Series/Index to be capitalized.
<code>Series.str.casefold(self)</code>	Convert strings in the Series/Index to be casefolded.
<code>Series.str.cat(self[, others, sep, na_rep, join])</code>	Concatenate strings in the Series/Index with given separator.
<code>Series.str.center(self, width[, fillchar])</code>	Filling left and right side of strings in the Series/Index with an additional character.
<code>Series.str.contains(self, pat[, case, ...])</code>	Test if pattern or regex is contained within a string of a Series or Index.
<code>Series.str.count(self, pat[, flags])</code>	Count occurrences of pattern in each string of the Series/Index.
<code>Series.str.decode(self, encoding[, errors])</code>	Decode character string in the Series/Index using indicated encoding.
<code>Series.str.encode(self, encoding[, errors])</code>	Encode character string in the Series/Index using indicated encoding.
<code>Series.str.endswith(self, pat[, na])</code>	Test if the end of each string element matches a pattern.
<code>Series.str.extract(self, pat[, flags, expand])</code>	Extract capture groups in the regex <i>pat</i> as columns in a DataFrame.
<code>Series.str.extractall(self, pat[, flags])</code>	For each subject string in the Series, extract groups from all matches of regular expression <i>pat</i> .
<code>Series.str.find(self, sub[, start, end])</code>	Return lowest indexes in each strings in the Series/Index where the substring is fully contained between [start:end].
<code>Series.str.findall(self, pat[, flags])</code>	Find all occurrences of pattern or regular expression in the Series/Index.
<code>Series.str.get(self, i)</code>	Extract element from each component at specified position.
<code>Series.str.index(self, sub[, start, end])</code>	Return lowest indexes in each strings where the substring is fully contained between [start:end].
<code>Series.str.join(self, sep)</code>	Join lists contained as elements in the Series/Index with passed delimiter.
<code>Series.str.len(self)</code>	Compute the length of each element in the Series/Index.
<code>Series.str.ljust(self, width[, fillchar])</code>	Filling right side of strings in the Series/Index with an additional character.
<code>Series.str.lower(self)</code>	Convert strings in the Series/Index to lowercase.
<code>Series.str.lstrip(self[, to_strip])</code>	Remove leading and trailing characters.

Continued on next page

Table 47 – continued from previous page

<code>Series.str.match(self, pat[, case, flags, na])</code>	Determine if each string matches a regular expression.
<code>Series.str.normalize(self, form)</code>	Return the Unicode normal form for the strings in the Series/Index.
<code>Series.str.pad(self, width[, side, fillchar])</code>	Pad strings in the Series/Index up to width.
<code>Series.str.partition(self[, sep, expand])</code>	Split the string at the first occurrence of <i>sep</i> .
<code>Series.str.repeat(self, repeats)</code>	Duplicate each string in the Series or Index.
<code>Series.str.replace(self, pat, repl[, n, ...])</code>	Replace occurrences of pattern/regex in the Series/Index with some other string.
<code>Series.str.rfind(self, sub[, start, end])</code>	Return highest indexes in each strings in the Series/Index where the substring is fully contained between [start:end].
<code>Series.str.rindex(self, sub[, start, end])</code>	Return highest indexes in each strings where the substring is fully contained between [start:end].
<code>Series.str.rjust(self, width[, fillchar])</code>	Filling left side of strings in the Series/Index with an additional character.
<code>Series.str.rpartition(self[, sep, expand])</code>	Split the string at the last occurrence of <i>sep</i> .
<code>Series.str.rstrip(self[, to_strip])</code>	Remove leading and trailing characters.
<code>Series.str.slice(self[, start, stop, step])</code>	Slice substrings from each element in the Series or Index.
<code>Series.str.slice_replace(self[, start, ...])</code>	Replace a positional slice of a string with another value.
<code>Series.str.split(self[, pat, n, expand])</code>	Split strings around given separator/delimiter.
<code>Series.str.rsplit(self[, pat, n, expand])</code>	Split strings around given separator/delimiter.
<code>Series.str.startswith(self, pat[, na])</code>	Test if the start of each string element matches a pattern.
<code>Series.str.strip(self[, to_strip])</code>	Remove leading and trailing characters.
<code>Series.str.swapcase(self)</code>	Convert strings in the Series/Index to be swappcased.
<code>Series.str.title(self)</code>	Convert strings in the Series/Index to titlecase.
<code>Series.str.translate(self, table)</code>	Map all characters in the string through the given mapping table.
<code>Series.str.upper(self)</code>	Convert strings in the Series/Index to uppercase.
<code>Series.str.wrap(self, width, \**kwargs)</code>	Wrap long strings in the Series/Index to be formatted in paragraphs with length less than a given width.
<code>Series.str.zfill(self, width)</code>	Pad strings in the Series/Index by prepending '0' characters.
<code>Series.str.isalnum(self)</code>	Check whether all characters in each string are alphanumeric.
<code>Series.str.isalpha(self)</code>	Check whether all characters in each string are alphabetic.
<code>Series.str.isdigit(self)</code>	Check whether all characters in each string are digits.
<code>Series.str.isspace(self)</code>	Check whether all characters in each string are whitespace.
<code>Series.str.islower(self)</code>	Check whether all characters in each string are lowercase.
<code>Series.str.isupper(self)</code>	Check whether all characters in each string are uppercase.
<code>Series.str.istitle(self)</code>	Check whether all characters in each string are titlecase.
<code>Series.str.isnumeric(self)</code>	Check whether all characters in each string are numeric.
<code>Series.str.isdecimal(self)</code>	Check whether all characters in each string are decimal.
<code>Series.str.get_dummies(self[, sep])</code>	Split each string in the Series by <i>sep</i> and return a DataFrame of dummy/indicator variables.

**pandas.Series.str.capitalize**`Series.str.capitalize` (*self*)

Convert strings in the Series/Index to be capitalized.

Equivalent to `str.capitalize()`.**Returns****Series or Index of object****See also:****`Series.str.lower`** Converts all characters to lowercase.**`Series.str.upper`** Converts all characters to uppercase.**`Series.str.title`** Converts first character of each word to uppercase and remaining to lowercase.**`Series.str.capitalize`** Converts first character to uppercase and remaining to lowercase.**`Series.str.swapcase`** Converts uppercase to lowercase and lowercase to uppercase.**`Series.str.casefold`** Removes all case distinctions in the string.**Examples**

```
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0          lower
1      CAPITALS
2  this is a sentence
3      SwApCaSe
dtype: object
```

```
>>> s.str.lower()
0          lower
1      capitals
2  this is a sentence
3      swapcase
dtype: object
```

```
>>> s.str.upper()
0          LOWER
1      CAPITALS
2  THIS IS A SENTENCE
3      SWAPCASE
dtype: object
```

```
>>> s.str.title()
0          Lower
1      Capitals
2  This Is A Sentence
3      Swapcase
dtype: object
```

```
>>> s.str.capitalize()
0          Lower
1      Capitals
2  This is a sentence
3      Swapcase
dtype: object
```

```
>>> s.str.swapcase()
0          LOWER
1      capitals
2  THIS IS A SENTENCE
3      sWaPcAsE
dtype: object
```

## pandas.Series.str.casefold

Series.str.casefold(*self*)

Convert strings in the Series/Index to be casefolded.

New in version 0.25.0.

Equivalent to `str.casefold()`.

**Returns**

**Series or Index of object**

**See also:**

**Series.str.lower** Converts all characters to lowercase.

**Series.str.upper** Converts all characters to uppercase.

**Series.str.title** Converts first character of each word to uppercase and remaining to lowercase.

**Series.str.capitalize** Converts first character to uppercase and remaining to lowercase.

**Series.str.swapcase** Converts uppercase to lowercase and lowercase to uppercase.

**Series.str.casefold** Removes all case distinctions in the string.

## Examples

```
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0          lower
1      CAPITALS
2  this is a sentence
3      SwApCaSe
dtype: object
```

```
>>> s.str.lower()
0          lower
1      capitals
2  this is a sentence
3      swapcase
dtype: object
```

```
>>> s.str.upper()
0          LOWER
1      CAPITALS
2  THIS IS A SENTENCE
3      SWAPCASE
dtype: object
```

```
>>> s.str.title()
0          Lower
```

(continues on next page)

(continued from previous page)

```

1          Capitals
2  This Is A Sentence
3          Swapcase
dtype: object

```

```

>>> s.str.capitalize()
0          Lower
1          Capitals
2  This is a sentence
3          Swapcase
dtype: object

```

```

>>> s.str.swapcase()
0          LOWER
1          capitals
2  THIS IS A SENTENCE
3          sWaPcAsE
dtype: object

```

### pandas.Series.str.cat

`Series.str.cat` (*self*, *others=None*, *sep=None*, *na\_rep=None*, *join='left'*)

Concatenate strings in the Series/Index with given separator.

If *others* is specified, this function concatenates the Series/Index and elements of *others* element-wise. If *others* is not passed, then all values in the Series/Index are concatenated into a single string with a given *sep*.

#### Parameters

**others** [Series, Index, DataFrame, np.ndarray or list-like] Series, Index, DataFrame, np.ndarray (one- or two-dimensional) and other list-likes of strings must have the same length as the calling Series/Index, with the exception of indexed objects (i.e. Series/Index/DataFrame) if *join* is not None.

If *others* is a list-like that contains a combination of Series, Index or np.ndarray (1-dim), then all elements will be unpacked and must satisfy the above criteria individually.

If *others* is None, the method returns the concatenation of all strings in the calling Series/Index.

**sep** [str, default ''] The separator between the different elements/columns. By default the empty string '' is used.

**na\_rep** [str or None, default None] Representation that is inserted for all missing values:

- If *na\_rep* is None, and *others* is None, missing values in the Series/Index are omitted from the result.
- If *na\_rep* is None, and *others* is not None, a row containing a missing value in any of the columns (before concatenation) will have a missing value in the result.

**join** [{ 'left', 'right', 'outer', 'inner' }, default 'left'] Determines the join-style between the calling Series/Index and any Series/Index/DataFrame in *others* (objects without an index need to match the length of the calling Series/Index). To disable alignment, use *.values* on any Series/Index/DataFrame in *others*.

New in version 0.23.0.

Changed in version 1.0.0: Changed default of *join* from None to 'left'.

## Returns

**str, Series or Index** If *others* is None, *str* is returned, otherwise a *Series/Index* (same type as caller) of objects is returned.

### See also:

**split** Split each string in the Series/Index.

**join** Join lists contained as elements in the Series/Index.

## Examples

When not passing *others*, all values are concatenated into a single string:

```
>>> s = pd.Series(['a', 'b', np.nan, 'd'])
>>> s.str.cat(sep=' ')
'a b d'
```

By default, NA values in the Series are ignored. Using *na\_rep*, they can be given a representation:

```
>>> s.str.cat(sep=' ', na_rep='?')
'a b ? d'
```

If *others* is specified, corresponding values are concatenated with the separator. Result will be a Series of strings.

```
>>> s.str.cat(['A', 'B', 'C', 'D'], sep=',')
0    a,A
1    b,B
2    NaN
3    d,D
dtype: object
```

Missing values will remain missing in the result, but can again be represented using *na\_rep*

```
>>> s.str.cat(['A', 'B', 'C', 'D'], sep=',', na_rep='-')
0    a,A
1    b,B
2    -,C
3    d,D
dtype: object
```

If *sep* is not specified, the values are concatenated without separation.

```
>>> s.str.cat(['A', 'B', 'C', 'D'], na_rep='-')
0    aA
1    bB
2    -C
3    dD
dtype: object
```

Series with different indexes can be aligned before concatenation. The *join*-keyword works as in other methods.

```
>>> t = pd.Series(['d', 'a', 'e', 'c'], index=[3, 0, 4, 2])
>>> s.str.cat(t, join='left', na_rep='-')
0    aa
1    b-
2    -c
3    dd
```

(continues on next page)

(continued from previous page)

```

dtype: object
>>>
>>> s.str.cat(t, join='outer', na_rep='-')
0    aa
1    b-
2    -c
3    dd
4    -e
dtype: object
>>>
>>> s.str.cat(t, join='inner', na_rep='-')
0    aa
2    -c
3    dd
dtype: object
>>>
>>> s.str.cat(t, join='right', na_rep='-')
3    dd
0    aa
4    -e
2    -c
dtype: object

```

For more examples, see [here](#).

### pandas.Series.str.center

`Series.str.center` (*self*, *width*, *fillchar=' '*)

Filling left and right side of strings in the Series/Index with an additional character. Equivalent to `str.center()`.

#### Parameters

**width** [int] Minimum width of resulting string; additional characters will be filled with `fillchar`.

**fillchar** [str] Additional character for filling, default is whitespace.

#### Returns

**filled** [Series/Index of objects.]

### pandas.Series.str.contains

`Series.str.contains` (*self*, *pat*, *case=True*, *flags=0*, *na=nan*, *regex=True*)

Test if pattern or regex is contained within a string of a Series or Index.

Return boolean Series or Index based on whether a given pattern or regex is contained within a string of a Series or Index.

#### Parameters

**pat** [str] Character sequence or regular expression.

**case** [bool, default True] If True, case sensitive.

**flags** [int, default 0 (no flags)] Flags to pass through to the re module, e.g. `re.IGNORECASE`.

**na** [default NaN] Fill value for missing values.

**regex** [bool, default True] If True, assumes the pat is a regular expression.

If False, treats the pat as a literal string.

### Returns

**Series or Index of boolean values** A Series or Index of boolean values indicating whether the given pattern is contained within the string of each element of the Series or Index.

### See also:

**match** Analogous, but stricter, relying on re.match instead of re.search.

**Series.str.startswith** Test if the start of each string element matches a pattern.

**Series.str.endswith** Same as startswith, but tests the end of string.

## Examples

Returning a Series of booleans using only a literal pattern.

```
>>> s1 = pd.Series(['Mouse', 'dog', 'house and parrot', '23', np.NaN])
>>> s1.str.contains('og', regex=False)
0    False
1     True
2    False
3    False
4     NaN
dtype: object
```

Returning an Index of booleans using only a literal pattern.

```
>>> ind = pd.Index(['Mouse', 'dog', 'house and parrot', '23.0', np.NaN])
>>> ind.str.contains('23', regex=False)
Index([False, False, False, True, nan], dtype='object')
```

Specifying case sensitivity using *case*.

```
>>> s1.str.contains('oG', case=True, regex=True)
0    False
1    False
2    False
3    False
4     NaN
dtype: object
```

Specifying *na* to be *False* instead of *NaN* replaces NaN values with *False*. If Series or Index does not contain NaN values the resultant dtype will be *bool*, otherwise, an *object* dtype.

```
>>> s1.str.contains('og', na=False, regex=True)
0    False
1     True
2    False
3    False
4    False
dtype: bool
```

Returning 'house' or 'dog' when either expression occurs in a string.

```
>>> s1.str.contains('house|dog', regex=True)
0    False
1     True
2     True
3    False
4     NaN
dtype: object
```

Ignoring case sensitivity using *flags* with regex.

```
>>> import re
>>> s1.str.contains('PARROT', flags=re.IGNORECASE, regex=True)
0    False
1    False
2     True
3    False
4     NaN
dtype: object
```

Returning any digit using regular expression.

```
>>> s1.str.contains('\d', regex=True)
0    False
1    False
2    False
3     True
4     NaN
dtype: object
```

Ensure *pat* is not a literal pattern when *regex* is set to *True*. Note in the following example one might expect only *s2[1]* and *s2[3]* to return *True*. However, *'0'* as a regex matches any character followed by a 0.

```
>>> s2 = pd.Series(['40', '40.0', '41', '41.0', '35'])
>>> s2.str.contains('.0', regex=True)
0     True
1     True
2    False
3     True
4    False
dtype: bool
```

## pandas.Series.str.count

`Series.str.count` (*self*, *pat*, *flags=0*, *\*\*kwargs*)

Count occurrences of pattern in each string of the Series/Index.

This function is used to count the number of times a particular regex pattern is repeated in each of the string elements of the *Series*.

### Parameters

**pat** [str] Valid regular expression.

**flags** [int, default 0, meaning no flags] Flags for the *re* module. For a complete list, [see here](#).

**\*\*kwargs** For compatibility with other string methods. Not used.

### Returns

**Series or Index** Same type as the calling object containing the integer counts.

**See also:**

**re** Standard library module for regular expressions.

**str.count** Standard library version, without regular expression support.

## Notes

Some characters need to be escaped when passing in *pat*. eg. '\$' has a special meaning in regex and must be escaped when finding this literal character.

## Examples

```
>>> s = pd.Series(['A', 'B', 'Aaba', 'Baca', np.nan, 'CABA', 'cat'])
>>> s.str.count('a')
0    0.0
1    0.0
2    2.0
3    2.0
4    NaN
5    0.0
6    1.0
dtype: float64
```

Escape '\$' to find the literal dollar sign.

```
>>> s = pd.Series(['$', 'B', 'Aab$', '$$ca', 'C$B$', 'cat'])
>>> s.str.count('\$')
0    1
1    0
2    1
3    2
4    2
5    0
dtype: int64
```

This is also available on Index

```
>>> pd.Index(['A', 'A', 'Aaba', 'cat']).str.count('a')
Int64Index([0, 0, 2, 1], dtype='int64')
```

## pandas.Series.str.decode

`Series.str.decode` (*self, encoding, errors='strict'*)

Decode character string in the Series/Index using indicated encoding. Equivalent to `str.decode()` in python2 and `bytes.decode()` in python3.

### Parameters

**encoding** [str]

**errors** [str, optional]

### Returns

**Series or Index**

### pandas.Series.str.encode

`Series.str.encode` (*self*, *encoding*, *errors='strict'*)

Encode character string in the Series/Index using indicated encoding. Equivalent to `str.encode()`.

#### Parameters

**encoding** [str]

**errors** [str, optional]

#### Returns

**encoded** [Series/Index of objects]

### pandas.Series.str.endswith

`Series.str.endswith` (*self*, *pat*, *na=nan*)

Test if the end of each string element matches a pattern.

Equivalent to `str.endswith()`.

#### Parameters

**pat** [str] Character sequence. Regular expressions are not accepted.

**na** [object, default NaN] Object shown if element tested is not a string.

#### Returns

**Series or Index of bool** A Series of booleans indicating whether the given pattern matches the end of each string element.

#### See also:

**`str.endswith`** Python standard library string method.

**`Series.str.startswith`** Same as `endswith`, but tests the start of string.

**`Series.str.contains`** Tests if string element contains a pattern.

### Examples

```
>>> s = pd.Series(['bat', 'bear', 'caT', np.nan])
>>> s
0    bat
1    bear
2    caT
3    NaN
dtype: object
```

```
>>> s.str.endswith('t')
0    True
1    False
2    False
3    NaN
dtype: object
```

Specifying *na* to be *False* instead of *NaN*.

```
>>> s.str.endswith('t', na=False)
0    True
1    False
2    False
3    False
dtype: bool
```

## pandas.Series.str.extract

`Series.str.extract` (*self*, *pat*, *flags=0*, *expand=True*)

Extract capture groups in the regex *pat* as columns in a DataFrame.

For each subject string in the Series, extract groups from the first match of regular expression *pat*.

### Parameters

**pat** [str] Regular expression pattern with capturing groups.

**flags** [int, default 0 (no flags)] Flags from the `re` module, e.g. `re.IGNORECASE`, that modify regular expression matching for things like case, spaces, etc. For more details, see `re`.

**expand** [bool, default True] If True, return DataFrame with one column per capture group. If False, return a Series/Index if there is one capture group or DataFrame if there are multiple capture groups.

### Returns

**DataFrame or Series or Index** A DataFrame with one row for each subject string, and one column for each group. Any capture group names in regular expression *pat* will be used for column names; otherwise capture group numbers will be used. The dtype of each result column is always object, even when no match is found. If `expand=False` and *pat* has only one capture group, then return a Series (if subject is a Series) or Index (if subject is an Index).

### See also:

**`extractall`** Returns all matches (not just the first match).

## Examples

A pattern with two groups will return a DataFrame with two columns. Non-matches will be NaN.

```
>>> s = pd.Series(['a1', 'b2', 'c3'])
>>> s.str.extract(r'([ab])(\d)')
   0  1
0  a  1
1  b  2
2 NaN NaN
```

A pattern may contain optional groups.

```
>>> s.str.extract(r'([ab])?(\d)')
   0  1
0  a  1
1  b  2
2 NaN 3
```

Named groups will become column names in the result.

```
>>> s.str.extract(r'(?P<letter>[ab])(?P<digit>\d)')
      letter digit
0         a     1
1         b     2
2        NaN    NaN
```

A pattern with one group will return a DataFrame with one column if `expand=True`.

```
>>> s.str.extract(r'[ab](\d)', expand=True)
      0
0     1
1     2
2    NaN
```

A pattern with one group will return a Series if `expand=False`.

```
>>> s.str.extract(r'[ab](\d)', expand=False)
0     1
1     2
2    NaN
dtype: object
```

## pandas.Series.str.extractall

`Series.str.extractall` (*self, pat, flags=0*)

For each subject string in the Series, extract groups from all matches of regular expression `pat`. When each subject string in the Series has exactly one match, `extractall(pat).xs(0, level='match')` is the same as `extract(pat)`.

### Parameters

**pat** [str] Regular expression pattern with capturing groups.

**flags** [int, default 0 (no flags)] A `re` module flag, for example `re.IGNORECASE`. These allow to modify regular expression matching for things like case, spaces, etc. Multiple flags can be combined with the bitwise OR operator, for example `re.IGNORECASE | re.MULTILINE`.

### Returns

**DataFrame** A DataFrame with one row for each match, and one column for each group. Its rows have a `MultiIndex` with first levels that come from the subject Series. The last level is named 'match' and indexes the matches in each item of the Series. Any capture group names in regular expression `pat` will be used for column names; otherwise capture group numbers will be used.

### See also:

**extract** Returns first match only (not all matches).

## Examples

A pattern with one group will return a DataFrame with one column. Indices with no matches will not appear in the result.

```
>>> s = pd.Series(["a1a2", "b1", "c1"], index=["A", "B", "C"])
>>> s.str.extractall(r"[ab](\d)")
      0
match
A 0    1
  1    2
B 0    1
```

Capture group names are used for column names of the result.

```
>>> s.str.extractall(r"[ab](?P<digit>\d)")
      digit
match
A 0         1
  1         2
B 0         1
```

A pattern with two groups will return a DataFrame with two columns.

```
>>> s.str.extractall(r"(?P<letter>[ab])(?P<digit>\d)")
      letter digit
match
A 0         a     1
  1         a     2
B 0         b     1
```

Optional groups that do not match are NaN in the result.

```
>>> s.str.extractall(r"(?P<letter>[ab])?(?P<digit>\d)")
      letter digit
match
A 0         a     1
  1         a     2
B 0         b     1
C 0         NaN   1
```

## pandas.Series.str.find

`Series.str.find(self, sub, start=0, end=None)`

Return lowest indexes in each strings in the Series/Index where the substring is fully contained between [start:end]. Return -1 on failure. Equivalent to standard `str.find()`.

### Parameters

**sub** [str] Substring being searched.

**start** [int] Left edge index.

**end** [int] Right edge index.

### Returns

**Series or Index of int.**

See also:

**rfind** Return highest indexes in each strings.

## pandas.Series.str.findall

`Series.str.findall` (*self*, *pat*, *flags=0*, *\*\*kwargs*)

Find all occurrences of pattern or regular expression in the Series/Index.

Equivalent to applying `re.findall()` to all the elements in the Series/Index.

### Parameters

**pat** [str] Pattern or regular expression.

**flags** [int, default 0] Flags from `re` module, e.g. `re.IGNORECASE` (default is 0, which means no flags).

### Returns

**Series/Index of lists of strings** All non-overlapping matches of pattern or regular expression in each string of this Series/Index.

### See also:

**count** Count occurrences of pattern or regular expression in each string of the Series/Index.

**extractall** For each string in the Series, extract groups from all matches of regular expression and return a DataFrame with one row for each match and one column for each group.

**re.findall** The equivalent `re` function to all non-overlapping matches of pattern or regular expression in string, as a list of strings.

## Examples

```
>>> s = pd.Series(['Lion', 'Monkey', 'Rabbit'])
```

The search for the pattern 'Monkey' returns one match:

```
>>> s.str.findall('Monkey')
0      []
1    [Monkey]
2      []
dtype: object
```

On the other hand, the search for the pattern 'MONKEY' doesn't return any match:

```
>>> s.str.findall('MONKEY')
0      []
1      []
2      []
dtype: object
```

Flags can be added to the pattern or regular expression. For instance, to find the pattern 'MONKEY' ignoring the case:

```
>>> import re
>>> s.str.findall('MONKEY', flags=re.IGNORECASE)
0      []
1    [Monkey]
2      []
dtype: object
```

When the pattern matches more than one string in the Series, all matches are returned:

```
>>> s.str.findall('on')
0    [on]
1    [on]
2     []
dtype: object
```

Regular expressions are supported too. For instance, the search for all the strings ending with the word 'on' is shown next:

```
>>> s.str.findall('on$')
0    [on]
1     []
2     []
dtype: object
```

If the pattern is found more than once in the same string, then a list of multiple strings is returned:

```
>>> s.str.findall('b')
0     []
1     []
2    [b, b]
dtype: object
```

## pandas.Series.str.get

`Series.str.get` (*self*, *i*)

Extract element from each component at specified position.

Extract element from lists, tuples, or strings in each element in the Series/Index.

### Parameters

**i** [int] Position of element to extract.

### Returns

**Series or Index**

## Examples

```
>>> s = pd.Series(["String",
...               (1, 2, 3),
...               ["a", "b", "c"],
...               123,
...               -456,
...               {1: "Hello", "2": "World"}])
>>> s
0          String
1          (1, 2, 3)
2          [a, b, c]
3              123
4             -456
5    {1: 'Hello', '2': 'World'}
dtype: object
```

```
>>> s.str.get(1)
0      t
1      2
2      b
3      NaN
4      NaN
5      Hello
dtype: object
```

```
>>> s.str.get(-1)
0      g
1      3
2      c
3      NaN
4      NaN
5      None
dtype: object
```

### pandas.Series.str.index

`Series.str.index` (*self, sub, start=0, end=None*)

Return lowest indexes in each strings where the substring is fully contained between [start:end]. This is the same as `str.find` except instead of returning -1, it raises a `ValueError` when the substring is not found. Equivalent to standard `str.index`.

#### Parameters

**sub** [str] Substring being searched.

**start** [int] Left edge index.

**end** [int] Right edge index.

#### Returns

**Series or Index of object**

#### See also:

**rindex** Return highest indexes in each strings.

### pandas.Series.str.join

`Series.str.join` (*self, sep*)

Join lists contained as elements in the Series/Index with passed delimiter.

If the elements of a Series are lists themselves, join the content of these lists using the delimiter passed to the function. This function is an equivalent to `str.join()`.

#### Parameters

**sep** [str] Delimiter to use between list entries.

#### Returns

**Series/Index: object** The list entries concatenated by intervening occurrences of the delimiter.

#### Raises

**AttributeError** If the supplied Series contains neither strings nor lists.

**See also:**

`str.join` Standard library version of this method.  
`Series.str.split` Split strings around given separator/delimiter.

**Notes**

If any of the list items is not a string object, the result of the join will be *NaN*.

**Examples**

Example with a list that contains non-string elements.

```
>>> s = pd.Series([[ 'lion', 'elephant', 'zebra'],
...                [1.1, 2.2, 3.3],
...                [ 'cat', np.nan, 'dog'],
...                [ 'cow', 4.5, 'goat'],
...                [ 'duck', [ 'swan', 'fish'], 'guppy']])
>>> s
0      [lion, elephant, zebra]
1      [1.1, 2.2, 3.3]
2      [cat, nan, dog]
3      [cow, 4.5, goat]
4      [duck, [swan, fish], guppy]
dtype: object
```

Join all lists using a '-'. The lists containing object(s) of types other than str will produce a NaN.

```
>>> s.str.join('-')
0      lion-elephant-zebra
1      NaN
2      NaN
3      NaN
4      NaN
dtype: object
```

**pandas.Series.str.len**

`Series.str.len` (*self*)

Compute the length of each element in the Series/Index. The element may be a sequence (such as a string, tuple or list) or a collection (such as a dictionary).

**Returns**

**Series or Index of int** A Series or Index of integer values indicating the length of each element in the Series or Index.

**See also:**

`str.len` Python built-in function returning the length of an object.  
`Series.size` Returns the length of the Series.

## Examples

Returns the length (number of characters) in a string. Returns the number of entries for dictionaries, lists or tuples.

```
>>> s = pd.Series(['dog',
...                '',
...                5,
...                {'foo' : 'bar'},
...                [2, 3, 5, 7],
...                ('one', 'two', 'three')])
>>> s
0          dog
1
2          5
3    {'foo': 'bar'}
4    [2, 3, 5, 7]
5    (one, two, three)
dtype: object
>>> s.str.len()
0    3.0
1    0.0
2    NaN
3    1.0
4    4.0
5    3.0
dtype: float64
```

### pandas.Series.str.ljust

`Series.str.ljust` (*self*, *width*, *fillchar*='')

Filling right side of strings in the Series/Index with an additional character. Equivalent to `str.ljust()`.

#### Parameters

**width** [int] Minimum width of resulting string; additional characters will be filled with `fillchar`.

**fillchar** [str] Additional character for filling, default is whitespace.

#### Returns

**filled** [Series/Index of objects.]

### pandas.Series.str.lower

`Series.str.lower` (*self*)

Convert strings in the Series/Index to lowercase.

Equivalent to `str.lower()`.

#### Returns

**Series or Index of object**

#### See also:

**`Series.str.lower`** Converts all characters to lowercase.

**`Series.str.upper`** Converts all characters to uppercase.

**`Series.str.title`** Converts first character of each word to uppercase and remaining to lowercase.

***Series.str.capitalize*** Converts first character to uppercase and remaining to lowercase.

***Series.str.swapcase*** Converts uppercase to lowercase and lowercase to uppercase.

***Series.str.casefold*** Removes all case distinctions in the string.

## Examples

```
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0          lower
1        CAPITALS
2  this is a sentence
3        SwApCaSe
dtype: object
```

```
>>> s.str.lower()
0          lower
1        capitals
2  this is a sentence
3        swapcase
dtype: object
```

```
>>> s.str.upper()
0          LOWER
1        CAPITALS
2  THIS IS A SENTENCE
3        SWAPCASE
dtype: object
```

```
>>> s.str.title()
0          Lower
1        Capitals
2  This Is A Sentence
3        Swapcase
dtype: object
```

```
>>> s.str.capitalize()
0          Lower
1        Capitals
2  This is a sentence
3        Swapcase
dtype: object
```

```
>>> s.str.swapcase()
0          LOWER
1        capitals
2  THIS IS A SENTENCE
3        sWApCaSe
dtype: object
```

## pandas.Series.str.lstrip

`Series.str.lstrip` (*self*, *to\_strip=None*)

Remove leading and trailing characters.

Strip whitespaces (including newlines) or a set of specified characters from each string in the Series/Index from left side. Equivalent to `str.lstrip()`.

### Parameters

**to\_strip** [str or None, default None] Specifying the set of characters to be removed. All combinations of this set of characters will be stripped. If None then whitespaces are removed.

### Returns

**Series or Index of object**

**See also:**

**`Series.str.strip`** Remove leading and trailing characters in Series/Index.

**`Series.str.lstrip`** Remove leading characters in Series/Index.

**`Series.str.rstrip`** Remove trailing characters in Series/Index.

## Examples

```
>>> s = pd.Series(['1. Ant. ', '2. Bee!\n', '3. Cat?\t', np.nan])
>>> s
0    1. Ant.
1    2. Bee!\n
2    3. Cat?\t
3         NaN
dtype: object
```

```
>>> s.str.strip()
0    1. Ant.
1    2. Bee!
2    3. Cat?
3         NaN
dtype: object
```

```
>>> s.str.lstrip('123.')
0    Ant.
1    Bee!\n
2    Cat?\t
3         NaN
dtype: object
```

```
>>> s.str.rstrip('!?\ \n\t')
0    1. Ant
1    2. Bee
2    3. Cat
3         NaN
dtype: object
```

```
>>> s.str.strip('123.!?\ \n\t')
0    Ant
```

(continues on next page)

(continued from previous page)

```
1    Bee
2    Cat
3    NaN
dtype: object
```

### pandas.Series.str.match

`Series.str.match` (*self*, *pat*, *case=True*, *flags=0*, *na=nan*)

Determine if each string matches a regular expression.

#### Parameters

**pat** [str] Character sequence or regular expression.

**case** [bool, default True] If True, case sensitive.

**flags** [int, default 0 (no flags)] Regex module flags, e.g. re.IGNORECASE.

**na** [default NaN] Fill value for missing values.

#### Returns

**Series/array of boolean values**

See also:

**contains** Analogous, but less strict, relying on re.search instead of re.match.

**extract** Extract matched groups.

### pandas.Series.str.normalize

`Series.str.normalize` (*self*, *form*)

Return the Unicode normal form for the strings in the Series/Index. For more information on the forms, see the `unicodedata.normalize()`.

#### Parameters

**form** [{ 'NFC', 'NFKC', 'NFD', 'NFKD' }] Unicode form.

#### Returns

**normalized** [Series/Index of objects]

### pandas.Series.str.pad

`Series.str.pad` (*self*, *width*, *side='left'*, *fillchar=' '*)

Pad strings in the Series/Index up to width.

#### Parameters

**width** [int] Minimum width of resulting string; additional characters will be filled with character defined in *fillchar*.

**side** [{ 'left', 'right', 'both' }, default 'left'] Side from which to fill resulting string.

**fillchar** [str, default ' '] Additional character for filling, default is whitespace.

#### Returns

**Series or Index of object** Returns Series or Index with minimum number of char in object.

See also:

**Series.str.rjust** Fills the left side of strings with an arbitrary character. Equivalent to `Series.str.pad(side='left')`.

**Series.str.ljust** Fills the right side of strings with an arbitrary character. Equivalent to `Series.str.pad(side='right')`.

**Series.str.center** Fills both sides of strings with an arbitrary character. Equivalent to `Series.str.pad(side='both')`.

**Series.str.zfill** Pad strings in the Series/Index by prepending '0' character. Equivalent to `Series.str.pad(side='left', fillchar='0')`.

## Examples

```
>>> s = pd.Series(["caribou", "tiger"])
>>> s
0    caribou
1     tiger
dtype: object
```

```
>>> s.str.pad(width=10)
0    caribou
1     tiger
dtype: object
```

```
>>> s.str.pad(width=10, side='right', fillchar='-')
0    caribou---
1     tiger-----
dtype: object
```

```
>>> s.str.pad(width=10, side='both', fillchar='-')
0    -caribou--
1    --tiger---
dtype: object
```

## pandas.Series.str.partition

`Series.str.partition` (*self*, *sep*=' ', *expand*=True)

Split the string at the first occurrence of *sep*.

This method splits the string at the first occurrence of *sep*, and returns 3 elements containing the part before the separator, the separator itself, and the part after the separator. If the separator is not found, return 3 elements containing the string itself, followed by two empty strings.

### Parameters

**sep** [str, default whitespace] String to split on.

**expand** [bool, default True] If True, return DataFrame/MultiIndex expanding dimensionality. If False, return Series/Index.

### Returns

DataFrame/MultiIndex or Series/Index of objects

See also:

**rpartition** Split the string at the last occurrence of *sep*.

**Series.str.split** Split strings around given separators.

**str.partition** Standard library version.

## Examples

```
>>> s = pd.Series(['Linda van der Berg', 'George Pitt-Rivers'])
>>> s
0    Linda van der Berg
1    George Pitt-Rivers
dtype: object
```

```
>>> s.str.partition()
      0 1          2
0  Linda  van der Berg
1  George  Pitt-Rivers
```

To partition by the last space instead of the first one:

```
>>> s.str.rpartition()
      0 1          2
0  Linda van der      Berg
1      George      Pitt-Rivers
```

To partition by something different than a space:

```
>>> s.str.partition('-')
      0 1          2
0  Linda van der Berg
1      George Pitt - Rivers
```

To return a Series containing tuples instead of a DataFrame:

```
>>> s.str.partition('-', expand=False)
0    (Linda van der Berg, , )
1    (George Pitt, -, Rivers)
dtype: object
```

Also available on indices:

```
>>> idx = pd.Index(['X 123', 'Y 999'])
>>> idx
Index(['X 123', 'Y 999'], dtype='object')
```

Which will create a MultiIndex:

```
>>> idx.str.partition()
MultiIndex([(('X', ' ', '123'),
             ('Y', ' ', '999'))],
           dtype='object')
```

Or an index with tuples with `expand=False`:

```
>>> idx.str.partition(expand=False)
Index([(('X', ' ', '123'), ('Y', ' ', '999'))], dtype='object')
```

## pandas.Series.str.repeat

`Series.str.repeat` (*self*, *repeats*)

Duplicate each string in the Series or Index.

### Parameters

**repeats** [int or sequence of int] Same value for all (int) or different value per (sequence).

### Returns

**Series or Index of object** Series or Index of repeated string objects specified by input parameter repeats.

## Examples

```
>>> s = pd.Series(['a', 'b', 'c'])
>>> s
0    a
1    b
2    c
dtype: object
```

Single int repeats string in Series

```
>>> s.str.repeat(repeats=2)
0    aa
1    bb
2    cc
dtype: object
```

Sequence of int repeats corresponding string in Series

```
>>> s.str.repeat(repeats=[1, 2, 3])
0    a
1    bb
2    ccc
dtype: object
```

## pandas.Series.str.replace

`Series.str.replace` (*self*, *pat*, *repl*, *n=-1*, *case=None*, *flags=0*, *regex=True*)

Replace occurrences of pattern/regex in the Series/Index with some other string. Equivalent to `str.replace()` or `re.sub()`.

### Parameters

**pat** [str or compiled regex] String can be a character sequence or regular expression.

**repl** [str or callable] Replacement string or a callable. The callable is passed the regex match object and must return a replacement string to be used. See `re.sub()`.

**n** [int, default -1 (all)] Number of replacements to make from start.

**case** [bool, default None] Determines if replace is case sensitive:

- If True, case sensitive (the default if *pat* is a string)
- Set to False for case insensitive

- Cannot be set if *pat* is a compiled regex.

**flags** [int, default 0 (no flags)] Regex module flags, e.g. re.IGNORECASE. Cannot be set if *pat* is a compiled regex.

**regex** [bool, default True] Determines if assumes the passed-in pattern is a regular expression:

- If True, assumes the passed-in pattern is a regular expression.
- If False, treats the pattern as a literal string
- Cannot be set to False if *pat* is a compiled regex or *repl* is a callable.

New in version 0.23.0.

### Returns

**Series or Index of object** A copy of the object with all matching occurrences of *pat* replaced by *repl*.

### Raises

#### ValueError

- if *regex* is False and *repl* is a callable or *pat* is a compiled regex
- if *pat* is a compiled regex and *case* or *flags* is set

### Notes

When *pat* is a compiled regex, all flags should be included in the compiled regex. Use of *case*, *flags*, or *regex=False* with a compiled regex will raise an error.

### Examples

When *pat* is a string and *regex* is True (the default), the given *pat* is compiled as a regex. When *repl* is a string, it replaces matching regex patterns as with `re.sub()`. NaN value(s) in the Series are left as is:

```
>>> pd.Series(['foo', 'fuz', np.nan]).str.replace('f.', 'ba', regex=True)
0    bao
1    baz
2    NaN
dtype: object
```

When *pat* is a string and *regex* is False, every *pat* is replaced with *repl* as with `str.replace()`:

```
>>> pd.Series(['f.o', 'fuz', np.nan]).str.replace('f.', 'ba', regex=False)
0    bao
1    fuz
2    NaN
dtype: object
```

When *repl* is a callable, it is called on every *pat* using `re.sub()`. The callable should expect one positional argument (a regex object) and return a string.

To get the idea:

```
>>> pd.Series(['foo', 'fuz', np.nan]).str.replace('f', repr)
0    <_sre.SRE_Match object; span=(0, 1), match='f'>oo
1    <_sre.SRE_Match object; span=(0, 1), match='f'>uz
2                                     NaN
dtype: object
```

Reverse every lowercase alphabetic word:

```
>>> repl = lambda m: m.group(0)[::-1]
>>> pd.Series(['foo 123', 'bar baz', np.nan]).str.replace(r'[a-z]+', repl)
0    oof 123
1    rab zab
2         NaN
dtype: object
```

Using regex groups (extract second group and swap case):

```
>>> pat = r"(?P<one>\w+) (?P<two>\w+) (?P<three>\w+)"
>>> repl = lambda m: m.group('two').swapcase()
>>> pd.Series(['One Two Three', 'Foo Bar Baz']).str.replace(pat, repl)
0    tWO
1    bAR
dtype: object
```

Using a compiled regex with flags

```
>>> import re
>>> regex_pat = re.compile(r'FUZ', flags=re.IGNORECASE)
>>> pd.Series(['foo', 'fuz', np.nan]).str.replace(regex_pat, 'bar')
0    foo
1    bar
2    NaN
dtype: object
```

## pandas.Series.str.rfind

`Series.str.rfind` (*self*, *sub*, *start=0*, *end=None*)

Return highest indexes in each strings in the Series/Index where the substring is fully contained between [start:end]. Return -1 on failure. Equivalent to standard `str.rfind()`.

### Parameters

- sub** [str] Substring being searched.
- start** [int] Left edge index.
- end** [int] Right edge index.

### Returns

**Series or Index of int.**

**See also:**

**find** Return lowest indexes in each strings.

## pandas.Series.str.rindex

`Series.str.rindex` (*self*, *sub*, *start=0*, *end=None*)

Return highest indexes in each strings where the substring is fully contained between [start:end]. This is the same as `str.rfind` except instead of returning -1, it raises a `ValueError` when the substring is not found. Equivalent to standard `str.rindex`.

### Parameters

**sub** [str] Substring being searched.

**start** [int] Left edge index.

**end** [int] Right edge index.

### Returns

**Series or Index of object**

See also:

***index*** Return lowest indexes in each strings.

## pandas.Series.str.rjust

`Series.str.rjust` (*self*, *width*, *fillchar=' '*)

Filling left side of strings in the Series/Index with an additional character. Equivalent to `str.rjust()`.

### Parameters

**width** [int] Minimum width of resulting string; additional characters will be filled with `fillchar`.

**fillchar** [str] Additional character for filling, default is whitespace.

### Returns

**filled** [Series/Index of objects.]

## pandas.Series.str.rpartition

`Series.str.rpartition` (*self*, *sep=' '*, *expand=True*)

Split the string at the last occurrence of *sep*.

This method splits the string at the last occurrence of *sep*, and returns 3 elements containing the part before the separator, the separator itself, and the part after the separator. If the separator is not found, return 3 elements containing two empty strings, followed by the string itself.

### Parameters

**sep** [str, default whitespace] String to split on.

**expand** [bool, default True] If True, return DataFrame/MultiIndex expanding dimensionality. If False, return Series/Index.

### Returns

**DataFrame/MultiIndex or Series/Index of objects**

See also:

***partition*** Split the string at the first occurrence of *sep*.

***Series.str.split*** Split strings around given separators.

***str.partition*** Standard library version.

## Examples

```
>>> s = pd.Series(['Linda van der Berg', 'George Pitt-Rivers'])
>>> s
0    Linda van der Berg
1    George Pitt-Rivers
dtype: object
```

```
>>> s.str.partition()
      0 1          2
0  Linda  van der Berg
1  George  Pitt-Rivers
```

To partition by the last space instead of the first one:

```
>>> s.str.rpartition()
      0 1          2
0  Linda van der      Berg
1      George      Pitt-Rivers
```

To partition by something different than a space:

```
>>> s.str.partition('-')
      0 1          2
0  Linda van der Berg
1      George Pitt - Rivers
```

To return a Series containing tuples instead of a DataFrame:

```
>>> s.str.partition('-', expand=False)
0    (Linda van der Berg, , )
1    (George Pitt, -, Rivers)
dtype: object
```

Also available on indices:

```
>>> idx = pd.Index(['X 123', 'Y 999'])
>>> idx
Index(['X 123', 'Y 999'], dtype='object')
```

Which will create a MultiIndex:

```
>>> idx.str.partition()
MultiIndex([(('X', ' ', '123'),
             ('Y', ' ', '999'))],
           dtype='object')
```

Or an index with tuples with `expand=False`:

```
>>> idx.str.partition(expand=False)
Index([(('X', ' ', '123'), ('Y', ' ', '999'))], dtype='object')
```

**pandas.Series.str.rstrip**

`Series.str.rstrip` (*self*, *to\_strip=None*)

Remove leading and trailing characters.

Strip whitespaces (including newlines) or a set of specified characters from each string in the Series/Index from right side. Equivalent to `str.rstrip()`.

**Parameters**

**to\_strip** [str or None, default None] Specifying the set of characters to be removed. All combinations of this set of characters will be stripped. If None then whitespaces are removed.

**Returns**

**Series or Index of object**

**See also:**

**`Series.str.strip`** Remove leading and trailing characters in Series/Index.

**`Series.str.lstrip`** Remove leading characters in Series/Index.

**`Series.str.rstrip`** Remove trailing characters in Series/Index.

**Examples**

```
>>> s = pd.Series(['1. Ant. ', '2. Bee!\n', '3. Cat?\t', np.nan])
>>> s
0    1. Ant.
1    2. Bee!\n
2    3. Cat?\t
3         NaN
dtype: object
```

```
>>> s.str.strip()
0    1. Ant.
1    2. Bee!
2    3. Cat?
3         NaN
dtype: object
```

```
>>> s.str.lstrip('123.')
0    Ant.
1    Bee!\n
2    Cat?\t
3         NaN
dtype: object
```

```
>>> s.str.rstrip('!?\ \n\t')
0    1. Ant
1    2. Bee
2    3. Cat
3         NaN
dtype: object
```

```
>>> s.str.strip('123.!?\ \n\t')
0    Ant
```

(continues on next page)

(continued from previous page)

```
1    Bee
2    Cat
3    NaN
dtype: object
```

### pandas.Series.str.slice

`Series.str.slice` (*self*, *start=None*, *stop=None*, *step=None*)

Slice substrings from each element in the Series or Index.

#### Parameters

**start** [int, optional] Start position for slice operation.

**stop** [int, optional] Stop position for slice operation.

**step** [int, optional] Step size for slice operation.

#### Returns

**Series or Index of object** Series or Index from sliced substring from original string object.

**See also:**

**`Series.str.slice_replace`** Replace a slice with a string.

**`Series.str.get`** Return element at position. Equivalent to `Series.str.slice(start=i, stop=i+1)` with *i* being the position.

### Examples

```
>>> s = pd.Series(["koala", "fox", "chameleon"])
>>> s
0      koala
1         fox
2  chameleon
dtype: object
```

```
>>> s.str.slice(start=1)
0      oala
1         ox
2   hameleon
dtype: object
```

```
>>> s.str.slice(start=-1)
0      a
1      x
2      n
dtype: object
```

```
>>> s.str.slice(stop=2)
0    ko
1    fo
2    ch
dtype: object
```

```
>>> s.str.slice(step=2)
0      kaa
1       fx
2    caeen
dtype: object
```

```
>>> s.str.slice(start=0, stop=5, step=3)
0      kl
1       f
2      cm
dtype: object
```

Equivalent behaviour to:

```
>>> s.str[0:5:3]
0      kl
1       f
2      cm
dtype: object
```

## pandas.Series.str.slice\_replace

`Series.str.slice_replace` (*self*, *start=None*, *stop=None*, *repl=None*)

Replace a positional slice of a string with another value.

### Parameters

**start** [int, optional] Left index position to use for the slice. If not specified (None), the slice is unbounded on the left, i.e. slice from the start of the string.

**stop** [int, optional] Right index position to use for the slice. If not specified (None), the slice is unbounded on the right, i.e. slice until the end of the string.

**repl** [str, optional] String for replacement. If not specified (None), the sliced region is replaced with an empty string.

### Returns

**Series or Index** Same type as the original object.

**See also:**

**`Series.str.slice`** Just slicing without replacement.

### Examples

```
>>> s = pd.Series(['a', 'ab', 'abc', 'abdc', 'abcde'])
>>> s
0      a
1     ab
2    abc
3   abdc
4  abcde
dtype: object
```

Specify just *start*, meaning replace *start* until the end of the string with *repl*.

```
>>> s.str.slice_replace(1, repl='X')
0    aX
1    aX
2    aX
3    aX
4    aX
dtype: object
```

Specify just *stop*, meaning the start of the string to *stop* is replaced with *repl*, and the rest of the string is included.

```
>>> s.str.slice_replace(stop=2, repl='X')
0      X
1      X
2     Xc
3    Xdc
4   Xcde
dtype: object
```

Specify *start* and *stop*, meaning the slice from *start* to *stop* is replaced with *repl*. Everything before or after *start* and *stop* is included as is.

```
>>> s.str.slice_replace(start=1, stop=3, repl='X')
0    aX
1    aX
2    aX
3   aXc
4  aXde
dtype: object
```

## pandas.Series.str.split

`Series.str.split` (*self*, *pat=None*, *n=-1*, *expand=False*)

Split strings around given separator/delimiter.

Splits the string in the Series/Index from the beginning, at the specified delimiter string. Equivalent to `str.split()`.

### Parameters

**pat** [str, optional] String or regular expression to split on. If not specified, split on whitespace.

**n** [int, default -1 (all)] Limit number of splits in output. None, 0 and -1 will be interpreted as return all splits.

**expand** [bool, default False] Expand the splitted strings into separate columns.

- If `True`, return DataFrame/MultiIndex expanding dimensionality.
- If `False`, return Series/Index, containing lists of strings.

### Returns

**Series, Index, DataFrame or MultiIndex** Type matches caller unless `expand=True` (see Notes).

See also:

**Series.str.split** Split strings around given separator/delimiter.

**Series.str.rsplit** Splits string around given separator/delimiter, starting from the right.

**Series.str.join** Join lists contained as elements in the Series/Index with passed delimiter.

`str.split` Standard library version for split.  
`str.rsplit` Standard library version for rsplit.

## Notes

The handling of the *n* keyword depends on the number of found splits:

- If found splits > *n*, make first *n* splits only
- If found splits <= *n*, make all splits
- If for a certain row the number of found splits < *n*, append *None* for padding up to *n* if `expand=True`

If using `expand=True`, Series and Index callers return DataFrame and MultiIndex objects, respectively.

## Examples

```
>>> s = pd.Series(["this is a regular sentence",
...               "https://docs.python.org/3/tutorial/index.html",
...               np.nan])
0          this is a regular sentence
1  https://docs.python.org/3/tutorial/index.html
2                                     NaN
dtype: object
```

In the default setting, the string is split by whitespace.

```
>>> s.str.split()
0          [this, is, a, regular, sentence]
1  [https://docs.python.org/3/tutorial/index.html]
2                                     NaN
dtype: object
```

Without the *n* parameter, the outputs of *rsplit* and *split* are identical.

```
>>> s.str.rsplit()
0          [this, is, a, regular, sentence]
1  [https://docs.python.org/3/tutorial/index.html]
2                                     NaN
dtype: object
```

The *n* parameter can be used to limit the number of splits on the delimiter. The outputs of *split* and *rsplit* are different.

```
>>> s.str.split(n=2)
0          [this, is, a regular, sentence]
1  [https://docs.python.org/3/tutorial/index.html]
2                                     NaN
dtype: object
```

```
>>> s.str.rsplit(n=2)
0          [this is a, regular, sentence]
1  [https://docs.python.org/3/tutorial/index.html]
2                                     NaN
dtype: object
```

The *pat* parameter can be used to split by other characters.

```
>>> s.str.split(pat = "/")
0          [this is a regular sentence]
1  [https:, , docs.python.org, 3, tutorial, index...
2                                     NaN
dtype: object
```

When using `expand=True`, the split elements will expand out into separate columns. If NaN is present, it is propagated throughout the columns during the split.

```
>>> s.str.split(expand=True)
           0      1      2      3
0          this  is   a  regular
1  https://docs.python.org/3/tutorial/index.html  None  None   None
2          NaN  NaN  NaN   NaN \

           4
0          sentence
1          None
2          NaN
```

For slightly more complex use cases like splitting the html document name from a url, a combination of parameter settings can be used.

```
>>> s.str.rsplit("/", n=1, expand=True)
           0      1
0          this is a regular sentence  None
1  https://docs.python.org/3/tutorial  index.html
2          NaN      NaN
```

Remember to escape special characters when explicitly using regular expressions.

```
>>> s = pd.Series(["1+1=2"])
```

```
>>> s.str.split(r"\+|=|=", expand=True)
           0      1      2
0          1      1      2
```

## pandas.Series.str.rsplit

`Series.str.rsplit` (*self*, *pat=None*, *n=-1*, *expand=False*)

Split strings around given separator/delimiter.

Splits the string in the Series/Index from the end, at the specified delimiter string. Equivalent to `str.rsplit()`.

### Parameters

**pat** [str, optional] String or regular expression to split on. If not specified, split on whitespace.

**n** [int, default -1 (all)] Limit number of splits in output. None, 0 and -1 will be interpreted as return all splits.

**expand** [bool, default False] Expand the splitted strings into separate columns.

- If `True`, return DataFrame/MultiIndex expanding dimensionality.
- If `False`, return Series/Index, containing lists of strings.

### Returns

**Series, Index, DataFrame or MultiIndex** Type matches caller unless `expand=True` (see Notes).

See also:

**`Series.str.split`** Split strings around given separator/delimiter.

**`Series.str.rsplit`** Splits string around given separator/delimiter, starting from the right.

**`Series.str.join`** Join lists contained as elements in the Series/Index with passed delimiter.

**`str.split`** Standard library version for split.

**`str.rsplit`** Standard library version for rsplit.

## Notes

The handling of the `n` keyword depends on the number of found splits:

- If found splits  $> n$ , make first  $n$  splits only
- If found splits  $\leq n$ , make all splits
- If for a certain row the number of found splits  $< n$ , append `None` for padding up to  $n$  if `expand=True`

If using `expand=True`, Series and Index callers return DataFrame and MultiIndex objects, respectively.

## Examples

```
>>> s = pd.Series(["this is a regular sentence",
...               "https://docs.python.org/3/tutorial/index.html",
...               np.nan])
0          this is a regular sentence
1  https://docs.python.org/3/tutorial/index.html
2                                     NaN
dtype: object
```

In the default setting, the string is split by whitespace.

```
>>> s.str.split()
0          [this, is, a, regular, sentence]
1  [https://docs.python.org/3/tutorial/index.html]
2                                     NaN
dtype: object
```

Without the `n` parameter, the outputs of `rsplit` and `split` are identical.

```
>>> s.str.rsplit()
0          [this, is, a, regular, sentence]
1  [https://docs.python.org/3/tutorial/index.html]
2                                     NaN
dtype: object
```

The `n` parameter can be used to limit the number of splits on the delimiter. The outputs of `split` and `rsplit` are different.

```
>>> s.str.split(n=2)
0          [this, is, a regular sentence]
1  [https://docs.python.org/3/tutorial/index.html]
2                                     NaN
dtype: object
```

```
>>> s.str.rsplit(n=2)
0          [this is a, regular, sentence]
1  [https://docs.python.org/3/tutorial/index.html]
2                                     NaN
dtype: object
```

The *pat* parameter can be used to split by other characters.

```
>>> s.str.split(pat = "/")
0          [this is a regular sentence]
1  [https:, , docs.python.org, 3, tutorial, index...]
2                                     NaN
dtype: object
```

When using `expand=True`, the split elements will expand out into separate columns. If NaN is present, it is propagated throughout the columns during the split.

```
>>> s.str.split(expand=True)
0          0      1      2      3
1  https://docs.python.org/3/tutorial/index.html  None  None  None
2          NaN  NaN  NaN  NaN \
          4
0      sentence
1          None
2          NaN
```

For slightly more complex use cases like splitting the html document name from a url, a combination of parameter settings can be used.

```
>>> s.str.rsplit("/", n=1, expand=True)
0          0      1
1  https://docs.python.org/3/tutorial  index.html
2          NaN      NaN
```

Remember to escape special characters when explicitly using regular expressions.

```
>>> s = pd.Series(["1+1=2"])
```

```
>>> s.str.split(r"\+|= ", expand=True)
0      1      2
0      1      1      2
```

### pandas.Series.str.startswith

`Series.str.startswith` (*self*, *pat*, *na=nan*)

Test if the start of each string element matches a pattern.

Equivalent to `str.startswith()`.

#### Parameters

**pat** [str] Character sequence. Regular expressions are not accepted.

**na** [object, default NaN] Object shown if element tested is not a string.

#### Returns

**Series or Index of bool** A Series of booleans indicating whether the given pattern matches the start of each string element.

See also:

**`str.startswith`** Python standard library string method.

**`Series.str.endswith`** Same as `startswith`, but tests the end of string.

**`Series.str.contains`** Tests if string element contains a pattern.

## Examples

```
>>> s = pd.Series(['bat', 'Bear', 'cat', np.nan])
>>> s
0    bat
1   Bear
2    cat
3   NaN
dtype: object
```

```
>>> s.str.startswith('b')
0     True
1    False
2    False
3     NaN
dtype: object
```

Specifying *na* to be *False* instead of *NaN*.

```
>>> s.str.startswith('b', na=False)
0     True
1    False
2    False
3    False
dtype: bool
```

## pandas.Series.str.strip

**`Series.str.strip`** (*self*, *to\_strip=None*)

Remove leading and trailing characters.

Strip whitespaces (including newlines) or a set of specified characters from each string in the Series/Index from left and right sides. Equivalent to `str.strip()`.

### Parameters

**`to_strip`** [str or None, default None] Specifying the set of characters to be removed. All combinations of this set of characters will be stripped. If None then whitespaces are removed.

### Returns

**Series or Index of object**

See also:

**`Series.str.strip`** Remove leading and trailing characters in Series/Index.

**`Series.str.lstrip`** Remove leading characters in Series/Index.

**`Series.str.rstrip`** Remove trailing characters in Series/Index.

## Examples

```
>>> s = pd.Series(['1. Ant. ', '2. Bee!\n', '3. Cat?\t', np.nan])
>>> s
0    1. Ant.
1    2. Bee!\n
2    3. Cat?\t
3           NaN
dtype: object
```

```
>>> s.str.strip()
0    1. Ant.
1    2. Bee!
2    3. Cat?
3           NaN
dtype: object
```

```
>>> s.str.lstrip('123.')
0    Ant.
1    Bee!\n
2    Cat?\t
3           NaN
dtype: object
```

```
>>> s.str.rstrip('!?\ \n\t')
0    1. Ant
1    2. Bee
2    3. Cat
3           NaN
dtype: object
```

```
>>> s.str.strip('123.!?\ \n\t')
0    Ant
1    Bee
2    Cat
3    NaN
dtype: object
```

## pandas.Series.str.swapcase

`Series.str.swapcase` (*self*)

Convert strings in the Series/Index to be swapped.

Equivalent to `str.swapcase()`.

### Returns

**Series or Index of object**

**See also:**

**`Series.str.lower`** Converts all characters to lowercase.

**`Series.str.upper`** Converts all characters to uppercase.

**`Series.str.title`** Converts first character of each word to uppercase and remaining to lowercase.

**`Series.str.capitalize`** Converts first character to uppercase and remaining to lowercase.

**`Series.str.swapcase`** Converts uppercase to lowercase and lowercase to uppercase.

**`Series.str.casefold`** Removes all case distinctions in the string.

## Examples

```
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0          lower
1      CAPITALS
2  this is a sentence
3      SwApCaSe
dtype: object
```

```
>>> s.str.lower()
0          lower
1      capitals
2  this is a sentence
3      swapcase
dtype: object
```

```
>>> s.str.upper()
0          LOWER
1      CAPITALS
2  THIS IS A SENTENCE
3      SWAPCASE
dtype: object
```

```
>>> s.str.title()
0          Lower
1      Capitals
2  This Is A Sentence
3      Swapcase
dtype: object
```

```
>>> s.str.capitalize()
0          Lower
1      Capitals
2  This is a sentence
3      Swapcase
dtype: object
```

```
>>> s.str.swapcase()
0          LOWER
1      capitals
2  THIS IS A SENTENCE
3      sWaPcAsE
dtype: object
```

## pandas.Series.str.title

`Series.str.title` (*self*)

Convert strings in the Series/Index to titlecase.

Equivalent to `str.title()`.

**Returns**

**Series or Index of object**

**See also:**

**`Series.str.lower`** Converts all characters to lowercase.

**`Series.str.upper`** Converts all characters to uppercase.

**`Series.str.title`** Converts first character of each word to uppercase and remaining to lowercase.

**`Series.str.capitalize`** Converts first character to uppercase and remaining to lowercase.

**`Series.str.swapcase`** Converts uppercase to lowercase and lowercase to uppercase.

**`Series.str.casefold`** Removes all case distinctions in the string.

## Examples

```
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0          lower
1        CAPITALS
2  this is a sentence
3        SwApCaSe
dtype: object
```

```
>>> s.str.lower()
0          lower
1        capitals
2  this is a sentence
3        swapcase
dtype: object
```

```
>>> s.str.upper()
0          LOWER
1        CAPITALS
2  THIS IS A SENTENCE
3        SWAPCASE
dtype: object
```

```
>>> s.str.title()
0          Lower
1        Capitals
2  This Is A Sentence
3        Swapcase
dtype: object
```

```
>>> s.str.capitalize()
0          Lower
1        Capitals
2  This is a sentence
3        Swapcase
dtype: object
```

```
>>> s.str.swapcase()
0          LOWER
1      capitals
2  THIS IS A SENTENCE
3      sWaPcAsE
dtype: object
```

### pandas.Series.str.translate

`Series.str.translate` (*self*, *table*)

Map all characters in the string through the given mapping table. Equivalent to standard `str.translate()`.

#### Parameters

**table** [dict] Table is a mapping of Unicode ordinals to Unicode ordinals, strings, or None. Unmapped characters are left untouched. Characters mapped to None are deleted. `str.maketrans()` is a helper function for making translation tables.

#### Returns

**Series or Index**

### pandas.Series.str.upper

`Series.str.upper` (*self*)

Convert strings in the Series/Index to uppercase.

Equivalent to `str.upper()`.

#### Returns

**Series or Index of object**

See also:

**`Series.str.lower`** Converts all characters to lowercase.

**`Series.str.upper`** Converts all characters to uppercase.

**`Series.str.title`** Converts first character of each word to uppercase and remaining to lowercase.

**`Series.str.capitalize`** Converts first character to uppercase and remaining to lowercase.

**`Series.str.swapcase`** Converts uppercase to lowercase and lowercase to uppercase.

**`Series.str.casefold`** Removes all case distinctions in the string.

### Examples

```
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0          lower
1      CAPITALS
2  this is a sentence
3      SwApCaSe
dtype: object
```

```
>>> s.str.lower()
0          lower
1      capitals
2  this is a sentence
```

(continues on next page)

(continued from previous page)

```
3          swapcase
dtype: object
```

```
>>> s.str.upper()
0          LOWER
1          CAPITALS
2  THIS IS A SENTENCE
3          SWAPCASE
dtype: object
```

```
>>> s.str.title()
0          Lower
1          Capitals
2  This Is A Sentence
3          Swapcase
dtype: object
```

```
>>> s.str.capitalize()
0          Lower
1          Capitals
2  This is a sentence
3          Swapcase
dtype: object
```

```
>>> s.str.swapcase()
0          LOWER
1          capitals
2  THIS IS A SENTENCE
3          sWaPcAsE
dtype: object
```

### pandas.Series.str.wrap

`Series.str.wrap` (*self*, *width*, *\*\*kwargs*)

Wrap long strings in the Series/Index to be formatted in paragraphs with length less than a given width.

This method has the same keyword parameters and defaults as `textwrap.TextWrapper`.

#### Parameters

- width** [int] Maximum line width.
- expand\_tabs** [bool, optional] If True, tab characters will be expanded to spaces (default: True).
- replace\_whitespace** [bool, optional] If True, each whitespace character (as defined by `string.whitespace`) remaining after tab expansion will be replaced by a single space (default: True).
- drop\_whitespace** [bool, optional] If True, whitespace that, after wrapping, happens to end up at the beginning or end of a line is dropped (default: True).
- break\_long\_words** [bool, optional] If True, then words longer than width will be broken in order to ensure that no lines are longer than width. If it is false, long words will not be broken, and some lines may be longer than width (default: True).

**break\_on\_hyphens** [bool, optional] If True, wrapping will occur preferably on whitespace and right after hyphens in compound words, as it is customary in English. If false, only whitespaces will be considered as potentially good places for line breaks, but you need to set `break_long_words` to false if you want truly insecable words (default: True).

#### Returns

Series or Index

#### Notes

Internally, this method uses a `textwrap.TextWrapper` instance with default settings. To achieve behavior matching R's stringr library `str_wrap` function, use the arguments:

- `expand_tabs = False`
- `replace_whitespace = True`
- `drop_whitespace = True`
- `break_long_words = False`
- `break_on_hyphens = False`

#### Examples

```
>>> s = pd.Series(['line to be wrapped', 'another line to be wrapped'])
>>> s.str.wrap(12)
0          line to be\nwrapped
1  another line\nto be\nwrapped
dtype: object
```

### pandas.Series.str.zfill

`Series.str.zfill` (*self*, *width*)

Pad strings in the Series/Index by prepending '0' characters.

Strings in the Series/Index are padded with '0' characters on the left of the string to reach a total string length *width*. Strings in the Series/Index with length greater or equal to *width* are unchanged.

#### Parameters

**width** [int] Minimum length of resulting string; strings with length less than *width* be prepended with '0' characters.

#### Returns

Series/Index of objects.

See also:

**Series.str.rjust** Fills the left side of strings with an arbitrary character.

**Series.str.ljust** Fills the right side of strings with an arbitrary character.

**Series.str.pad** Fills the specified sides of strings with an arbitrary character.

**Series.str.center** Fills boths sides of strings with an arbitrary character.

## Notes

Differs from `str.zfill()` which has special handling for '+'/'-' in the string.

## Examples

```
>>> s = pd.Series(['-1', '1', '1000', 10, np.nan])
>>> s
0      -1
1       1
2    1000
3       10
4      NaN
dtype: object
```

Note that 10 and NaN are not strings, therefore they are converted to NaN. The minus sign in '-1' is treated as a regular character and the zero is added to the left of it (`str.zfill()` would have moved it to the left). 1000 remains unchanged as it is longer than *width*.

```
>>> s.str.zfill(3)
0     0-1
1     001
2    1000
3     NaN
4     NaN
dtype: object
```

## pandas.Series.str.isalnum

`Series.str.isalnum(self)`

Check whether all characters in each string are alphanumeric.

This is equivalent to running the Python string method `str.isalnum()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

### Returns

**Series or Index of bool** Series or Index of boolean values with the same length as the original Series/Index.

See also:

**`Series.str.isalpha`** Check whether all characters are alphabetic.  
**`Series.str.isnumeric`** Check whether all characters are numeric.  
**`Series.str.isalnum`** Check whether all characters are alphanumeric.  
**`Series.str.isdigit`** Check whether all characters are digits.  
**`Series.str.isdecimal`** Check whether all characters are decimal.  
**`Series.str.isspace`** Check whether all characters are whitespace.  
**`Series.str.islower`** Check whether all characters are lowercase.  
**`Series.str.isupper`** Check whether all characters are uppercase.  
**`Series.str.istitle`** Check whether all characters are titlecase.

## Examples

### Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0    True
1   False
2   False
3   False
dtype: bool
```

```
>>> s1.str.isnumeric()
0   False
1   False
2    True
3   False
dtype: bool
```

```
>>> s1.str.isalnum()
0    True
1    True
2    True
3   False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0   False
1   False
2   False
dtype: bool
```

### More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '³', '', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0    True
1   False
2   False
3   False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0    True
```

(continues on next page)

(continued from previous page)

```
1    True
2    False
3    False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0    True
1    True
2    True
3    False
dtype: bool
```

### Checks for Whitespace

```
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0    True
1    True
2    False
dtype: bool
```

### Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```
>>> s5.str.islower()
0    True
1    False
2    False
3    False
dtype: bool
```

```
>>> s5.str.isupper()
0    False
1    False
2    True
3    False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0    False
1    True
2    False
3    False
dtype: bool
```

## pandas.Series.str.isalpha

`Series.str.isalpha` (*self*)

Check whether all characters in each string are alphabetic.

This is equivalent to running the Python string method `str.isalpha()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

### Returns

**Series or Index of bool** Series or Index of boolean values with the same length as the original Series/Index.

### See also:

**`Series.str.isalpha`** Check whether all characters are alphabetic.  
**`Series.str.isnumeric`** Check whether all characters are numeric.  
**`Series.str.isalnum`** Check whether all characters are alphanumeric.  
**`Series.str.isdigit`** Check whether all characters are digits.  
**`Series.str.isdecimal`** Check whether all characters are decimal.  
**`Series.str.isspace`** Check whether all characters are whitespace.  
**`Series.str.islower`** Check whether all characters are lowercase.  
**`Series.str.isupper`** Check whether all characters are uppercase.  
**`Series.str.istitle`** Check whether all characters are titlecase.

## Examples

### Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0    True
1   False
2   False
3   False
dtype: bool
```

```
>>> s1.str.isnumeric()
0   False
1   False
2    True
3   False
dtype: bool
```

```
>>> s1.str.isalnum()
0    True
1    True
2    True
3   False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
```

(continues on next page)

(continued from previous page)

```
0    False
1    False
2    False
dtype: bool
```

### More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '³', '¹', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0     True
1    False
2    False
3    False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0     True
1     True
2    False
3    False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0     True
1     True
2     True
3    False
dtype: bool
```

### Checks for Whitespace

```
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0     True
1     True
2    False
dtype: bool
```

### Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```
>>> s5.str.islower()
0     True
1    False
```

(continues on next page)

(continued from previous page)

```
2    False
3    False
dtype: bool
```

```
>>> s5.str.isupper()
0    False
1    False
2     True
3    False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0    False
1     True
2    False
3    False
dtype: bool
```

## pandas.Series.str.isdigit

`Series.str.isdigit` (*self*)

Check whether all characters in each string are digits.

This is equivalent to running the Python string method `str.isdigit()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

### Returns

**Series or Index of bool** Series or Index of boolean values with the same length as the original Series/Index.

See also:

**`Series.str.isalpha`** Check whether all characters are alphabetic.  
**`Series.str.isnumeric`** Check whether all characters are numeric.  
**`Series.str.isalnum`** Check whether all characters are alphanumeric.  
**`Series.str.isdigit`** Check whether all characters are digits.  
**`Series.str.isdecimal`** Check whether all characters are decimal.  
**`Series.str.isspace`** Check whether all characters are whitespace.  
**`Series.str.islower`** Check whether all characters are lowercase.  
**`Series.str.isupper`** Check whether all characters are uppercase.  
**`Series.str.istitle`** Check whether all characters are titlecase.

## Examples

### Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0    True
1   False
2   False
3   False
dtype: bool
```

```
>>> s1.str.isnumeric()
0   False
1   False
2    True
3   False
dtype: bool
```

```
>>> s1.str.isalnum()
0    True
1    True
2    True
3   False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0   False
1   False
2   False
dtype: bool
```

### More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '³', '', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0    True
1   False
2   False
3   False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0    True
```

(continues on next page)

(continued from previous page)

```
1    True
2    False
3    False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0    True
1    True
2    True
3    False
dtype: bool
```

### Checks for Whitespace

```
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0    True
1    True
2    False
dtype: bool
```

### Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```
>>> s5.str.islower()
0    True
1    False
2    False
3    False
dtype: bool
```

```
>>> s5.str.isupper()
0    False
1    False
2    True
3    False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0    False
1    True
2    False
3    False
dtype: bool
```

## pandas.Series.str.isspace

`Series.str.isspace` (*self*)

Check whether all characters in each string are whitespace.

This is equivalent to running the Python string method `str.isspace()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

### Returns

**Series or Index of bool** Series or Index of boolean values with the same length as the original Series/Index.

### See also:

**`Series.str.isalpha`** Check whether all characters are alphabetic.  
**`Series.str.isnumeric`** Check whether all characters are numeric.  
**`Series.str.isalnum`** Check whether all characters are alphanumeric.  
**`Series.str.isdigit`** Check whether all characters are digits.  
**`Series.str.isdecimal`** Check whether all characters are decimal.  
**`Series.str.isspace`** Check whether all characters are whitespace.  
**`Series.str.islower`** Check whether all characters are lowercase.  
**`Series.str.isupper`** Check whether all characters are uppercase.  
**`Series.str.istitle`** Check whether all characters are titlecase.

## Examples

### Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0    True
1   False
2   False
3   False
dtype: bool
```

```
>>> s1.str.isnumeric()
0   False
1   False
2    True
3   False
dtype: bool
```

```
>>> s1.str.isalnum()
0    True
1    True
2    True
3   False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
```

(continues on next page)

(continued from previous page)

```
0    False
1    False
2    False
dtype: bool
```

### More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '³', '¹', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0     True
1    False
2    False
3    False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0     True
1     True
2    False
3    False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0     True
1     True
2     True
3    False
dtype: bool
```

### Checks for Whitespace

```
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0     True
1     True
2    False
dtype: bool
```

### Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```
>>> s5.str.islower()
0     True
1    False
```

(continues on next page)

(continued from previous page)

```
2    False
3    False
dtype: bool
```

```
>>> s5.str.isupper()
0    False
1    False
2     True
3    False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0    False
1     True
2    False
3    False
dtype: bool
```

### pandas.Series.str.islower

`Series.str.islower` (*self*)

Check whether all characters in each string are lowercase.

This is equivalent to running the Python string method `str.islower()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

#### Returns

**Series or Index of bool** Series or Index of boolean values with the same length as the original Series/Index.

See also:

**`Series.str.isalpha`** Check whether all characters are alphabetic.  
**`Series.str.isnumeric`** Check whether all characters are numeric.  
**`Series.str.isalnum`** Check whether all characters are alphanumeric.  
**`Series.str.isdigit`** Check whether all characters are digits.  
**`Series.str.isdecimal`** Check whether all characters are decimal.  
**`Series.str.isspace`** Check whether all characters are whitespace.  
**`Series.str.islower`** Check whether all characters are lowercase.  
**`Series.str.isupper`** Check whether all characters are uppercase.  
**`Series.str.istitle`** Check whether all characters are titlecase.

## Examples

### Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0    True
1   False
2   False
3   False
dtype: bool
```

```
>>> s1.str.isnumeric()
0   False
1   False
2    True
3   False
dtype: bool
```

```
>>> s1.str.isalnum()
0    True
1    True
2    True
3   False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0   False
1   False
2   False
dtype: bool
```

### More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '³', '', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0    True
1   False
2   False
3   False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0    True
```

(continues on next page)

(continued from previous page)

**`Series.str.isalnum`** Check whether all characters are alphanumeric.  
**`Series.str.isdigit`** Check whether all characters are digits.  
**`Series.str.isdecimal`** Check whether all characters are decimal.  
**`Series.str.isspace`** Check whether all characters are whitespace.  
**`Series.str.islower`** Check whether all characters are lowercase.  
**`Series.str.isupper`** Check whether all characters are uppercase.  
**`Series.str.istitle`** Check whether all characters are titlecase.

## Examples

### Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0    True
1   False
2   False
3   False
dtype: bool
```

```
>>> s1.str.isnumeric()
0   False
1   False
2    True
3   False
dtype: bool
```

```
>>> s1.str.isalnum()
0    True
1    True
2    True
3   False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0   False
1   False
2   False
dtype: bool
```

### More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '³', '', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0    True
1   False
2   False
3   False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0    True
```

(continues on next page)

(continued from previous page)

```
1    True
2    False
3    False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0    True
1    True
2    True
3    False
dtype: bool
```

### Checks for Whitespace

```
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0    True
1    True
2    False
dtype: bool
```

### Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```
>>> s5.str.islower()
0    True
1    False
2    False
3    False
dtype: bool
```

```
>>> s5.str.isupper()
0    False
1    False
2    True
3    False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```

**`Series.str.isdigit`** Check whether all characters are digits.  
**`Series.str.isdecimal`** Check whether all characters are decimal.  
**`Series.str.isspace`** Check whether all characters are whitespace.  
**`Series.str.islower`** Check whether all characters are lowercase.  
**`Series.str.isupper`** Check whether all characters are uppercase.  
**`Series.str.istitle`** Check whether all characters are titlecase.

## Examples

### Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0    True
1   False
2   False
3   False
dtype: bool
```

```
>>> s1.str.isnumeric()
0   False
1   False
2    True
3   False
dtype: bool
```

```
>>> s1.str.isalnum()
0    True
1    True
2    True
3   False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
```

(continues on next page)

(continued from previous page)

```
0    False
1    False
2    False
dtype: bool
```

### More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '³', '¹', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0     True
1    False
2    False
3    False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0     True
1     True
2    False
3    False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0     True
1     True
2     True
3    False
dtype: bool
```

### Checks for Whitespace

```
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0     True
1     True
2    False
dtype: bool
```

### Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```
>>> s5.str.islower()
0     True
1    False
```

(continues on next page)

(continued from previous page)

```
2    False
3    False
dtype: bool
```

```
>>> s5.str.isupper()
0    False
1    False
2     True
3    False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0    False
1     True
2    False
3    False
dtype: bool
```

### pandas.Series.str.isdecimal

`Series.str.isdecimal` (*self*)

Check whether all characters in each string are decimal.

This is equivalent to running the Python string method `str.isdecimal()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

#### Returns

**Series or Index of bool** Series or Index of boolean values with the same length as the original Series/Index.

#### See also:

**`Series.str.isalpha`** Check whether all characters are alphabetic.  
**`Series.str.isnumeric`** Check whether all characters are numeric.  
**`Series.str.isalnum`** Check whether all characters are alphanumeric.  
**`Series.str.isdigit`** Check whether all characters are digits.  
**`Series.str.isdecimal`** Check whether all characters are decimal.  
**`Series.str.isspace`** Check whether all characters are whitespace.  
**`Series.str.islower`** Check whether all characters are lowercase.  
**`Series.str.isupper`** Check whether all characters are uppercase.  
**`Series.str.istitle`** Check whether all characters are titlecase.

## Examples

### Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0    True
1   False
2   False
3   False
dtype: bool
```

```
>>> s1.str.isnumeric()
0   False
1   False
2    True
3   False
dtype: bool
```

```
>>> s1.str.isalnum()
0    True
1    True
2    True
3   False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0   False
1   False
2   False
dtype: bool
```

### More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '³', '', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0    True
1   False
2   False
3   False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0    True
```

(continues on next page)

(continued from previous page)

```
1    True
2    False
3    False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0    True
1    True
2    True
3    False
dtype: bool
```

### Checks for Whitespace

```
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0    True
1    True
2    False
dtype: bool
```

### Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```
>>> s5.str.islower()
0    True
1    False
2    False
3    False
dtype: bool
```

```
>>> s5.str.isupper()
0    False
1    False
2    True
3    False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0    False
1    True
2    False
3    False
dtype: bool
```

## pandas.Series.str.get\_dummies

`Series.str.get_dummies` (*self*, *sep*='|')

Split each string in the Series by *sep* and return a DataFrame of dummy/indicator variables.

### Parameters

**sep** [str, default "|"] String to split on.

### Returns

**DataFrame** Dummy variables corresponding to values of the Series.

**See also:**

**`get_dummies`** Convert categorical variable into dummy/indicator variables.

## Examples

```
>>> pd.Series(['a|b', 'a', 'a|c']).str.get_dummies()
   a  b  c
0  1  1  0
1  1  0  0
2  1  0  1
```

```
>>> pd.Series(['a|b', np.nan, 'a|c']).str.get_dummies()
   a  b  c
0  1  1  0
1  0  0  0
2  1  0  1
```

## Categorical accessor

Categorical-dtype specific methods and attributes are available under the `Series.cat` accessor.

<code>Series.cat.categories</code>	The categories of this categorical.
<code>Series.cat.ordered</code>	Whether the categories have an ordered relationship.
<code>Series.cat.codes</code>	Return Series of codes as well as the index.

## pandas.Series.cat.categories

`Series.cat.categories`

The categories of this categorical.

`Setting` assigns new values to each category (effectively a rename of each individual category).

The assigned value has to be a list-like object. All items must be unique and the number of items in the new categories must be the same as the number of items in the old categories.

Assigning to `categories` is a inplace operation!

### Raises

**ValueError** If the new categories do not validate as categories or if the number of new categories is unequal the number of old categories

**See also:**

**`rename_categories`**

```

reorder_categories
add_categories
remove_categories
remove_unused_categories
set_categories

```

### pandas.Series.cat.ordered

Series.cat.ordered

Whether the categories have an ordered relationship.

### pandas.Series.cat.codes

Series.cat.codes

Return Series of codes as well as the index.

<i>Series.cat.rename_categories</i> (self, <i>\*args</i> , ...)	Rename categories.
<i>Series.cat.reorder_categories</i> (self, <i>\*args</i> , ...)	Reorder categories as specified in <i>new_categories</i> .
<i>Series.cat.add_categories</i> (self, <i>\*args</i> , ...)	Add new categories.
<i>Series.cat.remove_categories</i> (self, <i>\*args</i> , ...)	Remove the specified categories.
<i>Series.cat.remove_unused_categories</i> (self, ...)	Remove categories which are not used.
<i>Series.cat.set_categories</i> (self, <i>\*args</i> , ...)	Set the categories to the specified <i>new_categories</i> .
<i>Series.cat.as_ordered</i> (self, <i>\*args</i> , <i>\*\*kwargs</i> )	Set the Categorical to be ordered.
<i>Series.cat.as_unordered</i> (self, <i>\*args</i> , <i>\*\*kwargs</i> )	Set the Categorical to be unordered.

### pandas.Series.cat.rename\_categories

Series.cat.rename\_categories(*self*, *\*args*, *\*\*kwargs*)

Rename categories.

#### Parameters

**new\_categories** [list-like, dict-like or callable] New categories which will replace old categories.

- list-like: all items must be unique and the number of items in the new categories must match the existing number of categories.
- dict-like: specifies a mapping from old categories to new. Categories not contained in the mapping are passed through and extra categories in the mapping are ignored.

New in version 0.21.0..

- callable : a callable that is called on all items in the old categories and whose return values comprise the new categories.

New in version 0.23.0..

**inplace** [bool, default False] Whether or not to rename the categories inplace or return a copy of this categorical with renamed categories.

**Returns**

**cat** [Categorical or None] With `inplace=False`, the new categorical is returned. With `inplace=True`, there is no return value.

**Raises**

**ValueError** If new categories are list-like and do not have the same number of items than the current categories or do not validate as categories

See also:

*reorder\_categories*  
*add\_categories*  
*remove\_categories*  
*remove\_unused\_categories*  
*set\_categories*

**Examples**

```
>>> c = pd.Categorical(['a', 'a', 'b'])
>>> c.rename_categories([0, 1])
[0, 0, 1]
Categories (2, int64): [0, 1]
```

For dict-like `new_categories`, extra keys are ignored and categories not in the dictionary are passed through

```
>>> c.rename_categories({'a': 'A', 'c': 'C'})
[A, A, b]
Categories (2, object): [A, b]
```

You may also provide a callable to create the new categories

```
>>> c.rename_categories(lambda x: x.upper())
[A, A, B]
Categories (2, object): [A, B]
```

**pandas.Series.cat.reorder\_categories**

`Series.cat.reorder_categories` (*self*, \*args, \*\*kwargs)

Reorder categories as specified in `new_categories`.

`new_categories` need to include all old categories and no new category items.

**Parameters**

**new\_order** [Index-like] The categories in new order.

**ordered** [bool, optional] Whether or not the categorical is treated as a ordered categorical. If not given, do not change the ordered information.

**inplace** [bool, default False] Whether or not to reorder the categories inplace or return a copy of this categorical with reordered categories.

**Returns**

**cat** [Categorical with reordered categories or None if inplace.]

**Raises**

**ValueError** If the new categories do not contain all old category items or any new ones

See also:

*rename\_categories*  
*add\_categories*  
*remove\_categories*  
*remove\_unused\_categories*  
*set\_categories*

**pandas.Series.cat.add\_categories**

`Series.cat.add_categories` (*self*, \*args, \*\*kwargs)

Add new categories.

*new\_categories* will be included at the last/highest place in the categories and will be unused directly after this call.

**Parameters**

**new\_categories** [category or list-like of category] The new categories to be included.

**inplace** [bool, default False] Whether or not to add the categories inplace or return a copy of this categorical with added categories.

**Returns**

**cat** [Categorical with new categories added or None if inplace.]

**Raises**

**ValueError** If the new categories include old categories or do not validate as categories

See also:

*rename\_categories*  
*reorder\_categories*  
*remove\_categories*  
*remove\_unused\_categories*  
*set\_categories*

**pandas.Series.cat.remove\_categories**

`Series.cat.remove_categories` (*self*, \*args, \*\*kwargs)

Remove the specified categories.

*removals* must be included in the old categories. Values which were in the removed categories will be set to NaN

**Parameters**

**removals** [category or list of categories] The categories which should be removed.

**inplace** [bool, default False] Whether or not to remove the categories inplace or return a copy of this categorical with removed categories.

**Returns**

**cat** [Categorical with removed categories or None if inplace.]

**Raises**

**ValueError** If the removals are not contained in the categories

See also:

*rename\_categories*  
*reorder\_categories*  
*add\_categories*  
*remove\_unused\_categories*  
*set\_categories*

### pandas.Series.cat.remove\_unused\_categories

`Series.cat.remove_unused_categories` (*self*, \**args*, \*\**kwargs*)

Remove categories which are not used.

#### Parameters

**inplace** [bool, default False] Whether or not to drop unused categories inplace or return a copy of this categorical with unused categories dropped.

#### Returns

**cat** [Categorical with unused categories dropped or None if inplace.]

See also:

*rename\_categories*  
*reorder\_categories*  
*add\_categories*  
*remove\_categories*  
*set\_categories*

### pandas.Series.cat.set\_categories

`Series.cat.set_categories` (*self*, \**args*, \*\**kwargs*)

Set the categories to the specified *new\_categories*.

*new\_categories* can include new categories (which will result in unused categories) or remove old categories (which results in values set to NaN). If *rename==True*, the categories will simply be renamed (less or more items than in old categories will result in values set to NaN or in unused categories respectively).

This method can be used to perform more than one action of adding, removing, and reordering simultaneously and is therefore faster than performing the individual steps via the more specialised methods.

On the other hand this method does not do checks (e.g., whether the old categories are included in the new categories on a reorder), which can result in surprising changes, for example when using special string dtypes, which does not consider a S1 string equal to a single char python string.

#### Parameters

**new\_categories** [Index-like] The categories in new order.

**ordered** [bool, default False] Whether or not the categorical is treated as an ordered categorical. If not given, do not change the ordered information.

**rename** [bool, default False] Whether or not the *new\_categories* should be considered as a rename of the old categories or as reordered categories.

**inplace** [bool, default False] Whether or not to reorder the categories in-place or return a copy of this categorical with reordered categories.

#### Returns

**Categorical with reordered categories or None if inplace.**

**Raises**

**ValueError** If `new_categories` does not validate as categories

See also:

*rename\_categories*  
*reorder\_categories*  
*add\_categories*  
*remove\_categories*  
*remove\_unused\_categories*

### pandas.Series.cat.as\_ordered

`Series.cat.as_ordered` (*self*, \*args, \*\*kwargs)

Set the Categorical to be ordered.

**Parameters**

**inplace** [bool, default False] Whether or not to set the ordered attribute in-place or return a copy of this categorical with ordered set to True.

**Returns**

**Categorical** Ordered Categorical.

### pandas.Series.cat.as\_unordered

`Series.cat.as_unordered` (*self*, \*args, \*\*kwargs)

Set the Categorical to be unordered.

**Parameters**

**inplace** [bool, default False] Whether or not to set the ordered attribute in-place or return a copy of this categorical with ordered set to False.

**Returns**

**Categorical** Unordered Categorical.

### Sparse accessor

Sparse-dtype specific methods and attributes are provided under the `Series.sparse` accessor.

<code>Series.sparse.npoints</code>	The number of non- <code>fill_value</code> points.
<code>Series.sparse.density</code>	The percent of non- <code>fill_value</code> points, as decimal.
<code>Series.sparse.fill_value</code>	Elements in <code>data</code> that are <code>fill_value</code> are not stored.
<code>Series.sparse.sp_values</code>	An ndarray containing the non- <code>fill_value</code> values.

### pandas.Series.sparse.npoints

#### Series.sparse.npoints

The number of non- `fill_value` points.

#### Examples

```
>>> s = SparseArray([0, 0, 1, 1, 1], fill_value=0)
>>> s.npoints
3
```

### pandas.Series.sparse.density

#### Series.sparse.density

The percent of non- `fill_value` points, as decimal.

#### Examples

```
>>> s = SparseArray([0, 0, 1, 1, 1], fill_value=0)
>>> s.density
0.6
```

### pandas.Series.sparse.fill\_value

#### Series.sparse.fill\_value

Elements in *data* that are *fill\_value* are not stored.

For memory savings, this should be the most common value in the array.

### pandas.Series.sparse.sp\_values

#### Series.sparse.sp\_values

An ndarray containing the non- `fill_value` values.

#### Examples

```
>>> s = SparseArray([0, 0, 1, 0, 2], fill_value=0)
>>> s.sp_values
array([1, 2])
```

---

<code>Series.sparse.from_coo(A[, dense_index])</code>	Create a Series with sparse values from a <code>scipy.sparse.coo_matrix</code> .
<code>Series.sparse.to_coo(self[, row_levels, ...])</code>	Create a <code>scipy.sparse.coo_matrix</code> from a Series with <code>MultiIndex</code> .

---

### pandas.Series.sparse.from\_coo

**classmethod** `sparse.from_coo` (*A*, *dense\_index=False*)

Create a Series with sparse values from a `scipy.sparse.coo_matrix`.

#### Parameters

**A** [`scipy.sparse.coo_matrix`]

**dense\_index** [`bool`, default `False`] If `False` (default), the `SparseSeries` index consists of only the coords of the non-null entries of the original `coo_matrix`. If `True`, the `SparseSeries` index consists of the full sorted (row, col) coordinates of the `coo_matrix`.

#### Returns

**s** [`Series`] A Series with sparse values.

### Examples

```

>>> from scipy import sparse
>>> A = sparse.coo_matrix(([3.0, 1.0, 2.0], ([1, 0, 0], [0, 2, 3])),
                          shape=(3, 4))
>>> A
<3x4 sparse matrix of type '<class 'numpy.float64'>'
  with 3 stored elements in COOrdinate format>
>>> A.todense()
matrix([[ 0.,  0.,  1.,  2.],
        [ 3.,  0.,  0.,  0.],
        [ 0.,  0.,  0.,  0.]])
>>> ss = pd.Series.sparse.from_coo(A)
>>> ss
0 2 1
3 2
1 0 3
dtype: float64
BlockIndex
Block locations: array([0], dtype=int32)
Block lengths: array([3], dtype=int32)

```

### pandas.Series.sparse.to\_coo

**sparse.to\_coo** (*self*, *row\_levels=(0, )*, *column\_levels=(1, )*, *sort\_labels=False*)

Create a `scipy.sparse.coo_matrix` from a Series with `MultiIndex`.

Use `row_levels` and `column_levels` to determine the row and column coordinates respectively. `row_levels` and `column_levels` are the names (labels) or numbers of the levels. `{row_levels, column_levels}` must be a partition of the `MultiIndex` level names (or numbers).

#### Parameters

**row\_levels** [`tuple/list`]

**column\_levels** [`tuple/list`]

**sort\_labels** [`bool`, default `False`] Sort the row and column labels before forming the sparse matrix.

#### Returns

**y** [`scipy.sparse.coo_matrix`]

**rows** [list (row labels)]  
**columns** [list (column labels)]

### Examples

```
>>> s = pd.Series([3.0, np.nan, 1.0, 3.0, np.nan, np.nan])
>>> s.index = pd.MultiIndex.from_tuples([(1, 2, 'a', 0),
                                         (1, 2, 'a', 1),
                                         (1, 1, 'b', 0),
                                         (1, 1, 'b', 1),
                                         (2, 1, 'b', 0),
                                         (2, 1, 'b', 1)],
                                         names=['A', 'B', 'C', 'D'])

>>> ss = s.astype("Sparse")
>>> A, rows, columns = ss.sparse.to_coo(row_levels=['A', 'B'],
...                                     column_levels=['C', 'D'],
...                                     sort_labels=True)
>>> A
<3x4 sparse matrix of type '<class 'numpy.float64'>'
  with 3 stored elements in COOrdinate format>
>>> A.todense()
matrix([[ 0.,  0.,  1.,  3.],
 [ 3.,  0.,  0.,  0.],
 [ 0.,  0.,  0.,  0.]])
>>> rows
[(1, 1), (1, 2), (2, 1)]
>>> columns
[('a', 0), ('a', 1), ('b', 0), ('b', 1)]
```

### Metadata

`Series.attrs` is a dictionary for storing global metadata for this Series.

**Warning:** `Series.attrs` is considered experimental and may change without warning.

<code>Series.attrs</code>	Dictionary of global attributes on this object.
---------------------------	-------------------------------------------------

### 4.3.14 Plotting

`Series.plot` is both a callable method and a namespace attribute for specific plotting methods of the form `Series.plot.<kind>`.

<code>Series.plot([kind, ax, figsize, ...])</code>	Series plotting accessor and method
<code>Series.plot.area(self[, x, y])</code>	Draw a stacked area plot.
<code>Series.plot.bar(self[, x, y])</code>	Vertical bar plot.
<code>Series.plot.barh(self[, x, y])</code>	Make a horizontal bar plot.

Continued on next page

Table 54 – continued from previous page

<code>Series.plot.box(self[, by])</code>	Make a box plot of the DataFrame columns.
<code>Series.plot.density(self[, bw_method, ind])</code>	Generate Kernel Density Estimate plot using Gaussian kernels.
<code>Series.plot.hist(self[, by, bins])</code>	Draw one histogram of the DataFrame's columns.
<code>Series.plot.kde(self[, bw_method, ind])</code>	Generate Kernel Density Estimate plot using Gaussian kernels.
<code>Series.plot.line(self[, x, y])</code>	Plot Series or DataFrame as lines.
<code>Series.plot.pie(self, \**kwargs)</code>	Generate a pie plot.

## pandas.Series.plot.area

`Series.plot.area` (*self*, *x=None*, *y=None*, *\*\*kwargs*)

Draw a stacked area plot.

An area plot displays quantitative data visually. This function wraps the matplotlib area function.

### Parameters

- x** [label or position, optional] Coordinates for the X axis. By default uses the index.
- y** [label or position, optional] Column to plot. By default uses all columns.
- stacked** [bool, default True] Area plots are stacked by default. Set to False to create a unstacked plot.
- \*\*kwargs** Additional keyword arguments are documented in `DataFrame.plot()`.

### Returns

**matplotlib.axes.Axes or numpy.ndarray** Area plot, or array of area plots if subplots is True.

See also:

**DataFrame.plot** Make plots of DataFrame using matplotlib / pylab.

## Examples

Draw an area plot based on basic business metrics:

```
>>> df = pd.DataFrame({
...     'sales': [3, 2, 3, 9, 10, 6],
...     'signups': [5, 5, 6, 12, 14, 13],
...     'visits': [20, 42, 28, 62, 81, 50],
... }, index=pd.date_range(start='2018/01/01', end='2018/07/01',
...                          freq='M'))
>>> ax = df.plot.area()
```

Area plots are stacked by default. To produce an unstacked plot, pass `stacked=False`:

```
>>> ax = df.plot.area(stacked=False)
```

Draw an area plot for a single column:

```
>>> ax = df.plot.area(y='sales')
```

Draw with a different x:

```

>>> df = pd.DataFrame({
...     'sales': [3, 2, 3],
...     'visits': [20, 42, 28],
...     'day': [1, 2, 3],
... })
>>> ax = df.plot.area(x='day')

```

### pandas.Series.plot.bar

`Series.plot.bar` (*self*, *x=None*, *y=None*, *\*\*kwargs*)

Vertical bar plot.

A bar plot is a plot that presents categorical data with rectangular bars with lengths proportional to the values that they represent. A bar plot shows comparisons among discrete categories. One axis of the plot shows the specific categories being compared, and the other axis represents a measured value.

#### Parameters

**x** [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.

**y** [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.

**\*\*kwargs** Additional keyword arguments are documented in `DataFrame.plot()`.

**Returns**

**matplotlib.axes.Axes or np.ndarray of them** An ndarray is returned with one `matplotlib.axes.Axes` per column when `subplots=True`.

See also:

`DataFrame.plot.barh` Horizontal bar plot.

`DataFrame.plot` Make plots of a DataFrame.

`matplotlib.pyplot.bar` Make a bar plot with matplotlib.

**Examples**

Basic plot.

```
>>> df = pd.DataFrame({'lab':['A', 'B', 'C'], 'val':[10, 30, 20]})
>>> ax = df.plot.bar(x='lab', y='val', rot=0)
```

Plot a whole dataframe to a bar plot. Each column is assigned a distinct color, and each row is nested in a group along the horizontal axis.

```
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
...         'rabbit', 'giraffe', 'coyote', 'horse']
```

(continues on next page)

(continued from previous page)

```
>>> df = pd.DataFrame({'speed': speed,  
...                   'lifespan': lifespan}, index=index)  
>>> ax = df.plot.bar(rot=0)
```

Instead of nesting, the figure can be split by column with `subplots=True`. In this case, a `numpy.ndarray` of `matplotlib.axes.Axes` are returned.

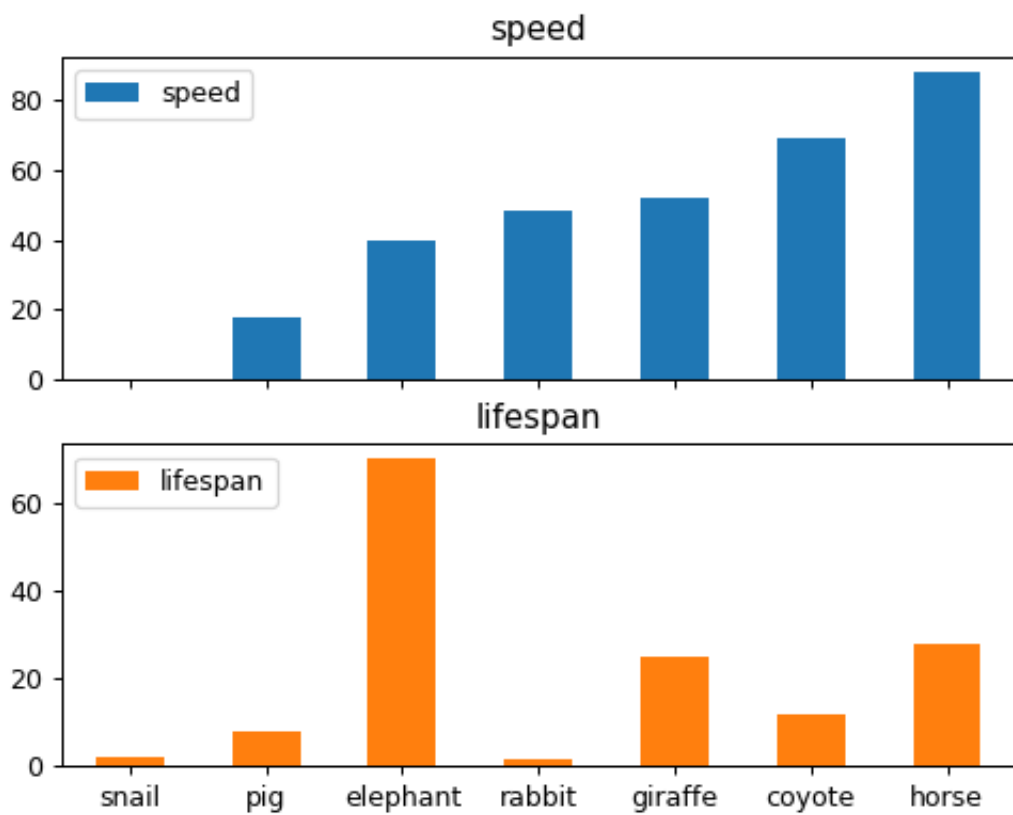

```
>>> axes = df.plot.bar(rot=0, subplots=True)  
>>> axes[1].legend(loc=2)
```

Plot a single column.

```
>>> ax = df.plot.bar(y='speed', rot=0)
```

Plot only selected categories for the DataFrame.

```
>>> ax = df.plot.bar(x='lifespan', rot=0)
```

## pandas.Series.plot.barh

`Series.plot.barh` (*self*, *x=None*, *y=None*, *\*\*kwargs*)

Make a horizontal bar plot.

A horizontal bar plot is a plot that presents quantitative data with rectangular bars with lengths proportional to the values that they represent. A bar plot shows comparisons among discrete categories. One axis of the plot shows the specific categories being compared, and the other axis represents a measured value.

### Parameters

**x** [label or position, default `DataFrame.index`] Column to be used for categories.

**y** [label or position, default All numeric columns in dataframe] Columns to be plotted from the DataFrame.

**\*\*kwargs** Keyword arguments to pass on to `DataFrame.plot()`.

### Returns

`matplotlib.axes.Axes` or `numpy.ndarray` of them

See also:

`DataFrame.plot.bar` Vertical bar plot.

`DataFrame.plot` Make plots of DataFrame using matplotlib.

`matplotlib.axes.Axes.bar` Plot a vertical bar plot using matplotlib.

## Examples

Basic example

```
>>> df = pd.DataFrame({'lab': ['A', 'B', 'C'], 'val': [10, 30, 20]})
>>> ax = df.plot.barh(x='lab', y='val')
```

Plot a whole DataFrame to a horizontal bar plot

```
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
...         'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...                   'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh()
```

Plot a column of the DataFrame to a horizontal bar plot

```
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
...         'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...                   'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh(y='speed')
```

Plot DataFrame versus the desired column

```
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
```

(continues on next page)

(continued from previous page)

```

...     'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...                     'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh(x='lifespan')

```

### pandas.Series.plot.box

`Series.plot.box` (*self*, *by=None*, *\*\*kwargs*)

Make a box plot of the DataFrame columns.

A box plot is a method for graphically depicting groups of numerical data through their quartiles. The box extends from the Q1 to Q3 quartile values of the data, with a line at the median (Q2). The whiskers extend from the edges of box to show the range of the data. The position of the whiskers is set by default to  $1.5 \times \text{IQR}$  ( $\text{IQR} = \text{Q3} - \text{Q1}$ ) from the edges of the box. Outlier points are those past the end of the whiskers.

For further details see Wikipedia's entry for [boxplot](#).

A consideration when using this chart is that the box and the whiskers can overlap, which is very common when plotting small sets of data.

#### Parameters

**by** [str or sequence] Column in the DataFrame to group by.

**\*\*kwargs** Additional keywords are documented in `DataFrame.plot()`.

### Returns

`matplotlib.axes.Axes` or `numpy.ndarray` of them

See also:

**`DataFrame.boxplot`** Another method to draw a box plot.

**`Series.plot.box`** Draw a box plot from a Series object.

**`matplotlib.pyplot.boxplot`** Draw a box plot in matplotlib.

### Examples

Draw a box plot from a DataFrame with four columns of randomly generated data.

```
>>> data = np.random.randn(25, 4)
>>> df = pd.DataFrame(data, columns=list('ABCD'))
>>> ax = df.plot.box()
```

## pandas.Series.plot.density

`Series.plot.density` (*self*, *bw\_method=None*, *ind=None*, *\*\*kwargs*)  
 Generate Kernel Density Estimate plot using Gaussian kernels.

In statistics, [kernel density estimation](#) (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

### Parameters

**bw\_method** [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be 'scott', 'silverman', a scalar constant or a callable. If None (default), 'scott' is used. See `scipy.stats.gaussian_kde` for more information.

**ind** [NumPy array or int, optional] Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If *ind* is a NumPy array, the KDE is evaluated at the points passed. If *ind* is an integer, *ind* number of equally spaced points are used.

**\*\*kwargs** Additional keyword arguments are documented in `pandas.% (this-datatype) s.plot ()`.

### Returns

`matplotlib.axes.Axes` or `numpy.ndarray` of them

See also:

`scipy.stats.gaussian_kde` Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.

### Examples

Given a Series of points randomly sampled from an unknown distribution, estimate its PDF using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```
>>> s = pd.Series([1, 2, 2.5, 3, 3.5, 4, 5])
>>> ax = s.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```
>>> ax = s.plot.kde(bw_method=0.3)
```

```
>>> ax = s.plot.kde(bw_method=3)
```

Finally, the *ind* parameter determines the evaluation points for the plot of the estimated PDF:

```
>>> ax = s.plot.kde(ind=[1, 2, 3, 4, 5])
```

For DataFrame, it works in the same way:

```
>>> df = pd.DataFrame({
...     'x': [1, 2, 2.5, 3, 3.5, 4, 5],
...     'y': [4, 4, 4.5, 5, 5.5, 6, 6],
... })
>>> ax = df.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```
>>> ax = df.plot.kde(bw_method=0.3)
```

```
>>> ax = df.plot.kde(bw_method=3)
```

Finally, the *ind* parameter determines the evaluation points for the plot of the estimated PDF:

```
>>> ax = df.plot.kde(ind=[1, 2, 3, 4, 5, 6])
```

### pandas.Series.plot.hist

`Series.plot.hist` (*self*, *by=None*, *bins=10*, *\*\*kwargs*)

Draw one histogram of the DataFrame's columns.

A histogram is a representation of the distribution of data. This function groups the values of all given Series in the DataFrame into bins and draws all bins in one `matplotlib.axes.Axes`. This is useful when the DataFrame's Series are in a similar scale.

#### Parameters

**by** [str or sequence, optional] Column in the DataFrame to group by.

**bins** [int, default 10] Number of histogram bins to be used.

**\*\*kwargs** Additional keyword arguments are documented in `DataFrame.plot()`.

### Returns

**class:matplotlib.AxesSubplot** Return a histogram plot.

See also:

**DataFrame.hist** Draw histograms per DataFrame's Series.

**Series.hist** Draw a histogram with Series' data.

### Examples

When we draw a dice 6000 times, we expect to get each value around 1000 times. But when we draw two dices and sum the result, the distribution is going to be quite different. A histogram illustrates those distributions.

```
>>> df = pd.DataFrame(  
...     np.random.randint(1, 7, 6000),  
...     columns = ['one'])  
>>> df['two'] = df['one'] + np.random.randint(1, 7, 6000)  
>>> ax = df.plot.hist(bins=12, alpha=0.5)
```

## pandas.Series.plot.kde

`Series.plot.kde` (*self*, *bw\_method=None*, *ind=None*, *\*\*kwargs*)

Generate Kernel Density Estimate plot using Gaussian kernels.

In statistics, [kernel density estimation](#) (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

### Parameters

**bw\_method** [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be 'scott', 'silverman', a scalar constant or a callable. If None (default), 'scott' is used. See `scipy.stats.gaussian_kde` for more information.

**ind** [NumPy array or int, optional] Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If *ind* is a NumPy array, the KDE is evaluated at the points passed. If *ind* is an integer, *ind* number of equally spaced points are used.

**\*\*kwargs** Additional keyword arguments are documented in `pandas.% (this-datatype) s.plot()`.

### Returns

`matplotlib.axes.Axes` or `numpy.ndarray` of them

See also:

`scipy.stats.gaussian_kde` Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.

## Examples

Given a Series of points randomly sampled from an unknown distribution, estimate its PDF using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```
>>> s = pd.Series([1, 2, 2.5, 3, 3.5, 4, 5])
>>> ax = s.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```
>>> ax = s.plot.kde(bw_method=0.3)
```

```
>>> ax = s.plot.kde(bw_method=3)
```

Finally, the *ind* parameter determines the evaluation points for the plot of the estimated PDF:

```
>>> ax = s.plot.kde(ind=[1, 2, 3, 4, 5])
```

For DataFrame, it works in the same way:

```
>>> df = pd.DataFrame({
...     'x': [1, 2, 2.5, 3, 3.5, 4, 5],
...     'y': [4, 4, 4.5, 5, 5.5, 6, 6],
... })
>>> ax = df.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```
>>> ax = df.plot.kde(bw_method=0.3)
```

```
>>> ax = df.plot.kde(bw_method=3)
```

Finally, the *ind* parameter determines the evaluation points for the plot of the estimated PDF:

```
>>> ax = df.plot.kde(ind=[1, 2, 3, 4, 5, 6])
```

### pandas.Series.plot.line

`Series.plot.line` (*self*, *x=None*, *y=None*, *\*\*kwargs*)

Plot Series or DataFrame as lines.

This function is useful to plot lines using DataFrame's values as coordinates.

#### Parameters

- x** [int or str, optional] Columns to use for the horizontal axis. Either the location or the label of the columns to be used. By default, it will use the DataFrame indices.
- y** [int, str, or list of them, optional] The values to be plotted. Either the location or the label of the columns to be used. By default, it will use the remaining DataFrame numeric columns.

**\*\*kwargs** Keyword arguments to pass on to `DataFrame.plot()`.

**Returns**

`matplotlib.axes.Axes` or `numpy.ndarray` Return an ndarray when `subplots=True`.

**See also:**

`matplotlib.pyplot.plot` Plot y versus x as lines and/or markers.

**Examples**

```
>>> s = pd.Series([1, 3, 2])
>>> s.plot.line()
```

The following example shows the populations for some animals over the years.

```
>>> df = pd.DataFrame({
...     'pig': [20, 18, 489, 675, 1776],
...     'horse': [4, 25, 281, 600, 1900]
... }, index=[1990, 1997, 2003, 2009, 2014])
>>> lines = df.plot.line()
```

An example with subplots, so an array of axes is returned.

```
>>> axes = df.plot.line(subplots=True)
>>> type(axes)
<class 'numpy.ndarray'>
```

The following example shows the relationship between both populations.

```
>>> lines = df.plot.line(x='pig', y='horse')
```

## pandas.Series.plot.pie

`Series.plot.pie` (*self*, *\*\*kwargs*)

Generate a pie plot.

A pie plot is a proportional representation of the numerical data in a column. This function wraps `matplotlib.pyplot.pie()` for the specified column. If no column reference is passed and `subplots=True` a pie plot is drawn for each numerical column independently.

### Parameters

**y** [int or label, optional] Label or position of the column to plot. If not provided, `subplots=True` argument must be passed.

**\*\*kwargs** Keyword arguments to pass on to `DataFrame.plot()`.

### Returns

**matplotlib.axes.Axes or np.ndarray of them** A NumPy array is returned when *subplots* is True.

See also:

**Series.plot.pie** Generate a pie plot for a Series.

**DataFrame.plot** Make plots of a DataFrame.

## Examples

In the example below we have a DataFrame with the information about planet's mass and radius. We pass the 'mass' column to the pie function to get a pie plot.

```
>>> df = pd.DataFrame({'mass': [0.330, 4.87, 5.97],
...                    'radius': [2439.7, 6051.8, 6378.1]},
...                    index=['Mercury', 'Venus', 'Earth'])
>>> plot = df.plot.pie(y='mass', figsize=(5, 5))
```

```
>>> plot = df.plot.pie(subplots=True, figsize=(6, 3))
```

*Series.hist*(self[, by, ax, grid, ...])

Draw histogram of the input series using matplotlib.

### 4.3.15 Serialization / IO / conversion

<code>Series.to_pickle(self, path, compression, ...)</code>	Pickle (serialize) object to file.
<code>Series.to_csv(self, path_or_buf, ...)</code>	Write object to a comma-separated values (csv) file.
<code>Series.to_dict(self[, into])</code>	Convert Series to {label -> value} dict or dict-like object.
<code>Series.to_excel(self, excel_writer[, ...])</code>	Write object to an Excel sheet.
<code>Series.to_frame(self[, name])</code>	Convert Series to DataFrame.
<code>Series.to_xarray(self)</code>	Return an xarray object from the pandas object.
<code>Series.to_hdf(self, path_or_buf, key, mode, ...)</code>	Write the contained data to an HDF5 file using HDFStore.
<code>Series.to_sql(self, name, con[, schema, ...])</code>	Write records stored in a DataFrame to a SQL database.
<code>Series.to_json(self, path_or_buf, ...)</code>	Convert the object to a JSON string.
<code>Series.to_string(self[, buf, na_rep, ...])</code>	Render a string representation of the Series.
<code>Series.to_clipboard(self, excel, sep, ...)</code>	Copy object to the system clipboard.
<code>Series.to_latex(self[, buf, columns, ...])</code>	Render object to a LaTeX tabular, longtable, or nested table/tabular.
<code>Series.to_markdown(self, buf, ...)</code>	Print Series in Markdown-friendly format.

{{ header }}

## 4.4 DataFrame

### 4.4.1 Constructor

`DataFrame([data, index, columns, dtype, copy])` Two-dimensional, size-mutable, potentially heterogeneous tabular data.

#### pandas.DataFrame

**class** pandas.DataFrame (data=None, index: Optional[Collection] = None, columns: Optional[Collection] = None, dtype: Union[str, numpy.dtype, ExtensionDtype, None] = None, copy: bool = False)

Two-dimensional, size-mutable, potentially heterogeneous tabular data.

Data structure also contains labeled axes (rows and columns). Arithmetic operations align on both row and column labels. This means that if two DataFrames are added, they will be aligned on their row and column labels. The result will then have the union of the two sets of labels. For example, if one of the DataFrames has a row labeled 'a' and the other has a row labeled 'b', the result will have rows labeled 'a' and 'b'. For more information on this, see the section on [Data Alignment](#).

**columns** [Index or array-like] Column labels to use for resulting frame. Will default to RangeIndex (0, 1, 2, ..., n) if no column labels are provided.

**dtype** [dtype, default None] Data type to force. Only a single dtype is allowed. If None, infer.

**copy** [bool, default False] Copy data from inputs. Only affects DataFrame / 2d ndarray input.

See also:

**DataFrame.from\_records** Constructor from tuples, also record arrays.

**DataFrame.from\_dict** From dicts of Series, arrays, or dicts.

**read\_csv**

**read\_table**

**read\_clipboard**

## Examples

Constructing DataFrame from a dictionary.

```
>>> d = {'col1': [1, 2], 'col2': [3, 4]}
>>> df = pd.DataFrame(data=d)
>>> df
   col1  col2
0     1     3
1     2     4
```

Notice that the inferred dtype is int64.

```
>>> df.dtypes
col1    int64
col2    int64
dtype: object
```

To enforce a single dtype:

```
>>> df = pd.DataFrame(data=d, dtype=np.int8)
>>> df.dtypes
col1    int8
col2    int8
dtype: object
```

Constructing DataFrame from numpy ndarray:

```
>>> df2 = pd.DataFrame(np.array([[1, 2, 3], [4, 5, 6], [7, 8, 9]]),
...                    columns=['a', 'b', 'c'])
>>> df2
   a  b  c
0  1  2  3
1  4  5  6
2  7  8  9
```

## Attributes

<i>T</i>	Transpose index and columns.
<i>at</i>	Access a single value for a row/column label pair.
<i>attrs</i>	Dictionary of global attributes on this object.
<i>axes</i>	Return a list representing the axes of the DataFrame.
<i>columns</i>	The column labels of the DataFrame.
<i>dtypes</i>	Return the dtypes in the DataFrame.
<i>empty</i>	Indicator whether DataFrame is empty.
<i>iat</i>	Access a single value for a row/column pair by integer position.
<i>iloc</i>	Purely integer-location based indexing for selection by position.
<i>index</i>	The index (row labels) of the DataFrame.
<i>loc</i>	Access a group of rows and columns by label(s) or a boolean array.
<i>ndim</i>	Return an int representing the number of axes / array dimensions.
<i>shape</i>	Return a tuple representing the dimensionality of the DataFrame.
<i>size</i>	Return an int representing the number of elements in this object.
<i>style</i>	Returns a Styler object.
<i>values</i>	Return a Numpy representation of the DataFrame.

## pandas.DataFrame.T

**property** `DataFrame.T`

Transpose index and columns.

Reflect the DataFrame over its main diagonal by writing rows as columns and vice-versa. The property `T` is an accessor to the method `transpose()`.

### Parameters

**\*args** [tuple, optional] Accepted for compatibility with NumPy.

**copy** [bool, default False] Whether to copy the data after transposing, even for DataFrames with a single dtype.

Note that a copy is always required for mixed dtype DataFrames, or for DataFrames with any extension types.

### Returns

**DataFrame** The transposed DataFrame.

**See also:**

[`numpy.transpose`](#) Permute the dimensions of a given array.

## Notes

Transposing a DataFrame with mixed dtypes will result in a homogeneous DataFrame with the *object* dtype. In such a case, a copy of the data is always made.

## Examples

### Square DataFrame with homogeneous dtype

```
>>> d1 = {'col1': [1, 2], 'col2': [3, 4]}
>>> df1 = pd.DataFrame(data=d1)
>>> df1
   col1  col2
0     1     3
1     2     4
```

```
>>> df1_transposed = df1.T # or df1.transpose()
>>> df1_transposed
      0  1
col1  1  2
col2  3  4
```

When the dtype is homogeneous in the original DataFrame, we get a transposed DataFrame with the same dtype:

```
>>> df1.dtypes
col1    int64
col2    int64
dtype: object
>>> df1_transposed.dtypes
0    int64
1    int64
dtype: object
```

### Non-square DataFrame with mixed dtypes

```
>>> d2 = {'name': ['Alice', 'Bob'],
...       'score': [9.5, 8],
...       'employed': [False, True],
...       'kids': [0, 0]}
>>> df2 = pd.DataFrame(data=d2)
>>> df2
   name  score  employed  kids
0  Alice   9.5     False     0
1   Bob    8.0      True     0
```

```
>>> df2_transposed = df2.T # or df2.transpose()
>>> df2_transposed
      0  1
name   Alice  Bob
score   9.5    8
employed False  True
kids     0    0
```

When the DataFrame has mixed dtypes, we get a transposed DataFrame with the *object* dtype:

```

>>> df2.dtypes
name          object
score         float64
employed      bool
kids          int64
dtype: object
>>> df2_transposed.dtypes
0          object
1          object
dtype: object

```

## pandas.DataFrame.at

### property DataFrame.at

Access a single value for a row/column label pair.

Similar to `loc`, in that both provide label-based lookups. Use `at` if you only need to get or set a single value in a DataFrame or Series.

#### Raises

**KeyError** If 'label' does not exist in DataFrame.

See also:

**DataFrame.iat** Access a single value for a row/column pair by integer position.

**DataFrame.loc** Access a group of rows and columns by label(s).

**Series.at** Access a single value using a label.

## Examples

```

>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
...                    index=[4, 5, 6], columns=['A', 'B', 'C'])
>>> df
   A  B  C
4  0  2  3
5  0  4  1
6 10 20 30

```

Get value at specified row/column pair

```

>>> df.at[4, 'B']
2

```

Set value at specified row/column pair

```

>>> df.at[4, 'B'] = 10
>>> df.at[4, 'B']
10

```

Get value within a Series

```

>>> df.loc[5].at['B']
4

```

## pandas.DataFrame.attrs

**property** DataFrame.attrs

Dictionary of global attributes on this object.

**Warning:** attrs is experimental and may change without warning.

## pandas.DataFrame.axes

**property** DataFrame.axes

Return a list representing the axes of the DataFrame.

It has the row axis labels and column axis labels as the only members. They are returned in that order.

### Examples

```
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.axes
[RangeIndex(start=0, stop=2, step=1), Index(['col1', 'col2'],
dtype='object')]
```

## pandas.DataFrame.columns

DataFrame.columns

The column labels of the DataFrame.

## pandas.DataFrame.dtypes

**property** DataFrame.dtypes

Return the dtypes in the DataFrame.

This returns a Series with the data type of each column. The result's index is the original DataFrame's columns. Columns with mixed types are stored with the object dtype. See *the User Guide* for more.

### Returns

**pandas.Series** The data type of each column.

### Examples

```
>>> df = pd.DataFrame({'float': [1.0],
...                   'int': [1],
...                   'datetime': [pd.Timestamp('20180310')],
...                   'string': ['foo']})
>>> df.dtypes
float          float64
int            int64
datetime      datetime64[ns]
string        object
dtype: object
```

## pandas.DataFrame.empty

**property** `DataFrame.empty`

Indicator whether DataFrame is empty.

True if DataFrame is entirely empty (no items), meaning any of the axes are of length 0.

### Returns

**bool** If DataFrame is empty, return True, if not return False.

**See also:**

***Series.dropna***

***DataFrame.dropna***

### Notes

If DataFrame contains only NaNs, it is still not considered empty. See the example below.

### Examples

An example of an actual empty DataFrame. Notice the index is empty:

```

>>> df_empty = pd.DataFrame({'A' : []})
>>> df_empty
Empty DataFrame
Columns: [A]
Index: []
>>> df_empty.empty
True

```

If we only have NaNs in our DataFrame, it is not considered empty! We will need to drop the NaNs to make the DataFrame empty:

```

>>> df = pd.DataFrame({'A' : [np.nan]})
>>> df
   A
0 NaN
>>> df.empty
False
>>> df.dropna().empty
True

```

## pandas.DataFrame.iat

**property** `DataFrame.iat`

Access a single value for a row/column pair by integer position.

Similar to `iloc`, in that both provide integer-based lookups. Use `iat` if you only need to get or set a single value in a DataFrame or Series.

### Raises

**IndexError** When integer position is out of bounds.

See also:

**DataFrame.at** Access a single value for a row/column label pair.

**DataFrame.loc** Access a group of rows and columns by label(s).

**DataFrame.iloc** Access a group of rows and columns by integer position(s).

## Examples

```
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
...                    columns=['A', 'B', 'C'])
>>> df
   A  B  C
0  0  2  3
1  0  4  1
2 10 20 30
```

Get value at specified row/column pair

```
>>> df.iat[1, 2]
1
```

Set value at specified row/column pair

```
>>> df.iat[1, 2] = 10
>>> df.iat[1, 2]
10
```

Get value within a series

```
>>> df.loc[0].iat[1]
2
```

## pandas.DataFrame.iloc

**property** DataFrame.ilo**c**

Purely integer-location based indexing for selection by position.

.iloc[] is primarily integer position based (from 0 to length-1 of the axis), but may also be used with a boolean array.

Allowed inputs are:

- An integer, e.g. 5.
- A list or array of integers, e.g. [4, 3, 0].
- A slice object with ints, e.g. 1:7.
- A boolean array.
- A callable function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above). This is useful in method chains, when you don't have a reference to the calling object, but would like to base your selection on some value.

`.iloc` will raise `IndexError` if a requested indexer is out-of-bounds, except *slice* indexers which allow out-of-bounds indexing (this conforms with python/numpy *slice* semantics).

See more at *Selection by Position*.

**See also:**

**`DataFrame.iat`** Fast integer location scalar accessor.

**`DataFrame.loc`** Purely label-location based indexer for selection by label.

**`Series.iloc`** Purely integer-location based indexing for selection by position.

## Examples

```
>>> mydict = [{'a': 1, 'b': 2, 'c': 3, 'd': 4},
...           {'a': 100, 'b': 200, 'c': 300, 'd': 400},
...           {'a': 1000, 'b': 2000, 'c': 3000, 'd': 4000 }]
>>> df = pd.DataFrame(mydict)
>>> df
   a     b     c     d
0   1     2     3     4
1  100   200   300   400
2 1000  2000  3000  4000
```

### Indexing just the rows

With a scalar integer.

```
>>> type(df.iloc[0])
<class 'pandas.core.series.Series'>
>>> df.iloc[0]
a     1
b     2
c     3
d     4
Name: 0, dtype: int64
```

With a list of integers.

```
>>> df.iloc[[0]]
   a  b  c  d
0  1  2  3  4
>>> type(df.iloc[[0]])
<class 'pandas.core.frame.DataFrame'>
```

```
>>> df.iloc[[0, 1]]
   a     b     c     d
0   1     2     3     4
1  100   200   300   400
```

With a *slice* object.

```
>>> df.iloc[:3]
   a     b     c     d
0   1     2     3     4
1  100   200   300   400
2 1000  2000  3000  4000
```

With a boolean mask the same length as the index.

```
>>> df.iloc[[True, False, True]]
   a    b    c    d
0   1    2    3    4
2 1000 2000 3000 4000
```

With a callable, useful in method chains. The *x* passed to the `lambda` is the `DataFrame` being sliced. This selects the rows whose index label even.

```
>>> df.iloc[lambda x: x.index % 2 == 0]
   a    b    c    d
0   1    2    3    4
2 1000 2000 3000 4000
```

### Indexing both axes

You can mix the indexer types for the index and columns. Use `:` to select the entire axis.

With scalar integers.

```
>>> df.iloc[0, 1]
2
```

With lists of integers.

```
>>> df.iloc[[0, 2], [1, 3]]
   b    d
0   2    4
2 2000 4000
```

With *slice* objects.

```
>>> df.iloc[1:3, 0:3]
   a    b    c
1  100  200  300
2 1000 2000 3000
```

With a boolean array whose length matches the columns.

```
>>> df.iloc[:, [True, False, True, False]]
   a    c
0   1    3
1  100  300
2 1000 3000
```

With a callable function that expects the `Series` or `DataFrame`.

```
>>> df.iloc[:, lambda df: [0, 2]]
   a    c
0   1    3
1  100  300
2 1000 3000
```

## pandas.DataFrame.index

### DataFrame.index

The index (row labels) of the DataFrame.

## pandas.DataFrame.loc

### property DataFrame.loc

Access a group of rows and columns by label(s) or a boolean array.

.loc[] is primarily label based, but may also be used with a boolean array.

Allowed inputs are:

- A single label, e.g. 5 or 'a', (note that 5 is interpreted as a *label* of the index, and **never** as an integer position along the index).
- A list or array of labels, e.g. ['a', 'b', 'c'].
- A slice object with labels, e.g. 'a':'f'.

**Warning:** Note that contrary to usual python slices, **both** the start and the stop are included

- A boolean array of the same length as the axis being sliced, e.g. [True, False, True].
- A callable function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above)

See more at *Selection by Label*

### Raises

**KeyError** If any items are not found.

See also:

**DataFrame.at** Access a single value for a row/column label pair.

**DataFrame.iloc** Access group of rows and columns by integer position(s).

**DataFrame.xs** Returns a cross-section (row(s) or column(s)) from the Series/DataFrame.

**Series.loc** Access group of values using labels.

## Examples

### Getting values

```

>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
...                    index=['cobra', 'viper', 'sidewinder'],
...                    columns=['max_speed', 'shield'])
>>> df

```

	max_speed	shield
cobra	1	2
viper	4	5
sidewinder	7	8

Single label. Note this returns the row as a Series.

```
>>> df.loc['viper']
max_speed    4
shield       5
Name: viper, dtype: int64
```

List of labels. Note using `[[]]` returns a DataFrame.

```
>>> df.loc[['viper', 'sidewinder']]
      max_speed  shield
viper          4      5
sidewinder     7      8
```

Single label for row and column

```
>>> df.loc['cobra', 'shield']
2
```

Slice with labels for row and single label for column. As mentioned above, note that both the start and stop of the slice are included.

```
>>> df.loc['cobra':'viper', 'max_speed']
cobra    1
viper    4
Name: max_speed, dtype: int64
```

Boolean list with the same length as the row axis

```
>>> df.loc[[False, False, True]]
      max_speed  shield
sidewinder     7      8
```

Conditional that returns a boolean Series

```
>>> df.loc[df['shield'] > 6]
      max_speed  shield
sidewinder     7      8
```

Conditional that returns a boolean Series with column labels specified

```
>>> df.loc[df['shield'] > 6, ['max_speed']]
      max_speed
sidewinder     7
```

Callable that returns a boolean Series

```
>>> df.loc[lambda df: df['shield'] == 8]
      max_speed  shield
sidewinder     7      8
```

## Setting values

Set value for all items matching the list of labels

```
>>> df.loc[['viper', 'sidewinder'], ['shield']] = 50
>>> df
      max_speed  shield
cobra          1      2
```

(continues on next page)

(continued from previous page)

viper	4	50
sidewinder	7	50

Set value for an entire row

```
>>> df.loc['cobra'] = 10
>>> df
      max_speed  shield
cobra          10     10
viper           4     50
sidewinder      7     50
```

Set value for an entire column

```
>>> df.loc[:, 'max_speed'] = 30
>>> df
      max_speed  shield
cobra          30     10
viper           30     50
sidewinder      30     50
```

Set value for rows matching callable condition

```
>>> df.loc[df['shield'] > 35] = 0
>>> df
      max_speed  shield
cobra          30     10
viper           0      0
sidewinder      0      0
```

### Getting values on a DataFrame with an index that has integer labels

Another example using integers for the index

```
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
...                    index=[7, 8, 9], columns=['max_speed', 'shield'])
>>> df
      max_speed  shield
7             1       2
8             4       5
9             7       8
```

Slice with integer labels for rows. As mentioned above, note that both the start and stop of the slice are included.

```
>>> df.loc[7:9]
      max_speed  shield
7             1       2
8             4       5
9             7       8
```

### Getting values with a MultiIndex

A number of examples using a DataFrame with a MultiIndex

```
>>> tuples = [
...     ('cobra', 'mark i'), ('cobra', 'mark ii'),
```

(continues on next page)

(continued from previous page)

```

...     ('sidewinder', 'mark i'), ('sidewinder', 'mark ii'),
...     ('viper', 'mark ii'), ('viper', 'mark iii')
... ]
>>> index = pd.MultiIndex.from_tuples(tuples)
>>> values = [[12, 2], [0, 4], [10, 20],
...           [1, 4], [7, 1], [16, 36]]
>>> df = pd.DataFrame(values, columns=['max_speed', 'shield'], index=index)
>>> df

```

		max_speed	shield
cobra	mark i	12	2
	mark ii	0	4
sidewinder	mark i	10	20
	mark ii	1	4
viper	mark ii	7	1
	mark iii	16	36

Single label. Note this returns a DataFrame with a single index.

```

>>> df.loc['cobra']

```

	max_speed	shield
mark i	12	2
mark ii	0	4

Single index tuple. Note this returns a Series.

```

>>> df.loc[('cobra', 'mark ii')]
max_speed    0
shield       4
Name: (cobra, mark ii), dtype: int64

```

Single label for row and column. Similar to passing in a tuple, this returns a Series.

```

>>> df.loc['cobra', 'mark i']
max_speed    12
shield       2
Name: (cobra, mark i), dtype: int64

```

Single tuple. Note using `[[]]` returns a DataFrame.

```

>>> df.loc[['cobra', 'mark ii']]

```

		max_speed	shield
cobra	mark ii	0	4

Single tuple for the index with a single label for the column

```

>>> df.loc[('cobra', 'mark i'), 'shield']
2

```

Slice from index tuple to single label

```

>>> df.loc[('cobra', 'mark i'):'viper']

```

		max_speed	shield
cobra	mark i	12	2
	mark ii	0	4
sidewinder	mark i	10	20
	mark ii	1	4

(continues on next page)

(continued from previous page)

viper	mark ii	7	1
	mark iii	16	36

Slice from index tuple to index tuple

```
>>> df.loc[('cobra', 'mark i'):(('viper', 'mark ii'))]
              max_speed  shield
cobra      mark i         12     2
           mark ii         0     4
sidewinder mark i         10    20
           mark ii         1     4
viper      mark ii         7     1
```

### pandas.DataFrame.ndim

**property** DataFrame.**ndim**

Return an int representing the number of axes / array dimensions.

Return 1 if Series. Otherwise return 2 if DataFrame.

**See also:**

**ndarray.ndim** Number of array dimensions.

### Examples

```
>>> s = pd.Series({'a': 1, 'b': 2, 'c': 3})
>>> s.ndim
1
```

```
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.ndim
2
```

### pandas.DataFrame.shape

**property** DataFrame.**shape**

Return a tuple representing the dimensionality of the DataFrame.

**See also:**

**ndarray.shape**

## Examples

```
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.shape
(2, 2)
```

```
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4],
...                   'col3': [5, 6]})
>>> df.shape
(2, 3)
```

## pandas.DataFrame.size

**property** DataFrame.**size**

Return an int representing the number of elements in this object.

Return the number of rows if Series. Otherwise return the number of rows times number of columns if DataFrame.

**See also:**

**ndarray.size** Number of elements in the array.

## Examples

```
>>> s = pd.Series({'a': 1, 'b': 2, 'c': 3})
>>> s.size
3
```

```
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.size
4
```

## pandas.DataFrame.style

**property** DataFrame.**style**

Returns a Styler object.

Contains methods for building a styled HTML representation of the DataFrame. a styled HTML representation fo the DataFrame.

**See also:**

*io.formats.style.Styler*

## pandas.DataFrame.values

**property** DataFrame.values

Return a Numpy representation of the DataFrame.

**Warning:** We recommend using `DataFrame.to_numpy()` instead.

Only the values in the DataFrame will be returned, the axes labels will be removed.

### Returns

**numpy.ndarray** The values of the DataFrame.

**See also:**

**DataFrame.to\_numpy** Recommended alternative to this method.

**DataFrame.index** Retrieve the index labels.

**DataFrame.columns** Retrieving the column names.

### Notes

The dtype will be a lower-common-denominator dtype (implicit upcasting); that is to say if the dtypes (even of numeric types) are mixed, the one that accommodates all will be chosen. Use this with care if you are not dealing with the blocks.

e.g. If the dtypes are float16 and float32, dtype will be upcast to float32. If dtypes are int32 and uint8, dtype will be upcast to int32. By `numpy.find_common_type()` convention, mixing int64 and uint64 will result in a float64 dtype.

### Examples

A DataFrame where all columns are the same type (e.g., int64) results in an array of the same type.

```
>>> df = pd.DataFrame({'age': [ 3, 29],
...                    'height': [94, 170],
...                    'weight': [31, 115]})
>>> df
   age  height  weight
0    3     94     31
1   29    170    115
>>> df.dtypes
age          int64
height       int64
weight       int64
dtype: object
>>> df.values
array([[ 3, 94, 31],
       [29, 170, 115]], dtype=int64)
```

A DataFrame with mixed type columns(e.g., str/object, int64, float32) results in an ndarray of the broadest type that accommodates these mixed types (e.g., object).

```

>>> df2 = pd.DataFrame([('parrot', 24.0, 'second'),
...                     ('lion', 80.5, 1),
...                     ('monkey', np.nan, None)],
...                     columns=('name', 'max_speed', 'rank'))
>>> df2.dtypes
name          object
max_speed     float64
rank          object
dtype: object
>>> df2.values
array([[ 'parrot', 24.0, 'second'],
       [ 'lion', 80.5, 1],
       [ 'monkey', nan, None]], dtype=object)

```

## Methods

<code>abs(self)</code>	Return a Series/DataFrame with absolute numeric value of each element.
<code>add(self, other[, axis, level, fill_value])</code>	Get Addition of dataframe and other, element-wise (binary operator <i>add</i> ).
<code>add_prefix(self, prefix)</code>	Prefix labels with string <i>prefix</i> .
<code>add_suffix(self, suffix)</code>	Suffix labels with string <i>suffix</i> .
<code>agg(self, func[, axis])</code>	Aggregate using one or more operations over the specified axis.
<code>aggregate(self, func[, axis])</code>	Aggregate using one or more operations over the specified axis.
<code>align(self, other[, join, axis, level, ...])</code>	Align two objects on their axes with the specified join method.
<code>all(self[, axis, bool_only, skipna, level])</code>	Return whether all elements are True, potentially over an axis.
<code>any(self[, axis, bool_only, skipna, level])</code>	Return whether any element is True, potentially over an axis.
<code>append(self, other[, ignore_index, ...])</code>	Append rows of <i>other</i> to the end of caller, returning a new object.
<code>apply(self, func[, axis, raw, result_type, args])</code>	Apply a function along an axis of the DataFrame.
<code>applymap(self, func)</code>	Apply a function to a Dataframe elementwise.
<code>asfreq(self, freq[, method, fill_value])</code>	Convert TimeSeries to specified frequency.
<code>asof(self, where[, subset])</code>	Return the last row(s) without any NaNs before <i>where</i> .
<code>assign(self, <i>kwargs</i>)</code>	Assign new columns to a DataFrame.
<code>astype(self, dtype, copy, errors)</code>	Cast a pandas object to a specified dtype <i>dtype</i> .
<code>at_time(self, time, asof[, axis])</code>	Select values at particular time of day (e.g.
<code>between_time(self, start_time, end_time, ...)</code>	Select values between particular times of the day (e.g., 9:00-9:30 AM).
<code>bfill(self[, axis, limit, downcast])</code>	Synonym for <code>DataFrame.fillna()</code> with <code>method='bfill'</code> .
<code>bool(self)</code>	Return the bool of a single element PandasObject.
<code>boxplot(self[, column, by, ax, fontsize, ...])</code>	Make a box plot from DataFrame columns.
<code>clip(self[, lower, upper, axis])</code>	Trim values at input threshold(s).
<code>combine(self, other, func[, fill_value, ...])</code>	Perform column-wise combine with another DataFrame.

Continued on next page

Table 59 – continued from previous page

<code>combine_first(self, other)</code>	Update null elements with value in the same location in <i>other</i> .
<code>convert_dtypes(self, infer_objects, ...)</code>	Convert columns to best possible dtypes using dtypes supporting <code>pd.NA</code> .
<code>copy(self, deep)</code>	Make a copy of this object's indices and data.
<code>corr(self[, method, min_periods])</code>	Compute pairwise correlation of columns, excluding NA/null values.
<code>corrwith(self, other[, axis, drop, method])</code>	Compute pairwise correlation.
<code>count(self[, axis, level, numeric_only])</code>	Count non-NA cells for each column or row.
<code>cov(self[, min_periods])</code>	Compute pairwise covariance of columns, excluding NA/null values.
<code>cummax(self[, axis, skipna])</code>	Return cumulative maximum over a DataFrame or Series axis.
<code>cummin(self[, axis, skipna])</code>	Return cumulative minimum over a DataFrame or Series axis.
<code>cumprod(self[, axis, skipna])</code>	Return cumulative product over a DataFrame or Series axis.
<code>cumsum(self[, axis, skipna])</code>	Return cumulative sum over a DataFrame or Series axis.
<code>describe(self[, percentiles, include, exclude])</code>	Generate descriptive statistics.
<code>diff(self[, periods, axis])</code>	First discrete difference of element.
<code>div(self, other[, axis, level, fill_value])</code>	Get Floating division of dataframe and other, element-wise (binary operator <i>truediv</i> ).
<code>divide(self, other[, axis, level, fill_value])</code>	Get Floating division of dataframe and other, element-wise (binary operator <i>truediv</i> ).
<code>dot(self, other)</code>	Compute the matrix multiplication between the DataFrame and other.
<code>drop(self[, labels, axis, index, columns, ...])</code>	Drop specified labels from rows or columns.
<code>drop_duplicates(self, subset, ...)</code>	Return DataFrame with duplicate rows removed.
<code>droplevel(self, level[, axis])</code>	Return DataFrame with requested index / column level(s) removed.
<code>dropna(self[, axis, how, thresh, subset, ...])</code>	Remove missing values.
<code>duplicated(self, subset, Sequence[Hashable], ...)</code>	Return boolean Series denoting duplicate rows.
<code>eq(self, other[, axis, level])</code>	Get Equal to of dataframe and other, element-wise (binary operator <i>eq</i> ).
<code>equals(self, other)</code>	Test whether two objects contain the same elements.
<code>eval(self, expr[, inplace])</code>	Evaluate a string describing operations on DataFrame columns.
<code>ewm(self[, com, span, halflife, alpha, ...])</code>	Provide exponential weighted functions.
<code>expanding(self[, min_periods, center, axis])</code>	Provide expanding transformations.
<code>explode(self, column, Tuple)</code>	Transform each element of a list-like to a row, replicating index values.
<code>ffill(self[, axis, limit, downcast])</code>	Synonym for <code>DataFrame.fillna()</code> with <code>method='ffill'</code> .
<code>fillna(self[, value, method, axis, inplace, ...])</code>	Fill NA/NaN values using the specified method.
<code>filter(self[, items, axis])</code>	Subset the dataframe rows or columns according to the specified index labels.
<code>first(self, offset)</code>	Method to subset initial periods of time series data based on a date offset.
<code>first_valid_index(self)</code>	Return index for first non-NA/null value.

Continued on next page

Table 59 – continued from previous page

<code>floordiv(self, other[, axis, level, fill_value])</code>	Get Integer division of dataframe and other, element-wise (binary operator <i>floordiv</i> ).
<code>from_dict(data[, orient, dtype, columns])</code>	Construct DataFrame from dict of array-like or dicts.
<code>from_records(data[, index, exclude, ...])</code>	Convert structured or record ndarray to DataFrame.
<code>ge(self, other[, axis, level])</code>	Get Greater than or equal to of dataframe and other, element-wise (binary operator <i>ge</i> ).
<code>get(self, key[, default])</code>	Get item from object for given key (ex: DataFrame column).
<code>groupby(self[, by, axis, level])</code>	Group DataFrame using a mapper or by a Series of columns.
<code>gt(self, other[, axis, level])</code>	Get Greater than of dataframe and other, element-wise (binary operator <i>gt</i> ).
<code>head(self, n)</code>	Return the first <i>n</i> rows.
<code>hist(data[, column, by, grid, xlabelsize, ...])</code>	Make a histogram of the DataFrame's.
<code>idxmax(self[, axis, skipna])</code>	Return index of first occurrence of maximum over requested axis.
<code>idxmin(self[, axis, skipna])</code>	Return index of first occurrence of minimum over requested axis.
<code>infer_objects(self)</code>	Attempt to infer better dtypes for object columns.
<code>info(self[, verbose, buf, max_cols, ...])</code>	Print a concise summary of a DataFrame.
<code>insert(self, loc, column, value[, ...])</code>	Insert column into DataFrame at specified location.
<code>interpolate(self[, method, axis, limit, ...])</code>	Interpolate values according to different methods.
<code>isin(self, values)</code>	Whether each element in the DataFrame is contained in values.
<code>isna(self)</code>	Detect missing values.
<code>isnull(self)</code>	Detect missing values.
<code>items(self)</code>	Iterate over (column name, Series) pairs.
<code>iteritems(self)</code>	Iterate over (column name, Series) pairs.
<code>iterrows(self)</code>	Iterate over DataFrame rows as (index, Series) pairs.
<code>itertuples(self[, index, name])</code>	Iterate over DataFrame rows as namedtuples.
<code>join(self, other[, on, how, lsuffix, ...])</code>	Join columns of another DataFrame.
<code>keys(self)</code>	Get the 'info axis' (see Indexing for more).
<code>kurt(self[, axis, skipna, level, numeric_only])</code>	Return unbiased kurtosis over requested axis.
<code>kurtosis(self[, axis, skipna, level, ...])</code>	Return unbiased kurtosis over requested axis.
<code>last(self, offset)</code>	Method to subset final periods of time series data based on a date offset.
<code>last_valid_index(self)</code>	Return index for last non-NA/null value.
<code>le(self, other[, axis, level])</code>	Get Less than or equal to of dataframe and other, element-wise (binary operator <i>le</i> ).
<code>lookup(self, row_labels, col_labels)</code>	Label-based "fancy indexing" function for DataFrame.
<code>lt(self, other[, axis, level])</code>	Get Less than of dataframe and other, element-wise (binary operator <i>lt</i> ).
<code>mad(self[, axis, skipna, level])</code>	Return the mean absolute deviation of the values for the requested axis.
<code>mask(self, cond[, other, inplace, axis, ...])</code>	Replace values where the condition is True.
<code>max(self[, axis, skipna, level, numeric_only])</code>	Return the maximum of the values for the requested axis.
<code>mean(self[, axis, skipna, level, numeric_only])</code>	Return the mean of the values for the requested axis.
<code>median(self[, axis, skipna, level, numeric_only])</code>	Return the median of the values for the requested axis.

Continued on next page

Table 59 – continued from previous page

<code>melt(self[, id_vars, value_vars, var_name, ...])</code>	Unpivot a DataFrame from wide to long format, optionally leaving identifiers set.
<code>memory_usage(self[, index, deep])</code>	Return the memory usage of each column in bytes.
<code>merge(self, right[, how, on, left_on, ...])</code>	Merge DataFrame or named Series objects with a database-style join.
<code>min(self[, axis, skipna, level, numeric_only])</code>	Return the minimum of the values for the requested axis.
<code>mod(self, other[, axis, level, fill_value])</code>	Get Modulo of dataframe and other, element-wise (binary operator <i>mod</i> ).
<code>mode(self[, axis, numeric_only, dropna])</code>	Get the mode(s) of each element along the selected axis.
<code>mul(self, other[, axis, level, fill_value])</code>	Get Multiplication of dataframe and other, element-wise (binary operator <i>mul</i> ).
<code>multiply(self, other[, axis, level, fill_value])</code>	Get Multiplication of dataframe and other, element-wise (binary operator <i>mul</i> ).
<code>ne(self, other[, axis, level])</code>	Get Not equal to of dataframe and other, element-wise (binary operator <i>ne</i> ).
<code>nlargest(self, n, columns[, keep])</code>	Return the first <i>n</i> rows ordered by <i>columns</i> in descending order.
<code>notna(self)</code>	Detect existing (non-missing) values.
<code>notnull(self)</code>	Detect existing (non-missing) values.
<code>nsmallest(self, n, columns[, keep])</code>	Return the first <i>n</i> rows ordered by <i>columns</i> in ascending order.
<code>nunique(self[, axis, dropna])</code>	Count distinct observations over requested axis.
<code>pct_change(self[, periods, fill_method, ...])</code>	Percentage change between the current and a prior element.
<code>pipe(self, func, *args, **kwargs)</code>	Apply <code>func(self, *args, **kwargs)</code> .
<code>pivot(self[, index, columns, values])</code>	Return reshaped DataFrame organized by given index / column values.
<code>pivot_table(self[, values, index, columns, ...])</code>	Create a spreadsheet-style pivot table as a DataFrame.
<code>plot</code>	alias of <code>pandas.plotting._core.PlotAccessor</code>
<code>pop(self, item)</code>	Return item and drop from frame.
<code>pow(self, other[, axis, level, fill_value])</code>	Get Exponential power of dataframe and other, element-wise (binary operator <i>pow</i> ).
<code>prod(self[, axis, skipna, level, ...])</code>	Return the product of the values for the requested axis.
<code>product(self[, axis, skipna, level, ...])</code>	Return the product of the values for the requested axis.
<code>quantile(self[, q, axis, numeric_only, ...])</code>	Return values at the given quantile over requested axis.
<code>query(self, expr[, inplace])</code>	Query the columns of a DataFrame with a boolean expression.
<code>radd(self, other[, axis, level, fill_value])</code>	Get Addition of dataframe and other, element-wise (binary operator <i>radd</i> ).
<code>rank(self[, axis])</code>	Compute numerical data ranks (1 through <i>n</i> ) along axis.
<code>rdiv(self, other[, axis, level, fill_value])</code>	Get Floating division of dataframe and other, element-wise (binary operator <i>rtruediv</i> ).

Table 59 – continued from previous page

<code>reindex(self[, labels, index, columns, ...])</code>	Conform DataFrame to new index with optional filling logic.
<code>reindex_like(self, other, method, ...[, ...])</code>	Return an object with matching indices as other object.
<code>rename(self[, mapper, index, columns, axis, ...])</code>	Alter axes labels.
<code>rename_axis(self[, mapper, index, columns, ...])</code>	Set the name of the axis for the index or columns.
<code>reorder_levels(self, order[, axis])</code>	Rearrange index levels using input order.
<code>replace(self[, to_replace, value, inplace, ...])</code>	Replace values given in <code>to_replace</code> with <code>value</code> .
<code>resample(self, rule[, axis, loffset, on, level])</code>	Resample time-series data.
<code>reset_index(self, level, Sequence[Hashable], ...)</code>	Reset the index, or a level of it.
<code>rfloordiv(self, other[, axis, level, fill_value])</code>	Get Integer division of dataframe and other, element-wise (binary operator <code>rfloordiv</code> ).
<code>rmod(self, other[, axis, level, fill_value])</code>	Get Modulo of dataframe and other, element-wise (binary operator <code>rmod</code> ).
<code>rmul(self, other[, axis, level, fill_value])</code>	Get Multiplication of dataframe and other, element-wise (binary operator <code>rmul</code> ).
<code>rolling(self, window[, min_periods, center, ...])</code>	Provide rolling window calculations.
<code>round(self[, decimals])</code>	Round a DataFrame to a variable number of decimal places.
<code>rpow(self, other[, axis, level, fill_value])</code>	Get Exponential power of dataframe and other, element-wise (binary operator <code>rpow</code> ).
<code>rsub(self, other[, axis, level, fill_value])</code>	Get Subtraction of dataframe and other, element-wise (binary operator <code>rsub</code> ).
<code>rtruediv(self, other[, axis, level, fill_value])</code>	Get Floating division of dataframe and other, element-wise (binary operator <code>rtruediv</code> ).
<code>sample(self[, n, frac, replace, weights, ...])</code>	Return a random sample of items from an axis of object.
<code>select_dtypes(self[, include, exclude])</code>	Return a subset of the DataFrame's columns based on the column dtypes.
<code>sem(self[, axis, skipna, level, ddof, ...])</code>	Return unbiased standard error of the mean over requested axis.
<code>set_axis(self, labels[, axis, inplace])</code>	Assign desired index to given axis.
<code>set_index(self, keys[, drop, append, ...])</code>	Set the DataFrame index using existing columns.
<code>shift(self[, periods, freq, axis, fill_value])</code>	Shift index by desired number of periods with an optional time <code>freq</code> .
<code>skew(self[, axis, skipna, level, numeric_only])</code>	Return unbiased skew over requested axis.
<code>slice_shift(self, periods[, axis])</code>	Equivalent to <code>shift</code> without copying data.
<code>sort_index(self[, axis, level, ascending, ...])</code>	Sort object by labels (along an axis).
<code>sort_values(self, by[, axis, ascending, ...])</code>	Sort by the values along either axis.
<code>sparse</code>	alias of <code>pandas.core.arrays.sparse.accessor.SparseFrameAccessor</code>
<code>squeeze(self[, axis])</code>	Squeeze 1 dimensional axis objects into scalars.
<code>stack(self[, level, dropna])</code>	Stack the prescribed level(s) from columns to index.
<code>std(self[, axis, skipna, level, ddof, ...])</code>	Return sample standard deviation over requested axis.
<code>sub(self, other[, axis, level, fill_value])</code>	Get Subtraction of dataframe and other, element-wise (binary operator <code>sub</code> ).
<code>subtract(self, other[, axis, level, fill_value])</code>	Get Subtraction of dataframe and other, element-wise (binary operator <code>sub</code> ).
<code>sum(self[, axis, skipna, level, ...])</code>	Return the sum of the values for the requested axis.

Continued on next page

Table 59 – continued from previous page

<code>swapaxes(self, axis1, axis2[, copy])</code>	Interchange axes and swap values axes appropriately.
<code>swaplevel(self[, i, j, axis])</code>	Swap levels <i>i</i> and <i>j</i> in a MultiIndex on a particular axis.
<code>tail(self, n)</code>	Return the last <i>n</i> rows.
<code>take(self, indices[, axis])</code>	Return the elements in the given <i>positional</i> indices along an axis.
<code>to_clipboard(self, excel, sep, ...)</code>	Copy object to the system clipboard.
<code>to_csv(self, path_or_buf, pathlib.Path, ...)</code>	Write object to a comma-separated values (csv) file.
<code>to_dict(self[, orient, into])</code>	Convert the DataFrame to a dictionary.
<code>to_excel(self, excel_writer[, sheet_name, ...])</code>	Write object to an Excel sheet.
<code>to_feather(self, path)</code>	Write out the binary feather-format for DataFrames.
<code>to_gbq(self, destination_table[, ...])</code>	Write a DataFrame to a Google BigQuery table.
<code>to_hdf(self, path_or_buf, key, mode, ...[, ...])</code>	Write the contained data to an HDF5 file using HDF-Store.
<code>to_html(self[, buf, columns, col_space, ...])</code>	Render a DataFrame as an HTML table.
<code>to_json(self, path_or_buf, pathlib.Path, ...)</code>	Convert the object to a JSON string.
<code>to_latex(self[, buf, columns, col_space, ...])</code>	Render object to a LaTeX tabular, longtable, or nested table/tabular.
<code>to_markdown(self, buf, NoneType] = None, ...)</code>	Print DataFrame in Markdown-friendly format.
<code>to_numpy(self[, dtype, copy])</code>	Convert the DataFrame to a NumPy array.
<code>to_parquet(self, path[, engine, ...])</code>	Write a DataFrame to the binary parquet format.
<code>to_period(self[, freq, axis, copy])</code>	Convert DataFrame from DatetimeIndex to PeriodIndex.
<code>to_pickle(self, path, compression, ...)</code>	Pickle (serialize) object to file.
<code>to_records(self[, index, column_dtypes, ...])</code>	Convert DataFrame to a NumPy record array.
<code>to_sql(self, name, con[, schema, ...])</code>	Write records stored in a DataFrame to a SQL database.
<code>to_stata(self, path[, convert_dates, ...])</code>	Export DataFrame object to Stata dta format.
<code>to_string(self, buf, pathlib.Path, IO[str], ...)</code>	Render a DataFrame to a console-friendly tabular output.
<code>to_timestamp(self[, freq, how, axis, copy])</code>	Cast to DatetimeIndex of timestamps, at <i>beginning</i> of period.
<code>to_xarray(self)</code>	Return an xarray object from the pandas object.
<code>transform(self, func[, axis])</code>	Call <code>func</code> on self producing a DataFrame with transformed values.
<code>transpose(self, \*args, copy)</code>	Transpose index and columns.
<code>truediv(self, other[, axis, level, fill_value])</code>	Get Floating division of dataframe and other, element-wise (binary operator <i>truediv</i> ).
<code>truncate(self[, before, after, axis])</code>	Truncate a Series or DataFrame before and after some index value.
<code>tshift(self, periods[, freq, axis])</code>	Shift the time index, using the index's frequency if available.
<code>tz_convert(self, tz[, axis, level])</code>	Convert tz-aware axis to target time zone.
<code>tz_localize(self, tz[, axis, level, ambiguous])</code>	Localize tz-naive index of a Series or DataFrame to target time zone.
<code>unstack(self[, level, fill_value])</code>	Pivot a level of the (necessarily hierarchical) index labels.
<code>update(self, other[, join, overwrite, ...])</code>	Modify in place using non-NA values from another DataFrame.
<code>var(self[, axis, skipna, level, ddof, ...])</code>	Return unbiased variance over requested axis.
<code>where(self, cond[, other, inplace, axis, ...])</code>	Replace values where the condition is False.

Continued on next page

Table 59 – continued from previous page

<code>xs(self, key[, axis, level])</code>	Return cross-section from the Series/DataFrame.
-------------------------------------------	-------------------------------------------------

**pandas.DataFrame.abs**

`DataFrame.abs` (*self*: *~FrameOrSeries*) → *~FrameOrSeries*

Return a Series/DataFrame with absolute numeric value of each element.

This function only applies to elements that are all numeric.

**Returns**

**abs** Series/DataFrame containing the absolute value of each element.

**See also:**

`numpy.absolute` Calculate the absolute value element-wise.

**Notes**

For complex inputs,  $1.2 + 1j$ , the absolute value is  $\sqrt{a^2 + b^2}$ .

**Examples**

Absolute numeric values in a Series.

```
>>> s = pd.Series([-1.10, 2, -3.33, 4])
>>> s.abs()
0    1.10
1    2.00
2    3.33
3    4.00
dtype: float64
```

Absolute numeric values in a Series with complex numbers.

```
>>> s = pd.Series([1.2 + 1j])
>>> s.abs()
0    1.56205
dtype: float64
```

Absolute numeric values in a Series with a Timedelta element.

```
>>> s = pd.Series([pd.Timedelta('1 days')])
>>> s.abs()
0    1 days
dtype: timedelta64[ns]
```

Select rows with data closest to certain value using `argsort` (from [StackOverflow](#)).

```
>>> df = pd.DataFrame({
...     'a': [4, 5, 6, 7],
...     'b': [10, 20, 30, 40],
...     'c': [100, 50, -30, -50]
... })
```

(continues on next page)

(continued from previous page)

```

>>> df
   a    b    c
0  4   10  100
1  5   20   50
2  6   30  -30
3  7   40  -50
>>> df.loc[(df.c - 43).abs().argsort()]
   a    b    c
1  5   20   50
0  4   10  100
2  6   30  -30
3  7   40  -50

```

### pandas.DataFrame.add

`DataFrame.add(self, other, axis='columns', level=None, fill_value=None)`

Get Addition of dataframe and other, element-wise (binary operator *add*).

Equivalent to `dataframe + other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *radd*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

#### Parameters

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

**level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

**fill\_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

#### Returns

**DataFrame** Result of the arithmetic operation.

See also:

**DataFrame.add** Add DataFrames.

**DataFrame.sub** Subtract DataFrames.

**DataFrame.mul** Multiply DataFrames.

**DataFrame.div** Divide DataFrames (float division).

**DataFrame.truediv** Divide DataFrames (float division).

**DataFrame.floordiv** Divide DataFrames (integer division).

**DataFrame.mod** Calculate modulo (remainder after division).

**DataFrame.pow** Calculate exponential power.

## Notes

Mismatched indices will be unioned together.

## Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

	angles	degrees
circle	0	360
triangle	3	180
rectangle	4	360

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

```
>>> df.add(1)
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

Divide by constant with reverse version.

```
>>> df.div(10)
```

	angles	degrees
circle	0.0	36.0
triangle	0.3	18.0
rectangle	0.4	36.0

```
>>> df.rdiv(10)
```

	angles	degrees
circle	inf	0.027778
triangle	3.333333	0.055556
rectangle	2.500000	0.027778

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
```

	angles	degrees
circle	-1	358
triangle	2	178
rectangle	3	358

```
>>> df.sub([1, 2], axis='columns')
```

	angles	degrees
circle	-1	358
triangle	2	178
rectangle	3	358

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
      angles  degrees
circle     -1     359
triangle     2     179
rectangle     3     359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                      index=['circle', 'triangle', 'rectangle'])
>>> other
      angles
circle      0
triangle     3
rectangle    4
```

```
>>> df * other
      angles  degrees
circle      0      NaN
triangle     9      NaN
rectangle   16      NaN
```

```
>>> df.mul(other, fill_value=0)
      angles  degrees
circle      0     0.0
triangle     9     0.0
rectangle   16     0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                              'degrees': [360, 180, 360, 360, 540, 720]},
...                              index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                     ['circle', 'triangle', 'rectangle',
...                                      'square', 'pentagon', 'hexagon']])
>>> df_multindex
      angles  degrees
A circle      0     360
  triangle     3     180
  rectangle     4     360
B square      4     360
  pentagon     5     540
  hexagon      6     720
```

```
>>> df_multindex.div(df_multindex, level=1, fill_value=0)
      angles  degrees
A circle   NaN     1.0
  triangle  1.0     1.0
  rectangle 1.0     1.0
B square   0.0     0.0
  pentagon 0.0     0.0
  hexagon  0.0     0.0
```

## pandas.DataFrame.add\_prefix

DataFrame.**add\_prefix** (*self*: ~FrameOrSeries, *prefix*: str) → ~FrameOrSeries  
Prefix labels with string *prefix*.

For Series, the row labels are prefixed. For DataFrame, the column labels are prefixed.

### Parameters

**prefix** [str] The string to add before each label.

### Returns

**Series or DataFrame** New Series or DataFrame with updated labels.

### See also:

**Series.add\_suffix** Suffix row labels with string *suffix*.

**DataFrame.add\_suffix** Suffix column labels with string *suffix*.

### Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64
```

```
>>> s.add_prefix('item_')
item_0    1
item_1    2
item_2    3
item_3    4
dtype: int64
```

```
>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
>>> df
   A  B
0  1  3
1  2  4
2  3  5
3  4  6
```

```
>>> df.add_prefix('col_')
   col_A  col_B
0      1      3
1      2      4
2      3      5
3      4      6
```

**pandas.DataFrame.add\_suffix**

`DataFrame.add_suffix` (*self*: ~FrameOrSeries, *suffix*: str) → ~FrameOrSeries  
 Suffix labels with string *suffix*.

For Series, the row labels are suffixed. For DataFrame, the column labels are suffixed.

**Parameters**

**suffix** [str] The string to add after each label.

**Returns**

**Series or DataFrame** New Series or DataFrame with updated labels.

**See also:**

**Series.add\_prefix** Prefix row labels with string *prefix*.

**DataFrame.add\_prefix** Prefix column labels with string *prefix*.

**Examples**

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64
```

```
>>> s.add_suffix('_item')
0_item    1
1_item    2
2_item    3
3_item    4
dtype: int64
```

```
>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
>>> df
   A  B
0  1  3
1  2  4
2  3  5
3  4  6
```

```
>>> df.add_suffix('_col')
   A_col  B_col
0     1     3
1     2     4
2     3     5
3     4     6
```

## pandas.DataFrame.agg

DataFrame.agg(*self*, *func*, *axis=0*, \**args*, \*\**kwargs*)

Aggregate using one or more operations over the specified axis.

New in version 0.20.0.

### Parameters

**func** [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. [np.sum, 'mean']
- dict of axis labels -> functions, function names or list of such.

**axis** [{0 or 'index', 1 or 'columns'}, default 0] If 0 or 'index': apply function to each column. If 1 or 'columns': apply function to each row.

**\*args** Positional arguments to pass to *func*.

**\*\*kwargs** Keyword arguments to pass to *func*.

### Returns

**scalar, Series or DataFrame** The return can be:

- scalar : when Series.agg is called with single function
- Series : when DataFrame.agg is called with a single function
- DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

**The aggregation operations are always performed over an axis, either the index (default) or the column axis. This behavior is different from numpy aggregation functions (*mean*, *median*, *prod*, *sum*, *std*, *var*), where the default is to compute the aggregation of the flattened array, e.g., `numpy.mean(arr_2d)` as opposed to `numpy.mean(arr_2d, axis=0)`.**

*agg* is an alias for *aggregate*. Use the alias.

See also:

**DataFrame.apply** Perform any type of operations.

**DataFrame.transform** Perform transformation type operations.

**core.groupby.GroupBy** Perform operations over groups.

**core.resample.Resampler** Perform operations over resampled bins.

**core.window.Rolling** Perform operations over rolling window.

**core.window.Expanding** Perform operations over expanding window.

`core.window.EWM` Perform operation over exponential weighted window.

## Notes

`agg` is an alias for `aggregate`. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

## Examples

```
>>> df = pd.DataFrame([[1, 2, 3],
...                    [4, 5, 6],
...                    [7, 8, 9],
...                    [np.nan, np.nan, np.nan]],
...                   columns=['A', 'B', 'C'])
```

Aggregate these functions over the rows.

```
>>> df.agg(['sum', 'min'])
      A      B      C
sum  12.0  15.0  18.0
min   1.0   2.0   3.0
```

Different aggregations per column.

```
>>> df.agg({'A' : ['sum', 'min'], 'B' : ['min', 'max']})
      A      B
max  NaN   8.0
min   1.0   2.0
sum  12.0  NaN
```

Aggregate over the columns.

```
>>> df.agg("mean", axis="columns")
0    2.0
1    5.0
2    8.0
3    NaN
dtype: float64
```

## pandas.DataFrame.aggregate

`DataFrame.aggregate` (*self, func, axis=0, \*args, \*\*kwargs*)

Aggregate using one or more operations over the specified axis.

New in version 0.20.0.

### Parameters

**func** [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to `DataFrame.apply`.

Accepted combinations are:

- function
- string function name

- list of functions and/or function names, e.g. `[np.sum, 'mean']`
- dict of axis labels -> functions, function names or list of such.

**axis** `[[0 or 'index', 1 or 'columns'], default 0]` If 0 or 'index': apply function to each column. If 1 or 'columns': apply function to each row.

**\*args** Positional arguments to pass to *func*.

**\*\*kwargs** Keyword arguments to pass to *func*.

### Returns

**scalar, Series or DataFrame** The return can be:

- scalar : when `Series.agg` is called with single function
- Series : when `DataFrame.agg` is called with a single function
- DataFrame : when `DataFrame.agg` is called with several functions

Return scalar, Series or DataFrame.

**The aggregation operations are always performed over an axis, either the index (default) or the column axis. This behavior is different from *numpy* aggregation functions (*mean, median, prod, sum, std, var*), where the default is to compute the aggregation of the flattened array, e.g., `numpy.mean(arr_2d)` as opposed to `numpy.mean(arr_2d, axis=0)`.**

*agg* is an alias for *aggregate*. Use the alias.

See also:

***DataFrame.apply*** Perform any type of operations.

***DataFrame.transform*** Perform transformation type operations.

***core.groupby.GroupBy*** Perform operations over groups.

***core.resample.Resampler*** Perform operations over resampled bins.

***core.window.Rolling*** Perform operations over rolling window.

***core.window.Expanding*** Perform operations over expanding window.

***core.window.EWM*** Perform operation over exponential weighted window.

### Notes

*agg* is an alias for *aggregate*. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

## Examples

```
>>> df = pd.DataFrame([[1, 2, 3],
...                    [4, 5, 6],
...                    [7, 8, 9],
...                    [np.nan, np.nan, np.nan]],
...                   columns=['A', 'B', 'C'])
```

Aggregate these functions over the rows.

```
>>> df.agg(['sum', 'min'])
      A      B      C
sum  12.0  15.0  18.0
min   1.0   2.0   3.0
```

Different aggregations per column.

```
>>> df.agg({'A' : ['sum', 'min'], 'B' : ['min', 'max']})
      A      B
max   NaN   8.0
min   1.0   2.0
sum  12.0  NaN
```

Aggregate over the columns.

```
>>> df.agg("mean", axis="columns")
0      2.0
1      5.0
2      8.0
3      NaN
dtype: float64
```

## pandas.DataFrame.align

`DataFrame.align` (*self*, *other*, *join*='outer', *axis*=None, *level*=None, *copy*=True, *fill\_value*=None, *method*=None, *limit*=None, *fill\_axis*=0, *broadcast\_axis*=None) → 'DataFrame'  
Align two objects on their axes with the specified join method.

Join method is specified for each axis Index.

### Parameters

**other** [DataFrame or Series]

**join** [{'outer', 'inner', 'left', 'right'}, default 'outer']

**axis** [allowed axis of the other object, default None] Align on index (0), columns (1), or both (None).

**level** [int or level name, default None] Broadcast across a level, matching Index values on the passed MultiIndex level.

**copy** [bool, default True] Always returns new objects. If copy=False and no reindexing is required then original objects are returned.

**fill\_value** [scalar, default np.NaN] Value to use for missing values. Defaults to NaN, but can be any “compatible” value.

**method** [{ 'backfill', 'bfill', 'pad', 'ffill', None }, default None] Method to use for filling holes in reindexed Series:

- pad / ffill: propagate last valid observation forward to next valid.
- backfill / bfill: use NEXT valid observation to fill gap.

**limit** [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

**fill\_axis** [{0 or 'index', 1 or 'columns'}, default 0] Filling axis, method and limit.

**broadcast\_axis** [{0 or 'index', 1 or 'columns'}, default None] Broadcast values along this axis, if aligning two objects of different dimensions.

#### Returns

**(left, right)** [(DataFrame, type of other)] Aligned objects.

### pandas.DataFrame.all

`DataFrame.all` (*self*, *axis=0*, *bool\_only=None*, *skipna=True*, *level=None*, *\*\*kwargs*)

Return whether all elements are True, potentially over an axis.

Returns True unless there at least one element within a series or along a Dataframe axis that is False or equivalent (e.g. zero or empty).

#### Parameters

**axis** [{0 or 'index', 1 or 'columns', None}, default 0] Indicate which axis or axes should be reduced.

- 0 / 'index' : reduce the index, return a Series whose index is the original column labels.
- 1 / 'columns' : reduce the columns, return a Series whose index is the original index.
- None : reduce all axes, return a scalar.

**bool\_only** [bool, default None] Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.

**skipna** [bool, default True] Exclude NA/null values. If the entire row/column is NA and skipna is True, then the result will be True, as for an empty row/column. If skipna is False, then NA are treated as True, because these are not equal to zero.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

**\*\*kwargs** [any, default None] Additional keywords have no effect but might be accepted for compatibility with NumPy.

#### Returns

**Series or DataFrame** If level is specified, then, DataFrame is returned; otherwise, Series is returned.

See also:

**Series.all** Return True if all elements are True.

**DataFrame.any** Return True if one (or more) elements are True.

## Examples

### Series

```
>>> pd.Series([True, True]).all()
True
>>> pd.Series([True, False]).all()
False
>>> pd.Series([]).all()
True
>>> pd.Series([np.nan]).all()
True
>>> pd.Series([np.nan]).all(skipna=False)
True
```

### DataFrames

Create a dataframe from a dictionary.

```
>>> df = pd.DataFrame({'col1': [True, True], 'col2': [True, False]})
>>> df
   col1  col2
0  True  True
1  True False
```

Default behaviour checks if column-wise values all return True.

```
>>> df.all()
col1     True
col2    False
dtype: bool
```

Specify axis='columns' to check if row-wise values all return True.

```
>>> df.all(axis='columns')
0     True
1    False
dtype: bool
```

Or axis=None for whether every value is True.

```
>>> df.all(axis=None)
False
```

**pandas.DataFrame.any**

`DataFrame.any` (*self*, *axis=0*, *bool\_only=None*, *skipna=True*, *level=None*, *\*\*kwargs*)

Return whether any element is True, potentially over an axis.

Returns False unless there at least one element within a series or along a Dataframe axis that is True or equivalent (e.g. non-zero or non-empty).

**Parameters**

**axis** [{0 or 'index', 1 or 'columns', None}, default 0] Indicate which axis or axes should be reduced.

- 0 / 'index' : reduce the index, return a Series whose index is the original column labels.
- 1 / 'columns' : reduce the columns, return a Series whose index is the original index.
- None : reduce all axes, return a scalar.

**bool\_only** [bool, default None] Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.

**skipna** [bool, default True] Exclude NA/null values. If the entire row/column is NA and skipna is True, then the result will be False, as for an empty row/column. If skipna is False, then NA are treated as True, because these are not equal to zero.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

**\*\*kwargs** [any, default None] Additional keywords have no effect but might be accepted for compatibility with NumPy.

**Returns**

**Series or DataFrame** If level is specified, then, DataFrame is returned; otherwise, Series is returned.

**See also:**

`numpy.any` Numpy version of this method.

`Series.any` Return whether any element is True.

`Series.all` Return whether all elements are True.

`DataFrame.any` Return whether any element is True over requested axis.

`DataFrame.all` Return whether all elements are True over requested axis.

**Examples****Series**

For Series input, the output is a scalar indicating whether any element is True.

```
>>> pd.Series([False, False]).any()
False
>>> pd.Series([True, False]).any()
True
>>> pd.Series([]).any()
```

(continues on next page)

(continued from previous page)

```
False
>>> pd.Series([np.nan]).any()
False
>>> pd.Series([np.nan]).any(skipna=False)
True
```

**DataFrame**

Whether each column contains at least one True element (the default).

```
>>> df = pd.DataFrame({"A": [1, 2], "B": [0, 2], "C": [0, 0]})
>>> df
   A  B  C
0  1  0  0
1  2  2  0
```

```
>>> df.any()
A    True
B    True
C    False
dtype: bool
```

Aggregating over the columns.

```
>>> df = pd.DataFrame({"A": [True, False], "B": [1, 2]})
>>> df
   A  B
0  True  1
1  False  2
```

```
>>> df.any(axis='columns')
0    True
1    True
dtype: bool
```

```
>>> df = pd.DataFrame({"A": [True, False], "B": [1, 0]})
>>> df
   A  B
0  True  1
1  False  0
```

```
>>> df.any(axis='columns')
0    True
1    False
dtype: bool
```

Aggregating over the entire DataFrame with axis=None.

```
>>> df.any(axis=None)
True
```

*any* for an empty DataFrame is an empty Series.

```
>>> pd.DataFrame([]).any()
Series([], dtype: bool)
```

## pandas.DataFrame.append

DataFrame.**append**(*self*, *other*, *ignore\_index=False*, *verify\_integrity=False*, *sort=False*) →

'DataFrame'  
Append rows of *other* to the end of caller, returning a new object.

Columns in *other* that are not in the caller are added as new columns.

### Parameters

**other** [DataFrame or Series/dict-like object, or list of these] The data to append.

**ignore\_index** [bool, default False] If True, do not use the index labels.

**verify\_integrity** [bool, default False] If True, raise ValueError on creating index with duplicates.

**sort** [bool, default False] Sort columns if the columns of *self* and *other* are not aligned.

New in version 0.23.0.

Changed in version 1.0.0: Changed to not sort by default.

### Returns

**DataFrame**

### See also:

**concat** General function to concatenate DataFrame or Series objects.

### Notes

If a list of dict/series is passed and the keys are all contained in the DataFrame's index, the order of the columns in the resulting DataFrame will be unchanged.

Iteratively appending rows to a DataFrame can be more computationally intensive than a single concatenate. A better solution is to append those rows to a list and then concatenate the list with the original DataFrame all at once.

### Examples

```
>>> df = pd.DataFrame([[1, 2], [3, 4]], columns=list('AB'))
>>> df
   A  B
0  1  2
1  3  4
>>> df2 = pd.DataFrame([[5, 6], [7, 8]], columns=list('AB'))
>>> df.append(df2)
   A  B
0  1  2
1  3  4
0  5  6
1  7  8
```

With *ignore\_index* set to True:

```
>>> df.append(df2, ignore_index=True)
   A  B
0  1  2
1  3  4
2  5  6
3  7  8
```

The following, while not recommended methods for generating DataFrames, show two ways to generate a DataFrame from multiple data sources.

Less efficient:

```
>>> df = pd.DataFrame(columns=['A'])
>>> for i in range(5):
...     df = df.append({'A': i}, ignore_index=True)
>>> df
   A
0  0
1  1
2  2
3  3
4  4
```

More efficient:

```
>>> pd.concat([pd.DataFrame([i], columns=['A']) for i in range(5)],
...           ignore_index=True)
   A
0  0
1  1
2  2
3  3
4  4
```

## pandas.DataFrame.apply

`DataFrame.apply` (*self*, *func*, *axis=0*, *raw=False*, *result\_type=None*, *args=()*, *\*\*kwargs*)

Apply a function along an axis of the DataFrame.

Objects passed to the function are Series objects whose index is either the DataFrame's index (*axis=0*) or the DataFrame's columns (*axis=1*). By default (*result\_type=None*), the final return type is inferred from the return type of the applied function. Otherwise, it depends on the *result\_type* argument.

### Parameters

**func** [function] Function to apply to each column or row.

**axis** [{0 or 'index', 1 or 'columns'}, default 0] Axis along which the function is applied:

- 0 or 'index': apply function to each column.
- 1 or 'columns': apply function to each row.

**raw** [bool, default False] Determines if row or column is passed as a Series or ndarray object:

- False: passes each row or column as a Series to the function.

- `True` : the passed function will receive ndarray objects instead. If you are just applying a NumPy reduction function this will achieve much better performance.

**result\_type** [{'expand', 'reduce', 'broadcast', None}, default None] These only act when `axis=1` (columns):

- 'expand' : list-like results will be turned into columns.
- 'reduce' : returns a Series if possible rather than expanding list-like results. This is the opposite of 'expand'.
- 'broadcast' : results will be broadcast to the original shape of the DataFrame, the original index and columns will be retained.

The default behaviour (None) depends on the return value of the applied function: list-like results will be returned as a Series of those. However if the apply function returns a Series these are expanded to columns.

New in version 0.23.0.

**args** [tuple] Positional arguments to pass to *func* in addition to the array/series.

**\*\*kwargs** Additional keyword arguments to pass as keywords arguments to *func*.

### Returns

**Series or DataFrame** Result of applying *func* along the given axis of the DataFrame.

See also:

**DataFrame.applymap** For elementwise operations.

**DataFrame.aggregate** Only perform aggregating type operations.

**DataFrame.transform** Only perform transforming type operations.

### Examples

```
>>> df = pd.DataFrame([[4, 9]] * 3, columns=['A', 'B'])
>>> df
   A  B
0  4  9
1  4  9
2  4  9
```

Using a numpy universal function (in this case the same as `np.sqrt(df)`):

```
>>> df.apply(np.sqrt)
   A    B
0  2.0  3.0
1  2.0  3.0
2  2.0  3.0
```

Using a reducing function on either axis

```
>>> df.apply(np.sum, axis=0)
A    12
B    27
dtype: int64
```

```
>>> df.apply(np.sum, axis=1)
0    13
1    13
2    13
dtype: int64
```

Returning a list-like will result in a Series

```
>>> df.apply(lambda x: [1, 2], axis=1)
0    [1, 2]
1    [1, 2]
2    [1, 2]
dtype: object
```

Passing `result_type='expand'` will expand list-like results to columns of a DataFrame

```
>>> df.apply(lambda x: [1, 2], axis=1, result_type='expand')
   0  1
0  1  2
1  1  2
2  1  2
```

Returning a Series inside the function is similar to passing `result_type='expand'`. The resulting column names will be the Series index.

```
>>> df.apply(lambda x: pd.Series([1, 2], index=['foo', 'bar']), axis=1)
   foo  bar
0    1    2
1    1    2
2    1    2
```

Passing `result_type='broadcast'` will ensure the same shape result, whether list-like or scalar is returned by the function, and broadcast it along the axis. The resulting column names will be the originals.

```
>>> df.apply(lambda x: [1, 2], axis=1, result_type='broadcast')
   A  B
0  1  2
1  1  2
2  1  2
```

## pandas.DataFrame.applymap

`DataFrame.applymap(self, func) → 'DataFrame'`

Apply a function to a DataFrame elementwise.

This method applies a function that accepts and returns a scalar to every element of a DataFrame.

### Parameters

**func** [callable] Python function, returns a single value from a single value.

### Returns

**DataFrame** Transformed DataFrame.

**See also:**

**DataFrame.apply** Apply a function along input axis of DataFrame.

## Notes

In the current implementation `applymap` calls `func` twice on the first column/row to decide whether it can take a fast or slow code path. This can lead to unexpected behavior if `func` has side-effects, as they will take effect twice for the first column/row.

## Examples

```
>>> df = pd.DataFrame([[1, 2.12], [3.356, 4.567]])
>>> df
   0    1
0  1.000  2.120
1  3.356  4.567
```

```
>>> df.applymap(lambda x: len(str(x)))
   0  1
0  3  4
1  5  5
```

Note that a vectorized version of `func` often exists, which will be much faster. You could square each number elementwise.

```
>>> df.applymap(lambda x: x**2)
   0    1
0  1.000000  4.494400
1  11.262736  20.857489
```

But it's better to avoid `applymap` in that case.

```
>>> df ** 2
   0    1
0  1.000000  4.494400
1  11.262736  20.857489
```

## pandas.DataFrame.asfreq

`DataFrame.asfreq` (*self*: ~FrameOrSeries, *freq*, *method=None*, *how: Union[str, NoneType] = None*, *normalize: bool = False*, *fill\_value=None*) → ~FrameOrSeries  
Convert TimeSeries to specified frequency.

Optionally provide filling method to pad/backfill missing values.

Returns the original data conformed to a new index with the specified frequency. `resample` is more appropriate if an operation, such as summarization, is necessary to represent the data at the new frequency.

### Parameters

**freq** [DateOffset or str]

**method** [{ 'backfill'/'bfill', 'pad'/'ffill' }, default None] Method to use for filling holes in reindexed Series (note this does not fill NaNs that already were present):

- 'pad' / 'ffill': propagate last valid observation forward to next valid
- 'backfill' / 'bfill': use NEXT valid observation to fill.

**how** [{ 'start', 'end' }, default end] For PeriodIndex only (see PeriodIndex.asfreq).

**normalize** [bool, default False] Whether to reset output index to midnight.

**fill\_value** [scalar, optional] Value to use for missing values, applied during upsampling (note this does not fill NaNs that already were present).

### Returns

**converted** [same type as caller]

**See also:**

*reindex*

### Notes

To learn more about the frequency strings, please see [this link](#).

### Examples

Start by creating a series with 4 one minute timestamps.

```
>>> index = pd.date_range('1/1/2000', periods=4, freq='T')
>>> series = pd.Series([0.0, None, 2.0, 3.0], index=index)
>>> df = pd.DataFrame({'s':series})
>>> df
```

	s
2000-01-01 00:00:00	0.0
2000-01-01 00:01:00	NaN
2000-01-01 00:02:00	2.0
2000-01-01 00:03:00	3.0

Upsample the series into 30 second bins.

```
>>> df.asfreq(freq='30S')
```

	s
2000-01-01 00:00:00	0.0
2000-01-01 00:00:30	NaN
2000-01-01 00:01:00	NaN
2000-01-01 00:01:30	NaN
2000-01-01 00:02:00	2.0
2000-01-01 00:02:30	NaN
2000-01-01 00:03:00	3.0

Upsample again, providing a fill value.

```
>>> df.asfreq(freq='30S', fill_value=9.0)
```

	s
2000-01-01 00:00:00	0.0
2000-01-01 00:00:30	9.0
2000-01-01 00:01:00	NaN
2000-01-01 00:01:30	9.0
2000-01-01 00:02:00	2.0
2000-01-01 00:02:30	9.0
2000-01-01 00:03:00	3.0

Upsample again, providing a method.

```
>>> df.asfreq(freq='30S', method='bfill')
      s
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30   NaN
2000-01-01 00:01:00   NaN
2000-01-01 00:01:30    2.0
2000-01-01 00:02:00    2.0
2000-01-01 00:02:30    3.0
2000-01-01 00:03:00    3.0
```

## pandas.DataFrame.asof

`DataFrame.asof` (*self*, *where*, *subset=None*)

Return the last row(s) without any NaNs before *where*.

The last row (for each element in *where*, if list) without any NaN is taken. In case of a *DataFrame*, the last row without NaN considering only the subset of columns (if not *None*)

If there is no good value, NaN is returned for a Series or a Series of NaN values for a DataFrame

### Parameters

**where** [date or array-like of dates] Date(s) before which the last row(s) are returned.

**subset** [str or array-like of str, default *None*] For DataFrame, if not *None*, only use these columns to check for NaNs.

### Returns

**scalar, Series, or DataFrame** The return can be:

- scalar : when *self* is a Series and *where* is a scalar
- Series: when *self* is a Series and *where* is an array-like, or when *self* is a DataFrame and *where* is a scalar
- DataFrame : when *self* is a DataFrame and *where* is an array-like

Return scalar, Series, or DataFrame.

### See also:

**`merge_asof`** Perform an asof merge. Similar to left join.

### Notes

Dates are assumed to be sorted. Raises if this is not the case.

## Examples

A Series and a scalar *where*.

```
>>> s = pd.Series([1, 2, np.nan, 4], index=[10, 20, 30, 40])
>>> s
10    1.0
20    2.0
30    NaN
40    4.0
dtype: float64
```

```
>>> s.asof(20)
2.0
```

For a sequence *where*, a Series is returned. The first value is NaN, because the first element of *where* is before the first index value.

```
>>> s.asof([5, 20])
5      NaN
20     2.0
dtype: float64
```

Missing values are not considered. The following is 2.0, not NaN, even though NaN is at the index location for 30.

```
>>> s.asof(30)
2.0
```

Take all columns into consideration

```
>>> df = pd.DataFrame({'a': [10, 20, 30, 40, 50],
...                    'b': [None, None, None, None, 500]},
...                   index=pd.DatetimeIndex(['2018-02-27 09:01:00',
...                                           '2018-02-27 09:02:00',
...                                           '2018-02-27 09:03:00',
...                                           '2018-02-27 09:04:00',
...                                           '2018-02-27 09:05:00']))
>>> df.asof(pd.DatetimeIndex(['2018-02-27 09:03:30',
...                           '2018-02-27 09:04:30']))
...
           a    b
2018-02-27 09:03:30 NaN NaN
2018-02-27 09:04:30 NaN NaN
```

Take a single column into consideration

```
>>> df.asof(pd.DatetimeIndex(['2018-02-27 09:03:30',
...                           '2018-02-27 09:04:30']),
...         subset=['a'])
...
           a    b
2018-02-27 09:03:30  30.0 NaN
2018-02-27 09:04:30  40.0 NaN
```

## pandas.DataFrame.assign

DataFrame.**assign** (*self*, **\*\*kwargs**) → 'DataFrame'

Assign new columns to a DataFrame.

Returns a new object with all original columns in addition to new ones. Existing columns that are re-assigned will be overwritten.

### Parameters

**\*\*kwargs** [dict of {str: callable or Series}] The column names are keywords. If the values are callable, they are computed on the DataFrame and assigned to the new columns. The callable must not change input DataFrame (though pandas doesn't check it). If the values are not callable, (e.g. a Series, scalar, or array), they are simply assigned.

### Returns

**DataFrame** A new DataFrame with the new columns in addition to all the existing columns.

### Notes

Assigning multiple columns within the same `assign` is possible. Later items in `**kwargs` may refer to newly created or modified columns in `'df'`; items are computed and assigned into `'df'` in order.

Changed in version 0.23.0: Keyword argument order is maintained.

### Examples

```
>>> df = pd.DataFrame({'temp_c': [17.0, 25.0]},
...                   index=['Portland', 'Berkeley'])
>>> df
```

	temp_c
Portland	17.0
Berkeley	25.0

Where the value is a callable, evaluated on `df`:

```
>>> df.assign(temp_f=lambda x: x.temp_c * 9 / 5 + 32)
```

	temp_c	temp_f
Portland	17.0	62.6
Berkeley	25.0	77.0

Alternatively, the same behavior can be achieved by directly referencing an existing Series or sequence:

```
>>> df.assign(temp_f=df['temp_c'] * 9 / 5 + 32)
```

	temp_c	temp_f
Portland	17.0	62.6
Berkeley	25.0	77.0

You can create multiple columns within the same `assign` where one of the columns depends on another one defined within the same `assign`:

```
>>> df.assign(temp_f=lambda x: x['temp_c'] * 9 / 5 + 32,
...           temp_k=lambda x: (x['temp_f'] + 459.67) * 5 / 9)
      temp_c  temp_f  temp_k
Portland   17.0   62.6  290.15
Berkeley   25.0   77.0  298.15
```

## pandas.DataFrame.astype

`DataFrame.astype` (*self*: ~FrameOrSeries, *dtype*, *copy*: bool = True, *errors*: str = 'raise') → ~FrameOrSeries  
Cast a pandas object to a specified dtype dtype.

### Parameters

**dtype** [data type, or dict of column name -> data type] Use a numpy.dtype or Python type to cast entire pandas object to the same type. Alternatively, use {col: dtype, ...}, where col is a column label and dtype is a numpy.dtype or Python type to cast one or more of the DataFrame's columns to column-specific types.

**copy** [bool, default True] Return a copy when copy=True (be very careful setting copy=False as changes to values then may propagate to other pandas objects).

**errors** [{'raise', 'ignore'}, default 'raise'] Control raising of exceptions on invalid data for provided dtype.

- raise: allow exceptions to be raised
- ignore: suppress exceptions. On error return original object.

### Returns

**casted** [same type as caller]

### See also:

**to\_datetime** Convert argument to datetime.

**to\_timedelta** Convert argument to timedelta.

**to\_numeric** Convert argument to a numeric type.

**numpy.ndarray.astype** Cast a numpy array to a specified type.

## Examples

Create a DataFrame:

```
>>> d = {'col1': [1, 2], 'col2': [3, 4]}
>>> df = pd.DataFrame(data=d)
>>> df.dtypes
col1    int64
col2    int64
dtype: object
```

Cast all columns to int32:

```
>>> df.astype('int32').dtypes
col1    int32
col2    int32
dtype: object
```

Cast col1 to int32 using a dictionary:

```
>>> df.astype({'col1': 'int32'}).dtypes
col1    int32
col2    int64
dtype: object
```

Create a series:

```
>>> ser = pd.Series([1, 2], dtype='int32')
>>> ser
0    1
1    2
dtype: int32
>>> ser.astype('int64')
0    1
1    2
dtype: int64
```

Convert to categorical type:

```
>>> ser.astype('category')
0    1
1    2
dtype: category
Categories (2, int64): [1, 2]
```

Convert to ordered categorical type with custom ordering:

```
>>> cat_dtype = pd.api.types.CategoricalDtype(
...     categories=[2, 1], ordered=True)
>>> ser.astype(cat_dtype)
0    1
1    2
dtype: category
Categories (2, int64): [2 < 1]
```

Note that using `copy=False` and changing data on a new pandas object may propagate changes:

```
>>> s1 = pd.Series([1, 2])
>>> s2 = s1.astype('int64', copy=False)
>>> s2[0] = 10
>>> s1 # note that s1[0] has changed too
0    10
1     2
dtype: int64
```

## pandas.DataFrame.at\_time

`DataFrame.at_time` (*self*: ~FrameOrSeries, *time*, *asof*: bool = False, *axis*=None) → ~FrameOrSeries

Select values at particular time of day (e.g. 9:30AM).

### Parameters

**time** [datetime.time or str]

**axis** [{0 or 'index', 1 or 'columns'}, default 0] New in version 0.24.0.

### Returns

Series or DataFrame

### Raises

**TypeError** If the index is not a *DatetimeIndex*

### See also:

***between\_time*** Select values between particular times of the day.

***first*** Select initial periods of time series based on a date offset.

***last*** Select final periods of time series based on a date offset.

***DatetimeIndex.indexer\_at\_time*** Get just the index locations for values at particular time of the day.

## Examples

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='12H')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
           A
2018-04-09 00:00:00  1
2018-04-09 12:00:00  2
2018-04-10 00:00:00  3
2018-04-10 12:00:00  4
```

```
>>> ts.at_time('12:00')
           A
2018-04-09 12:00:00  2
2018-04-10 12:00:00  4
```

## pandas.DataFrame.between\_time

`DataFrame.between_time` (*self*: ~FrameOrSeries, *start\_time*, *end\_time*, *include\_start*: bool = True, *include\_end*: bool = True, *axis*=None) → ~FrameOrSeries

Select values between particular times of the day (e.g., 9:00-9:30 AM).

By setting *start\_time* to be later than *end\_time*, you can get the times that are *not* between the two times.

### Parameters

**start\_time** [datetime.time or str]

**end\_time** [datetime.time or str]  
**include\_start** [bool, default True]  
**include\_end** [bool, default True]  
**axis** [{0 or 'index', 1 or 'columns'}, default 0] New in version 0.24.0.

**Returns**

**Series or DataFrame**

**Raises**

**TypeError** If the index is not a *DatetimeIndex*

**See also:**

**at\_time** Select values at a particular time of the day.

**first** Select initial periods of time series based on a date offset.

**last** Select final periods of time series based on a date offset.

**DatetimeIndex.indexer\_between\_time** Get just the index locations for values between particular times of the day.

**Examples**

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='1D20min')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
              A
2018-04-09 00:00:00  1
2018-04-10 00:20:00  2
2018-04-11 00:40:00  3
2018-04-12 01:00:00  4
```

```
>>> ts.between_time('0:15', '0:45')
              A
2018-04-10 00:20:00  2
2018-04-11 00:40:00  3
```

You get the times that are *not* between two times by setting `start_time` later than `end_time`:

```
>>> ts.between_time('0:45', '0:15')
              A
2018-04-09 00:00:00  1
2018-04-12 01:00:00  4
```

### pandas.DataFrame.bfill

`DataFrame.bfill` (*self*: ~FrameOrSeries, *axis=None*, *inplace: bool = False*, *limit=None*, *down-cast=None*) → Union[~FrameOrSeries, NoneType]

Synonym for `DataFrame.fillna()` with `method='bfill'`.

#### Returns

**%(klass)s or None** Object with missing values filled or None if `inplace=True`.

### pandas.DataFrame.bool

`DataFrame.bool` (*self*)

Return the bool of a single element PandasObject.

This must be a boolean scalar value, either True or False. Raise a `ValueError` if the PandasObject does not have exactly 1 element, or that element is not boolean

#### Returns

**bool** Same single boolean value converted to bool type.

### pandas.DataFrame.boxplot

`DataFrame.boxplot` (*self*, *column=None*, *by=None*, *ax=None*, *fontsize=None*, *rot=0*, *grid=True*, *figsize=None*, *layout=None*, *return\_type=None*, *backend=None*, *\*\*kwargs*)

Make a box plot from DataFrame columns.

Make a box-and-whisker plot from DataFrame columns, optionally grouped by some other columns. A box plot is a method for graphically depicting groups of numerical data through their quartiles. The box extends from the Q1 to Q3 quartile values of the data, with a line at the median (Q2). The whiskers extend from the edges of box to show the range of the data. The position of the whiskers is set by default to  $1.5 * IQR$  ( $IQR = Q3 - Q1$ ) from the edges of the box. Outlier points are those past the end of the whiskers.

For further details see Wikipedia's entry for [boxplot](#).

#### Parameters

**column** [str or list of str, optional] Column name or list of names, or vector. Can be any valid input to `pandas.DataFrame.groupby()`.

**by** [str or array-like, optional] Column in the DataFrame to `pandas.DataFrame.groupby()`. One box-plot will be done per value of columns in *by*.

**ax** [object of class `matplotlib.axes.Axes`, optional] The matplotlib axes to be used by boxplot.

**fontsize** [float or str] Tick label font size in points or as a string (e.g., *large*).

**rot** [int or float, default 0] The rotation angle of labels (in degrees) with respect to the screen coordinate system.

**grid** [bool, default True] Setting this to True will show the grid.

**figsize** [A tuple (width, height) in inches] The size of the figure to create in matplotlib.

**layout** [tuple (rows, columns), optional] For example, (3, 5) will display the subplots using 3 columns and 5 rows, starting from the top-left.

**return\_type** [{‘axes’, ‘dict’, ‘both’} or None, default ‘axes’] The kind of object to return. The default is `axes`.

- ‘axes’ returns the matplotlib axes the boxplot is drawn on.
- ‘dict’ returns a dictionary whose values are the matplotlib Lines of the boxplot.
- ‘both’ returns a namedtuple with the axes and dict.
- when grouping with `by`, a Series mapping columns to `return_type` is returned.

If `return_type` is `None`, a NumPy array of axes with the same shape as `layout` is returned.

**backend** [str, default None] Backend to use instead of the backend specified in the option `plotting.backend`. For instance, ‘matplotlib’. Alternatively, to specify the `plotting.backend` for the whole session, set `pd.options.plotting.backend`.

New in version 1.0.0.

**\*\*kwargs** All other plotting keyword arguments to be passed to `matplotlib.pyplot.boxplot()`.

### Returns

**result** See Notes.

### See also:

**`Series.plot.hist`** Make a histogram.

**`matplotlib.pyplot.boxplot`** Matplotlib equivalent plot.

### Notes

The return type depends on the `return_type` parameter:

- ‘axes’ : object of class `matplotlib.axes.Axes`
- ‘dict’ : dict of `matplotlib.lines.Line2D` objects
- ‘both’ : a namedtuple with structure (ax, lines)

For data grouped with `by`, return a Series of the above or a numpy array:

- `Series`
- `array` (for `return_type = None`)

Use `return_type='dict'` when you want to tweak the appearance of the lines after plotting. In this case a dict containing the Lines making up the boxes, caps, fliers, medians, and whiskers is returned.

## Examples

Boxplots can be created for every column in the dataframe by `df.boxplot()` or indicating the columns to be used:

```
>>> np.random.seed(1234)
>>> df = pd.DataFrame(np.random.randn(10, 4),
...                    columns=['Col1', 'Col2', 'Col3', 'Col4'])
>>> boxplot = df.boxplot(column=['Col1', 'Col2', 'Col3'])
```

Boxplots of variables distributions grouped by the values of a third variable can be created using the option `by`. For instance:

```
>>> df = pd.DataFrame(np.random.randn(10, 2),
...                    columns=['Col1', 'Col2'])
>>> df['X'] = pd.Series(['A', 'A', 'A', 'A', 'A',
...                     'B', 'B', 'B', 'B', 'B'])
>>> boxplot = df.boxplot(by='X')
```

A list of strings (i.e. `['X', 'Y']`) can be passed to `boxplot` in order to group the data by combination of the variables in the x-axis:

```
>>> df = pd.DataFrame(np.random.randn(10, 3),
...                    columns=['Col1', 'Col2', 'Col3'])
```

(continues on next page)

(continued from previous page)

```

>>> df['X'] = pd.Series(['A', 'A', 'A', 'A', 'A',
...                     'B', 'B', 'B', 'B', 'B'])
>>> df['Y'] = pd.Series(['A', 'B', 'A', 'B', 'A',
...                     'B', 'A', 'B', 'A', 'B'])
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by=['X', 'Y'])

```

The layout of boxplot can be adjusted giving a tuple to layout:

```

>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
...                       layout=(2, 1))

```

Additional formatting can be done to the boxplot, like suppressing the grid (`grid=False`), rotating the labels in the x-axis (i.e. `rot=45`) or changing the fontsize (i.e. `fontsize=15`):

```

>>> boxplot = df.boxplot(grid=False, rot=45, fontsize=15)

```

The parameter `return_type` can be used to select the type of element returned by `boxplot`. When `return_type='axes'` is selected, the matplotlib axes on which the boxplot is drawn are returned:

```

>>> boxplot = df.boxplot(column=['Col1', 'Col2'], return_type='axes')
>>> type(boxplot)
<class 'matplotlib.axes._subplots.AxesSubplot'>

```

When grouping with `by`, a Series mapping columns to `return_type` is returned:

```
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
...                       return_type='axes')
>>> type(boxplot)
<class 'pandas.core.series.Series'>
```

If `return_type` is `None`, a NumPy array of axes with the same shape as `layout` is returned:

```
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
...                       return_type=None)
>>> type(boxplot)
<class 'numpy.ndarray'>
```

## pandas.DataFrame.clip

`DataFrame.clip` (*self*: ~FrameOrSeries, *lower*=None, *upper*=None, *axis*=None, *inplace*: bool = False, \*args, \*\*kwargs) → ~FrameOrSeries  
Trim values at input threshold(s).

Assigns values outside boundary to boundary values. Thresholds can be singular values or array like, and in the latter case the clipping is performed element-wise in the specified axis.

### Parameters

**lower** [float or array\_like, default None] Minimum threshold value. All values below this threshold will be set to it.

**upper** [float or array\_like, default None] Maximum threshold value. All values above this threshold will be set to it.

**axis** [int or str axis name, optional] Align object with lower and upper along the given axis.

**inplace** [bool, default False] Whether to perform the operation in place on the data.  
New in version 0.21.0.

**\*args, \*\*kwargs** Additional keywords have no effect but might be accepted for compatibility with numpy.

### Returns

**Series or DataFrame** Same type as calling object with the values outside the clip boundaries replaced.

## Examples

```
>>> data = {'col_0': [9, -3, 0, -1, 5], 'col_1': [-2, -7, 6, 8, -5]}
>>> df = pd.DataFrame(data)
>>> df
   col_0  col_1
0      9     -2
1     -3     -7
2      0      6
3     -1      8
4      5     -5
```

Clips per column using lower and upper thresholds:

```
>>> df.clip(-4, 6)
   col_0  col_1
0      6    -2
1     -3    -4
2      0     6
3     -1     6
4      5    -4
```

Clips using specific lower and upper thresholds per column element:

```
>>> t = pd.Series([2, -4, -1, 6, 3])
>>> t
0     2
1    -4
2    -1
3     6
4     3
dtype: int64
```

```
>>> df.clip(t, t + 4, axis=0)
   col_0  col_1
0      6     2
1     -3    -4
2      0     3
3      6     8
4      5     3
```

## pandas.DataFrame.combine

`DataFrame.combine` (*self*, *other*: 'DataFrame', *func*, *fill\_value*=None, *overwrite*=True) → 'DataFrame'

Perform column-wise combine with another DataFrame.

Combines a DataFrame with *other* DataFrame using *func* to element-wise combine columns. The row and column indexes of the resulting DataFrame will be the union of the two.

### Parameters

**other** [DataFrame] The DataFrame to merge column-wise.

**func** [function] Function that takes two series as inputs and return a Series or a scalar. Used to merge the two dataframes column by columns.

**fill\_value** [scalar value, default None] The value to fill NaNs with prior to passing any column to the merge func.

**overwrite** [bool, default True] If True, columns in *self* that do not exist in *other* will be overwritten with NaNs.

### Returns

**DataFrame** Combination of the provided DataFrames.

See also:

**DataFrame.combine\_first** Combine two DataFrame objects and default to non-null values in frame calling the method.

## Examples

Combine using a simple function that chooses the smaller column.

```
>>> df1 = pd.DataFrame({'A': [0, 0], 'B': [4, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [3, 3]})
>>> take_smaller = lambda s1, s2: s1 if s1.sum() < s2.sum() else s2
>>> df1.combine(df2, take_smaller)
   A  B
0  0  3
1  0  3
```

Example using a true element-wise combine function.

```
>>> df1 = pd.DataFrame({'A': [5, 0], 'B': [2, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [3, 3]})
>>> df1.combine(df2, np.minimum)
   A  B
0  1  2
1  0  3
```

Using *fill\_value* fills Nones prior to passing the column to the merge function.

```
>>> df1 = pd.DataFrame({'A': [0, 0], 'B': [None, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [3, 3]})
>>> df1.combine(df2, take_smaller, fill_value=-5)
   A  B
0  0 -5.0
1  0  4.0
```

However, if the same element in both dataframes is None, that None is preserved

```
>>> df1 = pd.DataFrame({'A': [0, 0], 'B': [None, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [None, 3]})
>>> df1.combine(df2, take_smaller, fill_value=-5)
   A  B
0  0 -5.0
1  0  3.0
```

Example that demonstrates the use of *overwrite* and behavior when the axis differ between the dataframes.

```
>>> df1 = pd.DataFrame({'A': [0, 0], 'B': [4, 4]})
>>> df2 = pd.DataFrame({'B': [3, 3], 'C': [-10, 1], }, index=[1, 2])
>>> df1.combine(df2, take_smaller)
   A  B  C
0  NaN NaN NaN
1  NaN 3.0 -10.0
2  NaN 3.0  1.0
```

```
>>> df1.combine(df2, take_smaller, overwrite=False)
   A  B  C
0  0.0 NaN NaN
1  0.0 3.0 -10.0
2  NaN 3.0  1.0
```

Demonstrating the preference of the passed in dataframe.

```
>>> df2 = pd.DataFrame({'B': [3, 3], 'C': [1, 1]}, index=[1, 2])
>>> df2.combine(df1, take_smaller)
   A    B    C
0  0.0 NaN NaN
1  0.0  3.0 NaN
2  NaN  3.0 NaN
```

```
>>> df2.combine(df1, take_smaller, overwrite=False)
   A    B    C
0  0.0 NaN NaN
1  0.0  3.0  1.0
2  NaN  3.0  1.0
```

### pandas.DataFrame.combine\_first

`DataFrame.combine_first` (*self*, *other*: 'DataFrame') → 'DataFrame'

Update null elements with value in the same location in *other*.

Combine two DataFrame objects by filling null values in one DataFrame with non-null values from other DataFrame. The row and column indexes of the resulting DataFrame will be the union of the two.

#### Parameters

**other** [DataFrame] Provided DataFrame to use to fill null values.

#### Returns

**DataFrame**

#### See also:

**DataFrame.combine** Perform series-wise operation on two DataFrames using a given function.

### Examples

```
>>> df1 = pd.DataFrame({'A': [None, 0], 'B': [None, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [3, 3]})
>>> df1.combine_first(df2)
   A    B
0  1.0  3.0
1  0.0  4.0
```

Null values still persist if the location of that null value does not exist in *other*

```
>>> df1 = pd.DataFrame({'A': [None, 0], 'B': [4, None]})
>>> df2 = pd.DataFrame({'B': [3, 3], 'C': [1, 1]}, index=[1, 2])
>>> df1.combine_first(df2)
   A    B    C
0  NaN  4.0 NaN
1  0.0  3.0  1.0
2  NaN  3.0  1.0
```

## pandas.DataFrame.convert\_dtypes

`DataFrame.convert_dtypes` (*self*: ~FrameOrSeries, *infer\_objects*: bool = True, *convert\_string*: bool = True, *convert\_integer*: bool = True, *convert\_boolean*: bool = True) → ~FrameOrSeries

Convert columns to best possible dtypes using dtypes supporting `pd.NA`.

New in version 1.0.0.

### Parameters

**infer\_objects** [bool, default True] Whether object dtypes should be converted to the best possible types.

**convert\_string** [bool, default True] Whether object dtypes should be converted to `StringDtype()`.

**convert\_integer** [bool, default True] Whether, if possible, conversion can be done to integer extension types.

**convert\_boolean** [bool, defaults True] Whether object dtypes should be converted to `BooleanDtypes()`.

### Returns

**Series or DataFrame** Copy of input object with new dtype.

### See also:

***infer\_objects*** Infer dtypes of objects.

***to\_datetime*** Convert argument to datetime.

***to\_timedelta*** Convert argument to timedelta.

***to\_numeric*** Convert argument to a numeric type.

### Notes

By default, `convert_dtypes` will attempt to convert a `Series` (or each `Series` in a `DataFrame`) to dtypes that support `pd.NA`. By using the options `convert_string`, `convert_integer`, and `convert_boolean`, it is possible to turn off individual conversions to `StringDtype`, the integer extension types or `BooleanDtype`, respectively.

For object-dtyped columns, if `infer_objects` is `True`, use the inference rules as during normal `Series/DataFrame` construction. Then, if possible, convert to `StringDtype`, `BooleanDtype` or an appropriate integer extension type, otherwise leave as `object`.

If the dtype is integer, convert to an appropriate integer extension type.

If the dtype is numeric, and consists of all integers, convert to an appropriate integer extension type.

In the future, as new dtypes are added that support `pd.NA`, the results of this method will change to support those new dtypes.

## Examples

```
>>> df = pd.DataFrame(
...     {
...         "a": pd.Series([1, 2, 3], dtype=np.dtype("int32")),
...         "b": pd.Series(["x", "y", "z"], dtype=np.dtype("O")),
...         "c": pd.Series([True, False, np.nan], dtype=np.dtype("O")),
...         "d": pd.Series(["h", "i", np.nan], dtype=np.dtype("O")),
...         "e": pd.Series([10, np.nan, 20], dtype=np.dtype("float")),
...         "f": pd.Series([np.nan, 100.5, 200], dtype=np.dtype("float")),
...     }
... )
```

Start with a DataFrame with default dtypes.

```
>>> df
   a  b    c    d    e    f
0  1  x  True  h  10.0  NaN
1  2  y False  i   NaN 100.5
2  3  z   NaN NaN  20.0 200.0
```

```
>>> df.dtypes
a      int32
b      object
c      object
d      object
e     float64
f     float64
dtype: object
```

Convert the DataFrame to use best possible dtypes.

```
>>> dfn = df.convert_dtypes()
>>> dfn
   a  b    c    d    e    f
0  1  x  True  h   10  NaN
1  2  y False  i  <NA> 100.5
2  3  z  <NA> <NA>  20 200.0
```

```
>>> dfn.dtypes
a      Int32
b      string
c      boolean
d      string
e      Int64
f     float64
dtype: object
```

Start with a Series of strings and missing data represented by np.nan.

```
>>> s = pd.Series(["a", "b", np.nan])
>>> s
0      a
1      b
2     NaN
dtype: object
```

Obtain a Series with dtype `StringDtype`.

```
>>> s.convert_dtypes()
0      a
1      b
2    <NA>
dtype: string
```

## pandas.DataFrame.copy

`DataFrame.copy` (*self*: `~FrameOrSeries`, *deep*: `bool = True`) → `~FrameOrSeries`

Make a copy of this object's indices and data.

When `deep=True` (default), a new object will be created with a copy of the calling object's data and indices. Modifications to the data or indices of the copy will not be reflected in the original object (see notes below).

When `deep=False`, a new object will be created without copying the calling object's data or index (only references to the data and index are copied). Any changes to the data of the original will be reflected in the shallow copy (and vice versa).

### Parameters

**deep** [`bool`, default `True`] Make a deep copy, including a copy of the data and the indices. With `deep=False` neither the indices nor the data are copied.

### Returns

**copy** [`Series` or `DataFrame`] Object type matches caller.

### Notes

When `deep=True`, data is copied but actual Python objects will not be copied recursively, only the reference to the object. This is in contrast to `copy.deepcopy` in the Standard Library, which recursively copies object data (see examples below).

While `Index` objects are copied when `deep=True`, the underlying numpy array is not copied for performance reasons. Since `Index` is immutable, the underlying data can be safely shared and a copy is not needed.

### Examples

```
>>> s = pd.Series([1, 2], index=["a", "b"])
>>> s
a    1
b    2
dtype: int64
```

```
>>> s_copy = s.copy()
>>> s_copy
a    1
b    2
dtype: int64
```

**Shallow copy versus default (deep) copy:**

```
>>> s = pd.Series([1, 2], index=["a", "b"])
>>> deep = s.copy()
>>> shallow = s.copy(deep=False)
```

Shallow copy shares data and index with original.

```
>>> s is shallow
False
>>> s.values is shallow.values and s.index is shallow.index
True
```

Deep copy has own copy of data and index.

```
>>> s is deep
False
>>> s.values is deep.values or s.index is deep.index
False
```

Updates to the data shared by shallow copy and original is reflected in both; deep copy remains unchanged.

```
>>> s[0] = 3
>>> shallow[1] = 4
>>> s
a    3
b    4
dtype: int64
>>> shallow
a    3
b    4
dtype: int64
>>> deep
a    1
b    2
dtype: int64
```

Note that when copying an object containing Python objects, a deep copy will copy the data, but will not do so recursively. Updating a nested data object will be reflected in the deep copy.

```
>>> s = pd.Series([[1, 2], [3, 4]])
>>> deep = s.copy()
>>> s[0][0] = 10
>>> s
0    [10, 2]
1     [3, 4]
dtype: object
>>> deep
0    [10, 2]
1     [3, 4]
dtype: object
```

**pandas.DataFrame.corr**

`DataFrame.corr` (*self*, *method='pearson'*, *min\_periods=1*) → 'DataFrame'  
 Compute pairwise correlation of columns, excluding NA/null values.

**Parameters**

**method** [{ 'pearson', 'kendall', 'spearman' } or callable] Method of correlation:

- **pearson** : standard correlation coefficient
- **kendall** : Kendall Tau correlation coefficient
- **spearman** : Spearman rank correlation
- **callable**: callable with input two 1d ndarrays and returning a float. Note that the returned matrix from corr will have 1 along the diagonals and will be symmetric regardless of the callable's behavior.

New in version 0.24.0.

**min\_periods** [int, optional] Minimum number of observations required per pair of columns to have a valid result. Currently only available for Pearson and Spearman correlation.

**Returns**

**DataFrame** Correlation matrix.

See also:

**DataFrame.corrwith**

**Series.corr**

**Examples**

```
>>> def histogram_intersection(a, b):
...     v = np.minimum(a, b).sum().round(decimals=1)
...     return v
>>> df = pd.DataFrame([(0.2, 0.3), (0.0, 0.6), (0.6, 0.0), (0.2, 0.1)],
...                    columns=['dogs', 'cats'])
>>> df.corr(method=histogram_intersection)
      dogs  cats
dogs    1.0  0.3
cats    0.3  1.0
```

**pandas.DataFrame.corrwith**

`DataFrame.corrwith` (*self*, *other*, *axis=0*, *drop=False*, *method='pearson'*) → pandas.core.series.Series  
 Compute pairwise correlation.

Pairwise correlation is computed between rows or columns of DataFrame with rows or columns of Series or DataFrame. DataFrames are first aligned along both axes before computing the correlations.

**Parameters**

**other** [DataFrame, Series] Object with which to compute correlations.

**axis** [{0 or 'index', 1 or 'columns'}, default 0] The axis to use. 0 or 'index' to compute column-wise, 1 or 'columns' for row-wise.

**drop** [bool, default False] Drop missing indices from result.

**method** [{'pearson', 'kendall', 'spearman'} or callable] Method of correlation:

- pearson : standard correlation coefficient
- kendall : Kendall Tau correlation coefficient
- spearman : Spearman rank correlation
- **callable: callable with input two 1d ndarrays** and returning a float.

New in version 0.24.0.

#### Returns

**Series** Pairwise correlations.

See also:

*DataFrame.corr*

### pandas.DataFrame.count

`DataFrame.count` (*self*, *axis=0*, *level=None*, *numeric\_only=False*)

Count non-NA cells for each column or row.

The values *None*, *NaN*, *NaT*, and optionally *numpy.inf* (depending on *pandas.options.mode.use\_inf\_as\_na*) are considered NA.

#### Parameters

**axis** [{0 or 'index', 1 or 'columns'}, default 0] If 0 or 'index' counts are generated for each column. If 1 or 'columns' counts are generated for each **row**.

**level** [int or str, optional] If the axis is a *MultiIndex* (hierarchical), count along a particular *level*, collapsing into a *DataFrame*. A *str* specifies the level name.

**numeric\_only** [bool, default False] Include only *float*, *int* or *boolean* data.

#### Returns

**Series or DataFrame** For each column/row the number of non-NA/null entries. If *level* is specified returns a *DataFrame*.

See also:

*Series.count* Number of non-NA elements in a Series.

*DataFrame.shape* Number of DataFrame rows and columns (including NA elements).

*DataFrame.isna* Boolean same-sized DataFrame showing places of NA elements.

## Examples

Constructing DataFrame from a dictionary:

```
>>> df = pd.DataFrame({"Person":
...                     ["John", "Myla", "Lewis", "John", "Myla"],
...                     "Age": [24., np.nan, 21., 33, 26],
...                     "Single": [False, True, True, True, False]})
>>> df
   Person  Age  Single
0   John  24.0  False
1   Myla   NaN   True
2  Lewis  21.0   True
3   John  33.0   True
4   Myla  26.0  False
```

Notice the uncounted NA values:

```
>>> df.count()
Person      5
Age         4
Single      5
dtype: int64
```

Counts for each row:

```
>>> df.count(axis='columns')
0      3
1      2
2      3
3      3
4      3
dtype: int64
```

Counts for one level of a *MultiIndex*:

```
>>> df.set_index(["Person", "Single"]).count(level="Person")
      Age
Person
John      2
Lewis     1
Myla      1
```

## pandas.DataFrame.cov

`DataFrame.cov(self, min_periods=None) → 'DataFrame'`

Compute pairwise covariance of columns, excluding NA/null values.

Compute the pairwise covariance among the series of a DataFrame. The returned data frame is the [covariance matrix](#) of the columns of the DataFrame.

Both NA and null values are automatically excluded from the calculation. (See the note below about bias from missing values.) A threshold can be set for the minimum number of observations for each value created. Comparisons with observations below this threshold will be returned as NaN.

This method is generally used for the analysis of time series data to understand the relationship between different measures across time.

**Parameters**

**min\_periods** [int, optional] Minimum number of observations required per pair of columns to have a valid result.

**Returns**

**DataFrame** The covariance matrix of the series of the DataFrame.

**See also:**

**Series.cov** Compute covariance with another Series.

**core.window.EWM.cov** Exponential weighted sample covariance.

**core.window.Expanding.cov** Expanding sample covariance.

**core.window.Rolling.cov** Rolling sample covariance.

**Notes**

Returns the covariance matrix of the DataFrame's time series. The covariance is normalized by N-1.

For DataFrames that have Series that are missing data (assuming that data is [missing at random](#)) the returned covariance matrix will be an unbiased estimate of the variance and covariance between the member Series.

However, for many applications this estimate may not be acceptable because the estimate covariance matrix is not guaranteed to be positive semi-definite. This could lead to estimate correlations having absolute values which are greater than one, and/or a non-invertible covariance matrix. See [Estimation of covariance matrices](#) for more details.

**Examples**

```
>>> df = pd.DataFrame([(1, 2), (0, 3), (2, 0), (1, 1)],
...                   columns=['dogs', 'cats'])
>>> df.cov()
      dogs      cats
dogs  0.666667 -1.000000
cats -1.000000  1.666667
```

```
>>> np.random.seed(42)
>>> df = pd.DataFrame(np.random.randn(1000, 5),
...                   columns=['a', 'b', 'c', 'd', 'e'])
>>> df.cov()
      a          b          c          d          e
a  0.998438 -0.020161  0.059277 -0.008943  0.014144
b -0.020161  1.059352 -0.008543 -0.024738  0.009826
c  0.059277 -0.008543  1.010670 -0.001486 -0.000271
d -0.008943 -0.024738 -0.001486  0.921297 -0.013692
e  0.014144  0.009826 -0.000271 -0.013692  0.977795
```

**Minimum number of periods**

This method also supports an optional `min_periods` keyword that specifies the required minimum number of non-NA observations for each column pair in order to have a valid result:

```

>>> np.random.seed(42)
>>> df = pd.DataFrame(np.random.randn(20, 3),
...                   columns=['a', 'b', 'c'])
>>> df.loc[df.index[:5], 'a'] = np.nan
>>> df.loc[df.index[5:10], 'b'] = np.nan
>>> df.cov(min_periods=12)

```

	a	b	c
a	0.316741	NaN	-0.150812
b	NaN	1.248003	0.191417
c	-0.150812	0.191417	0.895202

## pandas.DataFrame.cummax

`DataFrame.cummax` (*self*, *axis=None*, *skipna=True*, \*args, \*\*kwargs)

Return cumulative maximum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative maximum.

### Parameters

**axis** [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

**skipna** [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

**\*args, \*\*kwargs** : Additional keywords have no effect but might be accepted for compatibility with NumPy.

### Returns

Series or DataFrame

See also:

**core.window.Expanding.max** Similar functionality but ignores NaN values.

**DataFrame.max** Return the maximum over DataFrame axis.

**DataFrame.cummax** Return cumulative maximum over DataFrame axis.

**DataFrame.cummin** Return cumulative minimum over DataFrame axis.

**DataFrame.cumsum** Return cumulative sum over DataFrame axis.

**DataFrame.cumprod** Return cumulative product over DataFrame axis.

## Examples

### Series

```

>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64

```

By default, NA values are ignored.

```
>>> s.cummax()
0    2.0
1    NaN
2    5.0
3    5.0
4    5.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cummax(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

### DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                   [3.0, np.nan],
...                   [1.0, 0.0]],
...                   columns=list('AB'))
>>> df
   A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the maximum in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cummax()
   A    B
0  2.0  1.0
1  3.0  NaN
2  3.0  1.0
```

To iterate over columns and find the maximum in each row, use `axis=1`

```
>>> df.cummax(axis=1)
   A    B
0  2.0  2.0
1  3.0  NaN
2  1.0  1.0
```

**pandas.DataFrame.cummin**

`DataFrame.cummin` (*self*, *axis=None*, *skipna=True*, *\*args*, *\*\*kwargs*)

Return cumulative minimum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative minimum.

**Parameters**

**axis** [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

**skipna** [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

**\*args, \*\*kwargs** : Additional keywords have no effect but might be accepted for compatibility with NumPy.

**Returns**

**Series or DataFrame**

**See also:**

**core.window.Expanding.min** Similar functionality but ignores NaN values.

**DataFrame.min** Return the minimum over DataFrame axis.

**DataFrame.cummax** Return cumulative maximum over DataFrame axis.

**DataFrame.cummin** Return cumulative minimum over DataFrame axis.

**DataFrame.cumsum** Return cumulative sum over DataFrame axis.

**DataFrame.cumprod** Return cumulative product over DataFrame axis.

**Examples****Series**

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cummin()
0    2.0
1    NaN
2    2.0
3   -1.0
4   -1.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cummin(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

### DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                   [3.0, np.nan],
...                   [1.0, 0.0]],
...                   columns=list('AB'))
>>> df
   A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the minimum in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cummin()
   A    B
0  2.0  1.0
1  2.0  NaN
2  1.0  0.0
```

To iterate over columns and find the minimum in each row, use `axis=1`

```
>>> df.cummin(axis=1)
   A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

## pandas.DataFrame.cumprod

`DataFrame.cumprod` (*self*, *axis=None*, *skipna=True*, *\*args*, *\*\*kwargs*)

Return cumulative product over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative product.

### Parameters

**axis** [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

**skipna** [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

**\*args, \*\*kwargs** : Additional keywords have no effect but might be accepted for compatibility with NumPy.

### Returns

Series or DataFrame

See also:

**core.window.Expanding.prod** Similar functionality but ignores NaN values.

**DataFrame.prod** Return the product over DataFrame axis.

**DataFrame.cummax** Return cumulative maximum over DataFrame axis.

**DataFrame.cummin** Return cumulative minimum over DataFrame axis.

**DataFrame.cumsum** Return cumulative sum over DataFrame axis.

**DataFrame.cumprod** Return cumulative product over DataFrame axis.

## Examples

### Series

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cumprod()
0    2.0
1    NaN
2   10.0
3  -10.0
4   -0.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cumprod(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

### DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                   [3.0, np.nan],
...                   [1.0, 0.0]],
...                   columns=list('AB'))
>>> df
   A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the product in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cumprod()
      A      B
0  2.0  1.0
1  6.0  NaN
2  6.0  0.0
```

To iterate over columns and find the product in each row, use `axis=1`

```
>>> df.cumprod(axis=1)
      A      B
0  2.0  2.0
1  3.0  NaN
2  1.0  0.0
```

### pandas.DataFrame.cumsum

`DataFrame.cumsum` (*self*, *axis=None*, *skipna=True*, *\*args*, *\*\*kwargs*)

Return cumulative sum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative sum.

#### Parameters

**axis** [{0 or 'index', 1 or 'columns'}], default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

**skipna** [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

**\*args, \*\*kwargs** : Additional keywords have no effect but might be accepted for compatibility with NumPy.

#### Returns

**Series or DataFrame**

See also:

**core.window.Expanding.sum** Similar functionality but ignores NaN values.

**DataFrame.sum** Return the sum over DataFrame axis.

**DataFrame.cummax** Return cumulative maximum over DataFrame axis.

**DataFrame.cummin** Return cumulative minimum over DataFrame axis.

**DataFrame.cumsum** Return cumulative sum over DataFrame axis.

**DataFrame.cumprod** Return cumulative product over DataFrame axis.

## Examples

### Series

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cumsum()
0    2.0
1    NaN
2    7.0
3    6.0
4    6.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cumsum(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

### DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                   [3.0, np.nan],
...                   [1.0, 0.0]],
...                   columns=list('AB'))
>>> df
   A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the sum in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cumsum()
   A    B
0  2.0  1.0
1  5.0  NaN
2  6.0  1.0
```

To iterate over columns and find the sum in each row, use `axis=1`

```
>>> df.cumsum(axis=1)
   A    B
```

(continues on next page)

(continued from previous page)

0	2.0	3.0
1	3.0	NaN
2	1.0	1.0

**pandas.DataFrame.describe**

`DataFrame.describe` (*self*: ~FrameOrSeries, *percentiles*=None, *include*=None, *exclude*=None) → ~FrameOrSeries  
Generate descriptive statistics.

Descriptive statistics include those that summarize the central tendency, dispersion and shape of a dataset's distribution, excluding NaN values.

Analyzes both numeric and object series, as well as `DataFrame` column sets of mixed data types. The output will vary depending on what is provided. Refer to the notes below for more detail.

**Parameters**

**percentiles** [list-like of numbers, optional] The percentiles to include in the output. All should fall between 0 and 1. The default is `[.25, .5, .75]`, which returns the 25th, 50th, and 75th percentiles.

**include** ['all', list-like of dtypes or None (default), optional] A white list of data types to include in the result. Ignored for `Series`. Here are the options:

- 'all': All columns of the input will be included in the output.
- A list-like of dtypes: Limits the results to the provided data types. To limit the result to numeric types submit `numpy.number`. To limit it instead to object columns submit the `numpy.object` data type. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(include=['O'])`). To select pandas categorical columns, use `'category'`
- None (default): The result will include all numeric columns.

**exclude** [list-like of dtypes or None (default), optional,] A black list of data types to omit from the result. Ignored for `Series`. Here are the options:

- A list-like of dtypes: Excludes the provided data types from the result. To exclude numeric types submit `numpy.number`. To exclude object columns submit the data type `numpy.object`. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(include=['O'])`). To exclude pandas categorical columns, use `'category'`
- None (default): The result will exclude nothing.

**Returns**

**Series or DataFrame** Summary statistics of the Series or DataFrame provided.

**See also:**

**`DataFrame.count`** Count number of non-NA/null observations.

**`DataFrame.max`** Maximum of the values in the object.

**`DataFrame.min`** Minimum of the values in the object.

**`DataFrame.mean`** Mean of the values.

**`DataFrame.std`** Standard deviation of the observations.

**DataFrame.select\_dtypes** Subset of a DataFrame including/excluding columns based on their dtype.

## Notes

For numeric data, the result's index will include `count`, `mean`, `std`, `min`, `max` as well as `lower`, 50 and upper percentiles. By default the lower percentile is 25 and the upper percentile is 75. The 50 percentile is the same as the median.

For object data (e.g. strings or timestamps), the result's index will include `count`, `unique`, `top`, and `freq`. The `top` is the most common value. The `freq` is the most common value's frequency. Timestamps also include the `first` and `last` items.

If multiple object values have the highest count, then the `count` and `top` results will be arbitrarily chosen from among those with the highest count.

For mixed data types provided via a DataFrame, the default is to return only an analysis of numeric columns. If the dataframe consists only of object and categorical data without any numeric columns, the default is to return an analysis of both the object and categorical columns. If `include='all'` is provided as an option, the result will include a union of attributes of each type.

The `include` and `exclude` parameters can be used to limit which columns in a DataFrame are analyzed for the output. The parameters are ignored when analyzing a Series.

## Examples

Describing a numeric Series.

```
>>> s = pd.Series([1, 2, 3])
>>> s.describe()
count      3.0
mean       2.0
std        1.0
min        1.0
25%        1.5
50%        2.0
75%        2.5
max        3.0
dtype: float64
```

Describing a categorical Series.

```
>>> s = pd.Series(['a', 'a', 'b', 'c'])
>>> s.describe()
count      4
unique     3
top        a
freq       2
dtype: object
```

Describing a timestamp Series.

```
>>> s = pd.Series([
...     np.datetime64("2000-01-01"),
...     np.datetime64("2010-01-01"),
...     np.datetime64("2010-01-01")
```

(continues on next page)

(continued from previous page)

```
... ])
>>> s.describe()
count                3
unique                2
top      2010-01-01 00:00:00
freq                2
first    2000-01-01 00:00:00
last     2010-01-01 00:00:00
dtype: object
```

Describing a DataFrame. By default only numeric fields are returned.

```
>>> df = pd.DataFrame({'categorical': pd.Categorical(['d', 'e', 'f']),
...                   'numeric': [1, 2, 3],
...                   'object': ['a', 'b', 'c']
...                   })
>>> df.describe()
      numeric
count      3.0
mean       2.0
std        1.0
min        1.0
25%        1.5
50%        2.0
75%        2.5
max        3.0
```

Describing all columns of a DataFrame regardless of data type.

```
>>> df.describe(include='all')
      categorical  numeric  object
count           3        3.0      3
unique           3        NaN      3
top             f        NaN      c
freq            1        NaN      1
mean           NaN        2.0     NaN
std            NaN        1.0     NaN
min            NaN        1.0     NaN
25%            NaN        1.5     NaN
50%            NaN        2.0     NaN
75%            NaN        2.5     NaN
max            NaN        3.0     NaN
```

Describing a column from a DataFrame by accessing it as an attribute.

```
>>> df.numeric.describe()
count      3.0
mean       2.0
std        1.0
min        1.0
25%        1.5
50%        2.0
75%        2.5
max        3.0
Name: numeric, dtype: float64
```

Including only numeric columns in a DataFrame description.

```
>>> df.describe(include=[np.number])
      numeric
count      3.0
mean       2.0
std        1.0
min        1.0
25%        1.5
50%        2.0
75%        2.5
max        3.0
```

Including only string columns in a DataFrame description.

```
>>> df.describe(include=[np.object])
      object
count      3
unique     3
top        c
freq       1
```

Including only categorical columns from a DataFrame description.

```
>>> df.describe(include=['category'])
      categorical
count          3
unique         3
top            f
freq           1
```

Excluding numeric columns from a DataFrame description.

```
>>> df.describe(exclude=[np.number])
      categorical  object
count           3      3
unique          3      3
top             f      c
freq            1      1
```

Excluding object columns from a DataFrame description.

```
>>> df.describe(exclude=[np.object])
      categorical  numeric
count           3      3.0
unique          3      NaN
top             f      NaN
freq            1      NaN
mean            NaN      2.0
std             NaN      1.0
min             NaN      1.0
25%            NaN      1.5
50%            NaN      2.0
75%            NaN      2.5
max            NaN      3.0
```

**pandas.DataFrame.diff**

`DataFrame.diff` (*self*, *periods=1*, *axis=0*) → 'DataFrame'

First discrete difference of element.

Calculates the difference of a DataFrame element compared with another element in the DataFrame (default is the element in the same column of the previous row).

**Parameters**

**periods** [int, default 1] Periods to shift for calculating difference, accepts negative values.

**axis** [{0 or 'index', 1 or 'columns'}, default 0] Take difference over rows (0) or columns (1).

**Returns**

**DataFrame**

**See also:**

**Series.diff** First discrete difference for a Series.

**DataFrame.pct\_change** Percent change over given number of periods.

**DataFrame.shift** Shift index by desired number of periods with an optional time freq.

**Notes**

For boolean dtypes, this uses `operator.xor()` rather than `operator.sub()`.

**Examples**

Difference with previous row

```
>>> df = pd.DataFrame({'a': [1, 2, 3, 4, 5, 6],
...                    'b': [1, 1, 2, 3, 5, 8],
...                    'c': [1, 4, 9, 16, 25, 36]})
>>> df
   a  b  c
0  1  1  1
1  2  1  4
2  3  2  9
3  4  3 16
4  5  5 25
5  6  8 36
```

```
>>> df.diff()
   a  b  c
0 NaN NaN NaN
1 1.0 0.0 3.0
2 1.0 1.0 5.0
3 1.0 1.0 7.0
4 1.0 2.0 9.0
5 1.0 3.0 11.0
```

Difference with previous column

```
>>> df.diff(axis=1)
   a    b    c
0 NaN  0.0  0.0
1 NaN -1.0  3.0
2 NaN -1.0  7.0
3 NaN -1.0 13.0
4 NaN  0.0 20.0
5 NaN  2.0 28.0
```

Difference with 3rd previous row

```
>>> df.diff( periods=3)
   a    b    c
0 NaN NaN NaN
1 NaN NaN NaN
2 NaN NaN NaN
3 3.0 2.0 15.0
4 3.0 4.0 21.0
5 3.0 6.0 27.0
```

Difference with following row

```
>>> df.diff( periods=-1)
   a    b    c
0 -1.0 0.0 -3.0
1 -1.0 -1.0 -5.0
2 -1.0 -1.0 -7.0
3 -1.0 -2.0 -9.0
4 -1.0 -3.0 -11.0
5 NaN NaN NaN
```

## pandas.DataFrame.div

`DataFrame.div` (*self*, *other*, *axis='columns'*, *level=None*, *fill\_value=None*)

Get Floating division of dataframe and other, element-wise (binary operator *truediv*).

Equivalent to `dataframe / other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *rtruediv*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

### Parameters

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

**level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

**fill\_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

### Returns

**DataFrame** Result of the arithmetic operation.

See also:

**DataFrame.add** Add DataFrames.

**DataFrame.sub** Subtract DataFrames.

**DataFrame.mul** Multiply DataFrames.

**DataFrame.div** Divide DataFrames (float division).

**DataFrame.truediv** Divide DataFrames (float division).

**DataFrame.floordiv** Divide DataFrames (integer division).

**DataFrame.mod** Calculate modulo (remainder after division).

**DataFrame.pow** Calculate exponential power.

## Notes

Mismatched indices will be unioned together.

## Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

	angles	degrees
circle	0	360
triangle	3	180
rectangle	4	360

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

```
>>> df.add(1)
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

Divide by constant with reverse version.

```
>>> df.div(10)
```

	angles	degrees
circle	0.0	36.0
triangle	0.3	18.0
rectangle	0.4	36.0

```
>>> df.rdiv(10)
           angles  degrees
circle      inf  0.027778
triangle  3.333333  0.055556
rectangle  2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
           angles  degrees
circle      -1    358
triangle     2    178
rectangle     3    358
```

```
>>> df.sub([1, 2], axis='columns')
           angles  degrees
circle      -1    358
triangle     2    178
rectangle     3    358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
           angles  degrees
circle      -1    359
triangle     2    179
rectangle     3    359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
           angles
circle          0
triangle         3
rectangle        4
```

```
>>> df * other
           angles  degrees
circle          0     NaN
triangle         9     NaN
rectangle       16     NaN
```

```
>>> df.mul(other, fill_value=0)
           angles  degrees
circle          0     0.0
triangle         9     0.0
rectangle       16     0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                               index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                       ['circle', 'triangle', 'rectangle',
...                                       'square', 'pentagon', 'hexagon']])
```

(continues on next page)

(continued from previous page)

```
>>> df_multindex
      angles  degrees
A circle    0    360
  triangle    3    180
  rectangle    4    360
B square    4    360
  pentagon    5    540
  hexagon    6    720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
      angles  degrees
A circle   NaN    1.0
  triangle  1.0    1.0
  rectangle  1.0    1.0
B square   0.0    0.0
  pentagon  0.0    0.0
  hexagon   0.0    0.0
```

### pandas.DataFrame.divide

`DataFrame.divide` (*self*, *other*, *axis='columns'*, *level=None*, *fill\_value=None*)

Get Floating division of dataframe and other, element-wise (binary operator *truediv*).

Equivalent to `dataframe / other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *rtruediv*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

#### Parameters

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

**level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

**fill\_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

#### Returns

**DataFrame** Result of the arithmetic operation.

See also:

**DataFrame.add** Add DataFrames.

**DataFrame.sub** Subtract DataFrames.

**DataFrame.mul** Multiply DataFrames.

**DataFrame.div** Divide DataFrames (float division).

**DataFrame.truediv** Divide DataFrames (float division).

**DataFrame.floordiv** Divide DataFrames (integer division).

**DataFrame.mod** Calculate modulo (remainder after division).

**DataFrame.pow** Calculate exponential power.

## Notes

Mismatched indices will be unioned together.

## Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

	angles	degrees
circle	0	360
triangle	3	180
rectangle	4	360

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

```
>>> df.add(1)
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

Divide by constant with reverse version.

```
>>> df.div(10)
```

	angles	degrees
circle	0.0	36.0
triangle	0.3	18.0
rectangle	0.4	36.0

```
>>> df.rdiv(10)
```

	angles	degrees
circle	inf	0.027778
triangle	3.333333	0.055556
rectangle	2.500000	0.027778

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
```

	angles	degrees
circle	-1	358
triangle	2	178
rectangle	3	358

```
>>> df.sub([1, 2], axis='columns')
          angles  degrees
circle      -1    358
triangle     2    178
rectangle    3    358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
          angles  degrees
circle      -1    359
triangle     2    179
rectangle    3    359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
          angles
circle         0
triangle        3
rectangle       4
```

```
>>> df * other
          angles  degrees
circle         0     NaN
triangle        9     NaN
rectangle      16     NaN
```

```
>>> df.mul(other, fill_value=0)
          angles  degrees
circle         0     0.0
triangle        9     0.0
rectangle      16     0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                              'degrees': [360, 180, 360, 360, 540, 720]},
...                              index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                      ['circle', 'triangle', 'rectangle',
...                                       'square', 'pentagon', 'hexagon']])
>>> df_multindex
          angles  degrees
A circle         0    360
  triangle        3    180

hexagon	0.0	0.0

## pandas.DataFrame.dot

DataFrame.**dot** (*self*, *other*)

Compute the matrix multiplication between the DataFrame and other.

This method computes the matrix product between the DataFrame and the values of an other Series, DataFrame or a numpy array.

It can also be called using `self @ other` in Python  $\geq 3.5$ .

### Parameters

**other** [Series, DataFrame or array-like] The other object to compute the matrix product with.

### Returns

**Series or DataFrame** If other is a Series, return the matrix product between self and other as a Serie. If other is a DataFrame or a numpy.array, return the matrix product of self and other in a DataFrame of a np.array.

### See also:

**Series.dot** Similar method for Series.

### Notes

The dimensions of DataFrame and other must be compatible in order to compute the matrix multiplication. In addition, the column names of DataFrame and the index of other must contain the same values, as they will be aligned prior to the multiplication.

The dot method for Series computes the inner product, instead of the matrix product here.

### Examples

Here we multiply a DataFrame with a Series.

```
>>> df = pd.DataFrame([[0, 1, -2, -1], [1, 1, 1, 1]])
>>> s = pd.Series([1, 1, 2, 1])
>>> df.dot(s)
0    -4
1     5
dtype: int64
```

Here we multiply a DataFrame with another DataFrame.

```
>>> other = pd.DataFrame([[0, 1], [1, 2], [-1, -1], [2, 0]])
>>> df.dot(other)
0    1
0    1    4
1    2    2
```

Note that the dot method give the same result as @

```
>>> df @ other
   0  1
0  1  4
1  2  2
```

The dot method works also if other is an np.array.

```
>>> arr = np.array([[0, 1], [1, 2], [-1, -1], [2, 0]])
>>> df.dot(arr)
   0  1
0  1  4
1  2  2
```

Note how shuffling of the objects does not change the result.

```
>>> s2 = s.reindex([1, 0, 2, 3])
>>> df.dot(s2)
   0  -4
   1   5
dtype: int64
```

## pandas.DataFrame.drop

`DataFrame.drop` (*self*, *labels=None*, *axis=0*, *index=None*, *columns=None*, *level=None*, *inplace=False*, *errors='raise'*)

Drop specified labels from rows or columns.

Remove rows or columns by specifying label names and corresponding axis, or by specifying directly index or column names. When using a multi-index, labels on different levels can be removed by specifying the level.

### Parameters

**labels** [single label or list-like] Index or column labels to drop.

**axis** [{0 or 'index', 1 or 'columns'}, default 0] Whether to drop labels from the index (0 or 'index') or columns (1 or 'columns').

**index** [single label or list-like] Alternative to specifying axis (*labels*, *axis=0* is equivalent to *index=labels*).

New in version 0.21.0.

**columns** [single label or list-like] Alternative to specifying axis (*labels*, *axis=1* is equivalent to *columns=labels*).

New in version 0.21.0.

**level** [int or level name, optional] For MultiIndex, level from which the labels will be removed.

**inplace** [bool, default False] If True, do operation inplace and return None.

**errors** [{ 'ignore', 'raise' }, default 'raise'] If 'ignore', suppress error and only existing labels are dropped.

### Returns

**DataFrame** DataFrame without the removed index or column labels.

**Raises**

**KeyError** If any of the labels is not found in the selected axis.

**See also:**

**DataFrame.ioc** Label-location based indexer for selection by label.

**DataFrame.dropna** Return DataFrame with labels on given axis omitted where (all or any) data are missing.

**DataFrame.drop\_duplicates** Return DataFrame with duplicate rows removed, optionally only considering certain columns.

**Series.drop** Return Series with specified index labels removed.

**Examples**

```
>>> df = pd.DataFrame(np.arange(12).reshape(3, 4),
...                    columns=['A', 'B', 'C', 'D'])
>>> df
   A  B  C  D
0  0  1  2  3
1  4  5  6  7
2  8  9 10 11
```

**Drop columns**

```
>>> df.drop(['B', 'C'], axis=1)
   A  D
0  0  3
1  4  7
2  8 11
```

```
>>> df.drop(columns=['B', 'C'])
   A  D
0  0  3
1  4  7
2  8 11
```

**Drop a row by index**

```
>>> df.drop([0, 1])
   A  B  C  D
2  8  9 10 11
```

**Drop columns and/or rows of MultiIndex DataFrame**

```
>>> midx = pd.MultiIndex(levels=[['lama', 'cow', 'falcon'],
...                             ['speed', 'weight', 'length']],
...                      codes=[[0, 0, 0, 1, 1, 1, 2, 2, 2],
...                             [0, 1, 2, 0, 1, 2, 0, 1, 2]])
>>> df = pd.DataFrame(index=midx, columns=['big', 'small'],
...                   data=[[45, 30], [200, 100], [1.5, 1], [30, 20],
...                          [250, 150], [1.5, 0.8], [320, 250],
...                          [1, 0.8], [0.3, 0.2]])
>>> df
```

(continues on next page)

(continued from previous page)

```

lama      big      small
speed    45.0     30.0
weight   200.0    100.0
length   1.5      1.0
cow       speed    30.0     20.0
weight   250.0    150.0
length   1.5      0.8
falcon   speed    320.0    250.0
weight   1.0      0.8
length   0.3      0.2

```

```

>>> df.drop(index='cow', columns='small')
lama      big
speed    45.0
weight   200.0
length   1.5
falcon   speed    320.0
weight   1.0
length   0.3

```

```

>>> df.drop(index='length', level=1)
lama      big      small
speed    45.0     30.0
weight   200.0    100.0
cow       speed    30.0     20.0
weight   250.0    150.0
falcon   speed    320.0    250.0
weight   1.0      0.8

```

### pandas.DataFrame.drop\_duplicates

`DataFrame.drop_duplicates` (*self*, *subset*: Union[Hashable, Sequence[Hashable], NoneType] = None, *keep*: Union[str, bool] = 'first', *inplace*: bool = False, *ignore\_index*: bool = False) → Union[ForwardRef('DataFrame'), NoneType]

Return DataFrame with duplicate rows removed.

Considering certain columns is optional. Indexes, including time indexes are ignored.

#### Parameters

**subset** [column label or sequence of labels, optional] Only consider certain columns for identifying duplicates, by default use all of the columns.

**keep** [{ 'first', 'last', False }, default 'first'] Determines which duplicates (if any) to keep. - *first* : Drop duplicates except for the first occurrence. - *last* : Drop duplicates except for the last occurrence. - *False* : Drop all duplicates.

**inplace** [bool, default False] Whether to drop duplicates in place or to return a copy.

**ignore\_index** [bool, default False] If True, the resulting axis will be labeled 0, 1, ..., n - 1.

New in version 1.0.0.

#### Returns

**DataFrame** DataFrame with duplicates removed or None if `inplace=True`.

### pandas.DataFrame.droplevel

DataFrame.**droplevel** (*self*: ~FrameOrSeries, *level*, *axis=0*) → ~FrameOrSeries

Return DataFrame with requested index / column level(s) removed.

New in version 0.24.0.

#### Parameters

**level** [int, str, or list-like] If a string is given, must be the name of a level. If list-like, elements must be names or positional indexes of levels.

**axis** [{0 or 'index', 1 or 'columns'}, default 0]

#### Returns

**DataFrame** DataFrame with requested index / column level(s) removed.

### Examples

```
>>> df = pd.DataFrame([
...     [1, 2, 3, 4],
...     [5, 6, 7, 8],
...     [9, 10, 11, 12]
... ]).set_index([0, 1]).rename_axis(['a', 'b'])
```

```
>>> df.columns = pd.MultiIndex.from_tuples([
...     ('c', 'e'), ('d', 'f')
... ], names=['level_1', 'level_2'])
```

```
>>> df
level_1  c  d
level_2  e  f
a b
1 2      3  4
5 6      7  8
9 10     11 12
```

```
>>> df.droplevel('a')
level_1  c  d
level_2  e  f
b
2      3  4
6      7  8
10     11 12
```

```
>>> df.droplevel('level2', axis=1)
level_1  c  d
a b
1 2      3  4
5 6      7  8
9 10     11 12
```

**pandas.DataFrame.dropna**

`DataFrame.dropna` (*self*, *axis=0*, *how='any'*, *thresh=None*, *subset=None*, *inplace=False*)  
Remove missing values.

See the *User Guide* for more on which values are considered missing, and how to work with missing data.

**Parameters**

**axis** [{0 or 'index', 1 or 'columns'}, default 0] Determine if rows or columns which contain missing values are removed.

- 0, or 'index' : Drop rows which contain missing values.
- 1, or 'columns' : Drop columns which contain missing value.

Changed in version 1.0.0: Pass tuple or list to drop on multiple axes. Only a single axis is allowed.

**how** [{'any', 'all'}, default 'any'] Determine if row or column is removed from DataFrame, when we have at least one NA or all NA.

- 'any' : If any NA values are present, drop that row or column.
- 'all' : If all values are NA, drop that row or column.

**thresh** [int, optional] Require that many non-NA values.

**subset** [array-like, optional] Labels along other axis to consider, e.g. if you are dropping rows these would be a list of columns to include.

**inplace** [bool, default False] If True, do operation inplace and return None.

**Returns**

**DataFrame** DataFrame with NA entries dropped from it.

See also:

**DataFrame.isna** Indicate missing values.

**DataFrame.notna** Indicate existing (non-missing) values.

**DataFrame.fillna** Replace missing values.

**Series.dropna** Drop missing values.

**Index.dropna** Drop missing indices.

**Examples**

```
>>> df = pd.DataFrame({"name": ['Alfred', 'Batman', 'Catwoman'],
...                    "toy": [np.nan, 'Batmobile', 'Bullwhip'],
...                    "born": [pd.NaT, pd.Timestamp("1940-04-25"),
...                              pd.NaT]})
>>> df
   name      toy      born
0  Alfred    NaN      NaT
1  Batman  Batmobile  1940-04-25
2  Catwoman  Bullwhip      NaT
```

Drop the rows where at least one element is missing.

```
>>> df.dropna()
      name      toy      born
1  Batman  Batmobile 1940-04-25
```

Drop the columns where at least one element is missing.

```
>>> df.dropna(axis='columns')
      name
0  Alfred
1  Batman
2  Catwoman
```

Drop the rows where all elements are missing.

```
>>> df.dropna(how='all')
      name      toy      born
0  Alfred      NaN      NaT
1  Batman  Batmobile 1940-04-25
2  Catwoman  Bullwhip      NaT
```

Keep only the rows with at least 2 non-NA values.

```
>>> df.dropna(thresh=2)
      name      toy      born
1  Batman  Batmobile 1940-04-25
2  Catwoman  Bullwhip      NaT
```

Define in which columns to look for missing values.

```
>>> df.dropna(subset=['name', 'born'])
      name      toy      born
1  Batman  Batmobile 1940-04-25
```

Keep the DataFrame with valid entries in the same variable.

```
>>> df.dropna(inplace=True)
>>> df
      name      toy      born
1  Batman  Batmobile 1940-04-25
```

## pandas.DataFrame.duplicated

`DataFrame.duplicated` (*self*, *subset*: Union[Hashable, Sequence[Hashable], NoneType] = None, *keep*: Union[str, bool] = 'first') → 'Series'

Return boolean Series denoting duplicate rows.

Considering certain columns is optional.

### Parameters

**subset** [column label or sequence of labels, optional] Only consider certain columns for identifying duplicates, by default use all of the columns.

**keep** [{‘first’, ‘last’, False}, default ‘first’] Determines which duplicates (if any) to mark.

- `first`: Mark duplicates as True except for the first occurrence.

- `last` : Mark duplicates as `True` except for the last occurrence.
- `False` : Mark all duplicates as `True`.

### Returns

Series

## pandas.DataFrame.eq

`DataFrame.eq` (*self*, *other*, *axis='columns'*, *level=None*)

Get Equal to of dataframe and other, element-wise (binary operator *eq*).

Among flexible wrappers (*eq*, *ne*, *le*, *lt*, *ge*, *gt*) to comparison operators.

Equivalent to `==`, `!=`, `<=`, `<`, `>=`, `>` with support to choose axis (rows or columns) and level for comparison.

### Parameters

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}, default 'columns'] Whether to compare by the index (0 or 'index') or columns (1 or 'columns').

**level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

### Returns

**DataFrame of bool** Result of the comparison.

### See also:

**DataFrame.eq** Compare DataFrames for equality elementwise.

**DataFrame.ne** Compare DataFrames for inequality elementwise.

**DataFrame.le** Compare DataFrames for less than inequality or equality elementwise.

**DataFrame.lt** Compare DataFrames for strictly less than inequality elementwise.

**DataFrame.ge** Compare DataFrames for greater than inequality or equality elementwise.

**DataFrame.gt** Compare DataFrames for strictly greater than inequality elementwise.

### Notes

Mismatched indices will be unioned together. *NaN* values are considered different (i.e. *NaN != NaN*).

## Examples

```
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                    'revenue': [100, 250, 300]},
...                    index=['A', 'B', 'C'])
>>> df
   cost  revenue
A    250     100
B    150     250
C    100     300
```

Comparison with a scalar, using either the operator or method:

```
>>> df == 100
   cost  revenue
A  False     True
B  False    False
C   True    False
```

```
>>> df.eq(100)
   cost  revenue
A  False     True
B  False    False
C   True    False
```

When *other* is a *Series*, the columns of a *DataFrame* are aligned with the index of *other* and broadcast:

```
>>> df != pd.Series([100, 250], index=["cost", "revenue"])
   cost  revenue
A   True     True
B   True    False
C  False     True
```

Use the method to control the broadcast axis:

```
>>> df.ne(pd.Series([100, 300], index=["A", "D"]), axis='index')
   cost  revenue
A   True    False
B   True     True
C   True     True
D   True     True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in *other*:

```
>>> df == [250, 100]
   cost  revenue
A   True     True
B  False    False
C  False    False
```

Use the method to control the axis:

```
>>> df.eq([250, 250, 100], axis='index')
   cost  revenue
A   True    False
```

(continues on next page)

(continued from previous page)

```
B False    True
C  True    False
```

Compare to a DataFrame of different shape.

```
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
...                        index=['A', 'B', 'C', 'D'])
>>> other
   revenue
A        300
B        250
C         100
D         150
```

```
>>> df.gt(other)
   cost  revenue
A False   False
B False   False
C False    True
D False   False
```

Compare to a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
...                               'revenue': [100, 250, 300, 200, 175, 225]},
...                               index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
...                                       ['A', 'B', 'C', 'A', 'B', 'C']])
>>> df_multindex
   cost  revenue
Q1 A   250     100
   B   150     250
   C   100     300
Q2 A   150     200
   B   300     175
   C   220     225
```

```
>>> df.le(df_multindex, level=1)
   cost  revenue
Q1 A   True    True
   B   True    True
   C   True    True
Q2 A  False    True
   B   True    False
   C   True    False
```

## pandas.DataFrame.equals

DataFrame.**equals** (*self*, *other*)

Test whether two objects contain the same elements.

This function allows two Series or DataFrames to be compared against each other to see if they have the same shape and elements. NaNs in the same location are considered equal. The column headers do not need to have the same type, but the elements within the columns must be the same dtype.

### Parameters

**other** [Series or DataFrame] The other Series or DataFrame to be compared with the first.

### Returns

**bool** True if all elements are the same in both objects, False otherwise.

### See also:

**Series.eq** Compare two Series objects of the same length and return a Series where each element is True if the element in each Series is equal, False otherwise.

**DataFrame.eq** Compare two DataFrame objects of the same shape and return a DataFrame where each element is True if the respective element in each DataFrame is equal, False otherwise.

**testing.assert\_series\_equal** Raises an AssertionError if left and right are not equal. Provides an easy interface to ignore inequality in dtypes, indexes and precision among others.

**testing.assert\_frame\_equal** Like assert\_series\_equal, but targets DataFrames.

**numpy.array\_equal** Return True if two arrays have the same shape and elements, False otherwise.

### Notes

This function requires that the elements have the same dtype as their respective elements in the other Series or DataFrame. However, the column labels do not need to have the same type, as long as they are still considered equal.

### Examples

```
>>> df = pd.DataFrame({'1': [10], '2': [20]})
>>> df
   1  2
0 10 20
```

DataFrames df and exactly\_equal have the same types and values for their elements and column labels, which will return True.

```
>>> exactly_equal = pd.DataFrame({'1': [10], '2': [20]})
>>> exactly_equal
   1  2
0 10 20
>>> df.equals(exactly_equal)
True
```

DataFrames df and different\_column\_type have the same element types and values, but have different types for the column labels, which will still return True.

```

>>> different_column_type = pd.DataFrame({1.0: [10], 2.0: [20]})
>>> different_column_type
   1.0  2.0
0    10   20
>>> df.equals(different_column_type)
True

```

DataFrames `df` and `different_data_type` have different types for the same values for their elements, and will return `False` even though their column labels are the same values and types.

```

>>> different_data_type = pd.DataFrame({1: [10.0], 2: [20.0]})
>>> different_data_type
   1    2
0 10.0 20.0
>>> df.equals(different_data_type)
False

```

### pandas.DataFrame.eval

`DataFrame.eval` (*self*, *expr*, *inplace=False*, *\*\*kwargs*)

Evaluate a string describing operations on DataFrame columns.

Operates on columns only, not specific rows or elements. This allows *eval* to run arbitrary code, which can make you vulnerable to code injection if you pass user input to this function.

#### Parameters

**expr** [str] The expression string to evaluate.

**inplace** [bool, default False] If the expression contains an assignment, whether to perform the operation inplace and mutate the existing DataFrame. Otherwise, a new DataFrame is returned.

**\*\*kwargs** See the documentation for *eval()* for complete details on the keyword arguments accepted by *query()*.

#### Returns

**ndarray, scalar, or pandas object** The result of the evaluation.

See also:

**DataFrame.query** Evaluates a boolean expression to query the columns of a frame.

**DataFrame.assign** Can evaluate an expression or function to create new values for a column.

**eval** Evaluate a Python expression as a string using various backends.

## Notes

For more details see the API documentation for `eval()`. For detailed examples see *enhancing performance with eval*.

## Examples

```
>>> df = pd.DataFrame({'A': range(1, 6), 'B': range(10, 0, -2)})
>>> df
   A  B
0  1 10
1  2  8
2  3  6
3  4  4
4  5  2
>>> df.eval('A + B')
0    11
1    10
2     9
3     8
4     7
dtype: int64
```

Assignment is allowed though by default the original DataFrame is not modified.

```
>>> df.eval('C = A + B')
   A  B  C
0  1 10 11
1  2  8 10
2  3  6  9
3  4  4  8
4  5  2  7
>>> df
   A  B
0  1 10
1  2  8
2  3  6
3  4  4
4  5  2
```

Use `inplace=True` to modify the original DataFrame.

```
>>> df.eval('C = A + B', inplace=True)
>>> df
   A  B  C
0  1 10 11
1  2  8 10
2  3  6  9
3  4  4  8
4  5  2  7
```

**pandas.DataFrame.ewm**

`DataFrame.ewm`(*self*, *com=None*, *span=None*, *halflife=None*, *alpha=None*, *min\_periods=0*, *adjust=True*, *ignore\_na=False*, *axis=0*)

Provide exponential weighted functions.

**Parameters**

**com** [float, optional] Specify decay in terms of center of mass,  $\alpha = 1/(1 + com)$ , for  $com \geq 0$ .

**span** [float, optional] Specify decay in terms of span,  $\alpha = 2/(span+1)$ , for  $span \geq 1$ .

**halflife** [float, optional] Specify decay in terms of half-life,  $\alpha = 1 - \exp(\log(0.5)/halflife)$ , for  $halflife > 0$ .

**alpha** [float, optional] Specify smoothing factor  $\alpha$  directly,  $0 < \alpha \leq 1$ .

**min\_periods** [int, default 0] Minimum number of observations in window required to have a value (otherwise result is NA).

**adjust** [bool, default True] Divide by decaying adjustment factor in beginning periods to account for imbalance in relative weightings (viewing EWMA as a moving average).

**ignore\_na** [bool, default False] Ignore missing values when calculating weights; specify True to reproduce pre-0.15.0 behavior.

**axis** [{0 or 'index', 1 or 'columns'}, default 0] The axis to use. The value 0 identifies the rows, and 1 identifies the columns.

**Returns**

**DataFrame** A Window sub-classed for the particular operation.

**See also:**

**rolling** Provides rolling window calculations.

**expanding** Provides expanding transformations.

**Notes**

Exactly one of center of mass, span, half-life, and alpha must be provided. Allowed values and relationship between the parameters are specified in the parameter descriptions above; see the link at the end of this section for a detailed explanation.

When `adjust` is True (default), weighted averages are calculated using weights  $(1-\alpha)^{(n-1)}$ ,  $(1-\alpha)^{(n-2)}$ , ...,  $1-\alpha$ , 1.

**When `adjust` is False, weighted averages are calculated recursively as:** `weighted_average[0] = arg[0]`; `weighted_average[i] = (1-alpha)*weighted_average[i-1] + alpha*arg[i]`.

When `ignore_na` is False (default), weights are based on absolute positions. For example, the weights of `x` and `y` used in calculating the final weighted average of `[x, None, y]` are  $(1-\alpha)^{**2}$  and 1 (if `adjust` is True), and  $(1-\alpha)^{**2}$  and `alpha` (if `adjust` is False).

When `ignore_na` is True (reproducing pre-0.15.0 behavior), weights are based on relative positions. For example, the weights of `x` and `y` used in calculating the final weighted average of `[x, None, y]` are `1-alpha` and 1 (if `adjust` is True), and `1-alpha` and `alpha` (if `adjust` is False).

More details can be found at [https://pandas.pydata.org/pandas-docs/stable/user\\_guide/computation.html#exponentially-weighted-windows](https://pandas.pydata.org/pandas-docs/stable/user_guide/computation.html#exponentially-weighted-windows)

### Examples

```
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
>>> df
   B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0
```

```
>>> df.ewm(com=0.5).mean()
   B
0  0.000000
1  0.750000
2  1.615385
3  1.615385
4  3.670213
```

### pandas.DataFrame.expanding

DataFrame.**expanding** (*self*, *min\_periods=1*, *center=False*, *axis=0*)

Provide expanding transformations.

#### Parameters

**min\_periods** [int, default 1] Minimum number of observations in window required to have a value (otherwise result is NA).

**center** [bool, default False] Set the labels at the center of the window.

**axis** [int or str, default 0]

#### Returns

a Window sub-classed for the particular operation

#### See also:

**rolling** Provides rolling window calculations.

**ewm** Provides exponential weighted functions.

## Notes

By default, the result is set to the right edge of the window. This can be changed to the center of the window by setting `center=True`.

## Examples

```
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
      B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0
```

```
>>> df.expanding(2).sum()
      B
0  NaN
1  1.0
2  3.0
3  3.0
4  7.0
```

## pandas.DataFrame.explode

`DataFrame.explode` (*self*, *column*: *Union[str, Tuple]*) → 'DataFrame'  
Transform each element of a list-like to a row, replicating index values.

New in version 0.25.0.

### Parameters

**column** [str or tuple] Column to explode.

### Returns

**DataFrame** Exploded lists to rows of the subset columns; index will be duplicated for these rows.

### Raises

**ValueError** : if columns of the frame are not unique.

### See also:

**DataFrame.unstack** Pivot a level of the (necessarily hierarchical) index labels.

**DataFrame.melt** Unpivot a DataFrame from wide format to long format.

**Series.explode** Explode a DataFrame from list-like columns to long format.

## Notes

This routine will explode list-likes including lists, tuples, Series, and np.ndarray. The result dtype of the subset rows will be object. Scalars will be returned unchanged. Empty list-likes will result in a np.nan for that row.

## Examples

```
>>> df = pd.DataFrame({'A': [[1, 2, 3], 'foo', [], [3, 4]], 'B': 1})
>>> df
```

	A	B
0	[1, 2, 3]	1
1	foo	1
2	[]	1
3	[3, 4]	1

```
>>> df.explode('A')
```

	A	B
0	1	1
0	2	1
0	3	1
1	foo	1
2	NaN	1
3	3	1
3	4	1

## pandas.DataFrame.ffill

`DataFrame.fffll` (*self*: ~FrameOrSeries, *axis=None*, *inplace: bool = False*, *limit=None*, *downcast=None*) → Union[~FrameOrSeries, NoneType]

Synonym for `DataFrame.fillna()` with `method='ffill'`.

### Returns

%(klass)s or None Object with missing values filled or None if `inplace=True`.

## pandas.DataFrame.fillna

`DataFrame.fillna` (*self*, *value=None*, *method=None*, *axis=None*, *inplace=False*, *limit=None*, *downcast=None*) → Union[ForwardRef('DataFrame'), NoneType]

Fill NA/NaN values using the specified method.

### Parameters

**value** [scalar, dict, Series, or DataFrame] Value to use to fill holes (e.g. 0), alternately a dict/Series/DataFrame of values specifying which value to use for each index (for a Series) or column (for a DataFrame). Values not in the dict/Series/DataFrame will not be filled. This value cannot be a list.

**method** [{ 'backfill', 'bfill', 'pad', 'ffill', None }, default None] Method to use for filling holes in reindexed Series `pad` / `ffill`: propagate last valid observation forward to next valid `backfill` / `bfill`: use next valid observation to fill gap.

**axis** [{0 or 'index', 1 or 'columns'}] Axis along which to fill missing values.

**inplace** [bool, default False] If True, fill in-place. Note: this will modify any other views on this object (e.g., a no-copy slice for a column in a DataFrame).

**limit** [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

**downcast** [dict, default is None] A dict of item->dtype of what to downcast if possible, or the string 'infer' which will try to downcast to an appropriate equal type (e.g. float64 to int64 if possible).

### Returns

**DataFrame or None** Object with missing values filled or None if `inplace=True`.

### See also:

***interpolate*** Fill NaN values using interpolation.

***reindex*** Conform object to new index.

***asfreq*** Convert TimeSeries to specified frequency.

### Examples

```
>>> df = pd.DataFrame([[np.nan, 2, np.nan, 0],
...                    [3, 4, np.nan, 1],
...                    [np.nan, np.nan, np.nan, 5],
...                    [np.nan, 3, np.nan, 4]],
...                   columns=list('ABCD'))
>>> df
   A    B    C    D
0 NaN  2.0 NaN  0
1  3.0  4.0 NaN  1
2 NaN  NaN NaN  5
3 NaN  3.0 NaN  4
```

Replace all NaN elements with 0s.

```
>>> df.fillna(0)
   A    B    C    D
0  0.0  2.0  0.0  0
1  3.0  4.0  0.0  1
2  0.0  0.0  0.0  5
3  0.0  3.0  0.0  4
```

We can also propagate non-null values forward or backward.

```
>>> df.fillna(method='ffill')
   A    B    C    D
0 NaN  2.0 NaN  0
1  3.0  4.0 NaN  1
2  3.0  4.0 NaN  5
3  3.0  3.0 NaN  4
```

Replace all NaN elements in column 'A', 'B', 'C', and 'D', with 0, 1, 2, and 3 respectively.

```
>>> values = {'A': 0, 'B': 1, 'C': 2, 'D': 3}
>>> df.fillna(value=values)
   A    B    C    D
0  0.0  2.0  2.0  0
1  3.0  4.0  2.0  1
2  0.0  1.0  2.0  5
3  0.0  3.0  2.0  4
```

Only replace the first NaN element.

```
>>> df.fillna(value=values, limit=1)
   A    B    C    D
0  0.0  2.0  2.0  0
1  3.0  4.0  NaN  1
2  NaN  1.0  NaN  5
3  NaN  3.0  NaN  4
```

## pandas.DataFrame.filter

`DataFrame.filter` (*self*: ~FrameOrSeries, *items=None*, *like: Union[str, NoneType] = None*, *regex: Union[str, NoneType] = None*, *axis=None*) → ~FrameOrSeries

Subset the dataframe rows or columns according to the specified index labels.

Note that this routine does not filter a dataframe on its contents. The filter is applied to the labels of the index.

### Parameters

**items** [list-like] Keep labels from axis which are in items.

**like** [str] Keep labels from axis for which “like in label == True”.

**regex** [str (regular expression)] Keep labels from axis for which `re.search(regex, label) == True`.

**axis** [{0 or ‘index’, 1 or ‘columns’, None}, default None] The axis to filter on, expressed either as an index (int) or axis name (str). By default this is the info axis, ‘index’ for Series, ‘columns’ for DataFrame.

### Returns

same type as input object

See also:

`DataFrame.loc`

### Notes

The `items`, `like`, and `regex` parameters are enforced to be mutually exclusive.

`axis` defaults to the info axis that is used when indexing with `[]`.

## Examples

```
>>> df = pd.DataFrame(np.array([[1, 2, 3], [4, 5, 6]]),
...                   index=['mouse', 'rabbit'],
...                   columns=['one', 'two', 'three'])
```

```
>>> # select columns by name
>>> df.filter(items=['one', 'three'])
      one  three
mouse   1     3
rabbit  4     6
```

```
>>> # select columns by regular expression
>>> df.filter(regex='e$', axis=1)
      one  three
mouse   1     3
rabbit  4     6
```

```
>>> # select rows containing 'bbi'
>>> df.filter(like='bbi', axis=0)
      one two three
rabbit  4  5   6
```

## pandas.DataFrame.first

`DataFrame.first` (*self*: ~FrameOrSeries, *offset*) → ~FrameOrSeries  
Method to subset initial periods of time series data based on a date offset.

### Parameters

**offset** [str, DateOffset, dateutil.relativedelta]

### Returns

**subset** [same type as caller]

### Raises

**TypeError** If the index is not a *DatetimeIndex*

### See also:

**last** Select final periods of time series based on a date offset.

**at\_time** Select values at a particular time of the day.

**between\_time** Select values between particular times of the day.

## Examples

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1,2,3,4]}, index=i)
>>> ts
           A
2018-04-09  1
2018-04-11  2
2018-04-13  3
2018-04-15  4
```

Get the rows for the first 3 days:

```
>>> ts.first('3D')
           A
2018-04-09  1
2018-04-11  2
```

Notice the data for 3 first calendar days were returned, not the first 3 days observed in the dataset, and therefore data for 2018-04-13 was not returned.

## pandas.DataFrame.first\_valid\_index

`DataFrame.first_valid_index` (*self*)  
Return index for first non-NA/null value.

### Returns

**scalar** [type of index]

### Notes

If all elements are non-NA/null, returns None. Also returns None for empty Series/DataFrame.

## pandas.DataFrame.floordiv

`DataFrame.floordiv` (*self, other, axis='columns', level=None, fill\_value=None*)  
Get Integer division of dataframe and other, element-wise (binary operator *floordiv*).

Equivalent to `dataframe // other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *rfloordiv*.

Among flexible wrappers (*add, sub, mul, div, mod, pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

### Parameters

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

**level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

**fill\_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

### Returns

**DataFrame** Result of the arithmetic operation.

### See also:

**DataFrame.add** Add DataFrames.

**DataFrame.sub** Subtract DataFrames.

**DataFrame.mul** Multiply DataFrames.

**DataFrame.div** Divide DataFrames (float division).

**DataFrame.truediv** Divide DataFrames (float division).

**DataFrame.floordiv** Divide DataFrames (integer division).

**DataFrame.mod** Calculate modulo (remainder after division).

**DataFrame.pow** Calculate exponential power.

### Notes

Mismatched indices will be unioned together.

### Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                   index=['circle', 'triangle', 'rectangle'])
>>> df
```

	angles	degrees
circle	0	360
triangle	3	180
rectangle	4	360

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

```
>>> df.add(1)
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

Divide by constant with reverse version.

```
>>> df.div(10)
      angles  degrees
circle    0.0   36.0
triangle  0.3   18.0
rectangle 0.4   36.0
```

```
>>> df.rdiv(10)
      angles  degrees
circle      inf  0.027778
triangle  3.333333  0.055556
rectangle  2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
      angles  degrees
circle     -1    358
triangle    2    178
rectangle   3    358
```

```
>>> df.sub([1, 2], axis='columns')
      angles  degrees
circle     -1    358
triangle    2    178
rectangle   3    358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
      angles  degrees
circle     -1    359
triangle    2    179
rectangle   3    359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
      angles
circle      0
triangle    3
rectangle   4
```

```
>>> df * other
      angles  degrees
circle      0     NaN
triangle    9     NaN
rectangle  16     NaN
```

```
>>> df.mul(other, fill_value=0)
      angles  degrees
circle      0     0.0
triangle    9     0.0
rectangle  16     0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                               index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                       ['circle', 'triangle', 'rectangle',
...                                       'square', 'pentagon', 'hexagon']])
>>> df_multindex
```

	angles	degrees
A circle	0	360
triangle	3	180
rectangle	4	360
B square	4	360
pentagon	5	540
hexagon	6	720

```
>>> df.div(df_multindex, level=1, fill_value=0)
```

	angles	degrees
A circle	NaN	1.0
triangle	1.0	1.0
rectangle	1.0	1.0
B square	0.0	0.0
pentagon	0.0	0.0
hexagon	0.0	0.0

## pandas.DataFrame.from\_dict

**classmethod** `DataFrame.from_dict` (*data*, *orient*='columns', *dtype*=None, *columns*=None)  
 → 'DataFrame'

Construct DataFrame from dict of array-like or dicts.

Creates DataFrame object from dictionary by columns or by index allowing dtype specification.

### Parameters

**data** [dict] Of the form {field : array-like} or {field : dict}.

**orient** [{‘columns’, ‘index’}, default ‘columns’] The “orientation” of the data. If the keys of the passed dict should be the columns of the resulting DataFrame, pass ‘columns’ (default). Otherwise if the keys should be rows, pass ‘index’.

**dtype** [dtype, default None] Data type to force, otherwise infer.

**columns** [list, default None] Column labels to use when *orient*='index'. Raises a `ValueError` if used with *orient*='columns'.

New in version 0.23.0.

### Returns

**DataFrame**

See also:

**DataFrame.from\_records** DataFrame from ndarray (structured dtype), list of tuples, dict, or DataFrame.

**DataFrame** DataFrame object creation using constructor.

## Examples

By default the keys of the dict become the DataFrame columns:

```
>>> data = {'col_1': [3, 2, 1, 0], 'col_2': ['a', 'b', 'c', 'd']}
>>> pd.DataFrame.from_dict(data)
   col_1 col_2
0      3    a
1      2    b
2      1    c
3      0    d
```

Specify `orient='index'` to create the DataFrame using dictionary keys as rows:

```
>>> data = {'row_1': [3, 2, 1, 0], 'row_2': ['a', 'b', 'c', 'd']}
>>> pd.DataFrame.from_dict(data, orient='index')
      0  1  2  3
row_1  3  2  1  0
row_2  a  b  c  d
```

When using the 'index' orientation, the column names can be specified manually:

```
>>> pd.DataFrame.from_dict(data, orient='index',
...                          columns=['A', 'B', 'C', 'D'])
      A  B  C  D
row_1  3  2  1  0
row_2  a  b  c  d
```

## pandas.DataFrame.from\_records

**classmethod** `DataFrame.from_records` (*data*, *index=None*, *exclude=None*, *columns=None*, *coerce\_float=False*, *nrows=None*) → 'DataFrame'  
Convert structured or record ndarray to DataFrame.

### Parameters

**data** [ndarray (structured dtype), list of tuples, dict, or DataFrame]

**index** [str, list of fields, array-like] Field of array to use as the index, alternately a specific set of input labels to use.

**exclude** [sequence, default None] Columns or fields to exclude.

**columns** [sequence, default None] Column names to use. If the passed data do not have names associated with them, this argument provides names for the columns. Otherwise this argument indicates the order of the columns in the result (any names not found in the data will become all-NA columns).

**coerce\_float** [bool, default False] Attempt to convert values of non-string, non-numeric objects (like `decimal.Decimal`) to floating point, useful for SQL result sets.

**nrows** [int, default None] Number of rows to read if data is an iterator.

### Returns

**DataFrame**

## pandas.DataFrame.ge

DataFrame.**ge** (*self*, *other*, *axis='columns'*, *level=None*)

Get Greater than or equal to of dataframe and other, element-wise (binary operator *ge*).

Among flexible wrappers (*eq*, *ne*, *le*, *lt*, *ge*, *gt*) to comparison operators.

Equivalent to `==`, `!=`, `<=`, `<`, `>=`, `>` with support to choose axis (rows or columns) and level for comparison.

### Parameters

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}, default 'columns'] Whether to compare by the index (0 or 'index') or columns (1 or 'columns').

**level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

### Returns

**DataFrame of bool** Result of the comparison.

See also:

**DataFrame.eq** Compare DataFrames for equality elementwise.

**DataFrame.ne** Compare DataFrames for inequality elementwise.

**DataFrame.le** Compare DataFrames for less than inequality or equality elementwise.

**DataFrame.lt** Compare DataFrames for strictly less than inequality elementwise.

**DataFrame.ge** Compare DataFrames for greater than inequality or equality elementwise.

**DataFrame.gt** Compare DataFrames for strictly greater than inequality elementwise.

### Notes

Mismatched indices will be unioned together. *NaN* values are considered different (i.e. *NaN != NaN*).

### Examples

```
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                    'revenue': [100, 250, 300]},
...                    index=['A', 'B', 'C'])
>>> df
   cost  revenue
A    250     100
B    150     250
C    100     300
```

Comparison with a scalar, using either the operator or method:

```
>>> df == 100
   cost  revenue
A  False     True
```

(continues on next page)

(continued from previous page)

```
B False False
C  True False
```

```
>>> df.eq(100)
      cost revenue
A False      True
B False      False
C  True      False
```

When *other* is a *Series*, the columns of a *DataFrame* are aligned with the index of *other* and broadcast:

```
>>> df != pd.Series([100, 250], index=["cost", "revenue"])
      cost revenue
A  True      True
B  True      False
C False      True
```

Use the method to control the broadcast axis:

```
>>> df.ne(pd.Series([100, 300], index=["A", "D"]), axis='index')
      cost revenue
A  True      False
B  True      True
C  True      True
D  True      True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in *other*:

```
>>> df == [250, 100]
      cost revenue
A  True      True
B False      False
C False      False
```

Use the method to control the axis:

```
>>> df.eq([250, 250, 100], axis='index')
      cost revenue
A  True      False
B False      True
C  True      False
```

Compare to a *DataFrame* of different shape.

```
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
...                       index=['A', 'B', 'C', 'D'])
>>> other
      revenue
A         300
B         250
C         100
D         150
```

```
>>> df.gt(other)
      cost revenue
```

(continues on next page)

(continued from previous page)

```
A False False
B False False
C False True
D False False
```

Compare to a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
...                               'revenue': [100, 250, 300, 200, 175, 225]},
...                               index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
...                                       ['A', 'B', 'C', 'A', 'B', 'C']])
>>> df_multindex
      cost  revenue
Q1 A    250     100
   B    150     250
   C    100     300
Q2 A    150     200
   B    300     175
   C    220     225
```

```
>>> df.le(df_multindex, level=1)
      cost  revenue
Q1 A    True     True
   B    True     True
   C    True     True
Q2 A    False    True
   B     True    False
   C     True    False
```

### pandas.DataFrame.get

DataFrame.**get** (*self*, *key*, *default=None*)

Get item from object for given key (ex: DataFrame column).

Returns default value if not found.

#### Parameters

**key** [object]

#### Returns

**value** [same type as items contained in object]

### pandas.DataFrame.groupby

DataFrame.**groupby** (*self*, *by=None*, *axis=0*, *level=None*, *as\_index: bool = True*, *sort: bool = True*, *group\_keys: bool = True*, *squeeze: bool = False*, *observed: bool = False*) → 'groupby\_generic.DataFrameGroupBy'

Group DataFrame using a mapper or by a Series of columns.

A groupby operation involves some combination of splitting the object, applying a function, and combining the results. This can be used to group large amounts of data and compute operations on these groups.

#### Parameters

**by** [mapping, function, label, or list of labels] Used to determine the groups for the groupby. If `by` is a function, it's called on each value of the object's index. If a dict or Series is passed, the Series or dict VALUES will be used to determine the groups (the Series' values are first aligned; see `.align()` method). If an ndarray is passed, the values are used as-is determine the groups. A label or list of labels may be passed to group by the columns in `self`. Notice that a tuple is interpreted as a (single) key.

**axis** [{0 or 'index', 1 or 'columns'}, default 0] Split along rows (0) or columns (1).

**level** [int, level name, or sequence of such, default None] If the axis is a MultiIndex (hierarchical), group by a particular level or levels.

**as\_index** [bool, default True] For aggregated output, return object with group labels as the index. Only relevant for DataFrame input. `as_index=False` is effectively "SQL-style" grouped output.

**sort** [bool, default True] Sort group keys. Get better performance by turning this off. Note this does not influence the order of observations within each group. Groupby preserves the order of rows within each group.

**group\_keys** [bool, default True] When calling `apply`, add group keys to index to identify pieces.

**squeeze** [bool, default False] Reduce the dimensionality of the return type if possible, otherwise return a consistent type.

**observed** [bool, default False] This only applies if any of the groupers are Categoricals. If True: only show observed values for categorical groupers. If False: show all values for categorical groupers.

New in version 0.23.0.

### Returns

**DataFrameGroupBy** Returns a groupby object that contains information about the groups.

### See also:

**resample** Convenience method for frequency conversion and resampling of time series.

### Notes

See the [user guide](#) for more.

### Examples

```
>>> df = pd.DataFrame({'Animal': ['Falcon', 'Falcon',
...                               'Parrot', 'Parrot'],
...                   'Max Speed': [380., 370., 24., 26.]})
>>> df
   Animal  Max Speed
0  Falcon    380.0
1  Falcon    370.0
2  Parrot     24.0
3  Parrot     26.0
>>> df.groupby(['Animal']).mean()
```

(continues on next page)

(continued from previous page)

	Max Speed
Animal	
Falcon	375.0
Parrot	25.0

### Hierarchical Indexes

We can groupby different levels of a hierarchical index using the *level* parameter:

```
>>> arrays = [['Falcon', 'Falcon', 'Parrot', 'Parrot'],
...           ['Captive', 'Wild', 'Captive', 'Wild']]
>>> index = pd.MultiIndex.from_arrays(arrays, names=('Animal', 'Type'))
>>> df = pd.DataFrame({'Max Speed': [390., 350., 30., 20.]},
...                   index=index)
>>> df
```

Animal	Type	Max Speed
Falcon	Captive	390.0
	Wild	350.0
Parrot	Captive	30.0
	Wild	20.0

```
>>> df.groupby(level=0).mean()
      Max Speed
Animal
Falcon    370.0
Parrot     25.0
>>> df.groupby(level="Type").mean()
      Max Speed
Type
Captive    210.0
Wild      185.0
```

### pandas.DataFrame.gt

DataFrame.**gt** (*self*, *other*, *axis='columns'*, *level=None*)

Get Greater than of dataframe and other, element-wise (binary operator *gt*).

Among flexible wrappers (*eq*, *ne*, *le*, *lt*, *ge*, *gt*) to comparison operators.

Equivalent to `==`, `!=`, `<=`, `<`, `>=`, `>` with support to choose axis (rows or columns) and level for comparison.

#### Parameters

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}, default 'columns'] Whether to compare by the index (0 or 'index') or columns (1 or 'columns').

**level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

#### Returns

**DataFrame of bool** Result of the comparison.

See also:

**DataFrame.eq** Compare DataFrames for equality elementwise.

**DataFrame.ne** Compare DataFrames for inequality elementwise.

**DataFrame.le** Compare DataFrames for less than inequality or equality elementwise.

**DataFrame.lt** Compare DataFrames for strictly less than inequality elementwise.

**DataFrame.ge** Compare DataFrames for greater than inequality or equality elementwise.

**DataFrame.gt** Compare DataFrames for strictly greater than inequality elementwise.

## Notes

Mismatched indices will be unioned together. *NaN* values are considered different (i.e. *NaN != NaN*).

## Examples

```
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                    'revenue': [100, 250, 300]},
...                    index=['A', 'B', 'C'])
>>> df
   cost  revenue
A   250     100
B   150     250
C   100     300
```

Comparison with a scalar, using either the operator or method:

```
>>> df == 100
   cost  revenue
A  False     True
B  False     False
C   True     False
```

```
>>> df.eq(100)
   cost  revenue
A  False     True
B  False     False
C   True     False
```

When *other* is a *Series*, the columns of a *DataFrame* are aligned with the index of *other* and broadcast:

```
>>> df != pd.Series([100, 250], index=["cost", "revenue"])
   cost  revenue
A   True     True
B   True     False
C  False     True
```

Use the method to control the broadcast axis:

```
>>> df.ne(pd.Series([100, 300], index=["A", "D"]), axis='index')
   cost  revenue
A   True     False
B   True     True
C   True     True
D   True     True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in *other*:

```
>>> df == [250, 100]
      cost  revenue
A   True    True
B  False   False
C  False   False
```

Use the method to control the axis:

```
>>> df.eq([250, 250, 100], axis='index')
      cost  revenue
A   True   False
B  False    True
C   True   False
```

Compare to a DataFrame of different shape.

```
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
...                       index=['A', 'B', 'C', 'D'])
>>> other
      revenue
A         300
B         250
C         100
D         150
```

```
>>> df.gt(other)
      cost  revenue
A  False   False
B  False   False
C  False    True
D  False   False
```

Compare to a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
...                              'revenue': [100, 250, 300, 200, 175, 225]},
...                              index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
...                                      ['A', 'B', 'C', 'A', 'B', 'C']])
>>> df_multindex
      cost  revenue
Q1 A   250    100
   B   150    250
   C   100    300
Q2 A   150    200
   B   300    175
   C   220    225
```

```
>>> df.le(df_multindex, level=1)
      cost  revenue
Q1 A   True    True
   B   True    True
   C   True    True
Q2 A  False    True
   B   True   False
   C   True   False
```

## pandas.DataFrame.head

DataFrame.**head** (*self*: ~FrameOrSeries, *n*: int = 5) → ~FrameOrSeries

Return the first *n* rows.

This function returns the first *n* rows for the object based on position. It is useful for quickly testing if your object has the right type of data in it.

For negative values of *n*, this function returns all rows except the last *n* rows, equivalent to `df[: -n]`.

### Parameters

**n** [int, default 5] Number of rows to select.

### Returns

**same type as caller** The first *n* rows of the caller object.

**See also:**

**DataFrame.tail** Returns the last *n* rows.

### Examples

```
>>> df = pd.DataFrame({'animal': ['alligator', 'bee', 'falcon', 'lion',
...                               'monkey', 'parrot', 'shark', 'whale', 'zebra']})
>>> df
   animal
0  alligator
1      bee
2   falcon
3     lion
4   monkey
5   parrot
6    shark
7    whale
8    zebra
```

Viewing the first 5 lines

```
>>> df.head()
   animal
0  alligator
1      bee
2   falcon
3     lion
4   monkey
```

Viewing the first *n* lines (three in this case)

```
>>> df.head(3)
   animal
0  alligator
1      bee
2   falcon
```

For negative values of *n*

```
>>> df.head(-3)
   animal
0  alligator
1     bee
2   falcon
3     lion
4   monkey
5   parrot
```

## pandas.DataFrame.hist

`DataFrame.hist` (*data*, *column=None*, *by=None*, *grid=True*, *xlabelsize=None*, *xrot=None*, *ylabelsize=None*, *yrot=None*, *ax=None*, *sharex=False*, *sharey=False*, *figsize=None*, *layout=None*, *bins=10*, *backend=None*, *\*\*kwargs*)

Make a histogram of the DataFrame's.

A **histogram** is a representation of the distribution of data. This function calls `matplotlib.pyplot.hist()`, on each series in the DataFrame, resulting in one histogram per column.

### Parameters

- data** [DataFrame] The pandas object holding the data.
- column** [str or sequence] If passed, will be used to limit data to a subset of columns.
- by** [object, optional] If passed, then used to form histograms for separate groups.
- grid** [bool, default True] Whether to show axis grid lines.
- xlabelsize** [int, default None] If specified changes the x-axis label size.
- xrot** [float, default None] Rotation of x axis labels. For example, a value of 90 displays the x labels rotated 90 degrees clockwise.
- ylabelsize** [int, default None] If specified changes the y-axis label size.
- yrot** [float, default None] Rotation of y axis labels. For example, a value of 90 displays the y labels rotated 90 degrees clockwise.
- ax** [Matplotlib axes object, default None] The axes to plot the histogram on.
- sharex** [bool, default True if ax is None else False] In case subplots=True, share x axis and set some x axis labels to invisible; defaults to True if ax is None otherwise False if an ax is passed in. Note that passing in both an ax and sharex=True will alter all x axis labels for all subplots in a figure.
- sharey** [bool, default False] In case subplots=True, share y axis and set some y axis labels to invisible.
- figsize** [tuple] The size in inches of the figure to create. Uses the value in `matplotlib.rcParams` by default.
- layout** [tuple, optional] Tuple of (rows, columns) for the layout of the histograms.
- bins** [int or sequence, default 10] Number of histogram bins to be used. If an integer is given, bins + 1 bin edges are calculated and returned. If bins is a sequence, gives bin edges, including left edge of first bin and right edge of last bin. In this case, bins is returned unmodified.
- backend** [str, default None] Backend to use instead of the backend specified in the option `plotting.backend`. For instance, 'matplotlib'. Alternatively, to

specify the `plotting.backend` for the whole session, set `pd.options.plotting.backend`.

New in version 1.0.0.

**\*\*kwargs** All other plotting keyword arguments to be passed to `matplotlib.pyplot.hist()`.

### Returns

`matplotlib.AxesSubplot` or `numpy.ndarray` of them

See also:

`matplotlib.pyplot.hist` Plot a histogram using matplotlib.

### Examples

This example draws a histogram based on the length and width of some animals, displayed in three bins

```
>>> df = pd.DataFrame({
...     'length': [1.5, 0.5, 1.2, 0.9, 3],
...     'width': [0.7, 0.2, 0.15, 0.2, 1.1]
... }, index=['pig', 'rabbit', 'duck', 'chicken', 'horse'])
>>> hist = df.hist(bins=3)
```

**pandas.DataFrame.idxmax**

`DataFrame.idxmax` (*self*, *axis=0*, *skipna=True*) → `pandas.core.series.Series`

Return index of first occurrence of maximum over requested axis.

NA/null values are excluded.

**Parameters**

**axis** [{0 or 'index', 1 or 'columns'}, default 0] The axis to use. 0 or 'index' for row-wise, 1 or 'columns' for column-wise.

**skipna** [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

**Returns**

**Series** Indexes of maxima along the specified axis.

**Raises****ValueError**

- If the row/column is empty

See also:

*Series.idxmax*

**Notes**

This method is the DataFrame version of `ndarray.argmax`.

**pandas.DataFrame.idxmin**

`DataFrame.idxmin` (*self*, *axis=0*, *skipna=True*) → `pandas.core.series.Series`

Return index of first occurrence of minimum over requested axis.

NA/null values are excluded.

**Parameters**

**axis** [{0 or 'index', 1 or 'columns'}, default 0] The axis to use. 0 or 'index' for row-wise, 1 or 'columns' for column-wise.

**skipna** [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

**Returns**

**Series** Indexes of minima along the specified axis.

**Raises****ValueError**

- If the row/column is empty

See also:

*Series.idxmin*

## Notes

This method is the DataFrame version of `ndarray.argmax`.

## `pandas.DataFrame.infer_objects`

`DataFrame.infer_objects` (*self*: `~FrameOrSeries`) → `~FrameOrSeries`

Attempt to infer better dtypes for object columns.

Attempts soft conversion of object-dtyped columns, leaving non-object and unconvertible columns unchanged. The inference rules are the same as during normal Series/DataFrame construction.

New in version 0.21.0.

### Returns

**converted** [same type as input object]

### See also:

**`to_datetime`** Convert argument to datetime.

**`to_timedelta`** Convert argument to timedelta.

**`to_numeric`** Convert argument to numeric type.

**`convert_dtypes`** Convert argument to best possible dtype.

## Examples

```
>>> df = pd.DataFrame({"A": ["a", 1, 2, 3]})
>>> df = df.iloc[1:]
>>> df
   A
1  1
2  2
3  3
```

```
>>> df.dtypes
A    object
dtype: object
```

```
>>> df.infer_objects().dtypes
A    int64
dtype: object
```

**pandas.DataFrame.info**

`DataFrame.info` (*self*, *verbose=None*, *buf=None*, *max\_cols=None*, *memory\_usage=None*, *null\_counts=None*) → None

Print a concise summary of a DataFrame.

This method prints information about a DataFrame including the index dtype and column dtypes, non-null values and memory usage.

**Parameters**

**verbose** [bool, optional] Whether to print the full summary. By default, the setting in `pandas.options.display.max_info_columns` is followed.

**buf** [writable buffer, defaults to `sys.stdout`] Where to send the output. By default, the output is printed to `sys.stdout`. Pass a writable buffer if you need to further process the output.

**max\_cols** [int, optional] When to switch from the verbose to the truncated output. If the DataFrame has more than *max\_cols* columns, the truncated output is used. By default, the setting in `pandas.options.display.max_info_columns` is used.

**memory\_usage** [bool, str, optional] Specifies whether total memory usage of the DataFrame elements (including the index) should be displayed. By default, this follows the `pandas.options.display.memory_usage` setting.

True always show memory usage. False never shows memory usage. A value of 'deep' is equivalent to "True with deep introspection". Memory usage is shown in human-readable units (base-2 representation). Without deep introspection a memory estimation is made based in column dtype and number of rows assuming values consume the same memory amount for corresponding dtypes. With deep memory introspection, a real memory usage calculation is performed at the cost of computational resources.

**null\_counts** [bool, optional] Whether to show the non-null counts. By default, this is shown only if the frame is smaller than `pandas.options.display.max_info_rows` and `pandas.options.display.max_info_columns`. A value of True always shows the counts, and False never shows the counts.

**Returns**

**None** This method prints a summary of a DataFrame and returns None.

**See also:**

***DataFrame.describe*** Generate descriptive statistics of DataFrame columns.

***DataFrame.memory\_usage*** Memory usage of DataFrame columns.

## Examples

```
>>> int_values = [1, 2, 3, 4, 5]
>>> text_values = ['alpha', 'beta', 'gamma', 'delta', 'epsilon']
>>> float_values = [0.0, 0.25, 0.5, 0.75, 1.0]
>>> df = pd.DataFrame({"int_col": int_values, "text_col": text_values,
...                    "float_col": float_values})
>>> df
   int_col text_col  float_col
0         1   alpha         0.00
1         2   beta         0.25
2         3   gamma         0.50
3         4   delta         0.75
4         5  epsilon         1.00
```

Prints information of all columns:

```
>>> df.info(verbose=True)
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5 entries, 0 to 4
Data columns (total 3 columns):
#   Column      Non-Null Count  Dtype
---  -
0   int_col     5 non-null     int64
1   text_col    5 non-null     object
2   float_col   5 non-null     float64
dtypes: float64(1), int64(1), object(1)
memory usage: 248.0+ bytes
```

Prints a summary of columns count and its dtypes but not per column information:

```
>>> df.info(verbose=False)
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5 entries, 0 to 4
Columns: 3 entries, int_col to float_col
dtypes: float64(1), int64(1), object(1)
memory usage: 248.0+ bytes
```

Pipe output of DataFrame.info to buffer instead of sys.stdout, get buffer content and writes to a text file:

```
>>> import io
>>> buffer = io.StringIO()
>>> df.info(buf=buffer)
>>> s = buffer.getvalue()
>>> with open("df_info.txt", "w",
...         encoding="utf-8") as f:
...     f.write(s)
260
```

The `memory_usage` parameter allows deep introspection mode, specially useful for big DataFrames and fine-tune memory optimization:

```
>>> random_strings_array = np.random.choice(['a', 'b', 'c'], 10 ** 6)
>>> df = pd.DataFrame({
...     'column_1': np.random.choice(['a', 'b', 'c'], 10 ** 6),
...     'column_2': np.random.choice(['a', 'b', 'c'], 10 ** 6),
...     'column_3': np.random.choice(['a', 'b', 'c'], 10 ** 6)
```

(continues on next page)

(continued from previous page)

```
... })
>>> df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 1000000 entries, 0 to 999999
Data columns (total 3 columns):
#   Column      Non-Null Count  Dtype
---  ---
0   column_1    1000000 non-null  object
1   column_2    1000000 non-null  object
2   column_3    1000000 non-null  object
dtypes: object(3)
memory usage: 22.9+ MB
```

```
>>> df.info(memory_usage='deep')
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 1000000 entries, 0 to 999999
Data columns (total 3 columns):
#   Column      Non-Null Count  Dtype
---  ---
0   column_1    1000000 non-null  object
1   column_2    1000000 non-null  object
2   column_3    1000000 non-null  object
dtypes: object(3)
memory usage: 188.8 MB
```

### pandas.DataFrame.insert

`DataFrame.insert` (*self*, *loc*, *column*, *value*, *allow\_duplicates=False*) → None  
 Insert column into DataFrame at specified location.

Raises a `ValueError` if *column* is already contained in the DataFrame, unless *allow\_duplicates* is set to `True`.

#### Parameters

- loc** [int] Insertion index. Must verify  $0 \leq \text{loc} \leq \text{len}(\text{columns})$ .
- column** [str, number, or hashable object] Label of the inserted column.
- value** [int, Series, or array-like]
- allow\_duplicates** [bool, optional]

### pandas.DataFrame.interpolate

`DataFrame.interpolate` (*self*, *method='linear'*, *axis=0*, *limit=None*, *inplace=False*,  
*limit\_direction='forward'*, *limit\_area=None*, *downcast=None*,  
*\*\*kwargs*)

Interpolate values according to different methods.

Please note that only `method='linear'` is supported for DataFrame/Series with a MultiIndex.

#### Parameters

- method** [str, default 'linear'] Interpolation technique to use. One of:

- ‘linear’: Ignore the index and treat the values as equally spaced. This is the only method supported on MultiIndexes.
- ‘time’: Works on daily and higher resolution data to interpolate given length of interval.
- ‘index’, ‘values’: use the actual numerical values of the index.
- ‘pad’: Fill in NaNs using existing values.
- ‘nearest’, ‘zero’, ‘slinear’, ‘quadratic’, ‘cubic’, ‘spline’, ‘barycentric’, ‘polynomial’: Passed to `scipy.interpolate.interp1d`. These methods use the numerical values of the index. Both ‘polynomial’ and ‘spline’ require that you also specify an *order* (int), e.g. `df.interpolate(method='polynomial', order=5)`.
- ‘krogh’, ‘piecewise\_polynomial’, ‘spline’, ‘pchip’, ‘akima’: Wrappers around the SciPy interpolation methods of similar names. See *Notes*.
- ‘from\_derivatives’: Refers to `scipy.interpolate.BPoly.from_derivatives` which replaces ‘piecewise\_polynomial’ interpolation method in scipy 0.18.

**axis** [{0 or ‘index’, 1 or ‘columns’, None}, default None] Axis to interpolate along.

**limit** [int, optional] Maximum number of consecutive NaNs to fill. Must be greater than 0.

**inplace** [bool, default False] Update the data in place if possible.

**limit\_direction** [{‘forward’, ‘backward’, ‘both’}, default ‘forward’] If limit is specified, consecutive NaNs will be filled in this direction.

**limit\_area** [{None, ‘inside’, ‘outside’}, default None] If limit is specified, consecutive NaNs will be filled with this restriction.

- None: No fill restriction.
- ‘inside’: Only fill NaNs surrounded by valid values (interpolate).
- ‘outside’: Only fill NaNs outside valid values (extrapolate).

New in version 0.23.0.

**downcast** [optional, ‘infer’ or None, defaults to None] Downcast dtypes if possible.

**\*\*kwargs** Keyword arguments to pass on to the interpolating function.

### Returns

**Series or DataFrame** Returns the same object type as the caller, interpolated at some or all NaN values.

### See also:

***fillna*** Fill missing values using different methods.

**`scipy.interpolate.Akima1DInterpolator`** Piecewise cubic polynomials (Akima interpolator).

**`scipy.interpolate.BPoly.from_derivatives`** Piecewise polynomial in the Bernstein basis.

**`scipy.interpolate.interp1d`** Interpolate a 1-D function.

**`scipy.interpolate.KroghInterpolator`** Interpolate polynomial (Krogh interpolator).

`scipy.interpolate.PchipInterpolator` PCHIP 1-d monotonic cubic interpolation.

`scipy.interpolate.CubicSpline` Cubic spline data interpolator.

## Notes

The ‘krogh’, ‘piecewise\_polynomial’, ‘spline’, ‘pchip’ and ‘akima’ methods are wrappers around the respective SciPy implementations of similar names. These use the actual numerical values of the index. For more information on their behavior, see the [SciPy documentation](#) and [SciPy tutorial](#).

## Examples

Filling in NaN in a *Series* via linear interpolation.

```
>>> s = pd.Series([0, 1, np.nan, 3])
>>> s
0    0.0
1    1.0
2    NaN
3    3.0
dtype: float64
>>> s.interpolate()
0    0.0
1    1.0
2    2.0
3    3.0
dtype: float64
```

Filling in NaN in a *Series* by padding, but filling at most two consecutive NaN at a time.

```
>>> s = pd.Series([np.nan, "single_one", np.nan,
...               "fill_two_more", np.nan, np.nan, np.nan,
...               4.71, np.nan])
>>> s
0          NaN
1    single_one
2          NaN
3    fill_two_more
4          NaN
5          NaN
6          NaN
7          4.71
8          NaN
dtype: object
>>> s.interpolate(method='pad', limit=2)
0          NaN
1    single_one
2    single_one
3    fill_two_more
4    fill_two_more
5    fill_two_more
6          NaN
7          4.71
8          4.71
dtype: object
```

Filling in NaN in a Series via polynomial interpolation or splines: Both ‘polynomial’ and ‘spline’ methods require that you also specify an `order` (int).

```
>>> s = pd.Series([0, 2, np.nan, 8])
>>> s.interpolate(method='polynomial', order=2)
0    0.000000
1    2.000000
2    4.666667
3    8.000000
dtype: float64
```

Fill the DataFrame forward (that is, going down) along each column using linear interpolation.

Note how the last entry in column ‘a’ is interpolated differently, because there is no entry after it to use for interpolation. Note how the first entry in column ‘b’ remains NaN, because there is no entry before it to use for interpolation.

```
>>> df = pd.DataFrame([(0.0, np.nan, -1.0, 1.0),
...                   (np.nan, 2.0, np.nan, np.nan),
...                   (2.0, 3.0, np.nan, 9.0),
...                   (np.nan, 4.0, -4.0, 16.0)],
...                   columns=list('abcd'))
>>> df
   a    b    c    d
0  0.0 NaN -1.0  1.0
1  NaN  2.0 NaN  NaN
2  2.0  3.0 NaN  9.0
3  NaN  4.0 -4.0 16.0
>>> df.interpolate(method='linear', limit_direction='forward', axis=0)
   a    b    c    d
0  0.0 NaN -1.0  1.0
1  1.0  2.0 -2.0  5.0
2  2.0  3.0 -3.0  9.0
3  2.0  4.0 -4.0 16.0
```

Using polynomial interpolation.

```
>>> df['d'].interpolate(method='polynomial', order=2)
0    1.0
1    4.0
2    9.0
3   16.0
Name: d, dtype: float64
```

## pandas.DataFrame.isin

`DataFrame.isin(self, values) → 'DataFrame'`

Whether each element in the DataFrame is contained in values.

### Parameters

**values** [iterable, Series, DataFrame or dict] The result will only be true at a location if all the labels match. If *values* is a Series, that’s the index. If *values* is a dict, the keys must be the column names, which must match. If *values* is a DataFrame, then both the index and column labels must match.

### Returns

**DataFrame.isin** DataFrame of booleans showing whether each element in the DataFrame is contained in values.

**See also:**

**DataFrame.eq** Equality test for DataFrame.

**Series.isin** Equivalent method on Series.

**Series.str.contains** Test if pattern or regex is contained within a string of a Series or Index.

## Examples

```
>>> df = pd.DataFrame({'num_legs': [2, 4], 'num_wings': [2, 0]},
...                    index=['falcon', 'dog'])
>>> df
```

	num_legs	num_wings
falcon	2	2
dog	4	0

When `values` is a list check whether every value in the DataFrame is present in the list (which animals have 0 or 2 legs or wings)

```
>>> df.isin([0, 2])
```

	num_legs	num_wings
falcon	True	True
dog	False	True

When `values` is a dict, we can pass values to check for each column separately:

```
>>> df.isin({'num_wings': [0, 3]})
```

	num_legs	num_wings
falcon	False	False
dog	False	True

When `values` is a Series or DataFrame the index and column must match. Note that 'falcon' does not match based on the number of legs in `df2`.

```
>>> other = pd.DataFrame({'num_legs': [8, 2], 'num_wings': [0, 2]},
...                      index=['spider', 'falcon'])
>>> df.isin(other)
```

	num_legs	num_wings
falcon	True	True
dog	False	False

## pandas.DataFrame.isna

`DataFrame.isna(self)` → 'DataFrame'

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as `None` or `numpy.NaN`, gets mapped to `True` values. Everything else gets mapped to `False` values. Characters such as empty strings `''` or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`).

**Returns**

**DataFrame.isna** Mask of bool values for each element in DataFrame that indicates whether an element is not an NA value.

**See also:**

**DataFrame.isnull** Alias of isna.

**DataFrame.notna** Boolean inverse of isna.

**DataFrame.dropna** Omit axes labels with missing values.

**isna** Top-level isna.

## Examples

Show which entries in a DataFrame are NA.

```
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
...                    'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                             pd.Timestamp('1940-04-25')],
...                    'name': ['Alfred', 'Batman', ''],
...                    'toy': [None, 'Batmobile', 'Joker']})
>>> df
   age      born  name      toy
0  5.0      NaT  Alfred    None
1  6.0  1939-05-27  Batman  Batmobile
2  NaN  1940-04-25         Joker
```

```
>>> df.isna()
   age  born  name  toy
0  False  True  False  True
1  False  False  False  False
2   True  False  False  False
```

Show which entries in a Series are NA.

```
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2    NaN
dtype: float64
```

```
>>> ser.isna()
0    False
1    False
2     True
dtype: bool
```

**pandas.DataFrame.isnull**

`DataFrame.isnull` (*self*) → 'DataFrame'

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as `None` or `numpy.NaN`, gets mapped to `True` values. Everything else gets mapped to `False` values. Characters such as empty strings `' '` or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`).

**Returns**

**DataFrame** Mask of bool values for each element in DataFrame that indicates whether an element is not an NA value.

**See also:**

**DataFrame.isnull** Alias of `isna`.

**DataFrame.notna** Boolean inverse of `isna`.

**DataFrame.dropna** Omit axes labels with missing values.

**isna** Top-level `isna`.

**Examples**

Show which entries in a DataFrame are NA.

```
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
...                    'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                             pd.Timestamp('1940-04-25')],
...                    'name': ['Alfred', 'Batman', ''],
...                    'toy': [None, 'Batmobile', 'Joker']})
>>> df
   age      born  name      toy
0  5.0      NaT  Alfred  None
1  6.0 1939-05-27  Batman  Batmobile
2  NaN 1940-04-25      Joker
```

```
>>> df.isna()
   age  born  name  toy
0  False  True  False  True
1  False  False  False  False
2   True  False  False  False
```

Show which entries in a Series are NA.

```
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2    NaN
dtype: float64
```

```
>>> ser.isna()
0    False
```

(continues on next page)

(continued from previous page)

```
1    False
2     True
dtype: bool
```

## pandas.DataFrame.items

`DataFrame.items(self)` → `Iterable[Tuple[Union[Hashable, NoneType], pandas.core.series.Series]]`

Iterate over (column name, Series) pairs.

Iterates over the DataFrame columns, returning a tuple with the column name and the content as a Series.

### Yields

**label** [object] The column names for the DataFrame being iterated over.

**content** [Series] The column entries belonging to each label, as a Series.

### See also:

**DataFrame.iterrows** Iterate over DataFrame rows as (index, Series) pairs.

**DataFrame.itertuples** Iterate over DataFrame rows as namedtuples of the values.

## Examples

```
>>> df = pd.DataFrame({'species': ['bear', 'bear', 'marsupial'],
...                    'population': [1864, 22000, 80000]},
...                    index=['panda', 'polar', 'koala'])
>>> df
   species  population
panda   bear         1864
polar   bear        22000
koala  marsupial    80000
>>> for label, content in df.items():
...     print('label:', label)
...     print('content:', content, sep='\n')
...
label: species
content:
panda      bear
polar      bear
koala  marsupial
Name: species, dtype: object
label: population
content:
panda      1864
polar     22000
koala     80000
Name: population, dtype: int64
```

**pandas.DataFrame.iteritems**

`DataFrame.iteritems` (*self*) → Iterable[Tuple[Union[Hashable, NoneType], pandas.core.series.Series]]

Iterate over (column name, Series) pairs.

Iterates over the DataFrame columns, returning a tuple with the column name and the content as a Series.

**Yields**

**label** [object] The column names for the DataFrame being iterated over.

**content** [Series] The column entries belonging to each label, as a Series.

**See also:**

**DataFrame.iterrows** Iterate over DataFrame rows as (index, Series) pairs.

**DataFrame.itertuples** Iterate over DataFrame rows as namedtuples of the values.

**Examples**

```
>>> df = pd.DataFrame({'species': ['bear', 'bear', 'marsupial'],
...                    'population': [1864, 22000, 80000]},
...                    index=['panda', 'polar', 'koala'])
>>> df
   species  population
panda   bear        1864
polar   bear       22000
koala  marsupial   80000
>>> for label, content in df.items():
...     print('label:', label)
...     print('content:', content, sep='\n')
...
label: species
content:
panda      bear
polar      bear
koala  marsupial
Name: species, dtype: object
label: population
content:
panda      1864
polar     22000
koala     80000
Name: population, dtype: int64
```

## pandas.DataFrame.iterrows

`DataFrame.iterrows` (*self*) → Iterable[Tuple[Union[Hashable, NoneType], pandas.core.series.Series]]

Iterate over DataFrame rows as (index, Series) pairs.

### Yields

**index** [label or tuple of label] The index of the row. A tuple for a *MultiIndex*.

**data** [Series] The data of the row as a Series.

**it** [generator] A generator that iterates over the rows of the frame.

### See also:

**DataFrame.itertuples** Iterate over DataFrame rows as namedtuples of the values.

**DataFrame.items** Iterate over (column name, Series) pairs.

### Notes

1. Because `iterrows` returns a Series for each row, it does **not** preserve dtypes across the rows (dtypes are preserved across columns for DataFrames). For example,

```
>>> df = pd.DataFrame([[1, 1.5]], columns=['int', 'float'])
>>> row = next(df.iterrows())[1]
>>> row
int      1.0
float    1.5
Name: 0, dtype: float64
>>> print(row['int'].dtype)
float64
>>> print(df['int'].dtype)
int64
```

To preserve dtypes while iterating over the rows, it is better to use `itertuples()` which returns namedtuples of the values and which is generally faster than `iterrows`.

2. You should **never modify** something you are iterating over. This is not guaranteed to work in all cases. Depending on the data types, the iterator returns a copy and not a view, and writing to it will have no effect.

## pandas.DataFrame.itertuples

`DataFrame.itertuples` (*self*, *index=True*, *name='Pandas'*)

Iterate over DataFrame rows as namedtuples.

### Parameters

**index** [bool, default True] If True, return the index as the first element of the tuple.

**name** [str or None, default "Pandas"] The name of the returned namedtuples or None to return regular tuples.

### Returns

**iterator** An object to iterate over namedtuples for each row in the DataFrame with the first field possibly being the index and following fields being the column values.

**See also:**

**DataFrame.iterrows** Iterate over DataFrame rows as (index, Series) pairs.

**DataFrame.items** Iterate over (column name, Series) pairs.

**Notes**

The column names will be renamed to positional names if they are invalid Python identifiers, repeated, or start with an underscore. On python versions < 3.7 regular tuples are returned for DataFrames with a large number of columns (>254).

**Examples**

```
>>> df = pd.DataFrame({'num_legs': [4, 2], 'num_wings': [0, 2]},
...                    index=['dog', 'hawk'])
>>> df
   num_legs  num_wings
dog         4         0
hawk        2         2
>>> for row in df.itertuples():
...     print(row)
...
Pandas(Index='dog', num_legs=4, num_wings=0)
Pandas(Index='hawk', num_legs=2, num_wings=2)
```

By setting the *index* parameter to `False` we can remove the index as the first element of the tuple:

```
>>> for row in df.itertuples(index=False):
...     print(row)
...
Pandas(num_legs=4, num_wings=0)
Pandas(num_legs=2, num_wings=2)
```

With the *name* parameter set we set a custom name for the yielded namedtuples:

```
>>> for row in df.itertuples(name='Animal'):
...     print(row)
...
Animal(Index='dog', num_legs=4, num_wings=0)
Animal(Index='hawk', num_legs=2, num_wings=2)
```

**pandas.DataFrame.join**

`DataFrame.join(self, other, on=None, how='left', lsuffix="", rsuffix="", sort=False) → 'DataFrame'`  
Join columns of another DataFrame.

Join columns with *other* DataFrame either on index or on a key column. Efficiently join multiple DataFrame objects by index at once by passing a list.

**Parameters**

**other** [DataFrame, Series, or list of DataFrame] Index should be similar to one of the columns in this one. If a Series is passed, its name attribute must be set, and that will be used as the column name in the resulting joined DataFrame.

**on** [str, list of str, or array-like, optional] Column or index level name(s) in the caller to join on the index in *other*, otherwise joins index-on-index. If multiple values given, the *other* DataFrame must have a MultiIndex. Can pass an array as the join key if it is not already contained in the calling DataFrame. Like an Excel VLOOKUP operation.

**how** [{ 'left', 'right', 'outer', 'inner' }, default 'left'] How to handle the operation of the two objects.

- left: use calling frame's index (or column if on is specified)
- right: use *other*'s index.
- outer: form union of calling frame's index (or column if on is specified) with *other*'s index, and sort it. lexicographically.
- inner: form intersection of calling frame's index (or column if on is specified) with *other*'s index, preserving the order of the calling's one.

**lsuffix** [str, default ''] Suffix to use from left frame's overlapping columns.

**rsuffix** [str, default ''] Suffix to use from right frame's overlapping columns.

**sort** [bool, default False] Order result DataFrame lexicographically by the join key. If False, the order of the join key depends on the join type (how keyword).

### Returns

**DataFrame** A dataframe containing columns from both the caller and *other*.

### See also:

**DataFrame.merge** For column(s)-on-columns(s) operations.

### Notes

Parameters *on*, *lsuffix*, and *rsuffix* are not supported when passing a list of *DataFrame* objects.

Support for specifying index levels as the *on* parameter was added in version 0.23.0.

### Examples

```
>>> df = pd.DataFrame({'key': ['K0', 'K1', 'K2', 'K3', 'K4', 'K5'],
...                    'A': ['A0', 'A1', 'A2', 'A3', 'A4', 'A5']})
```

```
>>> df
   key  A
0  K0  A0
1  K1  A1
2  K2  A2
3  K3  A3
4  K4  A4
5  K5  A5
```

```
>>> other = pd.DataFrame({'key': ['K0', 'K1', 'K2'],
...                       'B': ['B0', 'B1', 'B2']})
```

```
>>> other
   key  B
0  K0  B0
1  K1  B1
2  K2  B2
```

Join DataFrames using their indexes.

```
>>> df.join(other, lsuffix='_caller', rsuffix='_other')
   key_caller  A key_other  B
0          K0  A0         K0  B0
1          K1  A1         K1  B1
2          K2  A2         K2  B2
3          K3  A3         NaN NaN
4          K4  A4         NaN NaN
5          K5  A5         NaN NaN
```

If we want to join using the key columns, we need to set key to be the index in both *df* and *other*. The joined DataFrame will have key as its index.

```
>>> df.set_index('key').join(other.set_index('key'))
   A  B
key
K0  A0  B0
K1  A1  B1
K2  A2  B2
K3  A3  NaN
K4  A4  NaN
K5  A5  NaN
```

Another option to join using the key columns is to use the *on* parameter. DataFrame.join always uses *other*'s index but we can use any column in *df*. This method preserves the original DataFrame's index in the result.

```
>>> df.join(other.set_index('key'), on='key')
   key  A  B
0  K0  A0  B0
1  K1  A1  B1
2  K2  A2  B2
3  K3  A3  NaN
4  K4  A4  NaN
5  K5  A5  NaN
```

## pandas.DataFrame.keys

DataFrame.**keys** (*self*)

Get the 'info axis' (see Indexing for more).

This is index for Series, columns for DataFrame.

### Returns

**Index** Info axis.

### pandas.DataFrame.kurt

DataFrame.**kurt** (*self*, *axis=None*, *skipna=None*, *level=None*, *numeric\_only=None*, **\*\*kwargs**)

Return unbiased kurtosis over requested axis.

Kurtosis obtained using Fisher's definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1.

#### Parameters

**axis** [{index (0), columns (1)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

#### Returns

**Series or DataFrame (if level specified)**

### pandas.DataFrame.kurtosis

DataFrame.**kurtosis** (*self*, *axis=None*, *skipna=None*, *level=None*, *numeric\_only=None*, **\*\*kwargs**)

Return unbiased kurtosis over requested axis.

Kurtosis obtained using Fisher's definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1.

#### Parameters

**axis** [{index (0), columns (1)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

#### Returns

**Series or DataFrame (if level specified)**

## pandas.DataFrame.last

`DataFrame.last` (*self*: ~FrameOrSeries, *offset*) → ~FrameOrSeries  
 Method to subset final periods of time series data based on a date offset.

### Parameters

**offset** [str, DateOffset, dateutil.relativedelta]

### Returns

**subset** [same type as caller]

### Raises

**TypeError** If the index is not a *DatetimeIndex*

### See also:

**first** Select initial periods of time series based on a date offset.

**at\_time** Select values at a particular time of the day.

**between\_time** Select values between particular times of the day.

### Examples

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
```

	A
2018-04-09	1
2018-04-11	2
2018-04-13	3
2018-04-15	4

Get the rows for the last 3 days:

```
>>> ts.last('3D')
```

	A
2018-04-13	3
2018-04-15	4

Notice the data for 3 last calendar days were returned, not the last 3 observed days in the dataset, and therefore data for 2018-04-11 was not returned.

## pandas.DataFrame.last\_valid\_index

`DataFrame.last_valid_index` (*self*)  
 Return index for last non-NA/null value.

### Returns

**scalar** [type of index]

## Notes

If all elements are non-NA/null, returns None. Also returns None for empty Series/DataFrame.

## pandas.DataFrame.le

`DataFrame.le` (*self*, *other*, *axis='columns'*, *level=None*)

Get Less than or equal to of dataframe and other, element-wise (binary operator *le*).

Among flexible wrappers (*eq*, *ne*, *le*, *lt*, *ge*, *gt*) to comparison operators.

Equivalent to `==`, `!=`, `<=`, `<`, `>=`, `>` with support to choose axis (rows or columns) and level for comparison.

### Parameters

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}, default 'columns'] Whether to compare by the index (0 or 'index') or columns (1 or 'columns').

**level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

### Returns

**DataFrame of bool** Result of the comparison.

### See also:

**DataFrame.eq** Compare DataFrames for equality elementwise.

**DataFrame.ne** Compare DataFrames for inequality elementwise.

**DataFrame.le** Compare DataFrames for less than inequality or equality elementwise.

**DataFrame.lt** Compare DataFrames for strictly less than inequality elementwise.

**DataFrame.ge** Compare DataFrames for greater than inequality or equality elementwise.

**DataFrame.gt** Compare DataFrames for strictly greater than inequality elementwise.

## Notes

Mismatched indices will be unioned together. *NaN* values are considered different (i.e. *NaN != NaN*).

## Examples

```

>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                    'revenue': [100, 250, 300]},
...                    index=['A', 'B', 'C'])
>>> df
   cost  revenue
A    250     100
B    150     250
C    100     300

```

Comparison with a scalar, using either the operator or method:

```
>>> df == 100
      cost  revenue
A  False    True
B  False    False
C   True    False
```

```
>>> df.eq(100)
      cost  revenue
A  False    True
B  False    False
C   True    False
```

When *other* is a *Series*, the columns of a *DataFrame* are aligned with the index of *other* and broadcast:

```
>>> df != pd.Series([100, 250], index=["cost", "revenue"])
      cost  revenue
A   True    True
B   True    False
C  False    True
```

Use the method to control the broadcast axis:

```
>>> df.ne(pd.Series([100, 300], index=["A", "D"]), axis='index')
      cost  revenue
A   True    False
B   True    True
C   True    True
D   True    True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in *other*:

```
>>> df == [250, 100]
      cost  revenue
A   True    True
B  False    False
C  False    False
```

Use the method to control the axis:

```
>>> df.eq([250, 250, 100], axis='index')
      cost  revenue
A   True    False
B  False    True
C   True    False
```

Compare to a *DataFrame* of different shape.

```
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
...                       index=['A', 'B', 'C', 'D'])
>>> other
      revenue
A         300
B         250
C         100
D         150
```

```
>>> df.gt(other)
      cost  revenue
A  False   False
B  False   False
C  False    True
D  False   False
```

Compare to a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
...                               'revenue': [100, 250, 300, 200, 175, 225]},
...                               index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
...                                       ['A', 'B', 'C', 'A', 'B', 'C']])
>>> df_multindex
      cost  revenue
Q1 A    250     100
   B    150     250
   C    100     300
Q2 A    150     200
   B    300     175
   C    220     225
```

```
>>> df.le(df_multindex, level=1)
      cost  revenue
Q1 A   True    True
   B   True    True
   C   True    True
Q2 A  False    True
   B   True   False
   C   True   False
```

### pandas.DataFrame.lookup

`DataFrame.lookup` (*self*, *row\_labels*, *col\_labels*) → `numpy.ndarray`

Label-based “fancy indexing” function for DataFrame.

Given equal-length arrays of row and column labels, return an array of the values corresponding to each (row, col) pair.

#### Parameters

**row\_labels** [sequence] The row labels to use for lookup.

**col\_labels** [sequence] The column labels to use for lookup.

#### Returns

**numpy.ndarray**

## Examples

**values** [ndarray] The found values

### pandas.DataFrame.lt

`DataFrame.lt` (*self*, *other*, *axis='columns'*, *level=None*)

Get Less than of dataframe and other, element-wise (binary operator *lt*).

Among flexible wrappers (*eq*, *ne*, *le*, *lt*, *ge*, *gt*) to comparison operators.

Equivalent to `==`, `!=`, `<=`, `<`, `>=`, `>` with support to choose axis (rows or columns) and level for comparison.

#### Parameters

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}, default 'columns'] Whether to compare by the index (0 or 'index') or columns (1 or 'columns').

**level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

#### Returns

**DataFrame of bool** Result of the comparison.

See also:

**DataFrame.eq** Compare DataFrames for equality elementwise.

**DataFrame.ne** Compare DataFrames for inequality elementwise.

**DataFrame.le** Compare DataFrames for less than inequality or equality elementwise.

**DataFrame.lt** Compare DataFrames for strictly less than inequality elementwise.

**DataFrame.ge** Compare DataFrames for greater than inequality or equality elementwise.

**DataFrame.gt** Compare DataFrames for strictly greater than inequality elementwise.

## Notes

Mismatched indices will be unioned together. *NaN* values are considered different (i.e. *NaN != NaN*).

## Examples

```
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                    'revenue': [100, 250, 300]},
...                    index=['A', 'B', 'C'])
>>> df
   cost  revenue
A   250     100
B   150     250
C   100     300
```

Comparison with a scalar, using either the operator or method:

```
>>> df == 100
      cost  revenue
A  False    True
B  False    False
C   True    False
```

```
>>> df.eq(100)
      cost  revenue
A  False    True
B  False    False
C   True    False
```

When *other* is a *Series*, the columns of a *DataFrame* are aligned with the index of *other* and broadcast:

```
>>> df != pd.Series([100, 250], index=["cost", "revenue"])
      cost  revenue
A   True    True
B   True    False
C  False    True
```

Use the method to control the broadcast axis:

```
>>> df.ne(pd.Series([100, 300], index=["A", "D"]), axis='index')
      cost  revenue
A   True    False
B   True    True
C   True    True
D   True    True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in *other*:

```
>>> df == [250, 100]
      cost  revenue
A   True    True
B  False    False
C  False    False
```

Use the method to control the axis:

```
>>> df.eq([250, 250, 100], axis='index')
      cost  revenue
A   True    False
B  False    True
C   True    False
```

Compare to a *DataFrame* of different shape.

```
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
...                       index=['A', 'B', 'C', 'D'])
>>> other
      revenue
A         300
B         250
C         100
D         150
```

```
>>> df.gt(other)
      cost  revenue
A  False   False
B  False   False
C  False    True
D  False   False
```

Compare to a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
...                               'revenue': [100, 250, 300, 200, 175, 225]},
...                               index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
...                                       ['A', 'B', 'C', 'A', 'B', 'C']])
>>> df_multindex
      cost  revenue
Q1 A   250    100
   B   150    250
   C   100    300
Q2 A   150    200
   B   300    175
   C   220    225
```

```
>>> df.le(df_multindex, level=1)
      cost  revenue
Q1 A   True    True
   B   True    True
   C   True    True
Q2 A  False    True
   B   True   False
   C   True   False
```

## pandas.DataFrame.mad

DataFrame.**mad** (*self*, *axis=None*, *skipna=None*, *level=None*)

Return the mean absolute deviation of the values for the requested axis.

### Parameters

**axis** [{index (0), columns (1)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

### Returns

**Series or DataFrame (if level specified)**

## pandas.DataFrame.mask

`DataFrame.mask` (*self*, *cond*, *other=nan*, *inplace=False*, *axis=None*, *level=None*, *errors='raise'*, *try\_cast=False*)

Replace values where the condition is True.

### Parameters

**cond** [bool Series/DataFrame, array-like, or callable] Where *cond* is False, keep the original value. Where True, replace with corresponding value from *other*. If *cond* is callable, it is computed on the Series/DataFrame and should return boolean Series/DataFrame or array. The callable must not change input Series/DataFrame (though pandas doesn't check it).

**other** [scalar, Series/DataFrame, or callable] Entries where *cond* is True are replaced with corresponding value from *other*. If *other* is callable, it is computed on the Series/DataFrame and should return scalar or Series/DataFrame. The callable must not change input Series/DataFrame (though pandas doesn't check it).

**inplace** [bool, default False] Whether to perform the operation in place on the data.

**axis** [int, default None] Alignment axis if needed.

**level** [int, default None] Alignment level if needed.

**errors** [str, {'raise', 'ignore'}, default 'raise'] Note that currently this parameter won't affect the results and will always coerce to a suitable dtype.

- 'raise' : allow exceptions to be raised.
- 'ignore' : suppress exceptions. On error return original object.

**try\_cast** [bool, default False] Try to cast the result back to the input type (if possible).

### Returns

Same type as caller

See also:

`DataFrame.where()` Return an object of same shape as self.

### Notes

The mask method is an application of the if-then idiom. For each element in the calling DataFrame, if *cond* is False the element is used; otherwise the corresponding element from the DataFrame *other* is used.

The signature for `DataFrame.where()` differs from `numpy.where()`. Roughly `df1.where(m, df2)` is equivalent to `np.where(m, df1, df2)`.

For further details and examples see the mask documentation in *indexing*.

## Examples

```
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0    NaN
1    1.0
2    2.0
3    3.0
4    4.0
dtype: float64
```

```
>>> s.mask(s > 0)
0    0.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

```
>>> s.where(s > 1, 10)
0    10
1    10
2     2
3     3
4     4
dtype: int64
```

```
>>> df = pd.DataFrame(np.arange(10).reshape(-1, 2), columns=['A', 'B'])
>>> df
   A  B
0  0  1
1  2  3
2  4  5
3  6  7
4  8  9
>>> m = df % 3 == 0
>>> df.where(m, -df)
   A  B
0  0 -1
1 -2  3
2 -4 -5
3  6 -7
4 -8  9
>>> df.where(m, -df) == np.where(m, df, -df)
   A     B
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True
>>> df.where(m, -df) == df.mask(~m, -df)
   A     B
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True
```

**pandas.DataFrame.max**

`DataFrame.max` (*self*, *axis=None*, *skipna=None*, *level=None*, *numeric\_only=None*, *\*\*kwargs*)

Return the maximum of the values for the requested axis.

If you want the *index* of the maximum, use `idxmax`. This is the equivalent of the `numpy.ndarray` method `argmax`.

**Parameters**

**axis** [{index (0), columns (1)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

**Returns**

**Series or DataFrame (if level specified)**

**See also:**

**Series.sum** Return the sum.

**Series.min** Return the minimum.

**Series.max** Return the maximum.

**Series.idxmin** Return the index of the minimum.

**Series.idxmax** Return the index of the maximum.

**DataFrame.sum** Return the sum over the requested axis.

**DataFrame.min** Return the minimum over the requested axis.

**DataFrame.max** Return the maximum over the requested axis.

**DataFrame.idxmin** Return the index of the minimum over the requested axis.

**DataFrame.idxmax** Return the index of the maximum over the requested axis.

**Examples**

```
>>> idx = pd.MultiIndex.from_arrays([
...     ['warm', 'warm', 'cold', 'cold'],
...     ['dog', 'falcon', 'fish', 'spider']],
...     names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded  animal
warm     dog      4
         falcon   2
cold     fish     0
```

(continues on next page)

(continued from previous page)

```

        spider      8
Name: legs, dtype: int64

```

```

>>> s.max()
8

```

Max using level names, as well as indices.

```

>>> s.max(level='blooded')
blooded
warm      4
cold      8
Name: legs, dtype: int64

```

```

>>> s.max(level=0)
blooded
warm      4
cold      8
Name: legs, dtype: int64

```

### pandas.DataFrame.mean

`DataFrame.mean` (*self*, *axis=None*, *skipna=None*, *level=None*, *numeric\_only=None*, *\*\*kwargs*)  
Return the mean of the values for the requested axis.

#### Parameters

- axis** [{index (0), columns (1)}] Axis for the function to be applied on.
- skipna** [bool, default True] Exclude NA/null values when computing the result.
- level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
- numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- \*\*kwargs** Additional keyword arguments to be passed to the function.

#### Returns

**Series or DataFrame (if level specified)**

### pandas.DataFrame.median

`DataFrame.median` (*self*, *axis=None*, *skipna=None*, *level=None*, *numeric\_only=None*, *\*\*kwargs*)  
Return the median of the values for the requested axis.

#### Parameters

- axis** [{index (0), columns (1)}] Axis for the function to be applied on.
- skipna** [bool, default True] Exclude NA/null values when computing the result.
- level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

### Returns

**Series or DataFrame (if level specified)**

## pandas.DataFrame.melt

`DataFrame.melt` (*self*, *id\_vars=None*, *value\_vars=None*, *var\_name=None*, *value\_name='value'*, *col\_level=None*) → 'DataFrame'

Unpivot a DataFrame from wide to long format, optionally leaving identifiers set.

This function is useful to massage a DataFrame into a format where one or more columns are identifier variables (*id\_vars*), while all other columns, considered measured variables (*value\_vars*), are “unpivoted” to the row axis, leaving just two non-identifier columns, ‘variable’ and ‘value’. .. versionadded:: 0.20.0

### Parameters

**id\_vars** [tuple, list, or ndarray, optional] Column(s) to use as identifier variables.

**value\_vars** [tuple, list, or ndarray, optional] Column(s) to unpivot. If not specified, uses all columns that are not set as *id\_vars*.

**var\_name** [scalar] Name to use for the ‘variable’ column. If None it uses `frame.columns.name` or ‘variable’.

**value\_name** [scalar, default ‘value’] Name to use for the ‘value’ column.

**col\_level** [int or str, optional] If columns are a MultiIndex then use this level to melt.

### Returns

**DataFrame** Unpivoted DataFrame.

See also:

`melt`

`pivot_table`

`DataFrame.pivot`

`Series.explode`

### Examples

```
>>> df = pd.DataFrame({'A': {0: 'a', 1: 'b', 2: 'c'},
...                    'B': {0: 1, 1: 3, 2: 5},
...                    'C': {0: 2, 1: 4, 2: 6}})
>>> df
   A  B  C
0  a  1  2
1  b  3  4
2  c  5  6
```

```
>>> df.melt(id_vars=['A'], value_vars=['B'])
  A variable  value
0 a         B      1
1 b         B      3
2 c         B      5
```

```
>>> df.melt(id_vars=['A'], value_vars=['B', 'C'])
  A variable  value
0 a         B      1
1 b         B      3
2 c         B      5
3 a         C      2
4 b         C      4
5 c         C      6
```

The names of 'variable' and 'value' columns can be customized:

```
>>> df.melt(id_vars=['A'], value_vars=['B'],
...         var_name='myVarname', value_name='myValname')
  A myVarname myValname
0 a         B          1
1 b         B          3
2 c         B          5
```

If you have multi-index columns:

```
>>> df.columns = [list('ABC'), list('DEF')]
>>> df
  A B C
  D E F
0 a 1 2
1 b 3 4
2 c 5 6
```

```
>>> df.melt(col_level=0, id_vars=['A'], value_vars=['B'])
  A variable  value
0 a         B      1
1 b         B      3
2 c         B      5
```

```
>>> df.melt(id_vars=[('A', 'D')], value_vars=[('B', 'E')])
  (A, D) variable_0 variable_1  value
0      a         B          E      1
1      b         B          E      3
2      c         B          E      5
```

**pandas.DataFrame.memory\_usage**

`DataFrame.memory_usage` (*self*, *index=True*, *deep=False*) → `pandas.core.series.Series`

Return the memory usage of each column in bytes.

The memory usage can optionally include the contribution of the index and elements of *object* dtype.

This value is displayed in `DataFrame.info` by default. This can be suppressed by setting `pandas.options.display.memory_usage` to `False`.

**Parameters**

**index** [bool, default True] Specifies whether to include the memory usage of the `DataFrame`'s index in returned Series. If `index=True`, the memory usage of the index is the first item in the output.

**deep** [bool, default False] If True, introspect the data deeply by interrogating *object* dtypes for system-level memory consumption, and include it in the returned values.

**Returns**

**Series** A Series whose index is the original column names and whose values is the memory usage of each column in bytes.

**See also:**

`numpy.ndarray.nbytes` Total bytes consumed by the elements of an ndarray.

`Series.memory_usage` Bytes consumed by a Series.

`Categorical` Memory-efficient array for string values with many repeated values.

`DataFrame.info` Concise summary of a DataFrame.

**Examples**

```
>>> dtypes = ['int64', 'float64', 'complex128', 'object', 'bool']
>>> data = dict([(t, np.ones(shape=5000).astype(t))
...              for t in dtypes])
>>> df = pd.DataFrame(data)
>>> df.head()
   int64  float64      complex128  object  bool
0      1    1.0  1.000000+0.000000j      1  True
1      1    1.0  1.000000+0.000000j      1  True
2      1    1.0  1.000000+0.000000j      1  True
3      1    1.0  1.000000+0.000000j      1  True
4      1    1.0  1.000000+0.000000j      1  True
```

```
>>> df.memory_usage()
Index          128
int64         40000
float64       40000
complex128    80000
object        40000
bool          5000
dtype: int64
```

```
>>> df.memory_usage(index=False)
int64      40000
float64     40000
complex128  80000
object      40000
bool        5000
dtype: int64
```

The memory footprint of *object* dtype columns is ignored by default:

```
>>> df.memory_usage(deep=True)
Index      128
int64      40000
float64     40000
complex128  80000
object     160000
bool        5000
dtype: int64
```

Use a Categorical for efficient storage of an object-dtype column with many repeated values.

```
>>> df['object'].astype('category').memory_usage(deep=True)
5216
```

## pandas.DataFrame.merge

`DataFrame.merge(self, right, how='inner', on=None, left_on=None, right_on=None, left_index=False, right_index=False, sort=False, suffixes=('_x', '_y'), copy=True, indicator=False, validate=None) → 'DataFrame'`

Merge DataFrame or named Series objects with a database-style join.

The join is done on columns or indexes. If joining columns on columns, the DataFrame indexes *will be ignored*. Otherwise if joining indexes on indexes or indexes on a column or columns, the index will be passed on.

### Parameters

**right** [DataFrame or named Series] Object to merge with.

**how** [{ 'left', 'right', 'outer', 'inner' }, default 'inner'] Type of merge to be performed.

- left: use only keys from left frame, similar to a SQL left outer join; preserve key order.
- right: use only keys from right frame, similar to a SQL right outer join; preserve key order.
- outer: use union of keys from both frames, similar to a SQL full outer join; sort keys lexicographically.
- inner: use intersection of keys from both frames, similar to a SQL inner join; preserve the order of the left keys.

**on** [label or list] Column or index level names to join on. These must be found in both DataFrames. If *on* is None and not merging on indexes then this defaults to the intersection of the columns in both DataFrames.

**left\_on** [label or list, or array-like] Column or index level names to join on in the left DataFrame. Can also be an array or list of arrays of the length of the left DataFrame. These arrays are treated as if they are columns.

**right\_on** [label or list, or array-like] Column or index level names to join on in the right DataFrame. Can also be an array or list of arrays of the length of the right DataFrame. These arrays are treated as if they are columns.

**left\_index** [bool, default False] Use the index from the left DataFrame as the join key(s). If it is a MultiIndex, the number of keys in the other DataFrame (either the index or a number of columns) must match the number of levels.

**right\_index** [bool, default False] Use the index from the right DataFrame as the join key. Same caveats as left\_index.

**sort** [bool, default False] Sort the join keys lexicographically in the result DataFrame. If False, the order of the join keys depends on the join type (how keyword).

**suffixes** [tuple of (str, str), default ('\_x', '\_y')] Suffix to apply to overlapping column names in the left and right side, respectively. To raise an exception on overlapping columns use (False, False).

**copy** [bool, default True] If False, avoid copy if possible.

**indicator** [bool or str, default False] If True, adds a column to output DataFrame called “\_merge” with information on the source of each row. If string, column with information on source of each row will be added to output DataFrame, and column will be named value of string. Information column is Categorical-type and takes on a value of “left\_only” for observations whose merge key only appears in ‘left’ DataFrame, “right\_only” for observations whose merge key only appears in ‘right’ DataFrame, and “both” if the observation’s merge key is found in both.

**validate** [str, optional] If specified, checks if merge is of specified type.

- “one\_to\_one” or “1:1”: check if merge keys are unique in both left and right datasets.
- “one\_to\_many” or “1:m”: check if merge keys are unique in left dataset.
- “many\_to\_one” or “m:1”: check if merge keys are unique in right dataset.
- “many\_to\_many” or “m:m”: allowed, but does not result in checks.

New in version 0.21.0.

### Returns

**DataFrame** A DataFrame of the two merged objects.

### See also:

***merge\_ordered*** Merge with optional filling/interpolation.

***merge\_asof*** Merge on nearest keys.

***DataFrame.join*** Similar method using indices.

## Notes

Support for specifying index levels as the *on*, *left\_on*, and *right\_on* parameters was added in version 0.23.0  
 Support for merging named Series objects was added in version 0.24.0

## Examples

```
>>> df1 = pd.DataFrame({'lkey': ['foo', 'bar', 'baz', 'foo'],
...                     'value': [1, 2, 3, 5]})
>>> df2 = pd.DataFrame({'rkey': ['foo', 'bar', 'baz', 'foo'],
...                     'value': [5, 6, 7, 8]})
>>> df1
   lkey  value
0  foo     1
1  bar     2
2  baz     3
3  foo     5
>>> df2
   rkey  value
0  foo     5
1  bar     6
2  baz     7
3  foo     8
```

Merge df1 and df2 on the lkey and rkey columns. The value columns have the default suffixes, *\_x* and *\_y*, appended.

```
>>> df1.merge(df2, left_on='lkey', right_on='rkey')
   lkey  value_x rkey  value_y
0  foo         1  foo         5
1  foo         1  foo         8
2  foo         5  foo         5
3  foo         5  foo         8
4  bar         2  bar         6
5  baz         3  baz         7
```

Merge DataFrames df1 and df2 with specified left and right suffixes appended to any overlapping columns.

```
>>> df1.merge(df2, left_on='lkey', right_on='rkey',
...           suffixes=('_left', '_right'))
   lkey  value_left rkey  value_right
0  foo         1  foo         5
1  foo         1  foo         8
2  foo         5  foo         5
3  foo         5  foo         8
4  bar         2  bar         6
5  baz         3  baz         7
```

Merge DataFrames df1 and df2, but raise an exception if the DataFrames have any overlapping columns.

```
>>> df1.merge(df2, left_on='lkey', right_on='rkey', suffixes=(False, False))
Traceback (most recent call last):
...
ValueError: columns overlap but no suffix specified:
   Index(['value'], dtype='object')
```

**pandas.DataFrame.min**

`DataFrame.min` (*self*, *axis=None*, *skipna=None*, *level=None*, *numeric\_only=None*, **\*\*kwargs**)

Return the minimum of the values for the requested axis.

If you want the *index* of the minimum, use `idxmin`. This is the equivalent of the `numpy.ndarray` method `argmin`.

**Parameters**

**axis** [{index (0), columns (1)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

**Returns**

**Series or DataFrame (if level specified)**

**See also:**

**Series.sum** Return the sum.

**Series.min** Return the minimum.

**Series.max** Return the maximum.

**Series.idxmin** Return the index of the minimum.

**Series.idxmax** Return the index of the maximum.

**DataFrame.sum** Return the sum over the requested axis.

**DataFrame.min** Return the minimum over the requested axis.

**DataFrame.max** Return the maximum over the requested axis.

**DataFrame.idxmin** Return the index of the minimum over the requested axis.

**DataFrame.idxmax** Return the index of the maximum over the requested axis.

**Examples**

```
>>> idx = pd.MultiIndex.from_arrays([
...     ['warm', 'warm', 'cold', 'cold'],
...     ['dog', 'falcon', 'fish', 'spider']],
...     names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded  animal
warm     dog      4
         falcon   2
cold     fish     0
```

(continues on next page)

(continued from previous page)

```

        spider      8
Name: legs, dtype: int64

```

```

>>> s.min()
0

```

Min using level names, as well as indices.

```

>>> s.min(level='blooded')
blooded
warm      2
cold      0
Name: legs, dtype: int64

```

```

>>> s.min(level=0)
blooded
warm      2
cold      0
Name: legs, dtype: int64

```

## pandas.DataFrame.mod

`DataFrame.mod` (*self*, *other*, *axis*='columns', *level*=None, *fill\_value*=None)

Get Modulo of dataframe and other, element-wise (binary operator *mod*).

Equivalent to `dataframe % other`, but with support to substitute a *fill\_value* for missing data in one of the inputs. With reverse version, *rmod*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: +, -, \*, /, //, %, \*\*.

### Parameters

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

**level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

**fill\_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

### Returns

**DataFrame** Result of the arithmetic operation.

See also:

**DataFrame.add** Add DataFrames.

**DataFrame.sub** Subtract DataFrames.

**DataFrame.mul** Multiply DataFrames.

**DataFrame.div** Divide DataFrames (float division).

**DataFrame.truediv** Divide DataFrames (float division).

**DataFrame.floordiv** Divide DataFrames (integer division).

**DataFrame.mod** Calculate modulo (remainder after division).

**DataFrame.pow** Calculate exponential power.

## Notes

Mismatched indices will be unioned together.

## Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

	angles	degrees
circle	0	360
triangle	3	180
rectangle	4	360

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

```
>>> df.add(1)
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

Divide by constant with reverse version.

```
>>> df.div(10)
```

	angles	degrees
circle	0.0	36.0
triangle	0.3	18.0
rectangle	0.4	36.0

```
>>> df.rdiv(10)
```

	angles	degrees
circle	inf	0.027778
triangle	3.333333	0.055556
rectangle	2.500000	0.027778

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
      angles  degrees
circle     -1     358
triangle    2     178
rectangle   3     358
```

```
>>> df.sub([1, 2], axis='columns')
      angles  degrees
circle     -1     358
triangle    2     178
rectangle   3     358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
      angles  degrees
circle     -1     359
triangle    2     179
rectangle   3     359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
      angles
circle      0
triangle     3
rectangle    4
```

```
>>> df * other
      angles  degrees
circle      0      NaN
triangle     9      NaN
rectangle   16      NaN
```

```
>>> df.mul(other, fill_value=0)
      angles  degrees
circle      0      0.0
triangle     9      0.0
rectangle   16      0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                              index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                      ['circle', 'triangle', 'rectangle',
...                                       'square', 'pentagon', 'hexagon']])
>>> df_multindex
      angles  degrees
A circle      0      360
  triangle     3      180
  rectangle    4      360
B square      4      360
  pentagon     5      540
  hexagon      6      720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
          angles  degrees
A circle      NaN      1.0
  triangle    1.0      1.0
  rectangle    1.0      1.0
B square       0.0      0.0
  pentagon     0.0      0.0
  hexagon      0.0      0.0
```

## pandas.DataFrame.mode

DataFrame.**mode** (*self*, *axis=0*, *numeric\_only=False*, *dropna=True*) → 'DataFrame'

Get the mode(s) of each element along the selected axis.

The mode of a set of values is the value that appears most often. It can be multiple values.

### Parameters

**axis** [{0 or 'index', 1 or 'columns'}, default 0] The axis to iterate over while searching for the mode:

- 0 or 'index': get mode of each column
- 1 or 'columns': get mode of each row.

**numeric\_only** [bool, default False] If True, only apply to numeric columns.

**dropna** [bool, default True] Don't consider counts of NaN/NaT.

New in version 0.24.0.

### Returns

**DataFrame** The modes of each column or row.

See also:

**Series.mode** Return the highest frequency value in a Series.

**Series.value\_counts** Return the counts of values in a Series.

## Examples

```
>>> df = pd.DataFrame([('bird', 2, 2),
...                    ('mammal', 4, np.nan),
...                    ('arthropod', 8, 0),
...                    ('bird', 2, np.nan)],
...                    index=('falcon', 'horse', 'spider', 'ostrich'),
...                    columns=('species', 'legs', 'wings'))
>>> df
   species  legs  wings
falcon   bird     2    2.0
horse   mammal     4    NaN
spider  arthropod     8    0.0
ostrich   bird     2    NaN
```

By default, missing values are not considered, and the mode of wings are both 0 and 2. The second row of species and legs contains NaN, because they have only one mode, but the DataFrame has two rows.

```
>>> df.mode()
   species  legs  wings
0   bird    2.0   0.0
1   NaN    NaN   2.0
```

Setting `dropna=False` NaN values are considered and they can be the mode (like for wings).

```
>>> df.mode(dropna=False)
   species  legs  wings
0   bird    2   NaN
```

Setting `numeric_only=True`, only the mode of numeric columns is computed, and columns of other types are ignored.

```
>>> df.mode(numeric_only=True)
   legs  wings
0   2.0   0.0
1   NaN   2.0
```

To compute the mode over columns and not rows, use the axis parameter:

```
>>> df.mode(axis='columns', numeric_only=True)
           0    1
falcon    2.0 NaN
horse     4.0 NaN
spider    0.0 8.0
ostrich   2.0 NaN
```

## pandas.DataFrame.mul

`DataFrame.mul(self, other, axis='columns', level=None, fill_value=None)`

Get Multiplication of dataframe and other, element-wise (binary operator *mul*).

Equivalent to `dataframe * other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *rmul*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

### Parameters

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

**level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

**fill\_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

### Returns

**DataFrame** Result of the arithmetic operation.

See also:

**DataFrame.add** Add DataFrames.

**DataFrame.sub** Subtract DataFrames.

**DataFrame.mul** Multiply DataFrames.

**DataFrame.div** Divide DataFrames (float division).

**DataFrame.truediv** Divide DataFrames (float division).

**DataFrame.floordiv** Divide DataFrames (integer division).

**DataFrame.mod** Calculate modulo (remainder after division).

**DataFrame.pow** Calculate exponential power.

## Notes

Mismatched indices will be unioned together.

## Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

	angles	degrees
circle	0	360
triangle	3	180
rectangle	4	360

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

```
>>> df.add(1)
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

Divide by constant with reverse version.

```
>>> df.div(10)
```

	angles	degrees
circle	0.0	36.0
triangle	0.3	18.0
rectangle	0.4	36.0

```
>>> df.rdiv(10)
```

	angles	degrees
circle	inf	0.027778
triangle	3.333333	0.055556
rectangle	2.500000	0.027778

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
      angles  degrees
circle      -1     358
triangle     2     178
rectangle   3     358
```

```
>>> df.sub([1, 2], axis='columns')
      angles  degrees
circle      -1     358
triangle     2     178
rectangle   3     358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
      angles  degrees
circle      -1     359
triangle     2     179
rectangle   3     359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
      angles
circle      0
triangle     3
rectangle    4
```

```
>>> df * other
      angles  degrees
circle      0      NaN
triangle     9      NaN
rectangle   16      NaN
```

```
>>> df.mul(other, fill_value=0)
      angles  degrees
circle      0      0.0
triangle     9      0.0
rectangle   16      0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                              index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                      ['circle', 'triangle', 'rectangle',
...                                       'square', 'pentagon', 'hexagon']])
>>> df_multindex
      angles  degrees
A circle      0     360
  triangle     3     180
  rectangle     4     360
B square      4     360
```

(continues on next page)

(continued from previous page)

pentagon	5	540
hexagon	6	720

```

>>> df.div(df_multindex, level=1, fill_value=0)
      angles  degrees
A circle   NaN     1.0
  triangle   1.0     1.0
  rectangle   1.0     1.0
B square    0.0     0.0
  pentagon   0.0     0.0
  hexagon    0.0     0.0

```

### pandas.DataFrame.multiply

DataFrame.**multiply** (*self*, *other*, *axis*='columns', *level*=None, *fill\_value*=None)

Get Multiplication of dataframe and other, element-wise (binary operator *mul*).

Equivalent to `dataframe * other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *rmul*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: +, -, \*, /, //, %, \*\*.

#### Parameters

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

**level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

**fill\_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

#### Returns

**DataFrame** Result of the arithmetic operation.

See also:

**DataFrame.add** Add DataFrames.

**DataFrame.sub** Subtract DataFrames.

**DataFrame.mul** Multiply DataFrames.

**DataFrame.div** Divide DataFrames (float division).

**DataFrame.truediv** Divide DataFrames (float division).

**DataFrame.floordiv** Divide DataFrames (integer division).

**DataFrame.mod** Calculate modulo (remainder after division).

**DataFrame.pow** Calculate exponential power.

## Notes

Mismatched indices will be unioned together.

## Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

	angles	degrees
circle	0	360
triangle	3	180
rectangle	4	360

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

```
>>> df.add(1)
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

Divide by constant with reverse version.

```
>>> df.div(10)
```

	angles	degrees
circle	0.0	36.0
triangle	0.3	18.0
rectangle	0.4	36.0

```
>>> df.rdiv(10)
```

	angles	degrees
circle	inf	0.027778
triangle	3.333333	0.055556
rectangle	2.500000	0.027778

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
```

	angles	degrees
circle	-1	358
triangle	2	178
rectangle	3	358

```
>>> df.sub([1, 2], axis='columns')
```

	angles	degrees
circle	-1	358
triangle	2	178
rectangle	3	358

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...         axis='index')
      angles  degrees
circle     -1     359
triangle     2     179
rectangle     3     359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
      angles
circle      0
triangle     3
rectangle     4
```

```
>>> df * other
      angles  degrees
circle      0      NaN
triangle     9      NaN
rectangle   16      NaN
```

```
>>> df.mul(other, fill_value=0)
      angles  degrees
circle      0      0.0
triangle     9      0.0
rectangle   16      0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                              index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                       ['circle', 'triangle', 'rectangle',
...                                       'square', 'pentagon', 'hexagon']])
>>> df_multindex
      angles  degrees
A circle      0     360
  triangle     3     180
  rectangle     4     360
B square      4     360
  pentagon     5     540
  hexagon      6     720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
      angles  degrees
A circle   NaN      1.0
  triangle  1.0      1.0
  rectangle 1.0      1.0
B square   0.0      0.0
  pentagon 0.0      0.0
  hexagon  0.0      0.0
```

## pandas.DataFrame.ne

DataFrame.**ne** (*self*, *other*, *axis='columns'*, *level=None*)

Get Not equal to of dataframe and other, element-wise (binary operator *ne*).

Among flexible wrappers (*eq*, *ne*, *le*, *lt*, *ge*, *gt*) to comparison operators.

Equivalent to `==`, `!=`, `<=`, `<`, `>=`, `>` with support to choose axis (rows or columns) and level for comparison.

### Parameters

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}, default 'columns'] Whether to compare by the index (0 or 'index') or columns (1 or 'columns').

**level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

### Returns

**DataFrame of bool** Result of the comparison.

### See also:

**DataFrame.eq** Compare DataFrames for equality elementwise.

**DataFrame.ne** Compare DataFrames for inequality elementwise.

**DataFrame.le** Compare DataFrames for less than inequality or equality elementwise.

**DataFrame.lt** Compare DataFrames for strictly less than inequality elementwise.

**DataFrame.ge** Compare DataFrames for greater than inequality or equality elementwise.

**DataFrame.gt** Compare DataFrames for strictly greater than inequality elementwise.

### Notes

Mismatched indices will be unioned together. *NaN* values are considered different (i.e. *NaN != NaN*).

### Examples

```
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                    'revenue': [100, 250, 300]},
...                    index=['A', 'B', 'C'])
>>> df
   cost  revenue
A    250     100
B    150     250
C    100     300
```

Comparison with a scalar, using either the operator or method:

```
>>> df == 100
   cost  revenue
A  False     True
```

(continues on next page)

(continued from previous page)

```
B False False
C  True False
```

```
>>> df.eq(100)
      cost revenue
A False      True
B False      False
C  True      False
```

When *other* is a *Series*, the columns of a *DataFrame* are aligned with the index of *other* and broadcast:

```
>>> df != pd.Series([100, 250], index=["cost", "revenue"])
      cost revenue
A  True      True
B  True      False
C False      True
```

Use the method to control the broadcast axis:

```
>>> df.ne(pd.Series([100, 300], index=["A", "D"]), axis='index')
      cost revenue
A  True      False
B  True      True
C  True      True
D  True      True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in *other*:

```
>>> df == [250, 100]
      cost revenue
A  True      True
B False      False
C False      False
```

Use the method to control the axis:

```
>>> df.eq([250, 250, 100], axis='index')
      cost revenue
A  True      False
B False      True
C  True      False
```

Compare to a *DataFrame* of different shape.

```
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
...                       index=['A', 'B', 'C', 'D'])
>>> other
      revenue
A         300
B         250
C         100
D         150
```

```
>>> df.gt(other)
      cost revenue
```

(continues on next page)

(continued from previous page)

```
A False False
B False False
C False True
D False False
```

Compare to a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
...                               'revenue': [100, 250, 300, 200, 175, 225]},
...                               index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
...                                       ['A', 'B', 'C', 'A', 'B', 'C']])
>>> df_multindex
      cost  revenue
Q1 A    250     100
   B    150     250
   C    100     300
Q2 A    150     200
   B    300     175
   C    220     225
```

```
>>> df.le(df_multindex, level=1)
      cost  revenue
Q1 A    True     True
   B    True     True
   C    True     True
Q2 A    False    True
   B    True     False
   C    True     False
```

### pandas.DataFrame.nlargest

`DataFrame.nlargest` (*self*, *n*, *columns*, *keep='first'*) → 'DataFrame'

Return the first *n* rows ordered by *columns* in descending order.

Return the first *n* rows with the largest values in *columns*, in descending order. The columns that are not specified are returned as well, but not used for ordering.

This method is equivalent to `df.sort_values(columns, ascending=False).head(n)`, but more performant.

#### Parameters

**n** [int] Number of rows to return.

**columns** [label or list of labels] Column label(s) to order by.

**keep** [{ 'first', 'last', 'all' }, default 'first'] Where there are duplicate values:

- *first* : prioritize the first occurrence(s)
- *last* : prioritize the last occurrence(s)
- **all** [do not drop any duplicates, even it means] selecting more than *n* items.

New in version 0.24.0.

#### Returns

**DataFrame** The first *n* rows ordered by the given columns in descending order.

See also:

**DataFrame.nsmallest** Return the first *n* rows ordered by *columns* in ascending order.

**DataFrame.sort\_values** Sort DataFrame by the values.

**DataFrame.head** Return the first *n* rows without re-ordering.

## Notes

This function cannot be used with all column types. For example, when specifying columns with *object* or *category* dtypes, `TypeError` is raised.

## Examples

```
>>> df = pd.DataFrame({'population': [59000000, 65000000, 434000,
...                                  434000, 434000, 337000, 11300,
...                                  11300, 11300],
...                    'GDP': [1937894, 2583560, 12011, 4520, 12128,
...                             17036, 182, 38, 311],
...                    'alpha-2': ["IT", "FR", "MT", "MV", "BN",
...                                 "IS", "NR", "TV", "AI"]},
...                    index=["Italy", "France", "Malta",
...                             "Maldives", "Brunei", "Iceland",
...                             "Nauru", "Tuvalu", "Anguilla"])
>>> df
```

	population	GDP	alpha-2
Italy	59000000	1937894	IT
France	65000000	2583560	FR
Malta	434000	12011	MT
Maldives	434000	4520	MV
Brunei	434000	12128	BN
Iceland	337000	17036	IS
Nauru	11300	182	NR
Tuvalu	11300	38	TV
Anguilla	11300	311	AI

In the following example, we will use `nlargest` to select the three rows having the largest values in column “population”.

```
>>> df.nlargest(3, 'population')
```

	population	GDP	alpha-2
France	65000000	2583560	FR
Italy	59000000	1937894	IT
Malta	434000	12011	MT

When using `keep='last'`, ties are resolved in reverse order:

```
>>> df.nlargest(3, 'population', keep='last')
```

	population	GDP	alpha-2
France	65000000	2583560	FR
Italy	59000000	1937894	IT
Brunei	434000	12128	BN

When using `keep='all'`, all duplicate items are maintained:

```
>>> df.nlargest(3, 'population', keep='all')
      population      GDP alpha-2
France  65000000  2583560      FR
Italy   59000000  1937894      IT
Malta   434000    12011      MT
Maldives 434000    4520      MV
Brunei  434000    12128      BN
```

To order by the largest values in column “population” and then “GDP”, we can specify multiple columns like in the next example.

```
>>> df.nlargest(3, ['population', 'GDP'])
      population      GDP alpha-2
France  65000000  2583560      FR
Italy   59000000  1937894      IT
Brunei  434000    12128      BN
```

## pandas.DataFrame.notna

DataFrame.**notna** (*self*) → 'DataFrame'

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`). NA values, such as `None` or `numpy.NaN`, get mapped to False values.

### Returns

**DataFrame** Mask of bool values for each element in DataFrame that indicates whether an element is not an NA value.

**See also:**

**DataFrame.notnull** Alias of `notna`.

**DataFrame.isna** Boolean inverse of `notna`.

**DataFrame.droptna** Omit axes labels with missing values.

**notna** Top-level `notna`.

## Examples

Show which entries in a DataFrame are not NA.

```
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
...                    'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                              pd.Timestamp('1940-04-25')],
...                    'name': ['Alfred', 'Batman', ''],
...                    'toy': [None, 'Batmobile', 'Joker']})
>>> df
   age      born      name      toy
0  5.0      NaT  Alfred     None
1  6.0  1939-05-27  Batman  Batmobile
2  NaN  1940-04-25      Joker
```

```
>>> df.notna()
   age  born  name  toy
0  True False  True  False
1  True  True  True   True
2  False  True  True   True
```

Show which entries in a Series are not NA.

```
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2    NaN
dtype: float64
```

```
>>> ser.notna()
0     True
1     True
2    False
dtype: bool
```

## pandas.DataFrame.notnull

`DataFrame.notnull(self) → 'DataFrame'`

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`). NA values, such as `None` or `numpy.NaN`, get mapped to False values.

### Returns

**DataFrame** Mask of bool values for each element in DataFrame that indicates whether an element is not an NA value.

**See also:**

**DataFrame.notnull** Alias of `notna`.

**DataFrame.isna** Boolean inverse of `notna`.

**DataFrame.dropna** Omit axes labels with missing values.

**notna** Top-level `notna`.

## Examples

Show which entries in a DataFrame are not NA.

```
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
...                    'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                             pd.Timestamp('1940-04-25')],
...                    'name': ['Alfred', 'Batman', ''],
...                    'toy': [None, 'Batmobile', 'Joker']})
>>> df
```

(continues on next page)

(continued from previous page)

```

   age      born      name      toy
0  5.0      NaT    Alfred      None
1  6.0 1939-05-27   Batman  Batmobile
2  NaN 1940-04-25      Joker

```

```

>>> df.notna()
   age  born  name  toy
0  True False  True False
1  True  True  True  True
2  False  True  True  True

```

Show which entries in a Series are not NA.

```

>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2    NaN
dtype: float64

```

```

>>> ser.notna()
0     True
1     True
2    False
dtype: bool

```

### pandas.DataFrame.nsmallest

`DataFrame.nsmallest(self, n, columns, keep='first') → 'DataFrame'`

Return the first *n* rows ordered by *columns* in ascending order.

Return the first *n* rows with the smallest values in *columns*, in ascending order. The columns that are not specified are returned as well, but not used for ordering.

This method is equivalent to `df.sort_values(columns, ascending=True).head(n)`, but more performant.

#### Parameters

**n** [int] Number of items to retrieve.

**columns** [list or str] Column name or names to order by.

**keep** [{‘first’, ‘last’, ‘all’}, default ‘first’] Where there are duplicate values:

- `first`: take the first occurrence.
- `last`: take the last occurrence.
- `all`: do not drop any duplicates, even it means selecting more than *n* items.

New in version 0.24.0.

#### Returns

**DataFrame**

See also:

**DataFrame.nlargest** Return the first *n* rows ordered by *columns* in descending order.

**DataFrame.sort\_values** Sort DataFrame by the values.

**DataFrame.head** Return the first *n* rows without re-ordering.

## Examples

```
>>> df = pd.DataFrame({'population': [59000000, 65000000, 434000,
...                                  434000, 434000, 337000, 11300,
...                                  11300, 11300],
...                    'GDP': [1937894, 2583560, 12011, 4520, 12128,
...                             17036, 182, 38, 311],
...                    'alpha-2': ["IT", "FR", "MT", "MV", "BN",
...                                 "IS", "NR", "TV", "AI"]},
...                    index=["Italy", "France", "Malta",
...                             "Maldives", "Brunei", "Iceland",
...                             "Nauru", "Tuvalu", "Anguilla"])
>>> df
```

	population	GDP	alpha-2
Italy	59000000	1937894	IT
France	65000000	2583560	FR
Malta	434000	12011	MT
Maldives	434000	4520	MV
Brunei	434000	12128	BN
Iceland	337000	17036	IS
Nauru	11300	182	NR
Tuvalu	11300	38	TV
Anguilla	11300	311	AI

In the following example, we will use `nsmallest` to select the three rows having the smallest values in column “a”.

```
>>> df.nsmallest(3, 'population')
```

	population	GDP	alpha-2
Nauru	11300	182	NR
Tuvalu	11300	38	TV
Anguilla	11300	311	AI

When using `keep='last'`, ties are resolved in reverse order:

```
>>> df.nsmallest(3, 'population', keep='last')
```

	population	GDP	alpha-2
Anguilla	11300	311	AI
Tuvalu	11300	38	TV
Nauru	11300	182	NR

When using `keep='all'`, all duplicate items are maintained:

```
>>> df.nsmallest(3, 'population', keep='all')
```

	population	GDP	alpha-2
Nauru	11300	182	NR
Tuvalu	11300	38	TV
Anguilla	11300	311	AI

To order by the largest values in column “a” and then “c”, we can specify multiple columns like in the next example.

```
>>> df.nsmallest(3, ['population', 'GDP'])
      population  GDP alpha-2
Tuvalu          11300    38      TV
Nauru           11300   182      NR
Anguilla        11300   311      AI
```

### pandas.DataFrame.nunique

`DataFrame.nunique` (*self*, *axis=0*, *dropna=True*) → `pandas.core.series.Series`  
 Count distinct observations over requested axis.

Return Series with number of distinct observations. Can ignore NaN values.

#### Parameters

**axis** [{0 or 'index', 1 or 'columns'}, default 0] The axis to use. 0 or 'index' for row-wise, 1 or 'columns' for column-wise.

**dropna** [bool, default True] Don't include NaN in the counts.

#### Returns

##### Series

See also:

**Series.nunique** Method `nunique` for Series.

**DataFrame.count** Count non-NA cells for each column or row.

### Examples

```
>>> df = pd.DataFrame({'A': [1, 2, 3], 'B': [1, 1, 1]})
>>> df.nunique()
A    3
B    1
dtype: int64
```

```
>>> df.nunique(axis=1)
0    1
1    2
2    2
dtype: int64
```

### pandas.DataFrame.pct\_change

`DataFrame.pct_change` (*self*: *~FrameOrSeries*, *periods=1*, *fill\_method='pad'*, *limit=None*, *freq=None*, *\*\*kwargs*) → *~FrameOrSeries*  
 Percentage change between the current and a prior element.

Computes the percentage change from the immediately previous row by default. This is useful in comparing the percentage of change in a time series of elements.

#### Parameters

**periods** [int, default 1] Periods to shift for forming percent change.

**fill\_method** [str, default 'pad'] How to handle NAs before computing percent changes.

**limit** [int, default None] The number of consecutive NAs to fill before stopping.

**freq** [DateOffset, timedelta, or str, optional] Increment to use from time series API (e.g. 'M' or BDay()).

**\*\*kwargs** Additional keyword arguments are passed into *DataFrame.shift* or *Series.shift*.

### Returns

**chg** [Series or DataFrame] The same type as the calling object.

### See also:

**Series.diff** Compute the difference of two elements in a Series.

**DataFrame.diff** Compute the difference of two elements in a DataFrame.

**Series.shift** Shift the index by some number of periods.

**DataFrame.shift** Shift the index by some number of periods.

## Examples

### Series

```
>>> s = pd.Series([90, 91, 85])
>>> s
0    90
1    91
2    85
dtype: int64
```

```
>>> s.pct_change()
0         NaN
1    0.011111
2   -0.065934
dtype: float64
```

```
>>> s.pct_change(periods=2)
0         NaN
1         NaN
2   -0.055556
dtype: float64
```

See the percentage change in a Series where filling NAs with last valid observation forward to next valid.

```
>>> s = pd.Series([90, 91, None, 85])
>>> s
0    90.0
1    91.0
2     NaN
3    85.0
dtype: float64
```

```
>>> s.pct_change(fill_method='ffill')
0      NaN
1    0.011111
2    0.000000
3   -0.065934
dtype: float64
```

### DataFrame

Percentage change in French franc, Deutsche Mark, and Italian lira from 1980-01-01 to 1980-03-01.

```
>>> df = pd.DataFrame({
...     'FR': [4.0405, 4.0963, 4.3149],
...     'GR': [1.7246, 1.7482, 1.8519],
...     'IT': [804.74, 810.01, 860.13]},
...     index=['1980-01-01', '1980-02-01', '1980-03-01'])
>>> df
```

	FR	GR	IT
1980-01-01	4.0405	1.7246	804.74
1980-02-01	4.0963	1.7482	810.01
1980-03-01	4.3149	1.8519	860.13

```
>>> df.pct_change()
```

	FR	GR	IT
1980-01-01	NaN	NaN	NaN
1980-02-01	0.013810	0.013684	0.006549
1980-03-01	0.053365	0.059318	0.061876

Percentage of change in GOOG and APPL stock volume. Shows computing the percentage change between columns.

```
>>> df = pd.DataFrame({
...     '2016': [1769950, 30586265],
...     '2015': [1500923, 40912316],
...     '2014': [1371819, 41403351]},
...     index=['GOOG', 'APPL'])
>>> df
```

	2016	2015	2014
GOOG	1769950	1500923	1371819
APPL	30586265	40912316	41403351

```
>>> df.pct_change(axis='columns')
```

	2016	2015	2014
GOOG	NaN	-0.151997	-0.086016

## pandas.DataFrame.pipe

`DataFrame.pipe` (*self*, *func*, \**args*, \*\**kwargs*)  
Apply `func(self, *args, **kwargs)`.

### Parameters

**func** [function] Function to apply to the Series/DataFrame. `args`, and `kwargs` are passed into `func`. Alternatively a (`callable`, `data_keyword`) tuple where `data_keyword` is a string indicating the keyword of `callable` that expects the Series/DataFrame.

**args** [iterable, optional] Positional arguments passed into `func`.

**kwargs** [mapping, optional] A dictionary of keyword arguments passed into `func`.

### Returns

**object** [the return type of `func`.]

See also:

*DataFrame.apply*

*DataFrame.applymap*

*Series.map*

### Notes

Use `.pipe` when chaining together functions that expect Series, DataFrames or GroupBy objects. Instead of writing

```
>>> f(g(h(df), arg1=a), arg2=b, arg3=c)
```

You can write

```
>>> (df.pipe(h)
...   .pipe(g, arg1=a)
...   .pipe(f, arg2=b, arg3=c)
... )
```

If you have a function that takes the data as (say) the second argument, pass a tuple indicating which keyword expects the data. For example, suppose `f` takes its data as `arg2`:

```
>>> (df.pipe(h)
...   .pipe(g, arg1=a)
...   .pipe((f, 'arg2'), arg1=a, arg3=c)
... )
```

## pandas.DataFrame.pivot

DataFrame.**pivot** (*self*, *index=None*, *columns=None*, *values=None*) → 'DataFrame'

Return reshaped DataFrame organized by given index / column values.

Reshape data (produce a “pivot” table) based on column values. Uses unique values from specified *index* / *columns* to form axes of the resulting DataFrame. This function does not support data aggregation, multiple values will result in a MultiIndex in the columns. See the *User Guide* for more on reshaping.

### Parameters

**index** [str or object, optional] Column to use to make new frame’s index. If None, uses existing index.

**columns** [str or object] Column to use to make new frame’s columns.

**values** [str, object or a list of the previous, optional] Column(s) to use for populating new frame’s values. If not specified, all remaining columns will be used and the result will have hierarchically indexed columns.

Changed in version 0.23.0: Also accept list of column names.

### Returns

**DataFrame** Returns reshaped DataFrame.

### Raises

**ValueError:** When there are any *index*, *columns* combinations with multiple values. *DataFrame.pivot\_table* when you need to aggregate.

### See also:

**DataFrame.pivot\_table** Generalization of pivot that can handle duplicate values for one index/column pair.

**DataFrame.unstack** Pivot based on the index values instead of a column.

### Notes

For finer-tuned control, see hierarchical indexing documentation along with the related stack/unstack methods.

### Examples

```

>>> df = pd.DataFrame({'foo': ['one', 'one', 'one', 'two', 'two',
...                             'two'],
...                    'bar': ['A', 'B', 'C', 'A', 'B', 'C'],
...                    'baz': [1, 2, 3, 4, 5, 6],
...                    'zoo': ['x', 'y', 'z', 'q', 'w', 't']})
>>> df
   foo  bar  baz  zoo
0  one   A    1    x
1  one   B    2    y
2  one   C    3    z
3  two   A    4    q
4  two   B    5    w
5  two   C    6    t

```

```
>>> df.pivot(index='foo', columns='bar', values='baz')
bar A    B    C
foo
one 1    2    3
two 4    5    6
```

```
>>> df.pivot(index='foo', columns='bar')['baz']
bar A    B    C
foo
one 1    2    3
two 4    5    6
```

```
>>> df.pivot(index='foo', columns='bar', values=['baz', 'zoo'])
      baz      zoo
bar  A B C  A B C
foo
one  1 2 3  x y z
two  4 5 6  q w t
```

A `ValueError` is raised if there are any duplicates.

```
>>> df = pd.DataFrame({"foo": ['one', 'one', 'two', 'two'],
...                   "bar": ['A', 'A', 'B', 'C'],
...                   "baz": [1, 2, 3, 4]})
>>> df
   foo bar  baz
0  one  A    1
1  one  A    2
2  two  B    3
3  two  C    4
```

Notice that the first two rows are the same for our `index` and `columns` arguments.

```
>>> df.pivot(index='foo', columns='bar', values='baz')
Traceback (most recent call last):
...
ValueError: Index contains duplicate entries, cannot reshape
```

## pandas.DataFrame.pivot\_table

`DataFrame.pivot_table`(*self*, *values=None*, *index=None*, *columns=None*, *aggfunc='mean'*, *fill\_value=None*, *margins=False*, *dropna=True*, *margins\_name='All'*, *observed=False*) → 'DataFrame'

Create a spreadsheet-style pivot table as a DataFrame.

The levels in the pivot table will be stored in MultiIndex objects (hierarchical indexes) on the index and columns of the result DataFrame.

### Parameters

**values** [column to aggregate, optional]

**index** [column, Grouper, array, or list of the previous] If an array is passed, it must be the same length as the data. The list can contain any of the other types (except list). Keys to group by on the pivot table index. If an array is passed, it is being used as the same manner as column values.

**columns** [column, Grouper, array, or list of the previous] If an array is passed, it must be the same length as the data. The list can contain any of the other types (except list). Keys to group by on the pivot table column. If an array is passed, it is being used as the same manner as column values.

**aggfunc** [function, list of functions, dict, default numpy.mean] If list of functions passed, the resulting pivot table will have hierarchical columns whose top level are the function names (inferred from the function objects themselves) If dict is passed, the key is column to aggregate and value is function or list of functions.

**fill\_value** [scalar, default None] Value to replace missing values with.

**margins** [bool, default False] Add all row / columns (e.g. for subtotal / grand totals).

**dropna** [bool, default True] Do not include columns whose entries are all NaN.

**margins\_name** [str, default 'All'] Name of the row / column that will contain the totals when margins is True.

**observed** [bool, default False] This only applies if any of the groupers are Categoricals. If True: only show observed values for categorical groupers. If False: show all values for categorical groupers.

Changed in version 0.25.0.

### Returns

**DataFrame** An Excel style pivot table.

### See also:

**DataFrame.pivot** Pivot without aggregation that can handle non-numeric data.

### Examples

```
>>> df = pd.DataFrame({"A": ["foo", "foo", "foo", "foo", "foo",
...                          "bar", "bar", "bar", "bar"],
...                    "B": ["one", "one", "one", "two", "two",
...                          "one", "one", "two", "two"],
...                    "C": ["small", "large", "large", "small",
...                          "small", "large", "small", "small",
...                          "large"],
...                    "D": [1, 2, 2, 3, 3, 4, 5, 6, 7],
...                    "E": [2, 4, 5, 5, 6, 6, 8, 9, 9]})
>>> df
   A  B  C  D  E
0  foo one small  1  2
1  foo one large  2  4
2  foo one large  2  5
3  foo two small  3  5
4  foo two small  3  6
5  bar one large  4  6
6  bar one small  5  8
7  bar two small  6  9
8  bar two large  7  9
```

This first example aggregates values by taking the sum.

```
>>> table = pd.pivot_table(df, values='D', index=['A', 'B'],
...                          columns=['C'], aggfunc=np.sum)
>>> table
C          large  small
A  B
bar one    4.0    5.0
    two    7.0    6.0
foo one    4.0    1.0
    two    NaN    6.0
```

We can also fill missing values using the *fill\_value* parameter.

```
>>> table = pd.pivot_table(df, values='D', index=['A', 'B'],
...                          columns=['C'], aggfunc=np.sum, fill_value=0)
>>> table
C          large  small
A  B
bar one     4     5
    two     7     6
foo one     4     1
    two     0     6
```

The next example aggregates by taking the mean across multiple columns.

```
>>> table = pd.pivot_table(df, values=['D', 'E'], index=['A', 'C'],
...                          aggfunc={'D': np.mean,
...                                    'E': np.mean})
>>> table
A  C          D          E
bar large  5.500000  7.500000
    small  5.500000  8.500000
foo large  2.000000  4.500000
    small  2.333333  4.333333
```

We can also calculate multiple types of aggregations for any given value column.

```
>>> table = pd.pivot_table(df, values=['D', 'E'], index=['A', 'C'],
...                          aggfunc={'D': np.mean,
...                                    'E': [min, max, np.mean]})
>>> table
A  C          D          E          mean  min
    mean  max          mean  min
bar large  5.500000  9.0  7.500000  6.0
    small  5.500000  9.0  8.500000  8.0
foo large  2.000000  5.0  4.500000  4.0
    small  2.333333  6.0  4.333333  2.0
```

**pandas.DataFrame.plot**

`DataFrame.plot` (*self*, \*args, \*\*kwargs)

Make plots of Series or DataFrame.

Uses the backend specified by the option `plotting.backend`. By default, `matplotlib` is used.

**Parameters**

**data** [Series or DataFrame] The object for which the method is called.

**x** [label or position, default None] Only used if data is a DataFrame.

**y** [label, position or list of label, positions, default None] Allows plotting of one column versus another. Only used if data is a DataFrame.

**kind** [str] The kind of plot to produce:

- 'line' : line plot (default)
- 'bar' : vertical bar plot
- 'barh' : horizontal bar plot
- 'hist' : histogram
- 'box' : boxplot
- 'kde' : Kernel Density Estimation plot
- 'density' : same as 'kde'
- 'area' : area plot
- 'pie' : pie plot
- 'scatter' : scatter plot
- 'hexbin' : hexbin plot.

**figsize** [a tuple (width, height) in inches]

**use\_index** [bool, default True] Use index as ticks for x axis.

**title** [str or list] Title to use for the plot. If a string is passed, print the string at the top of the figure. If a list is passed and *subplots* is True, print each item in the list above the corresponding subplot.

**grid** [bool, default None (matlab style default)] Axis grid lines.

**legend** [bool or {'reverse'}] Place legend on axis subplots.

**style** [list or dict] The matplotlib line style per column.

**logx** [bool or 'sym', default False] Use log scaling or symlog scaling on x axis. .. versionchanged:: 0.25.0

**logy** [bool or 'sym' default False] Use log scaling or symlog scaling on y axis. .. versionchanged:: 0.25.0

**loglog** [bool or 'sym', default False] Use log scaling or symlog scaling on both x and y axes. .. versionchanged:: 0.25.0

**xticks** [sequence] Values to use for the xticks.

**yticks** [sequence] Values to use for the yticks.

**xlim** [2-tuple/list]

**ylim** [2-tuple/list]

**rot** [int, default None] Rotation for ticks (xticks for vertical, yticks for horizontal plots).

**fontsize** [int, default None] Font size for xticks and yticks.

**colormap** [str or matplotlib colormap object, default None] Colormap to select colors from. If string, load colormap with that name from matplotlib.

**colorbar** [bool, optional] If True, plot colorbar (only relevant for ‘scatter’ and ‘hexbin’ plots).

**position** [float] Specify relative alignments for bar plot layout. From 0 (left/bottom-end) to 1 (right/top-end). Default is 0.5 (center).

**table** [bool, Series or DataFrame, default False] If True, draw a table using the data in the DataFrame and the data will be transposed to meet matplotlib’s default layout. If a Series or DataFrame is passed, use passed data to draw a table.

**yerr** [DataFrame, Series, array-like, dict and str] See *Plotting with Error Bars* for detail.

**xerr** [DataFrame, Series, array-like, dict and str] Equivalent to `yerr`.

**mark\_right** [bool, default True] When using a secondary\_y axis, automatically mark the column labels with “(right)” in the legend.

**include\_bool** [bool, default is False] If True, boolean values can be plotted.

**backend** [str, default None] Backend to use instead of the backend specified in the option `plotting.backend`. For instance, ‘matplotlib’. Alternatively, to specify the `plotting.backend` for the whole session, set `pd.options.plotting.backend`.

New in version 1.0.0.

**\*\*kwargs** Options to pass to matplotlib plotting method.

### Returns

**matplotlib.axes.Axes or numpy.ndarray of them** If the backend is not the default matplotlib one, the return value will be the object returned by the backend.

### Notes

- See matplotlib documentation online for more on this subject
- If `kind = ‘bar’` or `‘barh’`, you can specify relative alignments for bar plot layout by *position* keyword. From 0 (left/bottom-end) to 1 (right/top-end). Default is 0.5 (center)

**pandas.DataFrame.pop**

`DataFrame.pop` (*self*: ~FrameOrSeries, *item*) → ~FrameOrSeries  
 Return item and drop from frame. Raise `KeyError` if not found.

**Parameters**

**item** [str] Label of column to be popped.

**Returns**

**Series**

**Examples**

```
>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
...                    ('parrot', 'bird', 24.0),
...                    ('lion', 'mammal', 80.5),
...                    ('monkey', 'mammal', np.nan)],
...                   columns=('name', 'class', 'max_speed'))
>>> df
   name  class  max_speed
0  falcon  bird    389.0
1  parrot  bird     24.0
2   lion  mammal    80.5
3  monkey  mammal     NaN
```

```
>>> df.pop('class')
0    bird
1    bird
2  mammal
3  mammal
Name: class, dtype: object
```

```
>>> df
   name  max_speed
0  falcon    389.0
1  parrot     24.0
2   lion     80.5
3  monkey     NaN
```

**pandas.DataFrame.pow**

`DataFrame.pow` (*self*, *other*, *axis*='columns', *level*=None, *fill\_value*=None)

Get Exponential power of dataframe and other, element-wise (binary operator `pow`).

Equivalent to `dataframe ** other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, `rpow`.

Among flexible wrappers (`add`, `sub`, `mul`, `div`, `mod`, `pow`) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

**Parameters**

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

**level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

**fill\_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

### Returns

**DataFrame** Result of the arithmetic operation.

### See also:

**DataFrame.add** Add DataFrames.

**DataFrame.sub** Subtract DataFrames.

**DataFrame.mul** Multiply DataFrames.

**DataFrame.div** Divide DataFrames (float division).

**DataFrame.truediv** Divide DataFrames (float division).

**DataFrame.floordiv** Divide DataFrames (integer division).

**DataFrame.mod** Calculate modulo (remainder after division).

**DataFrame.pow** Calculate exponential power.

### Notes

Mismatched indices will be unioned together.

### Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                   index=['circle', 'triangle', 'rectangle'])
>>> df
```

	angles	degrees
circle	0	360
triangle	3	180
rectangle	4	360

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

```
>>> df.add(1)
      angles  degrees
circle      1     361
triangle    4     181
rectangle   5     361
```

Divide by constant with reverse version.

```
>>> df.div(10)
      angles  degrees
circle    0.0    36.0
triangle  0.3    18.0
rectangle 0.4    36.0
```

```
>>> df.rdiv(10)
      angles  degrees
circle      inf  0.027778
triangle  3.333333  0.055556
rectangle  2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
      angles  degrees
circle     -1     358
triangle    2     178
rectangle   3     358
```

```
>>> df.sub([1, 2], axis='columns')
      angles  degrees
circle     -1     358
triangle    2     178
rectangle   3     358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
      angles  degrees
circle     -1     359
triangle    2     179
rectangle   3     359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
      angles
circle      0
triangle     3
rectangle    4
```

```
>>> df * other
      angles  degrees
circle      0      NaN
triangle     9      NaN
rectangle   16      NaN
```

```
>>> df.mul(other, fill_value=0)
      angles  degrees
circle      0      0.0
triangle    9      0.0
rectangle  16      0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                               index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                       ['circle', 'triangle', 'rectangle',
...                                       'square', 'pentagon', 'hexagon']])
>>> df_multindex
      angles  degrees
A circle      0      360
  triangle      3      180
  rectangle      4      360
B square      4      360
  pentagon      5      540
  hexagon      6      720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
      angles  degrees
A circle   NaN      1.0
  triangle  1.0      1.0
  rectangle  1.0      1.0
B square   0.0      0.0
  pentagon  0.0      0.0
  hexagon   0.0      0.0
```

## pandas.DataFrame.prod

DataFrame.**prod** (*self*, *axis=None*, *skipna=None*, *level=None*, *numeric\_only=None*, *min\_count=0*, *\*\*kwargs*)

Return the product of the values for the requested axis.

### Parameters

**axis** [{index (0), columns (1)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**min\_count** [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

New in version 0.22.0: Added with the default being 0. This means the sum of an all-NA or empty Series is 0, and the product of an all-NA or empty Series is 1.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

**Returns****Series or DataFrame (if level specified)****Examples**

By default, the product of an empty or all-NA Series is 1

```
>>> pd.Series([]).prod()
1.0
```

This can be controlled with the `min_count` parameter

```
>>> pd.Series([]).prod(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```
>>> pd.Series([np.nan]).prod()
1.0
```

```
>>> pd.Series([np.nan]).prod(min_count=1)
nan
```

**pandas.DataFrame.product**

`DataFrame.product` (*self*, *axis=None*, *skipna=None*, *level=None*, *numeric\_only=None*, *min\_count=0*, *\*\*kwargs*)

Return the product of the values for the requested axis.

**Parameters**

**axis** [{index (0), columns (1)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**min\_count** [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

New in version 0.22.0: Added with the default being 0. This means the sum of an all-NA or empty Series is 0, and the product of an all-NA or empty Series is 1.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

**Returns****Series or DataFrame (if level specified)**

## Examples

By default, the product of an empty or all-NA Series is 1

```
>>> pd.Series([]).prod()
1.0
```

This can be controlled with the `min_count` parameter

```
>>> pd.Series([]).prod(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```
>>> pd.Series([np.nan]).prod()
1.0
```

```
>>> pd.Series([np.nan]).prod(min_count=1)
nan
```

## pandas.DataFrame.quantile

`DataFrame.quantile` (*self*, *q*=0.5, *axis*=0, *numeric\_only*=True, *interpolation*='linear')

Return values at the given quantile over requested axis.

### Parameters

- q** [float or array-like, default 0.5 (50% quantile)] Value between  $0 \leq q \leq 1$ , the quantile(s) to compute.
- axis** [{0, 1, 'index', 'columns'} (default 0)] Equals 0 or 'index' for row-wise, 1 or 'columns' for column-wise.
- numeric\_only** [bool, default True] If False, the quantile of datetime and timedelta data will be computed as well.
- interpolation** [{'linear', 'lower', 'higher', 'midpoint', 'nearest'}] This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points *i* and *j*:
  - linear:  $i + (j - i) * fraction$ , where *fraction* is the fractional part of the index surrounded by *i* and *j*.
  - lower: *i*.
  - higher: *j*.
  - nearest: *i* or *j* whichever is nearest.
  - midpoint:  $(i + j) / 2$ .

### Returns

#### Series or DataFrame

If **q** is an array, a DataFrame will be returned where the index is *q*, the columns are the columns of *self*, and the values are the quantiles.

If **q** is a float, a Series will be returned where the index is the columns of *self* and the values are the quantiles.

See also:

`core.window.Rolling.quantile` Rolling quantile.

`numpy.percentile` Numpy function to compute the percentile.

## Examples

```
>>> df = pd.DataFrame(np.array([[1, 1], [2, 10], [3, 100], [4, 100]]),
...                   columns=['a', 'b'])
>>> df.quantile(.1)
a    1.3
b    3.7
Name: 0.1, dtype: float64
>>> df.quantile([.1, .5])
      a    b
0.1  1.3  3.7
0.5  2.5 55.0
```

Specifying `numeric_only=False` will also compute the quantile of datetime and timedelta data.

```
>>> df = pd.DataFrame({'A': [1, 2],
...                   'B': [pd.Timestamp('2010'),
...                          pd.Timestamp('2011')],
...                   'C': [pd.Timedelta('1 days'),
...                          pd.Timedelta('2 days')]})
>>> df.quantile(0.5, numeric_only=False)
A          1.5
B    2010-07-02 12:00:00
C          1 days 12:00:00
Name: 0.5, dtype: object
```

## pandas.DataFrame.query

`DataFrame.query` (*self, expr, inplace=False, \*\*kwargs*)

Query the columns of a DataFrame with a boolean expression.

### Parameters

**expr** [str] The query string to evaluate.

You can refer to variables in the environment by prefixing them with an '@' character like @a + b.

You can refer to column names that contain spaces or operators by surrounding them in backticks. This way you can also escape names that start with a digit, or those that are a Python keyword. Basically when it is not valid Python identifier. See notes down for more details.

For example, if one of your columns is called a a and you want to sum it with b, your query should be `a a` + b.

New in version 0.25.0: Backtick quoting introduced.

New in version 1.0.0: Expanding functionality of backtick quoting for more than only spaces.

**inplace** [bool] Whether the query should modify the data in place or return a modified copy.

**\*\*kwargs** See the documentation for `eval()` for complete details on the keyword arguments accepted by `DataFrame.query()`.

### Returns

**DataFrame** DataFrame resulting from the provided query expression.

### See also:

**eval** Evaluate a string describing operations on DataFrame columns.

**DataFrame.eval** Evaluate a string describing operations on DataFrame columns.

### Notes

The result of the evaluation of this expression is first passed to `DataFrame.loc` and if that fails because of a multidimensional key (e.g., a DataFrame) then the result will be passed to `DataFrame.__getitem__()`.

This method uses the top-level `eval()` function to evaluate the passed query.

The `query()` method uses a slightly modified Python syntax by default. For example, the `&` and `|` (bitwise) operators have the precedence of their boolean cousins, `and` and `or`. This *is* syntactically valid Python, however the semantics are different.

You can change the semantics of the expression by passing the keyword argument `parser='python'`. This enforces the same semantics as evaluation in Python space. Likewise, you can pass `engine='python'` to evaluate an expression using Python itself as a backend. This is not recommended as it is inefficient compared to using `numexpr` as the engine.

The `DataFrame.index` and `DataFrame.columns` attributes of the `DataFrame` instance are placed in the query namespace by default, which allows you to treat both the index and columns of the frame as a column in the frame. The identifier `index` is used for the frame index; you can also use the name of the index to identify it in a query. Please note that Python keywords may not be used as identifiers.

For further details and examples see the `query` documentation in *indexing*.

#### *Backtick quoted variables*

Backtick quoted variables are parsed as literal Python code and are converted internally to a Python valid identifier. This can lead to the following problems.

During parsing a number of disallowed characters inside the backtick quoted string are replaced by strings that are allowed as a Python identifier. These characters include all operators in Python, the space character, the question mark, the exclamation mark, the dollar sign, and the euro sign. For other characters that fall outside the ASCII range (U+0001..U+007F) and those that are not further specified in PEP 3131, the query parser will raise an error. This excludes whitespace different than the space character, but also the hashtag (as it is used for comments) and the backtick itself (backtick can also not be escaped).

In a special case, quotes that make a pair around a backtick can confuse the parser. For example, ``it's` > `that's`` will raise an error, as it forms a quoted string (`'s > `that'``) with a backtick inside.

See also the Python documentation about lexical analysis ([https://docs.python.org/3/reference/lexical\\_analysis.html](https://docs.python.org/3/reference/lexical_analysis.html)) in combination with the source code in `pandas.core.computation.parsing`.

## Examples

```
>>> df = pd.DataFrame({'A': range(1, 6),
...                    'B': range(10, 0, -2),
...                    'C C': range(10, 5, -1)})
>>> df
   A  B  C C
0  1 10  10
1  2  8   9
2  3  6   8
3  4  4   7
4  5  2   6
>>> df.query('A > B')
   A  B  C C
4  5  2   6
```

The previous expression is equivalent to

```
>>> df[df.A > df.B]
   A  B  C C
4  5  2   6
```

For columns with spaces in their name, you can use backtick quoting.

```
>>> df.query('B == `C C`')
   A  B  C C
0  1 10  10
```

The previous expression is equivalent to

```
>>> df[df.B == df['C C']]
   A  B  C C
0  1 10  10
```

## pandas.DataFrame.radd

`DataFrame.radd` (*self*, *other*, *axis='columns'*, *level=None*, *fill\_value=None*)

Get Addition of dataframe and other, element-wise (binary operator *radd*).

Equivalent to `other + dataframe`, but with support to substitute a *fill\_value* for missing data in one of the inputs. With reverse version, *add*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

### Parameters

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

**level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

**fill\_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before

computation. If data in both corresponding DataFrame locations is missing the result will be missing.

### Returns

**DataFrame** Result of the arithmetic operation.

### See also:

**DataFrame.add** Add DataFrames.

**DataFrame.sub** Subtract DataFrames.

**DataFrame.mul** Multiply DataFrames.

**DataFrame.div** Divide DataFrames (float division).

**DataFrame.truediv** Divide DataFrames (float division).

**DataFrame.floordiv** Divide DataFrames (integer division).

**DataFrame.mod** Calculate modulo (remainder after division).

**DataFrame.pow** Calculate exponential power.

### Notes

Mismatched indices will be unioned together.

### Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

	angles	degrees
circle	0	360
triangle	3	180
rectangle	4	360

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

```
>>> df.add(1)
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

Divide by constant with reverse version.

```
>>> df.div(10)
      angles  degrees
circle    0.0    36.0
triangle  0.3    18.0
rectangle 0.4    36.0
```

```
>>> df.rdiv(10)
      angles  degrees
circle      inf  0.027778
triangle  3.333333  0.055556
rectangle  2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
      angles  degrees
circle     -1    358
triangle   2    178
rectangle  3    358
```

```
>>> df.sub([1, 2], axis='columns')
      angles  degrees
circle     -1    358
triangle   2    178
rectangle  3    358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
      angles  degrees
circle     -1    359
triangle   2    179
rectangle  3    359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
      angles
circle     0
triangle   3
rectangle  4
```

```
>>> df * other
      angles  degrees
circle     0     NaN
triangle   9     NaN
rectangle  16     NaN
```

```
>>> df.mul(other, fill_value=0)
      angles  degrees
circle     0     0.0
triangle   9     0.0
rectangle  16     0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                               index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                       ['circle', 'triangle', 'rectangle',
...                                       'square', 'pentagon', 'hexagon']])
>>> df_multindex

```

	angles	degrees
A circle	0	360
triangle	3	180
rectangle	4	360
B square	4	360
pentagon	5	540
hexagon	6	720

```
>>> df.div(df_multindex, level=1, fill_value=0)

```

	angles	degrees
A circle	NaN	1.0
triangle	1.0	1.0
rectangle	1.0	1.0
B square	0.0	0.0
pentagon	0.0	0.0
hexagon	0.0	0.0

## pandas.DataFrame.rank

`DataFrame.rank` (*self*: ~FrameOrSeries, *axis*=0, *method*: str = 'average', *numeric\_only*: Union[bool, NoneType] = None, *na\_option*: str = 'keep', *ascending*: bool = True, *pct*: bool = False) → ~FrameOrSeries

Compute numerical data ranks (1 through n) along axis.

By default, equal values are assigned a rank that is the average of the ranks of those values.

### Parameters

**axis** [{0 or 'index', 1 or 'columns'}], default 0] Index to direct ranking.

**method** [{'average', 'min', 'max', 'first', 'dense'}], default 'average'] How to rank the group of records that have the same value (i.e. ties):

- average: average rank of the group
- min: lowest rank in the group
- max: highest rank in the group
- first: ranks assigned in order they appear in the array
- dense: like 'min', but rank always increases by 1 between groups.

**numeric\_only** [bool, optional] For DataFrame objects, rank only numeric columns if set to True.

**na\_option** [{'keep', 'top', 'bottom'}], default 'keep'] How to rank NaN values:

- keep: assign NaN rank to NaN values
- top: assign smallest rank to NaN values if ascending
- bottom: assign highest rank to NaN values if ascending.

**ascending** [bool, default True] Whether or not the elements should be ranked in ascending order.

**pct** [bool, default False] Whether or not to display the returned rankings in percentile form.

### Returns

**same type as caller** Return a Series or DataFrame with data ranks as values.

### See also:

**core.groupby.GroupBy.rank** Rank of values within each group.

### Examples

```
>>> df = pd.DataFrame(data={'Animal': ['cat', 'penguin', 'dog',
...                                   'spider', 'snake'],
...                        'Number_legs': [4, 2, 4, 8, np.nan]})
>>> df
   Animal  Number_legs
0     cat           4.0
1  penguin           2.0
2     dog           4.0
3  spider           8.0
4   snake           NaN
```

The following example shows how the method behaves with the above parameters:

- **default\_rank**: this is the default behaviour obtained without using any parameter.
- **max\_rank**: setting `method = 'max'` the records that have the same values are ranked using the highest rank (e.g.: since 'cat' and 'dog' are both in the 2nd and 3rd position, rank 3 is assigned.)
- **NA\_bottom**: choosing `na_option = 'bottom'`, if there are records with NaN values they are placed at the bottom of the ranking.
- **pct\_rank**: when setting `pct = True`, the ranking is expressed as percentile rank.

```
>>> df['default_rank'] = df['Number_legs'].rank()
>>> df['max_rank'] = df['Number_legs'].rank(method='max')
>>> df['NA_bottom'] = df['Number_legs'].rank(na_option='bottom')
>>> df['pct_rank'] = df['Number_legs'].rank(pct=True)
>>> df
   Animal  Number_legs  default_rank  max_rank  NA_bottom  pct_rank
0     cat           4.0           2.5         3.0         2.5      0.625
1  penguin           2.0           1.0         1.0         1.0      0.250
2     dog           4.0           2.5         3.0         2.5      0.625
3  spider           8.0           4.0         4.0         4.0      1.000
4   snake           NaN           NaN         NaN         5.0         NaN
```

## pandas.DataFrame.rdiv

`DataFrame.rdiv` (*self*, *other*, *axis*='columns', *level*=None, *fill\_value*=None)

Get Floating division of dataframe and other, element-wise (binary operator *rtruediv*).

Equivalent to `other / dataframe`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *truediv*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: +, -, \*, /, //, %, \*\*.

### Parameters

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

**level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

**fill\_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

### Returns

**DataFrame** Result of the arithmetic operation.

See also:

**DataFrame.add** Add DataFrames.

**DataFrame.sub** Subtract DataFrames.

**DataFrame.mul** Multiply DataFrames.

**DataFrame.div** Divide DataFrames (float division).

**DataFrame.truediv** Divide DataFrames (float division).

**DataFrame.floordiv** Divide DataFrames (integer division).

**DataFrame.mod** Calculate modulo (remainder after division).

**DataFrame.pow** Calculate exponential power.

### Notes

Mismatched indices will be unioned together.

## Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

	angles	degrees
circle	0	360
triangle	3	180
rectangle	4	360

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

```
>>> df.add(1)
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

Divide by constant with reverse version.

```
>>> df.div(10)
```

	angles	degrees
circle	0.0	36.0
triangle	0.3	18.0
rectangle	0.4	36.0

```
>>> df.rdiv(10)
```

	angles	degrees
circle	inf	0.027778
triangle	3.333333	0.055556
rectangle	2.500000	0.027778

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
```

	angles	degrees
circle	-1	358
triangle	2	178
rectangle	3	358

```
>>> df.sub([1, 2], axis='columns')
```

	angles	degrees
circle	-1	358
triangle	2	178
rectangle	3	358

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
```

	angles	degrees
circle	0	359
triangle	2	179
rectangle	3	359

(continues on next page)

(continued from previous page)

circle	-1	359
triangle	2	179
rectangle	3	359

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
```

	angles
circle	0
triangle	3
rectangle	4

```
>>> df * other
```

	angles	degrees
circle	0	NaN
triangle	9	NaN
rectangle	16	NaN

```
>>> df.mul(other, fill_value=0)
```

	angles	degrees
circle	0	0.0
triangle	9	0.0
rectangle	16	0.0

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                              'degrees': [360, 180, 360, 360, 540, 720]},
...                              index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                     ['circle', 'triangle', 'rectangle',
...                                      'square', 'pentagon', 'hexagon']])
>>> df_multindex
```

	angles	degrees
A circle	0	360
triangle	3	180
rectangle	4	360
B square	4	360
pentagon	5	540
hexagon	6	720

```
>>> df.div(df_multindex, level=1, fill_value=0)
```

	angles	degrees
A circle	NaN	1.0
triangle	1.0	1.0
rectangle	1.0	1.0
B square	0.0	0.0
pentagon	0.0	0.0
hexagon	0.0	0.0

**pandas.DataFrame.reindex**

`DataFrame.reindex` (*self*, *labels=None*, *index=None*, *columns=None*, *axis=None*, *method=None*, *copy=True*, *level=None*, *fill\_value=nan*, *limit=None*, *tolerance=None*)

Conform DataFrame to new index with optional filling logic.

Places NA/NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and `copy=False`.

**Parameters**

**labels** [array-like, optional] New labels / index to conform the axis specified by ‘axis’ to.

**index, columns** [array-like, optional] New labels / index to conform to, should be specified using keywords. Preferably an Index object to avoid duplicating data.

**axis** [int or str, optional] Axis to target. Can be either the axis name (‘index’, ‘columns’) or number (0, 1).

**method** [{None, ‘backfill’/‘bfill’, ‘pad’/‘ffill’, ‘nearest’}] Method to use for filling holes in reindexed DataFrame. Please note: this is only applicable to DataFrames/Series with a monotonically increasing/decreasing index.

- None (default): don’t fill gaps
- pad / ffill: Propagate last valid observation forward to next valid.
- backfill / bfill: Use next valid observation to fill gap.
- nearest: Use nearest valid observations to fill gap.

**copy** [bool, default True] Return a new object, even if the passed indexes are the same.

**level** [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

**fill\_value** [scalar, default np.NaN] Value to use for missing values. Defaults to NaN, but can be any “compatible” value.

**limit** [int, default None] Maximum number of consecutive elements to forward or backward fill.

**tolerance** [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations most satisfy the equation  $\text{abs}(\text{index}[\text{indexer}] - \text{target}) \leq \text{tolerance}$ .

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index’s type.

New in version 0.21.0: (list-like tolerance)

**Returns**

**DataFrame with changed index.**

See also:

**DataFrame.set\_index** Set row labels.

**DataFrame.reset\_index** Remove row labels or move them to new columns.

**DataFrame.reindex\_like** Change to same indices as other DataFrame.

## Examples

DataFrame.reindex supports two calling conventions

- (index=index\_labels, columns=column\_labels, ...)
- (labels, axis={'index', 'columns'}, ...)

We *highly* recommend using keyword arguments to clarify your intent.

Create a dataframe with some fictional data.

```
>>> index = ['Firefox', 'Chrome', 'Safari', 'IE10', 'Konqueror']
>>> df = pd.DataFrame({'http_status': [200, 200, 404, 404, 301],
...                    'response_time': [0.04, 0.02, 0.07, 0.08, 1.0]},
...                    index=index)
>>> df
```

	http_status	response_time
Firefox	200	0.04
Chrome	200	0.02
Safari	404	0.07
IE10	404	0.08
Konqueror	301	1.00

Create a new index and reindex the dataframe. By default values in the new index that do not have corresponding records in the dataframe are assigned NaN.

```
>>> new_index = ['Safari', 'Iceweasel', 'Comodo Dragon', 'IE10',
...              'Chrome']
>>> df.reindex(new_index)
```

	http_status	response_time
Safari	404.0	0.07
Iceweasel	NaN	NaN
Comodo Dragon	NaN	NaN
IE10	404.0	0.08
Chrome	200.0	0.02

We can fill in the missing values by passing a value to the keyword `fill_value`. Because the index is not monotonically increasing or decreasing, we cannot use arguments to the keyword `method` to fill the NaN values.

```
>>> df.reindex(new_index, fill_value=0)
```

	http_status	response_time
Safari	404	0.07
Iceweasel	0	0.00
Comodo Dragon	0	0.00
IE10	404	0.08
Chrome	200	0.02

```
>>> df.reindex(new_index, fill_value='missing')
```

	http_status	response_time
Safari	404	0.07
Iceweasel	missing	missing
Comodo Dragon	missing	missing
IE10	404	0.08
Chrome	200	0.02

We can also reindex the columns.

```
>>> df.reindex(columns=['http_status', 'user_agent'])
      http_status  user_agent
Firefox          200         NaN
Chrome           200         NaN
Safari           404         NaN
IE10             404         NaN
Konqueror        301         NaN
```

Or we can use “axis-style” keyword arguments

```
>>> df.reindex(['http_status', 'user_agent'], axis="columns")
      http_status  user_agent
Firefox          200         NaN
Chrome           200         NaN
Safari           404         NaN
IE10             404         NaN
Konqueror        301         NaN
```

To further illustrate the filling functionality in `reindex`, we will create a dataframe with a monotonically increasing index (for example, a sequence of dates).

```
>>> date_index = pd.date_range('1/1/2010', periods=6, freq='D')
>>> df2 = pd.DataFrame({"prices": [100, 101, np.nan, 100, 89, 88]},
...                    index=date_index)
>>> df2
      prices
2010-01-01  100.0
2010-01-02  101.0
2010-01-03    NaN
2010-01-04  100.0
2010-01-05   89.0
2010-01-06   88.0
```

Suppose we decide to expand the dataframe to cover a wider date range.

```
>>> date_index2 = pd.date_range('12/29/2009', periods=10, freq='D')
>>> df2.reindex(date_index2)
      prices
2009-12-29    NaN
2009-12-30    NaN
2009-12-31    NaN
2010-01-01  100.0
2010-01-02  101.0
2010-01-03    NaN
2010-01-04  100.0
2010-01-05   89.0
2010-01-06   88.0
2010-01-07    NaN
```

The index entries that did not have a value in the original data frame (for example, ‘2009-12-29’) are by default filled with `NaN`. If desired, we can fill in the missing values using one of several options.

For example, to back-propagate the last valid value to fill the `NaN` values, pass `bfill` as an argument to the method keyword.

```
>>> df2.reindex(date_index2, method='bfill')
      prices
```

(continues on next page)

(continued from previous page)

2009-12-29	100.0
2009-12-30	100.0
2009-12-31	100.0
2010-01-01	100.0
2010-01-02	101.0
2010-01-03	NaN
2010-01-04	100.0
2010-01-05	89.0
2010-01-06	88.0
2010-01-07	NaN

Please note that the NaN value present in the original dataframe (at index value 2010-01-03) will not be filled by any of the value propagation schemes. This is because filling while reindexing does not look at dataframe values, but only compares the original and desired indexes. If you do want to fill in the NaN values present in the original dataframe, use the `fillna()` method.

See the *user guide* for more.

### pandas.DataFrame.reindex\_like

`DataFrame.reindex_like` (*self*: ~FrameOrSeries, *other*, *method*: Union[str, NoneType] = None, *copy*: bool = True, *limit*=None, *tolerance*=None) → ~FrameOrSeries

Return an object with matching indices as other object.

Conform the object to the same index on all axes. Optional filling logic, placing NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and `copy=False`.

#### Parameters

**other** [Object of the same data type] Its row and column indices are used to define the new indices of this object.

**method** [{None, 'backfill'/'bfill', 'pad'/'ffill', 'nearest'}] Method to use for filling holes in reindexed DataFrame. Please note: this is only applicable to DataFrames/Series with a monotonically increasing/decreasing index.

- None (default): don't fill gaps
- pad / ffill: propagate last valid observation forward to next valid
- backfill / bfill: use next valid observation to fill gap
- nearest: use nearest valid observations to fill gap.

**copy** [bool, default True] Return a new object, even if the passed indexes are the same.

**limit** [int, default None] Maximum number of consecutive labels to fill for inexact matches.

**tolerance** [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations most satisfy the equation `abs(index[indexer] - target) <= tolerance`.

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index's type.

New in version 0.21.0: (list-like tolerance)

## Returns

**Series or DataFrame** Same type as caller, but with changed indices on each axis.

## See also:

**DataFrame.set\_index** Set row labels.

**DataFrame.reset\_index** Remove row labels or move them to new columns.

**DataFrame.reindex** Change to new indices or expand indices.

## Notes

Same as calling `.reindex(index=other.index, columns=other.columns,...)`.

## Examples

```
>>> df1 = pd.DataFrame([[24.3, 75.7, 'high'],
...                     [31, 87.8, 'high'],
...                     [22, 71.6, 'medium'],
...                     [35, 95, 'medium']],
...                    columns=['temp_celsius', 'temp_fahrenheit',
...                              'windspeed'],
...                    index=pd.date_range(start='2014-02-12',
...                                         end='2014-02-15', freq='D'))
```

```
>>> df1
      temp_celsius  temp_fahrenheit  windspeed
2014-02-12         24.3             75.7      high
2014-02-13         31.0             87.8      high
2014-02-14         22.0             71.6    medium
2014-02-15         35.0             95.0    medium
```

```
>>> df2 = pd.DataFrame([[28, 'low'],
...                     [30, 'low'],
...                     [35.1, 'medium']],
...                    columns=['temp_celsius', 'windspeed'],
...                    index=pd.DatetimeIndex(['2014-02-12', '2014-02-13',
...                                             '2014-02-15']))
```

```
>>> df2
      temp_celsius  windspeed
2014-02-12         28.0      low
2014-02-13         30.0      low
2014-02-15         35.1    medium
```

```
>>> df2.reindex_like(df1)
      temp_celsius  temp_fahrenheit  windspeed
2014-02-12         28.0             NaN      low
2014-02-13         30.0             NaN      low
2014-02-14         NaN             NaN      NaN
2014-02-15         35.1             NaN    medium
```

## pandas.DataFrame.rename

`DataFrame.rename` (*self*, *mapper=None*, *index=None*, *columns=None*, *axis=None*, *copy=True*, *inplace=False*, *level=None*, *errors='ignore'*)

Alter axes labels.

Function / dict values must be unique (1-to-1). Labels not contained in a dict / Series will be left as-is. Extra labels listed don't throw an error.

See the *user guide* for more.

### Parameters

**mapper** [dict-like or function] Dict-like or functions transformations to apply to that axis' values. Use either `mapper` and `axis` to specify the axis to target with `mapper`, or `index` and `columns`.

**index** [dict-like or function] Alternative to specifying axis (`mapper`, `axis=0` is equivalent to `index=mapper`).

**columns** [dict-like or function] Alternative to specifying axis (`mapper`, `axis=1` is equivalent to `columns=mapper`).

**axis** [int or str] Axis to target with `mapper`. Can be either the axis name ('index', 'columns') or number (0, 1). The default is 'index'.

**copy** [bool, default True] Also copy underlying data.

**inplace** [bool, default False] Whether to return a new DataFrame. If True then value of `copy` is ignored.

**level** [int or level name, default None] In case of a MultiIndex, only rename labels in the specified level.

**errors** [{'ignore', 'raise'}, default 'ignore'] If 'raise', raise a *KeyError* when a dict-like `mapper`, `index`, or `columns` contains labels that are not present in the Index being transformed. If 'ignore', existing keys will be renamed and extra keys will be ignored.

### Returns

**DataFrame** DataFrame with the renamed axis labels.

### Raises

**KeyError** If any of the labels is not found in the selected axis and "errors='raise'".

See also:

**DataFrame.rename\_axis** Set the name of the axis.

### Examples

`DataFrame.rename` supports two calling conventions

- `(index=index_mapper, columns=columns_mapper, ...)`
- `(mapper, axis={'index', 'columns'}, ...)`

We *highly* recommend using keyword arguments to clarify your intent.

Rename columns using a mapping:

```
>>> df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6]})
>>> df.rename(columns={"A": "a", "B": "c"})
   a  c
0  1  4
1  2  5
2  3  6
```

Rename index using a mapping:

```
>>> df.rename(index={0: "x", 1: "y", 2: "z"})
   A  B
x  1  4
y  2  5
z  3  6
```

Cast index labels to a different type:

```
>>> df.index
RangeIndex(start=0, stop=3, step=1)
>>> df.rename(index=str).index
Index(['0', '1', '2'], dtype='object')
```

```
>>> df.rename(columns={"A": "a", "B": "b", "C": "c"}, errors="raise")
Traceback (most recent call last):
KeyError: ['C'] not found in axis
```

Using axis-style parameters

```
>>> df.rename(str.lower, axis='columns')
   a  b
0  1  4
1  2  5
2  3  6
```

```
>>> df.rename({1: 2, 2: 4}, axis='index')
   A  B
0  1  4
2  2  5
4  3  6
```

## pandas.DataFrame.rename\_axis

`DataFrame.rename_axis` (*self*, *mapper=None*, *index=None*, *columns=None*, *axis=None*, *copy=True*, *inplace=False*)

Set the name of the axis for the index or columns.

### Parameters

**mapper** [scalar, list-like, optional] Value to set the axis name attribute.

**index, columns** [scalar, list-like, dict-like or function, optional] A scalar, list-like, dict-like or functions transformations to apply to that axis' values.

Use either `mapper` and `axis` to specify the axis to target with `mapper`, or `index` and/or `columns`.

Changed in version 0.24.0.

**axis** [{0 or 'index', 1 or 'columns'}, default 0] The axis to rename.

**copy** [bool, default True] Also copy underlying data.

**inplace** [bool, default False] Modifies the object directly, instead of creating a new Series or DataFrame.

### Returns

**Series, DataFrame, or None** The same type as the caller or None if *inplace* is True.

### See also:

**Series.rename** Alter Series index labels or name.

**DataFrame.rename** Alter DataFrame index labels or name.

**Index.rename** Set new names on index.

### Notes

DataFrame.rename\_axis supports two calling conventions

- (index=index\_mapper, columns=columns\_mapper, ...)
- (mapper, axis={'index', 'columns'}, ...)

The first calling convention will only modify the names of the index and/or the names of the Index object that is the columns. In this case, the parameter `copy` is ignored.

The second calling convention will modify the names of the the corresponding index if `mapper` is a list or a scalar. However, if `mapper` is dict-like or a function, it will use the deprecated behavior of modifying the axis *labels*.

We *highly* recommend using keyword arguments to clarify your intent.

### Examples

#### Series

```
>>> s = pd.Series(["dog", "cat", "monkey"])
>>> s
0      dog
1      cat
2  monkey
dtype: object
>>> s.rename_axis("animal")
animal
0      dog
1      cat
2  monkey
dtype: object
```

#### DataFrame

```
>>> df = pd.DataFrame({"num_legs": [4, 4, 2],
...                    "num_arms": [0, 0, 2]},
...                    ["dog", "cat", "monkey"])
>>> df
```

(continues on next page)

(continued from previous page)

```

      num_legs  num_arms
dog           4         0
cat           4         0
monkey        2         2
>>> df = df.rename_axis("animal")
>>> df
      num_legs  num_arms
animal
dog           4         0
cat           4         0
monkey        2         2
>>> df = df.rename_axis("limbs", axis="columns")
>>> df
limbs  num_legs  num_arms
animal
dog           4         0
cat           4         0
monkey        2         2

```

### MultiIndex

```

>>> df.index = pd.MultiIndex.from_product(['mammal'],
...                                       ['dog', 'cat', 'monkey'],
...                                       names=['type', 'name'])
>>> df
limbs      num_legs  num_arms
type  name
mammal dog           4         0
      cat           4         0
      monkey        2         2

```

```

>>> df.rename_axis(index={'type': 'class'})
limbs      num_legs  num_arms
class  name
mammal dog           4         0
      cat           4         0
      monkey        2         2

```

```

>>> df.rename_axis(columns=str.upper)
LIMBS      num_legs  num_arms
type  name
mammal dog           4         0
      cat           4         0
      monkey        2         2

```

### pandas.DataFrame.reorder\_levels

DataFrame.**reorder\_levels** (*self*, *order*, *axis=0*) → 'DataFrame'

Rearrange index levels using input order. May not drop or duplicate levels.

#### Parameters

**order** [list of int or list of str] List representing new level order. Reference level by number (position) or by key (label).

**axis** [int] Where to reorder levels.

#### Returns

DataFrame

### pandas.DataFrame.replace

DataFrame.**replace** (*self*, *to\_replace=None*, *value=None*, *inplace=False*, *limit=None*, *regex=False*, *method='pad'*)

Replace values given in *to\_replace* with *value*.

Values of the DataFrame are replaced with other values dynamically. This differs from updating with `.loc` or `.iloc`, which require you to specify a location to update with some value.

#### Parameters

**to\_replace** [str, regex, list, dict, Series, int, float, or None] How to find the values that will be replaced.

- numeric, str or regex:
  - numeric: numeric values equal to *to\_replace* will be replaced with *value*
  - str: string exactly matching *to\_replace* will be replaced with *value*
  - regex: regexs matching *to\_replace* will be replaced with *value*
- list of str, regex, or numeric:
  - First, if *to\_replace* and *value* are both lists, they **must** be the same length.
  - Second, if `regex=True` then all of the strings in **both** lists will be interpreted as regexs otherwise they will match directly. This doesn't matter much for *value* since there are only a few possible substitution regexes you can use.
  - str, regex and numeric rules apply as above.
- dict:
  - Dicts can be used to specify different replacement values for different existing values. For example, `{ 'a': 'b', 'y': 'z' }` replaces the value 'a' with 'b' and 'y' with 'z'. To use a dict in this way the *value* parameter should be *None*.
  - For a DataFrame a dict can specify that different values should be replaced in different columns. For example, `{ 'a': 1, 'b': 'z' }` looks for the value 1 in column 'a' and the value 'z' in column 'b' and replaces these values with whatever is specified in *value*. The *value* parameter should not be *None* in this case. You can treat this as a special case of passing two lists except that you are specifying the column to search in.

- For a DataFrame nested dictionaries, e.g., {'a': {'b': np.nan}}, are read as follows: look in column 'a' for the value 'b' and replace it with NaN. The *value* parameter should be `None` to use a nested dict in this way. You can nest regular expressions as well. Note that column names (the top-level dictionary keys in a nested dictionary) **cannot** be regular expressions.

- None:

- This means that the *regex* argument must be a string, compiled regular expression, or list, dict, ndarray or Series of such elements. If *value* is also `None` then this **must** be a nested dictionary or Series.

See the examples section for examples of each of these.

**value** [scalar, dict, list, str, regex, default `None`] Value to replace any values matching *to\_replace* with. For a DataFrame a dict of values can be used to specify which value to use for each column (columns not in the dict will not be filled). Regular expressions, strings and lists or dicts of such objects are also allowed.

**inplace** [bool, default `False`] If `True`, in place. Note: this will modify any other views on this object (e.g. a column from a DataFrame). Returns the caller if this is `True`.

**limit** [int, default `None`] Maximum size gap to forward or backward fill.

**regex** [bool or same types as *to\_replace*, default `False`] Whether to interpret *to\_replace* and/or *value* as regular expressions. If this is `True` then *to\_replace* must be a string. Alternatively, this could be a regular expression or a list, dict, or array of regular expressions in which case *to\_replace* must be `None`.

**method** [{'pad', 'ffill', 'bfill', `None`}] The method to use when for replacement, when *to\_replace* is a scalar, list or tuple and *value* is `None`.

Changed in version 0.23.0: Added to DataFrame.

## Returns

**DataFrame** Object after replacement.

## Raises

### AssertionError

- If *regex* is not a `bool` and *to\_replace* is not `None`.

### TypeError

- If *to\_replace* is a dict and *value* is not a list, dict, ndarray, or Series
- If *to\_replace* is `None` and *regex* is not compilable into a regular expression or is a list, dict, ndarray, or Series.
- When replacing multiple `bool` or `datetime64` objects and the arguments to *to\_replace* does not match the type of the value being replaced

### ValueError

- If a list or an ndarray is passed to *to\_replace* and *value* but they are not the same length.

See also:

**DataFrame.fillna** Fill NA values.

**DataFrame.where** Replace values based on boolean condition.

**`Series.str.replace`** Simple string replacement.

## Notes

- Regex substitution is performed under the hood with `re.sub`. The rules for substitution for `re.sub` are the same.
- Regular expressions will only substitute on strings, meaning you cannot provide, for example, a regular expression matching floating point numbers and expect the columns in your frame that have a numeric dtype to be matched. However, if those floating point numbers *are* strings, then you can do this.
- This method has *a lot* of options. You are encouraged to experiment and play with this method to gain intuition about how it works.
- When dict is used as the `to_replace` value, it is like key(s) in the dict are the `to_replace` part and value(s) in the dict are the `value` parameter.

## Examples

### Scalar `to_replace` and `value`

```
>>> s = pd.Series([0, 1, 2, 3, 4])
>>> s.replace(0, 5)
0    5
1    1
2    2
3    3
4    4
dtype: int64
```

```
>>> df = pd.DataFrame({'A': [0, 1, 2, 3, 4],
...                   'B': [5, 6, 7, 8, 9],
...                   'C': ['a', 'b', 'c', 'd', 'e']})
>>> df.replace(0, 5)
   A  B  C
0  5  5  a
1  1  6  b
2  2  7  c
3  3  8  d
4  4  9  e
```

### List-like `to_replace`

```
>>> df.replace([0, 1, 2, 3], 4)
   A  B  C
0  4  5  a
1  4  6  b
2  4  7  c
3  4  8  d
4  4  9  e
```

```
>>> df.replace([0, 1, 2, 3], [4, 3, 2, 1])
   A  B  C
0  4  5  a
```

(continues on next page)

(continued from previous page)

```

1  3  6  b
2  2  7  c
3  1  8  d
4  4  9  e

```

```

>>> s.replace([1, 2], method='bfill')
0    0
1    3
2    3
3    3
4    4
dtype: int64

```

**dict-like `to\_replace`**

```

>>> df.replace({0: 10, 1: 100})
   A  B  C
0  10  5  a
1 100  6  b
2   2  7  c
3   3  8  d
4   4  9  e

```

```

>>> df.replace({'A': 0, 'B': 5}, 100)
   A  B  C
0 100 100 a
1   1   6  b
2   2   7  c
3   3   8  d
4   4   9  e

```

```

>>> df.replace({'A': {0: 100, 4: 400}})
   A  B  C
0 100  5  a
1   1  6  b
2   2  7  c
3   3  8  d
4 400  9  e

```

**Regular expression `to\_replace`**

```

>>> df = pd.DataFrame({'A': ['bat', 'foo', 'bait'],
...                    'B': ['abc', 'bar', 'xyz']})
>>> df.replace(to_replace=r'^ba.$', value='new', regex=True)
   A  B
0  new abc
1  foo bar
2  bait xyz

```

```

>>> df.replace({'A': r'^ba.$'}, {'A': 'new'}, regex=True)
   A  B
0  new abc
1  foo bar
2  bait xyz

```

```
>>> df.replace(regex=r'^ba.$', value='new')
   A  B
0  new abc
1  foo new
2  bait xyz
```

```
>>> df.replace(regex={r'^ba.$': 'new', 'foo': 'xyz'})
   A  B
0  new abc
1  xyz new
2  bait xyz
```

```
>>> df.replace(regex=[r'^ba.$', 'foo'], value='new')
   A  B
0  new abc
1  new new
2  bait xyz
```

Note that when replacing multiple `bool` or `datetime64` objects, the data types in the `to_replace` parameter must match the data type of the value being replaced:

```
>>> df = pd.DataFrame({'A': [True, False, True],
...                   'B': [False, True, False]})
>>> df.replace({'a string': 'new value', True: False}) # raises
Traceback (most recent call last):
...
TypeError: Cannot compare types 'ndarray(dtype=bool)' and 'str'
```

This raises a `TypeError` because one of the dict keys is not of the correct type for replacement.

Compare the behavior of `s.replace({'a': None})` and `s.replace('a', None)` to understand the peculiarities of the `to_replace` parameter:

```
>>> s = pd.Series([10, 'a', 'a', 'b', 'a'])
```

When one uses a dict as the `to_replace` value, it is like the value(s) in the dict are equal to the `value` parameter. `s.replace({'a': None})` is equivalent to `s.replace(to_replace={'a': None}, value=None, method=None)`:

```
>>> s.replace({'a': None})
0    10
1    None
2    None
3     b
4    None
dtype: object
```

When `value=None` and `to_replace` is a scalar, list or tuple, `replace` uses the `method` parameter (default 'pad') to do the replacement. So this is why the 'a' values are being replaced by 10 in rows 1 and 2 and 'b' in row 4 in this case. The command `s.replace('a', None)` is actually equivalent to `s.replace(to_replace='a', value=None, method='pad')`:

```
>>> s.replace('a', None)
0    10
1    10
2    10
```

(continues on next page)

(continued from previous page)

```

3      b
4      b
dtype: object

```

## pandas.DataFrame.resample

`DataFrame.resample` (*self*, *rule*, *axis=0*, *closed: Union[str, NoneType] = None*, *label: Union[str, NoneType] = None*, *convention: str = 'start'*, *kind: Union[str, NoneType] = None*, *loffset=None*, *base: int = 0*, *on=None*, *level=None*)

Resample time-series data.

Convenience method for frequency conversion and resampling of time series. Object must have a datetime-like index (*DatetimeIndex*, *PeriodIndex*, or *TimedeltaIndex*), or pass datetime-like values to the *on* or *level* keyword.

### Parameters

- rule** [DateOffset, Timedelta or str] The offset string or object representing target conversion.
- axis** [{0 or 'index', 1 or 'columns'}, default 0] Which axis to use for up- or down-sampling. For *Series* this will default to 0, i.e. along the rows. Must be *DatetimeIndex*, *TimedeltaIndex* or *PeriodIndex*.
- closed** [{'right', 'left'}, default None] Which side of bin interval is closed. The default is 'left' for all frequency offsets except for 'M', 'A', 'Q', 'BM', 'BA', 'BQ', and 'W' which all have a default of 'right'.
- label** [{'right', 'left'}, default None] Which bin edge label to label bucket with. The default is 'left' for all frequency offsets except for 'M', 'A', 'Q', 'BM', 'BA', 'BQ', and 'W' which all have a default of 'right'.
- convention** [{'start', 'end', 's', 'e'}, default 'start'] For *PeriodIndex* only, controls whether to use the start or end of *rule*.
- kind** [{'timestamp', 'period'}, optional, default None] Pass 'timestamp' to convert the resulting index to a *DatetimeIndex* or 'period' to convert it to a *PeriodIndex*. By default the input representation is retained.
- loffset** [timedelta, default None] Adjust the resampled time labels.
- base** [int, default 0] For frequencies that evenly subdivide 1 day, the "origin" of the aggregated intervals. For example, for '5min' frequency, base could range from 0 through 4. Defaults to 0.
- on** [str, optional] For a *DataFrame*, column to use instead of index for resampling. Column must be datetime-like.
- level** [str or int, optional] For a *MultiIndex*, level (name or number) to use for resampling. *level* must be datetime-like.

### Returns

#### Resampler object

See also:

**groupby** Group by mapping, function, label, or list of labels.

**Series.resample** Resample a Series.

**DataFrame.resample** Resample a DataFrame.

## Notes

See the [user guide](#) for more.

To learn more about the offset strings, please see [this link](#).

## Examples

Start by creating a series with 9 one minute timestamps.

```
>>> index = pd.date_range('1/1/2000', periods=9, freq='T')
>>> series = pd.Series(range(9), index=index)
>>> series
2000-01-01 00:00:00    0
2000-01-01 00:01:00    1
2000-01-01 00:02:00    2
2000-01-01 00:03:00    3
2000-01-01 00:04:00    4
2000-01-01 00:05:00    5
2000-01-01 00:06:00    6
2000-01-01 00:07:00    7
2000-01-01 00:08:00    8
Freq: T, dtype: int64
```

Downsample the series into 3 minute bins and sum the values of the timestamps falling into a bin.

```
>>> series.resample('3T').sum()
2000-01-01 00:00:00    3
2000-01-01 00:03:00   12
2000-01-01 00:06:00   21
Freq: 3T, dtype: int64
```

Downsample the series into 3 minute bins as above, but label each bin using the right edge instead of the left. Please note that the value in the bucket used as the label is not included in the bucket, which it labels. For example, in the original series the bucket 2000-01-01 00:03:00 contains the value 3, but the summed value in the resampled bucket with the label 2000-01-01 00:03:00 does not include 3 (if it did, the summed value would be 6, not 3). To include this value close the right side of the bin interval as illustrated in the example below this one.

```
>>> series.resample('3T', label='right').sum()
2000-01-01 00:03:00    3
2000-01-01 00:06:00   12
2000-01-01 00:09:00   21
Freq: 3T, dtype: int64
```

Downsample the series into 3 minute bins as above, but close the right side of the bin interval.

```
>>> series.resample('3T', label='right', closed='right').sum()
2000-01-01 00:00:00    0
2000-01-01 00:03:00    6
2000-01-01 00:06:00   15
2000-01-01 00:09:00   15
Freq: 3T, dtype: int64
```

Upsample the series into 30 second bins.

```
>>> series.resample('30S').asfreq()[0:5] # Select first 5 rows
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30    NaN
2000-01-01 00:01:00    1.0
2000-01-01 00:01:30    NaN
2000-01-01 00:02:00    2.0
Freq: 30S, dtype: float64
```

Upsample the series into 30 second bins and fill the NaN values using the pad method.

```
>>> series.resample('30S').pad()[0:5]
2000-01-01 00:00:00    0
2000-01-01 00:00:30    0
2000-01-01 00:01:00    1
2000-01-01 00:01:30    1
2000-01-01 00:02:00    2
Freq: 30S, dtype: int64
```

Upsample the series into 30 second bins and fill the NaN values using the bfill method.

```
>>> series.resample('30S').bfill()[0:5]
2000-01-01 00:00:00    0
2000-01-01 00:00:30    1
2000-01-01 00:01:00    1
2000-01-01 00:01:30    2
2000-01-01 00:02:00    2
Freq: 30S, dtype: int64
```

Pass a custom function via apply

```
>>> def custom_resampler(array_like):
...     return np.sum(array_like) + 5
...
>>> series.resample('3T').apply(custom_resampler)
2000-01-01 00:00:00    8
2000-01-01 00:03:00   17
2000-01-01 00:06:00   26
Freq: 3T, dtype: int64
```

For a Series with a PeriodIndex, the keyword *convention* can be used to control whether to use the start or end of *rule*.

Resample a year by quarter using 'start' *convention*. Values are assigned to the first quarter of the period.

```
>>> s = pd.Series([1, 2], index=pd.period_range('2012-01-01',
...                                           freq='A',
...                                           periods=2))
>>> s
2012    1
2013    2
Freq: A-DEC, dtype: int64
>>> s.resample('Q', convention='start').asfreq()
2012Q1    1.0
2012Q2    NaN
2012Q3    NaN
2012Q4    NaN
```

(continues on next page)

(continued from previous page)

```

2013Q1    2.0
2013Q2    NaN
2013Q3    NaN
2013Q4    NaN
Freq: Q-DEC, dtype: float64

```

Resample quarters by month using 'end' *convention*. Values are assigned to the last month of the period.

```

>>> q = pd.Series([1, 2, 3, 4], index=pd.period_range('2018-01-01',
...                                                freq='Q',
...                                                periods=4))
>>> q
2018Q1    1
2018Q2    2
2018Q3    3
2018Q4    4
Freq: Q-DEC, dtype: int64
>>> q.resample('M', convention='end').asfreq()
2018-03    1.0
2018-04    NaN
2018-05    NaN
2018-06    2.0
2018-07    NaN
2018-08    NaN
2018-09    3.0
2018-10    NaN
2018-11    NaN
2018-12    4.0
Freq: M, dtype: float64

```

For DataFrame objects, the keyword *on* can be used to specify the column instead of the index for resampling.

```

>>> d = dict({'price': [10, 11, 9, 13, 14, 18, 17, 19],
...          'volume': [50, 60, 40, 100, 50, 100, 40, 50]})
>>> df = pd.DataFrame(d)
>>> df['week_starting'] = pd.date_range('01/01/2018',
...                                     periods=8,
...                                     freq='W')
>>> df
   price  volume week_starting
0     10     50  2018-01-07
1     11     60  2018-01-14
2      9     40  2018-01-21
3     13    100  2018-01-28
4     14     50  2018-02-04
5     18    100  2018-02-11
6     17     40  2018-02-18
7     19     50  2018-02-25
>>> df.resample('M', on='week_starting').mean()
           price  volume
week_starting
2018-01-31    10.75    62.5
2018-02-28    17.00    60.0

```

For a DataFrame with MultiIndex, the keyword *level* can be used to specify on which level the resampling needs to take place.

```

>>> days = pd.date_range('1/1/2000', periods=4, freq='D')
>>> d2 = dict({'price': [10, 11, 9, 13, 14, 18, 17, 19],
...          'volume': [50, 60, 40, 100, 50, 100, 40, 50]})
>>> df2 = pd.DataFrame(d2,
...                    index=pd.MultiIndex.from_product([days,
...                                                    ['morning',
...                                                    'afternoon']])
>>> df2

```

		price	volume
2000-01-01	morning	10	50
	afternoon	11	60
2000-01-02	morning	9	40
	afternoon	13	100
2000-01-03	morning	14	50
	afternoon	18	100
2000-01-04	morning	17	40
	afternoon	19	50

```

>>> df2.resample('D', level=0).sum()

```

	price	volume
2000-01-01	21	110
2000-01-02	22	140
2000-01-03	32	150
2000-01-04	36	90

### pandas.DataFrame.reset\_index

`DataFrame.reset_index(self, level: Union[Hashable, Sequence[Hashable], NoneType] = None, drop: bool = False, inplace: bool = False, col_level: Hashable = 0, col_fill: Union[Hashable, NoneType] = "")` → `Union[ForwardRef('DataFrame'), NoneType]`

Reset the index, or a level of it.

Reset the index of the DataFrame, and use the default one instead. If the DataFrame has a MultiIndex, this method can remove one or more levels.

#### Parameters

**level** [int, str, tuple, or list, default None] Only remove the given levels from the index. Removes all levels by default.

**drop** [bool, default False] Do not try to insert index into dataframe columns. This resets the index to the default integer index.

**inplace** [bool, default False] Modify the DataFrame in place (do not create a new object).

**col\_level** [int or str, default 0] If the columns have multiple levels, determines which level the labels are inserted into. By default it is inserted into the first level.

**col\_fill** [object, default ""] If the columns have multiple levels, determines how the other levels are named. If None then the index name is repeated.

#### Returns

**DataFrame or None** DataFrame with the new index or None if `inplace=True`.

See also:

**DataFrame.set\_index** Opposite of reset\_index.

**DataFrame.reindex** Change to new indices or expand indices.

**DataFrame.reindex\_like** Change to same indices as other DataFrame.

## Examples

```
>>> df = pd.DataFrame([('bird', 389.0),
...                    ('bird', 24.0),
...                    ('mammal', 80.5),
...                    ('mammal', np.nan)],
...                    index=['falcon', 'parrot', 'lion', 'monkey'],
...                    columns=('class', 'max_speed'))
>>> df
```

	class	max_speed
falcon	bird	389.0
parrot	bird	24.0
lion	mammal	80.5
monkey	mammal	NaN

When we reset the index, the old index is added as a column, and a new sequential index is used:

```
>>> df.reset_index()
   index  class  max_speed
0  falcon  bird    389.0
1  parrot  bird    24.0
2    lion  mammal    80.5
3  monkey  mammal     NaN
```

We can use the *drop* parameter to avoid the old index being added as a column:

```
>>> df.reset_index(drop=True)
   class  max_speed
0   bird    389.0
1   bird    24.0
2  mammal    80.5
3  mammal     NaN
```

You can also use *reset\_index* with *MultiIndex*.

```
>>> index = pd.MultiIndex.from_tuples([('bird', 'falcon'),
...                                   ('bird', 'parrot'),
...                                   ('mammal', 'lion'),
...                                   ('mammal', 'monkey')],
...                                   names=['class', 'name'])
>>> columns = pd.MultiIndex.from_tuples([('speed', 'max'),
...                                      ('species', 'type')])
>>> df = pd.DataFrame([(389.0, 'fly'),
...                    (24.0, 'fly'),
...                    (80.5, 'run'),
...                    (np.nan, 'jump')],
...                    index=index,
...                    columns=columns)
>>> df
```

	speed	species
	max	type
	389.0	fly
	24.0	fly
	80.5	run
	NaN	jump

(continues on next page)

(continued from previous page)

```

class name
bird falcon 389.0 fly
      parrot 24.0 fly
mammal lion 80.5 run
      monkey NaN jump

```

If the index has multiple levels, we can reset a subset of them:

```

>>> df.reset_index(level='class')
      class speed species
      max   type
name
falcon  bird 389.0 fly
parrot  bird 24.0 fly
lion    mammal 80.5 run
monkey  mammal NaN jump

```

If we are not dropping the index, by default, it is placed in the top level. We can place it in another level:

```

>>> df.reset_index(level='class', col_level=1)
      speed species
      class max   type
name
falcon  bird 389.0 fly
parrot  bird 24.0 fly
lion    mammal 80.5 run
monkey  mammal NaN jump

```

When the index is inserted under another level, we can specify under which one with the parameter *col\_fill*:

```

>>> df.reset_index(level='class', col_level=1, col_fill='species')
      species speed species
      class max   type
name
falcon  bird 389.0 fly
parrot  bird 24.0 fly
lion    mammal 80.5 run
monkey  mammal NaN jump

```

If we specify a nonexistent level for *col\_fill*, it is created:

```

>>> df.reset_index(level='class', col_level=1, col_fill='genus')
      genus speed species
      class max   type
name
falcon  bird 389.0 fly
parrot  bird 24.0 fly
lion    mammal 80.5 run
monkey  mammal NaN jump

```

## pandas.DataFrame.rfloordiv

DataFrame.**rfloordiv** (*self*, *other*, *axis*='columns', *level*=None, *fill\_value*=None)

Get Integer division of dataframe and other, element-wise (binary operator *rfloordiv*).

Equivalent to `other // dataframe`, but with support to substitute a *fill\_value* for missing data in one of the inputs. With reverse version, *floordiv*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: +, -, \*, /, //, %, \*\*.

### Parameters

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

**level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

**fill\_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

### Returns

**DataFrame** Result of the arithmetic operation.

See also:

**DataFrame.add** Add DataFrames.

**DataFrame.sub** Subtract DataFrames.

**DataFrame.mul** Multiply DataFrames.

**DataFrame.div** Divide DataFrames (float division).

**DataFrame.truediv** Divide DataFrames (float division).

**DataFrame.floordiv** Divide DataFrames (integer division).

**DataFrame.mod** Calculate modulo (remainder after division).

**DataFrame.pow** Calculate exponential power.

### Notes

Mismatched indices will be unioned together.

## Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

	angles	degrees
circle	0	360
triangle	3	180
rectangle	4	360

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

```
>>> df.add(1)
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

Divide by constant with reverse version.

```
>>> df.div(10)
```

	angles	degrees
circle	0.0	36.0
triangle	0.3	18.0
rectangle	0.4	36.0

```
>>> df.rdiv(10)
```

	angles	degrees
circle	inf	0.027778
triangle	3.333333	0.055556
rectangle	2.500000	0.027778

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
```

	angles	degrees
circle	-1	358
triangle	2	178
rectangle	3	358

```
>>> df.sub([1, 2], axis='columns')
```

	angles	degrees
circle	-1	358
triangle	2	178
rectangle	3	358

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
```

	angles	degrees
circle	0	359
triangle	2	179
rectangle	3	359

(continues on next page)

(continued from previous page)

circle	-1	359
triangle	2	179
rectangle	3	359

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                        index=['circle', 'triangle', 'rectangle'])
>>> other
```

	angles
circle	0
triangle	3
rectangle	4

```
>>> df * other
```

	angles	degrees
circle	0	NaN
triangle	9	NaN
rectangle	16	NaN

```
>>> df.mul(other, fill_value=0)
```

	angles	degrees
circle	0	0.0
triangle	9	0.0
rectangle	16	0.0

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                              index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                     ['circle', 'triangle', 'rectangle',
...                                      'square', 'pentagon', 'hexagon']])
>>> df_multindex
```

	angles	degrees
A circle	0	360
triangle	3	180
rectangle	4	360
B square	4	360
pentagon	5	540
hexagon	6	720

```
>>> df.div(df_multindex, level=1, fill_value=0)
```

	angles	degrees
A circle	NaN	1.0
triangle	1.0	1.0
rectangle	1.0	1.0
B square	0.0	0.0
pentagon	0.0	0.0
hexagon	0.0	0.0

**pandas.DataFrame.rmod**

`DataFrame.rmod` (*self*, *other*, *axis*='columns', *level*=None, *fill\_value*=None)

Get Modulo of dataframe and other, element-wise (binary operator *rmod*).

Equivalent to `other % dataframe`, but with support to substitute a *fill\_value* for missing data in one of the inputs. With reverse version, *mod*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: +, -, \*, /, //, %, \*\*.

**Parameters**

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

**level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

**fill\_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

**DataFrame** Result of the arithmetic operation.

See also:

**DataFrame.add** Add DataFrames.

**DataFrame.sub** Subtract DataFrames.

**DataFrame.mul** Multiply DataFrames.

**DataFrame.div** Divide DataFrames (float division).

**DataFrame.truediv** Divide DataFrames (float division).

**DataFrame.floordiv** Divide DataFrames (integer division).

**DataFrame.mod** Calculate modulo (remainder after division).

**DataFrame.pow** Calculate exponential power.

**Notes**

Mismatched indices will be unioned together.

## Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

	angles	degrees
circle	0	360
triangle	3	180
rectangle	4	360

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

```
>>> df.add(1)
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

Divide by constant with reverse version.

```
>>> df.div(10)
```

	angles	degrees
circle	0.0	36.0
triangle	0.3	18.0
rectangle	0.4	36.0

```
>>> df.rdiv(10)
```

	angles	degrees
circle	inf	0.027778
triangle	3.333333	0.055556
rectangle	2.500000	0.027778

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
```

	angles	degrees
circle	-1	358
triangle	2	178
rectangle	3	358

```
>>> df.sub([1, 2], axis='columns')
```

	angles	degrees
circle	-1	358
triangle	2	178
rectangle	3	358

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
```

	angles	degrees
circle	-1	359
triangle	1	179
rectangle	3	359

(continues on next page)

(continued from previous page)

```

A circle    NaN     1.0
  triangle  1.0     1.0
  rectangle  1.0     1.0
B square    0.0     0.0
  pentagon  0.0     0.0
  hexagon   0.0     0.0
```

## pandas.DataFrame.rmul

DataFrame.**rmul** (*self*, *other*, *axis='columns'*, *level=None*, *fill\_value=None*)

Get Multiplication of dataframe and other, element-wise (binary operator *rmul*).

Equivalent to `other * dataframe`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *mul*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

### Parameters

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

**level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

**fill\_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

### Returns

**DataFrame** Result of the arithmetic operation.

See also:

**DataFrame.add** Add DataFrames.

**DataFrame.sub** Subtract DataFrames.

**DataFrame.mul** Multiply DataFrames.

**DataFrame.div** Divide DataFrames (float division).

**DataFrame.truediv** Divide DataFrames (float division).

**DataFrame.floordiv** Divide DataFrames (integer division).

**DataFrame.mod** Calculate modulo (remainder after division).

**DataFrame.pow** Calculate exponential power.

### Notes

Mismatched indices will be unioned together.

## Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

	angles	degrees
circle	0	360
triangle	3	180
rectangle	4	360

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

```
>>> df.add(1)
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

Divide by constant with reverse version.

```
>>> df.div(10)
```

	angles	degrees
circle	0.0	36.0
triangle	0.3	18.0
rectangle	0.4	36.0

```
>>> df.rdiv(10)
```

	angles	degrees
circle	inf	0.027778
triangle	3.333333	0.055556
rectangle	2.500000	0.027778

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
```

	angles	degrees
circle	-1	358
triangle	2	178
rectangle	3	358

```
>>> df.sub([1, 2], axis='columns')
```

	angles	degrees
circle	-1	358
triangle	2	178
rectangle	3	358

```

pentagon	5	540
hexagon	6	720

```
>>> df.div(df_multindex, level=1, fill_value=0)
```

	angles	degrees
A circle	NaN	1.0
triangle	1.0	1.0
rectangle	1.0	1.0
B square	0.0	0.0
pentagon	0.0	0.0
hexagon	0.0	0.0

**pandas.DataFrame.rolling**

`DataFrame.rolling` (*self*, *window*, *min\_periods=None*, *center=False*, *win\_type=None*, *on=None*, *axis=0*, *closed=None*)

Provide rolling window calculations.

**Parameters**

**window** [int, offset, or BaseIndexer subclass] Size of the moving window. This is the number of observations used for calculating the statistic. Each window will be a fixed size.

If its an offset then this will be the time period of each window. Each window will be a variable sized based on the observations included in the time-period. This is only valid for datetimelike indexes.

If a BaseIndexer subclass is passed, calculates the window boundaries based on the defined `get_window_bounds` method. Additional rolling keyword arguments, namely *min\_periods*, *center*, and *closed* will be passed to `get_window_bounds`.

**min\_periods** [int, default None] Minimum number of observations in window required to have a value (otherwise result is NA). For a window that is specified by an offset, *min\_periods* will default to 1. Otherwise, *min\_periods* will default to the size of the window.

**center** [bool, default False] Set the labels at the center of the window.

**win\_type** [str, default None] Provide a window type. If `None`, all points are evenly weighted. See the notes below for further information.

**on** [str, optional] For a DataFrame, a datetime-like column or MultiIndex level on which to calculate the rolling window, rather than the DataFrame's index. Provided integer column is ignored and excluded from result since an integer index is not used to calculate the rolling window.

**axis** [int or str, default 0]

**closed** [str, default None] Make the interval closed on the 'right', 'left', 'both' or 'neither' endpoints. For offset-based windows, it defaults to 'right'. For fixed windows, defaults to 'both'. Remaining cases not implemented for fixed windows.

**Returns**

**a Window or Rolling sub-classed for the particular operation**

See also:

**expanding** Provides expanding transformations.

**ewm** Provides exponential weighted functions.

## Notes

By default, the result is set to the right edge of the window. This can be changed to the center of the window by setting `center=True`.

To learn more about the offsets & frequency strings, please see [this link](#).

The recognized `win_types` are:

- `boxcar`
- `triang`
- `blackman`
- `hamming`
- `bartlett`
- `parzen`
- `bohman`
- `blackmanharris`
- `nuttall`
- `barthann`
- `kaiser` (needs `beta`)
- `gaussian` (needs `std`)
- `general_gaussian` (needs `power`, `width`)
- `slepian` (needs `width`)
- `exponential` (needs `tau`), `center` is set to `None`.

If `win_type=None` all points are evenly weighted. To learn more about different window types see [scipy.signal window functions](#).

## Examples

```
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
>>> df
   B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0
```

Rolling sum with a window length of 2, using the 'triang' window type.

```
>>> df.rolling(2, win_type='triang').sum()
   B
0  NaN
1  0.5
2  1.5
3  NaN
4  NaN
```

Rolling sum with a window length of 2, using the 'gaussian' window type (note how we need to specify std).

```
>>> df.rolling(2, win_type='gaussian').sum(std=3)
      B
0     NaN
1  0.986207
2  2.958621
3     NaN
4     NaN
```

Rolling sum with a window length of 2, min\_periods defaults to the window length.

```
>>> df.rolling(2).sum()
      B
0  NaN
1  1.0
2  3.0
3  NaN
4  NaN
```

Same as above, but explicitly set the min\_periods

```
>>> df.rolling(2, min_periods=1).sum()
      B
0  0.0
1  1.0
2  3.0
3  2.0
4  4.0
```

A ragged (meaning not-a-regular frequency), time-indexed DataFrame

```
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]},
...                    index = [pd.Timestamp('20130101 09:00:00'),
...                               pd.Timestamp('20130101 09:00:02'),
...                               pd.Timestamp('20130101 09:00:03'),
...                               pd.Timestamp('20130101 09:00:05'),
...                               pd.Timestamp('20130101 09:00:06')])
```

```
>>> df
                B
2013-01-01 09:00:00  0.0
2013-01-01 09:00:02  1.0
2013-01-01 09:00:03  2.0
2013-01-01 09:00:05  NaN
2013-01-01 09:00:06  4.0
```

Contrasting to an integer rolling window, this will roll a variable length window corresponding to the time period. The default for min\_periods is 1.

```
>>> df.rolling('2s').sum()
                B
2013-01-01 09:00:00  0.0
2013-01-01 09:00:02  1.0
2013-01-01 09:00:03  3.0
2013-01-01 09:00:05  NaN
2013-01-01 09:00:06  4.0
```

**pandas.DataFrame.round**

`DataFrame.round(self, decimals=0, *args, **kwargs) → 'DataFrame'`

Round a DataFrame to a variable number of decimal places.

**Parameters**

**decimals** [int, dict, Series] Number of decimal places to round each column to. If an int is given, round each column to the same number of places. Otherwise dict and Series round to variable numbers of places. Column names should be in the keys if *decimals* is a dict-like, or in the index if *decimals* is a Series. Any columns not included in *decimals* will be left as is. Elements of *decimals* which are not columns of the input will be ignored.

**\*args** Additional keywords have no effect but might be accepted for compatibility with numpy.

**\*\*kwargs** Additional keywords have no effect but might be accepted for compatibility with numpy.

**Returns**

**DataFrame** A DataFrame with the affected columns rounded to the specified number of decimal places.

**See also:**

**numpy.around** Round a numpy array to the given number of decimals.

**Series.round** Round a Series to the given number of decimals.

**Examples**

```
>>> df = pd.DataFrame([(0.21, 0.32), (0.01, 0.67), (0.66, 0.03), (0.21, 0.18)],
...                    columns=['dogs', 'cats'])
>>> df
   dogs  cats
0  0.21  0.32
1  0.01  0.67
2  0.66  0.03
3  0.21  0.18
```

By providing an integer each column is rounded to the same number of decimal places

```
>>> df.round(1)
   dogs  cats
0   0.2   0.3
1   0.0   0.7
2   0.7   0.0
3   0.2   0.2
```

With a dict, the number of places for specific columns can be specified with the column names as key and the number of decimal places as value

```
>>> df.round({'dogs': 1, 'cats': 0})
   dogs  cats
0   0.2   0.0
1   0.0   1.0
```

(continues on next page)

(continued from previous page)

```
2  0.7  0.0
3  0.2  0.0
```

Using a Series, the number of places for specific columns can be specified with the column names as index and the number of decimal places as value

```
>>> decimals = pd.Series([0, 1], index=['cats', 'dogs'])
>>> df.round(decimals)
   dogs  cats
0  0.2  0.0
1  0.0  1.0
2  0.7  0.0
3  0.2  0.0
```

### pandas.DataFrame.rpow

DataFrame.**rpow** (*self*, *other*, *axis*='columns', *level*=None, *fill\_value*=None)

Get Exponential power of dataframe and other, element-wise (binary operator *rpow*).

Equivalent to `other ** dataframe`, but with support to substitute a *fill\_value* for missing data in one of the inputs. With reverse version, *pow*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: +, -, \*, /, //, %, \*\*.

#### Parameters

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

**level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

**fill\_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

#### Returns

**DataFrame** Result of the arithmetic operation.

See also:

**DataFrame.add** Add DataFrames.

**DataFrame.sub** Subtract DataFrames.

**DataFrame.mul** Multiply DataFrames.

**DataFrame.div** Divide DataFrames (float division).

**DataFrame.truediv** Divide DataFrames (float division).

**DataFrame.floordiv** Divide DataFrames (integer division).

**DataFrame.mod** Calculate modulo (remainder after division).

**DataFrame.pow** Calculate exponential power.

## Notes

Mismatched indices will be unioned together.

## Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

	angles	degrees
circle	0	360
triangle	3	180
rectangle	4	360

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

```
>>> df.add(1)
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

Divide by constant with reverse version.

```
>>> df.div(10)
```

	angles	degrees
circle	0.0	36.0
triangle	0.3	18.0
rectangle	0.4	36.0

```
>>> df.rdiv(10)
```

	angles	degrees
circle	inf	0.027778
triangle	3.333333	0.055556
rectangle	2.500000	0.027778

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
```

	angles	degrees
circle	-1	358
triangle	2	178
rectangle	3	358

```
>>> df.sub([1, 2], axis='columns')
```

	angles	degrees
circle	-1	358
triangle	2	178
rectangle	3	358

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
      angles  degrees
circle     -1     359
triangle     2     179
rectangle     3     359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
      angles
circle      0
triangle     3
rectangle     4
```

```
>>> df * other
      angles  degrees
circle      0      NaN
triangle     9      NaN
rectangle   16      NaN
```

```
>>> df.mul(other, fill_value=0)
      angles  degrees
circle      0      0.0
triangle     9      0.0
rectangle   16      0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                              'degrees': [360, 180, 360, 360, 540, 720]},
...                              index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                      ['circle', 'triangle', 'rectangle',
...                                       'square', 'pentagon', 'hexagon']])
>>> df_multindex
      angles  degrees
A circle      0     360
  triangle     3     180
  rectangle     4     360
B square      4     360
  pentagon     5     540
  hexagon      6     720
```

```
>>> df_multindex.div(df_multindex, level=1, fill_value=0)
      angles  degrees
A circle      NaN      1.0
  triangle     1.0      1.0
  rectangle     1.0      1.0
B square      0.0      0.0
  pentagon     0.0      0.0
  hexagon      0.0      0.0
```

## pandas.DataFrame.rsub

`DataFrame.rsub` (*self*, *other*, *axis*='columns', *level*=None, *fill\_value*=None)

Get Subtraction of dataframe and other, element-wise (binary operator *rsub*).

Equivalent to `other - dataframe`, but with support to substitute a *fill\_value* for missing data in one of the inputs. With reverse version, *sub*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: +, -, \*, /, //, %, \*\*.

### Parameters

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

**level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

**fill\_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

### Returns

**DataFrame** Result of the arithmetic operation.

See also:

**DataFrame.add** Add DataFrames.

**DataFrame.sub** Subtract DataFrames.

**DataFrame.mul** Multiply DataFrames.

**DataFrame.div** Divide DataFrames (float division).

**DataFrame.truediv** Divide DataFrames (float division).

**DataFrame.floordiv** Divide DataFrames (integer division).

**DataFrame.mod** Calculate modulo (remainder after division).

**DataFrame.pow** Calculate exponential power.

### Notes

Mismatched indices will be unioned together.

## Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

	angles	degrees
circle	0	360
triangle	3	180
rectangle	4	360

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

```
>>> df.add(1)
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

Divide by constant with reverse version.

```
>>> df.div(10)
```

	angles	degrees
circle	0.0	36.0
triangle	0.3	18.0
rectangle	0.4	36.0

```
>>> df.rdiv(10)
```

	angles	degrees
circle	inf	0.027778
triangle	3.333333	0.055556
rectangle	2.500000	0.027778

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
```

	angles	degrees
circle	-1	358
triangle	2	178
rectangle	3	358

```
>>> df.sub([1, 2], axis='columns')
```

	angles	degrees
circle	-1	358
triangle	2	178
rectangle	3	358

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
```

	angles	degrees
circle	0	359
triangle	2	179
rectangle	3	359

(continues on next page)

(continued from previous page)

```
circle      -1      359
triangle    2      179
rectangle   3      359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                        index=['circle', 'triangle', 'rectangle'])
>>> other
      angles
circle      0
triangle    3
rectangle   4
```

```
>>> df * other
      angles  degrees
circle      0     NaN
triangle    9     NaN
rectangle  16     NaN
```

```
>>> df.mul(other, fill_value=0)
      angles  degrees
circle      0     0.0
triangle    9     0.0
rectangle  16     0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                              index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                     ['circle', 'triangle', 'rectangle',
...                                      'square', 'pentagon', 'hexagon']])
>>> df_multindex
      angles  degrees
A circle      0     360
  triangle    3     180
  rectangle    4     360
B square      4     360
  pentagon    5     540
  hexagon     6     720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
      angles  degrees
A circle    NaN     1.0
  triangle  1.0     1.0
  rectangle  1.0     1.0
B square    0.0     0.0
  pentagon  0.0     0.0
  hexagon   0.0     0.0
```

**pandas.DataFrame.rtruediv**

`DataFrame.rtruediv` (*self*, *other*, *axis='columns'*, *level=None*, *fill\_value=None*)

Get Floating division of dataframe and other, element-wise (binary operator *rtruediv*).

Equivalent to `other / dataframe`, but with support to substitute a *fill\_value* for missing data in one of the inputs. With reverse version, *truediv*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

**Parameters**

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

**level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

**fill\_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

**DataFrame** Result of the arithmetic operation.

See also:

**DataFrame.add** Add DataFrames.

**DataFrame.sub** Subtract DataFrames.

**DataFrame.mul** Multiply DataFrames.

**DataFrame.div** Divide DataFrames (float division).

**DataFrame.truediv** Divide DataFrames (float division).

**DataFrame.floordiv** Divide DataFrames (integer division).

**DataFrame.mod** Calculate modulo (remainder after division).

**DataFrame.pow** Calculate exponential power.

**Notes**

Mismatched indices will be unioned together.

## Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

	angles	degrees
circle	0	360
triangle	3	180
rectangle	4	360

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

```
>>> df.add(1)
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

Divide by constant with reverse version.

```
>>> df.div(10)
```

	angles	degrees
circle	0.0	36.0
triangle	0.3	18.0
rectangle	0.4	36.0

```
>>> df.rdiv(10)
```

	angles	degrees
circle	inf	0.027778
triangle	3.333333	0.055556
rectangle	2.500000	0.027778

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
```

	angles	degrees
circle	-1	358
triangle	2	178
rectangle	3	358

      angles  degrees
A circle    NaN     1.0
  triangle  1.0     1.0
  rectangle  1.0     1.0
B square    0.0     0.0
  pentagon  0.0     0.0
  hexagon   0.0     0.0
```

## pandas.DataFrame.sample

`DataFrame.sample` (*self*: ~FrameOrSeries, *n*=None, *frac*=None, *replace*=False, *weights*=None, *random\_state*=None, *axis*=None) → ~FrameOrSeries

Return a random sample of items from an axis of object.

You can use *random\_state* for reproducibility.

### Parameters

**n** [int, optional] Number of items from axis to return. Cannot be used with *frac*. Default = 1 if *frac* = None.

**frac** [float, optional] Fraction of axis items to return. Cannot be used with *n*.

**replace** [bool, default False] Allow or disallow sampling of the same row more than once.

**weights** [str or ndarray-like, optional] Default 'None' results in equal probability weighting. If passed a Series, will align with target object on index. Index values in weights not found in sampled object will be ignored and index values in sampled object not in weights will be assigned weights of zero. If called on a DataFrame, will accept the name of a column when *axis* = 0. Unless weights are a Series, weights must be same length as axis being sampled. If weights do not sum to 1, they will be normalized to sum to 1. Missing values in the weights column will be treated as zero. Infinite values not allowed.

**random\_state** [int or numpy.random.RandomState, optional] Seed for the random number generator (if int), or numpy RandomState object.

**axis** [{0 or 'index', 1 or 'columns', None}, default None] Axis to sample. Accepts axis number or name. Default is stat axis for given data type (0 for Series and DataFrames).

### Returns

**Series or DataFrame** A new object of same type as caller containing *n* items randomly sampled from the caller object.

### See also:

`numpy.random.choice` Generates a random sample from a given 1-D numpy array.

### Notes

If *frac* > 1, *replacement* should be set to *True*.

### Examples

```
>>> df = pd.DataFrame({'num_legs': [2, 4, 8, 0],
...                   'num_wings': [2, 0, 0, 0],
...                   'num_specimen_seen': [10, 2, 1, 8]},
...                   index=['falcon', 'dog', 'spider', 'fish'])
>>> df
```

	num_legs	num_wings	num_specimen_seen
falcon	2	2	10
dog	4	0	2

(continues on next page)

(continued from previous page)

spider	8	0	1
fish	0	0	8

Extract 3 random elements from the Series `df['num_legs']`: Note that we use *random\_state* to ensure the reproducibility of the examples.

```
>>> df['num_legs'].sample(n=3, random_state=1)
fish      0
spider    8
falcon    2
Name: num_legs, dtype: int64
```

A random 50% sample of the DataFrame with replacement:

```
>>> df.sample(frac=0.5, replace=True, random_state=1)
   num_legs  num_wings  num_specimen_seen
dog         4         0                 2
fish        0         0                 8
```

An upsample sample of the DataFrame with replacement: Note that *replace* parameter has to be *True* for *frac* parameter > 1.

```
>>> df.sample(frac=2, replace=True, random_state=1)
   num_legs  num_wings  num_specimen_seen
dog         4         0                 2
fish        0         0                 8
falcon      2         2                 10
falcon      2         2                 10
fish        0         0                 8
dog         4         0                 2
fish        0         0                 8
dog         4         0                 2
```

Using a DataFrame column as weights. Rows with larger value in the *num\_specimen\_seen* column are more likely to be sampled.

```
>>> df.sample(n=2, weights='num_specimen_seen', random_state=1)
   num_legs  num_wings  num_specimen_seen
falcon      2         2                 10
fish        0         0                 8
```

## pandas.DataFrame.select\_dtypes

`DataFrame.select_dtypes` (*self*, *include=None*, *exclude=None*) → 'DataFrame'

Return a subset of the DataFrame's columns based on the column dtypes.

### Parameters

**include, exclude** [scalar or list-like] A selection of dtypes or strings to be included/excluded. At least one of these parameters must be supplied.

### Returns

**DataFrame** The subset of the frame including the dtypes in *include* and excluding the dtypes in *exclude*.

### Raises

### ValueError

- If both of `include` and `exclude` are empty
- If `include` and `exclude` have overlapping elements
- If any kind of string dtype is passed in.

### Notes

- To select all *numeric* types, use `np.number` or `'number'`
- To select strings you must use the `object` dtype, but note that this will return *all* object dtype columns
- See the [numpy dtype hierarchy](#)
- To select datetimes, use `np.datetime64`, `'datetime'` or `'datetime64'`
- To select timedeltas, use `np.timedelta64`, `'timedelta'` or `'timedelta64'`
- To select Pandas categorical dtypes, use `'category'`
- To select Pandas datetimetz dtypes, use `'datetimeetz'` (new in 0.20.0) or `'datetime64[ns, tz]'`

### Examples

```
>>> df = pd.DataFrame({'a': [1, 2] * 3,
...                    'b': [True, False] * 3,
...                    'c': [1.0, 2.0] * 3})
>>> df
```

	a	b	c
0	1	True	1.0
1	2	False	2.0
2	1	True	1.0
3	2	False	2.0
4	1	True	1.0
5	2	False	2.0

```
>>> df.select_dtypes(include='bool')
b
0 True
1 False
2 True
3 False
4 True
5 False
```

```
>>> df.select_dtypes(include=['float64'])
c
0 1.0
1 2.0
2 1.0
3 2.0
4 1.0
5 2.0
```

```
>>> df.select_dtypes(exclude=['int'])
      b    c
0  True  1.0
1 False  2.0
2  True  1.0
3 False  2.0
4  True  1.0
5 False  2.0
```

### pandas.DataFrame.sem

`DataFrame.sem`(*self*, *axis=None*, *skipna=None*, *level=None*, *ddof=1*, *numeric\_only=None*, *\*\*kwargs*)

Return unbiased standard error of the mean over requested axis.

Normalized by N-1 by default. This can be changed using the `ddof` argument

#### Parameters

**axis** [{index (0), columns (1)}]

**skipna** [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

**ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

#### Returns

Series or DataFrame (if level specified)

### pandas.DataFrame.set\_axis

`DataFrame.set_axis`(*self*, *labels*, *axis=0*, *inplace=False*)

Assign desired index to given axis.

Indexes for column or row labels can be changed by assigning a list-like or Index.

Changed in version 0.21.0: The signature is now *labels* and *axis*, consistent with the rest of pandas API. Previously, the *axis* and *labels* arguments were respectively the first and second positional arguments.

#### Parameters

**labels** [list-like, Index] The values for the new index.

**axis** [{0 or 'index', 1 or 'columns'}, default 0] The axis to update. The value 0 identifies the rows, and 1 identifies the columns.

**inplace** [bool, default False] Whether to return a new %(klass)s instance.

#### Returns

**renamed** [% (klass)s or None] An object of same type as caller if inplace=False, None otherwise.

**See also:**

**DataFrame.rename\_axis** Alter the name of the index or columns.

## Examples

### Series

```
>>> s = pd.Series([1, 2, 3])
>>> s
0    1
1    2
2    3
dtype: int64
```

```
>>> s.set_axis(['a', 'b', 'c'], axis=0)
a    1
b    2
c    3
dtype: int64
```

### DataFrame

```
>>> df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6]})
```

Change the row labels.

```
>>> df.set_axis(['a', 'b', 'c'], axis='index')
  A  B
a  1  4
b  2  5
c  3  6
```

Change the column labels.

```
>>> df.set_axis(['I', 'II'], axis='columns')
  I  II
0  1  4
1  2  5
2  3  6
```

Now, update the labels inplace.

```
>>> df.set_axis(['i', 'ii'], axis='columns', inplace=True)
>>> df
  i  ii
0  1  4
1  2  5
2  3  6
```

## pandas.DataFrame.set\_index

`DataFrame.set_index` (*self*, *keys*, *drop=True*, *append=False*, *inplace=False*, *verify\_integrity=False*)

Set the DataFrame index using existing columns.

Set the DataFrame index (row labels) using one or more existing columns or arrays (of the correct length). The index can replace the existing index or expand on it.

### Parameters

**keys** [label or array-like or list of labels/arrays] This parameter can be either a single column key, a single array of the same length as the calling DataFrame, or a list containing an arbitrary combination of column keys and arrays. Here, “array” encompasses *Series*, *Index*, *np.ndarray*, and instances of *Iterator*.

**drop** [bool, default True] Delete columns to be used as the new index.

**append** [bool, default False] Whether to append columns to existing index.

**inplace** [bool, default False] Modify the DataFrame in place (do not create a new object).

**verify\_integrity** [bool, default False] Check the new index for duplicates. Otherwise defer the check until necessary. Setting to False will improve the performance of this method.

### Returns

**DataFrame** Changed row labels.

See also:

**DataFrame.reset\_index** Opposite of `set_index`.

**DataFrame.reindex** Change to new indices or expand indices.

**DataFrame.reindex\_like** Change to same indices as other DataFrame.

### Examples

```
>>> df = pd.DataFrame({'month': [1, 4, 7, 10],
...                    'year': [2012, 2014, 2013, 2014],
...                    'sale': [55, 40, 84, 31]})
>>> df
   month  year  sale
0      1  2012   55
1      4  2014   40
2      7  2013   84
3     10  2014   31
```

Set the index to become the ‘month’ column:

```
>>> df.set_index('month')
   year  sale
month
1     2012   55
4     2014   40
7     2013   84
10    2014   31
```

Create a MultiIndex using columns 'year' and 'month':

```
>>> df.set_index(['year', 'month'])
      sale
year  month
2012  1     55
2014  4     40
2013  7     84
2014  10    31
```

Create a MultiIndex using an Index and a column:

```
>>> df.set_index([pd.Index([1, 2, 3, 4]), 'year'])
      month  sale
year
1  2012  1     55
2  2014  4     40
3  2013  7     84
4  2014  10    31
```

Create a MultiIndex using two Series:

```
>>> s = pd.Series([1, 2, 3, 4])
>>> df.set_index([s, s**2])
      month  year  sale
1  1      1  2012   55
2  4      4  2014   40
3  9      7  2013   84
4  16     10  2014   31
```

## pandas.DataFrame.shift

`DataFrame.shift` (*self*, *periods=1*, *freq=None*, *axis=0*, *fill\_value=None*) → 'DataFrame'

Shift index by desired number of periods with an optional time *freq*.

When *freq* is not passed, shift the index without realigning the data. If *freq* is passed (in this case, the index must be date or datetime, or it will raise a `NotImplementedError`), the index will be increased using the periods and the *freq*.

### Parameters

**periods** [int] Number of periods to shift. Can be positive or negative.

**freq** [DateOffset, tseries.offsets, timedelta, or str, optional] Offset to use from the tseries module or time rule (e.g. 'EOM'). If *freq* is specified then the index values are shifted but the data is not realigned. That is, use *freq* if you would like to extend the index when shifting and preserve the original data.

**axis** [{0 or 'index', 1 or 'columns', None}, default None] Shift direction.

**fill\_value** [object, optional] The scalar value to use for newly introduced missing values. the default depends on the dtype of *self*. For numeric data, `np.nan` is used. For datetime, timedelta, or period data, etc. `NaT` is used. For extension dtypes, `self.dtype.na_value` is used.

Changed in version 0.24.0.

### Returns

**DataFrame** Copy of input object, shifted.

**See also:**

**Index.shift** Shift values of Index.

**DatetimeIndex.shift** Shift values of DatetimeIndex.

**PeriodIndex.shift** Shift values of PeriodIndex.

**tshift** Shift the time index, using the index's frequency if available.

## Examples

```
>>> df = pd.DataFrame({'Col1': [10, 20, 15, 30, 45],
...                    'Col2': [13, 23, 18, 33, 48],
...                    'Col3': [17, 27, 22, 37, 52]})
```

```
>>> df.shift( periods=3)
   Col1  Col2  Col3
0    NaN   NaN   NaN
1    NaN   NaN   NaN
2    NaN   NaN   NaN
3   10.0  13.0  17.0
4   20.0  23.0  27.0
```

```
>>> df.shift( periods=1, axis='columns')
   Col1  Col2  Col3
0    NaN  10.0  13.0
1    NaN  20.0  23.0
2    NaN  15.0  18.0
3    NaN  30.0  33.0
4    NaN  45.0  48.0
```

```
>>> df.shift( periods=3, fill_value=0)
   Col1  Col2  Col3
0     0     0     0
1     0     0     0
2     0     0     0
3    10    13    17
4    20    23    27
```

## pandas.DataFrame.skew

`DataFrame.skew` (*self*, *axis=None*, *skipna=None*, *level=None*, *numeric\_only=None*, *\*\*kwargs*)  
Return unbiased skew over requested axis.

Normalized by N-1.

### Parameters

**axis** [{index (0), columns (1)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

**Returns**

**Series or DataFrame (if level specified)**

**pandas.DataFrame.slice\_shift**

`DataFrame.slice_shift` (*self*: ~FrameOrSeries, *periods*: int = 1, *axis*=0) → ~FrameOrSeries  
Equivalent to *shift* without copying data.

The shifted data will not include the dropped periods and the shifted axis will be smaller than the original.

**Parameters**

**periods** [int] Number of periods to move, can be positive or negative.

**Returns**

**shifted** [same type as caller]

**Notes**

While the *slice\_shift* is faster than *shift*, you may pay for it later during alignment.

**pandas.DataFrame.sort\_index**

`DataFrame.sort_index` (*self*, *axis*=0, *level*=None, *ascending*=True, *inplace*=False, *kind*='quicksort', *na\_position*='last', *sort\_remaining*=True, *ignore\_index*: bool = False)  
Sort object by labels (along an axis).

**Parameters**

**axis** [{0 or 'index', 1 or 'columns'}, default 0] The axis along which to sort. The value 0 identifies the rows, and 1 identifies the columns.

**level** [int or level name or list of ints or list of level names] If not None, sort on values in specified index level(s).

**ascending** [bool, default True] Sort ascending vs. descending.

**inplace** [bool, default False] If True, perform operation in-place.

**kind** [{ 'quicksort', 'mergesort', 'heapsort' }, default 'quicksort'] Choice of sorting algorithm. See also `ndarray.sort` for more information. *mergesort* is the only stable algorithm. For DataFrames, this option is only applied when sorting on a single column or label.

**na\_position** [{ 'first', 'last' }, default 'last'] Puts NaNs at the beginning if *first*; *last* puts NaNs at the end. Not implemented for MultiIndex.

**sort\_remaining** [bool, default True] If True and sorting by level and index is multi-level, sort by other levels too (in order) after sorting by specified level.

**ignore\_index** [bool, default False] If True, the resulting axis will be labeled 0, 1, ..., n - 1.

New in version 1.0.0.

#### Returns

**sorted\_obj** [DataFrame or None] DataFrame with sorted index if inplace=False, None otherwise.

### pandas.DataFrame.sort\_values

DataFrame.**sort\_values** (*self*, *by*, *axis=0*, *ascending=True*, *inplace=False*, *kind='quicksort'*, *na\_position='last'*, *ignore\_index=False*)

Sort by the values along either axis.

#### Parameters

**by** [str or list of str] Name or list of names to sort by.

- if *axis* is 0 or 'index' then *by* may contain index levels and/or column labels.
- if *axis* is 1 or 'columns' then *by* may contain column levels and/or index labels.

Changed in version 0.23.0: Allow specifying index or column level names.

**axis** [{0 or 'index', 1 or 'columns'}, default 0] Axis to be sorted.

**ascending** [bool or list of bool, default True] Sort ascending vs. descending. Specify list for multiple sort orders. If this is a list of bools, must match the length of the *by*.

**inplace** [bool, default False] If True, perform operation in-place.

**kind** [{'quicksort', 'mergesort', 'heapsort'}, default 'quicksort'] Choice of sorting algorithm. See also ndarray.sort for more information. *mergesort* is the only stable algorithm. For DataFrames, this option is only applied when sorting on a single column or label.

**na\_position** [{'first', 'last'}, default 'last'] Puts NaNs at the beginning if *first*; *last* puts NaNs at the end.

**ignore\_index** [bool, default False] If True, the resulting axis will be labeled 0, 1, ..., n - 1.

New in version 1.0.0.

#### Returns

**sorted\_obj** [DataFrame or None] DataFrame with sorted values if inplace=False, None otherwise.

## Examples

```
>>> df = pd.DataFrame({
...     'col1': ['A', 'A', 'B', np.nan, 'D', 'C'],
...     'col2': [2, 1, 9, 8, 7, 4],
...     'col3': [0, 1, 9, 4, 2, 3],
... })
>>> df
   col1  col2  col3
0    A     2     0
1    A     1     1
2    B     9     9
3  NaN     8     4
4    D     7     2
5    C     4     3
```

### Sort by col1

```
>>> df.sort_values(by=['col1'])
   col1  col2  col3
0    A     2     0
1    A     1     1
2    B     9     9
5    C     4     3
4    D     7     2
3  NaN     8     4
```

### Sort by multiple columns

```
>>> df.sort_values(by=['col1', 'col2'])
   col1  col2  col3
1    A     1     1
0    A     2     0
2    B     9     9
5    C     4     3
4    D     7     2
3  NaN     8     4
```

### Sort Descending

```
>>> df.sort_values(by='col1', ascending=False)
   col1  col2  col3
4    D     7     2
5    C     4     3
2    B     9     9
0    A     2     0
1    A     1     1
3  NaN     8     4
```

### Putting NAs first

```
>>> df.sort_values(by='col1', ascending=False, na_position='first')
   col1  col2  col3
3  NaN     8     4
4    D     7     2
5    C     4     3
2    B     9     9
```

(continues on next page)

(continued from previous page)

```
0  A    2    0
1  A    1    1
```

### pandas.DataFrame.sparse

`DataFrame.sparse()`  
 DataFrame accessor for sparse data.  
 New in version 0.25.0.

### pandas.DataFrame.squeeze

`DataFrame.squeeze(self, axis=None)`  
 Squeeze 1 dimensional axis objects into scalars.

Series or DataFrames with a single element are squeezed to a scalar. DataFrames with a single column or a single row are squeezed to a Series. Otherwise the object is unchanged.

This method is most useful when you don't know if your object is a Series or DataFrame, but you do know it has just a single column. In that case you can safely call *squeeze* to ensure you have a Series.

#### Parameters

**axis** [{0 or 'index', 1 or 'columns', None}, default None] A specific axis to squeeze.  
 By default, all length-1 axes are squeezed.

#### Returns

**DataFrame, Series, or scalar** The projection after squeezing *axis* or all the axes.

#### See also:

***Series.iloc*** Integer-location based indexing for selecting scalars.

***DataFrame.iloc*** Integer-location based indexing for selecting Series.

***Series.to\_frame*** Inverse of `DataFrame.squeeze` for a single-column DataFrame.

### Examples

```
>>> primes = pd.Series([2, 3, 5, 7])
```

Slicing might produce a Series with a single value:

```
>>> even_primes = primes[primes % 2 == 0]
>>> even_primes
0    2
dtype: int64
```

```
>>> even_primes.squeeze()
2
```

Squeezing objects with more than one value in every axis does nothing:

```
>>> odd_primes = primes[primes % 2 == 1]
>>> odd_primes
1    3
2    5
3    7
dtype: int64
```

```
>>> odd_primes.squeeze()
1    3
2    5
3    7
dtype: int64
```

Squeezing is even more effective when used with DataFrames.

```
>>> df = pd.DataFrame([[1, 2], [3, 4]], columns=['a', 'b'])
>>> df
   a  b
0  1  2
1  3  4
```

Slicing a single column will produce a DataFrame with the columns having only one value:

```
>>> df_a = df[['a']]
>>> df_a
   a
0  1
1  3
```

So the columns can be squeezed down, resulting in a Series:

```
>>> df_a.squeeze('columns')
0    1
1    3
Name: a, dtype: int64
```

Slicing a single row from a single column will produce a single scalar DataFrame:

```
>>> df_0a = df.loc[df.index < 1, ['a']]
>>> df_0a
   a
0  1
```

Squeezing the rows produces a single scalar Series:

```
>>> df_0a.squeeze('rows')
a    1
Name: 0, dtype: int64
```

Squeezing all axes will project directly into a scalar:

```
>>> df_0a.squeeze()
1
```

## pandas.DataFrame.stack

DataFrame.**stack** (*self*, *level=-1*, *dropna=True*)

Stack the prescribed level(s) from columns to index.

Return a reshaped DataFrame or Series having a multi-level index with one or more new inner-most levels compared to the current DataFrame. The new inner-most levels are created by pivoting the columns of the current dataframe:

- if the columns have a single level, the output is a Series;
- if the columns have multiple levels, the new index level(s) is (are) taken from the prescribed level(s) and the output is a DataFrame.

The new index levels are sorted.

### Parameters

**level** [int, str, list, default -1] Level(s) to stack from the column axis onto the index axis, defined as one index or label, or a list of indices or labels.

**dropna** [bool, default True] Whether to drop rows in the resulting Frame/Series with missing values. Stacking a column level onto the index axis can create combinations of index and column values that are missing from the original dataframe. See Examples section.

### Returns

**DataFrame or Series** Stacked dataframe or series.

See also:

**DataFrame.unstack** Unstack prescribed level(s) from index axis onto column axis.

**DataFrame.pivot** Reshape dataframe from long format to wide format.

**DataFrame.pivot\_table** Create a spreadsheet-style pivot table as a DataFrame.

## Notes

The function is named by analogy with a collection of books being reorganized from being side by side on a horizontal position (the columns of the dataframe) to being stacked vertically on top of each other (in the index of the dataframe).

## Examples

### Single level columns

```
>>> df_single_level_cols = pd.DataFrame([[0, 1], [2, 3]],
...                                     index=['cat', 'dog'],
...                                     columns=['weight', 'height'])
```

Stacking a dataframe with a single level column axis returns a Series:

```
>>> df_single_level_cols
   weight height
cat      0      1
dog      2      3
```

(continues on next page)

(continued from previous page)

```
>>> df_single_level_cols.stack()
cat  weight    0
     height    1
dog   weight    2
     height    3
dtype: int64
```

**Multi level columns: simple case**

```
>>> multicol1 = pd.MultiIndex.from_tuples([('weight', 'kg'),
...                                     ('weight', 'pounds')])
>>> df_multi_level_cols1 = pd.DataFrame([[1, 2], [2, 4]],
...                                    index=['cat', 'dog'],
...                                    columns=multicol1)
```

Stacking a dataframe with a multi-level column axis:

```
>>> df_multi_level_cols1
      weight
      kg   pounds
cat     1     2
dog     2     4
>>> df_multi_level_cols1.stack()
      weight
cat kg     1
   pounds  2
dog kg     2
   pounds  4
```

**Missing values**

```
>>> multicol2 = pd.MultiIndex.from_tuples([('weight', 'kg'),
...                                     ('height', 'm')])
>>> df_multi_level_cols2 = pd.DataFrame([[1.0, 2.0], [3.0, 4.0]],
...                                    index=['cat', 'dog'],
...                                    columns=multicol2)
```

It is common to have missing values when stacking a dataframe with multi-level columns, as the stacked dataframe typically has more values than the original dataframe. Missing values are filled with NaNs:

```
>>> df_multi_level_cols2
      weight height
      kg     m
cat   1.0   2.0
dog   3.0   4.0
>>> df_multi_level_cols2.stack()
      height weight
cat kg     NaN   1.0
   m     2.0   NaN
dog kg     NaN   3.0
   m     4.0   NaN
```

**Prescribing the level(s) to be stacked**

The first parameter controls which level or levels are stacked:

```

>>> df_multi_level_cols2.stack(0)
           kg      m
cat height NaN  2.0
   weight 1.0  NaN
dog height NaN  4.0
   weight 3.0  NaN
>>> df_multi_level_cols2.stack([0, 1])
cat height m      2.0
   weight kg     1.0
dog height m      4.0
   weight kg     3.0
dtype: float64

```

### Dropping missing values

```

>>> df_multi_level_cols3 = pd.DataFrame([[None, 1.0], [2.0, 3.0]],
...                                     index=['cat', 'dog'],
...                                     columns=multicol2)

```

Note that rows where all values are missing are dropped by default but this behaviour can be controlled via the `dropna` keyword parameter:

```

>>> df_multi_level_cols3
   weight height
           kg      m
cat   NaN     1.0
dog    2.0     3.0
>>> df_multi_level_cols3.stack(dropna=False)
           height weight
cat kg      NaN   NaN
   m        1.0   NaN
dog kg      NaN   2.0
   m        3.0   NaN
>>> df_multi_level_cols3.stack(dropna=True)
           height weight
cat m        1.0   NaN
dog kg       NaN   2.0
   m        3.0   NaN

```

### pandas.DataFrame.std

`DataFrame.std`(*self*, *axis=None*, *skipna=None*, *level=None*, *ddof=1*, *numeric\_only=None*, *\*\*kwargs*)

Return sample standard deviation over requested axis.

Normalized by N-1 by default. This can be changed using the `ddof` argument

#### Parameters

**axis** [{index (0), columns (1)}]

**skipna** [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

**ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is  $N - \text{ddof}$ , where  $N$  represents the number of elements.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

#### Returns

Series or DataFrame (if level specified)

### pandas.DataFrame.sub

`DataFrame.sub` (*self*, *other*, *axis='columns'*, *level=None*, *fill\_value=None*)

Get Subtraction of dataframe and other, element-wise (binary operator *sub*).

Equivalent to `dataframe - other`, but with support to substitute a *fill\_value* for missing data in one of the inputs. With reverse version, *rsub*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

#### Parameters

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

**level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

**fill\_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

#### Returns

**DataFrame** Result of the arithmetic operation.

#### See also:

**DataFrame.add** Add DataFrames.

**DataFrame.sub** Subtract DataFrames.

**DataFrame.mul** Multiply DataFrames.

**DataFrame.div** Divide DataFrames (float division).

**DataFrame.truediv** Divide DataFrames (float division).

**DataFrame.floordiv** Divide DataFrames (integer division).

**DataFrame.mod** Calculate modulo (remainder after division).

**DataFrame.pow** Calculate exponential power.

## Notes

Mismatched indices will be unioned together.

## Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

	angles	degrees
circle	0	360
triangle	3	180
rectangle	4	360

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

```
>>> df.add(1)
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

Divide by constant with reverse version.

```
>>> df.div(10)
```

	angles	degrees
circle	0.0	36.0
triangle	0.3	18.0
rectangle	0.4	36.0

```
>>> df.rdiv(10)
```

	angles	degrees
circle	inf	0.027778
triangle	3.333333	0.055556
rectangle	2.500000	0.027778

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
```

	angles	degrees
circle	-1	358
triangle	2	178
rectangle	3	358

```
>>> df.sub([1, 2], axis='columns')
```

	angles	degrees
circle	-1	358
triangle	2	178
rectangle	3	358

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...         axis='index')
           angles  degrees
circle      -1     359
triangle     2     179
rectangle    3     359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
           angles
circle           0
triangle         3
rectangle        4
```

```
>>> df * other
           angles  degrees
circle         0      NaN
triangle        9      NaN
rectangle       16      NaN
```

```
>>> df.mul(other, fill_value=0)
           angles  degrees
circle         0      0.0
triangle        9      0.0
rectangle       16      0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                              index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                      ['circle', 'triangle', 'rectangle',
...                                       'square', 'pentagon', 'hexagon']])
>>> df_multindex
           angles  degrees
A circle         0     360
  triangle         3     180
  rectangle         4     360
B square          4     360
  pentagon         5     540
  hexagon          6     720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
           angles  degrees
A circle      NaN      1.0
  triangle     1.0      1.0
  rectangle     1.0      1.0
B square       0.0      0.0
  pentagon     0.0      0.0
  hexagon      0.0      0.0
```

**pandas.DataFrame.subtract**

`DataFrame.subtract` (*self*, *other*, *axis='columns'*, *level=None*, *fill\_value=None*)

Get Subtraction of dataframe and other, element-wise (binary operator *sub*).

Equivalent to `dataframe - other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *rsub*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

**Parameters**

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

**level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

**fill\_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

**DataFrame** Result of the arithmetic operation.

See also:

**DataFrame.add** Add DataFrames.

**DataFrame.sub** Subtract DataFrames.

**DataFrame.mul** Multiply DataFrames.

**DataFrame.div** Divide DataFrames (float division).

**DataFrame.truediv** Divide DataFrames (float division).

**DataFrame.floordiv** Divide DataFrames (integer division).

**DataFrame.mod** Calculate modulo (remainder after division).

**DataFrame.pow** Calculate exponential power.

**Notes**

Mismatched indices will be unioned together.

## Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

	angles	degrees
circle	0	360
triangle	3	180
rectangle	4	360

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

```
>>> df.add(1)
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

Divide by constant with reverse version.

```
>>> df.div(10)
```

	angles	degrees
circle	0.0	36.0
triangle	0.3	18.0
rectangle	0.4	36.0

```
>>> df.rdiv(10)
```

	angles	degrees
circle	inf	0.027778
triangle	3.333333	0.055556
rectangle	2.500000	0.027778

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
```

	angles	degrees
circle	-1	358
triangle	2	178
rectangle	3	358

```
>>> df.sub([1, 2], axis='columns')
```

	angles	degrees
circle	-1	358
triangle	2	178
rectangle	3	358

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
```

	angles	degrees
circle	0	359
triangle	2	179
rectangle	3	359

(continues on next page)

(continued from previous page)

```
circle      -1      359
triangle    2      179
rectangle   3      359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
      angles
circle      0
triangle    3
rectangle   4
```

```
>>> df * other
      angles  degrees
circle      0     NaN
triangle    9     NaN
rectangle  16     NaN
```

```
>>> df.mul(other, fill_value=0)
      angles  degrees
circle      0     0.0
triangle    9     0.0
rectangle  16     0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                              'degrees': [360, 180, 360, 360, 540, 720]},
...                              index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                      ['circle', 'triangle', 'rectangle',
...                                       'square', 'pentagon', 'hexagon']])
>>> df_multindex
      angles  degrees
A circle      0     360
  triangle    3     180
  rectangle   4     360
B square      4     360
  pentagon    5     540
  hexagon     6     720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
      angles  degrees
A circle    NaN     1.0
  triangle  1.0     1.0
  rectangle  1.0     1.0
B square    0.0     0.0
  pentagon  0.0     0.0
  hexagon   0.0     0.0
```

## pandas.DataFrame.sum

`DataFrame.sum`(*self*, *axis=None*, *skipna=None*, *level=None*, *numeric\_only=None*, *min\_count=0*,  
*\*\*kwargs*)

Return the sum of the values for the requested axis.

This is equivalent to the method `numpy.sum`.

### Parameters

**axis** [{index (0), columns (1)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**min\_count** [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

New in version 0.22.0: Added with the default being 0. This means the sum of an all-NA or empty Series is 0, and the product of an all-NA or empty Series is 1.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

### Returns

Series or DataFrame (if level specified)

#### See also:

**Series.sum** Return the sum.

**Series.min** Return the minimum.

**Series.max** Return the maximum.

**Series.idxmin** Return the index of the minimum.

**Series.idxmax** Return the index of the maximum.

**DataFrame.sum** Return the sum over the requested axis.

**DataFrame.min** Return the minimum over the requested axis.

**DataFrame.max** Return the maximum over the requested axis.

**DataFrame.idxmin** Return the index of the minimum over the requested axis.

**DataFrame.idxmax** Return the index of the maximum over the requested axis.

## Examples

```
>>> idx = pd.MultiIndex.from_arrays([
...     ['warm', 'warm', 'cold', 'cold'],
...     ['dog', 'falcon', 'fish', 'spider']],
...     names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded  animal
warm     dog      4
         falcon   2
cold     fish     0
         spider   8
Name: legs, dtype: int64
```

```
>>> s.sum()
14
```

Sum using level names, as well as indices.

```
>>> s.sum(level='blooded')
blooded
warm     6
cold     8
Name: legs, dtype: int64
```

```
>>> s.sum(level=0)
blooded
warm     6
cold     8
Name: legs, dtype: int64
```

By default, the sum of an empty or all-NA Series is 0.

```
>>> pd.Series([]).sum() # min_count=0 is the default
0.0
```

This can be controlled with the `min_count` parameter. For example, if you'd like the sum of an empty series to be NaN, pass `min_count=1`.

```
>>> pd.Series([]).sum(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```
>>> pd.Series([np.nan]).sum()
0.0
```

```
>>> pd.Series([np.nan]).sum(min_count=1)
nan
```

### pandas.DataFrame.swapaxes

DataFrame.**swapaxes** (*self*: ~FrameOrSeries, *axis1*, *axis2*, *copy=True*) → ~FrameOrSeries  
Interchange axes and swap values axes appropriately.

#### Returns

**y** [same as input]

### pandas.DataFrame.swaplevel

DataFrame.**swaplevel** (*self*, *i=-2*, *j=-1*, *axis=0*) → 'DataFrame'  
Swap levels *i* and *j* in a MultiIndex on a particular axis.

#### Parameters

**i, j** [int or str] Levels of the indices to be swapped. Can pass level name as string.

#### Returns

**DataFrame**

### pandas.DataFrame.tail

DataFrame.**tail** (*self*: ~FrameOrSeries, *n: int = 5*) → ~FrameOrSeries  
Return the last *n* rows.

This function returns last *n* rows from the object based on position. It is useful for quickly verifying data, for example, after sorting or appending rows.

For negative values of *n*, this function returns all rows except the first *n* rows, equivalent to `df[n:]`.

#### Parameters

**n** [int, default 5] Number of rows to select.

#### Returns

**type of caller** The last *n* rows of the caller object.

#### See also:

**DataFrame.head** The first *n* rows of the caller object.

### Examples

```
>>> df = pd.DataFrame({'animal': ['alligator', 'bee', 'falcon', 'lion',
...                               'monkey', 'parrot', 'shark', 'whale', 'zebra']})
>>> df
   animal
0  alligator
1      bee
2   falcon
3     lion
4   monkey
5   parrot
6    shark
```

(continues on next page)

(continued from previous page)

```
7    whale
8    zebra
```

Viewing the last 5 lines

```
>>> df.tail()
      animal
4    monkey
5    parrot
6     shark
7     whale
8     zebra
```

Viewing the last  $n$  lines (three in this case)

```
>>> df.tail(3)
      animal
6     shark
7     whale
8     zebra
```

For negative values of  $n$

```
>>> df.tail(-3)
      animal
3     lion
4    monkey
5    parrot
6     shark
7     whale
8     zebra
```

### pandas.DataFrame.take

`DataFrame.take` (*self*: ~FrameOrSeries, *indices*, *axis*=0, *is\_copy*: Union[bool, NoneType] = None, *\*\*kwargs*) → ~FrameOrSeries

Return the elements in the given *positional* indices along an axis.

This means that we are not indexing according to actual values in the index attribute of the object. We are indexing according to the actual position of the element in the object.

#### Parameters

**indices** [array-like] An array of ints indicating which positions to take.

**axis** [{0 or 'index', 1 or 'columns', None}, default 0] The axis on which to select elements. 0 means that we are selecting rows, 1 means that we are selecting columns.

**is\_copy** [bool] Before pandas 1.0, `is_copy=False` can be specified to ensure that the return value is an actual copy. Starting with pandas 1.0, `take` always returns a copy, and the keyword is therefore deprecated.

Deprecated since version 1.0.0.

**\*\*kwargs** For compatibility with `numpy.take()`. Has no effect on the output.

#### Returns

**taken** [same type as caller] An array-like containing the elements taken from the object.

**See also:**

**DataFrame.loc** Select a subset of a DataFrame by labels.

**DataFrame.iloc** Select a subset of a DataFrame by positions.

**numpy.take** Take elements from an array along an axis.

## Examples

```
>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
...                    ('parrot', 'bird', 24.0),
...                    ('lion', 'mammal', 80.5),
...                    ('monkey', 'mammal', np.nan)],
...                    columns=['name', 'class', 'max_speed'],
...                    index=[0, 2, 3, 1])
>>> df
```

	name	class	max_speed
0	falcon	bird	389.0
2	parrot	bird	24.0
3	lion	mammal	80.5
1	monkey	mammal	NaN

Take elements at positions 0 and 3 along the axis 0 (default).

Note how the actual indices selected (0 and 1) do not correspond to our selected indices 0 and 3. That's because we are selecting the 0th and 3rd rows, not rows whose indices equal 0 and 3.

```
>>> df.take([0, 3])
```

	name	class	max_speed
0	falcon	bird	389.0
1	monkey	mammal	NaN

Take elements at indices 1 and 2 along the axis 1 (column selection).

```
>>> df.take([1, 2], axis=1)
```

	class	max_speed
0	bird	389.0
2	bird	24.0
3	mammal	80.5
1	mammal	NaN

We may take elements using negative integers for positive indices, starting from the end of the object, just like with Python lists.

```
>>> df.take([-1, -2])
```

	name	class	max_speed
1	monkey	mammal	NaN
3	lion	mammal	80.5

## pandas.DataFrame.to\_clipboard

`DataFrame.to_clipboard`(*self*, *excel*: bool = True, *sep*: Union[str, NoneType] = None, \*\**kwargs*) → None

Copy object to the system clipboard.

Write a text representation of object to the system clipboard. This can be pasted into Excel, for example.

### Parameters

**excel** [bool, default True] Produce output in a csv format for easy pasting into excel.

- True, use the provided separator for csv pasting.
- False, write a string representation of the object to the clipboard.

**sep** [str, default '\t'] Field delimiter.

**\*\*kwargs** These parameters will be passed to `DataFrame.to_csv`.

See also:

**`DataFrame.to_csv`** Write a DataFrame to a comma-separated values (csv) file.

**`read_clipboard`** Read text from clipboard and pass to `read_table`.

### Notes

Requirements for your platform.

- Linux : `xclip`, or `xsel` (with `PyQt4` modules)
- Windows : none
- OS X : none

### Examples

Copy the contents of a DataFrame to the clipboard.

```
>>> df = pd.DataFrame([[1, 2, 3], [4, 5, 6]], columns=['A', 'B', 'C'])
>>> df.to_clipboard(sep=',')
... # Write the following to the system clipboard:
... # ,A,B,C
... # 0,1,2,3
... # 1,4,5,6
```

We can omit the the index by passing the keyword `index` and setting it to false.

```
>>> df.to_clipboard(sep=',', index=False)
... # Write the following to the system clipboard:
... # A,B,C
... # 1,2,3
... # 4,5,6
```

## pandas.DataFrame.to\_csv

```
DataFrame.to_csv(self, path_or_buf: Union[str, pathlib.Path, IO[~AnyStr], NoneType] = None, sep: str = ',', na_rep: str = "", float_format: Union[str, NoneType] = None, columns: Union[Sequence[Union[Hashable, NoneType]], NoneType] = None, header: Union[bool, List[str]] = True, index: bool = True, index_label: Union[bool, str, Sequence[Union[Hashable, NoneType]], NoneType] = None, mode: str = 'w', encoding: Union[str, NoneType] = None, compression: Union[str, Mapping[str, str], NoneType] = 'infer', quoting: Union[int, NoneType] = None, quotechar: str = '"', line_terminator: Union[str, NoneType] = None, chunksize: Union[int, NoneType] = None, date_format: Union[str, NoneType] = None, doublequote: bool = True, escapechar: Union[str, NoneType] = None, decimal: Union[str, NoneType] = '.') → Union[str, NoneType]
```

Write object to a comma-separated values (csv) file.

Changed in version 0.24.0: The order of arguments for Series was changed.

### Parameters

**path\_or\_buf** [str or file handle, default None] File path or object, if None is provided the result is returned as a string. If a file object is passed it should be opened with `newline=""`, disabling universal newlines.

Changed in version 0.24.0: Was previously named “path” for Series.

**sep** [str, default ‘,’] String of length 1. Field delimiter for the output file.

**na\_rep** [str, default ‘’] Missing data representation.

**float\_format** [str, default None] Format string for floating point numbers.

**columns** [sequence, optional] Columns to write.

**header** [bool or list of str, default True] Write out the column names. If a list of strings is given it is assumed to be aliases for the column names.

Changed in version 0.24.0: Previously defaulted to False for Series.

**index** [bool, default True] Write row names (index).

**index\_label** [str or sequence, or False, default None] Column label for index column(s) if desired. If None is given, and `header` and `index` are True, then the index names are used. A sequence should be given if the object uses MultiIndex. If False do not print fields for index names. Use `index_label=False` for easier importing in R.

**mode** [str] Python write mode, default ‘w’.

**encoding** [str, optional] A string representing the encoding to use in the output file, defaults to ‘utf-8’.

**compression** [str or dict, default ‘infer’] If str, represents compression mode. If dict, value at ‘method’ is the compression mode. Compression mode may be any of the following possible values: {‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}. If compression mode is ‘infer’ and `path_or_buf` is path-like, then detect compression mode from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’ or ‘.xz’. (otherwise no compression). If dict given and mode is ‘zip’ or inferred as ‘zip’, other entries passed as additional compression options.

Changed in version 1.0.0: May now be a dict with key ‘method’ as compression mode and other entries as additional compression options if compression mode is ‘zip’.

**quoting** [optional constant from csv module] Defaults to `csv.QUOTE_MINIMAL`. If you have set a *float\_format* then floats are converted to strings and thus `csv.QUOTE_NONNUMERIC` will treat them as non-numeric.

**quotechar** [str, default `""`] String of length 1. Character used to quote fields.

**line\_terminator** [str, optional] The newline character or character sequence to use in the output file. Defaults to `os.linesep`, which depends on the OS in which this method is called (`'n'` for linux, `'rn'` for Windows, i.e.).

Changed in version 0.24.0.

**chunksize** [int or None] Rows to write at a time.

**date\_format** [str, default None] Format string for datetime objects.

**doublequote** [bool, default True] Control quoting of *quotechar* inside a field.

**escapechar** [str, default None] String of length 1. Character used to escape *sep* and *quotechar* when appropriate.

**decimal** [str, default `'.'`] Character recognized as decimal separator. E.g. use `','` for European data.

### Returns

**None or str** If *path\_or\_buf* is None, returns the resulting csv format as a string. Otherwise returns None.

### See also:

***read\_csv*** Load a CSV file into a DataFrame.

***to\_excel*** Write DataFrame to an Excel file.

### Examples

```
>>> df = pd.DataFrame({'name': ['Raphael', 'Donatello'],
...                    'mask': ['red', 'purple'],
...                    'weapon': ['sai', 'bo staff']})
>>> df.to_csv(index=False)
'name,mask,weapon\nRaphael,red,sai\nDonatello,purple,bo staff\n'
```

```
# create 'out.zip' containing 'out.csv' >>> compression_opts = dict(method='zip', ...
archive_name='out.csv') # doctest: +SKIP
```

```
>>> df.to_csv('out.zip', index=False,
...           compression=compression_opts)
```

## pandas.DataFrame.to\_dict

DataFrame.**to\_dict** (*self*, *orient='dict'*, *into=<class 'dict'>*)

Convert the DataFrame to a dictionary.

The type of the key-value pairs can be customized with the parameters (see below).

### Parameters

**orient** [str {'dict', 'list', 'series', 'split', 'records', 'index'}] Determines the type of the values of the dictionary.

- 'dict' (default) : dict like {column -> {index -> value}}
- 'list' : dict like {column -> [values]}
- 'series' : dict like {column -> Series(values)}
- 'split' : dict like {'index' -> [index], 'columns' -> [columns], 'data' -> [values]}
- 'records' : list like [{column -> value}, ... , {column -> value}]
- 'index' : dict like {index -> {column -> value}}

Abbreviations are allowed. *s* indicates *series* and *sp* indicates *split*.

**into** [class, default dict] The collections.abc.Mapping subclass used for all Mappings in the return value. Can be the actual class or an empty instance of the mapping type you want. If you want a collections.defaultdict, you must pass it initialized.

New in version 0.21.0.

### Returns

**dict, list or collections.abc.Mapping** Return a collections.abc.Mapping object representing the DataFrame. The resulting transformation depends on the *orient* parameter.

See also:

**DataFrame.from\_dict** Create a DataFrame from a dictionary.

**DataFrame.to\_json** Convert a DataFrame to JSON format.

### Examples

```

>>> df = pd.DataFrame({'col1': [1, 2],
...                    'col2': [0.5, 0.75]},
...                    index=['row1', 'row2'])
>>> df
   col1  col2
row1    1  0.50
row2    2  0.75
>>> df.to_dict()
{'col1': {'row1': 1, 'row2': 2}, 'col2': {'row1': 0.5, 'row2': 0.75}}

```

You can specify the return orientation.

```
>>> df.to_dict('series')
{'col1': row1    1
      row2    2
Name: col1, dtype: int64,
 'col2': row1    0.50
      row2    0.75
Name: col2, dtype: float64}
```

```
>>> df.to_dict('split')
{'index': ['row1', 'row2'], 'columns': ['col1', 'col2'],
 'data': [[1, 0.5], [2, 0.75]]}
```

```
>>> df.to_dict('records')
[{'col1': 1, 'col2': 0.5}, {'col1': 2, 'col2': 0.75}]
```

```
>>> df.to_dict('index')
{'row1': {'col1': 1, 'col2': 0.5}, 'row2': {'col1': 2, 'col2': 0.75}}
```

You can also specify the mapping type.

```
>>> from collections import OrderedDict, defaultdict
>>> df.to_dict(into=OrderedDict)
OrderedDict([('col1', OrderedDict([('row1', 1), ('row2', 2)]),
            ('col2', OrderedDict([('row1', 0.5), ('row2', 0.75)]))])
```

If you want a *defaultdict*, you need to initialize it:

```
>>> dd = defaultdict(list)
>>> df.to_dict('records', into=dd)
[defaultdict(<class 'list'>, {'col1': 1, 'col2': 0.5}),
 defaultdict(<class 'list'>, {'col1': 2, 'col2': 0.75})]
```

## pandas.DataFrame.to\_excel

`DataFrame.to_excel` (*self*, *excel\_writer*, *sheet\_name*='Sheet1', *na\_rep*="", *float\_format*=None, *columns*=None, *header*=True, *index*=True, *index\_label*=None, *startrow*=0, *startcol*=0, *engine*=None, *merge\_cells*=True, *encoding*=None, *inf\_rep*='inf', *verbose*=True, *freeze\_panes*=None) → None

Write object to an Excel sheet.

To write a single object to an Excel .xlsx file it is only necessary to specify a target file name. To write to multiple sheets it is necessary to create an *ExcelWriter* object with a target file name, and specify a sheet in the file to write to.

Multiple sheets may be written to by specifying unique *sheet\_name*. With all data written to the file it is necessary to save the changes. Note that creating an *ExcelWriter* object with a file name that already exists will result in the contents of the existing file being erased.

### Parameters

**excel\_writer** [str or *ExcelWriter* object] File path or existing *ExcelWriter*.

**sheet\_name** [str, default 'Sheet1'] Name of sheet which will contain *DataFrame*.

**na\_rep** [str, default ''] Missing data representation.

- float\_format** [str, optional] Format string for floating point numbers. For example `float_format="% .2f"` will format 0.1234 to 0.12.
- columns** [sequence or list of str, optional] Columns to write.
- header** [bool or list of str, default True] Write out the column names. If a list of string is given it is assumed to be aliases for the column names.
- index** [bool, default True] Write row names (index).
- index\_label** [str or sequence, optional] Column label for index column(s) if desired. If not specified, and *header* and *index* are True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.
- startrow** [int, default 0] Upper left cell row to dump data frame.
- startcol** [int, default 0] Upper left cell column to dump data frame.
- engine** [str, optional] Write engine to use, 'openpyxl' or 'xlsxwriter'. You can also set this via the options `io.excel.xlsx.writer`, `io.excel.xls.writer`, and `io.excel.xlsm.writer`.
- merge\_cells** [bool, default True] Write MultiIndex and Hierarchical Rows as merged cells.
- encoding** [str, optional] Encoding of the resulting excel file. Only necessary for xlwt, other writers support unicode natively.
- inf\_rep** [str, default 'inf'] Representation for infinity (there is no native representation for infinity in Excel).
- verbose** [bool, default True] Display more information in the error logs.
- freeze\_panes** [tuple of int (length 2), optional] Specifies the one-based bottommost row and rightmost column that is to be frozen.

**See also:**

- to\_csv*** Write DataFrame to a comma-separated values (csv) file.
- ExcelWriter*** Class for writing DataFrame objects into excel sheets.
- read\_excel*** Read an Excel file into a pandas DataFrame.
- read\_csv*** Read a comma-separated values (csv) file into DataFrame.

**Notes**

For compatibility with `to_csv()`, `to_excel` serializes lists and dicts to strings before writing.

Once a workbook has been saved it is not possible write further data without rewriting the whole workbook.

## Examples

Create, write to and save a workbook:

```
>>> df1 = pd.DataFrame([[ 'a', 'b'], [ 'c', 'd']],
...                     index=[ 'row 1', 'row 2'],
...                     columns=[ 'col 1', 'col 2'])
>>> df1.to_excel("output.xlsx")
```

To specify the sheet name:

```
>>> df1.to_excel("output.xlsx",
...              sheet_name='Sheet_name_1')
```

If you wish to write to more than one sheet in the workbook, it is necessary to specify an `ExcelWriter` object:

```
>>> df2 = df1.copy()
>>> with pd.ExcelWriter('output.xlsx') as writer:
...     df1.to_excel(writer, sheet_name='Sheet_name_1')
...     df2.to_excel(writer, sheet_name='Sheet_name_2')
```

`ExcelWriter` can also be used to append to an existing Excel file:

```
>>> with pd.ExcelWriter('output.xlsx',
...                     mode='a') as writer:
...     df.to_excel(writer, sheet_name='Sheet_name_3')
```

To set the library that is used to write the Excel file, you can pass the `engine` keyword (the default engine is automatically chosen depending on the file extension):

```
>>> df1.to_excel('output1.xlsx', engine='xlsxwriter')
```

## pandas.DataFrame.to\_feather

`DataFrame.to_feather(self, path) → None`  
Write out the binary feather-format for DataFrames.

### Parameters

**path** [str] String file path.

## pandas.DataFrame.to\_gbq

`DataFrame.to_gbq(self, destination_table, project_id=None, chunksize=None, reauth=False, if_exists='fail', auth_local_webserver=False, table_schema=None, location=None, progress_bar=True, credentials=None) → None`  
Write a DataFrame to a Google BigQuery table.

This function requires the `pandas-gbq` package.

See the [How to authenticate with Google BigQuery](#) guide for authentication instructions.

### Parameters

**destination\_table** [str] Name of table to be written, in the form `dataset.tablename`.

**project\_id** [str, optional] Google BigQuery Account project ID. Optional when available from the environment.

**chunksize** [int, optional] Number of rows to be inserted in each chunk from the dataframe. Set to `None` to load the whole dataframe at once.

**reauth** [bool, default False] Force Google BigQuery to re-authenticate the user. This is useful if multiple accounts are used.

**if\_exists** [str, default 'fail'] Behavior when the destination table exists. Value can be one of:

'fail' If table exists raise `pandas_gbq.gbq.TableCreationError`.

'replace' If table exists, drop it, recreate it, and insert data.

'append' If table exists, insert data. Create if does not exist.

**auth\_local\_webserver** [bool, default False] Use the [local webserver flow](#) instead of the [console flow](#) when getting user credentials.

*New in version 0.2.0 of pandas-gbq.*

**table\_schema** [list of dicts, optional] List of BigQuery table fields to which according DataFrame columns conform to, e.g. `[{'name': 'col1', 'type': 'STRING'}, ...]`. If schema is not provided, it will be generated according to dtypes of DataFrame columns. See BigQuery API documentation on available names of a field.

*New in version 0.3.1 of pandas-gbq.*

**location** [str, optional] Location where the load job should run. See the [BigQuery locations documentation](#) for a list of available locations. The location must match that of the target dataset.

*New in version 0.5.0 of pandas-gbq.*

**progress\_bar** [bool, default True] Use the library `tqdm` to show the progress bar for the upload, chunk by chunk.

*New in version 0.5.0 of pandas-gbq.*

**credentials** [`google.auth.credentials.Credentials`, optional] Credentials for accessing Google APIs. Use this parameter to override default credentials, such as to use Compute Engine `google.auth.compute_engine.Credentials` or Service Account `google.oauth2.service_account.Credentials` directly.

*New in version 0.8.0 of pandas-gbq.*

New in version 0.24.0.

**See also:**

[pandas\\_gbq.to\\_gbq](#) This function in the pandas-gbq library.

[read\\_gbq](#) Read a DataFrame from Google BigQuery.

**pandas.DataFrame.to\_hdf**

```
DataFrame.to_hdf (self, path_or_buf, key: str, mode: str = 'a', complevel: Union[int, NoneType] =
None, complib: Union[str, NoneType] = None, append: bool = False, format:
Union[str, NoneType] = None, index: bool = True, min_itemsize: Union[int,
Dict[str, int], NoneType] = None, nan_rep=None, dropna: Union[bool, None-
Type] = None, data_columns: Union[List[str], NoneType] = None, errors: str
= 'strict', encoding: str = 'UTF-8') → None
```

Write the contained data to an HDF5 file using HDFStore.

Hierarchical Data Format (HDF) is self-describing, allowing an application to interpret the structure and contents of a file with no outside information. One HDF file can hold a mix of related objects which can be accessed as a group or as individual objects.

In order to add another DataFrame or Series to an existing HDF file please use append mode and a different a key.

For more information see the *user guide*.

**Parameters**

**path\_or\_buf** [str or pandas.HDFStore] File path or HDFStore object.

**key** [str] Identifier for the group in the store.

**mode** [{ 'a', 'w', 'r+' }, default 'a'] Mode to open file:

- 'w': write, a new file is created (an existing file with the same name would be deleted).
- 'a': append, an existing file is opened for reading and writing, and if the file does not exist it is created.
- 'r+': similar to 'a', but the file must already exist.

**complevel** [{0-9}, optional] Specifies a compression level for data. A value of 0 disables compression.

**complib** [{ 'zlib', 'lzo', 'bzip2', 'blosc' }, default 'zlib'] Specifies the compression library to be used. As of v0.20.2 these additional compressors for Blosc are supported (default if no compressor specified: 'blosc:blosclz'): { 'blosc:blosclz', 'blosc:lz4', 'blosc:lz4hc', 'blosc:snappy', 'blosc:zlib', 'blosc:zstd' }. Specifying a compression library which is not available issues a ValueError.

**append** [bool, default False] For Table formats, append the input data to the existing.

**format** [{ 'fixed', 'table', None }, default 'fixed'] Possible values:

- 'fixed': Fixed format. Fast writing/reading. Not-appendable, nor searchable.
- 'table': Table format. Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data.
- If None, `pd.get_option('io.hdf.default_format')` is checked, followed by fallback to "fixed"

**errors** [str, default 'strict'] Specifies how encoding and decoding errors are to be handled. See the errors argument for `open()` for a full list of options.

**encoding** [str, default "UTF-8"]

**min\_itemsize** [dict or int, optional] Map column names to minimum string sizes for columns.

**nan\_rep** [Any, optional] How to represent null values as str. Not allowed with `append=True`.

**data\_columns** [list of columns or True, optional] List of columns to create as indexed data columns for on-disk queries, or True to use all columns. By default only the axes of the object are indexed. See *Query via data columns*. Applicable only to `format='table'`.

See also:

**DataFrame.read\_hdf** Read from HDF file.

**DataFrame.to\_parquet** Write a DataFrame to the binary parquet format.

**DataFrame.to\_sql** Write to a sql table.

**DataFrame.to\_feather** Write out feather-format for DataFrames.

**DataFrame.to\_csv** Write out to a csv file.

## Examples

```
>>> df = pd.DataFrame({'A': [1, 2, 3], 'B': [4, 5, 6]},
...                    index=['a', 'b', 'c'])
>>> df.to_hdf('data.h5', key='df', mode='w')
```

We can add another object to the same file:

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s.to_hdf('data.h5', key='s')
```

Reading from HDF file:

```
>>> pd.read_hdf('data.h5', 'df')
A  B
a  1  4
b  2  5
c  3  6
>>> pd.read_hdf('data.h5', 's')
0    1
1    2
2    3
3    4
dtype: int64
```

Deleting file with data:

```
>>> import os
>>> os.remove('data.h5')
```

**pandas.DataFrame.to\_html**

`DataFrame.to_html` (*self*, *buf=None*, *columns=None*, *col\_space=None*, *header=True*, *index=True*, *na\_rep='NaN'*, *formatters=None*, *float\_format=None*, *sparsify=None*, *index\_names=True*, *justify=None*, *max\_rows=None*, *max\_cols=None*, *show\_dimensions=False*, *decimal='.'*, *bold\_rows=True*, *classes=None*, *escape=True*, *notebook=False*, *border=None*, *table\_id=None*, *render\_links=False*, *encoding=None*)

Render a DataFrame as an HTML table.

**Parameters**

**buf** [str, Path or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.

**columns** [sequence, optional, default None] The subset of columns to write. Writes all columns by default.

**col\_space** [str or int, optional] The minimum width of each column in CSS length units. An int is assumed to be px units.

New in version 0.25.0: Ability to use str.

**header** [bool, optional] Whether to print column labels, default True.

**index** [bool, optional, default True] Whether to print index (row) labels.

**na\_rep** [str, optional, default 'NaN'] String representation of NAN to use.

**formatters** [list, tuple or dict of one-param. functions, optional] Formatter functions to apply to columns' elements by position or name. The result of each function must be a unicode string. List/tuple must be of length equal to the number of columns.

**float\_format** [one-parameter function, optional, default None] Formatter function to apply to columns' elements if they are floats. The result of this function must be a unicode string.

**sparsify** [bool, optional, default True] Set to False for a DataFrame with a hierarchical index to print every multiindex key at each row.

**index\_names** [bool, optional, default True] Prints the names of the indexes.

**justify** [str, default None] How to justify the column labels. If None uses the option from the print configuration (controlled by `set_option`), 'right' out of the box. Valid values are

- left
- right
- center
- justify
- justify-all
- start
- end
- inherit
- match-parent
- initial

- `unset`.

**max\_rows** [int, optional] Maximum number of rows to display in the console.

**min\_rows** [int, optional] The number of rows to display in the console in a truncated repr (when number of rows is above *max\_rows*).

**max\_cols** [int, optional] Maximum number of columns to display in the console.

**show\_dimensions** [bool, default False] Display DataFrame dimensions (number of rows by number of columns).

**decimal** [str, default ‘.’] Character recognized as decimal separator, e.g. ‘,’ in Europe.

**bold\_rows** [bool, default True] Make the row labels bold in the output.

**classes** [str or list or tuple, default None] CSS class(es) to apply to the resulting html table.

**escape** [bool, default True] Convert the characters `<`, `>`, and `&` to HTML-safe sequences.

**notebook** [{True, False}, default False] Whether the generated HTML is for IPython Notebook.

**border** [int] A `border=border` attribute is included in the opening `<table>` tag. Default `pd.options.display.html.border`.

**encoding** [str, default “utf-8”] Set character encoding.

New in version 1.0.

**table\_id** [str, optional] A css id is included in the opening `<table>` tag if specified.

New in version 0.23.0.

**render\_links** [bool, default False] Convert URLs to HTML links.

New in version 0.24.0.

### Returns

**str or None** If `buf` is `None`, returns the result as a string. Otherwise returns `None`.

### See also:

**`to_string`** Convert DataFrame to a string.

## pandas.DataFrame.to\_json

```
DataFrame.to_json(self, path_or_buf: Union[str, pathlib.Path, IO[~AnyStr], NoneType] = None, orient: Union[str, NoneType] = None, date_format: Union[str, NoneType] = None, double_precision: int = 10, force_ascii: bool = True, date_unit: str = 'ms', default_handler: Union[Callable[[Any], Union[str, int, float, bool, List, Dict]], NoneType] = None, lines: bool = False, compression: Union[str, NoneType] = 'infer', index: bool = True, indent: Union[int, NoneType] = None) → Union[str, NoneType]
```

Convert the object to a JSON string.

Note NaN’s and `None` will be converted to null and datetime objects will be converted to UNIX timestamps.

### Parameters

**path\_or\_buf** [str or file handle, optional] File path or object. If not specified, the result is returned as a string.

**orient** [str] Indication of expected JSON string format.

- Series:
  - default is 'index'
  - allowed values are: {'split', 'records', 'index', 'table'}.
- DataFrame:
  - default is 'columns'
  - allowed values are: {'split', 'records', 'index', 'columns', 'values', 'table'}.
- The format of the JSON string:
  - 'split' : dict like {'index' -> [index], 'columns' -> [columns], 'data' -> [values]}
  - 'records' : list like [{column -> value}, ... , {column -> value}]
  - 'index' : dict like {index -> {column -> value}}
  - 'columns' : dict like {column -> {index -> value}}
  - 'values' : just the values array
  - 'table' : dict like {'schema': {schema}, 'data': {data}}

Describing the data, where data component is like orient='records'.

Changed in version 0.20.0.

**date\_format** [{None, 'epoch', 'iso'}] Type of date conversion. 'epoch' = epoch milliseconds, 'iso' = ISO8601. The default depends on the *orient*. For orient='table', the default is 'iso'. For all other orients, the default is 'epoch'.

**double\_precision** [int, default 10] The number of decimal places to use when encoding floating point values.

**force\_ascii** [bool, default True] Force encoded string to be ASCII.

**date\_unit** [str, default 'ms' (milliseconds)] The time unit to encode to, governs timestamp and ISO8601 precision. One of 's', 'ms', 'us', 'ns' for second, millisecond, microsecond, and nanosecond respectively.

**default\_handler** [callable, default None] Handler to call if object cannot otherwise be converted to a suitable format for JSON. Should receive a single argument which is the object to convert and return a serialisable object.

**lines** [bool, default False] If 'orient' is 'records' write out line delimited json format. Will throw ValueError if incorrect 'orient' since others are not list like.

**compression** [{'infer', 'gzip', 'bz2', 'zip', 'xz', None}] A string representing the compression to use in the output file, only used when the first argument is a filename. By default, the compression is inferred from the filename.

New in version 0.21.0.

Changed in version 0.24.0: 'infer' option added and set to default

**index** [bool, default True] Whether to include the index values in the JSON string. Not including the index (`index=False`) is only supported when `orient` is 'split' or 'table'.

New in version 0.23.0.

**indent** [int, optional] Length of whitespace used to indent each record.

New in version 1.0.0.

### Returns

**None or str** If `path_or_buf` is None, returns the resulting json format as a string. Otherwise returns None.

**See also:**

*`read_json`*

### Notes

The behavior of `indent=0` varies from the `stdlib`, which does not indent the output but does insert newlines. Currently, `indent=0` and the default `indent=None` are equivalent in pandas, though this may change in a future release.

### Examples

```
>>> df = pd.DataFrame([[ 'a', 'b'], [ 'c', 'd']],
...                   index=[ 'row 1', 'row 2'],
...                   columns=[ 'col 1', 'col 2'])
>>> df.to_json(orient='split')
'{"columns":["col 1","col 2"],
  "index":["row 1","row 2"],
  "data":[["a","b"],["c","d"]}]'
```

Encoding/decoding a Dataframe using 'records' formatted JSON. Note that index labels are not preserved with this encoding.

```
>>> df.to_json(orient='records')
'[{"col 1":"a","col 2":"b"}, {"col 1":"c","col 2":"d"}]'
```

Encoding/decoding a Dataframe using 'index' formatted JSON:

```
>>> df.to_json(orient='index')
'{"row 1":{"col 1":"a","col 2":"b"},"row 2":{"col 1":"c","col 2":"d"}}'
```

Encoding/decoding a Dataframe using 'columns' formatted JSON:

```
>>> df.to_json(orient='columns')
'{"col 1":{"row 1":"a","row 2":"c"},"col 2":{"row 1":"b","row 2":"d"}}'
```

Encoding/decoding a Dataframe using 'values' formatted JSON:

```
>>> df.to_json(orient='values')
'[["a","b"],["c","d"]]
```

Encoding with Table Schema

```
>>> df.to_json(orient='table')
'{"schema": {"fields": [{"name": "index", "type": "string"},
                        {"name": "col 1", "type": "string"},
                        {"name": "col 2", "type": "string"}],
             "primaryKey": "index",
             "pandas_version": "0.20.0"},
 "data": [{"index": "row 1", "col 1": "a", "col 2": "b"},
           {"index": "row 2", "col 1": "c", "col 2": "d"}]}'
```

## pandas.DataFrame.to\_latex

`DataFrame.to_latex`(*self*, *buf=None*, *columns=None*, *col\_space=None*, *header=True*, *index=True*, *na\_rep='NaN'*, *formatters=None*, *float\_format=None*, *sparsify=None*, *index\_names=True*, *bold\_rows=False*, *column\_format=None*, *longtable=None*, *escape=None*, *encoding=None*, *decimal='.'*, *multicolumn=None*, *multicolumn\_format=None*, *multirow=None*, *caption=None*, *label=None*)

Render object to a LaTeX tabular, longtable, or nested table/tabular.

Requires `\usepackage{booktabs}`. The output can be copy/pasted into a main LaTeX document or read from an external file with `\input{table.tex}`.

Changed in version 0.20.2: Added to Series.

Changed in version 1.0.0: Added caption and label arguments.

### Parameters

**buf** [str, Path or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.

**columns** [list of label, optional] The subset of columns to write. Writes all columns by default.

**col\_space** [int, optional] The minimum width of each column.

**header** [bool or list of str, default True] Write out the column names. If a list of strings is given, it is assumed to be aliases for the column names.

**index** [bool, default True] Write row names (index).

**na\_rep** [str, default 'NaN'] Missing data representation.

**formatters** [list of functions or dict of {str: function}, optional] Formatter functions to apply to columns' elements by position or name. The result of each function must be a unicode string. List must be of length equal to the number of columns.

**float\_format** [one-parameter function or str, optional, default None] Formatter for floating point numbers. For example `float_format="% .2f"` and `float_format="{ :0.2f} ".format` will both result in 0.1234 being formatted as 0.12.

**sparsify** [bool, optional] Set to False for a DataFrame with a hierarchical index to print every multiindex key at each row. By default, the value will be read from the config module.

**index\_names** [bool, default True] Prints the names of the indexes.

**bold\_rows** [bool, default False] Make the row labels bold in the output.

**column\_format** [str, optional] The columns format as specified in [LaTeX table format](#) e.g. 'rcl' for 3 columns. By default, 'l' will be used for all columns except columns of numbers, which default to 'r'.

**longtable** [bool, optional] By default, the value will be read from the pandas config module. Use a longtable environment instead of tabular. Requires adding a `usepackage{longtable}` to your LaTeX preamble.

**escape** [bool, optional] By default, the value will be read from the pandas config module. When set to False prevents from escaping latex special characters in column names.

**encoding** [str, optional] A string representing the encoding to use in the output file, defaults to 'utf-8'.

**decimal** [str, default '.'] Character recognized as decimal separator, e.g. ',' in Europe.

**multicolumn** [bool, default True] Use multicolumn to enhance MultiIndex columns. The default will be read from the config module.

**multicolumn\_format** [str, default 'l'] The alignment for multicolumns, similar to `column_format` The default will be read from the config module.

**multirow** [bool, default False] Use multirow to enhance MultiIndex rows. Requires adding a `usepackage{multirow}` to your LaTeX preamble. Will print centered labels (instead of top-aligned) across the contained rows, separating groups via clines. The default will be read from the pandas config module.

**caption** [str, optional] The LaTeX caption to be placed inside `\caption{}` in the output.

New in version 1.0.0.

**label** [str, optional] The LaTeX label to be placed inside `\label{}` in the output. This is used with `\ref{}` in the main `.tex` file.

New in version 1.0.0.

### Returns

**str or None** If buf is None, returns the result as a string. Otherwise returns None.

### See also:

**DataFrame.to\_string** Render a DataFrame to a console-friendly tabular output.

**DataFrame.to\_html** Render a DataFrame as an HTML table.

### Examples

```
>>> df = pd.DataFrame({'name': ['Raphael', 'Donatello'],
...                    'mask': ['red', 'purple'],
...                    'weapon': ['sai', 'bo staff']})
>>> print(df.to_latex(index=False))
\begin{tabular}{lll}
\toprule
name & mask & weapon \\
\midrule
Raphael & red & sai \\
Donatello & purple & bo staff \\
\bottomrule
\end{tabular}
```

(continues on next page)

(continued from previous page)

```
\bottomrule
\end{tabular}
```

### pandas.DataFrame.to\_markdown

`DataFrame.to_markdown` (*self*, *buf*: Union[IO[str], NoneType] = None, *mode*: Union[str, NoneType] = None, *\*\*kwargs*) → Union[str, NoneType]

Print DataFrame in Markdown-friendly format.

New in version 1.0.0.

#### Parameters

**buf** [writable buffer, defaults to sys.stdout] Where to send the output. By default, the output is printed to sys.stdout. Pass a writable buffer if you need to further process the output.

**mode** [str, optional] Mode in which file is opened.

**\*\*kwargs** These parameters will be passed to *tabulate*.

#### Returns

**str** DataFrame in Markdown-friendly format.

### Examples

```
>>> df = pd.DataFrame(
...     data={"animal_1": ["elk", "pig"], "animal_2": ["dog", "quetzal"]}
... )
>>> print(df.to_markdown())
|   | animal_1 | animal_2 |
|---:|:-----|:-----|
| 0 | elk      | dog      |
| 1 | pig      | quetzal  |
```

### pandas.DataFrame.to\_numpy

`DataFrame.to_numpy` (*self*, *dtype*=None, *copy*=False) → numpy.ndarray

Convert the DataFrame to a NumPy array.

New in version 0.24.0.

By default, the dtype of the returned array will be the common NumPy dtype of all types in the DataFrame. For example, if the dtypes are `float16` and `float32`, the results dtype will be `float32`. This may require copying data and coercing values, which may be expensive.

#### Parameters

**dtype** [str or numpy.dtype, optional] The dtype to pass to `numpy.asarray()`.

**copy** [bool, default False] Whether to ensure that the returned value is a not a view on another array. Note that `copy=False` does not *ensure* that `to_numpy()` is no-copy. Rather, `copy=True` ensure that a copy is made, even if not strictly necessary.

## Returns

`numpy.ndarray`

See also:

**`Series.to_numpy`** Similar method for Series.

## Examples

```
>>> pd.DataFrame({"A": [1, 2], "B": [3, 4]}).to_numpy()
array([[1, 3],
       [2, 4]])
```

With heterogeneous data, the lowest common type will have to be used.

```
>>> df = pd.DataFrame({"A": [1, 2], "B": [3.0, 4.5]})
>>> df.to_numpy()
array([[1. , 3. ],
       [2. , 4.5]])
```

For a mix of numeric and non-numeric types, the output array will have object dtype.

```
>>> df['C'] = pd.date_range('2000', periods=2)
>>> df.to_numpy()
array([[1, 3.0, Timestamp('2000-01-01 00:00:00')],
       [2, 4.5, Timestamp('2000-01-02 00:00:00')]], dtype=object)
```

## `pandas.DataFrame.to_parquet`

`DataFrame.to_parquet` (*self*, *path*, *engine*='auto', *compression*='snappy', *index*=None, *partition\_cols*=None, *\*\*kwargs*) → None

Write a DataFrame to the binary parquet format.

New in version 0.21.0.

This function writes the dataframe as a [parquet file](#). You can choose different parquet backends, and have the option of compression. See *the user guide* for more details.

### Parameters

**path** [str] File path or Root Directory path. Will be used as Root Directory path while writing a partitioned dataset.

Changed in version 1.0.0.

Previously this was “fname”

**engine** [{‘auto’, ‘pyarrow’, ‘fastparquet’}, default ‘auto’] Parquet library to use. If ‘auto’, then the option `io.parquet.engine` is used. The default `io.parquet.engine` behavior is to try ‘pyarrow’, falling back to ‘fastparquet’ if ‘pyarrow’ is unavailable.

**compression** [{‘snappy’, ‘gzip’, ‘brotli’, None}, default ‘snappy’] Name of the compression to use. Use None for no compression.

**index** [bool, default None] If True, include the dataframe’s index(es) in the file output. If False, they will not be written to the file. If None, similar to True the

dataframe's index(es) will be saved. However, instead of being saved as values, the RangeIndex will be stored as a range in the metadata so it doesn't require much space and is faster. Other indexes will be included as columns in the file output.

New in version 0.24.0.

**partition\_cols** [list, optional, default None] Column names by which to partition the dataset. Columns are partitioned in the order they are given.

New in version 0.24.0.

**\*\*kwargs** Additional arguments passed to the parquet library. See *pandas io* for more details.

**See also:**

**`read_parquet`** Read a parquet file.

**`DataFrame.to_csv`** Write a csv file.

**`DataFrame.to_sql`** Write to a sql table.

**`DataFrame.to_hdf`** Write to hdf.

## Notes

This function requires either the `fastparquet` or `pyarrow` library.

## Examples

```
>>> df = pd.DataFrame(data={'col1': [1, 2], 'col2': [3, 4]})
>>> df.to_parquet('df.parquet.gzip',
...              compression='gzip')
>>> pd.read_parquet('df.parquet.gzip')
```

	col1	col2
0	1	3
1	2	4

## pandas.DataFrame.to\_period

`DataFrame.to_period(self, freq=None, axis=0, copy=True)` → 'DataFrame'

Convert DataFrame from DatetimeIndex to PeriodIndex.

Convert DataFrame from DatetimeIndex to PeriodIndex with desired frequency (inferred from index if not passed).

### Parameters

**freq** [str, default] Frequency of the PeriodIndex.

**axis** [{0 or 'index', 1 or 'columns'}, default 0] The axis to convert (the index by default).

**copy** [bool, default True] If False then underlying input data is not copied.

### Returns

**TimeSeries with PeriodIndex**

**pandas.DataFrame.to\_pickle**

`DataFrame.to_pickle` (*self*, *path*, *compression*: `Union[str, NoneType]` = 'infer', *protocol*: `int` = 4) → None  
 Pickle (serialize) object to file.

**Parameters**

**path** [str] File path where the pickled object will be stored.

**compression** [{ 'infer', 'gzip', 'bz2', 'zip', 'xz', None }, default 'infer'] A string representing the compression to use in the output file. By default, infers from the file extension in specified path.

**protocol** [int] Int which indicates which protocol should be used by the pickler, default HIGHEST\_PROTOCOL (see [?] paragraph 12.1.2). The possible values are 0, 1, 2, 3, 4. A negative value for the protocol parameter is equivalent to setting its value to HIGHEST\_PROTOCOL.

New in version 0.21.0..

**See also:**

**`read_pickle`** Load pickled pandas object (or any object) from file.

**`DataFrame.to_hdf`** Write DataFrame to an HDF5 file.

**`DataFrame.to_sql`** Write DataFrame to a SQL database.

**`DataFrame.to_parquet`** Write a DataFrame to the binary parquet format.

**Examples**

```
>>> original_df = pd.DataFrame({"foo": range(5), "bar": range(5, 10)})
>>> original_df
   foo  bar
0    0    5
1    1    6
2    2    7
3    3    8
4    4    9
>>> original_df.to_pickle("./dummy.pkl")
```

```
>>> unpickled_df = pd.read_pickle("./dummy.pkl")
>>> unpickled_df
   foo  bar
0    0    5
1    1    6
2    2    7
3    3    8
4    4    9
```

```
>>> import os
>>> os.remove("./dummy.pkl")
```

## pandas.DataFrame.to\_records

`DataFrame.to_records` (*self*, *index=True*, *column\_dtypes=None*, *index\_dtypes=None*) → `numpy.recarray`  
Convert DataFrame to a NumPy record array.

Index will be included as the first field of the record array if requested.

### Parameters

**index** [bool, default True] Include index in resulting record array, stored in ‘index’ field or using the index label, if set.

**column\_dtypes** [str, type, dict, default None] New in version 0.24.0.

If a string or type, the data type to store all columns. If a dictionary, a mapping of column names and indices (zero-indexed) to specific data types.

**index\_dtypes** [str, type, dict, default None] New in version 0.24.0.

If a string or type, the data type to store all index levels. If a dictionary, a mapping of index level names and indices (zero-indexed) to specific data types.

This mapping is applied only if *index=True*.

### Returns

**numpy.recarray** NumPy ndarray with the DataFrame labels as fields and each row of the DataFrame as entries.

### See also:

**DataFrame.from\_records** Convert structured or record ndarray to DataFrame.

**numpy.recarray** An ndarray that allows field access using attributes, analogous to typed columns in a spreadsheet.

### Examples

```
>>> df = pd.DataFrame({'A': [1, 2], 'B': [0.5, 0.75]},
...                   index=['a', 'b'])
>>> df
   A    B
a  1  0.5
b  2  0.75
>>> df.to_records()
rec.array([( 'a', 1, 0.5 ), ( 'b', 2, 0.75)],
          dtype=[('index', 'O'), ('A', '<i8'), ('B', '<f8')])
```

If the DataFrame index has no label then the recarray field name is set to ‘index’. If the index has a label then this is used as the field name:

```
>>> df.index = df.index.rename("I")
>>> df.to_records()
rec.array([( 'a', 1, 0.5 ), ( 'b', 2, 0.75)],
          dtype=[('I', 'O'), ('A', '<i8'), ('B', '<f8')])
```

The index can be excluded from the record array:

```
>>> df.to_records(index=False)
rec.array([(1, 0.5 ), (2, 0.75)],
          dtype=[('A', '<i8'), ('B', '<f8')])
```

Data types can be specified for the columns:

```
>>> df.to_records(column_dtypes={"A": "int32"})
rec.array([('a', 1, 0.5 ), ('b', 2, 0.75)],
          dtype=[('I', 'O'), ('A', '<i4'), ('B', '<f8')])
```

As well as for the index:

```
>>> df.to_records(index_dtypes="<S2")
rec.array([(b'a', 1, 0.5 ), (b'b', 2, 0.75)],
          dtype=[('I', 'S2'), ('A', '<i8'), ('B', '<f8')])
```

```
>>> index_dtypes = f"<S{df.index.str.len().max()}"
>>> df.to_records(index_dtypes=index_dtypes)
rec.array([(b'a', 1, 0.5 ), (b'b', 2, 0.75)],
          dtype=[('I', 'S1'), ('A', '<i8'), ('B', '<f8')])
```

## pandas.DataFrame.to\_sql

`DataFrame.to_sql` (*self*, *name*: str, *con*, *schema*=None, *if\_exists*: str = 'fail', *index*: bool = True, *index\_label*=None, *chunks*=None, *dtype*=None, *method*=None) → None

Write records stored in a DataFrame to a SQL database.

Databases supported by SQLAlchemy [?] are supported. Tables can be newly created, appended to, or overwritten.

### Parameters

**name** [str] Name of SQL table.

**con** [sqlalchemy.engine.Engine or sqlite3.Connection] Using SQLAlchemy makes it possible to use any DB supported by that library. Legacy support is provided for `sqlite3.Connection` objects. The user is responsible for engine disposal and connection closure for the SQLAlchemy connectable See [here](#)

**schema** [str, optional] Specify the schema (if database flavor supports this). If None, use default schema.

**if\_exists** [{ 'fail', 'replace', 'append' }, default 'fail'] How to behave if the table already exists.

- fail: Raise a `ValueError`.
- replace: Drop the table before inserting new values.
- append: Insert new values to the existing table.

**index** [bool, default True] Write DataFrame index as a column. Uses *index\_label* as the column name in the table.

**index\_label** [str or sequence, default None] Column label for index column(s). If None is given (default) and *index* is True, then the index names are used. A sequence should be given if the DataFrame uses `MultiIndex`.

**chunksize** [int, optional] Specify the number of rows in each batch to be written at a time. By default, all rows will be written at once.

**dtype** [dict or scalar, optional] Specifying the datatype for columns. If a dictionary is used, the keys should be the column names and the values should be the SQLAlchemy types or strings for the sqlite3 legacy mode. If a scalar is provided, it will be applied to all columns.

**method** [{None, 'multi', callable}, optional] Controls the SQL insertion clause used:

- None : Uses standard SQL INSERT clause (one per row).
- 'multi': Pass multiple values in a single INSERT clause.
- callable with signature (pd\_table, conn, keys, data\_iter).

Details and a sample callable implementation can be found in the section *insert method*.

New in version 0.24.0.

### Raises

**ValueError** When the table already exists and *if\_exists* is 'fail' (the default).

### See also:

**read\_sql** Read a DataFrame from a table.

### Notes

Timezone aware datetime columns will be written as `Timestamp with timezone` type with SQLAlchemy if supported by the database. Otherwise, the datetimes will be stored as timezone unaware timestamps local to the original timezone.

New in version 0.24.0.

### References

[?], [?]

### Examples

Create an in-memory SQLite database.

```
>>> from sqlalchemy import create_engine
>>> engine = create_engine('sqlite://', echo=False)
```

Create a table from scratch with 3 rows.

```
>>> df = pd.DataFrame({'name' : ['User 1', 'User 2', 'User 3']})
>>> df
   name
0  User 1
1  User 2
2  User 3
```

```
>>> df.to_sql('users', con=engine)
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 1'), (1, 'User 2'), (2, 'User 3')]
```

```
>>> df1 = pd.DataFrame({'name' : ['User 4', 'User 5']})
>>> df1.to_sql('users', con=engine, if_exists='append')
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 1'), (1, 'User 2'), (2, 'User 3'),
 (0, 'User 4'), (1, 'User 5')]
```

Overwrite the table with just df1.

```
>>> df1.to_sql('users', con=engine, if_exists='replace',
...          index_label='id')
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 4'), (1, 'User 5')]
```

Specify the dtype (especially useful for integers with missing values). Notice that while pandas is forced to store the data as floating point, the database supports nullable integers. When fetching the data with Python, we get back integer scalars.

```
>>> df = pd.DataFrame({"A": [1, None, 2]})
>>> df
   A
0  1.0
1  NaN
2  2.0
```

```
>>> from sqlalchemy.types import Integer
>>> df.to_sql('integers', con=engine, index=False,
...         dtype={"A": Integer()})
```

```
>>> engine.execute("SELECT * FROM integers").fetchall()
[(1,), (None,), (2,)]
```

## pandas.DataFrame.to\_stata

`DataFrame.to_stata`(*self*, *path*, *convert\_dates=None*, *write\_index=True*, *byteorder=None*, *time\_stamp=None*, *data\_label=None*, *variable\_labels=None*, *version=114*, *convert\_str1=None*)

Export DataFrame object to Stata dta format.

Writes the DataFrame to a Stata dataset file. “dta” files contain a Stata dataset.

### Parameters

**path** [str, buffer or path object] String, path object (pathlib.Path or py\_path.local.LocalPath) or object implementing a binary write() function. If using a buffer then the buffer will not be automatically closed after the file data has been written.

Changed in version 1.0.0.

Previously this was “fname”

**convert\_dates** [dict] Dictionary mapping columns containing datetime types to stata internal format to use when writing the dates. Options are ‘tc’, ‘td’, ‘tm’, ‘tw’, ‘th’,

'tq', 'ty'. Column can be either an integer or a name. Datetime columns that do not have a conversion type specified will be converted to 'tc'. Raises `NotImplementedError` if a datetime column has timezone information.

**write\_index** [bool] Write the index to Stata dataset.

**byteorder** [str] Can be ">", "<", "little", or "big". default is *sys.byteorder*.

**time\_stamp** [datetime] A datetime to use as file creation date. Default is the current time.

**data\_label** [str, optional] A label for the data set. Must be 80 characters or smaller.

**variable\_labels** [dict] Dictionary containing columns as keys and variable labels as values. Each label must be 80 characters or smaller.

**version** [{114, 117, 118, 119, None}, default 114] Version to use in the output dta file. Set to None to let pandas decide between 118 or 119 formats depending on the number of columns in the frame. Version 114 can be read by Stata 10 and later. Version 117 can be read by Stata 13 or later. Version 118 is supported in Stata 14 and later. Version 119 is supported in Stata 15 and later. Version 114 limits string variables to 244 characters or fewer while versions 117 and later allow strings with lengths up to 2,000,000 characters. Versions 118 and 119 support Unicode characters, and version 119 supports more than 32,767 variables.

New in version 0.23.0.

Changed in version 1.0.0: Added support for formats 118 and 119.

**convert\_strl** [list, optional] List of column names to convert to string columns to Stata StrL format. Only available if version is 117. Storing strings in the StrL format can produce smaller dta files if strings have more than 8 characters and values are repeated.

New in version 0.23.0.

#### Raises

##### **NotImplementedError**

- If datetimes contain timezone information
- Column dtype is not representable in Stata

##### **ValueError**

- Columns listed in `convert_dates` are neither `datetime64[ns]` or `datetime.datetime`
- Column listed in `convert_dates` is not in `DataFrame`
- Categorical label contains more than 32,000 characters

#### See also:

**read\_stata** Import Stata data files.

**io.stata.StataWriter** Low-level writer for Stata data files.

**io.stata.StataWriter117** Low-level writer for version 117 files.

## Examples

```
>>> df = pd.DataFrame({'animal': ['falcon', 'parrot', 'falcon',
...                               'parrot'],
...                   'speed': [350, 18, 361, 15]})
>>> df.to_stata('animals.dta')
```

## pandas.DataFrame.to\_string

`DataFrame.to_string` (*self*, *buf*: Union[str, pathlib.Path, IO[str], NoneType] = None, *columns*: Union[Sequence[str], NoneType] = None, *col\_space*: Union[int, NoneType] = None, *header*: Union[bool, Sequence[str]] = True, *index*: bool = True, *na\_rep*: str = 'NaN', *formatters*: Union[List[Callable], Tuple[Callable, ...], Mapping[Union[str, int], Callable], NoneType] = None, *float\_format*: Union[str, Callable, ForwardRef('EngFormatter'), NoneType] = None, *sparsify*: Union[bool, NoneType] = None, *index\_names*: bool = True, *justify*: Union[str, NoneType] = None, *max\_rows*: Union[int, NoneType] = None, *min\_rows*: Union[int, NoneType] = None, *max\_cols*: Union[int, NoneType] = None, *show\_dimensions*: bool = False, *decimal*: str = '.', *line\_width*: Union[int, NoneType] = None, *max\_colwidth*: Union[int, NoneType] = None, *encoding*: Union[str, NoneType] = None) → Union[str, NoneType]

Render a DataFrame to a console-friendly tabular output.

### Parameters

**buf** [str, Path or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.

**columns** [sequence, optional, default None] The subset of columns to write. Writes all columns by default.

**col\_space** [int, optional] The minimum width of each column.

**header** [bool or sequence, optional] Write out the column names. If a list of strings is given, it is assumed to be aliases for the column names.

**index** [bool, optional, default True] Whether to print index (row) labels.

**na\_rep** [str, optional, default 'NaN'] String representation of NAN to use.

**formatters** [list, tuple or dict of one-param. functions, optional] Formatter functions to apply to columns' elements by position or name. The result of each function must be a unicode string. List/tuple must be of length equal to the number of columns.

**float\_format** [one-parameter function, optional, default None] Formatter function to apply to columns' elements if they are floats. The result of this function must be a unicode string.

**sparsify** [bool, optional, default True] Set to False for a DataFrame with a hierarchical index to print every multiindex key at each row.

**index\_names** [bool, optional, default True] Prints the names of the indexes.

**justify** [str, default None] How to justify the column labels. If None uses the option from the print configuration (controlled by `set_option`), 'right' out of the box. Valid values are

- left

- right
- center
- justify
- justify-all
- start
- end
- inherit
- match-parent
- initial
- unset.

**max\_rows** [int, optional] Maximum number of rows to display in the console.

**min\_rows** [int, optional] The number of rows to display in the console in a truncated repr (when number of rows is above *max\_rows*).

**max\_cols** [int, optional] Maximum number of columns to display in the console.

**show\_dimensions** [bool, default False] Display DataFrame dimensions (number of rows by number of columns).

**decimal** [str, default '.'] Character recognized as decimal separator, e.g. ',' in Europe.

**line\_width** [int, optional] Width to wrap a line in characters.

**max\_colwidth** [int, optional] Max width to truncate each column in characters. By default, no limit.

New in version 1.0.0.

**encoding** [str, default "utf-8"] Set character encoding.

New in version 1.0.

### Returns

**str or None** If buf is None, returns the result as a string. Otherwise returns None.

### See also:

**to\_html** Convert DataFrame to HTML.

### Examples

```
>>> d = {'col1': [1, 2, 3], 'col2': [4, 5, 6]}
>>> df = pd.DataFrame(d)
>>> print(df.to_string())
  col1  col2
0     1     4
1     2     5
2     3     6
```

## pandas.DataFrame.to\_timestamp

`DataFrame.to_timestamp` (*self*, *freq=None*, *how='start'*, *axis=0*, *copy=True*) → 'DataFrame'  
 Cast to DatetimeIndex of timestamps, at *beginning* of period.

### Parameters

- freq** [str, default frequency of PeriodIndex] Desired frequency.
- how** [{'s', 'e', 'start', 'end'}] Convention for converting period to timestamp; start of period vs. end.
- axis** [{0 or 'index', 1 or 'columns'}, default 0] The axis to convert (the index by default).
- copy** [bool, default True] If False then underlying input data is not copied.

### Returns

**DataFrame with DatetimeIndex**

## pandas.DataFrame.to\_xarray

`DataFrame.to_xarray` (*self*)  
 Return an xarray object from the pandas object.

### Returns

**xarray.DataArray or xarray.Dataset** Data in the pandas structure converted to Dataset if the object is a DataFrame, or a DataArray if the object is a Series.

### See also:

**DataFrame.to\_hdf** Write DataFrame to an HDF5 file.

**DataFrame.to\_parquet** Write a DataFrame to the binary parquet format.

### Notes

See the [xarray docs](#)

### Examples

```
>>> df = pd.DataFrame([('falcon', 'bird', 389.0, 2),
...                    ('parrot', 'bird', 24.0, 2),
...                    ('lion', 'mammal', 80.5, 4),
...                    ('monkey', 'mammal', np.nan, 4)],
...                   columns=['name', 'class', 'max_speed',
...                             'num_legs'])
>>> df
```

	name	class	max_speed	num_legs
0	falcon	bird	389.0	2
1	parrot	bird	24.0	2
2	lion	mammal	80.5	4
3	monkey	mammal	NaN	4

```
>>> df.to_xarray()
<xarray.Dataset>
Dimensions:      (index: 4)
Coordinates:
  * index        (index) int64 0 1 2 3
Data variables:
  name          (index) object 'falcon' 'parrot' 'lion' 'monkey'
  class         (index) object 'bird' 'bird' 'mammal' 'mammal'
  max_speed     (index) float64 389.0 24.0 80.5 nan
  num_legs      (index) int64 2 2 4 4
```

```
>>> df['max_speed'].to_xarray()
<xarray.DataArray 'max_speed' (index: 4)>
array([389. , 24. , 80.5, nan])
Coordinates:
  * index      (index) int64 0 1 2 3
```

```
>>> dates = pd.to_datetime(['2018-01-01', '2018-01-01',
...                         '2018-01-02', '2018-01-02'])
>>> df_multiindex = pd.DataFrame({'date': dates,
...                               'animal': ['falcon', 'parrot',
...                                         'falcon', 'parrot'],
...                               'speed': [350, 18, 361, 15]})
>>> df_multiindex = df_multiindex.set_index(['date', 'animal'])
```

```
>>> df_multiindex
           speed
date animal
2018-01-01 falcon    350
             parrot    18
2018-01-02 falcon    361
             parrot    15
```

```
>>> df_multiindex.to_xarray()
<xarray.Dataset>
Dimensions:      (animal: 2, date: 2)
Coordinates:
  * date         (date) datetime64[ns] 2018-01-01 2018-01-02
  * animal      (animal) object 'falcon' 'parrot'
Data variables:
  speed        (date, animal) int64 350 18 361 15
```

## pandas.DataFrame.transform

`DataFrame.transform(self, func, axis=0, *args, **kwargs) → 'DataFrame'`

Call `func` on `self` producing a `DataFrame` with transformed values.

Produced `DataFrame` will have same axis length as `self`.

### Parameters

**func** [function, str, list or dict] Function to use for transforming the data. If a function, must either work when passed a `DataFrame` or when passed to `DataFrame.apply`.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. `[np.exp, 'sqrt']`
- dict of axis labels -> functions, function names or list of such.

**axis** `[[0 or 'index', 1 or 'columns'], default 0]` If 0 or 'index': apply function to each column. If 1 or 'columns': apply function to each row.

**\*args** Positional arguments to pass to *func*.

**\*\*kwargs** Keyword arguments to pass to *func*.

### Returns

**DataFrame** A DataFrame that must have the same length as self.

### Raises

**ValueError** [If the returned DataFrame has a different length than self.]

### See also:

**DataFrame.agg** Only perform aggregating type operations.

**DataFrame.apply** Invoke function on a DataFrame.

### Examples

```
>>> df = pd.DataFrame({'A': range(3), 'B': range(1, 4)})
>>> df
   A  B
0  0  1
1  1  2
2  2  3
>>> df.transform(lambda x: x + 1)
   A  B
0  1  2
1  2  3
2  3  4
```

Even though the resulting DataFrame must have the same length as the input DataFrame, it is possible to provide several input functions:

```
>>> s = pd.Series(range(3))
>>> s
0    0
1    1
2    2
dtype: int64
>>> s.transform([np.sqrt, np.exp])
      sqrt      exp
0  0.000000  1.000000
1  1.000000  2.718282
2  1.414214  7.389056
```

**pandas.DataFrame.transpose**

`DataFrame.transpose` (*self*, \*args, copy: bool = False) → 'DataFrame'

Transpose index and columns.

Reflect the DataFrame over its main diagonal by writing rows as columns and vice-versa. The property `T` is an accessor to the method `transpose()`.

**Parameters**

**\*args** [tuple, optional] Accepted for compatibility with NumPy.

**copy** [bool, default False] Whether to copy the data after transposing, even for DataFrames with a single dtype.

Note that a copy is always required for mixed dtype DataFrames, or for DataFrames with any extension types.

**Returns**

**DataFrame** The transposed DataFrame.

**See also:**

[numpy.transpose](#) Permute the dimensions of a given array.

**Notes**

Transposing a DataFrame with mixed dtypes will result in a homogeneous DataFrame with the *object* dtype. In such a case, a copy of the data is always made.

**Examples****Square DataFrame with homogeneous dtype**

```
>>> d1 = {'col1': [1, 2], 'col2': [3, 4]}
>>> df1 = pd.DataFrame(data=d1)
>>> df1
   col1  col2
0     1     3
1     2     4
```

```
>>> df1_transposed = df1.T # or df1.transpose()
>>> df1_transposed
      0  1
col1  1  2
col2  3  4
```

When the dtype is homogeneous in the original DataFrame, we get a transposed DataFrame with the same dtype:

```
>>> df1.dtypes
col1    int64
col2    int64
dtype: object
>>> df1_transposed.dtypes
0     int64
```

(continues on next page)

(continued from previous page)

```
1    int64
dtype: object
```

**Non-square DataFrame with mixed dtypes**

```
>>> d2 = {'name': ['Alice', 'Bob'],
...       'score': [9.5, 8],
...       'employed': [False, True],
...       'kids': [0, 0]}
>>> df2 = pd.DataFrame(data=d2)
>>> df2
   name  score  employed  kids
0  Alice   9.5     False    0
1   Bob    8.0      True    0
```

```
>>> df2_transposed = df2.T # or df2.transpose()
>>> df2_transposed
      0    1
name   Alice  Bob
score   9.5    8
employed False  True
kids     0    0
```

When the DataFrame has mixed dtypes, we get a transposed DataFrame with the *object* dtype:

```
>>> df2.dtypes
name          object
score         float64
employed         bool
kids           int64
dtype: object
>>> df2_transposed.dtypes
0    object
1    object
dtype: object
```

**pandas.DataFrame.truediv**

`DataFrame.truediv` (*self, other, axis='columns', level=None, fill\_value=None*)

Get Floating division of dataframe and other, element-wise (binary operator *truediv*).

Equivalent to `dataframe / other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *rtruediv*.

Among flexible wrappers (*add, sub, mul, div, mod, pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

**Parameters**

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

**level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

**fill\_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

### Returns

**DataFrame** Result of the arithmetic operation.

### See also:

**DataFrame.add** Add DataFrames.

**DataFrame.sub** Subtract DataFrames.

**DataFrame.mul** Multiply DataFrames.

**DataFrame.div** Divide DataFrames (float division).

**DataFrame.truediv** Divide DataFrames (float division).

**DataFrame.floordiv** Divide DataFrames (integer division).

**DataFrame.mod** Calculate modulo (remainder after division).

**DataFrame.pow** Calculate exponential power.

### Notes

Mismatched indices will be unioned together.

### Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

	angles	degrees
circle	0	360
triangle	3	180
rectangle	4	360

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

```
>>> df.add(1)
```

	angles	degrees
circle	1	361
triangle	4	181
rectangle	5	361

Divide by constant with reverse version.

```
>>> df.div(10)
      angles  degrees
circle    0.0   36.0
triangle  0.3   18.0
rectangle 0.4   36.0
```

```
>>> df.rdiv(10)
      angles  degrees
circle      inf  0.027778
triangle  3.333333  0.055556
rectangle  2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
      angles  degrees
circle     -1    358
triangle    2    178
rectangle   3    358
```

```
>>> df.sub([1, 2], axis='columns')
      angles  degrees
circle     -1    358
triangle    2    178
rectangle   3    358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
      angles  degrees
circle     -1    359
triangle    2    179
rectangle   3    359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
      angles
circle      0
triangle     3
rectangle    4
```

```
>>> df * other
      angles  degrees
circle      0     NaN
triangle     9     NaN
rectangle   16     NaN
```

```
>>> df.mul(other, fill_value=0)
      angles  degrees
circle      0     0.0
triangle     9     0.0
rectangle   16     0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                               index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                       ['circle', 'triangle', 'rectangle',
...                                       'square', 'pentagon', 'hexagon']])
>>> df_multindex
      angles  degrees
A circle      0     360
  triangle      3     180
  rectangle      4     360
B square       4     360
  pentagon      5     540
  hexagon       6     720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
      angles  degrees
A circle   NaN     1.0
  triangle  1.0     1.0
  rectangle 1.0     1.0
B square   0.0     0.0
  pentagon 0.0     0.0
  hexagon  0.0     0.0
```

### pandas.DataFrame.truncate

`DataFrame.truncate` (*self*: ~FrameOrSeries, *before*=None, *after*=None, *axis*=None, *copy*: bool = True) → ~FrameOrSeries

Truncate a Series or DataFrame before and after some index value.

This is a useful shorthand for boolean indexing based on index values above or below certain thresholds.

#### Parameters

**before** [date, str, int] Truncate all rows before this index value.

**after** [date, str, int] Truncate all rows after this index value.

**axis** [{0 or 'index', 1 or 'columns'}, optional] Axis to truncate. Truncates the index (rows) by default.

**copy** [bool, default is True,] Return a copy of the truncated section.

#### Returns

**type of caller** The truncated Series or DataFrame.

**See also:**

**DataFrame.loc** Select a subset of a DataFrame by label.

**DataFrame.iloc** Select a subset of a DataFrame by position.

## Notes

If the index being truncated contains only datetime values, *before* and *after* may be specified as strings instead of Timestamps.

## Examples

```
>>> df = pd.DataFrame({'A': ['a', 'b', 'c', 'd', 'e'],
...                   'B': ['f', 'g', 'h', 'i', 'j'],
...                   'C': ['k', 'l', 'm', 'n', 'o']},
...                   index=[1, 2, 3, 4, 5])
>>> df
   A B C
1  a f k
2  b g l
3  c h m
4  d i n
5  e j o
```

```
>>> df.truncate(before=2, after=4)
   A B C
2  b g l
3  c h m
4  d i n
```

The columns of a DataFrame can be truncated.

```
>>> df.truncate(before="A", after="B", axis="columns")
   A B
1  a f
2  b g
3  c h
4  d i
5  e j
```

For Series, only rows can be truncated.

```
>>> df['A'].truncate(before=2, after=4)
2    b
3    c
4    d
Name: A, dtype: object
```

The index values in `truncate` can be datetimes or string dates.

```
>>> dates = pd.date_range('2016-01-01', '2016-02-01', freq='s')
>>> df = pd.DataFrame(index=dates, data={'A': 1})
>>> df.tail()
                A
2016-01-31 23:59:56  1
2016-01-31 23:59:57  1
2016-01-31 23:59:58  1
2016-01-31 23:59:59  1
2016-02-01 00:00:00  1
```

```
>>> df.truncate(before=pd.Timestamp('2016-01-05'),
...             after=pd.Timestamp('2016-01-10')).tail()
      A
2016-01-09 23:59:56  1
2016-01-09 23:59:57  1
2016-01-09 23:59:58  1
2016-01-09 23:59:59  1
2016-01-10 00:00:00  1
```

Because the index is a `DatetimeIndex` containing only dates, we can specify *before* and *after* as strings. They will be coerced to `Timestamps` before truncation.

```
>>> df.truncate('2016-01-05', '2016-01-10').tail()
      A
2016-01-09 23:59:56  1
2016-01-09 23:59:57  1
2016-01-09 23:59:58  1
2016-01-09 23:59:59  1
2016-01-10 00:00:00  1
```

Note that `truncate` assumes a 0 value for any unspecified time component (midnight). This differs from partial string slicing, which returns any partially matching dates.

```
>>> df.loc['2016-01-05':'2016-01-10', :].tail()
      A
2016-01-10 23:59:55  1
2016-01-10 23:59:56  1
2016-01-10 23:59:57  1
2016-01-10 23:59:58  1
2016-01-10 23:59:59  1
```

### pandas.DataFrame.tshift

`DataFrame.tshift` (*self*: `~FrameOrSeries`, *periods*: `int = 1`, *freq*: `None`, *axis*: `0`) → `~FrameOrSeries`  
Shift the time index, using the index's frequency if available.

#### Parameters

**periods** [`int`] Number of periods to move, can be positive or negative.

**freq** [`DateOffset`, `timedelta`, or `str`, default `None`] Increment to use from the `tseries` module or time rule expressed as a string (e.g. 'EOM').

**axis** [`{0 or 'index', 1 or 'columns', None}`, default `0`] Corresponds to the axis that contains the Index.

#### Returns

**shifted** [`Series/DataFrame`]

## Notes

If freq is not specified then tries to use the freq or inferred\_freq attributes of the index. If neither of those attributes exist, a ValueError is thrown

## pandas.DataFrame.tz\_convert

`DataFrame.tz_convert` (*self*: ~FrameOrSeries, *tz*, *axis=0*, *level=None*, *copy: bool = True*) → ~FrameOrSeries  
Convert tz-aware axis to target time zone.

### Parameters

**tz** [str or tzinfo object]

**axis** [the axis to convert]

**level** [int, str, default None] If axis is a MultiIndex, convert a specific level. Otherwise must be None.

**copy** [bool, default True] Also make a copy of the underlying data.

### Returns

**%(klass)s** Object with time zone converted axis.

### Raises

**TypeError** If the axis is tz-naive.

## pandas.DataFrame.tz\_localize

`DataFrame.tz_localize` (*self*: ~FrameOrSeries, *tz*, *axis=0*, *level=None*, *copy: bool = True*, *ambiguous='raise'*, *nonexistent: str = 'raise'*) → ~FrameOrSeries  
Localize tz-naive index of a Series or DataFrame to target time zone.

This operation localizes the Index. To localize the values in a timezone-naive Series, use `Series.dt.tz_localize()`.

### Parameters

**tz** [str or tzinfo]

**axis** [the axis to localize]

**level** [int, str, default None] If axis is a MultiIndex, localize a specific level. Otherwise must be None.

**copy** [bool, default True] Also make a copy of the underlying data.

**ambiguous** ['infer', bool-ndarray, 'NaT', default 'raise'] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the *ambiguous* parameter dictates how ambiguous times should be handled.

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times

- 'raise' will raise an `AmbiguousTimeError` if there are ambiguous times.

**nonexistent** [str, default 'raise'] A nonexistent time does not exist in a particular time-zone where clocks moved forward due to DST. Valid values are:

- 'shift\_forward' will shift the nonexistent time forward to the closest existing time
- 'shift\_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return `NaT` where there are nonexistent times
- `timedelta` objects will shift nonexistent times by the `timedelta`
- 'raise' will raise an `NonExistentTimeError` if there are nonexistent times.

New in version 0.24.0.

### Returns

**Series or DataFrame** Same type as the input.

### Raises

**TypeError** If the `TimeSeries` is tz-aware and `tz` is not `None`.

## Examples

Localize local times:

```
>>> s = pd.Series([1],
...                index=pd.DatetimeIndex(['2018-09-15 01:30:00']))
>>> s.tz_localize('CET')
2018-09-15 01:30:00+02:00    1
dtype: int64
```

Be careful with DST changes. When there is sequential data, pandas can infer the DST time:

```
>>> s = pd.Series(range(7),
...                index=pd.DatetimeIndex(['2018-10-28 01:30:00',
...                                         '2018-10-28 02:00:00',
...                                         '2018-10-28 02:30:00',
...                                         '2018-10-28 02:00:00',
...                                         '2018-10-28 02:30:00',
...                                         '2018-10-28 03:00:00',
...                                         '2018-10-28 03:30:00']))
>>> s.tz_localize('CET', ambiguous='infer')
2018-10-28 01:30:00+02:00    0
2018-10-28 02:00:00+02:00    1
2018-10-28 02:30:00+02:00    2
2018-10-28 02:00:00+01:00    3
2018-10-28 02:30:00+01:00    4
2018-10-28 03:00:00+01:00    5
2018-10-28 03:30:00+01:00    6
dtype: int64
```

In some cases, inferring the DST is impossible. In such cases, you can pass an ndarray to the `ambiguous` parameter to set the DST explicitly

```

>>> s = pd.Series(range(3),
...               index=pd.DatetimeIndex(['2018-10-28 01:20:00',
...                                       '2018-10-28 02:36:00',
...                                       '2018-10-28 03:46:00']))
>>> s.tz_localize('CET', ambiguous=np.array([True, True, False]))
2018-10-28 01:20:00+02:00    0
2018-10-28 02:36:00+02:00    1
2018-10-28 03:46:00+01:00    2
dtype: int64

```

If the DST transition causes nonexistent times, you can shift these dates forward or backwards with a `timedelta` object or `'shift_forward'` or `'shift_backwards'`. `>>> s = pd.Series(range(2), ... index=pd.DatetimeIndex(['2015-03-29 02:30:00', ... '2015-03-29 03:30:00'])) >>> s.tz_localize('Europe/Warsaw', nonexistent='shift_forward')` 2015-03-29 03:00:00+02:00 0 2015-03-29 03:30:00+02:00 1 dtype: int64 `>>> s.tz_localize('Europe/Warsaw', nonexistent='shift_backward')` 2015-03-29 01:59:59.999999999+01:00 0 2015-03-29 03:30:00+02:00 1 dtype: int64 `>>> s.tz_localize('Europe/Warsaw', nonexistent=pd.Timedelta('1H'))` 2015-03-29 03:30:00+02:00 0 2015-03-29 03:30:00+02:00 1 dtype: int64

## pandas.DataFrame.unstack

`DataFrame.unstack` (*self*, *level=-1*, *fill\_value=None*)

Pivot a level of the (necessarily hierarchical) index labels.

Returns a `DataFrame` having a new level of column labels whose inner-most level consists of the pivoted index labels.

If the index is not a `MultiIndex`, the output will be a `Series` (the analogue of `stack` when the columns are not a `MultiIndex`).

The level involved will automatically get sorted.

### Parameters

**level** [int, str, or list of these, default -1 (last level)] Level(s) of index to unstack, can pass level name.

**fill\_value** [int, str or dict] Replace NaN with this value if the unstack produces missing values.

### Returns

**Series or DataFrame**

See also:

`DataFrame.pivot` Pivot a table based on column values.

`DataFrame.stack` Pivot a level of the column labels (inverse operation from `unstack`).

## Examples

```
>>> index = pd.MultiIndex.from_tuples([('one', 'a'), ('one', 'b'),
...                                  ('two', 'a'), ('two', 'b')])
>>> s = pd.Series(np.arange(1.0, 5.0), index=index)
>>> s
one  a    1.0
     b    2.0
two  a    3.0
     b    4.0
dtype: float64
```

```
>>> s.unstack(level=-1)
     a    b
one  1.0  2.0
two  3.0  4.0
```

```
>>> s.unstack(level=0)
     one  two
a    1.0   3.0
b    2.0   4.0
```

```
>>> df = s.unstack(level=0)
>>> df.unstack()
one  a    1.0
     b    2.0
two  a    3.0
     b    4.0
dtype: float64
```

## pandas.DataFrame.update

`DataFrame.update` (*self*, *other*, *join='left'*, *overwrite=True*, *filter\_func=None*, *errors='ignore'*) →

None  
Modify in place using non-NA values from another DataFrame.

Aligns on indices. There is no return value.

### Parameters

**other** [DataFrame, or object coercible into a DataFrame] Should have at least one matching index/column label with the original DataFrame. If a Series is passed, its name attribute must be set, and that will be used as the column name to align with the original DataFrame.

**join** [{'left'}, default 'left'] Only left join is implemented, keeping the index and columns of the original object.

**overwrite** [bool, default True] How to handle non-NA values for overlapping keys:

- True: overwrite original DataFrame's values with values from *other*.
- False: only update values that are NA in the original DataFrame.

**filter\_func** [callable(1d-array) -> bool 1d-array, optional] Can choose to replace values other than NA. Return True for values that should be updated.

**errors** [{‘raise’, ‘ignore’}], default ‘ignore’ If ‘raise’, will raise a ValueError if the DataFrame and *other* both contain non-NA data in the same place.

Changed in version 0.24.0: Changed from *raise\_conflict=False|True* to *errors='ignore'|'raise'*.

### Returns

**None** [method directly changes calling object]

### Raises

#### ValueError

- When *errors='raise'* and there’s overlapping non-NA data.
- When *errors* is not either ‘ignore’ or ‘raise’

#### NotImplementedError

- If *join != 'left'*

### See also:

[dict.update](#) Similar method for dictionaries.

[DataFrame.merge](#) For column(s)-on-columns(s) operations.

### Examples

```
>>> df = pd.DataFrame({'A': [1, 2, 3],
...                    'B': [400, 500, 600]})
>>> new_df = pd.DataFrame({'B': [4, 5, 6],
...                        'C': [7, 8, 9]})
>>> df.update(new_df)
>>> df
   A  B
0  1  4
1  2  5
2  3  6
```

The DataFrame’s length does not increase as a result of the update, only values at matching index/column labels are updated.

```
>>> df = pd.DataFrame({'A': ['a', 'b', 'c'],
...                    'B': ['x', 'y', 'z']})
>>> new_df = pd.DataFrame({'B': ['d', 'e', 'f', 'g', 'h', 'i']})
>>> df.update(new_df)
>>> df
   A  B
0  a  d
1  b  e
2  c  f
```

For Series, it’s name attribute must be set.

```
>>> df = pd.DataFrame({'A': ['a', 'b', 'c'],
...                    'B': ['x', 'y', 'z']})
>>> new_column = pd.Series(['d', 'e'], name='B', index=[0, 2])
>>> df.update(new_column)
```

(continues on next page)

(continued from previous page)

```

>>> df
   A  B
0  a  d
1  b  y
2  c  e
>>> df = pd.DataFrame({'A': ['a', 'b', 'c'],
...                    'B': ['x', 'y', 'z']})
>>> new_df = pd.DataFrame({'B': ['d', 'e']}, index=[1, 2])
>>> df.update(new_df)
>>> df
   A  B
0  a  x
1  b  d
2  c  e

```

If *other* contains NaNs the corresponding values are not updated in the original dataframe.

```

>>> df = pd.DataFrame({'A': [1, 2, 3],
...                    'B': [400, 500, 600]})
>>> new_df = pd.DataFrame({'B': [4, np.nan, 6]})
>>> df.update(new_df)
>>> df
   A     B
0  1   4.0
1  2  500.0
2  3   6.0

```

### pandas.DataFrame.var

`DataFrame.var` (*self*, *axis=None*, *skipna=None*, *level=None*, *ddof=1*, *numeric\_only=None*, *\*\*kwargs*)

Return unbiased variance over requested axis.

Normalized by N-1 by default. This can be changed using the *ddof* argument

#### Parameters

**axis** [{index (0), columns (1)}]

**skipna** [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

**ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

#### Returns

Series or DataFrame (if level specified)

## pandas.DataFrame.where

`DataFrame.where` (*self*, *cond*, *other=nan*, *inplace=False*, *axis=None*, *level=None*, *errors='raise'*, *try\_cast=False*)

Replace values where the condition is False.

### Parameters

**cond** [bool Series/DataFrame, array-like, or callable] Where *cond* is True, keep the original value. Where False, replace with corresponding value from *other*. If *cond* is callable, it is computed on the Series/DataFrame and should return boolean Series/DataFrame or array. The callable must not change input Series/DataFrame (though pandas doesn't check it).

**other** [scalar, Series/DataFrame, or callable] Entries where *cond* is False are replaced with corresponding value from *other*. If *other* is callable, it is computed on the Series/DataFrame and should return scalar or Series/DataFrame. The callable must not change input Series/DataFrame (though pandas doesn't check it).

**inplace** [bool, default False] Whether to perform the operation in place on the data.

**axis** [int, default None] Alignment axis if needed.

**level** [int, default None] Alignment level if needed.

**errors** [str, {'raise', 'ignore'}, default 'raise'] Note that currently this parameter won't affect the results and will always coerce to a suitable dtype.

- 'raise' : allow exceptions to be raised.
- 'ignore' : suppress exceptions. On error return original object.

**try\_cast** [bool, default False] Try to cast the result back to the input type (if possible).

### Returns

Same type as caller

See also:

`DataFrame.mask()` Return an object of same shape as self.

### Notes

The `where` method is an application of the if-then idiom. For each element in the calling `DataFrame`, if `cond` is `True` the element is used; otherwise the corresponding element from the `DataFrame` `other` is used.

The signature for `DataFrame.where()` differs from `numpy.where()`. Roughly `df1.where(m, df2)` is equivalent to `np.where(m, df1, df2)`.

For further details and examples see the `where` documentation in *indexing*.

## Examples

```
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0    NaN
1    1.0
2    2.0
3    3.0
4    4.0
dtype: float64
```

```
>>> s.mask(s > 0)
0    0.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

```
>>> s.where(s > 1, 10)
0    10
1    10
2     2
3     3
4     4
dtype: int64
```

```
>>> df = pd.DataFrame(np.arange(10).reshape(-1, 2), columns=['A', 'B'])
>>> df
   A  B
0  0  1
1  2  3
2  4  5
3  6  7
4  8  9
>>> m = df % 3 == 0
>>> df.where(m, -df)
   A  B
0  0 -1
1 -2  3
2 -4 -5
3  6 -7
4 -8  9
>>> df.where(m, -df) == np.where(m, df, -df)
   A    B
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True
>>> df.where(m, -df) == df.mask(~m, -df)
   A    B
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True
```

## pandas.DataFrame.xs

DataFrame.**xs** (*self*, *key*, *axis=0*, *level=None*, *drop\_level: bool = True*)

Return cross-section from the Series/DataFrame.

This method takes a *key* argument to select data at a particular level of a MultiIndex.

### Parameters

**key** [label or tuple of label] Label contained in the index, or partially in a MultiIndex.

**axis** [{0 or 'index', 1 or 'columns'}, default 0] Axis to retrieve cross-section on.

**level** [object, defaults to first n levels (n=1 or len(key))] In case of a key partially contained in a MultiIndex, indicate which levels are used. Levels can be referred by label or position.

**drop\_level** [bool, default True] If False, returns object with same levels as self.

### Returns

**Series or DataFrame** Cross-section from the original Series or DataFrame corresponding to the selected index levels.

### See also:

**DataFrame.loc** Access a group of rows and columns by label(s) or a boolean array.

**DataFrame.iloc** Purely integer-location based indexing for selection by position.

### Notes

*xs* can not be used to set values.

MultiIndex Slicers is a generic way to get/set values on any level or levels. It is a superset of *xs* functionality, see *MultiIndex Slicers*.

### Examples

```

>>> d = {'num_legs': [4, 4, 2, 2],
...      'num_wings': [0, 0, 2, 2],
...      'class': ['mammal', 'mammal', 'mammal', 'bird'],
...      'animal': ['cat', 'dog', 'bat', 'penguin'],
...      'locomotion': ['walks', 'walks', 'flies', 'walks']}
>>> df = pd.DataFrame(data=d)
>>> df = df.set_index(['class', 'animal', 'locomotion'])
>>> df

```

			num_legs	num_wings
class	animal	locomotion		
mammal	cat	walks	4	0
	dog	walks	4	0
	bat	flies	2	2
bird	penguin	walks	2	2

Get values at specified index

```
>>> df.xs('mammal')
          num_legs  num_wings
animal locomotion
cat     walks      4          0
dog     walks      4          0
bat     flies      2          2
```

Get values at several indexes

```
>>> df.xs(('mammal', 'dog'))
          num_legs  num_wings
locomotion
walks          4          0
```

Get values at specified index and level

```
>>> df.xs('cat', level=1)
          num_legs  num_wings
class locomotion
mammal walks      4          0
```

Get values at several indexes and levels

```
>>> df.xs(('bird', 'walks'),
...       level=[0, 'locomotion'])
          num_legs  num_wings
animal
penguin      2          2
```

Get values at specified column and axis

```
>>> df.xs('num_wings', axis=1)
class  animal  locomotion
mammal cat     walks      0
        dog     walks      0
        bat     flies      2
bird   penguin walks      2
Name: num_wings, dtype: int64
```

## 4.4.2 Attributes and underlying data

### Axes

*DataFrame.index*

The index (row labels) of the DataFrame.

*DataFrame.columns*

The column labels of the DataFrame.

*DataFrame.dtypes*

Return the dtypes in the DataFrame.

*DataFrame.select\_dtypes(self[, include, exclude])*

Return a subset of the DataFrame's columns based on the column dtypes.

*DataFrame.values*

Return a Numpy representation of the DataFrame.

*DataFrame.axes*

Return a list representing the axes of the DataFrame.

Continued on next page

Table 61 – continued from previous page

<code>DataFrame.ndim</code>	Return an int representing the number of axes / array dimensions.
<code>DataFrame.size</code>	Return an int representing the number of elements in this object.
<code>DataFrame.shape</code>	Return a tuple representing the dimensionality of the DataFrame.
<code>DataFrame.memory_usage(self[, index, deep])</code>	Return the memory usage of each column in bytes.
<code>DataFrame.empty</code>	Indicator whether DataFrame is empty.

### 4.4.3 Conversion

<code>DataFrame.astype(self, dtype, copy, errors)</code>	Cast a pandas object to a specified dtype <code>dtype</code> .
<code>DataFrame.convert_dtypes(self, ...)</code>	Convert columns to best possible dtypes using dtypes supporting <code>pd.NA</code> .
<code>DataFrame.infer_objects(self)</code>	Attempt to infer better dtypes for object columns.
<code>DataFrame.copy(self, deep)</code>	Make a copy of this object's indices and data.
<code>DataFrame.isna(self)</code>	Detect missing values.
<code>DataFrame.notna(self)</code>	Detect existing (non-missing) values.
<code>DataFrame.bool(self)</code>	Return the bool of a single element PandasObject.

### 4.4.4 Indexing, iteration

<code>DataFrame.head(self, n)</code>	Return the first $n$ rows.
<code>DataFrame.at</code>	Access a single value for a row/column label pair.
<code>DataFrame.iat</code>	Access a single value for a row/column pair by integer position.
<code>DataFrame.loc</code>	Access a group of rows and columns by label(s) or a boolean array.
<code>DataFrame.iloc</code>	Purely integer-location based indexing for selection by position.
<code>DataFrame.insert(self, loc, column, value[, ...])</code>	Insert column into DataFrame at specified location.
<code>DataFrame.__iter__(self)</code>	Iterate over info axis.
<code>DataFrame.items(self)</code>	Iterate over (column name, Series) pairs.
<code>DataFrame.iteritems(self)</code>	Iterate over (column name, Series) pairs.
<code>DataFrame.keys(self)</code>	Get the 'info axis' (see Indexing for more).
<code>DataFrame.iterrows(self)</code>	Iterate over DataFrame rows as (index, Series) pairs.
<code>DataFrame.itertuples(self[, index, name])</code>	Iterate over DataFrame rows as namedtuples.
<code>DataFrame.lookup(self, row_labels, col_labels)</code>	Label-based "fancy indexing" function for DataFrame.
<code>DataFrame.pop(self, item)</code>	Return item and drop from frame.
<code>DataFrame.tail(self, n)</code>	Return the last $n$ rows.
<code>DataFrame.xs(self, key[, axis, level])</code>	Return cross-section from the Series/DataFrame.
<code>DataFrame.get(self, key[, default])</code>	Get item from object for given key (ex: DataFrame column).
<code>DataFrame.isin(self, values)</code>	Whether each element in the DataFrame is contained in values.
<code>DataFrame.where(self, cond[, other, ...])</code>	Replace values where the condition is False.
<code>DataFrame.mask(self, cond[, other, inplace, ...])</code>	Replace values where the condition is True.

Continued on next page

Table 63 – continued from previous page

<code>DataFrame.query(self, expr[, inplace])</code>	Query the columns of a DataFrame with a boolean expression.
-----------------------------------------------------	-------------------------------------------------------------

**pandas.DataFrame.\_\_iter\_\_**

`DataFrame.__iter__(self)`

Iterate over info axis.

**Returns**

**iterator** Info axis as iterator.

For more information on `.at`, `.iat`, `.loc`, and `.iloc`, see the *indexing documentation*.

**4.4.5 Binary operator functions**

<code>DataFrame.add(self, other[, axis, level, ...])</code>	Get Addition of dataframe and other, element-wise (binary operator <i>add</i> ).
<code>DataFrame.sub(self, other[, axis, level, ...])</code>	Get Subtraction of dataframe and other, element-wise (binary operator <i>sub</i> ).
<code>DataFrame.mul(self, other[, axis, level, ...])</code>	Get Multiplication of dataframe and other, element-wise (binary operator <i>mul</i> ).
<code>DataFrame.div(self, other[, axis, level, ...])</code>	Get Floating division of dataframe and other, element-wise (binary operator <i>truediv</i> ).
<code>DataFrame.truediv(self, other[, axis, ...])</code>	Get Floating division of dataframe and other, element-wise (binary operator <i>truediv</i> ).
<code>DataFrame.floordiv(self, other[, axis, ...])</code>	Get Integer division of dataframe and other, element-wise (binary operator <i>floordiv</i> ).
<code>DataFrame.mod(self, other[, axis, level, ...])</code>	Get Modulo of dataframe and other, element-wise (binary operator <i>mod</i> ).
<code>DataFrame.pow(self, other[, axis, level, ...])</code>	Get Exponential power of dataframe and other, element-wise (binary operator <i>pow</i> ).
<code>DataFrame.dot(self, other)</code>	Compute the matrix multiplication between the DataFrame and other.
<code>DataFrame.radd(self, other[, axis, level, ...])</code>	Get Addition of dataframe and other, element-wise (binary operator <i>radd</i> ).
<code>DataFrame.rsub(self, other[, axis, level, ...])</code>	Get Subtraction of dataframe and other, element-wise (binary operator <i>rsub</i> ).
<code>DataFrame.rmul(self, other[, axis, level, ...])</code>	Get Multiplication of dataframe and other, element-wise (binary operator <i>rmul</i> ).
<code>DataFrame.rdiv(self, other[, axis, level, ...])</code>	Get Floating division of dataframe and other, element-wise (binary operator <i>rtruediv</i> ).
<code>DataFrame.rtruediv(self, other[, axis, ...])</code>	Get Floating division of dataframe and other, element-wise (binary operator <i>rtruediv</i> ).
<code>DataFrame.rfloordiv(self, other[, axis, ...])</code>	Get Integer division of dataframe and other, element-wise (binary operator <i>rfloordiv</i> ).
<code>DataFrame.rmod(self, other[, axis, level, ...])</code>	Get Modulo of dataframe and other, element-wise (binary operator <i>rmod</i> ).
<code>DataFrame.rpow(self, other[, axis, level, ...])</code>	Get Exponential power of dataframe and other, element-wise (binary operator <i>rpow</i> ).

Continued on next page

Table 64 – continued from previous page

<code>DataFrame.lt(self, other[, axis, level])</code>	Get Less than of dataframe and other, element-wise (binary operator <i>lt</i> ).
<code>DataFrame.gt(self, other[, axis, level])</code>	Get Greater than of dataframe and other, element-wise (binary operator <i>gt</i> ).
<code>DataFrame.le(self, other[, axis, level])</code>	Get Less than or equal to of dataframe and other, element-wise (binary operator <i>le</i> ).
<code>DataFrame.ge(self, other[, axis, level])</code>	Get Greater than or equal to of dataframe and other, element-wise (binary operator <i>ge</i> ).
<code>DataFrame.ne(self, other[, axis, level])</code>	Get Not equal to of dataframe and other, element-wise (binary operator <i>ne</i> ).
<code>DataFrame.eq(self, other[, axis, level])</code>	Get Equal to of dataframe and other, element-wise (binary operator <i>eq</i> ).
<code>DataFrame.combine(self, other, func[, ...])</code>	Perform column-wise combine with another DataFrame.
<code>DataFrame.combine_first(self, other)</code>	Update null elements with value in the same location in <i>other</i> .

#### 4.4.6 Function application, GroupBy & window

<code>DataFrame.apply(self, func[, axis, raw, ...])</code>	Apply a function along an axis of the DataFrame.
<code>DataFrame.applymap(self, func)</code>	Apply a function to a Dataframe elementwise.
<code>DataFrame.pipe(self, func, \*args, \*\*kwargs)</code>	Apply <code>func(self, *args, **kwargs)</code> .
<code>DataFrame.agg(self, func[, axis])</code>	Aggregate using one or more operations over the specified axis.
<code>DataFrame.aggregate(self, func[, axis])</code>	Aggregate using one or more operations over the specified axis.
<code>DataFrame.transform(self, func[, axis])</code>	Call <code>func</code> on self producing a DataFrame with transformed values.
<code>DataFrame.groupby(self[, by, axis, level])</code>	Group DataFrame using a mapper or by a Series of columns.
<code>DataFrame.rolling(self, window[, ...])</code>	Provide rolling window calculations.
<code>DataFrame.expanding(self[, min_periods, ...])</code>	Provide expanding transformations.
<code>DataFrame.ewm(self[, com, span, half-life, ...])</code>	Provide exponential weighted functions.

#### 4.4.7 Computations / descriptive stats

<code>DataFrame.abs(self)</code>	Return a Series/DataFrame with absolute numeric value of each element.
<code>DataFrame.all(self[, axis, bool_only, ...])</code>	Return whether all elements are True, potentially over an axis.
<code>DataFrame.any(self[, axis, bool_only, ...])</code>	Return whether any element is True, potentially over an axis.
<code>DataFrame.clip(self[, lower, upper, axis])</code>	Trim values at input threshold(s).
<code>DataFrame.corr(self[, method, min_periods])</code>	Compute pairwise correlation of columns, excluding NA/null values.
<code>DataFrame.corrwith(self, other[, axis, ...])</code>	Compute pairwise correlation.
<code>DataFrame.count(self[, axis, level, ...])</code>	Count non-NA cells for each column or row.

Continued on next page

Table 66 – continued from previous page

<code>DataFrame.cov(self[, min_periods])</code>	Compute pairwise covariance of columns, excluding NA/null values.
<code>DataFrame.cummax(self[, axis, skipna])</code>	Return cumulative maximum over a DataFrame or Series axis.
<code>DataFrame.cummin(self[, axis, skipna])</code>	Return cumulative minimum over a DataFrame or Series axis.
<code>DataFrame.cumprod(self[, axis, skipna])</code>	Return cumulative product over a DataFrame or Series axis.
<code>DataFrame.cumsum(self[, axis, skipna])</code>	Return cumulative sum over a DataFrame or Series axis.
<code>DataFrame.describe(self[, percentiles, ...])</code>	Generate descriptive statistics.
<code>DataFrame.diff(self[, periods, axis])</code>	First discrete difference of element.
<code>DataFrame.eval(self, expr[, inplace])</code>	Evaluate a string describing operations on DataFrame columns.
<code>DataFrame.kurt(self[, axis, skipna, level, ...])</code>	Return unbiased kurtosis over requested axis.
<code>DataFrame.kurtosis(self[, axis, skipna, ...])</code>	Return unbiased kurtosis over requested axis.
<code>DataFrame.mad(self[, axis, skipna, level])</code>	Return the mean absolute deviation of the values for the requested axis.
<code>DataFrame.max(self[, axis, skipna, level, ...])</code>	Return the maximum of the values for the requested axis.
<code>DataFrame.mean(self[, axis, skipna, level, ...])</code>	Return the mean of the values for the requested axis.
<code>DataFrame.median(self[, axis, skipna, ...])</code>	Return the median of the values for the requested axis.
<code>DataFrame.min(self[, axis, skipna, level, ...])</code>	Return the minimum of the values for the requested axis.
<code>DataFrame.mode(self[, axis, numeric_only, ...])</code>	Get the mode(s) of each element along the selected axis.
<code>DataFrame.pct_change(self[, periods, ...])</code>	Percentage change between the current and a prior element.
<code>DataFrame.prod(self[, axis, skipna, level, ...])</code>	Return the product of the values for the requested axis.
<code>DataFrame.product(self[, axis, skipna, ...])</code>	Return the product of the values for the requested axis.
<code>DataFrame.quantile(self[, q, axis, ...])</code>	Return values at the given quantile over requested axis.
<code>DataFrame.rank(self[, axis])</code>	Compute numerical data ranks (1 through n) along axis.
<code>DataFrame.round(self[, decimals])</code>	Round a DataFrame to a variable number of decimal places.
<code>DataFrame.sem(self[, axis, skipna, level, ...])</code>	Return unbiased standard error of the mean over requested axis.
<code>DataFrame.skew(self[, axis, skipna, level, ...])</code>	Return unbiased skew over requested axis.
<code>DataFrame.sum(self[, axis, skipna, level, ...])</code>	Return the sum of the values for the requested axis.
<code>DataFrame.std(self[, axis, skipna, level, ...])</code>	Return sample standard deviation over requested axis.
<code>DataFrame.var(self[, axis, skipna, level, ...])</code>	Return unbiased variance over requested axis.
<code>DataFrame.nunique(self[, axis, dropna])</code>	Count distinct observations over requested axis.

#### 4.4.8 Reindexing / selection / label manipulation

<code>DataFrame.add_prefix(self, prefix)</code>	Prefix labels with string <i>prefix</i> .
<code>DataFrame.add_suffix(self, suffix)</code>	Suffix labels with string <i>suffix</i> .
<code>DataFrame.align(self, other[, join, axis, ...])</code>	Align two objects on their axes with the specified join method.
<code>DataFrame.at_time(self, time, asof[, axis])</code>	Select values at particular time of day (e.g.
<code>DataFrame.between_time(self, start_time, ...)</code>	Select values between particular times of the day (e.g., 9:00-9:30 AM).
<code>DataFrame.drop(self[, labels, axis, index, ...])</code>	Drop specified labels from rows or columns.

Continued on next page

Table 67 – continued from previous page

<code>DataFrame.drop_duplicates(self, subset, ...)</code>	Return DataFrame with duplicate rows removed.
<code>DataFrame.duplicated(self, subset, ...)</code>	Return boolean Series denoting duplicate rows.
<code>DataFrame.equals(self, other)</code>	Test whether two objects contain the same elements.
<code>DataFrame.filter(self[, items, axis])</code>	Subset the dataframe rows or columns according to the specified index labels.
<code>DataFrame.first(self, offset)</code>	Method to subset initial periods of time series data based on a date offset.
<code>DataFrame.head(self, n)</code>	Return the first <i>n</i> rows.
<code>DataFrame.idxmax(self[, axis, skipna])</code>	Return index of first occurrence of maximum over requested axis.
<code>DataFrame.idxmin(self[, axis, skipna])</code>	Return index of first occurrence of minimum over requested axis.
<code>DataFrame.last(self, offset)</code>	Method to subset final periods of time series data based on a date offset.
<code>DataFrame.reindex(self[, labels, index, ...])</code>	Conform DataFrame to new index with optional filling logic.
<code>DataFrame.reindex_like(self, other, method, ...)</code>	Return an object with matching indices as other object.
<code>DataFrame.rename(self[, mapper, index, ...])</code>	Alter axes labels.
<code>DataFrame.rename_axis(self[, mapper, index, ...])</code>	Set the name of the axis for the index or columns.
<code>DataFrame.reset_index(self, level, ...)</code>	Reset the index, or a level of it.
<code>DataFrame.sample(self[, n, frac, replace, ...])</code>	Return a random sample of items from an axis of object.
<code>DataFrame.set_axis(self, labels[, axis, inplace])</code>	Assign desired index to given axis.
<code>DataFrame.set_index(self, keys[, drop, ...])</code>	Set the DataFrame index using existing columns.
<code>DataFrame.tail(self, n)</code>	Return the last <i>n</i> rows.
<code>DataFrame.take(self, indices[, axis])</code>	Return the elements in the given <i>positional</i> indices along an axis.
<code>DataFrame.truncate(self[, before, after, axis])</code>	Truncate a Series or DataFrame before and after some index value.

#### 4.4.9 Missing data handling

<code>DataFrame.dropna(self[, axis, how, thresh, ...])</code>	Remove missing values.
<code>DataFrame.fillna(self[, value, method, ...])</code>	Fill NA/NaN values using the specified method.
<code>DataFrame.replace(self[, to_replace, value, ...])</code>	Replace values given in <i>to_replace</i> with <i>value</i> .
<code>DataFrame.interpolate(self[, method, axis, ...])</code>	Interpolate values according to different methods.

#### 4.4.10 Reshaping, sorting, transposing

<code>DataFrame.droplevel(self, level[, axis])</code>	Return DataFrame with requested index / column level(s) removed.
<code>DataFrame.pivot(self[, index, columns, values])</code>	Return reshaped DataFrame organized by given index / column values.
<code>DataFrame.pivot_table(self[, values, index, ...])</code>	Create a spreadsheet-style pivot table as a DataFrame.

Continued on next page

Table 69 – continued from previous page

<code>DataFrame.reorder_levels(self, order[, axis])</code>	Rearrange index levels using input order.
<code>DataFrame.sort_values(self, by[, axis, ...])</code>	Sort by the values along either axis.
<code>DataFrame.sort_index(self[, axis, level, ...])</code>	Sort object by labels (along an axis).
<code>DataFrame.nlargest(self, n, columns[, keep])</code>	Return the first <i>n</i> rows ordered by <i>columns</i> in descending order.
<code>DataFrame.nsmallest(self, n, columns[, keep])</code>	Return the first <i>n</i> rows ordered by <i>columns</i> in ascending order.
<code>DataFrame.swaplevel(self[, i, j, axis])</code>	Swap levels <i>i</i> and <i>j</i> in a MultiIndex on a particular axis.
<code>DataFrame.stack(self[, level, dropna])</code>	Stack the prescribed level(s) from columns to index.
<code>DataFrame.unstack(self[, level, fill_value])</code>	Pivot a level of the (necessarily hierarchical) index labels.
<code>DataFrame.swapaxes(self, axis1, axis2[, copy])</code>	Interchange axes and swap values axes appropriately.
<code>DataFrame.melt(self[, id_vars, value_vars, ...])</code>	Unpivot a DataFrame from wide to long format, optionally leaving identifiers set.
<code>DataFrame.explode(self, column, Tuple)</code>	Transform each element of a list-like to a row, replicating index values.
<code>DataFrame.squeeze(self[, axis])</code>	Squeeze 1 dimensional axis objects into scalars.
<code>DataFrame.to_xarray(self)</code>	Return an xarray object from the pandas object.
<code>DataFrame.T</code>	Transpose index and columns.
<code>DataFrame.transpose(self, *args, copy)</code>	Transpose index and columns.

#### 4.4.11 Combining / joining / merging

<code>DataFrame.append(self, other[, ...])</code>	Append rows of <i>other</i> to the end of caller, returning a new object.
<code>DataFrame.assign(self, **kwargs)</code>	Assign new columns to a DataFrame.
<code>DataFrame.join(self, other[, on, how, ...])</code>	Join columns of another DataFrame.
<code>DataFrame.merge(self, right[, how, on, ...])</code>	Merge DataFrame or named Series objects with a database-style join.
<code>DataFrame.update(self, other[, join, ...])</code>	Modify in place using non-NA values from another DataFrame.

#### 4.4.12 Time series-related

<code>DataFrame.asfreq(self, freq[, method, ...])</code>	Convert TimeSeries to specified frequency.
<code>DataFrame.asof(self, where[, subset])</code>	Return the last row(s) without any NaNs before <i>where</i> .
<code>DataFrame.shift(self[, periods, freq, axis, ...])</code>	Shift index by desired number of periods with an optional time <i>freq</i> .
<code>DataFrame.slice_shift(self, periods[, axis])</code>	Equivalent to <i>shift</i> without copying data.
<code>DataFrame.tshift(self, periods[, freq, axis])</code>	Shift the time index, using the index's frequency if available.
<code>DataFrame.first_valid_index(self)</code>	Return index for first non-NA/null value.
<code>DataFrame.last_valid_index(self)</code>	Return index for last non-NA/null value.
<code>DataFrame.resample(self, rule[, axis, ...])</code>	Resample time-series data.
<code>DataFrame.to_period(self[, freq, axis, copy])</code>	Convert DataFrame from DatetimeIndex to PeriodIndex.

Continued on next page

Table 71 – continued from previous page

<code>DataFrame.to_timestamp(self[, freq, how, ...])</code>	Cast to DatetimeIndex of timestamps, at <i>beginning</i> of period.
<code>DataFrame.tz_convert(self, tz[, axis, level])</code>	Convert tz-aware axis to target time zone.
<code>DataFrame.tz_localize(self, tz[, axis, ...])</code>	Localize tz-naive index of a Series or DataFrame to target time zone.

#### 4.4.13 Metadata

`DataFrame.attrs` is a dictionary for storing global metadata for this DataFrame.

**Warning:** `DataFrame.attrs` is considered experimental and may change without warning.

<code>DataFrame.attrs</code>	Dictionary of global attributes on this object.
------------------------------	-------------------------------------------------

#### 4.4.14 Plotting

`DataFrame.plot` is both a callable method and a namespace attribute for specific plotting methods of the form `DataFrame.plot.<kind>`.

<code>DataFrame.plot([x, y, kind, ax, ...])</code>	DataFrame plotting accessor and method
<code>DataFrame.plot.area(self[, x, y])</code>	Draw a stacked area plot.
<code>DataFrame.plot.bar(self[, x, y])</code>	Vertical bar plot.
<code>DataFrame.plot.barh(self[, x, y])</code>	Make a horizontal bar plot.
<code>DataFrame.plot.box(self[, by])</code>	Make a box plot of the DataFrame columns.
<code>DataFrame.plot.density(self[, bw_method, ind])</code>	Generate Kernel Density Estimate plot using Gaussian kernels.
<code>DataFrame.plot.hexbin(self, x, y[, C, ...])</code>	Generate a hexagonal binning plot.
<code>DataFrame.plot.hist(self[, by, bins])</code>	Draw one histogram of the DataFrame's columns.
<code>DataFrame.plot.kde(self[, bw_method, ind])</code>	Generate Kernel Density Estimate plot using Gaussian kernels.
<code>DataFrame.plot.line(self[, x, y])</code>	Plot Series or DataFrame as lines.
<code>DataFrame.plot.pie(self, **kwargs)</code>	Generate a pie plot.
<code>DataFrame.plot.scatter(self, x, y[, s, c])</code>	Create a scatter plot with varying marker point size and color.

#### pandas.DataFrame.plot.area

`DataFrame.plot.area(self, x=None, y=None, **kwargs)`

Draw a stacked area plot.

An area plot displays quantitative data visually. This function wraps the matplotlib area function.

##### Parameters

**x** [label or position, optional] Coordinates for the X axis. By default uses the index.

**y** [label or position, optional] Column to plot. By default uses all columns.

**stacked** [bool, default True] Area plots are stacked by default. Set to False to create an unstacked plot.

**\*\*kwargs** Additional keyword arguments are documented in `DataFrame.plot()`.

#### Returns

**matplotlib.axes.Axes or numpy.ndarray** Area plot, or array of area plots if subplots is True.

#### See also:

**`DataFrame.plot`** Make plots of DataFrame using matplotlib / pylab.

#### Examples

Draw an area plot based on basic business metrics:

```
>>> df = pd.DataFrame({
...     'sales': [3, 2, 3, 9, 10, 6],
...     'signups': [5, 5, 6, 12, 14, 13],
...     'visits': [20, 42, 28, 62, 81, 50],
... }, index=pd.date_range(start='2018/01/01', end='2018/07/01',
...                          freq='M'))
>>> ax = df.plot.area()
```

Area plots are stacked by default. To produce an unstacked plot, pass `stacked=False`:

```
>>> ax = df.plot.area(stacked=False)
```

Draw an area plot for a single column:

```
>>> ax = df.plot.area(y='sales')
```

Draw with a different x:

```
>>> df = pd.DataFrame({
...     'sales': [3, 2, 3],
...     'visits': [20, 42, 28],
...     'day': [1, 2, 3],
... })
>>> ax = df.plot.area(x='day')
```

## pandas.DataFrame.plot.bar

DataFrame.plot.**bar** (*self*, *x=None*, *y=None*, *\*\*kwargs*)

Vertical bar plot.

A bar plot is a plot that presents categorical data with rectangular bars with lengths proportional to the values that they represent. A bar plot shows comparisons among discrete categories. One axis of the plot shows the specific categories being compared, and the other axis represents a measured value.

### Parameters

**x** [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.

**y** [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.

**\*\*kwargs** Additional keyword arguments are documented in `DataFrame.plot()`.

### Returns

**matplotlib.axes.Axes or np.ndarray of them** An ndarray is returned with one `matplotlib.axes.Axes` per column when `subplots=True`.

See also:

**DataFrame.plot.barh** Horizontal bar plot.

**DataFrame.plot** Make plots of a DataFrame.

**matplotlib.pyplot.bar** Make a bar plot with matplotlib.

## Examples

Basic plot.

```
>>> df = pd.DataFrame({'lab':['A', 'B', 'C'], 'val':[10, 30, 20]})
>>> ax = df.plot.bar(x='lab', y='val', rot=0)
```

Plot a whole dataframe to a bar plot. Each column is assigned a distinct color, and each row is nested in a group along the horizontal axis.

```
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
...         'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...                   'lifespan': lifespan}, index=index)
>>> ax = df.plot.bar(rot=0)
```

Instead of nesting, the figure can be split by column with `subplots=True`. In this case, a `numpy.ndarray` of `matplotlib.axes.Axes` are returned.

```
>>> axes = df.plot.bar(rot=0, subplots=True)
>>> axes[1].legend(loc=2)
```

Plot a single column.

```
>>> ax = df.plot.bar(y='speed', rot=0)
```

Plot only selected categories for the DataFrame.

```
>>> ax = df.plot.bar(x='lifespan', rot=0)
```

### pandas.DataFrame.plot.barh

`DataFrame.plot.barh` (*self*, *x=None*, *y=None*, *\*\*kwargs*)

Make a horizontal bar plot.

A horizontal bar plot is a plot that presents quantitative data with rectangular bars with lengths proportional to the values that they represent. A bar plot shows comparisons among discrete categories. One axis of the plot shows the specific categories being compared, and the other axis represents a measured value.

#### Parameters

**x** [label or position, default `DataFrame.index`] Column to be used for categories.

**y** [label or position, default All numeric columns in dataframe] Columns to be plotted from the DataFrame.

**\*\*kwargs** Keyword arguments to pass on to `DataFrame.plot()`.

#### Returns

`matplotlib.axes.Axes` or `numpy.ndarray` of them

See also:

`DataFrame.plot.bar` Vertical bar plot.

`DataFrame.plot` Make plots of DataFrame using matplotlib.  
`matplotlib.axes.Axes.bar` Plot a vertical bar plot using matplotlib.

## Examples

Basic example

```
>>> df = pd.DataFrame({'lab': ['A', 'B', 'C'], 'val': [10, 30, 20]})
>>> ax = df.plot.barh(x='lab', y='val')
```

Plot a whole DataFrame to a horizontal bar plot

```
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
...         'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...                   'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh()
```

Plot a column of the DataFrame to a horizontal bar plot

```
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
```

(continues on next page)

(continued from previous page)

```
>>> index = ['snail', 'pig', 'elephant',
...          'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...                    'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh(y='speed')
```

Plot DataFrame versus the desired column

```
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
...          'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...                    'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh(x='lifespan')
```

## pandas.DataFrame.plot.box

`DataFrame.plot.box` (*self*, *by=None*, *\*\*kwargs*)

Make a box plot of the DataFrame columns.

A box plot is a method for graphically depicting groups of numerical data through their quartiles. The box extends from the Q1 to Q3 quartile values of the data, with a line at the median (Q2). The whiskers extend from the edges of box to show the range of the data. The position of the whiskers is set by default to  $1.5 \times \text{IQR}$  ( $\text{IQR} = \text{Q3} - \text{Q1}$ ) from the edges of the box. Outlier points are those past the end of the whiskers.

For further details see Wikipedia's entry for [boxplot](#).

A consideration when using this chart is that the box and the whiskers can overlap, which is very common when plotting small sets of data.

### Parameters

**by** [str or sequence] Column in the DataFrame to group by.

**\*\*kwargs** Additional keywords are documented in `DataFrame.plot()`.

### Returns

`matplotlib.axes.Axes` or `numpy.ndarray` of them

See also:

**`DataFrame.boxplot`** Another method to draw a box plot.

**`Series.plot.box`** Draw a box plot from a Series object.

**`matplotlib.pyplot.boxplot`** Draw a box plot in matplotlib.

## Examples

Draw a box plot from a DataFrame with four columns of randomly generated data.

```
>>> data = np.random.randn(25, 4)
>>> df = pd.DataFrame(data, columns=list('ABCD'))
>>> ax = df.plot.box()
```

## pandas.DataFrame.plot.density

`DataFrame.plot.density` (*self*, *bw\_method=None*, *ind=None*, *\*\*kwargs*)

Generate Kernel Density Estimate plot using Gaussian kernels.

In statistics, [kernel density estimation](#) (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

### Parameters

**bw\_method** [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be 'scott', 'silverman', a scalar constant or a callable. If None (default), 'scott' is used. See `scipy.stats.gaussian_kde` for more information.

**ind** [NumPy array or int, optional] Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If *ind* is a NumPy array, the KDE is evaluated at the points passed. If *ind* is an integer, *ind* number of equally spaced points are used.

**\*\*kwargs** Additional keyword arguments are documented in `pandas.% (this-datatype)s.plot()`.

### Returns

`matplotlib.axes.Axes` or `numpy.ndarray` of them

See also:

`scipy.stats.gaussian_kde` Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.

### Examples

Given a Series of points randomly sampled from an unknown distribution, estimate its PDF using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```
>>> s = pd.Series([1, 2, 2.5, 3, 3.5, 4, 5])
>>> ax = s.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```
>>> ax = s.plot.kde(bw_method=0.3)
```

```
>>> ax = s.plot.kde(bw_method=3)
```

Finally, the `ind` parameter determines the evaluation points for the plot of the estimated PDF:

```
>>> ax = s.plot.kde(ind=[1, 2, 3, 4, 5])
```

For DataFrame, it works in the same way:

```
>>> df = pd.DataFrame({
...     'x': [1, 2, 2.5, 3, 3.5, 4, 5],
...     'y': [4, 4, 4.5, 5, 5.5, 6, 6],
... })
>>> ax = df.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```
>>> ax = df.plot.kde(bw_method=0.3)
```

```
>>> ax = df.plot.kde(bw_method=3)
```

Finally, the *ind* parameter determines the evaluation points for the plot of the estimated PDF:

```
>>> ax = df.plot.kde(ind=[1, 2, 3, 4, 5, 6])
```

## pandas.DataFrame.plot.hexbin

`DataFrame.plot.hexbin` (*self*, *x*, *y*, *C=None*, *reduce\_C\_function=None*, *gridsize=None*, *\*\*kwargs*)

Generate a hexagonal binning plot.

Generate a hexagonal binning plot of *x* versus *y*. If *C* is *None* (the default), this is a histogram of the number of occurrences of the observations at  $(x[i], y[i])$ .

If *C* is specified, specifies values at given coordinates  $(x[i], y[i])$ . These values are accumulated for each hexagonal bin and then reduced according to *reduce\_C\_function*, having as default the NumPy's mean function (`numpy.mean()`). (If *C* is specified, it must also be a 1-D sequence of the same length as *x* and *y*, or a column label.)

### Parameters

**x** [int or str] The column label or position for x points.

**y** [int or str] The column label or position for y points.

**C** [int or str, optional] The column label or position for the value of (*x*, *y*) point.

**reduce\_C\_function** [callable, default `np.mean`] Function of one argument that reduces all the values in a bin to a single number (e.g. `np.mean`, `np.max`, `np.sum`, `np.std`).

**gridsize** [int or tuple of (int, int), default 100] The number of hexagons in the x-direction. The corresponding number of hexagons in the y-direction is chosen in a way that the hexagons are approximately regular. Alternatively, *gridsize* can be a tuple with two elements specifying the number of hexagons in the x-direction and the y-direction.

**\*\*kwargs** Additional keyword arguments are documented in `DataFrame.plot()`.

### Returns

**matplotlib.AxesSubplot** The matplotlib `AXES` on which the hexbin is plotted.

See also:

**DataFrame.plot** Make plots of a DataFrame.

**matplotlib.pyplot.hexbin** Hexagonal binning plot using matplotlib, the matplotlib function that is used under the hood.

## Examples

The following examples are generated with random data from a normal distribution.

```
>>> n = 10000
>>> df = pd.DataFrame({'x': np.random.randn(n),
...                   'y': np.random.randn(n)})
>>> ax = df.plot.hexbin(x='x', y='y', gridsize=20)
```

The next example uses *C* and `np.sum` as *reduce\_C\_function*. Note that '*observations*' values ranges from 1 to 5 but the result plot shows values up to more than 25. This is because of the *reduce\_C\_function*.

```
>>> n = 500
>>> df = pd.DataFrame({
...     'coord_x': np.random.uniform(-3, 3, size=n),
...     'coord_y': np.random.uniform(30, 50, size=n),
...     'observations': np.random.randint(1, 5, size=n)
... })
>>> ax = df.plot.hexbin(x='coord_x',
...                     y='coord_y',
```

(continues on next page)

(continued from previous page)

```

...     C='observations',
...     reduce_C_function=np.sum,
...     gridsize=10,
...     cmap="viridis")

```

### pandas.DataFrame.plot.hist

`DataFrame.plot.hist` (*self*, *by=None*, *bins=10*, *\*\*kwargs*)

Draw one histogram of the DataFrame's columns.

A histogram is a representation of the distribution of data. This function groups the values of all given Series in the DataFrame into bins and draws all bins in one `matplotlib.axes.Axes`. This is useful when the DataFrame's Series are in a similar scale.

#### Parameters

**by** [str or sequence, optional] Column in the DataFrame to group by.

**bins** [int, default 10] Number of histogram bins to be used.

**\*\*kwargs** Additional keyword arguments are documented in `DataFrame.plot()`.

#### Returns

**class:matplotlib.AxesSubplot** Return a histogram plot.

See also:

**DataFrame.hist** Draw histograms per DataFrame's Series.

**Series.hist** Draw a histogram with Series' data.

### Examples

When we draw a dice 6000 times, we expect to get each value around 1000 times. But when we draw two dices and sum the result, the distribution is going to be quite different. A histogram illustrates those distributions.

```
>>> df = pd.DataFrame(  
...     np.random.randint(1, 7, 6000),  
...     columns = ['one'])  
>>> df['two'] = df['one'] + np.random.randint(1, 7, 6000)  
>>> ax = df.plot.hist(bins=12, alpha=0.5)
```

## pandas.DataFrame.plot.kde

`DataFrame.plot.kde` (*self*, *bw\_method=None*, *ind=None*, *\*\*kwargs*)  
 Generate Kernel Density Estimate plot using Gaussian kernels.

In statistics, [kernel density estimation](#) (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

### Parameters

**bw\_method** [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be 'scott', 'silverman', a scalar constant or a callable. If None (default), 'scott' is used. See `scipy.stats.gaussian_kde` for more information.

**ind** [NumPy array or int, optional] Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If *ind* is a NumPy array, the KDE is evaluated at the points passed. If *ind* is an integer, *ind* number of equally spaced points are used.

**\*\*kwargs** Additional keyword arguments are documented in `pandas.% (this-datatype) s.plot ()`.

### Returns

`matplotlib.axes.Axes` or `numpy.ndarray` of them

See also:

`scipy.stats.gaussian_kde` Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.

### Examples

Given a Series of points randomly sampled from an unknown distribution, estimate its PDF using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```
>>> s = pd.Series([1, 2, 2.5, 3, 3.5, 4, 5])
>>> ax = s.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```
>>> ax = s.plot.kde(bw_method=0.3)
```

```
>>> ax = s.plot.kde(bw_method=3)
```

Finally, the *ind* parameter determines the evaluation points for the plot of the estimated PDF:

```
>>> ax = s.plot.kde(ind=[1, 2, 3, 4, 5])
```

For DataFrame, it works in the same way:

```
>>> df = pd.DataFrame({
...     'x': [1, 2, 2.5, 3, 3.5, 4, 5],
...     'y': [4, 4, 4.5, 5, 5.5, 6, 6],
... })
>>> ax = df.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```
>>> ax = df.plot.kde(bw_method=0.3)
```

```
>>> ax = df.plot.kde(bw_method=3)
```

Finally, the *ind* parameter determines the evaluation points for the plot of the estimated PDF:

```
>>> ax = df.plot.kde(ind=[1, 2, 3, 4, 5, 6])
```

### pandas.DataFrame.plot.line

`DataFrame.plot.line` (*self*, *x=None*, *y=None*, *\*\*kwargs*)

Plot Series or DataFrame as lines.

This function is useful to plot lines using DataFrame's values as coordinates.

#### Parameters

- x** [int or str, optional] Columns to use for the horizontal axis. Either the location or the label of the columns to be used. By default, it will use the DataFrame indices.
- y** [int, str, or list of them, optional] The values to be plotted. Either the location or the label of the columns to be used. By default, it will use the remaining DataFrame numeric columns.

**\*\*kwargs** Keyword arguments to pass on to `DataFrame.plot()`.

**Returns**

`matplotlib.axes.Axes` or `numpy.ndarray` Return an ndarray when `subplots=True`.

**See also:**

`matplotlib.pyplot.plot` Plot y versus x as lines and/or markers.

**Examples**

```
>>> s = pd.Series([1, 3, 2])
>>> s.plot.line()
```

The following example shows the populations for some animals over the years.

```
>>> df = pd.DataFrame({
...     'pig': [20, 18, 489, 675, 1776],
...     'horse': [4, 25, 281, 600, 1900]
... }, index=[1990, 1997, 2003, 2009, 2014])
>>> lines = df.plot.line()
```

An example with subplots, so an array of axes is returned.

```
>>> axes = df.plot.line(subplots=True)
>>> type(axes)
<class 'numpy.ndarray'>
```

The following example shows the relationship between both populations.

```
>>> lines = df.plot.line(x='pig', y='horse')
```

### pandas.DataFrame.plot.pie

`DataFrame.plot.pie` (*self*, *\*\*kwargs*)

Generate a pie plot.

A pie plot is a proportional representation of the numerical data in a column. This function wraps `matplotlib.pyplot.pie()` for the specified column. If no column reference is passed and `subplots=True` a pie plot is drawn for each numerical column independently.

#### Parameters

**y** [int or label, optional] Label or position of the column to plot. If not provided, `subplots=True` argument must be passed.

**\*\*kwargs** Keyword arguments to pass on to `DataFrame.plot()`.

#### Returns

**matplotlib.axes.Axes or np.ndarray of them** A NumPy array is returned when *subplots* is True.

See also:

**Series.plot.pie** Generate a pie plot for a Series.

**DataFrame.plot** Make plots of a DataFrame.

## Examples

In the example below we have a DataFrame with the information about planet's mass and radius. We pass the 'mass' column to the pie function to get a pie plot.

```
>>> df = pd.DataFrame({'mass': [0.330, 4.87, 5.97],
...                   'radius': [2439.7, 6051.8, 6378.1]},
...                   index=['Mercury', 'Venus', 'Earth'])
>>> plot = df.plot.pie(y='mass', figsize=(5, 5))
```

```
>>> plot = df.plot.pie(subplots=True, figsize=(6, 3))
```

### pandas.DataFrame.plot.scatter

`DataFrame.plot.scatter` (*self*, *x*, *y*, *s=None*, *c=None*, *\*\*kwargs*)

Create a scatter plot with varying marker point size and color.

The coordinates of each point are defined by two dataframe columns and filled circles are used to represent each point. This kind of plot is useful to see complex correlations between two variables. Points could be for instance natural 2D coordinates like longitude and latitude in a map or, in general, any pair of metrics that can be plotted against each other.

#### Parameters

- x** [int or str] The column name or column position to be used as horizontal coordinates for each point.
- y** [int or str] The column name or column position to be used as vertical coordinates for each point.
- s** [scalar or array\_like, optional] The size of each point. Possible values are:
  - A single scalar so all points have the same size.
  - A sequence of scalars, which will be used for each point's size recursively. For instance, when passing [2,14] all points size will be either 2 or 14, alternatively.
- c** [str, int or array\_like, optional] The color of each point. Possible values are:
  - A single color string referred to by name, RGB or RGBA code, for instance 'red' or '#a98d19'.
  - A sequence of color strings referred to by name, RGB or RGBA code, which will be used for each point's color recursively. For instance ['green','yellow'] all points will be filled in green or yellow, alternatively.
  - A column name or position whose values will be used to color the marker points according to a colormap.

**\*\*kwargs** Keyword arguments to pass on to `DataFrame.plot()`.

#### Returns

`matplotlib.axes.Axes` or `numpy.ndarray` of them

See also:

`matplotlib.pyplot.scatter` Scatter plot using multiple input data formats.

## Examples

Let's see how to draw a scatter plot using coordinates from the values in a DataFrame's columns.

```
>>> df = pd.DataFrame([[5.1, 3.5, 0], [4.9, 3.0, 0], [7.0, 3.2, 1],
...                    [6.4, 3.2, 1], [5.9, 3.0, 2]],
...                    columns=['length', 'width', 'species'])
>>> ax1 = df.plot.scatter(x='length',
...                        y='width',
...                        c='DarkBlue')
```

And now with the color determined by a column as well.

```
>>> ax2 = df.plot.scatter(x='length',
...                        y='width',
...                        c='species',
...                        colormap='viridis')
```

<code>DataFrame.boxplot(self[, column, by, ax, ...])</code>	Make a box plot from DataFrame columns.
<code>DataFrame.hist(data[, column, by, grid, ...])</code>	Make a histogram of the DataFrame's.

---

### 4.4.15 Sparse accessor

Sparse-dtype specific methods and attributes are provided under the `DataFrame.sparse` accessor.

<code>DataFrame.sparse.density</code>	Ratio of non-sparse points to total (dense) data points.
---------------------------------------	----------------------------------------------------------

---

#### `pandas.DataFrame.sparse.density`

`DataFrame.sparse.density`  
Ratio of non-sparse points to total (dense) data points.

<code>DataFrame.sparse.from_spmatrix(data[, ...])</code>	Create a new DataFrame from a scipy sparse matrix.
<code>DataFrame.sparse.to_coo(self)</code>	Return the contents of the frame as a sparse SciPy COO matrix.
<code>DataFrame.sparse.to_dense(self)</code>	Convert a DataFrame with sparse values to dense.

---

#### `pandas.DataFrame.sparse.from_spmatrix`

**classmethod** `sparse.from_spmatrix` (*data*, *index=None*, *columns=None*)

Create a new DataFrame from a scipy sparse matrix.

New in version 0.25.0.

##### Parameters

**data** [`scipy.sparse.spmatrix`] Must be convertible to csc format.

**index, columns** [`Index`, optional] Row and column labels to use for the resulting DataFrame. Defaults to a `RangeIndex`.

##### Returns

**DataFrame** Each column of the DataFrame is stored as a `arrays.SparseArray`.

#### Examples

```
>>> import scipy.sparse
>>> mat = scipy.sparse.eye(3)
>>> pd.DataFrame.sparse.from_spmatrix(mat)
   0  1  2
0  1.0  0.0  0.0
1  0.0  1.0  0.0
2  0.0  0.0  1.0
```

**pandas.DataFrame.sparse.to\_coo**`sparse.to_coo` (*self*)

Return the contents of the frame as a sparse SciPy COO matrix.

New in version 0.25.0.

**Returns****coo\_matrix** [`scipy.sparse.spmatrix`] If the caller is heterogeneous and contains booleans or objects, the result will be of `dtype=object`. See Notes.**Notes**

The dtype will be the lowest-common-denominator type (implicit upcasting); that is to say if the dtypes (even of numeric types) are mixed, the one that accommodates all will be chosen.

e.g. If the dtypes are float16 and float32, dtype will be upcast to float32. By `numpy.find_common_type` convention, mixing int64 and uint64 will result in a float64 dtype.**pandas.DataFrame.sparse.to\_dense**`sparse.to_dense` (*self*)

Convert a DataFrame with sparse values to dense.

New in version 0.25.0.

**Returns****DataFrame** A DataFrame with the same values stored as dense arrays.**Examples**

```
>>> df = pd.DataFrame({"A": pd.arrays.SparseArray([0, 1, 0])})
>>> df.sparse.to_dense()
   A
0  0
1  1
2  0
```

**4.4.16 Serialization / IO / conversion**

<code>DataFrame.from_dict(data[, orient, dtype, ...])</code>	Construct DataFrame from dict of array-like or dicts.
<code>DataFrame.from_records(data[, index, ...])</code>	Convert structured or record ndarray to DataFrame.
<code>DataFrame.info(self[, verbose, buf, ...])</code>	Print a concise summary of a DataFrame.
<code>DataFrame.to_parquet(self, path[, engine, ...])</code>	Write a DataFrame to the binary parquet format.
<code>DataFrame.to_pickle(self, path, compression, ...)</code>	Pickle (serialize) object to file.
<code>DataFrame.to_csv(self, path_or_buf, ...)</code>	Write object to a comma-separated values (csv) file.
<code>DataFrame.to_hdf(self, path_or_buf, key, ...)</code>	Write the contained data to an HDF5 file using HDFStore.
<code>DataFrame.to_sql(self, name, con[, schema, ...])</code>	Write records stored in a DataFrame to a SQL database.
<code>DataFrame.to_dict(self[, orient, into])</code>	Convert the DataFrame to a dictionary.

Continued on next page

Table 78 – continued from previous page

<code>DataFrame.to_excel(self, excel_writer[, ...])</code>	Write object to an Excel sheet.
<code>DataFrame.to_json(self, path_or_buf, ...)</code>	Convert the object to a JSON string.
<code>DataFrame.to_html(self[, buf, columns, ...])</code>	Render a DataFrame as an HTML table.
<code>DataFrame.to_feather(self, path)</code>	Write out the binary feather-format for DataFrames.
<code>DataFrame.to_latex(self[, buf, columns, ...])</code>	Render object to a LaTeX tabular, longtable, or nested table/tabular.
<code>DataFrame.to_stata(self, path[, ...])</code>	Export DataFrame object to Stata dta format.
<code>DataFrame.to_gbq(self, destination_table[, ...])</code>	Write a DataFrame to a Google BigQuery table.
<code>DataFrame.to_records(self[, index, ...])</code>	Convert DataFrame to a NumPy record array.
<code>DataFrame.to_string(self, buf, pathlib.Path, ...)</code>	Render a DataFrame to a console-friendly tabular output.
<code>DataFrame.to_clipboard(self, excel, sep, ...)</code>	Copy object to the system clipboard.
<code>DataFrame.to_markdown(self, buf, ...)</code>	Print DataFrame in Markdown-friendly format.
<code>DataFrame.style</code>	Returns a Styler object.

{{ header }}

## 4.5 Pandas arrays

For most data types, pandas uses NumPy arrays as the concrete objects contained with a *Index*, *Series*, or *DataFrame*.

For some data types, pandas extends NumPy’s type system. String aliases for these types can be found at *dtypes*.

Kind of Data	Pandas Data Type	Scalar	Array
TZ-aware datetime	<i>DatetimeTZDtype</i>	<i>Timestamp</i>	<i>Datetime data</i>
Timedeltas	(none)	<i>Timedelta</i>	<i>Timedelta data</i>
Period (time spans)	<i>PeriodDtype</i>	<i>Period</i>	<i>Timespan data</i>
Intervals	<i>IntervalDtype</i>	<i>Interval</i>	<i>Interval data</i>
Nullable Integer	<i>Int64Dtype, ...</i>	(none)	<i>Nullable integer</i>
Categorical	<i>CategoricalDtype</i>	(none)	<i>Categorical data</i>
Sparse	<i>SparseDtype</i>	(none)	<i>Sparse data</i>
Strings	<i>StringDtype</i>	<i>str</i>	<i>Text data</i>
Boolean (with NA)	<i>BooleanDtype</i>	<i>bool</i>	<i>Boolean data with missing values</i>

Pandas and third-party libraries can extend NumPy’s type system (see *Extension types*). The top-level `array()` method can be used to create a new array, which may be stored in a *Series*, *Index*, or as a column in a *DataFrame*.

<code>array(data, dtype, numpy.dtype, ...)</code>	Create an array.
---------------------------------------------------	------------------

### 4.5.1 pandas.array

`pandas.array` (*data*: Sequence[object], *dtype*: Union[str, numpy.dtype, pandas.core.dtypes.base.ExtensionDtype, NoneType] = None, *copy*: bool = True) → pandas.core.dtypes.generic.ABCExtensionArray

Create an array.

New in version 0.24.0.

#### Parameters

**data** [Sequence of objects] The scalars inside *data* should be instances of the scalar type for *dtype*. It's expected that *data* represents a 1-dimensional array of data.

When *data* is an Index or Series, the underlying array will be extracted from *data*.

**dtype** [str, np.dtype, or ExtensionDtype, optional] The dtype to use for the array. This may be a NumPy dtype or an extension type registered with pandas using `pandas.api.extensions.register_extension_dtype()`.

If not specified, there are two possibilities:

1. When *data* is a *Series*, *Index*, or *ExtensionArray*, the *dtype* will be taken from the data.
2. Otherwise, pandas will attempt to infer the *dtype* from the data.

Note that when *data* is a NumPy array, `data.dtype` is *not* used for inferring the array type. This is because NumPy cannot represent all the types of data that can be held in extension arrays.

Currently, pandas will infer an extension dtype for sequences of

Scalar Type	Array Type
<code>pandas.Interval</code>	<code>pandas.arrays.IntervalArray</code>
<code>pandas.Period</code>	<code>pandas.arrays.PeriodArray</code>
<code>datetime.datetime</code>	<code>pandas.arrays.DatetimeArray</code>
<code>datetime.timedelta</code>	<code>pandas.arrays.TimedeltaArray</code>
<code>int</code>	<code>pandas.arrays.IntegerArray</code>
<code>str</code>	<code>pandas.arrays.StringArray</code>
<code>bool</code>	<code>pandas.arrays.BooleanArray</code>

For all other cases, NumPy's usual inference rules will be used.

Changed in version 1.0.0: Pandas infers nullable-integer dtype for integer data, string dtype for string data, and nullable-boolean dtype for boolean data.

**copy** [bool, default True] Whether to copy the data, even if not necessary. Depending on the type of *data*, creating the new array may require copying data, even if `copy=False`.

#### Returns

**ExtensionArray** The newly created array.

#### Raises

**ValueError** When *data* is not 1-dimensional.

**See also:**

**numpy.array** Construct a NumPy array.

**Series** Construct a pandas Series.

**Index** Construct a pandas Index.

**`arrays.PandasArray`** ExtensionArray wrapping a NumPy array.  
**`Series.array`** Extract the array stored within a Series.

## Notes

Omitting the `dtype` argument means pandas will attempt to infer the best array type from the values in the data. As new array types are added by pandas and 3rd party libraries, the “best” array type may change. We recommend specifying `dtype` to ensure that

1. the correct array type for the data is returned
  2. the returned array type doesn't change as new extension types are added by pandas and third-party libraries
- Additionally, if the underlying memory representation of the returned array matters, we recommend specifying the `dtype` as a concrete object rather than a string alias or allowing it to be inferred. For example, a future version of pandas or a 3rd-party library may include a dedicated ExtensionArray for string data. In this event, the following would no longer return a `arrays.PandasArray` backed by a NumPy array.

```
>>> pd.array(['a', 'b'], dtype=str)
<PandasArray>
['a', 'b']
Length: 2, dtype: str32
```

This would instead return the new ExtensionArray dedicated for string data. If you really need the new array to be backed by a NumPy array, specify that in the `dtype`.

```
>>> pd.array(['a', 'b'], dtype=np.dtype("<U1"))
<PandasArray>
['a', 'b']
Length: 2, dtype: str32
```

Finally, Pandas has arrays that mostly overlap with NumPy

- `arrays.DatetimeArray`
- `arrays.TimedeltaArray`

When data with a `datetime64[ns]` or `timedelta64[ns]` `dtype` is passed, pandas will always return a `DatetimeArray` or `TimedeltaArray` rather than a `PandasArray`. This is for symmetry with the case of timezone-aware data, which NumPy does not natively support.

```
>>> pd.array(['2015', '2016'], dtype='datetime64[ns]')
<DatetimeArray>
['2015-01-01 00:00:00', '2016-01-01 00:00:00']
Length: 2, dtype: datetime64[ns]
```

```
>>> pd.array(["1H", "2H"], dtype='timedelta64[ns]')
<TimedeltaArray>
['01:00:00', '02:00:00']
Length: 2, dtype: timedelta64[ns]
```

## Examples

If a `dtype` is not specified, pandas will infer the best `dtype` from the values. See the description of `dtype` for the types pandas infers for.

```
>>> pd.array([1, 2])
<IntegerArray>
[1, 2]
Length: 2, dtype: Int64
```

```
>>> pd.array([1, 2, np.nan])
<IntegerArray>
[1, 2, NaN]
Length: 3, dtype: Int64
```

```
>>> pd.array(["a", None, "c"])
<StringArray>
['a', nan, 'c']
Length: 3, dtype: string
```

```
>>> pd.array([pd.Period('2000', freq="D"), pd.Period("2000", freq="D")])
<PeriodArray>
['2000-01-01', '2000-01-01']
Length: 2, dtype: period[D]
```

You can use the string alias for `dtype`

```
>>> pd.array(['a', 'b', 'a'], dtype='category')
[a, b, a]
Categories (2, object): [a, b]
```

Or specify the actual `dtype`

```
>>> pd.array(['a', 'b', 'a'],
...          dtype=pd.CategoricalDtype(['a', 'b', 'c'], ordered=True))
[a, b, a]
Categories (3, object): [a < b < c]
```

If pandas does not infer a dedicated extension type a `arrays.PandasArray` is returned.

```
>>> pd.array([1.1, 2.2])
<PandasArray>
[1.1, 2.2]
Length: 2, dtype: float64
```

As mentioned in the “Notes” section, new extension types may be added in the future (by pandas or 3rd party libraries), causing the return value to no longer be a `arrays.PandasArray`. Specify the `dtype` as a NumPy `dtype` if you need to ensure there’s no future change in behavior.

```
>>> pd.array([1, 2], dtype=np.dtype("int32"))
<PandasArray>
[1, 2]
Length: 2, dtype: int32
```

`data` must be 1-dimensional. A `ValueError` is raised when the input has the wrong dimensionality.

```
>>> pd.array(1)
Traceback (most recent call last):
...
ValueError: Cannot pass scalar '1' to 'pandas.array'.
```

## 4.5.2 Datetime data

NumPy cannot natively represent timezone-aware datetimes. Pandas supports this with the `arrays.DatetimeArray` extension array, which can hold timezone-naive or timezone-aware values.

`Timestamp`, a subclass of `datetime.datetime`, is pandas' scalar type for timezone-naive or timezone-aware datetime data.

<code>Timestamp</code>	Pandas replacement for python <code>datetime.datetime</code> object.
------------------------	----------------------------------------------------------------------

---

### pandas.Timestamp

**class** pandas.**Timestamp**

Pandas replacement for python `datetime.datetime` object.

`Timestamp` is the pandas equivalent of python's `Datetime` and is interchangeable with it in most cases. It's the type used for the entries that make up a `DatetimeIndex`, and other timeseries oriented data structures in pandas.

#### Parameters

**ts\_input** [datetime-like, str, int, float] Value to be converted to `Timestamp`.

**freq** [str, `DateOffset`] Offset which `Timestamp` will have.

**tz** [str, `pytz.timezone`, `dateutil.tz.tzfile` or None] Time zone for time which `Timestamp` will have.

**unit** [str] Unit used for conversion if `ts_input` is of type `int` or `float`. The valid values are 'D', 'h', 'm', 's', 'ms', 'us', and 'ns'. For example, 's' means seconds and 'ms' means milliseconds.

**year, month, day** [int]

**hour, minute, second, microsecond** [int, optional, default 0]

**nanosecond** [int, optional, default 0] New in version 0.23.0.

**tzinfo** [`datetime.tzinfo`, optional, default None]

#### Notes

There are essentially three calling conventions for the constructor. The primary form accepts four parameters. They can be passed by position or keyword.

The other two forms mimic the parameters from `datetime.datetime`. They can be passed by either position or keyword, but not both mixed together.

## Examples

Using the primary calling convention:

This converts a datetime-like string

```
>>> pd.Timestamp('2017-01-01T12')
Timestamp('2017-01-01 12:00:00')
```

This converts a float representing a Unix epoch in units of seconds

```
>>> pd.Timestamp(1513393355.5, unit='s')
Timestamp('2017-12-16 03:02:35.500000')
```

This converts an int representing a Unix-epoch in units of seconds and for a particular timezone

```
>>> pd.Timestamp(1513393355, unit='s', tz='US/Pacific')
Timestamp('2017-12-15 19:02:35-0800', tz='US/Pacific')
```

Using the other two forms that mimic the API for `datetime.datetime`:

```
>>> pd.Timestamp(2017, 1, 1, 12)
Timestamp('2017-01-01 12:00:00')
```

```
>>> pd.Timestamp(year=2017, month=1, day=1, hour=12)
Timestamp('2017-01-01 12:00:00')
```

## Attributes

<i>asm8</i>	Return numpy datetime64 format in nanoseconds.
<i>dayofweek</i>	Return day of the week.
<i>dayofyear</i>	Return the day of the year.
<i>days_in_month</i>	Return the number of days in the month.
<i>daysinmonth</i>	Return the number of days in the month.
<i>freqstr</i>	Return the total number of days in the month.
<i>is_leap_year</i>	Return True if year is a leap year.
<i>is_month_end</i>	Return True if date is last day of month.
<i>is_month_start</i>	Return True if date is first day of month.
<i>is_quarter_end</i>	Return True if date is last day of the quarter.
<i>is_quarter_start</i>	Return True if date is first day of the quarter.
<i>is_year_end</i>	Return True if date is last day of the year.
<i>is_year_start</i>	Return True if date is first day of the year.
<i>quarter</i>	Return the quarter of the year.
<i>tz</i>	Alias for <code>tzinfo</code> .
<i>week</i>	Return the week number of the year.
<i>weekofyear</i>	Return the week number of the year.

### **pandas.Timestamp.asm8**

`Timestamp.asm8`  
Return numpy datetime64 format in nanoseconds.

### **pandas.Timestamp.dayofweek**

**property** `Timestamp.dayofweek`  
Return day of the week.

### **pandas.Timestamp.dayofyear**

**property** `Timestamp.dayofyear`  
Return the day of the year.

### **pandas.Timestamp.days\_in\_month**

**property** `Timestamp.days_in_month`  
Return the number of days in the month.

### **pandas.Timestamp.daysinmonth**

**property** `Timestamp.daysinmonth`  
Return the number of days in the month.

### **pandas.Timestamp.freqstr**

**property** `Timestamp.freqstr`  
Return the total number of days in the month.

### **pandas.Timestamp.is\_leap\_year**

**property** `Timestamp.is_leap_year`  
Return True if year is a leap year.

### **pandas.Timestamp.is\_month\_end**

**property** `Timestamp.is_month_end`  
Return True if date is last day of month.

### **pandas.Timestamp.is\_month\_start**

**property** `Timestamp.is_month_start`  
Return True if date is first day of month.

### **pandas.Timestamp.is\_quarter\_end**

**property** `Timestamp.is_quarter_end`  
Return True if date is last day of the quarter.

### **pandas.Timestamp.is\_quarter\_start**

**property** `Timestamp.is_quarter_start`  
Return True if date is first day of the quarter.

### **pandas.Timestamp.is\_year\_end**

**property** `Timestamp.is_year_end`  
Return True if date is last day of the year.

### **pandas.Timestamp.is\_year\_start**

**property** `Timestamp.is_year_start`  
Return True if date is first day of the year.

### **pandas.Timestamp.quarter**

**property** `Timestamp.quarter`  
Return the quarter of the year.

### **pandas.Timestamp.tz**

**property** `Timestamp.tz`  
Alias for tzinfo.

### **pandas.Timestamp.week**

**property** `Timestamp.week`  
Return the week number of the year.

**pandas.Timestamp.weekofyear****property** `Timestamp.weekofyear`

Return the week number of the year.

<b>day</b>	
<b>fold</b>	
<b>freq</b>	
<b>hour</b>	
<b>microsecond</b>	
<b>minute</b>	
<b>month</b>	
<b>nanosecond</b>	
<b>second</b>	
<b>tzinfo</b>	
<b>value</b>	
<b>year</b>	

**Methods**

<code>astimezone(self, tz)</code>	Convert tz-aware Timestamp to another time zone.
<code>ceil(self, freq[, ambiguous, nonexistent])</code>	return a new Timestamp ceiled to this resolution.
<code>combine(date, time)</code>	date, time -> datetime with same date and time fields.
<code>ctime()</code>	Return ctime() style string.
<code>date()</code>	Return date object with same year, month and day.
<code>day_name(self[, locale])</code>	Return the day name of the Timestamp with specified locale.
<code>dst()</code>	Return self.tzinfo.dst(self).
<code>floor(self, freq[, ambiguous, nonexistent])</code>	return a new Timestamp floored to this resolution.
<code>fromisoformat()</code>	string -> datetime from datetime.isoformat() output
<code>fromordinal(ordinal[, freq, tz])</code>	Passed an ordinal, translate and convert to a ts.
<code>fromtimestamp(ts)</code>	timestamp[, tz] -> tz's local time from POSIX timestamp.
<code>isocalendar()</code>	Return a 3-tuple containing ISO year, week number, and weekday.
<code>isoweekday()</code>	Return the day of the week represented by the date.
<code>month_name(self[, locale])</code>	Return the month name of the Timestamp with specified locale.
<code>normalize(self)</code>	Normalize Timestamp to midnight, preserving tz information.
<code>now([tz])</code>	Return new Timestamp object representing current time local to tz.
<code>replace(self[, year, month, day, hour, ...])</code>	implements datetime.replace, handles nanoseconds.
<code>round(self, freq[, ambiguous, nonexistent])</code>	Round the Timestamp to the specified resolution.
<code>strftime()</code>	format -> strftime() style string.
<code>strptime(string, format)</code>	Function is not implemented.
<code>time()</code>	Return time object with same time but with tzinfo=None.
<code>timestamp()</code>	Return POSIX timestamp as float.

Continued on next page

Table 82 – continued from previous page

<code>timetuple()</code>	Return time tuple, compatible with <code>time.localtime()</code> .
<code>timetz()</code>	Return time object with same time and <code>tzinfo</code> .
<code>to_datetime64()</code>	Return a <code>numpy.datetime64</code> object with 'ns' precision.
<code>to_julian_date(self)</code>	Convert <code>TimeStamp</code> to a Julian Date.
<code>to_numpy()</code>	Convert the <code>TimeStamp</code> to a NumPy <code>datetime64</code> .
<code>to_period(self[, freq])</code>	Return an period of which this timestamp is an observation.
<code>to_pydatetime()</code>	Convert a <code>TimeStamp</code> object to a native Python date-time object.
<code>today(cls[, tz])</code>	Return the current time in the local timezone.
<code>toordinal()</code>	Return proleptic Gregorian ordinal.
<code>tz_convert(self, tz)</code>	Convert tz-aware <code>TimeStamp</code> to another time zone.
<code>tz_localize(self, tz[, ambiguous, nonexistent])</code>	Convert naive <code>TimeStamp</code> to local time zone, or remove timezone from tz-aware <code>TimeStamp</code> .
<code>tzname()</code>	Return <code>self.tzinfo.tzname(self)</code> .
<code>utcfromtimestamp(ts)</code>	Construct a naive UTC datetime from a POSIX timestamp.
<code>utcnow()</code>	Return a new <code>TimeStamp</code> representing UTC day and time.
<code>utcoffset()</code>	Return <code>self.tzinfo.utcoffset(self)</code> .
<code>utctimetuple()</code>	Return UTC time tuple, compatible with <code>time.localtime()</code> .
<code>weekday()</code>	Return the day of the week represented by the date.

### **pandas.Timestamp.astimezone**

`TimeStamp.astimezone(self, tz)`

Convert tz-aware `TimeStamp` to another time zone.

#### **Parameters**

**tz** [str, `pytz.timezone`, `dateutil.tz.tzfile` or `None`] Time zone for time which `TimeStamp` will be converted to. `None` will remove timezone holding UTC time.

#### **Returns**

**converted** [`TimeStamp`]

#### **Raises**

**TypeError** If `TimeStamp` is tz-naive.

### **pandas.Timestamp.ceil**

`TimeStamp.ceil(self, freq, ambiguous='raise', nonexistent='raise')`

return a new `TimeStamp` ceiled to this resolution.

#### **Parameters**

**freq** [str] Frequency string indicating the ceiling resolution.

**ambiguous** [bool or {'raise', 'NaT'}, default 'raise'] The behavior is as follows:

- `bool` contains flags to determine if time is dst or not (note that this flag is only applicable for ambiguous fall dst dates).
- `'NaT'` will return `NaT` for an ambiguous time.
- `'raise'` will raise an `AmbiguousTimeError` for an ambiguous time.

New in version 0.24.0.

**nonexistent** [{`'raise'`, `'shift_forward'`, `'shift_backward'`, `'NaT'`, `timedelta`}, default `'raise'`] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- `'shift_forward'` will shift the nonexistent time forward to the closest existing time.
- `'shift_backward'` will shift the nonexistent time backward to the closest existing time.
- `'NaT'` will return `NaT` where there are nonexistent times.
- `timedelta` objects will shift nonexistent times by the `timedelta`.
- `'raise'` will raise an `NonExistentTimeError` if there are nonexistent times.

New in version 0.24.0.

#### Raises

**ValueError if the freq cannot be converted.**

### `pandas.Timestamp.combine`

**classmethod** `Timestamp.combine` (*date, time*)  
date, time -> datetime with same date and time fields.

### `pandas.Timestamp.ctime`

`Timestamp.ctime` ()  
Return `ctime()` style string.

### `pandas.Timestamp.date`

`Timestamp.date` ()  
Return date object with same year, month and day.

### `pandas.Timestamp.day_name`

`Timestamp.day_name` (*self, locale=None*) → 'unicode'  
Return the day name of the `Timestamp` with specified locale.

#### Parameters

**locale** [string, default `None` (English locale)] Locale determining the language in which to return the day name.

#### Returns

**day\_name** [string]

New in version 0.23.0: ..

### **pandas.Timestamp.dst**

`Timestamp.dst()`

Return `self.tzinfo.dst(self)`.

### **pandas.Timestamp.floor**

`Timestamp.floor(self, freq, ambiguous='raise', nonexistent='raise')`

return a new Timestamp floored to this resolution.

#### **Parameters**

**freq** [str] Frequency string indicating the flooring resolution.

**ambiguous** [bool or {'raise', 'NaT'}, default 'raise'] The behavior is as follows:

- bool contains flags to determine if time is dst or not (note that this flag is only applicable for ambiguous fall dst dates).
- 'NaT' will return NaT for an ambiguous time.
- 'raise' will raise an `AmbiguousTimeError` for an ambiguous time.

New in version 0.24.0.

**nonexistent** [{'raise', 'shift\_forward', 'shift\_backward', 'NaT', timedelta}, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift\_forward' will shift the nonexistent time forward to the closest existing time.
- 'shift\_backward' will shift the nonexistent time backward to the closest existing time.
- 'NaT' will return NaT where there are nonexistent times.
- timedelta objects will shift nonexistent times by the timedelta.
- 'raise' will raise an `NonExistentTimeError` if there are nonexistent times.

New in version 0.24.0.

#### **Raises**

**ValueError** if the `freq` cannot be converted.

### **pandas.Timestamp.fromisoformat**

`Timestamp.fromisoformat()`  
string -> datetime from datetime.isoformat() output

### **pandas.Timestamp.fromordinal**

**classmethod** `Timestamp.fromordinal` (*ordinal, freq=None, tz=None*)  
Passed an ordinal, translate and convert to a ts. Note: by definition there cannot be any tz info on the ordinal itself.

#### **Parameters**

- ordinal** [int] Date corresponding to a proleptic Gregorian ordinal.
- freq** [str, DateOffset] Offset to apply to the Timestamp.
- tz** [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for the Timestamp.

### **pandas.Timestamp.fromtimestamp**

**classmethod** `Timestamp.fromtimestamp` (*ts*)  
timestamp[, tz] -> tz's local time from POSIX timestamp.

### **pandas.Timestamp.isocalendar**

`Timestamp.isocalendar()`  
Return a 3-tuple containing ISO year, week number, and weekday.

### **pandas.Timestamp.isoweekday**

`Timestamp.isoweekday()`  
Return the day of the week represented by the date. Monday == 1 ... Sunday == 7

### **pandas.Timestamp.month\_name**

`Timestamp.month_name` (*self, locale=None*) → 'unicode'  
Return the month name of the Timestamp with specified locale.

#### **Parameters**

- locale** [string, default None (English locale)] Locale determining the language in which to return the month name.

#### **Returns**

- month\_name** [string]
- New in version 0.23.0: ..

**pandas.Timestamp.normalize**`Timestamp.normalize` (*self*)

Normalize Timestamp to midnight, preserving tz information.

**pandas.Timestamp.now****classmethod** `Timestamp.now` (*tz=None*)

Return new Timestamp object representing current time local to tz.

**Parameters****tz** [str or timezone object, default None] Timezone to localize to.**pandas.Timestamp.replace**`Timestamp.replace` (*self, year=None, month=None, day=None, hour=None, minute=None, second=None, microsecond=None, nanosecond=None, tzinfo=<class 'object'>, fold=0*)

implements datetime.replace, handles nanoseconds.

**Parameters****year** [int, optional]**month** [int, optional]**day** [int, optional]**hour** [int, optional]**minute** [int, optional]**second** [int, optional]**microsecond** [int, optional]**nanosecond** [int, optional]**tzinfo** [tz-convertible, optional]**fold** [int, optional, default is 0]**Returns****Timestamp with fields replaced****pandas.Timestamp.round**`Timestamp.round` (*self, freq, ambiguous='raise', nonexistent='raise'*)

Round the Timestamp to the specified resolution.

**Parameters****freq** [str] Frequency string indicating the rounding resolution.**ambiguous** [bool or {'raise', 'NaT'}, default 'raise'] The behavior is as follows:

- bool contains flags to determine if time is dst or not (note that this flag is only applicable for ambiguous fall dst dates).

- 'NaT' will return NaT for an ambiguous time.
- 'raise' will raise an AmbiguousTimeError for an ambiguous time.

New in version 0.24.0.

**nonexistent** [{ 'raise', 'shift\_forward', 'shift\_backward', 'NaT', timedelta}, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift\_forward' will shift the nonexistent time forward to the closest existing time.
- 'shift\_backward' will shift the nonexistent time backward to the closest existing time.
- 'NaT' will return NaT where there are nonexistent times.
- timedelta objects will shift nonexistent times by the timedelta.
- 'raise' will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

#### Returns

a new **Timestamp** rounded to the given resolution of *freq*

#### Raises

**ValueError** if the *freq* cannot be converted

### pandas.Timestamp.strftime

`Timestamp.strftime()`  
format -> strftime() style string.

### pandas.Timestamp.strptime

**classmethod** `Timestamp.strptime(string, format)`  
Function is not implemented. Use `pd.to_datetime()`.

### pandas.Timestamp.time

`Timestamp.time()`  
Return time object with same time but with `tzinfo=None`.

### **pandas.Timestamp.timestamp**

`Timestamp.timestamp()`  
Return POSIX timestamp as float.

### **pandas.Timestamp.timetuple**

`Timestamp.timetuple()`  
Return time tuple, compatible with `time.localtime()`.

### **pandas.Timestamp.timetz**

`Timestamp.timetz()`  
Return time object with same time and tzinfo.

### **pandas.Timestamp.to\_datetime64**

`Timestamp.to_datetime64()`  
Return a `numpy.datetime64` object with 'ns' precision.

### **pandas.Timestamp.to\_julian\_date**

`Timestamp.to_julian_date(self)`  
Convert `TimeStamp` to a Julian Date. 0 Julian date is noon January 1, 4713 BC.

### **pandas.Timestamp.to\_numpy**

`Timestamp.to_numpy()`  
Convert the `Timestamp` to a NumPy `datetime64`.  
New in version 0.25.0.

This is an alias method for `Timestamp.to_datetime64()`. The `dtype` and `copy` parameters are available here only for compatibility. Their values will not affect the return value.

#### **Returns**

`numpy.datetime64`

#### **See also:**

`DatetimeIndex.to_numpy` Similar method for `DatetimeIndex`.

### **pandas.Timestamp.to\_period**

`Timestamp.to_period(self, freq=None)`

Return an period of which this timestamp is an observation.

### **pandas.Timestamp.to\_pydatetime**

`Timestamp.to_pydatetime()`

Convert a Timestamp object to a native Python datetime object.

If `warn=True`, issue a warning if nanoseconds is nonzero.

### **pandas.Timestamp.today**

**classmethod** `Timestamp.today(cls, tz=None)`

Return the current time in the local timezone. This differs from `datetime.today()` in that it can be localized to a passed timezone.

#### **Parameters**

**tz** [str or timezone object, default None] Timezone to localize to.

### **pandas.Timestamp.toordinal**

`Timestamp.toordinal()`

Return proleptic Gregorian ordinal. January 1 of year 1 is day 1.

### **pandas.Timestamp.tz\_convert**

`Timestamp.tz_convert(self, tz)`

Convert tz-aware Timestamp to another time zone.

#### **Parameters**

**tz** [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time which Timestamp will be converted to. None will remove timezone holding UTC time.

#### **Returns**

**converted** [Timestamp]

#### **Raises**

**TypeError** If Timestamp is tz-naive.

**pandas.Timestamp.tz\_localize**

`Timestamp.tz_localize` (*self*, *tz*, *ambiguous='raise'*, *nonexistent='raise'*)

Convert naive Timestamp to local time zone, or remove timezone from tz-aware Timestamp.

**Parameters**

**tz** [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time which Timestamp will be converted to. None will remove timezone holding local time.

**ambiguous** [bool, 'NaT', default 'raise'] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the *ambiguous* parameter dictates how ambiguous times should be handled.

The behavior is as follows:

- bool contains flags to determine if time is dst or not (note that this flag is only applicable for ambiguous fall dst dates).
- 'NaT' will return NaT for an ambiguous time.
- 'raise' will raise an AmbiguousTimeError for an ambiguous time.

**nonexistent** ['shift\_forward', 'shift\_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

The behavior is as follows:

- 'shift\_forward' will shift the nonexistent time forward to the closest existing time.
- 'shift\_backward' will shift the nonexistent time backward to the closest existing time.
- 'NaT' will return NaT where there are nonexistent times.
- timedelta objects will shift nonexistent times by the timedelta.
- 'raise' will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

**Returns**

**localized** [Timestamp]

**Raises**

**TypeError** If the Timestamp is tz-aware and tz is not None.

### **pandas.Timestamp.tzname**

`Timestamp.tzname()`  
Return `self.tzinfo.tzname(self)`.

### **pandas.Timestamp.utctimestamp**

**classmethod** `Timestamp.utctimestamp(ts)`  
Construct a naive UTC datetime from a POSIX timestamp.

### **pandas.Timestamp.utcnow**

**classmethod** `Timestamp.utcnow()`  
Return a new `Timestamp` representing UTC day and time.

### **pandas.Timestamp.utcoffset**

`Timestamp.utcoffset()`  
Return `self.tzinfo.utcoffset(self)`.

### **pandas.Timestamp.utctimetuple**

`Timestamp.utctimetuple()`  
Return UTC time tuple, compatible with `time.localtime()`.

### **pandas.Timestamp.weekday**

`Timestamp.weekday()`  
Return the day of the week represented by the date. Monday == 0 ... Sunday == 6

<b>isoformat</b>	
------------------	--

## **Properties**

<code>Timestamp.asm8</code>	Return numpy datetime64 format in nanoseconds.
<code>Timestamp.day</code>	
<code>Timestamp.dayofweek</code>	Return day of the week.
<code>Timestamp.dayofyear</code>	Return the day of the year.
<code>Timestamp.days_in_month</code>	Return the number of days in the month.
<code>Timestamp.daysinmonth</code>	Return the number of days in the month.
<code>Timestamp.fold</code>	
<code>Timestamp.hour</code>	
<code>Timestamp.is_leap_year</code>	Return True if year is a leap year.
<code>Timestamp.is_month_end</code>	Return True if date is last day of month.
<code>Timestamp.is_month_start</code>	Return True if date is first day of month.

Continued on next page

Table 83 – continued from previous page

<i>Timestamp.is_quarter_end</i>	Return True if date is last day of the quarter.
<i>Timestamp.is_quarter_start</i>	Return True if date is first day of the quarter.
<i>Timestamp.is_year_end</i>	Return True if date is last day of the year.
<i>Timestamp.is_year_start</i>	Return True if date is first day of the year.
<i>Timestamp.max</i>	
<i>Timestamp.microsecond</i>	
<i>Timestamp.min</i>	
<i>Timestamp.minute</i>	
<i>Timestamp.month</i>	
<i>Timestamp.nanosecond</i>	
<i>Timestamp.quarter</i>	Return the quarter of the year.
<i>Timestamp.resolution</i>	
<i>Timestamp.second</i>	
<i>Timestamp.tz</i>	Alias for tzinfo.
<i>Timestamp.tzinfo</i>	
<i>Timestamp.value</i>	
<i>Timestamp.week</i>	Return the week number of the year.
<i>Timestamp.weekofyear</i>	Return the week number of the year.
<i>Timestamp.year</i>	

**pandas.Timestamp.day**Timestamp.**day****pandas.Timestamp.fold**Timestamp.**fold****pandas.Timestamp.hour**Timestamp.**hour****pandas.Timestamp.max**Timestamp.**max** = Timestamp('2262-04-11 23:47:16.854775807')**pandas.Timestamp.microsecond**Timestamp.**microsecond**

**pandas.Timestamp.min**

```
Timestamp.min = Timestamp('1677-09-21 00:12:43.145225')
```

**pandas.Timestamp.minute**

```
Timestamp.minute
```

**pandas.Timestamp.month**

```
Timestamp.month
```

**pandas.Timestamp.nanosecond**

```
Timestamp.nanosecond
```

**pandas.Timestamp.resolution**

```
Timestamp.resolution = Timedelta('0 days 00:00:00.000000')
```

**pandas.Timestamp.second**

```
Timestamp.second
```

**pandas.Timestamp.tzinfo**

```
Timestamp.tzinfo
```

**pandas.Timestamp.value**

```
Timestamp.value
```

**pandas.Timestamp.year**

```
Timestamp.year
```

## Methods

<code>Timestamp.astimezone(self, tz)</code>	Convert tz-aware Timestamp to another time zone.
<code>Timestamp.ceil(self, freq[, ambiguous, ...])</code>	return a new Timestamp ceiled to this resolution.
<code>Timestamp.combine(date, time)</code>	date, time -> datetime with same date and time fields.
<code>Timestamp.ctime()</code>	Return ctime() style string.
<code>Timestamp.date()</code>	Return date object with same year, month and day.
<code>Timestamp.day_name(self[, locale])</code>	Return the day name of the Timestamp with specified locale.
<code>Timestamp.dst()</code>	Return self.tzinfo.dst(self).
<code>Timestamp.floor(self, freq[, ambiguous, ...])</code>	return a new Timestamp floored to this resolution.
<code>Timestamp.freq</code>	
<code>Timestamp.freqstr</code>	Return the total number of days in the month.
<code>Timestamp.fromordinal(ordinal[, freq, tz])</code>	Passed an ordinal, translate and convert to a ts.
<code>Timestamp.fromtimestamp(ts)</code>	timestamp[, tz] -> tz's local time from POSIX timestamp.
<code>Timestamp.isocalendar()</code>	Return a 3-tuple containing ISO year, week number, and weekday.
<code>Timestamp.isoformat(self[, sep])</code>	
<code>Timestamp.isoweekday()</code>	Return the day of the week represented by the date.
<code>Timestamp.month_name(self[, locale])</code>	Return the month name of the Timestamp with specified locale.
<code>Timestamp.normalize(self)</code>	Normalize Timestamp to midnight, preserving tz information.
<code>Timestamp.now([tz])</code>	Return new Timestamp object representing current time local to tz.
<code>Timestamp.replace(self[, year, month, day, ...])</code>	implements datetime.replace, handles nanoseconds.
<code>Timestamp.round(self, freq[, ambiguous, ...])</code>	Round the Timestamp to the specified resolution.
<code>Timestamp.strftime()</code>	format -> strftime() style string.
<code>Timestamp.strptime(string, format)</code>	Function is not implemented.
<code>Timestamp.time()</code>	Return time object with same time but with tzinfo=None.
<code>Timestamp.timestamp()</code>	Return POSIX timestamp as float.
<code>Timestamp.timetuple()</code>	Return time tuple, compatible with time.localtime().
<code>Timestamp.timeztz()</code>	Return time object with same time and tzinfo.
<code>Timestamp.to_datetime64()</code>	Return a numpy.datetime64 object with 'ns' precision.
<code>Timestamp.to_numpy()</code>	Convert the Timestamp to a NumPy datetime64.
<code>Timestamp.to_julian_date(self)</code>	Convert Timestamp to a Julian Date.
<code>Timestamp.to_period(self[, freq])</code>	Return an period of which this timestamp is an observation.
<code>Timestamp.to_pydatetime()</code>	Convert a Timestamp object to a native Python datetime object.
<code>Timestamp.today(cls[, tz])</code>	Return the current time in the local timezone.
<code>Timestamp.toordinal()</code>	Return proleptic Gregorian ordinal.
<code>Timestamp.tz_convert(self, tz)</code>	Convert tz-aware Timestamp to another time zone.
<code>Timestamp.tz_localize(self, tz[, ambiguous, ...])</code>	Convert naive Timestamp to local time zone, or remove timezone from tz-aware Timestamp.
<code>Timestamp.tzname()</code>	Return self.tzinfo.tzname(self).
<code>Timestamp.utctimestamp(ts)</code>	Construct a naive UTC datetime from a POSIX timestamp.

Continued on next page

Table 84 – continued from previous page

<code>Timestamp.utcnow()</code>	Return a new Timestamp representing UTC day and time.
<code>Timestamp.utcoffset()</code>	Return <code>self.tzinfo.utcoffset(self)</code> .
<code>Timestamp.utctimetuple()</code>	Return UTC time tuple, compatible with <code>time.localtime()</code> .
<code>Timestamp.weekday()</code>	Return the day of the week represented by the date.

**pandas.Timestamp.freq**`Timestamp.freq`**pandas.Timestamp.isoformat**`Timestamp.isoformat` (*self*, *sep*="T")

A collection of timestamps may be stored in a `arrays.DatetimeArray`. For timezone-aware data, the `.dtype` of a `DatetimeArray` is a `DatetimeTZDtype`. For timezone-naive data, `np.dtype("datetime64[ns]")` is used.

If the data are tz-aware, then every value in the array must have the same timezone.

```
arrays.DatetimeArray(values[, dtype, freq, Pandas ExtensionArray for tz-naive or tz-aware date-
copy])
```

**pandas.arrays.DatetimeArray**

**class** `pandas.arrays.DatetimeArray` (*values*, *dtype*=`dtype('<M8[ns]')`, *freq*=`None`, *copy*=`False`)  
Pandas ExtensionArray for tz-naive or tz-aware datetime data.

New in version 0.24.0.

**Warning:** `DatetimeArray` is currently experimental, and its API may change without warning. In particular, `DatetimeArray.dtype` is expected to change to always be an instance of an `ExtensionDtype` subclass.

**Parameters**

**values** [Series, Index, `DatetimeArray`, ndarray] The datetime data.

For `DatetimeArray` *values* (or a Series or Index boxing one), *dtype* and *freq* will be extracted from *values*.

**dtype** [numpy.dtype or `DatetimeTZDtype`] Note that the only NumPy dtype allowed is 'datetime64[ns]'.

**freq** [str or Offset, optional] The frequency.

**copy** [bool, default False] Whether to copy the underlying array of values.

**Attributes**

None

**Methods**

None

*DatetimeTZDtype*([unit, tz])

An ExtensionDtype for timezone-aware datetime data.

**pandas.DatetimeTZDtype****class** pandas.**DatetimeTZDtype** (*unit='ns', tz=None*)

An ExtensionDtype for timezone-aware datetime data.

**This is not an actual numpy dtype**, but a duck type.**Parameters****unit** [str, default “ns”] The precision of the datetime data. Currently limited to "ns".**tz** [str, int, or datetime.tzinfo] The timezone.**Raises****pytz.UnknownTimeZoneError** When the requested timezone cannot be found.**Examples**

```
>>> pd.DatetimeTZDtype(tz='UTC')
datetime64[ns, UTC]
```

```
>>> pd.DatetimeTZDtype(tz='dateutil/US/Central')
datetime64[ns, tzfile('/usr/share/zoneinfo/US/Central')]
```

**Attributes***unit*

The precision of the datetime data.

*tz*

The timezone.

### pandas.DatetimeTZDtype.unit

**property** `DatetimeTZDtype.unit`  
The precision of the datetime data.

### pandas.DatetimeTZDtype.tz

**property** `DatetimeTZDtype.tz`  
The timezone.

### Methods

None	
------	--

## 4.5.3 Timedelta data

NumPy can natively represent timedeltas. Pandas provides *Timedelta* for symmetry with *Timestamp*.

<i>Timedelta</i>	Represents a duration, the difference between two dates or times.
------------------	-------------------------------------------------------------------

---

### pandas.Timedelta

**class** `pandas.Timedelta`  
Represents a duration, the difference between two dates or times.

Timedelta is the pandas equivalent of python's `datetime.timedelta` and is interchangeable with it in most cases.

#### Parameters

**value** [Timedelta, timedelta, np.timedelta64, string, or integer]

**unit** [str, default 'ns'] Denote the unit of the input, if input is an integer.

Possible values:

- 'Y', 'M', 'W', 'D', 'T', 'S', 'L', 'U', or 'N'
- 'days' or 'day'
- 'hours', 'hour', 'hr', or 'h'
- 'minutes', 'minute', 'min', or 'm'
- 'seconds', 'second', or 'sec'
- 'milliseconds', 'millisecond', 'millis', or 'milli'
- 'microseconds', 'microsecond', 'micros', or 'micro'
- 'nanoseconds', 'nanosecond', 'nanos', 'nano', or 'ns'.

**\*\*kwargs** Available kwargs: {days, seconds, microseconds, milliseconds, minutes, hours, weeks}. Values for construction in compat with `datetime.timedelta`. Numpy ints and floats will be coerced to python ints and floats.

## Notes

The `.value` attribute is always in ns.

## Attributes

<code>asm8</code>	Return a numpy timedelta64 array scalar view.
<code>components</code>	Return a components namedtuple-like.
<code>days</code>	Number of days.
<code>delta</code>	Return the timedelta in nanoseconds (ns), for internal compatibility.
<code>microseconds</code>	Number of microseconds ( $\geq 0$ and less than 1 second).
<code>nanoseconds</code>	Return the number of nanoseconds (n), where $0 \leq n < 1$ microsecond.
<code>resolution_string</code>	Return a string representing the lowest timedelta resolution.
<code>seconds</code>	Number of seconds ( $\geq 0$ and less than 1 day).

## pandas.Timedelta.asm8

`Timedelta.asm8`

Return a numpy timedelta64 array scalar view.

Provides access to the array scalar view (i.e. a combination of the value and the units) associated with the `numpy.timedelta64().view()`, including a 64-bit integer representation of the timedelta in nanoseconds (Python int compatible).

### Returns

**numpy timedelta64 array scalar view** Array scalar view of the timedelta in nanoseconds.

## Examples

```
>>> td = pd.Timedelta('1 days 2 min 3 us 42 ns')
>>> td.asm8
numpy.timedelta64(86520000003042, 'ns')
```

```
>>> td = pd.Timedelta('2 min 3 s')
>>> td.asm8
numpy.timedelta64(123000000000, 'ns')
```

```
>>> td = pd.Timedelta('3 ms 5 us')
>>> td.asm8
numpy.timedelta64(3005000, 'ns')
```

```
>>> td = pd.Timedelta(42, unit='ns')
>>> td.asm8
numpy.timedelta64(42, 'ns')
```

### **pandas.Timedelta.components**

`Timedelta.components`

Return a components namedtuple-like.

### **pandas.Timedelta.days**

`Timedelta.days`

Number of days.

### **pandas.Timedelta.delta**

`Timedelta.delta`

Return the timedelta in nanoseconds (ns), for internal compatibility.

#### **Returns**

**int** Timedelta in nanoseconds.

#### **Examples**

```
>>> td = pd.Timedelta('1 days 42 ns')
>>> td.delta
86400000000042
```

```
>>> td = pd.Timedelta('3 s')
>>> td.delta
3000000000
```

```
>>> td = pd.Timedelta('3 ms 5 us')
>>> td.delta
3005000
```

```
>>> td = pd.Timedelta(42, unit='ns')
>>> td.delta
42
```

### **pandas.Timedelta.microseconds**

`Timedelta.microseconds`

Number of microseconds ( $\geq 0$  and less than 1 second).

## pandas.Timedelta.nanoseconds

### Timedelta.nanoseconds

Return the number of nanoseconds (n), where  $0 \leq n < 1$  microsecond.

#### Returns

**int** Number of nanoseconds.

#### See also:

**Timedelta.components** Return all attributes with assigned values (i.e. days, hours, minutes, seconds, milliseconds, microseconds, nanoseconds).

## Examples

### Using string input

```
>>> td = pd.Timedelta('1 days 2 min 3 us 42 ns')
>>> td.nanoseconds
42
```

### Using integer input

```
>>> td = pd.Timedelta(42, unit='ns')
>>> td.nanoseconds
42
```

## pandas.Timedelta.resolution\_string

### Timedelta.resolution\_string

Return a string representing the lowest timedelta resolution.

Each timedelta has a defined resolution that represents the lowest OR most granular level of precision. Each level of resolution is represented by a short string as defined below:

Resolution: Return value

- Days: 'D'
- Hours: 'H'
- Minutes: 'T'
- Seconds: 'S'
- Milliseconds: 'L'
- Microseconds: 'U'
- Nanoseconds: 'N'

#### Returns

**str** Timedelta resolution.

## Examples

```
>>> td = pd.Timedelta('1 days 2 min 3 us 42 ns')
>>> td.resolution
'N'
```

```
>>> td = pd.Timedelta('1 days 2 min 3 us')
>>> td.resolution
'U'
```

```
>>> td = pd.Timedelta('2 min 3 s')
>>> td.resolution
'S'
```

```
>>> td = pd.Timedelta(36, unit='us')
>>> td.resolution
'U'
```

## pandas.Timedelta.seconds

### Timedelta.seconds

Number of seconds ( $\geq 0$  and less than 1 day).

<b>freq</b>	
<b>is_populated</b>	
<b>value</b>	

## Methods

<i>ceil</i> (self, freq)	Return a new Timedelta ceiled to this resolution.
<i>floor</i> (self, freq)	Return a new Timedelta floored to this resolution.
<i>isoformat</i> ()	Format Timedelta as ISO 8601 Duration like P[n]Y[n]M[n]DT[n]H[n]M[n]S, where the [n] s are replaced by the values.
<i>round</i> (self, freq)	Round the Timedelta to the specified resolution.
<i>to_numpy</i> ()	Convert the Timedelta to a NumPy timedelta64.
<i>to_pytimedelta</i> ()	Convert a pandas Timedelta object into a python timedelta object.
<i>to_timedelta64</i> ()	Return a numpy.timedelta64 object with 'ns' precision.
<i>total_seconds</i> ()	Total duration of timedelta in seconds (to ns precision).
<i>view</i> ()	Array view compatibility.

**pandas.Timedelta.ceil**`Timedelta.ceil (self, freq)`

Return a new Timedelta ceiled to this resolution.

**Parameters****freq** [str] Frequency string indicating the ceiling resolution.**pandas.Timedelta.floor**`Timedelta.floor (self, freq)`

Return a new Timedelta floored to this resolution.

**Parameters****freq** [str] Frequency string indicating the flooring resolution.**pandas.Timedelta.isoformat**`Timedelta.isoformat ()`Format Timedelta as ISO 8601 Duration like P [n] Y [n] M [n] DT [n] H [n] M [n] S, where the [n] s are replaced by the values. See [https://en.wikipedia.org/wiki/ISO\\_8601#Durations](https://en.wikipedia.org/wiki/ISO_8601#Durations).**Returns****formatted** [str]**See also:***Timestamp.isoformat***Notes**

The longest component is days, whose value may be larger than 365. Every component is always included, even if its value is 0. Pandas uses nanosecond precision, so up to 9 decimal places may be included in the seconds component. Trailing 0's are removed from the seconds component after the decimal. We do not 0 pad components, so it's ... *T5H...*, not ... *T05H...*

**Examples**

```
>>> td = pd.Timedelta(days=6, minutes=50, seconds=3,
...                   milliseconds=10, microseconds=10, nanoseconds=12)
>>> td.isoformat ()
'P6DT0H50M3.010010012S'
>>> pd.Timedelta(hours=1, seconds=10).isoformat ()
'P0DT0H0M10S'
>>> pd.Timedelta(hours=1, seconds=10).isoformat ()
'P0DT0H0M10S'
>>> pd.Timedelta(days=500.5).isoformat ()
'P500DT12H0MS'
```

### **pandas.Timedelta.round**

`Timedelta.round(self, freq)`

Round the Timedelta to the specified resolution.

#### **Parameters**

**freq** [str] Frequency string indicating the rounding resolution.

#### **Returns**

**a new Timedelta rounded to the given resolution of *freq***

#### **Raises**

**ValueError if the freq cannot be converted**

### **pandas.Timedelta.to\_numpy**

`Timedelta.to_numpy()`

Convert the Timedelta to a NumPy timedelta64.

New in version 0.25.0.

This is an alias method for `Timedelta.to_timedelta64()`. The dtype and copy parameters are available here only for compatibility. Their values will not affect the return value.

#### **Returns**

**numpy.timedelta64**

#### **See also:**

***Series.to\_numpy*** Similar method for Series.

### **pandas.Timedelta.to\_pytimedelta**

`Timedelta.to_pytimedelta()`

Convert a pandas Timedelta object into a python timedelta object.

Timedelta objects are internally saved as numpy datetime64[ns] dtype. Use `to_pytimedelta()` to convert to object dtype.

#### **Returns**

**datetime.timedelta or numpy.array of datetime.timedelta**

#### **See also:**

***to\_timedelta*** Convert argument to Timedelta type.

## Notes

Any nanosecond resolution will be lost.

### **pandas.Timedelta.to\_timedelta64**

`Timedelta.to_timedelta64()`

Return a `numpy.timedelta64` object with 'ns' precision.

### **pandas.Timedelta.total\_seconds**

`Timedelta.total_seconds()`

Total duration of `timedelta` in seconds (to ns precision).

### **pandas.Timedelta.view**

`Timedelta.view()`

Array view compatibility.

## Properties

<code>Timedelta.asm8</code>	Return a <code>numpy.timedelta64</code> array scalar view.
<code>Timedelta.components</code>	Return a components <code>namedtuple</code> -like.
<code>Timedelta.days</code>	Number of days.
<code>Timedelta.delta</code>	Return the <code>timedelta</code> in nanoseconds (ns), for internal compatibility.
<code>Timedelta.freq</code>	
<code>Timedelta.is_populated</code>	
<code>Timedelta.max</code>	
<code>Timedelta.microseconds</code>	Number of microseconds ( $\geq 0$ and less than 1 second).
<code>Timedelta.min</code>	
<code>Timedelta.nanoseconds</code>	Return the number of nanoseconds (n), where $0 \leq n < 1$ microsecond.
<code>Timedelta.resolution</code>	
<code>Timedelta.seconds</code>	Number of seconds ( $\geq 0$ and less than 1 day).
<code>Timedelta.value</code>	
<code>Timedelta.view()</code>	Array view compatibility.

### pandas.Timedelta.freq

Timedelta.**freq**

### pandas.Timedelta.is\_populated

Timedelta.**is\_populated**

### pandas.Timedelta.max

Timedelta.**max** = Timedelta('106751 days 23:47:16.854775')

### pandas.Timedelta.min

Timedelta.**min** = Timedelta('-106752 days +00:12:43.145224')

### pandas.Timedelta.resolution

Timedelta.**resolution** = Timedelta('0 days 00:00:00.000000')

### pandas.Timedelta.value

Timedelta.**value**

## Methods

<i>Timedelta.ceil</i> (self, freq)	Return a new Timedelta ceiled to this resolution.
<i>Timedelta.floor</i> (self, freq)	Return a new Timedelta floored to this resolution.
<i>Timedelta.isoformat</i> ()	Format Timedelta as ISO 8601 Duration like P[n]Y[n]M[n]DT[n]H[n]M[n]S, where the [n] s are replaced by the values.
<i>Timedelta.round</i> (self, freq)	Round the Timedelta to the specified resolution.
<i>Timedelta.to_pytimedelta</i> ()	Convert a pandas Timedelta object into a python timedelta object.
<i>Timedelta.to_timedelta64</i> ()	Return a numpy.timedelta64 object with 'ns' precision.
<i>Timedelta.to_numpy</i> ()	Convert the Timedelta to a NumPy timedelta64.
<i>Timedelta.total_seconds</i> ()	Total duration of timedelta in seconds (to ns precision).

A collection of timedeltas may be stored in a TimedeltaArray.

```
arrays.TimedeltaArray(values[, dtype, freq, Pandas ExtensionArray for timedelta data.  
...])
```

---

## pandas.arrays.TimedeltaArray

**class** pandas.arrays.TimedeltaArray (values, dtype=dtype('<m8[ns]'), freq=None, copy=False)  
Pandas ExtensionArray for timedelta data.

New in version 0.24.0.

**Warning:** TimedeltaArray is currently experimental, and its API may change without warning. In particular, TimedeltaArray.dtype is expected to change to be an instance of an ExtensionDtype subclass.

### Parameters

- values** [array-like] The timedelta data.
- dtype** [numpy.dtype] Currently, only `numpy.dtype("timedelta64[ns]")` is accepted.
- freq** [Offset, optional]
- copy** [bool, default False] Whether to copy the underlying array of data.

### Attributes

None	
------	--

### Methods

None	
------	--

## 4.5.4 Timespan data

Pandas represents spans of times as *Period* objects.

## 4.5.5 Period

*Period*

Represents a period of time.

### pandas.Period

**class** pandas.Period  
Represents a period of time.

#### Parameters

- value** [Period or str, default None] The time period represented (e.g., '4Q2005').
- freq** [str, default None] One of pandas period strings or corresponding objects.
- ordinal** [int, default None] The period offset from the gregorian proleptic epoch.

**year** [int, default None] Year value of the period.  
**month** [int, default 1] Month value of the period.  
**quarter** [int, default None] Quarter value of the period.  
**day** [int, default 1] Day value of the period.  
**hour** [int, default 0] Hour value of the period.  
**minute** [int, default 0] Minute value of the period.  
**second** [int, default 0] Second value of the period.

### Attributes

<i>day</i>	Get day of the month that a Period falls on.
<i>dayofweek</i>	Day of the week the period lies in, with Monday=0 and Sunday=6.
<i>dayofyear</i>	Return the day of the year.
<i>days_in_month</i>	Get the total number of days in the month that this period falls on.
<i>daysinmonth</i>	Get the total number of days of the month that the Period falls in.
<i>hour</i>	Get the hour of the day component of the Period.
<i>minute</i>	Get minute of the hour component of the Period.
<i>qyear</i>	Fiscal year the Period lies in according to its starting-quarter.
<i>second</i>	Get the second component of the Period.
<i>start_time</i>	Get the Timestamp for the start of the period.
<i>week</i>	Get the week of the year on the given Period.
<i>weekday</i>	Day of the week the period lies in, with Monday=0 and Sunday=6.

### pandas.Period.day

#### Period.day

Get day of the month that a Period falls on.

#### Returns

**int**

#### See also:

**Period.dayofweek** Get the day of the week.

**Period.dayofyear** Get the day of the year.

## Examples

```
>>> p = pd.Period("2018-03-11", freq='H')
>>> p.day
11
```

## pandas.Period.dayofweek

### Period.dayofweek

Day of the week the period lies in, with Monday=0 and Sunday=6.

If the period frequency is lower than daily (e.g. hourly), and the period spans over multiple days, the day at the start of the period is used.

If the frequency is higher than daily (e.g. monthly), the last day of the period is used.

### Returns

**int** Day of the week.

### See also:

**Period.dayofweek** Day of the week the period lies in.

**Period.weekday** Alias of Period.dayofweek.

**Period.day** Day of the month.

**Period.dayofyear** Day of the year.

## Examples

```
>>> per = pd.Period('2017-12-31 22:00', 'H')
>>> per.dayofweek
6
```

For periods that span over multiple days, the day at the beginning of the period is returned.

```
>>> per = pd.Period('2017-12-31 22:00', '4H')
>>> per.dayofweek
6
>>> per.start_time.dayofweek
6
```

For periods with a frequency higher than days, the last day of the period is returned.

```
>>> per = pd.Period('2018-01', 'M')
>>> per.dayofweek
2
>>> per.end_time.dayofweek
2
```

## pandas.Period.dayofyear

### Period.dayofyear

Return the day of the year.

This attribute returns the day of the year on which the particular date occurs. The return value ranges between 1 to 365 for regular years and 1 to 366 for leap years.

#### Returns

**int** The day of year.

#### See also:

**Period.day** Return the day of the month.

**Period.dayofweek** Return the day of week.

**PeriodIndex.dayofyear** Return the day of year of all indexes.

## Examples

```
>>> period = pd.Period("2015-10-23", freq='H')
>>> period.dayofyear
296
>>> period = pd.Period("2012-12-31", freq='D')
>>> period.dayofyear
366
>>> period = pd.Period("2013-01-01", freq='D')
>>> period.dayofyear
1
```

## pandas.Period.days\_in\_month

### Period.days\_in\_month

Get the total number of days in the month that this period falls on.

#### Returns

**int**

#### See also:

**Period.daysinmonth** Gets the number of days in the month.

**DatetimeIndex.daysinmonth** Gets the number of days in the month.

**calendar.monthrange** Returns a tuple containing weekday (0-6 ~ Mon-Sun) and number of days (28-31).

## Examples

```
>>> p = pd.Period('2018-2-17')
>>> p.days_in_month
28
```

```
>>> pd.Period('2018-03-01').days_in_month
31
```

Handles the leap year case as well:

```
>>> p = pd.Period('2016-2-17')
>>> p.days_in_month
29
```

## pandas.Period.daysinmonth

### Period.daysinmonth

Get the total number of days of the month that the Period falls in.

#### Returns

**int**

#### See also:

**Period.days\_in\_month** Return the days of the month.

**Period.dayofyear** Return the day of the year.

## Examples

```
>>> p = pd.Period("2018-03-11", freq='H')
>>> p.daysinmonth
31
```

## pandas.Period.hour

### Period.hour

Get the hour of the day component of the Period.

#### Returns

**int** The hour as an integer, between 0 and 23.

#### See also:

**Period.second** Get the second component of the Period.

**Period.minute** Get the minute component of the Period.

## Examples

```
>>> p = pd.Period("2018-03-11 13:03:12.050000")
>>> p.hour
13
```

Period longer than a day

```
>>> p = pd.Period("2018-03-11", freq="M")
>>> p.hour
0
```

## pandas.Period.minute

### Period.minute

Get minute of the hour component of the Period.

#### Returns

**int** The minute as an integer, between 0 and 59.

#### See also:

**Period.hour** Get the hour component of the Period.

**Period.second** Get the second component of the Period.

## Examples

```
>>> p = pd.Period("2018-03-11 13:03:12.050000")
>>> p.minute
3
```

## pandas.Period.qyear

### Period.qyear

Fiscal year the Period lies in according to its starting-quarter.

The *year* and the *qyear* of the period will be the same if the fiscal and calendar years are the same. When they are not, the fiscal year can be different from the calendar year of the period.

#### Returns

**int** The fiscal year of the period.

#### See also:

**Period.year** Return the calendar year of the period.

## Examples

If the natural and fiscal year are the same, *qyear* and *year* will be the same.

```
>>> per = pd.Period('2018Q1', freq='Q')
>>> per.qyear
2018
>>> per.year
2018
```

If the fiscal year starts in April (*Q-MAR*), the first quarter of 2018 will start in April 2017. *year* will then be 2018, but *qyear* will be the fiscal year, 2018.

```
>>> per = pd.Period('2018Q1', freq='Q-MAR')
>>> per.start_time
Timestamp('2017-04-01 00:00:00')
>>> per.qyear
2018
>>> per.year
2017
```

## pandas.Period.second

### Period.**second**

Get the second component of the Period.

#### Returns

**int** The second of the Period (ranges from 0 to 59).

#### See also:

**Period.hour** Get the hour component of the Period.

**Period.minute** Get the minute component of the Period.

## Examples

```
>>> p = pd.Period("2018-03-11 13:03:12.050000")
>>> p.second
12
```

## pandas.Period.start\_time

### Period.**start\_time**

Get the Timestamp for the start of the period.

#### Returns

**Timestamp**

#### See also:

**Period.end\_time** Return the end Timestamp.

**Period.dayofyear** Return the day of year.

*Period.daysinmonth* Return the days in that month.

*Period.dayofweek* Return the day of the week.

### Examples

```
>>> period = pd.Period('2012-1-1', freq='D')
>>> period
Period('2012-01-01', 'D')
```

```
>>> period.start_time
Timestamp('2012-01-01 00:00:00')
```

```
>>> period.end_time
Timestamp('2012-01-01 23:59:59.999999999')
```

### pandas.Period.week

*Period.week*

Get the week of the year on the given Period.

**Returns**

**int**

**See also:**

*Period.dayofweek* Get the day component of the Period.

*Period.weekday* Get the day component of the Period.

### Examples

```
>>> p = pd.Period("2018-03-11", "H")
>>> p.week
10
```

```
>>> p = pd.Period("2018-02-01", "D")
>>> p.week
5
```

```
>>> p = pd.Period("2018-01-06", "D")
>>> p.week
1
```

**pandas.Period.weekday****Period.weekday**

Day of the week the period lies in, with Monday=0 and Sunday=6.

If the period frequency is lower than daily (e.g. hourly), and the period spans over multiple days, the day at the start of the period is used.

If the frequency is higher than daily (e.g. monthly), the last day of the period is used.

**Returns**

**int** Day of the week.

**See also:**

**Period.dayofweek** Day of the week the period lies in.

**Period.weekday** Alias of Period.dayofweek.

**Period.day** Day of the month.

**Period.dayofyear** Day of the year.

**Examples**

```
>>> per = pd.Period('2017-12-31 22:00', 'H')
>>> per.dayofweek
6
```

For periods that span over multiple days, the day at the beginning of the period is returned.

```
>>> per = pd.Period('2017-12-31 22:00', '4H')
>>> per.dayofweek
6
>>> per.start_time.dayofweek
6
```

For periods with a frequency higher than days, the last day of the period is returned.

```
>>> per = pd.Period('2018-01', 'M')
>>> per.dayofweek
2
>>> per.end_time.dayofweek
2
```

<b>end_time</b>	
<b>freq</b>	
<b>freqstr</b>	
<b>is_leap_year</b>	
<b>month</b>	
<b>ordinal</b>	
<b>quarter</b>	
<b>weekofyear</b>	
<b>year</b>	

## Methods

<code>asfreq()</code>	Convert Period to desired frequency, at the start or end of the interval.
<code>strftime()</code>	Returns the string representation of the <i>Period</i> , depending on the selected <i>fmt</i> .
<code>to_timestamp()</code>	Return the Timestamp representation of the Period.

### `pandas.Period.asfreq`

`Period.asfreq()`

Convert Period to desired frequency, at the start or end of the interval.

#### Parameters

**freq** [str] The desired frequency.

**how** [{ 'E', 'S', 'end', 'start' }, default 'end'] Start or end of the timespan.

#### Returns

**resampled** [Period]

### `pandas.Period.strftime`

`Period.strftime()`

Returns the string representation of the *Period*, depending on the selected *fmt*. *fmt* must be a string containing one or several directives. The method recognizes the same directives as the `time.strftime()` function of the standard Python distribution, as well as the specific additional directives `%f`, `%F`, `%q`. (formatting & docs originally from `scikits.timeries`).

Directive	Meaning	Notes
%a	Locale's abbreviated weekday name.	
%A	Locale's full weekday name.	
%b	Locale's abbreviated month name.	
%B	Locale's full month name.	
%c	Locale's appropriate date and time representation.	
%d	Day of the month as a decimal number [01,31].	
%f	'Fiscal' year without a century as a decimal number [00,99]	(1)
%F	'Fiscal' year with a century as a decimal number	(2)
%H	Hour (24-hour clock) as a decimal number [00,23].	
%I	Hour (12-hour clock) as a decimal number [01,12].	
%j	Day of the year as a decimal number [001,366].	
%m	Month as a decimal number [01,12].	
%M	Minute as a decimal number [00,59].	
%p	Locale's equivalent of either AM or PM.	(3)
%q	Quarter as a decimal number [01,04]	
%S	Second as a decimal number [00,61].	(4)
%U	Week number of the year (Sunday as the first day of the week) as a decimal number [00,53]. All days in a new year preceding the first Sunday are considered to be in week 0.	(5)
%w	Weekday as a decimal number [0(Sunday),6].	
%W	Week number of the year (Monday as the first day of the week) as a decimal number [00,53]. All days in a new year preceding the first Monday are considered to be in week 0.	(5)
%x	Locale's appropriate date representation.	
%X	Locale's appropriate time representation.	
%y	Year without century as a decimal number [00,99].	
%Y	Year with century as a decimal number.	
%Z	Time zone name (no characters if no time zone exists).	
%%	A literal '%' character.	

## Notes

- (1) The %f directive is the same as %y if the frequency is not quarterly. Otherwise, it corresponds to the 'fiscal' year, as defined by the *qyear* attribute.
- (2) The %F directive is the same as %Y if the frequency is not quarterly. Otherwise, it corresponds to the 'fiscal' year, as defined by the *qyear* attribute.
- (3) The %p directive only affects the output hour field if the %I directive is used to parse the hour.
- (4) The range really is 0 to 61; this accounts for leap seconds and the (very rare) double leap seconds.
- (5) The %U and %W directives are only used in calculations when the day of the week and the year are specified.

## Examples

```
>>> a = Period(freq='Q-JUL', year=2006, quarter=1)
>>> a.strftime('%F-Q%q')
'2006-Q1'
>>> # Output the last month in the quarter of this date
>>> a.strftime('%b-%Y')
'Oct-2005'
>>>
>>> a = Period(freq='D', year=2001, month=1, day=1)
>>> a.strftime('%d-%b-%Y')
'01-Jan-2006'
>>> a.strftime('%b. %d, %Y was a %A')
'Jan. 01, 2001 was a Monday'
```

## pandas.Period.to\_timestamp

### Period.to\_timestamp()

Return the Timestamp representation of the Period.

Uses the target frequency specified at the part of the period specified by *how*, which is either *Start* or *Finish*.

#### Parameters

**freq** [str or DateOffset] Target frequency. Default is 'D' if self.freq is week or longer and 'S' otherwise.

**how** [str, default 'S' (start)] One of 'S', 'E'. Can be aliased as case insensitive 'Start', 'Finish', 'Begin', 'End'.

#### Returns

**Timestamp**

now	
-----	--

## Properties

<code>Period.day</code>	Get day of the month that a Period falls on.
<code>Period.dayofweek</code>	Day of the week the period lies in, with Monday=0 and Sunday=6.
<code>Period.dayofyear</code>	Return the day of the year.
<code>Period.days_in_month</code>	Get the total number of days in the month that this period falls on.
<code>Period.daysinmonth</code>	Get the total number of days of the month that the Period falls in.
<code>Period.end_time</code>	
<code>Period.freq</code>	
<code>Period.freqstr</code>	
<code>Period.hour</code>	Get the hour of the day component of the Period.
<code>Period.is_leap_year</code>	
<code>Period.minute</code>	Get minute of the hour component of the Period.

<code>Period.to_timestamp()</code>	Return the Timestamp representation of the Period.

## pandas.Period.now

Period.**now**()

A collection of timedeltas may be stored in a `arrays.PeriodArray`. Every period in a `PeriodArray` must have the same `freq`.

`arrays.PeriodArray(values[, freq, dtype, copy])` Pandas ExtensionArray for storing Period data.

## pandas.arrays.PeriodArray

**class** `pandas.arrays.PeriodArray` (*values, freq=None, dtype=None, copy=False*)

Pandas ExtensionArray for storing Period data.

Users should use `period_array()` to create new instances.

### Parameters

**values** [Union[PeriodArray, Series[period], ndarray[int], PeriodIndex]] The data to store. These should be arrays that can be directly converted to ordinals without inference or copy (`PeriodArray`, `ndarray[int64]`), or a box around such an array (`Series[period]`, `PeriodIndex`).

**freq** [str or DateOffset] The *freq* to use for the array. Mostly applicable when *values* is an ndarray of integers, when *freq* is required. When *values* is a `PeriodArray` (or box around), it's checked that `values.freq` matches *freq*.

**dtype** [PeriodDtype, optional] A `PeriodDtype` instance from which to extract a *freq*. If both *freq* and *dtype* are specified, then the frequencies must match.

**copy** [bool, default False] Whether to copy the ordinals before storing.

**See also:**

**period\_array** Create a new PeriodArray.

**PeriodIndex** Immutable Index for period data.

## Notes

There are two components to a PeriodArray

- ordinals : integer ndarray
- freq : pd.tseries.offsets.Offset

The values are physically stored as a 1-D ndarray of integers. These are called “ordinals” and represent some kind of offset from a base.

The *freq* indicates the span covered by each element of the array. All elements in the PeriodArray have the same *freq*.

## Attributes

None	
------	--

## Methods

None	
------	--

*PeriodDtype*

An ExtensionDtype for Period data.

## pandas.PeriodDtype

**class** pandas.**PeriodDtype**

An ExtensionDtype for Period data.

**This is not an actual numpy dtype**, but a duck type.

### Parameters

**freq** [str or DateOffset] The frequency of this PeriodDtype.

## Examples

```
>>> pd.PeriodDtype(freq='D')
period[D]
```

```
>>> pd.PeriodDtype(freq=pd.offsets.MonthEnd())
period[M]
```

## Attributes

<i>freq</i>	The frequency object of this PeriodDtype.
-------------	-------------------------------------------

---

### pandas.PeriodDtype.freq

**property** `PeriodDtype.freq`  
The frequency object of this PeriodDtype.

## Methods

None	
------	--

## 4.5.6 Interval data

Arbitrary intervals can be represented as *Interval* objects.

<i>Interval</i>	Immutable object implementing an Interval, a bounded slice-like interval.
-----------------	---------------------------------------------------------------------------

---

### pandas.Interval

#### **class** pandas.Interval

Immutable object implementing an Interval, a bounded slice-like interval.

##### Parameters

**left** [orderable scalar] Left bound for the interval.

**right** [orderable scalar] Right bound for the interval.

**closed** [{'right', 'left', 'both', 'neither'}, default 'right'] Whether the interval is closed on the left-side, right-side, both or neither. See the Notes for more detailed explanation.

##### See also:

**IntervalIndex** An Index of Interval objects that are all closed on the same side.

**cut** Convert continuous data into discrete bins (Categorical of Interval objects).

**qcut** Convert continuous data into bins (Categorical of Interval objects) based on quantiles.

**Period** Represents a period of time.

## Notes

The parameters *left* and *right* must be from the same type, you must be able to compare them and they must satisfy `left <= right`.

A closed interval (in mathematics denoted by square brackets) contains its endpoints, i.e. the closed interval  $[0, 5]$  is characterized by the conditions  $0 \leq x \leq 5$ . This is what `closed='both'` stands for. An open interval (in mathematics denoted by parentheses) does not contain its endpoints, i.e. the open interval  $(0, 5)$  is characterized by the conditions  $0 < x < 5$ . This is what `closed='neither'` stands for. Intervals can also be half-open or half-closed, i.e.  $[0, 5)$  is described by  $0 \leq x < 5$  (`closed='left'`) and  $(0, 5]$  is described by  $0 < x \leq 5$  (`closed='right'`).

## Examples

It is possible to build Intervals of different types, like numeric ones:

```
>>> iv = pd.Interval(left=0, right=5)
>>> iv
Interval(0, 5, closed='right')
```

You can check if an element belongs to it

```
>>> 2.5 in iv
True
```

You can test the bounds (closed='right', so  $0 < x \leq 5$ ):

```
>>> 0 in iv
False
>>> 5 in iv
True
>>> 0.0001 in iv
True
```

Calculate its length

```
>>> iv.length
5
```

You can operate with + and \* over an Interval and the operation is applied to each of its bounds, so the result depends on the type of the bound elements

```
>>> shifted_iv = iv + 3
>>> shifted_iv
Interval(3, 8, closed='right')
>>> extended_iv = iv * 10.0
>>> extended_iv
Interval(0.0, 50.0, closed='right')
```

To create a time interval you can use Timestamps as the bounds

```
>>> year_2017 = pd.Interval(pd.Timestamp('2017-01-01 00:00:00'),
...                          pd.Timestamp('2018-01-01 00:00:00'),
...                          closed='left')
>>> pd.Timestamp('2017-01-01 00:00:00') in year_2017
True
>>> year_2017.length
Timedelta('365 days 00:00:00')
```

And also you can create string intervals

```
>>> volume_1 = pd.Interval('Ant', 'Dog', closed='both')
>>> 'Bee' in volume_1
True
```

## Attributes

<i>closed</i>	Whether the interval is closed on the left-side, right-side, both or neither.
<i>closed_left</i>	Check if the interval is closed on the left side.
<i>closed_right</i>	Check if the interval is closed on the right side.
<i>is_empty</i>	Indicates if an interval is empty, meaning it contains no points.
<i>left</i>	Left bound for the interval.
<i>length</i>	Return the length of the Interval.
<i>mid</i>	Return the midpoint of the Interval.
<i>open_left</i>	Check if the interval is open on the left side.
<i>open_right</i>	Check if the interval is open on the right side.
<i>right</i>	Right bound for the interval.

### **pandas.Interval.closed**

#### **Interval.closed**

Whether the interval is closed on the left-side, right-side, both or neither.

### **pandas.Interval.closed\_left**

#### **Interval.closed\_left**

Check if the interval is closed on the left side.

For the meaning of *closed* and *open* see *Interval*.

#### **Returns**

**bool** True if the Interval is closed on the left-side.

### **pandas.Interval.closed\_right**

#### **Interval.closed\_right**

Check if the interval is closed on the right side.

For the meaning of *closed* and *open* see *Interval*.

#### **Returns**

**bool** True if the Interval is closed on the left-side.

### **pandas.Interval.is\_empty**

#### **Interval.is\_empty**

Indicates if an interval is empty, meaning it contains no points.

New in version 0.25.0.

#### **Returns**

**bool or ndarray** A boolean indicating if a scalar *Interval* is empty, or a boolean ndarray positionally indicating if an *Interval* in an *IntervalArray* or *IntervalIndex* is empty.

### Examples

An *Interval* that contains points is not empty:

```
>>> pd.Interval(0, 1, closed='right').is_empty
False
```

An *Interval* that does not contain any points is empty:

```
>>> pd.Interval(0, 0, closed='right').is_empty
True
>>> pd.Interval(0, 0, closed='left').is_empty
True
>>> pd.Interval(0, 0, closed='neither').is_empty
True
```

An *Interval* that contains a single point is not empty:

```
>>> pd.Interval(0, 0, closed='both').is_empty
False
```

An *IntervalArray* or *IntervalIndex* returns a boolean ndarray positionally indicating if an *Interval* is empty:

```
>>> ivs = [pd.Interval(0, 0, closed='neither'),
...        pd.Interval(1, 2, closed='neither')]
>>> pd.arrays.IntervalArray(ivs).is_empty
array([ True, False])
```

Missing values are not considered empty:

```
>>> ivs = [pd.Interval(0, 0, closed='neither'), np.nan]
>>> pd.IntervalIndex(ivs).is_empty
array([ True, False])
```

### pandas.Interval.left

`Interval.left`

Left bound for the interval.

### pandas.Interval.length

`Interval.length`

Return the length of the *Interval*.

### **pandas.Interval.mid**

`Interval.mid`

Return the midpoint of the Interval.

### **pandas.Interval.open\_left**

`Interval.open_left`

Check if the interval is open on the left side.

For the meaning of *closed* and *open* see *Interval*.

#### **Returns**

**bool** True if the Interval is closed on the left-side.

### **pandas.Interval.open\_right**

`Interval.open_right`

Check if the interval is open on the right side.

For the meaning of *closed* and *open* see *Interval*.

#### **Returns**

**bool** True if the Interval is closed on the left-side.

### **pandas.Interval.right**

`Interval.right`

Right bound for the interval.

### **Methods**

`overlaps()`

Check whether two Interval objects overlap.

---

### **pandas.Interval.overlaps**

`Interval.overlaps()`

Check whether two Interval objects overlap.

Two intervals overlap if they share a common point, including closed endpoints. Intervals that only have an open endpoint in common do not overlap.

New in version 0.24.0.

#### **Parameters**

**other** [Interval] Interval to check against for an overlap.

#### **Returns**

**bool** True if the two intervals overlap.

**See also:****IntervalArray.overlaps** The corresponding method for IntervalArray.**IntervalIndex.overlaps** The corresponding method for IntervalIndex.**Examples**

```
>>> i1 = pd.Interval(0, 2)
>>> i2 = pd.Interval(1, 3)
>>> i1.overlaps(i2)
True
>>> i3 = pd.Interval(4, 5)
>>> i1.overlaps(i3)
False
```

Intervals that share closed endpoints overlap:

```
>>> i4 = pd.Interval(0, 1, closed='both')
>>> i5 = pd.Interval(1, 2, closed='both')
>>> i4.overlaps(i5)
True
```

Intervals that only have an open endpoint in common do not overlap:

```
>>> i6 = pd.Interval(1, 2, closed='neither')
>>> i4.overlaps(i6)
False
```

**Properties**

<i>Interval.closed</i>	Whether the interval is closed on the left-side, right-side, both or neither.
<i>Interval.closed_left</i>	Check if the interval is closed on the left side.
<i>Interval.closed_right</i>	Check if the interval is closed on the right side.
<i>Interval.is_empty</i>	Indicates if an interval is empty, meaning it contains no points.
<i>Interval.left</i>	Left bound for the interval.
<i>Interval.length</i>	Return the length of the Interval.
<i>Interval.mid</i>	Return the midpoint of the Interval.
<i>Interval.open_left</i>	Check if the interval is open on the left side.
<i>Interval.open_right</i>	Check if the interval is open on the right side.
<i>Interval.overlaps()</i>	Check whether two Interval objects overlap.
<i>Interval.right</i>	Right bound for the interval.

A collection of intervals may be stored in an *arrays.IntervalArray*.

<i>arrays.IntervalArray</i>	Pandas array for interval data that are closed on the same side.
-----------------------------	------------------------------------------------------------------

## pandas.arrays.IntervalArray

### class pandas.arrays.IntervalArray

Pandas array for interval data that are closed on the same side.

New in version 0.24.0.

#### Parameters

**data** [array-like (1-dimensional)] Array-like containing Interval objects from which to build the IntervalArray.

**closed** [{‘left’, ‘right’, ‘both’, ‘neither’}, default ‘right’] Whether the intervals are closed on the left-side, right-side, both or neither.

**dtype** [dtype or None, default None] If None, dtype will be inferred.

New in version 0.23.0.

**copy** [bool, default False] Copy the input data.

**verify\_integrity** [bool, default True] Verify that the IntervalArray is valid.

#### See also:

**Index** The base pandas Index type.

**Interval** A bounded slice-like interval; the elements of an IntervalArray.

**interval\_range** Function to create a fixed frequency IntervalIndex.

**cut** Bin values into discrete Intervals.

**qcut** Bin values into equal-sized Intervals based on rank or sample quantiles.

#### Notes

See the [user guide](#) for more.

#### Examples

A new IntervalArray can be constructed directly from an array-like of Interval objects:

```
>>> pd.arrays.IntervalArray([pd.Interval(0, 1), pd.Interval(1, 5)])
<IntervalArray>
[(0, 1], (1, 5]]
Length: 2, closed: right, dtype: interval[int64]
```

It may also be constructed using one of the constructor methods: `IntervalArray.from_arrays()`, `IntervalArray.from_breaks()`, and `IntervalArray.from_tuples()`.

#### Attributes

<code>left</code>	Return the left endpoints of each Interval in the IntervalArray as an Index.
<code>right</code>	Return the right endpoints of each Interval in the IntervalArray as an Index.
<code>closed</code>	Whether the intervals are closed on the left-side, right-side, both or neither.

Continued on next page

Table 107 – continued from previous page

<i>mid</i>	Return the midpoint of each Interval in the IntervalArray as an Index.
<i>length</i>	Return an Index with entries denoting the length of each Interval in the IntervalArray.
<i>is_empty</i>	Indicates if an interval is empty, meaning it contains no points.
<i>is_non_overlapping_monotonic</i>	Return True if the IntervalArray is non-overlapping (no Intervals share points) and is either monotonic increasing or monotonic decreasing, else False.

**pandas.arrays.IntervalArray.left****property** IntervalArray.**left**

Return the left endpoints of each Interval in the IntervalArray as an Index.

**pandas.arrays.IntervalArray.right****property** IntervalArray.**right**

Return the right endpoints of each Interval in the IntervalArray as an Index.

**pandas.arrays.IntervalArray.closed****property** IntervalArray.**closed**

Whether the intervals are closed on the left-side, right-side, both or neither.

**pandas.arrays.IntervalArray.mid****property** IntervalArray.**mid**

Return the midpoint of each Interval in the IntervalArray as an Index.

**pandas.arrays.IntervalArray.length****property** IntervalArray.**length**

Return an Index with entries denoting the length of each Interval in the IntervalArray.

**pandas.arrays.IntervalArray.is\_empty**IntervalArray.**is\_empty**

Indicates if an interval is empty, meaning it contains no points.

New in version 0.25.0.

**Returns**

**bool or ndarray** A boolean indicating if a scalar Interval is empty, or a boolean ndarray positionally indicating if an Interval in an IntervalArray or IntervalIndex is empty.

## Examples

An Interval that contains points is not empty:

```
>>> pd.Interval(0, 1, closed='right').is_empty
False
```

An Interval that does not contain any points is empty:

```
>>> pd.Interval(0, 0, closed='right').is_empty
True
>>> pd.Interval(0, 0, closed='left').is_empty
True
>>> pd.Interval(0, 0, closed='neither').is_empty
True
```

An Interval that contains a single point is not empty:

```
>>> pd.Interval(0, 0, closed='both').is_empty
False
```

An IntervalArray or IntervalIndex returns a boolean ndarray positionally indicating if an Interval is empty:

```
>>> ivs = [pd.Interval(0, 0, closed='neither'),
...        pd.Interval(1, 2, closed='neither')]
>>> pd.arrays.IntervalArray(ivs).is_empty
array([ True, False])
```

Missing values are not considered empty:

```
>>> ivs = [pd.Interval(0, 0, closed='neither'), np.nan]
>>> pd.IntervalIndex(ivs).is_empty
array([ True, False])
```

## pandas.arrays.IntervalArray.is\_non\_overlapping\_monotonic

**property** IntervalArray.is\_non\_overlapping\_monotonic

Return True if the IntervalArray is non-overlapping (no Intervals share points) and is either monotonic increasing or monotonic decreasing, else False.

## Methods

<i>from_arrays</i> (left, right[, closed, copy, dtype])	Construct from two arrays defining the left and right bounds.
<i>from_tuples</i> (data[, closed, copy, dtype])	Construct an IntervalArray from an array-like of tuples.
<i>from_breaks</i> (breaks[, closed, copy, dtype])	Construct an IntervalArray from an array of splits.
<i>contains</i> (self, other)	Check elementwise if the Intervals contain the value.
<i>overlaps</i> (self, other)	Check elementwise if an Interval overlaps the values in the IntervalArray.

Continued on next page

Table 108 – continued from previous page

<code>set_closed(self, closed)</code>	Return an IntervalArray identical to the current one, but closed on the specified side.
<code>to_tuples(self[, na_tuple])</code>	Return an ndarray of tuples of the form (left, right).

**pandas.arrays.IntervalArray.from\_arrays**

**classmethod** `IntervalArray.from_arrays` (*left*, *right*, *closed='right'*, *copy=False*, *dtype=None*)

Construct from two arrays defining the left and right bounds.

**Parameters**

**left** [array-like (1-dimensional)] Left bounds for each interval.

**right** [array-like (1-dimensional)] Right bounds for each interval.

**closed** [{'left', 'right', 'both', 'neither'}, default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.

**copy** [bool, default False] Copy the data.

**dtype** [dtype, optional] If None, dtype will be inferred.

New in version 0.23.0.

**Returns**

**IntervalArray**

**Raises**

**ValueError** When a value is missing in only one of *left* or *right*. When a value in *left* is greater than the corresponding value in *right*.

**See also:**

**interval\_range** Function to create a fixed frequency IntervalIndex.

**IntervalArray.from\_breaks** Construct an IntervalArray from an array of splits.

**IntervalArray.from\_tuples** Construct an IntervalArray from an array-like of tuples.

**Notes**

Each element of *left* must be less than or equal to the *right* element at the same position. If an element is missing, it must be missing in both *left* and *right*. A `TypeError` is raised when using an unsupported type for *left* or *right*. At the moment, 'category', 'object', and 'string' subtypes are not supported.

```
>>> pd.arrays.IntervalArray.from_arrays([0, 1, 2], [1, 2, 3])
<IntervalArray>
[(0, 1], (1, 2], (2, 3]]
Length: 3, closed: right, dtype: interval[int64]
```

## pandas.arrays.IntervalArray.from\_tuples

**classmethod** `IntervalArray.from_tuples` (*data*, *closed='right'*, *copy=False*, *dtype=None*)  
Construct an IntervalArray from an array-like of tuples.

### Parameters

- data** [array-like (1-dimensional)] Array of tuples.
- closed** [{'left', 'right', 'both', 'neither'}, default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.
- copy** [bool, default False] By-default copy the data, this is compat only and ignored.
- dtype** [dtype or None, default None] If None, dtype will be inferred.

New in version 0.23.0.

### Returns

**IntervalArray**

See also:

**interval\_range** Function to create a fixed frequency IntervalIndex.

**IntervalArray.from\_arrays** Construct an IntervalArray from a left and right array.

**IntervalArray.from\_breaks** Construct an IntervalArray from an array of splits.

### Examples

```
>>> pd.arrays.IntervalArray.from_tuples([(0, 1), (1, 2)])
<IntervalArray>
[(0, 1], (1, 2]]
Length: 2, closed: right, dtype: interval[int64]
```

## pandas.arrays.IntervalArray.from\_breaks

**classmethod** `IntervalArray.from_breaks` (*breaks*, *closed='right'*, *copy=False*, *dtype=None*)  
Construct an IntervalArray from an array of splits.

### Parameters

- breaks** [array-like (1-dimensional)] Left and right bounds for each interval.
- closed** [{'left', 'right', 'both', 'neither'}, default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.
- copy** [bool, default False] Copy the data.
- dtype** [dtype or None, default None] If None, dtype will be inferred.

New in version 0.23.0.

### Returns

**IntervalArray**

See also:

**interval\_range** Function to create a fixed frequency IntervalIndex.

**IntervalArray.from\_arrays** Construct from a left and right array.

**IntervalArray.from\_tuples** Construct from a sequence of tuples.

## Examples

```
>>> pd.arrays.IntervalArray.from_breaks([0, 1, 2, 3])
<IntervalArray>
[(0, 1], (1, 2], (2, 3]]
Length: 3, closed: right, dtype: interval[int64]
```

## pandas.arrays.IntervalArray.contains

`IntervalArray.contains` (*self*, *other*)

Check elementwise if the Intervals contain the value.

Return a boolean mask whether the value is contained in the Intervals of the IntervalArray.

New in version 0.25.0.

### Parameters

**other** [scalar] The value to check whether it is contained in the Intervals.

### Returns

**boolean array**

See also:

**Interval.contains** Check whether Interval object contains value.

**IntervalArray.overlaps** Check if an Interval overlaps the values in the IntervalArray.

## Examples

```
>>> intervals = pd.arrays.IntervalArray.from_tuples([(0, 1), (1, 3), (2, 4)])
>>> intervals
<IntervalArray>
[(0, 1], (1, 3], (2, 4]]
Length: 3, closed: right, dtype: interval[int64]
```

```
>>> intervals.contains(0.5)
array([ True, False, False])
```

## pandas.arrays.IntervalArray.overlaps

IntervalArray.**overlaps** (*self*, *other*)

Check elementwise if an Interval overlaps the values in the IntervalArray.

Two intervals overlap if they share a common point, including closed endpoints. Intervals that only have an open endpoint in common do not overlap.

New in version 0.24.0.

### Parameters

**other** [IntervalArray] Interval to check against for an overlap.

### Returns

**ndarray** Boolean array positionally indicating where an overlap occurs.

**See also:**

**Interval.overlaps** Check whether two Interval objects overlap.

### Examples

```
>>> data = [(0, 1), (1, 3), (2, 4)]
>>> intervals = pd.arrays.IntervalArray.from_tuples(data)
>>> intervals
<IntervalArray>
[(0, 1], (1, 3], (2, 4]]
Length: 3, closed: right, dtype: interval[int64]
```

```
>>> intervals.overlaps(pd.Interval(0.5, 1.5))
array([ True,  True, False])
```

Intervals that share closed endpoints overlap:

```
>>> intervals.overlaps(pd.Interval(1, 3, closed='left'))
array([ True,  True,  True])
```

Intervals that only have an open endpoint in common do not overlap:

```
>>> intervals.overlaps(pd.Interval(1, 2, closed='right'))
array([False,  True, False])
```

## pandas.arrays.IntervalArray.set\_closed

IntervalArray.**set\_closed** (*self*, *closed*)

Return an IntervalArray identical to the current one, but closed on the specified side.

New in version 0.24.0.

### Parameters

**closed** [{'left', 'right', 'both', 'neither'}] Whether the intervals are closed on the left-side, right-side, both or neither.

### Returns

`new_index` [IntervalArray]

### Examples

```
>>> index = pd.arrays.IntervalArray.from_breaks(range(4))
>>> index
<IntervalArray>
[[0, 1], (1, 2], (2, 3]]
Length: 3, closed: right, dtype: interval[int64]
>>> index.set_closed('both')
<IntervalArray>
[[0, 1], [1, 2], [2, 3]]
Length: 3, closed: both, dtype: interval[int64]
```

### pandas.arrays.IntervalArray.to\_tuples

IntervalArray.**to\_tuples** (*self*, *na\_tuple=True*)

Return an ndarray of tuples of the form (left, right).

#### Parameters

**na\_tuple** [boolean, default True] Returns NA as a tuple if True, (nan, nan), or just as the NA value itself if False, nan.

New in version 0.23.0.

#### Returns

**tuples:** ndarray

*IntervalDtype*

An ExtensionDtype for Interval data.

### pandas.IntervalDtype

**class** pandas.**IntervalDtype**

An ExtensionDtype for Interval data.

**This is not an actual numpy dtype**, but a duck type.

#### Parameters

**subtype** [str, np.dtype] The dtype of the Interval bounds.

### Examples

```
>>> pd.IntervalDtype(subtype='int64')
interval[int64]
```

## Attributes

<code>subtype</code>	The dtype of the Interval bounds.
----------------------	-----------------------------------

---

## pandas.IntervalDtype.subtype

**property** `IntervalDtype.subtype`  
The dtype of the Interval bounds.

## Methods

None	
------	--

## 4.5.7 Nullable integer

`numpy.ndarray` cannot natively represent integer-data with missing values. Pandas provides this through `arrays.IntegerArray`.

<code>arrays.IntegerArray(values, mask[, copy])</code>	Array of integer (optional missing) values.
--------------------------------------------------------	---------------------------------------------

---

## pandas.arrays.IntegerArray

**class** `pandas.arrays.IntegerArray` (*values, mask, copy=False*)  
Array of integer (optional missing) values.

New in version 0.24.0.

Changed in version 1.0.0: Now uses `pandas.NA` as the missing value rather than `numpy.nan`.

**Warning:** `IntegerArray` is currently experimental, and its API or internal implementation may change without warning.

We represent an `IntegerArray` with 2 numpy arrays:

- `data`: contains a numpy integer array of the appropriate dtype
- `mask`: a boolean array holding a mask on the data, True is missing

To construct an `IntegerArray` from generic array-like input, use `pandas.array()` with one of the integer dtypes (see examples).

See *Nullable integer data type* for more.

### Parameters

**values** [`numpy.ndarray`] A 1-d integer-dtype array.

**mask** [`numpy.ndarray`] A 1-d boolean-dtype array indicating missing values.

**copy** [`bool`, default `False`] Whether to copy the *values* and *mask*.

### Returns

**IntegerArray**

## Examples

Create an IntegerArray with `pandas.array()`.

```
>>> int_array = pd.array([1, None, 3], dtype=pd.Int32Dtype())
>>> int_array
<IntegerArray>
[1, <NA>, 3]
Length: 3, dtype: Int32
```

String aliases for the dtypes are also available. They are capitalized.

```
>>> pd.array([1, None, 3], dtype='Int32')
<IntegerArray>
[1, <NA>, 3]
Length: 3, dtype: Int32
```

```
>>> pd.array([1, None, 3], dtype='UInt16')
<IntegerArray>
[1, <NA>, 3]
Length: 3, dtype: UInt16
```

## Attributes

None

## Methods

None	
------	--

<i>Int8Dtype</i>	An ExtensionDtype for int8 integer data.
<i>Int16Dtype</i>	An ExtensionDtype for int16 integer data.
<i>Int32Dtype</i>	An ExtensionDtype for int32 integer data.
<i>Int64Dtype</i>	An ExtensionDtype for int64 integer data.
<i>UInt8Dtype</i>	An ExtensionDtype for uint8 integer data.
<i>UInt16Dtype</i>	An ExtensionDtype for uint16 integer data.
<i>UInt32Dtype</i>	An ExtensionDtype for uint32 integer data.
<i>UInt64Dtype</i>	An ExtensionDtype for uint64 integer data.

### pandas.Int8Dtype

**class** pandas.Int8Dtype

An ExtensionDtype for int8 integer data.

Changed in version 1.0.0: Now uses pandas.NA as its missing value, rather than numpy.nan.

#### Attributes

None	
------	--

#### Methods

None	
------	--

### pandas.Int16Dtype

**class** pandas.Int16Dtype

An ExtensionDtype for int16 integer data.

Changed in version 1.0.0: Now uses pandas.NA as its missing value, rather than numpy.nan.

#### Attributes

None	
------	--

#### Methods

None	
------	--

### pandas.Int32Dtype

**class** pandas.Int32Dtype

An ExtensionDtype for int32 integer data.

Changed in version 1.0.0: Now uses pandas.NA as its missing value, rather than numpy.nan.

### Attributes

None	
------	--

### Methods

None	
------	--

## pandas.Int64Dtype

**class** pandas.Int64Dtype

An ExtensionDtype for int64 integer data.

Changed in version 1.0.0: Now uses pandas.NA as its missing value, rather than numpy.nan.

### Attributes

None	
------	--

### Methods

None	
------	--

## pandas.UInt8Dtype

**class** pandas.UInt8Dtype

An ExtensionDtype for uint8 integer data.

Changed in version 1.0.0: Now uses pandas.NA as its missing value, rather than numpy.nan.

### Attributes

None	
------	--

### Methods

None	
------	--

### pandas.UInt16Dtype

**class** pandas.UInt16Dtype

An ExtensionDtype for uint16 integer data.

Changed in version 1.0.0: Now uses pandas.NA as its missing value, rather than numpy.nan.

#### Attributes

None	
------	--

#### Methods

None	
------	--

### pandas.UInt32Dtype

**class** pandas.UInt32Dtype

An ExtensionDtype for uint32 integer data.

Changed in version 1.0.0: Now uses pandas.NA as its missing value, rather than numpy.nan.

#### Attributes

None	
------	--

#### Methods

None	
------	--

### pandas.UInt64Dtype

**class** pandas.UInt64Dtype

An ExtensionDtype for uint64 integer data.

Changed in version 1.0.0: Now uses pandas.NA as its missing value, rather than numpy.nan.

## Attributes

None

## 4.5.8 Categorical data

Pandas defines a custom data type for representing data that can take only a limited, fixed set of values. The dtype of a `Categorical` can be described by a `pandas.api.types.CategoricalDtype`.

<code>CategoricalDtype(categories, ordered)</code>	Type for categorical data with the categories and orderedness.
----------------------------------------------------	----------------------------------------------------------------

### `pandas.CategoricalDtype`

**class** `pandas.CategoricalDtype` (*categories=None, ordered: Optional[bool] = False*)

Type for categorical data with the categories and orderedness.

Changed in version 0.21.0.

#### Parameters

**categories** [sequence, optional] Must be unique, and must not contain any nulls.

**ordered** [bool or None, default False] Whether or not this categorical is treated as a ordered categorical. None can be used to maintain the ordered value of existing categoricals when used in operations that combine categoricals, e.g. `astype`, and will resolve to False if there is no existing ordered to maintain.

See also:

*Categorical*

#### Notes

This class is useful for specifying the type of a `Categorical` independent of the values. See *CategoricalDtype* for more.

#### Examples

```
>>> t = pd.CategoricalDtype(categories=['b', 'a'], ordered=True)
>>> pd.Series(['a', 'b', 'a', 'c'], dtype=t)
0      a
1      b
2      a
3     NaN
dtype: category
Categories (2, object): [b < a]
```

## Attributes

<i>categories</i>	An Index containing the unique categories allowed.
<i>ordered</i>	Whether the categories have an ordered relationship.

### pandas.CategoricalDtype.categories

**property** `CategoricalDtype.categories`  
An Index containing the unique categories allowed.

### pandas.CategoricalDtype.ordered

**property** `CategoricalDtype.ordered`  
Whether the categories have an ordered relationship.

## Methods

None	
------	--

<i>CategoricalDtype.categories</i>	An Index containing the unique categories allowed.
<i>CategoricalDtype.ordered</i>	Whether the categories have an ordered relationship.

Categorical data can be stored in a `pandas.Categorical`

<code>Categorical(values[, categories, ordered, ...])</code>	Represent a categorical variable in classic R / S-plus fashion.
--------------------------------------------------------------	-----------------------------------------------------------------

## pandas.Categorical

**class** `pandas.Categorical` (*values, categories=None, ordered=None, dtype=None, fastpath=False*)  
Represent a categorical variable in classic R / S-plus fashion.

*Categoricals* can only take on only a limited, and usually fixed, number of possible values (*categories*). In contrast to statistical categorical variables, a *Categorical* might have an order, but numerical operations (additions, divisions, ...) are not possible.

All values of the *Categorical* are either in *categories* or *np.nan*. Assigning values outside of *categories* will raise a *ValueError*. Order is defined by the order of the *categories*, not lexical order of the values.

### Parameters

- values** [list-like] The values of the categorical. If categories are given, values not in categories will be replaced with NaN.
- categories** [Index-like (unique), optional] The unique categories for this categorical. If not given, the categories are assumed to be the unique values of *values* (sorted, if possible, otherwise in the order in which they appear).
- ordered** [bool, default False] Whether or not this categorical is treated as an ordered categorical. If True, the resulting categorical will be ordered. An ordered categorical respects,

when sorted, the order of its *categories* attribute (which in turn is the *categories* argument, if provided).

**dtype** [CategoricalDtype] An instance of `CategoricalDtype` to use for this categorical.

New in version 0.21.0.

### Raises

**ValueError** If the categories do not validate.

**TypeError** If an explicit `ordered=True` is given but no *categories* and the *values* are not sortable.

### See also:

**`CategoricalDtype`** Type for categorical data.

**`CategoricalIndex`** An Index with an underlying `Categorical`.

### Notes

See the [user guide](#) for more.

### Examples

```
>>> pd.Categorical([1, 2, 3, 1, 2, 3])
[1, 2, 3, 1, 2, 3]
Categories (3, int64): [1, 2, 3]
```

```
>>> pd.Categorical(['a', 'b', 'c', 'a', 'b', 'c'])
[a, b, c, a, b, c]
Categories (3, object): [a, b, c]
```

Ordered *Categoricals* can be sorted according to the custom order of the categories and can have a min and max value.

```
>>> c = pd.Categorical(['a', 'b', 'c', 'a', 'b', 'c'], ordered=True,
...                   categories=['c', 'b', 'a'])
>>> c
[a, b, c, a, b, c]
Categories (3, object): [c < b < a]
>>> c.min()
'c'
```

### Attributes

<code>categories</code>	The categories of this categorical.
<code>codes</code>	The category codes of this categorical.
<code>ordered</code>	Whether the categories have an ordered relationship.
<code>dtype</code>	The <code>CategoricalDtype</code> for this instance.

## `pandas.Categorical.categories`

**property** `Categorical.categories`

The categories of this categorical.

Setting assigns new values to each category (effectively a rename of each individual category).

The assigned value has to be a list-like object. All items must be unique and the number of items in the new categories must be the same as the number of items in the old categories.

Assigning to *categories* is a inplace operation!

### **Raises**

**ValueError** If the new categories do not validate as categories or if the number of new categories is unequal the number of old categories

**See also:**

`rename_categories`

`reorder_categories`

`add_categories`

`remove_categories`

`remove_unused_categories`

`set_categories`

## `pandas.Categorical.codes`

**property** `Categorical.codes`

The category codes of this categorical.

Level codes are an array of integer which are the positions of the real values in the categories array.

There is not setter, use the other categorical methods and the normal item setter to change values in the categorical.

## `pandas.Categorical.ordered`

**property** `Categorical.ordered`

Whether the categories have an ordered relationship.

## `pandas.Categorical.dtype`

**property** `Categorical.dtype`

The `CategoricalDtype` for this instance.

## Methods

<code>from_codes(codes[, categories, ordered, dtype])</code>	Make a Categorical type from codes and categories or dtype.
<code>__array__(self[, dtype])</code>	The numpy array interface.

### pandas.Categorical.from\_codes

**classmethod** `Categorical.from_codes` (*codes*, *categories=None*, *ordered=None*, *dtype=None*)

Make a Categorical type from codes and categories or dtype.

This constructor is useful if you already have codes and categories/dtype and so do not need the (computation intensive) factorization step, which is usually done on the constructor.

If your data does not follow this convention, please use the normal constructor.

#### Parameters

**codes** [array-like of int] An integer array, where each integer points to a category in categories or dtype.categories, or else is -1 for NaN.

**categories** [index-like, optional] The categories for the categorical. Items need to be unique. If the categories are not given here, then they must be provided in *dtype*.

**ordered** [bool, optional] Whether or not this categorical is treated as an ordered categorical. If not given here or in *dtype*, the resulting categorical will be unordered.

**dtype** [CategoricalDtype or “category”, optional] If *CategoricalDtype*, cannot be used together with *categories* or *ordered*.

New in version 0.24.0: When *dtype* is provided, neither *categories* nor *ordered* should be provided.

#### Returns

**Categorical**

#### Examples

```
>>> dtype = pd.CategoricalDtype(['a', 'b'], ordered=True)
>>> pd.Categorical.from_codes(codes=[0, 1, 0, 1], dtype=dtype)
[a, b, a, b]
Categories (2, object): [a < b]
```

### pandas.Categorical.\_\_array\_\_

`Categorical.__array__(self, dtype=None) → numpy.ndarray`

The numpy array interface.

#### Returns

**numpy.array** A numpy array of either the specified dtype or, if dtype==None (default), the same dtype as categorical.categories.dtype.

The alternative `Categorical.from_codes()` constructor can be used when you have the categories and integer codes already:

<code>Categorical.from_codes(codes[, categories, ...])</code>	Make a Categorical type from codes and categories or dtype.
---------------------------------------------------------------	-------------------------------------------------------------

---

The dtype information is available on the `Categorical`

<code>Categorical.dtype</code>	The CategoricalDtype for this instance.
<code>Categorical.categories</code>	The categories of this categorical.
<code>Categorical.ordered</code>	Whether the categories have an ordered relationship.
<code>Categorical.codes</code>	The category codes of this categorical.

---

`np.asarray(categorical)` works by implementing the array interface. Be aware, that this converts the Categorical back to a NumPy array, so categories and order information is not preserved!

<code>Categorical.__array__(self[, dtype])</code>	The numpy array interface.
---------------------------------------------------	----------------------------

---

A Categorical can be stored in a Series or DataFrame. To create a Series of dtype `category`, use `cat = s.astype(dtype)` or `Series(..., dtype=dtype)` where `dtype` is either

- the string `'category'`
- an instance of `CategoricalDtype`.

If the Series is of dtype `CategoricalDtype`, `Series.cat` can be used to change the categorical data. See *Categorical accessor* for more.

### 4.5.9 Sparse data

Data where a single value is repeated many times (e.g. 0 or NaN) may be stored efficiently as a `arrays.SparseArray`.

<code>arrays.SparseArray(data[, sparse_index, ...])</code>	An ExtensionArray for storing sparse data.
------------------------------------------------------------	--------------------------------------------

---

#### **pandas.arrays.SparseArray**

**class** `pandas.arrays.SparseArray` (*data*, *sparse\_index=None*, *index=None*, *fill\_value=None*, *kind='integer'*, *dtype=None*, *copy=False*)

An ExtensionArray for storing sparse data.

Changed in version 0.24.0: Implements the ExtensionArray interface.

**Parameters**

**data** [array-like] A dense array of values to store in the SparseArray. This may contain *fill\_value*.

**sparse\_index** [SparseIndex, optional]

**index** [Index]

**fill\_value** [scalar, optional] Elements in *data* that are *fill\_value* are not stored in the SparseArray. For memory savings, this should be the most common value in *data*. By default, *fill\_value* depends on the dtype of *data*:

data.dtype	na_value
float	np.nan
int	0
bool	False
datetime64	pd.NaT
timedelta64	pd.NaT

The fill value is potentially specified in three ways. In order of precedence, these are

1. The *fill\_value* argument
2. `dtype.fill_value` if *fill\_value* is None and *dtype* is a `SparseDtype`
3. `data.dtype.fill_value` if *fill\_value* is None and *dtype* is not a `SparseDtype` and *data* is a `SparseArray`.

**kind** [[‘integer’, ‘block’], default ‘integer’] The type of storage for sparse locations.

- ‘block’: Stores a *block* and *block\_length* for each contiguous *span* of sparse values. This is best when sparse data tends to be clumped together, with large regions of *fill-value* values between sparse values.
- ‘integer’: uses an integer to store the location of each sparse value.

**dtype** [np.dtype or SparseDtype, optional] The dtype to use for the `SparseArray`. For numpy dtypes, this determines the dtype of `self.sp_values`. For `SparseDtype`, this determines `self.sp_values` and `self.fill_value`.

**copy** [bool, default False] Whether to explicitly copy the incoming *data* array.

## Attributes

None	
------	--

## Methods

None	
------	--

`SparseDtype(dtype, fill_value)`

Dtype for data stored in `SparseArray`.

## pandas.SparseDtype

```
class pandas.SparseDtype (dtype: Union[str, numpy.dtype, ExtensionDtype] = <class 'numpy.float64'>, fill_value: Any = None)
```

Dtype for data stored in `SparseArray`.

This dtype implements the pandas `ExtensionDtype` interface.

New in version 0.24.0.

### Parameters

**dtype** [str, ExtensionDtype, numpy.dtype, type, default `numpy.float64`] The dtype of the underlying array storing the non-fill value values.

**fill\_value** [scalar, optional] The scalar value not stored in the SparseArray. By default, this depends on *dtype*.

dtype	na_value
float	np.nan
int	0
bool	False
datetime64	pd.NaT
timedelta64	pd.NaT

The default value may be overridden by specifying a *fill\_value*.

### Attributes

None	
------	--

### Methods

None	
------	--

The `Series.sparse` accessor may be used to access sparse-specific attributes and methods if the `Series` contains sparse values. See *Sparse accessor* for more.

## 4.5.10 Text data

When working with text data, where each valid element is a string or missing, we recommend using `StringDtype` (with the alias "string").

---

`arrays.StringArray(values[, copy])`                      Extension array for string data.

---

### pandas.arrays.StringArray

**class** `pandas.arrays.StringArray` (*values, copy=False*)

Extension array for string data.

New in version 1.0.0.

<b>Warning:</b> <code>StringArray</code> is considered experimental. The implementation and parts of the API may change without warning.
------------------------------------------------------------------------------------------------------------------------------------------

#### Parameters

**values** [array-like] The array of data.

<b>Warning:</b> Currently, this expects an object-dtype ndarray where the elements are Python strings or <code>pandas.NA</code> . This may change without warning in the future.
----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

Use `pandas.array()` with `dtype="string"` for a stable way of creating a `StringArray` from any sequence.

**copy** [bool, default False] Whether to copy the array of data.

#### See also:

**array** The recommended function for creating a `StringArray`.

**Series.str** The string methods are available on Series backed by a `StringArray`.

#### Notes

`StringArray` returns a `BooleanArray` for comparison methods.

#### Examples

```
>>> pd.array(['This is', 'some text', None, 'data.'], dtype="string")
<StringArray>
['This is', 'some text', <NA>, 'data.']
Length: 4, dtype: string
```

Unlike object dtype arrays, `StringArray` doesn't allow non-string values.

```
>>> pd.array(['1', 1], dtype="string")
Traceback (most recent call last):
...
ValueError: StringArray requires an object-dtype ndarray of strings.
```

For comparison methods, this returns a `pandas.BooleanArray`

```
>>> pd.array(["a", None, "c"], dtype="string") == "a"
<BooleanArray>
[True, <NA>, False]
Length: 3, dtype: boolean
```

#### Attributes

None

#### Methods

None

*StringDtype*

Extension dtype for string data.

## pandas.StringDtype

**class** pandas.**StringDtype**  
Extension dtype for string data.  
New in version 1.0.0.

**Warning:** StringDtype is considered experimental. The implementation and parts of the API may change without warning.  
In particular, StringDtype.na\_value may change to no longer be `numpy.nan`.

### Examples

```
>>> pd.StringDtype()  
StringDtype
```

### Attributes

None	
------	--

### Methods

None	
------	--

The `Series.str` accessor is available for `Series` backed by a `arrays.StringArray`. See *String handling* for more.

## 4.5.11 Boolean data with missing values

The boolean dtype (with the alias "boolean") provides support for storing boolean data (True, False values) with missing values, which is not possible with a `bool numpy.ndarray`.

---

`arrays.BooleanArray(values, mask[, copy])`      Array of boolean (True/False) data with missing values.

---

## pandas.arrays.BooleanArray

**class** pandas.arrays.**BooleanArray** (*values: numpy.ndarray, mask: numpy.ndarray, copy: bool = False*)  
Array of boolean (True/False) data with missing values.

This is a pandas Extension array for boolean data, under the hood represented by 2 numpy arrays: a boolean array with the data and a boolean array with the mask (True indicating missing).

BooleanArray implements Kleene logic (sometimes called three-value logic) for logical operations. See *Kleene Logical Operations* for more.

To construct an BooleanArray from generic array-like input, use `pandas.array()` specifying `dtype=`

"boolean" (see examples below).

New in version 1.0.0.

**Warning:** BooleanArray is considered experimental. The implementation and parts of the API may change without warning.

### Parameters

**values** [numpy.ndarray] A 1-d boolean-dtype array with the data.

**mask** [numpy.ndarray] A 1-d boolean-dtype array indicating missing values (True indicates missing).

**copy** [bool, default False] Whether to copy the *values* and *mask* arrays.

### Returns

**BooleanArray**

### Examples

Create an BooleanArray with `pandas.array()`:

```
>>> pd.array([True, False, None], dtype="boolean")
<BooleanArray>
[True, False, <NA>]
Length: 3, dtype: boolean
```

### Attributes

None	
------	--

### Methods

None	
------	--

*BooleanDtype*

Extension dtype for boolean data.

## pandas.BooleanDtype

**class** pandas.**BooleanDtype**

Extension dtype for boolean data.

New in version 1.0.0.

**Warning:** BooleanDtype is considered experimental. The implementation and parts of the API may change without warning.

## Examples

```
>>> pd.BooleanDtype()  
BooleanDtype
```

## Attributes

## 4.6 Panel

*Panel* was removed in 0.25.0. For prior documentation, see the [0.24 documentation](#)

{{ header }}

## 4.7 Index objects

### 4.7.1 Index

Many of these methods or variants thereof are available on the objects that contain an index (Series/DataFrame) and those should most likely be used before calling these methods directly.

*Index*

Immutable ndarray implementing an ordered, sliceable set.

---

### pandas.Index

**class** pandas.Index

Immutable ndarray implementing an ordered, sliceable set. The basic object storing axis labels for all pandas objects.

#### Parameters

**data** [array-like (1-dimensional)]

**dtype** [NumPy dtype (default: object)] If dtype is None, we find the dtype that best fits the data. If an actual dtype is provided, we coerce to that dtype if it's safe. Otherwise, an error will be raised.

**copy** [bool] Make a copy of input ndarray.

**name** [object] Name to be stored in the index.

**tupleize\_cols** [bool (default: True)] When True, attempt to create a MultiIndex if possible.

See also:

**RangeIndex** Index implementing a monotonic integer range.

**CategoricalIndex** Index of *Categorical*s.

**MultiIndex** A multi-level, or hierarchical, Index.

**IntervalIndex** An Index of *Interval*s.

**DatetimeIndex, TimedeltaIndex, PeriodIndex**

**Int64Index, UInt64Index, Float64Index**

## Notes

An Index instance can **only** contain hashable objects

## Examples

```
>>> pd.Index([1, 2, 3])
Int64Index([1, 2, 3], dtype='int64')
```

```
>>> pd.Index(list('abc'))
Index(['a', 'b', 'c'], dtype='object')
```

## Attributes

<i>T</i>	Return the transpose, which is by definition self.
<i>array</i>	The ExtensionArray of the data backing this Series or Index.
<i>asi8</i>	Integer representation of the values.
<i>dtype</i>	Return the dtype object of the underlying data.
<i>hasnans</i>	Return if I have any nans; enables various perf speedups.
<i>inferred_type</i>	Return a string of the type inferred from the values.
<i>is_monotonic</i>	Alias for <i>is_monotonic_increasing</i> .
<i>is_monotonic_decreasing</i>	Return if the index is monotonic decreasing (only equal or decreasing) values.
<i>is_monotonic_increasing</i>	Return if the index is monotonic increasing (only equal or increasing) values.
<i>is_unique</i>	Return if the index has unique values.
<i>nbytes</i>	Return the number of bytes in the underlying data.
<i>ndim</i>	Number of dimensions of the underlying data, by definition 1.
<i>nlevels</i>	Number of levels.
<i>shape</i>	Return a tuple of the shape of the underlying data.
<i>size</i>	Return the number of elements in the underlying data.
<i>values</i>	Return an array representing the data in the Index.

## pandas.Index.T

**property** `Index.T`

Return the transpose, which is by definition self.

## pandas.Index.array

`Index.array`

The ExtensionArray of the data backing this Series or Index.

New in version 0.24.0.

### Returns

**ExtensionArray** An ExtensionArray of the values stored within. For extension types, this is the actual array. For NumPy native types, this is a thin (no copy) wrapper around `numpy.ndarray`.

`.array` differs `.values` which may require converting the data to a different form.

### See also:

***Index.to\_numpy*** Similar method that always returns a NumPy array.

***Series.to\_numpy*** Similar method that always returns a NumPy array.

## Notes

This table lays out the different array types for each extension dtype within pandas.

dtype	array type
category	Categorical
period	PeriodArray
interval	IntervalArray
IntegerNA	IntegerArray
string	StringArray
boolean	BooleanArray
datetime64[ns, tz]	DatetimeArray

For any 3rd-party extension types, the array type will be an ExtensionArray.

For all remaining dtypes `.array` will be a `arrays.NumpyExtensionArray` wrapping the actual ndarray stored within. If you absolutely need a NumPy array (possibly with copying / coercing data), then use `Series.to_numpy()` instead.

## Examples

For regular NumPy types like int, and float, a PandasArray is returned.

```
>>> pd.Series([1, 2, 3]).array
<PandasArray>
[1, 2, 3]
Length: 3, dtype: int64
```

For extension types, like Categorical, the actual ExtensionArray is returned

```
>>> ser = pd.Series(pd.Categorical(['a', 'b', 'a']))
>>> ser.array
[a, b, a]
Categories (2, object): [a, b]
```

### pandas.Index.asi8

**property** `Index.asi8`

Integer representation of the values.

#### Returns

**ndarray** An ndarray with int64 dtype.

### pandas.Index.dtype

`Index.dtype`

Return the dtype object of the underlying data.

### pandas.Index.hasnans

`Index.hasnans`

Return if I have any nans; enables various perf speedups.

### pandas.Index.inferred\_type

`Index.inferred_type`

Return a string of the type inferred from the values.

### pandas.Index.is\_monotonic

**property** `Index.is_monotonic`

Alias for `is_monotonic_increasing`.

### **pandas.Index.is\_monotonic\_decreasing**

**property** `Index.is_monotonic_decreasing`

Return if the index is monotonic decreasing (only equal or decreasing) values.

#### **Examples**

```
>>> Index([3, 2, 1]).is_monotonic_decreasing
True
>>> Index([3, 2, 2]).is_monotonic_decreasing
True
>>> Index([3, 1, 2]).is_monotonic_decreasing
False
```

### **pandas.Index.is\_monotonic\_increasing**

**property** `Index.is_monotonic_increasing`

Return if the index is monotonic increasing (only equal or increasing) values.

#### **Examples**

```
>>> Index([1, 2, 3]).is_monotonic_increasing
True
>>> Index([1, 2, 2]).is_monotonic_increasing
True
>>> Index([1, 3, 2]).is_monotonic_increasing
False
```

### **pandas.Index.is\_unique**

**Index.is\_unique**

Return if the index has unique values.

### **pandas.Index.nbytes**

**property** `Index.nbytes`

Return the number of bytes in the underlying data.

### **pandas.Index.ndim**

**property** `Index.ndim`

Number of dimensions of the underlying data, by definition 1.

**pandas.Index.nlevels**

**property** `Index.nlevels`  
Number of levels.

**pandas.Index.shape**

**property** `Index.shape`  
Return a tuple of the shape of the underlying data.

**pandas.Index.size**

**property** `Index.size`  
Return the number of elements in the underlying data.

**pandas.Index.values**

**property** `Index.values`  
Return an array representing the data in the Index.

**Warning:** We recommend using `Index.array` or `Index.to_numpy()`, depending on whether you need a reference to the underlying data or a NumPy array.

**Returns**

**array:** `numpy.ndarray` or `ExtensionArray`

**See also:**

**`Index.array`** Reference to the underlying data.

**`Index.to_numpy`** A NumPy array representing the underlying data.

<b>empty</b>	
<b>has_duplicates</b>	
<b>is_all_dates</b>	
<b>name</b>	
<b>names</b>	

## Methods

<code>all(self, *args, **kwargs)</code>	Return whether all elements are True.
<code>any(self, *args, **kwargs)</code>	Return whether any element is True.
<code>append(self, other)</code>	Append a collection of Index options together.
<code>argmax(self[, axis, skipna])</code>	Return an ndarray of the maximum argument index.
<code>argmin(self[, axis, skipna])</code>	Return a ndarray of the minimum argument index.
<code>argsort(self, *args, **kwargs)</code>	Return the integer indices that would sort the index.
<code>asof(self, label)</code>	Return the label from the index, or, if not present, the previous one.
<code>asof_locs(self, where, mask)</code>	Find the locations (indices) of the labels from the index for every entry in the <i>where</i> argument.
<code>astype(self, dtype[, copy])</code>	Create an Index with values cast to dtypes.
<code>copy(self[, name, deep, dtype])</code>	Make a copy of this object.
<code>delete(self, loc)</code>	Make new Index with passed location(-s) deleted.
<code>difference(self, other[, sort])</code>	Return a new Index with elements from the index that are not in <i>other</i> .
<code>drop(self, labels[, errors])</code>	Make new Index with passed list of labels deleted.
<code>drop_duplicates(self[, keep])</code>	Return Index with duplicate values removed.
<code>droplevel(self[, level])</code>	Return index with requested level(s) removed.
<code>dropna(self[, how])</code>	Return Index without NA/NaN values.
<code>duplicated(self[, keep])</code>	Indicate duplicate index values.
<code>equals(self, other)</code>	Determine if two Index objects contain the same elements.
<code>factorize(self[, sort, na_sentinel])</code>	Encode the object as an enumerated type or categorical variable.
<code>fillna(self[, value, downcast])</code>	Fill NA/NaN values with the specified value.
<code>format(self[, name, formatter])</code>	Render a string representation of the Index.
<code>get_indexer(self, target[, method, limit, ...])</code>	Compute indexer and mask for new index given the current index.
<code>get_indexer_for(self, target, **kwargs)</code>	Guaranteed return of an indexer even when non-unique.
<code>get_indexer_non_unique(self, target)</code>	Compute indexer and mask for new index given the current index.
<code>get_level_values(self, level)</code>	Return an Index of values for requested level.
<code>get_loc(self, key[, method, tolerance])</code>	Get integer location, slice or boolean mask for requested label.
<code>get_slice_bound(self, label, side, kind)</code>	Calculate slice bound that corresponds to given label.
<code>get_value(self, series, key)</code>	Fast lookup of value from 1-dimensional ndarray.
<code>groupby(self, values)</code>	Group the index labels by a given array of values.
<code>holds_integer(self)</code>	Whether the type is an integer type.
<code>identical(self, other)</code>	Similar to equals, but check that other comparable attributes are also equal.
<code>insert(self, loc, item)</code>	Make new Index inserting new item at location.
<code>intersection(self, other[, sort])</code>	Form the intersection of two Index objects.
<code>is_(self, other)</code>	More flexible, faster check like <code>is</code> but that works through views.
<code>is_categorical(self)</code>	Check if the Index holds categorical data.
<code>is_type_compatible(self, kind)</code>	Whether the index type is compatible with the provided type.

Continued on next page

Table 130 – continued from previous page

<code>isin(self, values[, level])</code>	Return a boolean array where the index values are in <i>values</i> .
<code>isna(self)</code>	Detect missing values.
<code>isnull(self)</code>	Detect missing values.
<code>item(self)</code>	Return the first element of the underlying data as a python scalar.
<code>join(self, other[, how, level, ...])</code>	Compute <code>join_index</code> and indexers to conform data structures to the new index.
<code>map(self, mapper[, na_action])</code>	Map values using input correspondence (a dict, Series, or function).
<code>max(self[, axis, skipna])</code>	Return the maximum value of the Index.
<code>memory_usage(self[, deep])</code>	Memory usage of the values.
<code>min(self[, axis, skipna])</code>	Return the minimum value of the Index.
<code>notna(self)</code>	Detect existing (non-missing) values.
<code>notnull(self)</code>	Detect existing (non-missing) values.
<code>nunique(self[, dropna])</code>	Return number of unique elements in the object.
<code>putmask(self, mask, value)</code>	Return a new Index of the values set with the mask.
<code>ravel(self[, order])</code>	Return an ndarray of the flattened values of the underlying data.
<code>reindex(self, target[, method, level, ...])</code>	Create index with target's values (move/add/delete values as necessary).
<code>rename(self, name[, inplace])</code>	Alter Index or MultiIndex name.
<code>repeat(self, repeats[, axis])</code>	Repeat elements of a Index.
<code>searchsorted(self, value[, side, sorter])</code>	Find indices where elements should be inserted to maintain order.
<code>set_names(self, names[, level, inplace])</code>	Set Index or MultiIndex name.
<code>set_value(self, arr, key, value)</code>	(DEPRECATED) Fast lookup of value from 1-dimensional ndarray.
<code>shift(self[, periods, freq])</code>	Shift index by desired number of time frequency increments.
<code>slice_indexer(self[, start, end, step, kind])</code>	For an ordered or unique index, compute the slice indexer for input labels and step.
<code>slice_locs(self[, start, end, step, kind])</code>	Compute slice locations for input labels.
<code>sort(self, *args, **kwargs)</code>	Use <code>sort_values</code> instead.
<code>sort_values(self[, return_indexer, ascending])</code>	Return a sorted copy of the index.
<code>sortlevel(self[, level, ascending, ...])</code>	For internal compatibility with with the Index API.
<code>str</code>	alias of <code>pandas.core.strings.StringMethods</code>
<code>symmetric_difference(self, other[, ...])</code>	Compute the symmetric difference of two Index objects.
<code>take(self, indices[, axis, allow_fill, ...])</code>	Return a new Index of the values selected by the indices.
<code>to_flat_index(self)</code>	Identity method.
<code>to_frame(self[, index, name])</code>	Create a DataFrame with a column containing the Index.
<code>to_list(self)</code>	Return a list of the values.
<code>to_native_types(self[, slicer])</code>	Format specified values of <i>self</i> and return them.
<code>to_numpy(self[, dtype, copy, na_value])</code>	A NumPy ndarray representing the values in this Series or Index.
<code>to_series(self[, index, name])</code>	Create a Series with both index and values equal to the index keys.

Continued on next page

Table 130 – continued from previous page

<code>tolist(self)</code>	Return a list of the values.
<code>transpose(self, *args, **kwargs)</code>	Return the transpose, which is by definition self.
<code>union(self, other[, sort])</code>	Form the union of two Index objects.
<code>unique(self[, level])</code>	Return unique values in the index.
<code>value_counts(self[, normalize, sort, ...])</code>	Return a Series containing counts of unique values.
<code>where(self, cond[, other])</code>	Return an Index of same shape as self and whose corresponding entries are from self where cond is True and otherwise are from other.

## pandas.Index.all

`Index.all` (*self*, \*args, \*\*kwargs)

Return whether all elements are True.

### Parameters

**\*args** These parameters will be passed to `numpy.all`.

**\*\*kwargs** These parameters will be passed to `numpy.all`.

### Returns

**all** [bool or array\_like (if axis is specified)] A single element array\_like may be converted to bool.

### See also:

**Index.any** Return whether any element in an Index is True.

**Series.any** Return whether any element in a Series is True.

**Series.all** Return whether all elements in a Series are True.

## Notes

Not a Number (NaN), positive infinity and negative infinity evaluate to True because these are not equal to zero.

## Examples

### all

True, because nonzero integers are considered True.

```
>>> pd.Index([1, 2, 3]).all()
True
```

False, because 0 is considered False.

```
>>> pd.Index([0, 1, 2]).all()
False
```

### any

True, because 1 is considered True.

```
>>> pd.Index([0, 0, 1]).any()
True
```

False, because 0 is considered False.

```
>>> pd.Index([0, 0, 0]).any()
False
```

## pandas.Index.any

`Index.any` (*self*, \*args, \*\*kwargs)

Return whether any element is True.

### Parameters

**\*args** These parameters will be passed to `numpy.any`.

**\*\*kwargs** These parameters will be passed to `numpy.any`.

### Returns

**any** [bool or array\_like (if axis is specified)] A single element array\_like may be converted to bool.

### See also:

**`Index.all`** Return whether all elements are True.

**`Series.all`** Return whether all elements are True.

### Notes

Not a Number (NaN), positive infinity and negative infinity evaluate to True because these are not equal to zero.

### Examples

```
>>> index = pd.Index([0, 1, 2])
>>> index.any()
True
```

```
>>> index = pd.Index([0, 0, 0])
>>> index.any()
False
```

### **pandas.Index.append**

`Index.append` (*self*, *other*)

Append a collection of Index options together.

#### **Parameters**

**other** [Index or list/tuple of indices]

#### **Returns**

**appended** [Index]

### **pandas.Index.argmax**

`Index.argmax` (*self*, *axis=None*, *skipna=True*, *\*args*, *\*\*kwargs*)

Return an ndarray of the maximum argument indexer.

#### **Parameters**

**axis** [{None}] Dummy argument for consistency with Series.

**skipna** [bool, default True]

#### **Returns**

**numpy.ndarray** Indices of the maximum values.

See also:

`numpy.ndarray.argmax`

### **pandas.Index.argmin**

`Index.argmin` (*self*, *axis=None*, *skipna=True*, *\*args*, *\*\*kwargs*)

Return an ndarray of the minimum argument indexer.

#### **Parameters**

**axis** [{None}] Dummy argument for consistency with Series.

**skipna** [bool, default True]

#### **Returns**

**numpy.ndarray**

See also:

`numpy.ndarray.argmin`

## pandas.Index.argsort

`Index.argsort` (*self*, \*args, \*\*kwargs)

Return the integer indices that would sort the index.

### Parameters

**\*args** Passed to `numpy.ndarray.argsort`.

**\*\*kwargs** Passed to `numpy.ndarray.argsort`.

### Returns

**numpy.ndarray** Integer indices that would sort the index if used as an indexer.

### See also:

**numpy.argsort** Similar method for NumPy arrays.

**Index.sort\_values** Return sorted copy of Index.

### Examples

```
>>> idx = pd.Index(['b', 'a', 'd', 'c'])
>>> idx
Index(['b', 'a', 'd', 'c'], dtype='object')
```

```
>>> order = idx.argsort()
>>> order
array([1, 0, 3, 2])
```

```
>>> idx[order]
Index(['a', 'b', 'c', 'd'], dtype='object')
```

## pandas.Index.asof

`Index.asof` (*self*, label)

Return the label from the index, or, if not present, the previous one.

Assuming that the index is sorted, return the passed index label if it is in the index, or return the previous index label if the passed one is not in the index.

### Parameters

**label** [object] The label up to which the method returns the latest index label.

### Returns

**object** The passed label if it is in the index. The previous label if the passed label is not in the sorted index or *NaN* if there is no such label.

### See also:

**Series.asof** Return the latest value in a Series up to the passed index.

**merge\_asof** Perform an asof merge (similar to left join but it matches on nearest key rather than equal key).

**Index.get\_loc** An *asof* is a thin wrapper around *get\_loc* with `method='pad'`.

## Examples

*Index.asof* returns the latest index label up to the passed label.

```
>>> idx = pd.Index(['2013-12-31', '2014-01-02', '2014-01-03'])
>>> idx.asof('2014-01-01')
'2013-12-31'
```

If the label is in the index, the method returns the passed label.

```
>>> idx.asof('2014-01-02')
'2014-01-02'
```

If all of the labels in the index are later than the passed label, NaN is returned.

```
>>> idx.asof('1999-01-02')
nan
```

If the index is not sorted, an error is raised.

```
>>> idx_not_sorted = pd.Index(['2013-12-31', '2015-01-02',
...                           '2014-01-03'])
>>> idx_not_sorted.asof('2013-12-31')
Traceback (most recent call last):
ValueError: index must be monotonic increasing or decreasing
```

## pandas.Index.asof\_locs

`Index.asof_locs` (*self, where, mask*)

Find the locations (indices) of the labels from the index for every entry in the *where* argument.

As in the *asof* function, if the label (a particular entry in *where*) is not in the index, the latest index label up to the passed label is chosen and its index returned.

If all of the labels in the index are later than a label in *where*, -1 is returned.

*mask* is used to ignore NA values in the index during calculation.

### Parameters

**where** [Index] An Index consisting of an array of timestamps.

**mask** [array-like] Array of booleans denoting where values in the original data are not NA.

### Returns

**numpy.ndarray** An array of locations (indices) of the labels from the Index which correspond to the return values of the *asof* function for every element in *where*.

## pandas.Index.astype

`Index.astype` (*self*, *dtype*, *copy=True*)

Create an Index with values cast to dtypes. The class of a new Index is determined by dtype. When conversion is impossible, a ValueError exception is raised.

### Parameters

**dtype** [numpy dtype or pandas type] Note that any signed integer *dtype* is treated as 'int64', and any unsigned integer *dtype* is treated as 'uint64', regardless of the size.

**copy** [bool, default True] By default, astype always returns a newly allocated object. If copy is set to False and internal requirements on dtype are satisfied, the original data is used to create a new Index or the original Index is returned.

### Returns

**Index** Index with values cast to specified dtype.

## pandas.Index.copy

`Index.copy` (*self*, *name=None*, *deep=False*, *dtype=None*, *\*\*kwargs*)

Make a copy of this object. Name and dtype sets those attributes on the new object.

### Parameters

**name** [str, optional]

**deep** [bool, default False]

**dtype** [numpy dtype or pandas type]

### Returns

**copy** [Index]

### Notes

In most cases, there should be no functional difference from using `deep`, but if `deep` is passed it will attempt to `deepcopy`.

## pandas.Index.delete

`Index.delete` (*self*, *loc*)

Make new Index with passed location(-s) deleted.

### Returns

**new\_index** [Index]

## pandas.Index.difference

`Index.difference` (*self*, *other*, *sort=None*)

Return a new Index with elements from the index that are not in *other*.

This is the set difference of two Index objects.

### Parameters

**other** [Index or array-like]

**sort** [False or None, default None] Whether to sort the resulting index. By default, the values are attempted to be sorted, but any `TypeError` from incomparable elements is caught by pandas.

- `None` : Attempt to sort the result, but catch any `TypeError`s from comparing incomparable elements.
- `False` : Do not sort the result.

New in version 0.24.0.

Changed in version 0.24.1: Changed the default value from `True` to `None` (without change in behaviour).

### Returns

**difference** [Index]

### Examples

```
>>> idx1 = pd.Index([2, 1, 3, 4])
>>> idx2 = pd.Index([3, 4, 5, 6])
>>> idx1.difference(idx2)
Int64Index([1, 2], dtype='int64')
>>> idx1.difference(idx2, sort=False)
Int64Index([2, 1], dtype='int64')
```

## pandas.Index.drop

`Index.drop` (*self*, *labels*, *errors='raise'*)

Make new Index with passed list of labels deleted.

### Parameters

**labels** [array-like]

**errors** [{`'ignore'`, `'raise'`}, default `'raise'`] If `'ignore'`, suppress error and existing labels are dropped.

### Returns

**dropped** [Index]

### Raises

**KeyError** If not all of the labels are found in the selected axis

## pandas.Index.drop\_duplicates

`Index.drop_duplicates` (*self*, *keep='first'*)  
Return Index with duplicate values removed.

### Parameters

**keep** [{‘first’, ‘last’, `False`}, default ‘first’]

- ‘first’ : Drop duplicates except for the first occurrence.
- ‘last’ : Drop duplicates except for the last occurrence.
- `False` : Drop all duplicates.

### Returns

**deduplicated** [Index]

See also:

***Series.drop\_duplicates*** Equivalent method on Series.

***DataFrame.drop\_duplicates*** Equivalent method on DataFrame.

***Index.duplicated*** Related method on Index, indicating duplicate Index values.

## Examples

Generate an pandas.Index with duplicate values.

```
>>> idx = pd.Index(['lama', 'cow', 'lama', 'beetle', 'lama', 'hippo'])
```

The *keep* parameter controls which duplicate values are removed. The value ‘first’ keeps the first occurrence for each set of duplicated entries. The default value of *keep* is ‘first’.

```
>>> idx.drop_duplicates(keep='first')
Index(['lama', 'cow', 'beetle', 'hippo'], dtype='object')
```

The value ‘last’ keeps the last occurrence for each set of duplicated entries.

```
>>> idx.drop_duplicates(keep='last')
Index(['cow', 'beetle', 'lama', 'hippo'], dtype='object')
```

The value `False` discards all sets of duplicated entries.

```
>>> idx.drop_duplicates(keep=False)
Index(['cow', 'beetle', 'hippo'], dtype='object')
```

### pandas.Index.droplevel

`Index.droplevel` (*self*, *level=0*)

Return index with requested level(s) removed.

If resulting index has only 1 level left, the result will be of Index type, not MultiIndex.

New in version 0.23.1: (support for non-MultiIndex)

#### Parameters

**level** [int, str, or list-like, default 0] If a string is given, must be the name of a level. If list-like, elements must be names or indexes of levels.

#### Returns

**Index or MultiIndex**

### pandas.Index.dropna

`Index.dropna` (*self*, *how='any'*)

Return Index without NA/NaN values.

#### Parameters

**how** [{ 'any', 'all' }, default 'any'] If the Index is a MultiIndex, drop the value when any or all levels are NaN.

#### Returns

**valid** [Index]

### pandas.Index.duplicated

`Index.duplicated` (*self*, *keep='first'*)

Indicate duplicate index values.

Duplicated values are indicated as `True` values in the resulting array. Either all duplicates, all except the first, or all except the last occurrence of duplicates can be indicated.

#### Parameters

**keep** [{ 'first', 'last', False }, default 'first'] The value or values in a set of duplicates to mark as missing.

- 'first' : Mark duplicates as `True` except for the first occurrence.
- 'last' : Mark duplicates as `True` except for the last occurrence.
- False : Mark all duplicates as `True`.

#### Returns

**numpy.ndarray**

See also:

***Series.duplicated*** Equivalent method on `pandas.Series`.

***DataFrame.duplicated*** Equivalent method on `pandas.DataFrame`.

***Index.drop\_duplicates*** Remove duplicate values from Index.

## Examples

By default, for each set of duplicated values, the first occurrence is set to False and all others to True:

```
>>> idx = pd.Index(['lama', 'cow', 'lama', 'beetle', 'lama'])
>>> idx.duplicated()
array([False, False,  True, False,  True])
```

which is equivalent to

```
>>> idx.duplicated(keep='first')
array([False, False,  True, False,  True])
```

By using 'last', the last occurrence of each set of duplicated values is set on False and all others on True:

```
>>> idx.duplicated(keep='last')
array([ True, False,  True, False, False])
```

By setting keep on False, all duplicates are True:

```
>>> idx.duplicated(keep=False)
array([ True, False,  True, False,  True])
```

## pandas.Index.equals

`Index.equals(self, other) → bool`

Determine if two Index objects contain the same elements.

### Returns

**bool** True if “other” is an Index and it has the same elements as calling index; False otherwise.

## pandas.Index.factorize

`Index.factorize(self, sort=False, na_sentinel=-1)`

Encode the object as an enumerated type or categorical variable.

This method is useful for obtaining a numeric representation of an array when all that matters is identifying distinct values. *factorize* is available as both a top-level function `pandas.factorize()`, and as a method `Series.factorize()` and `Index.factorize()`.

### Parameters

**sort** [bool, default False] Sort *uniques* and shuffle *codes* to maintain the relationship.

**na\_sentinel** [int, default -1] Value to mark “not found”.

### Returns

**codes** [ndarray] An integer ndarray that’s an indexer into *uniques*. `uniques.take(codes)` will have the same values as *values*.

**uniques** [ndarray, Index, or Categorical] The unique valid values. When *values* is Categorical, *uniques* is a Categorical. When *values* is some other pandas object, an *Index* is returned. Otherwise, a 1-D ndarray is returned.

---

**Note:** Even if there's a missing value in *values*, *uniques* will *not* contain an entry for it.

---

**See also:****cut** Discretize continuous-valued array.**unique** Find the unique value in an array.**Examples**

These examples all show `factorize` as a top-level method like `pd.factorize(values)`. The results are identical for methods like `Series.factorize()`.

```
>>> codes, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'])
>>> codes
array([0, 0, 1, 2, 0])
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

With `sort=True`, the *uniques* will be sorted, and *codes* will be shuffled so that the relationship is the maintained.

```
>>> codes, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'], sort=True)
>>> codes
array([1, 1, 0, 2, 1])
>>> uniques
array(['a', 'b', 'c'], dtype=object)
```

Missing values are indicated in *codes* with *na\_sentinel* (-1 by default). Note that missing values are never included in *uniques*.

```
>>> codes, uniques = pd.factorize(['b', None, 'a', 'c', 'b'])
>>> codes
array([ 0, -1,  1,  2,  0])
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

Thus far, we've only factorized lists (which are internally coerced to NumPy arrays). When factorizing pandas objects, the type of *uniques* will differ. For Categoricals, a *Categorical* is returned.

```
>>> cat = pd.Categorical(['a', 'a', 'c'], categories=['a', 'b', 'c'])
>>> codes, uniques = pd.factorize(cat)
>>> codes
array([0, 0, 1])
>>> uniques
[a, c]
Categories (3, object): [a, b, c]
```

Notice that 'b' is in `uniques.categories`, despite not being present in `cat.values`.

For all other pandas objects, an Index of the appropriate type is returned.

```
>>> cat = pd.Series(['a', 'a', 'c'])
>>> codes, uniques = pd.factorize(cat)
```

(continues on next page)

(continued from previous page)

```
>>> codes
array([0, 0, 1])
>>> uniques
Index(['a', 'c'], dtype='object')
```

### pandas.Index.fillna

`Index.fillna` (*self*, *value=None*, *downcast=None*)

Fill NA/NaN values with the specified value.

#### Parameters

- value** [scalar] Scalar value to use to fill holes (e.g. 0). This value cannot be a list-likes.
- downcast** [dict, default is None] a dict of item->dtype of what to downcast if possible, or the string 'infer' which will try to downcast to an appropriate equal type (e.g. float64 to int64 if possible).

#### Returns

**filled** [Index]

### pandas.Index.format

`Index.format` (*self*, *name=False*, *formatter=None*, *\*\*kwargs*)

Render a string representation of the Index.

### pandas.Index.get\_indexer

`Index.get_indexer` (*self*, *target*, *method=None*, *limit=None*, *tolerance=None*)

Compute indexer and mask for new index given the current index. The indexer should be then used as an input to `ndarray.take` to align the current data to the new index.

#### Parameters

- target** [Index]
- method** [{None, 'pad'/'ffill', 'backfill'/'bfill', 'nearest'}], optional
- default: exact matches only.
  - pad / ffill: find the PREVIOUS index value if no exact match.
  - backfill / bfill: use NEXT index value if no exact match
  - nearest: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.
- limit** [int, optional] Maximum number of consecutive labels in `target` to match for inexact matches.
- tolerance** [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations most satisfy the equation  $\text{abs}(\text{index}[\text{indexer}] - \text{target}) \leq \text{tolerance}$ .

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple,

array, Series, and must be the same size as the index and its dtype must exactly match the index's type.

New in version 0.21.0: (list-like tolerance)

#### Returns

**indexer** [ndarray of int] Integers from 0 to n - 1 indicating that the index at these positions matches the corresponding target values. Missing values in the target are marked by -1.

#### Examples

```
>>> index = pd.Index(['c', 'a', 'b'])
>>> index.get_indexer(['a', 'b', 'x'])
array([ 1,  2, -1])
```

Notice that the return value is an array of locations in `index` and `x` is marked by -1, as it is not in `index`.

#### `pandas.Index.get_indexer_for`

`Index.get_indexer_for` (*self*, *target*, *\*\*kwargs*)

Guaranteed return of an indexer even when non-unique.

This dispatches to `get_indexer` or `get_indexer_non_unique` as appropriate.

#### Returns

**numpy.ndarray** List of indices.

#### `pandas.Index.get_indexer_non_unique`

`Index.get_indexer_non_unique` (*self*, *target*)

Compute indexer and mask for new index given the current index. The indexer should be then used as an input to `ndarray.take` to align the current data to the new index.

#### Parameters

**target** [Index]

#### Returns

**indexer** [ndarray of int] Integers from 0 to n - 1 indicating that the index at these positions matches the corresponding target values. Missing values in the target are marked by -1.

**missing** [ndarray of int] An indexer into the target of the values not found. These correspond to the -1 in the indexer array.

## pandas.Index.get\_level\_values

`Index.get_level_values` (*self*, *level*)

Return an Index of values for requested level.

This is primarily useful to get an individual level of values from a MultiIndex, but is provided on Index as well for compatibility.

### Parameters

**level** [int or str] It is either the integer position or the name of the level.

### Returns

**Index** Calling object, as there is only one level in the Index.

See also:

**MultiIndex.get\_level\_values** Get values for a level of a MultiIndex.

### Notes

For Index, level should be 0, since there are no multiple levels.

### Examples

```
>>> idx = pd.Index(list('abc'))
>>> idx
Index(['a', 'b', 'c'], dtype='object')
```

Get level values by supplying *level* as integer:

```
>>> idx.get_level_values(0)
Index(['a', 'b', 'c'], dtype='object')
```

## pandas.Index.get\_loc

`Index.get_loc` (*self*, *key*, *method=None*, *tolerance=None*)

Get integer location, slice or boolean mask for requested label.

### Parameters

**key** [label]

**method** [{None, 'pad'/'ffill', 'backfill'/'bfill', 'nearest'}], optional

- default: exact matches only.
- pad / ffill: find the PREVIOUS index value if no exact match.
- backfill / bfill: use NEXT index value if no exact match
- nearest: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.

**tolerance** [int or float, optional] Maximum distance from index value for inexact matches. The value of the index at the matching location most satisfy the equation  $\text{abs}(\text{index}[\text{loc}] - \text{key}) \leq \text{tolerance}$ .

New in version 0.21.0: (list-like tolerance)

#### Returns

**loc** [int if unique index, slice if monotonic index, else mask]

#### Examples

```
>>> unique_index = pd.Index(list('abc'))
>>> unique_index.get_loc('b')
1
```

```
>>> monotonic_index = pd.Index(list('abbc'))
>>> monotonic_index.get_loc('b')
slice(1, 3, None)
```

```
>>> non_monotonic_index = pd.Index(list('abcb'))
>>> non_monotonic_index.get_loc('b')
array([False,  True,  False,  True], dtype=bool)
```

#### pandas.Index.get\_slice\_bound

`Index.get_slice_bound` (*self, label, side, kind*)

Calculate slice bound that corresponds to given label.

Returns leftmost (one-past-the-rightmost if `side=='right'`) position of given label.

#### Parameters

**label** [object]

**side** [{'left', 'right'}]

**kind** [{'ix', 'loc', 'getitem'}]

#### Returns

**int** Index of label.

#### pandas.Index.get\_value

`Index.get_value` (*self, series, key*)

Fast lookup of value from 1-dimensional ndarray. Only use this if you know what you're doing.

#### Returns

**scalar** A value in the Series with the index of the key value in self.

**pandas.Index.groupby**

`Index.groupby` (*self*, *values*) → Dict[Hashable, numpy.ndarray]  
 Group the index labels by a given array of values.

**Parameters**

**values** [array] Values used to determine the groups.

**Returns**

**dict** {group name -> group labels}

**pandas.Index.holds\_integer**

`Index.holds_integer` (*self*)  
 Whether the type is an integer type.

**pandas.Index.identical**

`Index.identical` (*self*, *other*) → bool  
 Similar to equals, but check that other comparable attributes are also equal.

**Returns**

**bool** If two Index objects have equal elements and same type True, otherwise False.

**pandas.Index.insert**

`Index.insert` (*self*, *loc*, *item*)  
 Make new Index inserting new item at location.  
 Follows Python list.append semantics for negative values.

**Parameters**

**loc** [int]

**item** [object]

**Returns**

**new\_index** [Index]

**pandas.Index.intersection**

`Index.intersection` (*self*, *other*, *sort=False*)  
 Form the intersection of two Index objects.  
 This returns a new Index with elements common to the index and *other*.

**Parameters**

**other** [Index or array-like]

**sort** [False or None, default False] Whether to sort the resulting index.

- False : do not sort the result.

- None : sort the result, except when *self* and *other* are equal or when the values cannot be compared.

New in version 0.24.0.

Changed in version 0.24.1: Changed the default from `True` to `False`, to match the behaviour of 0.23.4 and earlier.

### Returns

**intersection** [Index]

### Examples

```
>>> idx1 = pd.Index([1, 2, 3, 4])
>>> idx2 = pd.Index([3, 4, 5, 6])
>>> idx1.intersection(idx2)
Int64Index([3, 4], dtype='int64')
```

## pandas.Index.is\_

`Index.is_(self, other) → bool`

More flexible, faster check like `is` but that works through views.

Note: this is *not* the same as `Index.identical()`, which checks that metadata is also the same.

### Parameters

**other** [object] other object to compare against.

### Returns

**True if both have same underlying data, False otherwise** [bool]

## pandas.Index.is\_categorical

`Index.is_categorical(self) → bool`

Check if the Index holds categorical data.

### Returns

**boolean** True if the Index is categorical.

### See also:

**CategoricalIndex** Index for categorical data.

## Examples

```
>>> idx = pd.Index(["Watermelon", "Orange", "Apple",
...                 "Watermelon"]).astype("category")
>>> idx.is_categorical()
True
```

```
>>> idx = pd.Index([1, 3, 5, 7])
>>> idx.is_categorical()
False
```

```
>>> s = pd.Series(["Peter", "Victor", "Elisabeth", "Mar"])
>>> s
0      Peter
1      Victor
2  Elisabeth
3         Mar
dtype: object
>>> s.index.is_categorical()
False
```

## pandas.Index.is\_type\_compatible

`Index.is_type_compatible` (*self*, *kind*) → bool  
Whether the index type is compatible with the provided type.

## pandas.Index.isin

`Index.isin` (*self*, *values*, *level=None*)  
Return a boolean array where the index values are in *values*.

Compute boolean array of whether each index value is found in the passed set of values. The length of the returned boolean array matches the length of the index.

### Parameters

**values** [set or list-like] Sought values.

**level** [str or int, optional] Name or position of the index level to use (if the index is a *MultiIndex*).

### Returns

**is\_contained** [ndarray] NumPy array of boolean values.

### See also:

**Series.isin** Same for Series.

**DataFrame.isin** Same method for DataFrames.

## Notes

In the case of *MultiIndex* you must either specify *values* as a list-like object containing tuples that are the same length as the number of levels, or specify *level*. Otherwise it will raise a `ValueError`.

If *level* is specified:

- if it is the name of one *and only one* index level, use that level;
- otherwise it should be a number indicating level position.

## Examples

```
>>> idx = pd.Index([1,2,3])
>>> idx
Int64Index([1, 2, 3], dtype='int64')
```

Check whether each index value in a list of values. `>>> idx.isin([1, 4])` `array([ True, False, False])`

```
>>> midx = pd.MultiIndex.from_arrays([[1,2,3],
...                                  ['red', 'blue', 'green']],
...                                  names=('number', 'color'))
>>> midx
MultiIndex(levels=[[1, 2, 3], ['blue', 'green', 'red']],
            codes=[[0, 1, 2], [2, 0, 1]],
            names=['number', 'color'])
```

Check whether the strings in the ‘color’ level of the `MultiIndex` are in a list of colors.

```
>>> midx.isin(['red', 'orange', 'yellow'], level='color')
array([ True, False, False])
```

To check across the levels of a `MultiIndex`, pass a list of tuples:

```
>>> midx.isin([(1, 'red'), (3, 'red')])
array([ True, False, False])
```

For a `DatetimeIndex`, string values in *values* are converted to `Timestamps`.

```
>>> dates = ['2000-03-11', '2000-03-12', '2000-03-13']
>>> dti = pd.to_datetime(dates)
>>> dti
DatetimeIndex(['2000-03-11', '2000-03-12', '2000-03-13'],
              dtype='datetime64[ns]', freq=None)
```

```
>>> dti.isin(['2000-03-11'])
array([ True, False, False])
```

**pandas.Index.isna**`Index.isna` (*self*)

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as `None`, `numpy.NaN` or `pd.NaT`, get mapped to `True` values. Everything else get mapped to `False` values. Characters such as empty strings `''` or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`).

**Returns**`numpy.ndarray` A boolean array of whether my values are NA.**See also:****`Index.notna`** Boolean inverse of `isna`.**`Index.dropna`** Omit entries with missing values.**`isna`** Top-level `isna`.**`Series.isna`** Detect missing values in Series object.**Examples**Show which entries in a `pandas.Index` are NA. The result is an array.

```
>>> idx = pd.Index([5.2, 6.0, np.NaN])
>>> idx
Float64Index([5.2, 6.0, nan], dtype='float64')
>>> idx.isna()
array([False, False,  True], dtype=bool)
```

Empty strings are not considered NA values. `None` is considered an NA value.

```
>>> idx = pd.Index(['black', '', 'red', None])
>>> idx
Index(['black', '', 'red', None], dtype='object')
>>> idx.isna()
array([False, False, False,  True], dtype=bool)
```

For datetimes, `NaT` (Not a Time) is considered as an NA value.

```
>>> idx = pd.DatetimeIndex([pd.Timestamp('1940-04-25'),
...                          pd.Timestamp(''), None, pd.NaT])
>>> idx
DatetimeIndex(['1940-04-25', 'NaT', 'NaT', 'NaT'],
              dtype='datetime64[ns]', freq=None)
>>> idx.isna()
array([False,  True,  True,  True], dtype=bool)
```

**pandas.Index.isnull**`Index.isnull` (*self*)

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as `None`, `numpy.NaN` or `pd.NaT`, get mapped to `True` values. Everything else get mapped to `False` values. Characters such as empty strings `''` or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`).

**Returns**`numpy.ndarray` A boolean array of whether my values are NA.**See also:****`Index.notna`** Boolean inverse of `isna`.**`Index.dropna`** Omit entries with missing values.**`isna`** Top-level `isna`.**`Series.isna`** Detect missing values in Series object.**Examples**Show which entries in a `pandas.Index` are NA. The result is an array.

```
>>> idx = pd.Index([5.2, 6.0, np.NaN])
>>> idx
Float64Index([5.2, 6.0, nan], dtype='float64')
>>> idx.isna()
array([False, False,  True], dtype=bool)
```

Empty strings are not considered NA values. `None` is considered an NA value.

```
>>> idx = pd.Index(['black', '', 'red', None])
>>> idx
Index(['black', '', 'red', None], dtype='object')
>>> idx.isna()
array([False, False, False,  True], dtype=bool)
```

For datetimes, `NaT` (Not a Time) is considered as an NA value.

```
>>> idx = pd.DatetimeIndex([pd.Timestamp('1940-04-25'),
...                          pd.Timestamp(''), None, pd.NaT])
>>> idx
DatetimeIndex(['1940-04-25', 'NaT', 'NaT', 'NaT'],
              dtype='datetime64[ns]', freq=None)
>>> idx.isna()
array([False,  True,  True,  True], dtype=bool)
```

**pandas.Index.item**`Index.item(self)`

Return the first element of the underlying data as a python scalar.

**Returns****scalar** The first element of %(klass)s.**Raises****ValueError** If the data is not length-1.**pandas.Index.join**`Index.join(self, other, how='left', level=None, return_indexers=False, sort=False)`

Compute join\_index and indexers to conform data structures to the new index.

**Parameters****other** [Index]**how** [{'left', 'right', 'inner', 'outer'}]**level** [int or level name, default None]**return\_indexers** [bool, default False]**sort** [bool, default False] Sort the join keys lexicographically in the result Index. If False, the order of the join keys depends on the join type (how keyword).**Returns****join\_index, (left\_indexer, right\_indexer)****pandas.Index.map**`Index.map(self, mapper, na_action=None)`

Map values using input correspondence (a dict, Series, or function).

**Parameters****mapper** [function, dict, or Series] Mapping correspondence.**na\_action** [{None, 'ignore'}] If 'ignore', propagate NA values, without passing them to the mapping correspondence.**Returns****applied** [Union[Index, MultiIndex], inferred] The output of the mapping function applied to the index. If the function returns a tuple with more than one element a MultiIndex will be returned.

## pandas.Index.max

`Index.max` (*self*, *axis=None*, *skipna=True*, \*args, \*\*kwargs)

Return the maximum value of the Index.

### Parameters

**axis** [int, optional] For compatibility with NumPy. Only 0 or None are allowed.

**skipna** [bool, default True]

### Returns

**scalar** Maximum value.

### See also:

**`Index.min`** Return the minimum value in an Index.

**`Series.max`** Return the maximum value in a Series.

**`DataFrame.max`** Return the maximum values in a DataFrame.

## Examples

```
>>> idx = pd.Index([3, 2, 1])
>>> idx.max()
3
```

```
>>> idx = pd.Index(['c', 'b', 'a'])
>>> idx.max()
'c'
```

For a MultiIndex, the maximum is determined lexicographically.

```
>>> idx = pd.MultiIndex.from_product([('a', 'b'), (2, 1)])
>>> idx.max()
('b', 2)
```

## pandas.Index.memory\_usage

`Index.memory_usage` (*self*, *deep=False*)

Memory usage of the values.

### Parameters

**deep** [bool] Introspect the data deeply, interrogate *object* dtypes for system-level memory consumption.

### Returns

**bytes used**

### See also:

`numpy.ndarray.nbytes`

## Notes

Memory usage does not include memory consumed by elements that are not components of the array if `deep=False` or if used on PyPy

## pandas.Index.min

`Index.min` (*self*, *axis=None*, *skipna=True*, \*args, \*\*kwargs)

Return the minimum value of the Index.

### Parameters

**axis** [{None}] Dummy argument for consistency with Series.

**skipna** [bool, default True]

### Returns

**scalar** Minimum value.

### See also:

**`Index.max`** Return the maximum value of the object.

**`Series.min`** Return the minimum value in a Series.

**`DataFrame.min`** Return the minimum values in a DataFrame.

## Examples

```
>>> idx = pd.Index([3, 2, 1])
>>> idx.min()
1
```

```
>>> idx = pd.Index(['c', 'b', 'a'])
>>> idx.min()
'a'
```

For a MultiIndex, the minimum is determined lexicographically.

```
>>> idx = pd.MultiIndex.from_product(['a', 'b'], (2, 1))
>>> idx.min()
('a', 1)
```

## pandas.Index.notna

`Index.notna` (*self*)

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`). NA values, such as `None` or `numpy.NaN`, get mapped to False values.

### Returns

**numpy.ndarray** Boolean array to indicate which entries are not NA.

See also:

***Index.notnull*** Alias of notna.

***Index.isna*** Inverse of notna.

***notna*** Top-level notna.

## Examples

Show which entries in an Index are not NA. The result is an array.

```
>>> idx = pd.Index([5.2, 6.0, np.NaN])
>>> idx
Float64Index([5.2, 6.0, nan], dtype='float64')
>>> idx.notna()
array([ True,  True, False])
```

Empty strings are not considered NA values. None is considered a NA value.

```
>>> idx = pd.Index(['black', '', 'red', None])
>>> idx
Index(['black', '', 'red', None], dtype='object')
>>> idx.notna()
array([ True,  True,  True, False])
```

## pandas.Index.notnull

`Index.notnull` (*self*)

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`). NA values, such as `None` or `numpy.NaN`, get mapped to False values.

### Returns

**`numpy.ndarray`** Boolean array to indicate which entries are not NA.

See also:

***Index.notnull*** Alias of notna.

***Index.isna*** Inverse of notna.

***notna*** Top-level notna.

## Examples

Show which entries in an Index are not NA. The result is an array.

```
>>> idx = pd.Index([5.2, 6.0, np.NaN])
>>> idx
Float64Index([5.2, 6.0, nan], dtype='float64')
>>> idx.notna()
array([ True,  True, False])
```

Empty strings are not considered NA values. None is considered a NA value.

```
>>> idx = pd.Index(['black', '', 'red', None])
>>> idx
Index(['black', '', 'red', None], dtype='object')
>>> idx.notna()
array([ True,  True,  True, False])
```

## pandas.Index.nunique

`Index.nunique` (*self*, *dropna=True*)

Return number of unique elements in the object.

Excludes NA values by default.

### Parameters

**dropna** [bool, default True] Don't include NaN in the count.

### Returns

**int**

**See also:**

**DataFrame.nunique** Method `nunique` for DataFrame.

**Series.count** Count non-NA/null observations in the Series.

## Examples

```
>>> s = pd.Series([1, 3, 5, 7, 7])
>>> s
0    1
1    3
2    5
3    7
4    7
dtype: int64
```

```
>>> s.nunique()
4
```

### **pandas.Index.putmask**

`Index.putmask` (*self*, *mask*, *value*)

Return a new Index of the values set with the mask.

#### **Returns**

**Index**

**See also:**

`numpy.ndarray.putmask`

### **pandas.Index.ravel**

`Index.ravel` (*self*, *order='C'*)

Return an ndarray of the flattened values of the underlying data.

#### **Returns**

**numpy.ndarray** Flattened array.

**See also:**

`numpy.ndarray.ravel`

### **pandas.Index.reindex**

`Index.reindex` (*self*, *target*, *method=None*, *level=None*, *limit=None*, *tolerance=None*)

Create index with target's values (move/add/delete values as necessary).

#### **Parameters**

**target** [an iterable]

#### **Returns**

**new\_index** [pd.Index] Resulting index.

**indexer** [np.ndarray or None] Indices of output values in original index.

### **pandas.Index.rename**

`Index.rename` (*self*, *name*, *inplace=False*)

Alter Index or MultiIndex name.

Able to set new names without level. Defaults to returning new index. Length of names must match number of levels in MultiIndex.

#### **Parameters**

**name** [label or list of labels] Name(s) to set.

**inplace** [bool, default False] Modifies the object directly, instead of creating a new Index or MultiIndex.

#### **Returns**

**Index** The same type as the caller or None if inplace is True.

See also:

**`Index.set_names`** Able to set new names partially and by level.

## Examples

```
>>> idx = pd.Index(['A', 'C', 'A', 'B'], name='score')
>>> idx.rename('grade')
Index(['A', 'C', 'A', 'B'], dtype='object', name='grade')
```

```
>>> idx = pd.MultiIndex.from_product(['python', 'cobra'],
...                                  [2018, 2019]),
...                                  names=['kind', 'year'])
>>> idx
MultiIndex([('python', 2018),
            ('python', 2019),
            ('cobra', 2018),
            ('cobra', 2019)],
            names=['kind', 'year'])
>>> idx.rename(['species', 'year'])
MultiIndex([('python', 2018),
            ('python', 2019),
            ('cobra', 2018),
            ('cobra', 2019)],
            names=['species', 'year'])
>>> idx.rename('species')
Traceback (most recent call last):
TypeError: Must pass list-like as `names`.
```

## pandas.Index.repeat

`Index.repeat` (*self*, *repeats*, *axis=None*)

Repeat elements of a Index.

Returns a new Index where each element of the current Index is repeated consecutively a given number of times.

### Parameters

**repeats** [int or array of ints] The number of repetitions for each element. This should be a non-negative integer. Repeating 0 times will return an empty Index.

**axis** [None] Must be None. Has no effect but is accepted for compatibility with numpy.

### Returns

**repeated\_index** [Index] Newly created Index with repeated elements.

See also:

**`Series.repeat`** Equivalent function for Series.

**`numpy.repeat`** Similar method for `numpy.ndarray`.

## Examples

```
>>> idx = pd.Index(['a', 'b', 'c'])
>>> idx
Index(['a', 'b', 'c'], dtype='object')
>>> idx.repeat(2)
Index(['a', 'a', 'b', 'b', 'c', 'c'], dtype='object')
>>> idx.repeat([1, 2, 3])
Index(['a', 'b', 'b', 'c', 'c', 'c'], dtype='object')
```

## pandas.Index.searchsorted

`Index.searchsorted` (*self*, *value*, *side*='left', *sorter*=None)

Find indices where elements should be inserted to maintain order.

Find the indices into a sorted Index *self* such that, if the corresponding elements in *value* were inserted before the indices, the order of *self* would be preserved.

---

**Note:** The Index *must* be monotonically sorted, otherwise wrong locations will likely be returned. Pandas does *not* check this for you.

---

### Parameters

**value** [array\_like] Values to insert into *self*.

**side** [{'left', 'right'}, optional] If 'left', the index of the first suitable location found is given. If 'right', return the last such index. If there is no suitable index, return either 0 or N (where N is the length of *self*).

**sorter** [1-D array\_like, optional] Optional array of integer indices that sort *self* into ascending order. They are typically the result of `np.argsort`.

### Returns

**int or array of int** A scalar or array of insertion points with the same shape as *value*.

Changed in version 0.24.0: If *value* is a scalar, an int is now always returned. Previously, scalar inputs returned an 1-item array for *Series* and *Categorical*.

See also:

[`sort\_values`](#)

[`numpy.searchsorted`](#)

## Notes

Binary search is used to find the required insertion points.

## Examples

```
>>> x = pd.Series([1, 2, 3])
>>> x
0    1
1    2
2    3
dtype: int64
```

```
>>> x.searchsorted(4)
3
```

```
>>> x.searchsorted([0, 4])
array([0, 3])
```

```
>>> x.searchsorted([1, 3], side='left')
array([0, 2])
```

```
>>> x.searchsorted([1, 3], side='right')
array([1, 3])
```

```
>>> x = pd.Categorical(['apple', 'bread', 'bread',
                       'cheese', 'milk'], ordered=True)
[apple, bread, bread, cheese, milk]
Categories (4, object): [apple < bread < cheese < milk]
```

```
>>> x.searchsorted('bread')
1
```

```
>>> x.searchsorted(['bread'], side='right')
array([3])
```

If the values are not monotonically sorted, wrong locations may be returned:

```
>>> x = pd.Series([2, 1, 3])
>>> x.searchsorted(1)
0 # wrong result, correct would be 1
```

## pandas.Index.set\_names

Index.**set\_names** (*self*, *names*, *level=None*, *inplace=False*)  
Set Index or MultiIndex name.

Able to set new names partially and by level.

### Parameters

**names** [label or list of label] Name(s) to set.

**level** [int, label or list of int or label, optional] If the index is a MultiIndex, level(s) to set (None for all levels). Otherwise level must be None.

**inplace** [bool, default False] Modifies the object directly, instead of creating a new Index or MultiIndex.

### Returns

**Index** The same type as the caller or None if inplace is True.

### See also:

**Index.rename** Able to set new names without level.

### Examples

```
>>> idx = pd.Index([1, 2, 3, 4])
>>> idx
Int64Index([1, 2, 3, 4], dtype='int64')
>>> idx.set_names('quarter')
Int64Index([1, 2, 3, 4], dtype='int64', name='quarter')
```

```
>>> idx = pd.MultiIndex.from_product(['python', 'cobra'],
...                                  [2018, 2019])
>>> idx
MultiIndex([( 'python', 2018),
            ( 'python', 2019),
            ( 'cobra', 2018),
            ( 'cobra', 2019)],
           )
>>> idx.set_names(['kind', 'year'], inplace=True)
>>> idx
MultiIndex([( 'python', 2018),
            ( 'python', 2019),
            ( 'cobra', 2018),
            ( 'cobra', 2019)],
           names=['kind', 'year'])
>>> idx.set_names('species', level=0)
MultiIndex([( 'python', 2018),
            ( 'python', 2019),
            ( 'cobra', 2018),
            ( 'cobra', 2019)],
           names=['species', 'year'])
```

### pandas.Index.set\_value

Index.**set\_value** (*self*, *arr*, *key*, *value*)

Fast lookup of value from 1-dimensional ndarray.

Deprecated since version 1.0.

## Notes

Only use this if you know what you're doing.

### pandas.Index.shift

`Index.shift` (*self*, *periods=1*, *freq=None*)

Shift index by desired number of time frequency increments.

This method is for shifting the values of datetime-like indexes by a specified time increment a given number of times.

#### Parameters

**periods** [int, default 1] Number of periods (or increments) to shift by, can be positive or negative.

**freq** [pandas.DateOffset, pandas.Timedelta or str, optional] Frequency increment to shift by. If None, the index is shifted by its own *freq* attribute. Offset aliases are valid strings, e.g., 'D', 'W', 'M' etc.

#### Returns

**pandas.Index** Shifted index.

#### See also:

**Series.shift** Shift values of Series.

## Notes

This method is only implemented for datetime-like index classes, i.e., `DatetimeIndex`, `PeriodIndex` and `TimedeltaIndex`.

## Examples

Put the first 5 month starts of 2011 into an index.

```
>>> month_starts = pd.date_range('1/1/2011', periods=5, freq='MS')
>>> month_starts
DatetimeIndex(['2011-01-01', '2011-02-01', '2011-03-01', '2011-04-01',
              '2011-05-01'],
              dtype='datetime64[ns]', freq='MS')
```

Shift the index by 10 days.

```
>>> month_starts.shift(10, freq='D')
DatetimeIndex(['2011-01-11', '2011-02-11', '2011-03-11', '2011-04-11',
              '2011-05-11'],
              dtype='datetime64[ns]', freq=None)
```

The default value of *freq* is the *freq* attribute of the index, which is 'MS' (month start) in this example.

```
>>> month_starts.shift(10)
DatetimeIndex(['2011-11-01', '2011-12-01', '2012-01-01', '2012-02-01',
              '2012-03-01'],
              dtype='datetime64[ns]', freq='MS')
```

### pandas.Index.slice\_indexer

Index.**slice\_indexer** (*self*, *start=None*, *end=None*, *step=None*, *kind=None*)

For an ordered or unique index, compute the slice indexer for input labels and step.

#### Parameters

**start** [label, default None] If None, defaults to the beginning.

**end** [label, default None] If None, defaults to the end.

**step** [int, default None]

**kind** [str, default None]

#### Returns

**indexer** [slice]

#### Raises

**KeyError** [If key does not exist, or key is not unique and index is] not ordered.

#### Notes

This function assumes that the data is sorted, so use at your own peril

#### Examples

This is a method on all index types. For example you can do:

```
>>> idx = pd.Index(list('abcd'))
>>> idx.slice_indexer(start='b', end='c')
slice(1, 3)
```

```
>>> idx = pd.MultiIndex.from_arrays([list('abcd'), list('efgh')])
>>> idx.slice_indexer(start='b', end=('c', 'g'))
slice(1, 3)
```

### pandas.Index.slice\_locs

Index.**slice\_locs** (*self*, *start=None*, *end=None*, *step=None*, *kind=None*)

Compute slice locations for input labels.

#### Parameters

**start** [label, default None] If None, defaults to the beginning.

**end** [label, default None] If None, defaults to the end.

**step** [int, defaults None] If None, defaults to 1.

**kind** [{ 'ix', 'loc', 'getitem' } or None]

#### Returns

**start, end** [int]

#### See also:

***Index.get\_loc*** Get location for a single label.

#### Notes

This method only works if the index is monotonic or unique.

#### Examples

```
>>> idx = pd.Index(list('abcd'))
>>> idx.slice_locs(start='b', end='c')
(1, 3)
```

### pandas.Index.sort

**Index.sort** (*self*, \*args, \*\*kwargs)  
Use `sort_values` instead.

### pandas.Index.sort\_values

**Index.sort\_values** (*self*, *return\_indexer=False*, *ascending=True*)  
Return a sorted copy of the index.

Return a sorted copy of the index, and optionally return the indices that sorted the index itself.

#### Parameters

**return\_indexer** [bool, default False] Should the indices that would sort the index be returned.

**ascending** [bool, default True] Should the index values be sorted in an ascending order.

#### Returns

**sorted\_index** [pandas.Index] Sorted copy of the index.

**indexer** [numpy.ndarray, optional] The indices that the index itself was sorted by.

#### See also:

***Series.sort\_values*** Sort values of a Series.

***DataFrame.sort\_values*** Sort values in a DataFrame.

## Examples

```
>>> idx = pd.Index([10, 100, 1, 1000])
>>> idx
Int64Index([10, 100, 1, 1000], dtype='int64')
```

Sort values in ascending order (default behavior).

```
>>> idx.sort_values()
Int64Index([1, 10, 100, 1000], dtype='int64')
```

Sort values in descending order, and also get the indices *idx* was sorted by.

```
>>> idx.sort_values(ascending=False, return_indexer=True)
(Int64Index([1000, 100, 10, 1], dtype='int64'), array([3, 1, 0, 2]))
```

## pandas.Index.sortlevel

`Index.sortlevel` (*self*, *level=None*, *ascending=True*, *sort\_remaining=None*)

For internal compatibility with with the Index API.

Sort the Index. This is for compat with MultiIndex

### Parameters

**ascending** [bool, default True] False to sort in descending order

**level, sort\_remaining** are compat parameters

### Returns

**Index**

## pandas.Index.str

`Index.str` ()

Vectorized string functions for Series and Index. NAs stay NA unless handled otherwise by a particular method. Patterned after Python's string methods, with some inspiration from R's stringr package.

## Examples

```
>>> s.str.split('_')
>>> s.str.replace('_', '')
```

## pandas.Index.symmetric\_difference

`Index.symmetric_difference` (*self*, *other*, *result\_name=None*, *sort=None*)

Compute the symmetric difference of two Index objects.

### Parameters

**other** [Index or array-like]

**result\_name** [str]

**sort** [False or None, default None] Whether to sort the resulting index. By default, the values are attempted to be sorted, but any `TypeError` from incomparable elements is caught by pandas.

- `None` : Attempt to sort the result, but catch any `TypeError`s from comparing incomparable elements.
- `False` : Do not sort the result.

New in version 0.24.0.

Changed in version 0.24.1: Changed the default value from `True` to `None` (without change in behaviour).

### Returns

**symmetric\_difference** [Index]

### Notes

`symmetric_difference` contains elements that appear in either `idx1` or `idx2` but not both. Equivalent to the Index created by `idx1.difference(idx2) | idx2.difference(idx1)` with duplicates dropped.

### Examples

```
>>> idx1 = pd.Index([1, 2, 3, 4])
>>> idx2 = pd.Index([2, 3, 4, 5])
>>> idx1.symmetric_difference(idx2)
Int64Index([1, 5], dtype='int64')
```

You can also use the `^` operator:

```
>>> idx1 ^ idx2
Int64Index([1, 5], dtype='int64')
```

### **pandas.Index.take**

`Index.take` (*self*, *indices*, *axis=0*, *allow\_fill=True*, *fill\_value=None*, *\*\*kwargs*)

Return a new Index of the values selected by the indices.

For internal compatibility with numpy arrays.

#### **Parameters**

**indices** [list] Indices to be taken.

**axis** [int, optional] The axis over which to select values, always 0.

**allow\_fill** [bool, default True]

**fill\_value** [bool, default None] If `allow_fill=True` and `fill_value` is not `None`, indices specified by -1 is regarded as NA. If Index doesn't hold NA, raise `ValueError`.

#### **Returns**

**numpy.ndarray** Elements of given indices.

**See also:**

[`numpy.ndarray.take`](#)

### **pandas.Index.to\_flat\_index**

`Index.to_flat_index` (*self*)

Identity method.

New in version 0.24.0.

This is implemented for compatibility with subclass implementations when chaining.

#### **Returns**

**pd.Index** Caller.

**See also:**

[`MultiIndex.to\_flat\_index`](#) Subclass implementation.

### **pandas.Index.to\_frame**

`Index.to_frame` (*self*, *index=True*, *name=None*)

Create a DataFrame with a column containing the Index.

New in version 0.24.0.

#### **Parameters**

**index** [bool, default True] Set the index of the returned DataFrame as the original Index.

**name** [object, default None] The passed name should substitute for the index name (if it has one).

#### **Returns**

**DataFrame** DataFrame containing the original Index data.

**See also:**

**`Index.to_series`** Convert an Index to a Series.

**`Series.to_frame`** Convert Series to DataFrame.

### Examples

```
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')
>>> idx.to_frame()
      animal
animal
Ant      Ant
Bear    Bear
Cow     Cow
```

By default, the original Index is reused. To enforce a new Index:

```
>>> idx.to_frame(index=False)
      animal
0      Ant
1     Bear
2      Cow
```

To override the name of the resulting column, specify *name*:

```
>>> idx.to_frame(index=False, name='zoo')
      zoo
0      Ant
1     Bear
2      Cow
```

### pandas.Index.to\_list

`Index.to_list` (*self*)

Return a list of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

#### Returns

list

**See also:**

`numpy.ndarray.tolist`

## pandas.Index.to\_native\_types

`Index.to_native_types` (*self*,  *slicer=None*, *\*\*kwargs*)

Format specified values of *self* and return them.

### Parameters

**slicer** [int, array-like] An indexer into *self* that specifies which values are used in the formatting process.

**kwargs** [dict] Options for specifying how the values should be formatted. These options include the following:

- 1) **na\_rep** [str] The value that serves as a placeholder for NULL values
- 2) **quoting** [bool or None] Whether or not there are quoted values in *self*
- 3) **date\_format** [str] The format used to represent date-like values.

### Returns

`numpy.ndarray` Formatted values.

## pandas.Index.to\_numpy

`Index.to_numpy` (*self*,  *dtype=None*,  *copy=False*,  *na\_value=<object object at 0x7f80b4e0f690>*, *\*\*kwargs*)

A NumPy ndarray representing the values in this Series or Index.

New in version 0.24.0.

### Parameters

**dtype** [str or `numpy.dtype`, optional] The dtype to pass to `numpy.asarray()`.

**copy** [bool, default False] Whether to ensure that the returned value is a not a view on another array. Note that `copy=False` does not *ensure* that `to_numpy()` is no-copy. Rather, `copy=True` ensure that a copy is made, even if not strictly necessary.

**na\_value** [Any, optional] The value to use for missing values. The default value depends on *dtype* and the type of the array.

New in version 1.0.0.

**\*\*kwargs** Additional keywords passed through to the `to_numpy` method of the underlying array (for extension arrays).

New in version 1.0.0.

### Returns

`numpy.ndarray`

See also:

**`Series.array`** Get the actual data stored within.

**`Index.array`** Get the actual data stored within.

**`DataFrame.to_numpy`** Similar method for DataFrame.

## Notes

The returned array will be the same up to equality (values equal in *self* will be equal in the returned array; likewise for values that are not equal). When *self* contains an ExtensionArray, the dtype may be different. For example, for a category-dtype Series, `to_numpy()` will return a NumPy array and the categorical dtype will be lost.

For NumPy dtypes, this will be a reference to the actual data stored in this Series or Index (assuming `copy=False`). Modifying the result in place will modify the data stored in the Series or Index (not that we recommend doing that).

For extension types, `to_numpy()` may require copying data and coercing the result to a NumPy type (possibly object), which may be expensive. When you need a no-copy reference to the underlying data, `Series.array` should be used instead.

This table lays out the different dtypes and default return types of `to_numpy()` for various dtypes within pandas.

dtype	array type
category[T]	ndarray[T] (same dtype as input)
period	ndarray[object] (Periods)
interval	ndarray[object] (Intervals)
IntegerNA	ndarray[object]
datetime64[ns]	datetime64[ns]
datetime64[ns, tz]	ndarray[object] (Timestamps)

## Examples

```
>>> ser = pd.Series(pd.Categorical(['a', 'b', 'a']))
>>> ser.to_numpy()
array(['a', 'b', 'a'], dtype=object)
```

Specify the *dtype* to control how datetime-aware data is represented. Use `dtype=object` to return an ndarray of pandas *Timestamp* objects, each with the correct `tz`.

```
>>> ser = pd.Series(pd.date_range('2000', periods=2, tz="CET"))
>>> ser.to_numpy(dtype=object)
array([Timestamp('2000-01-01 00:00:00+0100', tz='CET', freq='D'),
       Timestamp('2000-01-02 00:00:00+0100', tz='CET', freq='D')],
      dtype=object)
```

Or `dtype='datetime64[ns]'` to return an ndarray of native `datetime64` values. The values are converted to UTC and the timezone info is dropped.

```
>>> ser.to_numpy(dtype="datetime64[ns]")
...
array(['1999-12-31T23:00:00.000000000', '2000-01-01T23:00:00...'],
      dtype='datetime64[ns]')
```

### pandas.Index.to\_series

`Index.to_series` (*self*, *index=None*, *name=None*)

Create a Series with both index and values equal to the index keys.

Useful with `map` for returning an indexer based on an index.

#### Parameters

**index** [Index, optional] Index of resulting Series. If None, defaults to original index.

**name** [str, optional] Name of resulting Series. If None, defaults to name of original index.

#### Returns

**Series** The dtype will be based on the type of the Index values.

### pandas.Index.tolist

`Index.tolist` (*self*)

Return a list of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

#### Returns

list

See also:

`numpy.ndarray.tolist`

### pandas.Index.transpose

`Index.transpose` (*self*, *\*args*, *\*\*kwargs*)

Return the transpose, which is by definition self.

#### Returns

%(klass)s

### pandas.Index.union

`Index.union` (*self*, *other*, *sort=None*)

Form the union of two Index objects.

If the Index objects are incompatible, both Index objects will be cast to dtype('object') first.

Changed in version 0.25.0.

#### Parameters

**other** [Index or array-like]

**sort** [bool or None, default None] Whether to sort the resulting Index.

- None : Sort the result, except when

1. *self* and *other* are equal.
2. *self* or *other* has length 0.
3. Some values in *self* or *other* cannot be compared. A RuntimeWarning is issued in this case.

- False : do not sort the result.

New in version 0.24.0.

Changed in version 0.24.1: Changed the default value from True to None (without change in behaviour).

### Returns

**union** [Index]

### Examples

Union matching dtypes

```
>>> idx1 = pd.Index([1, 2, 3, 4])
>>> idx2 = pd.Index([3, 4, 5, 6])
>>> idx1.union(idx2)
Int64Index([1, 2, 3, 4, 5, 6], dtype='int64')
```

Union mismatched dtypes

```
>>> idx1 = pd.Index(['a', 'b', 'c', 'd'])
>>> idx2 = pd.Index([1, 2, 3, 4])
>>> idx1.union(idx2)
Index(['a', 'b', 'c', 'd', 1, 2, 3, 4], dtype='object')
```

## pandas.Index.unique

`Index.unique` (*self*, *level=None*)

Return unique values in the index. Uniques are returned in order of appearance, this does NOT sort.

### Parameters

**level** [int or str, optional, default None] Only return values from specified level (for MultiIndex).

New in version 0.23.0.

### Returns

**Index without duplicates**

See also:

`unique`

`Series.unique`

## pandas.Index.value\_counts

`Index.value_counts` (*self*, *normalize=False*, *sort=True*, *ascending=False*, *bins=None*, *dropna=True*)

Return a Series containing counts of unique values.

The resulting object will be in descending order so that the first element is the most frequently-occurring element. Excludes NA values by default.

### Parameters

**normalize** [bool, default False] If True then the object returned will contain the relative frequencies of the unique values.

**sort** [bool, default True] Sort by frequencies.

**ascending** [bool, default False] Sort in ascending order.

**bins** [int, optional] Rather than count values, group them into half-open bins, a convenience for `pd.cut`, only works with numeric data.

**dropna** [bool, default True] Don't include counts of NaN.

### Returns

#### Series

See also:

**Series.count** Number of non-NA elements in a Series.

**DataFrame.count** Number of non-NA elements in a DataFrame.

### Examples

```
>>> index = pd.Index([3, 1, 2, 3, 4, np.nan])
>>> index.value_counts()
3.0    2
4.0    1
2.0    1
1.0    1
dtype: int64
```

With *normalize* set to *True*, returns the relative frequency by dividing all values by the sum of values.

```
>>> s = pd.Series([3, 1, 2, 3, 4, np.nan])
>>> s.value_counts(normalize=True)
3.0    0.4
4.0    0.2
2.0    0.2
1.0    0.2
dtype: float64
```

### bins

Bins can be useful for going from a continuous variable to a categorical variable; instead of counting unique apparitions of values, divide the index in the specified number of half-open bins.

```
>>> s.value_counts(bins=3)
(2.0, 3.0]    2
(0.996, 2.0]  2
(3.0, 4.0]    1
dtype: int64
```

**dropna**

With *dropna* set to *False* we can also see NaN index values.

```
>>> s.value_counts(dropna=False)
3.0    2
NaN    1
4.0    1
2.0    1
1.0    1
dtype: int64
```

**pandas.Index.where**

`Index.where` (*self*, *cond*, *other=None*)

Return an Index of same shape as self and whose corresponding entries are from self where cond is True and otherwise are from other.

**Parameters**

**cond** [bool array-like with the same length as self]

**other** [scalar, or array-like]

**Returns**

**Index**

<b>is_boolean</b>	
<b>is_floating</b>	
<b>is_integer</b>	
<b>is_interval</b>	
<b>is_mixed</b>	
<b>is_numeric</b>	
<b>is_object</b>	
<b>view</b>	

**Properties**

<i>Index.values</i>	Return an array representing the data in the Index.
<i>Index.is_monotonic</i>	Alias for <code>is_monotonic_increasing</code> .
<i>Index.is_monotonic_increasing</i>	Return if the index is monotonic increasing (only equal or increasing) values.
<i>Index.is_monotonic_decreasing</i>	Return if the index is monotonic decreasing (only equal or decreasing) values.
<i>Index.is_unique</i>	Return if the index has unique values.
<i>Index.has_duplicates</i>	

Continued on next page

Table 131 – continued from previous page

<i>Index.hasnans</i>	Return if I have any nans; enables various perf speedups.
<i>Index.dtype</i>	Return the dtype object of the underlying data.
<i>Index.inferred_type</i>	Return a string of the type inferred from the values.
<i>Index.is_all_dates</i>	
<i>Index.shape</i>	Return a tuple of the shape of the underlying data.
<i>Index.name</i>	
<i>Index.names</i>	
<i>Index.nbytes</i>	Return the number of bytes in the underlying data.
<i>Index.ndim</i>	Number of dimensions of the underlying data, by definition 1.
<i>Index.size</i>	Return the number of elements in the underlying data.
<i>Index.empty</i>	
<i>Index.T</i>	Return the transpose, which is by definition self.
<i>Index.memory_usage(self[, deep])</i>	Memory usage of the values.

### **pandas.Index.has\_duplicates**

**property** `Index.has_duplicates`

### **pandas.Index.is\_all\_dates**

`Index.is_all_dates`

### **pandas.Index.name**

**property** `Index.name`

### **pandas.Index.names**

**property** `Index.names`

### **pandas.Index.empty**

**property** `Index.empty`

### **Modifying and computations**

<i>Index.all(self, *args, **kwargs)</i>	Return whether all elements are True.
<i>Index.any(self, *args, **kwargs)</i>	Return whether any element is True.
<i>Index.argmin(self[, axis, skipna])</i>	Return a ndarray of the minimum argument indexer.
<i>Index.argmax(self[, axis, skipna])</i>	Return an ndarray of the maximum argument indexer.
<i>Index.copy(self[, name, deep, dtype])</i>	Make a copy of this object.
<i>Index.delete(self, loc)</i>	Make new Index with passed location(-s) deleted.
<i>Index.drop(self, labels[, errors])</i>	Make new Index with passed list of labels deleted.

Continued on next page

Table 132 – continued from previous page

<code>Index.drop_duplicates(self[, keep])</code>	Return Index with duplicate values removed.
<code>Index.duplicated(self[, keep])</code>	Indicate duplicate index values.
<code>Index.equals(self, other)</code>	Determine if two Index objects contain the same elements.
<code>Index.factorize(self[, sort, na_sentinel])</code>	Encode the object as an enumerated type or categorical variable.
<code>Index.identical(self, other)</code>	Similar to equals, but check that other comparable attributes are also equal.
<code>Index.insert(self, loc, item)</code>	Make new Index inserting new item at location.
<code>Index.is_(self, other)</code>	More flexible, faster check like <code>is</code> but that works through views.
<code>Index.is_boolean(self)</code>	
<code>Index.is_categorical(self)</code>	Check if the Index holds categorical data.
<code>Index.is_floating(self)</code>	
<code>Index.is_integer(self)</code>	
<code>Index.is_interval(self)</code>	
<code>Index.is_mixed(self)</code>	
<code>Index.is_numeric(self)</code>	
<code>Index.is_object(self)</code>	
<code>Index.min(self[, axis, skipna])</code>	Return the minimum value of the Index.
<code>Index.max(self[, axis, skipna])</code>	Return the maximum value of the Index.
<code>Index.reindex(self, target[, method, level, ...])</code>	Create index with target's values (move/add/delete values as necessary).
<code>Index.rename(self, name[, inplace])</code>	Alter Index or MultiIndex name.
<code>Index.repeat(self, repeats[, axis])</code>	Repeat elements of a Index.
<code>Index.where(self, cond[, other])</code>	Return an Index of same shape as self and whose corresponding entries are from self where cond is True and otherwise are from other.
<code>Index.take(self, indices[, axis, ...])</code>	Return a new Index of the values selected by the indices.
<code>Index.putmask(self, mask, value)</code>	Return a new Index of the values set with the mask.
<code>Index.unique(self[, level])</code>	Return unique values in the index.
<code>Index.nunique(self[, dropna])</code>	Return number of unique elements in the object.
<code>Index.value_counts(self[, normalize, sort, ...])</code>	Return a Series containing counts of unique values.

**pandas.Index.is\_boolean**

`Index.is_boolean(self)` → bool

### **pandas.Index.is\_floating**

`Index.is_floating` (*self*) → bool

### **pandas.Index.is\_integer**

`Index.is_integer` (*self*) → bool

### **pandas.Index.is\_interval**

`Index.is_interval` (*self*) → bool

### **pandas.Index.is\_mixed**

`Index.is_mixed` (*self*) → bool

### **pandas.Index.is\_numeric**

`Index.is_numeric` (*self*) → bool

### **pandas.Index.is\_object**

`Index.is_object` (*self*) → bool

## **Compatibility with MultiIndex**

---

<code>Index.set_names(self, names[, level, inplace])</code>	Set Index or MultiIndex name.
<code>Index.droplevel(self[, level])</code>	Return index with requested level(s) removed.

---

## **Missing values**

---

<code>Index.fillna(self[, value, downcast])</code>	Fill NA/NaN values with the specified value.
<code>Index.dropna(self[, how])</code>	Return Index without NA/NaN values.
<code>Index.isna(self)</code>	Detect missing values.
<code>Index.notna(self)</code>	Detect existing (non-missing) values.

---

## Conversion

<code>Index.astype(self, dtype[, copy])</code>	Create an Index with values cast to dtypes.
<code>Index.item(self)</code>	Return the first element of the underlying data as a python scalar.
<code>Index.map(self, mapper[, na_action])</code>	Map values using input correspondence (a dict, Series, or function).
<code>Index.ravel(self[, order])</code>	Return an ndarray of the flattened values of the underlying data.
<code>Index.to_list(self)</code>	Return a list of the values.
<code>Index.to_native_types(self[, slicer])</code>	Format specified values of <i>self</i> and return them.
<code>Index.to_series(self[, index, name])</code>	Create a Series with both index and values equal to the index keys.
<code>Index.to_frame(self[, index, name])</code>	Create a DataFrame with a column containing the Index.
<code>Index.view(self[, cls])</code>	

## pandas.Index.view

`Index.view(self, cls=None)`

## Sorting

<code>Index.argsort(self, *args, **kwargs)</code>	Return the integer indices that would sort the index.
<code>Index.searchsorted(self, value[, side, sorter])</code>	Find indices where elements should be inserted to maintain order.
<code>Index.sort_values(self[, return_indexer, ...])</code>	Return a sorted copy of the index.

## Time-specific operations

<code>Index.shift(self[, periods, freq])</code>	Shift index by desired number of time frequency increments.
-------------------------------------------------	-------------------------------------------------------------

## Combining / joining / set operations

<code>Index.append(self, other)</code>	Append a collection of Index options together.
<code>Index.join(self, other[, how, level, ...])</code>	Compute join_index and indexers to conform data structures to the new index.
<code>Index.intersection(self, other[, sort])</code>	Form the intersection of two Index objects.
<code>Index.union(self, other[, sort])</code>	Form the union of two Index objects.
<code>Index.difference(self, other[, sort])</code>	Return a new Index with elements from the index that are not in <i>other</i> .
<code>Index.symmetric_difference(self, other[, ...])</code>	Compute the symmetric difference of two Index objects.

## Selecting

<code>Index.asof(self, label)</code>	Return the label from the index, or, if not present, the previous one.
<code>Index.asof_locs(self, where, mask)</code>	Find the locations (indices) of the labels from the index for every entry in the <i>where</i> argument.
<code>Index.get_indexer(self, target[, method, ...])</code>	Compute indexer and mask for new index given the current index.
<code>Index.get_indexer_for(self, target, \**kwargs)</code>	Guaranteed return of an indexer even when non-unique.
<code>Index.get_indexer_non_unique(self, target)</code>	Compute indexer and mask for new index given the current index.
<code>Index.get_level_values(self, level)</code>	Return an Index of values for requested level.
<code>Index.get_loc(self, key[, method, tolerance])</code>	Get integer location, slice or boolean mask for requested label.
<code>Index.get_slice_bound(self, label, side, kind)</code>	Calculate slice bound that corresponds to given label.
<code>Index.get_value(self, series, key)</code>	Fast lookup of value from 1-dimensional ndarray.
<code>Index.isin(self, values[, level])</code>	Return a boolean array where the index values are in <i>values</i> .
<code>Index.slice_indexer(self[, start, end, ...])</code>	For an ordered or unique index, compute the slice indexer for input labels and step.
<code>Index.slice_locs(self[, start, end, step, kind])</code>	Compute slice locations for input labels.

### 4.7.2 Numeric Index

<code>RangeIndex</code>	Immutable Index implementing a monotonic integer range.
<code>Int64Index</code>	Immutable ndarray implementing an ordered, sliceable set.
<code>UInt64Index</code>	Immutable ndarray implementing an ordered, sliceable set.
<code>Float64Index</code>	Immutable ndarray implementing an ordered, sliceable set.

### pandas.RangeIndex

**class** pandas.**RangeIndex**

Immutable Index implementing a monotonic integer range.

RangeIndex is a memory-saving special case of Int64Index limited to representing monotonic ranges. Using RangeIndex may in some instances improve computing speed.

This is the default index type used by DataFrame and Series when no explicit index is provided by the user.

#### Parameters

- start** [int (default: 0), or other RangeIndex instance] If int and “stop” is not given, interpreted as “stop” instead.
- stop** [int (default: 0)]
- step** [int (default: 1)]
- name** [object, optional] Name to be stored in the index.

**copy** [bool, default False] Unused, accepted for homogeneity with other index types.

**See also:**

**Index** The base pandas Index type.

**Int64Index** Index of int64 data.

**Attributes**

<i>start</i>	The value of the <i>start</i> parameter (0 if this was not supplied).
<i>stop</i>	The value of the <i>stop</i> parameter.
<i>step</i>	The value of the <i>step</i> parameter (1 if this was not supplied).

**pandas.RangeIndex.start**

RangeIndex.**start**

The value of the *start* parameter (0 if this was not supplied).

**pandas.RangeIndex.stop**

RangeIndex.**stop**

The value of the *stop* parameter.

**pandas.RangeIndex.step**

RangeIndex.**step**

The value of the *step* parameter (1 if this was not supplied).

**Methods**

<i>from_range</i> (data[, name, dtype])	Create RangeIndex from a range object.
-----------------------------------------	----------------------------------------

**pandas.RangeIndex.from\_range**

**classmethod** RangeIndex.**from\_range** (*data*, *name=None*, *dtype=None*)

Create RangeIndex from a range object.

**Returns**

**RangeIndex**

## pandas.Int64Index

**class** pandas.Int64Index

Immutable ndarray implementing an ordered, sliceable set. The basic object storing axis labels for all pandas objects. Int64Index is a special case of *Index* with purely integer labels. .

### Parameters

- data** [array-like (1-dimensional)]
- dtype** [NumPy dtype (default: int64)]
- copy** [bool] Make a copy of input ndarray.
- name** [object] Name to be stored in the index.

### See also:

**Index** The base pandas Index type.

### Notes

An Index instance can **only** contain hashable objects.

### Attributes

None	
------	--

### Methods

None	
------	--

## pandas.UInt64Index

**class** pandas.UInt64Index

Immutable ndarray implementing an ordered, sliceable set. The basic object storing axis labels for all pandas objects. UInt64Index is a special case of *Index* with purely unsigned integer labels. .

### Parameters

- data** [array-like (1-dimensional)]
- dtype** [NumPy dtype (default: uint64)]
- copy** [bool] Make a copy of input ndarray.
- name** [object] Name to be stored in the index.

### See also:

**Index** The base pandas Index type.

## Notes

An Index instance can **only** contain hashable objects.

## Attributes

None	
------	--

## Methods

None	
------	--

## pandas.Float64Index

**class** pandas.**Float64Index**

Immutable ndarray implementing an ordered, sliceable set. The basic object storing axis labels for all pandas objects. Float64Index is a special case of *Index* with purely float labels. .

### Parameters

**data** [array-like (1-dimensional)]

**dtype** [NumPy dtype (default: float64)]

**copy** [bool] Make a copy of input ndarray.

**name** [object] Name to be stored in the index.

### See also:

**Index** The base pandas Index type.

## Notes

An Index instance can **only** contain hashable objects.

## Attributes

None	
------	--

## Methods

None	
------	--

*RangeIndex.start*

The value of the *start* parameter (0 if this was not supplied).

*RangeIndex.stop*

The value of the *stop* parameter.

---

Continued on next page

Table 143 – continued from previous page

---

<code>RangeIndex.step</code>	The value of the <code>step</code> parameter (1 if this was not supplied).
<code>RangeIndex.from_range(data[, name, dtype])</code>	Create <code>RangeIndex</code> from a range object.

---

### 4.7.3 CategoricalIndex

---

<code>CategoricalIndex</code>	Index based on an underlying <code>Categorical</code> .
-------------------------------	---------------------------------------------------------

---

#### pandas.CategoricalIndex

**class** pandas.**CategoricalIndex**

Index based on an underlying `Categorical`.

`CategoricalIndex`, like `Categorical`, can only take on a limited, and usually fixed, number of possible values (*categories*). Also, like `Categorical`, it might have an order, but numerical operations (additions, divisions, ...) are not possible.

#### Parameters

**data** [array-like (1-dimensional)] The values of the categorical. If *categories* are given, values not in *categories* will be replaced with NaN.

**categories** [index-like, optional] The categories for the categorical. Items need to be unique. If the categories are not given here (and also not in *dtype*), they will be inferred from the *data*.

**ordered** [bool, optional] Whether or not this categorical is treated as an ordered categorical. If not given here or in *dtype*, the resulting categorical will be unordered.

**dtype** [`CategoricalDtype` or “category”, optional] If `CategoricalDtype`, cannot be used together with *categories* or *ordered*.

New in version 0.21.0.

**copy** [bool, default False] Make a copy of input ndarray.

**name** [object, optional] Name to be stored in the index.

#### Raises

**ValueError** If the categories do not validate.

**TypeError** If an explicit `ordered=True` is given but no *categories* and the *values* are not sortable.

#### See also:

**Index** The base pandas Index type.

**Categorical** A categorical array.

**CategoricalDtype** Type for categorical data.

## Notes

See the [user guide](#) for more.

## Examples

```
>>> pd.CategoricalIndex(['a', 'b', 'c', 'a', 'b', 'c'])
CategoricalIndex(['a', 'b', 'c', 'a', 'b', 'c'], categories=['a', 'b', 'c'],
↳ordered=False, dtype='category') # noqa
```

CategoricalIndex can also be instantiated from a Categorical:

```
>>> c = pd.Categorical(['a', 'b', 'c', 'a', 'b', 'c'])
>>> pd.CategoricalIndex(c)
CategoricalIndex(['a', 'b', 'c', 'a', 'b', 'c'], categories=['a', 'b', 'c'],
↳ordered=False, dtype='category') # noqa
```

Ordered CategoricalIndex can have a min and max value.

```
>>> ci = pd.CategoricalIndex(['a','b','c','a','b','c'], ordered=True,
...                           categories=['c', 'b', 'a'])
>>> ci
CategoricalIndex(['a', 'b', 'c', 'a', 'b', 'c'], categories=['c', 'b', 'a'],
↳ordered=True, dtype='category') # noqa
>>> ci.min()
'c'
```

## Attributes

<i>codes</i>	The category codes of this categorical.
<i>categories</i>	The categories of this categorical.
<i>ordered</i>	Whether the categories have an ordered relationship.

### pandas.CategoricalIndex.codes

**property** CategoricalIndex.codes

The category codes of this categorical.

Level codes are an array of integer which are the positions of the real values in the categories array.

There is not setter, use the other categorical methods and the normal item setter to change values in the categorical.

## pandas.CategoricalIndex.categories

### property CategoricalIndex.categories

The categories of this categorical.

Setting assigns new values to each category (effectively a rename of each individual category).

The assigned value has to be a list-like object. All items must be unique and the number of items in the new categories must be the same as the number of items in the old categories.

Assigning to *categories* is an inplace operation!

#### Raises

**ValueError** If the new categories do not validate as categories or if the number of new categories is unequal the number of old categories

See also:

*rename\_categories*

*reorder\_categories*

*add\_categories*

*remove\_categories*

*remove\_unused\_categories*

*set\_categories*

## pandas.CategoricalIndex.ordered

### property CategoricalIndex.ordered

Whether the categories have an ordered relationship.

#### Methods

<i>rename_categories</i> (self, *args, **kwargs)	Rename categories.
<i>reorder_categories</i> (self, *args, **kwargs)	Reorder categories as specified in <i>new_categories</i> .
<i>add_categories</i> (self, *args, **kwargs)	Add new categories.
<i>remove_categories</i> (self, *args, **kwargs)	Remove the specified categories.
<i>remove_unused_categories</i> (self, *args, ...)	Remove categories which are not used.
<i>set_categories</i> (self, *args, **kwargs)	Set the categories to the specified <i>new_categories</i> .
<i>as_ordered</i> (self, *args, **kwargs)	Set the Categorical to be ordered.
<i>as_unordered</i> (self, *args, **kwargs)	Set the Categorical to be unordered.
<i>map</i> (self, mapper)	Map values using input correspondence (a dict, Series, or function).

**pandas.CategoricalIndex.rename\_categories**

`CategoricalIndex.rename_categories` (*self*, \*args, \*\*kwargs)

Rename categories.

**Parameters**

**new\_categories** [list-like, dict-like or callable] New categories which will replace old categories.

- list-like: all items must be unique and the number of items in the new categories must match the existing number of categories.
- dict-like: specifies a mapping from old categories to new. Categories not contained in the mapping are passed through and extra categories in the mapping are ignored.

New in version 0.21.0..

- callable : a callable that is called on all items in the old categories and whose return values comprise the new categories.

New in version 0.23.0..

**inplace** [bool, default False] Whether or not to rename the categories inplace or return a copy of this categorical with renamed categories.

**Returns**

**cat** [Categorical or None] With `inplace=False`, the new categorical is returned. With `inplace=True`, there is no return value.

**Raises**

**ValueError** If new categories are list-like and do not have the same number of items than the current categories or do not validate as categories

See also:

*reorder\_categories*

*add\_categories*

*remove\_categories*

*remove\_unused\_categories*

*set\_categories*

**Examples**

```
>>> c = pd.Categorical(['a', 'a', 'b'])
>>> c.rename_categories([0, 1])
[0, 0, 1]
Categories (2, int64): [0, 1]
```

For dict-like `new_categories`, extra keys are ignored and categories not in the dictionary are passed through

```
>>> c.rename_categories({'a': 'A', 'c': 'C'})
[A, A, b]
Categories (2, object): [A, b]
```

You may also provide a callable to create the new categories

```
>>> c.rename_categories(lambda x: x.upper())
[A, A, B]
Categories (2, object): [A, B]
```

## pandas.CategoricalIndex.reorder\_categories

`CategoricalIndex.reorder_categories` (*self*, \*args, \*\*kwargs)

Reorder categories as specified in *new\_categories*.

*new\_categories* need to include all old categories and no new category items.

### Parameters

**new\_categories** [Index-like] The categories in new order.

**ordered** [bool, optional] Whether or not the categorical is treated as a ordered categorical. If not given, do not change the ordered information.

**inplace** [bool, default False] Whether or not to reorder the categories inplace or return a copy of this categorical with reordered categories.

### Returns

**cat** [Categorical with reordered categories or None if inplace.]

### Raises

**ValueError** If the new categories do not contain all old category items or any new ones

See also:

*rename\_categories*

*add\_categories*

*remove\_categories*

*remove\_unused\_categories*

*set\_categories*

## pandas.CategoricalIndex.add\_categories

`CategoricalIndex.add_categories` (*self*, \*args, \*\*kwargs)

Add new categories.

*new\_categories* will be included at the last/highest place in the categories and will be unused directly after this call.

### Parameters

**new\_categories** [category or list-like of category] The new categories to be included.

**inplace** [bool, default False] Whether or not to add the categories inplace or return a copy of this categorical with added categories.

**Returns**

**cat** [Categorical with new categories added or None if inplace.]

**Raises**

**ValueError** If the new categories include old categories or do not validate as categories

**See also:**

*rename\_categories*

*reorder\_categories*

*remove\_categories*

*remove\_unused\_categories*

*set\_categories*

**pandas.CategoricalIndex.remove\_categories**

`CategoricalIndex.remove_categories` (*self*, \**args*, \*\**kwargs*)

Remove the specified categories.

*removals* must be included in the old categories. Values which were in the removed categories will be set to NaN

**Parameters**

**removals** [category or list of categories] The categories which should be removed.

**inplace** [bool, default False] Whether or not to remove the categories inplace or return a copy of this categorical with removed categories.

**Returns**

**cat** [Categorical with removed categories or None if inplace.]

**Raises**

**ValueError** If the removals are not contained in the categories

**See also:**

*rename\_categories*

*reorder\_categories*

*add\_categories*

*remove\_unused\_categories*

*set\_categories*

### `pandas.CategoricalIndex.remove_unused_categories`

`CategoricalIndex.remove_unused_categories` (*self*, \*args, \*\*kwargs)

Remove categories which are not used.

#### Parameters

**inplace** [bool, default False] Whether or not to drop unused categories inplace or return a copy of this categorical with unused categories dropped.

#### Returns

**cat** [Categorical with unused categories dropped or None if inplace.]

See also:

*rename\_categories*

*reorder\_categories*

*add\_categories*

*remove\_categories*

*set\_categories*

### `pandas.CategoricalIndex.set_categories`

`CategoricalIndex.set_categories` (*self*, \*args, \*\*kwargs)

Set the categories to the specified `new_categories`.

`new_categories` can include new categories (which will result in unused categories) or remove old categories (which results in values set to NaN). If `rename==True`, the categories will simply be renamed (less or more items than in old categories will result in values set to NaN or in unused categories respectively).

This method can be used to perform more than one action of adding, removing, and reordering simultaneously and is therefore faster than performing the individual steps via the more specialised methods.

On the other hand this method does not do checks (e.g., whether the old categories are included in the new categories on a reorder), which can result in surprising changes, for example when using special string dtypes, which does not consider a S1 string equal to a single char python string.

#### Parameters

**new\_categories** [Index-like] The categories in new order.

**ordered** [bool, default False] Whether or not the categorical is treated as a ordered categorical. If not given, do not change the ordered information.

**rename** [bool, default False] Whether or not the `new_categories` should be considered as a rename of the old categories or as reordered categories.

**inplace** [bool, default False] Whether or not to reorder the categories in-place or return a copy of this categorical with reordered categories.

#### Returns

**Categorical with reordered categories or None if inplace.**

#### Raises

**ValueError** If `new_categories` does not validate as categories

See also:

*rename\_categories*  
*reorder\_categories*  
*add\_categories*  
*remove\_categories*  
*remove\_unused\_categories*

### **pandas.CategoricalIndex.as\_ordered**

`CategoricalIndex.as_ordered` (*self*, \*args, \*\*kwargs)

Set the Categorical to be ordered.

#### **Parameters**

**inplace** [bool, default False] Whether or not to set the ordered attribute in-place or return a copy of this categorical with ordered set to True.

#### **Returns**

**Categorical** Ordered Categorical.

### **pandas.CategoricalIndex.as\_unordered**

`CategoricalIndex.as_unordered` (*self*, \*args, \*\*kwargs)

Set the Categorical to be unordered.

#### **Parameters**

**inplace** [bool, default False] Whether or not to set the ordered attribute in-place or return a copy of this categorical with ordered set to False.

#### **Returns**

**Categorical** Unordered Categorical.

### **pandas.CategoricalIndex.map**

`CategoricalIndex.map` (*self*, mapper)

Map values using input correspondence (a dict, Series, or function).

Maps the values (their categories, not the codes) of the index to new categories. If the mapping correspondence is one-to-one the result is a *CategoricalIndex* which has the same order property as the original, otherwise an *Index* is returned.

If a *dict* or *Series* is used any unmapped category is mapped to *NaN*. Note that if this happens an *Index* will be returned.

#### **Parameters**

**mapper** [function, dict, or Series] Mapping correspondence.

#### **Returns**

**pandas.CategoricalIndex** or **pandas.Index** Mapped index.

See also:

**Index.map** Apply a mapping correspondence on an *Index*.

**Series.map** Apply a mapping correspondence on a *Series*.

**Series.apply** Apply more complex functions on a *Series*.

## Examples

```
>>> idx = pd.CategoricalIndex(['a', 'b', 'c'])
>>> idx
CategoricalIndex(['a', 'b', 'c'], categories=['a', 'b', 'c'],
                 ordered=False, dtype='category')
>>> idx.map(lambda x: x.upper())
CategoricalIndex(['A', 'B', 'C'], categories=['A', 'B', 'C'],
                 ordered=False, dtype='category')
>>> idx.map({'a': 'first', 'b': 'second', 'c': 'third'})
CategoricalIndex(['first', 'second', 'third'], categories=['first',
                 'second', 'third'], ordered=False, dtype='category')
```

If the mapping is one-to-one the ordering of the categories is preserved:

```
>>> idx = pd.CategoricalIndex(['a', 'b', 'c'], ordered=True)
>>> idx
CategoricalIndex(['a', 'b', 'c'], categories=['a', 'b', 'c'],
                 ordered=True, dtype='category')
>>> idx.map({'a': 3, 'b': 2, 'c': 1})
CategoricalIndex([3, 2, 1], categories=[3, 2, 1], ordered=True,
                 dtype='category')
```

If the mapping is not one-to-one an *Index* is returned:

```
>>> idx.map({'a': 'first', 'b': 'second', 'c': 'first'})
Index(['first', 'second', 'first'], dtype='object')
```

If a *dict* is used, all unmapped categories are mapped to *NaN* and the result is an *Index*:

```
>>> idx.map({'a': 'first', 'b': 'second'})
Index(['first', 'second', nan], dtype='object')
```

## Categorical components

<code>CategoricalIndex.codes</code>	The category codes of this categorical.
<code>CategoricalIndex.categories</code>	The categories of this categorical.
<code>CategoricalIndex.ordered</code>	Whether the categories have an ordered relationship.
<code>CategoricalIndex.rename_categories(self, ...)</code>	Rename categories.
<code>CategoricalIndex.reorder_categories(self, ...)</code>	Reorder categories as specified in <code>new_categories</code> .
<code>CategoricalIndex.add_categories(self, ...)</code>	Add new categories.
<code>CategoricalIndex.remove_categories(self, ...)</code>	Remove the specified categories.

Continued on next page

Table 147 – continued from previous page

<code>CategoricalIndex.remove_unused_categories(...)</code>	Remove categories which are not used.
<code>CategoricalIndex.set_categories(self, ...)</code>	Set the categories to the specified new_categories.
<code>CategoricalIndex.as_ordered(self, *args, ...)</code>	Set the Categorical to be ordered.
<code>CategoricalIndex.as_unordered(self, *args, ...)</code>	Set the Categorical to be unordered.

## Modifying and computations

<code>CategoricalIndex.map(self, mapper)</code>	Map values using input correspondence (a dict, Series, or function).
<code>CategoricalIndex.equals(self, other)</code>	Determine if two CategoricalIndex objects contain the same elements.

## pandas.CategoricalIndex.equals

`CategoricalIndex.equals(self, other)`

Determine if two CategoricalIndex objects contain the same elements.

### Returns

**bool** If two CategoricalIndex objects have equal elements True, otherwise False.

## 4.7.4 IntervalIndex

<code>IntervalIndex</code>	Immutable index of intervals that are closed on the same side.
----------------------------	----------------------------------------------------------------

## pandas.IntervalIndex

**class** pandas.IntervalIndex

Immutable index of intervals that are closed on the same side.

New in version 0.20.0.

### Parameters

**data** [array-like (1-dimensional)] Array-like containing Interval objects from which to build the IntervalIndex.

**closed** [{'left', 'right', 'both', 'neither'}, default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.

**dtype** [dtype or None, default None] If None, dtype will be inferred.

New in version 0.23.0.

**copy** [bool, default False] Copy the input data.

**name** [object, optional] Name to be stored in the index.

**verify\_integrity** [bool, default True] Verify that the IntervalIndex is valid.

See also:

**Index** The base pandas Index type.

**Interval** A bounded slice-like interval; the elements of an IntervalIndex.

**interval\_range** Function to create a fixed frequency IntervalIndex.

**cut** Bin values into discrete Intervals.

**qcut** Bin values into equal-sized Intervals based on rank or sample quantiles.

## Notes

See the [user guide](#) for more.

## Examples

A new IntervalIndex is typically constructed using `interval_range()`:

```
>>> pd.interval_range(start=0, end=5)
IntervalIndex([(0, 1], (1, 2], (2, 3], (3, 4], (4, 5]],
              closed='right',
              dtype='interval[int64]')
```

It may also be constructed using one of the constructor methods: `IntervalIndex.from_arrays()`, `IntervalIndex.from_breaks()`, and `IntervalIndex.from_tuples()`.

See further examples in the doc strings of `interval_range` and the mentioned constructor methods.

## Attributes

<code>left</code>	Return the left endpoints of each Interval in the IntervalArray as an Index.
<code>right</code>	Return the right endpoints of each Interval in the IntervalArray as an Index.
<code>closed</code>	Whether the intervals are closed on the left-side, right-side, both or neither.
<code>mid</code>	Return the midpoint of each Interval in the IntervalArray as an Index.
<code>length</code>	Return an Index with entries denoting the length of each Interval in the IntervalArray.
<code>is_empty</code>	Indicates if an interval is empty, meaning it contains no points.
<code>is_non_overlapping_monotonic</code>	Return True if the IntervalArray is non-overlapping (no Intervals share points) and is either monotonic increasing or monotonic decreasing, else False.
<code>is_overlapping</code>	Return True if the IntervalIndex has overlapping intervals, else False.
<code>values</code>	Return the IntervalIndex's data as an IntervalArray.

**pandas.IntervalIndex.left****property** `IntervalIndex.left`

Return the left endpoints of each Interval in the IntervalArray as an Index.

**pandas.IntervalIndex.right****property** `IntervalIndex.right`

Return the right endpoints of each Interval in the IntervalArray as an Index.

**pandas.IntervalIndex.closed**`IntervalIndex.closed`

Whether the intervals are closed on the left-side, right-side, both or neither.

**pandas.IntervalIndex.mid**`IntervalIndex.mid`

Return the midpoint of each Interval in the IntervalArray as an Index.

**pandas.IntervalIndex.length****property** `IntervalIndex.length`

Return an Index with entries denoting the length of each Interval in the IntervalArray.

**pandas.IntervalIndex.is\_empty**`IntervalIndex.is_empty`

Indicates if an interval is empty, meaning it contains no points.

New in version 0.25.0.

**Returns****bool or ndarray** A boolean indicating if a scalar *Interval* is empty, or a boolean ndarray positionally indicating if an *Interval* in an *IntervalArray* or *IntervalIndex* is empty.**Examples**An *Interval* that contains points is not empty:

```
>>> pd.Interval(0, 1, closed='right').is_empty
False
```

An *Interval* that does not contain any points is empty:

```
>>> pd.Interval(0, 0, closed='right').is_empty
True
>>> pd.Interval(0, 0, closed='left').is_empty
True
>>> pd.Interval(0, 0, closed='neither').is_empty
True
```

An Interval that contains a single point is not empty:

```
>>> pd.Interval(0, 0, closed='both').is_empty
False
```

An *IntervalArray* or *IntervalIndex* returns a boolean ndarray positionally indicating if an Interval is empty:

```
>>> ivs = [pd.Interval(0, 0, closed='neither'),
...        pd.Interval(1, 2, closed='neither')]
>>> pd.arrays.IntervalArray(ivs).is_empty
array([ True, False])
```

Missing values are not considered empty:

```
>>> ivs = [pd.Interval(0, 0, closed='neither'), np.nan]
>>> pd.IntervalIndex(ivs).is_empty
array([ True, False])
```

## pandas.IntervalIndex.is\_non\_overlapping\_monotonic

### IntervalIndex.is\_non\_overlapping\_monotonic

Return True if the IntervalArray is non-overlapping (no Intervals share points) and is either monotonic increasing or monotonic decreasing, else False.

## pandas.IntervalIndex.is\_overlapping

### property IntervalIndex.is\_overlapping

Return True if the IntervalIndex has overlapping intervals, else False.

Two intervals overlap if they share a common point, including closed endpoints. Intervals that only have an open endpoint in common do not overlap.

New in version 0.24.0.

#### Returns

**bool** Boolean indicating if the IntervalIndex has overlapping intervals.

#### See also:

**Interval.overlaps** Check whether two Interval objects overlap.

**IntervalIndex.overlaps** Check an IntervalIndex elementwise for overlaps.

## Examples

```
>>> index = pd.IntervalIndex.from_tuples([(0, 2), (1, 3), (4, 5)])
>>> index
IntervalIndex([(0, 2], [1, 3], [4, 5]],
              closed='right',
              dtype='interval[int64]')
>>> index.is_overlapping
True
```

Intervals that share closed endpoints overlap:

```
>>> index = pd.interval_range(0, 3, closed='both')
>>> index
IntervalIndex([[0, 1], [1, 2], [2, 3]],
              closed='both',
              dtype='interval[int64]')
>>> index.is_overlapping
True
```

Intervals that only have an open endpoint in common do not overlap:

```
>>> index = pd.interval_range(0, 3, closed='left')
>>> index
IntervalIndex([[0, 1), [1, 2), [2, 3)],
              closed='left',
              dtype='interval[int64]')
>>> index.is_overlapping
False
```

## pandas.IntervalIndex.values

### IntervalIndex.values

Return the IntervalIndex's data as an IntervalArray.

## Methods

<i>from_arrays</i> (left, right, closed[, name, dtype])	Construct from two arrays defining the left and right bounds.
<i>from_tuples</i> (data, closed[, name, dtype])	Construct an IntervalIndex from an array-like of tuples.
<i>from_breaks</i> (breaks, closed[, name, dtype])	Construct an IntervalIndex from an array of splits.
<i>contains</i> (self, *args, **kwargs)	Check elementwise if the Intervals contain the value.
<i>overlaps</i> (self, *args, **kwargs)	Check elementwise if an Interval overlaps the values in the IntervalArray.
<i>set_closed</i> (self, *args, **kwargs)	Return an IntervalArray identical to the current one, but closed on the specified side.
<i>to_tuples</i> (self, *args, **kwargs)	Return an ndarray of tuples of the form (left, right).

## pandas.IntervalIndex.from\_arrays

**classmethod** `IntervalIndex.from_arrays` (*left*, *right*, *closed*: *str* = 'right', *name*=None, *copy*: *bool* = False, *dtype*=None)

Construct from two arrays defining the left and right bounds.

### Parameters

**left** [array-like (1-dimensional)] Left bounds for each interval.

**right** [array-like (1-dimensional)] Right bounds for each interval.

**closed** [{ 'left', 'right', 'both', 'neither' }, default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.

**copy** [bool, default False] Copy the data.

**dtype** [dtype, optional] If None, dtype will be inferred.

New in version 0.23.0.

### Returns

**IntervalIndex**

### Raises

**ValueError** When a value is missing in only one of *left* or *right*. When a value in *left* is greater than the corresponding value in *right*.

### See also:

***interval\_range*** Function to create a fixed frequency IntervalIndex.

***IntervalIndex.from\_breaks*** Construct an IntervalIndex from an array of splits.

***IntervalIndex.from\_tuples*** Construct an IntervalIndex from an array-like of tuples.

### Notes

Each element of *left* must be less than or equal to the *right* element at the same position. If an element is missing, it must be missing in both *left* and *right*. A `TypeError` is raised when using an unsupported type for *left* or *right*. At the moment, 'category', 'object', and 'string' subtypes are not supported.

### Examples

```
>>> pd.IntervalIndex.from_arrays([0, 1, 2], [1, 2, 3])
IntervalIndex([(0, 1], (1, 2], (2, 3]],
              closed='right',
              dtype='interval[int64]')
```

## pandas.IntervalIndex.from\_tuples

**classmethod** `IntervalIndex.from_tuples` (*data*, *closed*: *str* = 'right', *name*=None, *copy*: *bool* = False, *dtype*=None)

Construct an IntervalIndex from an array-like of tuples.

### Parameters

**data** [array-like (1-dimensional)] Array of tuples.

**closed** [{'left', 'right', 'both', 'neither'}, default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.

**copy** [bool, default False] By-default copy the data, this is compat only and ignored.

**dtype** [dtype or None, default None] If None, dtype will be inferred.

New in version 0.23.0.

### Returns

**IntervalIndex**

See also:

***interval\_range*** Function to create a fixed frequency IntervalIndex.

***IntervalIndex.from\_arrays*** Construct an IntervalIndex from a left and right array.

***IntervalIndex.from\_breaks*** Construct an IntervalIndex from an array of splits.

### Examples

```
>>> pd.IntervalIndex.from_tuples([(0, 1), (1, 2)])
IntervalIndex([(0, 1), (1, 2)],
              closed='right',
              dtype='interval[int64]')
```

## pandas.IntervalIndex.from\_breaks

**classmethod** `IntervalIndex.from_breaks` (*breaks*, *closed*: *str* = 'right', *name*=None, *copy*: *bool* = False, *dtype*=None)

Construct an IntervalIndex from an array of splits.

### Parameters

**breaks** [array-like (1-dimensional)] Left and right bounds for each interval.

**closed** [{'left', 'right', 'both', 'neither'}, default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.

**copy** [bool, default False] Copy the data.

**dtype** [dtype or None, default None] If None, dtype will be inferred.

New in version 0.23.0.

### Returns

**IntervalIndex**

See also:

***interval\_range*** Function to create a fixed frequency IntervalIndex.

***IntervalIndex.from\_arrays*** Construct from a left and right array.

***IntervalIndex.from\_tuples*** Construct from a sequence of tuples.

## Examples

```
>>> pd.IntervalIndex.from_breaks([0, 1, 2, 3])
IntervalIndex([(0, 1], (1, 2], (2, 3]],
              closed='right',
              dtype='interval[int64]')
```

## pandas.IntervalIndex.contains

`IntervalIndex.contains` (*self*, \*args, \*\*kwargs)

Check elementwise if the Intervals contain the value.

Return a boolean mask whether the value is contained in the Intervals of the IntervalArray.

New in version 0.25.0.

### Parameters

**other** [scalar] The value to check whether it is contained in the Intervals.

### Returns

**boolean array**

**See also:**

**`Interval.contains`** Check whether Interval object contains value.

**`IntervalArray.overlaps`** Check if an Interval overlaps the values in the IntervalArray.

## Examples

```
>>> intervals = pd.arrays.IntervalArray.from_tuples([(0, 1), (1, 3), (2, 4)])
>>> intervals
<IntervalArray>
[(0, 1], (1, 3], (2, 4]]
Length: 3, closed: right, dtype: interval[int64]
```

```
>>> intervals.contains(0.5)
array([ True, False, False])
```

## pandas.IntervalIndex.overlaps

IntervalIndex.**overlaps** (*self*, \*args, \*\*kwargs)

Check elementwise if an Interval overlaps the values in the IntervalArray.

Two intervals overlap if they share a common point, including closed endpoints. Intervals that only have an open endpoint in common do not overlap.

New in version 0.24.0.

### Parameters

**other** [IntervalArray] Interval to check against for an overlap.

### Returns

**ndarray** Boolean array positionally indicating where an overlap occurs.

**See also:**

**Interval.overlaps** Check whether two Interval objects overlap.

### Examples

```
>>> data = [(0, 1), (1, 3), (2, 4)]
>>> intervals = pd.arrays.IntervalArray.from_tuples(data)
>>> intervals
<IntervalArray>
[(0, 1], (1, 3], (2, 4]]
Length: 3, closed: right, dtype: interval[int64]
```

```
>>> intervals.overlaps(pd.Interval(0.5, 1.5))
array([ True,  True, False])
```

Intervals that share closed endpoints overlap:

```
>>> intervals.overlaps(pd.Interval(1, 3, closed='left'))
array([ True,  True,  True])
```

Intervals that only have an open endpoint in common do not overlap:

```
>>> intervals.overlaps(pd.Interval(1, 2, closed='right'))
array([False,  True, False])
```

## pandas.IntervalIndex.set\_closed

IntervalIndex.**set\_closed** (*self*, \*args, \*\*kwargs)

Return an IntervalArray identical to the current one, but closed on the specified side.

New in version 0.24.0.

### Parameters

**closed** [{'left', 'right', 'both', 'neither'}] Whether the intervals are closed on the left-side, right-side, both or neither.

### Returns

`new_index` [IntervalArray]

### Examples

```
>>> index = pd.arrays.IntervalArray.from_breaks(range(4))
>>> index
<IntervalArray>
[[0, 1], (1, 2], (2, 3]]
Length: 3, closed: right, dtype: interval[int64]
>>> index.set_closed('both')
<IntervalArray>
[[0, 1], [1, 2], [2, 3]]
Length: 3, closed: both, dtype: interval[int64]
```

### pandas.IntervalIndex.to\_tuples

`IntervalIndex.to_tuples` (*self*, \*args, \*\*kwargs)

Return an ndarray of tuples of the form (left, right).

#### Parameters

**na\_tuple** [boolean, default True] Returns NA as a tuple if True, (nan, nan), or just as the NA value itself if False, nan.

New in version 0.23.0.

#### Returns

**tuples:** ndarray

### IntervalIndex components

<code>IntervalIndex.from_arrays(left, closed)</code>	<code>right</code>	Construct from two arrays defining the left and right bounds.
<code>IntervalIndex.from_tuples(data, ...)</code>	<code>closed[, ...]</code>	Construct an IntervalIndex from an array-like of tuples.
<code>IntervalIndex.from_breaks(breaks, ...)</code>	<code>closed[, ...]</code>	Construct an IntervalIndex from an array of splits.
<code>IntervalIndex.left</code>		Return the left endpoints of each Interval in the IntervalArray as an Index.
<code>IntervalIndex.right</code>		Return the right endpoints of each Interval in the IntervalArray as an Index.
<code>IntervalIndex.mid</code>		Return the midpoint of each Interval in the IntervalArray as an Index.
<code>IntervalIndex.closed</code>		Whether the intervals are closed on the left-side, right-side, both or neither.
<code>IntervalIndex.length</code>		Return an Index with entries denoting the length of each Interval in the IntervalArray.
<code>IntervalIndex.values</code>		Return the IntervalIndex's data as an IntervalArray.
<code>IntervalIndex.is_empty</code>		Indicates if an interval is empty, meaning it contains no points.

Continued on next page

Table 152 – continued from previous page

<code>IntervalIndex.is_non_overlapping_monotonic</code>		Return True if the IntervalArray is non-overlapping (no Intervals share points) and is either monotonic increasing or monotonic decreasing, else False.
<code>IntervalIndex.is_overlapping</code>		Return True if the IntervalIndex has overlapping intervals, else False.
<code>IntervalIndex.get_loc(self, key, method, ...)</code>		Get integer location, slice or boolean mask for requested label.
<code>IntervalIndex.get_indexer(self, target, ...)</code>		Compute indexer and mask for new index given the current index.
<code>IntervalIndex.set_closed(self, *args, ...)</code>		Return an IntervalArray identical to the current one, but closed on the specified side.
<code>IntervalIndex.contains(self, *args, **kwargs)</code>		Check elementwise if the Intervals contain the value.
<code>IntervalIndex.overlaps(self, *args, **kwargs)</code>		Check elementwise if an Interval overlaps the values in the IntervalArray.
<code>IntervalIndex.to_tuples(self, *args, **kwargs)</code>		Return an ndarray of tuples of the form (left, right).

### pandas.IntervalIndex.get\_loc

`IntervalIndex.get_loc(self, key: Any, method: Union[str, NoneType] = None, tolerance=None) → Union[int, slice, numpy.ndarray]`

Get integer location, slice or boolean mask for requested label.

#### Parameters

**key** [label]

**method** [{None}, optional]

- default: matches where the label is within an interval only.

#### Returns

**int if unique index, slice if monotonic index, else mask**

### Examples

```
>>> i1, i2 = pd.Interval(0, 1), pd.Interval(1, 2)
>>> index = pd.IntervalIndex([i1, i2])
>>> index.get_loc(1)
0
```

You can also supply a point inside an interval.

```
>>> index.get_loc(1.5)
1
```

If a label is in several intervals, you get the locations of all the relevant intervals.

```
>>> i3 = pd.Interval(0, 2)
>>> overlapping_index = pd.IntervalIndex([i1, i2, i3])
>>> overlapping_index.get_loc(0.5)
array([ True, False,  True])
```

Only exact matches will be returned if an interval is provided.

```
>>> index.get_loc(pd.Interval(0, 1))
0
```

## pandas.IntervalIndex.get\_indexer

`IntervalIndex.get_indexer` (*self*, *target*: ~AnyArrayLike, *method*: Union[str, NoneType] = None, *limit*: Union[int, NoneType] = None, *tolerance*: Union[Any, NoneType] = None) → numpy.ndarray

Compute indexer and mask for new index given the current index. The indexer should be then used as an input to `ndarray.take` to align the current data to the new index.

### Parameters

**target** [IntervalIndex or list of Intervals]

**method** [{None, 'pad'/'ffill', 'backfill'/'bfill', 'nearest'}, optional]

- default: exact matches only.
- pad / ffill: find the PREVIOUS index value if no exact match.
- backfill / bfill: use NEXT index value if no exact match
- nearest: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.

**limit** [int, optional] Maximum number of consecutive labels in `target` to match for inexact matches.

**tolerance** [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations must satisfy the equation  $\text{abs}(\text{index}[\text{indexer}] - \text{target}) \leq \text{tolerance}$ .

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index's type.

New in version 0.21.0: (list-like tolerance)

### Returns

**indexer** [ndarray of int] Integers from 0 to `n - 1` indicating that the index at these positions matches the corresponding target values. Missing values in the target are marked by `-1`.

### Raises

**NotImplementedError** If any method argument other than the default of `None` is specified as these are not yet implemented.

## Examples

```
>>> index = pd.Index(['c', 'a', 'b'])
>>> index.get_indexer(['a', 'b', 'x'])
array([ 1,  2, -1])
```

Notice that the return value is an array of locations in `index` and `x` is marked by `-1`, as it is not in `index`.

## 4.7.5 MultiIndex

*MultiIndex*

A multi-level, or hierarchical, index object for pandas objects.

### pandas.MultiIndex

**class** pandas.**MultiIndex**

A multi-level, or hierarchical, index object for pandas objects.

#### Parameters

**levels** [sequence of arrays] The unique labels for each level.

**codes** [sequence of arrays] Integers for each level designating which label at each location.

New in version 0.24.0.

**sortorder** [optional int] Level of sortedness (must be lexicographically sorted by that level).

**names** [optional sequence of objects] Names for each of the index levels. (name is accepted for compat).

**copy** [bool, default False] Copy the meta-data.

**verify\_integrity** [bool, default True] Check that the levels/codes are consistent and valid.

See also:

***MultiIndex.from\_arrays*** Convert list of arrays to MultiIndex.

***MultiIndex.from\_product*** Create a MultiIndex from the cartesian product of iterables.

***MultiIndex.from\_tuples*** Convert list of tuples to a MultiIndex.

***MultiIndex.from\_frame*** Make a MultiIndex from a DataFrame.

***Index*** The base pandas Index type.

### Notes

See the [user guide](#) for more.

## Examples

A new `MultiIndex` is typically constructed using one of the helper methods `MultiIndex.from_arrays()`, `MultiIndex.from_product()` and `MultiIndex.from_tuples()`. For example (using `.from_arrays()`):

```
>>> arrays = [[1, 1, 2, 2], ['red', 'blue', 'red', 'blue']]
>>> pd.MultiIndex.from_arrays(arrays, names=('number', 'color'))
MultiIndex([(1, 'red'),
            (1, 'blue'),
            (2, 'red'),
            (2, 'blue')],
            names=['number', 'color'])
```

See further examples for how to construct a `MultiIndex` in the doc strings of the mentioned helper methods.

## Attributes

<code>names</code>	Names of levels in <code>MultiIndex</code> .
<code>nlevels</code>	Integer number of levels in this <code>MultiIndex</code> .
<code>levshape</code>	A tuple with the length of each level.

### `pandas.MultiIndex.names`

**property** `MultiIndex.names`  
Names of levels in `MultiIndex`.

### `pandas.MultiIndex.nlevels`

**property** `MultiIndex.nlevels`  
Integer number of levels in this `MultiIndex`.

### `pandas.MultiIndex.levshape`

**property** `MultiIndex.levshape`  
A tuple with the length of each level.

levels	
codes	

## Methods

<i>from_arrays</i> (arrays[, sortorder, names])	Convert arrays to MultiIndex.
<i>from_tuples</i> (tuples[, sortorder, names])	Convert list of tuples to MultiIndex.
<i>from_product</i> (iterables[, sortorder, names])	Make a MultiIndex from the cartesian product of multiple iterables.
<i>from_frame</i> (df[, sortorder, names])	Make a MultiIndex from a DataFrame.
<i>set_levels</i> (self, levels[, level, inplace, ...])	Set new levels on MultiIndex.
<i>set_codes</i> (self, codes[, level, inplace, ...])	Set new codes on MultiIndex.
<i>to_frame</i> (self[, index, name])	Create a DataFrame with the levels of the MultiIndex as columns.
<i>to_flat_index</i> (self)	Convert a MultiIndex to an Index of Tuples containing the level values.
<i>is_lexsorted</i> (self)	Return True if the codes are lexicographically sorted.
<i>sortlevel</i> (self[, level, ascending, ...])	Sort MultiIndex at the requested level.
<i>droplevel</i> (self[, level])	Return index with requested level(s) removed.
<i>swaplevel</i> (self[, i, j])	Swap level i with level j.
<i>reorder_levels</i> (self, order)	Rearrange levels using input order.
<i>remove_unused_levels</i> (self)	Create a new MultiIndex from the current that removes unused levels, meaning that they are not expressed in the labels.
<i>get_locs</i> (self, seq)	Get location for a sequence of labels.

## pandas.MultiIndex.from\_arrays

**classmethod** MultiIndex.**from\_arrays** (arrays, sortorder=None, names=<object object at 0x7f80b4e0f690>)

Convert arrays to MultiIndex.

### Parameters

**arrays** [list / sequence of array-likes] Each array-like gives one level's value for each data point. len(arrays) is the number of levels.

**sortorder** [int or None] Level of sortedness (must be lexicographically sorted by that level).

**names** [list / sequence of str, optional] Names for the levels in the index.

### Returns

**MultiIndex**

See also:

**MultiIndex.from\_tuples** Convert list of tuples to MultiIndex.

**MultiIndex.from\_product** Make a MultiIndex from cartesian product of iterables.

**MultiIndex.from\_frame** Make a MultiIndex from a DataFrame.

## Examples

```
>>> arrays = [[1, 1, 2, 2], ['red', 'blue', 'red', 'blue']]
>>> pd.MultiIndex.from_arrays(arrays, names=('number', 'color'))
MultiIndex([(1, 'red'),
            (1, 'blue'),
            (2, 'red'),
            (2, 'blue')],
            names=['number', 'color'])
```

## pandas.MultiIndex.from\_tuples

**classmethod** `MultiIndex.from_tuples` (*tuples*, *sortorder=None*, *names=None*)  
Convert list of tuples to MultiIndex.

### Parameters

**tuples** [list / sequence of tuple-likes] Each tuple is the index of one row/column.

**sortorder** [int or None] Level of sortedness (must be lexicographically sorted by that level).

**names** [list / sequence of str, optional] Names for the levels in the index.

### Returns

**MultiIndex**

See also:

***MultiIndex.from\_arrays*** Convert list of arrays to MultiIndex.

***MultiIndex.from\_product*** Make a MultiIndex from cartesian product of iterables.

***MultiIndex.from\_frame*** Make a MultiIndex from a DataFrame.

## Examples

```
>>> tuples = [(1, 'red'), (1, 'blue'),
...          (2, 'red'), (2, 'blue')]
>>> pd.MultiIndex.from_tuples(tuples, names=('number', 'color'))
MultiIndex([(1, 'red'),
            (1, 'blue'),
            (2, 'red'),
            (2, 'blue')],
            names=['number', 'color'])
```

**pandas.MultiIndex.from\_product**

**classmethod** `MultiIndex.from_product` (*iterables, sortorder=None, names=<object object at 0x7f80b4e0f690>*)

Make a MultiIndex from the cartesian product of multiple iterables.

**Parameters**

**iterables** [list / sequence of iterables] Each iterable has unique labels for each level of the index.

**sortorder** [int or None] Level of sortedness (must be lexicographically sorted by that level).

**names** [list / sequence of str, optional] Names for the levels in the index.

Changed in version 1.0.0: If not explicitly provided, names will be inferred from the elements of iterables if an element has a name attribute

**Returns**

**MultiIndex**

See also:

***MultiIndex.from\_arrays*** Convert list of arrays to MultiIndex.

***MultiIndex.from\_tuples*** Convert list of tuples to MultiIndex.

***MultiIndex.from\_frame*** Make a MultiIndex from a DataFrame.

**Examples**

```
>>> numbers = [0, 1, 2]
>>> colors = ['green', 'purple']
>>> pd.MultiIndex.from_product([numbers, colors],
...                             names=['number', 'color'])
MultiIndex([(0, 'green'),
            (0, 'purple'),
            (1, 'green'),
            (1, 'purple'),
            (2, 'green'),
            (2, 'purple')],
           names=['number', 'color'])
```

**pandas.MultiIndex.from\_frame**

**classmethod** `MultiIndex.from_frame` (*df, sortorder=None, names=None*)

Make a MultiIndex from a DataFrame.

New in version 0.24.0.

**Parameters**

**df** [DataFrame] DataFrame to be converted to MultiIndex.

**sortorder** [int, optional] Level of sortedness (must be lexicographically sorted by that level).

**names** [list-like, optional] If no names are provided, use the column names, or tuple of column names if the columns is a MultiIndex. If a sequence, overwrite names with the given sequence.

### Returns

**MultiIndex** The MultiIndex representation of the given DataFrame.

### See also:

***MultiIndex.from\_arrays*** Convert list of arrays to MultiIndex.

***MultiIndex.from\_tuples*** Convert list of tuples to MultiIndex.

***MultiIndex.from\_product*** Make a MultiIndex from cartesian product of iterables.

### Examples

```
>>> df = pd.DataFrame([['HI', 'Temp'], ['HI', 'Precip'],
...                    ['NJ', 'Temp'], ['NJ', 'Precip']],
...                   columns=['a', 'b'])
>>> df
   a      b
0  HI  Temp
1  HI  Precip
2  NJ  Temp
3  NJ  Precip
```

```
>>> pd.MultiIndex.from_frame(df)
MultiIndex([('HI', 'Temp'),
           ('HI', 'Precip'),
           ('NJ', 'Temp'),
           ('NJ', 'Precip')],
          names=['a', 'b'])
```

### Using explicit names, instead of the column names

```
>>> pd.MultiIndex.from_frame(df, names=['state', 'observation'])
MultiIndex([('HI', 'Temp'),
           ('HI', 'Precip'),
           ('NJ', 'Temp'),
           ('NJ', 'Precip')],
          names=['state', 'observation'])
```

## pandas.MultiIndex.set\_levels

**MultiIndex.set\_levels** (*self*, *levels*, *level=None*, *inplace=False*, *verify\_integrity=True*)  
Set new levels on MultiIndex. Defaults to returning new index.

### Parameters

**levels** [sequence or list of sequence] New level(s) to apply.

**level** [int, level name, or sequence of int/level names (default None)] Level(s) to set (None for all levels).

**inplace** [bool] If True, mutates in place.

**verify\_integrity** [bool, default True] If True, checks that levels and codes are compatible.

### Returns

**new index (of same type and class...etc)**

### Examples

```
>>> idx = pd.MultiIndex.from_tuples([(1, 'one'), (1, 'two'),
                                     (2, 'one'), (2, 'two'),
                                     (3, 'one'), (3, 'two')],
                                   names=['foo', 'bar'])
>>> idx.set_levels(['a', 'b', 'c'], [1, 2])
MultiIndex([('a', 1),
            ('a', 2),
            ('b', 1),
            ('b', 2),
            ('c', 1),
            ('c', 2)],
           names=['foo', 'bar'])
>>> idx.set_levels(['a', 'b', 'c'], level=0)
MultiIndex([('a', 'one'),
            ('a', 'two'),
            ('b', 'one'),
            ('b', 'two'),
            ('c', 'one'),
            ('c', 'two')],
           names=['foo', 'bar'])
>>> idx.set_levels(['a', 'b'], level='bar')
MultiIndex([(1, 'a'),
            (1, 'b'),
            (2, 'a'),
            (2, 'b'),
            (3, 'a'),
            (3, 'b')],
           names=['foo', 'bar'])
```

If any of the levels passed to `set_levels()` exceeds the existing length, all of the values from that argument will be stored in the `MultiIndex` levels, though the values will be truncated in the `MultiIndex` output.

```
>>> idx.set_levels(['a', 'b', 'c'], [1, 2, 3, 4], level=[0, 1])
MultiIndex([('a', 1),
            ('a', 2),
            ('b', 1),
            ('b', 2)],
           names=['foo', 'bar'])
>>> idx.set_levels(['a', 'b', 'c'], [1, 2, 3, 4], level=[0, 1]).levels
FrozenList(['a', 'b', 'c'], [1, 2, 3, 4])
```

**pandas.MultiIndex.set\_codes**

`MultiIndex.set_codes` (*self*, *codes*, *level=None*, *inplace=False*, *verify\_integrity=True*)

Set new codes on MultiIndex. Defaults to returning new index.

New in version 0.24.0: New name for deprecated method `set_labels`.

**Parameters**

**codes** [sequence or list of sequence] New codes to apply.

**level** [int, level name, or sequence of int/level names (default None)] Level(s) to set (None for all levels).

**inplace** [bool] If True, mutates in place.

**verify\_integrity** [bool (default True)] If True, checks that levels and codes are compatible.

**Returns**

**new index (of same type and class... etc)**

**Examples**

```
>>> idx = pd.MultiIndex.from_tuples([(1, 'one'),
                                     (1, 'two'),
                                     (2, 'one'),
                                     (2, 'two')],
                                     names=['foo', 'bar'])
>>> idx.set_codes([[1, 0, 1, 0], [0, 0, 1, 1]])
MultiIndex([(2, 'one'),
            (1, 'one'),
            (2, 'two'),
            (1, 'two')],
            names=['foo', 'bar'])
>>> idx.set_codes([1, 0, 1, 0], level=0)
MultiIndex([(2, 'one'),
            (1, 'two'),
            (2, 'one'),
            (1, 'two')],
            names=['foo', 'bar'])
>>> idx.set_codes([0, 0, 1, 1], level='bar')
MultiIndex([(1, 'one'),
            (1, 'one'),
            (2, 'two'),
            (2, 'two')],
            names=['foo', 'bar'])
>>> idx.set_codes([[1, 0, 1, 0], [0, 0, 1, 1]], level=[0, 1])
MultiIndex([(2, 'one'),
            (1, 'one'),
            (2, 'two'),
            (1, 'two')],
            names=['foo', 'bar'])
```

## pandas.MultiIndex.to\_frame

`MultiIndex.to_frame` (*self*, *index=True*, *name=None*)

Create a DataFrame with the levels of the MultiIndex as columns.

Column ordering is determined by the DataFrame constructor with data as a dict.

New in version 0.24.0.

### Parameters

**index** [bool, default True] Set the index of the returned DataFrame as the original MultiIndex.

**name** [list / sequence of strings, optional] The passed names should substitute index level names.

### Returns

**DataFrame** [a DataFrame containing the original MultiIndex data.]

See also:

**DataFrame**

## pandas.MultiIndex.to\_flat\_index

`MultiIndex.to_flat_index` (*self*)

Convert a MultiIndex to an Index of Tuples containing the level values.

New in version 0.24.0.

### Returns

**pd.Index** Index with the MultiIndex data represented in Tuples.

### Notes

This method will simply return the caller if called by anything other than a MultiIndex.

### Examples

```

>>> index = pd.MultiIndex.from_product(
...     [['foo', 'bar'], ['baz', 'qux']],
...     names=['a', 'b'])
>>> index.to_flat_index()
Index([('foo', 'baz'), ('foo', 'qux'),
      ('bar', 'baz'), ('bar', 'qux')],
      dtype='object')

```

### **pandas.MultiIndex.is\_lexsorted**

`MultiIndex.is_lexsorted` (*self*) → bool  
Return True if the codes are lexicographically sorted.

#### **Returns**

**bool**

### **pandas.MultiIndex.sortlevel**

`MultiIndex.sortlevel` (*self*, *level=0*, *ascending=True*, *sort\_remaining=True*)  
Sort MultiIndex at the requested level. The result will respect the original ordering of the associated factor at that level.

#### **Parameters**

**level** [list-like, int or str, default 0] If a string is given, must be a name of the level. If list-like must be names or ints of levels.

**ascending** [bool, default True] False to sort in descending order. Can also be a list to specify a directed ordering.

**sort\_remaining** [sort by the remaining levels after level]

#### **Returns**

**sorted\_index** [pd.MultiIndex] Resulting index.

**indexer** [np.ndarray] Indices of output values in original index.

### **pandas.MultiIndex.droplevel**

`MultiIndex.droplevel` (*self*, *level=0*)  
Return index with requested level(s) removed.

If resulting index has only 1 level left, the result will be of Index type, not MultiIndex.

New in version 0.23.1: (support for non-MultiIndex)

#### **Parameters**

**level** [int, str, or list-like, default 0] If a string is given, must be the name of a level. If list-like, elements must be names or indexes of levels.

#### **Returns**

**Index or MultiIndex**

**pandas.MultiIndex.swaplevel**

`MultiIndex.swaplevel` (*self*, *i*=-2, *j*=-1)

Swap level *i* with level *j*.

Calling this method does not change the ordering of the values.

**Parameters**

**i** [int, str, default -2] First level of index to be swapped. Can pass level name as string. Type of parameters can be mixed.

**j** [int, str, default -1] Second level of index to be swapped. Can pass level name as string. Type of parameters can be mixed.

**Returns**

**MultiIndex** A new MultiIndex.

**See also:**

**Series.swaplevel** Swap levels *i* and *j* in a MultiIndex.

**Dataframe.swaplevel** Swap levels *i* and *j* in a MultiIndex on a particular axis.

**Examples**

```
>>> mi = pd.MultiIndex(levels=[['a', 'b'], ['bb', 'aa']],
...                     codes=[[0, 0, 1, 1], [0, 1, 0, 1]])
>>> mi
MultiIndex([(('a', 'bb'),
             ('a', 'aa'),
             ('b', 'bb'),
             ('b', 'aa')),
           ])
>>> mi.swaplevel(0, 1)
MultiIndex([(('bb', 'a'),
             ('aa', 'a'),
             ('bb', 'b'),
             ('aa', 'b')),
           ])
```

**pandas.MultiIndex.reorder\_levels**

`MultiIndex.reorder_levels` (*self*, *order*)

Rearrange levels using input order. May not drop or duplicate levels.

**Returns**

**MultiIndex**

### pandas.MultiIndex.remove\_unused\_levels

`MultiIndex.remove_unused_levels` (*self*)

Create a new MultiIndex from the current that removes unused levels, meaning that they are not expressed in the labels.

The resulting MultiIndex will have the same outward appearance, meaning the same `.values` and ordering. It will also be `.equals()` to the original.

#### Returns

**MultiIndex**

#### Examples

```
>>> mi = pd.MultiIndex.from_product([range(2), list('ab')])
>>> mi
MultiIndex([(0, 'a'),
            (0, 'b'),
            (1, 'a'),
            (1, 'b')],
           )
```

```
>>> mi[2:]
MultiIndex([(1, 'a'),
            (1, 'b')],
           )
```

The 0 from the first level is not represented and can be removed

```
>>> mi2 = mi[2:].remove_unused_levels()
>>> mi2.levels
FrozenList([[1], ['a', 'b']])
```

### pandas.MultiIndex.get\_locs

`MultiIndex.get_locs` (*self, seq*)

Get location for a sequence of labels.

#### Parameters

**seq** [label, slice, list, mask or a sequence of such] You should use one of the above for each level. If a level should not be used, set it to `slice(None)`.

#### Returns

**numpy.ndarray** NumPy array of integers suitable for passing to `iloc`.

**See also:**

**`MultiIndex.get_loc`** Get location for a label or a tuple of labels.

**`MultiIndex.slice_locs`** Get slice location given start label(s) and end label(s).

## Examples

```
>>> mi = pd.MultiIndex.from_arrays([list('abb'), list('def')])
```

```
>>> mi.get_locs('b')
array([1, 2], dtype=int64)
```

```
>>> mi.get_locs([slice(None), ['e', 'f']])
array([1, 2], dtype=int64)
```

```
>>> mi.get_locs([[True, False, True], slice('e', 'f')])
array([2], dtype=int64)
```

*IndexSlice*

Create an object to more easily perform multi-index slicing.

## pandas.IndexSlice

`pandas.IndexSlice = <pandas.core.indexing._IndexSlice object>`

Create an object to more easily perform multi-index slicing.

**See also:**

***MultiIndex.remove\_unused\_levels*** New MultiIndex with no unused levels.

## Notes

See *Defined Levels* for further info on slicing a MultiIndex.

## Examples

```
>>> midx = pd.MultiIndex.from_product(['A0', 'A1'], ['B0', 'B1', 'B2', 'B3'])
>>> columns = ['foo', 'bar']
>>> dfmi = pd.DataFrame(np.arange(16).reshape((len(midx), len(columns))),
                       index=midx, columns=columns)
```

Using the default slice command:

```
>>> dfmi.loc[(slice(None), slice('B0', 'B1')), :]
      foo  bar
A0 B0    0   1
   B1    2   3
A1 B0    8   9
   B1   10  11
```

Using the IndexSlice class for a more intuitive command:

```
>>> idx = pd.IndexSlice
>>> dfmi.loc[idx[:, 'B0':'B1'], :]
      foo  bar
A0 B0    0   1
   B1    2   3
```

(continues on next page)

(continued from previous page)

A1	B0	8	9
	B1	10	11

## Multindex constructors

<code>MultiIndex.from_arrays(arrays[, sortorder, ...])</code>	Convert arrays to MultiIndex.
<code>MultiIndex.from_tuples(tuples[, sortorder, ...])</code>	Convert list of tuples to MultiIndex.
<code>MultiIndex.from_product(iterables[, ...])</code>	Make a MultiIndex from the cartesian product of multiple iterables.
<code>MultiIndex.from_frame(df[, sortorder, names])</code>	Make a MultiIndex from a DataFrame.

## Multindex properties

<code>MultiIndex.names</code>	Names of levels in MultiIndex.
<code>MultiIndex.levels</code>	
<code>MultiIndex.codes</code>	
<code>MultiIndex.nlevels</code>	Integer number of levels in this MultiIndex.
<code>MultiIndex.levshape</code>	A tuple with the length of each level.

## pandas.MultiIndex.levels

**property** `MultiIndex.levels`

## pandas.MultiIndex.codes

**property** `MultiIndex.codes`

## Multindex components

<code>MultiIndex.set_levels(self, levels[, level, ...])</code>	Set new levels on MultiIndex.
<code>MultiIndex.set_codes(self, codes[, level, ...])</code>	Set new codes on MultiIndex.
<code>MultiIndex.to_flat_index(self)</code>	Convert a MultiIndex to an Index of Tuples containing the level values.
<code>MultiIndex.to_frame(self[, index, name])</code>	Create a DataFrame with the levels of the MultiIndex as columns.
<code>MultiIndex.is_lexsorted(self)</code>	Return True if the codes are lexicographically sorted.
<code>MultiIndex.sortlevel(self[, level, ...])</code>	Sort MultiIndex at the requested level.
<code>MultiIndex.droplevel(self[, level])</code>	Return index with requested level(s) removed.
<code>MultiIndex.swaplevel(self[, i, j])</code>	Swap level i with level j.
<code>MultiIndex.reorder_levels(self, order)</code>	Rearrange levels using input order.

Continued on next page

Table 159 – continued from previous page

<code>MultiIndex.remove_unused_levels(self)</code>	Create a new MultiIndex from the current that removes unused levels, meaning that they are not expressed in the labels.
----------------------------------------------------	-------------------------------------------------------------------------------------------------------------------------

## Multindex selecting

<code>MultiIndex.get_loc(self, key[, method])</code>	Get location for a label or a tuple of labels as an integer, slice or boolean mask.
<code>MultiIndex.get_locs(self, seq)</code>	Get location for a sequence of labels.
<code>MultiIndex.get_loc_level(self, key[, level])</code>	Get both the location for the requested label(s) and the resulting sliced index.
<code>MultiIndex.get_indexer(self, target[, ...])</code>	Compute indexer and mask for new index given the current index.
<code>MultiIndex.get_level_values(self, level)</code>	Return vector of label values for requested level, equal to the length of the index.

## pandas.MultiIndex.get\_loc

`MultiIndex.get_loc(self, key, method=None)`

Get location for a label or a tuple of labels as an integer, slice or boolean mask.

### Parameters

**key** [label or tuple of labels (one for each level)]

**method** [None]

### Returns

**loc** [int, slice object or boolean mask] If the key is past the lexsort depth, the return may be a boolean mask array, otherwise it is always a slice or int.

### See also:

**Index.get\_loc** The `get_loc` method for (single-level) index.

**MultiIndex.slice\_locs** Get slice location given start label(s) and end label(s).

**MultiIndex.get\_locs** Get location for a label/slice/list/mask or a sequence of such.

## Notes

The key cannot be a slice, list of same-level labels, a boolean mask, or a sequence of such. If you want to use those, use `MultiIndex.get_locs()` instead.

## Examples

```
>>> mi = pd.MultiIndex.from_arrays([list('abb'), list('def')])
```

```
>>> mi.get_loc('b')
slice(1, 3, None)
```

```
>>> mi.get_loc(('b', 'e'))
1
```

## pandas.MultiIndex.get\_loc\_level

`MultiIndex.get_loc_level` (*self*, *key*, *level=0*, *drop\_level: bool = True*)

Get both the location for the requested label(s) and the resulting sliced index.

### Parameters

**key** [label or sequence of labels]

**level** [int/level name or list thereof, optional]

**drop\_level** [bool, default True] If `False`, the resulting index will not drop any level.

### Returns

**loc** [A 2-tuple where the elements are:] Element 0: int, slice object or boolean array Element 1: The resulting sliced multiindex/index. If the key contains all levels, this will be `None`.

See also:

**`MultiIndex.get_loc`** Get location for a label or a tuple of labels.

**`MultiIndex.get_locs`** Get location for a label/slice/list/mask or a sequence of such.

## Examples

```
>>> mi = pd.MultiIndex.from_arrays([list('abb'), list('def')],
...                               names=['A', 'B'])
```

```
>>> mi.get_loc_level('b')
(slice(1, 3, None), Index(['e', 'f'], dtype='object', name='B'))
```

```
>>> mi.get_loc_level('e', level='B')
(array([False, True, False], dtype=bool),
 Index(['b'], dtype='object', name='A'))
```

```
>>> mi.get_loc_level(['b', 'e'])
(1, None)
```

## pandas.MultiIndex.get\_indexer

`MultiIndex.get_indexer` (*self*, *target*, *method=None*, *limit=None*, *tolerance=None*)

Compute indexer and mask for new index given the current index. The indexer should be then used as an input to `ndarray.take` to align the current data to the new index.

### Parameters

**target** [MultiIndex or list of tuples]

**method** [{None, 'pad'/'ffill', 'backfill'/'bfill', 'nearest'}, optional]

- default: exact matches only.
- pad / ffill: find the PREVIOUS index value if no exact match.
- backfill / bfill: use NEXT index value if no exact match
- nearest: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.

**limit** [int, optional] Maximum number of consecutive labels in `target` to match for inexact matches.

**tolerance** [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations most satisfy the equation  $\text{abs}(\text{index}[\text{indexer}] - \text{target}) \leq \text{tolerance}$ .

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index's type.

New in version 0.21.0: (list-like tolerance)

### Returns

**indexer** [ndarray of int] Integers from 0 to  $n - 1$  indicating that the index at these positions matches the corresponding target values. Missing values in the target are marked by -1.

### Examples

```
>>> index = pd.Index(['c', 'a', 'b'])
>>> index.get_indexer(['a', 'b', 'x'])
array([ 1,  2, -1])
```

Notice that the return value is an array of locations in `index` and `x` is marked by -1, as it is not in `index`.

## pandas.MultiIndex.get\_level\_values

`MultiIndex.get_level_values` (*self*, *level*)

Return vector of label values for requested level, equal to the length of the index.

### Parameters

**level** [int or str] `level` is either the integer position of the level in the `MultiIndex`, or the name of the level.

### Returns

**values** [Index] Values is a level of this `MultiIndex` converted to a single `Index` (or subclass thereof).

### Examples

Create a `MultiIndex`:

```
>>> mi = pd.MultiIndex.from_arrays((list('abc'), list('def')))
>>> mi.names = ['level_1', 'level_2']
```

Get level values by supplying level as either integer or name:

```
>>> mi.get_level_values(0)
Index(['a', 'b', 'c'], dtype='object', name='level_1')
>>> mi.get_level_values('level_2')
Index(['d', 'e', 'f'], dtype='object', name='level_2')
```

## 4.7.6 DatetimeIndex

*DatetimeIndex*

Immutable ndarray of datetime64 data, represented internally as int64, and which can be boxed to Timestamp objects that are subclasses of datetime and carry meta-data such as frequency information.

---

### pandas.DatetimeIndex

**class** pandas.DatetimeIndex

Immutable ndarray of datetime64 data, represented internally as int64, and which can be boxed to Timestamp objects that are subclasses of datetime and carry metadata such as frequency information.

#### Parameters

**data** [array-like (1-dimensional), optional] Optional datetime-like data to construct index with.

**copy** [bool] Make a copy of input ndarray.

**freq** [str or pandas offset object, optional] One of pandas date offset strings or corresponding objects. The string 'infer' can be passed in order to set the frequency of the index as the inferred frequency upon creation.

**tz** [pytz.timezone or dateutil.tz.tzfile]

**ambiguous** ['infer', bool-ndarray, 'NaT', default 'raise'] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the *ambiguous* parameter dictates how ambiguous times should be handled.

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False signifies a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times.

**name** [object] Name to be stored in the index.

**dayfirst** [bool, default False] If True, parse dates in *data* with the day first order.

**yearfirst** [bool, default False] If True parse dates in *data* with the year first order.

#### See also:

**Index** The base pandas Index type.

**TimedeltaIndex** Index of timedelta64 data.

**PeriodIndex** Index of Period data.

**to\_datetime** Convert argument to datetime.

**date\_range** Create a fixed-frequency DatetimeIndex.

## Notes

To learn more about the frequency strings, please see [this link](#).

## Attributes

<i>year</i>	The year of the datetime.
<i>month</i>	The month as January=1, December=12.
<i>day</i>	The month as January=1, December=12.
<i>hour</i>	The hours of the datetime.
<i>minute</i>	The minutes of the datetime.
<i>second</i>	The seconds of the datetime.
<i>microsecond</i>	The microseconds of the datetime.
<i>nanosecond</i>	The nanoseconds of the datetime.
<i>date</i>	Returns numpy array of python datetime.date objects (namely, the date part of Timestamps without time-zone information).
<i>time</i>	Returns numpy array of datetime.time.
<i>timetz</i>	Returns numpy array of datetime.time also containing timezone information.
<i>dayofyear</i>	The ordinal day of the year.
<i>weekofyear</i>	The week ordinal of the year.
<i>week</i>	The week ordinal of the year.
<i>dayofweek</i>	The day of the week with Monday=0, Sunday=6.
<i>weekday</i>	The day of the week with Monday=0, Sunday=6.
<i>quarter</i>	The quarter of the date.
<i>tz</i>	Return timezone, if any.
<i>freq</i>	Return the frequency object if it is set, otherwise None.
<i>freqstr</i>	Return the frequency object as a string if its set, otherwise None
<i>is_month_start</i>	Indicates whether the date is the first day of the month.
<i>is_month_end</i>	Indicates whether the date is the last day of the month.
<i>is_quarter_start</i>	Indicator for whether the date is the first day of a quarter.
<i>is_quarter_end</i>	Indicator for whether the date is the last day of a quarter.
<i>is_year_start</i>	Indicate whether the date is the first day of a year.
<i>is_year_end</i>	Indicate whether the date is the last day of the year.
<i>is_leap_year</i>	Boolean indicator if the date belongs to a leap year.
<i>inferred_freq</i>	Tries to return a string representing a frequency guess, generated by infer_freq.

### **pandas.DatetimeIndex.year**

**property** `DatetimeIndex.year`  
The year of the datetime.

### **pandas.DatetimeIndex.month**

**property** `DatetimeIndex.month`  
The month as January=1, December=12.

### **pandas.DatetimeIndex.day**

**property** `DatetimeIndex.day`  
The month as January=1, December=12.

### **pandas.DatetimeIndex.hour**

**property** `DatetimeIndex.hour`  
The hours of the datetime.

### **pandas.DatetimeIndex.minute**

**property** `DatetimeIndex.minute`  
The minutes of the datetime.

### **pandas.DatetimeIndex.second**

**property** `DatetimeIndex.second`  
The seconds of the datetime.

### **pandas.DatetimeIndex.microsecond**

**property** `DatetimeIndex.microsecond`  
The microseconds of the datetime.

### **pandas.DatetimeIndex.nanosecond**

**property** `DatetimeIndex.nanosecond`  
The nanoseconds of the datetime.

### **pandas.DatetimeIndex.date**

**property** `DatetimeIndex.date`

Returns numpy array of python `datetime.date` objects (namely, the date part of Timestamps without time-zone information).

### **pandas.DatetimeIndex.time**

**property** `DatetimeIndex.time`

Returns numpy array of `datetime.time`. The time part of the Timestamps.

### **pandas.DatetimeIndex.timetz**

**property** `DatetimeIndex.timetz`

Returns numpy array of `datetime.time` also containing timezone information. The time part of the Timestamps.

### **pandas.DatetimeIndex.dayofyear**

**property** `DatetimeIndex.dayofyear`

The ordinal day of the year.

### **pandas.DatetimeIndex.weekofyear**

**property** `DatetimeIndex.weekofyear`

The week ordinal of the year.

### **pandas.DatetimeIndex.week**

**property** `DatetimeIndex.week`

The week ordinal of the year.

### **pandas.DatetimeIndex.dayofweek**

**property** `DatetimeIndex.dayofweek`

The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the *dt* accessor) or `DatetimeIndex`.

#### **Returns**

**Series or Index** Containing integers indicating the day number.

**See also:**

*Series.dt.dayofweek* Alias.

*Series.dt.weekday* Alias.

***Series.dt.day\_name*** Returns the name of the day of the week.

### Examples

```
>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31    5
2017-01-01    6
2017-01-02    0
2017-01-03    1
2017-01-04    2
2017-01-05    3
2017-01-06    4
2017-01-07    5
2017-01-08    6
Freq: D, dtype: int64
```

### pandas.DatetimeIndex.weekday

**property** `DatetimeIndex.weekday`

The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the *dt* accessor) or `DatetimeIndex`.

#### Returns

**Series or Index** Containing integers indicating the day number.

**See also:**

***Series.dt.dayofweek*** Alias.

***Series.dt.weekday*** Alias.

***Series.dt.day\_name*** Returns the name of the day of the week.

### Examples

```
>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31    5
2017-01-01    6
2017-01-02    0
2017-01-03    1
2017-01-04    2
2017-01-05    3
2017-01-06    4
2017-01-07    5
2017-01-08    6
Freq: D, dtype: int64
```

**pandas.DatetimeIndex.quarter****property** `DatetimeIndex.quarter`

The quarter of the date.

**pandas.DatetimeIndex.tz****property** `DatetimeIndex.tz`

Return timezone, if any.

**Returns****datetime.tzinfo, pytz.tzinfo.BaseTZInfo, dateutil.tz.tz.tzfile, or None** Returns None when the array is tz-naive.**pandas.DatetimeIndex.freq****property** `DatetimeIndex.freq`

Return the frequency object if it is set, otherwise None.

**pandas.DatetimeIndex.freqstr****property** `DatetimeIndex.freqstr`

Return the frequency object as a string if its set, otherwise None

**pandas.DatetimeIndex.is\_month\_start****property** `DatetimeIndex.is_month_start`

Indicates whether the date is the first day of the month.

**Returns****Series or array** For Series, returns a Series with boolean values. For DatetimeIndex, returns a boolean array.**See also:****`is_month_start`** Return a boolean indicating whether the date is the first day of the month.**`is_month_end`** Return a boolean indicating whether the date is the last day of the month.**Examples**

This method is available on Series with datetime values under the `.dt` accessor, and directly on `DatetimeIndex`.

```

>>> s = pd.Series(pd.date_range("2018-02-27", periods=3))
>>> s
0    2018-02-27
1    2018-02-28
2    2018-03-01
dtype: datetime64[ns]

```

(continues on next page)

(continued from previous page)

```
>>> s.dt.is_month_start
0    False
1    False
2     True
dtype: bool
>>> s.dt.is_month_end
0    False
1     True
2    False
dtype: bool
```

```
>>> idx = pd.date_range("2018-02-27", periods=3)
>>> idx.is_month_start
array([False, False,  True])
>>> idx.is_month_end
array([False,  True, False])
```

## pandas.DatetimeIndex.is\_month\_end

### property `DatetimeIndex.is_month_end`

Indicates whether the date is the last day of the month.

#### Returns

**Series or array** For Series, returns a Series with boolean values. For `DatetimeIndex`, returns a boolean array.

#### See also:

***is\_month\_start*** Return a boolean indicating whether the date is the first day of the month.

***is\_month\_end*** Return a boolean indicating whether the date is the last day of the month.

## Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on `DatetimeIndex`.

```
>>> s = pd.Series(pd.date_range("2018-02-27", periods=3))
>>> s
0    2018-02-27
1    2018-02-28
2    2018-03-01
dtype: datetime64[ns]
>>> s.dt.is_month_start
0    False
1    False
2     True
dtype: bool
>>> s.dt.is_month_end
0    False
1     True
2    False
dtype: bool
```

## pandas.DatetimeIndex.is\_quarter\_end

**property** `DatetimeIndex.is_quarter_end`

Indicator for whether the date is the last day of a quarter.

### Returns

**is\_quarter\_end** [Series or DatetimeIndex] The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

### See also:

**quarter** Return the quarter of the date.

**is\_quarter\_start** Similar property indicating the quarter start.

## Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on `DatetimeIndex`.

```
>>> df = pd.DataFrame({'dates': pd.date_range("2017-03-30",
...                                     periods=4)})
>>> df.assign(quarter=df.dates.dt.quarter,
...          is_quarter_end=df.dates.dt.is_quarter_end)
   dates      quarter  is_quarter_end
0 2017-03-30         1             False
1 2017-03-31         1              True
2 2017-04-01         2             False
3 2017-04-02         2             False
```

```
>>> idx = pd.date_range('2017-03-30', periods=4)
>>> idx
DatetimeIndex(['2017-03-30', '2017-03-31', '2017-04-01', '2017-04-02'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_quarter_end
array([False,  True,  False,  False])
```

## pandas.DatetimeIndex.is\_year\_start

**property** `DatetimeIndex.is_year_start`

Indicate whether the date is the first day of a year.

### Returns

**Series or DatetimeIndex** The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

### See also:

**is\_year\_end** Similar property indicating the last day of the year.

## Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on `DatetimeIndex`.

```
>>> dates = pd.Series(pd.date_range("2017-12-30", periods=3))
>>> dates
0    2017-12-30
1    2017-12-31
2    2018-01-01
dtype: datetime64[ns]
```

```
>>> dates.dt.is_year_start
0    False
1    False
2     True
dtype: bool
```

```
>>> idx = pd.date_range("2017-12-30", periods=3)
>>> idx
DatetimeIndex(['2017-12-30', '2017-12-31', '2018-01-01'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_year_start
array([False, False,  True])
```

## pandas.DatetimeIndex.is\_year\_end

### property `DatetimeIndex.is_year_end`

Indicate whether the date is the last day of the year.

#### Returns

**Series or DatetimeIndex** The same type as the original data with boolean values. Series will have the same name and index. `DatetimeIndex` will have the same name.

#### See also:

**`is_year_start`** Similar property indicating the start of the year.

## Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on `DatetimeIndex`.

```
>>> dates = pd.Series(pd.date_range("2017-12-30", periods=3))
>>> dates
0    2017-12-30
1    2017-12-31
2    2018-01-01
dtype: datetime64[ns]
```

```
>>> dates.dt.is_year_end
0    False
1     True
2    False
dtype: bool
```

```
>>> idx = pd.date_range("2017-12-30", periods=3)
>>> idx
DatetimeIndex(['2017-12-30', '2017-12-31', '2018-01-01'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_year_end
array([False,  True,  False])
```

### pandas.DatetimeIndex.is\_leap\_year

#### property DatetimeIndex.is\_leap\_year

Boolean indicator if the date belongs to a leap year.

A leap year is a year, which has 366 days (instead of 365) including 29th of February as an intercalary day. Leap years are years which are multiples of four with the exception of years divisible by 100 but not by 400.

#### Returns

**Series or ndarray** Booleans indicating if dates belong to a leap year.

#### Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on `DatetimeIndex`.

```
>>> idx = pd.date_range("2012-01-01", "2015-01-01", freq="Y")
>>> idx
DatetimeIndex(['2012-12-31', '2013-12-31', '2014-12-31'],
              dtype='datetime64[ns]', freq='A-DEC')
>>> idx.is_leap_year
array([ True,  False,  False], dtype=bool)
```

```
>>> dates = pd.Series(idx)
>>> dates_series
0    2012-12-31
1    2013-12-31
2    2014-12-31
dtype: datetime64[ns]
>>> dates_series.dt.is_leap_year
0     True
1    False
2    False
dtype: bool
```

**pandas.DatetimeIndex.inferred\_freq****DatetimeIndex.inferred\_freq**

Tryies to return a string representing a frequency guess, generated by `infer_freq`. Returns None if it can't autodetect the frequency.

**Methods**

<code>normalize(self, *args, **kwargs)</code>	Convert times to midnight.
<code>strftime(self, *args, **kwargs)</code>	Convert to Index using specified <code>date_format</code> .
<code>snap(self[, freq])</code>	Snap time stamps to nearest occurring frequency.
<code>tz_convert(self, *args, **kwargs)</code>	Convert tz-aware Datetime Array/Index from one time zone to another.
<code>tz_localize(self, *args, **kwargs)</code>	Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index.
<code>round(self, *args, **kwargs)</code>	Perform round operation on the data to the specified <i>freq</i> .
<code>floor(self, *args, **kwargs)</code>	Perform floor operation on the data to the specified <i>freq</i> .
<code>ceil(self, *args, **kwargs)</code>	Perform ceil operation on the data to the specified <i>freq</i> .
<code>to_period(self, *args, **kwargs)</code>	Cast to PeriodArray/Index at a particular frequency.
<code>to_perioddelta(self, *args, **kwargs)</code>	Calculate TimedeltaArray of difference between index values and index converted to PeriodArray at specified <i>freq</i> .
<code>to_pydatetime(self, *args, **kwargs)</code>	Return Datetime Array/Index as object ndarray of <code>datetime.datetime</code> objects.
<code>to_series(self[, keep_tz, index, name])</code>	Create a Series with both index and values equal to the index keys useful with <code>map</code> for returning an indexer based on an index.
<code>to_frame(self[, index, name])</code>	Create a DataFrame with a column containing the Index.
<code>month_name(self, *args, **kwargs)</code>	Return the month names of the DateTimeIndex with specified locale.
<code>day_name(self, *args, **kwargs)</code>	Return the day names of the DateTimeIndex with specified locale.
<code>mean(self, *args, **kwargs)</code>	Return the mean value of the Array.

**pandas.DatetimeIndex.normalize****DatetimeIndex.normalize** (*self*, \*args, \*\*kwargs)

Convert times to midnight.

The time component of the date-time is converted to midnight i.e. 00:00:00. This is useful in cases, when the time does not matter. Length is unaltered. The timezones are unaffected.

This method is available on Series with datetime values under the `.dt` accessor, and directly on Datetime Array/Index.

**Returns**

**DatetimeArray, DatetimeIndex or Series** The same type as the original data. Series

will have the same name and index. `DatetimeIndex` will have the same name.

**See also:**

**`floor`** Floor the datetimes to the specified freq.

**`ceil`** Ceil the datetimes to the specified freq.

**`round`** Round the datetimes to the specified freq.

**Examples**

```
>>> idx = pd.date_range(start='2014-08-01 10:00', freq='H',
...                     periods=3, tz='Asia/Calcutta')
>>> idx
DatetimeIndex(['2014-08-01 10:00:00+05:30',
               '2014-08-01 11:00:00+05:30',
               '2014-08-01 12:00:00+05:30'],
              dtype='datetime64[ns, Asia/Calcutta]', freq='H')
>>> idx.normalize()
DatetimeIndex(['2014-08-01 00:00:00+05:30',
               '2014-08-01 00:00:00+05:30',
               '2014-08-01 00:00:00+05:30'],
              dtype='datetime64[ns, Asia/Calcutta]', freq=None)
```

**pandas.DatetimeIndex.strftime**

`DatetimeIndex.strftime` (*self*, \*args, \*\*kwargs)

Convert to Index using specified `date_format`.

Return an Index of formatted strings specified by `date_format`, which supports the same string format as the python standard library. Details of the string format can be found in [python string format doc](#).

**Parameters**

**`date_format`** [str] Date format string (e.g. “%Y-%m-%d”).

**Returns**

**`ndarray`** NumPy ndarray of formatted strings.

**See also:**

**`to_datetime`** Convert the given argument to datetime.

**`DatetimeIndex.normalize`** Return `DatetimeIndex` with times to midnight.

**`DatetimeIndex.round`** Round the `DatetimeIndex` to the specified freq.

**`DatetimeIndex.floor`** Floor the `DatetimeIndex` to the specified freq.

## Examples

```
>>> rng = pd.date_range(pd.Timestamp("2018-03-10 09:00"),
...                      periods=3, freq='s')
>>> rng.strftime('%B %d, %Y, %r')
Index(['March 10, 2018, 09:00:00 AM', 'March 10, 2018, 09:00:01 AM',
       'March 10, 2018, 09:00:02 AM'],
      dtype='object')
```

### pandas.DatetimeIndex.snap

`DatetimeIndex.snap` (*self*, *freq='S'*)  
Snap time stamps to nearest occurring frequency.

#### Returns

**DatetimeIndex**

### pandas.DatetimeIndex.tz\_convert

`DatetimeIndex.tz_convert` (*self*, *\*args*, *\*\*kwargs*)  
Convert tz-aware Datetime Array/Index from one time zone to another.

#### Parameters

**tz** [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time. Corresponding timestamps would be converted to this time zone of the Datetime Array/Index. A *tz* of None will convert to UTC and remove the timezone information.

#### Returns

**Array or Index**

#### Raises

**TypeError** If Datetime Array/Index is tz-naive.

#### See also:

**DatetimeIndex.tz** A timezone that has a variable offset from UTC.

**DatetimeIndex.tz\_localize** Localize tz-naive DatetimeIndex to a given time zone, or remove timezone from a tz-aware DatetimeIndex.

## Examples

With the *tz* parameter, we can change the DatetimeIndex to other time zones:

```
>>> dti = pd.date_range(start='2014-08-01 09:00',
...                      freq='H', periods=3, tz='Europe/Berlin')
```

```
>>> dti
DatetimeIndex(['2014-08-01 09:00:00+02:00',
               '2014-08-01 10:00:00+02:00',
               '2014-08-01 11:00:00+02:00'],
              dtype='datetime64[ns, Europe/Berlin]', freq='H')
```

```
>>> dti.tz_convert('US/Central')
DatetimeIndex(['2014-08-01 02:00:00-05:00',
              '2014-08-01 03:00:00-05:00',
              '2014-08-01 04:00:00-05:00'],
              dtype='datetime64[ns, US/Central]', freq='H')
```

With the `tz=None`, we can remove the timezone (after converting to UTC if necessary):

```
>>> dti = pd.date_range(start='2014-08-01 09:00', freq='H',
...                      periods=3, tz='Europe/Berlin')
```

```
>>> dti
DatetimeIndex(['2014-08-01 09:00:00+02:00',
              '2014-08-01 10:00:00+02:00',
              '2014-08-01 11:00:00+02:00'],
              dtype='datetime64[ns, Europe/Berlin]', freq='H')
```

```
>>> dti.tz_convert(None)
DatetimeIndex(['2014-08-01 07:00:00',
              '2014-08-01 08:00:00',
              '2014-08-01 09:00:00'],
              dtype='datetime64[ns]', freq='H')
```

## pandas.DatetimeIndex.tz\_localize

`DatetimeIndex.tz_localize` (*self*, \*args, \*\*kwargs)

Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index.

This method takes a time zone (tz) naive Datetime Array/Index object and makes this time zone aware. It does not move the time to another time zone. Time zone localization helps to switch from time zone aware to time zone unaware objects.

### Parameters

**tz** [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone to convert timestamps to. Passing `None` will remove the time zone information preserving local time.

**ambiguous** ['infer', 'NaT', bool array, default 'raise'] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the *ambiguous* parameter dictates how ambiguous times should be handled.

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False signifies a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an `AmbiguousTimeError` if there are ambiguous times.

**nonexistent** ['shift\_forward', 'shift\_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift\_forward' will shift the nonexistent time forward to the closest existing time

- ‘shift\_backward’ will shift the nonexistent time backward to the closest existing time
- ‘NaT’ will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- ‘raise’ will raise a NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

### Returns

**Same type as self** Array/Index converted to the specified time zone.

### Raises

**TypeError** If the Datetime Array/Index is tz-aware and tz is not None.

### See also:

**DatetimeIndex.tz\_convert** Convert tz-aware DatetimeIndex from one time zone to another.

### Examples

```
>>> tz_naive = pd.date_range('2018-03-01 09:00', periods=3)
>>> tz_naive
DatetimeIndex(['2018-03-01 09:00:00', '2018-03-02 09:00:00',
              '2018-03-03 09:00:00'],
              dtype='datetime64[ns]', freq='D')
```

Localize DatetimeIndex in US/Eastern time zone:

```
>>> tz_aware = tz_naive.tz_localize(tz='US/Eastern')
>>> tz_aware
DatetimeIndex(['2018-03-01 09:00:00-05:00',
              '2018-03-02 09:00:00-05:00',
              '2018-03-03 09:00:00-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq='D')
```

With the tz=None, we can remove the time zone information while keeping the local time (not converted to UTC):

```
>>> tz_aware.tz_localize(None)
DatetimeIndex(['2018-03-01 09:00:00', '2018-03-02 09:00:00',
              '2018-03-03 09:00:00'],
              dtype='datetime64[ns]', freq='D')
```

Be careful with DST changes. When there is sequential data, pandas can infer the DST time:

```
>>> s = pd.to_datetime(pd.Series(['2018-10-28 01:30:00',
...                               '2018-10-28 02:00:00',
...                               '2018-10-28 02:30:00',
...                               '2018-10-28 02:00:00',
...                               '2018-10-28 02:30:00',
...                               '2018-10-28 03:00:00',
...                               '2018-10-28 03:30:00']))
>>> s.dt.tz_localize('CET', ambiguous='infer')
0    2018-10-28 01:30:00+02:00
```

(continues on next page)

(continued from previous page)

```

1 2018-10-28 02:00:00+02:00
2 2018-10-28 02:30:00+02:00
3 2018-10-28 02:00:00+01:00
4 2018-10-28 02:30:00+01:00
5 2018-10-28 03:00:00+01:00
6 2018-10-28 03:30:00+01:00
dtype: datetime64[ns, CET]

```

In some cases, inferring the DST is impossible. In such cases, you can pass an ndarray to the `ambiguous` parameter to set the DST explicitly

```

>>> s = pd.to_datetime(pd.Series(['2018-10-28 01:20:00',
...                               '2018-10-28 02:36:00',
...                               '2018-10-28 03:46:00']))
>>> s.dt.tz_localize('CET', ambiguous=np.array([True, True, False]))
0 2015-03-29 03:00:00+02:00
1 2015-03-29 03:30:00+02:00
dtype: datetime64[ns, Europe/Warsaw]

```

If the DST transition causes nonexistent times, you can shift these dates forward or backwards with a `timedelta` object or `'shift_forward'` or `'shift_backwards'`.

```

>>> s = pd.to_datetime(pd.Series(['2015-03-29 02:30:00',
...                               '2015-03-29 03:30:00']))
>>> s.dt.tz_localize('Europe/Warsaw', nonexistent='shift_forward')
0 2015-03-29 03:00:00+02:00
1 2015-03-29 03:30:00+02:00
dtype: datetime64[ns, 'Europe/Warsaw']
>>> s.dt.tz_localize('Europe/Warsaw', nonexistent='shift_backward')
0 2015-03-29 01:59:59.999999999+01:00
1 2015-03-29 03:30:00+02:00
dtype: datetime64[ns, 'Europe/Warsaw']
>>> s.dt.tz_localize('Europe/Warsaw', nonexistent=pd.Timedelta('1H'))
0 2015-03-29 03:30:00+02:00
1 2015-03-29 03:30:00+02:00
dtype: datetime64[ns, 'Europe/Warsaw']

```

## pandas.DatetimeIndex.round

`DatetimeIndex.round` (*self*, \*args, \*\*kwargs)

Perform round operation on the data to the specified *freq*.

### Parameters

**freq** [str or Offset] The frequency level to round the index to. Must be a fixed frequency like 'S' (second) not 'ME' (month end). See *frequency aliases* for a list of possible *freq* values.

**ambiguous** ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for `DatetimeIndex`:

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times

- ‘raise’ will raise an `AmbiguousTimeError` if there are ambiguous times.

New in version 0.24.0.

**nonexistent** [‘shift\_forward’, ‘shift\_backward’, ‘NaT’, `timedelta`, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- ‘shift\_forward’ will shift the nonexistent time forward to the closest existing time
- ‘shift\_backward’ will shift the nonexistent time backward to the closest existing time
- ‘NaT’ will return `NaT` where there are nonexistent times
- `timedelta` objects will shift nonexistent times by the `timedelta`
- ‘raise’ will raise an `NonExistentTimeError` if there are nonexistent times.

New in version 0.24.0.

### Returns

**DatetimeIndex, TimedeltaIndex, or Series** Index of the same type for a `DatetimeIndex` or `TimedeltaIndex`, or a `Series` with the same index for a `Series`.

### Raises

**ValueError** if the *freq* cannot be converted.

## Examples

### DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
              '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.round('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
              '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq=None)
```

### Series

```
>>> pd.Series(rng).dt.round("H")
0    2018-01-01 12:00:00
1    2018-01-01 12:00:00
2    2018-01-01 12:00:00
dtype: datetime64[ns]
```

## pandas.DatetimeIndex.floor

`DatetimeIndex.floor` (*self*, \*args, \*\*kwargs)  
 Perform floor operation on the data to the specified *freq*.

### Parameters

**freq** [str or Offset] The frequency level to floor the index to. Must be a fixed frequency like 'S' (second) not 'ME' (month end). See *frequency aliases* for a list of possible *freq* values.

**ambiguous** ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for `DatetimeIndex`:

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an `AmbiguousTimeError` if there are ambiguous times.

New in version 0.24.0.

**nonexistent** ['shift\_forward', 'shift\_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift\_forward' will shift the nonexistent time forward to the closest existing time
- 'shift\_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise an `NonExistentTimeError` if there are nonexistent times.

New in version 0.24.0.

### Returns

**DatetimeIndex, TimedeltaIndex, or Series** Index of the same type for a `DatetimeIndex` or `TimedeltaIndex`, or a `Series` with the same index for a `Series`.

### Raises

**ValueError** if the *freq* cannot be converted.

## Examples

### DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
              '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.floor('H')
```

(continues on next page)

(continued from previous page)

```
DatetimeIndex(['2018-01-01 11:00:00', '2018-01-01 12:00:00',
              '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq=None)
```

**Series**

```
>>> pd.Series(rng).dt.floor("H")
0    2018-01-01 11:00:00
1    2018-01-01 12:00:00
2    2018-01-01 12:00:00
dtype: datetime64[ns]
```

**pandas.DatetimeIndex.ceil**`DatetimeIndex.ceil` (*self*, \*args, \*\*kwargs)Perform ceil operation on the data to the specified *freq*.**Parameters**

**freq** [str or Offset] The frequency level to ceil the index to. Must be a fixed frequency like 'S' (second) not 'ME' (month end). See *frequency aliases* for a list of possible *freq* values.

**ambiguous** ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for `DatetimeIndex`:

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an `AmbiguousTimeError` if there are ambiguous times.

New in version 0.24.0.

**nonexistent** ['shift\_forward', 'shift\_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift\_forward' will shift the nonexistent time forward to the closest existing time
- 'shift\_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise a `NonExistentTimeError` if there are nonexistent times.

New in version 0.24.0.

**Returns**

**DatetimeIndex, TimedeltaIndex, or Series** Index of the same type for a `DatetimeIndex` or `TimedeltaIndex`, or a `Series` with the same index for a `Series`.

**Raises**

**ValueError if the *freq* cannot be converted.**

## Examples

### DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
              '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.ceil('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
              '2018-01-01 13:00:00'],
              dtype='datetime64[ns]', freq=None)
```

### Series

```
>>> pd.Series(rng).dt.ceil("H")
0    2018-01-01 12:00:00
1    2018-01-01 12:00:00
2    2018-01-01 13:00:00
dtype: datetime64[ns]
```

## pandas.DatetimeIndex.to\_period

`DatetimeIndex.to_period(self, *args, **kwargs)`

Cast to PeriodArray/Index at a particular frequency.

Converts DatetimeArray/Index to PeriodArray/Index.

### Parameters

**freq** [str or Offset, optional] One of pandas' *offset strings* or an Offset object. Will be inferred by default.

### Returns

**PeriodArray/Index**

### Raises

**ValueError** When converting a DatetimeArray/Index with non-regular values, so that a frequency cannot be inferred.

### See also:

**PeriodIndex** Immutable ndarray holding ordinal values.

**DatetimeIndex.to\_pydatetime** Return DatetimeIndex as object.

## Examples

```
>>> df = pd.DataFrame({"y": [1, 2, 3]},
...                    index=pd.to_datetime(["2000-03-31 00:00:00",
...                    "2000-05-31 00:00:00",
...                    "2000-08-31 00:00:00"]))
>>> df.index.to_period("M")
PeriodIndex(['2000-03', '2000-05', '2000-08'],
            dtype='period[M]', freq='M')
```

Infer the daily frequency

```
>>> idx = pd.date_range("2017-01-01", periods=2)
>>> idx.to_period()
PeriodIndex(['2017-01-01', '2017-01-02'],
            dtype='period[D]', freq='D')
```

### pandas.DatetimeIndex.to\_perioddelta

`DatetimeIndex.to_perioddelta` (*self*, \*args, \*\*kwargs)

Calculate TimedeltaArray of difference between index values and index converted to PeriodArray at specified freq. Used for vectorized offsets.

#### Parameters

**freq** [Period frequency]

#### Returns

**TimedeltaArray/Index**

### pandas.DatetimeIndex.to\_pydatetime

`DatetimeIndex.to_pydatetime` (*self*, \*args, \*\*kwargs)

Return Datetime Array/Index as object ndarray of datetime.datetime objects.

#### Returns

**datetimes** [ndarray]

### pandas.DatetimeIndex.to\_series

`DatetimeIndex.to_series` (*self*, keep\_tz=<object object at 0x7f80b4e0f690>, index=None, name=None)

Create a Series with both index and values equal to the index keys useful with map for returning an indexer based on an index.

#### Parameters

**keep\_tz** [optional, defaults True] Return the data keeping the timezone.

If keep\_tz is True:

If the timezone is not set, the resulting Series will have a datetime64[ns] dtype.

Otherwise the Series will have an `datetime64[ns, tz]` dtype; the tz will be preserved.

If `keep_tz` is False:

Series will have a `datetime64[ns]` dtype. TZ aware objects will have the tz removed.

Changed in version 1.0.0: The default value is now True. In a future version, this keyword will be removed entirely. Stop passing the argument to obtain the future behavior and silence the warning.

**index** [Index, optional] Index of resulting Series. If None, defaults to original index.

**name** [str, optional] Name of resulting Series. If None, defaults to name of original index.

#### Returns

Series

### pandas.DatetimeIndex.to\_frame

`DatetimeIndex.to_frame` (*self*, *index=True*, *name=None*)

Create a DataFrame with a column containing the Index.

New in version 0.24.0.

#### Parameters

**index** [bool, default True] Set the index of the returned DataFrame as the original Index.

**name** [object, default None] The passed name should substitute for the index name (if it has one).

#### Returns

**DataFrame** DataFrame containing the original Index data.

See also:

***Index.to\_series*** Convert an Index to a Series.

***Series.to\_frame*** Convert Series to DataFrame.

### Examples

```
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')
>>> idx.to_frame()
      animal
animal
Ant      Ant
Bear    Bear
Cow     Cow
```

By default, the original Index is reused. To enforce a new Index:

```
>>> idx.to_frame(index=False)
      animal
0      Ant
1     Bear
2      Cow
```

To override the name of the resulting column, specify *name*:

```
>>> idx.to_frame(index=False, name='zoo')
      zoo
0      Ant
1     Bear
2      Cow
```

### pandas.DatetimeIndex.month\_name

`DatetimeIndex.month_name` (*self*, \*args, \*\*kwargs)

Return the month names of the `DatetimeIndex` with specified locale.

New in version 0.23.0.

#### Parameters

**locale** [str, optional] Locale determining the language in which to return the month name. Default is English locale.

#### Returns

**Index** Index of month names.

### Examples

```
>>> idx = pd.date_range(start='2018-01', freq='M', periods=3)
>>> idx
DatetimeIndex(['2018-01-31', '2018-02-28', '2018-03-31'],
              dtype='datetime64[ns]', freq='M')
>>> idx.month_name()
Index(['January', 'February', 'March'], dtype='object')
```

### pandas.DatetimeIndex.day\_name

`DatetimeIndex.day_name` (*self*, \*args, \*\*kwargs)

Return the day names of the `DatetimeIndex` with specified locale.

New in version 0.23.0.

#### Parameters

**locale** [str, optional] Locale determining the language in which to return the day name. Default is English locale.

#### Returns

**Index** Index of day names.

## Examples

```
>>> idx = pd.date_range(start='2018-01-01', freq='D', periods=3)
>>> idx
DatetimeIndex(['2018-01-01', '2018-01-02', '2018-01-03'],
              dtype='datetime64[ns]', freq='D')
>>> idx.day_name()
Index(['Monday', 'Tuesday', 'Wednesday'], dtype='object')
```

## pandas.DatetimeIndex.mean

`DatetimeIndex.mean` (*self*, \*args, \*\*kwargs)

Return the mean value of the Array.

New in version 0.25.0.

### Parameters

**skipna** [bool, default True] Whether to ignore any NaT elements.

### Returns

**scalar** Timestamp or Timedelta.

### See also:

[`numpy.ndarray.mean`](#) Returns the average of array elements along a given axis.

[`Series.mean`](#) Return the mean value in a Series.

### Notes

mean is only defined for Datetime and Timedelta dtypes, not for Period.

## Time/Date components

<code>DatetimeIndex.year</code>	The year of the datetime.
<code>DatetimeIndex.month</code>	The month as January=1, December=12.
<code>DatetimeIndex.day</code>	The month as January=1, December=12.
<code>DatetimeIndex.hour</code>	The hours of the datetime.
<code>DatetimeIndex.minute</code>	The minutes of the datetime.
<code>DatetimeIndex.second</code>	The seconds of the datetime.
<code>DatetimeIndex.microsecond</code>	The microseconds of the datetime.
<code>DatetimeIndex.nanosecond</code>	The nanoseconds of the datetime.
<code>DatetimeIndex.date</code>	Returns numpy array of python datetime.date objects (namely, the date part of Timestamps without timezone information).
<code>DatetimeIndex.time</code>	Returns numpy array of datetime.time.
<code>DatetimeIndex.timetz</code>	Returns numpy array of datetime.time also containing timezone information.
<code>DatetimeIndex.dayofyear</code>	The ordinal day of the year.
<code>DatetimeIndex.weekofyear</code>	The week ordinal of the year.

Continued on next page

Table 164 – continued from previous page

<code>DatetimeIndex.week</code>	The week ordinal of the year.
<code>DatetimeIndex.dayofweek</code>	The day of the week with Monday=0, Sunday=6.
<code>DatetimeIndex.weekday</code>	The day of the week with Monday=0, Sunday=6.
<code>DatetimeIndex.quarter</code>	The quarter of the date.
<code>DatetimeIndex.tz</code>	Return timezone, if any.
<code>DatetimeIndex.freq</code>	Return the frequency object if it is set, otherwise None.
<code>DatetimeIndex.freqstr</code>	Return the frequency object as a string if its set, otherwise None
<code>DatetimeIndex.is_month_start</code>	Indicates whether the date is the first day of the month.
<code>DatetimeIndex.is_month_end</code>	Indicates whether the date is the last day of the month.
<code>DatetimeIndex.is_quarter_start</code>	Indicator for whether the date is the first day of a quarter.
<code>DatetimeIndex.is_quarter_end</code>	Indicator for whether the date is the last day of a quarter.
<code>DatetimeIndex.is_year_start</code>	Indicate whether the date is the first day of a year.
<code>DatetimeIndex.is_year_end</code>	Indicate whether the date is the last day of the year.
<code>DatetimeIndex.is_leap_year</code>	Boolean indicator if the date belongs to a leap year.
<code>DatetimeIndex.inferred_freq</code>	Tryies to return a string representing a frequency guess, generated by <code>infer_freq</code> .

## Selecting

<code>DatetimeIndex.indexer_at_time(self, time[, asof])</code>	Return index locations of index values at particular time of day (e.g.
<code>DatetimeIndex.indexer_between_time(self, ...)</code>	Return index locations of values between particular times of day (e.g., 9:00-9:30AM).

## pandas.DatetimeIndex.indexer\_at\_time

`DatetimeIndex.indexer_at_time` (*self, time, asof=False*)

Return index locations of index values at particular time of day (e.g. 9:30AM).

### Parameters

**time** [datetime.time or str] datetime.time or string in appropriate format (“%H:%M”, “%H%M”, “%I:%M%p”, “%I%M%p”, “%H:%M:%S”, “%H%M%S”, “%I:%M:%S%p”, “%I%M%S%p”).

### Returns

**values\_at\_time** [array of integers]

See also:

`indexer_between_time`, `DataFrame.at_time`

## pandas.DatetimeIndex.indexer\_between\_time

`DatetimeIndex.indexer_between_time` (*self*, *start\_time*, *end\_time*, *include\_start=True*, *include\_end=True*)

Return index locations of values between particular times of day (e.g., 9:00-9:30AM).

### Parameters

**start\_time, end\_time** [`datetime.time`, `str`] `datetime.time` or string in appropriate format (“%H:%M”, “%H%M”, “%I:%M%p”, “%I%M%p”, “%H:%M:%S”, “%H%M%S”, “%I:%M:%S%p”, “%I%M%S%p”).

**include\_start** [`bool`, default `True`]

**include\_end** [`bool`, default `True`]

### Returns

**values\_between\_time** [`array of integers`]

See also:

`indexer_at_time`, `DataFrame.between_time`

## Time-specific operations

<code>DatetimeIndex.normalize</code> ( <i>self</i> , <i>\*args</i> , <i>\*\*kwargs</i> )	Convert times to midnight.
<code>DatetimeIndex.strftime</code> ( <i>self</i> , <i>\*args</i> , <i>\*\*kwargs</i> )	Convert to Index using specified <code>date_format</code> .
<code>DatetimeIndex.snap</code> ( <i>self</i> [, <i>freq</i> ])	Snap time stamps to nearest occurring frequency.
<code>DatetimeIndex.tz_convert</code> ( <i>self</i> , <i>\*args</i> , ...)	Convert tz-aware Datetime Array/Index from one time zone to another.
<code>DatetimeIndex.tz_localize</code> ( <i>self</i> , <i>\*args</i> , ...)	Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index.
<code>DatetimeIndex.round</code> ( <i>self</i> , <i>\*args</i> , <i>\*\*kwargs</i> )	Perform round operation on the data to the specified <i>freq</i> .
<code>DatetimeIndex.floor</code> ( <i>self</i> , <i>\*args</i> , <i>\*\*kwargs</i> )	Perform floor operation on the data to the specified <i>freq</i> .
<code>DatetimeIndex.ceil</code> ( <i>self</i> , <i>\*args</i> , <i>\*\*kwargs</i> )	Perform ceil operation on the data to the specified <i>freq</i> .
<code>DatetimeIndex.month_name</code> ( <i>self</i> , <i>\*args</i> , ...)	Return the month names of the <code>DateTImeIndex</code> with specified locale.
<code>DatetimeIndex.day_name</code> ( <i>self</i> , <i>\*args</i> , <i>\*\*kwargs</i> )	Return the day names of the <code>DateTImeIndex</code> with specified locale.

## Conversion

<code>DatetimeIndex.to_period</code> ( <i>self</i> , <i>\*args</i> , <i>\*\*kwargs</i> )	Cast to <code>PeriodArray/Index</code> at a particular frequency.
<code>DatetimeIndex.to_perioddelta</code> ( <i>self</i> , <i>\*args</i> , ...)	Calculate <code>TimedeltaArray</code> of difference between index values and index converted to <code>PeriodArray</code> at specified <i>freq</i> .
<code>DatetimeIndex.to_pydatetime</code> ( <i>self</i> , <i>\*args</i> , ...)	Return Datetime Array/Index as object ndarray of <code>datetime.datetime</code> objects.

Continued on next page

Table 167 – continued from previous page

<code>DatetimeIndex.to_series(self[, keep_tz, ...])</code>	Create a Series with both index and values equal to the index keys useful with map for returning an indexer based on an index.
<code>DatetimeIndex.to_frame(self[, index, name])</code>	Create a DataFrame with a column containing the Index.

## Methods

<code>DatetimeIndex.mean(self, *args, **kwargs)</code>	Return the mean value of the Array.
--------------------------------------------------------	-------------------------------------

## 4.7.7 TimedeltaIndex

<code>TimedeltaIndex</code>	Immutable ndarray of timedelta64 data, represented internally as int64, and which can be boxed to timedelta objects.
-----------------------------	----------------------------------------------------------------------------------------------------------------------

### pandas.TimedeltaIndex

#### class pandas.TimedeltaIndex

Immutable ndarray of timedelta64 data, represented internally as int64, and which can be boxed to timedelta objects.

##### Parameters

- data** [array-like (1-dimensional), optional] Optional timedelta-like data to construct index with.
- unit** [unit of the arg (D,h,m,s,ms,us,ns) denote the unit, optional] Which is an integer/float number.
- freq** [str or pandas offset object, optional] One of pandas date offset strings or corresponding objects. The string ‘infer’ can be passed in order to set the frequency of the index as the inferred frequency upon creation.
- copy** [bool] Make a copy of input ndarray.
- name** [object] Name to be stored in the index.

##### See also:

- Index** The base pandas Index type.
- Timedelta** Represents a duration between two dates or times.
- DatetimeIndex** Index of datetime64 data.
- PeriodIndex** Index of Period data.
- timedelta\_range** Create a fixed-frequency TimedeltaIndex.

## Notes

To learn more about the frequency strings, please see [this link](#).

## Attributes

<i>days</i>	Number of days for each element.
<i>seconds</i>	Number of seconds ( $\geq 0$ and less than 1 day) for each element.
<i>microseconds</i>	Number of microseconds ( $\geq 0$ and less than 1 second) for each element.
<i>nanoseconds</i>	Number of nanoseconds ( $\geq 0$ and less than 1 microsecond) for each element.
<i>components</i>	Return a dataframe of the components (days, hours, minutes, seconds, milliseconds, microseconds, nanoseconds) of the Timedeltas.
<i>inferred_freq</i>	Tryies to return a string representing a frequency guess, generated by infer_freq.

### **pandas.TimedeltaIndex.days**

**property** `TimedeltaIndex.days`  
Number of days for each element.

### **pandas.TimedeltaIndex.seconds**

**property** `TimedeltaIndex.seconds`  
Number of seconds ( $\geq 0$  and less than 1 day) for each element.

### **pandas.TimedeltaIndex.microseconds**

**property** `TimedeltaIndex.microseconds`  
Number of microseconds ( $\geq 0$  and less than 1 second) for each element.

### **pandas.TimedeltaIndex.nanoseconds**

**property** `TimedeltaIndex.nanoseconds`  
Number of nanoseconds ( $\geq 0$  and less than 1 microsecond) for each element.

## pandas.TimedeltaIndex.components

### property `TimedeltaIndex.components`

Return a dataframe of the components (days, hours, minutes, seconds, milliseconds, microseconds, nanoseconds) of the Timedeltas.

#### Returns

a **DataFrame**

## pandas.TimedeltaIndex.inferred\_freq

### `TimedeltaIndex.inferred_freq`

Tryies to return a string representing a frequency guess, generated by `infer_freq`. Returns None if it can't autodetect the frequency.

## Methods

<code>to_pytimedelta(self, *args, **kwargs)</code>	Return Timedelta Array/Index as object ndarray of <code>datetime.timedelta</code> objects.
<code>to_series(self[, index, name])</code>	Create a Series with both index and values equal to the index keys.
<code>round(self, *args, **kwargs)</code>	Perform round operation on the data to the specified <i>freq</i> .
<code>floor(self, *args, **kwargs)</code>	Perform floor operation on the data to the specified <i>freq</i> .
<code>ceil(self, *args, **kwargs)</code>	Perform ceil operation on the data to the specified <i>freq</i> .
<code>to_frame(self[, index, name])</code>	Create a DataFrame with a column containing the Index.
<code>mean(self, *args, **kwargs)</code>	Return the mean value of the Array.

## pandas.TimedeltaIndex.to\_pytimedelta

### `TimedeltaIndex.to_pytimedelta` (*self*, \*args, \*\*kwargs)

Return Timedelta Array/Index as object ndarray of `datetime.timedelta` objects.

#### Returns

**datetimes** [ndarray]

## pandas.TimedeltaIndex.to\_series

### `TimedeltaIndex.to_series` (*self*, *index=None*, *name=None*)

Create a Series with both index and values equal to the index keys.

Useful with `map` for returning an indexer based on an index.

#### Parameters

**index** [Index, optional] Index of resulting Series. If None, defaults to original index.

**name** [str, optional] Name of resulting Series. If None, defaults to name of original index.

**Returns**

**Series** The dtype will be based on the type of the Index values.

**pandas.TimedeltaIndex.round**

`TimedeltaIndex.round(self, *args, **kwargs)`

Perform round operation on the data to the specified *freq*.

**Parameters**

**freq** [str or Offset] The frequency level to round the index to. Must be a fixed frequency like 'S' (second) not 'ME' (month end). See *frequency aliases* for a list of possible *freq* values.

**ambiguous** ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for DatetimeIndex:

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times.

New in version 0.24.0.

**nonexistent** ['shift\_forward', 'shift\_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift\_forward' will shift the nonexistent time forward to the closest existing time
- 'shift\_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise a NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

**Returns**

**DatetimeIndex, TimedeltaIndex, or Series** Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

**Raises**

**ValueError** if the *freq* cannot be converted.

## Examples

### DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
              '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.round('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
              '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq=None)
```

### Series

```
>>> pd.Series(rng).dt.round("H")
0    2018-01-01 12:00:00
1    2018-01-01 12:00:00
2    2018-01-01 12:00:00
dtype: datetime64[ns]
```

## pandas.TimedeltaIndex.floor

`TimedeltaIndex.floor` (*self*, \*args, \*\*kwargs)

Perform floor operation on the data to the specified *freq*.

### Parameters

**freq** [str or Offset] The frequency level to floor the index to. Must be a fixed frequency like 'S' (second) not 'ME' (month end). See *frequency aliases* for a list of possible *freq* values.

**ambiguous** ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for `DatetimeIndex`:

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an `AmbiguousTimeError` if there are ambiguous times.

New in version 0.24.0.

**nonexistent** ['shift\_forward', 'shift\_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift\_forward' will shift the nonexistent time forward to the closest existing time
- 'shift\_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta

- ‘raise’ will raise an `NonExistentTimeError` if there are nonexistent times.

New in version 0.24.0.

### Returns

**DatetimeIndex, TimedeltaIndex, or Series** Index of the same type for a `DatetimeIndex` or `TimedeltaIndex`, or a `Series` with the same index for a `Series`.

### Raises

**ValueError** if the *freq* cannot be converted.

## Examples

### DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
              '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.floor('H')
DatetimeIndex(['2018-01-01 11:00:00', '2018-01-01 12:00:00',
              '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq=None)
```

### Series

```
>>> pd.Series(rng).dt.floor("H")
0    2018-01-01 11:00:00
1    2018-01-01 12:00:00
2    2018-01-01 12:00:00
dtype: datetime64[ns]
```

## pandas.TimedeltaIndex.ceil

`TimedeltaIndex.ceil` (*self*, \*args, \*\*kwargs)

Perform ceil operation on the data to the specified *freq*.

### Parameters

**freq** [str or Offset] The frequency level to ceil the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See *frequency aliases* for a list of possible *freq* values.

**ambiguous** [‘infer’, bool-ndarray, ‘NaT’, default ‘raise’] Only relevant for `DatetimeIndex`:

- ‘infer’ will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- ‘NaT’ will return NaT where there are ambiguous times
- ‘raise’ will raise an `AmbiguousTimeError` if there are ambiguous times.

New in version 0.24.0.

**nonexistent** ['shift\_forward', 'shift\_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift\_forward' will shift the nonexistent time forward to the closest existing time
- 'shift\_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise a NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

### Returns

**DatetimeIndex, TimedeltaIndex, or Series** Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

### Raises

**ValueError** if the *freq* cannot be converted.

## Examples

### DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
              '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.ceil('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
              '2018-01-01 13:00:00'],
              dtype='datetime64[ns]', freq=None)
```

### Series

```
>>> pd.Series(rng).dt.ceil("H")
0    2018-01-01 12:00:00
1    2018-01-01 12:00:00
2    2018-01-01 13:00:00
dtype: datetime64[ns]
```

## pandas.TimedeltaIndex.to\_frame

`TimedeltaIndex.to_frame` (*self*, *index=True*, *name=None*)

Create a DataFrame with a column containing the Index.

New in version 0.24.0.

### Parameters

**index** [bool, default True] Set the index of the returned DataFrame as the original Index.

**name** [object, default None] The passed name should substitute for the index name (if it has one).

**Returns**

**DataFrame** DataFrame containing the original Index data.

**See also:**

***Index.to\_series*** Convert an Index to a Series.

***Series.to\_frame*** Convert Series to DataFrame.

**Examples**

```
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')
>>> idx.to_frame()
      animal
animal
Ant      Ant
Bear    Bear
Cow     Cow
```

By default, the original Index is reused. To enforce a new Index:

```
>>> idx.to_frame(index=False)
      animal
0      Ant
1     Bear
2     Cow
```

To override the name of the resulting column, specify *name*:

```
>>> idx.to_frame(index=False, name='zoo')
      zoo
0      Ant
1     Bear
2     Cow
```

**pandas.TimedeltaIndex.mean**

`TimedeltaIndex.mean(self, *args, **kwargs)`

Return the mean value of the Array.

New in version 0.25.0.

**Parameters**

**skipna** [bool, default True] Whether to ignore any NaT elements.

**Returns**

**scalar** Timestamp or Timedelta.

**See also:**

***numpy.ndarray.mean*** Returns the average of array elements along a given axis.

***Series.mean*** Return the mean value in a Series.

## Notes

mean is only defined for Datetime and Timedelta dtypes, not for Period.

## Components

<code>TimedeltaIndex.days</code>	Number of days for each element.
<code>TimedeltaIndex.seconds</code>	Number of seconds ( $\geq 0$ and less than 1 day) for each element.
<code>TimedeltaIndex.microseconds</code>	Number of microseconds ( $\geq 0$ and less than 1 second) for each element.
<code>TimedeltaIndex.nanoseconds</code>	Number of nanoseconds ( $\geq 0$ and less than 1 microsecond) for each element.
<code>TimedeltaIndex.components</code>	Return a dataframe of the components (days, hours, minutes, seconds, milliseconds, microseconds, nanoseconds) of the Timedeltas.
<code>TimedeltaIndex.inferred_freq</code>	Tryies to return a string representing a frequency guess, generated by <code>infer_freq</code> .

## Conversion

<code>TimedeltaIndex.to_pytimedelta(self, *args, ...)</code>	Return Timedelta Array/Index as object ndarray of date-time.timedelta objects.
<code>TimedeltaIndex.to_series(self[, index, name])</code>	Create a Series with both index and values equal to the index keys.
<code>TimedeltaIndex.round(self, *args, **kwargs)</code>	Perform round operation on the data to the specified <i>freq</i> .
<code>TimedeltaIndex.floor(self, *args, **kwargs)</code>	Perform floor operation on the data to the specified <i>freq</i> .
<code>TimedeltaIndex.ceil(self, *args, **kwargs)</code>	Perform ceil operation on the data to the specified <i>freq</i> .
<code>TimedeltaIndex.to_frame(self[, index, name])</code>	Create a DataFrame with a column containing the Index.

## Methods

<code>TimedeltaIndex.mean(self, *args, **kwargs)</code>	Return the mean value of the Array.
---------------------------------------------------------	-------------------------------------

## 4.7.8 PeriodIndex

<code>PeriodIndex</code>	Immutable ndarray holding ordinal values indicating regular periods in time.
--------------------------	------------------------------------------------------------------------------

## pandas.PeriodIndex

### class pandas.PeriodIndex

Immutable ndarray holding ordinal values indicating regular periods in time.

Index keys are boxed to Period objects which carries the metadata (eg, frequency information).

#### Parameters

**data** [array-like (1d int np.ndarray or PeriodArray), optional] Optional period-like data to construct index with.

**copy** [bool] Make a copy of input ndarray.

**freq** [str or period object, optional] One of pandas period strings or corresponding objects

**year** [int, array, or Series, default None]

**month** [int, array, or Series, default None]

**quarter** [int, array, or Series, default None]

**day** [int, array, or Series, default None]

**hour** [int, array, or Series, default None]

**minute** [int, array, or Series, default None]

**second** [int, array, or Series, default None]

**tz** [object, default None] Timezone for converting datetime64 data to Periods.

**dtype** [str or PeriodDtype, default None]

#### See also:

**Index** The base pandas Index type.

**Period** Represents a period of time.

**DatetimeIndex** Index with datetime64 data.

**TimedeltaIndex** Index of timedelta64 data.

**period\_range** Create a fixed-frequency PeriodIndex.

## Examples

```
>>> idx = pd.PeriodIndex(year=year_arr, quarter=q_arr)
```

## Attributes

<i>day</i>	The days of the period.
<i>dayofweek</i>	The day of the week with Monday=0, Sunday=6.
<i>dayofyear</i>	The ordinal day of the year.
<i>days_in_month</i>	The number of days in the month.
<i>daysinmonth</i>	The number of days in the month.
<i>freq</i>	Return the frequency object if it is set, otherwise None.
<i>freqstr</i>	Return the frequency object as a string if its set, otherwise None
<i>hour</i>	The hour of the period.
<i>is_leap_year</i>	Logical indicating if the date belongs to a leap year.

Continued on next page

Table 176 – continued from previous page

<i>minute</i>	The minute of the period.
<i>month</i>	The month as January=1, December=12.
<i>quarter</i>	The quarter of the date.
<i>second</i>	The second of the period.
<i>week</i>	The week ordinal of the year.
<i>weekday</i>	The day of the week with Monday=0, Sunday=6.
<i>weekofyear</i>	The week ordinal of the year.
<i>year</i>	The year of the period.

**pandas.PeriodIndex.day**

**property** `PeriodIndex.day`  
The days of the period.

**pandas.PeriodIndex.dayofweek**

**property** `PeriodIndex.dayofweek`  
The day of the week with Monday=0, Sunday=6.

**pandas.PeriodIndex.dayofyear**

**property** `PeriodIndex.dayofyear`  
The ordinal day of the year.

**pandas.PeriodIndex.days\_in\_month**

**property** `PeriodIndex.days_in_month`  
The number of days in the month.

**pandas.PeriodIndex.daysinmonth**

**property** `PeriodIndex.daysinmonth`  
The number of days in the month.

**pandas.PeriodIndex.freq**

**property** `PeriodIndex.freq`  
Return the frequency object if it is set, otherwise None.

### **pandas.PeriodIndex.freqstr**

**property** `PeriodIndex.freqstr`

Return the frequency object as a string if its set, otherwise None

### **pandas.PeriodIndex.hour**

**property** `PeriodIndex.hour`

The hour of the period.

### **pandas.PeriodIndex.is\_leap\_year**

**property** `PeriodIndex.is_leap_year`

Logical indicating if the date belongs to a leap year.

### **pandas.PeriodIndex.minute**

**property** `PeriodIndex.minute`

The minute of the period.

### **pandas.PeriodIndex.month**

**property** `PeriodIndex.month`

The month as January=1, December=12.

### **pandas.PeriodIndex.quarter**

**property** `PeriodIndex.quarter`

The quarter of the date.

### **pandas.PeriodIndex.second**

**property** `PeriodIndex.second`

The second of the period.

### **pandas.PeriodIndex.week**

**property** `PeriodIndex.week`

The week ordinal of the year.

**pandas.PeriodIndex.weekday****property** `PeriodIndex.weekday`

The day of the week with Monday=0, Sunday=6.

**pandas.PeriodIndex.weekofyear****property** `PeriodIndex.weekofyear`

The week ordinal of the year.

**pandas.PeriodIndex.year****property** `PeriodIndex.year`

The year of the period.

<b>end_time</b>	
<b>qyear</b>	
<b>start_time</b>	

**Methods**

<code>asfreq(self, *args, **kwargs)</code>	Convert the Period Array/Index to the specified frequency <i>freq</i> .
<code>strftime(self, *args, **kwargs)</code>	Convert to Index using specified <code>date_format</code> .
<code>to_timestamp(self, *args, **kwargs)</code>	Cast to DatetimeArray/Index.

**pandas.PeriodIndex.asfreq**`PeriodIndex.asfreq(self, *args, **kwargs)`Convert the Period Array/Index to the specified frequency *freq*.**Parameters****freq** [str] A frequency.**how** [str {'E', 'S'}] Whether the elements should be aligned to the end or start within a period.

- 'E', 'END', or 'FINISH' for end,
- 'S', 'START', or 'BEGIN' for start.

January 31st ('END') vs. January 1st ('START') for example.

**Returns****Period Array/Index** Constructed with the new frequency.

## Examples

```
>>> pidx = pd.period_range('2010-01-01', '2015-01-01', freq='A')
>>> pidx
PeriodIndex(['2010', '2011', '2012', '2013', '2014', '2015'],
            dtype='period[A-DEC]', freq='A-DEC')
```

```
>>> pidx.asfreq('M')
PeriodIndex(['2010-12', '2011-12', '2012-12', '2013-12', '2014-12',
            '2015-12'], dtype='period[M]', freq='M')
```

```
>>> pidx.asfreq('M', how='S')
PeriodIndex(['2010-01', '2011-01', '2012-01', '2013-01', '2014-01',
            '2015-01'], dtype='period[M]', freq='M')
```

## pandas.PeriodIndex.strftime

`PeriodIndex.strftime` (*self*, \*args, \*\*kwargs)

Convert to Index using specified date\_format.

Return an Index of formatted strings specified by date\_format, which supports the same string format as the python standard library. Details of the string format can be found in [python string format doc](#).

### Parameters

**date\_format** [str] Date format string (e.g. “%Y-%m-%d”).

### Returns

**ndarray** NumPy ndarray of formatted strings.

### See also:

**to\_datetime** Convert the given argument to datetime.

**DatetimeIndex.normalize** Return DatetimeIndex with times to midnight.

**DatetimeIndex.round** Round the DatetimeIndex to the specified freq.

**DatetimeIndex.floor** Floor the DatetimeIndex to the specified freq.

## Examples

```
>>> rng = pd.date_range(pd.Timestamp("2018-03-10 09:00"),
...                    periods=3, freq='s')
>>> rng.strftime('%B %d, %Y, %r')
Index(['March 10, 2018, 09:00:00 AM', 'March 10, 2018, 09:00:01 AM',
      'March 10, 2018, 09:00:02 AM'],
      dtype='object')
```

**pandas.PeriodIndex.to\_timestamp**

`PeriodIndex.to_timestamp` (*self*, \*args, \*\*kwargs)

Cast to DatetimeArray/Index.

**Parameters**

**freq** [str or DateOffset, optional] Target frequency. The default is 'D' for week or longer, 'S' otherwise.

**how** [{ 's', 'e', 'start', 'end' }] Whether to use the start or end of the time period being converted.

**Returns**

DatetimeArray/Index

**Properties**

<code>PeriodIndex.day</code>	The days of the period.
<code>PeriodIndex.dayofweek</code>	The day of the week with Monday=0, Sunday=6.
<code>PeriodIndex.dayofyear</code>	The ordinal day of the year.
<code>PeriodIndex.days_in_month</code>	The number of days in the month.
<code>PeriodIndex.daysinmonth</code>	The number of days in the month.
<code>PeriodIndex.end_time</code>	
<code>PeriodIndex.freq</code>	Return the frequency object if it is set, otherwise None.
<code>PeriodIndex.freqstr</code>	Return the frequency object as a string if its set, otherwise None
<code>PeriodIndex.hour</code>	The hour of the period.
<code>PeriodIndex.is_leap_year</code>	Logical indicating if the date belongs to a leap year.
<code>PeriodIndex.minute</code>	The minute of the period.
<code>PeriodIndex.month</code>	The month as January=1, December=12.
<code>PeriodIndex.quarter</code>	The quarter of the date.
<code>PeriodIndex.qyear</code>	
<code>PeriodIndex.second</code>	The second of the period.
<code>PeriodIndex.start_time</code>	
<code>PeriodIndex.week</code>	The week ordinal of the year.
<code>PeriodIndex.weekday</code>	The day of the week with Monday=0, Sunday=6.
<code>PeriodIndex.weekofyear</code>	The week ordinal of the year.
<code>PeriodIndex.year</code>	The year of the period.

**pandas.PeriodIndex.end\_time**

**property** `PeriodIndex.end_time`

## pandas.PeriodIndex.qyear

**property** PeriodIndex.qyear

## pandas.PeriodIndex.start\_time

**property** PeriodIndex.start\_time

## Methods

<i>PeriodIndex.asfreq</i> (self, *args, **kwargs)	Convert the Period Array/Index to the specified frequency <i>freq</i> .
<i>PeriodIndex.strftime</i> (self, *args, **kwargs)	Convert to Index using specified <i>date_format</i> .
<i>PeriodIndex.to_timestamp</i> (self, *args, ...)	Cast to DatetimeArray/Index.

## 4.8 Date offsets

### 4.8.1 DateOffset

<i>DateOffset</i> ([n, normalize])	Standard kind of date increment used for a date range.
------------------------------------	--------------------------------------------------------

---

#### pandas.tseries.offsets.DateOffset

**class** pandas.tseries.offsets.DateOffset (*n=1, normalize=False, \*\*kws*)

Standard kind of date increment used for a date range.

Works exactly like `relativedelta` in terms of the keyword args you pass in, use of the keyword `n` is discouraged—you would be better off specifying `n` in the keywords you use, but regardless it is there for you. `n` is needed for `DateOffset` subclasses.

`DateOffset` work as follows. Each offset specify a set of dates that conform to the `DateOffset`. For example, `Bday` defines this set to be the set of dates that are weekdays (M-F). To test if a date is in the set of a `DateOffset` `dateOffset` we can use the `is_on_offset` method: `dateOffset.is_on_offset(date)`.

If a date is not on a valid date, the `rollback` and `rollforward` methods can be used to roll the date to the nearest valid date before/after the date.

`DateOffsets` can be created to move dates forward a given number of valid dates. For example, `Bday(2)` can be added to a date to move it two business days forward. If the date does not start on a valid date, first it is moved to a valid date. Thus pseudo code is:

```
def __add__(date): date = rollback(date) # does nothing if date is valid return date + <n number of periods>
```

When a date offset is created for a negative number of periods, the date is first rolled forward. The pseudo code is:

```
def __add__(date): date = rollforward(date) # does nothing is date is valid return date + <n number of periods>
```

Zero presents a problem. Should it roll forward or back? We arbitrarily have it rollforward:

```
date + BDay(0) == BDay.rollforward(date)
```

Since 0 is a bit weird, we suggest avoiding its use.

### Parameters

**n** [int, default 1] The number of time periods the offset represents.

**normalize** [bool, default False] Whether to round the result of a DateOffset addition down to the previous midnight.

**\*\*kwargs** Temporal parameter that add to or replace the offset value.

Parameters that **add** to the offset (like Timedelta):

- years
- months
- weeks
- days
- hours
- minutes
- seconds
- microseconds
- nanoseconds

Parameters that **replace** the offset value:

- year
- month
- day
- weekday
- hour
- minute
- second
- microsecond
- nanosecond.

**See also:**

[dateutil.relativedelta.relativedelta](#) The relativedelta type is designed to be applied to an existing datetime and can replace specific components of that datetime, or represents an interval of time.

### Examples

```
>>> from pandas.tseries.offsets import DateOffset
>>> ts = pd.Timestamp('2017-01-01 09:10:11')
>>> ts + DateOffset(months=3)
Timestamp('2017-04-01 09:10:11')
```

```
>>> ts = pd.Timestamp('2017-01-01 09:10:11')
>>> ts + DateOffset(months=2)
Timestamp('2017-03-01 09:10:11')
```

## Attributes

*base* Returns a copy of the calling offset object with n=1 and all other attributes equal.

---

### pandas.tseries.offsets.DateOffset.base

**property** `DateOffset.base`

Returns a copy of the calling offset object with n=1 and all other attributes equal.

<b>freqstr</b>	
<b>kwds</b>	
<b>name</b>	
<b>nanos</b>	
<b>rule_code</b>	

## Methods

*apply\_index*(self, other) Vectorized apply of DateOffset to DatetimeIndex, raises NotImplementedError for offsets without a vectorized implementation.

---

*rollback*(self, dt) Roll provided date backward to next offset only if not on offset.

---

*rollforward*(self, dt) Roll provided date forward to next offset only if not on offset.

---

### pandas.tseries.offsets.DateOffset.apply\_index

`DateOffset.apply_index` (*self*, *other*)

Vectorized apply of DateOffset to DatetimeIndex, raises NotImplementedError for offsets without a vectorized implementation.

**Parameters**

**i** [DatetimeIndex]

**Returns**

**y** [DatetimeIndex]

**pandas.tseries.offsets.DateOffset.rollback**`DateOffset.rollback(self, dt)`

Roll provided date backward to next offset only if not on offset.

**Returns****TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.**pandas.tseries.offsets.DateOffset.rollforward**`DateOffset.rollforward(self, dt)`

Roll provided date forward to next offset only if not on offset.

**Returns****TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

<code>__call__</code>	
<code>apply</code>	
<code>copy</code>	
<code>isAnchored</code>	
<code>is_anchored</code>	
<code>is_on_offset</code>	
<code>onOffset</code>	

**Properties**`DateOffset.freqstr``DateOffset.kwds``DateOffset.name``DateOffset.nanos``DateOffset.normalize``DateOffset.rule_code`**pandas.tseries.offsets.DateOffset.freqstr**`DateOffset.freqstr`

### **pandas.tseries.offsets.DateOffset.kwds**

**property** `DateOffset.kwds`

### **pandas.tseries.offsets.DateOffset.name**

**property** `DateOffset.name`

### **pandas.tseries.offsets.DateOffset.nanos**

**property** `DateOffset.nanos`

### **pandas.tseries.offsets.DateOffset.normalize**

`DateOffset.normalize = False`

### **pandas.tseries.offsets.DateOffset.rule\_code**

**property** `DateOffset.rule_code`

## **Methods**

*`DateOffset.apply(self, other)`*

---

*`DateOffset.copy(self)`*

---

*`DateOffset.isAnchored(self)`*

---

*`DateOffset.onOffset(self, dt)`*

---

*`DateOffset.is_anchored(self)`*

---

*`DateOffset.is_on_offset(self, dt)`*

---

### **pandas.tseries.offsets.DateOffset.apply**

`DateOffset.apply` (*self, other*)

**pandas.tseries.offsets.DateOffset.copy**`DateOffset.copy(self)`**pandas.tseries.offsets.DateOffset.isAnchored**`DateOffset.isAnchored(self)`**pandas.tseries.offsets.DateOffset.onOffset**`DateOffset.onOffset(self, dt)`**pandas.tseries.offsets.DateOffset.is\_anchored**`DateOffset.is_anchored(self)`**pandas.tseries.offsets.DateOffset.is\_on\_offset**`DateOffset.is_on_offset(self, dt)`

## 4.8.2 BusinessDay

`BusinessDay([n, normalize, offset])`

DateOffset subclass representing possibly n business days.

**pandas.tseries.offsets.BusinessDay**

**class** pandas.tseries.offsets.**BusinessDay** (*n=1*, *normalize=False*, *offset=datetime.timedelta(0)*)  
 DateOffset subclass representing possibly n business days.

**Attributes**`base`

Returns a copy of the calling offset object with n=1 and all other attributes equal.

`offset`

Alias for self.\_offset.

**pandas.tseries.offsets.BusinessDay.base**

**property** BusinessDay.**base**

Returns a copy of the calling offset object with n=1 and all other attributes equal.

**pandas.tseries.offsets.BusinessDay.offset**

**property** BusinessDay.**offset**

Alias for self.\_offset.

<b>freqstr</b>	
<b>kwds</b>	
<b>name</b>	
<b>nanos</b>	
<b>rule_code</b>	

**Methods**

<i>rollback</i> (self, dt)	Roll provided date backward to next offset only if not on offset.
<i>rollforward</i> (self, dt)	Roll provided date forward to next offset only if not on offset.

**pandas.tseries.offsets.BusinessDay.rollback**

BusinessDay.**rollback** (*self*, *dt*)

Roll provided date backward to next offset only if not on offset.

**Returns**

**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

**pandas.tseries.offsets.BusinessDay.rollforward**

BusinessDay.**rollforward** (*self*, *dt*)

Roll provided date forward to next offset only if not on offset.

**Returns**

**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

<b>__call__</b>	
<b>apply</b>	
<b>apply_index</b>	
<b>copy</b>	
<b>isAnchored</b>	
<b>is_anchored</b>	
<b>is_on_offset</b>	
<b>onOffset</b>	

## Properties

*BusinessDay.freqstr*

---

*BusinessDay.kwds*

---

*BusinessDay.name*

---

*BusinessDay.nanos*

---

*BusinessDay.normalize*

---

*BusinessDay.rule\_code*

---

### **pandas.tseries.offsets.BusinessDay.freqstr**

`BusinessDay.freqstr`

### **pandas.tseries.offsets.BusinessDay.kwds**

**property** `BusinessDay.kwds`

### **pandas.tseries.offsets.BusinessDay.name**

**property** `BusinessDay.name`

### **pandas.tseries.offsets.BusinessDay.nanos**

**property** `BusinessDay.nanos`

### **pandas.tseries.offsets.BusinessDay.normalize**

`BusinessDay.normalize = False`

### **pandas.tseries.offsets.BusinessDay.rule\_code**

**property** `BusinessDay.rule_code`

## Methods

*BusinessDay.apply(self, other)*

---

*BusinessDay.apply\_index(self, other)*

---

*BusinessDay.copy(self)*

---

*BusinessDay.isAnchored(self)*

---

*BusinessDay.onOffset(self, dt)*

---

*BusinessDay.is\_anchored(self)*

---

*BusinessDay.is\_on\_offset(self, dt)*

---

**pandas.tseries.offsets.BusinessDay.apply**

`BusinessDay.apply` (*self*, *other*)

**pandas.tseries.offsets.BusinessDay.apply\_index**

`BusinessDay.apply_index` (*self*, *other*)

**pandas.tseries.offsets.BusinessDay.copy**

`BusinessDay.copy` (*self*)

**pandas.tseries.offsets.BusinessDay.isAnchored**

`BusinessDay.isAnchored` (*self*)

**pandas.tseries.offsets.BusinessDay.onOffset**

`BusinessDay.onOffset` (*self*, *dt*)

**pandas.tseries.offsets.BusinessDay.is\_anchored**

`BusinessDay.is_anchored` (*self*)

**pandas.tseries.offsets.BusinessDay.is\_on\_offset**

`BusinessDay.is_on_offset` (*self*, *dt*)

### 4.8.3 BusinessHour

`BusinessHour`(*n*, *normalize*, *start*, *end*, *offset*)

DateOffset subclass representing possibly *n* business hours.

---

**pandas.tseries.offsets.BusinessHour**

**class** `pandas.tseries.offsets.BusinessHour` (*n=1*, *normalize=False*, *start='09:00'*,  
*end='17:00'*, *offset=datetime.timedelta(0)*)

DateOffset subclass representing possibly *n* business hours.

## Attributes

<i>base</i>	Returns a copy of the calling offset object with n=1 and all other attributes equal.
<i>next_bday</i>	Used for moving to next business day.
<i>offset</i>	Alias for self._offset.

### pandas.tseries.offsets.BusinessHour.base

**property** BusinessHour.**base**

Returns a copy of the calling offset object with n=1 and all other attributes equal.

### pandas.tseries.offsets.BusinessHour.next\_bday

BusinessHour.**next\_bday**

Used for moving to next business day.

### pandas.tseries.offsets.BusinessHour.offset

**property** BusinessHour.**offset**

Alias for self.\_offset.

<b>freqstr</b>	
<b>kwds</b>	
<b>name</b>	
<b>nanos</b>	
<b>rule_code</b>	

## Methods

<i>apply_index</i> (self, other)	Vectorized apply of DateOffset to DatetimeIndex, raises NotImplementedError for offsets without a vectorized implementation.
<i>rollback</i> (self, dt)	Roll provided date backward to next offset only if not on offset.
<i>rollforward</i> (self, dt)	Roll provided date forward to next offset only if not on offset.

### pandas.tseries.offsets.BusinessHour.apply\_index

`BusinessHour.apply_index` (*self, other*)

Vectorized apply of DateOffset to DatetimeIndex, raises NotImplementedError for offsets without a vectorized implementation.

#### Parameters

**i** [DatetimeIndex]

#### Returns

**y** [DatetimeIndex]

### pandas.tseries.offsets.BusinessHour.rollback

`BusinessHour.rollback` (*self, dt*)

Roll provided date backward to next offset only if not on offset.

### pandas.tseries.offsets.BusinessHour.rollforward

`BusinessHour.rollforward` (*self, dt*)

Roll provided date forward to next offset only if not on offset.

<code>__call__</code>

## 4.8.4 CustomBusinessDay

*CustomBusinessDay*([*n*, *normalize*, *weekmask*, *DateOffset* subclass representing possibly *n* custom business days, excluding holidays.  
...])

---

### pandas.tseries.offsets.CustomBusinessDay

```
class pandas.tseries.offsets.CustomBusinessDay (n=1, normalize=False, week-  
mask='Mon Tue Wed Thu Fri', holidays=None, calendar=None,  
offset=datetime.timedelta(0))
```

DateOffset subclass representing possibly *n* custom business days, excluding holidays.

#### Parameters

**n** [int, default 1]

**normalize** [bool, default False] Normalize start/end dates to midnight before generating date range.

**weekmask** [str, Default 'Mon Tue Wed Thu Fri'] Weekmask of valid business days, passed to `numpy.busdaycalendar`.

**holidays** [list] List/array of dates to exclude from the set of valid business days, passed to `numpy.busdaycalendar`.

**calendar** [pd.HolidayCalendar or np.busdaycalendar]

**offset** [timedelta, default timedelta(0)]

## Attributes

<i>base</i>	Returns a copy of the calling offset object with n=1 and all other attributes equal.
<i>offset</i>	Alias for self._offset.

### pandas.tseries.offsets.CustomBusinessDay.base

**property** CustomBusinessDay.**base**

Returns a copy of the calling offset object with n=1 and all other attributes equal.

### pandas.tseries.offsets.CustomBusinessDay.offset

**property** CustomBusinessDay.**offset**

Alias for self.\_offset.

<b>freqstr</b>	
<b>kwds</b>	
<b>name</b>	
<b>nanos</b>	
<b>rule_code</b>	

## Methods

<i>apply_index</i> (self, i)	Vectorized apply of DateOffset to DatetimeIndex, raises NotImplementedError for offsets without a vectorized implementation.
<i>rollback</i> (self, dt)	Roll provided date backward to next offset only if not on offset.
<i>rollforward</i> (self, dt)	Roll provided date forward to next offset only if not on offset.

### pandas.tseries.offsets.CustomBusinessDay.apply\_index

CustomBusinessDay.**apply\_index** (*self*, *i*)

Vectorized apply of DateOffset to DatetimeIndex, raises NotImplementedError for offsets without a vectorized implementation.

**Parameters****i** [DatetimeIndex]**Returns****y** [DatetimeIndex]

### **pandas.tseries.offsets.CustomBusinessDay.rollback**

`CustomBusinessDay.rollback` (*self*, *dt*)

Roll provided date backward to next offset only if not on offset.

#### **Returns**

**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

### **pandas.tseries.offsets.CustomBusinessDay.rollforward**

`CustomBusinessDay.rollforward` (*self*, *dt*)

Roll provided date forward to next offset only if not on offset.

#### **Returns**

**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

## 4.8.5 CustomBusinessHour

*CustomBusinessHour*(*n*, *normalize*, *weekmask*, *DateOffset* subclass representing possibly *n* custom business days.  
...])

---

### pandas.tseries.offsets.CustomBusinessHour

```
class pandas.tseries.offsets.CustomBusinessHour (n=1, normalize=False, week-  
mask='Mon Tue Wed Thu Fri', holidays=None, calendar=None,  
start='09:00', end='17:00', off-  
set=datetime.timedelta(0))
```

DateOffset subclass representing possibly *n* custom business days.

#### Attributes

<i>base</i>	Returns a copy of the calling offset object with <i>n=1</i> and all other attributes equal.
<i>next_bday</i>	Used for moving to next business day.
<i>offset</i>	Alias for <i>self._offset</i> .

---

**pandas.tseries.offsets.CustomBusinessHour.base****property** CustomBusinessHour.**base**

Returns a copy of the calling offset object with n=1 and all other attributes equal.

**pandas.tseries.offsets.CustomBusinessHour.next\_bday**CustomBusinessHour.**next\_bday**

Used for moving to next business day.

**pandas.tseries.offsets.CustomBusinessHour.offset****property** CustomBusinessHour.**offset**

Alias for self.\_offset.

<b>freqstr</b>	
<b>kwds</b>	
<b>name</b>	
<b>nanos</b>	
<b>rule_code</b>	

**Methods**

<i>apply_index</i> (self, other)	Vectorized apply of DateOffset to DatetimeIndex, raises NotImplementedError for offsets without a vectorized implementation.
<i>rollback</i> (self, dt)	Roll provided date backward to next offset only if not on offset.
<i>rollforward</i> (self, dt)	Roll provided date forward to next offset only if not on offset.

**pandas.tseries.offsets.CustomBusinessHour.apply\_index**CustomBusinessHour.**apply\_index** (*self*, *other*)

Vectorized apply of DateOffset to DatetimeIndex, raises NotImplementedError for offsets without a vectorized implementation.

**Parameters**

**i** [DatetimeIndex]

**Returns**

**y** [DatetimeIndex]

### **pandas.tseries.offsets.CustomBusinessHour.rollback**

`CustomBusinessHour.rollback` (*self*, *dt*)

Roll provided date backward to next offset only if not on offset.

### **pandas.tseries.offsets.CustomBusinessHour.rollforward**

`CustomBusinessHour.rollforward` (*self*, *dt*)

Roll provided date forward to next offset only if not on offset.

## **4.8.11 CustomBusinessMonthEnd**

---

`CustomBusinessMonthEnd`(*n*, *normalize*, ...) DateOffset subclass representing custom business month(s).

---

### **pandas.tseries.offsets.CustomBusinessMonthEnd**

**class** `pandas.tseries.offsets.CustomBusinessMonthEnd` (*n=1*, *normalize=False*, *weekmask='Mon Tue Wed Thu Fri'*, *holidays=None*, *calendar=None*, *offset=datetime.timedelta(0)*)

DateOffset subclass representing custom business month(s).

Increments between end of month dates.

#### **Parameters**

**n** [int, default 1] The number of months represented.

**normalize** [bool, default False] Normalize start/end dates to midnight before generating date range.

**weekmask** [str, Default 'Mon Tue Wed Thu Fri'] Weekmask of valid business days, passed to `numpy.busdaycalendar`.

**holidays** [list] List/array of dates to exclude from the set of valid business days, passed to `numpy.busdaycalendar`.

**calendar** [pd.HolidayCalendar or np.busdaycalendar] Calendar to integrate.

**offset** [timedelta, default timedelta(0)] Time offset to apply.

### Attributes

<code>base</code>	Returns a copy of the calling offset object with n=1 and all other attributes equal.
<code>cbday_roll</code>	Define default roll function to be called in apply method.
<code>month_roll</code>	Define default roll function to be called in apply method.
<code>offset</code>	Alias for <code>self._offset</code> .

### `pandas.tseries.offsets.CustomBusinessMonthEnd.base`

**property** `CustomBusinessMonthEnd.base`

Returns a copy of the calling offset object with n=1 and all other attributes equal.

### `pandas.tseries.offsets.CustomBusinessMonthEnd.cbday_roll`

`CustomBusinessMonthEnd.cbday_roll`

Define default roll function to be called in apply method.

### `pandas.tseries.offsets.CustomBusinessMonthEnd.month_roll`

`CustomBusinessMonthEnd.month_roll`

Define default roll function to be called in apply method.

### `pandas.tseries.offsets.CustomBusinessMonthEnd.offset`

**property** `CustomBusinessMonthEnd.offset`

Alias for `self._offset`.

<code>freqstr</code>	
<code>kwds</code>	
<code>m_offset</code>	
<code>name</code>

<code>rule_code</code>	

## Methods

<code>apply_index(self, other)</code>	Vectorized apply of DateOffset to DatetimeIndex, raises NotImplementedError for offsets without a vectorized implementation.
<code>rollback(self, dt)</code>	Roll provided date backward to next offset only if not on offset.
<code>rollforward(self, dt)</code>	Roll provided date forward to next offset only if not on offset.

### pandas.tseries.offsets.CustomBusinessMonthEnd.apply\_index

`CustomBusinessMonthEnd.apply_index(self, other)`

Vectorized apply of DateOffset to DatetimeIndex, raises NotImplementedError for offsets without a vectorized implementation.

#### Parameters

**i** [DatetimeIndex]

#### Returns

**y** [DatetimeIndex]

### pandas.tseries.offsets.CustomBusinessMonthEnd.rollback

`CustomBusinessMonthEnd.rollback(self, dt)`

Roll provided date backward to next offset only if not on offset.

#### Returns

**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

### pandas.tseries.offsets.CustomBusinessMonthEnd.rollforward

`CustomBusinessMonthEnd.rollforward(self, dt)`

Roll provided date forward to next offset only if not on offset.

#### Returns

**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

### pandas.tseries.offsets.CustomBusinessMonthBegin

```
class pandas.tseries.offsets.CustomBusinessMonthBegin (n=1, normalize=False,
weekmask='Mon Tue Wed Thu Fri', holidays=None,
calendar=None, offset=datetime.timedelta(0))
```

DateOffset subclass representing custom business month(s).

Increments between beginning of month dates.

#### Parameters

**n** [int, default 1] The number of months represented.

**normalize** [bool, default False] Normalize start/end dates to midnight before generating date range.

**weekmask** [str, Default 'Mon Tue Wed Thu Fri'] Weekmask of valid business days, passed to `numpy.busdaycalendar`.

**holidays** [list] List/array of dates to exclude from the set of valid business days, passed to `numpy.busdaycalendar`.

**calendar** [pd.HolidayCalendar or np.busdaycalendar] Calendar to integrate.

**offset** [timedelta, default timedelta(0)] Time offset to apply.

#### Attributes

<i>base</i>	Returns a copy of the calling offset object with n=1 and all other attributes equal.
<i>cbday_roll</i>	Define default roll function to be called in apply method.
<i>month_roll</i>	Define default roll function to be called in apply method.
<i>offset</i>	Alias for self._offset.

### pandas.tseries.offsets.CustomBusinessMonthBegin.base

**property** CustomBusinessMonthBegin.**base**

Returns a copy of the calling offset object with n=1 and all other attributes equal.

**pandas.tseries.offsets.CustomBusinessMonthBegin.cbdays\_roll**`CustomBusinessMonthBegin.cbdays_roll`

Define default roll function to be called in apply method.

**pandas.tseries.offsets.CustomBusinessMonthBegin.month\_roll**`CustomBusinessMonthBegin.month_roll`

Define default roll function to be called in apply method.

**pandas.tseries.offsets.CustomBusinessMonthBegin.offset****property** `CustomBusinessMonthBegin.offset`Alias for `self._offset`.

<b>freqstr</b>	
<b>kwds</b>	
<b>m_offset</b>	
<b>name</b>	
<b>nanos</b>	
<b>rule_code</b>	

**Methods**

<code>apply_index(self, other)</code>	Vectorized apply of DateOffset to DatetimeIndex, raises NotImplementedError for offsets without a vectorized implementation.
<code>rollback(self, dt)</code>	Roll provided date backward to next offset only if not on offset.
<code>rollforward(self, dt)</code>	Roll provided date forward to next offset only if not on offset.

**pandas.tseries.offsets.CustomBusinessMonthBegin.apply\_index**`CustomBusinessMonthBegin.apply_index` (*self, other*)

Vectorized apply of DateOffset to DatetimeIndex, raises NotImplementedError for offsets without a vectorized implementation.

**Parameters****i** [DatetimeIndex]**Returns****y** [DatetimeIndex]

### **pandas.tseries.offsets.CustomBusinessMonthBegin.rollback**

`CustomBusinessMonthBegin.rollback` (*self*, *dt*)

Roll provided date backward to next offset only if not on offset.

#### **Returns**

**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

### **pandas.tseries.offsets.CustomBusinessMonthBegin.rollforward**

`CustomBusinessMonthBegin.rollforward` (*self*, *dt*)

Roll provided date forward to next offset only if not on offset.

#### **Returns**

**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

CustomBusinessMonthBegin.**is\_on\_offset** (*self*, *dt*)

### 4.8.13 SemiMonthOffset

*SemiMonthOffset*([*n*, *normalize*, *day\_of\_month*])

#### Attributes

---

**pandas.tseries.offsets.SemiMonthOffset**

```
class pandas.tseries.offsets.SemiMonthOffset (n=1, normalize=False,  
                                              day_of_month=None)
```

## Attributes

*base* Returns a copy of the calling offset object with `n=1` and all other attributes equal.

---

### pandas.tseries.offsets.SemiMonthOffset.base

**property** `SemiMonthOffset.base`

Returns a copy of the calling offset object with `n=1` and all other attributes equal.

<b>freqstr</b>	
<b>kwds</b>	
<b>name</b>	
<b>nanos</b>	
<b>rule_code</b>	

## Methods

*rollback*(self, dt) Roll provided date backward to next offset only if not on offset.

---

*rollforward*(self, dt) Roll provided date forward to next offset only if not on offset.

---

### pandas.tseries.offsets.SemiMonthOffset.rollback

`SemiMonthOffset.rollback`(self, dt)

Roll provided date backward to next offset only if not on offset.

**Returns**

**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

### pandas.tseries.offsets.SemiMonthOffset.rollforward

`SemiMonthOffset.rollforward`(self, dt)

Roll provided date forward to next offset only if not on offset.

**Returns**

**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

---

*SemiMonthOffset.is\_on\_offset(self, dt)*

---

#### **pandas.tseries.offsets.SemiMonthOffset.apply**

`SemiMonthOffset.apply(self, other)`

#### **pandas.tseries.offsets.SemiMonthOffset.apply\_index**

`SemiMonthOffset.apply_index(self, other)`

#### **pandas.tseries.offsets.SemiMonthOffset.copy**

`SemiMonthOffset.copy(self)`

#### **pandas.tseries.offsets.SemiMonthOffset.isAnchored**

`SemiMonthOffset.isAnchored(self)`

#### **pandas.tseries.offsets.SemiMonthOffset.onOffset**

`SemiMonthOffset.onOffset(self, dt)`

#### **pandas.tseries.offsets.SemiMonthOffset.is\_anchored**

`SemiMonthOffset.is_anchored(self)`

#### **pandas.tseries.offsets.SemiMonthOffset.is\_on\_offset**

`SemiMonthOffset.is_on_offset(self, dt)`

### **4.8.14 SemiMonthEnd**

`SemiMonthEnd([n, normalize, day_of_month])`

Two DateOffset's per month repeating on the last day of the month and `day_of_month`.

---

#### **pandas.tseries.offsets.SemiMonthEnd**

**class** `pandas.tseries.offsets.SemiMonthEnd` (*n=1, normalize=False, day\_of\_month=None*)

Two DateOffset's per month repeating on the last day of the month and `day_of_month`.

##### **Parameters**

**n** [int]

**normalize** [bool, default False]

**day\_of\_month** [int, {1, 3, ..., 27}, default 15]

## Attributes

*base* Returns a copy of the calling offset object with n=1 and all other attributes equal.

---

### pandas.tseries.offsets.SemiMonthEnd.base

**property** `SemiMonthEnd.base`

Returns a copy of the calling offset object with n=1 and all other attributes equal.

<b>freqstr</b>	
<b>kwds</b>	
<b>name</b>	
<b>nanos</b>	
<b>rule_code</b>	

## Methods

*rollback*(self, dt) Roll provided date backward to next offset only if not on offset.

---

*rollforward*(self, dt) Roll provided date forward to next offset only if not on offset.

---

### pandas.tseries.offsets.SemiMonthEnd.rollback

`SemiMonthEnd.rollback` (*self*, *dt*)

Roll provided date backward to next offset only if not on offset.

#### Returns

**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

### pandas.tseries.offsets.SemiMonthEnd.rollforward

`SemiMonthEnd.rollforward` (*self*, *dt*)

Roll provided date forward to next offset only if not on offset.

#### Returns

**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

`Week.copy` (*self*)

### **pandas.tseries.offsets.Week.isAnchored**

`Week.isAnchored` (*self*)

### **pandas.tseries.offsets.Week.onOffset**

`Week.onOffset` (*self*, *dt*)

### **pandas.tseries.offsets.Week.is\_anchored**

`Week.is_anchored` (*self*)

### **pandas.tseries.offsets.Week.is\_on\_offset**

`Week.is_on_offset` (*self*, *dt*)

## **4.8.17 WeekOfMonth**

*WeekOfMonth*(*n*, *normalize*, *week*, *weekday*)

Describes monthly dates like “the Tuesday of the 2nd week of each month”.

---

### **pandas.tseries.offsets.WeekOfMonth**

**class** `pandas.tseries.offsets.WeekOfMonth` (*n=1*, *normalize=False*, *week=0*, *weekday=0*)

Describes monthly dates like “the Tuesday of the 2nd week of each month”.

#### **Parameters**

**n** [int]

**week** [int {0, 1, 2, 3, ...}, default 0] A specific integer for the week of the month. e.g. 0 is 1st week of month, 1 is the 2nd week, etc.

**weekday** [int {0, 1, ..., 6}, default 0] A specific integer for the day of the week.

- 0 is Monday

- 1 is Tuesday
- 2 is Wednesday
- 3 is Thursday
- 4 is Friday
- 5 is Saturday
- 6 is Sunday.

### Attributes

*base* Returns a copy of the calling offset object with n=1 and all other attributes equal.

---

### pandas.tseries.offsets.WeekOfMonth.base

#### property WeekOfMonth.base

Returns a copy of the calling offset object with n=1 and all other attributes equal.

### Methods

*apply\_index*(self, other) Vectorized apply of DateOffset to DatetimeIndex, raises NotImplementedError for offsets without a vectorized implementation.

---

*rollback*(self, dt) Roll provided date backward to next offset only if not on offset.

---

*rollforward*(self, dt) Roll provided date forward to next offset only if not on offset.

---

### pandas.tseries.offsets.WeekOfMonth.apply\_index

#### WeekOfMonth.apply\_index (self, other)

Vectorized apply of DateOffset to DatetimeIndex, raises NotImplementedError for offsets without a vectorized implementation.

#### Parameters

**i** [DatetimeIndex]

#### Returns

**y** [DatetimeIndex]

### `pandas.tseries.offsets.WeekOfMonth.rollback`

`WeekOfMonth.rollback` (*self*, *dt*)

Roll provided date backward to next offset only if not on offset.

#### Returns

**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

### `pandas.tseries.offsets.WeekOfMonth.rollforward`

`WeekOfMonth.rollforward` (*self*, *dt*)

Roll provided date forward to next offset only if not on offset.

#### Returns

**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

`WeekOfMonth.is_on_offset` (*self*, *dt*)

## **4.8.18 LastWeekOfMonth**

`LastWeekOfMonth`(*n*, *normalize*, *weekday*)

Describes monthly dates in last week of month like “the last Tuesday of each month”.

---

### **pandas.tseries.offsets.LastWeekOfMonth**

**class** `pandas.tseries.offsets.LastWeekOfMonth` (*n=1*, *normalize=False*, *weekday=0*)  
Describes monthly dates in last week of month like “the last Tuesday of each month”.

#### **Parameters**

**n** [int, default 1]

**weekday** [int {0, 1, ..., 6}, default 0] A specific integer for the day of the week.

- 0 is Monday
- 1 is Tuesday
- 2 is Wednesday
- 3 is Thursday
- 4 is Friday
- 5 is Saturday
- 6 is Sunday.

## Attributes

*base* Returns a copy of the calling offset object with n=1 and all other attributes equal.

---

*rollforward*(self, dt) Roll provided date forward to next offset only if not on offset.

---

### pandas.tseries.offsets.LastWeekOfMonth.apply\_index

LastWeekOfMonth.**apply\_index** (*self, other*)

Vectorized apply of DateOffset to DatetimeIndex, raises NotImplementedError for offsets without a vectorized implementation.

**Parameters**

**i** [DatetimeIndex]

**Returns**

**y** [DatetimeIndex]

### `pandas.tseries.offsets.LastWeekOfMonth.rollback`

`LastWeekOfMonth.rollback` (*self*, *dt*)

Roll provided date backward to next offset only if not on offset.

#### Returns

**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

### `pandas.tseries.offsets.LastWeekOfMonth.rollforward`

`LastWeekOfMonth.rollforward` (*self*, *dt*)

Roll provided date forward to next offset only if not on offset.

#### Returns

**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

Roll provided date backward to next offset only if not on offset.

**Returns**

**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

### pandas.tseries.offsets.BYearBegin.rollforward

`BYearBegin.rollforward` (*self*, *dt*)

Roll provided date forward to next offset only if not on offset.

**Returns**

**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

`YearBegin.is_on_offset` (*self*, *dt*)

## **4.8.29 FY5253**

---

`FY5253`(*n*, *normalize*, *weekday*, ...)

Describes 52-53 week fiscal year.

---

### **pandas.tseries.offsets.FY5253**

**class** `pandas.tseries.offsets.FY5253` (*n=1*, *normalize=False*, *weekday=0*, *startingMonth=1*,  
*variation='nearest'*)

Describes 52-53 week fiscal year. This is also known as a 4-4-5 calendar.

It is used by companies that desire that their fiscal year always end on the same day of the week.

It is a method of managing accounting periods. It is a common calendar structure for some industries, such as retail, manufacturing and parking industry.

For more information see: [http://en.wikipedia.org/wiki/4-4-5\\_calendar](http://en.wikipedia.org/wiki/4-4-5_calendar)

The year may either:

- end on the last X day of the Y month.

- end on the last X day closest to the last day of the Y month. X is a specific day of the week. Y is a certain month of the year

**Parameters**

**n** [int]

**weekday** [int {0, 1, ..., 6}, default 0] A specific integer for the day of the week.

- 0 is Monday
- 1 is Tuesday
- 2 is Wednesday
- 3 is Thursday
- 4 is Friday
- 5 is Saturday
- 6 is Sunday.

**startingMonth** [int {1, 2, ..., 12}, default 1] The month in which the fiscal year ends.

**variation** [str, default “nearest”] Method of employing 4-4-5 calendar.

There are two options:

- “nearest” means year end is **weekday** closest to last day of month in year.
- “last” means year end is final **weekday** of the final month in fiscal year.

**Attributes**

*base*

Returns a copy of the calling offset object with n=1 and all other attributes equal.

---

**pandas.tseries.offsets.FY5253.base**

**property** `FY5253.base`

Returns a copy of the calling offset object with n=1 and all other attributes equal.

<b>freqstr</b>	
<b>kwds</b>	
<b>name</b>	
<b>nanos</b>	
<b>rule_code</b>	

## Methods

<code>apply_index(self, other)</code>	Vectorized apply of DateOffset to DatetimeIndex, raises NotImplementedError for offsets without a vectorized implementation.
<code>rollback(self, dt)</code>	Roll provided date backward to next offset only if not on offset.
<code>rollforward(self, dt)</code>	Roll provided date forward to next offset only if not on offset.

### pandas.tseries.offsets.FY5253.apply\_index

`FY5253.apply_index(self, other)`

Vectorized apply of DateOffset to DatetimeIndex, raises NotImplementedError for offsets without a vectorized implementation.

#### Parameters

**i** [DatetimeIndex]

#### Returns

**y** [DatetimeIndex]

### pandas.tseries.offsets.FY5253.rollback

`FY5253.rollback(self, dt)`

Roll provided date backward to next offset only if not on offset.

#### Returns

**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

### pandas.tseries.offsets.FY5253.rollforward

`FY5253.rollforward(self, dt)`

Roll provided date forward to next offset only if not on offset.

#### Returns

**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

`FY5253.is_on_offset` (*self*, *dt*)

## **4.8.30 FY5253Quarter**

`FY5253Quarter`(*n*, *normalize*, *weekday*, ...)

DateOffset increments between business quarter dates for 52-53 week fiscal year (also known as a 4-4-5 calendar).

---

## pandas.tseries.offsets.FY5253Quarter

**class** pandas.tseries.offsets.FY5253Quarter (*n=1, normalize=False, weekday=0, startingMonth=1, qtr\_with\_extra\_week=1, variation='nearest'*)

DateOffset increments between business quarter dates for 52-53 week fiscal year (also known as a 4-4-5 calendar).

It is used by companies that desire that their fiscal year always end on the same day of the week.

It is a method of managing accounting periods. It is a common calendar structure for some industries, such as retail, manufacturing and parking industry.

For more information see: [http://en.wikipedia.org/wiki/4-4-5\\_calendar](http://en.wikipedia.org/wiki/4-4-5_calendar)

The year may either:

- end on the last X day of the Y month.
- end on the last X day closest to the last day of the Y month.

X is a specific day of the week. Y is a certain month of the year

startingMonth = 1 corresponds to dates like 1/31/2007, 4/30/2007, ... startingMonth = 2 corresponds to dates like 2/28/2007, 5/31/2007, ... startingMonth = 3 corresponds to dates like 3/30/2007, 6/29/2007, ...

### Parameters

**n** [int]

**weekday** [int {0, 1, ..., 6}, default 0] A specific integer for the day of the week.

- 0 is Monday
- 1 is Tuesday
- 2 is Wednesday
- 3 is Thursday
- 4 is Friday
- 5 is Saturday
- 6 is Sunday.

**startingMonth** [int {1, 2, ..., 12}, default 1] The month in which fiscal years end.

**qtr\_with\_extra\_week** [int {1, 2, 3, 4}, default 1] The quarter number that has the leap or 14 week when needed.

**variation** [str, default "nearest"] Method of employing 4-4-5 calendar.

There are two options:

- "nearest" means year end is **weekday** closest to last day of month in year.
- "last" means year end is final **weekday** of the final month in fiscal year.

## Attributes

*base* Returns a copy of the calling offset object with `n=1` and all other attributes equal.

---

### `pandas.tseries.offsets.FY5253Quarter.base`

**property** `FY5253Quarter.base`

Returns a copy of the calling offset object with `n=1` and all other attributes equal.

## Methods

*apply\_index*(self, other) Vectorized apply of DateOffset to DatetimeIndex, raises `NotImplementedError` for offsets without a vectorized implementation.

---

*rollback*(self, dt) Roll provided date backward to next offset only if not on offset.

---

*rollforward*(self, dt) Roll provided date forward to next offset only if not on offset.

---

### `pandas.tseries.offsets.FY5253Quarter.apply_index`

`FY5253Quarter.apply_index` (*self*, *other*)

Vectorized apply of DateOffset to DatetimeIndex, raises `NotImplementedError` for offsets without a vectorized implementation.

**Parameters**

**i** [DatetimeIndex]

**Returns**

**y** [DatetimeIndex]

### pandas.tseries.offsets.FY5253Quarter.rollback

`FY5253Quarter.rollback` (*self*, *dt*)

Roll provided date backward to next offset only if not on offset.

#### Returns

**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

### pandas.tseries.offsets.FY5253Quarter.rollforward

`FY5253Quarter.rollforward` (*self*, *dt*)

Roll provided date forward to next offset only if not on offset.

#### Returns

**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

### pandas.tseries.offsets.Easter.apply\_index

#### `Easter.apply_index` (*self, other*)

Vectorized apply of DateOffset to DatetimeIndex, raises NotImplementedError for offsets without a vectorized implementation.

#### Parameters

**i** [DatetimeIndex]

#### Returns

**y** [DatetimeIndex]

### pandas.tseries.offsets.Easter.rollback

`Easter.rollback` (*self*, *dt*)

Roll provided date backward to next offset only if not on offset.

#### Returns

**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

### pandas.tseries.offsets.Easter.rollforward

`Easter.rollforward` (*self*, *dt*)

Roll provided date forward to next offset only if not on offset.

#### Returns

**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

<code>apply_index(self, other)</code>	Vectorized apply of DateOffset to DatetimeIndex, raises NotImplementedError for offsets without a vectorized implementation.
<code>rollback(self, dt)</code>	Roll provided date backward to next offset only if not on offset.
<code>rollforward(self, dt)</code>	Roll provided date forward to next offset only if not on offset.

**pandas.tseries.offsets.Tick.apply**

`Tick.apply(self, other)`

**pandas.tseries.offsets.Tick.apply\_index**

`Tick.apply_index(self, other)`

Vectorized apply of DateOffset to DatetimeIndex, raises NotImplementedError for offsets without a vectorized implementation.

**Parameters**

`i` [DatetimeIndex]

**Returns**

`y` [DatetimeIndex]

### `pandas.tseries.offsets.Tick.rollback`

`Tick.rollback` (*self*, *dt*)

Roll provided date backward to next offset only if not on offset.

#### Returns

**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

### `pandas.tseries.offsets.Tick.rollforward`

`Tick.rollforward` (*self*, *dt*)

Roll provided date forward to next offset only if not on offset.

#### Returns

**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

#### **pandas.tseries.offsets.BMonthBegin.rollforward**

`BMonthBegin.rollforward` (*self*, *dt*)

Roll provided date forward to next offset only if not on offset.

**Returns**

**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

### **4.8.43 CBMonthEnd**

*CBMonthEnd*

alias of `pandas.tseries.offsets.  
CustomBusinessMonthEnd`

---

#### **pandas.tseries.offsets.CBMonthEnd**

`pandas.tseries.offsets.CBMonthEnd`

alias of `pandas.tseries.offsets.CustomBusinessMonthEnd`

## Properties

<code>CBMonthEnd.base</code>	Returns a copy of the calling offset object with <code>n=1</code> and all other attributes equal.
<code>CBMonthEnd.cbday_roll</code>	Define default roll function to be called in apply method.
<code>CBMonthEnd.freqstr</code>	
<code>CBMonthEnd.kwds</code>	
<code>CBMonthEnd.m_offset</code>	
<code>CBMonthEnd.month_roll</code>	Define default roll function to be called in apply method.
<code>CBMonthEnd.name</code>	
<code>CBMonthEnd.nanos</code>	
<code>CBMonthEnd.normalize</code>	
<code>CBMonthEnd.offset</code>	Alias for <code>self._offset</code> .
<code>CBMonthEnd.rule_code</code>	

### **pandas.tseries.offsets.CBMonthEnd.base**

**property** `CBMonthEnd.base`

Returns a copy of the calling offset object with `n=1` and all other attributes equal.

### **pandas.tseries.offsets.CBMonthEnd.cbday\_roll**

`CBMonthEnd.cbday_roll`

Define default roll function to be called in apply method.

### **pandas.tseries.offsets.CBMonthEnd.freqstr**

`CBMonthEnd.freqstr`

### **pandas.tseries.offsets.CBMonthEnd.kwds**

**property** `CBMonthEnd.kwds`

### **pandas.tseries.offsets.CBMonthEnd.m\_offset**

`CBMonthEnd.m_offset`

### **pandas.tseries.offsets.CBMonthEnd.month\_roll**

`CBMonthEnd.month_roll`

Define default roll function to be called in apply method.

### `pandas.tseries.offsets.CBMonthEnd.name`

**property** `CBMonthEnd.name`

### `pandas.tseries.offsets.CBMonthEnd.nanos`

**property** `CBMonthEnd.nanos`

### `pandas.tseries.offsets.CBMonthEnd.normalize`

`CBMonthEnd.normalize = False`

### `pandas.tseries.offsets.CBMonthEnd.offset`

**property** `CBMonthEnd.offset`  
Alias for `self._offset`.

### `pandas.tseries.offsets.CBMonthEnd.rule_code`

**property** `CBMonthEnd.rule_code`

## Methods

<code>CBMonthEnd.apply(self, other)</code>	
<code>CBMonthEnd.apply_index(self, other)</code>	Vectorized apply of DateOffset to DatetimeIndex, raises NotImplementedError for offsets without a vectorized implementation.
<code>CBMonthEnd.copy(self)</code>	
<code>CBMonthEnd.isAnchored(self)</code>	
<code>CBMonthEnd.onOffset(self, dt)</code>	
<code>CBMonthEnd.is_anchored(self)</code>	
<code>CBMonthEnd.is_on_offset(self, dt)</code>	
<code>CBMonthEnd.rollback(self, dt)</code>	Roll provided date backward to next offset only if not on offset.
<code>CBMonthEnd.rollforward(self, dt)</code>	Roll provided date forward to next offset only if not on offset.

### **pandas.tseries.offsets.CBMonthEnd.apply**

CBMonthEnd.**apply** (*self*, *other*)

### **pandas.tseries.offsets.CBMonthEnd.apply\_index**

CBMonthEnd.**apply\_index** (*self*, *other*)

Vectorized apply of DateOffset to DatetimeIndex, raises NotImplementedError for offsets without a vectorized implementation.

#### **Parameters**

**i** [DatetimeIndex]

#### **Returns**

**y** [DatetimeIndex]

### **pandas.tseries.offsets.CBMonthEnd.copy**

CBMonthEnd.**copy** (*self*)

### **pandas.tseries.offsets.CBMonthEnd.isAnchored**

CBMonthEnd.**isAnchored** (*self*)

### **pandas.tseries.offsets.CBMonthEnd.onOffset**

CBMonthEnd.**onOffset** (*self*, *dt*)

### **pandas.tseries.offsets.CBMonthEnd.is\_anchored**

CBMonthEnd.**is\_anchored** (*self*)

### **pandas.tseries.offsets.CBMonthEnd.is\_on\_offset**

CBMonthEnd.**is\_on\_offset** (*self*, *dt*)

### **pandas.tseries.offsets.CBMonthEnd.rollback**

CBMonthEnd.**rollback** (*self*, *dt*)

Roll provided date backward to next offset only if not on offset.

#### **Returns**

**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

## pandas.tseries.offsets.CBMonthEnd.rollforward

CBMonthEnd.**rollforward** (*self*, *dt*)

Roll provided date forward to next offset only if not on offset.

### Returns

**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

## 4.8.44 CBMonthBegin

---

*CBMonthBegin* alias of *pandas.tseries.offsets.CustomBusinessMonthBegin*

---

## pandas.tseries.offsets.CBMonthBegin

pandas.tseries.offsets.**CBMonthBegin**

alias of *pandas.tseries.offsets.CustomBusinessMonthBegin*

### Properties

<i>CBMonthBegin.base</i>	Returns a copy of the calling offset object with n=1 and all other attributes equal.
<i>CBMonthBegin.cbdays_rolloff</i>	Define default roll function to be called in apply method.
<i>CBMonthBegin.freqstr</i>	
<i>CBMonthBegin.kwds</i>	
<i>CBMonthBegin.m_offset</i>	
<i>CBMonthBegin.month_rolloff</i>	Define default roll function to be called in apply method.
<i>CBMonthBegin.name</i>	
<i>CBMonthBegin.nanos</i>	
<i>CBMonthBegin.normalize</i>	
<i>CBMonthBegin.offset</i>	Alias for self._offset.
<i>CBMonthBegin.rule_code</i>	

## pandas.tseries.offsets.CBMonthBegin.base

**property** *CBMonthBegin.base*

Returns a copy of the calling offset object with n=1 and all other attributes equal.

**pandas.tseries.offsets.CBMonthBegin.cbday\_roll**

`CBMonthBegin.cbday_roll`

Define default roll function to be called in apply method.

**pandas.tseries.offsets.CBMonthBegin.freqstr**

`CBMonthBegin.freqstr`

**pandas.tseries.offsets.CBMonthBegin.kwds**

**property** `CBMonthBegin.kwds`

**pandas.tseries.offsets.CBMonthBegin.m\_offset**

`CBMonthBegin.m_offset`

**pandas.tseries.offsets.CBMonthBegin.month\_roll**

`CBMonthBegin.month_roll`

Define default roll function to be called in apply method.

**pandas.tseries.offsets.CBMonthBegin.name**

**property** `CBMonthBegin.name`

**pandas.tseries.offsets.CBMonthBegin.nanos**

**property** `CBMonthBegin.nanos`

**pandas.tseries.offsets.CBMonthBegin.normalize**

`CBMonthBegin.normalize = False`

**pandas.tseries.offsets.CBMonthBegin.offset**

**property** `CBMonthBegin.offset`

Alias for `self._offset`.

## pandas.tseries.offsets.CBMonthBegin.rule\_code

**property** CBMonthBegin.rule\_code

## Methods

<i>CBMonthBegin.apply</i> (self, other)	
<i>CBMonthBegin.apply_index</i> (self, other)	Vectorized apply of DateOffset to DatetimeIndex, raises NotImplementedError for offsets without a vectorized implementation.
<i>CBMonthBegin.copy</i> (self)	
<i>CBMonthBegin.isAnchored</i> (self)	
<i>CBMonthBegin.onOffset</i> (self, dt)	
<i>CBMonthBegin.is_anchored</i> (self)	
<i>CBMonthBegin.is_on_offset</i> (self, dt)	
<i>CBMonthBegin.rollback</i> (self, dt)	Roll provided date backward to next offset only if not on offset.
<i>CBMonthBegin.rollforward</i> (self, dt)	Roll provided date forward to next offset only if not on offset.

## pandas.tseries.offsets.CBMonthBegin.apply

CBMonthBegin.**apply** (*self*, *other*)

## pandas.tseries.offsets.CBMonthBegin.apply\_index

CBMonthBegin.**apply\_index** (*self*, *other*)

Vectorized apply of DateOffset to DatetimeIndex, raises NotImplementedError for offsets without a vectorized implementation.

### Parameters

**i** [DatetimeIndex]

### Returns

**y** [DatetimeIndex]

## pandas.tseries.offsets.CBMonthBegin.copy

CBMonthBegin.**copy** (*self*)

#### **pandas.tseries.offsets.CBMonthBegin.isAnchored**

`CBMonthBegin.isAnchored` (*self*)

#### **pandas.tseries.offsets.CBMonthBegin.onOffset**

`CBMonthBegin.onOffset` (*self*, *dt*)

#### **pandas.tseries.offsets.CBMonthBegin.is\_anchored**

`CBMonthBegin.is_anchored` (*self*)

#### **pandas.tseries.offsets.CBMonthBegin.is\_on\_offset**

`CBMonthBegin.is_on_offset` (*self*, *dt*)

#### **pandas.tseries.offsets.CBMonthBegin.rollback**

`CBMonthBegin.rollback` (*self*, *dt*)

Roll provided date backward to next offset only if not on offset.

**Returns**

**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

#### **pandas.tseries.offsets.CBMonthBegin.rollforward**

`CBMonthBegin.rollforward` (*self*, *dt*)

Roll provided date forward to next offset only if not on offset.

**Returns**

**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

### **4.8.45 CDay**

*CDay*

alias of `pandas.tseries.offsets.CustomBusinessDay`

---

## pandas.tseries.offsets.CDay

pandas.tseries.offsets.CDay

alias of `pandas.tseries.offsets.CustomBusinessDay`

### Properties

<code>CDay.base</code>	Returns a copy of the calling offset object with <code>n=1</code> and all other attributes equal.
<code>CDay.freqstr</code>	
<code>CDay.kwds</code>	
<code>CDay.name</code>	
<code>CDay.nanos</code>	
<code>CDay.normalize</code>	
<code>CDay.offset</code>	Alias for <code>self._offset</code> .
<code>CDay.rule_code</code>	

## pandas.tseries.offsets.CDay.base

**property** `CDay.base`

Returns a copy of the calling offset object with `n=1` and all other attributes equal.

## pandas.tseries.offsets.CDay.freqstr

`CDay.freqstr`

## pandas.tseries.offsets.CDay.kwds

**property** `CDay.kwds`

## pandas.tseries.offsets.CDay.name

**property** `CDay.name`

## pandas.tseries.offsets.CDay.nanos

**property** `CDay.nanos`

**pandas.tseries.offsets.CDay.normalize**`CDay.normalize = False`**pandas.tseries.offsets.CDay.offset**

**property** `CDay.offset`  
Alias for `self._offset`.

**pandas.tseries.offsets.CDay.rule\_code**

**property** `CDay.rule_code`

**Methods**

<code>CDay.apply(self, other)</code>	
<code>CDay.apply_index(self, i)</code>	Vectorized apply of DateOffset to DatetimeIndex, raises NotImplementedError for offsets without a vectorized implementation.
<code>CDay.copy(self)</code>	
<code>CDay.isAnchored(self)</code>	
<code>CDay.onOffset(self, dt)</code>	
<code>CDay.is_anchored(self)</code>	
<code>CDay.is_on_offset(self, dt)</code>	
<code>CDay.rollback(self, dt)</code>	Roll provided date backward to next offset only if not on offset.
<code>CDay.rollforward(self, dt)</code>	Roll provided date forward to next offset only if not on offset.

**pandas.tseries.offsets.CDay.apply**`CDay.apply(self, other)`**pandas.tseries.offsets.CDay.apply\_index**`CDay.apply_index(self, i)`

Vectorized apply of DateOffset to DatetimeIndex, raises NotImplementedError for offsets without a vectorized implementation.

**Parameters**

**i** [DatetimeIndex]

**Returns**

**y** [DatetimeIndex]

### pandas.tseries.offsets.CDay.copy

`CDay.copy` (*self*)

### pandas.tseries.offsets.CDay.isAnchored

`CDay.isAnchored` (*self*)

### pandas.tseries.offsets.CDay.onOffset

`CDay.onOffset` (*self*, *dt*)

### pandas.tseries.offsets.CDay.is\_anchored

`CDay.is_anchored` (*self*)

### pandas.tseries.offsets.CDay.is\_on\_offset

`CDay.is_on_offset` (*self*, *dt*)

### pandas.tseries.offsets.CDay.rollback

`CDay.rollback` (*self*, *dt*)

Roll provided date backward to next offset only if not on offset.

**Returns**

**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

### pandas.tseries.offsets.CDay.rollforward

`CDay.rollforward` (*self*, *dt*)

Roll provided date forward to next offset only if not on offset.

**Returns**

**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

## 4.9 Frequencies

`to_offset`(freq)

Return DateOffset object from string or tuple representation or datetime.timedelta object.

---

### 4.9.1 pandas.tseries.frequencies.to\_offset

`pandas.tseries.frequencies.to_offset(freq)` → Union[pandas.tseries.offsets.DateOffset, NoneType]

Return DateOffset object from string or tuple representation or datetime.timedelta object.

#### Parameters

**freq** [str, tuple, datetime.timedelta, DateOffset or None]

#### Returns

**DateOffset** None if freq is None.

#### Raises

**ValueError** If freq is an invalid frequency

#### See also:

#### DateOffset

#### Examples

```
>>> to_offset('5min')
<5 * Minutes>
```

```
>>> to_offset('1D1H')
<25 * Hours>
```

```
>>> to_offset(('W', 2))
<2 * Weeks: weekday=6>
```

```
>>> to_offset((2, 'B'))
<2 * BusinessDays>
```

```
>>> to_offset(datetime.timedelta(days=1))
<Day>
```

```
>>> to_offset(Hour())
<Hour>
```

{{ header }}

## 4.10 Window

Rolling objects are returned by `.rolling` calls: `pandas.DataFrame.rolling()`, `pandas.Series.rolling()`, etc. Expanding objects are returned by `.expanding` calls: `pandas.DataFrame.expanding()`, `pandas.Series.expanding()`, etc. EWM objects are returned by `.ewm` calls: `pandas.DataFrame.ewm()`, `pandas.Series.ewm()`, etc.

### 4.10.1 Standard moving window functions

<code>Rolling.count(self)</code>	The rolling count of any non-NaN observations inside the window.
<code>Rolling.sum(self, *args, **kwargs)</code>	Calculate rolling sum of given DataFrame or Series.
<code>Rolling.mean(self, *args, **kwargs)</code>	Calculate the rolling mean of the values.
<code>Rolling.median(self, **kwargs)</code>	Calculate the rolling median.
<code>Rolling.var(self, ddof)</code>	Calculate unbiased rolling variance.
<code>Rolling.std(self, ddof)</code>	Calculate rolling standard deviation.
<code>Rolling.min(self, *args, **kwargs)</code>	Calculate the rolling minimum.
<code>Rolling.max(self, *args, **kwargs)</code>	Calculate the rolling maximum.
<code>Rolling.corr(self[, other, pairwise])</code>	Calculate rolling correlation.
<code>Rolling.cov(self[, other, pairwise, ddof])</code>	Calculate the rolling sample covariance.
<code>Rolling.skew(self, **kwargs)</code>	Unbiased rolling skewness.
<code>Rolling.kurt(self, **kwargs)</code>	Calculate unbiased rolling kurtosis.
<code>Rolling.apply(self, func[, raw, engine, ...])</code>	The rolling function's apply function.
<code>Rolling.aggregate(self, func, *args, **kwargs)</code>	Aggregate using one or more operations over the specified axis.
<code>Rolling.quantile(self, quantile[, interpolation])</code>	Calculate the rolling quantile.
<code>Window.mean(self, *args, **kwargs)</code>	Calculate the window mean of the values.
<code>Window.sum(self, *args, **kwargs)</code>	Calculate window sum of given DataFrame or Series.
<code>Window.var(self, ddof)</code>	Calculate unbiased window variance.
<code>Window.std(self, ddof)</code>	Calculate window standard deviation.

#### pandas.core.window.rolling.Rolling.count

`Rolling.count` (*self*)

The rolling count of any non-NaN observations inside the window.

##### Returns

**Series or DataFrame** Returned object type is determined by the caller of the rolling calculation.

##### See also:

**Series.rolling** Calling object with Series data.

**DataFrame.rolling** Calling object with DataFrames.

**DataFrame.count** Count of the full DataFrame.

##### Examples

```
>>> s = pd.Series([2, 3, np.nan, 10])
>>> s.rolling(2).count()
0    1.0
1    2.0
2    1.0
3    1.0
dtype: float64
>>> s.rolling(3).count()
0    1.0
1    2.0
2    2.0
3    2.0
```

(continues on next page)

(continued from previous page)

```
dtype: float64
>>> s.rolling(4).count()
0    1.0
1    2.0
2    2.0
3    3.0
dtype: float64
```

### pandas.core.window.rolling.Rolling.sum

Rolling.**sum**(*self*, \*args, \*\*kwargs)

Calculate rolling sum of given DataFrame or Series.

#### Parameters

**\*args, \*\*kwargs** For compatibility with other rolling methods. Has no effect on the computed value.

#### Returns

**Series or DataFrame** Same type as the input, with the same index, containing the rolling sum.

#### See also:

**Series.sum** Reducing sum for Series.

**DataFrame.sum** Reducing sum for DataFrame.

### Examples

```
>>> s = pd.Series([1, 2, 3, 4, 5])
>>> s
0    1
1    2
2    3
3    4
4    5
dtype: int64
```

```
>>> s.rolling(3).sum()
0    NaN
1    NaN
2    6.0
3    9.0
4   12.0
dtype: float64
```

```
>>> s.expanding(3).sum()
0    NaN
1    NaN
2    6.0
3   10.0
4   15.0
dtype: float64
```

```
>>> s.rolling(3, center=True).sum()
0      NaN
1      6.0
2      9.0
3     12.0
4      NaN
dtype: float64
```

For DataFrame, each rolling sum is computed column-wise.

```
>>> df = pd.DataFrame({"A": s, "B": s ** 2})
>>> df
   A  B
0  1  1
1  2  4
2  3  9
3  4 16
4  5 25
```

```
>>> df.rolling(3).sum()
   A    B
0  NaN  NaN
1  NaN  NaN
2  6.0 14.0
3  9.0 29.0
4 12.0 50.0
```

### pandas.core.window.rolling.Rolling.mean

Rolling.**mean** (*self*, \*args, \*\*kwargs)

Calculate the rolling mean of the values.

#### Parameters

**\*args** Under Review.

**\*\*kwargs** Under Review.

#### Returns

**Series or DataFrame** Returned object type is determined by the caller of the rolling calculation.

#### See also:

**Series.rolling** Calling object with Series data.

**DataFrame.rolling** Calling object with DataFrames.

**Series.mean** Equivalent method for Series.

**DataFrame.mean** Equivalent method for DataFrame.

## Examples

The below examples will show rolling mean calculations with window sizes of two and three, respectively.

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s.rolling(2).mean()
0    NaN
1    1.5
2    2.5
3    3.5
dtype: float64
```

```
>>> s.rolling(3).mean()
0    NaN
1    NaN
2    2.0
3    3.0
dtype: float64
```

## pandas.core.window.rolling.Rolling.median

Rolling.**median** (*self*, *\*\*kwargs*)

Calculate the rolling median.

### Parameters

**\*\*kwargs** For compatibility with other rolling methods. Has no effect on the computed median.

### Returns

**Series or DataFrame** Returned type is the same as the original object.

**See also:**

**Series.rolling** Calling object with Series data.

**DataFrame.rolling** Calling object with DataFrames.

**Series.median** Equivalent method for Series.

**DataFrame.median** Equivalent method for DataFrame.

## Examples

Compute the rolling median of a series with a window size of 3.

```
>>> s = pd.Series([0, 1, 2, 3, 4])
>>> s.rolling(3).median()
0    NaN
1    NaN
2    1.0
3    2.0
4    3.0
dtype: float64
```

## pandas.core.window.rolling.Rolling.var

`Rolling.var` (*self*, *ddof=1*, \*args, \*\*kwargs)

Calculate unbiased rolling variance.

Normalized by N-1 by default. This can be changed using the *ddof* argument.

### Parameters

**ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is  $N - \text{ddof}$ , where  $N$  represents the number of elements.

**\*args, \*\*kwargs** For NumPy compatibility. No additional arguments are used.

### Returns

**Series or DataFrame** Returns the same object type as the caller of the rolling calculation.

### See also:

**Series.rolling** Calling object with Series data.

**DataFrame.rolling** Calling object with DataFrames.

**Series.var** Equivalent method for Series.

**DataFrame.var** Equivalent method for DataFrame.

**numpy.var** Equivalent method for Numpy array.

### Notes

The default *ddof* of 1 used in `Series.var()` is different than the default *ddof* of 0 in `numpy.var()`.

A minimum of 1 period is required for the rolling calculation.

### Examples

```
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
>>> s.rolling(3).var()
0      NaN
1      NaN
2    0.333333
3    1.000000
4    1.000000
5    1.333333
6    0.000000
dtype: float64
```

```
>>> s.expanding(3).var()
0      NaN
1      NaN
2    0.333333
3    0.916667
4    0.800000
5    0.700000
6    0.619048
dtype: float64
```

**pandas.core.window.rolling.Rolling.std**

`Rolling.std` (*self*, *ddof=1*, \*args, \*\*kwargs)

Calculate rolling standard deviation.

Normalized by N-1 by default. This can be changed using the *ddof* argument.

**Parameters**

**ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is  $N - \text{ddof}$ , where  $N$  represents the number of elements.

**\*args, \*\*kwargs** For NumPy compatibility. No additional arguments are used.

**Returns**

**Series or DataFrame** Returns the same object type as the caller of the rolling calculation.

**See also:**

**Series.rolling** Calling object with Series data.

**DataFrame.rolling** Calling object with DataFrames.

**Series.std** Equivalent method for Series.

**DataFrame.std** Equivalent method for DataFrame.

**numpy.std** Equivalent method for Numpy array.

**Notes**

The default *ddof* of 1 used in `Series.std` is different than the default *ddof* of 0 in `numpy.std`.

A minimum of one period is required for the rolling calculation.

**Examples**

```
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
>>> s.rolling(3).std()
0      NaN
1      NaN
2    0.577350
3    1.000000
4    1.000000
5    1.154701
6    0.000000
dtype: float64
```

```
>>> s.expanding(3).std()
0      NaN
1      NaN
2    0.577350
3    0.957427
4    0.894427
5    0.836660
6    0.786796
dtype: float64
```

### pandas.core.window.rolling.Rolling.min

Rolling.**min**(*self*, \*args, \*\*kwargs)

Calculate the rolling minimum.

#### Parameters

**\*\*kwargs** Under Review.

#### Returns

**Series or DataFrame** Returned object type is determined by the caller of the rolling calculation.

#### See also:

**Series.rolling** Calling object with a Series.

**DataFrame.rolling** Calling object with a DataFrame.

**Series.min** Similar method for Series.

**DataFrame.min** Similar method for DataFrame.

### Examples

Performing a rolling minimum with a window size of 3.

```
>>> s = pd.Series([4, 3, 5, 2, 6])
>>> s.rolling(3).min()
0    NaN
1    NaN
2    3.0
3    2.0
4    2.0
dtype: float64
```

### pandas.core.window.rolling.Rolling.max

Rolling.**max**(*self*, \*args, \*\*kwargs)

Calculate the rolling maximum.

#### Parameters

**\*args, \*\*kwargs** Arguments and keyword arguments to be passed into func.

#### Returns

**Series or DataFrame** Return type is determined by the caller.

#### See also:

**Series.rolling** Series rolling.

**DataFrame.rolling** DataFrame rolling.

**pandas.core.window.rolling.Rolling.corr**

`Rolling.corr` (*self*, *other=None*, *pairwise=None*, *\*\*kwargs*)

Calculate rolling correlation.

**Parameters**

**other** [Series, DataFrame, or ndarray, optional] If not supplied then will default to *self*.

**pairwise** [bool, default None] Calculate pairwise combinations of columns within a DataFrame. If *other* is not specified, defaults to *True*, otherwise defaults to *False*. Not relevant for *Series*.

**\*\*kwargs** Unused.

**Returns**

**Series or DataFrame** Returned object type is determined by the caller of the rolling calculation.

**See also:**

**Series.rolling** Calling object with Series data.

**DataFrame.rolling** Calling object with DataFrames.

**Series.corr** Equivalent method for Series.

**DataFrame.corr** Equivalent method for DataFrame.

**rolling.cov** Similar method to calculate covariance.

**numpy.corrcoef** NumPy Pearson's correlation calculation.

**Notes**

This function uses Pearson's definition of correlation ([https://en.wikipedia.org/wiki/Pearson\\_correlation\\_coefficient](https://en.wikipedia.org/wiki/Pearson_correlation_coefficient)).

When *other* is not specified, the output will be self correlation (e.g. all 1's), except for *DataFrame* inputs with *pairwise* set to *True*.

Function will return NaN for correlations of equal valued sequences; this is the result of a 0/0 division error.

When *pairwise* is set to *False*, only matching columns between *self* and *other* will be used.

When *pairwise* is set to *True*, the output will be a MultiIndex DataFrame with the original index on the first level, and the *other* DataFrame columns on the second level.

In the case of missing elements, only complete pairwise observations will be used.

**Examples**

The below example shows a rolling calculation with a window size of four matching the equivalent function call using `numpy.corrcoef()`.

```
>>> v1 = [3, 3, 3, 5, 8]
>>> v2 = [3, 4, 4, 4, 8]
>>> # numpy returns a 2X2 array, the correlation coefficient
>>> # is the number at entry [0][1]
>>> print(f"{np.corrcoef(v1[:-1], v2[:-1])[0][1]:.6f}")
0.333333
>>> print(f"{np.corrcoef(v1[1:], v2[1:])[0][1]:.6f}")
0.916949
>>> s1 = pd.Series(v1)
```

(continues on next page)

(continued from previous page)

```

>>> s2 = pd.Series(v2)
>>> s1.rolling(4).corr(s2)
0      NaN
1      NaN
2      NaN
3    0.333333
4    0.916949
dtype: float64

```

The below example shows a similar rolling calculation on a DataFrame using the pairwise option.

```

>>> matrix = np.array([[51., 35.], [49., 30.], [47., 32.], [46., 31.], [50.,
↳36.]])
>>> print(np.corrcoef(matrix[:-1,0], matrix[:-1,1]).round(7))
[[1.      0.6263001]
 [0.6263001 1.      ]]
>>> print(np.corrcoef(matrix[1:,0], matrix[1:,1]).round(7))
[[1.      0.5553681]
 [0.5553681 1.      ]]
>>> df = pd.DataFrame(matrix, columns=['X', 'Y'])
>>> df
   X    Y
0 51.0 35.0
1 49.0 30.0
2 47.0 32.0
3 46.0 31.0
4 50.0 36.0
>>> df.rolling(4).corr(pairwise=True)
   X      Y
0 X   NaN  NaN
  Y   NaN  NaN
1 X   NaN  NaN
  Y   NaN  NaN
2 X   NaN  NaN
  Y   NaN  NaN
3 X  1.000000  0.626300
  Y  0.626300  1.000000
4 X  1.000000  0.555368
  Y  0.555368  1.000000

```

### pandas.core.window.rolling.Rolling.cov

Rolling.cov(*self*, *other=None*, *pairwise=None*, *ddof=1*, *\*\*kwargs*)

Calculate the rolling sample covariance.

#### Parameters

**other** [Series, DataFrame, or ndarray, optional] If not supplied then will default to self and produce pairwise output.

**pairwise** [bool, default None] If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndexed DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.

**ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is  $N -$

$ddof$ , where  $N$  represents the number of elements.

**\*\*kwargs** Keyword arguments to be passed into func.

**Returns**

**Series or DataFrame** Return type is determined by the caller.

**See also:**

**Series.rolling** Series rolling.

**DataFrame.rolling** DataFrame rolling.

### **pandas.core.window.rolling.Rolling.skew**

`Rolling.skew` (*self*, **\*\*kwargs**)

Unbiased rolling skewness.

**Parameters**

**\*\*kwargs** Keyword arguments to be passed into func.

**Returns**

**Series or DataFrame** Return type is determined by the caller.

**See also:**

**Series.rolling** Series rolling.

**DataFrame.rolling** DataFrame rolling.

### **pandas.core.window.rolling.Rolling.kurt**

`Rolling.kurt` (*self*, **\*\*kwargs**)

Calculate unbiased rolling kurtosis.

This function uses Fisher's definition of kurtosis without bias.

**Parameters**

**\*\*kwargs** Under Review.

**Returns**

**Series or DataFrame** Returned object type is determined by the caller of the rolling calculation.

**See also:**

**Series.rolling** Calling object with Series data.

**DataFrame.rolling** Calling object with DataFrames.

**Series.kurt** Equivalent method for Series.

**DataFrame.kurt** Equivalent method for DataFrame.

**scipy.stats.skew** Third moment of a probability density.

**scipy.stats.kurtosis** Reference SciPy method.

## Notes

A minimum of 4 periods is required for the rolling calculation.

## Examples

The example below will show a rolling calculation with a window size of four matching the equivalent function call using `scipy.stats`.

```
>>> arr = [1, 2, 3, 4, 999]
>>> import scipy.stats
>>> print(f"{scipy.stats.kurtosis(arr[:-1], bias=False):.6f}")
-1.200000
>>> print(f"{scipy.stats.kurtosis(arr[1:], bias=False):.6f}")
3.999946
>>> s = pd.Series(arr)
>>> s.rolling(4).kurt()
0      NaN
1      NaN
2      NaN
3    -1.200000
4     3.999946
dtype: float64
```

## pandas.core.window.rolling.Rolling.apply

`Rolling.apply` (*self*, *func*, *raw=False*, *engine='cython'*, *engine\_kwargs=None*, *args=None*, *kwargs=None*)

The rolling function's apply function.

### Parameters

**func** [function] Must produce a single value from an ndarray input if `raw=True` or a single value from a Series if `raw=False`. Can also accept a Numba JIT function with `engine='numba'` specified.

Changed in version 1.0.0.

**raw** [bool, default None]

- `False` : passes each row or column as a Series to the function.
- `True` : the passed function will receive ndarray objects instead. If you are just applying a NumPy reduction function this will achieve much better performance.

**engine** [str, default 'cython']

- `'cython'` : Runs rolling apply through C-extensions from cython.
- `'numba'` : Runs rolling apply through JIT compiled code from numba. Only available when `raw` is set to `True`.

New in version 1.0.0.

**engine\_kwargs** [dict, default None]

- For `'cython'` engine, there are no accepted `engine_kwargs`
- For `'numba'` engine, the engine can accept `nopython`, `nogil` and `parallel` dictionary keys. The values must either be `True` or `False`. The default `engine_kwargs` for the `'numba'` engine is `{'nopython': True,`

'nogil': False, 'parallel': False} and will be applied to both the `func` and the `apply` rolling aggregation.

New in version 1.0.0.

**args** [tuple, default None] Positional arguments to be passed into `func`.

**kwargs** [dict, default None] Keyword arguments to be passed into `func`.

#### Returns

**Series or DataFrame** Return type is determined by the caller.

See also:

**Series.rolling** Series rolling.

**DataFrame.rolling** DataFrame rolling.

#### Notes

See *Rolling Apply* for extended documentation and performance considerations for the Numba engine.

### pandas.core.window.rolling.Rolling.aggregate

`Rolling.aggregate` (*self*, *func*, \**args*, \*\**kwargs*)

Aggregate using one or more operations over the specified axis.

#### Parameters

**func** [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a Series/Dataframe or when passed to Series/Dataframe.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. [`np.sum`, 'mean']
- dict of axis labels -> functions, function names or list of such.

**\*args** Positional arguments to pass to *func*.

**\*\*kwargs** Keyword arguments to pass to *func*.

#### Returns

**scalar, Series or DataFrame** The return can be:

- scalar : when `Series.agg` is called with single function
- Series : when `DataFrame.agg` is called with a single function
- DataFrame : when `DataFrame.agg` is called with several functions

Return scalar, Series or DataFrame.

See also:

**Series.rolling**

**DataFrame.rolling**

## Notes

*agg* is an alias for *aggregate*. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

## Examples

```
>>> df = pd.DataFrame(np.random.randn(10, 3), columns=['A', 'B', 'C'])
>>> df
```

	A	B	C
0	-2.385977	-0.102758	0.438822
1	-1.004295	0.905829	-0.954544
2	0.735167	-0.165272	-1.619346
3	-0.702657	-1.340923	-0.706334
4	-0.246845	0.211596	-0.901819
5	2.463718	3.157577	-1.380906
6	-1.142255	2.340594	-0.039875
7	1.396598	-1.647453	1.677227
8	-0.543425	1.761277	-0.220481
9	-0.640505	0.289374	-1.550670

```
>>> df.rolling(3).sum()
```

	A	B	C
0	NaN	NaN	NaN
1	NaN	NaN	NaN
2	-2.655105	0.637799	-2.135068
3	-0.971785	-0.600366	-3.280224
4	-0.214334	-1.294599	-3.227500
5	1.514216	2.028250	-2.989060
6	1.074618	5.709767	-2.322600
7	2.718061	3.850718	0.256446
8	-0.289082	2.454418	1.416871
9	0.212668	0.403198	-0.093924

```
>>> df.rolling(3).agg({'A': 'sum', 'B': 'min'})
```

	A	B
0	NaN	NaN
1	NaN	NaN
2	-2.655105	-0.165272
3	-0.971785	-1.340923
4	-0.214334	-1.340923
5	1.514216	-1.340923
6	1.074618	0.211596
7	2.718061	-1.647453
8	-0.289082	-1.647453
9	0.212668	-1.647453

**pandas.core.window.rolling.Rolling.quantile**

`Rolling.quantile` (*self*, *quantile*, *interpolation='linear'*, *\*\*kwargs*)

Calculate the rolling quantile.

**Parameters**

**quantile** [float] Quantile to compute.  $0 \leq \text{quantile} \leq 1$ .

**interpolation** [{'linear', 'lower', 'higher', 'midpoint', 'nearest'}] New in version 0.23.0.

This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points  $i$  and  $j$ :

- linear:  $i + (j - i) * \text{fraction}$ , where *fraction* is the fractional part of the index surrounded by  $i$  and  $j$ .
- lower:  $i$ .
- higher:  $j$ .
- nearest:  $i$  or  $j$  whichever is nearest.
- midpoint:  $(i + j) / 2$ .

**\*\*kwargs** For compatibility with other rolling methods. Has no effect on the result.

**Returns**

**Series or DataFrame** Returned object type is determined by the caller of the rolling calculation.

**See also:**

**Series.quantile** Computes value at the given quantile over all data in Series.

**DataFrame.quantile** Computes values at the given quantile over requested axis in DataFrame.

**Examples**

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s.rolling(2).quantile(.4, interpolation='lower')
0    NaN
1    1.0
2    2.0
3    3.0
dtype: float64
```

```
>>> s.rolling(2).quantile(.4, interpolation='midpoint')
0    NaN
1    1.5
2    2.5
3    3.5
dtype: float64
```

### pandas.core.window.rolling.Window.mean

Window.**mean**(*self*, \*args, \*\*kwargs)

Calculate the window mean of the values.

#### Parameters

**\*args** Under Review.

**\*\*kwargs** Under Review.

#### Returns

**Series or DataFrame** Returned object type is determined by the caller of the window calculation.

#### See also:

**Series.window** Calling object with Series data.

**DataFrame.window** Calling object with DataFrames.

**Series.mean** Equivalent method for Series.

**DataFrame.mean** Equivalent method for DataFrame.

### Examples

The below examples will show rolling mean calculations with window sizes of two and three, respectively.

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s.rolling(2).mean()
0    NaN
1    1.5
2    2.5
3    3.5
dtype: float64
```

```
>>> s.rolling(3).mean()
0    NaN
1    NaN
2    2.0
3    3.0
dtype: float64
```

### pandas.core.window.rolling.Window.sum

Window.**sum**(*self*, \*args, \*\*kwargs)

Calculate window sum of given DataFrame or Series.

#### Parameters

**\*args, \*\*kwargs** For compatibility with other window methods. Has no effect on the computed value.

#### Returns

**Series or DataFrame** Same type as the input, with the same index, containing the window sum.

#### See also:

**Series.sum** Reducing sum for Series.

**DataFrame.sum** Reducing sum for DataFrame.

## Examples

```
>>> s = pd.Series([1, 2, 3, 4, 5])
>>> s
0    1
1    2
2    3
3    4
4    5
dtype: int64
```

```
>>> s.rolling(3).sum()
0    NaN
1    NaN
2    6.0
3    9.0
4   12.0
dtype: float64
```

```
>>> s.expanding(3).sum()
0    NaN
1    NaN
2    6.0
3   10.0
4   15.0
dtype: float64
```

```
>>> s.rolling(3, center=True).sum()
0    NaN
1    6.0
2    9.0
3   12.0
4    NaN
dtype: float64
```

For DataFrame, each window sum is computed column-wise.

```
>>> df = pd.DataFrame({"A": s, "B": s ** 2})
>>> df
   A  B
0  1  1
1  2  4
2  3  9
3  4 16
4  5 25
```

```
>>> df.rolling(3).sum()
   A    B
0  NaN  NaN
1  NaN  NaN
2  6.0 14.0
3  9.0 29.0
4 12.0 50.0
```

## pandas.core.window.rolling.Window.var

Window.**var** (*self*, *ddof=1*, \*args, \*\*kwargs)  
Calculate unbiased window variance.

New in version 1.0.0.

Normalized by N-1 by default. This can be changed using the *ddof* argument.

### Parameters

**ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is  $N - \text{ddof}$ , where N represents the number of elements.

**\*args, \*\*kwargs** For NumPy compatibility. No additional arguments are used.

### Returns

**Series or DataFrame** Returns the same object type as the caller of the window calculation.

### See also:

**Series.window** Calling object with Series data.

**DataFrame.window** Calling object with DataFrames.

**Series.var** Equivalent method for Series.

**DataFrame.var** Equivalent method for DataFrame.

**numpy.var** Equivalent method for Numpy array.

### Notes

The default *ddof* of 1 used in `Series.var()` is different than the default *ddof* of 0 in `numpy.var()`.

A minimum of 1 period is required for the rolling calculation.

### Examples

```
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
>>> s.rolling(3).var()
0          NaN
1          NaN
2    0.333333
3    1.000000
4    1.000000
5    1.333333
6    0.000000
dtype: float64
```

```
>>> s.expanding(3).var()
0          NaN
1          NaN
2    0.333333
3    0.916667
4    0.800000
5    0.700000
6    0.619048
dtype: float64
```

**pandas.core.window.rolling.Window.std**

`Window.std` (*self*, *ddof=1*, \*args, \*\*kwargs)

Calculate window standard deviation.

New in version 1.0.0.

Normalized by N-1 by default. This can be changed using the *ddof* argument.

**Parameters**

**ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is  $N - \text{ddof}$ , where  $N$  represents the number of elements.

**\*args, \*\*kwargs** For NumPy compatibility. No additional arguments are used.

**Returns**

**Series or DataFrame** Returns the same object type as the caller of the window calculation.

**See also:**

**Series.window** Calling object with Series data.

**DataFrame.window** Calling object with DataFrames.

**Series.std** Equivalent method for Series.

**DataFrame.std** Equivalent method for DataFrame.

**numpy.std** Equivalent method for Numpy array.

**Notes**

The default *ddof* of 1 used in `Series.std` is different than the default *ddof* of 0 in `numpy.std`.

A minimum of one period is required for the rolling calculation.

**Examples**

```
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
>>> s.rolling(3).std()
0         NaN
1         NaN
2    0.577350
3    1.000000
4    1.000000
5    1.154701
6    0.000000
dtype: float64
```

```
>>> s.expanding(3).std()
0         NaN
1         NaN
2    0.577350
3    0.957427
4    0.894427
5    0.836660
6    0.786796
dtype: float64
```

## 4.10.2 Standard expanding window functions

<code>Expanding.count(self, **kwargs)</code>	The expanding count of any non-NaN observations inside the window.
<code>Expanding.sum(self, *args, **kwargs)</code>	Calculate expanding sum of given DataFrame or Series.
<code>Expanding.mean(self, *args, **kwargs)</code>	Calculate the expanding mean of the values.
<code>Expanding.median(self, **kwargs)</code>	Calculate the expanding median.
<code>Expanding.var(self[, ddof])</code>	Calculate unbiased expanding variance.
<code>Expanding.std(self[, ddof])</code>	Calculate expanding standard deviation.
<code>Expanding.min(self, *args, **kwargs)</code>	Calculate the expanding minimum.
<code>Expanding.max(self, *args, **kwargs)</code>	Calculate the expanding maximum.
<code>Expanding.corr(self[, other, pairwise])</code>	Calculate expanding correlation.
<code>Expanding.cov(self[, other, pairwise, ddof])</code>	Calculate the expanding sample covariance.
<code>Expanding.skew(self, **kwargs)</code>	Unbiased expanding skewness.
<code>Expanding.kurt(self, **kwargs)</code>	Calculate unbiased expanding kurtosis.
<code>Expanding.apply(self, func[, raw, args, kwargs])</code>	The expanding function's apply function.
<code>Expanding.aggregate(self, func, *args, ...)</code>	Aggregate using one or more operations over the specified axis.
<code>Expanding.quantile(self, quantile[, ...])</code>	Calculate the expanding quantile.

### pandas.core.window.expanding.Expanding.count

`Expanding.count` (*self*, *\*\*kwargs*)

The expanding count of any non-NaN observations inside the window.

#### Returns

**Series or DataFrame** Returned object type is determined by the caller of the expanding calculation.

#### See also:

**Series.expanding** Calling object with Series data.

**DataFrame.expanding** Calling object with DataFrames.

**DataFrame.count** Count of the full DataFrame.

#### Examples

```
>>> s = pd.Series([2, 3, np.nan, 10])
>>> s.rolling(2).count()
0    1.0
1    2.0
2    1.0
3    1.0
dtype: float64
>>> s.rolling(3).count()
0    1.0
1    2.0
2    2.0
3    2.0
dtype: float64
>>> s.rolling(4).count()
0    1.0
1    2.0
```

(continues on next page)

(continued from previous page)

```
2    2.0
3    3.0
dtype: float64
```

## pandas.core.window.expanding.Expanding.sum

Expanding.**sum**(*self*, \*args, \*\*kwargs)

Calculate expanding sum of given DataFrame or Series.

### Parameters

**\*args, \*\*kwargs** For compatibility with other expanding methods. Has no effect on the computed value.

### Returns

**Series or DataFrame** Same type as the input, with the same index, containing the expanding sum.

### See also:

**Series.sum** Reducing sum for Series.

**DataFrame.sum** Reducing sum for DataFrame.

## Examples

```
>>> s = pd.Series([1, 2, 3, 4, 5])
>>> s
0    1
1    2
2    3
3    4
4    5
dtype: int64
```

```
>>> s.rolling(3).sum()
0    NaN
1    NaN
2    6.0
3    9.0
4   12.0
dtype: float64
```

```
>>> s.expanding(3).sum()
0    NaN
1    NaN
2    6.0
3   10.0
4   15.0
dtype: float64
```

```
>>> s.rolling(3, center=True).sum()
0    NaN
1    6.0
2    9.0
```

(continues on next page)

(continued from previous page)

```
3    12.0
4     NaN
dtype: float64
```

For DataFrame, each expanding sum is computed column-wise.

```
>>> df = pd.DataFrame({"A": s, "B": s ** 2})
>>> df
   A  B
0  1  1
1  2  4
2  3  9
3  4 16
4  5 25
```

```
>>> df.rolling(3).sum()
   A    B
0  NaN  NaN
1  NaN  NaN
2  6.0 14.0
3  9.0 29.0
4 12.0 50.0
```

## pandas.core.window.expanding.Expanding.mean

Expanding.**mean** (*self*, \*args, \*\*kwargs)

Calculate the expanding mean of the values.

### Parameters

\*args Under Review.

\*\*kwargs Under Review.

### Returns

**Series or DataFrame** Returned object type is determined by the caller of the expanding calculation.

### See also:

**Series.expanding** Calling object with Series data.

**DataFrame.expanding** Calling object with DataFrames.

**Series.mean** Equivalent method for Series.

**DataFrame.mean** Equivalent method for DataFrame.

## Examples

The below examples will show rolling mean calculations with window sizes of two and three, respectively.

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s.rolling(2).mean()
0    NaN
1    1.5
2    2.5
3    3.5
dtype: float64
```

```
>>> s.rolling(3).mean()
0    NaN
1    NaN
2    2.0
3    3.0
dtype: float64
```

### pandas.core.window.expanding.Expanding.median

Expanding.**median** (*self*, *\*\*kwargs*)

Calculate the expanding median.

#### Parameters

**\*\*kwargs** For compatibility with other expanding methods. Has no effect on the computed median.

#### Returns

**Series or DataFrame** Returned type is the same as the original object.

**See also:**

**Series.expanding** Calling object with Series data.

**DataFrame.expanding** Calling object with DataFrames.

**Series.median** Equivalent method for Series.

**DataFrame.median** Equivalent method for DataFrame.

### Examples

Compute the rolling median of a series with a window size of 3.

```
>>> s = pd.Series([0, 1, 2, 3, 4])
>>> s.rolling(3).median()
0    NaN
1    NaN
2    1.0
3    2.0
4    3.0
dtype: float64
```

### pandas.core.window.expanding.Expanding.var

Expanding.**var** (*self*, *ddof=1*, *\*args*, *\*\*kwargs*)

Calculate unbiased expanding variance.

Normalized by N-1 by default. This can be changed using the *ddof* argument.

#### Parameters

**ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is  $N - \text{ddof}$ , where  $N$  represents the number of elements.

**\*args, \*\*kwargs** For NumPy compatibility. No additional arguments are used.

#### Returns

**Series or DataFrame** Returns the same object type as the caller of the expanding calculation.

**See also:**

- Series.expanding** Calling object with Series data.
- DataFrame.expanding** Calling object with DataFrames.
- Series.var** Equivalent method for Series.
- DataFrame.var** Equivalent method for DataFrame.
- numpy.var** Equivalent method for Numpy array.

**Notes**

The default *ddof* of 1 used in `Series.var()` is different than the default *ddof* of 0 in `numpy.var()`.  
A minimum of 1 period is required for the rolling calculation.

**Examples**

```
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
>>> s.rolling(3).var()
0          NaN
1          NaN
2    0.333333
3    1.000000
4    1.000000
5    1.333333
6    0.000000
dtype: float64
```

```
>>> s.expanding(3).var()
0          NaN
1          NaN
2    0.333333
3    0.916667
4    0.800000
5    0.700000
6    0.619048
dtype: float64
```

**pandas.core.window.expanding.Expanding.std**

Expanding.**std**(*self*, *ddof=1*, \*args, \*\*kwargs)

Calculate expanding standard deviation.

Normalized by N-1 by default. This can be changed using the *ddof* argument.

**Parameters**

**ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is  $N - ddof$ , where  $N$  represents the number of elements.

**\*args, \*\*kwargs** For NumPy compatibility. No additional arguments are used.

**Returns**

**Series or DataFrame** Returns the same object type as the caller of the expanding calculation.

**See also:**

**Series.expanding** Calling object with Series data.  
**DataFrame.expanding** Calling object with DataFrames.  
**Series.std** Equivalent method for Series.  
**DataFrame.std** Equivalent method for DataFrame.  
**numpy.std** Equivalent method for Numpy array.

## Notes

The default *ddof* of 1 used in `Series.std` is different than the default *ddof* of 0 in `numpy.std`.  
 A minimum of one period is required for the rolling calculation.

## Examples

```
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
>>> s.rolling(3).std()
0      NaN
1      NaN
2    0.577350
3    1.000000
4    1.000000
5    1.154701
6    0.000000
dtype: float64
```

```
>>> s.expanding(3).std()
0      NaN
1      NaN
2    0.577350
3    0.957427
4    0.894427
5    0.836660
6    0.786796
dtype: float64
```

## pandas.core.window.expanding.Expanding.min

`Expanding.min` (*self*, \*args, \*\*kwargs)

Calculate the expanding minimum.

### Parameters

**\*\*kwargs** Under Review.

### Returns

**Series or DataFrame** Returned object type is determined by the caller of the expanding calculation.

### See also:

**Series.expanding** Calling object with a Series.  
**DataFrame.expanding** Calling object with a DataFrame.  
**Series.min** Similar method for Series.  
**DataFrame.min** Similar method for DataFrame.

## Examples

Performing a rolling minimum with a window size of 3.

```
>>> s = pd.Series([4, 3, 5, 2, 6])
>>> s.rolling(3).min()
0    NaN
1    NaN
2    3.0
3    2.0
4    2.0
dtype: float64
```

## pandas.core.window.expanding.Expanding.max

Expanding.**max** (*self*, \*args, \*\*kwargs)

Calculate the expanding maximum.

### Parameters

**\*args, \*\*kwargs** Arguments and keyword arguments to be passed into func.

### Returns

**Series or DataFrame** Return type is determined by the caller.

See also:

**Series.expanding** Series expanding.

**DataFrame.expanding** DataFrame expanding.

## pandas.core.window.expanding.Expanding.corr

Expanding.**corr** (*self*, *other=None*, *pairwise=None*, \*\*kwargs)

Calculate expanding correlation.

### Parameters

**other** [Series, DataFrame, or ndarray, optional] If not supplied then will default to self.

**pairwise** [bool, default None] Calculate pairwise combinations of columns within a DataFrame. If *other* is not specified, defaults to *True*, otherwise defaults to *False*. Not relevant for *Series*.

**\*\*kwargs** Unused.

### Returns

**Series or DataFrame** Returned object type is determined by the caller of the expanding calculation.

See also:

**Series.expanding** Calling object with Series data.

**DataFrame.expanding** Calling object with DataFrames.

**Series.corr** Equivalent method for Series.

**DataFrame.corr** Equivalent method for DataFrame.

**expanding.cov** Similar method to calculate covariance.

**numpy.corrcoef** NumPy Pearson's correlation calculation.

## Notes

This function uses Pearson's definition of correlation ([https://en.wikipedia.org/wiki/Pearson\\_correlation\\_coefficient](https://en.wikipedia.org/wiki/Pearson_correlation_coefficient)).

When *other* is not specified, the output will be self correlation (e.g. all 1's), except for *DataFrame* inputs with *pairwise* set to *True*.

Function will return NaN for correlations of equal valued sequences; this is the result of a 0/0 division error.

When *pairwise* is set to *False*, only matching columns between *self* and *other* will be used.

When *pairwise* is set to *True*, the output will be a MultiIndex DataFrame with the original index on the first level, and the *other* DataFrame columns on the second level.

In the case of missing elements, only complete pairwise observations will be used.

## Examples

The below example shows a rolling calculation with a window size of four matching the equivalent function call using `numpy.corrcoef()`.

```
>>> v1 = [3, 3, 3, 5, 8]
>>> v2 = [3, 4, 4, 4, 8]
>>> # numpy returns a 2X2 array, the correlation coefficient
>>> # is the number at entry [0][1]
>>> print(f"{np.corrcoef(v1[:-1], v2[:-1])[0][1]:.6f}")
0.333333
>>> print(f"{np.corrcoef(v1[1:], v2[1:])[0][1]:.6f}")
0.916949
>>> s1 = pd.Series(v1)
>>> s2 = pd.Series(v2)
>>> s1.rolling(4).corr(s2)
0         NaN
1         NaN
2         NaN
3    0.333333
4    0.916949
dtype: float64
```

The below example shows a similar rolling calculation on a DataFrame using the *pairwise* option.

```
>>> matrix = np.array([[51., 35.], [49., 30.], [47., 32.], [46., 31.], [50.,
↪36.]])
>>> print(np.corrcoef(matrix[:-1,0], matrix[:-1,1]).round(7))
[[1.         0.6263001]
 [0.6263001  1.         ]]
>>> print(np.corrcoef(matrix[1:,0], matrix[1:,1]).round(7))
[[1.         0.5553681]
 [0.5553681  1.         ]]
>>> df = pd.DataFrame(matrix, columns=['X', 'Y'])
>>> df
   X    Y
0 51.0 35.0
1 49.0 30.0
2 47.0 32.0
3 46.0 31.0
4 50.0 36.0
```

(continues on next page)

(continued from previous page)

```
>>> df.rolling(4).corr(pairwise=True)
      X      Y
0 X   NaN   NaN
  Y   NaN   NaN
1 X   NaN   NaN
  Y   NaN   NaN
2 X   NaN   NaN
  Y   NaN   NaN
3 X  1.000000  0.626300
  Y  0.626300  1.000000
4 X  1.000000  0.555368
  Y  0.555368  1.000000
```

### pandas.core.window.expanding.Expanding.cov

Expanding.cov(*self*, *other=None*, *pairwise=None*, *ddof=1*, *\*\*kwargs*)

Calculate the expanding sample covariance.

#### Parameters

**other** [Series, DataFrame, or ndarray, optional] If not supplied then will default to self and produce pairwise output.

**pairwise** [bool, default None] If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndexed DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.

**ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is  $N - \text{ddof}$ , where  $N$  represents the number of elements.

**\*\*kwargs** Keyword arguments to be passed into func.

#### Returns

**Series or DataFrame** Return type is determined by the caller.

See also:

**Series.expanding** Series expanding.

**DataFrame.expanding** DataFrame expanding.

### pandas.core.window.expanding.Expanding.skew

Expanding.skew(*self*, *\*\*kwargs*)

Unbiased expanding skewness.

#### Parameters

**\*\*kwargs** Keyword arguments to be passed into func.

#### Returns

**Series or DataFrame** Return type is determined by the caller.

See also:

**Series.expanding** Series expanding.

**DataFrame.expanding** DataFrame expanding.

**pandas.core.window.expanding.Expanding.kurt**

Expanding.**kurt** (*self*, *\*\*kwargs*)

Calculate unbiased expanding kurtosis.

This function uses Fisher's definition of kurtosis without bias.

**Parameters**

**\*\*kwargs** Under Review.

**Returns**

**Series or DataFrame** Returned object type is determined by the caller of the expanding calculation.

**See also:**

**Series.expanding** Calling object with Series data.

**DataFrame.expanding** Calling object with DataFrames.

**Series.kurt** Equivalent method for Series.

**DataFrame.kurt** Equivalent method for DataFrame.

**scipy.stats.skew** Third moment of a probability density.

**scipy.stats.kurtosis** Reference SciPy method.

**Notes**

A minimum of 4 periods is required for the expanding calculation.

**Examples**

The example below will show an expanding calculation with a window size of four matching the equivalent function call using *scipy.stats*.

```
>>> arr = [1, 2, 3, 4, 999]
>>> import scipy.stats
>>> print(f"{scipy.stats.kurtosis(arr[:-1], bias=False):.6f}")
-1.200000
>>> print(f"{scipy.stats.kurtosis(arr, bias=False):.6f}")
4.999874
>>> s = pd.Series(arr)
>>> s.expanding(4).kurt()
0         NaN
1         NaN
2         NaN
3    -1.200000
4     4.999874
dtype: float64
```

## pandas.core.window.expanding.Expanding.apply

Expanding.**apply** (*self*, *func*, *raw=False*, *args=()*, *kwargs={}*)

The expanding function's apply function.

### Parameters

**func** [function] Must produce a single value from an ndarray input if *raw=True* or a single value from a Series if *raw=False*. Can also accept a Numba JIT function with *engine='numba'* specified.

Changed in version 1.0.0.

**raw** [bool, default None]

- *False* : passes each row or column as a Series to the function.
- *True* : the passed function will receive ndarray objects instead. If you are just applying a NumPy reduction function this will achieve much better performance.

**engine** [str, default 'cython']

- 'cython' : Runs rolling apply through C-extensions from cython.
- 'numba' : Runs rolling apply through JIT compiled code from numba. Only available when *raw* is set to *True*.

New in version 1.0.0.

**engine\_kwargs** [dict, default None]

- For 'cython' engine, there are no accepted *engine\_kwargs*
- For 'numba' engine, the engine can accept *nopython*, *nogil* and *parallel* dictionary keys. The values must either be *True* or *False*. The default *engine\_kwargs* for the 'numba' engine is {'nopython': *True*, 'nogil': *False*, 'parallel': *False*} and will be applied to both the *func* and the apply rolling aggregation.

New in version 1.0.0.

**args** [tuple, default None] Positional arguments to be passed into *func*.

**kwargs** [dict, default None] Keyword arguments to be passed into *func*.

### Returns

**Series or DataFrame** Return type is determined by the caller.

See also:

**Series.expanding** Series expanding.

**DataFrame.expanding** DataFrame expanding.

### Notes

See *Rolling Apply* for extended documentation and performance considerations for the Numba engine.

**pandas.core.window.expanding.Expanding.aggregate**

Expanding.**aggregate** (*self*, *func*, \**args*, \*\**kwargs*)

Aggregate using one or more operations over the specified axis.

**Parameters**

**func** [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a Series/Dataframe or when passed to Series/Dataframe.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. [np.sum, 'mean']
- dict of axis labels -> functions, function names or list of such.

\***args** Positional arguments to pass to *func*.

\*\***kwargs** Keyword arguments to pass to *func*.

**Returns**

**scalar, Series or DataFrame** The return can be:

- scalar : when Series.agg is called with single function
- Series : when DataFrame.agg is called with a single function
- DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

See also:

**DataFrame.expanding.aggregate**

**DataFrame.rolling.aggregate**

**DataFrame.aggregate**

**Notes**

*agg* is an alias for *aggregate*. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

**Examples**

```
>>> df = pd.DataFrame(np.random.randn(10, 3), columns=['A', 'B', 'C'])
>>> df
```

	A	B	C
0	-2.385977	-0.102758	0.438822
1	-1.004295	0.905829	-0.954544
2	0.735167	-0.165272	-1.619346
3	-0.702657	-1.340923	-0.706334
4	-0.246845	0.211596	-0.901819
5	2.463718	3.157577	-1.380906
6	-1.142255	2.340594	-0.039875
7	1.396598	-1.647453	1.677227
8	-0.543425	1.761277	-0.220481
9	-0.640505	0.289374	-1.550670

```
>>> df.ewm(alpha=0.5).mean()
      A          B          C
0 -2.385977 -0.102758  0.438822
1 -1.464856  0.569633 -0.490089
2 -0.207700  0.149687 -1.135379
3 -0.471677 -0.645305 -0.906555
4 -0.355635 -0.203033 -0.904111
5  1.076417  1.503943 -1.146293
6 -0.041654  1.925562 -0.588728
7  0.680292  0.132049  0.548693
8  0.067236  0.948257  0.163353
9 -0.286980  0.618493 -0.694496
```

## pandas.core.window.expanding.Expanding.quantile

Expanding.**quantile** (*self*, *quantile*, *interpolation='linear'*, *\*\*kwargs*)

Calculate the expanding quantile.

### Parameters

**quantile** [float] Quantile to compute.  $0 \leq \text{quantile} \leq 1$ .

**interpolation** [{"linear", "lower", "higher", "midpoint", "nearest"}] New in version 0.23.0.

This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points *i* and *j*:

- linear:  $i + (j - i) * \text{fraction}$ , where *fraction* is the fractional part of the index surrounded by *i* and *j*.
- lower: *i*.
- higher: *j*.
- nearest: *i* or *j* whichever is nearest.
- midpoint:  $(i + j) / 2$ .

**\*\*kwargs** For compatibility with other expanding methods. Has no effect on the result.

### Returns

**Series or DataFrame** Returned object type is determined by the caller of the expanding calculation.

See also:

**Series.quantile** Computes value at the given quantile over all data in Series.

**DataFrame.quantile** Computes values at the given quantile over requested axis in DataFrame.

## Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s.rolling(2).quantile(.4, interpolation='lower')
0      NaN
1      1.0
2      2.0
3      3.0
dtype: float64
```

```
>>> s.rolling(2).quantile(.4, interpolation='midpoint')
0      NaN
1      1.5
2      2.5
3      3.5
dtype: float64
```

### 4.10.3 Exponentially-weighted moving window functions

<i>EWM.mean</i> (self, <i>*args</i> , <i>**kwargs</i> )	Exponential weighted moving average.
<i>EWM.std</i> (self[, <i>bias</i> ])	Exponential weighted moving stddev.
<i>EWM.var</i> (self[, <i>bias</i> ])	Exponential weighted moving variance.
<i>EWM.corr</i> (self[, <i>other</i> , <i>pairwise</i> ])	Exponential weighted sample correlation.
<i>EWM.cov</i> (self[, <i>other</i> , <i>pairwise</i> , <i>bias</i> ])	Exponential weighted sample covariance.

#### pandas.core.window.ewm.EWM.mean

*EWM.mean* (*self*, *\*args*, *\*\*kwargs*)  
Exponential weighted moving average.

##### Parameters

*\*args*, *\*\*kwargs* Arguments and keyword arguments to be passed into func.

##### Returns

**Series or DataFrame** Return type is determined by the caller.

##### See also:

**Series.ewm** Series ewm.

**DataFrame.ewm** DataFrame ewm.

#### pandas.core.window.ewm.EWM.std

*EWM.std* (*self*, *bias=False*, *\*args*, *\*\*kwargs*)  
Exponential weighted moving stddev.

##### Parameters

**bias** [bool, default False] Use a standard estimation bias correction.

*\*args*, *\*\*kwargs* Arguments and keyword arguments to be passed into func.

##### Returns

**Series or DataFrame** Return type is determined by the caller.

##### See also:

**Series.ewm** Series ewm.

**DataFrame.ewm** DataFrame ewm.

### pandas.core.window.ewm.EWM.var

`EWM.var` (*self*, *bias=False*, \*args, \*\*kwargs)  
Exponential weighted moving variance.

#### Parameters

**bias** [bool, default False] Use a standard estimation bias correction.

**\*args, \*\*kwargs** Arguments and keyword arguments to be passed into func.

#### Returns

**Series or DataFrame** Return type is determined by the caller.

See also:

**Series.ewm** Series ewm.

**DataFrame.ewm** DataFrame ewm.

### pandas.core.window.ewm.EWM.corr

`EWM.corr` (*self*, *other=None*, *pairwise=None*, \*\*kwargs)  
Exponential weighted sample correlation.

#### Parameters

**other** [Series, DataFrame, or ndarray, optional] If not supplied then will default to self and produce pairwise output.

**pairwise** [bool, default None] If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndex DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.

**\*\*kwargs** Keyword arguments to be passed into func.

#### Returns

**Series or DataFrame** Return type is determined by the caller.

See also:

**Series.ewm** Series ewm.

**DataFrame.ewm** DataFrame ewm.

### pandas.core.window.ewm.EWM.cov

`EWM.cov` (*self*, *other=None*, *pairwise=None*, *bias=False*, \*\*kwargs)  
Exponential weighted sample covariance.

#### Parameters

**other** [Series, DataFrame, or ndarray, optional] If not supplied then will default to self and produce pairwise output.

**pairwise** [bool, default None] If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndex DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.

**bias** [bool, default False] Use a standard estimation bias correction.

**\*\*kwargs** Keyword arguments to be passed into func.

#### Returns

**Series or DataFrame** Return type is determined by the caller.

**See also:**

**Series.ewm** Series ewm.

**DataFrame.ewm** DataFrame ewm.

## 4.10.4 Window Indexer

Base class for defining custom window boundaries.

---

`api.indexers.BaseIndexer([index_array, ...])` Base class for window bounds calculations

---

### pandas.api.indexers.BaseIndexer

**class** pandas.api.indexers.**BaseIndexer** (*index\_array: Optional[numpy.ndarray] = None, window\_size: int = 0, \*\*kwargs*)  
 Base class for window bounds calculations

#### Methods

---

`get_window_bounds(self, num_values, ...)` Computes the bounds of a window.

---

### pandas.api.indexers.BaseIndexer.get\_window\_bounds

`BaseIndexer.get_window_bounds` (*self, num\_values: int = 0, min\_periods: Union[int, NoneType] = None, center: Union[bool, NoneType] = None, closed: Union[str, NoneType] = None*) → Tuple[numpy.ndarray, numpy.ndarray]

Computes the bounds of a window.

#### Parameters

**num\_values** [int, default 0] number of values that will be aggregated over

**window\_size** [int, default 0] the number of rows in a window

**min\_periods** [int, default None] min\_periods passed from the top level rolling API

**center** [bool, default None] center passed from the top level rolling API

**closed** [str, default None] closed passed from the top level rolling API

**win\_type** [str, default None] win\_type passed from the top level rolling API

#### Returns

**A tuple of ndarray[int64]s, indicating the boundaries of each window**

{{ header }}

## 4.11 GroupBy

GroupBy objects are returned by groupby calls: `pandas.DataFrame.groupby()`, `pandas.Series.groupby()`, etc.

### 4.11.1 Indexing, iteration

<code>GroupBy.__iter__(self)</code>	Groupby iterator.
<code>GroupBy.groups</code>	Dict {group name -> group labels}.
<code>GroupBy.indices</code>	Dict {group name -> group indices}.
<code>GroupBy.get_group(self, name[, obj])</code>	Construct DataFrame from group with provided name.

#### `pandas.core.groupby.GroupBy.__iter__`

`GroupBy.__iter__(self)`  
Groupby iterator.

**Returns**

Generator yielding sequence of (name, subsetting object)  
for each group

#### `pandas.core.groupby.GroupBy.groups`

**property** `GroupBy.groups`  
Dict {group name -> group labels}.

#### `pandas.core.groupby.GroupBy.indices`

**property** `GroupBy.indices`  
Dict {group name -> group indices}.

#### `pandas.core.groupby.GroupBy.get_group`

`GroupBy.get_group(self, name, obj=None)`  
Construct DataFrame from group with provided name.

**Parameters**

**name** [object] The name of the group to get as a DataFrame.

**obj** [DataFrame, default None] The DataFrame to take the DataFrame out of. If it is None, the object groupby was called on will be used.

**Returns**

**group** [same type as obj]

---

`Grouper([key, level, freq, axis, sort])`

A Grouper allows the user to specify a groupby instruction for an object.

---

## pandas.Grouper

**class** pandas.Grouper (*key=None, level=None, freq=None, axis=0, sort=False*)

A Grouper allows the user to specify a groupby instruction for an object.

This specification will select a column via the key parameter, or if the level and/or axis parameters are given, a level of the index of the target object.

If *axis* and/or *level* are passed as keywords to both *Grouper* and *groupby*, the values passed to *Grouper* take precedence.

### Parameters

**key** [str, defaults to None] Groupby key, which selects the grouping column of the target.

**level** [name/number, defaults to None] The level for the target index.

**freq** [str / frequency object, defaults to None] This will groupby the specified frequency if the target selection (via key or level) is a datetime-like object. For full specification of available frequencies, please see [here](#).

**axis** [str, int, defaults to 0] Number/name of the axis.

**sort** [bool, default to False] Whether to sort the resulting labels.

**closed** [{ 'left' or 'right' }] Closed end of interval. Only when *freq* parameter is passed.

**label** [{ 'left' or 'right' }] Interval boundary to use for labeling. Only when *freq* parameter is passed.

**convention** [{ 'start', 'end', 'e', 's' }] If grouper is PeriodIndex and *freq* parameter is passed.

**base** [int, default 0] Only when *freq* parameter is passed.

**loffset** [str, DateOffset, timedelta object] Only when *freq* parameter is passed.

### Returns

A specification for a groupby instruction

### Examples

Syntactic sugar for `df.groupby('A')`

```
>>> df.groupby(Grouper(key='A'))
```

Specify a resample operation on the column 'date'

```
>>> df.groupby(Grouper(key='date', freq='60s'))
```

Specify a resample operation on the level 'date' on the columns axis with a frequency of 60s

```
>>> df.groupby(Grouper(level='date', freq='60s', axis=1))
```

## Attributes

<b>ax</b>	
<b>groups</b>	

### 4.11.2 Function application

<code>GroupBy.apply(self, func, *args, **kwargs)</code>	Apply function <i>func</i> group-wise and combine the results together.
<code>GroupBy.agg(self, func, *args, **kwargs)</code>	
<code>GroupBy.aggregate(self, func, *args, **kwargs)</code>	
<code>GroupBy.transform(self, func, *args, **kwargs)</code>	
<code>GroupBy.pipe(self, func, *args, **kwargs)</code>	Apply a function <i>func</i> with arguments to this GroupBy object and return the function's result.

### pandas.core.groupby.GroupBy.apply

`GroupBy.apply(self, func, *args, **kwargs)`

Apply function *func* group-wise and combine the results together.

The function passed to *apply* must take a dataframe as its first argument and return a DataFrame, Series or scalar. *apply* will then take care of combining the results back together into a single dataframe or series. *apply* is therefore a highly flexible grouping method.

While *apply* is a very flexible method, its downside is that using it can be quite a bit slower than using more specific methods like *agg* or *transform*. Pandas offers a wide range of method that will be much faster than using *apply* for their specific purposes, so try to use them before reaching for *apply*.

#### Parameters

**func** [callable] A callable that takes a dataframe as its first argument, and returns a dataframe, a series or a scalar. In addition the callable may take positional and keyword arguments.

**args, kwargs** [tuple and dict] Optional positional and keyword arguments to pass to *func*.

#### Returns

**applied** [Series or DataFrame]

See also:

**pipe** Apply function to the full GroupBy object instead of to each group.

**aggregate** Apply aggregate function to the GroupBy object.

**transform** Apply function column-by-column to the GroupBy object.

**Series.apply** Apply a function to a Series.

**DataFrame.apply** Apply a function to each row or column of a DataFrame.

**pandas.core.groupby.GroupBy.agg**

GroupBy.**agg** (*self*, *func*, \**args*, \*\**kwargs*)

**pandas.core.groupby.GroupBy.aggregate**

GroupBy.**aggregate** (*self*, *func*, \**args*, \*\**kwargs*)

**pandas.core.groupby.GroupBy.transform**

GroupBy.**transform** (*self*, *func*, \**args*, \*\**kwargs*)

**pandas.core.groupby.GroupBy.pipe**

GroupBy.**pipe** (*self*, *func*, \**args*, \*\**kwargs*)

Apply a function *func* with arguments to this GroupBy object and return the function's result.

New in version 0.21.0.

Use *.pipe* when you want to improve readability by chaining together functions that expect Series, DataFrames, GroupBy or Resampler objects. Instead of writing

```
>>> h(g(f(df.groupby('group')), arg1=a), arg2=b, arg3=c)
```

You can write

```
>>> (df.groupby('group')
...   .pipe(f)
...   .pipe(g, arg1=a)
...   .pipe(h, arg2=b, arg3=c))
```

which is much more readable.

**Parameters**

**func** [callable or tuple of (callable, string)] Function to apply to this GroupBy object or, alternatively, a (*callable*, *data\_keyword*) tuple where *data\_keyword* is a string indicating the keyword of *callable* that expects the GroupBy object.

**args** [iterable, optional] Positional arguments passed into *func*.

**kwargs** [dict, optional] A dictionary of keyword arguments passed into *func*.

**Returns**

**object** [the return type of *func*.]

**See also:**

**Series.pipe** Apply a function with arguments to a series.

**DataFrame.pipe** Apply a function with arguments to a dataframe.

**apply** Apply function to each group instead of to the full GroupBy object.

## Notes

See more [here](#)

## Examples

```
>>> df = pd.DataFrame({'A': 'a b a b'.split(), 'B': [1, 2, 3, 4]})
>>> df
   A  B
0  a  1
1  b  2
2  a  3
3  b  4
```

To get the difference between each groups maximum and minimum value in one pass, you can do

```
>>> df.groupby('A').pipe(lambda x: x.max() - x.min())
   B
A
a  2
b  2
```

### 4.11.3 Computations / descriptive stats

<code>GroupBy.all(self, skipna)</code>	Return True if all values in the group are truthful, else False.
<code>GroupBy.any(self, skipna)</code>	Return True if any value in the group is truthful, else False.
<code>GroupBy.bfill(self[, limit])</code>	Backward fill the values.
<code>GroupBy.count(self)</code>	Compute count of group, excluding missing values.
<code>GroupBy.cumcount(self, ascending)</code>	Number each item in each group from 0 to the length of that group - 1.
<code>GroupBy.cummax(self[, axis])</code>	Cumulative max for each group.
<code>GroupBy.cummin(self[, axis])</code>	Cumulative min for each group.
<code>GroupBy.cumprod(self[, axis])</code>	Cumulative product for each group.
<code>GroupBy.cumsum(self[, axis])</code>	Cumulative sum for each group.
<code>GroupBy.ffill(self[, limit])</code>	Forward fill the values.
<code>GroupBy.first(self, **kwargs)</code>	Compute first of group values.
<code>GroupBy.head(self[, n])</code>	Return first n rows of each group.
<code>GroupBy.last(self, **kwargs)</code>	Compute last of group values.
<code>GroupBy.max(self, **kwargs)</code>	Compute max of group values.
<code>GroupBy.mean(self, *args, **kwargs)</code>	Compute mean of groups, excluding missing values.
<code>GroupBy.median(self, **kwargs)</code>	Compute median of groups, excluding missing values.
<code>GroupBy.min(self, **kwargs)</code>	Compute min of group values.
<code>GroupBy.ngroup(self, ascending)</code>	Number each group from 0 to the number of groups - 1.
<code>GroupBy.nth(self, n, List[int], dropna, ...)</code>	Take the nth row from each group if n is an int, or a subset of rows if n is a list of ints.
<code>GroupBy.ohlc(self)</code>	Compute sum of values, excluding missing values.
<code>GroupBy.prod(self, **kwargs)</code>	Compute prod of group values.
<code>GroupBy.rank(self, method, ascending, ...)</code>	Provide the rank of values within each group.

Continued on next page

Table 402 – continued from previous page

<code>GroupBy.pct_change(self[, periods, ...])</code>	Calculate <code>pct_change</code> of each value to previous entry in group.
<code>GroupBy.size(self)</code>	Compute group sizes.
<code>GroupBy.sem(self, ddof)</code>	Compute standard error of the mean of groups, excluding missing values.
<code>GroupBy.std(self, ddof, *args, **kwargs)</code>	Compute standard deviation of groups, excluding missing values.
<code>GroupBy.sum(self, **kwargs)</code>	Compute sum of group values.
<code>GroupBy.var(self, ddof, *args, **kwargs)</code>	Compute variance of groups, excluding missing values.
<code>GroupBy.tail(self[, n])</code>	Return last <code>n</code> rows of each group.

**pandas.core.groupby.GroupBy.all**

`GroupBy.all` (*self*, *skipna*: *bool = True*)

Return True if all values in the group are truthful, else False.

**Parameters**

**skipna** [bool, default True] Flag to ignore nan values during truth testing.

**Returns**

**bool**

See also:

`Series.groupby`

`DataFrame.groupby`

**pandas.core.groupby.GroupBy.any**

`GroupBy.any` (*self*, *skipna*: *bool = True*)

Return True if any value in the group is truthful, else False.

**Parameters**

**skipna** [bool, default True] Flag to ignore nan values during truth testing.

**Returns**

**bool**

See also:

`Series.groupby`

`DataFrame.groupby`

**pandas.core.groupby.GroupBy.bfill**

`GroupBy.bfill` (*self*, *limit=None*)

Backward fill the values.

**Parameters**

**limit** [int, optional] Limit of how many values to fill.

**Returns**

**Series or DataFrame** Object with missing values filled.

See also:

`Series.backfill`  
`DataFrame.backfill`  
`Series.fillna`  
`DataFrame.fillna`

### `pandas.core.groupby.GroupBy.count`

`GroupBy.count` (*self*)

Compute count of group, excluding missing values.

**Returns**

**Series or DataFrame** Count of values within each group.

**See also:**

`Series.groupby`  
`DataFrame.groupby`

### `pandas.core.groupby.GroupBy.cumcount`

`GroupBy.cumcount` (*self*, *ascending: bool = True*)

Number each item in each group from 0 to the length of that group - 1.

Essentially this is equivalent to

```
>>> self.apply(lambda x: pd.Series(np.arange(len(x)), x.index))
```

**Parameters**

**ascending** [bool, default True] If False, number in reverse, from length of group - 1 to 0.

**Returns**

**Series** Sequence number of each element within each group.

**See also:**

***ngroup*** Number the groups themselves.

### Examples

```
>>> df = pd.DataFrame([[ 'a' ], [ 'a' ], [ 'a' ], [ 'b' ], [ 'b' ], [ 'a' ]],
...                   columns=[ 'A' ])
>>> df
   A
0  a
1  a
2  a
3  b
4  b
5  a
>>> df.groupby( 'A' ).cumcount ()
0    0
1    1
2    2
3    0
4    1
```

(continues on next page)

(continued from previous page)

```
5    3
dtype: int64
>>> df.groupby('A').cumcount(ascending=False)
0    3
1    2
2    1
3    1
4    0
5    0
dtype: int64
```

### **pandas.core.groupby.GroupBy.cummax**

`GroupBy.cummax` (*self*, *axis=0*, *\*\*kwargs*)

Cumulative max for each group.

**Returns**

**Series or DataFrame**

**See also:**

**`Series.groupby`**

**`DataFrame.groupby`**

### **pandas.core.groupby.GroupBy.cummin**

`GroupBy.cummin` (*self*, *axis=0*, *\*\*kwargs*)

Cumulative min for each group.

**Returns**

**Series or DataFrame**

**See also:**

**`Series.groupby`**

**`DataFrame.groupby`**

### **pandas.core.groupby.GroupBy.cumprod**

`GroupBy.cumprod` (*self*, *axis=0*, *\*args*, *\*\*kwargs*)

Cumulative product for each group.

**Returns**

**Series or DataFrame**

**See also:**

**`Series.groupby`**

**`DataFrame.groupby`**

### pandas.core.groupby.GroupBy.cumsum

GroupBy.**cumsum** (*self*, *axis=0*, \*args, \*\*kwargs)  
Cumulative sum for each group.

**Returns**

**Series or DataFrame**

See also:

**Series.groupby**

**DataFrame.groupby**

### pandas.core.groupby.GroupBy.ffill

GroupBy.**ffill** (*self*, *limit=None*)  
Forward fill the values.

**Parameters**

**limit** [int, optional] Limit of how many values to fill.

**Returns**

**Series or DataFrame** Object with missing values filled.

See also:

**Series.pad**

**DataFrame.pad**

**Series.fillna**

**DataFrame.fillna**

### pandas.core.groupby.GroupBy.first

GroupBy.**first** (*self*, \*\*kwargs)  
Compute first of group values.

**Returns**

**Series or DataFrame** Computed first of values within each group.

### pandas.core.groupby.GroupBy.head

GroupBy.**head** (*self*, *n=5*)  
Return first n rows of each group.

Similar to `.apply(lambda x: x.head(n))`, but it returns a subset of rows from the original DataFrame with original index and order preserved (`as_index` flag is ignored).

Does not work for negative values of *n*.

**Returns**

**Series or DataFrame**

See also:

**Series.groupby**

**DataFrame.groupby**

## Examples

```
>>> df = pd.DataFrame([[1, 2], [1, 4], [5, 6]],
...                    columns=['A', 'B'])
>>> df.groupby('A').head(1)
   A  B
0  1  2
2  5  6
>>> df.groupby('A').head(-1)
Empty DataFrame
Columns: [A, B]
Index: []
```

### pandas.core.groupby.GroupBy.last

GroupBy.**last** (*self*, *\*\*kwargs*)  
Compute last of group values.

#### Returns

**Series or DataFrame** Computed last of values within each group.

### pandas.core.groupby.GroupBy.max

GroupBy.**max** (*self*, *\*\*kwargs*)  
Compute max of group values.

#### Returns

**Series or DataFrame** Computed max of values within each group.

### pandas.core.groupby.GroupBy.mean

GroupBy.**mean** (*self*, *\*args*, *\*\*kwargs*)  
Compute mean of groups, excluding missing values.

#### Returns

**pandas.Series or pandas.DataFrame**

See also:

**Series.groupby**

**DataFrame.groupby**

## Examples

```
>>> df = pd.DataFrame({'A': [1, 1, 2, 1, 2],
...                   'B': [np.nan, 2, 3, 4, 5],
...                   'C': [1, 2, 1, 1, 2]}, columns=['A', 'B', 'C'])
```

Groupby one column and return the mean of the remaining columns in each group.

```
>>> df.groupby('A').mean()
   B      C
A
```

(continues on next page)

(continued from previous page)

```
1  3.0  1.333333
2  4.0  1.500000
```

Groupby two columns and return the mean of the remaining column.

```
>>> df.groupby(['A', 'B']).mean()
      C
A B
1 2.0  2
   4.0  1
2 3.0  1
   5.0  2
```

Groupby one column and return the mean of only particular column in the group.

```
>>> df.groupby('A')['B'].mean()
A
1    3.0
2    4.0
Name: B, dtype: float64
```

### pandas.core.groupby.GroupBy.median

GroupBy.**median** (*self*, *\*\*kwargs*)

Compute median of groups, excluding missing values.

For multiple groupings, the result index will be a MultiIndex

#### Returns

**Series or DataFrame** Median of values within each group.

See also:

**Series.groupby**

**DataFrame.groupby**

### pandas.core.groupby.GroupBy.min

GroupBy.**min** (*self*, *\*\*kwargs*)

Compute min of group values.

#### Returns

**Series or DataFrame** Computed min of values within each group.

### pandas.core.groupby.GroupBy.ngroup

GroupBy.**ngroup** (*self*, *ascending: bool = True*)

Number each group from 0 to the number of groups - 1.

This is the enumerative complement of cumcount. Note that the numbers given to the groups match the order in which the groups would be seen when iterating over the groupby object, not the order they are first observed.

#### Parameters

**ascending** [bool, default True] If False, number in reverse, from number of group - 1 to 0.

#### Returns

**Series** Unique numbers for each group.

**See also:**

**cumcount** Number the rows in each group.

## Examples

```
>>> df = pd.DataFrame({"A": list("aaabba")})
>>> df
   A
0  a
1  a
2  a
3  b
4  b
5  a
>>> df.groupby('A').ngroup()
   0
0  0
1  0
2  0
3  1
4  1
5  0
dtype: int64
>>> df.groupby('A').ngroup(ascending=False)
   1
0  1
1  1
2  1
3  0
4  0
5  1
dtype: int64
>>> df.groupby(["A", [1,1,2,3,2,1]]).ngroup()
   0
0  0
1  0
2  1
3  3
4  2
5  0
dtype: int64
```

## pandas.core.groupby.GroupBy.nth

`GroupBy.nth(self, n: Union[int, List[int]], dropna: Union[str, NoneType] = None) → pandas.core.frame.DataFrame`

Take the `nth` row from each group if `n` is an int, or a subset of rows if `n` is a list of ints.

If `dropna`, will take the `nth` non-null row, `dropna` is either 'all' or 'any'; this is equivalent to calling `dropna(how=dropna)` before the `groupby`.

### Parameters

**n** [int or list of ints] A single `nth` value for the row or a list of `nth` values.

**dropna** [None or str, optional] Apply the specified `dropna` operation before counting which row is the `nth` row. Needs to be None, 'any' or 'all'.

### Returns

**Series or DataFrame** N-th value within each group.

See also:

**Series.groupby**

**DataFrame.groupby**

## Examples

```
>>> df = pd.DataFrame({'A': [1, 1, 2, 1, 2],
...                    'B': [np.nan, 2, 3, 4, 5]}, columns=['A', 'B'])
>>> g = df.groupby('A')
>>> g.nth(0)
   B
A
1 NaN
2 3.0
>>> g.nth(1)
   B
A
1 2.0
2 5.0
>>> g.nth(-1)
   B
A
1 4.0
2 5.0
>>> g.nth([0, 1])
   B
A
1 NaN
1 2.0
2 3.0
2 5.0
```

Specifying *dropna* allows count ignoring NaN

```
>>> g.nth(0, dropna='any')
   B
A
1 2.0
2 3.0
```

NaNs denote group exhausted when using *dropna*

```
>>> g.nth(3, dropna='any')
   B
A
1 NaN
2 NaN
```

Specifying *as\_index=False* in *groupby* keeps the original index.

```
>>> df.groupby('A', as_index=False).nth(1)
   A  B
1  1  2.0
4  2  5.0
```

**pandas.core.groupby.GroupBy.ohlc**

`GroupBy.ohlc(self)` → `pandas.core.frame.DataFrame`  
 Compute sum of values, excluding missing values.

For multiple groupings, the result index will be a `MultiIndex`

**Returns**

**DataFrame** Open, high, low and close values within each group.

See also:

`Series.groupby`

`DataFrame.groupby`

**pandas.core.groupby.GroupBy.prod**

`GroupBy.prod(self, **kwargs)`  
 Compute prod of group values.

**Returns**

**Series or DataFrame** Computed prod of values within each group.

**pandas.core.groupby.GroupBy.rank**

`GroupBy.rank(self, method: str = 'average', ascending: bool = True, na_option: str = 'keep', pct: bool = False, axis: int = 0)`  
 Provide the rank of values within each group.

**Parameters**

**method** [{ 'average', 'min', 'max', 'first', 'dense' }, default 'average']

- average: average rank of group.
- min: lowest rank in group.
- max: highest rank in group.
- first: ranks assigned in order they appear in the array.
- dense: like 'min', but rank always increases by 1 between groups.

**ascending** [bool, default True] False for ranks by high (1) to low (N).

**na\_option** [{ 'keep', 'top', 'bottom' }, default 'keep']

- keep: leave NA values where they are.
- top: smallest rank if ascending.
- bottom: smallest rank if descending.

**pct** [bool, default False] Compute percentage rank of data within each group.

**axis** [int, default 0] The axis of the object over which to compute the rank.

**Returns**

**DataFrame with ranking of values within each group**

See also:

`Series.groupby`

`DataFrame.groupby`

### pandas.core.groupby.GroupBy.pct\_change

GroupBy.**pct\_change** (*self*, *periods=1*, *fill\_method='pad'*, *limit=None*, *freq=None*, *axis=0*)  
Calculate pct\_change of each value to previous entry in group.

#### Returns

**Series or DataFrame** Percentage changes within each group.

See also:

**Series.groupby**

**DataFrame.groupby**

### pandas.core.groupby.GroupBy.size

GroupBy.**size** (*self*)  
Compute group sizes.

#### Returns

**Series** Number of rows in each group.

See also:

**Series.groupby**

**DataFrame.groupby**

### pandas.core.groupby.GroupBy.sem

GroupBy.**sem** (*self*, *ddof: int = 1*)  
Compute standard error of the mean of groups, excluding missing values.  
For multiple groupings, the result index will be a MultiIndex.

#### Parameters

**ddof** [int, default 1] Degrees of freedom.

#### Returns

**Series or DataFrame** Standard error of the mean of values within each group.

See also:

**Series.groupby**

**DataFrame.groupby**

### pandas.core.groupby.GroupBy.std

GroupBy.**std** (*self*, *ddof: int = 1*, *\*args*, *\*\*kwargs*)  
Compute standard deviation of groups, excluding missing values.  
For multiple groupings, the result index will be a MultiIndex.

#### Parameters

**ddof** [int, default 1] Degrees of freedom.

#### Returns

**Series or DataFrame** Standard deviation of values within each group.

See also:

**Series.groupby**

**DataFrame.groupby**

**pandas.core.groupby.GroupBy.sum**`GroupBy.sum(self, **kwargs)`

Compute sum of group values.

**Returns****Series or DataFrame** Computed sum of values within each group.**pandas.core.groupby.GroupBy.var**`GroupBy.var(self, ddof: int = 1, *args, **kwargs)`

Compute variance of groups, excluding missing values.

For multiple groupings, the result index will be a MultiIndex.

**Parameters****ddof** [int, default 1] Degrees of freedom.**Returns****Series or DataFrame** Variance of values within each group.**See also:****Series.groupby****DataFrame.groupby****pandas.core.groupby.GroupBy.tail**`GroupBy.tail(self, n=5)`Return last *n* rows of each group.Similar to `.apply(lambda x: x.tail(n))`, but it returns a subset of rows from the original DataFrame with original index and order preserved (`as_index` flag is ignored).Does not work for negative values of *n*.**Returns****Series or DataFrame****See also:****Series.groupby****DataFrame.groupby****Examples**

```

>>> df = pd.DataFrame([[ 'a', 1], [ 'a', 2], [ 'b', 1], [ 'b', 2]],
...                    columns=[ 'A', 'B'])
>>> df.groupby('A').tail(1)
   A  B
1  a  2
3  b  2
>>> df.groupby('A').tail(-1)
Empty DataFrame
Columns: [A, B]
Index: []

```

The following methods are available in both `SeriesGroupBy` and `DataFrameGroupBy` objects, but may differ slightly, usually in that the `DataFrameGroupBy` version usually permits the specification of an axis argument, and often an argument indicating whether to restrict application to columns of a specific data type.

<code>DataFrameGroupBy.all(self, skipna)</code>	Return True if all values in the group are truthful, else False.
<code>DataFrameGroupBy.any(self, skipna)</code>	Return True if any value in the group is truthful, else False.
<code>DataFrameGroupBy.bfill(self[, limit])</code>	Backward fill the values.
<code>DataFrameGroupBy.corr</code>	Compute pairwise correlation of columns, excluding NA/null values.
<code>DataFrameGroupBy.count(self)</code>	Compute count of group, excluding missing values.
<code>DataFrameGroupBy.cov</code>	Compute pairwise covariance of columns, excluding NA/null values.
<code>DataFrameGroupBy.cummax(self[, axis])</code>	Cumulative max for each group.
<code>DataFrameGroupBy.cummin(self[, axis])</code>	Cumulative min for each group.
<code>DataFrameGroupBy.cumprod(self[, axis])</code>	Cumulative product for each group.
<code>DataFrameGroupBy.cumsum(self[, axis])</code>	Cumulative sum for each group.
<code>DataFrameGroupBy.describe(self, *\kwargs)</code>	Generate descriptive statistics.
<code>DataFrameGroupBy.diff</code>	First discrete difference of element.
<code>DataFrameGroupBy.ffill(self[, limit])</code>	Forward fill the values.
<code>DataFrameGroupBy.fillna</code>	Fill NA/NaN values using the specified method.
<code>DataFrameGroupBy.filter(self, func[, dropna])</code>	Return a copy of a DataFrame excluding elements from groups that do not satisfy the boolean criterion specified by func.
<code>DataFrameGroupBy.hist</code>	Make a histogram of the DataFrame's.
<code>DataFrameGroupBy.idxmax</code>	Return index of first occurrence of maximum over requested axis.
<code>DataFrameGroupBy.idxmin</code>	Return index of first occurrence of minimum over requested axis.
<code>DataFrameGroupBy.mad</code>	Return the mean absolute deviation of the values for the requested axis.
<code>DataFrameGroupBy.nunique(self, dropna)</code>	Return DataFrame with number of distinct observations per group for each column.
<code>DataFrameGroupBy.pct_change(self[, periods, ...])</code>	Calculate pct_change of each value to previous entry in group.
<code>DataFrameGroupBy.plot</code>	Class implementing the .plot attribute for groupby objects.
<code>DataFrameGroupBy.quantile(self[, q])</code>	Return group values at the given quantile, a la <code>numpy.percentile</code> .
<code>DataFrameGroupBy.rank(self, method, ...)</code>	Provide the rank of values within each group.
<code>DataFrameGroupBy.resample(self, rule, ...)</code>	Provide resampling when using a <code>TimeGrouper</code> .
<code>DataFrameGroupBy.shift(self[, periods, ...])</code>	Shift each group by periods observations.
<code>DataFrameGroupBy.size(self)</code>	Compute group sizes.
<code>DataFrameGroupBy.skew</code>	Return unbiased skew over requested axis.
<code>DataFrameGroupBy.take</code>	Return the elements in the given <i>positional</i> indices along an axis.
<code>DataFrameGroupBy.tshift</code>	Shift the time index, using the index's frequency if available.

### pandas.core.groupby.DataFrameGroupBy.all

DataFrameGroupBy.**all** (*self*, *skipna*: *bool = True*)

Return True if all values in the group are truthful, else False.

#### Parameters

**skipna** [bool, default True] Flag to ignore nan values during truth testing.

#### Returns

**bool**

See also:

**Series.groupby**

**DataFrame.groupby**

### pandas.core.groupby.DataFrameGroupBy.any

DataFrameGroupBy.**any** (*self*, *skipna*: *bool = True*)

Return True if any value in the group is truthful, else False.

#### Parameters

**skipna** [bool, default True] Flag to ignore nan values during truth testing.

#### Returns

**bool**

See also:

**Series.groupby**

**DataFrame.groupby**

### pandas.core.groupby.DataFrameGroupBy.bfill

DataFrameGroupBy.**bfill** (*self*, *limit=None*)

Backward fill the values.

#### Parameters

**limit** [int, optional] Limit of how many values to fill.

#### Returns

**Series or DataFrame** Object with missing values filled.

See also:

**Series.backfill**

**DataFrame.backfill**

**Series.fillna**

**DataFrame.fillna**

## pandas.core.groupby.DataFrameGroupBy.corr

**property** DataFrameGroupBy.corr

Compute pairwise correlation of columns, excluding NA/null values.

### Parameters

**method** [{‘pearson’, ‘kendall’, ‘spearman’} or callable] Method of correlation:

- pearson : standard correlation coefficient
- kendall : Kendall Tau correlation coefficient
- spearman : Spearman rank correlation
- **callable: callable with input two 1d ndarrays** and returning a float. Note that the returned matrix from corr will have 1 along the diagonals and will be symmetric regardless of the callable’s behavior.

New in version 0.24.0.

**min\_periods** [int, optional] Minimum number of observations required per pair of columns to have a valid result. Currently only available for Pearson and Spearman correlation.

### Returns

**DataFrame** Correlation matrix.

See also:

**DataFrame.corrwith**

**Series.corr**

### Examples

```
>>> def histogram_intersection(a, b):
...     v = np.minimum(a, b).sum().round(decimals=1)
...     return v
>>> df = pd.DataFrame([(0.2, 0.3), (0.0, 0.6), (0.6, 0.0), (0.2, 0.1)],
...                    columns=['dogs', 'cats'])
>>> df.corr(method=histogram_intersection)
      dogs  cats
dogs  1.0  0.3
cats  0.3  1.0
```

## pandas.core.groupby.DataFrameGroupBy.count

DataFrameGroupBy.count (*self*)

Compute count of group, excluding missing values.

### Returns

**DataFrame** Count of values within each group.

**pandas.core.groupby.DataFrameGroupBy.cov****property** DataFrameGroupBy.cov

Compute pairwise covariance of columns, excluding NA/null values.

Compute the pairwise covariance among the series of a DataFrame. The returned data frame is the [covariance matrix](#) of the columns of the DataFrame.

Both NA and null values are automatically excluded from the calculation. (See the note below about bias from missing values.) A threshold can be set for the minimum number of observations for each value created. Comparisons with observations below this threshold will be returned as NaN.

This method is generally used for the analysis of time series data to understand the relationship between different measures across time.

**Parameters****min\_periods** [int, optional] Minimum number of observations required per pair of columns to have a valid result.**Returns****DataFrame** The covariance matrix of the series of the DataFrame.**See also:****Series.cov** Compute covariance with another Series.**core.window.EWM.cov** Exponential weighted sample covariance.**core.window.Expanding.cov** Expanding sample covariance.**core.window.Rolling.cov** Rolling sample covariance.**Notes**

Returns the covariance matrix of the DataFrame's time series. The covariance is normalized by N-1.

For DataFrames that have Series that are missing data (assuming that data is [missing at random](#)) the returned covariance matrix will be an unbiased estimate of the variance and covariance between the member Series.However, for many applications this estimate may not be acceptable because the estimate covariance matrix is not guaranteed to be positive semi-definite. This could lead to estimate correlations having absolute values which are greater than one, and/or a non-invertible covariance matrix. See [Estimation of covariance matrices](#) for more details.**Examples**

```
>>> df = pd.DataFrame([(1, 2), (0, 3), (2, 0), (1, 1)],
...                    columns=['dogs', 'cats'])
>>> df.cov()
           dogs      cats
dogs  0.666667 -1.000000
cats -1.000000  1.666667
```

```
>>> np.random.seed(42)
>>> df = pd.DataFrame(np.random.randn(1000, 5),
...                    columns=['a', 'b', 'c', 'd', 'e'])
>>> df.cov()
           a          b          c          d          e
a  0.998438 -0.020161  0.059277 -0.008943  0.014144
b -0.020161  1.059352 -0.008543 -0.024738  0.009826
```

(continues on next page)

(continued from previous page)

```
c  0.059277 -0.008543  1.010670 -0.001486 -0.000271
d -0.008943 -0.024738 -0.001486  0.921297 -0.013692
e  0.014144  0.009826 -0.000271 -0.013692  0.977795
```

**Minimum number of periods**

This method also supports an optional `min_periods` keyword that specifies the required minimum number of non-NA observations for each column pair in order to have a valid result:

```
>>> np.random.seed(42)
>>> df = pd.DataFrame(np.random.randn(20, 3),
...                   columns=['a', 'b', 'c'])
>>> df.loc[df.index[:5], 'a'] = np.nan
>>> df.loc[df.index[5:10], 'b'] = np.nan
>>> df.cov(min_periods=12)
           a         b         c
a  0.316741      NaN -0.150812
b      NaN  1.248003  0.191417
c -0.150812  0.191417  0.895202
```

**pandas.core.groupby.DataFrameGroupBy.cummax**

`DataFrameGroupBy.cummax` (*self*, *axis=0*, *\*\*kwargs*)  
Cumulative max for each group.

**Returns**

**Series or DataFrame**

See also:

`Series.groupby`

`DataFrame.groupby`

**pandas.core.groupby.DataFrameGroupBy.cummin**

`DataFrameGroupBy.cummin` (*self*, *axis=0*, *\*\*kwargs*)  
Cumulative min for each group.

**Returns**

**Series or DataFrame**

See also:

`Series.groupby`

`DataFrame.groupby`

**pandas.core.groupby.DataFrameGroupBy.cumprod**

`DataFrameGroupBy.cumprod` (*self*, *axis=0*, *\*args*, *\*\*kwargs*)  
Cumulative product for each group.

**Returns**

**Series or DataFrame**

See also:

`Series.groupby`

`DataFrame.groupby`

**pandas.core.groupby.DataFrameGroupBy.cumsum**

DataFrameGroupBy.**cumsum** (*self*, *axis=0*, \**args*, \*\**kwargs*)

Cumulative sum for each group.

**Returns**

**Series or DataFrame**

See also:

**Series.groupby**

**DataFrame.groupby**

**pandas.core.groupby.DataFrameGroupBy.describe**

DataFrameGroupBy.**describe** (*self*, \*\**kwargs*)

Generate descriptive statistics.

Descriptive statistics include those that summarize the central tendency, dispersion and shape of a dataset's distribution, excluding NaN values.

Analyzes both numeric and object series, as well as DataFrame column sets of mixed data types. The output will vary depending on what is provided. Refer to the notes below for more detail.

**Parameters**

**percentiles** [list-like of numbers, optional] The percentiles to include in the output. All should fall between 0 and 1. The default is [.25, .5, .75], which returns the 25th, 50th, and 75th percentiles.

**include** ['all', list-like of dtypes or None (default), optional] A white list of data types to include in the result. Ignored for Series. Here are the options:

- 'all' : All columns of the input will be included in the output.
- A list-like of dtypes : Limits the results to the provided data types. To limit the result to numeric types submit `numpy.number`. To limit it instead to object columns submit the `numpy.object` data type. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(include=['O'])`). To select pandas categorical columns, use 'category'
- None (default) : The result will include all numeric columns.

**exclude** [list-like of dtypes or None (default), optional,] A black list of data types to omit from the result. Ignored for Series. Here are the options:

- A list-like of dtypes : Excludes the provided data types from the result. To exclude numeric types submit `numpy.number`. To exclude object columns submit the data type `numpy.object`. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(include=['O'])`). To exclude pandas categorical columns, use 'category'
- None (default) : The result will exclude nothing.

**Returns**

**Series or DataFrame** Summary statistics of the Series or Dataframe provided.

See also:

**DataFrame.count** Count number of non-NA/null observations.

**DataFrame.max** Maximum of the values in the object.

**DataFrame.min** Minimum of the values in the object.

**DataFrame.mean** Mean of the values.

**DataFrame.std** Standard deviation of the observations.

**DataFrame.select\_dtypes** Subset of a DataFrame including/excluding columns based on their dtype.

## Notes

For numeric data, the result's index will include `count`, `mean`, `std`, `min`, `max` as well as lower, 50 and upper percentiles. By default the lower percentile is 25 and the upper percentile is 75. The 50 percentile is the same as the median.

For object data (e.g. strings or timestamps), the result's index will include `count`, `unique`, `top`, and `freq`. The `top` is the most common value. The `freq` is the most common value's frequency. Timestamps also include the `first` and `last` items.

If multiple object values have the highest count, then the `count` and `top` results will be arbitrarily chosen from among those with the highest count.

For mixed data types provided via a `DataFrame`, the default is to return only an analysis of numeric columns. If the dataframe consists only of object and categorical data without any numeric columns, the default is to return an analysis of both the object and categorical columns. If `include='all'` is provided as an option, the result will include a union of attributes of each type.

The `include` and `exclude` parameters can be used to limit which columns in a `DataFrame` are analyzed for the output. The parameters are ignored when analyzing a `Series`.

## Examples

Describing a numeric Series.

```
>>> s = pd.Series([1, 2, 3])
>>> s.describe()
count      3.0
mean       2.0
std        1.0
min        1.0
25%        1.5
50%        2.0
75%        2.5
max        3.0
dtype: float64
```

Describing a categorical Series.

```
>>> s = pd.Series(['a', 'a', 'b', 'c'])
>>> s.describe()
count      4
unique     3
top        a
freq       2
dtype: object
```

Describing a timestamp Series.

```
>>> s = pd.Series([
...     np.datetime64("2000-01-01"),
...     np.datetime64("2010-01-01"),
...     np.datetime64("2010-01-01")
```

(continues on next page)

(continued from previous page)

```
... ])
>>> s.describe()
count          3
unique         2
top    2010-01-01 00:00:00
freq          2
first    2000-01-01 00:00:00
last     2010-01-01 00:00:00
dtype: object
```

Describing a DataFrame. By default only numeric fields are returned.

```
>>> df = pd.DataFrame({'categorical': pd.Categorical(['d', 'e', 'f']),
...                   'numeric': [1, 2, 3],
...                   'object': ['a', 'b', 'c']}
... )
>>> df.describe()
      numeric
count      3.0
mean       2.0
std        1.0
min        1.0
25%        1.5
50%        2.0
75%        2.5
max        3.0
```

Describing all columns of a DataFrame regardless of data type.

```
>>> df.describe(include='all')
      categorical  numeric  object
count           3        3.0      3
unique          3        NaN      3
top            f        NaN      c
freq           1        NaN      1
mean          NaN        2.0     NaN
std           NaN        1.0     NaN
min           NaN        1.0     NaN
25%           NaN        1.5     NaN
50%           NaN        2.0     NaN
75%           NaN        2.5     NaN
max           NaN        3.0     NaN
```

Describing a column from a DataFrame by accessing it as an attribute.

```
>>> df.numeric.describe()
count      3.0
mean       2.0
std        1.0
min        1.0
25%        1.5
50%        2.0
75%        2.5
max        3.0
Name: numeric, dtype: float64
```

Including only numeric columns in a DataFrame description.

```
>>> df.describe(include=[np.number])
      numeric
count      3.0
mean       2.0
std        1.0
min        1.0
25%        1.5
50%        2.0
75%        2.5
max        3.0
```

Including only string columns in a DataFrame description.

```
>>> df.describe(include=[np.object])
      object
count      3
unique     3
top        c
freq       1
```

Including only categorical columns from a DataFrame description.

```
>>> df.describe(include=['category'])
      categorical
count          3
unique         3
top            f
freq           1
```

Excluding numeric columns from a DataFrame description.

```
>>> df.describe(exclude=[np.number])
      categorical  object
count           3      3
unique          3      3
top             f      c
freq            1      1
```

Excluding object columns from a DataFrame description.

```
>>> df.describe(exclude=[np.object])
      categorical  numeric
count           3      3.0
unique          3      NaN
top             f      NaN
freq            1      NaN
mean            NaN      2.0
std             NaN      1.0
min             NaN      1.0
25%            NaN      1.5
50%            NaN      2.0
75%            NaN      2.5
max            NaN      3.0
```

**pandas.core.groupby.DataFrameGroupBy.diff****property** DataFrameGroupBy.diff

First discrete difference of element.

Calculates the difference of a DataFrame element compared with another element in the DataFrame (default is the element in the same column of the previous row).

**Parameters****periods** [int, default 1] Periods to shift for calculating difference, accepts negative values.**axis** [{0 or 'index', 1 or 'columns'}, default 0] Take difference over rows (0) or columns (1).**Returns****DataFrame****See also:****Series.diff** First discrete difference for a Series.**DataFrame.pct\_change** Percent change over given number of periods.**DataFrame.shift** Shift index by desired number of periods with an optional time freq.**Notes**

For boolean dtypes, this uses operator .xor() rather than operator .sub().

**Examples**

Difference with previous row

```
>>> df = pd.DataFrame({'a': [1, 2, 3, 4, 5, 6],
...                   'b': [1, 1, 2, 3, 5, 8],
...                   'c': [1, 4, 9, 16, 25, 36]})
>>> df
   a  b  c
0  1  1  1
1  2  1  4
2  3  2  9
3  4  3 16
4  5  5 25
5  6  8 36
```

```
>>> df.diff()
   a  b  c
0 NaN NaN NaN
1 1.0 0.0 3.0
2 1.0 1.0 5.0
3 1.0 1.0 7.0
4 1.0 2.0 9.0
5 1.0 3.0 11.0
```

Difference with previous column

```
>>> df.diff(axis=1)
   a  b  c
0 NaN 0.0 0.0
1 NaN -1.0 3.0
```

(continues on next page)

(continued from previous page)

```

2 NaN -1.0  7.0
3 NaN -1.0 13.0
4 NaN  0.0 20.0
5 NaN  2.0 28.0

```

Difference with 3rd previous row

```

>>> df.diff(periods=3)
   a    b    c
0 NaN NaN NaN
1 NaN NaN NaN
2 NaN NaN NaN
3 3.0 2.0 15.0
4 3.0 4.0 21.0
5 3.0 6.0 27.0

```

Difference with following row

```

>>> df.diff(periods=-1)
   a    b    c
0 -1.0 0.0 -3.0
1 -1.0 -1.0 -5.0
2 -1.0 -1.0 -7.0
3 -1.0 -2.0 -9.0
4 -1.0 -3.0 -11.0
5 NaN NaN NaN

```

**pandas.core.groupby.DataFrameGroupBy.fill**DataFrameGroupBy.**fill** (*self*, *limit=None*)

Forward fill the values.

**Parameters****limit** [int, optional] Limit of how many values to fill.**Returns****Series or DataFrame** Object with missing values filled.

See also:

**Series.pad****DataFrame.pad****Series.fillna****DataFrame.fillna****pandas.core.groupby.DataFrameGroupBy.fillna****property** DataFrameGroupBy.**fillna**

Fill NA/NaN values using the specified method.

**Parameters****value** [scalar, dict, Series, or DataFrame] Value to use to fill holes (e.g. 0), alternately a dict/Series/DataFrame of values specifying which value to use for each index (for a Series) or column (for a DataFrame). Values not in the dict/Series/DataFrame will not be filled. This value cannot be a list.

**method** [{‘backfill’, ‘bfill’, ‘pad’, ‘ffill’, None}, default None] Method to use for filling holes in reindexed Series pad / ffill: propagate last valid observation forward to next valid backfill / bfill: use next valid observation to fill gap.

**axis** [{0 or ‘index’, 1 or ‘columns’}] Axis along which to fill missing values.

**inplace** [bool, default False] If True, fill in-place. Note: this will modify any other views on this object (e.g., a no-copy slice for a column in a DataFrame).

**limit** [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

**downcast** [dict, default is None] A dict of item->dtype of what to downcast if possible, or the string ‘infer’ which will try to downcast to an appropriate equal type (e.g. float64 to int64 if possible).

### Returns

**DataFrame or None** Object with missing values filled or None if inplace=True.

See also:

**interpolate** Fill NaN values using interpolation.

**reindex** Conform object to new index.

**asfreq** Convert TimeSeries to specified frequency.

### Examples

```
>>> df = pd.DataFrame([[np.nan, 2, np.nan, 0],
...                   [3, 4, np.nan, 1],
...                   [np.nan, np.nan, np.nan, 5],
...                   [np.nan, 3, np.nan, 4]],
...                   columns=list('ABCD'))
>>> df
   A    B    C    D
0 NaN  2.0 NaN  0
1  3.0  4.0 NaN  1
2 NaN  NaN NaN  5
3 NaN  3.0 NaN  4
```

Replace all NaN elements with 0s.

```
>>> df.fillna(0)
   A    B    C    D
0  0.0  2.0  0.0  0
1  3.0  4.0  0.0  1
2  0.0  0.0  0.0  5
3  0.0  3.0  0.0  4
```

We can also propagate non-null values forward or backward.

```
>>> df.fillna(method='ffill')
   A    B    C    D
0 NaN  2.0 NaN  0
1  3.0  4.0 NaN  1
```

(continues on next page)

(continued from previous page)

```
2  3.0 4.0 NaN 5
3  3.0 3.0 NaN 4
```

Replace all NaN elements in column 'A', 'B', 'C', and 'D', with 0, 1, 2, and 3 respectively.

```
>>> values = {'A': 0, 'B': 1, 'C': 2, 'D': 3}
>>> df.fillna(value=values)
   A  B  C  D
0  0.0 2.0 2.0 0
1  3.0 4.0 2.0 1
2  0.0 1.0 2.0 5
3  0.0 3.0 2.0 4
```

Only replace the first NaN element.

```
>>> df.fillna(value=values, limit=1)
   A  B  C  D
0  0.0 2.0 2.0 0
1  3.0 4.0 NaN 1
2  NaN 1.0 NaN 5
3  NaN 3.0 NaN 4
```

## pandas.core.groupby.DataFrameGroupBy.filter

DataFrameGroupBy.**filter** (*self, func, dropna=True, \*args, \*\*kwargs*)

Return a copy of a DataFrame excluding elements from groups that do not satisfy the boolean criterion specified by *func*.

### Parameters

**f** [function] Function to apply to each subframe. Should return True or False.

**dropna** [Drop groups that do not pass the filter. True by default;] If False, groups that evaluate False are filled with NaNs.

### Returns

**filtered** [DataFrame]

## Notes

Each subframe is endowed the attribute 'name' in case you need to know which group you are working on.

## Examples

```
>>> df = pd.DataFrame({'A' : ['foo', 'bar', 'foo', 'bar',
...                          'foo', 'bar'],
...                   'B' : [1, 2, 3, 4, 5, 6],
...                   'C' : [2.0, 5., 8., 1., 2., 9.]})
>>> grouped = df.groupby('A')
>>> grouped.filter(lambda x: x['B'].mean() > 3.)
   A  B  C
1  bar  2  5.0
3  bar  4  1.0
5  bar  6  9.0
```

**pandas.core.groupby.DataFrameGroupBy.hist****property** DataFrameGroupBy.**hist**

Make a histogram of the DataFrame's.

A [histogram](#) is a representation of the distribution of data. This function calls `matplotlib.pyplot.hist()`, on each series in the DataFrame, resulting in one histogram per column.

**Parameters**

- data** [DataFrame] The pandas object holding the data.
  - column** [str or sequence] If passed, will be used to limit data to a subset of columns.
  - by** [object, optional] If passed, then used to form histograms for separate groups.
  - grid** [bool, default True] Whether to show axis grid lines.
  - xlabelsize** [int, default None] If specified changes the x-axis label size.
  - xrot** [float, default None] Rotation of x axis labels. For example, a value of 90 displays the x labels rotated 90 degrees clockwise.
  - ylabelsize** [int, default None] If specified changes the y-axis label size.
  - yrot** [float, default None] Rotation of y axis labels. For example, a value of 90 displays the y labels rotated 90 degrees clockwise.
  - ax** [Matplotlib axes object, default None] The axes to plot the histogram on.
  - sharex** [bool, default True if ax is None else False] In case subplots=True, share x axis and set some x axis labels to invisible; defaults to True if ax is None otherwise False if an ax is passed in. Note that passing in both an ax and sharex=True will alter all x axis labels for all subplots in a figure.
  - sharey** [bool, default False] In case subplots=True, share y axis and set some y axis labels to invisible.
  - figsize** [tuple] The size in inches of the figure to create. Uses the value in `matplotlib.rcParams` by default.
  - layout** [tuple, optional] Tuple of (rows, columns) for the layout of the histograms.
  - bins** [int or sequence, default 10] Number of histogram bins to be used. If an integer is given, bins + 1 bin edges are calculated and returned. If bins is a sequence, gives bin edges, including left edge of first bin and right edge of last bin. In this case, bins is returned unmodified.
  - backend** [str, default None] Backend to use instead of the backend specified in the option `plotting.backend`. For instance, 'matplotlib'. Alternatively, to specify the `plotting.backend` for the whole session, set `pd.options.plotting.backend`.
- New in version 1.0.0.
- \*\*kwargs** All other plotting keyword arguments to be passed to `matplotlib.pyplot.hist()`.

**Returns****matplotlib.AxesSubplot or numpy.ndarray of them**

See also:

[matplotlib.pyplot.hist](#) Plot a histogram using matplotlib.

## Examples

This example draws a histogram based on the length and width of some animals, displayed in three bins

```
>>> df = pd.DataFrame({
...     'length': [1.5, 0.5, 1.2, 0.9, 3],
...     'width': [0.7, 0.2, 0.15, 0.2, 1.1]
... }, index=['pig', 'rabbit', 'duck', 'chicken', 'horse'])
>>> hist = df.hist(bins=3)
```

### pandas.core.groupby.DataFrameGroupBy.idxmax

**property** DataFrameGroupBy.idxmax

Return index of first occurrence of maximum over requested axis.

NA/null values are excluded.

#### Parameters

**axis** [{0 or 'index', 1 or 'columns'}, default 0] The axis to use. 0 or 'index' for row-wise, 1 or 'columns' for column-wise.

**skipna** [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

#### Returns

**Series** Indexes of maxima along the specified axis.

**Raises**

**ValueError**

- If the row/column is empty

**See also:**

**Series.idxmax**

**Notes**

This method is the DataFrame version of `ndarray.argmax`.

**pandas.core.groupby.DataFrameGroupBy.idxmin**

**property** DataFrameGroupBy.**idxmin**

Return index of first occurrence of minimum over requested axis.

NA/null values are excluded.

**Parameters**

**axis** [{0 or 'index', 1 or 'columns'}, default 0] The axis to use. 0 or 'index' for row-wise, 1 or 'columns' for column-wise.

**skipna** [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

**Returns**

**Series** Indexes of minima along the specified axis.

**Raises**

**ValueError**

- If the row/column is empty

**See also:**

**Series.idxmin**

**Notes**

This method is the DataFrame version of `ndarray.argmin`.

**pandas.core.groupby.DataFrameGroupBy.mad**

**property** DataFrameGroupBy.**mad**

Return the mean absolute deviation of the values for the requested axis.

**Parameters**

**axis** [{index (0), columns (1)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

**Returns**

**Series or DataFrame (if level specified)**

**pandas.core.groupby.DataFrameGroupBy.nunique**

DataFrameGroupBy.**nunique** (*self*, *dropna*: bool = True)

Return DataFrame with number of distinct observations per group for each column.

**Parameters**

**dropna** [bool, default True] Don't include NaN in the counts.

**Returns**

**nunique: DataFrame**

**Examples**

```
>>> df = pd.DataFrame({'id': ['spam', 'egg', 'egg', 'spam',
...                           'ham', 'ham'],
...                   'value1': [1, 5, 5, 2, 5, 5],
...                   'value2': list('abbaxy')})
>>> df
   id  value1  value2
0  spam      1      a
1  egg      5      b
2  egg      5      b
3  spam      2      a
4  ham      5      x
5  ham      5      y
```

```
>>> df.groupby('id').nunique()
   id  value1  value2
id
egg    1      1      1
ham    1      1      2
spam   1      2      1
```

Check for rows with the same id but conflicting values:

```
>>> df.groupby('id').filter(lambda g: (g.nunique() > 1).any())
   id  value1  value2
0  spam      1      a
3  spam      2      a
4  ham      5      x
5  ham      5      y
```

**pandas.core.groupby.DataFrameGroupBy.pct\_change**

DataFrameGroupBy.**pct\_change** (*self*, *periods=1*, *fill\_method='pad'*, *limit=None*, *freq=None*, *axis=0*)  
 Calculate pct\_change of each value to previous entry in group.

**Returns**

**Series or DataFrame** Percentage changes within each group.

See also:

**Series.groupby**

**DataFrame.groupby**

**pandas.core.groupby.DataFrameGroupBy.plot**

**property** DataFrameGroupBy.**plot**  
 Class implementing the .plot attribute for groupby objects.

**pandas.core.groupby.DataFrameGroupBy.quantile**

DataFrameGroupBy.**quantile** (*self*, *q=0.5*, *interpolation: str = 'linear'*)  
 Return group values at the given quantile, a la numpy.percentile.

**Parameters**

**q** [float or array-like, default 0.5 (50% quantile)] Value(s) between 0 and 1 providing the quantile(s) to compute.

**interpolation** [{'linear', 'lower', 'higher', 'midpoint', 'nearest'}] Method to use when the desired quantile falls between two points.

**Returns**

**Series or DataFrame** Return type determined by caller of GroupBy object.

See also:

**Series.quantile** Similar method for Series.

**DataFrame.quantile** Similar method for DataFrame.

**numpy.percentile** NumPy method to compute qth percentile.

**Examples**

```
>>> df = pd.DataFrame([
...     ['a', 1], ['a', 2], ['a', 3],
...     ['b', 1], ['b', 3], ['b', 5]
... ], columns=['key', 'val'])
>>> df.groupby('key').quantile()
val
key
a    2.0
b    3.0
```

## pandas.core.groupby.DataFrameGroupBy.rank

DataFrameGroupBy.**rank** (*self*, *method*: str = 'average', *ascending*: bool = True, *na\_option*: str = 'keep', *pct*: bool = False, *axis*: int = 0)

Provide the rank of values within each group.

### Parameters

**method** [{ 'average', 'min', 'max', 'first', 'dense' }, default 'average']

- average: average rank of group.
- min: lowest rank in group.
- max: highest rank in group.
- first: ranks assigned in order they appear in the array.
- dense: like 'min', but rank always increases by 1 between groups.

**ascending** [bool, default True] False for ranks by high (1) to low (N).

**na\_option** [{ 'keep', 'top', 'bottom' }, default 'keep']

- keep: leave NA values where they are.
- top: smallest rank if ascending.
- bottom: smallest rank if descending.

**pct** [bool, default False] Compute percentage rank of data within each group.

**axis** [int, default 0] The axis of the object over which to compute the rank.

### Returns

**DataFrame with ranking of values within each group**

See also:

**Series.groupby**

**DataFrame.groupby**

## pandas.core.groupby.DataFrameGroupBy.resample

DataFrameGroupBy.**resample** (*self*, *rule*, *\*args*, *\*\*kwargs*)

Provide resampling when using a TimeGrouper.

Given a grouper, the function resamples it according to a string “string” -> “frequency”.

See the *frequency aliases* documentation for more details.

### Parameters

**rule** [str or DateOffset] The offset string or object representing target grouper conversion.

**\*args, \*\*kwargs** Possible arguments are *how*, *fill\_method*, *limit*, *kind* and *on*, and other arguments of *TimeGrouper*.

### Returns

**Grouper** Return a new grouper with our resampler appended.

See also:

**Grouper** Specify a frequency to resample with when grouping by a key.

**DatetimeIndex.resample** Frequency conversion and resampling of time series.

## Examples

```
>>> idx = pd.date_range('1/1/2000', periods=4, freq='T')
>>> df = pd.DataFrame(data=4 * [range(2)],
...                   index=idx,
...                   columns=['a', 'b'])
>>> df.iloc[2, 0] = 5
>>> df
```

	a	b
2000-01-01 00:00:00	0	1
2000-01-01 00:01:00	0	1
2000-01-01 00:02:00	5	1
2000-01-01 00:03:00	0	1

Downsample the DataFrame into 3 minute bins and sum the values of the timestamps falling into a bin.

```
>>> df.groupby('a').resample('3T').sum()
```

a		a	b
0	2000-01-01 00:00:00	0	2
	2000-01-01 00:03:00	0	1
5	2000-01-01 00:00:00	5	1

Upsample the series into 30 second bins.

```
>>> df.groupby('a').resample('30S').sum()
```

a		a	b
0	2000-01-01 00:00:00	0	1
	2000-01-01 00:00:30	0	0
	2000-01-01 00:01:00	0	1
	2000-01-01 00:01:30	0	0
	2000-01-01 00:02:00	0	0
	2000-01-01 00:02:30	0	0
5	2000-01-01 00:03:00	0	1
	2000-01-01 00:02:00	5	1

Resample by month. Values are assigned to the month of the period.

```
>>> df.groupby('a').resample('M').sum()
```

a		a	b
0	2000-01-31	0	3
	2000-01-31	5	1

Downsample the series into 3 minute bins as above, but close the right side of the bin interval.

```
>>> df.groupby('a').resample('3T', closed='right').sum()
```

a		a	b
0	1999-12-31 23:57:00	0	1
	2000-01-01 00:00:00	0	2
5	2000-01-01 00:00:00	5	1

Downsample the series into 3 minute bins and close the right side of the bin interval, but label each bin using the right edge instead of the left.

```
>>> df.groupby('a').resample('3T', closed='right', label='right').sum()
      a  b
a
0  2000-01-01 00:00:00  0  1
   2000-01-01 00:03:00  0  2
5  2000-01-01 00:03:00  5  1
```

Add an offset of twenty seconds.

```
>>> df.groupby('a').resample('3T', loffset='20s').sum()
      a  b
a
0  2000-01-01 00:00:20  0  2
   2000-01-01 00:03:20  0  1
5  2000-01-01 00:00:20  5  1
```

### pandas.core.groupby.DataFrameGroupBy.shift

DataFrameGroupBy.**shift** (*self*, *periods=1*, *freq=None*, *axis=0*, *fill\_value=None*)

Shift each group by periods observations.

#### Parameters

**periods** [int, default 1] Number of periods to shift.

**freq** [frequency string]

**axis** [axis to shift, default 0]

**fill\_value** [optional] New in version 0.24.0.

#### Returns

**Series or DataFrame** Object shifted within each group.

See also:

**Series.groupby**

**DataFrame.groupby**

### pandas.core.groupby.DataFrameGroupBy.size

DataFrameGroupBy.**size** (*self*)

Compute group sizes.

#### Returns

**Series** Number of rows in each group.

See also:

**Series.groupby**

**DataFrame.groupby**

**pandas.core.groupby.DataFrameGroupBy.skew****property** DataFrameGroupBy.**skew**

Return unbiased skew over requested axis.

Normalized by N-1.

**Parameters****axis** [{index (0), columns (1)}] Axis for the function to be applied on.**skipna** [bool, default True] Exclude NA/null values when computing the result.**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.**\*\*kwargs** Additional keyword arguments to be passed to the function.**Returns****Series or DataFrame (if level specified)****pandas.core.groupby.DataFrameGroupBy.take****property** DataFrameGroupBy.**take**Return the elements in the given *positional* indices along an axis.

This means that we are not indexing according to actual values in the index attribute of the object. We are indexing according to the actual position of the element in the object.

**Parameters****indices** [array-like] An array of ints indicating which positions to take.**axis** [{0 or 'index', 1 or 'columns', None}, default 0] The axis on which to select elements. 0 means that we are selecting rows, 1 means that we are selecting columns.**is\_copy** [bool] Before pandas 1.0, `is_copy=False` can be specified to ensure that the return value is an actual copy. Starting with pandas 1.0, `take` always returns a copy, and the keyword is therefore deprecated.

Deprecated since version 1.0.0.

**\*\*kwargs** For compatibility with `numpy.take()`. Has no effect on the output.**Returns****taken** [same type as caller] An array-like containing the elements taken from the object.**See also:****DataFrame.loc** Select a subset of a DataFrame by labels.**DataFrame.iloc** Select a subset of a DataFrame by positions.**numpy.take** Take elements from an array along an axis.

## Examples

```
>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
...                    ('parrot', 'bird', 24.0),
...                    ('lion', 'mammal', 80.5),
...                    ('monkey', 'mammal', np.nan)],
...                    columns=['name', 'class', 'max_speed'],
...                    index=[0, 2, 3, 1])
>>> df
   name  class  max_speed
0  falcon  bird    389.0
2  parrot  bird     24.0
3   lion  mammal    80.5
1  monkey  mammal     NaN
```

Take elements at positions 0 and 3 along the axis 0 (default).

Note how the actual indices selected (0 and 1) do not correspond to our selected indices 0 and 3. That's because we are selecting the 0th and 3rd rows, not rows whose indices equal 0 and 3.

```
>>> df.take([0, 3])
   name  class  max_speed
0  falcon  bird    389.0
1  monkey  mammal     NaN
```

Take elements at indices 1 and 2 along the axis 1 (column selection).

```
>>> df.take([1, 2], axis=1)
   class  max_speed
0   bird    389.0
2   bird     24.0
3  mammal    80.5
1  mammal     NaN
```

We may take elements using negative integers for positive indices, starting from the end of the object, just like with Python lists.

```
>>> df.take([-1, -2])
   name  class  max_speed
1  monkey  mammal     NaN
3   lion  mammal    80.5
```

## pandas.core.groupby.DataFrameGroupBy.tshift

### property DataFrameGroupBy.tshift

Shift the time index, using the index's frequency if available.

#### Parameters

**periods** [int] Number of periods to move, can be positive or negative.

**freq** [DateOffset, timedelta, or str, default None] Increment to use from the tseries module or time rule expressed as a string (e.g. 'EOM').

**axis** [{0 or 'index', 1 or 'columns', None}, default 0] Corresponds to the axis that contains the Index.

#### Returns

**shifted** [Series/DataFrame]**Notes**

If `freq` is not specified then tries to use the `freq` or `inferred_freq` attributes of the index. If neither of those attributes exist, a `ValueError` is thrown

The following methods are available only for `SeriesGroupBy` objects.

<code>SeriesGroupBy.nlargest</code>	Return the largest $n$ elements.
<code>SeriesGroupBy.nsmallest</code>	Return the smallest $n$ elements.
<code>SeriesGroupBy.nunique(self, dropna)</code>	Return number of unique elements in the group.
<code>SeriesGroupBy.unique</code>	Return unique values of Series object.
<code>SeriesGroupBy.value_counts(self[,...])</code>	
<code>SeriesGroupBy.is_monotonic_increasing</code>	Return boolean if values in the object are monotonic_increasing.
<code>SeriesGroupBy.is_monotonic_decreasing</code>	Return boolean if values in the object are monotonic_decreasing.

**pandas.core.groupby.SeriesGroupBy.nlargest****property** `SeriesGroupBy.nlargest`Return the largest  $n$  elements.**Parameters**

**n** [int, default 5] Return this many descending sorted values.

**keep** [{‘first’, ‘last’, ‘all’}, default ‘first’] When there are duplicate values that cannot all fit in a Series of  $n$  elements:

- **first** [return the first  $n$  occurrences in order] of appearance.
- **last** [return the last  $n$  occurrences in reverse] order of appearance.
- **all** [keep all occurrences. This can result in a Series of] size larger than  $n$ .

**Returns**

**Series** The  $n$  largest values in the Series, sorted in decreasing order.

**See also:**

**Series.nsmallest** Get the  $n$  smallest elements.

**Series.sort\_values** Sort Series by values.

**Series.head** Return the first  $n$  rows.

**Notes**

Faster than `.sort_values(ascending=False).head(n)` for small  $n$  relative to the size of the Series object.

## Examples

```
>>> countries_population = {"Italy": 59000000, "France": 65000000,
...                          "Malta": 434000, "Maldives": 434000,
...                          "Brunei": 434000, "Iceland": 337000,
...                          "Nauru": 11300, "Tuvalu": 11300,
...                          "Anguilla": 11300, "Monserat": 5200}
>>> s = pd.Series(countries_population)
>>> s
Italy          59000000
France         65000000
Malta           434000
Maldives        434000
Brunei          434000
Iceland         337000
Nauru           11300
Tuvalu          11300
Anguilla        11300
Monserat         5200
dtype: int64
```

The  $n$  largest elements where  $n=5$  by default.

```
>>> s.nlargest()
France         65000000
Italy          59000000
Malta           434000
Maldives        434000
Brunei          434000
dtype: int64
```

The  $n$  largest elements where  $n=3$ . Default *keep* value is 'first' so Malta will be kept.

```
>>> s.nlargest(3)
France         65000000
Italy          59000000
Malta           434000
dtype: int64
```

The  $n$  largest elements where  $n=3$  and keeping the last duplicates. Brunei will be kept since it is the last with value 434000 based on the index order.

```
>>> s.nlargest(3, keep='last')
France         65000000
Italy          59000000
Brunei          434000
dtype: int64
```

The  $n$  largest elements where  $n=3$  with all duplicates kept. Note that the returned Series has five elements due to the three duplicates.

```
>>> s.nlargest(3, keep='all')
France         65000000
Italy          59000000
Malta           434000
Maldives        434000
Brunei          434000
dtype: int64
```

**pandas.core.groupby.SeriesGroupBy.nsmallest****property** SeriesGroupBy.nsmallestReturn the smallest  $n$  elements.**Parameters****n** [int, default 5] Return this many ascending sorted values.**keep** [{‘first’, ‘last’, ‘all’}, default ‘first’] When there are duplicate values that cannot all fit in a Series of  $n$  elements:

- **first** [return the first  $n$  occurrences in order] of appearance.
- **last** [return the last  $n$  occurrences in reverse] order of appearance.
- **all** [keep all occurrences. This can result in a Series of] size larger than  $n$ .

**Returns****Series** The  $n$  smallest values in the Series, sorted in increasing order.**See also:****Series.nlargest** Get the  $n$  largest elements.**Series.sort\_values** Sort Series by values.**Series.head** Return the first  $n$  rows.**Notes**Faster than `.sort_values().head(n)` for small  $n$  relative to the size of the Series object.**Examples**

```
>>> countries_population = {"Italy": 59000000, "France": 65000000,
...                          "Brunei": 434000, "Malta": 434000,
...                          "Maldives": 434000, "Iceland": 337000,
...                          "Nauru": 11300, "Tuvalu": 11300,
...                          "Anguilla": 11300, "Monserat": 5200}
>>> s = pd.Series(countries_population)
>>> s
Italy          59000000
France         65000000
Brunei          434000
Malta           434000
Maldives        434000
Iceland         337000
Nauru           11300
Tuvalu          11300
Anguilla        11300
Monserat         5200
dtype: int64
```

The  $n$  smallest elements where  $n=5$  by default.

```
>>> s.nsmallest()
Monserat         5200
Nauru            11300
Tuvalu           11300
```

(continues on next page)

(continued from previous page)

```

Anguilla      11300
Iceland      337000
dtype: int64

```

The  $n$  smallest elements where  $n=3$ . Default *keep* value is 'first' so Nauru and Tuvalu will be kept.

```

>>> s.nsmallest(3)
Monserat      5200
Nauru         11300
Tuvalu        11300
dtype: int64

```

The  $n$  smallest elements where  $n=3$  and keeping the last duplicates. Anguilla and Tuvalu will be kept since they are the last with value 11300 based on the index order.

```

Monserat      5200
Anguilla      11300
Tuvalu        11300
dtype: int64

```

The  $n$  smallest elements where  $n=3$  with all duplicates kept. Note that the returned Series has four elements due to the three duplicates.

```

>>> s.nsmallest(3, keep='all')
Monserat      5200
Nauru         11300
Tuvalu        11300
Anguilla      11300
dtype: int64

```

### pandas.core.groupby.SeriesGroupBy.nunique

SeriesGroupBy.**nunique** (*self*, *dropna: bool = True*) → pandas.core.series.Series

Return number of unique elements in the group.

#### Returns

**Series** Number of unique values within each group.

### pandas.core.groupby.SeriesGroupBy.unique

**property** SeriesGroupBy.**unique**

Return unique values of Series object.

Uniques are returned in order of appearance. Hash table-based unique, therefore does NOT sort.

#### Returns

**ndarray or ExtensionArray** The unique values returned as a NumPy array. See Notes.

**See also:**

**unique** Top-level unique method for any 1-d array-like object.

**Index.unique** Return Index with unique values from an Index object.

## Notes

Returns the unique values as a NumPy array. In case of an extension-array backed Series, a new `ExtensionArray` of that type with just the unique values is returned. This includes

- Categorical
- Period
- Datetime with Timezone
- Interval
- Sparse
- IntegerNA

See Examples section.

## Examples

```
>>> pd.Series([2, 1, 3, 3], name='A').unique()
array([2, 1, 3])
```

```
>>> pd.Series([pd.Timestamp('2016-01-01') for _ in range(3)]).unique()
array(['2016-01-01T00:00:00.000000000'], dtype='datetime64[ns]')
```

```
>>> pd.Series([pd.Timestamp('2016-01-01', tz='US/Eastern')
...           for _ in range(3)]).unique()
<DatetimeArray>
['2016-01-01 00:00:00-05:00']
Length: 1, dtype: datetime64[ns, US/Eastern]
```

An unordered Categorical will return categories in the order of appearance.

```
>>> pd.Series(pd.Categorical(list('baabc'))).unique()
[b, a, c]
Categories (3, object): [b, a, c]
```

An ordered Categorical preserves the category ordering.

```
>>> pd.Series(pd.Categorical(list('baabc'), categories=list('abc'),
...                         ordered=True)).unique()
[b, a, c]
Categories (3, object): [a < b < c]
```

## pandas.core.groupby.SeriesGroupBy.value\_counts

`SeriesGroupBy.value_counts` (*self*, *normalize=False*, *sort=True*, *ascending=False*, *bins=None*, *dropna=True*)

### pandas.core.groupby.SeriesGroupBy.is\_monotonic\_increasing

**property** SeriesGroupBy.**is\_monotonic\_increasing**  
Return boolean if values in the object are monotonic\_increasing.

**Returns**

**bool**

### pandas.core.groupby.SeriesGroupBy.is\_monotonic\_decreasing

**property** SeriesGroupBy.**is\_monotonic\_decreasing**  
Return boolean if values in the object are monotonic\_decreasing.

**Returns**

**bool**

The following methods are available only for DataFrameGroupBy objects.

---

<i>DataFrameGroupBy</i> . <i>corrwith</i>	Compute pairwise correlation.
<i>DataFrameGroupBy</i> . <i>boxplot</i> (grouped[,...])	Make box plots from DataFrameGroupBy data.

---

### pandas.core.groupby.DataFrameGroupBy.corrwith

**property** DataFrameGroupBy.**corrwith**  
Compute pairwise correlation.

Pairwise correlation is computed between rows or columns of DataFrame with rows or columns of Series or DataFrame. DataFrames are first aligned along both axes before computing the correlations.

**Parameters**

**other** [DataFrame, Series] Object with which to compute correlations.

**axis** [{0 or 'index', 1 or 'columns'}, default 0] The axis to use. 0 or 'index' to compute column-wise, 1 or 'columns' for row-wise.

**drop** [bool, default False] Drop missing indices from result.

**method** [{'pearson', 'kendall', 'spearman'} or callable] Method of correlation:

- pearson : standard correlation coefficient
- kendall : Kendall Tau correlation coefficient
- spearman : Spearman rank correlation
- **callable: callable with input two 1d ndarrays** and returning a float.

New in version 0.24.0.

**Returns**

**Series** Pairwise correlations.

**See also:**

**DataFrame.corr**

**pandas.core.groupby.DataFrameGroupBy.boxplot**

DataFrameGroupBy.**boxplot** (*grouped*, *subplots=True*, *column=None*, *fontsize=None*, *rot=0*,  
*grid=True*, *ax=None*, *figsize=None*, *layout=None*, *sharex=False*,  
*sharey=True*, *backend=None*, *\*\*kwargs*)

Make box plots from DataFrameGroupBy data.

**Parameters**

**grouped** [Grouped DataFrame]

**subplots** [bool]

- `False` - no subplots will be used
- `True` - create a subplot for each group.

**column** [column name or list of names, or vector] Can be any valid input to `groupby`.

**fontsize** [int or str]

**rot** [label rotation angle]

**grid** [Setting this to `True` will show the grid]

**ax** [Matplotlib axis object, default `None`]

**figsize** [A tuple (width, height) in inches]

**layout** [tuple (optional)] The layout of the plot: (rows, columns).

**sharex** [bool, default `False`] Whether x-axes will be shared among subplots.

New in version 0.23.1.

**sharey** [bool, default `True`] Whether y-axes will be shared among subplots.

New in version 0.23.1.

**backend** [str, default `None`] Backend to use instead of the backend specified in the option `plotting.backend`. For instance, `'matplotlib'`. Alternatively, to specify the `plotting.backend` for the whole session, set `pd.options.plotting.backend`.

New in version 1.0.0.

**\*\*kwargs** All other plotting keyword arguments to be passed to matplotlib's `boxplot` function.

**Returns**

**dict of key/value = group key/DataFrame.boxplot return value**

**or DataFrame.boxplot return value in case `subplots=figures=False`**

## Examples

```
>>> import itertools
>>> tuples = [t for t in itertools.product(range(1000), range(4))]
>>> index = pd.MultiIndex.from_tuples(tuples, names=['lv10', 'lv11'])
>>> data = np.random.randn(len(index), 4)
>>> df = pd.DataFrame(data, columns=list('ABCD'), index=index)
>>>
>>> grouped = df.groupby(level='lv11')
>>> boxplot_frame_groupby(grouped)
>>>
>>> grouped = df.unstack(level='lv11').groupby(level=0, axis=1)
>>> boxplot_frame_groupby(grouped, subplots=False)
```

{{ header }}

## 4.12 Resampling

Resampler objects are returned by `resample` calls: `pandas.DataFrame.resample()`, `pandas.Series.resample()`.

### 4.12.1 Indexing, iteration

<code>Resampler.__iter__(self)</code>	Resampler iterator.
<code>Resampler.groups</code>	Dict {group name -> group labels}.
<code>Resampler.indices</code>	Dict {group name -> group indices}.
<code>Resampler.get_group(self, name[, obj])</code>	Construct DataFrame from group with provided name.

#### `pandas.core.resample.Resampler.__iter__`

`Resampler.__iter__(self)`

Resampler iterator.

#### Returns

Generator yielding sequence of (name, subsetted object)

for each group.

See also:

`GroupBy.__iter__`

#### `pandas.core.resample.Resampler.groups`

**property** `Resampler.groups`

Dict {group name -> group labels}.

**pandas.core.resample.Resampler.indices**

**property** `Resampler.indices`  
Dict {group name -> group indices}.

**pandas.core.resample.Resampler.get\_group**

`Resampler.get_group(self, name, obj=None)`  
Construct DataFrame from group with provided name.

**Parameters**

- name** [object] The name of the group to get as a DataFrame.
- obj** [DataFrame, default None] The DataFrame to take the DataFrame out of. If it is None, the object groupby was called on will be used.

**Returns**

**group** [same type as obj]

**4.12.2 Function application**

<code>Resampler.apply(self, func, *args, **kwargs)</code>	Aggregate using one or more operations over the specified axis.
<code>Resampler.aggregate(self, func, *args, ...)</code>	Aggregate using one or more operations over the specified axis.
<code>Resampler.transform(self, arg, *args, ...)</code>	Call function producing a like-indexed Series on each group and return a Series with the transformed values.
<code>Resampler.pipe(self, func, *args, **kwargs)</code>	Apply a function <i>func</i> with arguments to this Resampler object and return the function's result.

**pandas.core.resample.Resampler.apply**

`Resampler.apply(self, func, *args, **kwargs)`  
Aggregate using one or more operations over the specified axis.

**Parameters**

**func** [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. `[np.sum, 'mean']`
- dict of axis labels -> functions, function names or list of such.

**\*args** Positional arguments to pass to *func*.

**\*\*kwargs** Keyword arguments to pass to *func*.

**Returns**

**scalar, Series or DataFrame** The return can be:

- scalar : when Series.agg is called with single function
- Series : when DataFrame.agg is called with a single function
- DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

See also:

**DataFrame.groupby.aggregate**  
**DataFrame.resample.transform**  
**DataFrame.aggregate**

## Notes

agg is an alias for aggregate. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

## Examples

```
>>> s = pd.Series([1,2,3,4,5],
                  index=pd.date_range('20130101', periods=5, freq='s'))
2013-01-01 00:00:00    1
2013-01-01 00:00:01    2
2013-01-01 00:00:02    3
2013-01-01 00:00:03    4
2013-01-01 00:00:04    5
Freq: S, dtype: int64
```

```
>>> r = s.resample('2s')
DatetimeIndexResampler [freq=<2 * Seconds>, axis=0, closed=left,
                        label=left, convention=start, base=0]
```

```
>>> r.agg(np.sum)
2013-01-01 00:00:00    3
2013-01-01 00:00:02    7
2013-01-01 00:00:04    5
Freq: 2S, dtype: int64
```

```
>>> r.agg(['sum', 'mean', 'max'])
                sum  mean  max
2013-01-01 00:00:00    3   1.5   2
2013-01-01 00:00:02    7   3.5   4
2013-01-01 00:00:04    5   5.0   5
```

```
>>> r.agg({'result' : lambda x: x.mean() / x.std(),
          'total' : np.sum})
                total  result
2013-01-01 00:00:00    3  2.121320
2013-01-01 00:00:02    7  4.949747
2013-01-01 00:00:04    5         NaN
```

**pandas.core.resample.Resampler.aggregate**Resampler.**aggregate** (*self*, *func*, \**args*, \*\**kwargs*)

Aggregate using one or more operations over the specified axis.

**Parameters****func** [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. [np.sum, 'mean']
- dict of axis labels -> functions, function names or list of such.

**\*args** Positional arguments to pass to *func*.**\*\*kwargs** Keyword arguments to pass to *func*.**Returns****scalar, Series or DataFrame** The return can be:

- scalar : when Series.agg is called with single function
- Series : when DataFrame.agg is called with a single function
- DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

**See also:**

**DataFrame.groupby.aggregate**  
**DataFrame.resample.transform**  
**DataFrame.aggregate**

**Notes***agg* is an alias for *aggregate*. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

**Examples**

```
>>> s = pd.Series([1,2,3,4,5],
                  index=pd.date_range('20130101', periods=5, freq='s'))
2013-01-01 00:00:00    1
2013-01-01 00:00:01    2
2013-01-01 00:00:02    3
2013-01-01 00:00:03    4
2013-01-01 00:00:04    5
Freq: S, dtype: int64
```

```
>>> r = s.resample('2s')
DatetimeIndexResampler [freq=<2 * Seconds>, axis=0, closed=left,
                        label=left, convention=start, base=0]
```

```
>>> r.agg(np.sum)
2013-01-01 00:00:00    3
2013-01-01 00:00:02    7
2013-01-01 00:00:04    5
Freq: 2S, dtype: int64
```

```
>>> r.agg(['sum', 'mean', 'max'])
              sum  mean  max
2013-01-01 00:00:00    3   1.5   2
2013-01-01 00:00:02    7   3.5   4
2013-01-01 00:00:04    5   5.0   5
```

```
>>> r.agg({'result' : lambda x: x.mean() / x.std(),
          'total' : np.sum})
              total  result
2013-01-01 00:00:00    3  2.121320
2013-01-01 00:00:02    7  4.949747
2013-01-01 00:00:04    5         NaN
```

### pandas.core.resample.Resampler.transform

Resampler.**transform**(*self*, *arg*, \**args*, \*\**kwargs*)

Call function producing a like-indexed Series on each group and return a Series with the transformed values.

#### Parameters

**arg** [function] To apply to each group. Should return a Series with the same index.

#### Returns

**transformed** [Series]

### Examples

```
>>> resampled.transform(lambda x: (x - x.mean()) / x.std())
```

### pandas.core.resample.Resampler.pipe

Resampler.**pipe**(*self*, *func*, \**args*, \*\**kwargs*)

Apply a function *func* with arguments to this Resampler object and return the function's result.

New in version 0.23.0.

Use *.pipe* when you want to improve readability by chaining together functions that expect Series, DataFrames, GroupBy or Resampler objects. Instead of writing

```
>>> h(g(f(df.groupby('group')), arg1=a), arg2=b, arg3=c)
```

You can write

```
>>> (df.groupby('group')
...   .pipe(f)
...   .pipe(g, arg1=a)
...   .pipe(h, arg2=b, arg3=c))
```

which is much more readable.

#### Parameters

**func** [callable or tuple of (callable, string)] Function to apply to this Resampler object or, alternatively, a (*callable*, *data\_keyword*) tuple where *data\_keyword* is a string indicating the keyword of *callable* that expects the Resampler object.

**args** [iterable, optional] Positional arguments passed into *func*.

**kwargs** [dict, optional] A dictionary of keyword arguments passed into *func*.

#### Returns

**object** [the return type of *func*.]

#### See also:

**Series.pipe** Apply a function with arguments to a series.

**DataFrame.pipe** Apply a function with arguments to a dataframe.

**apply** Apply function to each group instead of to the full Resampler object.

#### Notes

See more [here](#)

#### Examples

```
>>> df = pd.DataFrame({'A': [1, 2, 3, 4]},
...                    index=pd.date_range('2012-08-02', periods=4))
>>> df
           A
2012-08-02  1
2012-08-03  2
2012-08-04  3
2012-08-05  4
```

To get the difference between each 2-day period's maximum and minimum value in one pass, you can do

```
>>> df.resample('2D').pipe(lambda x: x.max() - x.min())
           A
2012-08-02  1
2012-08-04  1
```

### 4.12.3 Upsampling

<code>Resampler.ffill(self[, limit])</code>	Forward fill the values.
<code>Resampler.backfill(self[, limit])</code>	Backward fill the new missing values in the resampled data.
<code>Resampler.bfill(self[, limit])</code>	Backward fill the new missing values in the resampled data.
<code>Resampler.pad(self[, limit])</code>	Forward fill the values.
<code>Resampler.nearest(self[, limit])</code>	Resample by using the nearest value.
<code>Resampler.fillna(self, method[, limit])</code>	Fill missing values introduced by upsampling.
<code>Resampler.asfreq(self[, fill_value])</code>	Return the values at the new freq, essentially a reindex.

Continued on next page

Table 408 – continued from previous page

---

`Resampler.interpolate(self[, method, axis, Interpolate values according to different methods.  
...])`

---

### **pandas.core.resample.Resampler.ffill**

`Resampler.ffill` (*self*, *limit=None*)

Forward fill the values.

#### **Parameters**

**limit** [int, optional] Limit of how many values to fill.

#### **Returns**

**An upsampled Series.**

See also:

**Series.fillna**

**DataFrame.fillna**

### **pandas.core.resample.Resampler.backfill**

`Resampler.backfill` (*self*, *limit=None*)

Backward fill the new missing values in the resampled data.

In statistics, imputation is the process of replacing missing data with substituted values [?]. When resampling data, missing values may appear (e.g., when the resampling frequency is higher than the original frequency). The backward fill will replace NaN values that appeared in the resampled data with the next value in the original sequence. Missing values that existed in the original data will not be modified.

#### **Parameters**

**limit** [int, optional] Limit of how many values to fill.

#### **Returns**

**Series, DataFrame** An upsampled Series or DataFrame with backward filled NaN values.

See also:

**bfill** Alias of backfill.

**fillna** Fill NaN values using the specified method, which can be ‘backfill’.

**nearest** Fill NaN values with nearest neighbor starting from center.

**pad** Forward fill NaN values.

**Series.fillna** Fill NaN values in the Series using the specified method, which can be ‘backfill’.

**DataFrame.fillna** Fill NaN values in the DataFrame using the specified method, which can be ‘backfill’.

## Examples

### Resampling a Series:

```
>>> s = pd.Series([1, 2, 3],
...               index=pd.date_range('20180101', periods=3, freq='h'))
>>> s
2018-01-01 00:00:00    1
2018-01-01 01:00:00    2
2018-01-01 02:00:00    3
Freq: H, dtype: int64
```

```
>>> s.resample('30min').backfill()
2018-01-01 00:00:00    1
2018-01-01 00:30:00    2
2018-01-01 01:00:00    2
2018-01-01 01:30:00    3
2018-01-01 02:00:00    3
Freq: 30T, dtype: int64
```

```
>>> s.resample('15min').backfill(limit=2)
2018-01-01 00:00:00    1.0
2018-01-01 00:15:00    NaN
2018-01-01 00:30:00    2.0
2018-01-01 00:45:00    2.0
2018-01-01 01:00:00    2.0
2018-01-01 01:15:00    NaN
2018-01-01 01:30:00    3.0
2018-01-01 01:45:00    3.0
2018-01-01 02:00:00    3.0
Freq: 15T, dtype: float64
```

### Resampling a DataFrame that has missing values:

```
>>> df = pd.DataFrame({'a': [2, np.nan, 6], 'b': [1, 3, 5]},
...                   index=pd.date_range('20180101', periods=3,
...                                       freq='h'))
>>> df
              a  b
2018-01-01 00:00:00  2.0  1
2018-01-01 01:00:00  NaN  3
2018-01-01 02:00:00  6.0  5
```

```
>>> df.resample('30min').backfill()
              a  b
2018-01-01 00:00:00  2.0  1
2018-01-01 00:30:00  NaN  3
2018-01-01 01:00:00  NaN  3
2018-01-01 01:30:00  6.0  5
2018-01-01 02:00:00  6.0  5
```

```
>>> df.resample('15min').backfill(limit=2)
              a  b
2018-01-01 00:00:00  2.0  1.0
2018-01-01 00:15:00  NaN  NaN
2018-01-01 00:30:00  NaN  3.0
```

(continues on next page)

(continued from previous page)

```

2018-01-01 00:45:00 NaN 3.0
2018-01-01 01:00:00 NaN 3.0
2018-01-01 01:15:00 NaN NaN
2018-01-01 01:30:00 6.0 5.0
2018-01-01 01:45:00 6.0 5.0
2018-01-01 02:00:00 6.0 5.0

```

## pandas.core.resample.Resampler.bfill

Resampler.**bfill** (*self*, *limit=None*)

Backward fill the new missing values in the resampled data.

In statistics, imputation is the process of replacing missing data with substituted values [?]. When resampling data, missing values may appear (e.g., when the resampling frequency is higher than the original frequency). The backward fill will replace NaN values that appeared in the resampled data with the next value in the original sequence. Missing values that existed in the original data will not be modified.

### Parameters

**limit** [int, optional] Limit of how many values to fill.

### Returns

**Series, DataFrame** An upsampled Series or DataFrame with backward filled NaN values.

See also:

**bfill** Alias of backfill.

**fillna** Fill NaN values using the specified method, which can be 'backfill'.

**nearest** Fill NaN values with nearest neighbor starting from center.

**pad** Forward fill NaN values.

**Series.fillna** Fill NaN values in the Series using the specified method, which can be 'backfill'.

**DataFrame.fillna** Fill NaN values in the DataFrame using the specified method, which can be 'backfill'.

## Examples

Resampling a Series:

```

>>> s = pd.Series([1, 2, 3],
...               index=pd.date_range('20180101', periods=3, freq='h'))
>>> s
2018-01-01 00:00:00    1
2018-01-01 01:00:00    2
2018-01-01 02:00:00    3
Freq: H, dtype: int64

```

```

>>> s.resample('30min').backfill()
2018-01-01 00:00:00    1
2018-01-01 00:30:00    2
2018-01-01 01:00:00    2
2018-01-01 01:30:00    3

```

(continues on next page)

(continued from previous page)

```
2018-01-01 02:00:00    3
Freq: 30T, dtype: int64
```

```
>>> s.resample('15min').backfill(limit=2)
2018-01-01 00:00:00    1.0
2018-01-01 00:15:00    NaN
2018-01-01 00:30:00    2.0
2018-01-01 00:45:00    2.0
2018-01-01 01:00:00    2.0

2018-01-01 01:30:00  6.0  5
2018-01-01 02:00:00  6.0  5
```

```
>>> df.resample('15min').backfill(limit=2)
              a  b
2018-01-01 00:00:00  2.0  1.0
2018-01-01 00:15:00  NaN  NaN
2018-01-01 00:30:00  NaN  3.0
2018-01-01 00:45:00  NaN  3.0
2018-01-01 01:00:00  NaN  3.0
2018-01-01 01:15:00  NaN  NaN
2018-01-01 01:30:00  6.0  5.0
2018-01-01 01:45:00  6.0  5.0
2018-01-01 02:00:00  6.0  5.0
```

**pandas.core.resample.Resampler.pad**Resampler.**pad** (*self*, *limit=None*)

Forward fill the values.

**Parameters****limit** [int, optional] Limit of how many values to fill.**Returns****An upsampled Series.****See also:****Series.fillna****DataFrame.fillna****pandas.core.resample.Resampler.nearest**Resampler.**nearest** (*self*, *limit=None*)

Resample by using the nearest value.

When resampling data, missing values may appear (e.g., when the resampling frequency is higher than the original frequency). The *nearest* method will replace NaN values that appeared in the resampled data with the value from the nearest member of the sequence, based on the index value. Missing values that existed in the original data will not be modified. If *limit* is given, fill only this many values in each direction for each of the original values.

**Parameters****limit** [int, optional] Limit of how many values to fill.

New in version 0.21.0.

**Returns****Series or DataFrame** An upsampled Series or DataFrame with NaN values filled with their nearest value.**See also:****backfill** Backward fill the new missing values in the resampled data.**pad** Forward fill NaN values.**Examples**

```
>>> s = pd.Series([1, 2],
...               index=pd.date_range('20180101',
...                                   periods=2,
...                                   freq='lh'))
>>> s
2018-01-01 00:00:00    1
2018-01-01 01:00:00    2
Freq: H, dtype: int64
```

```
>>> s.resample('15min').nearest()
2018-01-01 00:00:00    1
2018-01-01 00:15:00    1
2018-01-01 00:30:00    2
2018-01-01 00:45:00    2
```

(continues on next page)

(continued from previous page)

```
2018-01-01 01:00:00    2
Freq: 15T, dtype: int64
```

Limit the number of upsampled values imputed by the nearest:

```
>>> s.resample('15min').nearest(limit=1)
2018-01-01 00:00:00    1.0
2018-01-01 00:15:00    1.0
2018-01-01 00:30:00    NaN
2018-01-01 00:45:00    2.0
2018-01-01 01:00:00    2.0
Freq: 15T, dtype: float64
```

### pandas.core.resample.Resampler.fillna

Resampler.**fillna** (*self*, *method*, *limit=None*)

Fill missing values introduced by upsampling.

In statistics, imputation is the process of replacing missing data with substituted values [?]. When resampling data, missing values may appear (e.g., when the resampling frequency is higher than the original frequency).

Missing values that existed in the original data will not be modified.

#### Parameters

**method** [{ 'pad', 'backfill', 'ffill', 'bfill', 'nearest' }] Method to use for filling holes in resampled data

- 'pad' or 'ffill': use previous valid observation to fill gap (forward fill).
- 'backfill' or 'bfill': use next valid observation to fill gap.
- 'nearest': use nearest valid observation to fill gap.

**limit** [int, optional] Limit of how many consecutive missing values to fill.

#### Returns

**Series or DataFrame** An upsampled Series or DataFrame with missing values filled.

See also:

**backfill** Backward fill NaN values in the resampled data.

**pad** Forward fill NaN values in the resampled data.

**nearest** Fill NaN values in the resampled data with nearest neighbor starting from center.

**interpolate** Fill NaN values using interpolation.

**Series.fillna** Fill NaN values in the Series using the specified method, which can be 'bfill' and 'ffill'.

**DataFrame.fillna** Fill NaN values in the DataFrame using the specified method, which can be 'bfill' and 'ffill'.

## References

## Examples

Resampling a Series:

```
>>> s = pd.Series([1, 2, 3],
...               index=pd.date_range('20180101', periods=3, freq='h'))
>>> s
2018-01-01 00:00:00    1
2018-01-01 01:00:00    2
2018-01-01 02:00:00    3
Freq: H, dtype: int64
```

Without filling the missing values you get:

```
>>> s.resample("30min").asfreq()
2018-01-01 00:00:00    1.0
2018-01-01 00:30:00    NaN
2018-01-01 01:00:00    2.0
2018-01-01 01:30:00    NaN
2018-01-01 02:00:00    3.0
Freq: 30T, dtype: float64
```

```
>>> s.resample('30min').fillna("backfill")
2018-01-01 00:00:00    1
2018-01-01 00:30:00    2
2018-01-01 01:00:00    2
2018-01-01 01:30:00    3
2018-01-01 02:00:00    3
Freq: 30T, dtype: int64
```

```
>>> s.resample('15min').fillna("backfill", limit=2)
2018-01-01 00:00:00    1.0
2018-01-01 00:15:00    NaN
2018-01-01 00:30:00    2.0
2018-01-01 00:45:00    2.0
2018-01-01 01:00:00    2.0
2018-01-01 01:15:00    NaN
2018-01-01 01:30:00    3.0
2018-01-01 01:45:00    3.0
2018-01-01 02:00:00    3.0
Freq: 15T, dtype: float64
```

```
>>> s.resample('30min').fillna("pad")
2018-01-01 00:00:00    1
2018-01-01 00:30:00    1
2018-01-01 01:00:00    2
2018-01-01 01:30:00    2
2018-01-01 02:00:00    3
Freq: 30T, dtype: int64
```

```
>>> s.resample('30min').fillna("nearest")
2018-01-01 00:00:00    1
2018-01-01 00:30:00    2
2018-01-01 01:00:00    2
2018-01-01 01:30:00    3
2018-01-01 02:00:00    3
Freq: 30T, dtype: int64
```

Missing values present before the upsampling are not affected.

```
>>> sm = pd.Series([1, None, 3],
...                index=pd.date_range('20180101', periods=3, freq='h'))
>>> sm
2018-01-01 00:00:00    1.0
2018-01-01 01:00:00    NaN
2018-01-01 02:00:00    3.0
Freq: H, dtype: float64
```

```
>>> sm.resample('30min').fillna('backfill')
2018-01-01 00:00:00    1.0
2018-01-01 00:30:00    NaN
2018-01-01 01:00:00    NaN
2018-01-01 01:30:00    3.0
2018-01-01 02:00:00    3.0
Freq: 30T, dtype: float64
```

```
>>> sm.resample('30min').fillna('pad')
2018-01-01 00:00:00    1.0
2018-01-01 00:30:00    1.0
2018-01-01 01:00:00    NaN
2018-01-01 01:30:00    NaN
2018-01-01 02:00:00    3.0
Freq: 30T, dtype: float64
```

```
>>> sm.resample('30min').fillna('nearest')
2018-01-01 00:00:00    1.0
2018-01-01 00:30:00    NaN
2018-01-01 01:00:00    NaN
2018-01-01 01:30:00    3.0
2018-01-01 02:00:00    3.0
Freq: 30T, dtype: float64
```

DataFrame resampling is done column-wise. All the same options are available.

```
>>> df = pd.DataFrame({'a': [2, np.nan, 6], 'b': [1, 3, 5]},
...                    index=pd.date_range('20180101', periods=3,
...                    freq='h'))
>>> df
              a  b
2018-01-01 00:00:00  2.0  1
2018-01-01 01:00:00  NaN  3
2018-01-01 02:00:00  6.0  5
```

```
>>> df.resample('30min').fillna("bfill")
              a  b
2018-01-01 00:00:00  2.0  1
```

(continues on next page)

(continued from previous page)

2018-01-01 00:30:00	NaN	3
2018-01-01 01:00:00	NaN	3
2018-01-01 01:30:00	6.0	5
2018-01-01 02:00:00	6.0	5

### pandas.core.resample.Resampler.asfreq

Resampler.**asfreq**(*self*, *fill\_value=None*)

Return the values at the new freq, essentially a reindex.

#### Parameters

**fill\_value** [scalar, optional] Value to use for missing values, applied during upsampling (note this does not fill NaNs that already were present).

#### Returns

**DataFrame or Series** Values at the specified freq.

See also:

**Series.asfreq**

**DataFrame.asfreq**

### pandas.core.resample.Resampler.interpolate

Resampler.**interpolate**(*self*, *method='linear'*, *axis=0*, *limit=None*, *inplace=False*, *limit\_direction='forward'*, *limit\_area=None*, *downcast=None*, *\*\*kwargs*)

Interpolate values according to different methods.

Please note that only `method='linear'` is supported for DataFrame/Series with a MultiIndex.

#### Parameters

**method** [str, default 'linear'] Interpolation technique to use. One of:

- 'linear': Ignore the index and treat the values as equally spaced. This is the only method supported on MultiIndexes.
- 'time': Works on daily and higher resolution data to interpolate given length of interval.
- 'index', 'values': use the actual numerical values of the index.
- 'pad': Fill in NaNs using existing values.
- 'nearest', 'zero', 'slinear', 'quadratic', 'cubic', 'spline', 'barycentric', 'polynomial': Passed to `scipy.interpolate.interp1d`. These methods use the numerical values of the index. Both 'polynomial' and 'spline' require that you also specify an *order* (int), e.g. `df.interpolate(method='polynomial', order=5)`.
- 'krogh', 'piecewise\_polynomial', 'spline', 'pchip', 'akima': Wrappers around the SciPy interpolation methods of similar names. See *Notes*.
- 'from\_derivatives': Refers to `scipy.interpolate.BPoly.from_derivatives` which replaces 'piecewise\_polynomial' interpolation method in scipy 0.18.

**axis** [{0 or 'index', 1 or 'columns', None}, default None] Axis to interpolate along.

**limit** [int, optional] Maximum number of consecutive NaNs to fill. Must be greater than 0.

**inplace** [bool, default False] Update the data in place if possible.

**limit\_direction** [{‘forward’, ‘backward’, ‘both’}, default ‘forward’] If limit is specified, consecutive NaNs will be filled in this direction.

**limit\_area** [{None, ‘inside’, ‘outside’}, default None] If limit is specified, consecutive NaNs will be filled with this restriction.

- None: No fill restriction.
- ‘inside’: Only fill NaNs surrounded by valid values (interpolate).
- ‘outside’: Only fill NaNs outside valid values (extrapolate).

New in version 0.23.0.

**downcast** [optional, ‘infer’ or None, defaults to None] Downcast dtypes if possible.

**\*\*kwargs** Keyword arguments to pass on to the interpolating function.

### Returns

**Series or DataFrame** Returns the same object type as the caller, interpolated at some or all NaN values.

### See also:

**fillna** Fill missing values using different methods.

**scipy.interpolate.Akima1DInterpolator** Piecewise cubic polynomials (Akima interpolator).

**scipy.interpolate.BPoly.from\_derivatives** Piecewise polynomial in the Bernstein basis.

**scipy.interpolate.interpld** Interpolate a 1-D function.

**scipy.interpolate.KroghInterpolator** Interpolate polynomial (Krogh interpolator).

**scipy.interpolate.PchipInterpolator** PCHIP 1-d monotonic cubic interpolation.

**scipy.interpolate.CubicSpline** Cubic spline data interpolator.

### Notes

The ‘krogh’, ‘piecewise\_polynomial’, ‘spline’, ‘pchip’ and ‘akima’ methods are wrappers around the respective SciPy implementations of similar names. These use the actual numerical values of the index. For more information on their behavior, see the [SciPy documentation](#) and [SciPy tutorial](#).

### Examples

Filling in NaN in a *Series* via linear interpolation.

```
>>> s = pd.Series([0, 1, np.nan, 3])
>>> s
0    0.0
1    1.0
2    NaN
3    3.0
dtype: float64
>>> s.interpolate()
0    0.0
1    1.0
2    2.0
3    3.0
dtype: float64
```

Filling in NaN in a *Series* by padding, but filling at most two consecutive NaN at a time.

```

>>> s = pd.Series([np.nan, "single_one", np.nan,
...               "fill_two_more", np.nan, np.nan, np.nan,
...               4.71, np.nan])
>>> s
0          NaN
1    single_one
2          NaN
3    fill_two_more
4          NaN
5          NaN
6          NaN
7          4.71
8          NaN
dtype: object
>>> s.interpolate(method='pad', limit=2)
0          NaN
1    single_one
2    single_one
3    fill_two_more
4    fill_two_more
5    fill_two_more
6          NaN
7          4.71
8          4.71
dtype: object

```

Filling in NaN in a Series via polynomial interpolation or splines: Both 'polynomial' and 'spline' methods require that you also specify an `order` (int).

```

>>> s = pd.Series([0, 2, np.nan, 8])
>>> s.interpolate(method='polynomial', order=2)
0    0.000000
1    2.000000
2    4.666667
3    8.000000
dtype: float64

```

Fill the DataFrame forward (that is, going down) along each column using linear interpolation.

Note how the last entry in column 'a' is interpolated differently, because there is no entry after it to use for interpolation. Note how the first entry in column 'b' remains NaN, because there is no entry before it to use for interpolation.

```

>>> df = pd.DataFrame([(0.0, np.nan, -1.0, 1.0),
...                   (np.nan, 2.0, np.nan, np.nan),
...                   (2.0, 3.0, np.nan, 9.0),
...                   (np.nan, 4.0, -4.0, 16.0)],
...                   columns=list('abcd'))
>>> df
   a    b    c    d
0  0.0 NaN -1.0  1.0
1 NaN  2.0 NaN  NaN
2  2.0  3.0 NaN  9.0
3 NaN  4.0 -4.0 16.0
>>> df.interpolate(method='linear', limit_direction='forward', axis=0)
   a    b    c    d
0  0.0 NaN -1.0  1.0

```

(continues on next page)

(continued from previous page)

```

1  1.0  2.0 -2.0   5.0
2  2.0  3.0 -3.0   9.0
3  2.0  4.0 -4.0  16.0

```

Using polynomial interpolation.

```

>>> df['d'].interpolate(method='polynomial', order=2)
0     1.0
1     4.0
2     9.0
3    16.0
Name: d, dtype: float64

```

#### 4.12.4 Computations / descriptive stats

<i>Resampler.count</i> (self)	Compute count of group, excluding missing values.
<i>Resampler.nunique</i> (self[, _method])	Return number of unique elements in the group.
<i>Resampler.first</i> (self[, _method])	Compute first of group values.
<i>Resampler.last</i> (self[, _method])	Compute last of group values.
<i>Resampler.max</i> (self[, _method])	Compute max of group values.
<i>Resampler.mean</i> (self[, _method])	Compute mean of groups, excluding missing values.
<i>Resampler.median</i> (self[, _method])	Compute median of groups, excluding missing values.
<i>Resampler.min</i> (self[, _method])	Compute min of group values.
<i>Resampler.ohlc</i> (self[, _method])	Compute sum of values, excluding missing values.
<i>Resampler.prod</i> (self[, _method, min_count])	Compute prod of group values.
<i>Resampler.size</i> (self)	Compute group sizes.
<i>Resampler.sem</i> (self[, _method])	Compute standard error of the mean of groups, excluding missing values.
<i>Resampler.std</i> (self[, ddof])	Compute standard deviation of groups, excluding missing values.
<i>Resampler.sum</i> (self[, _method, min_count])	Compute sum of group values.
<i>Resampler.var</i> (self[, ddof])	Compute variance of groups, excluding missing values.
<i>Resampler.quantile</i> (self[, q])	Return value at the given quantile.

#### pandas.core.resample.Resampler.count

`Resampler.count` (*self*)

Compute count of group, excluding missing values.

##### Returns

**Series or DataFrame** Count of values within each group.

See also:

**Series.groupby**

**DataFrame.groupby**

### **pandas.core.resample.Resampler.nunique**

`Resampler.nunique` (*self*, *\_method='nunique'*)  
Return number of unique elements in the group.  
**Returns**

**Series** Number of unique values within each group.

### **pandas.core.resample.Resampler.first**

`Resampler.first` (*self*, *\_method='first'*, *\*args*, *\*\*kwargs*)  
Compute first of group values.  
**Returns**

**Series or DataFrame** Computed first of values within each group.

### **pandas.core.resample.Resampler.last**

`Resampler.last` (*self*, *\_method='last'*, *\*args*, *\*\*kwargs*)  
Compute last of group values.  
**Returns**

**Series or DataFrame** Computed last of values within each group.

### **pandas.core.resample.Resampler.max**

`Resampler.max` (*self*, *\_method='max'*, *\*args*, *\*\*kwargs*)  
Compute max of group values.  
**Returns**

**Series or DataFrame** Computed max of values within each group.

### **pandas.core.resample.Resampler.mean**

`Resampler.mean` (*self*, *\_method='mean'*, *\*args*, *\*\*kwargs*)  
Compute mean of groups, excluding missing values.  
**Returns**

**pandas.Series or pandas.DataFrame**

See also:

`Series.groupby`

`DataFrame.groupby`

## Examples

```
>>> df = pd.DataFrame({'A': [1, 1, 2, 1, 2],
...                    'B': [np.nan, 2, 3, 4, 5],
...                    'C': [1, 2, 1, 1, 2]}, columns=['A', 'B', 'C'])
```

Groupby one column and return the mean of the remaining columns in each group.

```
>>> df.groupby('A').mean()
      B      C
A
1  3.0  1.333333
2  4.0  1.500000
```

Groupby two columns and return the mean of the remaining column.

```
>>> df.groupby(['A', 'B']).mean()
      C
A B
1 2.0  2
   4.0  1
2 3.0  1
   5.0  2
```

Groupby one column and return the mean of only particular column in the group.

```
>>> df.groupby('A')['B'].mean()
A
1      3.0
2      4.0
Name: B, dtype: float64
```

## pandas.core.resample.Resampler.median

`Resampler.median` (*self*, *\_method='median'*, *\*args*, *\*\*kwargs*)  
Compute median of groups, excluding missing values.

For multiple groupings, the result index will be a MultiIndex

### Returns

**Series or DataFrame** Median of values within each group.

See also:

**Series.groupby**

**DataFrame.groupby**

### pandas.core.resample.Resampler.min

`Resampler.min` (*self*, *\_method='min'*, \*args, \*\*kwargs)

Compute min of group values.

**Returns**

**Series or DataFrame** Computed min of values within each group.

### pandas.core.resample.Resampler.ohlc

`Resampler.ohlc` (*self*, *\_method='ohlc'*, \*args, \*\*kwargs)

Compute sum of values, excluding missing values.

For multiple groupings, the result index will be a MultiIndex

**Returns**

**DataFrame** Open, high, low and close values within each group.

**See also:**

**Series.groupby**

**DataFrame.groupby**

### pandas.core.resample.Resampler.prod

`Resampler.prod` (*self*, *\_method='prod'*, *min\_count=0*, \*args, \*\*kwargs)

Compute prod of group values.

**Returns**

**Series or DataFrame** Computed prod of values within each group.

### pandas.core.resample.Resampler.size

`Resampler.size` (*self*)

Compute group sizes.

**Returns**

**Series** Number of rows in each group.

**See also:**

**Series.groupby**

**DataFrame.groupby**

### pandas.core.resample.Resampler.sem

`Resampler.sem` (*self*, *\_method='sem'*, \*args, \*\*kwargs)

Compute standard error of the mean of groups, excluding missing values.

For multiple groupings, the result index will be a MultiIndex.

**Parameters**

**ddof** [int, default 1] Degrees of freedom.

**Returns**

**Series or DataFrame** Standard error of the mean of values within each group.

**See also:**

**Series.groupby**  
**DataFrame.groupby**

### **pandas.core.resample.Resampler.std**

`Resampler.std(self, ddof=1, *args, **kwargs)`

Compute standard deviation of groups, excluding missing values.

#### **Parameters**

**ddof** [int, default 1] Degrees of freedom.

#### **Returns**

**DataFrame or Series** Standard deviation of values within each group.

### **pandas.core.resample.Resampler.sum**

`Resampler.sum(self, _method='sum', min_count=0, *args, **kwargs)`

Compute sum of group values.

#### **Returns**

**Series or DataFrame** Computed sum of values within each group.

### **pandas.core.resample.Resampler.var**

`Resampler.var(self, ddof=1, *args, **kwargs)`

Compute variance of groups, excluding missing values.

#### **Parameters**

**ddof** [int, default 1] Degrees of freedom.

#### **Returns**

**DataFrame or Series** Variance of values within each group.

### **pandas.core.resample.Resampler.quantile**

`Resampler.quantile(self, q=0.5, **kwargs)`

Return value at the given quantile.

New in version 0.24.0.

#### **Parameters**

**q** [float or array-like, default 0.5 (50% quantile)]

#### **Returns**

**DataFrame or Series** Quantile of values within each group.

See also:

**Series.quantile**  
**DataFrame.quantile**  
**DataFrameGroupBy.quantile**

{{ header }}

## 4.13 Style

Styler objects are returned by `pandas.DataFrame.style`.

### 4.13.1 Styler constructor

---

<code>Styler(data[, precision, table_styles, ...])</code>	Helps style a DataFrame or Series according to the data with HTML and CSS.
<code>Styler.from_custom_template(searchpath, name)</code>	Factory function for creating a subclass of Styler.

---

#### `pandas.io.formats.style.Styler`

**class** `pandas.io.formats.style.Styler` (*data, precision=None, table\_styles=None, uuid=None, caption=None, table\_attributes=None, cell\_ids=True, na\_rep: Optional[str] = None*)

Helps style a DataFrame or Series according to the data with HTML and CSS.

#### Parameters

**data** [Series or DataFrame] Data to be styled - either a Series or DataFrame.

**precision** [int] Precision to round floats to, defaults to `pd.options.display.precision`.

**table\_styles** [list-like, default None] List of {selector: (attr, value)} dicts; see Notes.

**uuid** [str, default None] A unique identifier to avoid CSS collisions; generated automatically.

**caption** [str, default None] Caption to attach to the table.

**table\_attributes** [str, default None] Items that show up in the opening `<table>` tag in addition to automatic (by default) id.

**cell\_ids** [bool, default True] If True, each cell will have an `id` attribute in their HTML tag. The `id` takes the form `T_<uuid>_row<num_row>_col<num_col>` where `<uuid>` is the unique identifier, `<num_row>` is the row number and `<num_col>` is the column number.

**na\_rep** [str, optional] Representation for missing values. If `na_rep` is None, no special formatting is applied

New in version 1.0.0.

#### See also:

**DataFrame.style** Return a Styler object containing methods for building a styled HTML representation for the DataFrame.

## Notes

Most styling will be done by passing style functions into `Styler.apply` or `Styler.applymap`. Style functions should return values with strings containing CSS `'attr: value'` that will be applied to the indicated cells.

If using in the Jupyter notebook, `Styler` has defined a `_repr_html_` to automatically render itself. Otherwise call `Styler.render` to get the generated HTML.

CSS classes are attached to the generated HTML

- Index and Column names include `index_name` and `level<k>` where *k* is its level in a `MultiIndex`
- Index label cells include
  - `row_heading`
  - `row<n>` where *n* is the numeric position of the row
  - `level<k>` where *k* is the level in a `MultiIndex`
- Column label cells include `* col_heading * col<n>` where *n* is the numeric position of the column  
`* evel<k>` where *k* is the level in a `MultiIndex`
- Blank cells include `blank`
- Data cells include `data`

## Attributes

<b>env</b>	(Jinja2 <code>jinja2.Environment</code> )
<b>template</b>	(Jinja2 <code>Template</code> )
<b>loader</b>	(Jinja2 <code>Loader</code> )

## Methods

<code>apply(self, func[, axis, subset])</code>	Apply a function column-wise, row-wise, or table-wise.
<code>applymap(self, func[, subset])</code>	Apply a function elementwise.
<code>background_gradient(self[, cmap, low, high, ...])</code>	Color the background in a gradient style.
<code>bar(self[, subset, axis, color, width, ...])</code>	Draw bar chart in the cell backgrounds.
<code>clear(self)</code>	Reset the styler, removing any previously applied styles.
<code>export(self)</code>	Export the styles to applied to the current <code>Styler</code> .
<code>format(self, formatter[, subset])</code>	Format the text display value of cells.
<code>from_custom_template(searchpath, name)</code>	Factory function for creating a subclass of <code>Styler</code> .
<code>hide_columns(self, subset)</code>	Hide columns from rendering.
<code>hide_index(self)</code>	Hide any indices from rendering.
<code>highlight_max(self[, subset, color, axis])</code>	Highlight the maximum by shading the background.
<code>highlight_min(self[, subset, color, axis])</code>	Highlight the minimum by shading the background.
<code>highlight_null(self[, null_color])</code>	Shade the background <code>null_color</code> for missing values.
<code>pipe(self, func, <i>*args</i>, <i>**kwargs</i>)</code>	Apply <code>func(self, <i>*args</i>, <i>**kwargs</i>)</code> , and return the result.
<code>render(self, <i>**kwargs</i>)</code>	Render the built up styles to HTML.
<code>set_caption(self, caption)</code>	Set the caption on a <code>Styler</code> .

Continued on next page

Table 411 – continued from previous page

<code>set_na_rep(self, na_rep)</code>	Set the missing data representation on a Styler.
<code>set_precision(self, precision)</code>	Set the precision used to render.
<code>set_properties(self[, subset])</code>	Method to set one or more non-data dependent properties or each cell.
<code>set_table_attributes(self, attributes)</code>	Set the table attributes.
<code>set_table_styles(self, table_styles)</code>	Set the table styles on a Styler.
<code>set_uuid(self, uuid)</code>	Set the uuid for a Styler.
<code>to_excel(self, excel_writer[, sheet_name, ...])</code>	Write Styler to an Excel sheet.
<code>use(self, styles)</code>	Set the styles on the current Styler.
<code>where(self, cond, value[, other, subset])</code>	Apply a function elementwise.

### `pandas.io.formats.style.Styler.apply`

`Styler.apply` (*self*, *func*, *axis=0*, *subset=None*, *\*\*kwargs*)

Apply a function column-wise, row-wise, or table-wise.

Updates the HTML representation with the result.

#### Parameters

**func** [function] *func* should take a Series or DataFrame (depending on *axis*), and return an object with the same shape. Must return a DataFrame with identical index and column labels when *axis=None*.

**axis** [{0 or 'index', 1 or 'columns', None}, default 0] Apply to each column (*axis=0* or 'index'), to each row (*axis=1* or 'columns'), or to the entire DataFrame at once with *axis=None*.

**subset** [IndexSlice] A valid indexer to limit data to *before* applying the function. Consider using a `pandas.IndexSlice`.

**\*\*kwargs** [dict] Pass along to *func*.

#### Returns

**self** [Styler]

#### Notes

The output shape of *func* should match the input, i.e. if *x* is the input row, column, or table (depending on *axis*), then `func(x).shape == x.shape` should be true.

This is similar to `DataFrame.apply`, except that *axis=None* applies the function to the entire DataFrame at once, rather than column-wise or row-wise.

## Examples

```
>>> def highlight_max(x):
...     return ['background-color: yellow' if v == x.max() else ''
...            for v in x]
...
>>> df = pd.DataFrame(np.random.randn(5, 2))
>>> df.style.apply(highlight_max)
```

### pandas.io.formats.style.Styler.applymap

`Styler.applymap` (*self*, *func*, *subset=None*, *\*\*kwargs*)

Apply a function elementwise.

Updates the HTML representation with the result.

#### Parameters

**func** [function] *func* should take a scalar and return a scalar.

**subset** [IndexSlice] A valid indexer to limit data to *before* applying the function. Consider using a `pandas.IndexSlice`.

**\*\*kwargs** [dict] Pass along to *func*.

#### Returns

**self** [Styler]

See also:

`Styler.where`

### pandas.io.formats.style.Styler.background\_gradient

`Styler.background_gradient` (*self*, *cmap='PuBu'*, *low=0*, *high=0*, *axis=0*, *subset=None*, *text\_color\_threshold=0.408*, *vmin: Union[float, NoneType] = None*, *vmax: Union[float, NoneType] = None*)

Color the background in a gradient style.

The background color is determined according to the data in each column (optionally row). Requires `matplotlib`.

#### Parameters

**cmap** [str or colormap] Matplotlib colormap.

**low** [float] Compress the range by the low.

**high** [float] Compress the range by the high.

**axis** [{0 or 'index', 1 or 'columns', None}, default 0] Apply to each column (*axis=0* or 'index'), to each row (*axis=1* or 'columns'), or to the entire DataFrame at once with *axis=None*.

**subset** [IndexSlice] A valid slice for *data* to limit the style application to.

**text\_color\_threshold** [float or int] Luminance threshold for determining text color. Facilitates text visibility across varying background colors. From 0 to 1. 0 = all text is dark colored, 1 = all text is light colored.

New in version 0.24.0.

**vmin** [float, optional] Minimum data value that corresponds to colormap minimum value. When None (default): the minimum value of the data will be used.

New in version 1.0.0.

**vmax** [float, optional] Maximum data value that corresponds to colormap maximum value. When None (default): the maximum value of the data will be used.

New in version 1.0.0.

### Returns

**self** [Styler]

### Raises

**ValueError** If `text_color_threshold` is not a value from 0 to 1.

### Notes

Set `text_color_threshold` or tune `low` and `high` to keep the text legible by not using the entire range of the color map. The range of the data is extended by `low * (x.max() - x.min())` and `high * (x.max() - x.min())` before normalizing.

## pandas.io.formats.style.Styler.bar

`Styler.bar`(*self*, *subset=None*, *axis=0*, *color='#d65f5f'*, *width=100*, *align='left'*, *vmin=None*, *vmax=None*)  
Draw bar chart in the cell backgrounds.

### Parameters

**subset** [IndexSlice, optional] A valid slice for *data* to limit the style application to.

**axis** [{0 or 'index', 1 or 'columns', None}, default 0] Apply to each column (`axis=0` or `'index'`), to each row (`axis=1` or `'columns'`), or to the entire `DataFrame` at once with `axis=None`.

**color** [str or 2-tuple/list] If a str is passed, the color is the same for both negative and positive numbers. If 2-tuple/list is used, the first element is the `color_negative` and the second is the `color_positive` (eg: `['#d65f5f', '#5fba7d']`).

**width** [float, default 100] A number between 0 or 100. The largest value will cover *width* percent of the cell's width.

**align** [{ 'left', 'zero', 'mid' }, default 'left'] How to align the bars with the cells.

- `'left'` : the min value starts at the left of the cell.
- `'zero'` : a value of zero is located at the center of the cell.
- `'mid'` : the center of the cell is at  $(\text{max}-\text{min})/2$ , or if values are all negative (positive) the zero is aligned at the right (left) of the cell.

**vmin** [float, optional] Minimum bar value, defining the left hand limit of the bar drawing range, lower values are clipped to *vmin*. When None (default): the minimum value of the data will be used.

New in version 0.24.0.

**vmax** [float, optional] Maximum bar value, defining the right hand limit of the bar drawing range, higher values are clipped to *vmax*. When None (default): the maximum value of the data will be used.

New in version 0.24.0.

#### Returns

**self** [Styler]

### pandas.io.formats.style.Styler.clear

`Styler.clear(self)`

Reset the styler, removing any previously applied styles.

Returns None.

### pandas.io.formats.style.Styler.export

`Styler.export(self)`

Export the styles to applied to the current Styler.

Can be applied to a second style with `Styler.use`.

#### Returns

**styles** [list]

See also:

*Styler.use*

### pandas.io.formats.style.Styler.format

`Styler.format(self, formatter, subset=None, na_rep: Union[str, NoneType] = None)`

Format the text display value of cells.

#### Parameters

**formatter** [str, callable, dict or None] If *formatter* is None, the default formatter is used

**subset** [IndexSlice] An argument to `DataFrame.loc` that restricts which elements *formatter* is applied to.

**na\_rep** [str, optional] Representation for missing values. If *na\_rep* is None, no special formatting is applied

New in version 1.0.0.

#### Returns

**self** [Styler]

## Notes

`formatter` is either an `a` or a dict `{column name: a}` where `a` is one of

- `str`: this will be wrapped in: `a.format(x)`
- callable: called with the value of an individual cell

The default display value for numeric values is the “general” (`g`) format with `pd.options.display.precision`.

## Examples

```
>>> df = pd.DataFrame(np.random.randn(4, 2), columns=['a', 'b'])
>>> df.style.format(" {:.2%}")
>>> df['c'] = ['a', 'b', 'c', 'd']
>>> df.style.format({'c': str.upper})
```

## `pandas.io.formats.style.Styler.from_custom_template`

**classmethod** `Styler.from_custom_template` (*searchpath, name*)

Factory function for creating a subclass of `Styler`.

Uses a custom template and Jinja environment.

### Parameters

**searchpath** [str or list] Path or paths of directories containing the templates.

**name** [str] Name of your custom template to use for rendering.

### Returns

**MyStyler** [subclass of `Styler`] Has the correct `env` and `template` class attributes set.

## `pandas.io.formats.style.Styler.hide_columns`

`Styler.hide_columns` (*self, subset*)

Hide columns from rendering.

New in version 0.23.0.

### Parameters

**subset** [IndexSlice] An argument to `DataFrame.loc` that identifies which columns are hidden.

### Returns

**self** [`Styler`]

### pandas.io.formats.style.Styler.hide\_index

`Styler.hide_index` (*self*)

Hide any indices from rendering.

New in version 0.23.0.

#### Returns

`self` [Styler]

### pandas.io.formats.style.Styler.highlight\_max

`Styler.highlight_max` (*self*, *subset=None*, *color='yellow'*, *axis=0*)

Highlight the maximum by shading the background.

#### Parameters

**subset** [IndexSlice, default None] A valid slice for data to limit the style application to.

**color** [str, default 'yellow']

**axis** [{0 or 'index', 1 or 'columns', None}, default 0] Apply to each column (*axis=0* or 'index'), to each row (*axis=1* or 'columns'), or to the entire DataFrame at once with *axis=None*.

#### Returns

`self` [Styler]

### pandas.io.formats.style.Styler.highlight\_min

`Styler.highlight_min` (*self*, *subset=None*, *color='yellow'*, *axis=0*)

Highlight the minimum by shading the background.

#### Parameters

**subset** [IndexSlice, default None] A valid slice for data to limit the style application to.

**color** [str, default 'yellow']

**axis** [{0 or 'index', 1 or 'columns', None}, default 0] Apply to each column (*axis=0* or 'index'), to each row (*axis=1* or 'columns'), or to the entire DataFrame at once with *axis=None*.

#### Returns

`self` [Styler]

### pandas.io.formats.style.Styler.highlight\_null

`Styler.highlight_null` (*self*, *null\_color='red'*)  
Shade the background *null\_color* for missing values.

#### Parameters

**null\_color** [str]

#### Returns

**self** [Styler]

### pandas.io.formats.style.Styler.pipe

`Styler.pipe` (*self*, *func*, \**args*, \*\**kwargs*)  
Apply `func(self, *args, **kwargs)`, and return the result.  
New in version 0.24.0.

#### Parameters

**func** [function] Function to apply to the Styler. Alternatively, a (callable, keyword) tuple where *keyword* is a string indicating the keyword of callable that expects the Styler.

**\*args** [optional] Arguments passed to *func*.

**\*\*kwargs** [optional] A dictionary of keyword arguments passed into *func*.

#### Returns

**object** : The value returned by *func*.

#### See also:

**DataFrame.pipe** Analogous method for DataFrame.

**Styler.apply** Apply a function row-wise, column-wise, or table-wise to modify the dataframe's styling.

#### Notes

Like `DataFrame.pipe()`, this method can simplify the application of several user-defined functions to a styler. Instead of writing:

```
f(g(df.style.set_precision(3), arg1=a), arg2=b, arg3=c)
```

users can write:

```
(df.style.set_precision(3)
 .pipe(g, arg1=a)
 .pipe(f, arg2=b, arg3=c))
```

In particular, this allows users to define functions that take a styler object, along with other parameters, and return the styler after making styling changes (such as calling `Styler.apply()` or `Styler.set_properties()`). Using `.pipe`, these user-defined style “transformations” can be interleaved with calls to the built-in Styler interface.

## Examples

```
>>> def format_conversion(styler):
...     return (styler.set_properties(**{'text-align': 'right'})
...             .format({'conversion': '{:.1%}'))
```

The user-defined `format_conversion` function above can be called within a sequence of other style modifications:

```
>>> df = pd.DataFrame({'trial': list(range(5)),
...                   'conversion': [0.75, 0.85, np.nan, 0.7, 0.72]})
>>> (df.style
...   .highlight_min(subset=['conversion'], color='yellow')
...   .pipe(format_conversion)
...   .set_caption("Results with minimum conversion highlighted."))
```

## pandas.io.formats.style.Styler.render

`Styler.render` (*self*, *\*\*kwargs*)

Render the built up styles to HTML.

### Parameters

**\*\*kwargs** Any additional keyword arguments are passed through to `self.template.render`. This is useful when you need to provide additional variables for a custom template.

### Returns

**rendered** [str] The rendered HTML.

## Notes

`Styler` objects have defined the `_repr_html_` method which automatically calls `self.render()` when it's the last item in a Notebook cell. When calling `Styler.render()` directly, wrap the result in `IPython.display.HTML` to view the rendered HTML in the notebook.

Pandas uses the following keys in `render`. Arguments passed in `**kwargs` take precedence, so think carefully if you want to override them:

- `head`
- `cellstyle`
- `body`
- `uuid`
- `precision`
- `table_styles`
- `caption`
- `table_attributes`

### **pandas.io.formats.style.Styler.set\_caption**

`Styler.set_caption` (*self*, *caption*)

Set the caption on a Styler.

#### **Parameters**

**caption** [str]

#### **Returns**

**self** [Styler]

### **pandas.io.formats.style.Styler.set\_na\_rep**

`Styler.set_na_rep` (*self*, *na\_rep: str*) → 'Styler'

Set the missing data representation on a Styler.

New in version 1.0.0.

#### **Parameters**

**na\_rep** [str]

#### **Returns**

**self** [Styler]

### **pandas.io.formats.style.Styler.set\_precision**

`Styler.set_precision` (*self*, *precision*)

Set the precision used to render.

#### **Parameters**

**precision** [int]

#### **Returns**

**self** [Styler]

### **pandas.io.formats.style.Styler.set\_properties**

`Styler.set_properties` (*self*, *subset=None*, *\*\*kwargs*)

Method to set one or more non-data dependent properties on each cell.

#### **Parameters**

**subset** [IndexSlice] A valid slice for `data` to limit the style application to.

**\*\*kwargs** [dict] A dictionary of property, value pairs to be set for each cell.

#### **Returns**

**self** [Styler]

## Examples

```
>>> df = pd.DataFrame(np.random.randn(10, 4))
>>> df.style.set_properties(color="white", align="right")
>>> df.style.set_properties(**{'background-color': 'yellow'})
```

## pandas.io.formats.style.Styler.set\_table\_attributes

`Styler.set_table_attributes` (*self*, *attributes*)

Set the table attributes.

These are the items that show up in the opening `<table>` tag in addition to to automatic (by default) id.

### Parameters

**attributes** [str]

### Returns

**self** [Styler]

## Examples

```
>>> df = pd.DataFrame(np.random.randn(10, 4))
>>> df.style.set_table_attributes('class="pure-table"')
# ... <table class="pure-table"> ...
```

## pandas.io.formats.style.Styler.set\_table\_styles

`Styler.set_table_styles` (*self*, *table\_styles*)

Set the table styles on a Styler.

These are placed in a `<style>` tag before the generated HTML table.

### Parameters

**table\_styles** [list] Each individual `table_style` should be a dictionary with `selector` and `props` keys. `selector` should be a CSS selector that the style will be applied to (automatically prefixed by the table's UUID) and `props` should be a list of tuples with (`attribute`, `value`).

### Returns

**self** [Styler]

## Examples

```
>>> df = pd.DataFrame(np.random.randn(10, 4))
>>> df.style.set_table_styles(
...     [{'selector': 'tr:hover',
...       'props': [('background-color', 'yellow')]}])
... )
```

### pandas.io.formats.style.Styler.set\_uuid

`Styler.set_uuid(self, uuid)`  
Set the uuid for a Styler.

#### Parameters

**uuid** [str]

#### Returns

**self** [Styler]

### pandas.io.formats.style.Styler.to\_excel

`Styler.to_excel(self, excel_writer, sheet_name='Sheet1', na_rep="", float_format=None, columns=None, header=True, index=True, index_label=None, startrow=0, startcol=0, engine=None, merge_cells=True, encoding=None, inf_rep='inf', verbose=True, freeze_panes=None)`

Write Styler to an Excel sheet.

To write a single Styler to an Excel .xlsx file it is only necessary to specify a target file name. To write to multiple sheets it is necessary to create an *ExcelWriter* object with a target file name, and specify a sheet in the file to write to.

Multiple sheets may be written to by specifying unique *sheet\_name*. With all data written to the file it is necessary to save the changes. Note that creating an *ExcelWriter* object with a file name that already exists will result in the contents of the existing file being erased.

#### Parameters

**excel\_writer** [str or ExcelWriter object] File path or existing ExcelWriter.

**sheet\_name** [str, default 'Sheet1'] Name of sheet which will contain DataFrame.

**na\_rep** [str, default ''] Missing data representation.

**float\_format** [str, optional] Format string for floating point numbers. For example `float_format="%.2f"` will format 0.1234 to 0.12.

**columns** [sequence or list of str, optional] Columns to write.

**header** [bool or list of str, default True] Write out the column names. If a list of string is given it is assumed to be aliases for the column names.

**index** [bool, default True] Write row names (index).

**index\_label** [str or sequence, optional] Column label for index column(s) if desired. If not specified, and *header* and *index* are True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.

**startrow** [int, default 0] Upper left cell row to dump data frame.

- startcol** [int, default 0] Upper left cell column to dump data frame.
- engine** [str, optional] Write engine to use, 'openpyxl' or 'xlsxwriter'. You can also set this via the options `io.excel.xlsx.writer`, `io.excel.xls.writer`, and `io.excel.xlsm.writer`.
- merge\_cells** [bool, default True] Write MultiIndex and Hierarchical Rows as merged cells.
- encoding** [str, optional] Encoding of the resulting excel file. Only necessary for xlwt, other writers support unicode natively.
- inf\_rep** [str, default 'inf'] Representation for infinity (there is no native representation for infinity in Excel).
- verbose** [bool, default True] Display more information in the error logs.
- freeze\_panes** [tuple of int (length 2), optional] Specifies the one-based bottommost row and rightmost column that is to be frozen.

**See also:**

**to\_csv** Write DataFrame to a comma-separated values (csv) file.

**ExcelWriter** Class for writing DataFrame objects into excel sheets.

**read\_excel** Read an Excel file into a pandas DataFrame.

**read\_csv** Read a comma-separated values (csv) file into DataFrame.

**Notes**

For compatibility with `to_csv()`, `to_excel` serializes lists and dicts to strings before writing.

Once a workbook has been saved it is not possible write further data without rewriting the whole workbook.

**Examples**

Create, write to and save a workbook:

```
>>> df1 = pd.DataFrame([[ 'a', 'b'], [ 'c', 'd']],
...                    index=[ 'row 1', 'row 2'],
...                    columns=[ 'col 1', 'col 2'])
>>> df1.to_excel("output.xlsx")
```

To specify the sheet name:

```
>>> df1.to_excel("output.xlsx",
...             sheet_name='Sheet_name_1')
```

If you wish to write to more than one sheet in the workbook, it is necessary to specify an `ExcelWriter` object:

```
>>> df2 = df1.copy()
>>> with pd.ExcelWriter('output.xlsx') as writer:
...     df1.to_excel(writer, sheet_name='Sheet_name_1')
...     df2.to_excel(writer, sheet_name='Sheet_name_2')
```

ExcelWriter can also be used to append to an existing Excel file:

```
>>> with pd.ExcelWriter('output.xlsx',
...                     mode='a') as writer:
...     df.to_excel(writer, sheet_name='Sheet_name_3')
```

To set the library that is used to write the Excel file, you can pass the *engine* keyword (the default engine is automatically chosen depending on the file extension):

```
>>> df1.to_excel('output1.xlsx', engine='xlsxwriter')
```

### pandas.io.formats.style.Styler.use

`Styler.use` (*self*, *styles*)

Set the styles on the current Styler.

Possibly uses styles from `Styler.export`.

#### Parameters

**styles** [list] List of style functions.

#### Returns

**self** [Styler]

See also:

*Styler.export*

### pandas.io.formats.style.Styler.where

`Styler.where` (*self*, *cond*, *value*, *other=None*, *subset=None*, *\*\*kwargs*)

Apply a function elementwise.

Updates the HTML representation with a style which is selected in accordance with the return value of a function.

New in version 0.21.0.

#### Parameters

**cond** [callable] *cond* should take a scalar and return a boolean.

**value** [str] Applied when *cond* returns true.

**other** [str] Applied when *cond* returns false.

**subset** [IndexSlice] A valid indexer to limit *data* to *before* applying the function.  
Consider using a `pandas.IndexSlice`.

**\*\*kwargs** [dict] Pass along to *cond*.

#### Returns

**self** [Styler]

See also:

*Styler.applymap*

### 4.13.2 Styler properties

---

*Styler.env*

---

*Styler.template*

---

*Styler.loader*

---

#### pandas.io.formats.style.Styler.env

`Styler.env = <jinja2.environment.Environment object>`

#### pandas.io.formats.style.Styler.template

`Styler.template = <Template 'html.tpl'>`

#### pandas.io.formats.style.Styler.loader

`Styler.loader = <jinja2.loaders.PackageLoader object>`

### 4.13.3 Style application

<i>Styler.apply</i> (self, func[, axis, subset])	Apply a function column-wise, row-wise, or table-wise.
<i>Styler.applymap</i> (self, func[, subset])	Apply a function elementwise.
<i>Styler.where</i> (self, cond, value[, other, subset])	Apply a function elementwise.
<i>Styler.format</i> (self, formatter[, subset])	Format the text display value of cells.
<i>Styler.set_precision</i> (self, precision)	Set the precision used to render.
<i>Styler.set_table_styles</i> (self, table_styles)	Set the table styles on a Styler.
<i>Styler.set_table_attributes</i> (self, attributes)	Set the table attributes.
<i>Styler.set_caption</i> (self, caption)	Set the caption on a Styler.
<i>Styler.set_properties</i> (self[, subset])	Method to set one or more non-data dependent properties or each cell.
<i>Styler.set_uuid</i> (self, uuid)	Set the uuid for a Styler.
<i>Styler.set_na_rep</i> (self, na_rep)	Set the missing data representation on a Styler.
<i>Styler.clear</i> (self)	Reset the styler, removing any previously applied styles.
<i>Styler.pipe</i> (self, func, *args, **kwargs)	Apply <code>func(self, *args, **kwargs)</code> , and return the result.

### 4.13.4 Builtin styles

<i>Styler.highlight_max</i> (self[, subset, color, axis])	Highlight the maximum by shading the background.
<i>Styler.highlight_min</i> (self[, subset, color, axis])	Highlight the minimum by shading the background.
<i>Styler.highlight_null</i> (self[, null_color])	Shade the background <code>null_color</code> for missing values.

Continued on next page

Table 414 – continued from previous page

<code>Styler.background_gradient(self[, cmap, ...])</code>	Color the background in a gradient style.
<code>Styler.bar(self[, subset, axis, color, ...])</code>	Draw bar chart in the cell backgrounds.

### 4.13.5 Style export and import

<code>Styler.render(self, **kwargs)</code>	Render the built up styles to HTML.
<code>Styler.export(self)</code>	Export the styles to applied to the current Styler.
<code>Styler.use(self, styles)</code>	Set the styles on the current Styler.
<code>Styler.to_excel(self, excel_writer[, ...])</code>	Write Styler to an Excel sheet.

{{ header }}

## 4.14 Plotting

The following functions are contained in the `pandas.plotting` module.

<code>andrews_curves(frame, class_column[, ax, ...])</code>	Generate a matplotlib plot of Andrews curves, for visualising clusters of multivariate data.
<code>autocorrelation_plot(series[, ax])</code>	Autocorrelation plot for time series.
<code>bootstrap_plot(series[, fig, size, samples])</code>	Bootstrap plot on mean, median and mid-range statistics.
<code>boxplot(data[, column, by, ax, fontsize, ...])</code>	Make a box plot from DataFrame columns.
<code>deregister_matplotlib_converters()</code>	Remove pandas' formatters and converters.
<code>lag_plot(series[, lag, ax])</code>	Lag plot for time series.
<code>parallel_coordinates(frame, class_column[, ...])</code>	Parallel coordinates plotting.
<code>plot_params</code>	Stores pandas plotting options.
<code>radviz(frame, class_column[, ax, color, ...])</code>	Plot a multidimensional dataset in 2D.
<code>register_matplotlib_converters()</code>	Register Pandas Formatters and Converters with matplotlib.
<code>scatter_matrix(frame[, alpha, figsize, ax, ...])</code>	Draw a matrix of scatter plots.
<code>table(ax, data[, rowLabels, colLabels])</code>	Helper function to convert DataFrame and Series to matplotlib.table.

### 4.14.1 pandas.plotting.andrews\_curves

`pandas.plotting.andrews_curves` (*frame, class\_column, ax=None, samples=200, color=None, colormap=None, \*\*kwargs*)

Generate a matplotlib plot of Andrews curves, for visualising clusters of multivariate data.

Andrews curves have the functional form:

$$f(t) = x_1/\sqrt{2} + x_2 \sin(t) + x_3 \cos(t) + x_4 \sin(2t) + x_5 \cos(2t) + \dots$$

Where  $x$  coefficients correspond to the values of each dimension and  $t$  is linearly spaced between  $-\pi$  and  $+\pi$ .

Each row of `frame` then corresponds to a single curve.

#### Parameters

**frame** [DataFrame] Data to be plotted, preferably normalized to (0.0, 1.0).

**class\_column** [Name of the column containing class names]

**ax** [matplotlib axes object, default None]

**samples** [Number of points to plot in each curve]

**color** [list or tuple, optional] Colors to use for the different classes.

**colormap** [str or matplotlib colormap object, default None] Colormap to select colors from. If string, load colormap with that name from matplotlib.

**\*\*kwargs** Options to pass to matplotlib plotting method.

**Returns**

*class:matplotlib.axis.Axes*

### 4.14.2 pandas.plotting.autocorrelation\_plot

`pandas.plotting.autocorrelation_plot` (*series*, *ax=None*, *\*\*kwargs*)

Autocorrelation plot for time series.

**Parameters**

**series** [Time series]

**ax** [Matplotlib axis object, optional]

**\*\*kwargs** Options to pass to matplotlib plotting method.

**Returns**

*class:matplotlib.axis.Axes*

### 4.14.3 pandas.plotting.bootstrap\_plot

`pandas.plotting.bootstrap_plot` (*series*, *fig=None*, *size=50*, *samples=500*, *\*\*kws*)

Bootstrap plot on mean, median and mid-range statistics.

The bootstrap plot is used to estimate the uncertainty of a statistic by relying on random sampling with replacement [?]. This function will generate bootstrapping plots for mean, median and mid-range statistics for the given number of samples of the given size.

**Parameters**

**series** [pandas.Series] Pandas Series from where to get the samplings for the bootstrapping.

**fig** [matplotlib.figure.Figure, default None] If given, it will use the *fig* reference for plotting instead of creating a new one with default parameters.

**size** [int, default 50] Number of data points to consider during each sampling. It must be greater or equal than the length of the *series*.

**samples** [int, default 500] Number of times the bootstrap procedure is performed.

**\*\*kws** Options to pass to matplotlib plotting method.

**Returns**

*matplotlib.figure.Figure* Matplotlib figure.

See also:

**DataFrame.plot** Basic plotting for DataFrame objects.

**Series.plot** Basic plotting for Series objects.

## Examples

```
>>> s = pd.Series(np.random.uniform(size=100))
>>> fig = pd.plotting.bootstrap_plot(s)
```

## 4.14.4 pandas.plotting.boxplot

`pandas.plotting.boxplot` (*data*, *column=None*, *by=None*, *ax=None*, *fontsize=None*, *rot=0*, *grid=True*, *figsize=None*, *layout=None*, *return\_type=None*, *\*\*kwargs*)

Make a box plot from DataFrame columns.

Make a box-and-whisker plot from DataFrame columns, optionally grouped by some other columns. A box plot is a method for graphically depicting groups of numerical data through their quartiles. The box extends from the Q1 to Q3 quartile values of the data, with a line at the median (Q2). The whiskers extend from the edges of box to show the range of the data. The position of the whiskers is set by default to  $1.5 * IQR$  ( $IQR = Q3 - Q1$ ) from the edges of the box. Outlier points are those past the end of the whiskers.

For further details see Wikipedia's entry for [boxplot](#).

**Parameters**

**column** [str or list of str, optional] Column name or list of names, or vector. Can be any valid input to `pandas.DataFrame.groupby()`.

**by** [str or array-like, optional] Column in the DataFrame to `pandas.DataFrame.groupby()`. One box-plot will be done per value of columns in *by*.

**ax** [object of class `matplotlib.axes.Axes`, optional] The matplotlib axes to be used by `boxplot`.

**fontsize** [float or str] Tick label font size in points or as a string (e.g., *large*).

**rot** [int or float, default 0] The rotation angle of labels (in degrees) with respect to the screen coordinate system.

**grid** [bool, default True] Setting this to True will show the grid.

**figsize** [A tuple (width, height) in inches] The size of the figure to create in matplotlib.

**layout** [tuple (rows, columns), optional] For example, (3, 5) will display the subplots using 3 columns and 5 rows, starting from the top-left.

**return\_type** [{ 'axes', 'dict', 'both' } or None, default 'axes'] The kind of object to return. The default is `axes`.

- 'axes' returns the matplotlib axes the boxplot is drawn on.
- 'dict' returns a dictionary whose values are the matplotlib Lines of the boxplot.
- 'both' returns a namedtuple with the axes and dict.
- when grouping with `by`, a Series mapping columns to `return_type` is returned.

If `return_type` is `None`, a NumPy array of axes with the same shape as `layout` is returned.

**\*\*kwargs** All other plotting keyword arguments to be passed to `matplotlib.pyplot.boxplot()`.

### Returns

**result** See Notes.

### See also:

**Series.plot.hist** Make a histogram.

**matplotlib.pyplot.boxplot** Matplotlib equivalent plot.

### Notes

The return type depends on the `return_type` parameter:

- 'axes' : object of class `matplotlib.axes.Axes`
- 'dict' : dict of `matplotlib.lines.Line2D` objects
- 'both' : a namedtuple with structure (ax, lines)

For data grouped with `by`, return a Series of the above or a numpy array:

- `Series`
- `array` (for `return_type = None`)

Use `return_type='dict'` when you want to tweak the appearance of the lines after plotting. In this case a dict containing the Lines making up the boxes, caps, fliers, medians, and whiskers is returned.

## Examples

Boxplots can be created for every column in the dataframe by `df.boxplot()` or indicating the columns to be used:

```
>>> np.random.seed(1234)
>>> df = pd.DataFrame(np.random.randn(10, 4),
...                    columns=['Col1', 'Col2', 'Col3', 'Col4'])
>>> boxplot = df.boxplot(column=['Col1', 'Col2', 'Col3'])
```

Boxplots of variables distributions grouped by the values of a third variable can be created using the option `by`. For instance:

```
>>> df = pd.DataFrame(np.random.randn(10, 2),
...                    columns=['Col1', 'Col2'])
>>> df['X'] = pd.Series(['A', 'A', 'A', 'A', 'A',
...                      'B', 'B', 'B', 'B', 'B'])
>>> boxplot = df.boxplot(by='X')
```

A list of strings (i.e. `['X', 'Y']`) can be passed to `boxplot` in order to group the data by combination of the variables in the x-axis:

```
>>> df = pd.DataFrame(np.random.randn(10, 3),
...                    columns=['Col1', 'Col2', 'Col3'])
```

(continues on next page)

(continued from previous page)

```

>>> df['X'] = pd.Series(['A', 'A', 'A', 'A', 'A',
...                      'B', 'B', 'B', 'B', 'B'])
>>> df['Y'] = pd.Series(['A', 'B', 'A', 'B', 'A',
...                      'B', 'A', 'B', 'A', 'B'])
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by=['X', 'Y'])

```

The layout of boxplot can be adjusted giving a tuple to layout:

```

>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
...                       layout=(2, 1))

```

Additional formatting can be done to the boxplot, like suppressing the grid (`grid=False`), rotating the labels in the x-axis (i.e. `rot=45`) or changing the fontsize (i.e. `fontsize=15`):

```

>>> boxplot = df.boxplot(grid=False, rot=45, fontsize=15)

```

The parameter `return_type` can be used to select the type of element returned by `boxplot`. When `return_type='axes'` is selected, the matplotlib axes on which the boxplot is drawn are returned:

```

>>> boxplot = df.boxplot(column=['Col1', 'Col2'], return_type='axes')
>>> type(boxplot)
<class 'matplotlib.axes._subplots.AxesSubplot'>

```

When grouping with `by`, a Series mapping columns to `return_type` is returned:

```
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
...                       return_type='axes')
>>> type(boxplot)
<class 'pandas.core.series.Series'>
```

If `return_type` is `None`, a NumPy array of axes with the same shape as `layout` is returned:

```
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
...                       return_type=None)
>>> type(boxplot)
<class 'numpy.ndarray'>
```

#### 4.14.5 pandas.plotting.deregister\_matplotlib\_converters

`pandas.plotting.deregister_matplotlib_converters()`

Remove pandas' formatters and converters.

Removes the custom converters added by `register()`. This attempts to set the state of the registry back to the state before pandas registered its own units. Converters for pandas' own types like `Timestamp` and `Period` are removed completely. Converters for types pandas overwrites, like `datetime.datetime`, are restored to their original value.

See also:

*`register_matplotlib_converters`*

#### 4.14.6 pandas.plotting.lag\_plot

`pandas.plotting.lag_plot(series, lag=1, ax=None, **kwds)`

Lag plot for time series.

##### Parameters

**series** [Time series]

**lag** [lag of the scatter plot, default 1]

**ax** [Matplotlib axis object, optional]

**\*\*kwds** Matplotlib scatter method keyword arguments.

##### Returns

class:*matplotlib.axis.Axes*

#### 4.14.7 pandas.plotting.parallel\_coordinates

`pandas.plotting.parallel_coordinates(frame, class_column, cols=None, ax=None, color=None, use_columns=False, xticks=None, colormap=None, axvlines=True, axvlines_kwds=None, sort_labels=False, **kwargs)`

Parallel coordinates plotting.

##### Parameters

**frame** [DataFrame]

**class\_column** [str] Column name containing class names.

**cols** [list, optional] A list of column names to use.

**ax** [matplotlib.axis, optional] Matplotlib axis object.

**color** [list or tuple, optional] Colors to use for the different classes.

**use\_columns** [bool, optional] If true, columns will be used as xticks.

**xticks** [list or tuple, optional] A list of values to use for xticks.

**colormap** [str or matplotlib colormap, default None] Colormap to use for line colors.

**axvlines** [bool, optional] If true, vertical lines will be added at each xtick.

**axvlines\_kwds** [keywords, optional] Options to be passed to axvline method for vertical lines.

**sort\_labels** [bool, default False] Sort class\_column labels, useful when assigning colors.

**\*\*kwargs** Options to pass to matplotlib plotting method.

**Returns**

**class:***matplotlib.axis.Axes*

**Examples**

```
>>> from matplotlib import pyplot as plt
>>> df = pd.read_csv('https://raw.githubusercontent.com/pandas-dev/pandas/master'
                    '/pandas/tests/data/csv/iris.csv')
>>> pd.plotting.parallel_coordinates(
    df, 'Name',
    color=( '#556270', '#4ECDC4', '#C7F464' ))
>>> plt.show()
```

**4.14.8 pandas.plotting.plot\_params**

`pandas.plotting.plot_params = {'xaxis.compat': False}`  
Stores pandas plotting options.

Allows for parameter aliasing so you can just use parameter names that are the same as the plot function parameters, but is stored in a canonical format that makes it easy to breakdown into groups later.

**4.14.9 pandas.plotting.radviz**

`pandas.plotting.radviz (frame, class_column, ax=None, color=None, colormap=None, **kwargs)`  
Plot a multidimensional dataset in 2D.

Each Series in the DataFrame is represented as a evenly distributed slice on a circle. Each data point is rendered in the circle according to the value on each Series. Highly correlated Series in the DataFrame are placed closer on the unit circle.

RadViz allow to project a N-dimensional data set into a 2D space where the influence of each dimension can be interpreted as a balance between the influence of all dimensions.

More info available at the [original article](#) describing RadViz.

**Parameters**

**frame** [DataFrame] Pandas object holding the data.

**class\_column** [str] Column name containing the name of the data point category.

**ax** [`matplotlib.axes.Axes`, optional] A plot instance to which to add the information.

**color** [list[str] or tuple[str], optional] Assign a color to each category. Example: ['blue', 'green'].

**colormap** [str or `matplotlib.colors.Colormap`, default None] Colormap to select colors from. If string, load colormap with that name from matplotlib.

**\*\*kwargs** Options to pass to matplotlib scatter plotting method.

**Returns**

class:`matplotlib.axes.Axes`

See also:

`plotting.andrews_curves` Plot clustering visualization.

**Examples**

```
>>> df = pd.DataFrame({
...     'SepalLength': [6.5, 7.7, 5.1, 5.8, 7.6, 5.0, 5.4, 4.6,
...                    6.7, 4.6],
...     'SepalWidth': [3.0, 3.8, 3.8, 2.7, 3.0, 2.3, 3.0, 3.2,
...                   3.3, 3.6],
...     'PetalLength': [5.5, 6.7, 1.9, 5.1, 6.6, 3.3, 4.5, 1.4,
...                    5.7, 1.0],
...     'PetalWidth': [1.8, 2.2, 0.4, 1.9, 2.1, 1.0, 1.5, 0.2,
...                   2.1, 0.2],
...     'Category': ['virginica', 'virginica', 'setosa',
...                  'virginica', 'virginica', 'versicolor',
...                  'versicolor', 'setosa', 'virginica',
...                  'setosa']
... })
>>> rad_viz = pd.plotting.radviz(df, 'Category')
```

**4.14.10 pandas.plotting.register\_matplotlib\_converters**

`pandas.plotting.register_matplotlib_converters()`

Register Pandas Formatters and Converters with matplotlib.

This function modifies the global `matplotlib.units.registry` dictionary. Pandas adds custom converters for

- `pd.Timestamp`
- `pd.Period`
- `np.datetime64`
- `datetime.datetime`
- `datetime.date`
- `datetime.time`

See also:

`deregister_matplotlib_converters`

### 4.14.11 pandas.plotting.scatter\_matrix

`pandas.plotting.scatter_matrix` (*frame*, *alpha*=0.5, *figsize*=None, *ax*=None, *grid*=False, *diagonal*='hist', *marker*='.', *density\_kwds*=None, *hist\_kwds*=None, *range\_padding*=0.05, *\*\*kwargs*)

Draw a matrix of scatter plots.

#### Parameters

- frame** [DataFrame]
- alpha** [float, optional] Amount of transparency applied.
- figsize** [(float,float), optional] A tuple (width, height) in inches.
- ax** [Matplotlib axis object, optional]
- grid** [bool, optional] Setting this to True will show the grid.
- diagonal** [{ 'hist', 'kde' }] Pick between 'kde' and 'hist' for either Kernel Density Estimation or Histogram plot in the diagonal.
- marker** [str, optional] Matplotlib marker type, default '.'.
- density\_kwds** [keywords] Keyword arguments to be passed to kernel density estimate plot.
- hist\_kwds** [keywords] Keyword arguments to be passed to hist function.
- range\_padding** [float, default 0.05] Relative extension of axis range in x and y with respect to (x\_max - x\_min) or (y\_max - y\_min).
- \*\*kwargs** Keyword arguments to be passed to scatter function.

#### Returns

**numpy.ndarray** A matrix of scatter plots.

#### Examples

```
>>> df = pd.DataFrame(np.random.randn(1000, 4), columns=['A', 'B', 'C', 'D'])
>>> scatter_matrix(df, alpha=0.2)
```

### 4.14.12 pandas.plotting.table

`pandas.plotting.table` (*ax*, *data*, *rowLabels*=None, *colLabels*=None, *\*\*kwargs*)

Helper function to convert DataFrame and Series to matplotlib.table.

#### Parameters

- ax** [Matplotlib axes object]
- data** [DataFrame or Series] Data for table contents.
- \*\*kwargs** Keyword arguments to be passed to matplotlib.table.table. If *rowLabels* or *colLabels* is not specified, data index or column name will be used.

#### Returns

**matplotlib table object**

```
{{ header }}
```

## 4.15 General utility functions

### 4.15.1 Working with options

<code>describe_option(pat[, _print_desc])</code>	Prints the description for one or more registered options.
<code>reset_option(pat)</code>	Reset one or more options to their default value.
<code>get_option(pat)</code>	Retrieves the value of the specified option.
<code>set_option(pat, value)</code>	Sets the value of the specified option.
<code>option_context(*args)</code>	Context manager to temporarily set options in the <i>with</i> statement context.

#### **pandas.describe\_option**

`pandas.describe_option(pat, _print_desc=False) = <pandas._config.config.CallableDynamicDoc object>`

Prints the description for one or more registered options.

Call with not arguments to get a listing for all registered options.

Available options:

- `compute.[use_bottleneck, use_numexpr]`
- `display.[chop_threshold, colheader_justify, column_space, date_dayfirst, date_yearfirst, encoding, expand_frame_repr, float_format]`
- `display.html.[border, table_schema, use_mathjax]`
- `display.[large_repr]`
- `display.latex.[escape, longtable, multicolumn, multicolumn_format, multirow, repr]`
- `display.[max_categories, max_columns, max_colwidth, max_info_columns, max_info_rows, max_rows, max_seq_items, memory_usage, min_rows, multi_sparse, notebook_repr_html, pprint_nest_depth, precision, show_dimensions]`
- `display.unicode.[ambiguous_as_wide, east_asian_width]`
- `display.[width]`
- `io.excel.ods.[reader]`
- `io.excel.xls.[reader, writer]`
- `io.excel.xlsb.[reader]`
- `io.excel.xlsm.[reader, writer]`
- `io.excel.xlsx.[reader, writer]`
- `io.hdf.[default_format, dropna_table]`
- `io.parquet.[engine]`
- `mode.[chained_assignment, sim_interactive, use_inf_as_na, use_inf_as_null]`
- `plotting.[backend]`
- `plotting.matplotlib.[register_converters]`

#### **Parameters**

**pat** [str] Regexp pattern. All matching keys will have their description displayed.

**\_print\_desc** [bool, default True] If True (default) the description(s) will be printed to stdout. Otherwise, the description(s) will be returned as a unicode string (for testing).

#### **Returns**

**None by default, the description(s) as a unicode string if \_print\_desc is False**

## Notes

The available options with its descriptions:

**compute.use\_bottleneck** [bool] Use the bottleneck library to accelerate if it is installed, the default is True  
 Valid values: False,True [default: True] [currently: True]**compute.use\_numexpr** : bool Use the numexpr library to accelerate computation if it is installed, the default is True Valid values: False,True [default: True] [currently: True]**display.chop\_threshold** : float or None if set to a float value, all float values smaller then the given threshold will be displayed as exactly 0 by repr and friends. [default: None] [currently: None]**display.colheader\_justify** : ‘left’/‘right’ Controls the justification of column headers. used by DataFrameFormatter. [default: right] [currently: right]**display.column\_space** No description available. [default: 12] [currently: 12]**display.date\_dayfirst** : boolean When True, prints and parses dates with the day first, eg 20/01/2005 [default: False] [currently: False]**display.date\_yearfirst** : boolean When True, prints and parses dates with the year first, eg 2005/01/20 [default: False] [currently: False]**display.encoding** : str/unicode Defaults to the detected encoding of the console. Specifies the encoding to be used for strings returned by to\_string, these are generally strings meant to be displayed on the console. [default: UTF-8] [currently: UTF-8]**display.expand\_frame\_repr** : boolean Whether to print out the full DataFrame repr for wide DataFrames across multiple lines, *max\_columns* is still respected, but the output will wrap-around across multiple “pages” if its width exceeds *display.width*. [default: True] [currently: True]**display.float\_format** : callable The callable should accept a floating point number and return a string with the desired format of the number. This is used in some places like SeriesFormatter. See `formats.format.EngFormatter` for an example. [default: None] [currently: None]**display.html.border** : int A `border=value` attribute is inserted in the `<table>` tag for the DataFrame HTML repr. [default: 1] [currently: 1]**display.html.table\_schema** : boolean Whether to publish a Table Schema representation for frontends that support it. (default: False) [default: False] [currently: False]**display.html.use\_mathjax** : boolean When True, Jupyter notebook will process table contents using MathJax, rendering mathematical expressions enclosed by the dollar symbol. (default: True) [default: True] [currently: True]**display.large\_repr** : ‘truncate’/‘info’ For DataFrames exceeding `max_rows/max_cols`, the repr (and HTML repr) can show a truncated table (the default from 0.13), or switch to the view from `df.info()` (the behaviour in earlier versions of pandas). [default: truncate] [currently: truncate]**display.latex.escape** : bool This specifies if the `to_latex` method of a Dataframe uses escapes special characters. Valid values: False,True [default: True] [currently: True]**display.latex.longtable** :bool This specifies if the `to_latex` method of a Dataframe uses the longtable format. Valid values: False,True [default: False] [currently: False]**display.latex.multicolumn** : bool This specifies if the `to_latex` method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: True] [currently: True]**display.latex.multicolumn\_format** : bool This specifies if the `to_latex` method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: 1] [currently: 1]**display.latex.multirow** : bool This specifies if the `to_latex` method of a Dataframe uses multirows to pretty-print MultiIndex rows. Valid values: False,True [default: False] [currently: False]**display.latex.repr** : boolean Whether to produce a latex DataFrame representation for jupyter environments that support it. (default: False) [default: False] [currently: False]**display.max\_categories** : int This sets the maximum number of categories pandas should output when printing out a *Categorical* or a Series of dtype “category”. [default: 8] [currently: 8]**display.max\_columns** : int If `max_cols` is exceeded, switch to truncate view. Depending on *large\_repr*, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and *large\_repr* equals ‘truncate’ this can be set to 0 and pandas will auto-detect the width of the terminal and print a truncated object which fits the screen width. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 0] [currently: 0]**display.max\_colwidth** : int or None The maximum width in characters of a column in the repr of a pandas data structure. When the column overflows, a “...” placeholder is embedded in the output. A ‘None’ value means unlimited. [default: 50] [currently: 50]**display.max\_info\_columns** : int `max_info_columns` is used in `DataFrame.info` method to decide if per column information will be printed. [default: 100] [currently: 100]**display.max\_info\_rows** : int or None `df.info()` will usually show null-counts for each column. For large frames this can be quite

slow. `max_info_rows` and `max_info_cols` limit this null check only to frames with smaller dimensions than specified. [default: 1690785] [currently: 1690785]`display.max_rows` : int If `max_rows` is exceeded, switch to truncate view. Depending on `large_repr`, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and `large_repr` equals ‘truncate’ this can be set to 0 and pandas will auto-detect the height of the terminal and print a truncated object which fits the screen height. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 60] [currently: 60]`display.max_seq_items` : int or None when pretty-printing a long sequence, no more than `max_seq_items` will be printed. If items are omitted, they will be denoted by the addition of “...” to the resulting string.

If set to None, the number of items to be printed is unlimited. [default: 100] [currently: 100]`display.memory_usage` : bool, string or None This specifies if the memory usage of a DataFrame should be displayed when `df.info()` is called. Valid values True,False,‘deep’ [default: True] [currently: True]`display.min_rows` : int The numbers of rows to show in a truncated view (when `max_rows` is exceeded). Ignored when `max_rows` is set to None or 0. When set to None, follows the value of `max_rows`. [default: 10] [currently: 10]`display.multi_sparse` : boolean “sparsify” MultiIndex display (don’t display repeated elements in outer levels within groups) [default: True] [currently: True]`display.notebook_repr_html` : boolean When True, IPython notebook will use html representation for pandas objects (if it is available). [default: True] [currently: True]`display.pprint_nest_depth` : int Controls the number of nested levels to process when pretty-printing [default: 3] [currently: 3]`display.precision` : int Floating point output precision (number of significant digits). This is only a suggestion [default: 6] [currently: 6]`display.show_dimensions` : boolean or ‘truncate’ Whether to print out dimensions at the end of DataFrame repr. If ‘truncate’ is specified, only print out the dimensions if the frame is truncated (e.g. not display all rows and/or columns) [default: truncate] [currently: truncate]`display.unicode.ambiguous_as_wide` : boolean Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]`display.unicode.east_asian_width` : boolean Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]`display.width` : int Width of the display in characters. In case python/IPython is running in a terminal this can be set to None and pandas will correctly auto-detect the width. Note that the IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to correctly detect the width. [default: 80] [currently: 80]`io.excel.ods.reader` : string The default Excel reader engine for ‘ods’ files. Available options: auto, odf. [default: auto] [currently: auto]`io.excel.xls.reader` : string The default Excel reader engine for ‘xls’ files. Available options: auto, xlrd. [default: auto] [currently: auto]`io.excel.xls.writer` : string The default Excel writer engine for ‘xls’ files. Available options: auto, xlwt. [default: auto] [currently: auto]`io.excel.xlsb.reader` : string The default Excel reader engine for ‘xlsb’ files. Available options: auto, pyxlsb. [default: auto] [currently: auto]`io.excel.xlsm.reader` : string The default Excel reader engine for ‘xlsm’ files. Available options: auto, xlrd, openpyxl. [default: auto] [currently: auto]`io.excel.xlsm.writer` : string The default Excel writer engine for ‘xlsm’ files. Available options: auto, openpyxl. [default: auto] [currently: auto]`io.excel.xlsx.reader` : string The default Excel reader engine for ‘xlsx’ files. Available options: auto, xlrd, openpyxl. [default: auto] [currently: auto]`io.excel.xlsx.writer` : string The default Excel writer engine for ‘xlsx’ files. Available options: auto, openpyxl, xlsxwriter. [default: auto] [currently: auto]`io.hdf.default_format` : format default format writing format, if None, then put will default to ‘fixed’ and append will default to ‘table’ [default: None] [currently: None]`io.hdf.dropna_table` : boolean drop ALL nan rows when appending to a table [default: False] [currently: False]`io.parquet.engine` : string The default parquet reader/writer engine. Available options: ‘auto’, ‘pyarrow’, ‘fastparquet’, the default is ‘auto’ [default: auto] [currently: auto]`mode.chained_assignment` : string Raise an exception, warn, or no action if trying to use chained assignment, The default is warn [default: warn] [currently: warn]`mode.sim_interactive` : boolean Whether to simulate interactive mode for purposes of testing [default: False] [currently: False]`mode.use_inf_as_na` : boolean True means treat None, NaN, INF, -INF as NA (old way), False means None and NaN are null, but INF, -INF are not NA (new way). [default: False] [currently: False]`mode.use_inf_as_null` : boolean use\_inf\_as\_null had been deprecated and

will be removed in a future version. Use `use_inf_as_na` instead. [default: False] [currently: False] (Deprecated, use `mode.use_inf_as_na` instead.)  
`plotting.backend` : str The plotting backend to use. The default value is “matplotlib”, the backend provided with pandas. Other backends can be specified by providing the name of the module that implements the backend. [default: matplotlib] [currently: matplotlib]  
`plotting.matplotlib.register_converters` : bool or ‘auto’. Whether to register converters with matplotlib’s units registry for dates, times, datetimes, and Periods. Toggling to False will remove the converters, restoring any converters that pandas overwrote. [default: auto] [currently: auto]

## pandas.reset\_option

`pandas.reset_option(pat) = <pandas._config.config.CallableDynamicDoc object>`

Reset one or more options to their default value.

Pass “all” as argument to reset all options.

Available options:

- `compute`.`[use_bottleneck, use_numexpr]`
- `display`.`[chop_threshold, colheader_justify, column_space, date_dayfirst, date_yearfirst, encoding, expand_frame_repr, float_format]`
- `display.html`.`[border, table_schema, use_mathjax]`
- `display`.`[large_repr]`
- `display.latex`.`[escape, longtable, multicolumn, multicolumn_format, multirow, repr]`
- `display`.`[max_categories, max_columns, max_colwidth, max_info_columns, max_info_rows, max_rows, max_seq_items, memory_usage, min_rows, multi_sparse, notebook_repr_html, pprint_nest_depth, precision, show_dimensions]`
- `display.unicode`.`[ambiguous_as_wide, east_asian_width]`
- `display`.`[width]`
- `io.excel.ods`.`[reader]`
- `io.excel.xls`.`[reader, writer]`
- `io.excel.xlsb`.`[reader]`
- `io.excel.xlsm`.`[reader, writer]`
- `io.excel.xlsx`.`[reader, writer]`
- `io.hdf`.`[default_format, dropna_table]`
- `io.parquet`.`[engine]`
- `mode`.`[chained_assignment, sim_interactive, use_inf_as_na, use_inf_as_null]`
- `plotting`.`[backend]`
- `plotting.matplotlib`.`[register_converters]`

### Parameters

**pat** [str/regex] If specified only options matching *prefix\** will be reset. Note: partial matches are supported for convenience, but unless you use the full option name (e.g. `x.y.z.option_name`), your code may break in future versions if new options with similar names are introduced.

### Returns

None

## Notes

The available options with its descriptions:

**compute.use\_bottleneck** [bool] Use the bottleneck library to accelerate if it is installed, the default is True  
Valid values: False,True [default: True] [currently: True] **compute.use\_numexpr** : bool Use the numexpr library to accelerate computation if it is installed, the default is True Valid values: False,True [default: True] [currently: True] **display.chop\_threshold** : float or None if set to a float value, all float values smaller than the given threshold will be displayed as exactly 0 by repr and friends. [default: None] [currently: None] **display.colheader\_justify** : 'left'/'right' Controls the justification of column headers. used by DataFrameFormatter. [default: right] [currently: right] **display.column\_space** No description available. [default: 12] [currently: 12] **display.date\_dayfirst** : boolean When True, prints and parses dates with the day first, eg 20/01/2005 [default: False] [currently: False] **display.date\_yearfirst** : boolean When True, prints and parses dates with the year first, eg 2005/01/20 [default: False] [currently: False] **display.encoding** : str/unicode Defaults to the detected encoding of the console. Specifies the encoding to be used for strings returned by to\_string, these are generally strings meant to be displayed on the console. [default: UTF-8] [currently: UTF-8] **display.expand\_frame\_repr** : boolean Whether to print out the full DataFrame repr for wide DataFrames across multiple lines, *max\_columns* is still respected, but the output will wrap-around across multiple “pages” if its width exceeds *display.width*. [default: True] [currently: True] **display.float\_format** : callable The callable should accept a floating point number and return a string with the desired format of the number. This is used in some places like SeriesFormatter. See `formats.format.EngFormatter` for an example. [default: None] [currently: None] **display.html.border** : int A `border=value` attribute is inserted in the `<table>` tag for the DataFrame HTML repr. [default: 1] [currently: 1] **display.html.table\_schema** : boolean Whether to publish a Table Schema representation for frontends that support it. (default: False) [default: False] [currently: False] **display.html.use\_mathjax** : boolean When True, Jupyter notebook will process table contents using MathJax, rendering mathematical expressions enclosed by the dollar symbol. (default: True) [default: True] [currently: True] **display.large\_repr** : 'truncate'/'info' For DataFrames exceeding `max_rows/max_cols`, the repr (and HTML repr) can show a truncated table (the default from 0.13), or switch to the view from `df.info()` (the behaviour in earlier versions of pandas). [default: truncate] [currently: truncate] **display.latex.escape** : bool This specifies if the `to_latex` method of a Dataframe uses escapes special characters. Valid values: False,True [default: True] [currently: True] **display.latex.longtable** :bool This specifies if the `to_latex` method of a Dataframe uses the longtable format. Valid values: False,True [default: False] [currently: False] **display.latex.multicolumn** : bool This specifies if the `to_latex` method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: True] [currently: True] **display.latex.multicolumn\_format** : bool This specifies if the `to_latex` method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: 1] [currently: 1] **display.latex.multirow** : bool This specifies if the `to_latex` method of a Dataframe uses multirows to pretty-print MultiIndex rows. Valid values: False,True [default: False] [currently: False] **display.latex.repr** : boolean Whether to produce a latex DataFrame representation for jupyter environments that support it. (default: False) [default: False] [currently: False] **display.max\_categories** : int This sets the maximum number of categories pandas should output when printing out a *Categorical* or a Series of dtype “category”. [default: 8] [currently: 8] **display.max\_columns** : int If `max_cols` is exceeded, switch to truncate view. Depending on *large\_repr*, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and *large\_repr* equals ‘truncate’ this can be set to 0 and pandas will auto-detect the width of the terminal and print a truncated object which fits the screen width. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 0] [currently: 0] **display.max\_colwidth** : int or None The maximum width in characters of a column in the repr of a pandas data structure. When the column overflows, a “...” placeholder is embedded in the output. A ‘None’ value means unlimited. [default: 50] [currently: 50] **display.max\_info\_columns** : int `max_info_columns` is used in `DataFrame.info` method to decide if per column information will be printed. [default: 100] [currently: 100] **display.max\_info\_rows** : int or None `df.info()` will usually show null-counts for each column. For large frames this can be quite

slow. `max_info_rows` and `max_info_cols` limit this null check only to frames with smaller dimensions than specified. [default: 1690785] [currently: 1690785]`display.max_rows` : int If `max_rows` is exceeded, switch to truncate view. Depending on `large_repr`, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and `large_repr` equals ‘truncate’ this can be set to 0 and pandas will auto-detect the height of the terminal and print a truncated object which fits the screen height. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 60] [currently: 60]`display.max_seq_items` : int or None when pretty-printing a long sequence, no more than `max_seq_items` will be printed. If items are omitted, they will be denoted by the addition of “...” to the resulting string.

If set to None, the number of items to be printed is unlimited. [default: 100] [currently: 100]`display.memory_usage` : bool, string or None This specifies if the memory usage of a DataFrame should be displayed when `df.info()` is called. Valid values True,False,‘deep’ [default: True] [currently: True]`display.min_rows` : int The numbers of rows to show in a truncated view (when `max_rows` is exceeded). Ignored when `max_rows` is set to None or 0. When set to None, follows the value of `max_rows`. [default: 10] [currently: 10]`display.multi_sparse` : boolean “sparsify” MultiIndex display (don’t display repeated elements in outer levels within groups) [default: True] [currently: True]`display.notebook_repr_html` : boolean When True, IPython notebook will use html representation for pandas objects (if it is available). [default: True] [currently: True]`display.pprint_nest_depth` : int Controls the number of nested levels to process when pretty-printing [default: 3] [currently: 3]`display.precision` : int Floating point output precision (number of significant digits). This is only a suggestion [default: 6] [currently: 6]`display.show_dimensions` : boolean or ‘truncate’ Whether to print out dimensions at the end of DataFrame repr. If ‘truncate’ is specified, only print out the dimensions if the frame is truncated (e.g. not display all rows and/or columns) [default: truncate] [currently: truncate]`display.unicode.ambiguous_as_wide` : boolean Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]`display.unicode.east_asian_width` : boolean Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]`display.width` : int Width of the display in characters. In case python/IPython is running in a terminal this can be set to None and pandas will correctly auto-detect the width. Note that the IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to correctly detect the width. [default: 80] [currently: 80]`io.excel.ods.reader` : string The default Excel reader engine for ‘ods’ files. Available options: auto, odf. [default: auto] [currently: auto]`io.excel.xls.reader` : string The default Excel reader engine for ‘xls’ files. Available options: auto, xlrd. [default: auto] [currently: auto]`io.excel.xls.writer` : string The default Excel writer engine for ‘xls’ files. Available options: auto, xlwt. [default: auto] [currently: auto]`io.excel.xlsb.reader` : string The default Excel reader engine for ‘xlsb’ files. Available options: auto, pyxlsb. [default: auto] [currently: auto]`io.excel.xlsm.reader` : string The default Excel reader engine for ‘xlsm’ files. Available options: auto, xlrd, openpyxl. [default: auto] [currently: auto]`io.excel.xlsm.writer` : string The default Excel writer engine for ‘xlsm’ files. Available options: auto, openpyxl. [default: auto] [currently: auto]`io.excel.xlsx.reader` : string The default Excel reader engine for ‘xlsx’ files. Available options: auto, xlrd, openpyxl. [default: auto] [currently: auto]`io.excel.xlsx.writer` : string The default Excel writer engine for ‘xlsx’ files. Available options: auto, openpyxl, xlsxwriter. [default: auto] [currently: auto]`io.hdf.default_format` : format default format writing format, if None, then put will default to ‘fixed’ and append will default to ‘table’ [default: None] [currently: None]`io.hdf.dropna_table` : boolean drop ALL nan rows when appending to a table [default: False] [currently: False]`io.parquet.engine` : string The default parquet reader/writer engine. Available options: ‘auto’, ‘pyarrow’, ‘fastparquet’, the default is ‘auto’ [default: auto] [currently: auto]`mode.chained_assignment` : string Raise an exception, warn, or no action if trying to use chained assignment, The default is warn [default: warn] [currently: warn]`mode.sim_interactive` : boolean Whether to simulate interactive mode for purposes of testing [default: False] [currently: False]`mode.use_inf_as_na` : boolean True means treat None, NaN, INF, -INF as NA (old way), False means None and NaN are null, but INF, -INF are not NA (new way). [default: False] [currently: False]`mode.use_inf_as_null` : boolean use\_inf\_as\_null had been deprecated and

will be removed in a future version. Use `use_inf_as_na` instead. [default: False] [currently: False] (Deprecated, use `mode.use_inf_as_na` instead.)  
`plotting.backend` : str The plotting backend to use. The default value is “matplotlib”, the backend provided with pandas. Other backends can be specified by providing the name of the module that implements the backend. [default: matplotlib] [currently: matplotlib]  
`plotting.matplotlib.register_converters` : bool or ‘auto’. Whether to register converters with matplotlib’s units registry for dates, times, datetimes, and Periods. Toggling to False will remove the converters, restoring any converters that pandas overwrote. [default: auto] [currently: auto]

## pandas.get\_option

`pandas.get_option(pat)` = <pandas.\_config.config.CallableDynamicDoc object>

Retrieves the value of the specified option.

Available options:

- `compute`.`[use_bottleneck, use_numexpr]`
- `display`.`[chop_threshold, colheader_justify, column_space, date_dayfirst, date_yearfirst, encoding, expand_frame_repr, float_format]`
- `display.html`.`[border, table_schema, use_mathjax]`
- `display`.`[large_repr]`
- `display.latex`.`[escape, longtable, multicolumn, multicolumn_format, multirow, repr]`
- `display`.`[max_categories, max_columns, max_colwidth, max_info_columns, max_info_rows, max_rows, max_seq_items, memory_usage, min_rows, multi_sparse, notebook_repr_html, pprint_nest_depth, precision, show_dimensions]`
- `display.unicode`.`[ambiguous_as_wide, east_asian_width]`
- `display`.`[width]`
- `io.excel.ods`.`[reader]`
- `io.excel.xls`.`[reader, writer]`
- `io.excel.xlsb`.`[reader]`
- `io.excel.xlsm`.`[reader, writer]`
- `io.excel.xlsx`.`[reader, writer]`
- `io.hdf`.`[default_format, dropna_table]`
- `io.parquet`.`[engine]`
- `mode`.`[chained_assignment, sim_interactive, use_inf_as_na, use_inf_as_null]`
- `plotting`.`[backend]`
- `plotting.matplotlib`.`[register_converters]`

### Parameters

**pat** [str] Regexp which should match a single option. Note: partial matches are supported for convenience, but unless you use the full option name (e.g. `x.y.z.option_name`), your code may break in future versions if new options with similar names are introduced.

### Returns

**result** [the value of the option]

### Raises

**OptionError** [if no such option exists]

## Notes

The available options with its descriptions:

**compute.use\_bottleneck** [bool] Use the bottleneck library to accelerate if it is installed, the default is True  
 Valid values: False,True [default: True] [currently: True]**compute.use\_numexpr** : bool Use the numexpr library to accelerate computation if it is installed, the default is True Valid values: False,True [default: True] [currently: True]**display.chop\_threshold** : float or None if set to a float value, all float values smaller then the given threshold will be displayed as exactly 0 by repr and friends. [default: None] [currently: None]**display.colheader\_justify** : ‘left’/‘right’ Controls the justification of column headers. used by DataFrameFormatter. [default: right] [currently: right]**display.column\_space** No description available. [default: 12] [currently: 12]**display.date\_dayfirst** : boolean When True, prints and parses dates with the day first, eg 20/01/2005 [default: False] [currently: False]**display.date\_yearfirst** : boolean When True, prints and parses dates with the year first, eg 2005/01/20 [default: False] [currently: False]**display.encoding** : str/unicode Defaults to the detected encoding of the console. Specifies the encoding to be used for strings returned by to\_string, these are generally strings meant to be displayed on the console. [default: UTF-8] [currently: UTF-8]**display.expand\_frame\_repr** : boolean Whether to print out the full DataFrame repr for wide DataFrames across multiple lines, *max\_columns* is still respected, but the output will wrap-around across multiple “pages” if its width exceeds *display.width*. [default: True] [currently: True]**display.float\_format** : callable The callable should accept a floating point number and return a string with the desired format of the number. This is used in some places like SeriesFormatter. See `formats.format.EngFormatter` for an example. [default: None] [currently: None]**display.html.border** : int A `border=value` attribute is inserted in the `<table>` tag for the DataFrame HTML repr. [default: 1] [currently: 1]**display.html.table\_schema** : boolean Whether to publish a Table Schema representation for frontends that support it. (default: False) [default: False] [currently: False]**display.html.use\_mathjax** : boolean When True, Jupyter notebook will process table contents using MathJax, rendering mathematical expressions enclosed by the dollar symbol. (default: True) [default: True] [currently: True]**display.large\_repr** : ‘truncate’/‘info’ For DataFrames exceeding `max_rows/max_cols`, the repr (and HTML repr) can show a truncated table (the default from 0.13), or switch to the view from `df.info()` (the behaviour in earlier versions of pandas). [default: truncate] [currently: truncate]**display.latex.escape** : bool This specifies if the `to_latex` method of a Dataframe uses escapes special characters. Valid values: False,True [default: True] [currently: True]**display.latex.longtable** :bool This specifies if the `to_latex` method of a Dataframe uses the longtable format. Valid values: False,True [default: False] [currently: False]**display.latex.multicolumn** : bool This specifies if the `to_latex` method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: True] [currently: True]**display.latex.multicolumn\_format** : bool This specifies if the `to_latex` method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: 1] [currently: 1]**display.latex.multirow** : bool This specifies if the `to_latex` method of a Dataframe uses multirows to pretty-print MultiIndex rows. Valid values: False,True [default: False] [currently: False]**display.latex.repr** : boolean Whether to produce a latex DataFrame representation for jupyter environments that support it. (default: False) [default: False] [currently: False]**display.max\_categories** : int This sets the maximum number of categories pandas should output when printing out a *Categorical* or a Series of dtype “category”. [default: 8] [currently: 8]**display.max\_columns** : int If `max_cols` is exceeded, switch to truncate view. Depending on *large\_repr*, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and *large\_repr* equals ‘truncate’ this can be set to 0 and pandas will auto-detect the width of the terminal and print a truncated object which fits the screen width. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 0] [currently: 0]**display.max\_colwidth** : int or None The maximum width in characters of a column in the repr of a pandas data structure. When the column overflows, a “...” placeholder is embedded in the output. A ‘None’ value means unlimited. [default: 50] [currently: 50]**display.max\_info\_columns** : int `max_info_columns` is used in `DataFrame.info` method to decide if per column information will be printed. [default: 100] [currently: 100]**display.max\_info\_rows** : int or None `df.info()` will usually show null-counts for each column. For large frames this can be quite

slow. `max_info_rows` and `max_info_cols` limit this null check only to frames with smaller dimensions than specified. [default: 1690785] [currently: 1690785]`display.max_rows` : int If `max_rows` is exceeded, switch to truncate view. Depending on `large_repr`, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and `large_repr` equals ‘truncate’ this can be set to 0 and pandas will auto-detect the height of the terminal and print a truncated object which fits the screen height. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 60] [currently: 60]`display.max_seq_items` : int or None when pretty-printing a long sequence, no more than `max_seq_items` will be printed. If items are omitted, they will be denoted by the addition of “...” to the resulting string.

If set to None, the number of items to be printed is unlimited. [default: 100] [currently: 100]`display.memory_usage` : bool, string or None This specifies if the memory usage of a DataFrame should be displayed when `df.info()` is called. Valid values True,False,‘deep’ [default: True] [currently: True]`display.min_rows` : int The numbers of rows to show in a truncated view (when `max_rows` is exceeded). Ignored when `max_rows` is set to None or 0. When set to None, follows the value of `max_rows`. [default: 10] [currently: 10]`display.multi_sparse` : boolean “sparsify” MultiIndex display (don’t display repeated elements in outer levels within groups) [default: True] [currently: True]`display.notebook_repr_html` : boolean When True, IPython notebook will use html representation for pandas objects (if it is available). [default: True] [currently: True]`display.pprint_nest_depth` : int Controls the number of nested levels to process when pretty-printing [default: 3] [currently: 3]`display.precision` : int Floating point output precision (number of significant digits). This is only a suggestion [default: 6] [currently: 6]`display.show_dimensions` : boolean or ‘truncate’ Whether to print out dimensions at the end of DataFrame repr. If ‘truncate’ is specified, only print out the dimensions if the frame is truncated (e.g. not display all rows and/or columns) [default: truncate] [currently: truncate]`display.unicode.ambiguous_as_wide` : boolean Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]`display.unicode.east_asian_width` : boolean Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]`display.width` : int Width of the display in characters. In case python/IPython is running in a terminal this can be set to None and pandas will correctly auto-detect the width. Note that the IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to correctly detect the width. [default: 80] [currently: 80]`io.excel.ods.reader` : string The default Excel reader engine for ‘ods’ files. Available options: auto, odf. [default: auto] [currently: auto]`io.excel.xls.reader` : string The default Excel reader engine for ‘xls’ files. Available options: auto, xlrd. [default: auto] [currently: auto]`io.excel.xls.writer` : string The default Excel writer engine for ‘xls’ files. Available options: auto, xlwt. [default: auto] [currently: auto]`io.excel.xlsb.reader` : string The default Excel reader engine for ‘xlsb’ files. Available options: auto, pyxlsb. [default: auto] [currently: auto]`io.excel.xlsm.reader` : string The default Excel reader engine for ‘xlsm’ files. Available options: auto, xlrd, openpyxl. [default: auto] [currently: auto]`io.excel.xlsm.writer` : string The default Excel writer engine for ‘xlsm’ files. Available options: auto, openpyxl. [default: auto] [currently: auto]`io.excel.xlsx.reader` : string The default Excel reader engine for ‘xlsx’ files. Available options: auto, xlrd, openpyxl. [default: auto] [currently: auto]`io.excel.xlsx.writer` : string The default Excel writer engine for ‘xlsx’ files. Available options: auto, openpyxl, xlsxwriter. [default: auto] [currently: auto]`io.hdf.default_format` : format default format writing format, if None, then put will default to ‘fixed’ and append will default to ‘table’ [default: None] [currently: None]`io.hdf.dropna_table` : boolean drop ALL nan rows when appending to a table [default: False] [currently: False]`io.parquet.engine` : string The default parquet reader/writer engine. Available options: ‘auto’, ‘pyarrow’, ‘fastparquet’, the default is ‘auto’ [default: auto] [currently: auto]`mode.chained_assignment` : string Raise an exception, warn, or no action if trying to use chained assignment, The default is warn [default: warn] [currently: warn]`mode.sim_interactive` : boolean Whether to simulate interactive mode for purposes of testing [default: False] [currently: False]`mode.use_inf_as_na` : boolean True means treat None, NaN, INF, -INF as NA (old way), False means None and NaN are null, but INF, -INF are not NA (new way). [default: False] [currently: False]`mode.use_inf_as_null` : boolean use\_inf\_as\_null had been deprecated and

will be removed in a future version. Use `use_inf_as_na` instead. [default: False] [currently: False] (Deprecated, use `mode.use_inf_as_na` instead.)  
`plotting.backend` : str The plotting backend to use. The default value is “matplotlib”, the backend provided with pandas. Other backends can be specified by providing the name of the module that implements the backend. [default: matplotlib] [currently: matplotlib]  
`plotting.matplotlib.register_converters` : bool or ‘auto’. Whether to register converters with matplotlib’s units registry for dates, times, datetimes, and Periods. Toggling to False will remove the converters, restoring any converters that pandas overwrote. [default: auto] [currently: auto]

## pandas.set\_option

`pandas.set_option(pat, value) = <pandas._config.config.CallableDynamicDoc object>`

Sets the value of the specified option.

Available options:

- `compute`.`[use_bottleneck, use_numexpr]`
- `display`.`[chop_threshold, colheader_justify, column_space, date_dayfirst, date_yearfirst, encoding, expand_frame_repr, float_format]`
- `display.html`.`[border, table_schema, use_mathjax]`
- `display`.`[large_repr]`
- `display.latex`.`[escape, longtable, multicolumn, multicolumn_format, multirow, repr]`
- `display`.`[max_categories, max_columns, max_colwidth, max_info_columns, max_info_rows, max_rows, max_seq_items, memory_usage, min_rows, multi_sparse, notebook_repr_html, pprint_nest_depth, precision, show_dimensions]`
- `display.unicode`.`[ambiguous_as_wide, east_asian_width]`
- `display`.`[width]`
- `io.excel.ods`.`[reader]`
- `io.excel.xls`.`[reader, writer]`
- `io.excel.xlsb`.`[reader]`
- `io.excel.xlsm`.`[reader, writer]`
- `io.excel.xlsx`.`[reader, writer]`
- `io.hdf`.`[default_format, dropna_table]`
- `io.parquet`.`[engine]`
- `mode`.`[chained_assignment, sim_interactive, use_inf_as_na, use_inf_as_null]`
- `plotting`.`[backend]`
- `plotting.matplotlib`.`[register_converters]`

### Parameters

**pat** [str] Regexp which should match a single option. Note: partial matches are supported for convenience, but unless you use the full option name (e.g. `x.y.z.option_name`), your code may break in future versions if new options with similar names are introduced.

**value** [object] New value of option.

### Returns

None

### Raises

**OptionError** if no such option exists

## Notes

The available options with its descriptions:

**compute.use\_bottleneck** [bool] Use the bottleneck library to accelerate if it is installed, the default is True  
Valid values: False,True [default: True] [currently: True] **compute.use\_numexpr** : bool Use the numexpr library to accelerate computation if it is installed, the default is True Valid values: False,True [default: True] [currently: True] **display.chop\_threshold** : float or None if set to a float value, all float values smaller than the given threshold will be displayed as exactly 0 by repr and friends. [default: None] [currently: None] **display.colheader\_justify** : 'left'/'right' Controls the justification of column headers. used by DataFrameFormatter. [default: right] [currently: right] **display.column\_space** No description available. [default: 12] [currently: 12] **display.date\_dayfirst** : boolean When True, prints and parses dates with the day first, eg 20/01/2005 [default: False] [currently: False] **display.date\_yearfirst** : boolean When True, prints and parses dates with the year first, eg 2005/01/20 [default: False] [currently: False] **display.encoding** : str/unicode Defaults to the detected encoding of the console. Specifies the encoding to be used for strings returned by to\_string, these are generally strings meant to be displayed on the console. [default: UTF-8] [currently: UTF-8] **display.expand\_frame\_repr** : boolean Whether to print out the full DataFrame repr for wide DataFrames across multiple lines, *max\_columns* is still respected, but the output will wrap-around across multiple “pages” if its width exceeds *display.width*. [default: True] [currently: True] **display.float\_format** : callable The callable should accept a floating point number and return a string with the desired format of the number. This is used in some places like SeriesFormatter. See `formats.format.EngFormatter` for an example. [default: None] [currently: None] **display.html.border** : int A `border=value` attribute is inserted in the `<table>` tag for the DataFrame HTML repr. [default: 1] [currently: 1] **display.html.table\_schema** : boolean Whether to publish a Table Schema representation for frontends that support it. (default: False) [default: False] [currently: False] **display.html.use\_mathjax** : boolean When True, Jupyter notebook will process table contents using MathJax, rendering mathematical expressions enclosed by the dollar symbol. (default: True) [default: True] [currently: True] **display.large\_repr** : 'truncate'/'info' For DataFrames exceeding *max\_rows*/*max\_cols*, the repr (and HTML repr) can show a truncated table (the default from 0.13), or switch to the view from `df.info()` (the behaviour in earlier versions of pandas). [default: truncate] [currently: truncate] **display.latex.escape** : bool This specifies if the `to_latex` method of a Dataframe uses escapes special characters. Valid values: False,True [default: True] [currently: True] **display.latex.longtable** :bool This specifies if the `to_latex` method of a Dataframe uses the longtable format. Valid values: False,True [default: False] [currently: False] **display.latex.multicolumn** : bool This specifies if the `to_latex` method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: True] [currently: True] **display.latex.multicolumn\_format** : bool This specifies if the `to_latex` method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: 1] [currently: 1] **display.latex.multirow** : bool This specifies if the `to_latex` method of a Dataframe uses multirows to pretty-print MultiIndex rows. Valid values: False,True [default: False] [currently: False] **display.latex.repr** : boolean Whether to produce a latex DataFrame representation for jupyter environments that support it. (default: False) [default: False] [currently: False] **display.max\_categories** : int This sets the maximum number of categories pandas should output when printing out a *Categorical* or a Series of dtype “category”. [default: 8] [currently: 8] **display.max\_columns** : int If *max\_cols* is exceeded, switch to truncate view. Depending on *large\_repr*, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and *large\_repr* equals ‘truncate’ this can be set to 0 and pandas will auto-detect the width of the terminal and print a truncated object which fits the screen width. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 0] [currently: 0] **display.max\_colwidth** : int or None The maximum width in characters of a column in the repr of a pandas data structure. When the column overflows, a “...” placeholder is embedded in the output. A ‘None’ value means unlimited. [default: 50] [currently: 50] **display.max\_info\_columns** : int *max\_info\_columns* is used in `DataFrame.info` method to decide if per column information will be printed. [default: 100] [currently: 100] **display.max\_info\_rows** : int or None `df.info()` will usually show null-counts for each column. For large frames this can be quite

slow. `max_info_rows` and `max_info_cols` limit this null check only to frames with smaller dimensions than specified. [default: 1690785] [currently: 1690785]`display.max_rows` : int If `max_rows` is exceeded, switch to truncate view. Depending on `large_repr`, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and `large_repr` equals ‘truncate’ this can be set to 0 and pandas will auto-detect the height of the terminal and print a truncated object which fits the screen height. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 60] [currently: 60]`display.max_seq_items` : int or None when pretty-printing a long sequence, no more than `max_seq_items` will be printed. If items are omitted, they will be denoted by the addition of “...” to the resulting string.

If set to None, the number of items to be printed is unlimited. [default: 100] [currently: 100]`display.memory_usage` : bool, string or None This specifies if the memory usage of a DataFrame should be displayed when `df.info()` is called. Valid values True,False,‘deep’ [default: True] [currently: True]`display.min_rows` : int The numbers of rows to show in a truncated view (when `max_rows` is exceeded). Ignored when `max_rows` is set to None or 0. When set to None, follows the value of `max_rows`. [default: 10] [currently: 10]`display.multi_sparse` : boolean “sparsify” MultiIndex display (don’t display repeated elements in outer levels within groups) [default: True] [currently: True]`display.notebook_repr_html` : boolean When True, IPython notebook will use html representation for pandas objects (if it is available). [default: True] [currently: True]`display.pprint_nest_depth` : int Controls the number of nested levels to process when pretty-printing [default: 3] [currently: 3]`display.precision` : int Floating point output precision (number of significant digits). This is only a suggestion [default: 6] [currently: 6]`display.show_dimensions` : boolean or ‘truncate’ Whether to print out dimensions at the end of DataFrame repr. If ‘truncate’ is specified, only print out the dimensions if the frame is truncated (e.g. not display all rows and/or columns) [default: truncate] [currently: truncate]`display.unicode.ambiguous_as_wide` : boolean Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]`display.unicode.east_asian_width` : boolean Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]`display.width` : int Width of the display in characters. In case python/IPython is running in a terminal this can be set to None and pandas will correctly auto-detect the width. Note that the IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to correctly detect the width. [default: 80] [currently: 80]`io.excel.ods.reader` : string The default Excel reader engine for ‘ods’ files. Available options: auto, odf. [default: auto] [currently: auto]`io.excel.xls.reader` : string The default Excel reader engine for ‘xls’ files. Available options: auto, xlrd. [default: auto] [currently: auto]`io.excel.xls.writer` : string The default Excel writer engine for ‘xls’ files. Available options: auto, xlwt. [default: auto] [currently: auto]`io.excel.xlsb.reader` : string The default Excel reader engine for ‘xlsb’ files. Available options: auto, pyxlsb. [default: auto] [currently: auto]`io.excel.xlsm.reader` : string The default Excel reader engine for ‘xlsm’ files. Available options: auto, xlrd, openpyxl. [default: auto] [currently: auto]`io.excel.xlsm.writer` : string The default Excel writer engine for ‘xlsm’ files. Available options: auto, openpyxl. [default: auto] [currently: auto]`io.excel.xlsx.reader` : string The default Excel reader engine for ‘xlsx’ files. Available options: auto, xlrd, openpyxl. [default: auto] [currently: auto]`io.excel.xlsx.writer` : string The default Excel writer engine for ‘xlsx’ files. Available options: auto, openpyxl, xlsxwriter. [default: auto] [currently: auto]`io.hdf.default_format` : format default format writing format, if None, then put will default to ‘fixed’ and append will default to ‘table’ [default: None] [currently: None]`io.hdf.dropna_table` : boolean drop ALL nan rows when appending to a table [default: False] [currently: False]`io.parquet.engine` : string The default parquet reader/writer engine. Available options: ‘auto’, ‘pyarrow’, ‘fastparquet’, the default is ‘auto’ [default: auto] [currently: auto]`mode.chained_assignment` : string Raise an exception, warn, or no action if trying to use chained assignment, The default is warn [default: warn] [currently: warn]`mode.sim_interactive` : boolean Whether to simulate interactive mode for purposes of testing [default: False] [currently: False]`mode.use_inf_as_na` : boolean True means treat None, NaN, INF, -INF as NA (old way), False means None and NaN are null, but INF, -INF are not NA (new way). [default: False] [currently: False]`mode.use_inf_as_null` : boolean use\_inf\_as\_null had been deprecated and

will be removed in a future version. Use `use_inf_as_na` instead. [default: False] [currently: False] (Deprecated, use `mode.use_inf_as_na` instead.)  
`plotting.backend` : str The plotting backend to use. The default value is “matplotlib”, the backend provided with pandas. Other backends can be specified by providing the name of the module that implements the backend. [default: matplotlib] [currently: matplotlib]  
`plotting.matplotlib.register_converters` : bool or ‘auto’. Whether to register converters with matplotlib’s units registry for dates, times, datetimes, and Periods. Toggling to False will remove the converters, restoring any converters that pandas overwrote. [default: auto] [currently: auto]

## pandas.option\_context

**class** pandas.**option\_context** (\*args)

Context manager to temporarily set options in the *with* statement context.

You need to invoke as `option_context(pat, val, [(pat, val), ...])`.

### Examples

```
>>> with option_context('display.max_rows', 10, 'display.max_columns', 5):  
.....
```

## 4.15.2 Testing functions

---

`testing.assert_frame_equal(left, right[, ...])` Check that left and right DataFrame are equal.

---

`testing.assert_series_equal(left, right[, ...])` Check that left and right Series are equal.

---

`testing.assert_index_equal(left, right, ...)` Check that left and right Index are equal.

---

`testing.assert_extension_array_equal(left, right)` Check that left and right ExtensionArrays are equal.

---

## pandas.testing.assert\_frame\_equal

`pandas.testing.assert_frame_equal(left, right, check_dtype=True, check_index_type='equiv', check_column_type='equiv', check_frame_type=True, check_less_precise=False, check_names=True, by_blocks=False, check_exact=False, check_datetimelike_compat=False, check_categorical=True, check_like=False, obj='DataFrame')`

Check that left and right DataFrame are equal.

This function is intended to compare two DataFrames and output any differences. It is mostly intended for use in unit tests. Additional parameters allow varying the strictness of the equality checks performed.

### Parameters

**left** [DataFrame] First DataFrame to compare.

**right** [DataFrame] Second DataFrame to compare.

**check\_dtype** [bool, default True] Whether to check the DataFrame dtype is identical.

**check\_index\_type** [bool or {'equiv'}, default 'equiv'] Whether to check the Index class, dtype and inferred\_type are identical.

**check\_column\_type** [bool or {'equiv'}, default 'equiv'] Whether to check the columns class, dtype and inferred\_type are identical. Is passed as the `exact` argument of `assert_index_equal()`.

**check\_frame\_type** [bool, default True] Whether to check the DataFrame class is identical.

**check\_less\_precise** [bool or int, default False] Specify comparison precision. Only used when `check_exact` is False. 5 digits (False) or 3 digits (True) after decimal points are compared. If int, then specify the digits to compare.

When comparing two numbers, if the first number has magnitude less than  $1e-5$ , we compare the two numbers directly and check whether they are equivalent within the specified precision. Otherwise, we compare the **ratio** of the second number to the first number and check whether it is equivalent to 1 within the specified precision.

**check\_names** [bool, default True] Whether to check that the `names` attribute for both the `index` and `column` attributes of the DataFrame is identical.

**by\_blocks** [bool, default False] Specify how to compare internal data. If False, compare by columns. If True, compare by blocks.

**check\_exact** [bool, default False] Whether to compare number exactly.

**check\_datetimelike\_compat** [bool, default False] Compare datetime-like which is comparable ignoring dtype.

**check\_categorical** [bool, default True] Whether to compare internal Categorical exactly.

**check\_like** [bool, default False] If True, ignore the order of index & columns. Note: index labels must match their respective rows (same as in columns) - same labels must be with the same data.

**obj** [str, default 'DataFrame'] Specify object name being compared, internally used to show appropriate assertion message.

See also:

**assert\_series\_equal** Equivalent method for asserting Series equality.

**DataFrame.equals** Check DataFrame equality.

## Examples

This example shows comparing two DataFrames that are equal but with columns of differing dtypes.

```
>>> from pandas.testing import assert_frame_equal
>>> df1 = pd.DataFrame({'a': [1, 2], 'b': [3, 4]})
>>> df2 = pd.DataFrame({'a': [1, 2], 'b': [3.0, 4.0]})
```

df1 equals itself.

```
>>> assert_frame_equal(df1, df1)
```

df1 differs from df2 as column 'b' is of a different type.

```
>>> assert_frame_equal(df1, df2)
Traceback (most recent call last):
...
AssertionError: Attributes of DataFrame.iloc[:, 1] (column name="b") are different
```

Attribute “dtype” are different [left]: int64 [right]: float64

Ignore differing dtypes in columns with `check_dtype`.

```
>>> assert_frame_equal(df1, df2, check_dtype=False)
```

### pandas.testing.assert\_series\_equal

`pandas.testing.assert_series_equal` (*left*, *right*, *check\_dtype=True*, *check\_index\_type='equiv'*, *check\_series\_type=True*, *check\_less\_precise=False*, *check\_names=True*, *check\_exact=False*, *check\_datetimelike\_compat=False*, *check\_categorical=True*, *obj='Series'*)

Check that left and right Series are equal.

#### Parameters

**left** [Series]

**right** [Series]

**check\_dtype** [bool, default True] Whether to check the Series dtype is identical.

**check\_index\_type** [bool or {'equiv'}], default 'equiv' Whether to check the Index class, dtype and inferred\_type are identical.

**check\_series\_type** [bool, default True] Whether to check the Series class is identical.

**check\_less\_precise** [bool or int, default False] Specify comparison precision. Only used when `check_exact` is False. 5 digits (False) or 3 digits (True) after decimal points are compared. If int, then specify the digits to compare.

When comparing two numbers, if the first number has magnitude less than  $1e-5$ , we compare the two numbers directly and check whether they are equivalent within the specified precision. Otherwise, we compare the **ratio** of the second number to the first number and check whether it is equivalent to 1 within the specified precision.

**check\_names** [bool, default True] Whether to check the Series and Index names attribute.

**check\_exact** [bool, default False] Whether to compare number exactly.

**check\_datetimelike\_compat** [bool, default False] Compare datetime-like which is comparable ignoring dtype.

**check\_categorical** [bool, default True] Whether to compare internal Categorical exactly.

**obj** [str, default 'Series'] Specify object name being compared, internally used to show appropriate assertion message.

### pandas.testing.assert\_index\_equal

`pandas.testing.assert_index_equal` (*left: pandas.core.indexes.base.Index*, *right: pandas.core.indexes.base.Index*, *exact: Union[bool, str] = 'equiv'*, *check\_names: bool = True*, *check\_less\_precise: Union[bool, int] = False*, *check\_exact: bool = True*, *check\_categorical: bool = True*, *obj: str = 'Index'*) → None

Check that left and right Index are equal.

#### Parameters

**left** [Index]

- right** [Index]
- exact** [bool or {'equiv'}, default 'equiv'] Whether to check the Index class, dtype and inferred\_type are identical. If 'equiv', then RangeIndex can be substituted for Int64Index as well.
- check\_names** [bool, default True] Whether to check the names attribute.
- check\_less\_precise** [bool or int, default False] Specify comparison precision. Only used when check\_exact is False. 5 digits (False) or 3 digits (True) after decimal points are compared. If int, then specify the digits to compare.
- check\_exact** [bool, default True] Whether to compare number exactly.
- check\_categorical** [bool, default True] Whether to compare internal Categorical exactly.
- obj** [str, default 'Index'] Specify object name being compared, internally used to show appropriate assertion message.

### pandas.testing.assert\_extension\_array\_equal

```
pandas.testing.assert_extension_array_equal(left, right, check_dtype=True,
                                           check_less_precise=False,
                                           check_exact=False)
```

Check that left and right ExtensionArrays are equal.

#### Parameters

- left, right** [ExtensionArray] The two arrays to compare
- check\_dtype** [bool, default True] Whether to check if the ExtensionArray dtypes are identical.
- check\_less\_precise** [bool or int, default False] Specify comparison precision. Only used when check\_exact is False. 5 digits (False) or 3 digits (True) after decimal points are compared. If int, then specify the digits to compare.
- check\_exact** [bool, default False] Whether to compare number exactly.

#### Notes

Missing values are checked separately from valid values. A mask of missing values is computed for each and checked to match. The remaining all-valid values are cast to object dtype and checked.

## 4.15.3 Exceptions and warnings

<code>errors.DtypeWarning</code>	Warning raised when reading different dtypes in a column from a file.
<code>errors.EmptyDataError</code>	Exception that is thrown in <code>pd.read_csv</code> (by both the C and Python engines) when empty data or header is encountered.
<code>errors.OutOfBoundsDatetime</code>	
<code>errors.ParserError</code>	Exception that is raised by an error encountered in parsing file contents.
<code>errors.ParserWarning</code>	Warning raised when reading a file that doesn't use the default 'c' parser.

Continued on next page

Table 419 – continued from previous page

<code>errors.PerformanceWarning</code>	Warning raised when there is a possible performance impact.
<code>errors.UnsortedIndexError</code>	Error raised when attempting to get a slice of a MultiIndex, and the index has not been lexsorted.
<code>errors.UnsupportedFunctionCall</code>	Exception raised when attempting to call a numpy function on a pandas object, but that function is not supported by the object e.g.

## pandas.errors.DtypeWarning

### exception `pandas.errors.DtypeWarning`

Warning raised when reading different dtypes in a column from a file.

Raised for a dtype incompatibility. This can happen whenever `read_csv` or `read_table` encounter non-uniform dtypes in a column(s) of a given CSV file.

#### See also:

**`read_csv`** Read CSV (comma-separated) file into a DataFrame.

**`read_table`** Read general delimited file into a DataFrame.

#### Notes

This warning is issued when dealing with larger files because the dtype checking happens per chunk read.

Despite the warning, the CSV file is read with mixed types in a single column which will be an object type. See the examples below to better understand this issue.

#### Examples

This example creates and reads a large CSV file with a column that contains *int* and *str*.

```
>>> df = pd.DataFrame({'a': (['1'] * 100000 + ['X'] * 100000 +
...                          ['1'] * 100000),
...                   'b': ['b'] * 300000})
>>> df.to_csv('test.csv', index=False)
>>> df2 = pd.read_csv('test.csv')
... # DtypeWarning: Columns (0) have mixed types
```

Important to notice that `df2` will contain both *str* and *int* for the same input, '1'.

```
>>> df2.iloc[262140, 0]
'1'
>>> type(df2.iloc[262140, 0])
<class 'str'>
>>> df2.iloc[262150, 0]
1
>>> type(df2.iloc[262150, 0])
<class 'int'>
```

One way to solve this issue is using the `dtype` parameter in the `read_csv` and `read_table` functions to explicit the conversion:

```
>>> df2 = pd.read_csv('test.csv', sep=',', dtype={'a': str})
```

No warning was issued.

```
>>> import os
>>> os.remove('test.csv')
```

### pandas.errors.EmptyDataError

#### exception pandas.errors.EmptyDataError

Exception that is thrown in `pd.read_csv` (by both the C and Python engines) when empty data or header is encountered.

### pandas.errors.OutOfBoundsDatetime

#### exception pandas.errors.OutOfBoundsDatetime

### pandas.errors.ParserError

#### exception pandas.errors.ParserError

Exception that is raised by an error encountered in parsing file contents.

This is a generic error raised for errors encountered when functions like `read_csv` or `read_html` are parsing contents of a file.

#### See also:

**read\_csv** Read CSV (comma-separated) file into a DataFrame.

**read\_html** Read HTML table into a DataFrame.

### pandas.errors.ParserWarning

#### exception pandas.errors.ParserWarning

Warning raised when reading a file that doesn't use the default 'c' parser.

Raised by `pd.read_csv` and `pd.read_table` when it is necessary to change parsers, generally from the default 'c' parser to 'python'.

It happens due to a lack of support or functionality for parsing a particular attribute of a CSV file with the requested engine.

Currently, 'c' unsupported options include the following parameters:

1. `sep` other than a single character (e.g. regex separators)
2. `skipfooter` higher than 0
3. `sep=None` with `delim_whitespace=False`

The warning can be avoided by adding `engine='python'` as a parameter in `pd.read_csv` and `pd.read_table` methods.

#### See also:

**pd.read\_csv** Read CSV (comma-separated) file into DataFrame.

**pd.read\_table** Read general delimited file into DataFrame.

## Examples

Using a *sep* in *pd.read\_csv* other than a single character:

```
>>> import io
>>> csv = '''a;b;c
...      1;1,8
...      1;2,1'''
>>> df = pd.read_csv(io.StringIO(csv), sep='[;,]')
... # ParserWarning: Falling back to the 'python' engine...
```

Adding *engine='python'* to *pd.read\_csv* removes the Warning:

```
>>> df = pd.read_csv(io.StringIO(csv), sep='[;,]', engine='python')
```

## pandas.errors.PerformanceWarning

**exception** pandas.errors.PerformanceWarning  
Warning raised when there is a possible performance impact.

## pandas.errors.UnsortedIndexError

**exception** pandas.errors.UnsortedIndexError  
Error raised when attempting to get a slice of a MultiIndex, and the index has not been lexsorted. Subclass of *KeyError*.

## pandas.errors.UnsupportedFunctionCall

**exception** pandas.errors.UnsupportedFunctionCall  
Exception raised when attempting to call a numpy function on a pandas object, but that function is not supported by the object e.g. `np.cumsum(groupby_object)`.

## 4.15.4 Data types related functionality

<code>api.types.union_categoricals(to_union, ...)</code>	Combine list-like of Categorical-like, unioning categories.
<code>api.types.infer_dtype()</code>	Efficiently infer the type of a passed val, or list-like array of values.
<code>api.types.pandas_dtype(dtype)</code>	Convert input into a pandas only dtype object or a numpy dtype object.

## pandas.api.types.union\_categoricals

`pandas.api.types.union_categoricals` (*to\_union, sort\_categories: bool = False, ignore\_order: bool = False*)

Combine list-like of Categorical-like, unioning categories.

All categories must have the same dtype.

### Parameters

**to\_union** [list-like] Categorical, CategoricalIndex, or Series with dtype='category'.

**sort\_categories** [bool, default False] If true, resulting categories will be lexsorted, otherwise they will be ordered as they appear in the data.

**ignore\_order** [bool, default False] If true, the ordered attribute of the Categoricals will be ignored. Results in an unordered categorical.

### Returns

**Categorical**

### Raises

#### TypeError

- all inputs do not have the same dtype
- all inputs do not have the same ordered property
- all inputs are ordered and their categories are not identical
- `sort_categories=True` and Categoricals are ordered

**ValueError** Empty list of categoricals passed

### Notes

To learn more about categories, see [link](#)

### Examples

```
>>> from pandas.api.types import union_categoricals
```

If you want to combine categoricals that do not necessarily have the same categories, `union_categoricals` will combine a list-like of categoricals. The new categories will be the union of the categories being combined.

```
>>> a = pd.Categorical(["b", "c"])
>>> b = pd.Categorical(["a", "b"])
>>> union_categoricals([a, b])
[b, c, a, b]
Categories (3, object): [b, c, a]
```

By default, the resulting categories will be ordered as they appear in the `categories` of the data. If you want the categories to be lexsorted, use `sort_categories=True` argument.

```
>>> union_categoricals([a, b], sort_categories=True)
[b, c, a, b]
Categories (3, object): [a, b, c]
```

`union_categoricals` also works with the case of combining two categoricals of the same categories and order information (e.g. what you could also *append* for).

```
>>> a = pd.Categorical(["a", "b"], ordered=True)
>>> b = pd.Categorical(["a", "b", "a"], ordered=True)
>>> union_categoricals([a, b])
[a, b, a, b, a]
Categories (2, object): [a < b]
```

Raises `TypeError` because the categories are ordered and not identical.

```
>>> a = pd.Categorical(["a", "b"], ordered=True)
>>> b = pd.Categorical(["a", "b", "c"], ordered=True)
>>> union_categoricals([a, b])
TypeError: to union ordered Categoricals, all categories must be the same
```

New in version 0.20.0

Ordered categoricals with different categories or orderings can be combined by using the `ignore_ordered=True` argument.

```
>>> a = pd.Categorical(["a", "b", "c"], ordered=True)
>>> b = pd.Categorical(["c", "b", "a"], ordered=True)
>>> union_categoricals([a, b], ignore_order=True)
[a, b, c, c, b, a]
Categories (3, object): [a, b, c]
```

`union_categoricals` also works with a `CategoricalIndex`, or `Series` containing categorical data, but note that the resulting array will always be a plain `Categorical`

```
>>> a = pd.Series(["b", "c"], dtype='category')
>>> b = pd.Series(["a", "b"], dtype='category')
>>> union_categoricals([a, b])
[b, c, a, b]
Categories (3, object): [b, c, a]
```

## pandas.api.types.infer\_dtype

`pandas.api.types.infer_dtype()`

Efficiently infer the type of a passed val, or list-like array of values. Return a string describing the type.

### Parameters

**value** [scalar, list, ndarray, or pandas type]

**skipna** [bool, default True] Ignore NaN values when inferring the type.

New in version 0.21.0.

### Returns

**str** Describing the common type of the input data.

### Results can include:

- **string**
- **bytes**
- **floating**

- **integer**
- **mixed-integer**
- **mixed-integer-float**
- **decimal**
- **complex**
- **categorical**
- **boolean**
- **datetime64**
- **datetime**
- **date**
- **timedelta64**
- **timedelta**
- **time**
- **period**
- **mixed**

#### Raises

**TypeError** If ndarray-like but cannot infer the dtype

#### Notes

- ‘mixed’ is the catchall for anything that is not otherwise specialized
- ‘mixed-integer-float’ are floats and integers
- ‘mixed-integer’ are integers mixed with non-integers

#### Examples

```
>>> infer_dtype(['foo', 'bar'])
'string'
```

```
>>> infer_dtype(['a', np.nan, 'b'], skipna=True)
'string'
```

```
>>> infer_dtype(['a', np.nan, 'b'], skipna=False)
'mixed'
```

```
>>> infer_dtype([b'foo', b'bar'])
'bytes'
```

```
>>> infer_dtype([1, 2, 3])
'integer'
```

```
>>> infer_dtype([1, 2, 3.5])
'mixed-integer-float'
```

```
>>> infer_dtype([1.0, 2.0, 3.5])
'floating'
```

```
>>> infer_dtype(['a', 1])
'mixed-integer'
```

```
>>> infer_dtype([Decimal(1), Decimal(2.0)])
'decimal'
```

```
>>> infer_dtype([True, False])
'boolean'
```

```
>>> infer_dtype([True, False, np.nan])
'mixed'
```

```
>>> infer_dtype([pd.Timestamp('20130101')])
'datetime'
```

```
>>> infer_dtype([datetime.date(2013, 1, 1)])
'date'
```

```
>>> infer_dtype([np.datetime64('2013-01-01')])
'datetime64'
```

```
>>> infer_dtype([datetime.timedelta(0, 1, 1)])
'timedelta'
```

```
>>> infer_dtype(pd.Series(list('aabc')).astype('category'))
'categorical'
```

## pandas.api.types.pandas\_dtype

pandas.api.types.pandas\_dtype(*dtype*)

Convert input into a pandas only dtype object or a numpy dtype object.

### Parameters

**dtype** [object to be converted]

### Returns

**np.dtype or a pandas dtype**

### Raises

**TypeError** if not a dtype

## Dtype introspection

<code>api.types.is_bool_dtype(arr_or_dtype)</code>	Check whether the provided array or dtype is of a boolean dtype.
<code>api.types.is_categorical_dtype(arr_or_dtype)</code>	Check whether an array-like or dtype is of the Categorical dtype.
<code>api.types.is_complex_dtype(arr_or_dtype)</code>	Check whether the provided array or dtype is of a complex dtype.
<code>api.types.is_datetime64_any_dtype(arr_or_dtype)</code>	Check whether the provided array or dtype is of the datetime64 dtype.
<code>api.types.is_datetime64_dtype(arr_or_dtype)</code>	Check whether an array-like or dtype is of the datetime64 dtype.
<code>api.types.is_datetime64_ns_dtype(arr_or_dtype)</code>	Check whether the provided array or dtype is of the datetime64[ns] dtype.
<code>api.types.is_datetime64tz_dtype(arr_or_dtype)</code>	Check whether an array-like or dtype is of a DatetimeTZ dtype.
<code>api.types.is_extension_type(arr)</code>	(DEPRECATED) Check whether an array-like is of a pandas extension class instance.
<code>api.types.is_extension_array_dtype(arr_or_dtype)</code>	Check if an object is a pandas extension array type.
<code>api.types.is_float_dtype(arr_or_dtype)</code>	Check whether the provided array or dtype is of a float dtype.
<code>api.types.is_int64_dtype(arr_or_dtype)</code>	Check whether the provided array or dtype is of the int64 dtype.
<code>api.types.is_integer_dtype(arr_or_dtype)</code>	Check whether the provided array or dtype is of an integer dtype.
<code>api.types.is_interval_dtype(arr_or_dtype)</code>	Check whether an array-like or dtype is of the Interval dtype.
<code>api.types.is_numeric_dtype(arr_or_dtype)</code>	Check whether the provided array or dtype is of a numeric dtype.
<code>api.types.is_object_dtype(arr_or_dtype)</code>	Check whether an array-like or dtype is of the object dtype.
<code>api.types.is_period_dtype(arr_or_dtype)</code>	Check whether an array-like or dtype is of the Period dtype.
<code>api.types.is_signed_integer_dtype(arr_or_dtype)</code>	Check whether the provided array or dtype is of a signed integer dtype.
<code>api.types.is_string_dtype(arr_or_dtype)</code>	Check whether the provided array or dtype is of the string dtype.
<code>api.types.is_timedelta64_dtype(arr_or_dtype)</code>	Check whether an array-like or dtype is of the timedelta64 dtype.
<code>api.types.is_timedelta64_ns_dtype(arr_or_dtype)</code>	Check whether the provided array or dtype is of the timedelta64[ns] dtype.
<code>api.types.is_unsigned_integer_dtype(arr_or_dtype)</code>	Check whether the provided array or dtype is of an unsigned integer dtype.
<code>api.types.is_sparse(arr)</code>	Check whether an array-like is a 1-D pandas sparse array.

### pandas.api.types.is\_bool\_dtype

pandas.api.types.is\_bool\_dtype(arr\_or\_dtype) → bool  
Check whether the provided array or dtype is of a boolean dtype.

#### Parameters

**arr\_or\_dtype** [array-like] The array or dtype to check.

#### Returns

**boolean** Whether or not the array or dtype is of a boolean dtype.

#### Notes

An ExtensionArray is considered boolean when the `_is_boolean` attribute is set to True.

#### Examples

```
>>> is_bool_dtype(str)
False
>>> is_bool_dtype(int)
False
>>> is_bool_dtype(bool)
True
>>> is_bool_dtype(np.bool)
True
>>> is_bool_dtype(np.array(['a', 'b']))
False
>>> is_bool_dtype(pd.Series([1, 2]))
False
>>> is_bool_dtype(np.array([True, False]))
True
>>> is_bool_dtype(pd.Categorical([True, False]))
True
>>> is_bool_dtype(pd.arrays.SparseArray([True, False]))
True
```

### pandas.api.types.is\_categorical\_dtype

pandas.api.types.is\_categorical\_dtype(arr\_or\_dtype) → bool  
Check whether an array-like or dtype is of the Categorical dtype.

#### Parameters

**arr\_or\_dtype** [array-like] The array-like or dtype to check.

#### Returns

**boolean** Whether or not the array-like or dtype is of the Categorical dtype.

## Examples

```

>>> is_categorical_dtype(object)
False
>>> is_categorical_dtype(CategoricalDtype())
True
>>> is_categorical_dtype([1, 2, 3])
False
>>> is_categorical_dtype(pd.Categorical([1, 2, 3]))
True
>>> is_categorical_dtype(pd.CategoricalIndex([1, 2, 3]))
True

```

## pandas.api.types.is\_complex\_dtype

`pandas.api.types.is_complex_dtype(arr_or_dtype) → bool`

Check whether the provided array or dtype is of a complex dtype.

### Parameters

**arr\_or\_dtype** [array-like] The array or dtype to check.

### Returns

**boolean** Whether or not the array or dtype is of a complex dtype.

## Examples

```

>>> is_complex_dtype(str)
False
>>> is_complex_dtype(int)
False
>>> is_complex_dtype(np.complex)
True
>>> is_complex_dtype(np.array(['a', 'b']))
False
>>> is_complex_dtype(pd.Series([1, 2]))
False
>>> is_complex_dtype(np.array([1 + 1j, 5]))
True

```

## pandas.api.types.is\_datetime64\_any\_dtype

`pandas.api.types.is_datetime64_any_dtype(arr_or_dtype) → bool`

Check whether the provided array or dtype is of the datetime64 dtype.

### Parameters

**arr\_or\_dtype** [array-like] The array or dtype to check.

### Returns

**boolean** Whether or not the array or dtype is of the datetime64 dtype.

## Examples

```
>>> is_datetime64_any_dtype(str)
False
>>> is_datetime64_any_dtype(int)
False
>>> is_datetime64_any_dtype(np.datetime64) # can be tz-naive
True
>>> is_datetime64_any_dtype(DatetimeTZDtype("ns", "US/Eastern"))
True
>>> is_datetime64_any_dtype(np.array(['a', 'b']))
False
>>> is_datetime64_any_dtype(np.array([1, 2]))
False
>>> is_datetime64_any_dtype(np.array([], dtype=np.datetime64))
True
>>> is_datetime64_any_dtype(pd.DatetimeIndex([1, 2, 3],
                                             dtype=np.datetime64))
True
```

## pandas.api.types.is\_datetime64\_dtype

pandas.api.types.is\_datetime64\_dtype(arr\_or\_dtype) → bool

Check whether an array-like or dtype is of the datetime64 dtype.

### Parameters

**arr\_or\_dtype** [array-like] The array-like or dtype to check.

### Returns

**boolean** Whether or not the array-like or dtype is of the datetime64 dtype.

## Examples

```
>>> is_datetime64_dtype(object)
False
>>> is_datetime64_dtype(np.datetime64)
True
>>> is_datetime64_dtype(np.array([], dtype=int))
False
>>> is_datetime64_dtype(np.array([], dtype=np.datetime64))
True
>>> is_datetime64_dtype([1, 2, 3])
False
```

### pandas.api.types.is\_datetime64\_ns\_dtype

pandas.api.types.is\_datetime64\_ns\_dtype(arr\_or\_dtype) → bool

Check whether the provided array or dtype is of the datetime64[ns] dtype.

#### Parameters

**arr\_or\_dtype** [array-like] The array or dtype to check.

#### Returns

**boolean** Whether or not the array or dtype is of the datetime64[ns] dtype.

#### Examples

```

>>> is_datetime64_ns_dtype(str)
False
>>> is_datetime64_ns_dtype(int)
False
>>> is_datetime64_ns_dtype(np.datetime64) # no unit
False
>>> is_datetime64_ns_dtype(DatetimeTZDtype("ns", "US/Eastern"))
True
>>> is_datetime64_ns_dtype(np.array(['a', 'b']))
False
>>> is_datetime64_ns_dtype(np.array([1, 2]))
False
>>> is_datetime64_ns_dtype(np.array([], dtype=np.datetime64)) # no unit
False
>>> is_datetime64_ns_dtype(np.array([],
                                dtype="datetime64[ps]")) # wrong unit
False
>>> is_datetime64_ns_dtype(pd.DatetimeIndex([1, 2, 3],
                                                dtype=np.datetime64)) # has 'ns' unit
True

```

### pandas.api.types.is\_datetime64tz\_dtype

pandas.api.types.is\_datetime64tz\_dtype(arr\_or\_dtype) → bool

Check whether an array-like or dtype is of a DatetimeTZDtype dtype.

#### Parameters

**arr\_or\_dtype** [array-like] The array-like or dtype to check.

#### Returns

**boolean** Whether or not the array-like or dtype is of a DatetimeTZDtype dtype.

## Examples

```
>>> is_datetime64tz_dtype(object)
False
>>> is_datetime64tz_dtype([1, 2, 3])
False
>>> is_datetime64tz_dtype(pd.DatetimeIndex([1, 2, 3])) # tz-naive
False
>>> is_datetime64tz_dtype(pd.DatetimeIndex([1, 2, 3], tz="US/Eastern"))
True
```

```
>>> dtype = DatetimeTZDtype("ns", tz="US/Eastern")
>>> s = pd.Series([], dtype=dtype)
>>> is_datetime64tz_dtype(dtype)
True
>>> is_datetime64tz_dtype(s)
True
```

## pandas.api.types.is\_extension\_type

`pandas.api.types.is_extension_type(arr) → bool`

Check whether an array-like is of a pandas extension class instance.

Deprecated since version 1.0.0: Use `is_extension_array_dtype` instead.

Extension classes include categoricals, pandas sparse objects (i.e. classes represented within the pandas library and not ones external to it like scipy sparse matrices), and datetime-like arrays.

### Parameters

**arr** [array-like] The array-like to check.

### Returns

**boolean** Whether or not the array-like is of a pandas extension class instance.

## Examples

```
>>> is_extension_type([1, 2, 3])
False
>>> is_extension_type(np.array([1, 2, 3]))
False
>>>
>>> cat = pd.Categorical([1, 2, 3])
>>>
>>> is_extension_type(cat)
True
>>> is_extension_type(pd.Series(cat))
True
>>> is_extension_type(pd.arrays.SparseArray([1, 2, 3]))
True
>>> from scipy.sparse import bsr_matrix
>>> is_extension_type(bsr_matrix([1, 2, 3]))
False
>>> is_extension_type(pd.DatetimeIndex([1, 2, 3]))
False
```

(continues on next page)

(continued from previous page)

```

>>> is_extension_type(pd.DatetimeIndex([1, 2, 3], tz="US/Eastern"))
True
>>>
>>> dtype = DatetimeTZDtype("ns", tz="US/Eastern")
>>> s = pd.Series([], dtype=dtype)
>>> is_extension_type(s)
True

```

## pandas.api.types.is\_extension\_array\_dtype

`pandas.api.types.is_extension_array_dtype(arr_or_dtype) → bool`

Check if an object is a pandas extension array type.

See the *Use Guide* for more.

### Parameters

**arr\_or\_dtype** [object] For array-like input, the `.dtype` attribute will be extracted.

### Returns

**bool** Whether the `arr_or_dtype` is an extension array type.

## Notes

This checks whether an object implements the pandas extension array interface. In pandas, this includes:

- Categorical
- Sparse
- Interval
- Period
- DatetimeArray
- TimedeltaArray

Third-party libraries may implement arrays or types satisfying this interface as well.

## Examples

```

>>> from pandas.api.types import is_extension_array_dtype
>>> arr = pd.Categorical(['a', 'b'])
>>> is_extension_array_dtype(arr)
True
>>> is_extension_array_dtype(arr.dtype)
True

```

```

>>> arr = np.array(['a', 'b'])
>>> is_extension_array_dtype(arr.dtype)
False

```

### pandas.api.types.is\_float\_dtype

`pandas.api.types.is_float_dtype(arr_or_dtype) → bool`  
Check whether the provided array or dtype is of a float dtype.

This function is internal and should not be exposed in the public API.

#### Parameters

**arr\_or\_dtype** [array-like] The array or dtype to check.

#### Returns

**boolean** Whether or not the array or dtype is of a float dtype.

### Examples

```
>>> is_float_dtype(str)
False
>>> is_float_dtype(int)
False
>>> is_float_dtype(float)
True
>>> is_float_dtype(np.array(['a', 'b']))
False
>>> is_float_dtype(pd.Series([1, 2]))
False
>>> is_float_dtype(pd.Index([1, 2.]))
True
```

### pandas.api.types.is\_int64\_dtype

`pandas.api.types.is_int64_dtype(arr_or_dtype) → bool`  
Check whether the provided array or dtype is of the int64 dtype.

#### Parameters

**arr\_or\_dtype** [array-like] The array or dtype to check.

#### Returns

**boolean** Whether or not the array or dtype is of the int64 dtype.

### Notes

Depending on system architecture, the return value of `is_int64_dtype(int)` will be True if the OS uses 64-bit integers and False if the OS uses 32-bit integers.

## Examples

```

>>> is_int64_dtype(str)
False
>>> is_int64_dtype(np.int32)
False
>>> is_int64_dtype(np.int64)
True
>>> is_int64_dtype('int8')
False
>>> is_int64_dtype('Int8')
False
>>> is_int64_dtype(pd.Int64Dtype)
True
>>> is_int64_dtype(float)
False
>>> is_int64_dtype(np.uint64) # unsigned
False
>>> is_int64_dtype(np.array(['a', 'b']))
False
>>> is_int64_dtype(np.array([1, 2], dtype=np.int64))
True
>>> is_int64_dtype(pd.Index([1, 2.])) # float
False
>>> is_int64_dtype(np.array([1, 2], dtype=np.uint32)) # unsigned
False

```

## pandas.api.types.is\_integer\_dtype

`pandas.api.types.is_integer_dtype(arr_or_dtype) → bool`

Check whether the provided array or dtype is of an integer dtype.

Unlike in `in_any_int_dtype`, `timedelta64` instances will return `False`.

Changed in version 0.24.0: The nullable Integer dtypes (e.g. `pandas.Int64Dtype`) are also considered as integer by this function.

### Parameters

**arr\_or\_dtype** [array-like] The array or dtype to check.

### Returns

**boolean** Whether or not the array or dtype is of an integer dtype and not an instance of `timedelta64`.

## Examples

```

>>> is_integer_dtype(str)
False
>>> is_integer_dtype(int)
True
>>> is_integer_dtype(float)
False
>>> is_integer_dtype(np.uint64)
True
>>> is_integer_dtype('int8')

```

(continues on next page)

(continued from previous page)

```
True
>>> is_integer_dtype('Int8')
True
>>> is_integer_dtype(pd.Int8Dtype)
True
>>> is_integer_dtype(np.datetime64)
False
>>> is_integer_dtype(np.timedelta64)
False
>>> is_integer_dtype(np.array(['a', 'b']))
False
>>> is_integer_dtype(pd.Series([1, 2]))
True
>>> is_integer_dtype(np.array([], dtype=np.timedelta64))
False
>>> is_integer_dtype(pd.Index([1, 2.])) # float
False
```

### pandas.api.types.is\_interval\_dtype

`pandas.api.types.is_interval_dtype(arr_or_dtype) → bool`  
Check whether an array-like or dtype is of the Interval dtype.

#### Parameters

**arr\_or\_dtype** [array-like] The array-like or dtype to check.

#### Returns

**boolean** Whether or not the array-like or dtype is of the Interval dtype.

### Examples

```
>>> is_interval_dtype(object)
False
>>> is_interval_dtype(IntervalDtype())
True
>>> is_interval_dtype([1, 2, 3])
False
>>>
>>> interval = pd.Interval(1, 2, closed="right")
>>> is_interval_dtype(interval)
False
>>> is_interval_dtype(pd.IntervalIndex([interval]))
True
```

### pandas.api.types.is\_numeric\_dtype

pandas.api.types.is\_numeric\_dtype(arr\_or\_dtype) → bool

Check whether the provided array or dtype is of a numeric dtype.

#### Parameters

**arr\_or\_dtype** [array-like] The array or dtype to check.

#### Returns

**boolean** Whether or not the array or dtype is of a numeric dtype.

#### Examples

```
>>> is_numeric_dtype(str)
False
>>> is_numeric_dtype(int)
True
>>> is_numeric_dtype(float)
True
>>> is_numeric_dtype(np.uint64)
True
>>> is_numeric_dtype(np.datetime64)
False
>>> is_numeric_dtype(np.timedelta64)
False
>>> is_numeric_dtype(np.array(['a', 'b']))
False
>>> is_numeric_dtype(pd.Series([1, 2]))
True
>>> is_numeric_dtype(pd.Index([1, 2.]))
True
>>> is_numeric_dtype(np.array([], dtype=np.timedelta64))
False
```

### pandas.api.types.is\_object\_dtype

pandas.api.types.is\_object\_dtype(arr\_or\_dtype) → bool

Check whether an array-like or dtype is of the object dtype.

#### Parameters

**arr\_or\_dtype** [array-like] The array-like or dtype to check.

#### Returns

**boolean** Whether or not the array-like or dtype is of the object dtype.

## Examples

```
>>> is_object_dtype(object)
True
>>> is_object_dtype(int)
False
>>> is_object_dtype(np.array([], dtype=object))
True
>>> is_object_dtype(np.array([], dtype=int))
False
>>> is_object_dtype([1, 2, 3])
False
```

## pandas.api.types.is\_period\_dtype

pandas.api.types.is\_period\_dtype(arr\_or\_dtype) → bool

Check whether an array-like or dtype is of the Period dtype.

### Parameters

**arr\_or\_dtype** [array-like] The array-like or dtype to check.

### Returns

**boolean** Whether or not the array-like or dtype is of the Period dtype.

## Examples

```
>>> is_period_dtype(object)
False
>>> is_period_dtype(PeriodDtype(freq="D"))
True
>>> is_period_dtype([1, 2, 3])
False
>>> is_period_dtype(pd.Period("2017-01-01"))
False
>>> is_period_dtype(pd.PeriodIndex([], freq="A"))
True
```

## pandas.api.types.is\_signed\_integer\_dtype

pandas.api.types.is\_signed\_integer\_dtype(arr\_or\_dtype) → bool

Check whether the provided array or dtype is of a signed integer dtype.

Unlike in *in\_any\_int\_dtype*, *timedelta64* instances will return False.

Changed in version 0.24.0: The nullable Integer dtypes (e.g. *pandas.Int64Dtype*) are also considered as integer by this function.

### Parameters

**arr\_or\_dtype** [array-like] The array or dtype to check.

### Returns

**boolean** Whether or not the array or dtype is of a signed integer dtype and not an instance of *timedelta64*.

## Examples

```

>>> is_signed_integer_dtype(str)
False
>>> is_signed_integer_dtype(int)
True
>>> is_signed_integer_dtype(float)
False
>>> is_signed_integer_dtype(np.uint64) # unsigned
False
>>> is_signed_integer_dtype('int8')
True
>>> is_signed_integer_dtype('Int8')
True
>>> is_signed_dtype(pd.Int8Dtype)
True
>>> is_signed_integer_dtype(np.datetime64)
False
>>> is_signed_integer_dtype(np.timedelta64)
False
>>> is_signed_integer_dtype(np.array(['a', 'b']))
False
>>> is_signed_integer_dtype(pd.Series([1, 2]))
True
>>> is_signed_integer_dtype(np.array([], dtype=np.timedelta64))
False
>>> is_signed_integer_dtype(pd.Index([1, 2.])) # float
False
>>> is_signed_integer_dtype(np.array([1, 2], dtype=np.uint32)) # unsigned
False

```

## pandas.api.types.is\_string\_dtype

pandas.api.types.is\_string\_dtype(arr\_or\_dtype) → bool

Check whether the provided array or dtype is of the string dtype.

### Parameters

**arr\_or\_dtype** [array-like] The array or dtype to check.

### Returns

**boolean** Whether or not the array or dtype is of the string dtype.

## Examples

```

>>> is_string_dtype(str)
True
>>> is_string_dtype(object)
True
>>> is_string_dtype(int)
False
>>>
>>> is_string_dtype(np.array(['a', 'b']))
True

```

(continues on next page)

(continued from previous page)

```
>>> is_string_dtype(pd.Series([1, 2]))
False
```

### pandas.api.types.is\_timedelta64\_dtype

pandas.api.types.is\_timedelta64\_dtype(arr\_or\_dtype) → bool

Check whether an array-like or dtype is of the timedelta64 dtype.

#### Parameters

**arr\_or\_dtype** [array-like] The array-like or dtype to check.

#### Returns

**boolean** Whether or not the array-like or dtype is of the timedelta64 dtype.

#### Examples

```
>>> is_timedelta64_dtype(object)
False
>>> is_timedelta64_dtype(np.timedelta64)
True
>>> is_timedelta64_dtype([1, 2, 3])
False
>>> is_timedelta64_dtype(pd.Series([], dtype="timedelta64[ns]"))
True
>>> is_timedelta64_dtype('0 days')
False
```

### pandas.api.types.is\_timedelta64\_ns\_dtype

pandas.api.types.is\_timedelta64\_ns\_dtype(arr\_or\_dtype) → bool

Check whether the provided array or dtype is of the timedelta64[ns] dtype.

This is a very specific dtype, so generic ones like *np.timedelta64* will return False if passed into this function.

#### Parameters

**arr\_or\_dtype** [array-like] The array or dtype to check.

#### Returns

**boolean** Whether or not the array or dtype is of the timedelta64[ns] dtype.

#### Examples

```
>>> is_timedelta64_ns_dtype(np.dtype('m8[ns]'))
True
>>> is_timedelta64_ns_dtype(np.dtype('m8[ps]')) # Wrong frequency
False
>>> is_timedelta64_ns_dtype(np.array([1, 2], dtype='m8[ns]'))
True
>>> is_timedelta64_ns_dtype(np.array([1, 2], dtype=np.timedelta64))
False
```

## pandas.api.types.is\_unsigned\_integer\_dtype

pandas.api.types.is\_unsigned\_integer\_dtype(arr\_or\_dtype) → bool

Check whether the provided array or dtype is of an unsigned integer dtype.

Changed in version 0.24.0: The nullable Integer dtypes (e.g. pandas.UInt64Dtype) are also considered as integer by this function.

### Parameters

**arr\_or\_dtype** [array-like] The array or dtype to check.

### Returns

**boolean** Whether or not the array or dtype is of an unsigned integer dtype.

## Examples

```

>>> is_unsigned_integer_dtype(str)
False
>>> is_unsigned_integer_dtype(int) # signed
False
>>> is_unsigned_integer_dtype(float)
False
>>> is_unsigned_integer_dtype(np.uint64)
True
>>> is_unsigned_integer_dtype('uint8')
True
>>> is_unsigned_integer_dtype('UInt8')
True
>>> is_unsigned_integer_dtype(pd.UInt8Dtype)
True
>>> is_unsigned_integer_dtype(np.array(['a', 'b']))
False
>>> is_unsigned_integer_dtype(pd.Series([1, 2])) # signed
False
>>> is_unsigned_integer_dtype(pd.Index([1, 2.])) # float
False
>>> is_unsigned_integer_dtype(np.array([1, 2], dtype=np.uint32))
True

```

## pandas.api.types.is\_sparse

pandas.api.types.is\_sparse(arr) → bool

Check whether an array-like is a 1-D pandas sparse array.

Check that the one-dimensional array-like is a pandas sparse array. Returns True if it is a pandas sparse array, not another type of sparse array.

### Parameters

**arr** [array-like] Array-like to check.

### Returns

**bool** Whether or not the array-like is a pandas sparse array.

## Examples

Returns *True* if the parameter is a 1-D pandas sparse array.

```
>>> is_sparse(pd.arrays.SparseArray([0, 0, 1, 0]))
True
>>> is_sparse(pd.Series(pd.arrays.SparseArray([0, 0, 1, 0])))
True
```

Returns *False* if the parameter is not sparse.

```
>>> is_sparse(np.array([0, 0, 1, 0]))
False
>>> is_sparse(pd.Series([0, 1, 0, 0]))
False
```

Returns *False* if the parameter is not a pandas sparse array.

```
>>> from scipy.sparse import bsr_matrix
>>> is_sparse(bsr_matrix([0, 1, 0, 0]))
False
```

Returns *False* if the parameter has more than one dimension.

## Iterable introspection

<code>api.types.is_dict_like(obj)</code>	Check if the object is dict-like.
<code>api.types.is_file_like(obj)</code>	Check if the object is a file-like object.
<code>api.types.is_list_like()</code>	Check if the object is list-like.
<code>api.types.is_named_tuple(obj)</code>	Check if the object is a named tuple.
<code>api.types.is_iterator(obj)</code>	Check if the object is an iterator.

## pandas.api.types.is\_dict\_like

`pandas.api.types.is_dict_like(obj) → bool`

Check if the object is dict-like.

### Parameters

**obj** [The object to check]

### Returns

**is\_dict\_like** [bool] Whether *obj* has dict-like properties.

## Examples

```

>>> is_dict_like({1: 2})
True
>>> is_dict_like([1, 2, 3])
False
>>> is_dict_like(dict)
False
>>> is_dict_like(dict())
True

```

## pandas.api.types.is\_file\_like

`pandas.api.types.is_file_like(obj) → bool`

Check if the object is a file-like object.

For objects to be considered file-like, they must be an iterator AND have either a *read* and/or *write* method as an attribute.

Note: file-like objects must be iterable, but iterable objects need not be file-like.

### Parameters

**obj** [The object to check]

### Returns

**is\_file\_like** [bool] Whether *obj* has file-like properties.

## Examples

```

>>> buffer(StringIO("data"))
>>> is_file_like(buffer)
True
>>> is_file_like([1, 2, 3])
False

```

## pandas.api.types.is\_list\_like

`pandas.api.types.is_list_like()`

Check if the object is list-like.

Objects that are considered list-like are for example Python lists, tuples, sets, NumPy arrays, and Pandas Series.

Strings and datetime objects, however, are not considered list-like.

### Parameters

**obj** [object] Object to check.

**allow\_sets** [bool, default True] If this parameter is False, sets will not be considered list-like.

New in version 0.24.0.

### Returns

**bool** Whether *obj* has list-like properties.

## Examples

```
>>> is_list_like([1, 2, 3])
True
>>> is_list_like({1, 2, 3})
True
>>> is_list_like(datetime(2017, 1, 1))
False
>>> is_list_like("foo")
False
>>> is_list_like(1)
False
>>> is_list_like(np.array([2]))
True
>>> is_list_like(np.array(2))
False
```

## pandas.api.types.is\_named\_tuple

pandas.api.types.is\_named\_tuple(*obj*) → bool

Check if the object is a named tuple.

### Parameters

**obj** [The object to check]

### Returns

**is\_named\_tuple** [bool] Whether *obj* is a named tuple.

## Examples

```
>>> Point = namedtuple("Point", ["x", "y"])
>>> p = Point(1, 2)
>>>
>>> is_named_tuple(p)
True
>>> is_named_tuple((1, 2))
False
```

## pandas.api.types.is\_iterator

pandas.api.types.is\_iterator(*obj*) → bool

Check if the object is an iterator.

For example, lists are considered iterators but not strings or datetime objects.

### Parameters

**obj** [The object to check]

### Returns

**is\_iter** [bool] Whether *obj* is an iterator.

## Examples

```

>>> is_iterator([1, 2, 3])
True
>>> is_iterator(datetime(2017, 1, 1))
False
>>> is_iterator("foo")
False
>>> is_iterator(1)
False

```

## Scalar introspection

`api.types.is_bool()`

**Returns**

---

`api.types.is_categorical(arr)`

Check whether an array-like is a Categorical instance.

---

`api.types.is_complex()`

**Returns**

---

`api.types.is_float()`

**Returns**

---

`api.types.is_hashable(obj)`

Return True if hash(obj) will succeed, False otherwise.

---

`api.types.is_integer()`

**Returns**

---

`api.types.is_interval()`

---

`api.types.is_number(obj)`

Check if the object is a number.

---

`api.types.is_re(obj)`

Check if the object is a regex pattern instance.

---

`api.types.is_re_compilable(obj)`

Check if the object can be compiled into a regex pattern instance.

---

`api.types.is_scalar()`

**Parameters**

## pandas.api.types.is\_bool

`pandas.api.types.is_bool()`

**Returns**

**bool**

### pandas.api.types.is\_categorical

pandas.api.types.is\_categorical(arr) → bool

Check whether an array-like is a Categorical instance.

#### Parameters

**arr** [array-like] The array-like to check.

#### Returns

**boolean** Whether or not the array-like is of a Categorical instance.

#### Examples

```
>>> is_categorical([1, 2, 3])
False
```

Categoricals, Series Categoricals, and CategoricalIndex will return True.

```
>>> cat = pd.Categorical([1, 2, 3])
>>> is_categorical(cat)
True
>>> is_categorical(pd.Series(cat))
True
>>> is_categorical(pd.CategoricalIndex([1, 2, 3]))
True
```

### pandas.api.types.is\_complex

pandas.api.types.is\_complex()

#### Returns

**bool**

### pandas.api.types.is\_float

pandas.api.types.is\_float()

#### Returns

**bool**

### pandas.api.types.is\_hashable

pandas.api.types.is\_hashable(obj) → bool

Return True if hash(obj) will succeed, False otherwise.

Some types will pass a test against collections.abc.Hashable but fail when they are actually hashed with hash().

Distinguish between these and other types by trying the call to hash() and seeing if they raise TypeError.

#### Returns

**bool**

## Examples

```
>>> a = ([,])
>>> isinstance(a, collections.abc.Hashable)
True
>>> is_hashable(a)
False
```

### pandas.api.types.is\_integer

```
pandas.api.types.is_integer()
```

#### Returns

**bool**

### pandas.api.types.is\_interval

```
pandas.api.types.is_interval()
```

### pandas.api.types.is\_number

```
pandas.api.types.is_number(obj) → bool
```

Check if the object is a number.

Returns True when the object is a number, and False if is not.

#### Parameters

**obj** [any type] The object to check if is a number.

#### Returns

**is\_number** [bool] Whether *obj* is a number or not.

**See also:**

**api.types.is\_integer** Checks a subgroup of numbers.

## Examples

```
>>> pd.api.types.is_number(1)
True
>>> pd.api.types.is_number(7.15)
True
```

Booleans are valid because they are int subclass.

```
>>> pd.api.types.is_number(False)
True
```

```
>>> pd.api.types.is_number("foo")
False
>>> pd.api.types.is_number("5")
False
```

### pandas.api.types.is\_re

pandas.api.types.is\_re(obj) → bool

Check if the object is a regex pattern instance.

#### Parameters

**obj** [The object to check]

#### Returns

**is\_regex** [bool] Whether *obj* is a regex pattern.

#### Examples

```
>>> is_re(re.compile("."))
True
>>> is_re("foo")
False
```

### pandas.api.types.is\_re\_compilable

pandas.api.types.is\_re\_compilable(obj) → bool

Check if the object can be compiled into a regex pattern instance.

#### Parameters

**obj** [The object to check]

#### Returns

**is\_regex\_compilable** [bool] Whether *obj* can be compiled as a regex pattern.

#### Examples

```
>>> is_re_compilable("."))
True
>>> is_re_compilable(1)
False
```

### pandas.api.types.is\_scalar

pandas.api.types.is\_scalar()

#### Parameters

**val** [object] This includes:

- numpy array scalar (e.g. np.int64)
- Python builtin numerics
- Python builtin byte arrays and strings
- None
- datetime.datetime
- datetime.timedelta

- Period
- decimal.Decimal
- Interval
- DateOffset
- Fraction
- Number.

### Returns

**bool** Return True if given object is scalar.

### Examples

```
>>> dt = datetime.datetime(2018, 10, 3)
>>> pd.api.types.is_scalar(dt)
True
```

```
>>> pd.api.types.is_scalar([2, 3])
False
```

```
>>> pd.api.types.is_scalar({0: 1, 2: 3})
False
```

```
>>> pd.api.types.is_scalar((0, 2))
False
```

pandas supports PEP 3141 numbers:

```
>>> from fractions import Fraction
>>> pd.api.types.is_scalar(Fraction(3, 5))
True
```

{{ header }}

## 4.16 Extensions

These are primarily intended for library authors looking to extend pandas objects.

<code>api.extensions.register_extension_dtype</code>	Register an ExtensionType with pandas as class decorator.
<code>api.extensions.register_dataframe_accessor</code>	Register a custom accessor on DataFrame objects.
<code>api.extensions.register_series_accessor</code>	Register a custom accessor on Series objects.
<code>api.extensions.register_index_accessor</code>	Register a custom accessor on Index objects.
<code>api.extensions.ExtensionDtype</code>	A custom data type, to be paired with an ExtensionArray.

### 4.16.1 pandas.api.extensions.register\_extension\_dtype

pandas.api.extensions.**register\_extension\_dtype** (*cls*: Type[pandas.core.dtypes.base.ExtensionDtype])  
→ Type[pandas.core.dtypes.base.ExtensionDtype]

Register an ExtensionType with pandas as class decorator.

New in version 0.24.0.

This enables operations like `.astype(name)` for the name of the ExtensionDtype.

#### Returns

**callable** A class decorator.

#### Examples

```
>>> from pandas.api.extensions import register_extension_dtype
>>> from pandas.api.extensions import ExtensionDtype
>>> @register_extension_dtype
... class MyExtensionDtype(ExtensionDtype):
...     pass
```

### 4.16.2 pandas.api.extensions.register\_dataframe\_accessor

pandas.api.extensions.**register\_dataframe\_accessor** (*name*)

Register a custom accessor on DataFrame objects.

#### Parameters

**name** [str] Name under which the accessor should be registered. A warning is issued if this name conflicts with a preexisting attribute.

#### Returns

**callable** A class decorator.

See also:

*register\_series\_accessor, register\_index\_accessor*

#### Notes

When accessed, your accessor will be initialized with the pandas object the user is interacting with. So the signature must be

```
def __init__(self, pandas_object): # noqa: E999
    ...
```

For consistency with pandas methods, you should raise an `AttributeError` if the data passed to your accessor has an incorrect dtype.

```
>>> pd.Series(['a', 'b']).dt
Traceback (most recent call last):
...
AttributeError: Can only use .dt accessor with datetimelike values
```

## Examples

In your library code:

```
import pandas as pd

@pd.api.extensions.register_dataframe_accessor("geo")
class GeoAccessor:
    def __init__(self, pandas_obj):
        self._obj = pandas_obj

    @property
    def center(self):
        # return the geographic center point of this DataFrame
        lat = self._obj.latitude
        lon = self._obj.longitude
        return (float(lon.mean()), float(lat.mean()))

    def plot(self):
        # plot this array's data on a map, e.g., using Cartopy
        pass
```

Back in an interactive IPython session:

```
>>> ds = pd.DataFrame({'longitude': np.linspace(0, 10),
...                    'latitude': np.linspace(0, 20)})
>>> ds.geo.center
(5.0, 10.0)
>>> ds.geo.plot()
# plots data on a map
```

### 4.16.3 pandas.api.extensions.register\_series\_accessor

pandas.api.extensions.**register\_series\_accessor**(*name*)

Register a custom accessor on Series objects.

#### Parameters

**name** [str] Name under which the accessor should be registered. A warning is issued if this name conflicts with a preexisting attribute.

#### Returns

**callable** A class decorator.

See also:

*register\_dataframe\_accessor*, *register\_index\_accessor*

## Notes

When accessed, your accessor will be initialized with the pandas object the user is interacting with. So the signature must be

```
def __init__(self, pandas_object): # noqa: E999
    ...
```

For consistency with pandas methods, you should raise an `AttributeError` if the data passed to your accessor has an incorrect dtype.

```
>>> pd.Series(['a', 'b']).dt
Traceback (most recent call last):
...
AttributeError: Can only use .dt accessor with datetimelike values
```

## Examples

In your library code:

```
import pandas as pd

@pd.api.extensions.register_dataframe_accessor("geo")
class GeoAccessor:
    def __init__(self, pandas_obj):
        self._obj = pandas_obj

    @property
    def center(self):
        # return the geographic center point of this DataFrame
        lat = self._obj.latitude
        lon = self._obj.longitude
        return (float(lon.mean()), float(lat.mean()))

    def plot(self):
        # plot this array's data on a map, e.g., using Cartopy
        pass
```

Back in an interactive IPython session:

```
>>> ds = pd.DataFrame({'longitude': np.linspace(0, 10),
...                    'latitude': np.linspace(0, 20)})
>>> ds.geo.center
(5.0, 10.0)
>>> ds.geo.plot()
# plots data on a map
```

#### 4.16.4 pandas.api.extensions.register\_index\_accessor

pandas.api.extensions.register\_index\_accessor(*name*)

Register a custom accessor on Index objects.

##### Parameters

**name** [str] Name under which the accessor should be registered. A warning is issued if this name conflicts with a preexisting attribute.

##### Returns

**callable** A class decorator.

See also:

*register\_dataframe\_accessor*, *register\_series\_accessor*

##### Notes

When accessed, your accessor will be initialized with the pandas object the user is interacting with. So the signature must be

```
def __init__(self, pandas_object): # noqa: E999
    ...
```

For consistency with pandas methods, you should raise an `AttributeError` if the data passed to your accessor has an incorrect dtype.

```
>>> pd.Series(['a', 'b']).dt
Traceback (most recent call last):
...
AttributeError: Can only use .dt accessor with datetimelike values
```

##### Examples

In your library code:

```
import pandas as pd

@pd.api.extensions.register_dataframe_accessor("geo")
class GeoAccessor:
    def __init__(self, pandas_obj):
        self._obj = pandas_obj

    @property
    def center(self):
        # return the geographic center point of this DataFrame
        lat = self._obj.latitude
        lon = self._obj.longitude
        return (float(lon.mean()), float(lat.mean()))

    def plot(self):
        # plot this array's data on a map, e.g., using Cartopy
        pass
```

Back in an interactive IPython session:

```

>>> ds = pd.DataFrame({'longitude': np.linspace(0, 10),
...                    'latitude': np.linspace(0, 20)})
>>> ds.geo.center
(5.0, 10.0)
>>> ds.geo.plot()
# plots data on a map

```

## 4.16.5 pandas.api.extensions.ExtensionDtype

**class** pandas.api.extensions.**ExtensionDtype**

A custom data type, to be paired with an ExtensionArray.

New in version 0.23.0.

**See also:**

**extensions.register\_extension\_dtype**

**extensions.ExtensionArray**

### Notes

The interface includes the following abstract methods that must be implemented by subclasses:

- type
- name
- construct\_from\_string

The following attributes influence the behavior of the dtype in pandas operations

- `_is_numeric`
- `_is_boolean`

Optionally one can override `construct_array_type` for construction with the name of this dtype via the Registry. See `extensions.register_extension_dtype()`.

- `construct_array_type`

The `na_value` class attribute can be used to set the default NA value for this type. `numpy.nan` is used by default.

ExtensionDtypes are required to be hashable. The base class provides a default implementation, which relies on the `_metadata` class attribute. `_metadata` should be a tuple containing the strings that define your data type. For example, with `PeriodDtype` that's the `freq` attribute.

**If you have a parametrized dtype you should set the ``\_metadata`` class property.**

Ideally, the attributes in `_metadata` will match the parameters to your `ExtensionDtype.__init__` (if any). If any of the attributes in `_metadata` don't implement the standard `__eq__` or `__hash__`, the default implementations here will not work.

Changed in version 0.24.0: Added `_metadata`, `__hash__`, and changed the default definition of `__eq__`.

For interaction with Apache Arrow (pyarrow), a `__from_arrow__` method can be implemented: this method receives a pyarrow Array or ChunkedArray as only argument and is expected to return the appropriate pandas ExtensionArray for this dtype and the passed values:

```

class ExtensionDtype:

    def __from_arrow__(
        self, array: pyarrow.Array/ChunkedArray
    ) -> ExtensionArray:
        ...

```

This class does not inherit from `'abc.ABCMeta'` for performance reasons. Methods and properties required by the interface raise `pandas.errors.AbstractMethodError` and no `register` method is provided for registering virtual subclasses.

### Attributes

<i>kind</i>	A character code (one of 'biufcmMOSUV'), default 'O'
<i>na_value</i>	Default NA value to use for this type.
<i>name</i>	A string identifying the data type.
<i>names</i>	Ordered list of field names, or None if there are no fields.
<i>type</i>	The scalar type for the array, e.g.

### `pandas.api.extensions.ExtensionDtype.kind`

**property** `ExtensionDtype.kind`

A character code (one of 'biufcmMOSUV'), default 'O'

This should match the NumPy dtype used when the array is converted to an ndarray, which is probably 'O' for object if the extension type cannot be represented as a built-in NumPy type.

**See also:**

`numpy.dtype.kind`

### `pandas.api.extensions.ExtensionDtype.na_value`

**property** `ExtensionDtype.na_value`

Default NA value to use for this type.

This is used in e.g. `ExtensionArray.take`. This should be the user-facing “boxed” version of the NA value, not the physical NA value for storage. e.g. for `JSONArray`, this is an empty dictionary.

### `pandas.api.extensions.ExtensionDtype.name`

**property** `ExtensionDtype.name`

A string identifying the data type.

Will be used for display in, e.g. `Series.dtype`

### `pandas.api.extensions.ExtensionDtype.names`

**property** `ExtensionDtype.names`

Ordered list of field names, or None if there are no fields.

This is for compatibility with NumPy arrays, and may be removed in the future.

## pandas.api.extensions.ExtensionDtype.type

**property** ExtensionDtype.type

The scalar type for the array, e.g. `int`

It's expected `ExtensionArray[item]` returns an instance of `ExtensionDtype.type` for scalar `item`, assuming that value is valid (not NA). NA values do not need to be instances of `type`.

## Methods

<code>construct_array_type()</code>	Return the array type associated with this dtype.
<code>construct_from_string(string)</code>	Construct this type from a string.
<code>is_dtype(dtype)</code>	Check if we match 'dtype'.

## pandas.api.extensions.ExtensionDtype.construct\_array\_type

**classmethod** ExtensionDtype.construct\_array\_type()

Return the array type associated with this dtype.

### Returns

`type`

## pandas.api.extensions.ExtensionDtype.construct\_from\_string

**classmethod** ExtensionDtype.construct\_from\_string(*string: str*)

Construct this type from a string.

This is useful mainly for data types that accept parameters. For example, a period dtype accepts a frequency parameter that can be set as `period[H]` (where H means hourly frequency).

By default, in the abstract class, just the name of the type is expected. But subclasses can overwrite this method to accept parameters.

### Parameters

**string** [str] The name of the type, for example `category`.

### Returns

**ExtensionDtype** Instance of the dtype.

### Raises

**TypeError** If a class cannot be constructed from this 'string'.

## Examples

For extension dtypes with arguments the following may be an adequate implementation.

```
>>> @classmethod
... def construct_from_string(cls, string):
...     pattern = re.compile(r"^my_type\[ (?P<arg_name>.+)\]$")
...     match = pattern.match(string)
...     if match:
...         return cls(**match.groupdict())
...     else:
...         raise TypeError(f"Cannot construct a '{cls.__name__}' from
...             " "{string}")
```

### pandas.api.extensions.ExtensionDtype.is\_dtype

**classmethod** `ExtensionDtype.is_dtype(dtype) → bool`  
 Check if we match 'dtype'.

#### Parameters

**dtype** [object] The object to check.

#### Returns

**is\_dtype** [bool]

## Notes

The default implementation is True if

1. `cls.construct_from_string(dtype)` is an instance of `cls`.
2. `dtype` is an object and is an instance of `cls`
3. `dtype` has a `dtype` attribute, and any of the above conditions is true for `dtype.dtype`.

*api.extensions.ExtensionArray*

Abstract base class for custom 1-D array types.

*arrays.PandasArray(values[, copy])*

A pandas ExtensionArray for NumPy data.

## 4.16.6 pandas.api.extensions.ExtensionArray

**class** `pandas.api.extensions.ExtensionArray`

Abstract base class for custom 1-D array types.

pandas will recognize instances of this class as proper arrays with a custom type and will not attempt to coerce them to objects. They may be stored directly inside a `DataFrame` or `Series`.

New in version 0.23.0.

## Notes

The interface includes the following abstract methods that must be implemented by subclasses:

- `_from_sequence`
- `_from_factorized`
- `__getitem__`
- `__len__`
- `dtype`
- `nbytes`
- `isna`
- `take`
- `copy`
- `_concat_same_type`

A default repr displaying the type, (truncated) data, length, and dtype is provided. It can be customized or replaced by by overriding:

- `__repr__`: A default repr for the ExtensionArray.
- `_formatter`: Print scalars inside a Series or DataFrame.

Some methods require casting the ExtensionArray to an ndarray of Python objects with `self.astype(object)`, which may be expensive. When performance is a concern, we highly recommend overriding the following methods:

- `fillna`
- `dropna`
- `unique`
- `factorize / _values_for_factorize`
- `argsort / _values_for_argsort`
- `searchsorted`

The remaining methods implemented on this class should be performant, as they only compose abstract methods. Still, a more efficient implementation may be available, and these methods can be overridden.

One can implement methods to handle array reductions.

- `_reduce`

One can implement methods to handle parsing from strings that will be used in methods such as `pandas.io.parsers.read_csv`.

- `_from_sequence_of_strings`

This class does not inherit from `'abc.ABCMeta'` for performance reasons. Methods and properties required by the interface raise `pandas.errors.AbstractMethodError` and no `register` method is provided for registering virtual subclasses.

ExtensionArrays are limited to 1 dimension.

They may be backed by none, one, or many NumPy arrays. For example, `pandas.Categorical` is an extension array backed by two arrays, one for codes and one for categories. An array of IPv6 address may be backed by a NumPy structured array with two fields, one for the lower 64 bits and one for the upper 64 bits. Or they may be backed by some other storage type, like Python lists. Pandas makes no assumptions on how the data are stored, just that it can be converted to a NumPy array. The ExtensionArray interface does not impose any rules on how this data is stored. However, currently, the backing data cannot be stored in attributes called `.values` or `._values` to ensure full compatibility with pandas internals. But other names as `.data`, `._data`, `._items`, ... can be freely used.

If implementing NumPy's `__array_ufunc__` interface, pandas expects that

1. You defer by returning `NotImplemented` when any Series are present in *inputs*. Pandas will extract the arrays and call the ufunc again.
2. You define a `_HANDLED_TYPES` tuple as an attribute on the class. Pandas inspect this to determine whether the ufunc is valid for the types present.

See *NumPy Universal Functions* for more.

## Attributes

<i>dtype</i>	An instance of 'ExtensionDtype'.
<i>nbytes</i>	The number of bytes needed to store this object in memory.
<i>ndim</i>	Extension Arrays are only allowed to be 1-dimensional.
<i>shape</i>	Return a tuple of the array dimensions.

### pandas.api.extensions.ExtensionArray.dtype

**property** `ExtensionArray.dtype`  
An instance of 'ExtensionDtype'.

### pandas.api.extensions.ExtensionArray.nbytes

**property** `ExtensionArray.nbytes`  
The number of bytes needed to store this object in memory.

### pandas.api.extensions.ExtensionArray.ndim

**property** `ExtensionArray.ndim`  
Extension Arrays are only allowed to be 1-dimensional.

### pandas.api.extensions.ExtensionArray.shape

**property** `ExtensionArray.shape`  
Return a tuple of the array dimensions.

## Methods

<i>argsort</i> (self, ascending, kind, \*args, ...)	Return the indices that would sort this array.
<i>astype</i> (self, dtype[, copy])	Cast to a NumPy array with 'dtype'.
<i>copy</i> (self)	Return a copy of the array.
<i>dropna</i> (self)	Return ExtensionArray without NA values.
<i>factorize</i> (self, na_sentinel)	Encode the extension array as an enumerated type.
<i>fillna</i> (self[, value, method, limit])	Fill NA/NaN values using the specified method.
<i>isna</i> (self)	A 1-D array indicating if each value is missing.
<i>ravel</i> (self[, order])	Return a flattened view on this array.
<i>repeat</i> (self, repeats[, axis])	Repeat elements of a ExtensionArray.
<i>searchsorted</i> (self, value[, side, sorter])	Find indices where elements should be inserted to maintain order.
<i>shift</i> (self, periods, fill_value)	Shift values by desired number.
<i>take</i> (self, indices, allow_fill, fill_value)	Take elements from an array.
<i>unique</i> (self)	Compute the ExtensionArray of unique values.
<i>view</i> (self[, dtype])	Return a view on the array.
<i>_concat_same_type</i> (to_concat)	Concatenate multiple array.

Continued on next page

Table 429 – continued from previous page

<code>_formatter(self, boxed)</code>	Formatting function for scalar values.
<code>_from_factorized(values, original)</code>	Reconstruct an ExtensionArray after factorization.
<code>_from_sequence(scalars[, dtype, copy])</code>	Construct a new ExtensionArray from a sequence of scalars.
<code>_from_sequence_of_strings(strings[, dtype, copy])</code>	Construct a new ExtensionArray from a sequence of strings.
<code>_ndarray_values</code>	Internal pandas method for lossy conversion to a NumPy ndarray.
<code>_reduce(self, name[, skipna])</code>	Return a scalar result of performing the reduction operation.
<code>_values_for_argsort(self)</code>	Return values for sorting.
<code>_values_for_factorize(self)</code>	Return an array and missing value suitable for factorization.

### pandas.api.extensions.ExtensionArray.argsort

`ExtensionArray.argsort` (*self*, *ascending*: bool = True, *kind*: str = 'quicksort', \*args, \*\*kwargs)  
→ numpy.ndarray

Return the indices that would sort this array.

#### Parameters

**ascending** [bool, default True] Whether the indices should result in an ascending or descending sort.

**kind** [{ 'quicksort', 'mergesort', 'heapsort' }, optional] Sorting algorithm.

**\*args, \*\*kwargs**: passed through to `numpy.argsort()`.

#### Returns

**ndarray** Array of indices that sort `self`. If NaN values are contained, NaN values are placed at the end.

#### See also:

`numpy.argsort` Sorting implementation used internally.

### pandas.api.extensions.ExtensionArray.astype

`ExtensionArray.astype` (*self*, *dtype*, *copy*=True)  
Cast to a NumPy array with 'dtype'.

#### Parameters

**dtype** [str or dtype] Typecode or data-type to which the array is cast.

**copy** [bool, default True] Whether to copy the data, even if not necessary. If False, a copy is made only if the old dtype does not match the new dtype.

#### Returns

**array** [ndarray] NumPy ndarray with 'dtype' for its dtype.

**pandas.api.extensions.ExtensionArray.copy**

`ExtensionArray.copy(self)` → `pandas.core.dtypes.generic.ABCExtensionArray`  
 Return a copy of the array.

**Returns**

`ExtensionArray`

**pandas.api.extensions.ExtensionArray.dropna**

`ExtensionArray.dropna(self)`  
 Return `ExtensionArray` without NA values.

**Returns**

`valid` [`ExtensionArray`]

**pandas.api.extensions.ExtensionArray.factorize**

`ExtensionArray.factorize(self, na_sentinel: int = -1)` → `Tuple[numpy.ndarray, pandas.core.dtypes.generic.ABCExtensionArray]`  
 Encode the extension array as an enumerated type.

**Parameters**

`na_sentinel` [int, default -1] Value to use in the `codes` array to indicate missing values.

**Returns**

`codes` [ndarray] An integer NumPy array that's an indexer into the original `ExtensionArray`.

`uniques` [`ExtensionArray`] An `ExtensionArray` containing the unique values of `self`.

---

**Note:** `uniques` will *not* contain an entry for the NA value of the `ExtensionArray` if there are any missing values present in `self`.

---

**See also:**

**`factorize`** Top-level factorize method that dispatches here.

**Notes**

`pandas.factorize()` offers a `sort` keyword as well.

### pandas.api.extensions.ExtensionArray.fillna

`ExtensionArray.fillna` (*self*, *value=None*, *method=None*, *limit=None*)

Fill NA/NaN values using the specified method.

#### Parameters

**value** [scalar, array-like] If a scalar value is passed it is used to fill all missing values. Alternatively, an array-like ‘value’ can be given. It’s expected that the array-like have the same length as ‘self’.

**method** [{‘backfill’, ‘bfill’, ‘pad’, ‘ffill’, None}, default None] Method to use for filling holes in reindexed Series pad / ffill: propagate last valid observation forward to next valid backfill / bfill: use NEXT valid observation to fill gap.

**limit** [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled.

#### Returns

**ExtensionArray** With NA/NaN filled.

### pandas.api.extensions.ExtensionArray.isna

`ExtensionArray.isna` (*self*) → ~ArrayLike

A 1-D array indicating if each value is missing.

#### Returns

**na\_values** [Union[np.ndarray, ExtensionArray]] In most cases, this should return a NumPy ndarray. For exceptional cases like `SparseArray`, where returning an ndarray would be expensive, an `ExtensionArray` may be returned.

#### Notes

If returning an `ExtensionArray`, then

- `na_values._is_boolean` should be True
- `na_values` should implement `ExtensionArray._reduce()`
- `na_values.any` and `na_values.all` should be implemented

### pandas.api.extensions.ExtensionArray.ravel

`ExtensionArray.ravel` (*self*, *order='C'*) → pandas.core.dtypes.generic.ABCExtensionArray

Return a flattened view on this array.

#### Parameters

**order** [{None, ‘C’, ‘F’, ‘A’, ‘K’}, default ‘C’]

#### Returns

**ExtensionArray**

## Notes

- Because ExtensionArrays are 1D-only, this is a no-op.
- The “order” argument is ignored, is for compatibility with NumPy.

## pandas.api.extensions.ExtensionArray.repeat

`ExtensionArray.repeat` (*self*, *repeats*, *axis=None*)

Repeat elements of a ExtensionArray.

Returns a new ExtensionArray where each element of the current ExtensionArray is repeated consecutively a given number of times.

### Parameters

**repeats** [int or array of ints] The number of repetitions for each element. This should be a non-negative integer. Repeating 0 times will return an empty ExtensionArray.

**axis** [None] Must be None. Has no effect but is accepted for compatibility with numpy.

### Returns

**repeated\_array** [ExtensionArray] Newly created ExtensionArray with repeated elements.

### See also:

**Series.repeat** Equivalent function for Series.

**Index.repeat** Equivalent function for Index.

**numpy.repeat** Similar method for `numpy.ndarray`.

**ExtensionArray.take** Take arbitrary positions.

## Examples

```
>>> cat = pd.Categorical(['a', 'b', 'c'])
>>> cat
[a, b, c]
Categories (3, object): [a, b, c]
>>> cat.repeat(2)
[a, a, b, b, c, c]
Categories (3, object): [a, b, c]
>>> cat.repeat([1, 2, 3])
[a, b, b, c, c, c]
Categories (3, object): [a, b, c]
```

### pandas.api.extensions.ExtensionArray.searchsorted

`ExtensionArray.searchsorted(self, value, side='left', sorter=None)`

Find indices where elements should be inserted to maintain order.

New in version 0.24.0.

Find the indices into a sorted array *self* (*a*) such that, if the corresponding elements in *value* were inserted before the indices, the order of *self* would be preserved.

Assuming that *self* is sorted:

<i>side</i>	returned index <i>i</i> satisfies
left	$self[i-1] < value \leq self[i]$
right	$self[i-1] \leq value < self[i]$

#### Parameters

**value** [array\_like] Values to insert into *self*.

**side** [{'left', 'right'}, optional] If 'left', the index of the first suitable location found is given. If 'right', return the last such index. If there is no suitable index, return either 0 or N (where N is the length of *self*).

**sorter** [1-D array\_like, optional] Optional array of integer indices that sort array *a* into ascending order. They are typically the result of `argsort`.

#### Returns

**array of ints** Array of insertion points with the same shape as *value*.

#### See also:

`numpy.searchsorted` Similar method from NumPy.

### pandas.api.extensions.ExtensionArray.shift

`ExtensionArray.shift(self, periods: int = 1, fill_value: object = None) → pandas.core.dtypes.generic.ABCExtensionArray`

Shift values by desired number.

Newly introduced missing values are filled with `self.dtype.na_value`.

New in version 0.24.0.

#### Parameters

**periods** [int, default 1] The number of periods to shift. Negative values are allowed for shifting backwards.

**fill\_value** [object, optional] The scalar value to use for newly introduced missing values. The default is `self.dtype.na_value`.

New in version 0.24.0.

#### Returns

**ExtensionArray** Shifted.

## Notes

If `self` is empty or `periods` is 0, a copy of `self` is returned.

If `periods > len(self)`, then an array of size `len(self)` is returned, with all values filled with `self.dtype.na_value`.

## `pandas.api.extensions.ExtensionArray.take`

`ExtensionArray.take(self, indices: Sequence[int], allow_fill: bool = False, fill_value: Any = None) → pandas.core.dtypes.generic.ABCExtensionArray`

Take elements from an array.

### Parameters

**indices** [sequence of int] Indices to be taken.

**allow\_fill** [bool, default False] How to handle negative values in *indices*.

- False: negative values in *indices* indicate positional indices from the right (the default). This is similar to `numpy.take()`.
- True: negative values in *indices* indicate missing values. These values are set to *fill\_value*. Any other other negative values raise a `ValueError`.

**fill\_value** [any, optional] Fill value to use for NA-indices when *allow\_fill* is True. This may be `None`, in which case the default NA value for the type, `self.dtype.na_value`, is used.

For many `ExtensionArrays`, there will be two representations of *fill\_value*: a user-facing “boxed” scalar, and a low-level physical NA value. *fill\_value* should be the user-facing version, and the implementation should handle translating that to the physical version for processing the `take` if necessary.

### Returns

`ExtensionArray`

### Raises

**IndexError** When the indices are out of bounds for the array.

**ValueError** When *indices* contains negative values other than `-1` and *allow\_fill* is True.

See also:

`numpy.take`

`api.extensions.take`

## Notes

`ExtensionArray.take` is called by `Series.__getitem__`, `.loc`, `iloc`, when *indices* is a sequence of values. Additionally, it's called by `Series.reindex()`, or any other method that causes realignment, with a *fill\_value*.

## Examples

Here's an example implementation, which relies on casting the extension array to object dtype. This uses the helper method `pandas.api.extensions.take()`.

```
def take(self, indices, allow_fill=False, fill_value=None):
    from pandas.core.algorithms import take

    # If the ExtensionArray is backed by an ndarray, then
    # just pass that here instead of coercing to object.
    data = self.astype(object)

    if allow_fill and fill_value is None:
        fill_value = self.dtype.na_value

    # fill value should always be translated from the scalar
    # type for the array, to the physical storage type for
    # the data, before passing to take.

    result = take(data, indices, fill_value=fill_value,
                  allow_fill=allow_fill)
    return self._from_sequence(result, dtype=self.dtype)
```

## `pandas.api.extensions.ExtensionArray.unique`

`ExtensionArray.unique` (*self*)  
Compute the `ExtensionArray` of unique values.

### Returns

**uniques** [`ExtensionArray`]

## `pandas.api.extensions.ExtensionArray.view`

`ExtensionArray.view` (*self*, *dtype=None*) → Union[`pandas.core.dtypes.generic.ABCExtensionArray`,  
`numpy.ndarray`]

Return a view on the array.

### Parameters

**dtype** [str, np.dtype, or `ExtensionDtype`, optional] Default None.

### Returns

**ExtensionArray** A view of the `ExtensionArray`.

**pandas.api.extensions.ExtensionArray.\_concat\_same\_type**

**classmethod** `ExtensionArray._concat_same_type` (*to\_concat*: Se-  
quence[pandas.core.dtypes.generic.ABCExtensionArray])  
 → pan-  
das.core.dtypes.generic.ABCExtensionArray

Concatenate multiple array.

**Parameters**

**to\_concat** [sequence of this type]

**Returns**

**ExtensionArray**

**pandas.api.extensions.ExtensionArray.\_formatter**

`ExtensionArray._formatter` (*self*, *boxed*: *bool* = *False*) → Callable[[Any], Union[str, None-  
 Type]]

Formatting function for scalar values.

This is used in the default ‘`__repr__`’. The returned formatting function receives instances of your scalar type.

**Parameters**

**boxed** [bool, default False] An indicated for whether or not your array is being printed within a Series, DataFrame, or Index (True), or just by itself (False). This may be useful if you want scalar values to appear differently within a Series versus on its own (e.g. quoted or not).

**Returns**

**Callable[[Any], str]** A callable that gets instances of the scalar type and returns a string. By default, `repr()` is used when `boxed=False` and `str()` is used when `boxed=True`.

**pandas.api.extensions.ExtensionArray.\_from\_factorized**

**classmethod** `ExtensionArray._from_factorized` (*values*, *original*)  
 Reconstruct an ExtensionArray after factorization.

**Parameters**

**values** [ndarray] An integer ndarray with the factorized values.

**original** [ExtensionArray] The original ExtensionArray that factorize was called on.

**See also:**

*factorize*

*ExtensionArray.factorize*

### `pandas.api.extensions.ExtensionArray._from_sequence`

**classmethod** `ExtensionArray._from_sequence` (*scalars, dtype=None, copy=False*)

Construct a new `ExtensionArray` from a sequence of scalars.

#### Parameters

**scalars** [Sequence] Each element will be an instance of the scalar type for this array, `cls.dtype.type`.

**dtype** [dtype, optional] Construct for this particular dtype. This should be a `Dtype` compatible with the `ExtensionArray`.

**copy** [bool, default False] If True, copy the underlying data.

#### Returns

`ExtensionArray`

### `pandas.api.extensions.ExtensionArray._from_sequence_of_strings`

**classmethod** `ExtensionArray._from_sequence_of_strings` (*strings, dtype=None, copy=False*)

Construct a new `ExtensionArray` from a sequence of strings.

New in version 0.24.0.

#### Parameters

**strings** [Sequence] Each element will be an instance of the scalar type for this array, `cls.dtype.type`.

**dtype** [dtype, optional] Construct for this particular dtype. This should be a `Dtype` compatible with the `ExtensionArray`.

**copy** [bool, default False] If True, copy the underlying data.

#### Returns

`ExtensionArray`

### `pandas.api.extensions.ExtensionArray._ndarray_values`

**property** `ExtensionArray._ndarray_values`

Internal pandas method for lossy conversion to a NumPy ndarray.

This method is not part of the pandas interface.

The expectation is that this is cheap to compute, and is primarily used for interacting with our indexers.

#### Returns

`array` [ndarray]

**pandas.api.extensions.ExtensionArray.\_reduce**

`ExtensionArray._reduce` (*self*, *name*, *skipna=True*, *\*\*kwargs*)

Return a scalar result of performing the reduction operation.

**Parameters**

**name** [str] Name of the function, supported values are: { any, all, min, max, sum, mean, median, prod, std, var, sem, kurt, skew }.

**skipna** [bool, default True] If True, skip NaN values.

**\*\*kwargs** Additional keyword arguments passed to the reduction function. Currently, *ddof* is the only supported kwarg.

**Returns**

scalar

**Raises**

**TypeError** [subclass does not define reductions]

**pandas.api.extensions.ExtensionArray.\_values\_for\_argsort**

`ExtensionArray._values_for_argsort` (*self*) → `numpy.ndarray`

Return values for sorting.

**Returns**

**ndarray** The transformed values should maintain the ordering between values within the array.

See also:

*ExtensionArray.argsort*

**pandas.api.extensions.ExtensionArray.\_values\_for\_factorize**

`ExtensionArray._values_for_factorize` (*self*) → `Tuple[numpy.ndarray, Any]`

Return an array and missing value suitable for factorization.

**Returns**

**values** [`ndarray`] An array suitable for factorization. This should maintain order and be a supported dtype (`Float64`, `Int64`, `UInt64`, `String`, `Object`). By default, the extension array is cast to object dtype.

**na\_value** [object] The value in *values* to consider missing. This will be treated as NA in the factorization routines, so it will be coded as *na\_sentinal* and not included in *uniques*. By default, `np.nan` is used.

## Notes

The values returned by this method are also used in `pandas.util.hash_pandas_object()`.

### 4.16.7 pandas.arrays.PandasArray

**class** `pandas.arrays.PandasArray` (*values*: Union[`numpy.ndarray`, `PandasArray`], *copy*: bool = `False`)

A pandas ExtensionArray for NumPy data.

New in version 0.24.0.

This is mostly for internal compatibility, and is not especially useful on its own.

#### Parameters

**values** [`ndarray`] The NumPy `ndarray` to wrap. Must be 1-dimensional.

**copy** [bool, default `False`] Whether to copy *values*.

#### Attributes

None	
------	--

#### Methods

None	
------	--

Additionally, we have some utility methods for ensuring your object behaves correctly.

`api.indexers.check_array_indexer(array, indexer)` Check if *indexer* is a valid array indexer for *array*.

---

### 4.16.8 pandas.api.indexers.check\_array\_indexer

`pandas.api.indexers.check_array_indexer` (*array*: ~AnyArrayLike, *indexer*: Any) → Any  
Check if *indexer* is a valid array indexer for *array*.

For a boolean mask, *array* and *indexer* are checked to have the same length. The dtype is validated, and if it is an integer or boolean ExtensionArray, it is checked if there are missing values present, and it is converted to the appropriate numpy array. Other dtypes will raise an error.

Non-array indexers (integer, slice, Ellipsis, tuples, ..) are passed through as is.

New in version 1.0.0.

#### Parameters

**array** [array-like] The array that is being indexed (only used for the length).

**indexer** [array-like or list-like] The array-like that's used to index. List-like input that is not yet a numpy array or an ExtensionArray is converted to one. Other input types are passed through as is

#### Returns

**numpy.ndarray** The validated indexer as a numpy array that can be used to index.

#### Raises

**IndexError** When the lengths don't match.

**ValueError** When *indexer* cannot be converted to a numpy ndarray to index (e.g. presence of missing values).

#### See also:

**api.types.is\_bool\_dtype** Check if *key* is of boolean dtype.

### Examples

When checking a boolean mask, a boolean ndarray is returned when the arguments are all valid.

```
>>> mask = pd.array([True, False])
>>> arr = pd.array([1, 2])
>>> pd.api.indexers.check_array_indexer(arr, mask)
array([ True, False])
```

An **IndexError** is raised when the lengths don't match.

```
>>> mask = pd.array([True, False, True])
>>> pd.api.indexers.check_array_indexer(arr, mask)
Traceback (most recent call last):
...
IndexError: Boolean index has wrong length: 3 instead of 2.
```

A **ValueError** is raised when the mask cannot be converted to a bool-dtype ndarray.

```
>>> mask = pd.array([True, pd.NA])
>>> pd.api.indexers.check_array_indexer(arr, mask)
Traceback (most recent call last):
...
ValueError: Cannot mask with a boolean indexer containing NA values
```

A numpy boolean mask will get passed through (if the length is correct):

```
>>> mask = np.array([True, False])
>>> pd.api.indexers.check_array_indexer(arr, mask)
array([ True, False])
```

Similarly for integer indexers, an integer ndarray is returned when it is a valid indexer, otherwise an error is (for integer indexers, a matching length is not required):

```
>>> indexer = pd.array([0, 2], dtype="Int64")
>>> arr = pd.array([1, 2, 3])
>>> pd.api.indexers.check_array_indexer(arr, indexer)
array([0, 2])
```

```
>>> indexer = pd.array([0, pd.NA], dtype="Int64")
>>> pd.api.indexers.check_array_indexer(arr, indexer)
Traceback (most recent call last):
...
ValueError: Cannot index with an integer indexer containing NA values
```

For non-integer/boolean dtypes, an appropriate error is raised:

```
>>> indexer = np.array([0., 2.], dtype="float64")
>>> pd.api.indexers.check_array_indexer(arr, indexer)
Traceback (most recent call last):
...
IndexError: arrays used as indices must be of integer or boolean type
```

The sentinel `pandas.api.extensions.no_default` is used as the default value in some methods. Use an `is` comparison to check if the user provides a non-default value.

```
{{ header }}
```

### 5.1.1 Where to start?

All contributions, bug reports, bug fixes, documentation improvements, enhancements, and ideas are welcome.

If you are brand new to pandas or open-source development, we recommend going through the [GitHub “issues” tab](#) to find issues that interest you. There are a number of issues listed under [Docs](#) and [good first issue](#) where you could start out. Once you’ve found an interesting issue, you can return here to get your development environment setup.

When you start working on an issue, it’s a good idea to assign the issue to yourself, so nobody else duplicates the work on it. GitHub restricts assigning issues to maintainers of the project only. In most projects, and until recently in pandas, contributors added a comment letting others know they are working on an issue. While this is ok, you need to check each issue individually, and it’s not possible to find the unassigned ones.

For this reason, we implemented a workaround consisting of adding a comment with the exact text *take*. When you do it, a GitHub action will automatically assign you the issue (this will take seconds, and may require refreshint the page

to see it). By doing this, it's possible to filter the list of issues and find only the unassigned ones.

So, a good way to find an issue to start contributing to pandas is to check the list of [unassigned good first issues](#) and assign yourself one you like by writing a comment with the exact text *take*.

If for whatever reason you are not able to continue working with the issue, please try to unassign it, so other people know it's available again. You can check the list of assigned issues, since people may not be working in them anymore. If you want to work on one that is assigned, feel free to kindly ask the current assignee if you can take it (please allow at least a week of inactivity before considering work in the issue discontinued).

Feel free to ask questions on the [mailing list](#) or on [Gitter](#).

## 5.1.2 Bug reports and enhancement requests

Bug reports are an important part of making *pandas* more stable. Having a complete bug report will allow others to reproduce the bug and provide insight into fixing. See [this stackoverflow article](#) and [this blogpost](#) for tips on writing a good bug report.

Trying the bug-producing code out on the *master* branch is often a worthwhile exercise to confirm the bug still exists. It is also worth searching existing bug reports and pull requests to see if the issue has already been reported and/or fixed.

Bug reports must:

1. Include a short, self-contained Python snippet reproducing the problem. You can format the code nicely by using [GitHub Flavored Markdown](#):

```
```python
>>> from pandas import DataFrame
>>> df = DataFrame(...)
...
```
```

2. Include the full version string of *pandas* and its dependencies. You can use the built-in function:

```
>>> import pandas as pd
>>> pd.show_versions()
```

3. Explain why the current behavior is wrong/not desired and what you expect instead.

The issue will then show up to the *pandas* community and be open to comments/ideas from others.

## 5.1.3 Working with the code

Now that you have an issue you want to fix, enhancement to add, or documentation to improve, you need to learn how to work with GitHub and the *pandas* code base.

### Version control, Git, and GitHub

To the new user, working with Git is one of the more daunting aspects of contributing to *pandas*. It can very quickly become overwhelming, but sticking to the guidelines below will help keep the process straightforward and mostly trouble free. As always, if you are having difficulties please feel free to ask for help.

The code is hosted on [GitHub](#). To contribute you will need to sign up for a [free GitHub account](#). We use [Git](#) for version control to allow many people to work together on the project.

Some great resources for learning Git:

- the [GitHub help pages](#).
- the [NumPy's documentation](#).
- Matthew Brett's [Pydagogue](#).

### Getting started with Git

[GitHub has instructions](#) for installing git, setting up your SSH key, and configuring git. All these steps need to be completed before you can work seamlessly between your local repository and GitHub.

### Forking

You will need your own fork to work on the code. Go to the [pandas project page](#) and hit the `Fork` button. You will want to clone your fork to your machine:

```
git clone https://github.com/your-user-name/pandas.git pandas-yourname
cd pandas-yourname
git remote add upstream https://github.com/pandas-dev/pandas.git
```

This creates the directory *pandas-yourname* and connects your repository to the upstream (main project) *pandas* repository.

### Creating a development environment

To test out code changes, you'll need to build pandas from source, which requires a C compiler and Python environment. If you're making documentation changes, you can skip to *Contributing to the documentation* but you won't be able to build the documentation locally before pushing your changes.

### Installing a C compiler

Pandas uses C extensions (mostly written using Cython) to speed up certain operations. To install pandas from source, you need to compile these C extensions, which means you need a C compiler. This process depends on which platform you're using.

#### Windows

You will need [Build Tools for Visual Studio 2017](#).

**Warning:** You DO NOT need to install Visual Studio 2019. You only need "Build Tools for Visual Studio 2019" found by scrolling down to "All downloads" -> "Tools for Visual Studio 2019".

## Mac OS

Information about compiler installation can be found here: <https://devguide.python.org/setup/#macos>

## Unix

Some Linux distributions will come with a pre-installed C compiler. To find out which compilers (and versions) are installed on your system:

```
# for Debian/Ubuntu:
dpkg --get-selections | grep compiler
# for Red Hat/RHEL/CentOS/Fedora:
yum list installed | grep -i --color compiler
```

**GCC (GNU Compiler Collection)**, is a widely used compiler, which supports C and a number of other languages. If GCC is listed as an installed compiler nothing more is required. If no C compiler is installed (or you wish to install a newer version) you can install a compiler (GCC in the example code below) with:

```
# for recent Debian/Ubuntu:
sudo apt install build-essential
# for Red Hat/RHEL/CentOS/Fedora
yum groupinstall "Development Tools"
```

For other Linux distributions, consult your favourite search engine for compiler installation instructions.

Let us know if you have any difficulties by opening an issue or reaching out on [Gitter](#).

## Creating a Python environment

Now that you have a C compiler, create an isolated pandas development environment:

- Install either [Anaconda](#) or [miniconda](#)
- Make sure your conda is up to date (`conda update conda`)
- Make sure that you have *cloned the repository*
- `cd` to the *pandas* source directory

We'll now kick off a three-step process:

1. Install the build dependencies
2. Build and install pandas
3. Install the optional dependencies

```
# Create and activate the build environment
conda env create -f environment.yml
conda activate pandas-dev

# or with older versions of Anaconda:
source activate pandas-dev

# Build and install pandas
python setup.py build_ext --inplace -j 4
python -m pip install -e . --no-build-isolation --no-use-pep517
```

At this point you should be able to import pandas from your locally built version:

```
$ python # start an interpreter
>>> import pandas
>>> print(pandas.__version__)
0.22.0.dev0+29.g4ad6d4d74
```

This will create the new environment, and not touch any of your existing environments, nor any existing Python installation.

To view your environments:

```
conda info -e
```

To return to your root environment:

```
conda deactivate
```

See the full conda docs [here](#).

### Creating a Python environment (pip)

If you aren't using conda for your development environment, follow these instructions. You'll need to have at least Python 3.6.1 installed on your system.

#### Unix/Mac OS

```
# Create a virtual environment
# Use an ENV_DIR of your choice. We'll use ~/virtualenvs/pandas-dev
# Any parent directories should already exist
python3 -m venv ~/virtualenvs/pandas-dev

# Activate the virtualenv
. ~/virtualenvs/pandas-dev/bin/activate

# Install the build dependencies
python -m pip install -r requirements-dev.txt

# Build and install pandas
python setup.py build_ext --inplace -j 0
python -m pip install -e . --no-build-isolation --no-use-pep517
```

#### Windows

Below is a brief overview on how to set-up a virtual environment with Powershell under Windows. For details please refer to the [official virtualenv user guide](#)

Use an ENV\_DIR of your choice. We'll use ~virtualenvspandas-dev where '~' is the folder pointed to by either \$env:USERPROFILE (Powershell) or %USERPROFILE% (cmd.exe) environment variable. Any parent directories should already exist.

```
# Create a virtual environment
python -m venv $env:USERPROFILE\virtualenvs\pandas-dev

# Activate the virtualenv. Use activate.bat for cmd.exe
~\virtualenvs\pandas-dev\Scripts\Activate.ps1

# Install the build dependencies
python -m pip install -r requirements-dev.txt
```

(continues on next page)

(continued from previous page)

```
# Build and install pandas
python setup.py build_ext --inplace -j 0
python -m pip install -e . --no-build-isolation --no-use-pep517
```

## Creating a branch

You want your master branch to reflect only production-ready code, so create a feature branch for making your changes. For example:

```
git branch shiny-new-feature
git checkout shiny-new-feature
```

The above can be simplified to:

```
git checkout -b shiny-new-feature
```

This changes your working directory to the shiny-new-feature branch. Keep any changes in this branch specific to one bug or feature so it is clear what the branch brings to *pandas*. You can have many shiny-new-features and switch in between them using the git checkout command.

When creating this branch, make sure your master branch is up to date with the latest upstream master version. To update your local master branch, you can do:

```
git checkout master
git pull upstream master --ff-only
```

When you want to update the feature branch with changes in master after you created the branch, check the section on *updating a PR*.

## 5.1.4 Contributing to the documentation

Contributing to the documentation benefits everyone who uses *pandas*. We encourage you to help us improve the documentation, and you don't have to be an expert on *pandas* to do so! In fact, there are sections of the docs that are worse off after being written by experts. If something in the docs doesn't make sense to you, updating the relevant section after you figure it out is a great way to ensure it will help the next person.

### Documentation:

- *About the pandas documentation*
- *Updating a pandas docstring*
- *How to build the pandas documentation*
  - *Requirements*
  - *Building the documentation*
  - *Building master branch documentation*

## About the *pandas* documentation

The documentation is written in **reStructuredText**, which is almost like writing in plain English, and built using [Sphinx](#). The Sphinx Documentation has an excellent [introduction to reST](#). Review the Sphinx docs to perform more complex changes to the documentation as well.

Some other important things to know about the docs:

- The *pandas* documentation consists of two parts: the docstrings in the code itself and the docs in this folder `doc/`.

The docstrings provide a clear explanation of the usage of the individual functions, while the documentation in this folder consists of tutorial-like overviews per topic together with some other information (what's new, installation, etc).

- The docstrings follow a pandas convention, based on the **Numpy Docstring Standard**. Follow the *pandas docstring guide* for detailed instructions on how to write a correct docstring. `{{ header }}`

## pandas docstring guide

### About docstrings and standards

A Python docstring is a string used to document a Python module, class, function or method, so programmers can understand what it does without having to read the details of the implementation.

Also, it is a common practice to generate online (html) documentation automatically from docstrings. [Sphinx](#) serves this purpose.

Next example gives an idea on how a docstring looks like:

```
def add(num1, num2):
    """
    Add up two integer numbers.

    This function simply wraps the `+` operator, and does not
    do anything interesting, except for illustrating what is
    the docstring of a very simple function.

    Parameters
    -----
    num1 : int
        First number to add
    num2 : int
        Second number to add

    Returns
    -----
    int
        The sum of `num1` and `num2`

    See Also
    -----
    subtract : Subtract one integer from another

    Examples
    -----
    >>> add(2, 2)
```

(continues on next page)

(continued from previous page)

```
4
>>> add(25, 0)
25
>>> add(10, -10)
0
"""
return num1 + num2
```

Some standards exist about docstrings, so they are easier to read, and they can be exported to other formats such as html or pdf.

The first conventions every Python docstring should follow are defined in [PEP-257](#).

As PEP-257 is quite open, and some other standards exist on top of it. In the case of pandas, the numpy docstring convention is followed. The conventions is explained in this document:

- [numpydoc docstring guide](#) (which is based in the original [Guide to NumPy/SciPy documentation](#))

numpydoc is a Sphinx extension to support the numpy docstring convention.

The standard uses reStructuredText (reST). reStructuredText is a markup language that allows encoding styles in plain text files. Documentation about reStructuredText can be found in:

- [Sphinx reStructuredText primer](#)
- [Quick reStructuredText reference](#)
- [Full reStructuredText specification](#)

Pandas has some helpers for sharing docstrings between related classes, see *Sharing docstrings*.

The rest of this document will summarize all the above guides, and will provide additional convention specific to the pandas project.

## Writing a docstring

### General rules

Docstrings must be defined with three double-quotes. No blank lines should be left before or after the docstring. The text starts in the next line after the opening quotes. The closing quotes have their own line (meaning that they are not at the end of the last sentence).

In rare occasions reST styles like bold text or italics will be used in docstrings, but is it common to have inline code, which is presented between backticks. It is considered inline code:

- The name of a parameter
- Python code, a module, function, built-in, type, literal... (e.g. `os`, `list`, `numpy.abs`, `datetime.date`, `True`)
- A pandas class (in the form `:class:`pandas.Series``)
- A pandas method (in the form `:meth:`pandas.Series.sum``)
- A pandas function (in the form `:func:`pandas.to_datetime``)

---

**Note:** To display only the last component of the linked class, method or function, prefix it with `~`. For example, `:class:`~pandas.Series`` will link to `pandas.Series` but only display the last part, `Series` as the

link text. See [Sphinx cross-referencing syntax](#) for details.

---

**Good:**

```
def add_values(arr):  
    """  
    Add the values in `arr`.  
  
    This is equivalent to Python `sum` of :meth:`pandas.Series.sum`.  
  
    Some sections are omitted here for simplicity.  
    """  
    return sum(arr)
```

**Bad:**

```
def func():  
  
    """Some function.  
  
    With several mistakes in the docstring.  
  
    It has a blank like after the signature `def func():`.  
  
    The text 'Some function' should go in the line after the  
    opening quotes of the docstring, not in the same line.  
  
    There is a blank line between the docstring and the first line  
    of code `foo = 1`.  
  
    The closing quotes should be in the next line, not in this one."""  
  
    foo = 1  
    bar = 2  
    return foo + bar
```

### Section 1: Short summary

The short summary is a single sentence that expresses what the function does in a concise way.

The short summary must start with a capital letter, end with a dot, and fit in a single line. It needs to express what the object does without providing details. For functions and methods, the short summary must start with an infinitive verb.

**Good:**

```
def astype(dtype):  
    """  
    Cast Series type.  
  
    This section will provide further details.  
    """  
    pass
```

**Bad:**

```
def astype(dtype):
    """
    Casts Series type.

    Verb in third-person of the present simple, should be infinitive.
    """
    pass
```

```
def astype(dtype):
    """
    Method to cast Series type.

    Does not start with verb.
    """
    pass
```

```
def astype(dtype):
    """
    Cast Series type

    Missing dot at the end.
    """
    pass
```

```
def astype(dtype):
    """
    Cast Series type from its current type to the new type defined in
    the parameter dtype.

    Summary is too verbose and doesn't fit in a single line.
    """
    pass
```

## Section 2: Extended summary

The extended summary provides details on what the function does. It should not go into the details of the parameters, or discuss implementation notes, which go in other sections.

A blank line is left between the short summary and the extended summary. And every paragraph in the extended summary is finished by a dot.

The extended summary should provide details on why the function is useful and their use cases, if it is not too generic.

```
def unstack():
    """
    Pivot a row index to columns.

    When using a MultiIndex, a level can be pivoted so each value in
    the index becomes a column. This is especially useful when a subindex
    is repeated for the main index, and data is easier to visualize as a
    pivot table.

    The index level will be automatically removed from the index when added
    as columns.
```

(continues on next page)

(continued from previous page)

```
"""
pass
```

### Section 3: Parameters

The details of the parameters will be added in this section. This section has the title “Parameters”, followed by a line with a hyphen under each letter of the word “Parameters”. A blank line is left before the section title, but not after, and not between the line with the word “Parameters” and the one with the hyphens.

After the title, each parameter in the signature must be documented, including *\*args* and *\*\*kwargs*, but not *self*.

The parameters are defined by their name, followed by a space, a colon, another space, and the type (or types). Note that the space between the name and the colon is important. Types are not defined for *\*args* and *\*\*kwargs*, but must be defined for all other parameters. After the parameter definition, it is required to have a line with the parameter description, which is indented, and can have multiple lines. The description must start with a capital letter, and finish with a dot.

For keyword arguments with a default value, the default will be listed after a comma at the end of the type. The exact form of the type in this case will be “int, default 0”. In some cases it may be useful to explain what the default argument means, which can be added after a comma “int, default -1, meaning all cpus”.

In cases where the default value is *None*, meaning that the value will not be used. Instead of “str, default None”, it is preferred to write “str, optional”. When *None* is a value being used, we will keep the form “str, default None”. For example, in `df.to_csv(compression=None)`, *None* is not a value being used, but means that compression is optional, and no compression is being used if not provided. In this case we will use *str, optional*. Only in cases like `func(value=None)` and *None* is being used in the same way as *0* or *foo* would be used, then we will specify “str, int or None, default None”.

#### Good:

```
class Series:
    def plot(self, kind, color='blue', **kwargs):
        """
        Generate a plot.

        Render the data in the Series as a matplotlib plot of the
        specified kind.

        Parameters
        -----
        kind : str
            Kind of matplotlib plot.
        color : str, default 'blue'
            Color name or rgb code.
        **kwargs
            These parameters will be passed to the matplotlib plotting
            function.
        """
        pass
```

#### Bad:

```
class Series:
    def plot(self, kind, **kwargs):
        """
```

(continues on next page)

(continued from previous page)

```
Generate a plot.
```

```
Render the data in the Series as a matplotlib plot of the
specified kind.
```

```
Note the blank line between the parameters title and the first
parameter. Also, note that after the name of the parameter `kind`
and before the colon, a space is missing.
```

```
Also, note that the parameter descriptions do not start with a
capital letter, and do not finish with a dot.
```

```
Finally, the `**kwargs` parameter is missing.
```

```
Parameters
```

```
-----
```

```
kind: str
      kind of matplotlib plot
"""
pass
```

## Parameter types

When specifying the parameter types, Python built-in data types can be used directly (the Python type is preferred to the more verbose string, integer, boolean, etc):

- int
- float
- str
- bool

For complex types, define the subtypes. For *dict* and *tuple*, as more than one type is present, we use the brackets to help read the type (curly brackets for *dict* and normal brackets for *tuple*):

- list of int
- dict of {str : int}
- tuple of (str, int, int)
- tuple of (str,)
- set of str

In case where there are just a set of values allowed, list them in curly brackets and separated by commas (followed by a space). If the values are ordinal and they have an order, list them in this order. Otherwise, list the default value first, if there is one:

- {0, 10, 25}
- {'simple', 'advanced'}
- {'low', 'medium', 'high'}
- {'cat', 'dog', 'bird'}

If the type is defined in a Python module, the module must be specified:

- datetime.date
- datetime.datetime
- decimal.Decimal

If the type is in a package, the module must be also specified:

- numpy.ndarray
- scipy.sparse.coo\_matrix

If the type is a pandas type, also specify pandas except for Series and DataFrame:

- Series
- DataFrame
- pandas.Index
- pandas.Categorical
- pandas.arrays.SparseArray

If the exact type is not relevant, but must be compatible with a numpy array, array-like can be specified. If Any type that can be iterated is accepted, iterable can be used:

- array-like
- iterable

If more than one type is accepted, separate them by commas, except the last two types, that need to be separated by the word 'or':

- int or float
- float, decimal.Decimal or None
- str or list of str

If None is one of the accepted values, it always needs to be the last in the list.

For axis, the convention is to use something like:

- axis : {0 or 'index', 1 or 'columns', None}, default None

## Section 4: Returns or Yields

If the method returns a value, it will be documented in this section. Also if the method yields its output.

The title of the section will be defined in the same way as the "Parameters". With the names "Returns" or "Yields" followed by a line with as many hyphens as the letters in the preceding word.

The documentation of the return is also similar to the parameters. But in this case, no name will be provided, unless the method returns or yields more than one value (a tuple of values).

The types for "Returns" and "Yields" are the same as the ones for the "Parameters". Also, the description must finish with a dot.

For example, with a single value:

```
def sample():
    """
    Generate and return a random number.
```

(continues on next page)

(continued from previous page)

```
The value is sampled from a continuous uniform distribution between
0 and 1.
```

```
Returns
```

```
-----
```

```
float
```

```
    Random number generated.
```

```
"""
```

```
return np.random.random()
```

With more than one value:

```
import string
```

```
def random_letters():
```

```
    """
```

```
    Generate and return a sequence of random letters.
```

```
    The length of the returned string is also random, and is also
    returned.
```

```
Returns
```

```
-----
```

```
length : int
```

```
    Length of the returned string.
```

```
letters : str
```

```
    String of random letters.
```

```
"""
```

```
length = np.random.randint(1, 10)
```

```
letters = ''.join(np.random.choice(string.ascii_lowercase)
```

```
                    for i in range(length))
```

```
return length, letters
```

If the method yields its value:

```
def sample_values():
```

```
    """
```

```
    Generate an infinite sequence of random numbers.
```

```
    The values are sampled from a continuous uniform distribution between
    0 and 1.
```

```
Yields
```

```
-----
```

```
float
```

```
    Random number generated.
```

```
"""
```

```
while True:
```

```
    yield np.random.random()
```

## Section 5: See Also

This section is used to let users know about pandas functionality related to the one being documented. In rare cases, if no related methods or functions can be found at all, this section can be skipped.

An obvious example would be the `head()` and `tail()` methods. As `tail()` does the equivalent as `head()` but at the end of the `Series` or `DataFrame` instead of at the beginning, it is good to let the users know about it.

To give an intuition on what can be considered related, here there are some examples:

- `loc` and `iloc`, as they do the same, but in one case providing indices and in the other positions
- `max` and `min`, as they do the opposite
- `iterrows`, `itertuples` and `items`, as it is easy that a user looking for the method to iterate over columns ends up in the method to iterate over rows, and vice-versa
- `fillna` and `dropna`, as both methods are used to handle missing values
- `read_csv` and `to_csv`, as they are complementary
- `merge` and `join`, as one is a generalization of the other
- `astype` and `pandas.to_datetime`, as users may be reading the documentation of `astype` to know how to cast as a date, and the way to do it is with `pandas.to_datetime`
- `where` is related to `numpy.where`, as its functionality is based on it

When deciding what is related, you should mainly use your common sense and think about what can be useful for the users reading the documentation, especially the less experienced ones.

When relating to other libraries (mainly `numpy`), use the name of the module first (not an alias like `np`). If the function is in a module which is not the main one, like `scipy.sparse`, list the full module (e.g. `scipy.sparse.coo_matrix`).

This section, as the previous, also has a header, “See Also” (note the capital S and A). Also followed by the line with hyphens, and preceded by a blank line.

After the header, we will add a line for each related method or function, followed by a space, a colon, another space, and a short description that illustrated what this method or function does, why is it relevant in this context, and what are the key differences between the documented function and the one referencing. The description must also finish with a dot.

Note that in “Returns” and “Yields”, the description is located in the following line than the type. But in this section it is located in the same line, with a colon in between. If the description does not fit in the same line, it can continue in the next ones, but it has to be indented in them.

For example:

```
class Series:
    def head(self):
        """
        Return the first 5 elements of the Series.

        This function is mainly useful to preview the values of the
        Series without displaying the whole of it.

        Returns
        -----
        Series
            Subset of the original series with the 5 first values.
```

(continues on next page)

(continued from previous page)

```

See Also
-----
Series.tail : Return the last 5 elements of the Series.
Series.iloc : Return a slice of the elements in the Series,
              which can also be used to return the first or last n.
"""
return self.iloc[:5]

```

## Section 6: Notes

This is an optional section used for notes about the implementation of the algorithm. Or to document technical aspects of the function behavior.

Feel free to skip it, unless you are familiar with the implementation of the algorithm, or you discover some counter-intuitive behavior while writing the examples for the function.

This section follows the same format as the extended summary section.

## Section 7: Examples

This is one of the most important sections of a docstring, even if it is placed in the last position. As often, people understand concepts better with examples, than with accurate explanations.

Examples in docstrings, besides illustrating the usage of the function or method, must be valid Python code, that in a deterministic way returns the presented output, and that can be copied and run by users.

They are presented as a session in the Python terminal. `>>>` is used to present code. `...` is used for code continuing from the previous line. Output is presented immediately after the last line of code generating the output (no blank lines in between). Comments describing the examples can be added with blank lines before and after them.

The way to present examples is as follows:

1. Import required libraries (except `numpy` and `pandas`)
2. Create the data required for the example
3. Show a very basic example that gives an idea of the most common use case
4. Add examples with explanations that illustrate how the parameters can be used for extended functionality

A simple example could be:

```

class Series:

    def head(self, n=5):
        """
        Return the first elements of the Series.

        This function is mainly useful to preview the values of the
        Series without displaying the whole of it.

        Parameters
        -----
        n : int
            Number of values to return.

```

(continues on next page)

(continued from previous page)

```

Return
-----
pandas.Series
    Subset of the original series with the n first values.

See Also
-----
tail : Return the last n elements of the Series.

Examples
-----
>>> s = pd.Series(['Ant', 'Bear', 'Cow', 'Dog', 'Falcon',
...               'Lion', 'Monkey', 'Rabbit', 'Zebra'])
>>> s.head()
0    Ant
1    Bear
2    Cow
3    Dog
4    Falcon
dtype: object

With the `n` parameter, we can change the number of returned rows:

>>> s.head(n=3)
0    Ant
1    Bear
2    Cow
dtype: object
"""
return self.iloc[:n]

```

The examples should be as concise as possible. In cases where the complexity of the function requires long examples, is recommended to use blocks with headers in bold. Use double star `**` to make a text bold, like in `**this example**`.

### Conventions for the examples

Code in examples is assumed to always start with these two lines which are not shown:

```

import numpy as np
import pandas as pd

```

Any other module used in the examples must be explicitly imported, one per line (as recommended in **PEP 8#imports**) and avoiding aliases. Avoid excessive imports, but if needed, imports from the standard library go first, followed by third-party libraries (like matplotlib).

When illustrating examples with a single `Series` use the name `s`, and if illustrating with a single `DataFrame` use the name `df`. For indices, `idx` is the preferred name. If a set of homogeneous `Series` or `DataFrame` is used, name them `s1`, `s2`, `s3...` or `df1`, `df2`, `df3...`. If the data is not homogeneous, and more than one structure is needed, name them with something meaningful, for example `df_main` and `df_to_join`.

Data used in the example should be as compact as possible. The number of rows is recommended to be around 4, but make it a number that makes sense for the specific example. For example in the `head` method, it requires to be higher than 5, to show the example with the default values. If doing the mean, we could use something like `[1, 2, 3]`, so it is easy to see that the value returned is the mean.

For more complex examples (grouping for example), avoid using data without interpretation, like a matrix of random numbers with columns A, B, C, D... And instead use a meaningful example, which makes it easier to understand the concept. Unless required by the example, use names of animals, to keep examples consistent. And numerical properties of them.

When calling the method, keywords arguments `head(n=3)` are preferred to positional arguments `head(3)`.

**Good:**

```
class Series:

    def mean(self):
        """
        Compute the mean of the input.

        Examples
        -----
        >>> s = pd.Series([1, 2, 3])
        >>> s.mean()
        2
        """
        pass

    def fillna(self, value):
        """
        Replace missing values by `value`.

        Examples
        -----
        >>> s = pd.Series([1, np.nan, 3])
        >>> s.fillna(0)
        [1, 0, 3]
        """
        pass

    def groupby_mean(self):
        """
        Group by index and return mean.

        Examples
        -----
        >>> s = pd.Series([380., 370., 24., 26],
        ...                 name='max_speed',
        ...                 index=['falcon', 'falcon', 'parrot', 'parrot'])
        >>> s.groupby_mean()
        index
        falcon    375.0
        parrot    25.0
        Name: max_speed, dtype: float64
        """
        pass

    def contains(self, pattern, case_sensitive=True, na=numpy.nan):
        """
        Return whether each value contains `pattern`.

        In this case, we are illustrating how to use sections, even
```

(continues on next page)

(continued from previous page)

```

if the example is simple enough and does not require them.

Examples
-----
>>> s = pd.Series('Antelope', 'Lion', 'Zebra', np.nan)
>>> s.contains(pattern='a')
0    False
1    False
2     True
3     NaN
dtype: bool

**Case sensitivity**

With `case_sensitive` set to `False` we can match `a` with both
`a` and `A`:

>>> s.contains(pattern='a', case_sensitive=False)
0     True
1    False
2     True
3     NaN
dtype: bool

**Missing values**

We can fill missing values in the output using the `na` parameter:

>>> s.contains(pattern='a', na=False)
0    False
1    False
2     True
3    False
dtype: bool
"""
pass

```

**Bad:**

```

def method(foo=None, bar=None):
    """
    A sample DataFrame method.

    Do not import numpy and pandas.

    Try to use meaningful data, when it makes the example easier
    to understand.

    Try to avoid positional arguments like in `df.method(1)`. They
    can be all right if previously defined with a meaningful name,
    like in `present_value(interest_rate)`, but avoid them otherwise.

    When presenting the behavior with different parameters, do not place
    all the calls one next to the other. Instead, add a short sentence
    explaining what the example shows.

    Examples

```

(continues on next page)

(continued from previous page)

```

-----
>>> import numpy as np
>>> import pandas as pd
>>> df = pd.DataFrame(np.random.randn(3, 3),
...                   columns=('a', 'b', 'c'))
>>> df.method(1)
21
>>> df.method(bar=14)
123
"""
pass

```

## Tips for getting your examples pass the doctests

Getting the examples pass the doctests in the validation script can sometimes be tricky. Here are some attention points:

- Import all needed libraries (except for pandas and numpy, those are already imported as `import pandas as pd` and `import numpy as np`) and define all variables you use in the example.
- Try to avoid using random data. However random data might be OK in some cases, like if the function you are documenting deals with probability distributions, or if the amount of data needed to make the function result meaningful is too much, such that creating it manually is very cumbersome. In those cases, always use a fixed random seed to make the generated examples predictable. Example:

```

>>> np.random.seed(42)
>>> df = pd.DataFrame({'normal': np.random.normal(100, 5, 20)})

```

- If you have a code snippet that wraps multiple lines, you need to use `'...'` on the continued lines:

```

>>> df = pd.DataFrame([[1, 2, 3], [4, 5, 6]], index=['a', 'b', 'c'],
...                   columns=['A', 'B'])

```

- If you want to show a case where an exception is raised, you can do:

```

>>> pd.to_datetime(["712-01-01"])
Traceback (most recent call last):
OutOfBoundsDatetime: Out of bounds nanosecond timestamp: 712-01-01 00:00:00

```

It is essential to include the “Traceback (most recent call last):”, but for the actual error only the error name is sufficient.

- If there is a small part of the result that can vary (e.g. a hash in an object representation), you can use `...` to represent this part.

If you want to show that `s.plot()` returns a matplotlib `AxesSubplot` object, this will fail the doctest

```

>>> s.plot()
<matplotlib.axes._subplots.AxesSubplot at 0x7efd0c0b0690>

```

However, you can do (notice the comment that needs to be added)

```

>>> s.plot()
<matplotlib.axes._subplots.AxesSubplot at ...>

```

## Plots in examples

There are some methods in pandas returning plots. To render the plots generated by the examples in the documentation, the `.. plot::` directive exists.

To use it, place the next code after the “Examples” header as shown below. The plot will be generated automatically when building the documentation.

```
class Series:
    def plot(self):
        """
        Generate a plot with the `Series` data.

        Examples
        -----

        .. plot::
           :context: close-figs

           >>> s = pd.Series([1, 2, 3])
           >>> s.plot()
        """
    pass
```

## Sharing docstrings

Pandas has a system for sharing docstrings, with slight variations, between classes. This helps us keep docstrings consistent, while keeping things clear for the user reading. It comes at the cost of some complexity when writing.

Each shared docstring will have a base template with variables, like `%(klass)s`. The variables filled in later on using the `Substitution` decorator. Finally, docstrings can be appended to with the `Appender` decorator.

In this example, we’ll create a parent docstring normally (this is like `pandas.core.generic.NDFrame`). Then we’ll have two children (like `pandas.core.series.Series` and `pandas.core.frame.DataFrame`). We’ll substitute the children’s class names in this docstring.

```
class Parent:
    def my_function(self):
        """Apply my function to %(klass)s."""
        ...

class ChildA(Parent):
    @Substitution(klass="ChildA")
    @Appender(Parent.my_function.__doc__)
    def my_function(self):
        ...

class ChildB(Parent):
    @Substitution(klass="ChildB")
    @Appender(Parent.my_function.__doc__)
    def my_function(self):
        ...
```

The resulting docstrings are

```
>>> print(Parent.my_function.__doc__)
Apply my function to %(klass)s.
>>> print(ChildA.my_function.__doc__)
Apply my function to ChildA.
>>> print(ChildB.my_function.__doc__)
Apply my function to ChildB.
```

Notice two things:

1. We “append” the parent docstring to the children docstrings, which are initially empty.
2. Python decorators are applied inside out. So the order is Append then Substitution, even though Substitution comes first in the file.

Our files will often contain a module-level `_shared_doc_kwargs` with some common substitution values (things like `klass`, `axes`, etc).

You can substitute and append in one shot with something like

```
@Appender(template % _shared_doc_kwargs)
def my_function(self):
    ...
```

where `template` may come from a module-level `_shared_docs` dictionary mapping function names to docstrings. Wherever possible, we prefer using `Appender` and `Substitution`, since the docstring-writing processes is slightly closer to normal.

See `pandas.core.generic.NDFrame.fillna` for an example `template`, and `pandas.core.series.Series.fillna` and `pandas.core.generic.frame.fillna` for the filled versions.

- The tutorials make heavy use of the `ipython directive` sphinx extension. This directive lets you put code in the documentation which will be run during the doc build. For example:

```
.. ipython:: python

    x = 2
    x**3
```

will be rendered as:

```
In [1]: x = 2

In [2]: x**3
Out[2]: 8
```

Almost all code examples in the docs are run (and the output saved) during the doc build. This approach means that code examples will always be up to date, but it does make the doc building a bit more complex.

- Our API documentation in `doc/source/api.rst` houses the auto-generated documentation from the docstrings. For classes, there are a few subtleties around controlling which methods and attributes have pages auto-generated.

We have two autosummary templates for classes.

1. `_templates/autosummary/class.rst`. Use this when you want to automatically generate a page for every public method and attribute on the class. The `Attributes` and `Methods` sections will be automatically added to the class’ rendered documentation by `numpydoc`. See `DataFrame` for an example.

2. `_templates/autosummary/class_without_autosummary`. Use this when you want to pick a subset of methods / attributes to auto-generate pages for. When using this template, you should include an `Attributes` and `Methods` section in the class docstring. See `CategoricalIndex` for an example.

Every method should be included in a `toctree` in `api.rst`, else Sphinx will emit a warning.

---

**Note:** The `.rst` files are used to automatically generate Markdown and HTML versions of the docs. For this reason, please do not edit `CONTRIBUTING.md` directly, but instead make any changes to `doc/source/development/contributing.rst`. Then, to generate `CONTRIBUTING.md`, use `pandoc` with the following command:

```
pandoc doc/source/development/contributing.rst -t markdown_github > CONTRIBUTING.md
```

---

The utility script `scripts/validate_docstrings.py` can be used to get a csv summary of the API documentation. And also validate common errors in the docstring of a specific class, function or method. The summary also compares the list of methods documented in `doc/source/api.rst` (which is used to generate the [API Reference page](#)) and the actual public methods. This will identify methods documented in `doc/source/api.rst` that are not actually class methods, and existing methods that are not documented in `doc/source/api.rst`.

### Updating a *pandas* docstring

When improving a single function or method's docstring, it is not necessarily needed to build the full documentation (see next section). However, there is a script that checks a docstring (for example for the `DataFrame.mean` method):

```
python scripts/validate_docstrings.py pandas.DataFrame.mean
```

This script will indicate some formatting errors if present, and will also run and test the examples included in the docstring. Check the *pandas docstring guide* for a detailed guide on how to format the docstring.

The examples in the docstring ('doctests') must be valid Python code, that in a deterministic way returns the presented output, and that can be copied and run by users. This can be checked with the script above, and is also tested on Travis. A failing doctest will be a blocker for merging a PR. Check the *examples* section in the docstring guide for some tips and tricks to get the doctests passing.

When doing a PR with a docstring update, it is good to post the output of the validation script in a comment on github.

### How to build the *pandas* documentation

#### Requirements

First, you need to have a development environment to be able to build pandas (see the docs on *creating a development environment above*).

## Building the documentation

So how do you build the docs? Navigate to your local `doc/` directory in the console and run:

```
python make.py html
```

Then you can find the HTML output in the folder `doc/build/html/`.

The first time you build the docs, it will take quite a while because it has to run all the code examples and build all the generated docstring pages. In subsequent evocations, sphinx will try to only build the pages that have been modified.

If you want to do a full clean build, do:

```
python make.py clean
python make.py html
```

You can tell `make.py` to compile only a single section of the docs, greatly reducing the turn-around time for checking your changes.

```
# omit autosummary and API section
python make.py clean
python make.py --no-api

# compile the docs with only a single section, relative to the "source" folder.
# For example, compiling only this guide (doc/source/development/contributing.rst)
python make.py clean
python make.py --single development/contributing.rst

# compile the reference docs for a single function
python make.py clean
python make.py --single pandas.DataFrame.join
```

For comparison, a full documentation build may take 15 minutes, but a single section may take 15 seconds. Subsequent builds, which only process portions you have changed, will be faster.

You can also specify to use multiple cores to speed up the documentation build:

```
python make.py html --num-jobs 4
```

Open the following file in a web browser to see the full documentation you just built:

```
doc/build/html/index.html
```

And you'll have the satisfaction of seeing your new and improved documentation!

## Building master branch documentation

When pull requests are merged into the `pandas` `master` branch, the main parts of the documentation are also built by Travis-CI. These docs are then hosted [here](#), see also the *Continuous Integration* section.

## 5.1.5 Contributing to the code base

### Code Base:

- *Code standards*
- *Optional dependencies*
  - *C (cpplint)*
  - *Python (PEP8 / black)*
  - *Import formatting*
  - *Backwards compatibility*
- *Type Hints*
  - *Style Guidelines*
  - *Pandas-specific Types*
  - *Validating Type Hints*
- *Testing with continuous integration*
- *Test-driven development/code writing*
  - *Writing tests*
  - *Transitioning to pytest*
  - *Using pytest*
  - *Using hypothesis*
  - *Testing warnings*
- *Running the test suite*
- *Running the performance test suite*
- *Documenting your code*

### Code standards

Writing good code is not just about what you write. It is also about *how* you write it. During *Continuous Integration* testing, several tools will be run to check your code for stylistic errors. Generating any warnings will cause the test to fail. Thus, good style is a requirement for submitting code to *pandas*.

There is a tool in *pandas* to help contributors verify their changes before contributing them to the project:

```
./ci/code_checks.sh
```

The script verifies the linting of code files, it looks for common mistake patterns (like missing spaces around sphinx directives that make the documentation not being rendered properly) and it also validates the doctests. It is possible to run the checks independently by using the parameters `lint`, `patterns` and `doctests` (e.g. `./ci/code_checks.sh lint`).

In addition, because a lot of people use our library, it is important that we do not make sudden changes to the code that could have the potential to break a lot of user code as a result, that is, we need it to be as *backwards compatible* as possible to avoid mass breakages.

Additional standards are outlined on the [pandas code style guide](#)

## Optional dependencies

Optional dependencies (e.g. `matplotlib`) should be imported with the private helper `pandas.compat._optional.import_optional_dependency`. This ensures a consistent error message when the dependency is not met.

All methods using an optional dependency should include a test asserting that an `ImportError` is raised when the optional dependency is not found. This test should be skipped if the library is present.

All optional dependencies should be documented in *Optional dependencies* and the minimum required version should be set in the `pandas.compat._optional.VERSIONS` dict.

## C (cpplint)

*pandas* uses the [Google](#) standard. Google provides an open source style checker called `cpplint`, but we use a fork of it that can be found [here](#). Here are *some* of the more common `cpplint` issues:

- we restrict line-length to 80 characters to promote readability
- every header file must include a header guard to avoid name collisions if re-included

*Continuous Integration* will run the `cpplint` tool and report any stylistic errors in your code. Therefore, it is helpful before submitting code to run the check yourself:

```
cpplint --extensions=c,h --headers=h --filter=--readability/casting,-runtime/int,-
↳build/include_subdir modified-c-file
```

You can also run this command on an entire directory if necessary:

```
cpplint --extensions=c,h --headers=h --filter=--readability/casting,-runtime/int,-
↳build/include_subdir --recursive modified-c-directory
```

To make your commits compliant with this standard, you can install the [ClangFormat](#) tool, which can be downloaded [here](#). To configure, in your home directory, run the following command:

```
clang-format style=google -dump-config > .clang-format
```

Then modify the file to ensure that any indentation width parameters are at least four. Once configured, you can run the tool as follows:

```
clang-format modified-c-file
```

This will output what your file will look like if the changes are made, and to apply them, run the following command:

```
clang-format -i modified-c-file
```

To run the tool on an entire directory, you can run the following analogous commands:

```
clang-format modified-c-directory/*.c modified-c-directory/*.h
clang-format -i modified-c-directory/*.c modified-c-directory/*.h
```

Do note that this tool is best-effort, meaning that it will try to correct as many errors as possible, but it may not correct *all* of them. Thus, it is recommended that you run `cpplint` to double check and make any other style fixes manually.

### Python (PEP8 / black)

*pandas* follows the [PEP8](#) standard and uses [Black](#) and [Flake8](#) to ensure a consistent code format throughout the project.

*Continuous Integration* will run those tools and report any stylistic errors in your code. Therefore, it is helpful before submitting code to run the check yourself:

```
black pandas
git diff upstream/master -u -- "*.py" | flake8 --diff
```

to auto-format your code. Additionally, many editors have plugins that will apply `black` as you edit files.

You should use a `black` version `>= 19.10b0` as previous versions are not compatible with the *pandas* codebase.

Optionally, you may wish to setup [pre-commit hooks](#) to automatically run `black` and `flake8` when you make a `git` commit. This can be done by installing `pre-commit`:

```
pip install pre-commit
```

and then running:

```
pre-commit install
```

from the root of the *pandas* repository. Now `black` and `flake8` will be run each time you commit changes. You can skip these checks with `git commit --no-verify`.

One caveat about `git diff upstream/master -u -- "*.py" | flake8 --diff`: this command will catch any stylistic errors in your changes specifically, but be beware it may not catch all of them. For example, if you delete the only usage of an imported function, it is stylistically incorrect to import an unused function. However, style-checking the diff will not catch this because the actual import is not part of the diff. Thus, for completeness, you should run this command, though it will take longer:

```
git diff upstream/master --name-only -- "*.py" | xargs -r flake8
```

Note that on OSX, the `-r` flag is not available, so you have to omit it and run this slightly modified command:

```
git diff upstream/master --name-only -- "*.py" | xargs flake8
```

Windows does not support the `xargs` command (unless installed for example via the [MinGW](#) toolchain), but one can imitate the behaviour as follows:

```
for /f %i in ('git diff upstream/master --name-only -- "*.py"') do flake8 %i
```

This will get all the files being changed by the PR (and ending with `.py`), and run `flake8` on them, one after the other.

### Import formatting

*pandas* uses [isort](#) to standardise import formatting across the codebase.

A guide to import layout as per `pep8` can be found [here](#).

A summary of our current import sections ( in order ):

- Future
- Python Standard Library
- Third Party

- `pandas._libs`, `pandas.compat`, `pandas.util._*`, `pandas.errors` (largely not dependent on `pandas.core`)
- `pandas.core.dtypes` (largely not dependent on the rest of `pandas.core`)
- Rest of `pandas.core.*`
- Non-core `pandas.io`, `pandas.plotting`, `pandas.tseries`
- Local application/library specific imports

Imports are alphabetically sorted within these sections.

As part of *Continuous Integration* checks we run:

```
isort --recursive --check-only pandas
```

to check that imports are correctly formatted as per the *setup.cfg*.

If you see output like the below in *Continuous Integration* checks:

```
Check import format using isort
ERROR: /home/travis/build/pandas-dev/pandas/pandas/io/pytables.py Imports are
↳incorrectly sorted
Check import format using isort DONE
The command "ci/code_checks.sh" exited with 1
```

You should run:

```
isort pandas/io/pytables.py
```

to automatically format imports correctly. This will modify your local copy of the files.

The *-recursive* flag can be passed to sort all files in a directory.

You can then verify the changes look ok, then *git commit* and *push*.

## Backwards compatibility

Please try to maintain backward compatibility. *pandas* has lots of users with lots of existing code, so don't break it if at all possible. If you think breakage is required, clearly state why as part of the pull request. Also, be careful when changing method signatures and add deprecation warnings where needed. Also, add the deprecated sphinx directive to the deprecated functions or methods.

If a function with the same arguments as the one being deprecated exist, you can use the `pandas.util._decorators.deprecate`:

```
from pandas.util._decorators import deprecate

deprecate('old_func', 'new_func', '0.21.0')
```

Otherwise, you need to do it manually:

```
import warnings

def old_func():
    """Summary of the function.
```

(continues on next page)

(continued from previous page)

```
.. deprecated:: 0.21.0
    Use new_func instead.
"""
warnings.warn('Use new_func instead.', FutureWarning, stacklevel=2)
new_func()

def new_func():
    pass
```

You'll also need to

1. Write a new test that asserts a warning is issued when calling with the deprecated argument
2. Update all of pandas existing tests and code to use the new argument

See *Testing warnings* for more.

## Type Hints

*pandas* strongly encourages the use of **PEP 484** style type hints. New development should contain type hints and pull requests to annotate existing code are accepted as well!

## Style Guidelines

Types imports should follow the `from typing import ...` convention. So rather than

```
import typing

primes: typing.List[int] = []
```

You should write

```
from typing import List, Optional, Union

primes: List[int] = []
```

`Optional` should be used where applicable, so instead of

```
maybe_primes: List[Union[int, None]] = []
```

You should write

```
maybe_primes: List[Optional[int]] = []
```

In some cases in the code base classes may define class variables that shadow builtins. This causes an issue as described in [Mypy 1775](#). The defensive solution here is to create an unambiguous alias of the builtin and use that without your annotation. For example, if you come across a definition like

```
class SomeClass1:
    str = None
```

The appropriate way to annotate this would be as follows

```
str_type = str

class SomeClass2:
    str: str_type = None
```

In some cases you may be tempted to use `cast` from the typing module when you know better than the analyzer. This occurs particularly when using custom inference functions. For example

```
from typing import cast

from pandas.core.dtypes.common import is_number

def cannot_infer_bad(obj: Union[str, int, float]):

    if is_number(obj):
        ...
    else: # Reasonably only str objects would reach this but...
        obj = cast(str, obj) # Mypy complains without this!
        return obj.upper()
```

The limitation here is that while a human can reasonably understand that `is_number` would catch the `int` and `float` types mypy cannot make that same inference just yet (see [mypy #5206](#)). While the above works, the use of `cast` is **strongly discouraged**. Where applicable a refactor of the code to appease static analysis is preferable

```
def cannot_infer_good(obj: Union[str, int, float]):

    if isinstance(obj, str):
        return obj.upper()
    else:
        ...
```

With custom types and inference this is not always possible so exceptions are made, but every effort should be exhausted to avoid `cast` before going down such paths.

## Pandas-specific Types

Commonly used types specific to *pandas* will appear in `pandas._typing` and you should use these where applicable. This module is private for now but ultimately this should be exposed to third party libraries who want to implement type checking against pandas.

For example, quite a few functions in *pandas* accept a `dtype` argument. This can be expressed as a string like "object", a numpy.dtype like `np.int64` or even a pandas `ExtensionDtype` like `pd.CategoricalDtype`. Rather than burden the user with having to constantly annotate all of those options, this can simply be imported and reused from the `pandas._typing` module

```
from pandas._typing import Dtype

def as_type(dtype: Dtype) -> ...:
    ...
```

This module will ultimately house types for repeatedly used concepts like “path-like”, “array-like”, “numeric”, etc... and can also hold aliases for commonly appearing parameters like *axis*. Development of this module is active so be sure to refer to the source for the most up to date list of available types.

## Validating Type Hints

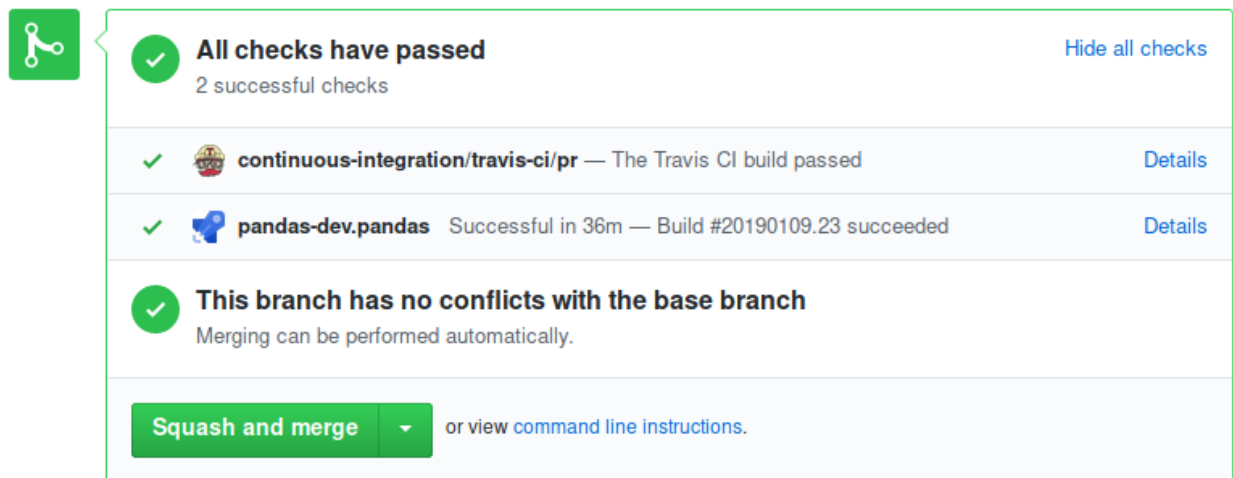

*pandas* uses [mypy](#) to statically analyze the code base and type hints. After making any change you can ensure your type hints are correct by running

```
mypy pandas
```

## Testing with continuous integration

The *pandas* test suite will run automatically on [Travis-CI](#) and [Azure Pipelines](#) continuous integration services, once your pull request is submitted. However, if you wish to run the test suite on a branch prior to submitting the pull request, then the continuous integration services need to be hooked to your GitHub repository. Instructions are here for [Travis-CI](#) and [Azure Pipelines](#).

A pull-request will be considered for merging when you have an all ‘green’ build. If any tests are failing, then you will get a red ‘X’, where you can click through to see the individual failed tests. This is an example of a green build.

---

**Note:** Each time you push to *your* fork, a *new* run of the tests will be triggered on the CI. You can enable the auto-cancel feature, which removes any non-currently-running tests for that same pull-request, for [Travis-CI here](#).

---

## Test-driven development/code writing

*pandas* is serious about testing and strongly encourages contributors to embrace [test-driven development \(TDD\)](#). This development process “relies on the repetition of a very short development cycle: first the developer writes an (initially failing) automated test case that defines a desired improvement or new function, then produces the minimum amount of code to pass that test.” So, before actually writing any code, you should write your tests. Often the test can be taken from the original GitHub issue. However, it is always worth considering additional use cases and writing corresponding tests.

Adding tests is one of the most common requests after code is pushed to *pandas*. Therefore, it is worth getting in the habit of writing tests ahead of time so this is never an issue.

Like many packages, *pandas* uses [pytest](#) and the convenient extensions in [numpy.testing](#).

---

**Note:** The earliest supported pytest version is 5.0.1.

---

## Writing tests

All tests should go into the `tests` subdirectory of the specific package. This folder contains many current examples of tests, and we suggest looking to these for inspiration. If your test requires working with files or network connectivity, there is more information on the [testing page](#) of the wiki.

The `pandas._testing` module has many special `assert` functions that make it easier to make statements about whether `Series` or `DataFrame` objects are equivalent. The easiest way to verify that your code is correct is to explicitly construct the result you expect, then compare the actual result to the expected correct result:

```
def test_pivot(self):
    data = {
        'index' : ['A', 'B', 'C', 'C', 'B', 'A'],
        'columns' : ['One', 'One', 'One', 'Two', 'Two', 'Two'],
        'values' : [1., 2., 3., 3., 2., 1.]
    }

    frame = DataFrame(data)
    pivoted = frame.pivot(index='index', columns='columns', values='values')

    expected = DataFrame({
        'One' : {'A' : 1., 'B' : 2., 'C' : 3.},
        'Two' : {'A' : 1., 'B' : 2., 'C' : 3.}
    })

    assert_frame_equal(pivoted, expected)
```

Please remember to add the Github Issue Number as a comment to a new test. E.g. “# brief comment, see GH#28907”

## Transitioning to pytest

*pandas* existing test structure is *mostly* class-based, meaning that you will typically find tests wrapped in a class.

```
class TestReallyCoolFeature:
    pass
```

Going forward, we are moving to a more *functional* style using the `pytest` framework, which offers a richer testing framework that will facilitate testing and developing. Thus, instead of writing test classes, we will write test functions like this:

```
def test_really_cool_feature():
    pass
```

## Using pytest

Here is an example of a self-contained set of tests that illustrate multiple features that we like to use.

- functional style: tests are like `test_*` and *only* take arguments that are either fixtures or parameters
- `pytest.mark` can be used to set metadata on test functions, e.g. `skip` or `xfail`.
- using `parametrize`: allow testing of multiple cases
- to set a mark on a parameter, `pytest.param(..., marks=...)` syntax should be used
- `fixture`, code for object construction, on a per-test basis
- using bare `assert` for scalars and truth-testing
- `tm.assert_series_equal` (and its counter part `tm.assert_frame_equal`), for pandas object comparisons.
- the typical pattern of constructing an expected and comparing versus the result

We would name this file `test_cool_feature.py` and put in an appropriate place in the `pandas/tests/` structure.

```
import pytest
import numpy as np
import pandas as pd

@pytest.mark.parametrize('dtype', ['int8', 'int16', 'int32', 'int64'])
def test_dtypes(dtype):
    assert str(np.dtype(dtype)) == dtype

@pytest.mark.parametrize(
    'dtype', ['float32', pytest.param('int16', marks=pytest.mark.skip),
            pytest.param('int32', marks=pytest.mark.xfail(
                reason='to show how it works'))])
def test_mark(dtype):
    assert str(np.dtype(dtype)) == 'float32'

@pytest.fixture
def series():
    return pd.Series([1, 2, 3])

@pytest.fixture(params=['int8', 'int16', 'int32', 'int64'])
def dtype(request):
    return request.param

def test_series(series, dtype):
    result = series.astype(dtype)
    assert result.dtype == dtype

    expected = pd.Series([1, 2, 3], dtype=dtype)
    tm.assert_series_equal(result, expected)
```

A test run of this yields

```

((pandas) bash-3.2$ pytest test_cool_feature.py -v
===== test session starts =====
platform darwin -- Python 3.6.2, pytest-3.6.0, py-1.4.31, pluggy-0.4.0
collected 11 items

tester.py::test_dtypes[int8] PASSED
tester.py::test_dtypes[int16] PASSED
tester.py::test_dtypes[int32] PASSED
tester.py::test_dtypes[int64] PASSED
tester.py::test_mark[float32] PASSED
tester.py::test_mark[int16] SKIPPED
tester.py::test_mark[int32] xfail
tester.py::test_series[int8] PASSED
tester.py::test_series[int16] PASSED
tester.py::test_series[int32] PASSED
tester.py::test_series[int64] PASSED

```

Tests that we have parametrized are now accessible via the test name, for example we could run these with `-k int8` to sub-select *only* those tests which match `int8`.

```

((pandas) bash-3.2$ pytest test_cool_feature.py -v -k int8
===== test session starts =====
platform darwin -- Python 3.6.2, pytest-3.6.0, py-1.4.31, pluggy-0.4.0
collected 11 items

test_cool_feature.py::test_dtypes[int8] PASSED
test_cool_feature.py::test_series[int8] PASSED

```

## Using hypothesis

Hypothesis is a library for property-based testing. Instead of explicitly parametrizing a test, you can describe *all* valid inputs and let Hypothesis try to find a failing input. Even better, no matter how many random examples it tries, Hypothesis always reports a single minimal counterexample to your assertions - often an example that you would never have thought to test.

See [Getting Started with Hypothesis](#) for more of an introduction, then refer to the [Hypothesis documentation](#) for details.

```

import json
from hypothesis import given, strategies as st

any_json_value = st.deferred(lambda: st.one_of(
    st.none(), st.booleans(), st.floats(allow_nan=False), st.text(),
    st.lists(any_json_value), st.dictionaries(st.text(), any_json_value)
))

@given(value=any_json_value)
def test_json_roundtrip(value):
    result = json.loads(json.dumps(value))
    assert value == result

```

This test shows off several useful features of Hypothesis, as well as demonstrating a good use-case: checking properties that should hold over a large or complicated domain of inputs.

To keep the Pandas test suite running quickly, parametrized tests are preferred if the inputs or logic are simple, with

Hypothesis tests reserved for cases with complex logic or where there are too many combinations of options or subtle interactions to test (or think of!) all of them.

### Testing warnings

By default, one of pandas CI workers will fail if any unhandled warnings are emitted.

If your change involves checking that a warning is actually emitted, use `tm.assert_produces_warning(ExpectedWarning)`.

```
import pandas._testing as tm

df = pd.DataFrame()
with tm.assert_produces_warning(FutureWarning):
    df.some_operation()
```

We prefer this to the `pytest.warns` context manager because ours checks that the warning's `stacklevel` is set correctly. The `stacklevel` is what ensure the *user's* file name and line number is printed in the warning, rather than something internal to pandas. It represents the number of function calls from user code (e.g. `df.some_operation()`) to the function that actually emits the warning. Our linter will fail the build if you use `pytest.warns` in a test.

If you have a test that would emit a warning, but you aren't actually testing the warning itself (say because it's going to be removed in the future, or because we're matching a 3rd-party library's behavior), then use `pytest.mark.filterwarnings` to ignore the error.

```
@pytest.mark.filterwarnings("ignore:msg:category")
def test_thing(self):
    ...
```

If the test generates a warning of class `category` whose message starts with `msg`, the warning will be ignored and the test will pass.

If you need finer-grained control, you can use Python's usual `warnings` module to control whether a warning is ignored / raised at different places within a single test.

```
with warnings.catch_warnings():
    warnings.simplefilter("ignore", FutureWarning)
    # Or use warnings.filterwarnings(...)
```

Alternatively, consider breaking up the unit test.

### Running the test suite

The tests can then be run directly inside your Git clone (without having to install *pandas*) by typing:

```
pytest pandas
```

The tests suite is exhaustive and takes around 20 minutes to run. Often it is worth running only a subset of tests first around your changes before running the entire suite.

The easiest way to do this is with:

```
pytest pandas/path/to/test.py -k regex_matching_test_name
```

Or with one of the following constructs:

```
pytest pandas/tests/[test-module].py
pytest pandas/tests/[test-module].py::[TestClass]
pytest pandas/tests/[test-module].py::[TestClass]::[test_method]
```

Using `pytest-xdist`, one can speed up local testing on multicore machines. To use this feature, you will need to install `pytest-xdist` via:

```
pip install pytest-xdist
```

Two scripts are provided to assist with this. These scripts distribute testing across 4 threads.

On Unix variants, one can type:

```
test_fast.sh
```

On Windows, one can type:

```
test_fast.bat
```

This can significantly reduce the time it takes to locally run tests before submitting a pull request.

For more, see the [pytest](#) documentation.

Furthermore one can run

```
pd.test()
```

with an imported pandas to run tests similarly.

## Running the performance test suite

Performance matters and it is worth considering whether your code has introduced performance regressions. *pandas* is in the process of migrating to [asv benchmarks](#) to enable easy monitoring of the performance of critical *pandas* operations. These benchmarks are all found in the `pandas/asv_bench` directory. `asv` supports both python2 and python3.

To use all features of `asv`, you will need either `conda` or `virtualenv`. For more details please check the [asv installation webpage](#).

To install `asv`:

```
pip install git+https://github.com/spacetelescope/asv
```

If you need to run a benchmark, change your directory to `asv_bench/` and run:

```
asv continuous -f 1.1 upstream/master HEAD
```

You can replace `HEAD` with the name of the branch you are working on, and report benchmarks that changed by more than 10%. The command uses `conda` by default for creating the benchmark environments. If you want to use `virtualenv` instead, write:

```
asv continuous -f 1.1 -E virtualenv upstream/master HEAD
```

The `-E virtualenv` option should be added to all `asv` commands that run benchmarks. The default value is defined in `asv.conf.json`.

Running the full test suite can take up to one hour and use up to 3GB of RAM. Usually it is sufficient to paste only a subset of the results into the pull request to show that the committed changes do not cause unexpected performance

regressions. You can run specific benchmarks using the `-b` flag, which takes a regular expression. For example, this will only run tests from a `pandas/asv_bench/benchmarks/groupby.py` file:

```
asv continuous -f 1.1 upstream/master HEAD -b ^groupby
```

If you want to only run a specific group of tests from a file, you can do it using `.` as a separator. For example:

```
asv continuous -f 1.1 upstream/master HEAD -b groupby.GroupByMethods
```

will only run the `GroupByMethods` benchmark defined in `groupby.py`.

You can also run the benchmark suite using the version of `pandas` already installed in your current Python environment. This can be useful if you do not have `virtualenv` or `conda`, or are using the `setup.py develop` approach discussed above; for the in-place build you need to set `PYTHONPATH`, e.g. `PYTHONPATH="$PWD/.."` `asv [remaining arguments]`. You can run benchmarks using an existing Python environment by:

```
asv run -e -E existing
```

or, to use a specific Python interpreter,:

```
asv run -e -E existing:python3.6
```

This will display `stderr` from the benchmarks, and use your local `python` that comes from your `$PATH`.

Information on how to write a benchmark and how to use `asv` can be found in the [asv documentation](#).

### Documenting your code

Changes should be reflected in the release notes located in `doc/source/whatsnew/vx.y.z.rst`. This file contains an ongoing change log for each release. Add an entry to this file to document your fix, enhancement or (unavoidable) breaking change. Make sure to include the GitHub issue number when adding your entry (using `issue: `1234`` where 1234 is the issue/pull request number).

If your code is an enhancement, it is most likely necessary to add usage examples to the existing documentation. This can be done following the section regarding documentation *above*. Further, to let users know when this feature was added, the `versionadded` directive is used. The sphinx syntax for that is:

```
.. versionadded:: 0.21.0
```

This will put the text *New in version 0.21.0* wherever you put the sphinx directive. This should also be put in the docstring when adding a new function or method ([example](#)) or a new keyword argument ([example](#)).

## 5.1.6 Contributing your changes to *pandas*

### Committing your code

Keep style fixes to a separate commit to make your pull request more readable.

Once you've made changes, you can see them by typing:

```
git status
```

If you have created a new file, it is not being tracked by `git`. Add it by typing:

```
git add path/to/file-to-be-added.py
```

Doing ‘git status’ again should give something like:

```
# On branch shiny-new-feature
#
#       modified:   /relative/path/to/file-you-added.py
#
```

Finally, commit your changes to your local repository with an explanatory message. *Pandas* uses a convention for commit message prefixes and layout. Here are some common prefixes along with general guidelines for when to use them:

- ENH: Enhancement, new functionality
- BUG: Bug fix
- DOC: Additions/updates to documentation
- TST: Additions/updates to tests
- BLD: Updates to the build process/scripts
- PERF: Performance improvement
- TYP: Type annotations
- CLN: Code cleanup

The following defines how a commit message should be structured. Please reference the relevant GitHub issues in your commit message using GH1234 or #1234. Either style is fine, but the former is generally preferred:

- a subject line with < 80 chars.
- One blank line.
- Optionally, a commit message body.

Now you can commit your changes in your local repository:

```
git commit -m
```

## Pushing your changes

When you want your changes to appear publicly on your GitHub page, push your forked feature branch’s commits:

```
git push origin shiny-new-feature
```

Here `origin` is the default name given to your remote repository on GitHub. You can see the remote repositories:

```
git remote -v
```

If you added the upstream repository as described above you will see something like:

```
origin  git@github.com:yourname/pandas.git (fetch)
origin  git@github.com:yourname/pandas.git (push)
upstream      git://github.com/pandas-dev/pandas.git (fetch)
upstream      git://github.com/pandas-dev/pandas.git (push)
```

Now your code is on GitHub, but it is not yet a part of the *pandas* project. For that to happen, a pull request needs to be submitted on GitHub.

### Review your code

When you're ready to ask for a code review, file a pull request. Before you do, once again make sure that you have followed all the guidelines outlined in this document regarding code style, tests, performance tests, and documentation. You should also double check your branch changes against the branch it was based on:

1. Navigate to your repository on GitHub – <https://github.com/your-user-name/pandas>
2. Click on `Branches`
3. Click on the `Compare` button for your feature branch
4. Select the `base` and `compare` branches, if necessary. This will be `master` and `shiny-new-feature`, respectively.

### Finally, make the pull request

If everything looks good, you are ready to make a pull request. A pull request is how code from a local repository becomes available to the GitHub community and can be looked at and eventually merged into the master version. This pull request and its associated changes will eventually be committed to the master branch and available in the next release. To submit a pull request:

1. Navigate to your repository on GitHub
2. Click on the `Pull Request` button
3. You can then click on `Commits` and `Files Changed` to make sure everything looks okay one last time
4. Write a description of your changes in the `Preview Discussion` tab
5. Click `Send Pull Request`.

This request then goes to the repository maintainers, and they will review the code.

### Updating your pull request

Based on the review you get on your pull request, you will probably need to make some changes to the code. In that case, you can make them in your branch, add a new commit to that branch, push it to GitHub, and the pull request will be automatically updated. Pushing them to GitHub again is done by:

```
git push origin shiny-new-feature
```

This will automatically update your pull request with the latest code and restart the *Continuous Integration* tests.

Another reason you might need to update your pull request is to solve conflicts with changes that have been merged into the master branch since you opened your pull request.

To do this, you need to “merge upstream master” in your branch:

```
git checkout shiny-new-feature
git fetch upstream
git merge upstream/master
```

If there are no conflicts (or they could be fixed automatically), a file with a default commit message will open, and you can simply save and quit this file.

If there are merge conflicts, you need to solve those conflicts. See for example at <https://help.github.com/articles/resolving-a-merge-conflict-using-the-command-line/> for an explanation on how to do this. Once the conflicts are merged and the files where the conflicts were solved are added, you can run `git commit` to save those fixes.

If you have uncommitted changes at the moment you want to update the branch with master, you will need to `stash` them prior to updating (see the [stash docs](#)). This will effectively store your changes and they can be reapplied after updating.

After the feature branch has been update locally, you can now update your pull request by pushing to the branch on GitHub:

```
git push origin shiny-new-feature
```

### Delete your merged branch (optional)

Once your feature branch is accepted into upstream, you'll probably want to get rid of the branch. First, merge upstream master into your branch so git knows it is safe to delete your branch:

```
git fetch upstream
git checkout master
git merge upstream/master
```

Then you can do:

```
git branch -d shiny-new-feature
```

Make sure you use a lower-case `-d`, or else git won't warn you if your feature branch has not actually been merged.

The branch will still exist on GitHub, so to delete it there do:

```
git push origin --delete shiny-new-feature
```

```
{{ header }}
```

## 5.2 pandas code style guide

### Table of contents:

- *Patterns*
  - *foo.\_\_class\_\_*
- *String formatting*
  - *Concatenated strings*
    - \* *f-strings*
    - \* *White spaces*
  - *Representation function (aka 'repr()')*

## 5.2.1 Patterns

### foo.\_\_class\_\_

*pandas* uses `type(foo)` instead of `foo.__class__` as it is making the code more readable.

For example:

#### Good:

```
foo = "bar"
type(foo)
```

#### Bad:

```
foo = "bar"
foo.__class__
```

## 5.2.2 String formatting

### Concatenated strings

#### f-strings

*pandas* uses f-strings formatting instead of `%` and `.format()` string formatters.

The convention of using f-strings on a string that is concatenated over several lines, is to prefix only the lines containing the value needs to be interpreted.

For example:

#### Good:

```
foo = "old_function"
bar = "new_function"

my_warning_message = (
    f"Warning, {foo} is deprecated, "
    "please use the new and way better "
    f"{bar}"
)
```

#### Bad:

```
foo = "old_function"
bar = "new_function"

my_warning_message = (
    f"Warning, {foo} is deprecated, "
    f"please use the new and way better "
    f"{bar}"
)
```

## White spaces

Putting the white space only at the end of the previous line, so there is no whitespace at the beginning of the concatenated string.

For example:

### Good:

```
example_string = (
    "Some long concatenated string, "
    "with good placement of the "
    "whitespaces"
)
```

### Bad:

```
example_string = (
    "Some long concatenated string,"
    " with bad placement of the"
    " whitespaces"
)
```

## Representation function (aka 'repr()')

*pandas* uses 'repr()' instead of '%r' and '!r'.

The use of 'repr()' will only happen when the value is not an obvious string.

For example:

### Good:

```
value = str
f"Unknown recived value, got: {repr(value)}"
```

### Good:

```
value = str
f"Unknown recived type, got: '{type(value).__name__}'"
```

## 5.3 Pandas Maintenance

This guide is for pandas' maintainers. It may also be interesting to contributors looking to understand the pandas development process and what steps are necessary to become a maintainer.

The main contributing guide is available at [Contributing to pandas-gbq](#).

### 5.3.1 Roles

Pandas uses two levels of permissions: **triage** and **core** team members.

Triage members can label and close issues and pull requests.

Core team members can label and close issues and pull request, and can merge pull requests.

GitHub publishes the full [list of permissions](#).

### 5.3.2 Tasks

Pandas is largely a volunteer project, so these tasks shouldn't be read as "expectations" of triage and maintainers. Rather, they're general descriptions of what it means to be a maintainer.

- Triage newly filed issues (see *Issue Triage*)
- Review newly opened pull requests
- Respond to updates on existing issues and pull requests
- Drive discussion and decisions on stalled issues and pull requests
- Provide experience / wisdom on API design questions to ensure consistency and maintainability
- Project organization (run / attend developer meetings, represent pandas)

<http://matthewrocklin.com/blog/2019/05/18/maintainer> may be interesting background reading.

### 5.3.3 Issue Triage

Here's a typical workflow for triaging a newly opened issue.

#### 1. Thank the reporter for opening an issue

The issue tracker is many people's first interaction with the pandas project itself, beyond just using the library. As such, we want it to be a welcoming, pleasant experience.

#### 2. Is the necessary information provided?

Ideally reporters would fill out the issue template, but many don't. If crucial information (like the version of pandas they used), is missing feel free to ask for that and label the issue with "Needs info". The report should follow the guidelines in *Bug reports and enhancement requests*. You may want to link to that if they didn't follow the template.

Make sure that the title accurately reflects the issue. Edit it yourself if it's not clear.

#### 3. Is this a duplicate issue?

We have many open issues. If a new issue is clearly a duplicate, label the new issue as "Duplicate" assign the milestone "No Action", and close the issue with a link to the original issue. Make sure to still thank the reporter, and encourage them to chime in on the original issue, and perhaps try to fix it.

If the new issue provides relevant information, such as a better or slightly different example, add it to the original issue as a comment or an edit to the original post.

#### 4. Is the issue minimal and reproducible?

For bug reports, we ask that the reporter provide a minimal reproducible example. See <http://matthewrocklin.com/blog/work/2018/02/28/minimal-bug-reports> for a good explanation. If the example is not reproducible, or if it's *clearly* not minimal, feel free to ask the reporter if they can provide an example or simplify the provided

one. Do acknowledge that writing minimal reproducible examples is hard work. If the reporter is struggling, you can try to write one yourself and we'll edit the original post to include it.

If a reproducible example can't be provided, add the "Needs info" label.

If a reproducible example is provided, but you see a simplification, edit the original post with your simpler reproducible example.

#### 5. Is this a clearly defined feature request?

Generally, pandas prefers to discuss and design new features in issues, before a pull request is made. Encourage the submitter to include a proposed API for the new feature. Having them write a full docstring is a good way to pin down specifics.

We'll need a discussion from several pandas maintainers before deciding whether the proposal is in scope for pandas.

#### 6. Is this a usage question?

We prefer that usage questions are asked on StackOverflow with the pandas tag. <https://stackoverflow.com/questions/tagged/pandas>

If it's easy to answer, feel free to link to the relevant documentation section, let them know that in the future this kind of question should be on StackOverflow, and close the issue.

#### 7. What labels and milestones should I add?

Apply the relevant labels. This is a bit of an art, and comes with experience. Look at similar issues to get a feel for how things are labeled.

If the issue is clearly defined and the fix seems relatively straightforward, label the issue as "Good first issue".

Typically, new issues will be assigned the "Contributions welcome" milestone, unless it's known that this issue should be addressed in a specific release (say because it's a large regression).

### 5.3.4 Closing Issues

Be delicate here: many people interpret closing an issue as us saying that the conversation is over. It's typically best to give the reporter some time to respond or self-close their issue if it's determined that the behavior is not a bug, or the feature is out of scope. Sometimes reporters just go away though, and we'll close the issue after the conversation has died.

### 5.3.5 Reviewing Pull Requests

Anybody can review a pull request: regular contributors, triagers, or core-team members. Here are some guidelines to check.

- Tests should be in a sensible location.
- New public APIs should be included somewhere in `doc/source/reference/`.
- New / changed API should use the `versionadded` or `versionchanged` directives in the docstring.
- User-facing changes should have a `whatsnew` in the appropriate file.
- Regression tests should reference the original GitHub issue number like `# GH-1234`.

### 5.3.6 Cleaning up old Issues

Every open issue in pandas has a cost. Open issues make finding duplicates harder, and can make it harder to know what needs to be done in pandas. That said, closing issues isn't a goal on its own. Our goal is to make pandas the best it can be, and that's best done by ensuring that the quality of our open issues is high.

Occasionally, bugs are fixed but the issue isn't linked to in the Pull Request. In these cases, comment that "This has been fixed, but could use a test." and label the issue as "Good First Issue" and "Needs Test".

If an older issue doesn't follow our issue template, edit the original post to include a minimal example, the actual output, and the expected output. Uniformity in issue reports is valuable.

If an older issue lacks a reproducible example, label it as "Needs Info" and ask them to provide one (or write one yourself if possible). If one isn't provide reasonably soon, close it according to the policies in *Closing Issues*.

### 5.3.7 Cleaning up old Pull Requests

Occasionally, contributors are unable to finish off a pull request. If some time has passed (two weeks, say) since the last review requesting changes, gently ask if they're still interested in working on this. If another two weeks or so passes with no response, thank them for their work and close the pull request. Comment on the original issue that "There's a stalled PR at #1234 that may be helpful.", and perhaps label the issue as "Good first issue" if the PR was relatively close to being accepted.

Additionally, core-team members can push to contributors branches. This can be helpful for pushing an important PR across the line, or for fixing a small merge conflict.

### 5.3.8 Becoming a pandas maintainer

The full process is outlined in our [governance documents](#). In summary, we're happy to give triage permissions to anyone who shows interest by being helpful on the issue tracker.

The current list of core-team members is at <https://github.com/pandas-dev/pandas-governance/blob/master/people.md>  
{ { header } }

## 5.4 Internals

This section will provide a look into some of pandas internals. It's primarily intended for developers of pandas itself.

### 5.4.1 Indexing

In pandas there are a few objects implemented which can serve as valid containers for the axis labels:

- `Index`: the generic "ordered set" object, an ndarray of object dtype assuming nothing about its contents. The labels must be hashable (and likely immutable) and unique. Populates a dict of label to location in Cython to do  $O(1)$  lookups.
- `Int64Index`: a version of `Index` highly optimized for 64-bit integer data, such as time stamps
- `Float64Index`: a version of `Index` highly optimized for 64-bit float data
- `MultiIndex`: the standard hierarchical index object
- `DatetimeIndex`: An `Index` object with `Timestamp` boxed elements (impl are the int64 values)
- `TimedeltaIndex`: An `Index` object with `Timedelta` boxed elements (impl are the in64 values)

- `PeriodIndex`: An `Index` object with `Period` elements

There are functions that make the creation of a regular index easy:

- `date_range`: fixed frequency date range generated from a time rule or `DateOffset`. An ndarray of Python `datetime` objects
- `period_range`: fixed frequency date range generated from a time rule or `DateOffset`. An ndarray of `Period` objects, representing timespans

The motivation for having an `Index` class in the first place was to enable different implementations of indexing. This means that it's possible for you, the user, to implement a custom `Index` subclass that may be better suited to a particular application than the ones provided in pandas.

From an internal implementation point of view, the relevant methods that an `Index` must define are one or more of the following (depending on how incompatible the new object internals are with the `Index` functions):

- `get_loc`: returns an “indexer” (an integer, or in some cases a slice object) for a label
- `slice_locs`: returns the “range” to slice between two labels
- `get_indexer`: Computes the indexing vector for reindexing / data alignment purposes. See the source / docstrings for more on this
- `get_indexer_non_unique`: Computes the indexing vector for reindexing / data alignment purposes when the index is non-unique. See the source / docstrings for more on this
- `reindex`: Does any pre-conversion of the input index then calls `get_indexer`
- `union`, `intersection`: computes the union or intersection of two `Index` objects
- `insert`: Inserts a new label into an `Index`, yielding a new object
- `delete`: Delete a label, yielding a new object
- `drop`: Deletes a set of labels
- `take`: Analogous to `ndarray.take`

## Multindex

Internally, the `MultiIndex` consists of a few things: the **levels**, the integer **codes** (until version 0.24 named *labels*), and the level **names**:

```
In [1]: index = pd.MultiIndex.from_product([range(3), ['one', 'two']],
...:                                     names=['first', 'second'])
...:

-----

NameError                                Traceback (most recent call last)
<ipython-input-1-325313b74147> in <module>
----> 1 index = pd.MultiIndex.from_product([range(3), ['one', 'two']],
      2                                     names=['first', 'second'])

NameError: name 'pd' is not defined

In [2]: index
-----

NameError                                Traceback (most recent call last)
<ipython-input-2-c17665332d8f> in <module>
----> 1 index

NameError: name 'index' is not defined
```

(continues on next page)

```
In [3]: index.levels
-----
NameError                                Traceback (most recent call last)
<ipython-input-3-caa84382af6f> in <module>
----> 1 index.levels

NameError: name 'index' is not defined

In [4]: index.codes
-----
NameError                                Traceback (most recent call last)
<ipython-input-4-9caf1b7e70ce> in <module>
----> 1 index.codes

NameError: name 'index' is not defined

In [5]: index.names
-----
NameError                                Traceback (most recent call last)
<ipython-input-5-f95ab7546e25> in <module>
----> 1 index.names

NameError: name 'index' is not defined
```

You can probably guess that the codes determine which unique element is identified with that location at each layer of the index. It's important to note that sortedness is determined **solely** from the integer codes and does not check (or care) whether the levels themselves are sorted. Fortunately, the constructors `from_tuples` and `from_arrays` ensure that this is true, but if you compute the levels and codes yourself, please be careful.

## Values

Pandas extends NumPy's type system with custom types, like `Categorical` or datetimes with a timezone, so we have multiple notions of "values". For 1-D containers (`Index` classes and `Series`) we have the following convention:

- `cls._ndarray_values` is *always* a NumPy `ndarray`. Ideally, `_ndarray_values` is cheap to compute. For example, for a `Categorical`, this returns the codes, not the array of objects.
- `cls._values` refers to the "best possible" array. This could be an `ndarray`, `ExtensionArray`, or in `Index` subclass (note: we're in the process of removing the index subclasses here so that it's always an `ndarray` or `ExtensionArray`).

So, for example, `Series[category]._values` is a `Categorical`, while `Series[category]._ndarray_values` is the underlying codes.

## 5.4.2 Subclassing pandas data structures

This section has been moved to *Subclassing pandas data structures*. `{{ header }}`

## 5.5 Extending pandas

While pandas provides a rich set of methods, containers, and data types, your needs may not be fully satisfied. Pandas offers a few options for extending pandas.

### 5.5.1 Registering custom accessors

Libraries can use the decorators `pandas.api.extensions.register_dataframe_accessor()`, `pandas.api.extensions.register_series_accessor()`, and `pandas.api.extensions.register_index_accessor()`, to add additional “namespaces” to pandas objects. All of these follow a similar convention: you decorate a class, providing the name of attribute to add. The class’s `__init__` method gets the object being decorated. For example:

```
@pd.api.extensions.register_dataframe_accessor("geo")
class GeoAccessor:
    def __init__(self, pandas_obj):
        self._validate(pandas_obj)
        self._obj = pandas_obj

    @staticmethod
    def _validate(obj):
        # verify there is a column latitude and a column longitude
        if 'latitude' not in obj.columns or 'longitude' not in obj.columns:
            raise AttributeError("Must have 'latitude' and 'longitude'.")

    @property
    def center(self):
        # return the geographic center point of this DataFrame
        lat = self._obj.latitude
        lon = self._obj.longitude
        return (float(lon.mean()), float(lat.mean()))

    def plot(self):
        # plot this array's data on a map, e.g., using Cartopy
        pass
```

Now users can access your methods using the `geo` namespace:

```
>>> ds = pd.DataFrame({'longitude': np.linspace(0, 10),
...                   'latitude': np.linspace(0, 20)})
>>> ds.geo.center
(5.0, 10.0)
>>> ds.geo.plot()
# plots data on a map
```

This can be a convenient way to extend pandas objects without subclassing them. If you write a custom accessor, make a pull request adding it to our ecosystem page.

We highly recommend validating the data in your accessor’s `__init__`. In our `GeoAccessor`, we validate that the data contains the expected columns, raising an `AttributeError` when the validation fails. For a `Series` accessor, you should validate the `dtype` if the accessor applies only to certain `dtypes`.

## 5.5.2 Extension types

New in version 0.23.0.

**Warning:** The `pandas.api.extensions.ExtensionDtype` and `pandas.api.extensions.ExtensionArray` APIs are new and experimental. They may change between versions without warning.

Pandas defines an interface for implementing data types and arrays that *extend* NumPy's type system. Pandas itself uses the extension system for some types that aren't built into NumPy (categorical, period, interval, datetime with timezone).

Libraries can define a custom array and data type. When pandas encounters these objects, they will be handled properly (i.e. not converted to an ndarray of objects). Many methods like `pandas.isna()` will dispatch to the extension type's implementation.

If you're building a library that implements the interface, please publicize it on [ecosystem.extensions](https://ecosystem.extensions).

The interface consists of two classes.

### ExtensionDtype

A `pandas.api.extensions.ExtensionDtype` is similar to a `numpy.dtype` object. It describes the data type. Implementors are responsible for a few unique items like the name.

One particularly important item is the `type` property. This should be the class that is the scalar type for your data. For example, if you were writing an extension array for IP Address data, this might be `ipaddress.IPv4Address`.

See the [extension dtype source](#) for interface definition.

New in version 0.24.0.

`pandas.api.extensions.ExtensionDtype` can be registered to pandas to allow creation via a string dtype name. This allows one to instantiate `Series` and `.astype()` with a registered string name, for example `'category'` is a registered string accessor for the `CategoricalDtype`.

See the [extension dtype dtypes](#) for more on how to register dtypes.

### ExtensionArray

This class provides all the array-like functionality. ExtensionArrays are limited to 1 dimension. An ExtensionArray is linked to an ExtensionDtype via the `dtype` attribute.

Pandas makes no restrictions on how an extension array is created via its `__new__` or `__init__`, and puts no restrictions on how you store your data. We do require that your array be convertible to a NumPy array, even if this is relatively expensive (as it is for `Categorical`).

They may be backed by none, one, or many NumPy arrays. For example, `pandas.Categorical` is an extension array backed by two arrays, one for codes and one for categories. An array of IPv6 addresses may be backed by a NumPy structured array with two fields, one for the lower 64 bits and one for the upper 64 bits. Or they may be backed by some other storage type, like Python lists.

See the [extension array source](#) for the interface definition. The docstrings and comments contain guidance for properly implementing the interface.

## ExtensionArray Operator Support

New in version 0.24.0.

By default, there are no operators defined for the class `ExtensionArray`. There are two approaches for providing operator support for your `ExtensionArray`:

1. Define each of the operators on your `ExtensionArray` subclass.
2. Use an operator implementation from pandas that depends on operators that are already defined on the underlying elements (scalars) of the `ExtensionArray`.

---

**Note:** Regardless of the approach, you may want to set `__array_priority__` if you want your implementation to be called when involved in binary operations with NumPy arrays.

---

For the first approach, you define selected operators, e.g., `__add__`, `__le__`, etc. that you want your `ExtensionArray` subclass to support.

The second approach assumes that the underlying elements (i.e., scalar type) of the `ExtensionArray` have the individual operators already defined. In other words, if your `ExtensionArray` named `MyExtensionArray` is implemented so that each element is an instance of the class `MyExtensionElement`, then if the operators are defined for `MyExtensionElement`, the second approach will automatically define the operators for `MyExtensionArray`.

A mixin class, `ExtensionScalarOpsMixin` supports this second approach. If developing an `ExtensionArray` subclass, for example `MyExtensionArray`, can simply include `ExtensionScalarOpsMixin` as a parent class of `MyExtensionArray`, and then call the methods `_add_arithmetic_ops()` and/or `_add_comparison_ops()` to hook the operators into your `MyExtensionArray` class, as follows:

```
from pandas.api.extensions import ExtensionArray, ExtensionScalarOpsMixin

class MyExtensionArray(ExtensionArray, ExtensionScalarOpsMixin):
    pass

MyExtensionArray._add_arithmetic_ops()
MyExtensionArray._add_comparison_ops()
```

---

**Note:** Since pandas automatically calls the underlying operator on each element one-by-one, this might not be as performant as implementing your own version of the associated operators directly on the `ExtensionArray`.

---

For arithmetic operations, this implementation will try to reconstruct a new `ExtensionArray` with the result of the element-wise operation. Whether or not that succeeds depends on whether the operation returns a result that's valid for the `ExtensionArray`. If an `ExtensionArray` cannot be reconstructed, an `ndarray` containing the scalars returned instead.

For ease of implementation and consistency with operations between pandas and NumPy `ndarrays`, we recommend *not* handling `Series` and `Indexes` in your binary ops. Instead, you should detect these cases and return `NotImplemented`. When pandas encounters an operation like `op(Series, ExtensionArray)`, pandas will

1. unbox the array from the `Series` (`Series.array`)
2. call `result = op(values, ExtensionArray)`
3. re-box the result in a `Series`

## NumPy Universal Functions

Series implements `__array_ufunc__`. As part of the implementation, pandas unboxes the `ExtensionArray` from the `Series`, applies the ufunc, and re-boxes it if necessary.

If applicable, we highly recommend that you implement `__array_ufunc__` in your extension array to avoid coercion to an ndarray. See [the numpy documentation](#) for an example.

As part of your implementation, we require that you defer to pandas when a pandas container (`Series`, `DataFrame`, `Index`) is detected in `inputs`. If any of those is present, you should return `NotImplemented`. Pandas will take care of unboxing the array from the container and re-calling the ufunc with the unwrapped input.

## Testing extension arrays

We provide a test suite for ensuring that your extension arrays satisfy the expected behavior. To use the test suite, you must provide several pytest fixtures and inherit from the base test class. The required fixtures are found in <https://github.com/pandas-dev/pandas/blob/master/pandas/tests/extension/conftest.py>.

To use a test, subclass it:

```
from pandas.tests.extension import base

class TestConstructors(base.BaseConstructorsTests):
    pass
```

See [https://github.com/pandas-dev/pandas/blob/master/pandas/tests/extension/base/\\_\\_init\\_\\_.py](https://github.com/pandas-dev/pandas/blob/master/pandas/tests/extension/base/__init__.py) for a list of all the tests available.

## Compatibility with Apache Arrow

An `ExtensionArray` can support conversion to / from `pyarrow` arrays (and thus support for example serialization to the Parquet file format) by implementing two methods: `ExtensionArray.__arrow_array__` and `ExtensionDtype.__from_arrow__`.

The `ExtensionArray.__arrow_array__` ensures that `pyarrow` knows how to convert the specific extension array into a `pyarrow.Array` (also when included as a column in a pandas `DataFrame`):

```
class MyExtensionArray(ExtensionArray):
    ...

    def __arrow_array__(self, type=None):
        # convert the underlying array values to a pyarrow Array
        import pyarrow
        return pyarrow.array(..., type=type)
```

The `ExtensionDtype.__from_arrow__` method then controls the conversion back from `pyarrow` to a pandas `ExtensionArray`. This method receives a `pyarrow.Array` or `ChunkedArray` as only argument and is expected to return the appropriate pandas `ExtensionArray` for this dtype and the passed values:

```
class ExtensionDtype:
    ...

    def __from_arrow__(self, array: pyarrow.Array/ChunkedArray) -> ExtensionArray:
        ...
```

See more in the [Arrow documentation](#).

Those methods have been implemented for the nullable integer and string extension dtypes included in pandas, and ensure roundtrip to pyarrow and the Parquet file format.

### 5.5.3 Subclassing pandas data structures

**Warning:** There are some easier alternatives before considering subclassing pandas data structures.

1. Extensible method chains with *pipe*
2. Use *composition*. See [here](#).
3. Extending by *registering an accessor*
4. Extending by *extension type*

This section describes how to subclass pandas data structures to meet more specific needs. There are two points that need attention:

1. Override constructor properties.
2. Define original properties

**Note:** You can find a nice example in [geopandas](#) project.

#### Override constructor properties

Each data structure has several *constructor properties* for returning a new data structure as the result of an operation. By overriding these properties, you can retain subclasses through pandas data manipulations.

There are 3 constructor properties to be defined:

- `_constructor`: Used when a manipulation result has the same dimensions as the original.
- `_constructor_sliced`: Used when a manipulation result has one lower dimension(s) as the original, such as DataFrame single columns slicing.
- `_constructor_expanddim`: Used when a manipulation result has one higher dimension as the original, such as `Series.to_frame()`.

Following table shows how pandas data structures define constructor properties by default.

| Property Attributes                 | Series              | DataFrame           |
|-------------------------------------|---------------------|---------------------|
| <code>_constructor</code>           | Series              | DataFrame           |
| <code>_constructor_sliced</code>    | NotImplementedError | Series              |
| <code>_constructor_expanddim</code> | DataFrame           | NotImplementedError |

Below example shows how to define `SubclassedSeries` and `SubclassedDataFrame` overriding constructor properties.

```
class SubclassedSeries(pd.Series):
    @property
```

(continues on next page)

(continued from previous page)

```
def _constructor(self):
    return SubclassedSeries

@property
def _constructor_expanddim(self):
    return SubclassedDataFrame

class SubclassedDataFrame(pd.DataFrame):

    @property
    def _constructor(self):
        return SubclassedDataFrame

    @property
    def _constructor_sliced(self):
        return SubclassedSeries
```

```
>>> s = SubclassedSeries([1, 2, 3])
>>> type(s)
<class '__main__.SubclassedSeries'>

>>> to_framed = s.to_frame()
>>> type(to_framed)
<class '__main__.SubclassedDataFrame'>

>>> df = SubclassedDataFrame({'A': [1, 2, 3], 'B': [4, 5, 6], 'C': [7, 8, 9]})
>>> df
   A  B  C
0  1  4  7
1  2  5  8
2  3  6  9

>>> type(df)
<class '__main__.SubclassedDataFrame'>

>>> sliced1 = df[['A', 'B']]
>>> sliced1
   A  B
0  1  4
1  2  5
2  3  6

>>> type(sliced1)
<class '__main__.SubclassedDataFrame'>

>>> sliced2 = df['A']
>>> sliced2
0    1
1    2
2    3
Name: A, dtype: int64

>>> type(sliced2)
<class '__main__.SubclassedSeries'>
```

## Define original properties

To let original data structures have additional properties, you should let pandas know what properties are added. pandas maps unknown properties to data names overriding `__getattr__`. Defining original properties can be done in one of 2 ways:

1. Define `_internal_names` and `_internal_names_set` for temporary properties which WILL NOT be passed to manipulation results.
2. Define `_metadata` for normal properties which will be passed to manipulation results.

Below is an example to define two original properties, “`internal_cache`” as a temporary property and “`added_property`” as a normal property

```
class SubclassedDataFrame2(pd.DataFrame):

    # temporary properties
    _internal_names = pd.DataFrame._internal_names + ['internal_cache']
    _internal_names_set = set(_internal_names)

    # normal properties
    _metadata = ['added_property']

    @property
    def _constructor(self):
        return SubclassedDataFrame2
```

```
>>> df = SubclassedDataFrame2({'A': [1, 2, 3], 'B': [4, 5, 6], 'C': [7, 8, 9]})
>>> df
   A  B  C
0  1  4  7
1  2  5  8
2  3  6  9

>>> df.internal_cache = 'cached'
>>> df.added_property = 'property'

>>> df.internal_cache
cached
>>> df.added_property
property

# properties defined in _internal_names is reset after manipulation
>>> df[['A', 'B']].internal_cache
AttributeError: 'SubclassedDataFrame2' object has no attribute 'internal_cache'

# properties defined in _metadata are retained
>>> df[['A', 'B']].added_property
property
```

## 5.5.4 Plotting backends

Starting in 0.25 pandas can be extended with third-party plotting backends. The main idea is letting users select a plotting backend different than the provided one based on Matplotlib. For example:

```
>>> pd.set_option('plotting.backend', 'backend.module')
>>> pd.Series([1, 2, 3]).plot()
```

This would be more or less equivalent to:

```
>>> import backend.module
>>> backend.module.plot(pd.Series([1, 2, 3]))
```

The backend module can then use other visualization tools (Bokeh, Altair, ...) to generate the plots.

Libraries implementing the plotting backend should use [entry points](#) to make their backend discoverable to pandas. The key is "pandas\_plotting\_backends". For example, pandas registers the default "matplotlib" backend as follows.

```
# in setup.py
setup( # noqa: F821
    ...,
    entry_points={
        "pandas_plotting_backends": [
            "matplotlib = pandas:plotting._matplotlib",
        ],
    },
)
```

More information on how to implement a third-party plotting backend can be found at [https://github.com/pandas-dev/pandas/blob/master/pandas/plotting/\\_init\\_\\_.py#L1](https://github.com/pandas-dev/pandas/blob/master/pandas/plotting/_init__.py#L1). {{ header }}

## 5.6 Developer

This section will focus on downstream applications of pandas.

### 5.6.1 Storing pandas DataFrame objects in Apache Parquet format

The [Apache Parquet](#) format provides key-value metadata at the file and column level, stored in the footer of the Parquet file:

```
5: optional list<KeyValue> key_value_metadata
```

where KeyValue is

```
struct KeyValue {
  1: required string key
  2: optional string value
}
```

So that a `pandas.DataFrame` can be faithfully reconstructed, we store a pandas metadata key in the `FileMetaData` with the value stored as :

```
{'index_columns': [<descr0>, <descr1>, ...],
 'column_indexes': [<ci0>, <ci1>, ..., <ciN>],
 'columns': [<c0>, <c1>, ...],
 'pandas_version': $VERSION,
 'creator': {
   'library': $LIBRARY,
   'version': $LIBRARY_VERSION
 }}
```

The “descriptor” values <descr0> in the 'index\_columns' field are strings (referring to a column) or dictionaries with values as described below.

The <c0>/<ci0> and so forth are dictionaries containing the metadata for each column, *including the index columns*. This has JSON form:

```
{'name': column_name,
 'field_name': parquet_column_name,
 'pandas_type': pandas_type,
 'numpy_type': numpy_type,
 'metadata': metadata}
```

See below for the detailed specification for these.

## Index Metadata Descriptors

RangeIndex can be stored as metadata only, not requiring serialization. The descriptor format for these as is follows:

```
index = pd.RangeIndex(0, 10, 2)
{'kind': 'range',
 'name': index.name,
 'start': index.start,
 'stop': index.stop,
 'step': index.step}
```

Other index types must be serialized as data columns along with the other DataFrame columns. The metadata for these is a string indicating the name of the field in the data columns, for example '\_\_index\_level\_0\_\_'.

If an index has a non-None name attribute, and there is no other column with a name matching that value, then the index.name value can be used as the descriptor. Otherwise (for unnamed indexes and ones with names colliding with other column names) a disambiguating name with pattern matching \_\_index\_level\_\d+\_\_ should be used. In cases of named indexes as data columns, name attribute is always stored in the column descriptors as above.

## Column Metadata

pandas\_type is the logical type of the column, and is one of:

- Boolean: 'bool'
- Integers: 'int8', 'int16', 'int32', 'int64', 'uint8', 'uint16', 'uint32', 'uint64'
- Floats: 'float16', 'float32', 'float64'
- Date and Time Types: 'datetime', 'datetimetz', 'timedelta'
- String: 'unicode', 'bytes'
- Categorical: 'categorical'

- Other Python objects: 'object'

The `numpy_type` is the physical storage type of the column, which is the result of `str(dtype)` for the underlying NumPy array that holds the data. So for `datetimetz` this is `datetime64[ns]` and for `categorical`, it may be any of the supported integer categorical types.

The `metadata` field is `None` except for:

- `datetimetz`: {'timezone': zone, 'unit': 'ns'}, e.g. {'timezone': 'America/New\_York', 'unit': 'ns'}. The 'unit' is optional, and if omitted it is assumed to be nanoseconds.
- `categorical`: {'num\_categories': K, 'ordered': is\_ordered, 'type': \$TYPE}
  - Here 'type' is optional, and can be a nested pandas type specification here (but not categorical)
- `unicode`: {'encoding': encoding}
  - The encoding is optional, and if not present is UTF-8
- `object`: {'encoding': encoding}. Objects can be serialized and stored in `BYTE_ARRAY` Parquet columns. The encoding can be one of:
  - 'pickle'
  - 'bson'
  - 'json'
- `timedelta`: {'unit': 'ns'}. The 'unit' is optional, and if omitted it is assumed to be nanoseconds. This metadata is optional altogether

For types other than these, the 'metadata' key can be omitted. Implementations can assume `None` if the key is not present.

As an example of fully-formed metadata:

```
{'index_columns': ['__index_level_0__'],
 'column_indexes': [
   {'name': None,
    'field_name': 'None',
    'pandas_type': 'unicode',
    'numpy_type': 'object',
    'metadata': {'encoding': 'UTF-8'}}
 ],
 'columns': [
   {'name': 'c0',
    'field_name': 'c0',
    'pandas_type': 'int8',
    'numpy_type': 'int8',
    'metadata': None},
   {'name': 'c1',
    'field_name': 'c1',
    'pandas_type': 'bytes',
    'numpy_type': 'object',
    'metadata': None},
   {'name': 'c2',
    'field_name': 'c2',
    'pandas_type': 'categorical',
    'numpy_type': 'int16',
    'metadata': {'num_categories': 1000, 'ordered': False}},
   {'name': 'c3',
    'field_name': 'c3',
    'pandas_type': 'datetimetz',
```

(continues on next page)

(continued from previous page)

```

'numpy_type': 'datetime64[ns]',
'metadata': {'timezone': 'America/Los_Angeles'}},
{'name': 'c4',
 'field_name': 'c4',
 'pandas_type': 'object',
 'numpy_type': 'object',
 'metadata': {'encoding': 'pickle'}},
{'name': None,
 'field_name': '__index_level_0__',
 'pandas_type': 'int64',
 'numpy_type': 'int64',
 'metadata': None}
],
'pandas_version': '0.20.0',
'creator': {
  'library': 'pyarrow',
  'version': '0.13.0'
}}

```

## 5.7 Policies

### 5.7.1 Version Policy

Changed in version 1.0.0.

Pandas uses a loose variant of semantic versioning ([SemVer](#)) to govern deprecations, API compatibility, and version numbering.

A pandas release number is made up of MAJOR.MINOR.PATCH.

API breaking changes should only occur in **major** releases. These changes will be documented, with clear guidance on what is changing, why it's changing, and how to migrate existing code to the new behavior.

Whenever possible, a deprecation path will be provided rather than an outright breaking change.

Pandas will introduce deprecations in **minor** releases. These deprecations will preserve the existing behavior while emitting a warning that provide guidance on:

- How to achieve similar behavior if an alternative is available
- The pandas version in which the deprecation will be enforced.

We will not introduce new deprecations in patch releases.

Deprecations will only be enforced in **major** releases. For example, if a behavior is deprecated in pandas 1.2.0, it will continue to work, with a warning, for all releases in the 1.x series. The behavior will change and the deprecation removed in the next next major release (2.0.0).

---

**Note:** Pandas will sometimes make *behavior changing* bug fixes, as part of minor or patch releases. Whether or not a change is a bug fix or an API-breaking change is a judgement call. We'll do our best, and we invite you to participate in development discussion on the issue tracker or mailing list.

---

These policies do not apply to features marked as **experimental** in the documentation. Pandas may change the behavior of experimental features at any time.

## 5.7.2 Python Support

Pandas will only drop support for specific Python versions (e.g. 3.6.x, 3.7.x) in pandas **major** releases.

## 5.8 Roadmap

This page provides an overview of the major themes in pandas' development. Each of these items requires a relatively large amount of effort to implement. These may be achieved more quickly with dedicated funding or interest from contributors.

An item being on the roadmap does not mean that it will *necessarily* happen, even with unlimited funding. During the implementation period we may discover issues preventing the adoption of the feature.

Additionally, an item *not* being on the roadmap does not exclude it from inclusion in pandas. The roadmap is intended for larger, fundamental changes to the project that are likely to take months or years of developer time. Smaller-scoped items will continue to be tracked on our [issue tracker](#).

See *Roadmap Evolution* for proposing changes to this document.

### 5.8.1 Extensibility

Pandas *Extension types* allow for extending NumPy types with custom data types and array storage. Pandas uses extension types internally, and provides an interface for 3rd-party libraries to define their own custom data types.

Many parts of pandas still unintentionally convert data to a NumPy array. These problems are especially pronounced for nested data.

We'd like to improve the handling of extension arrays throughout the library, making their behavior more consistent with the handling of NumPy arrays. We'll do this by cleaning up pandas' internals and adding new methods to the extension array interface.

### 5.8.2 String data type

Currently, pandas stores text data in an `object`-dtype NumPy array. The current implementation has two primary drawbacks: First, `object`-dtype is not specific to strings: any Python object can be stored in an `object`-dtype array, not just strings. Second: this is not efficient. The NumPy memory model isn't especially well-suited to variable width text data.

To solve the first issue, we propose a new extension type for string data. This will initially be opt-in, with users explicitly requesting `dtype="string"`. The array backing this string dtype may initially be the current implementation: an `object`-dtype NumPy array of Python strings.

To solve the second issue (performance), we'll explore alternative in-memory array libraries (for example, Apache Arrow). As part of the work, we may need to implement certain operations expected by pandas users (for example the algorithm used in `Series.str.upper`). That work may be done outside of pandas.

### 5.8.3 Apache Arrow interoperability

Apache Arrow is a cross-language development platform for in-memory data. The Arrow logical types are closely aligned with typical pandas use cases.

We'd like to provide better-integrated support for Arrow memory and data types within pandas. This will let us take advantage of its I/O capabilities and provide for better interoperability with other languages and libraries using Arrow.

### 5.8.4 Block manager rewrite

We'd like to replace pandas current internal data structures (a collection of 1 or 2-D arrays) with a simpler collection of 1-D arrays.

Pandas internal data model is quite complex. A DataFrame is made up of one or more 2-dimensional "blocks", with one or more blocks per dtype. This collection of 2-D arrays is managed by the BlockManager.

The primary benefit of the BlockManager is improved performance on certain operations (construction from a 2D array, binary operations, reductions across the columns), especially for wide DataFrames. However, the BlockManager substantially increases the complexity and maintenance burden of pandas.

By replacing the BlockManager we hope to achieve

- Substantially simpler code
- Easier extensibility with new logical types
- Better user control over memory use and layout
- Improved micro-performance
- Option to provide a C / Cython API to pandas' internals

See [these design documents](#) for more.

### 5.8.5 Decoupling of indexing and internals

The code for getting and setting values in pandas' data structures needs refactoring. In particular, we must clearly separate code that converts keys (e.g., the argument to `DataFrame.loc`) to positions from code that uses these positions to get or set values. This is related to the proposed BlockManager rewrite. Currently, the BlockManager sometimes uses label-based, rather than position-based, indexing. We propose that it should only work with positional indexing, and the translation of keys to positions should be entirely done at a higher level.

Indexing is a complicated API with many subtleties. This refactor will require care and attention. More details are discussed at [https://github.com/pandas-dev/pandas/wiki/\(Tentative\)-rules-for-restructuring-indexing-code](https://github.com/pandas-dev/pandas/wiki/(Tentative)-rules-for-restructuring-indexing-code)

### 5.8.6 Numba-accelerated operations

Numba is a JIT compiler for Python code. We'd like to provide ways for users to apply their own Numba-jitted functions where pandas accepts user-defined functions (for example, `Series.apply()`, `DataFrame.apply()`, `DataFrame.applymap()`, and in `groupby` and `window` contexts). This will improve the performance of user-defined-functions in these operations by staying within compiled code.

## 5.8.7 Documentation improvements

We'd like to improve the content, structure, and presentation of the pandas documentation. Some specific goals include

- Overhaul the HTML theme with a modern, responsive design ([GH15556](#))
- Improve the “Getting Started” documentation, designing and writing learning paths for users different backgrounds (e.g. brand new to programming, familiar with other languages like R, already familiar with Python).
- Improve the overall organization of the documentation and specific subsections of the documentation to make navigation and finding content easier.

## 5.8.8 Package docstring validation

To improve the quality and consistency of pandas docstrings, we've developed tooling to check docstrings in a variety of ways. [https://github.com/pandas-dev/pandas/blob/master/scripts/validate\\_docstrings.py](https://github.com/pandas-dev/pandas/blob/master/scripts/validate_docstrings.py) contains the checks.

Like many other projects, pandas uses the `numpydoc` style for writing docstrings. With the collaboration of the `numpydoc` maintainers, we'd like to move the checks to a package other than pandas so that other projects can easily use them as well.

## 5.8.9 Performance monitoring

Pandas uses `airspeed velocity` to monitor for performance regressions. ASV itself is a fabulous tool, but requires some additional work to be integrated into an open source project's workflow.

The `asv-runner` organization, currently made up of pandas maintainers, provides tools built on top of ASV. We have a physical machine for running a number of project's benchmarks, and tools managing the benchmark runs and reporting on results.

We'd like to fund improvements and maintenance of these tools to

- Be more stable. Currently, they're maintained on the nights and weekends when a maintainer has free time.
- Tune the system for benchmarks to improve stability, following <https://pyperf.readthedocs.io/en/latest/system.html>
- Build a GitHub bot to request ASV runs *before* a PR is merged. Currently, the benchmarks are only run nightly.

## 5.8.10 Roadmap Evolution

Pandas continues to evolve. The direction is primarily determined by community interest. Everyone is welcome to review existing items on the roadmap and to propose a new item.

Each item on the roadmap should be a short summary of a larger design proposal. The proposal should include

1. Short summary of the changes, which would be appropriate for inclusion in the roadmap if accepted.
2. Motivation for the changes.
3. An explanation of why the change is in scope for pandas.
4. Detailed design: Preferably with example-usage (even if not implemented yet) and API documentation
5. API Change: Any API changes that may result from the proposal.

That proposal may then be submitted as a GitHub issue, where the pandas maintainers can review and comment on the design. The [pandas mailing list](#) should be notified of the proposal.

When there's agreement that an implementation would be welcome, the roadmap should be updated to include the summary and a link to the discussion issue.

## 5.9 Developer Meetings

We hold regular developer meetings on the second Wednesday of each month at 18:00 UTC. These meetings and their minutes are open to the public. All are welcome to join.

### 5.9.1 Minutes

The minutes of past meetings are available in [this Google Document](#).

### 5.9.2 Calendar

This calendar shows all the developer meetings.

You can subscribe to this calendar with the following links:

- [iCal](#)
- [Google calendar](#)

Additionally, we'll sometimes have one-off meetings on specific topics. These will be published on the same calendar.  
{{ header }}

## RELEASE NOTES

This is the list of changes to pandas between each release. For full details, see the commit logs at <http://github.com/pandas-dev/pandas>. For install and upgrade instructions, see [Installing statsmodels](#).

### 6.1 Version 1.0

### 6.2 Version 0.25

#### 6.2.1 What's new in 0.25.3 (October 31, 2019)

These are the changes in pandas 0.25.3. See release for a full changelog including other versions of pandas.

#### Bug fixes

##### Groupby/resample/rolling

- Bug in `DataFrameGroupBy.quantile()` where NA values in the grouping could cause segfaults or incorrect results (GH28882)

#### Contributors

A total of 3 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

- Will Ayd
- William Ayd
- jbrockmendel

## 6.2.2 What's new in 0.25.2 (October 15, 2019)

These are the changes in pandas 0.25.2. See release for a full changelog including other versions of pandas.

---

**Note:** Pandas 0.25.2 adds compatibility for Python 3.8 ([GH28147](#)).

---

### Bug fixes

#### Indexing

- Fix regression in `DataFrame.reindex()` not following the `limit` argument ([GH28631](#)).
- Fix regression in `RangeIndex.get_indexer()` for decreasing `RangeIndex` where target values may be improperly identified as missing/present ([GH28678](#))

#### I/O

- Fix regression in notebook display where `<th>` tags were missing for `DataFrame.index` values ([GH28204](#)).
- Regression in `to_csv()` where writing a `Series` or `DataFrame` indexed by an `IntervalIndex` would incorrectly raise a `TypeError` ([GH28210](#))
- Fix `to_csv()` with `ExtensionArray` with list-like values ([GH28840](#)).

#### Groupby/resample/rolling

- Bug incorrectly raising an `IndexError` when passing a list of quantiles to `pandas.core.groupby.DataFrameGroupBy.quantile()` ([GH28113](#)).
- Bug in `pandas.core.groupby.GroupBy.shift()`, `pandas.core.groupby.GroupBy.bfill()` and `pandas.core.groupby.GroupBy.ffill()` where timezone information would be dropped ([GH19995](#), [GH27992](#))

#### Other

- Compatibility with Python 3.8 in `DataFrame.query()` ([GH27261](#))
- Fix to ensure that tab-completion in an IPython console does not raise warnings for deprecated attributes ([GH27900](#)).

#### Contributors

A total of 6 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

- Felix Divo +
- Jeremy Schendel
- Joris Van den Bossche
- MeeseeksMachine

- Tom Augspurger
- jbrockmendel

### 6.2.3 What's new in 0.25.1 (August 21, 2019)

These are the changes in pandas 0.25.1. See release for a full changelog including other versions of pandas.

#### I/O and LZMA

Some users may unknowingly have an incomplete Python installation lacking the *lzma* module from the standard library. In this case, `import pandas` failed due to an `ImportError` (GH27575). Pandas will now warn, rather than raising an `ImportError` if the *lzma* module is not present. Any subsequent attempt to use *lzma* methods will raise a `RuntimeError`. A possible fix for the lack of the *lzma* module is to ensure you have the necessary libraries and then re-install Python. For example, on MacOS installing Python with *pyenv* may lead to an incomplete Python installation due to unmet system dependencies at compilation time (like *xz*). Compilation will succeed, but Python might fail at run time. The issue can be solved by installing the necessary dependencies and then re-installing Python.

#### Bug fixes

##### Categorical

- Bug in `Categorical.fillna()` that would replace all values, not just those that are NaN (GH26215)

##### Datetimelike

- Bug in `to_datetime()` where passing a timezone-naive `DatetimeArray` or `DatetimeIndex` and `utc=True` would incorrectly return a timezone-naive result (GH27733)
- Bug in `Period.to_timestamp()` where a `Period` outside the `Timestamp` implementation bounds (roughly 1677-09-21 to 2262-04-11) would return an incorrect `Timestamp` instead of raising `OutOfBoundsDatetime` (GH19643)
- Bug in iterating over `DatetimeIndex` when the underlying data is read-only (GH28055)

##### Timezones

- Bug in `Index` where a numpy object array with a timezone aware `Timestamp` and `np.nan` would not return a `DatetimeIndex` (GH27011)

##### Numeric

- Bug in `Series.interpolate()` when using a timezone aware `DatetimeIndex` (GH27548)
- Bug when printing negative floating point complex numbers would raise an `IndexError` (GH27484)
- Bug where `DataFrame` arithmetic operators such as `DataFrame.mul()` with a `Series` with `axis=1` would raise an `AttributeError` on `DataFrame` larger than the minimum threshold to invoke `numexpr` (GH27636)
- Bug in `DataFrame` arithmetic where missing values in results were incorrectly masked with NaN instead of `Inf` (GH27464)

## Conversion

- Improved the warnings for the deprecated methods `Series.real()` and `Series.imag()` (GH27610)

## Interval

- Bug in `IntervalIndex` where `dir(obj)` would raise `ValueError` (GH27571)

## Indexing

- Bug in partial-string indexing returning a NumPy array rather than a `Series` when indexing with a scalar like `.loc['2015']` (GH27516)
- Break reference cycle involving `Index` and other index classes to allow garbage collection of index objects without running the GC. (GH27585, GH27840)
- Fix regression in assigning values to a single column of a `DataFrame` with a `MultiIndex` columns (GH27841).
- Fix regression in `.ix` fallback with an `IntervalIndex` (GH27865).

## Missing

- Bug in `pandas.isnull()` or `pandas.isna()` when the input is a type e.g. `type(pandas.Series())` (GH27482)

## I/O

- Avoid calling `S3File.s3` when reading parquet, as this was removed in `s3fs` version 0.3.0 (GH27756)
- Better error message when a negative header is passed in `pandas.read_csv()` (GH27779)
- Follow the `min_rows` display option (introduced in v0.25.0) correctly in the HTML repr in the notebook (GH27991).

## Plotting

- Added a `pandas_plotting_backends` entrypoint group for registering plot backends. See *Plotting backends* for more (GH26747).
- Fixed the re-instatement of Matplotlib datetime converters after calling `pandas.plotting.deregister_matplotlib_converters()` (GH27481).
- Fix compatibility issue with matplotlib when passing a pandas `Index` to a plot call (GH27775).

## Groupby/resample/rolling

- Fixed regression in `pandas.core.groupby.DataFrameGroupBy.quantile()` raising when multiple quantiles are given (GH27526)
- Bug in `pandas.core.groupby.DataFrameGroupBy.transform()` where applying a timezone conversion lambda function would drop timezone information (GH27496)
- Bug in `pandas.core.groupby.GroupBy.nth()` where `observed=False` was being ignored for Categorical groupers (GH26385)
- Bug in windowing over read-only arrays (GH27766)
- Fixed segfault in `pandas.core.groupby.DataFrameGroupBy.quantile` when an invalid quantile was passed (GH27470)

## Reshaping

- A `KeyError` is now raised if `.unstack()` is called on a `Series` or `DataFrame` with a flat `Index` passing a name which is not the correct one (GH18303)
- Bug `merge_asof()` could not merge `Timedelta` objects when passing `tolerance` kwarg (GH27642)
- Bug in `DataFrame.crosstab()` when `margins` set to `True` and `normalize` is not `False`, an error is raised. (GH27500)
- `DataFrame.join()` now suppresses the `FutureWarning` when the `sort` parameter is specified (GH21952)
- Bug in `DataFrame.join()` raising with readonly arrays (GH27943)

## Sparse

- Bug in reductions for `Series` with `Sparse` dtypes (GH27080)

## Other

- Bug in `Series.replace()` and `DataFrame.replace()` when replacing timezone-aware timestamps using a dict-like replacer (GH27720)
- Bug in `Series.rename()` when using a custom type indexer. Now any value that isn't callable or dict-like is treated as a scalar. (GH27814)

## Contributors

A total of 5 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

- Jeff Reback
- Joris Van den Bossche
- MeeseeksMachine +
- Tom Augspurger
- jbrockmendel

## 6.2.4 What's new in 0.25.0 (July 18, 2019)

**Warning:** Starting with the 0.25.x series of releases, pandas only supports Python 3.5.3 and higher. See [Dropping Python 2.7](#) for more details.

**Warning:** The minimum supported Python version will be bumped to 3.6 in a future release.

**Warning:** *Panel* has been fully removed. For N-D labeled data structures, please use `xarray`

**Warning:** `read_pickle()` and `read_msgpack()` are only guaranteed backwards compatible back to pandas version 0.20.3 (GH27082)

{{ header }}

These are the changes in pandas 0.25.0. See release for a full changelog including other versions of pandas.

### Enhancements

#### Groupby aggregation with relabeling

Pandas has added special groupby behavior, known as “named aggregation”, for naming the output columns when applying multiple aggregation functions to specific columns (GH18366, GH26512).

```
In [1]: animals = pd.DataFrame({'kind': ['cat', 'dog', 'cat', 'dog'],
...:                           'height': [9.1, 6.0, 9.5, 34.0],
...:                           'weight': [7.9, 7.5, 9.9, 198.0]})
...:

In [2]: animals
Out [2]:
   kind  height  weight
0  cat     9.1     7.9
1  dog     6.0     7.5
2  cat     9.5     9.9
3  dog    34.0   198.0

[4 rows x 3 columns]

In [3]: animals.groupby("kind").agg(
...:     min_height=pd.NamedAgg(column='height', aggfunc='min'),
...:     max_height=pd.NamedAgg(column='height', aggfunc='max'),
...:     average_weight=pd.NamedAgg(column='weight', aggfunc=np.mean),
...: )
Out [3]:
   min_height  max_height  average_weight
kind
cat         9.1         9.5             8.5
dog        34.0        198.0            71.25
```

(continues on next page)

(continued from previous page)

```
cat      9.1      9.5      8.90
dog      6.0     34.0     102.75

[2 rows x 3 columns]
```

Pass the desired columns names as the `**kwargs` to `.agg`. The values of `**kwargs` should be tuples where the first element is the column selection, and the second element is the aggregation function to apply. Pandas provides the `pandas.NamedAgg` namedtuple to make it clearer what the arguments to the function are, but plain tuples are accepted as well.

```
In [4]: animals.groupby("kind").agg(
...:     min_height=('height', 'min'),
...:     max_height=('height', 'max'),
...:     average_weight=('weight', np.mean),
...: )
...:
Out [4]:
      min_height  max_height  average_weight
kind
cat           9.1         9.5           8.90
dog           6.0        34.0          102.75

[2 rows x 3 columns]
```

Named aggregation is the recommended replacement for the deprecated “dict-of-dicts” approach to naming the output of column-specific aggregations (*Deprecate `groupby.agg()` with a dictionary when renaming*).

A similar approach is now available for Series groupby objects as well. Because there’s no need for column selection, the values can just be the functions to apply

```
In [5]: animals.groupby("kind").height.agg(
...:     min_height="min",
...:     max_height="max",
...: )
...:
Out [5]:
      min_height  max_height
kind
cat           9.1         9.5
dog           6.0        34.0

[2 rows x 2 columns]
```

This type of aggregation is the recommended alternative to the deprecated behavior when passing a dict to a Series groupby aggregation (*Deprecate `groupby.agg()` with a dictionary when renaming*).

See *Named aggregation* for more.

## Groupby Aggregation with multiple lambdas

You can now provide multiple lambda functions to a list-like aggregation in `pandas.core.groupby.GroupBy.agg` (GH26430).

```
In [6]: animals.groupby('kind').height.agg([
...:     lambda x: x.iloc[0], lambda x: x.iloc[-1]
...: ])
...:
Out [6]:
      <lambda_0>  <lambda_1>
kind
cat           9.1         9.5
dog           6.0        34.0

[2 rows x 2 columns]
```

```
In [7]: animals.groupby('kind').agg([
...:     lambda x: x.iloc[0] - x.iloc[1],
...:     lambda x: x.iloc[0] + x.iloc[1]
...: ])
...:
Out [7]:
      height      weight
      <lambda_0> <lambda_1> <lambda_0> <lambda_1>
kind
cat      -0.4      18.6      -2.0      17.8
dog     -28.0      40.0     -190.5     205.5

[2 rows x 4 columns]
```

Previously, these raised a `SpecificationError`.

## Better repr for MultiIndex

Printing of `MultiIndex` instances now shows tuples of each row and ensures that the tuple items are vertically aligned, so it's now easier to understand the structure of the `MultiIndex`. (GH13480):

The repr now looks like this:

```
In [8]: pd.MultiIndex.from_product(['a', 'abc'], range(500))
Out [8]:
MultiIndex([( 'a',  0),
            ( 'a',  1),
            ( 'a',  2),
            ( 'a',  3),
            ( 'a',  4),
            ( 'a',  5),
            ( 'a',  6),
            ( 'a',  7),
            ( 'a',  8),
            ( 'a',  9),
            ...
            ('abc', 490),
            ('abc', 491),
            ('abc', 492),
```

(continues on next page)

(continued from previous page)

```

('abc', 493),
('abc', 494),
('abc', 495),
('abc', 496),
('abc', 497),
('abc', 498),
('abc', 499)],
length=1000)

```

Previously, outputting a `MultiIndex` printed all the levels and codes of the `MultiIndex`, which was visually unappealing and made the output more difficult to navigate. For example (limiting the range to 5):

```

In [1]: pd.MultiIndex.from_product(['a', 'abc'], range(5))
Out[1]: MultiIndex(levels=[['a', 'abc'], [0, 1, 2, 3]],
...:          codes=[[0, 0, 0, 0, 1, 1, 1, 1], [0, 1, 2, 3, 0, 1, 2, 3]])

```

In the new repr, all values will be shown, if the number of rows is smaller than `options.display.max_seq_items` (default: 100 items). Horizontally, the output will truncate, if it's wider than `options.display.width` (default: 80 characters).

### Shorter truncated repr for Series and DataFrame

Currently, the default display options of pandas ensure that when a `Series` or `DataFrame` has more than 60 rows, its repr gets truncated to this maximum of 60 rows (the `display.max_rows` option). However, this still gives a repr that takes up a large part of the vertical screen estate. Therefore, a new option `display.min_rows` is introduced with a default of 10 which determines the number of rows showed in the truncated repr:

- For small `Series` or `DataFrames`, up to `max_rows` number of rows is shown (default: 60).
- For larger `Series` or `DataFrame` with a length above `max_rows`, only `min_rows` number of rows is shown (default: 10, i.e. the first and last 5 rows).

This dual option allows to still see the full content of relatively small objects (e.g. `df.head(20)` shows all 20 rows), while giving a brief repr for large objects.

To restore the previous behaviour of a single threshold, set `pd.options.display.min_rows = None`.

### Json normalize with max\_level param support

`json_normalize()` normalizes the provided input dict to all nested levels. The new `max_level` parameter provides more control over which level to end normalization ([GH23843](#)):

The repr now looks like this:

```

from pandas.io.json import json_normalize
data = [{
    'CreatedBy': {'Name': 'User001'},
    'Lookup': {'TextField': 'Some text',
              'UserField': {'Id': 'ID001', 'Name': 'Name001'}},
    'Image': {'a': 'b'}
}]
json_normalize(data, max_level=1)

```

## Series.explode to split list-like values to rows

Series and DataFrame have gained the DataFrame.explode() methods to transform list-likes to individual rows. See *section on Exploding list-like column* in docs for more information ([GH16538](#), [GH10511](#))

Here is a typical usecase. You have comma separated string in a column.

```
In [9]: df = pd.DataFrame([{'var1': 'a,b,c', 'var2': 1},
...:                      {'var1': 'd,e,f', 'var2': 2}])
...:

In [10]: df
Out[10]:
   var1  var2
0  a,b,c    1
1  d,e,f    2

[2 rows x 2 columns]
```

Creating a long form DataFrame is now straightforward using chained operations

```
In [11]: df.assign(var1=df.var1.str.split(',')).explode('var1')
Out[11]:
   var1  var2
0     a    1
0     b    1
0     c    1
1     d    2
1     e    2
1     f    2

[6 rows x 2 columns]
```

## Other enhancements

- DataFrame.plot() keywords logy, logx and loglog can now accept the value 'sym' for symlog scaling. ([GH24867](#))
- Added support for ISO week year format ('%G-%V-%u') when parsing datetimes using to\_datetime() ([GH16607](#))
- Indexing of DataFrame and Series now accepts zerodim np.ndarray ([GH24919](#))
- Timestamp.replace() now supports the fold argument to disambiguate DST transition times ([GH25017](#))
- DataFrame.at\_time() and Series.at\_time() now support datetime.time objects with time-zones ([GH24043](#))
- DataFrame.pivot\_table() now accepts an observed parameter which is passed to underlying calls to DataFrame.groupby() to speed up grouping categorical data. ([GH24923](#))
- Series.str has gained Series.str.casefold() method to removes all case distinctions present in a string ([GH25405](#))
- DataFrame.set\_index() now works for instances of abc.Iterator, provided their output is of the same length as the calling frame ([GH22484](#), [GH24984](#))

- `DatetimeIndex.union()` now supports the `sort` argument. The behavior of the `sort` parameter matches that of `Index.union()` (GH24994)
- `RangeIndex.union()` now supports the `sort` argument. If `sort=False` an unsorted `Int64Index` is always returned. `sort=None` is the default and returns a monotonically increasing `RangeIndex` if possible or a sorted `Int64Index` if not (GH24471)
- `TimedeltaIndex.intersection()` now also supports the `sort` keyword (GH24471)
- `DataFrame.rename()` now supports the `errors` argument to raise errors when attempting to rename nonexistent keys (GH13473)
- Added *Sparse accessor* for working with a `DataFrame` whose values are sparse (GH25681)
- `RangeIndex` has gained `start`, `stop`, and `step` attributes (GH25710)
- `datetime.timezone` objects are now supported as arguments to `timezone` methods and constructors (GH25065)
- `DataFrame.query()` and `DataFrame.eval()` now supports quoting column names with backticks to refer to names with spaces (GH6508)
- `merge_asof()` now gives a more clear error message when merge keys are categoricals that are not equal (GH26136)
- `pandas.core.window.Rolling()` supports exponential (or Poisson) window type (GH21303)
- Error message for missing required imports now includes the original import error's text (GH23868)
- `DatetimeIndex` and `TimedeltaIndex` now have a `mean` method (GH24757)
- `DataFrame.describe()` now formats integer percentiles without decimal point (GH26660)
- Added support for reading SPSS `.sav` files using `read_spss()` (GH26537)
- Added new option `plotting.backend` to be able to select a plotting backend different than the existing `matplotlib` one. Use `pandas.set_option('plotting.backend', '<backend-module>')` where `<backend-module>` is a library implementing the pandas plotting API (GH14130)
- `pandas.offsets.BusinessHour` supports multiple opening hours intervals (GH15481)
- `read_excel()` can now use `openpyxl` to read Excel files via the `engine='openpyxl'` argument. This will become the default in a future release (GH11499)
- `pandas.io.excel.read_excel()` supports reading OpenDocument tables. Specify `engine='odf'` to enable. Consult the *IO User Guide* for more details (GH9070)
- `Interval`, `IntervalIndex`, and `IntervalArray` have gained an `is_empty` attribute denoting if the given interval(s) are empty (GH27219)

## Backwards incompatible API changes

### Indexing with date strings with UTC offsets

Indexing a `DataFrame` or `Series` with a `DatetimeIndex` with a date string with a UTC offset would previously ignore the UTC offset. Now, the UTC offset is respected in indexing. (GH24076, GH16785)

```
In [12]: df = pd.DataFrame([0], index=pd.DatetimeIndex(['2019-01-01'], tz='US/Pacific
↪'))
```

```
In [13]: df
Out [13]:
```

(continues on next page)

(continued from previous page)

```

                0
2019-01-01 00:00:00-08:00 0

[1 rows x 1 columns]
```

*Previous behavior:*

```

In [3]: df['2019-01-01 00:00:00+04:00':'2019-01-01 01:00:00+04:00']
Out [3]:
                0
2019-01-01 00:00:00-08:00 0
```

*New behavior:*

```

In [14]: df['2019-01-01 12:00:00+04:00':'2019-01-01 13:00:00+04:00']
Out [14]:
                0
2019-01-01 00:00:00-08:00 0

[1 rows x 1 columns]
```

### MultiIndex constructed from levels and codes

Constructing a `MultiIndex` with `NaN` levels or codes value `< -1` was allowed previously. Now, construction with codes value `< -1` is not allowed and `NaN` levels' corresponding codes would be reassigned as `-1`. (GH19387)

*Previous behavior:*

```

In [1]: pd.MultiIndex(levels=[[np.nan, None, pd.NaT, 128, 2]],
...:                  codes=[[0, -1, 1, 2, 3, 4]])
...:
...:
Out [1]: MultiIndex(levels=[[nan, None, NaT, 128, 2]],
...:                  codes=[[0, -1, 1, 2, 3, 4]])

In [2]: pd.MultiIndex(levels=[[1, 2]], codes=[[0, -2]])
Out [2]: MultiIndex(levels=[[1, 2]],
...:                  codes=[[0, -2]])
```

*New behavior:*

```

In [15]: pd.MultiIndex(levels=[[np.nan, None, pd.NaT, 128, 2]],
...:                  codes=[[0, -1, 1, 2, 3, 4]])
...:
...:
Out [15]:
MultiIndex([(nan,),
            (nan,),
            (nan,),
            (nan,),
            (128,),
            ( 2,)],
           )

In [16]: pd.MultiIndex(levels=[[1, 2]], codes=[[0, -2]])
-----
ValueError                                Traceback (most recent call last)
```

(continues on next page)

(continued from previous page)

```

<ipython-input-16-225a01af3975> in <module>
----> 1 pd.MultiIndex(levels=[[1, 2]], codes=[[0, -2]])

/pandas/pandas/core/indexes/multi.py in __new__(cls, levels, codes, sortorder, names,
-> dtype, copy, name, verify_integrity, _set_identity)

    279         if verify_integrity:
--> 280             new_codes = result._verify_integrity()
    281             result._codes = new_codes
    282

/pandas/pandas/core/indexes/multi.py in _verify_integrity(self, codes, levels)
    352         )
    353         if len(level_codes) and level_codes.min() < -1:
--> 354             raise ValueError(f"On level {i}, code value ({level_codes.
->min()}) < -1")
    355         if not level.is_unique:
    356             raise ValueError(

ValueError: On level 0, code value (-2) < -1

```

### Groupby . apply ON DataFrame evaluates first group only once

The implementation of `DataFrameGroupBy.apply()` previously evaluated the supplied function consistently twice on the first group to infer if it is safe to use a fast code path. Particularly for functions with side effects, this was an undesired behavior and may have led to surprises. (GH2936, GH2656, GH7739, GH10519, GH12155, GH20084, GH21417)

Now every group is evaluated only a single time.

```

In [17]: df = pd.DataFrame({"a": ["x", "y"], "b": [1, 2]})

In [18]: df
Out[18]:
   a  b
0  x  1
1  y  2

[2 rows x 2 columns]

In [19]: def func(group):
.....:     print(group.name)
.....:     return group
.....:

```

*Previous behavior:*

```

In [3]: df.groupby('a').apply(func)
x
x
y
Out[3]:
   a  b
0  x  1
1  y  2

```

*New behavior:*

```
In [20]: df.groupby("a").apply(func)
x
y
Out [20]:
   a  b
0  x  1
1  y  2

[2 rows x 2 columns]
```

## Concatenating sparse values

When passed DataFrames whose values are sparse, `concat()` will now return a Series or DataFrame with sparse values, rather than a SparseDataFrame (GH25702).

```
In [21]: df = pd.DataFrame({"A": pd.SparseArray([0, 1])})
```

*Previous behavior:*

```
In [2]: type(pd.concat([df, df]))
pandas.core.sparse.frame.SparseDataFrame
```

*New behavior:*

```
In [22]: type(pd.concat([df, df]))
Out [22]: pandas.core.frame.DataFrame
```

This now matches the existing behavior of `concat` on Series with sparse values. `concat()` will continue to return a SparseDataFrame when all the values are instances of SparseDataFrame.

This change also affects routines using `concat()` internally, like `get_dummies()`, which now returns a DataFrame in all cases (previously a SparseDataFrame was returned if all the columns were dummy encoded, and a DataFrame otherwise).

Providing any SparseSeries or SparseDataFrame to `concat()` will cause a SparseSeries or SparseDataFrame to be returned, as before.

## The `.str`-accessor performs stricter type checks

Due to the lack of more fine-grained dtypes, `Series.str` so far only checked whether the data was of object dtype. `Series.str` will now infer the dtype data *within* the Series; in particular, 'bytes'-only data will raise an exception (except for `Series.str.decode()`, `Series.str.get()`, `Series.str.len()`, `Series.str.slice()`), see GH23163, GH23011, GH23551.

*Previous behavior:*

```
In [1]: s = pd.Series(np.array(['a', 'ba', 'cba'], 'S'), dtype=object)

In [2]: s
Out [2]:
0    b'a'
1    b'ba'
2    b'cba'
```

(continues on next page)

(continued from previous page)

```
dtype: object

In [3]: s.str.startswith(b'a')
Out[3]:
0      True
1      False
2      False
dtype: bool
```

*New behavior:*

```
In [23]: s = pd.Series(np.array(['a', 'ba', 'cba'], 'S'), dtype=object)

In [24]: s
Out[24]:
0      b'a'
1      b'ba'
2      b'cba'
Length: 3, dtype: object

In [25]: s.str.startswith(b'a')
-----
TypeError                                 Traceback (most recent call last)
<ipython-input-25-ac784692b361> in <module>
----> 1 s.str.startswith(b'a')

/pandas/pandas/core/strings.py in wrapper(self, *args, **kwargs)
    1949             f"inferred dtype '{self._inferred_dtype}'."
    1950         )
-> 1951         raise TypeError(msg)
    1952     return func(self, *args, **kwargs)
    1953

TypeError: Cannot use .str.startswith with values of inferred dtype 'bytes'.
```

## Categorical dtypes are preserved during groupby

Previously, columns that were categorical, but not the groupby key(s) would be converted to object dtype during groupby operations. Pandas now will preserve these dtypes. (GH18502)

```
In [26]: cat = pd.Categorical(["foo", "bar", "bar", "qux"], ordered=True)

In [27]: df = pd.DataFrame({'payload': [-1, -2, -1, -2], 'col': cat})

In [28]: df
Out[28]:
  payload col
0      -1  foo
1      -2  bar
2      -1  bar
3      -2  qux

[4 rows x 2 columns]

In [29]: df.dtypes
```

(continues on next page)

(continued from previous page)

```
Out [29]:
payload      int64
col          category
Length: 2, dtype: object
```

*Previous Behavior:*

```
In [5]: df.groupby('payload').first().col.dtype
Out[5]: dtype('O')
```

*New Behavior:*

```
In [30]: df.groupby('payload').first().col.dtype
Out[30]: CategoricalDtype(categories=['bar', 'foo', 'qux'], ordered=True)
```

### Incompatible Index type unions

When performing `Index.union()` operations between objects of incompatible dtypes, the result will be a base `Index` of dtype `object`. This behavior holds true for unions between `Index` objects that previously would have been prohibited. The dtype of empty `Index` objects will now be evaluated before performing union operations rather than simply returning the other `Index` object. `Index.union()` can now be considered commutative, such that `A.union(B) == B.union(A)` (GH23525).

*Previous behavior:*

```
In [1]: pd.period_range('19910905', periods=2).union(pd.Int64Index([1, 2, 3]))
...
ValueError: can only call with other PeriodIndex-ed objects

In [2]: pd.Index([], dtype=object).union(pd.Index([1, 2, 3]))
Out[2]: Int64Index([1, 2, 3], dtype='int64')
```

*New behavior:*

```
In [31]: pd.period_range('19910905', periods=2).union(pd.Int64Index([1, 2, 3]))
Out[31]: Index([1991-09-05, 1991-09-06, 1, 2, 3], dtype='object')

In [32]: pd.Index([], dtype=object).union(pd.Index([1, 2, 3]))
Out[32]: Index([1, 2, 3], dtype='object')
```

Note that integer- and floating-dtype indexes are considered “compatible”. The integer values are coerced to floating point, which may result in loss of precision. See *Set operations on Index objects* for more.

### DataFrame groupby ffill/bfill no longer return group labels

The methods `ffill`, `bfill`, `pad` and `backfill` of `DataFrameGroupBy` previously included the group labels in the return value, which was inconsistent with other groupby transforms. Now only the filled values are returned. (GH21521)

```
In [33]: df = pd.DataFrame({"a": ["x", "y"], "b": [1, 2]})

In [34]: df
Out[34]:
```

(continues on next page)

(continued from previous page)

```

  a  b
0  x  1
1  y  2

[2 rows x 2 columns]
```

*Previous behavior:*

```

In [3]: df.groupby("a").ffill()
Out[3]:
  a  b
0  x  1
1  y  2
```

*New behavior:*

```

In [35]: df.groupby("a").ffill()
Out[35]:
  b
0  1
1  2

[2 rows x 1 columns]
```

**DataFrame describe on an empty categorical / object column will return top and freq**

When calling `DataFrame.describe()` with an empty categorical / object column, the ‘top’ and ‘freq’ columns were previously omitted, which was inconsistent with the output for non-empty columns. Now the ‘top’ and ‘freq’ columns will always be included, with `numpy.nan` in the case of an empty DataFrame ([GH26397](#))

```

In [36]: df = pd.DataFrame({"empty_col": pd.Categorical([])})

In [37]: df
Out[37]:
Empty DataFrame
Columns: [empty_col]
Index: []

[0 rows x 1 columns]
```

*Previous behavior:*

```

In [3]: df.describe()
Out[3]:
      empty_col
count          0
unique          0
```

*New behavior:*

```

In [38]: df.describe()
Out[38]:
      empty_col
count          0
```

(continues on next page)

(continued from previous page)

```
unique      0
top        NaN
freq        NaN

[4 rows x 1 columns]
```

### `__str__` methods now call `__repr__` rather than vice versa

Pandas has until now mostly defined string representations in a Pandas objects's `__str__`/`__unicode__`/`__bytes__` methods, and called `__str__` from the `__repr__` method, if a specific `__repr__` method is not found. This is not needed for Python3. In Pandas 0.25, the string representations of Pandas objects are now generally defined in `__repr__`, and calls to `__str__` in general now pass the call on to the `__repr__`, if a specific `__str__` method doesn't exist, as is standard for Python. This change is backward compatible for direct usage of Pandas, but if you subclass Pandas objects *and* give your subclasses specific `__str__`/`__repr__` methods, you may have to adjust your `__str__`/`__repr__` methods ([GH26495](#)).

### Indexing an `IntervalIndex` with `Interval` objects

Indexing methods for `IntervalIndex` have been modified to require exact matches only for `Interval` queries. `IntervalIndex` methods previously matched on any overlapping `Interval`. Behavior with scalar points, e.g. querying with an integer, is unchanged ([GH16316](#)).

```
In [39]: ii = pd.IntervalIndex.from_tuples([(0, 4), (1, 5), (5, 8)])

In [40]: ii
Out[40]:
IntervalIndex([(0, 4], (1, 5], (5, 8]],
              closed='right',
              dtype='interval[int64]')
```

The `in` operator (`__contains__`) now only returns `True` for exact matches to `Intervals` in the `IntervalIndex`, whereas this would previously return `True` for any `Interval` overlapping an `Interval` in the `IntervalIndex`.

*Previous behavior:*

```
In [4]: pd.Interval(1, 2, closed='neither') in ii
Out[4]: True

In [5]: pd.Interval(-10, 10, closed='both') in ii
Out[5]: True
```

*New behavior:*

```
In [41]: pd.Interval(1, 2, closed='neither') in ii
Out[41]: False

In [42]: pd.Interval(-10, 10, closed='both') in ii
Out[42]: False
```

The `get_loc()` method now only returns locations for exact matches to `Interval` queries, as opposed to the previous behavior of returning locations for overlapping matches. A `KeyError` will be raised if an exact match is not found.

*Previous behavior:*

```
In [6]: ii.get_loc(pd.Interval(1, 5))
Out[6]: array([0, 1])

In [7]: ii.get_loc(pd.Interval(2, 6))
Out[7]: array([0, 1, 2])
```

*New behavior:*

```
In [6]: ii.get_loc(pd.Interval(1, 5))
Out[6]: 1

In [7]: ii.get_loc(pd.Interval(2, 6))
-----
KeyError: Interval(2, 6, closed='right')
```

Likewise, `get_indexer()` and `get_indexer_non_unique()` will also only return locations for exact matches to Interval queries, with `-1` denoting that an exact match was not found.

These indexing changes extend to querying a Series or DataFrame with an IntervalIndex index.

```
In [43]: s = pd.Series(list('abc'), index=ii)

In [44]: s
Out[44]:
(0, 4]    a
(1, 5]    b
(5, 8]    c
Length: 3, dtype: object
```

Selecting from a Series or DataFrame using `[]` (`__getitem__`) or `loc` now only returns exact matches for Interval queries.

*Previous behavior:*

```
In [8]: s[pd.Interval(1, 5)]
Out[8]:
(0, 4]    a
(1, 5]    b
dtype: object

In [9]: s.loc[pd.Interval(1, 5)]
Out[9]:
(0, 4]    a
(1, 5]    b
dtype: object
```

*New behavior:*

```
In [45]: s[pd.Interval(1, 5)]
Out[45]: 'b'

In [46]: s.loc[pd.Interval(1, 5)]
Out[46]: 'b'
```

Similarly, a `KeyError` will be raised for non-exact matches instead of returning overlapping matches.

*Previous behavior:*

```
In [9]: s[pd.Interval(2, 3)]
Out[9]:
(0, 4]    a
(1, 5]    b
dtype: object

In [10]: s.loc[pd.Interval(2, 3)]
Out[10]:
(0, 4]    a
(1, 5]    b
dtype: object
```

*New behavior:*

```
In [6]: s[pd.Interval(2, 3)]
-----
KeyError: Interval(2, 3, closed='right')

In [7]: s.loc[pd.Interval(2, 3)]
-----
KeyError: Interval(2, 3, closed='right')
```

The `overlaps()` method can be used to create a boolean indexer that replicates the previous behavior of returning overlapping matches.

*New behavior:*

```
In [47]: idxr = s.index.overlaps(pd.Interval(2, 3))

In [48]: idxr
Out[48]: array([ True,  True, False])

In [49]: s[idxr]
Out[49]:
(0, 4]    a
(1, 5]    b
Length: 2, dtype: object

In [50]: s.loc[idxr]
Out[50]:
(0, 4]    a
(1, 5]    b
Length: 2, dtype: object
```

## Binary ufuncs on Series now align

Applying a binary ufunc like `numpy.power()` now aligns the inputs when both are `Series` ([GH23293](#)).

```
In [51]: s1 = pd.Series([1, 2, 3], index=['a', 'b', 'c'])
In [52]: s2 = pd.Series([3, 4, 5], index=['d', 'c', 'b'])
In [53]: s1
Out[53]:
a    1
b    2
```

(continues on next page)

(continued from previous page)

```
c      3
Length: 3, dtype: int64

In [54]: s2
Out[54]:
d      3
c      4
b      5
Length: 3, dtype: int64
```

*Previous behavior*

```
In [5]: np.power(s1, s2)
Out[5]:
a      1
b     16
c    243
dtype: int64
```

*New behavior*

```
In [55]: np.power(s1, s2)
Out[55]:
a      1.0
b     32.0
c     81.0
d      NaN
Length: 4, dtype: float64
```

This matches the behavior of other binary operations in pandas, like `Series.add()`. To retain the previous behavior, convert the other `Series` to an array before applying the ufunc.

```
In [56]: np.power(s1, s2.array)
Out[56]:
a      1
b     16
c    243
Length: 3, dtype: int64
```

**Categorical.argsort now places missing values at the end**

`Categorical.argsort()` now places missing values at the end of the array, making it consistent with NumPy and the rest of pandas (GH21801).

```
In [57]: cat = pd.Categorical(['b', None, 'a'], categories=['a', 'b'], ordered=True)
```

*Previous behavior*

```
In [2]: cat = pd.Categorical(['b', None, 'a'], categories=['a', 'b'], ordered=True)
In [3]: cat.argsort()
Out[3]: array([1, 2, 0])

In [4]: cat[cat.argsort()]
```

(continues on next page)

(continued from previous page)

```
Out [4]:  
[NaN, a, b]  
categories (2, object): [a < b]
```

*New behavior*

```
In [58]: cat.argsort()  
Out [58]: array([2, 0, 1])  
  
In [59]: cat[cat.argsort()]  
Out [59]:  
[a, b, NaN]  
Categories (2, object): [a < b]
```

### Column order is preserved when passing a list of dicts to DataFrame

Starting with Python 3.7 the key-order of `dict` is [guaranteed](#). In practice, this has been true since Python 3.6. The `DataFrame` constructor now treats a list of dicts in the same way as it does a list of `OrderedDict`, i.e. preserving the order of the dicts. This change applies only when pandas is running on Python  $\geq 3.6$  ([GH27309](#)).

```
In [60]: data = [  
.....:     {'name': 'Joe', 'state': 'NY', 'age': 18},  
.....:     {'name': 'Jane', 'state': 'KY', 'age': 19, 'hobby': 'Minecraft'},  
.....:     {'name': 'Jean', 'state': 'OK', 'age': 20, 'finances': 'good'}  
.....: ]  
.....:
```

*Previous Behavior:*

The columns were lexicographically sorted previously,

```
In [1]: pd.DataFrame(data)  
Out[1]:  
   age  finances  hobby  name  state  
0   18     NaN     NaN   Joe   NY  
1   19     NaN  Minecraft  Jane   KY  
2   20     good     NaN   Jean   OK
```

*New Behavior:*

The column order now matches the insertion-order of the keys in the `dict`, considering all the records from top to bottom. As a consequence, the column order of the resulting `DataFrame` has changed compared to previous pandas versions.

```
In [61]: pd.DataFrame(data)  
Out [61]:  
   name  state  age  hobby  finances  
0   Joe    NY   18   NaN    NaN  
1  Jane    KY   19  Minecraft  NaN  
2  Jean    OK   20   NaN    good  
  
[3 rows x 5 columns]
```

## Increased minimum versions for dependencies

Due to dropping support for Python 2.7, a number of optional dependencies have updated minimum versions (GH25725, GH24942, GH25752). Independently, some minimum supported versions of dependencies were updated (GH23519, GH25554). If installed, we now require:

| Package         | Minimum Version | Required |
|-----------------|-----------------|----------|
| numpy           | 1.13.3          | X        |
| pytz            | 2015.4          | X        |
| python-dateutil | 2.6.1           | X        |
| bottleneck      | 1.2.1           |          |
| numexpr         | 2.6.2           |          |
| pytest (dev)    | 4.0.2           |          |

For [optional libraries](#) the general recommendation is to use the latest version. The following table lists the lowest version per library that is currently being tested throughout the development of pandas. Optional libraries below the lowest tested version may still work, but are not considered supported.

| Package        | Minimum Version |
|----------------|-----------------|
| beautifulsoup4 | 4.6.0           |
| fastparquet    | 0.2.1           |
| gcsfs          | 0.2.2           |
| lxml           | 3.8.0           |
| matplotlib     | 2.2.2           |
| openpyxl       | 2.4.8           |
| pyarrow        | 0.9.0           |
| pymysql        | 0.7.1           |
| pytables       | 3.4.2           |
| scipy          | 0.19.0          |
| sqlalchemy     | 1.1.4           |
| xarray         | 0.8.2           |
| xlrd           | 1.1.0           |
| xlswriter      | 0.9.8           |
| xlwt           | 1.2.0           |

See [Dependencies](#) and [Optional dependencies](#) for more.

## Other API changes

- `DatetimeTZDtype` will now standardize pytz timezones to a common timezone instance (GH24713)
- `Timestamp` and `Timedelta` scalars now implement the `to_numpy()` method as aliases to `Timestamp.to_datetime64()` and `Timedelta.to_timedelta64()`, respectively. (GH24653)
- `Timestamp.strptime()` will now raise a `NotImplementedError` (GH25016)
- Comparing `Timestamp` with unsupported objects now returns `NotImplemented` instead of raising `TypeError`. This implies that unsupported rich comparisons are delegated to the other object, and are now consistent with Python 3 behavior for `datetime` objects (GH24011)
- Bug in `DatetimeIndex.snap()` which didn't preserving the name of the input `Index` (GH25575)
- The `arg` argument in `pandas.core.groupby.DataFrameGroupBy.agg()` has been renamed to `func` (GH26089)

- The `arg` argument in `pandas.core.window._Window.aggregate()` has been renamed to `func` (GH26372)
- Most Pandas classes had a `__bytes__` method, which was used for getting a python2-style bytestring representation of the object. This method has been removed as a part of dropping Python2 (GH26447)
- The `.str`-accessor has been disabled for 1-level `MultiIndex`, use `MultiIndex.to_flat_index()` if necessary (GH23679)
- Removed support of `gtk` package for clipboards (GH26563)
- Using an unsupported version of Beautiful Soup 4 will now raise an `ImportError` instead of a `ValueError` (GH27063)
- `Series.to_excel()` and `DataFrame.to_excel()` will now raise a `ValueError` when saving time-zone aware data. (GH27008, GH7056)
- `ExtensionArray.argsort()` places NA values at the end of the sorted array. (GH21801)
- `DataFrame.to_hdf()` and `Series.to_hdf()` will now raise a `NotImplementedError` when saving a `MultiIndex` with extension data types for a fixed format. (GH7775)
- Passing duplicate names in `read_csv()` will now raise a `ValueError` (GH17346)

### Deprecations

#### Sparse subclasses

The `SparseSeries` and `SparseDataFrame` subclasses are deprecated. Their functionality is better-provided by a `Series` or `DataFrame` with sparse values.

#### Previous way

```
df = pd.SparseDataFrame({"A": [0, 0, 1, 2]})
df.dtypes
```

#### New way

```
In [62]: df = pd.DataFrame({"A": pd.SparseArray([0, 0, 1, 2])})
In [63]: df.dtypes
Out [63]:
A      Sparse[int64, 0]
Length: 1, dtype: object
```

The memory usage of the two approaches is identical. See *Migrating* for more (GH19239).

#### msgpack format

The `msgpack` format is deprecated as of 0.25 and will be removed in a future version. It is recommended to use `pyarrow` for on-the-wire transmission of pandas objects. (GH27084)

## Other deprecations

- The deprecated `.ix[]` indexer now raises a more visible `FutureWarning` instead of `DeprecationWarning` (GH26438).
- Deprecated the `units=M` (months) and `units=Y` (year) parameters for units of `pandas.to_timedelta()`, `pandas.Timedelta()` and `pandas.TimedeltaIndex()` (GH16344)
- `pandas.concat()` has deprecated the `join_axes`-keyword. Instead, use `DataFrame.reindex()` or `DataFrame.reindex_like()` on the result or on the inputs (GH21951)
- The `SparseArray.values` attribute is deprecated. You can use `np.asarray(...)` or the `SparseArray.to_dense()` method instead (GH26421).
- The functions `pandas.to_datetime()` and `pandas.to_timedelta()` have deprecated the `box` keyword. Instead, use `to_numpy()` or `Timestamp.to_datetime64()` or `Timedelta.to_timedelta64()`. (GH24416)
- The `DataFrame.compound()` and `Series.compound()` methods are deprecated and will be removed in a future version (GH26405).
- The internal attributes `_start`, `_stop` and `_step` attributes of `RangeIndex` have been deprecated. Use the public attributes `start`, `stop` and `step` instead (GH26581).
- The `Series.ftype()`, `Series.ftypes()` and `DataFrame.ftypes()` methods are deprecated and will be removed in a future version. Instead, use `Series.dtype()` and `DataFrame.dtypes()` (GH26705).
- The `Series.get_values()`, `DataFrame.get_values()`, `Index.get_values()`, `SparseArray.get_values()` and `Categorical.get_values()` methods are deprecated. One of `np.asarray(...)` or `to_numpy()` can be used instead (GH19617).
- The ‘outer’ method on NumPy ufuncs, e.g. `np.subtract.outer` has been deprecated on `Series` objects. Convert the input to an array with `Series.array` first (GH27186)
- `Timedelta.resolution()` is deprecated and replaced with `Timedelta.resolution_string()`. In a future version, `Timedelta.resolution()` will be changed to behave like the standard library `datetime.timedelta.resolution` (GH21344)
- `read_table()` has been undeprecated. (GH25220)
- `Index.dtype_str` is deprecated. (GH18262)
- `Series.imag` and `Series.real` are deprecated. (GH18262)
- `Series.put()` is deprecated. (GH18262)
- `Index.item()` and `Series.item()` is deprecated. (GH18262)
- The default value `ordered=None` in `CategoricalDtype` has been deprecated in favor of `ordered=False`. When converting between categorical types `ordered=True` must be explicitly passed in order to be preserved. (GH26336)
- `Index.contains()` is deprecated. Use `key` in `index(__contains__)` instead (GH17753).
- `DataFrame.get_dtype_counts()` is deprecated. (GH18262)
- `Categorical.ravel()` will return a `Categorical` instead of a `np.ndarray` (GH27199)

## Removal of prior version deprecations/changes

- Removed `Panel` (GH25047, GH25191, GH25231)
- Removed the previously deprecated `sheetname` keyword in `read_excel()` (GH16442, GH20938)
- Removed the previously deprecated `TimeGrouper` (GH16942)
- Removed the previously deprecated `parse_cols` keyword in `read_excel()` (GH16488)
- Removed the previously deprecated `pd.options.html.border` (GH16970)
- Removed the previously deprecated `convert_objects` (GH11221)
- Removed the previously deprecated `select` method of `DataFrame` and `Series` (GH17633)
- Removed the previously deprecated behavior of `Series` treated as list-like in `rename_categories()` (GH17982)
- Removed the previously deprecated `DataFrame.reindex_axis` and `Series.reindex_axis` (GH17842)
- Removed the previously deprecated behavior of altering column or index labels with `Series.rename_axis()` or `DataFrame.rename_axis()` (GH17842)
- Removed the previously deprecated `tupleize_cols` keyword argument in `read_html()`, `read_csv()`, and `DataFrame.to_csv()` (GH17877, GH17820)
- Removed the previously deprecated `DataFrame.from_csv` and `Series.from_csv` (GH17812)
- Removed the previously deprecated `raise_on_error` keyword argument in `DataFrame.where()` and `DataFrame.mask()` (GH17744)
- Removed the previously deprecated `ordered` and `categories` keyword arguments in `astype` (GH17742)
- Removed the previously deprecated `cdate_range` (GH17691)
- Removed the previously deprecated `True` option for the `dropna` keyword argument in `SeriesGroupBy.nth()` (GH17493)
- Removed the previously deprecated `convert` keyword argument in `Series.take()` and `DataFrame.take()` (GH17352)
- Removed the previously deprecated behavior of arithmetic operations with `datetime.date` objects (GH21152)

## Performance improvements

- Significant speedup in `SparseArray` initialization that benefits most operations, fixing performance regression introduced in v0.20.0 (GH24985)
- `DataFrame.to_stata()` is now faster when outputting data with any string or non-native endian columns (GH25045)
- Improved performance of `Series.searchsorted()`. The speedup is especially large when the dtype is `int8/int16/int32` and the searched key is within the integer bounds for the dtype (GH22034)
- Improved performance of `pandas.core.groupby.GroupBy.quantile()` (GH20405)
- Improved performance of slicing and other selected operation on a `RangeIndex` (GH26565, GH26617, GH26722)
- `RangeIndex` now performs standard lookup without instantiating an actual hashtable, hence saving memory (GH16685)

- Improved performance of `read_csv()` by faster tokenizing and faster parsing of small float numbers (GH25784)
- Improved performance of `read_csv()` by faster parsing of N/A and boolean values (GH25804)
- Improved performance of `IntervalIndex.is_monotonic`, `IntervalIndex.is_monotonic_increasing` and `IntervalIndex.is_monotonic_decreasing` by removing conversion to `MultiIndex` (GH24813)
- Improved performance of `DataFrame.to_csv()` when writing datetime dtypes (GH25708)
- Improved performance of `read_csv()` by much faster parsing of MM/YYYY and DD/MM/YYYY datetime formats (GH25922)
- Improved performance of `nanops` for dtypes that cannot store NaNs. Speedup is particularly prominent for `Series.all()` and `Series.any()` (GH25070)
- Improved performance of `Series.map()` for dictionary mappers on categorical series by mapping the categories instead of mapping all values (GH23785)
- Improved performance of `IntervalIndex.intersection()` (GH24813)
- Improved performance of `read_csv()` by faster concatenating date columns without extra conversion to string for integer/float zero and float NaN; by faster checking the string for the possibility of being a date (GH25754)
- Improved performance of `IntervalIndex.is_unique` by removing conversion to `MultiIndex` (GH24813)
- Restored performance of `DatetimeIndex.__iter__()` by re-enabling specialized code path (GH26702)
- Improved performance when building `MultiIndex` with at least one `CategoricalIndex` level (GH22044)
- Improved performance by removing the need for a garbage collect when checking for `SettingWithCopyWarning` (GH27031)
- For `to_datetime()` changed default value of `cache` parameter to `True` (GH26043)
- Improved performance of `DatetimeIndex` and `PeriodIndex` slicing given non-unique, monotonic data (GH27136).
- Improved performance of `pd.read_json()` for index-oriented data. (GH26773)
- Improved performance of `MultiIndex.shape()` (GH27384).

## Bug fixes

### Categorical

- Bug in `DataFrame.at()` and `Series.at()` that would raise exception if the index was a `CategoricalIndex` (GH20629)
- Fixed bug in comparison of ordered `Categorical` that contained missing values with a scalar which sometimes incorrectly resulted in `True` (GH26504)
- Bug in `DataFrame.dropna()` when the `DataFrame` has a `CategoricalIndex` containing `Interval` objects incorrectly raised a `TypeError` (GH25087)

## Datetimelike

- Bug in `to_datetime()` which would raise an (incorrect) `ValueError` when called with a date far into the future and the `format` argument specified instead of raising `OutOfBoundsDatetime` (GH23830)
- Bug in `to_datetime()` which would raise `InvalidIndexError: Reindexing only valid with uniquely valued Index objects` when called with `cache=True`, with `arg` including at least two different elements from the set `{None, numpy.nan, pandas.NaT}` (GH22305)
- Bug in `DataFrame` and `Series` where timezone aware data with `dtype='datetime64[ns]` was not cast to naive (GH25843)
- Improved `Timestamp` type checking in various datetime functions to prevent exceptions when using a subclassed `datetime` (GH25851)
- Bug in `Series` and `DataFrame repr` where `np.datetime64('NaT')` and `np.timedelta64('NaT')` with `dtype=object` would be represented as `NaN` (GH25445)
- Bug in `to_datetime()` which does not replace the invalid argument with `NaT` when error is set to `coerce` (GH26122)
- Bug in adding `DateOffset` with nonzero month to `DatetimeIndex` would raise `ValueError` (GH26258)
- Bug in `to_datetime()` which raises unhandled `OverflowError` when called with mix of invalid dates and `NaN` values with `format='%Y%m%d'` and `error='coerce'` (GH25512)
- Bug in `isin()` for datetimelike indexes; `DatetimeIndex`, `TimedeltaIndex` and `PeriodIndex` where the `levels` parameter was ignored. (GH26675)
- Bug in `to_datetime()` which raises `TypeError` for `format='%Y%m%d'` when called for invalid integer dates with length `>= 6` digits with `errors='ignore'`
- Bug when comparing a `PeriodIndex` against a zero-dimensional numpy array (GH26689)
- Bug in constructing a `Series` or `DataFrame` from a numpy `datetime64` array with a non-ns unit and out-of-bound timestamps generating rubbish data, which will now correctly raise an `OutOfBoundsDatetime` error (GH26206).
- Bug in `date_range()` with unnecessary `OverflowError` being raised for very large or very small dates (GH26651)
- Bug where adding `Timestamp` to a `np.timedelta64` object would raise instead of returning a `Timestamp` (GH24775)
- Bug where comparing a zero-dimensional numpy array containing a `np.datetime64` object to a `Timestamp` would incorrect raise `TypeError` (GH26916)
- Bug in `to_datetime()` which would raise `ValueError: Tz-aware datetime.datetime cannot be converted to datetime64 unless utc=True` when called with `cache=True`, with `arg` including datetime strings with different offset (GH26097)
-

## Timedelta

- Bug in `TimedeltaIndex.intersection()` where for non-monotonic indices in some cases an empty Index was returned when in fact an intersection existed (GH25913)
- Bug with comparisons between `Timedelta` and `NaT` raising `TypeError` (GH26039)
- Bug when adding or subtracting a `BusinessHour` to a `Timestamp` with the resulting time landing in a following or prior day respectively (GH26381)
- Bug when comparing a `TimedeltaIndex` against a zero-dimensional numpy array (GH26689)

## Timezones

- Bug in `DatetimeIndex.to_frame()` where timezone aware data would be converted to timezone naive data (GH25809)
- Bug in `to_datetime()` with `utc=True` and datetime strings that would apply previously parsed UTC offsets to subsequent arguments (GH24992)
- Bug in `Timestamp.tz_localize()` and `Timestamp.tz_convert()` does not propagate `freq` (GH25241)
- Bug in `Series.at()` where setting `Timestamp` with timezone raises `TypeError` (GH25506)
- Bug in `DataFrame.update()` when updating with timezone aware data would return timezone naive data (GH25807)
- Bug in `to_datetime()` where an uninformative `RuntimeError` was raised when passing a naive `Timestamp` with datetime strings with mixed UTC offsets (GH25978)
- Bug in `to_datetime()` with `unit='ns'` would drop timezone information from the parsed argument (GH26168)
- Bug in `DataFrame.join()` where joining a timezone aware index with a timezone aware column would result in a column of `NaN` (GH26335)
- Bug in `date_range()` where ambiguous or nonexistent start or end times were not handled by the ambiguous or nonexistent keywords respectively (GH27088)
- Bug in `DatetimeIndex.union()` when combining a timezone aware and timezone unaware `DatetimeIndex` (GH21671)
- Bug when applying a numpy reduction function (e.g. `numpy.minimum()`) to a timezone aware `Series` (GH15552)

## Numeric

- Bug in `to_numeric()` in which large negative numbers were being improperly handled (GH24910)
- Bug in `to_numeric()` in which numbers were being coerced to float, even though `errors` was not `coerce` (GH24910)
- Bug in `to_numeric()` in which invalid values for `errors` were being allowed (GH26466)
- Bug in `format` in which floating point complex numbers were not being formatted to proper display precision and trimming (GH25514)
- Bug in error messages in `DataFrame.corr()` and `Series.corr()`. Added the possibility of using a callable. (GH25729)

- Bug in `Series.divmod()` and `Series.rdivmod()` which would raise an (incorrect) `ValueError` rather than return a pair of `Series` objects as result (GH25557)
- Raises a helpful exception when a non-numeric index is sent to `interpolate()` with methods which require numeric index. (GH21662)
- Bug in `eval()` when comparing floats with scalar operators, for example: `x < -0.1` (GH25928)
- Fixed bug where casting all-boolean array to integer extension array failed (GH25211)
- Bug in `divmod` with a `Series` object containing zeros incorrectly raising `AttributeError` (GH26987)
- Inconsistency in `Series` floor-division (`//`) and `divmod` filling `positive//zero` with `NaN` instead of `Inf` (GH27321)
- 

### Conversion

- Bug in `DataFrame.astype()` when passing a dict of columns and types the `errors` parameter was ignored. (GH25905)
- 
- 

### Strings

- Bug in the `__name__` attribute of several methods of `Series.str`, which were set incorrectly (GH23551)
- Improved error message when passing `Series` of wrong dtype to `Series.str.cat()` (GH22722)
- 

### Interval

- Construction of `Interval` is restricted to numeric, `Timestamp` and `Timedelta` endpoints (GH23013)
- Fixed bug in `Series/DataFrame` not displaying `NaN` in `IntervalIndex` with missing values (GH25984)
- Bug in `IntervalIndex.get_loc()` where a `KeyError` would be incorrectly raised for a decreasing `IntervalIndex` (GH25860)
- Bug in `Index` constructor where passing mixed closed `Interval` objects would result in a `ValueError` instead of an object dtype `Index` (GH27172)

### Indexing

- Improved exception message when calling `DataFrame.iloc()` with a list of non-numeric objects (GH25753).
- Improved exception message when calling `.iloc` or `.loc` with a boolean indexer with different length (GH26658).
- Bug in `KeyError` exception message when indexing a `MultiIndex` with a non-existent key not displaying the original key (GH27250).

- Bug in `.iloc` and `.loc` with a boolean indexer not raising an `IndexError` when too few items are passed (GH26658).
- Bug in `DataFrame.loc()` and `Series.loc()` where `KeyError` was not raised for a `MultiIndex` when the key was less than or equal to the number of levels in the `MultiIndex` (GH14885).
- Bug in which `DataFrame.append()` produced an erroneous warning indicating that a `KeyError` will be thrown in the future when the data to be appended contains new columns (GH22252).
- Bug in which `DataFrame.to_csv()` caused a segfault for a reindexed data frame, when the indices were single-level `MultiIndex` (GH26303).
- Fixed bug where assigning a `arrays.PandasArray` to a `pandas.core.frame.DataFrame` would raise error (GH26390)
- Allow keyword arguments for callable local reference used in the `DataFrame.query()` string (GH26426)
- Fixed a `KeyError` when indexing a `MultiIndex`` level with a list containing exactly one label, which is missing (GH27148)
- Bug which produced `AttributeError` on partial matching `Timestamp` in a `MultiIndex` (GH26944)
- Bug in `Categorical` and `CategoricalIndex` with `Interval` values when using the `in` operator (`__contains`) with objects that are not comparable to the values in the `Interval` (GH23705)
- Bug in `DataFrame.loc()` and `DataFrame.iloc()` on a `DataFrame` with a single timezone-aware `datetime64[ns]` column incorrectly returning a scalar instead of a `Series` (GH27110)
- Bug in `CategoricalIndex` and `Categorical` incorrectly raising `ValueError` instead of `TypeError` when a list is passed using the `in` operator (`__contains__`) (GH21729)
- Bug in setting a new value in a `Series` with a `Timedelta` object incorrectly casting the value to an integer (GH22717)
- Bug in `Series` setting a new key (`__setitem__`) with a timezone-aware `datetime` incorrectly raising `ValueError` (GH12862)
- Bug in `DataFrame.iloc()` when indexing with a read-only indexer (GH17192)
- Bug in `Series` setting an existing tuple key (`__setitem__`) with timezone-aware `datetime` values incorrectly raising `TypeError` (GH20441)

## Missing

- Fixed misleading exception message in `Series.interpolate()` if argument order is required, but omitted (GH10633, GH24014).
- Fixed class type displayed in exception message in `DataFrame.dropna()` if invalid axis parameter passed (GH25555)
- A `ValueError` will now be thrown by `DataFrame.fillna()` when `limit` is not a positive integer (GH27042)
-

## Multindex

- Bug in which incorrect exception raised by `Timedelta` when testing the membership of `MultiIndex` (GH24570)

- 

## I/O

- Bug in `DataFrame.to_html()` where values were truncated using display options instead of outputting the full content (GH17004)
- Fixed bug in missing text when using `to_clipboard()` if copying utf-16 characters in Python 3 on Windows (GH25040)
- Bug in `read_json()` for `orient='table'` when it tries to infer dtypes by default, which is not applicable as dtypes are already defined in the JSON schema (GH21345)
- Bug in `read_json()` for `orient='table'` and float index, as it infers index dtype by default, which is not applicable because index dtype is already defined in the JSON schema (GH25433)
- Bug in `read_json()` for `orient='table'` and string of float column names, as it makes a column name type conversion to `Timestamp`, which is not applicable because column names are already defined in the JSON schema (GH25435)
- Bug in `json_normalize()` for `errors='ignore'` where missing values in the input data, were filled in resulting `DataFrame` with the string "nan" instead of `numpy.nan` (GH25468)
- `DataFrame.to_html()` now raises `TypeError` when using an invalid type for the `classes` parameter instead of `AssertionError` (GH25608)
- Bug in `DataFrame.to_string()` and `DataFrame.to_latex()` that would lead to incorrect output when the header keyword is used (GH16718)
- Bug in `read_csv()` not properly interpreting the UTF8 encoded filenames on Windows on Python 3.6+ (GH15086)
- Improved performance in `pandas.read_stata()` and `pandas.io.stata.StataReader` when converting columns that have missing values (GH25772)
- Bug in `DataFrame.to_html()` where header numbers would ignore display options when rounding (GH17280)
- Bug in `read_hdf()` where reading a table from an HDF5 file written directly with `PyTables` fails with a `ValueError` when using a sub-selection via the `start` or `stop` arguments (GH11188)
- Bug in `read_hdf()` not properly closing store after a `KeyError` is raised (GH25766)
- Improved the explanation for the failure when value labels are repeated in Stata dta files and suggested work-arounds (GH25772)
- Improved `pandas.read_stata()` and `pandas.io.stata.StataReader` to read incorrectly formatted 118 format files saved by Stata (GH25960)
- Improved the `col_space` parameter in `DataFrame.to_html()` to accept a string so CSS length values can be set correctly (GH25941)
- Fixed bug in loading objects from S3 that contain # characters in the URL (GH25945)
- Adds `use_bqstorage_api` parameter to `read_gbq()` to speed up downloads of large data frames. This feature requires version 0.10.0 of the `pandas-gbq` library as well as the `google-cloud-bigquery-storage` and `fastavro` libraries. (GH26104)

- Fixed memory leak in `DataFrame.to_json()` when dealing with numeric data (GH24889)
- Bug in `read_json()` where date strings with Z were not converted to a UTC timezone (GH26168)
- Added `cache_dates=True` parameter to `read_csv()`, which allows to cache unique dates when they are parsed (GH25990)
- `DataFrame.to_excel()` now raises a `ValueError` when the caller's dimensions exceed the limitations of Excel (GH26051)
- Fixed bug in `pandas.read_csv()` where a BOM would result in incorrect parsing using `engine='python'` (GH26545)
- `read_excel()` now raises a `ValueError` when input is of type `pandas.io.excel.ExcelFile` and `engine` param is passed since `pandas.io.excel.ExcelFile` has an `engine` defined (GH26566)
- Bug while selecting from `HDFStore` with `where=''` specified (GH26610).
- Fixed bug in `DataFrame.to_excel()` where custom objects (i.e. `PeriodIndex`) inside merged cells were not being converted into types safe for the Excel writer (GH27006)
- Bug in `read_hdf()` where reading a timezone aware `DatetimeIndex` would raise a `TypeError` (GH11926)
- Bug in `to_msgpack()` and `read_msgpack()` which would raise a `ValueError` rather than a `FileNotFoundError` for an invalid path (GH27160)
- Fixed bug in `DataFrame.to_parquet()` which would raise a `ValueError` when the dataframe had no columns (GH27339)
- Allow parsing of `PeriodDtype` columns when using `read_csv()` (GH26934)

## Plotting

- Fixed bug where `api.extensions.ExtensionArray` could not be used in matplotlib plotting (GH25587)
- Bug in an error message in `DataFrame.plot()`. Improved the error message if non-numeric are passed to `DataFrame.plot()` (GH25481)
- Bug in incorrect ticklabel positions when plotting an index that are non-numeric / non-datetime (GH7612, GH15912, GH22334)
- Fixed bug causing plots of `PeriodIndex` timeseries to fail if the frequency is a multiple of the frequency rule code (GH14763)
- Fixed bug when plotting a `DatetimeIndex` with `datetime.timezone.utc` timezone (GH17173)
- 
-

## Groupby/resample/rolling

- Bug in `pandas.core.resample.Resampler.agg()` with a timezone aware index where `OverflowError` would raise when passing a list of functions ([GH22660](#))
- Bug in `pandas.core.groupby.DataFrameGroupBy.nunique()` in which the names of column levels were lost ([GH23222](#))
- Bug in `pandas.core.groupby.GroupBy.agg()` when applying an aggregation function to timezone aware data ([GH23683](#))
- Bug in `pandas.core.groupby.GroupBy.first()` and `pandas.core.groupby.GroupBy.last()` where timezone information would be dropped ([GH21603](#))
- Bug in `pandas.core.groupby.GroupBy.size()` when grouping only NA values ([GH23050](#))
- Bug in `Series.groupby()` where observed kwarg was previously ignored ([GH24880](#))
- Bug in `Series.groupby()` where using groupby with a MultiIndex Series with a list of labels equal to the length of the series caused incorrect grouping ([GH25704](#))
- Ensured that ordering of outputs in groupby aggregation functions is consistent across all versions of Python ([GH25692](#))
- Ensured that result group order is correct when grouping on an ordered Categorical and specifying `observed=True` ([GH25871](#), [GH25167](#))
- Bug in `pandas.core.window.Rolling.min()` and `pandas.core.window.Rolling.max()` that caused a memory leak ([GH25893](#))
- Bug in `pandas.core.window.Rolling.count()` and `pandas.core.window.Expanding.count` was previously ignoring the axis keyword ([GH13503](#))
- Bug in `pandas.core.groupby.GroupBy.idxmax()` and `pandas.core.groupby.GroupBy.idxmin()` with datetime column would return incorrect dtype ([GH25444](#), [GH15306](#))
- Bug in `pandas.core.groupby.GroupBy.cumsum()`, `pandas.core.groupby.GroupBy.cumprod()`, `pandas.core.groupby.GroupBy.cummin()` and `pandas.core.groupby.GroupBy.cummax()` with categorical column having absent categories, would return incorrect result or segfault ([GH16771](#))
- Bug in `pandas.core.groupby.GroupBy.nth()` where NA values in the grouping would return incorrect results ([GH26011](#))
- Bug in `pandas.core.groupby.SeriesGroupBy.transform()` where transforming an empty group would raise a `ValueError` ([GH26208](#))
- Bug in `pandas.core.frame.DataFrame.groupby()` where passing a `pandas.core.groupby.Grouper.Grouper` would return incorrect groups when using the `.groups` accessor ([GH26326](#))
- Bug in `pandas.core.groupby.GroupBy.agg()` where incorrect results are returned for uint64 columns. ([GH26310](#))
- Bug in `pandas.core.window.Rolling.median()` and `pandas.core.window.Rolling.quantile()` where `MemoryError` is raised with empty window ([GH26005](#))
- Bug in `pandas.core.window.Rolling.median()` and `pandas.core.window.Rolling.quantile()` where incorrect results are returned with `closed='left'` and `closed='neither'` ([GH26005](#))
- Improved `pandas.core.window.Rolling`, `pandas.core.window.Window` and `pandas.core.window.EWM` functions to exclude nuisance columns from results instead of raising errors and raise a `DataError` only if all columns are nuisance ([GH12537](#))

- Bug in `pandas.core.window.Rolling.max()` and `pandas.core.window.Rolling.min()` where incorrect results are returned with an empty variable window (GH26005)
- Raise a helpful exception when an unsupported weighted window function is used as an argument of `pandas.core.window.Window.aggregate()` (GH26597)

## Reshaping

- Bug in `pandas.merge()` adds a string of None, if None is assigned in suffixes instead of remain the column name as-is (GH24782).
- Bug in `merge()` when merging by index name would sometimes result in an incorrectly numbered index (missing index values are now assigned NA) (GH24212, GH25009)
- `to_records()` now accepts dtypes to its `column_dtypes` parameter (GH24895)
- Bug in `concat()` where order of `OrderedDict` (and `dict` in Python 3.6+) is not respected, when passed in as `objs` argument (GH21510)
- Bug in `pivot_table()` where columns with NaN values are dropped even if `dropna` argument is `False`, when the `aggfunc` argument contains a `list` (GH22159)
- Bug in `concat()` where the resulting `freq` of two `DatetimeIndex` with the same `freq` would be dropped (GH3232).
- Bug in `merge()` where merging with equivalent Categorical dtypes was raising an error (GH22501)
- bug in `DataFrame` instantiating with a dict of iterators or generators (e.g. `pd.DataFrame({'A': reversed(range(3))})`) raised an error (GH26349).
- Bug in `DataFrame` instantiating with a range (e.g. `pd.DataFrame(range(3))`) raised an error (GH26342).
- Bug in `DataFrame` constructor when passing non-empty tuples would cause a segmentation fault (GH25691)
- Bug in `Series.apply()` failed when the series is a timezone aware `DatetimeIndex` (GH25959)
- Bug in `pandas.cut()` where large bins could incorrectly raise an error due to an integer overflow (GH26045)
- Bug in `DataFrame.sort_index()` where an error is thrown when a multi-indexed `DataFrame` is sorted on all levels with the initial level sorted last (GH26053)
- Bug in `Series.nlargest()` treats `True` as smaller than `False` (GH26154)
- Bug in `DataFrame.pivot_table()` with a `IntervalIndex` as pivot index would raise `TypeError` (GH25814)
- Bug in which `DataFrame.from_dict()` ignored order of `OrderedDict` when `orient='index'` (GH8425).
- Bug in `DataFrame.transpose()` where transposing a `DataFrame` with a timezone-aware datetime column would incorrectly raise `ValueError` (GH26825)
- Bug in `pivot_table()` when pivoting a timezone aware column as the values would remove timezone information (GH14948)
- Bug in `merge_asof()` when specifying multiple `by` columns where one is `datetime64[ns, tz]` dtype (GH26649)

## Sparse

- Significant speedup in `SparseArray` initialization that benefits most operations, fixing performance regression introduced in v0.20.0 (GH24985)
- Bug in `SparseFrame` constructor where passing `None` as the data would cause `default_fill_value` to be ignored (GH16807)
- Bug in `SparseDataFrame` when adding a column in which the length of values does not match length of index, `AssertionError` is raised instead of raising `ValueError` (GH25484)
- Introduce a better error message in `Series.sparse.from_coo()` so it returns a `TypeError` for inputs that are not `coo` matrices (GH26554)
- Bug in `numpy.modf()` on a `SparseArray`. Now a tuple of `SparseArray` is returned (GH26946).

## Build Changes

- Fix install error with PyPy on macOS (GH26536)

## ExtensionArray

- Bug in `factorize()` when passing an `ExtensionArray` with a custom `na_sentinel` (GH25696).
- `Series.count()` miscounts NA values in `ExtensionArrays` (GH26835)
- Added `Series.__array_ufunc__` to better handle NumPy ufuncs applied to `Series` backed by extension arrays (GH23293).
- Keyword argument `deep` has been removed from `ExtensionArray.copy()` (GH27083)

## Other

- Removed unused C functions from vendored UltraJSON implementation (GH26198)
- Allow `Index` and `RangeIndex` to be passed to `numpy.min` and `numpy.max` functions (GH26125)
- Use actual class name in repr of empty objects of a `Series` subclass (GH27001).
- Bug in `DataFrame` where passing an object array of timezone-aware `datetime` objects would incorrectly raise `ValueError` (GH13287)

## Contributors

## 6.3 Version 0.24

### 6.3.1 Whats new in 0.24.2 (March 12, 2019)

**Warning:** The 0.24.x series of releases will be the last to support Python 2. Future feature releases will support Python 3 only. See [Dropping Python 2.7](#) for more.

{{ header }}

These are the changes in pandas 0.24.2. See release for a full changelog including other versions of pandas.

#### Fixed regressions

- Fixed regression in `DataFrame.all()` and `DataFrame.any()` where `bool_only=True` was ignored ([GH25101](#))
- Fixed issue in `DataFrame` construction with passing a mixed list of mixed types could segfault. ([GH25075](#))
- Fixed regression in `DataFrame.apply()` causing `RecursionError` when dict-like classes were passed as argument. ([GH25196](#))
- Fixed regression in `DataFrame.replace()` where `regex=True` was only replacing patterns matching the start of the string ([GH25259](#))
- Fixed regression in `DataFrame.duplicated()`, where empty dataframe was not returning a boolean dtyped Series. ([GH25184](#))
- Fixed regression in `Series.min()` and `Series.max()` where `numeric_only=True` was ignored when the Series contained Categorical data ([GH25299](#))
- Fixed regression in subtraction between Series objects with `datetime64[ns]` dtype incorrectly raising `OverflowError` when the Series on the right contains null values ([GH25317](#))
- Fixed regression in `TimedeltaIndex` where `np.sum(index)` incorrectly returned a zero-dimensional object instead of a scalar ([GH25282](#))
- Fixed regression in `IntervalDtype` construction where passing an incorrect string with 'Interval' as a prefix could result in a `RecursionError`. ([GH25338](#))
- Fixed regression in creating a period-dtype array from a read-only NumPy array of period objects. ([GH25403](#))

- Fixed regression in `Categorical`, where constructing it from a categorical `Series` and an explicit `categories=` that differed from that in the `Series` created an invalid object which could trigger segfaults. (GH25318)
- Fixed regression in `to_timedelta()` losing precision when converting floating data to `Timedelta` data (GH25077).
- Fixed pip installing from source into an environment without NumPy (GH25193)
- Fixed regression in `DataFrame.replace()` where large strings of numbers would be coerced into `int64`, causing an `OverflowError` (GH25616)
- Fixed regression in `factorize()` when passing a custom `na_sentinel` value with `sort=True` (GH25409).
- Fixed regression in `DataFrame.to_csv()` writing duplicate line endings with `gzip compress` (GH25311)

## Bug fixes

### I/O

- Better handling of terminal printing when the terminal dimensions are not known (GH25080)
- Bug in reading a HDF5 table-format `DataFrame` created in Python 2, in Python 3 (GH24925)
- Bug in reading a JSON with `orient='table'` generated by `DataFrame.to_json()` with `index=False` (GH25170)
- Bug where float indexes could have misaligned values when printing (GH25061)

### Categorical

- Bug where calling `Series.replace()` on categorical data could return a `Series` with incorrect dimensions (GH24971)
- 
- 

### Reshaping

- Bug in `transform()` where applying a function to a timezone aware column would return a timezone naive result (GH24198)
- Bug in `DataFrame.join()` when joining on a timezone aware `DatetimeIndex` (GH23931)

### Visualization

- Bug in `Series.plot()` where a secondary y axis could not be set to log scale (GH25545)

### Other

- Bug in `Series.is_unique()` where single occurrences of `NaN` were not considered unique (GH25180)
- Bug in `merge()` when merging an empty `DataFrame` with an `Int64` column or a non-empty `DataFrame` with an `Int64` column that is all `NaN` (GH25183)
- Bug in `IntervalTree` where a `RecursionError` occurs upon construction due to an overflow when adding endpoints, which also causes `IntervalIndex` to crash during indexing operations (GH25485)
- Bug in `Series.size` raising for some extension-array-backed `Series`, rather than returning the size (GH25580)
- Bug in resampling raising for nullable integer-dtype columns (GH25580)

## 6.3.2 Whats new in 0.24.1 (February 3, 2019)

**Warning:** The 0.24.x series of releases will be the last to support Python 2. Future feature releases will support Python 3 only. See [Dropping Python 2.7](#) for more.

{{ header }}

These are the changes in pandas 0.24.1. See release for a full changelog including other versions of pandas. See *What's new in 0.24.0 (January 25, 2019)* for the 0.24.0 changelog.

### API changes

#### Changing the `sort` parameter for `Index` set operations

The default `sort` value for `Index.union()` has changed from `True` to `None` ([GH24959](#)). The default *behavior*, however, remains the same: the result is sorted, unless

1. `self` and `other` are identical
2. `self` or `other` is empty
3. `self` or `other` contain values that can not be compared (a `RuntimeWarning` is raised).

This change will allow `sort=True` to mean “always sort” in a future release.

The same change applies to `Index.difference()` and `Index.symmetric_difference()`, which would not sort the result when the values could not be compared.

The `sort` option for `Index.intersection()` has changed in three ways.

1. The default has changed from `True` to `False`, to restore the pandas 0.23.4 and earlier behavior of not sorting by default.
2. The behavior of `sort=True` can now be obtained with `sort=None`. This will sort the result only if the values in `self` and `other` are not identical.
3. The value `sort=True` is no longer allowed. A future version of pandas will properly support `sort=True` meaning “always sort”.

### Fixed regressions

- Fixed regression in `DataFrame.to_dict()` with `records` orient raising an `AttributeError` when the `DataFrame` contained more than 255 columns, or wrongly converting column names that were not valid python identifiers ([GH24939](#), [GH24940](#)).
- Fixed regression in `read_sql()` when passing certain queries with MySQL/pymysql ([GH24988](#)).
- Fixed regression in `Index.intersection` incorrectly sorting the values by default ([GH24959](#)).
- Fixed regression in `merge()` when merging an empty `DataFrame` with multiple timezone-aware columns on one of the timezone-aware columns ([GH25014](#)).
- Fixed regression in `Series.rename_axis()` and `DataFrame.rename_axis()` where passing `None` failed to remove the axis name ([GH25034](#)).
- Fixed regression in `to_timedelta()` with `box=False` incorrectly returning a `datetime64` object instead of a `timedelta64` object ([GH24961](#)).

- Fixed regression where custom hashable types could not be used as column keys in `DataFrame.set_index()` (GH24969)

## Bug fixes

### Reshaping

- Bug in `DataFrame.groupby()` with `Groupby` when there is a time change (DST) and grouping frequency is '1d' (GH24972)

### Visualization

- Fixed the warning for implicitly registered matplotlib converters not showing. See *Restore Matplotlib datetime converter registration* for more (GH24963).

### Other

- Fixed `AttributeError` when printing a `DataFrame`'s HTML repr after accessing the IPython config object (GH25036)

## Contributors

A total of 7 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

### 6.3.3 What's new in 0.24.0 (January 25, 2019)

**Warning:** The 0.24.x series of releases will be the last to support Python 2. Future feature releases will support Python 3 only. See [Dropping Python 2.7](#) for more details.

{{ header }}

This is a major release from 0.23.4 and includes a number of API changes, new features, enhancements, and performance improvements along with a large number of bug fixes.

Highlights include:

- *Optional Integer NA Support*
- *New APIs for accessing the array backing a Series or Index*
- *A new top-level method for creating arrays*
- *Store Interval and Period data in a Series or DataFrame*

- *Support for joining on two MultiIndexes*

Check the *API Changes* and *deprecations* before updating.

These are the changes in pandas 0.24.0. See release for a full changelog including other versions of pandas.

### Enhancements

#### Optional integer NA support

Pandas has gained the ability to hold integer dtypes with missing values. This long requested feature is enabled through the use of *extension types*.

---

**Note:** IntegerArray is currently experimental. Its API or implementation may change without warning.

---

We can construct a `Series` with the specified dtype. The dtype string `Int64` is a pandas `ExtensionDtype`. Specifying a list or array using the traditional missing value marker of `np.nan` will infer to integer dtype. The display of the `Series` will also use the `NaN` to indicate missing values in string outputs. ([GH20700](#), [GH20747](#), [GH22441](#), [GH21789](#), [GH22346](#))

```
In [1]: s = pd.Series([1, 2, np.nan], dtype='Int64')

In [2]: s
Out [2]:
0      1
1      2
2    <NA>
Length: 3, dtype: Int64
```

Operations on these dtypes will propagate `NaN` as other pandas operations.

```
# arithmetic
In [3]: s + 1
Out [3]:
0      2
1      3
2    <NA>
Length: 3, dtype: Int64

# comparison
In [4]: s == 1
Out [4]:
0     True
1    False
2    <NA>
Length: 3, dtype: boolean

# indexing
In [5]: s.iloc[1:3]
Out [5]:
1      2
2    <NA>
Length: 2, dtype: Int64

# operate with other dtypes
```

(continues on next page)

(continued from previous page)

```
In [6]: s + s.iloc[1:3].astype('Int8')
Out[6]:
0    <NA>
1     4
2    <NA>
Length: 3, dtype: Int64

# coerce when needed
In [7]: s + 0.01
Out[7]:
0    1.01
1    2.01
2     NaN
Length: 3, dtype: float64
```

These dtypes can operate as part of a DataFrame.

```
In [8]: df = pd.DataFrame({'A': s, 'B': [1, 1, 3], 'C': list('aab')})

In [9]: df
Out[9]:
   A  B  C
0   1  1  a
1   2  1  a
2  <NA> 3  b

[3 rows x 3 columns]

In [10]: df.dtypes
Out[10]:
A      Int64
B     int64
C     object
Length: 3, dtype: object
```

These dtypes can be merged, reshaped, and casted.

```
In [11]: pd.concat([df[['A']], df[['B', 'C']], axis=1).dtypes
Out[11]:
A      Int64
B     int64
C     object
Length: 3, dtype: object

In [12]: df['A'].astype(float)
Out[12]:
0    1.0
1    2.0
2     NaN
Name: A, Length: 3, dtype: float64
```

Reduction and groupby operations such as sum work.

```
In [13]: df.sum()
Out[13]:
A      3
B      5
```

(continues on next page)

(continued from previous page)

```
C    aab
Length: 3, dtype: object

In [14]: df.groupby('B').A.sum()
Out [14]:
B
1     3
3     0
Name: A, Length: 2, dtype: Int64
```

**Warning:** The Integer NA support currently uses the capitalized dtype version, e.g. `Int8` as compared to the traditional `int8`. This may be changed at a future date.

See *Nullable integer data type* for more.

## Accessing the values in a Series or Index

`Series.array` and `Index.array` have been added for extracting the array backing a Series or Index. (GH19954, GH23623)

```
In [15]: idx = pd.period_range('2000', periods=4)

In [16]: idx.array
Out [16]:
<PeriodArray>
['2000-01-01', '2000-01-02', '2000-01-03', '2000-01-04']
Length: 4, dtype: period[D]

In [17]: pd.Series(idx).array
Out [17]:
<PeriodArray>
['2000-01-01', '2000-01-02', '2000-01-03', '2000-01-04']
Length: 4, dtype: period[D]
```

Historically, this would have been done with `series.values`, but with `.values` it was unclear whether the returned value would be the actual array, some transformation of it, or one of pandas custom arrays (like Categorical). For example, with `PeriodIndex`, `.values` generates a new ndarray of period objects each time.

```
In [18]: idx.values
Out [18]:
array([Period('2000-01-01', 'D'), Period('2000-01-02', 'D'),
       Period('2000-01-03', 'D'), Period('2000-01-04', 'D')], dtype=object)

In [19]: id(idx.values)
Out [19]: 140189617625008

In [20]: id(idx.values)
Out [20]: 140186961626976
```

If you need an actual NumPy array, use `Series.to_numpy()` or `Index.to_numpy()`.

```
In [21]: idx.to_numpy()
Out [21]:
array([Period('2000-01-01', 'D'), Period('2000-01-02', 'D'),
       Period('2000-01-03', 'D'), Period('2000-01-04', 'D')], dtype=object)

In [22]: pd.Series(idx).to_numpy()
Out [22]:
array([Period('2000-01-01', 'D'), Period('2000-01-02', 'D'),
       Period('2000-01-03', 'D'), Period('2000-01-04', 'D')], dtype=object)
```

For Series and Indexes backed by normal NumPy arrays, Series.array will return a new arrays. PandasArray, which is a thin (no-copy) wrapper around a `numpy.ndarray`. PandasArray isn't especially useful on its own, but it does provide the same interface as any extension array defined in pandas or by a third-party library.

```
In [23]: ser = pd.Series([1, 2, 3])

In [24]: ser.array
Out [24]:
<PandasArray>
[1, 2, 3]
Length: 3, dtype: int64

In [25]: ser.to_numpy()
Out [25]: array([1, 2, 3])
```

We haven't removed or deprecated `Series.values` or `DataFrame.values`, but we highly recommend and using `.array` or `.to_numpy()` instead.

See *Dtypes and Attributes and Underlying Data* for more.

### pandas.array: a new top-level method for creating arrays

A new top-level method `array()` has been added for creating 1-dimensional arrays (GH22860). This can be used to create any *extension array*, including extension arrays registered by 3rd party libraries. See the *dtypes docs* for more on extension arrays.

```
In [26]: pd.array([1, 2, np.nan], dtype='Int64')
Out [26]:
<IntegerArray>
[1, 2, <NA>]
Length: 3, dtype: Int64

In [27]: pd.array(['a', 'b', 'c'], dtype='category')
Out [27]:
[a, b, c]
Categories (3, object): [a, b, c]
```

Passing data for which there isn't dedicated extension type (e.g. float, integer, etc.) will return a new `arrays.PandasArray`, which is just a thin (no-copy) wrapper around a `numpy.ndarray` that satisfies the pandas extension array interface.

```
In [28]: pd.array([1, 2, 3])
Out [28]:
<IntegerArray>
```

(continues on next page)

(continued from previous page)

```
[1, 2, 3]
Length: 3, dtype: Int64
```

On their own, a `PandasArray` isn't a very useful object. But if you need write low-level code that works generically for any `ExtensionArray`, `PandasArray` satisfies that need.

Notice that by default, if no `dtype` is specified, the `dtype` of the returned array is inferred from the data. In particular, note that the first example of `[1, 2, np.nan]` would have returned a floating-point array, since `NaN` is a float.

```
In [29]: pd.array([1, 2, np.nan])
Out [29]:
<IntegerArray>
[1, 2, <NA>]
Length: 3, dtype: Int64
```

## Storing Interval and Period data in Series and DataFrame

Interval and Period data may now be stored in a `Series` or `DataFrame`, in addition to an `IntervalIndex` and `PeriodIndex` like previously ([GH19453](#), [GH22862](#)).

```
In [30]: ser = pd.Series(pd.interval_range(0, 5))

In [31]: ser
Out [31]:
0    (0, 1]
1    (1, 2]
2    (2, 3]
3    (3, 4]
4    (4, 5]
Length: 5, dtype: interval

In [32]: ser.dtype
Out [32]: interval[int64]
```

For periods:

```
In [33]: pser = pd.Series(pd.period_range("2000", freq="D", periods=5))

In [34]: pser
Out [34]:
0    2000-01-01
1    2000-01-02
2    2000-01-03
3    2000-01-04
4    2000-01-05
Length: 5, dtype: period[D]

In [35]: pser.dtype
Out [35]: period[D]
```

Previously, these would be cast to a NumPy array with object dtype. In general, this should result in better performance when storing an array of intervals or periods in a `Series` or column of a `DataFrame`.

Use `Series.array` to extract the underlying array of intervals or periods from the `Series`:

```

In [36]: ser.array
Out [36]:
<IntervalArray>
[(0, 1], (1, 2], (2, 3], (3, 4], (4, 5]]
Length: 5, closed: right, dtype: interval[int64]

In [37]: pser.array
Out [37]:
<PeriodArray>
['2000-01-01', '2000-01-02', '2000-01-03', '2000-01-04', '2000-01-05']
Length: 5, dtype: period[D]

```

These return an instance of `arrays.IntervalArray` or `arrays.PeriodArray`, the new extension arrays that back interval and period data.

**Warning:** For backwards compatibility, `Series.values` continues to return a NumPy array of objects for Interval and Period data. We recommend using `Series.array` when you need the array of data stored in the Series, and `Series.to_numpy()` when you know you need a NumPy array.

See *Dtypes and Attributes and Underlying Data* for more.

### Joining with two multi-indexes

`DataFrame.merge()` and `DataFrame.join()` can now be used to join multi-indexed Dataframe instances on the overlapping index levels ([GH6360](#))

See the *Merge, join, and concatenate* documentation section.

```

In [38]: index_left = pd.MultiIndex.from_tuples([('K0', 'X0'), ('K0', 'X1'),
.....:                                         ('K1', 'X2')],
.....:                                         names=['key', 'X'])
.....:

In [39]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2'],
.....:                       'B': ['B0', 'B1', 'B2']}, index=index_left)
.....:

In [40]: index_right = pd.MultiIndex.from_tuples([('K0', 'Y0'), ('K1', 'Y1'),
.....:                                          ('K2', 'Y2'), ('K2', 'Y3')],
.....:                                          names=['key', 'Y'])
.....:

In [41]: right = pd.DataFrame({'C': ['C0', 'C1', 'C2', 'C3'],
.....:                        'D': ['D0', 'D1', 'D2', 'D3']}, index=index_right)
.....:

In [42]: left.join(right)
Out [42]:
      A  B  C  D
key X  Y
K0  X0 Y0  A0 B0 C0 D0
     X1 Y0  A1 B1 C0 D0
K1  X2 Y1  A2 B2 C1 D1

[3 rows x 4 columns]

```

For earlier versions this can be done using the following.

```
In [43]: pd.merge(left.reset_index(), right.reset_index(),
.....:             on='key', how='inner').set_index(['key', 'X', 'Y'])
.....:
Out [43]:
```

|          | A  | B  | C  | D  |
|----------|----|----|----|----|
| key X Y  |    |    |    |    |
| K0 X0 Y0 | A0 | B0 | C0 | D0 |
| X1 Y0    | A1 | B1 | C0 | D0 |
| K1 X2 Y1 | A2 | B2 | C1 | D1 |

[3 rows x 4 columns]

### read\_html Enhancements

read\_html() previously ignored colspan and rowspan attributes. Now it understands them, treating them as sequences of cells with the same value. (GH17054)

```
In [44]: result = pd.read_html("""
.....: <table>
.....:   <thead>
.....:     <tr>
.....:       <th>A</th><th>B</th><th>C</th>
.....:     </tr>
.....:   </thead>
.....:   <tbody>
.....:     <tr>
.....:       <td colspan="2">1</td><td>2</td>
.....:     </tr>
.....:   </tbody>
.....: </table>""")
.....:
```

*Previous behavior:*

```
In [13]: result
Out [13]:
[  A B C
 0  1 2 NaN]
```

*New behavior:*

```
In [45]: result
Out [45]:
[  A B C
 0  1 1 2

[1 rows x 3 columns]]
```

## New `Styler.pipe()` method

The `Styler` class has gained a `pipe()` method. This provides a convenient way to apply users' predefined styling functions, and can help reduce "boilerplate" when using `DataFrame` styling functionality repeatedly within a notebook. (GH23229)

```
In [46]: df = pd.DataFrame({'N': [1250, 1500, 1750], 'X': [0.25, 0.35, 0.50]})

In [47]: def format_and_align(styler):
....:     return (styler.format({'N': '{:,}', 'X': '{:.1%}'})
....:             .set_properties(**{'text-align': 'right'}))
....:

In [48]: df.style.pipe(format_and_align).set_caption('Summary of results.')
Out[48]: <pandas.io.formats.style.Styler at 0x7f807285f550>
```

Similar methods already exist for other classes in pandas, including `DataFrame.pipe()`, `GroupBy.pipe()`, and `Resampler.pipe()`.

## Renaming names in a MultiIndex

`DataFrame.rename_axis()` now supports index and columns arguments and `Series.rename_axis()` supports index argument (GH19978).

This change allows a dictionary to be passed so that some of the names of a `MultiIndex` can be changed.

Example:

```
In [49]: mi = pd.MultiIndex.from_product([list('AB'), list('CD'), list('EF')],
....:                                     names=['AB', 'CD', 'EF'])
....:

In [50]: df = pd.DataFrame(list(range(len(mi))), index=mi, columns=['N'])

In [51]: df
Out[51]:
      N
AB CD EF
A  C  E  0
   F  1
   D  E  2
   F  3
B  C  E  4
   F  5
   D  E  6
   F  7

[8 rows x 1 columns]

In [52]: df.rename_axis(index={'CD': 'New'})
Out[52]:
      N
AB New EF
A  C  E  0
   F  1
   D  E  2
```

(continues on next page)

(continued from previous page)

```

      F    3
B C    E    4
      F    5
      D    E    6
      F    7

[8 rows x 1 columns]
```

See the *Advanced documentation on renaming* for more details.

## Other enhancements

- `merge()` now directly allows merge between objects of type `DataFrame` and named `Series`, without the need to convert the `Series` object into a `DataFrame` beforehand ([GH21220](#))
- `ExcelWriter` now accepts `mode` as a keyword argument, enabling append to existing workbooks when using the `openpyxl` engine ([GH3441](#))
- `FrozenList` has gained the `.union()` and `.difference()` methods. This functionality greatly simplifies `groupby`'s that rely on explicitly excluding certain columns. See *Splitting an object into groups* for more information ([GH15475](#), [GH15506](#)).
- `DataFrame.to_parquet()` now accepts `index` as an argument, allowing the user to override the engine's default behavior to include or omit the dataframe's indexes from the resulting Parquet file. ([GH20768](#))
- `read_feather()` now accepts `columns` as an argument, allowing the user to specify which columns should be read. ([GH24025](#))
- `DataFrame.corr()` and `Series.corr()` now accept a callable for generic calculation methods of correlation, e.g. histogram intersection ([GH22684](#))
- `DataFrame.to_string()` now accepts `decimal` as an argument, allowing the user to specify which decimal separator should be used in the output. ([GH23614](#))
- `DataFrame.to_html()` now accepts `render_links` as an argument, allowing the user to generate HTML with links to any URLs that appear in the `DataFrame`. See the *section on writing HTML* in the IO docs for example usage. ([GH2679](#))
- `pandas.read_csv()` now supports pandas extension types as an argument to `dtype`, allowing the user to use pandas extension types when reading CSVs. ([GH23228](#))
- The `shift()` method now accepts `fill_value` as an argument, allowing the user to specify a value which will be used instead of NA/NaT in the empty periods. ([GH15486](#))
- `to_datetime()` now supports the `%Z` and `%z` directive when passed into `format` ([GH13486](#))
- `Series.mode()` and `DataFrame.mode()` now support the `dropna` parameter which can be used to specify whether NaN/NaT values should be considered ([GH17534](#))
- `DataFrame.to_csv()` and `Series.to_csv()` now support the `compression` keyword when a file handle is passed. ([GH21227](#))
- `Index.droplevel()` is now implemented also for flat indexes, for compatibility with `MultiIndex` ([GH21115](#))
- `Series.droplevel()` and `DataFrame.droplevel()` are now implemented ([GH20342](#))
- Added support for reading from/writing to Google Cloud Storage via the `gcsfs` library ([GH19454](#), [GH23094](#))

- `DataFrame.to_gbq()` and `read_gbq()` signature and documentation updated to reflect changes from the [Pandas-GBQ library version 0.8.0](#). Adds a `credentials` argument, which enables the use of any kind of [google-auth credentials](#). ([GH21627](#), [GH22557](#), [GH23662](#))
- New method `HDFStore.walk()` will recursively walk the group hierarchy of an HDF5 file ([GH10932](#))
- `read_html()` copies cell data across `colspan` and `rowspan`, and it treats all-th table rows as headers if `header` kwarg is not given and there is no `thead` ([GH17054](#))
- `Series.nlargest()`, `Series.nsmallest()`, `DataFrame.nlargest()`, and `DataFrame.nsmallest()` now accept the value "all" for the `keep` argument. This keeps all ties for the `n`th largest/smallest value ([GH16818](#))
- `IntervalIndex` has gained the `set_closed()` method to change the existing `closed` value ([GH21670](#))
- `to_csv()`, `to_csvz()`, `to_json()`, and `to_jsonz()` now support `compression='infer'` to infer compression based on filename extension ([GH15008](#)). The default compression for `to_csv`, `to_json`, and `to_pickle` methods has been updated to 'infer' ([GH22004](#)).
- `DataFrame.to_sql()` now supports writing `TIMESTAMP WITH TIME ZONE` types for supported databases. For databases that don't support timezones, datetime data will be stored as timezone unaware local timestamps. See the [Datetime data types](#) for implications ([GH9086](#)).
- `to_timedelta()` now supports iso-formated timedelta strings ([GH21877](#))
- `Series` and `DataFrame` now support `Iterable` objects in the constructor ([GH2193](#))
- `DatetimeIndex` has gained the `DatetimeIndex.timetz` attribute. This returns the local time with timezone information. ([GH21358](#))
- `round()`, `ceil()`, and `floor()` for `DatetimeIndex` and `Timestamp` now support an ambiguous argument for handling datetimes that are rounded to ambiguous times ([GH18946](#)) and a nonexistent argument for handling datetimes that are rounded to nonexistent times. See [Nonexistent times when localizing](#) ([GH22647](#))
- The result of `resample()` is now iterable similar to `groupby()` ([GH15314](#)).
- `Series.resample()` and `DataFrame.resample()` have gained the `pandas.core.resample.Resampler.quantile()` ([GH15023](#)).
- `DataFrame.resample()` and `Series.resample()` with a `PeriodIndex` will now respect the `base` argument in the same fashion as with a `DatetimeIndex`. ([GH23882](#))
- `pandas.api.types.is_list_like()` has gained a keyword `allow_sets` which is `True` by default; if `False`, all instances of `set` will not be considered "list-like" anymore ([GH23061](#))
- `Index.to_frame()` now supports overriding column name(s) ([GH22580](#)).
- `Categorical.from_codes()` now can take a `dtype` parameter as an alternative to passing categories and `ordered` ([GH24398](#)).
- New attribute `__git_version__` will return git commit sha of current build ([GH21295](#)).
- Compatibility with Matplotlib 3.0 ([GH22790](#)).
- Added `Interval.overlaps()`, `arrays.IntervalArray.overlaps()`, and `IntervalIndex.overlaps()` for determining overlaps between interval-like objects ([GH21998](#))
- `read_fwf()` now accepts keyword `infer_nrows` ([GH15138](#)).
- `to_parquet()` now supports writing a `DataFrame` as a directory of parquet files partitioned by a subset of the columns when `engine = 'pyarrow'` ([GH23283](#))

- `Timestamp.tz_localize()`, `DatetimeIndex.tz_localize()`, and `Series.tz_localize()` have gained the nonexistent argument for alternative handling of nonexistent times. See *Nonexistent times when localizing* (GH8917, GH24466)
- `Index.difference()`, `Index.intersection()`, `Index.union()`, and `Index.symmetric_difference()` now have an optional `sort` parameter to control whether the results should be sorted if possible (GH17839, GH24471)
- `read_excel()` now accepts `usecols` as a list of column names or callable (GH18273)
- `MultiIndex.to_flat_index()` has been added to flatten multiple levels into a single-level `Index` object.
- `DataFrame.to_stata()` and `pandas.io.stata.StataWriter117` can write mixed sting columns to Stata `strl` format (GH23633)
- `DataFrame.between_time()` and `DataFrame.at_time()` have gained the `axis` parameter (GH8839)
- `DataFrame.to_records()` now accepts `index_dtypes` and `column_dtypes` parameters to allow different data types in stored column and index records (GH18146)
- `IntervalIndex` has gained the `is_overlapping` attribute to indicate if the `IntervalIndex` contains any overlapping intervals (GH23309)
- `pandas.DataFrame.to_sql()` has gained the `method` argument to control SQL insertion clause. See the *insertion method* section in the documentation. (GH8953)
- `DataFrame.corrwith()` now supports Spearman's rank correlation, Kendall's tau as well as callable correlation methods. (GH21925)
- `DataFrame.to_json()`, `DataFrame.to_csv()`, `DataFrame.to_pickle()`, and other export methods now support tilde(~) in path argument. (GH23473)

## Backwards incompatible API changes

Pandas 0.24.0 includes a number of API breaking changes.

## Increased minimum versions for dependencies

We have updated our minimum supported versions of dependencies (GH21242, GH18742, GH23774, GH24767). If installed, we now require:

| Package      | Minimum Version | Required |
|--------------|-----------------|----------|
| numpy        | 1.12.0          | X        |
| bottleneck   | 1.2.0           |          |
| fastparquet  | 0.2.1           |          |
| matplotlib   | 2.0.0           |          |
| numexpr      | 2.6.1           |          |
| pandas-gbq   | 0.8.0           |          |
| pyarrow      | 0.9.0           |          |
| pytables     | 3.4.2           |          |
| scipy        | 0.18.1          |          |
| xlrd         | 1.0.0           |          |
| pytest (dev) | 3.6             |          |

Additionally we no longer depend on feather-format for feather based storage and replaced it with references to pyarrow (GH21639 and GH23053).

### **`os.linesep` is used for `line_terminator` of `DataFrame.to_csv`**

`DataFrame.to_csv()` now uses `os.linesep()` rather than `'\n'` for the default line terminator (GH20353). This change only affects when running on Windows, where `'\r\n'` was used for line terminator even when `'\n'` was passed in `line_terminator`.

*Previous behavior on Windows:*

```
In [1]: data = pd.DataFrame({"string_with_lf": ["a\nbc"],
...:                        "string_with_crlf": ["a\r\nbc"]})

In [2]: # When passing file PATH to to_csv,
...: # line_terminator does not work, and csv is saved with '\r\n'.
...: # Also, this converts all '\n's in the data to '\r\n'.
...: data.to_csv("test.csv", index=False, line_terminator='\n')

In [3]: with open("test.csv", mode='rb') as f:
...:     print(f.read())
Out[3]: b'string_with_lf,string_with_crlf\r\n"a\r\nbc","a\r\r\nbc"\r\n'

In [4]: # When passing file OBJECT with newline option to
...: # to_csv, line_terminator works.
...: with open("test2.csv", mode='w', newline='\n') as f:
...:     data.to_csv(f, index=False, line_terminator='\n')

In [5]: with open("test2.csv", mode='rb') as f:
...:     print(f.read())
Out[5]: b'string_with_lf,string_with_crlf\n"a\nbc","a\r\nbc"\n'
```

*New behavior on Windows:*

Passing `line_terminator` explicitly, set the line terminator to that character.

```
In [1]: data = pd.DataFrame({"string_with_lf": ["a\nbc"],
...:                        "string_with_crlf": ["a\r\nbc"]})

In [2]: data.to_csv("test.csv", index=False, line_terminator='\n')

In [3]: with open("test.csv", mode='rb') as f:
...:     print(f.read())
Out[3]: b'string_with_lf,string_with_crlf\n"a\nbc","a\r\nbc"\n'
```

On Windows, the value of `os.linesep` is `'\r\n'`, so if `line_terminator` is not set, `'\r\n'` is used for line terminator.

```
In [1]: data = pd.DataFrame({"string_with_lf": ["a\nbc"],
...:                        "string_with_crlf": ["a\r\nbc"]})

In [2]: data.to_csv("test.csv", index=False)

In [3]: with open("test.csv", mode='rb') as f:
...:     print(f.read())
Out[3]: b'string_with_lf,string_with_crlf\r\n"a\nbc","a\r\nbc"\r\n'
```

For file objects, specifying `newline` is not sufficient to set the line terminator. You must pass in the `line_terminator` explicitly, even in this case.

```
In [1]: data = pd.DataFrame({"string_with_lf": ["a\nbc"],
...:                        "string_with_crlf": ["a\r\nbc"]})

In [2]: with open("test2.csv", mode='w', newline='\n') as f:
...:     data.to_csv(f, index=False)

In [3]: with open("test2.csv", mode='rb') as f:
...:     print(f.read())
Out[3]: b'string_with_lf,string_with_crlf\r\n"a\nbc","a\r\nbc"\r\n'
```

### Proper handling of `np.NaN` in a string data-typed column with the Python engine

There was bug in `read_excel()` and `read_csv()` with the Python engine, where missing values turned to `'nan'` with `dtype=str` and `na_filter=True`. Now, these missing values are converted to the string missing indicator, `np.nan`. (GH20377)

*Previous behavior:*

```
In [5]: data = 'a,b,c\n1,,3\n4,5,6'
In [6]: df = pd.read_csv(StringIO(data), engine='python', dtype=str, na_filter=True)
In [7]: df.loc[0, 'b']
Out[7]:
'nan'
```

*New behavior:*

```
In [53]: data = 'a,b,c\n1,,3\n4,5,6'

In [54]: df = pd.read_csv(StringIO(data), engine='python', dtype=str, na_filter=True)

In [55]: df.loc[0, 'b']
Out[55]: nan
```

Notice how we now instead output `np.nan` itself instead of a stringified form of it.

### Parsing datetime strings with timezone offsets

Previously, parsing datetime strings with UTC offsets with `to_datetime()` or `DatetimeIndex` would automatically convert the datetime to UTC without timezone localization. This is inconsistent from parsing the same datetime string with `Timestamp` which would preserve the UTC offset in the `tz` attribute. Now, `to_datetime()` preserves the UTC offset in the `tz` attribute when all the datetime strings have the same UTC offset (GH17697, GH11736, GH22457)

*Previous behavior:*

```
In [2]: pd.to_datetime("2015-11-18 15:30:00+05:30")
Out[2]: Timestamp('2015-11-18 10:00:00')

In [3]: pd.Timestamp("2015-11-18 15:30:00+05:30")
Out[3]: Timestamp('2015-11-18 15:30:00+0530', tz='pytz.FixedOffset(330)')
```

```
# Different UTC offsets would automatically convert the datetimes to UTC (without a_
↳UTC timezone)
```

(continues on next page)

(continued from previous page)

```
In [4]: pd.to_datetime(["2015-11-18 15:30:00+05:30", "2015-11-18 16:30:00+06:30"])
Out [4]: DatetimeIndex(['2015-11-18 10:00:00', '2015-11-18 10:00:00'], dtype=
↳ 'datetime64[ns]', freq=None)
```

*New behavior:*

```
In [56]: pd.to_datetime("2015-11-18 15:30:00+05:30")
Out [56]: Timestamp('2015-11-18 15:30:00+0530', tz='pytz.FixedOffset(330)')

In [57]: pd.Timestamp("2015-11-18 15:30:00+05:30")
Out [57]: Timestamp('2015-11-18 15:30:00+0530', tz='pytz.FixedOffset(330)')
```

Parsing datetime strings with the same UTC offset will preserve the UTC offset in the tz

```
In [58]: pd.to_datetime(["2015-11-18 15:30:00+05:30"] * 2)
Out [58]: DatetimeIndex(['2015-11-18 15:30:00+05:30', '2015-11-18 15:30:00+05:30'],
↳ dtype='datetime64[ns, pytz.FixedOffset(330)]', freq=None)
```

Parsing datetime strings with different UTC offsets will now create an Index of datetime.datetime objects with different UTC offsets

```
In [59]: idx = pd.to_datetime(["2015-11-18 15:30:00+05:30",
.....:                        "2015-11-18 16:30:00+06:30"])
.....:

In [60]: idx
Out [60]: Index([2015-11-18 15:30:00+05:30, 2015-11-18 16:30:00+06:30], dtype='object')

In [61]: idx[0]
Out [61]: datetime.datetime(2015, 11, 18, 15, 30, tzinfo=tzoffset(None, 19800))

In [62]: idx[1]
Out [62]: datetime.datetime(2015, 11, 18, 16, 30, tzinfo=tzoffset(None, 23400))
```

Passing utc=True will mimic the previous behavior but will correctly indicate that the dates have been converted to UTC

```
In [63]: pd.to_datetime(["2015-11-18 15:30:00+05:30",
.....:                    "2015-11-18 16:30:00+06:30"], utc=True)
.....:

Out [63]: DatetimeIndex(['2015-11-18 10:00:00+00:00', '2015-11-18 10:00:00+00:00'],
↳ dtype='datetime64[ns, UTC]', freq=None)
```

### Parsing mixed-timezones with read\_csv()

read\_csv() no longer silently converts mixed-timezone columns to UTC (GH24987).

*Previous behavior*

```
>>> import io
>>> content = """\
... a
... 2000-01-01T00:00:00+05:00
... 2000-01-01T00:00:00+06:00"""
>>> df = pd.read_csv(io.StringIO(content), parse_dates=['a'])
```

(continues on next page)

(continued from previous page)

```
>>> df.a
0    1999-12-31 19:00:00
1    1999-12-31 18:00:00
Name: a, dtype: datetime64[ns]
```

*New behavior*

```
In [64]: import io

In [65]: content = """\
.....: a
.....: 2000-01-01T00:00:00+05:00
.....: 2000-01-01T00:00:00+06:00"""
.....:

In [66]: df = pd.read_csv(io.StringIO(content), parse_dates=['a'])

In [67]: df.a
Out[67]:
0    2000-01-01 00:00:00+05:00
1    2000-01-01 00:00:00+06:00
Name: a, Length: 2, dtype: object
```

As can be seen, the dtype is object; each value in the column is a string. To convert the strings to an array of datetimes, the `date_parser` argument

```
In [68]: df = pd.read_csv(io.StringIO(content), parse_dates=['a'],
.....:                    date_parser=lambda col: pd.to_datetime(col, utc=True))
.....:

In [69]: df.a
Out[69]:
0    1999-12-31 19:00:00+00:00
1    1999-12-31 18:00:00+00:00
Name: a, Length: 2, dtype: datetime64[ns, UTC]
```

See *Parsing datetime strings with timezone offsets* for more.

**Time values in `dt.end_time` and `to_timestamp(how='end')`**

The time values in `Period` and `PeriodIndex` objects are now set to '23:59:59.999999999' when calling `Series.dt.end_time`, `Period.end_time`, `PeriodIndex.end_time`, `Period.to_timestamp()` with `how='end'`, or `PeriodIndex.to_timestamp()` with `how='end'` (GH17157)

*Previous behavior:*

```
In [2]: p = pd.Period('2017-01-01', 'D')
In [3]: pi = pd.PeriodIndex([p])

In [4]: pd.Series(pi).dt.end_time[0]
Out[4]: Timestamp(2017-01-01 00:00:00)

In [5]: p.end_time
Out[5]: Timestamp(2017-01-01 23:59:59.999999999)
```

*New behavior:*

Calling `Series.dt.end_time` will now result in a time of `'23:59:59.999999999'` as is the case with `Period.end_time`, for example

```
In [70]: p = pd.Period('2017-01-01', 'D')
In [71]: pi = pd.PeriodIndex([p])
In [72]: pd.Series(pi).dt.end_time[0]
Out [72]: Timestamp('2017-01-01 23:59:59.999999999')
In [73]: p.end_time
Out [73]: Timestamp('2017-01-01 23:59:59.999999999')
```

### Series.unique for Timezone-Aware Data

The return type of `Series.unique()` for `datetime` with timezone values has changed from an `numpy.ndarray` of `Timestamp` objects to a `arrays.DatetimeArray` ([GH24024](#)).

```
In [74]: ser = pd.Series([pd.Timestamp('2000', tz='UTC'),
.....:                    pd.Timestamp('2000', tz='UTC')])
.....:
```

*Previous behavior:*

```
In [3]: ser.unique()
Out [3]: array([Timestamp('2000-01-01 00:00:00+0000', tz='UTC')], dtype=object)
```

*New behavior:*

```
In [75]: ser.unique()
Out [75]:
<DatetimeArray>
['2000-01-01 00:00:00+00:00']
Length: 1, dtype: datetime64[ns, UTC]
```

### Sparse data structure refactor

`SparseArray`, the array backing `SparseSeries` and the columns in a `SparseDataFrame`, is now an extension array ([GH21978](#), [GH19056](#), [GH22835](#)). To conform to this interface and for consistency with the rest of pandas, some API breaking changes were made:

- `SparseArray` is no longer a subclass of `numpy.ndarray`. To convert a `SparseArray` to a NumPy array, use `numpy.asarray()`.
- `SparseArray.dtype` and `SparseSeries.dtype` are now instances of `SparseDtype`, rather than `np.dtype`. Access the underlying dtype with `SparseDtype.subdtype`.
- `numpy.asarray(sparse_array)` now returns a dense array with all the values, not just the non-fill-value values ([GH14167](#)).
- `SparseArray.take` now matches the API of `pandas.api.extensions.ExtensionArray.take()` ([GH19506](#)):
  - The default value of `allow_fill` has changed from `False` to `True`.
  - The `out` and `mode` parameters are now longer accepted (previously, this raised if they were specified).

– Passing a scalar for `indices` is no longer allowed.

- The result of `concat()` with a mix of sparse and dense Series is a Series with sparse values, rather than a `SparseSeries`.
- `SparseDataFrame.combine` and `DataFrame.combine_first` no longer supports combining a sparse column with a dense column while preserving the sparse subtype. The result will be an object-dtype `SparseArray`.
- Setting `SparseArray.fill_value` to a fill value with a different dtype is now allowed.
- `DataFrame[column]` is now a Series with sparse values, rather than a `SparseSeries`, when slicing a single column with sparse values ([GH23559](#)).
- The result of `Series.where()` is now a Series with sparse values, like with other extension arrays ([GH24077](#)).

Some new warnings are issued for operations that require or are likely to materialize a large dense array:

- A `errors.PerformanceWarning` is issued when using `fillna` with a method, as a dense array is constructed to create the filled array. Filling with a value is the efficient way to fill a sparse array.
- A `errors.PerformanceWarning` is now issued when concatenating sparse Series with differing fill values. The fill value from the first sparse array continues to be used.

In addition to these API breaking changes, many *Performance Improvements and Bug Fixes* have been made.

Finally, a `Series.sparse` accessor was added to provide sparse-specific methods like `Series.sparse.from_coo()`.

```
In [76]: s = pd.Series([0, 0, 1, 1, 1], dtype='Sparse[int]')
In [77]: s.sparse.density
Out[77]: 0.6
```

### `get_dummies()` always returns a DataFrame

Previously, when `sparse=True` was passed to `get_dummies()`, the return value could be either a `DataFrame` or a `SparseDataFrame`, depending on whether all or a just a subset of the columns were dummy-encoded. Now, a `DataFrame` is always returned ([GH24284](#)).

#### *Previous behavior*

The first `get_dummies()` returns a `DataFrame` because the column A is not dummy encoded. When just ["B", "C"] are passed to `get_dummies`, then all the columns are dummy-encoded, and a `SparseDataFrame` was returned.

```
In [2]: df = pd.DataFrame({"A": [1, 2], "B": ['a', 'b'], "C": ['a', 'a']})
In [3]: type(pd.get_dummies(df, sparse=True))
Out[3]: pandas.core.frame.DataFrame

In [4]: type(pd.get_dummies(df[['B', 'C']], sparse=True))
Out[4]: pandas.core.sparse.frame.SparseDataFrame
```

#### *New behavior*

Now, the return type is consistently a `DataFrame`.

```
In [78]: type(pd.get_dummies(df, sparse=True))
Out[78]: pandas.core.frame.DataFrame

In [79]: type(pd.get_dummies(df[['B', 'C']], sparse=True))
Out[79]: pandas.core.frame.DataFrame
```

**Note:** There's no difference in memory usage between a SparseDataFrame and a DataFrame with sparse values. The memory usage will be the same as in the previous version of pandas.

### Raise ValueError in DataFrame.to\_dict(orient='index')

Bug in DataFrame.to\_dict() raises ValueError when used with orient='index' and a non-unique index instead of losing data (GH22801)

```
In [80]: df = pd.DataFrame({'a': [1, 2], 'b': [0.5, 0.75]}, index=['A', 'A'])

In [81]: df
Out[81]:
   a  b
A  1  0.50
A  2  0.75

[2 rows x 2 columns]

In [82]: df.to_dict(orient='index')
-----
ValueError                                Traceback (most recent call last)
<ipython-input-82-f5309a7c6adb> in <module>
----> 1 df.to_dict(orient='index')

/pandas/pandas/core/frame.py in to_dict(self, orient, into)
    1431         elif orient.lower().startswith("i"):
    1432             if not self.index.is_unique:
-> 1433                 raise ValueError("DataFrame index must be unique for orient=
↪ 'index'.")
    1434         return into_c(
    1435             (t[0], dict(zip(self.columns, t[1:])))

ValueError: DataFrame index must be unique for orient='index'.
```

### Tick DateOffset normalize restrictions

Creating a Tick object (Day, Hour, Minute, Second, Milli, Micro, Nano) with normalize=True is no longer supported. This prevents unexpected behavior where addition could fail to be monotone or associative. (GH21427)

*Previous behavior:*

```
In [2]: ts = pd.Timestamp('2018-06-11 18:01:14')

In [3]: ts
Out[3]: Timestamp('2018-06-11 18:01:14')
```

(continues on next page)

(continued from previous page)

```
In [4]: tic = pd.offsets.Hour(n=2, normalize=True)
      ...:

In [5]: tic
Out[5]: <2 * Hours>

In [6]: ts + tic
Out[6]: Timestamp('2018-06-11 00:00:00')

In [7]: ts + tic + tic + tic == ts + (tic + tic + tic)
Out[7]: False
```

*New behavior:*

```
In [83]: ts = pd.Timestamp('2018-06-11 18:01:14')

In [84]: tic = pd.offsets.Hour(n=2)

In [85]: ts + tic + tic + tic == ts + (tic + tic + tic)
Out[85]: True
```

## Period subtraction

Subtraction of a Period from another Period will give a DateOffset. instead of an integer (GH21314)

*Previous behavior:*

```
In [2]: june = pd.Period('June 2018')

In [3]: april = pd.Period('April 2018')

In [4]: june - april
Out [4]: 2
```

*New behavior:*

```
In [86]: june = pd.Period('June 2018')

In [87]: april = pd.Period('April 2018')

In [88]: june - april
Out[88]: <2 * MonthEnds>
```

Similarly, subtraction of a Period from a PeriodIndex will now return an Index of DateOffset objects instead of an Int64Index

*Previous behavior:*

```
In [2]: pi = pd.period_range('June 2018', freq='M', periods=3)

In [3]: pi - pi[0]
Out[3]: Int64Index([0, 1, 2], dtype='int64')
```

*New behavior:*

```
In [89]: pi = pd.period_range('June 2018', freq='M', periods=3)
In [90]: pi - pi[0]
Out [90]: Index([<0 * MonthEnds>, <MonthEnd>, <2 * MonthEnds>], dtype='object')
```

### Addition/subtraction of NaN from DataFrame

Adding or subtracting NaN from a DataFrame column with `timedelta64[ns]` dtype will now raise a `TypeError` instead of returning all-NaT. This is for compatibility with `TimedeltaIndex` and `Series` behavior (GH22163)

```
In [91]: df = pd.DataFrame([pd.Timedelta(days=1)])
In [92]: df
Out [92]:
      0
0 1 days

[1 rows x 1 columns]
```

*Previous behavior:*

```
In [4]: df = pd.DataFrame([pd.Timedelta(days=1)])
In [5]: df - np.nan
Out [5]:
      0
0 NaT
```

*New behavior:*

```
In [2]: df - np.nan
...
TypeError: unsupported operand type(s) for -: 'TimedeltaIndex' and 'float'
```

### DataFrame comparison operations broadcasting changes

Previously, the broadcasting behavior of DataFrame comparison operations (`==`, `!=`, ...) was inconsistent with the behavior of arithmetic operations (`+`, `-`, ...). The behavior of the comparison operations has been changed to match the arithmetic operations in these cases. (GH22880)

The affected cases are:

- operating against a 2-dimensional `np.ndarray` with either 1 row or 1 column will now broadcast the same way a `np.ndarray` would (GH23000).
- a list or tuple with length matching the number of rows in the DataFrame will now raise `ValueError` instead of operating column-by-column (GH22880).
- a list or tuple with length matching the number of columns in the DataFrame will now operate row-by-row instead of raising `ValueError` (GH22880).

```
In [93]: arr = np.arange(6).reshape(3, 2)
```

(continues on next page)

(continued from previous page)

```
In [94]: df = pd.DataFrame(arr)
```

```
In [95]: df
```

```
Out [95]:
```

```
   0  1
0  0  1
1  2  3
2  4  5
```

```
[3 rows x 2 columns]
```

*Previous behavior:*

```
In [5]: df == arr[[0], :]
```

```
...: # comparison previously broadcast where arithmetic would raise
```

```
Out [5]:
```

```
   0     1
0  True  True
1  False False
2  False False
```

```
In [6]: df + arr[[0], :]
```

```
...
```

```
ValueError: Unable to coerce to DataFrame, shape must be (3, 2): given (1, 2)
```

```
In [7]: df == (1, 2)
```

```
...: # length matches number of columns;
```

```
...: # comparison previously raised where arithmetic would broadcast
```

```
...
```

```
ValueError: Invalid broadcasting comparison [(1, 2)] with block values
```

```
In [8]: df + (1, 2)
```

```
Out [8]:
```

```
   0  1
0  1  3
1  3  5
2  5  7
```

```
In [9]: df == (1, 2, 3)
```

```
...: # length matches number of rows
```

```
...: # comparison previously broadcast where arithmetic would raise
```

```
Out [9]:
```

```
   0     1
0  False  True
1   True  False
2  False  False
```

```
In [10]: df + (1, 2, 3)
```

```
...
```

```
ValueError: Unable to coerce to Series, length must be 2: given 3
```

*New behavior:*

```
# Comparison operations and arithmetic operations both broadcast.
```

```
In [96]: df == arr[[0], :]
```

```
Out [96]:
```

```
   0     1
0  True  True
1  False False
2  False False
```

(continues on next page)

(continued from previous page)

```

```
...
```

```
ValueError: Unable to coerce to Series, length must be 2: given 3
```

### DataFrame arithmetic operations broadcasting changes

DataFrame arithmetic operations when operating with 2-dimensional `np.ndarray` objects now broadcast in the same way as `np.ndarray` broadcast. ([GH23000](#))

```
In [100]: arr = np.arange(6).reshape(3, 2)
```

```
In [101]: df = pd.DataFrame(arr)
```

```
In [102]: df
```

```
Out [102]:
```

```
  0  1
0  0  1
1  2  3
```

(continues on next page)

(continued from previous page)

```
2  4  5
[3 rows x 2 columns]
```

*Previous behavior:*

```
In [5]: df + arr[[0], :] # 1 row, 2 columns
...
ValueError: Unable to coerce to DataFrame, shape must be (3, 2): given (1, 2)
In [6]: df + arr[:, [1]] # 1 column, 3 rows
...
ValueError: Unable to coerce to DataFrame, shape must be (3, 2): given (3, 1)
```

*New behavior:*

```
In [103]: df + arr[[0], :] # 1 row, 2 columns
Out [103]:
   0  1
0  0  2
1  2  4
2  4  6

[3 rows x 2 columns]

In [104]: df + arr[:, [1]] # 1 column, 3 rows
Out [104]:
   0  1
0  1  2
1  5  6
2  9 10

[3 rows x 2 columns]
```

## Series and Index data-dtype incompatibilities

Series and Index constructors now raise when the data is incompatible with a passed dtype= (GH15832)

*Previous behavior:*

```
In [4]: pd.Series([-1], dtype="uint64")
Out [4]:
0    18446744073709551615
dtype: uint64
```

*New behavior:*

```
In [4]: pd.Series([-1], dtype="uint64")
Out [4]:
...
OverflowError: Trying to coerce negative values to unsigned integers
```

## Concatenation Changes

Calling `pandas.concat()` on a `Categorical` of ints with NA values now causes them to be processed as objects when concatenating with anything other than another `Categorical` of ints ([GH19214](#))

```
In [105]: s = pd.Series([0, 1, np.nan])
In [106]: c = pd.Series([0, 1, np.nan], dtype="category")
```

### Previous behavior

```
In [3]: pd.concat([s, c])
Out[3]:
0    0.0
1    1.0
2    NaN
0    0.0
1    1.0
2    NaN
dtype: float64
```

### New behavior

```
In [107]: pd.concat([s, c])
Out[107]:
0     0
1     1
2    NaN
0     0
1     1
2    NaN
Length: 6, dtype: object
```

## Datetimelike API changes

- For `DatetimeIndex` and `TimedeltaIndex` with non-None `freq` attribute, addition or subtraction of integer-dtyped array or `Index` will return an object of the same class ([GH19959](#))
- `DateOffset` objects are now immutable. Attempting to alter one of these will now raise `AttributeError` ([GH21341](#))
- `PeriodIndex` subtraction of another `PeriodIndex` will now return an object-dtype `Index` of `DateOffset` objects instead of raising a `TypeError` ([GH20049](#))
- `cut()` and `qcut()` now returns a `DatetimeIndex` or `TimedeltaIndex` bins when the input is `datetime` or `timedelta` dtype respectively and `retbins=True` ([GH19891](#))
- `DatetimeIndex.to_period()` and `Timestamp.to_period()` will issue a warning when timezone information will be lost ([GH21333](#))
- `PeriodIndex.tz_convert()` and `PeriodIndex.tz_localize()` have been removed ([GH21781](#))

## Other API changes

- A newly constructed empty `DataFrame` with integer as the dtype will now only be cast to `float64` if index is specified (GH22858)
- `Series.str.cat()` will now raise if `others` is a set (GH23009)
- Passing scalar values to `DatetimeIndex` or `TimedeltaIndex` will now raise `TypeError` instead of `ValueError` (GH23539)
- `max_rows` and `max_cols` parameters removed from `HTMLFormatter` since truncation is handled by `DataFrameFormatter` (GH23818)
- `read_csv()` will now raise a `ValueError` if a column with missing values is declared as having dtype `bool` (GH20591)
- The column order of the resultant `DataFrame` from `MultiIndex.to_frame()` is now guaranteed to match the `MultiIndex.names` order. (GH22420)
- Incorrectly passing a `DatetimeIndex` to `MultiIndex.from_tuples()`, rather than a sequence of tuples, now raises a `TypeError` rather than a `ValueError` (GH24024)
- `pd.offsets.generate_range()` argument `time_rule` has been removed; use `offset` instead (GH24157)
- In 0.23.x, pandas would raise a `ValueError` on a merge of a numeric column (e.g. `int` dtyped column) and an object dtyped column (GH9780). We have re-enabled the ability to merge object and other dtypes; pandas will still raise on a merge between a numeric and an object dtyped column that is composed only of strings (GH21681)
- Accessing a level of a `MultiIndex` with a duplicate name (e.g. in `get_level_values()`) now raises a `ValueError` instead of a `KeyError` (GH21678).
- Invalid construction of `IntervalDtype` will now always raise a `TypeError` rather than a `ValueError` if the subtype is invalid (GH21185)
- Trying to reindex a `DataFrame` with a non unique `MultiIndex` now raises a `ValueError` instead of an `Exception` (GH21770)
- Index subtraction will attempt to operate element-wise instead of raising `TypeError` (GH19369)
- `pandas.io.formats.style.Styler` supports a `number-format` property when using `to_excel()` (GH22015)
- `DataFrame.corr()` and `Series.corr()` now raise a `ValueError` along with a helpful error message instead of a `KeyError` when supplied with an invalid method (GH22298)
- `shift()` will now always return a copy, instead of the previous behaviour of returning self when shifting by 0 (GH22397)
- `DataFrame.set_index()` now gives a better (and less frequent) `KeyError`, raises a `ValueError` for incorrect types, and will not fail on duplicate column names with `drop=True`. (GH22484)
- Slicing a single row of a `DataFrame` with multiple `ExtensionArrays` of the same type now preserves the dtype, rather than coercing to object (GH22784)
- `DateOffset` attribute `_cacheable` and method `_should_cache` have been removed (GH23118)
- `Series.searchsorted()`, when supplied a scalar value to search for, now returns a scalar instead of an array (GH23801).
- `Categorical.searchsorted()`, when supplied a scalar value to search for, now returns a scalar instead of an array (GH23466).

- `Categorical.searchsorted()` now raises a `KeyError` rather than a `ValueError`, if a searched for key is not found in its categories (GH23466).
- `Index.hasnans()` and `Series.hasnans()` now always return a python boolean. Previously, a python or a numpy boolean could be returned, depending on circumstances (GH23294).
- The order of the arguments of `DataFrame.to_html()` and `DataFrame.to_string()` is rearranged to be consistent with each other. (GH23614)
- `CategoricalIndex.reindex()` now raises a `ValueError` if the target index is non-unique and not equal to the current index. It previously only raised if the target index was not of a categorical dtype (GH23963).
- `Series.to_list()` and `Index.to_list()` are now aliases of `Series.tolist` respectively `Index.tolist` (GH8826)
- The result of `SparseSeries.unstack` is now a `DataFrame` with sparse values, rather than a `SparseDataFrame` (GH24372).
- `DatetimeIndex` and `TimedeltaIndex` no longer ignore the dtype precision. Passing a non-nanosecond resolution dtype will raise a `ValueError` (GH24753)

## Extension type changes

### Equality and hashability

Pandas now requires that extension dtypes be hashable (i.e. the respective `ExtensionDtype` objects; hashability is not a requirement for the values of the corresponding `ExtensionArray`). The base class implements a default `__eq__` and `__hash__`. If you have a parametrized dtype, you should update the `ExtensionDtype._metadata` tuple to match the signature of your `__init__` method. See `pandas.api.extensions.ExtensionDtype` for more (GH22476).

### New and changed methods

- `dropna()` has been added (GH21185)
- `repeat()` has been added (GH24349)
- The `ExtensionArray` constructor, `_from_sequence` now take the keyword arg `copy=False` (GH21185)
- `pandas.api.extensions.ExtensionArray.shift()` added as part of the basic `ExtensionArray` interface (GH22387).
- `searchsorted()` has been added (GH24350)
- Support for reduction operations such as `sum`, `mean` via opt-in base class method override (GH22762)
- `ExtensionArray.isna()` is allowed to return an `ExtensionArray` (GH22325).

### Dtype changes

- `ExtensionDtype` has gained the ability to instantiate from string dtypes, e.g. `decimal` would instantiate a registered `DecimalDtype`; furthermore the `ExtensionDtype` has gained the method `construct_array_type` (GH21185)
- Added `ExtensionDtype._is_numeric` for controlling whether an extension dtype is considered numeric (GH22290).
- Added `pandas.api.types.register_extension_dtype()` to register an extension type with pandas (GH22664)
- Updated the `.type` attribute for `PeriodDtype`, `DatetimeTZDtype`, and `IntervalDtype` to be instances of the dtype (`Period`, `Timestamp`, and `Interval` respectively) (GH22938)

## Operator support

A `Series` based on an `ExtensionArray` now supports arithmetic and comparison operators (GH19577). There are two approaches for providing operator support for an `ExtensionArray`:

1. Define each of the operators on your `ExtensionArray` subclass.
2. Use an operator implementation from pandas that depends on operators that are already defined on the underlying elements (scalars) of the `ExtensionArray`.

See the *ExtensionArray Operator Support* documentation section for details on both ways of adding operator support.

## Other changes

- A default repr for `pandas.api.extensions.ExtensionArray` is now provided (GH23601).
- `ExtensionArray._formatting_values()` is deprecated. Use `ExtensionArray._formatter` instead. (GH23601)
- An `ExtensionArray` with a boolean dtype now works correctly as a boolean indexer. `pandas.api.types.is_bool_dtype()` now properly considers them boolean (GH22326)

## Bug fixes

- Bug in `Series.get()` for `Series` using `ExtensionArray` and integer index (GH21257)
- `shift()` now dispatches to `ExtensionArray.shift()` (GH22386)
- `Series.combine()` works correctly with `ExtensionArray` inside of `Series` (GH20825)
- `Series.combine()` with scalar argument now works for any function type (GH21248)
- `Series.astype()` and `DataFrame.astype()` now dispatch to `ExtensionArray.astype()` (GH21185).
- Slicing a single row of a `DataFrame` with multiple `ExtensionArrays` of the same type now preserves the dtype, rather than coercing to object (GH22784)
- Bug when concatenating multiple `Series` with different extension dtypes not casting to object dtype (GH22994)
- `Series` backed by an `ExtensionArray` now work with `util.hash_pandas_object()` (GH23066)
- `DataFrame.stack()` no longer converts to object dtype for `DataFrames` where each column has the same extension dtype. The output `Series` will have the same dtype as the columns (GH23077).
- `Series.unstack()` and `DataFrame.unstack()` no longer convert extension arrays to object-dtype `ndarrays`. Each column in the output `DataFrame` will now have the same dtype as the input (GH23077).
- Bug when grouping `Dataframe.groupby()` and aggregating on `ExtensionArray` it was not returning the actual `ExtensionArray` dtype (GH23227).
- Bug in `pandas.merge()` when merging on an extension array-backed column (GH23020).

## Deprecations

- `MultiIndex.labels` has been deprecated and replaced by `MultiIndex.codes`. The functionality is unchanged. The new name better reflects the natures of these codes and makes the `MultiIndex` API more similar to the API for `CategoricalIndex` (GH13443). As a consequence, other uses of the name `labels` in `MultiIndex` have also been deprecated and replaced with `codes`:
  - You should initialize a `MultiIndex` instance using a parameter named `codes` rather than `labels`.
  - `MultiIndex.set_labels` has been deprecated in favor of `MultiIndex.set_codes()`.
  - For method `MultiIndex.copy()`, the `labels` parameter has been deprecated and replaced by a `codes` parameter.
- `DataFrame.to_stata()`, `read_stata()`, `StataReader` and `StataWriter` have deprecated the `encoding` argument. The encoding of a Stata dta file is determined by the file type and cannot be changed (GH21244)
- `MultiIndex.to_hierarchical()` is deprecated and will be removed in a future version (GH21613)
- `Series.ptp()` is deprecated. Use `numpy.ptp` instead (GH21614)
- `Series.compress()` is deprecated. Use `Series[condition]` instead (GH18262)
- The signature of `Series.to_csv()` has been uniformed to that of `DataFrame.to_csv()`: the name of the first argument is now `path_or_buf`, the order of subsequent arguments has changed, the `header` argument now defaults to `True`. (GH19715)
- `Categorical.from_codes()` has deprecated providing float values for the `codes` argument. (GH21767)
- `pandas.read_table()` is deprecated. Instead, use `read_csv()` passing `sep='\t'` if necessary. This deprecation has been removed in 0.25.0. (GH21948)
- `Series.str.cat()` has deprecated using arbitrary list-likes *within* list-likes. A list-like container may still contain many `Series`, `Index` or 1-dimensional `np.ndarray`, or alternatively, only scalar values. (GH21950)
- `FrozenNDArray.searchsorted()` has deprecated the `v` parameter in favor of `value` (GH14645)
- `DatetimeIndex.shift()` and `PeriodIndex.shift()` now accept `periods` argument instead of `n` for consistency with `Index.shift()` and `Series.shift()`. Using `n` throws a deprecation warning (GH22458, GH22912)
- The `fastpath` keyword of the different `Index` constructors is deprecated (GH23110).
- `Timestamp.tz_localize()`, `DatetimeIndex.tz_localize()`, and `Series.tz_localize()` have deprecated the `errors` argument in favor of the nonexistent `argument` (GH8917)
- The class `FrozenNDArray` has been deprecated. When unpickling, `FrozenNDArray` will be unpickled to `np.ndarray` once this class is removed (GH9031)
- The methods `DataFrame.update()` and `Panel.update()` have deprecated the `raise_conflict=False|True` keyword in favor of `errors='ignore'|'raise'` (GH23585)
- The methods `Series.str.partition()` and `Series.str.rpartition()` have deprecated the `pat` keyword in favor of `sep` (GH22676)
- Deprecated the `nthreads` keyword of `pandas.read_feather()` in favor of `use_threads` to reflect the changes in `pyarrow>=0.11.0`. (GH23053)
- `pandas.read_excel()` has deprecated accepting `usecols` as an integer. Please pass in a list of ints from 0 to `usecols` inclusive instead (GH23527)

- Constructing a `TimedeltaIndex` from data with `datetime64`-typed data is deprecated, will raise `TypeError` in a future version (GH23539)
- Constructing a `DatetimeIndex` from data with `timedelta64`-typed data is deprecated, will raise `TypeError` in a future version (GH23675)
- The `keep_tz=False` option (the default) of the `keep_tz` keyword of `DatetimeIndex.to_series()` is deprecated (GH17832).
- Timezone converting a tz-aware `datetime.datetime` or `Timestamp` with `Timestamp` and the `tz` argument is now deprecated. Instead, use `Timestamp.tz_convert()` (GH23579)
- `pandas.api.types.is_period()` is deprecated in favor of `pandas.api.types.is_period_dtype` (GH23917)
- `pandas.api.types.is_datetimetz()` is deprecated in favor of `pandas.api.types.is_datetime64tz` (GH23917)
- Creating a `TimedeltaIndex`, `DatetimeIndex`, or `PeriodIndex` by passing range arguments `start`, `end`, and `periods` is deprecated in favor of `timedelta_range()`, `date_range()`, or `period_range()` (GH23919)
- Passing a string alias like `'datetime64[ns, UTC]'` as the `unit` parameter to `DatetimeTZDtype` is deprecated. Use `DatetimeTZDtype.construct_from_string` instead (GH23990).
- The `skipna` parameter of `infer_dtype()` will switch to `True` by default in a future version of pandas (GH17066, GH24050)
- In `Series.where()` with Categorical data, providing an `other` that is not present in the categories is deprecated. Convert the categorical to a different dtype or add the `other` to the categories first (GH24077).
- `Series.clip_lower()`, `Series.clip_upper()`, `DataFrame.clip_lower()` and `DataFrame.clip_upper()` are deprecated and will be removed in a future version. Use `Series.clip(lower=threshold)`, `Series.clip(upper=threshold)` and the equivalent `DataFrame` methods (GH24203)
- `Series.nonzero()` is deprecated and will be removed in a future version (GH18262)
- Passing an integer to `Series.fillna()` and `DataFrame.fillna()` with `timedelta64[ns]` dtypes is deprecated, will raise `TypeError` in a future version. Use `obj.fillna(pd.Timedelta(...))` instead (GH24694)
- `Series.cat.categorical`, `Series.cat.name` and `Series.cat.index` have been deprecated. Use the attributes on `Series.cat` or `Series` directly. (GH24751).
- Passing a dtype without a precision like `np.dtype('datetime64')` or `timedelta64` to `Index`, `DatetimeIndex` and `TimedeltaIndex` is now deprecated. Use the nanosecond-precision dtype instead (GH24753).

### Integer addition/subtraction with datetimes and timedeltas is deprecated

In the past, users could—in some cases—add or subtract integers or integer-dtype arrays from `Timestamp`, `DatetimeIndex` and `TimedeltaIndex`.

This usage is now deprecated. Instead add or subtract integer multiples of the object's `freq` attribute (GH21939, GH23878).

*Previous behavior:*

```

In [5]: ts = pd.Timestamp('1994-05-06 12:15:16', freq=pd.offsets.Hour())
In [6]: ts + 2
Out[6]: Timestamp('1994-05-06 14:15:16', freq='H')

In [7]: tdi = pd.timedelta_range('1D', periods=2)
In [8]: tdi - np.array([2, 1])
Out[8]: TimedeltaIndex(['-1 days', '1 days'], dtype='timedelta64[ns]', freq=None)

In [9]: dti = pd.date_range('2001-01-01', periods=2, freq='7D')
In [10]: dti + pd.Index([1, 2])
Out[10]: DatetimeIndex(['2001-01-08', '2001-01-22'], dtype='datetime64[ns]',
↳freq=None)

```

*New behavior:*

```

In [108]: ts = pd.Timestamp('1994-05-06 12:15:16', freq=pd.offsets.Hour())

In [109]: ts + 2 * ts.freq
Out[109]: Timestamp('1994-05-06 14:15:16', freq='H')

In [110]: tdi = pd.timedelta_range('1D', periods=2)

In [111]: tdi - np.array([2 * tdi.freq, 1 * tdi.freq])
Out[111]: TimedeltaIndex(['-1 days', '1 days'], dtype='timedelta64[ns]', freq=None)

In [112]: dti = pd.date_range('2001-01-01', periods=2, freq='7D')

In [113]: dti + pd.Index([1 * dti.freq, 2 * dti.freq])
Out[113]: DatetimeIndex(['2001-01-08', '2001-01-22'], dtype='datetime64[ns]',
↳freq=None)

```

## Passing integer data and a timezone to datetimeindex

The behavior of `DatetimeIndex` when passed integer data and a timezone is changing in a future version of pandas. Previously, these were interpreted as wall times in the desired timezone. In the future, these will be interpreted as wall times in UTC, which are then converted to the desired timezone ([GH24559](#)).

The default behavior remains the same, but issues a warning:

```

In [3]: pd.DatetimeIndex([946684800000000000], tz="US/Central")
/bin/ipython:1: FutureWarning:
    Passing integer-dtype data and a timezone to DatetimeIndex. Integer values
    will be interpreted differently in a future version of pandas. Previously,
    these were viewed as datetime64[ns] values representing the wall time
    *in the specified timezone*. In the future, these will be viewed as
    datetime64[ns] values representing the wall time *in UTC*. This is similar
    to a nanosecond-precision UNIX epoch. To accept the future behavior, use

        pd.to_datetime(integer_data, utc=True).tz_convert(tz)

    To keep the previous behavior, use

        pd.to_datetime(integer_data).tz_localize(tz)

#!/bin/python3
Out[3]: DatetimeIndex(['2000-01-01 00:00:00-06:00'], dtype='datetime64[ns, US/
↳Central]', freq=None)

```

(continues on next page)

As the warning message explains, opt in to the future behavior by specifying that the integer values are UTC, and then converting to the final timezone:

```
In [114]: pd.to_datetime([946684800000000000], utc=True).tz_convert('US/Central')
Out [114]: DatetimeIndex(['1999-12-31 18:00:00-06:00'], dtype='datetime64[ns, US/
↪Central]', freq=None)
```

The old behavior can be retained with by localizing directly to the final timezone:

```
In [115]: pd.to_datetime([946684800000000000]).tz_localize('US/Central')
Out [115]: DatetimeIndex(['2000-01-01 00:00:00-06:00'], dtype='datetime64[ns, US/
↪Central]', freq=None)
```

## Converting timezone-aware Series and Index to NumPy arrays

The conversion from a Series or Index with timezone-aware datetime data will change to preserve timezones by default (GH23569).

NumPy doesn't have a dedicated dtype for timezone-aware datetimes. In the past, converting a Series or DatetimeIndex with timezone-aware datetimes would convert to a NumPy array by

1. converting the tz-aware data to UTC
2. dropping the timezone-info
3. returning a `numpy.ndarray` with `datetime64[ns]` dtype

Future versions of pandas will preserve the timezone information by returning an object-dtype NumPy array where each value is a `Timestamp` with the correct timezone attached

```
In [116]: ser = pd.Series(pd.date_range('2000', periods=2, tz="CET"))

In [117]: ser
Out [117]:
0    2000-01-01 00:00:00+01:00
1    2000-01-02 00:00:00+01:00
Length: 2, dtype: datetime64[ns, CET]
```

The default behavior remains the same, but issues a warning

```
In [8]: np.asarray(ser)
/bin/ipython:1: FutureWarning: Converting timezone-aware DatetimeArray to timezone-
↪naive
    ndarray with 'datetime64[ns]' dtype. In the future, this will return an ndarray
    with 'object' dtype where each element is a 'pandas.Timestamp' with the correct
    ↪'tz'.

    To accept the future behavior, pass 'dtype=object'.
    To keep the old behavior, pass 'dtype="datetime64[ns]"'.
    #!/bin/python3
Out [8]:
array(['1999-12-31T23:00:00.000000000', '2000-01-01T23:00:00.000000000'],
      dtype='datetime64[ns]')
```

The previous or future behavior can be obtained, without any warnings, by specifying the dtype

*Previous behavior*

```
In [118]: np.asarray(ser, dtype='datetime64[ns]')
Out [118]:
array(['1999-12-31T23:00:00.000000000', '2000-01-01T23:00:00.000000000'],
      dtype='datetime64[ns]')
```

*Future behavior*

```
# New behavior
In [119]: np.asarray(ser, dtype=object)
Out [119]:
array([Timestamp('2000-01-01 00:00:00+0100', tz='CET', freq='D'),
      Timestamp('2000-01-02 00:00:00+0100', tz='CET', freq='D')],
      dtype=object)
```

Or by using `Series.to_numpy()`

```
In [120]: ser.to_numpy()
Out [120]:
array([Timestamp('2000-01-01 00:00:00+0100', tz='CET', freq='D'),
      Timestamp('2000-01-02 00:00:00+0100', tz='CET', freq='D')],
      dtype=object)

In [121]: ser.to_numpy(dtype="datetime64[ns]")
Out [121]:
array(['1999-12-31T23:00:00.000000000', '2000-01-01T23:00:00.000000000'],
      dtype='datetime64[ns]')
```

All the above applies to a `DatetimeIndex` with tz-aware values as well.

**Removal of prior version deprecations/changes**

- The `LongPanel` and `WidePanel` classes have been removed ([GH10892](#))
- `Series.repeat()` has renamed the `reps` argument to `repeats` ([GH14645](#))
- Several private functions were removed from the (non-public) module `pandas.core.common` ([GH22001](#))
- Removal of the previously deprecated module `pandas.core.datetools` ([GH14105](#), [GH14094](#))
- Strings passed into `DataFrame.groupby()` that refer to both column and index levels will raise a `ValueError` ([GH14432](#))
- `Index.repeat()` and `MultiIndex.repeat()` have renamed the `n` argument to `repeats` ([GH14645](#))
- The `Series` constructor and `.astype` method will now raise a `ValueError` if timestamp dtypes are passed in without a unit (e.g. `np.datetime64`) for the `dtype` parameter ([GH15987](#))
- Removal of the previously deprecated `as_indexer` keyword completely from `str.match()` ([GH22356](#), [GH6581](#))
- The modules `pandas.types`, `pandas.computation`, and `pandas.util.decorators` have been removed ([GH16157](#), [GH16250](#))
- Removed the `pandas.formats.style` shim for `pandas.io.formats.style.Styler` ([GH16059](#))
- `pandas.pnow`, `pandas.match`, `pandas.groupby`, `pd.get_store`, `pd.Expr`, and `pd.Term` have been removed ([GH15538](#), [GH15940](#))

- `Categorical.searchsorted()` and `Series.searchsorted()` have renamed the `v` argument to `value` (GH14645)
- `pandas.parser`, `pandas.lib`, and `pandas.tslib` have been removed (GH15537)
- `Index.searchsorted()` have renamed the `key` argument to `value` (GH14645)
- `DataFrame consolidate` and `Series consolidate` have been removed (GH15501)
- Removal of the previously deprecated module `pandas.json` (GH19944)
- The module `pandas.tools` has been removed (GH15358, GH16005)
- `SparseArray.get_values()` and `SparseArray.to_dense()` have dropped the `fill` parameter (GH14686)
- `DataFrame.sortlevel` and `Series.sortlevel` have been removed (GH15099)
- `SparseSeries.to_dense()` has dropped the `sparse_only` parameter (GH14686)
- `DataFrame.astype()` and `Series.astype()` have renamed the `raise_on_error` argument to `errors` (GH14967)
- `is_sequence`, `is_any_int_dtype`, and `is_floating_dtype` have been removed from `pandas.api.types` (GH16163, GH16189)

### Performance improvements

- Slicing `Series` and `DataFrames` with an monotonically increasing `CategoricalIndex` is now very fast and has speed comparable to slicing with an `Int64Index`. The speed increase is both when indexing by label (using `.loc`) and position (`.iloc`) (GH20395) Slicing a monotonically increasing `CategoricalIndex` itself (i.e. `ci[1000:2000]`) shows similar speed improvements as above (GH21659)
- Improved performance of `CategoricalIndex.equals()` when comparing to another `CategoricalIndex` (GH24023)
- Improved performance of `Series.describe()` in case of numeric dtypes (GH21274)
- Improved performance of `pandas.core.groupby.GroupBy.rank()` when dealing with tied rankings (GH21237)
- Improved performance of `DataFrame.set_index()` with columns consisting of `Period` objects (GH21582, GH21606)
- Improved performance of `Series.at()` and `Index.get_value()` for Extension Arrays values (e.g. `Categorical`) (GH24204)
- Improved performance of membership checks in `Categorical` and `CategoricalIndex` (i.e. `x in cat`-style checks are much faster). `CategoricalIndex.contains()` is likewise much faster (GH21369, GH21508)
- Improved performance of `HDFStore.groups()` (and dependent functions like `HDFStore.keys()`). (i.e. `x in store` checks are much faster) (GH21372)
- Improved the performance of `pandas.get_dummies()` with `sparse=True` (GH21997)
- Improved performance of `IndexEngine.get_indexer_non_unique()` for sorted, non-unique indexes (GH9466)
- Improved performance of `PeriodIndex.unique()` (GH23083)
- Improved performance of `concat()` for `Series` objects (GH23404)

- Improved performance of `DatetimeIndex.normalize()` and `Timestamp.normalize()` for time-zone naive or UTC datetimes (GH23634)
- Improved performance of `DatetimeIndex.tz_localize()` and various `DatetimeIndex` attributes with dateutil UTC timezone (GH23772)
- Fixed a performance regression on Windows with Python 3.7 of `read_csv()` (GH23516)
- Improved performance of `Categorical` constructor for `Series` objects (GH23814)
- Improved performance of `where()` for `Categorical` data (GH24077)
- Improved performance of iterating over a `Series`. Using `DataFrame.itertuples()` now creates iterators without internally allocating lists of all elements (GH20783)
- Improved performance of `Period` constructor, additionally benefitting `PeriodArray` and `PeriodIndex` creation (GH24084, GH24118)
- Improved performance of tz-aware `DatetimeArray` binary operations (GH24491)

## Bug fixes

### Categorical

- Bug in `Categorical.from_codes()` where NaN values in codes were silently converted to 0 (GH21767). In the future this will raise a `ValueError`. Also changes the behavior of `.from_codes([1, 2, 0])`.
- Bug in `Categorical.sort_values()` where NaN values were always positioned in front regardless of `na_position` value. (GH22556).
- Bug when indexing with a boolean-valued `Categorical`. Now a boolean-valued `Categorical` is treated as a boolean mask (GH22665)
- Constructing a `CategoricalIndex` with empty values and boolean categories was raising a `ValueError` after a change to dtype coercion (GH22702).
- Bug in `Categorical.take()` with a user-provided `fill_value` not encoding the `fill_value`, which could result in a `ValueError`, incorrect results, or a segmentation fault (GH23296).
- In `Series.unstack()`, specifying a `fill_value` not present in the categories now raises a `TypeError` rather than ignoring the `fill_value` (GH23284)
- Bug when resampling `DataFrame.resample()` and aggregating on categorical data, the categorical dtype was getting lost. (GH23227)
- Bug in many methods of the `.str`-accessor, which always failed on calling the `CategoricalIndex.str` constructor (GH23555, GH23556)
- Bug in `Series.where()` losing the categorical dtype for categorical data (GH24077)
- Bug in `Categorical.apply()` where NaN values could be handled unpredictably. They now remain unchanged (GH24241)
- Bug in `Categorical` comparison methods incorrectly raising `ValueError` when operating against a `DataFrame` (GH24630)
- Bug in `Categorical.set_categories()` where setting fewer new categories with `rename=True` caused a segmentation fault (GH24675)

## Datetimelike

- Fixed bug where two `DateOffset` objects with different `normalize` attributes could evaluate as equal (GH21404)
- Fixed bug where `Timestamp.resolution()` incorrectly returned 1-microsecond `timedelta` instead of 1-nanosecond `Timedelta` (GH21336, GH21365)
- Bug in `to_datetime()` that did not consistently return an `Index` when `box=True` was specified (GH21864)
- Bug in `DatetimeIndex` comparisons where string comparisons incorrectly raises `TypeError` (GH22074)
- Bug in `DatetimeIndex` comparisons when comparing against `timedelta64[ns]` dtypes arrays; in some cases `TypeError` was incorrectly raised, in others it incorrectly failed to raise (GH22074)
- Bug in `DatetimeIndex` comparisons when comparing against object-dtype arrays (GH22074)
- Bug in `DataFrame` with `datetime64[ns]` dtype addition and subtraction with `Timedelta`-like objects (GH22005, GH22163)
- Bug in `DataFrame` with `datetime64[ns]` dtype addition and subtraction with `DateOffset` objects returning an object dtype instead of `datetime64[ns]` dtype (GH21610, GH22163)
- Bug in `DataFrame` with `datetime64[ns]` dtype comparing against `NaT` incorrectly (GH22242, GH22163)
- Bug in `DataFrame` with `datetime64[ns]` dtype subtracting `Timestamp`-like object incorrectly returned `datetime64[ns]` dtype instead of `timedelta64[ns]` dtype (GH8554, GH22163)
- Bug in `DataFrame` with `datetime64[ns]` dtype subtracting `np.datetime64` object with non-nanosecond unit failing to convert to nanoseconds (GH18874, GH22163)
- Bug in `DataFrame` comparisons against `Timestamp`-like objects failing to raise `TypeError` for inequality checks with mismatched types (GH8932, GH22163)
- Bug in `DataFrame` with mixed dtypes including `datetime64[ns]` incorrectly raising `TypeError` on equality comparisons (GH13128, GH22163)
- Bug in `DataFrame.values` returning a `DatetimeIndex` for a single-column `DataFrame` with tz-aware datetime values. Now a 2-D `numpy.ndarray` of `Timestamp` objects is returned (GH24024)
- Bug in `DataFrame.eq()` comparison against `NaT` incorrectly returning `True` or `NaN` (GH15697, GH22163)
- Bug in `DatetimeIndex` subtraction that incorrectly failed to raise `OverflowError` (GH22492, GH22508)
- Bug in `DatetimeIndex` incorrectly allowing indexing with `Timedelta` object (GH20464)
- Bug in `DatetimeIndex` where frequency was being set if original frequency was `None` (GH22150)
- Bug in rounding methods of `DatetimeIndex` (`round()`, `ceil()`, `floor()`) and `Timestamp` (`round()`, `ceil()`, `floor()`) could give rise to loss of precision (GH22591)
- Bug in `to_datetime()` with an `Index` argument that would drop the name from the result (GH21697)
- Bug in `PeriodIndex` where adding or subtracting a `timedelta` or `Tick` object produced incorrect results (GH22988)
- Bug in the `Series` repr with period-dtype data missing a space before the data (GH23601)
- Bug in `date_range()` when decrementing a start date to a past end date by a negative frequency (GH23270)
- Bug in `Series.min()` which would return `NaN` instead of `NaT` when called on a series of `NaT` (GH23282)
- Bug in `Series.combine_first()` not properly aligning categoricals, so that missing values in `self` where not filled by valid values from `other` (GH24147)

- Bug in `DataFrame.combine()` with datetimelike values raising a `TypeError` (GH23079)
- Bug in `date_range()` with frequency of `Day` or higher where dates sufficiently far in the future could wrap around to the past instead of raising `OutOfBoundsDatetime` (GH14187)
- Bug in `period_range()` ignoring the frequency of `start` and `end` when those are provided as `Period` objects (GH20535).
- Bug in `PeriodIndex` with attribute `freq.n` greater than 1 where adding a `DateOffset` object would return incorrect results (GH23215)
- Bug in `Series` that interpreted string indices as lists of characters when setting datetimelike values (GH23451)
- Bug in `DataFrame` when creating a new column from an `ndarray` of `Timestamp` objects with timezones creating an object-dtype column, rather than `datetime` with `timezone` (GH23932)
- Bug in `Timestamp` constructor which would drop the frequency of an input `Timestamp` (GH22311)
- Bug in `DatetimeIndex` where calling `np.array(dtindex, dtype=object)` would incorrectly return an array of long objects (GH23524)
- Bug in `Index` where passing a timezone-aware `DatetimeIndex` and `dtype=object` would incorrectly raise a `ValueError` (GH23524)
- Bug in `Index` where calling `np.array(dtindex, dtype=object)` on a timezone-naive `DatetimeIndex` would return an array of `datetime` objects instead of `Timestamp` objects, potentially losing nanosecond portions of the timestamps (GH23524)
- Bug in `Categorical.__setitem__` not allowing setting with another `Categorical` when both are unordered and have the same categories, but in a different order (GH24142)
- Bug in `date_range()` where using dates with millisecond resolution or higher could return incorrect values or the wrong number of values in the index (GH24110)
- Bug in `DatetimeIndex` where constructing a `DatetimeIndex` from a `Categorical` or `CategoricalIndex` would incorrectly drop timezone information (GH18664)
- Bug in `DatetimeIndex` and `TimedeltaIndex` where indexing with `Ellipsis` would incorrectly lose the index's `freq` attribute (GH21282)
- Clarified error message produced when passing an incorrect `freq` argument to `DatetimeIndex` with `NaT` as the first entry in the passed data (GH11587)
- Bug in `to_datetime()` where `box` and `utc` arguments were ignored when passing a `DataFrame` or `dict` of unit mappings (GH23760)
- Bug in `Series.dt` where the cache would not update properly after an in-place operation (GH24408)
- Bug in `PeriodIndex` where comparisons against an array-like object with length 1 failed to raise `ValueError` (GH23078)
- Bug in `DatetimeIndex.astype()`, `PeriodIndex.astype()` and `TimedeltaIndex.astype()` ignoring the sign of the `dtype` for unsigned integer dtypes (GH24405).
- Fixed bug in `Series.max()` with `datetime64[ns]`-dtype failing to return `NaT` when nulls are present and `skipna=False` is passed (GH24265)
- Bug in `to_datetime()` where arrays of `datetime` objects containing both timezone-aware and timezone-naive datetimes would fail to raise `ValueError` (GH24569)
- Bug in `to_datetime()` with invalid `datetime` format doesn't coerce input to `NaT` even if `errors='coerce'` (GH24763)

## Timedelta

- Bug in `DataFrame` with `timedelta64[ns]` dtype division by `Timedelta`-like scalar incorrectly returning `timedelta64[ns]` dtype instead of `float64` dtype (GH20088, GH22163)
- Bug in adding a `Index` with object dtype to a `Series` with `timedelta64[ns]` dtype incorrectly raising (GH22390)
- Bug in multiplying a `Series` with numeric dtype against a `timedelta` object (GH22390)
- Bug in `Series` with numeric dtype when adding or subtracting an array or `Series` with `timedelta64` dtype (GH22390)
- Bug in `Index` with numeric dtype when multiplying or dividing an array with dtype `timedelta64` (GH22390)
- Bug in `TimedeltaIndex` incorrectly allowing indexing with `Timestamp` object (GH20464)
- Fixed bug where subtracting `Timedelta` from an object-dtyped array would raise `TypeError` (GH21980)
- Fixed bug in adding a `DataFrame` with all-`timedelta64[ns]` dtypes to a `DataFrame` with all-integer dtypes returning incorrect results instead of raising `TypeError` (GH22696)
- Bug in `TimedeltaIndex` where adding a timezone-aware datetime scalar incorrectly returned a timezone-naive `DatetimeIndex` (GH23215)
- Bug in `TimedeltaIndex` where adding `np.timedelta64('NaT')` incorrectly returned an all-`NaT` `DatetimeIndex` instead of an all-`NaT` `TimedeltaIndex` (GH23215)
- Bug in `Timedelta` and `to_timedelta()` have inconsistencies in supported unit string (GH21762)
- Bug in `TimedeltaIndex` division where dividing by another `TimedeltaIndex` raised `TypeError` instead of returning a `Float64Index` (GH23829, GH22631)
- Bug in `TimedeltaIndex` comparison operations where comparing against non-`Timedelta`-like objects would raise `TypeError` instead of returning all-`False` for `__eq__` and all-`True` for `__ne__` (GH24056)
- Bug in `Timedelta` comparisons when comparing with a `Tick` object incorrectly raising `TypeError` (GH24710)

## Timezones

- Bug in `Index.shift()` where an `AssertionError` would raise when shifting across DST (GH8616)
- Bug in `Timestamp` constructor where passing an invalid timezone offset designator (Z) would not raise a `ValueError` (GH8910)
- Bug in `Timestamp.replace()` where replacing at a DST boundary would retain an incorrect offset (GH7825)
- Bug in `Series.replace()` with `datetime64[ns, tz]` data when replacing `NaT` (GH11792)
- Bug in `Timestamp` when passing different string date formats with a timezone offset would produce different timezone offsets (GH12064)
- Bug when comparing a tz-naive `Timestamp` to a tz-aware `DatetimeIndex` which would coerce the `DatetimeIndex` to tz-naive (GH12601)
- Bug in `Series.truncate()` with a tz-aware `DatetimeIndex` which would cause a core dump (GH9243)
- Bug in `Series` constructor which would coerce tz-aware and tz-naive `Timestamp` to tz-aware (GH13051)
- Bug in `Index` with `datetime64[ns, tz]` dtype that did not localize integer data correctly (GH20964)

- Bug in `DatetimeIndex` where constructing with an integer and `tz` would not localize correctly (GH12619)
- Fixed bug where `DataFrame.describe()` and `Series.describe()` on tz-aware datetimes did not show *first* and *last* result (GH21328)
- Bug in `DatetimeIndex` comparisons failing to raise `TypeError` when comparing timezone-aware `DatetimeIndex` against `np.datetime64` (GH22074)
- Bug in `DataFrame` assignment with a timezone-aware scalar (GH19843)
- Bug in `DataFrame.asof()` that raised a `TypeError` when attempting to compare tz-naive and tz-aware timestamps (GH21194)
- Bug when constructing a `DatetimeIndex` with `Timestamp` constructed with the `replace` method across DST (GH18785)
- Bug when setting a new value with `DataFrame.loc()` with a `DatetimeIndex` with a DST transition (GH18308, GH20724)
- Bug in `Index.unique()` that did not re-localize tz-aware dates correctly (GH21737)
- Bug when indexing a `Series` with a DST transition (GH21846)
- Bug in `DataFrame.resample()` and `Series.resample()` where an `AmbiguousTimeError` or `NonExistentTimeError` would raise if a timezone aware timeseries ended on a DST transition (GH19375, GH10117)
- Bug in `DataFrame.drop()` and `Series.drop()` when specifying a tz-aware `Timestamp` key to drop from a `DatetimeIndex` with a DST transition (GH21761)
- Bug in `DatetimeIndex` constructor where `NaT` and `dateutil.tz.tzlocal` would raise an `OutOfBoundsDatetime` error (GH23807)
- Bug in `DatetimeIndex.tz_localize()` and `Timestamp.tz_localize()` with `dateutil.tz.tzlocal` near a DST transition that would return an incorrectly localized datetime (GH23807)
- Bug in `Timestamp` constructor where a `dateutil.tz.tzutc` timezone passed with a `datetime.datetime` argument would be converted to a `pytz.UTC` timezone (GH23807)
- Bug in `to_datetime()` where `utc=True` was not respected when specifying a unit and `errors='ignore'` (GH23758)
- Bug in `to_datetime()` where `utc=True` was not respected when passing a `Timestamp` (GH24415)
- Bug in `DataFrame.any()` returns wrong value when `axis=1` and the data is of datetimelike type (GH23070)
- Bug in `DatetimeIndex.to_period()` where a timezone aware index was converted to UTC first before creating `PeriodIndex` (GH22905)
- Bug in `DataFrame.tz_localize()`, `DataFrame.tz_convert()`, `Series.tz_localize()`, and `Series.tz_convert()` where `copy=False` would mutate the original argument inplace (GH6326)
- Bug in `DataFrame.max()` and `DataFrame.min()` with `axis=1` where a `Series` with `NaN` would be returned when all columns contained the same timezone (GH10390)

## Offsets

- Bug in `FY5253` where date offsets could incorrectly raise an `AssertionError` in arithmetic operations ([GH14774](#))
- Bug in `DateOffset` where keyword arguments `week` and `milliseconds` were accepted and ignored. Passing these will now raise `ValueError` ([GH19398](#))
- Bug in adding `DateOffset` with `DataFrame` or `PeriodIndex` incorrectly raising `TypeError` ([GH23215](#))
- Bug in comparing `DateOffset` objects with non-`DateOffset` objects, particularly strings, raising `ValueError` instead of returning `False` for equality checks and `True` for not-equal checks ([GH23524](#))

## Numeric

- Bug in `Series.__rmatmul__` doesn't support matrix vector multiplication ([GH21530](#))
- Bug in `factorize()` fails with read-only array ([GH12813](#))
- Fixed bug in `unique()` handled signed zeros inconsistently: for some inputs `0.0` and `-0.0` were treated as equal and for some inputs as different. Now they are treated as equal for all inputs ([GH21866](#))
- Bug in `DataFrame.agg()`, `DataFrame.transform()` and `DataFrame.apply()` where, when supplied with a list of functions and `axis=1` (e.g. `df.apply(['sum', 'mean'], axis=1)`), a `TypeError` was wrongly raised. For all three methods such calculation are now done correctly. ([GH16679](#)).
- Bug in `Series` comparison against datetime-like scalars and arrays ([GH22074](#))
- Bug in `DataFrame` multiplication between boolean dtype and integer returning object dtype instead of integer dtype ([GH22047](#), [GH22163](#))
- Bug in `DataFrame.apply()` where, when supplied with a string argument and additional positional or keyword arguments (e.g. `df.apply('sum', min_count=1)`), a `TypeError` was wrongly raised ([GH22376](#))
- Bug in `DataFrame.astype()` to extension dtype may raise `AttributeError` ([GH22578](#))
- Bug in `DataFrame` with `timedelta64[ns]` dtype arithmetic operations with `ndarray` with integer dtype incorrectly treating the ndarray as `timedelta64[ns]` dtype ([GH23114](#))
- Bug in `Series.rpow()` with object dtype `NaN` for `1 ** NA` instead of `1` ([GH22922](#)).
- `Series.agg()` can now handle numpy NaN-aware methods like `numpy.nansum()` ([GH19629](#))
- Bug in `Series.rank()` and `DataFrame.rank()` when `pct=True` and more than  $2^{24}$  rows are present resulted in percentages greater than 1.0 ([GH18271](#))
- Calls such as `DataFrame.round()` with a non-unique `CategoricalIndex()` now return expected data. Previously, data would be improperly duplicated ([GH21809](#)).
- Added `log10`, `floor` and `ceil` to the list of supported functions in `DataFrame.eval()` ([GH24139](#), [GH24353](#))
- Logical operations `&`, `|`, `^` between `Series` and `Index` will no longer raise `ValueError` ([GH22092](#))
- Checking PEP 3141 numbers in `is_scalar()` function returns `True` ([GH22903](#))
- Reduction methods like `Series.sum()` now accept the default value of `keepdims=False` when called from a NumPy ufunc, rather than raising a `TypeError`. Full support for `keepdims` has not been implemented ([GH24356](#)).

## Conversion

- Bug in `DataFrame.combine_first()` in which column types were unexpectedly converted to float (GH20699)
- Bug in `DataFrame.clip()` in which column types are not preserved and casted to float (GH24162)
- Bug in `DataFrame.clip()` when order of columns of dataframes doesn't match, result observed is wrong in numeric values (GH20911)
- Bug in `DataFrame.astype()` where converting to an extension dtype when duplicate column names are present causes a `RecursionError` (GH24704)

## Strings

- Bug in `Index.str.partition()` was not nan-safe (GH23558).
- Bug in `Index.str.split()` was not nan-safe (GH23677).
- Bug `Series.str.contains()` not respecting the `na` argument for a Categorical dtype Series (GH22158)
- Bug in `Index.str.cat()` when the result contained only NaN (GH24044)

## Interval

- Bug in the `IntervalIndex` constructor where the `closed` parameter did not always override the inferred `closed` (GH19370)
- Bug in the `IntervalIndex` repr where a trailing comma was missing after the list of intervals (GH20611)
- Bug in `Interval` where scalar arithmetic operations did not retain the `closed` value (GH22313)
- Bug in `IntervalIndex` where indexing with datetime-like values raised a `KeyError` (GH20636)
- Bug in `IntervalTree` where data containing NaN triggered a warning and resulted in incorrect indexing queries with `IntervalIndex` (GH23352)

## Indexing

- Bug in `DataFrame.ne()` fails if columns contain column name "dtype" (GH22383)
- The traceback from a `KeyError` when asking `.loc` for a single missing label is now shorter and more clear (GH21557)
- `PeriodIndex` now emits a `KeyError` when a malformed string is looked up, which is consistent with the behavior of `DatetimeIndex` (GH22803)
- When `.ix` is asked for a missing integer label in a `MultiIndex` with a first level of integer type, it now raises a `KeyError`, consistently with the case of a flat `Int64Index`, rather than falling back to positional indexing (GH21593)
- Bug in `Index.reindex()` when reindexing a tz-naive and tz-aware `DatetimeIndex` (GH8306)
- Bug in `Series.reindex()` when reindexing an empty series with a `datetime64[ns, tz]` dtype (GH20869)
- Bug in `DataFrame` when setting values with `.loc` and a timezone aware `DatetimeIndex` (GH11365)

- `DataFrame.__getitem__` now accepts dictionaries and dictionary keys as list-likes of labels, consistently with `Series.__getitem__` (GH21294)
- Fixed `DataFrame[np.nan]` when columns are non-unique (GH21428)
- Bug when indexing `DatetimeIndex` with nanosecond resolution dates and timezones (GH11679)
- Bug where indexing with a Numpy array containing negative values would mutate the indexer (GH21867)
- Bug where mixed indexes wouldn't allow integers for `.at` (GH19860)
- `Float64Index.get_loc` now raises `KeyError` when boolean key passed. (GH19087)
- Bug in `DataFrame.loc()` when indexing with an `IntervalIndex` (GH19977)
- `Index` no longer mangles `None`, `NaN` and `NaT`, i.e. they are treated as three different keys. However, for numeric `Index` all three are still coerced to a `NaN` (GH22332)
- Bug in `scalar in Index` if `scalar` is a float while the `Index` is of integer dtype (GH22085)
- Bug in `MultiIndex.set_levels()` when `levels` value is not subscriptable (GH23273)
- Bug where setting a `timedelta` column by `Index` causes it to be casted to double, and therefore lose precision (GH23511)
- Bug in `Index.union()` and `Index.intersection()` where name of the `Index` of the result was not computed correctly for certain cases (GH9943, GH9862)
- Bug in `Index` slicing with boolean `Index` may raise `TypeError` (GH22533)
- Bug in `PeriodArray.__setitem__` when accepting slice and list-like value (GH23978)
- Bug in `DatetimeIndex`, `TimedeltaIndex` where indexing with `Ellipsis` would lose their `freq` attribute (GH21282)
- Bug in `iat` where using it to assign an incompatible value would create a new column (GH23236)

## Missing

- Bug in `DataFrame.fillna()` where a `ValueError` would raise when one column contained a `datetime64[ns, tz]` dtype (GH15522)
- Bug in `Series.hasnans()` that could be incorrectly cached and return incorrect answers if null elements are introduced after an initial call (GH19700)
- `Series.isin()` now treats all `NaN`-floats as equal also for `np.object`-dtype. This behavior is consistent with the behavior for `float64` (GH22119)
- `unique()` no longer mangles `NaN`-floats and the `NaT`-object for `np.object`-dtype, i.e. `NaT` is no longer coerced to a `NaN`-value and is treated as a different entity. (GH22295)
- `DataFrame` and `Series` now properly handle numpy masked arrays with hardened masks. Previously, constructing a `DataFrame` or `Series` from a masked array with a hard mask would create a pandas object containing the underlying value, rather than the expected `NaN`. (GH24574)
- Bug in `DataFrame` constructor where `dtype` argument was not honored when handling numpy masked record arrays. (GH24874)

## MultiIndex

- Bug in `io.formats.style.Styler.applymap()` where `subset=` with `MultiIndex` slice would reduce to `Series` (GH19861)
- Removed compatibility for `MultiIndex` pickles prior to version 0.8.0; compatibility with `MultiIndex` pickles from version 0.13 forward is maintained (GH21654)
- `MultiIndex.get_loc_level()` (and as a consequence, `.loc` on a `Series` or `DataFrame` with a `MultiIndex` index) will now raise a `KeyError`, rather than returning an empty slice, if asked a label which is present in the `levels` but is unused (GH22221)
- `MultiIndex` has gained the `MultiIndex.from_frame()`, it allows constructing a `MultiIndex` object from a `DataFrame` (GH22420)
- Fix `TypeError` in Python 3 when creating `MultiIndex` in which some levels have mixed types, e.g. when some labels are tuples (GH15457)

## I/O

- Bug in `read_csv()` in which a column specified with `CategoricalDtype` of boolean categories was not being correctly coerced from string values to booleans (GH20498)
- Bug in `read_csv()` in which unicode column names were not being properly recognized with Python 2.x (GH13253)
- Bug in `DataFrame.to_sql()` when writing timezone aware data (`datetime64[ns, tz]` dtype) would raise a `TypeError` (GH9086)
- Bug in `DataFrame.to_sql()` where a naive `DatetimeIndex` would be written as `TIMESTAMP WITH TIMEZONE` type in supported databases, e.g. PostgreSQL (GH23510)
- Bug in `read_excel()` when `parse_cols` is specified with an empty dataset (GH9208)
- `read_html()` no longer ignores all-whitespace `<tr>` within `<thead>` when considering the `skiprows` and `header` arguments. Previously, users had to decrease their `header` and `skiprows` values on such tables to work around the issue. (GH21641)
- `read_excel()` will correctly show the deprecation warning for previously deprecated `sheetname` (GH17994)
- `read_csv()` and `read_table()` will throw `UnicodeError` and not `coredump` on badly encoded strings (GH22748)
- `read_csv()` will correctly parse timezone-aware datetimes (GH22256)
- Bug in `read_csv()` in which memory management was prematurely optimized for the C engine when the data was being read in chunks (GH23509)
- Bug in `read_csv()` in unnamed columns were being improperly identified when extracting a multi-index (GH23687)
- `read_sas()` will parse numbers in `sas7bdat`-files that have width less than 8 bytes correctly. (GH21616)
- `read_sas()` will correctly parse `sas7bdat` files with many columns (GH22628)
- `read_sas()` will correctly parse `sas7bdat` files with data page types having also bit 7 set (so page type is  $128 + 256 = 384$ ) (GH16615)
- Bug in `read_sas()` in which an incorrect error was raised on an invalid file format. (GH24548)

- Bug in `detect_client_encoding()` where potential `IOError` goes unhandled when importing in a `mod_wsgi` process due to restricted access to `stdout`. (GH21552)
- Bug in `DataFrame.to_html()` with `index=False` misses truncation indicators (...) on truncated `DataFrame` (GH15019, GH22783)
- Bug in `DataFrame.to_html()` with `index=False` when both columns and row index are `MultiIndex` (GH22579)
- Bug in `DataFrame.to_html()` with `index_names=False` displaying index name (GH22747)
- Bug in `DataFrame.to_html()` with `header=False` not displaying row index names (GH23788)
- Bug in `DataFrame.to_html()` with `sparsify=False` that caused it to raise `TypeError` (GH22887)
- Bug in `DataFrame.to_string()` that broke column alignment when `index=False` and width of first column's values is greater than the width of first column's header (GH16839, GH13032)
- Bug in `DataFrame.to_string()` that caused representations of `DataFrame` to not take up the whole window (GH22984)
- Bug in `DataFrame.to_csv()` where a single level `MultiIndex` incorrectly wrote a tuple. Now just the value of the index is written (GH19589).
- `HDFStore` will raise `ValueError` when the `format` kwarg is passed to the constructor (GH13291)
- Bug in `HDFStore.append()` when appending a `DataFrame` with an empty string column and `min_itemsize < 8` (GH12242)
- Bug in `read_csv()` in which memory leaks occurred in the C engine when parsing `NaN` values due to insufficient cleanup on completion or error (GH21353)
- Bug in `read_csv()` in which incorrect error messages were being raised when `skipfooter` was passed in along with `nrows`, `iterator`, or `chunksize` (GH23711)
- Bug in `read_csv()` in which `MultiIndex` index names were being improperly handled in the cases when they were not provided (GH23484)
- Bug in `read_csv()` in which unnecessary warnings were being raised when the dialect's values conflicted with the default arguments (GH23761)
- Bug in `read_html()` in which the error message was not displaying the valid flavors when an invalid one was provided (GH23549)
- Bug in `read_excel()` in which extraneous header names were extracted, even though none were specified (GH11733)
- Bug in `read_excel()` in which column names were not being properly converted to string sometimes in Python 2.x (GH23874)
- Bug in `read_excel()` in which `index_col=None` was not being respected and parsing index columns anyway (GH18792, GH20480)
- Bug in `read_excel()` in which `usecols` was not being validated for proper column names when passed in as a string (GH20480)
- Bug in `DataFrame.to_dict()` when the resulting dict contains non-Python scalars in the case of numeric data (GH23753)
- `DataFrame.to_string()`, `DataFrame.to_html()`, `DataFrame.to_latex()` will correctly format output when a string is passed as the `float_format` argument (GH21625, GH22270)
- Bug in `read_csv()` that caused it to raise `OverflowError` when trying to use 'inf' as `na_value` with integer index column (GH17128)

- Bug in `read_csv()` that caused the C engine on Python 3.6+ on Windows to improperly read CSV filenames with accented or special characters ([GH15086](#))
- Bug in `read_fwf()` in which the compression type of a file was not being properly inferred ([GH22199](#))
- Bug in `pandas.io.json.json_normalize()` that caused it to raise `TypeError` when two consecutive elements of `record_path` are dicts ([GH22706](#))
- Bug in `DataFrame.to_stata()`, `pandas.io.stata.StataWriter` and `pandas.io.stata.StataWriter117` where an exception would leave a partially written and invalid dta file ([GH23573](#))
- Bug in `DataFrame.to_stata()` and `pandas.io.stata.StataWriter117` that produced invalid files when using `strLs` with non-ASCII characters ([GH23573](#))
- Bug in `HDFStore` that caused it to raise `ValueError` when reading a Dataframe in Python 3 from fixed format written in Python 2 ([GH24510](#))
- Bug in `DataFrame.to_string()` and more generally in the floating `repr` formatter. Zeros were not trimmed if `inf` was present in a column while it was the case with NA values. Zeros are now trimmed as in the presence of NA ([GH24861](#)).
- Bug in the `repr` when truncating the number of columns and having a wide last column ([GH24849](#)).

## Plotting

- Bug in `DataFrame.plot.scatter()` and `DataFrame.plot.hexbin()` caused x-axis label and tick-labels to disappear when `colorbar` was on in IPython inline backend ([GH10611](#), [GH10678](#), and [GH20455](#))
- Bug in plotting a Series with datetimes using `matplotlib.axes.Axes.scatter()` ([GH22039](#))
- Bug in `DataFrame.plot.bar()` caused bars to use multiple colors instead of a single one ([GH20585](#))
- Bug in validating color parameter caused extra color to be appended to the given color array. This happened to multiple plotting functions using `matplotlib`. ([GH20726](#))

## Groupby/resample/rolling

- Bug in `pandas.core.window.Rolling.min()` and `pandas.core.window.Rolling.max()` with `closed='left'`, a datetime-like index and only one entry in the series leading to `segfault` ([GH24718](#))
- Bug in `pandas.core.groupby.GroupBy.first()` and `pandas.core.groupby.GroupBy.last()` with `as_index=False` leading to the loss of timezone information ([GH15884](#))
- Bug in `DateFrame.resample()` when downsampling across a DST boundary ([GH8531](#))
- Bug in date anchoring for `DateFrame.resample()` with `offset Day` when `n > 1` ([GH24127](#))
- Bug where `ValueError` is wrongly raised when calling `count()` method of a `SeriesGroupBy` when the grouping variable only contains NaNs and `numpy` version `< 1.13` ([GH21956](#)).
- Multiple bugs in `pandas.core.window.Rolling.min()` with `closed='left'` and a datetime-like index leading to incorrect results and also `segfault`. ([GH21704](#))
- Bug in `pandas.core.resample.Resampler.apply()` when passing positional arguments to applied `func` ([GH14615](#)).
- Bug in `Series.resample()` when passing `numpy.timedelta64` to `loffset` kwarg ([GH7687](#)).
- Bug in `pandas.core.resample.Resampler.asfreq()` when frequency of `TimedeltaIndex` is a subperiod of a new frequency ([GH13022](#)).

- Bug in `pandas.core.groupby.SeriesGroupBy.mean()` when values were integral but could not fit inside of `int64`, overflowing instead. (GH22487)
- `pandas.core.groupby.RollingGroupBy.agg()` and `pandas.core.groupby.ExpandingGroupBy.agg()` now support multiple aggregation functions as parameters (GH15072)
- Bug in `DataFrame.resample()` and `Series.resample()` when resampling by a weekly offset ('W') across a DST transition (GH9119, GH21459)
- Bug in `DataFrame.expanding()` in which the `axis` argument was not being respected during aggregations (GH23372)
- Bug in `pandas.core.groupby.GroupBy.transform()` which caused missing values when the input function can accept a `DataFrame` but renames it (GH23455).
- Bug in `pandas.core.groupby.GroupBy.nth()` where column order was not always preserved (GH20760)
- Bug in `pandas.core.groupby.GroupBy.rank()` with `method='dense'` and `pct=True` when a group has only one member would raise a `ZeroDivisionError` (GH23666).
- Calling `pandas.core.groupby.GroupBy.rank()` with empty groups and `pct=True` was raising a `ZeroDivisionError` (GH22519)
- Bug in `DataFrame.resample()` when resampling `NaT` in `TimeDeltaIndex` (GH13223).
- Bug in `DataFrame.groupby()` did not respect the `observed` argument when selecting a column and instead always used `observed=False` (GH23970)
- Bug in `pandas.core.groupby.SeriesGroupBy.pct_change()` or `pandas.core.groupby.DataFrameGroupBy.pct_change()` would previously work across groups when calculating the percent change, where it now correctly works per group (GH21200, GH21235).
- Bug preventing hash table creation with very large number ( $2^{32}$ ) of rows (GH22805)
- Bug in `groupby` when grouping on categorical causes `ValueError` and incorrect grouping if `observed=True` and `nan` is present in categorical column (GH24740, GH21151).

## Reshaping

- Bug in `pandas.concat()` when joining resampled `DataFrames` with timezone aware index (GH13783)
- Bug in `pandas.concat()` when joining only `Series` the `names` argument of `concat` is no longer ignored (GH23490)
- Bug in `Series.combine_first()` with `datetime64[ns, tz]` dtype which would return tz-naive result (GH21469)
- Bug in `Series.where()` and `DataFrame.where()` with `datetime64[ns, tz]` dtype (GH21546)
- Bug in `DataFrame.where()` with an empty `DataFrame` and empty `cond` having non-bool dtype (GH21947)
- Bug in `Series.mask()` and `DataFrame.mask()` with list conditionals (GH21891)
- Bug in `DataFrame.replace()` raises `RecursionError` when converting `OutOfBounds` `datetime64[ns, tz]` (GH20380)
- `pandas.core.groupby.GroupBy.rank()` now raises a `ValueError` when an invalid value is passed for argument `na_option` (GH22124)
- Bug in `get_dummies()` with Unicode attributes in Python 2 (GH22084)
- Bug in `DataFrame.replace()` raises `RecursionError` when replacing empty lists (GH22083)

- Bug in `Series.replace()` and `DataFrame.replace()` when dict is used as the `to_replace` value and one key in the dict is another key's value, the results were inconsistent between using integer key and using string key (GH20656)
- Bug in `DataFrame.drop_duplicates()` for empty `DataFrame` which incorrectly raises an error (GH20516)
- Bug in `pandas.wide_to_long()` when a string is passed to the `stubnames` argument and a column name is a substring of that stubname (GH22468)
- Bug in `merge()` when merging `datetime64[ns, tz]` data that contained a DST transition (GH18885)
- Bug in `merge_asof()` when merging on float values within defined tolerance (GH22981)
- Bug in `pandas.concat()` when concatenating a multicolumn `DataFrame` with tz-aware data against a `DataFrame` with a different number of columns (GH22796)
- Bug in `merge_asof()` where confusing error message raised when attempting to merge with missing values (GH23189)
- Bug in `DataFrame.nsmallest()` and `DataFrame.nlargest()` for dataframes that have a `MultiIndex` for columns (GH23033).
- Bug in `pandas.melt()` when passing column names that are not present in `DataFrame` (GH23575)
- Bug in `DataFrame.append()` with a `Series` with a `dateutil` timezone would raise a `TypeError` (GH23682)
- Bug in `Series` construction when passing no data and `dtype=str` (GH22477)
- Bug in `cut()` with `bins` as an overlapping `IntervalIndex` where multiple bins were returned per item instead of raising a `ValueError` (GH23980)
- Bug in `pandas.concat()` when joining `Series datetimetz` with `Series category` would lose timezone (GH23816)
- Bug in `DataFrame.join()` when joining on partial `MultiIndex` would drop names (GH20452).
- `DataFrame.nlargest()` and `DataFrame.nsmallest()` now returns the correct `n` values when `keep != 'all'` also when tied on the first columns (GH22752)
- Constructing a `DataFrame` with an `index` argument that wasn't already an instance of `Index` was broken (GH22227).
- Bug in `DataFrame` prevented list subclasses to be used to construction (GH21226)
- Bug in `DataFrame.unstack()` and `DataFrame.pivot_table()` returning a misleading error message when the resulting `DataFrame` has more elements than `int32` can handle. Now, the error message is improved, pointing towards the actual problem (GH20601)
- Bug in `DataFrame.unstack()` where a `ValueError` was raised when unstacking timezone aware values (GH18338)
- Bug in `DataFrame.stack()` where timezone aware values were converted to timezone naive values (GH19420)
- Bug in `merge_asof()` where a `TypeError` was raised when `by_col` were timezone aware values (GH21184)
- Bug showing an incorrect shape when throwing error during `DataFrame` construction. (GH20742)

## Sparse

- Updating a boolean, datetime, or timedelta column to be Sparse now works (GH22367)
- Bug in `Series.to_sparse()` with Series already holding sparse data not constructing properly (GH22389)
- Providing a `sparse_index` to the `SparseArray` constructor no longer defaults the na-value to `np.nan` for all dtypes. The correct `na_value` for `data.dtype` is now used.
- Bug in `SparseArray.nbytes` under-reporting its memory usage by not including the size of its sparse index.
- Improved performance of `Series.shift()` for non-NA `fill_value`, as values are no longer converted to a dense array.
- Bug in `DataFrame.groupby` not including `fill_value` in the groups for non-NA `fill_value` when grouping by a sparse column (GH5078)
- Bug in unary inversion operator (`~`) on a `SparseSeries` with boolean values. The performance of this has also been improved (GH22835)
- Bug in `SparseArray.unique()` not returning the unique values (GH19595)
- Bug in `SparseArray.nonzero()` and `SparseDataFrame.dropna()` returning shifted/incorrect results (GH21172)
- Bug in `DataFrame.apply()` where dtypes would lose sparseness (GH23744)
- Bug in `concat()` when concatenating a list of Series with all-sparse values changing the `fill_value` and converting to a dense Series (GH24371)

## Style

- `background_gradient()` now takes a `text_color_threshold` parameter to automatically lighten the text color based on the luminance of the background color. This improves readability with dark background colors without the need to limit the background colormap range. (GH21258)
- `background_gradient()` now also supports tablewise application (in addition to rowwise and columnwise) with `axis=None` (GH15204)
- `bar()` now also supports tablewise application (in addition to rowwise and columnwise) with `axis=None` and setting clipping range with `vmin` and `vmax` (GH21548 and GH21526). NaN values are also handled properly.

## Build changes

- Building pandas for development now requires `cython >= 0.28.2` (GH21688)
- Testing pandas now requires `hypothesis >= 3.58`. You can find the [Hypothesis docs here](#), and a pandas-specific introduction *in the contributing guide*. (GH22280)
- Building pandas on macOS now targets minimum macOS 10.9 if run on macOS 10.9 or above (GH23424)

## Other

- Bug where C variables were declared with external linkage causing import errors if certain other C libraries were imported before Pandas. ([GH24113](#))

## Contributors

A total of 337 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

## 6.4 Version 0.23

### 6.4.1 What's new in 0.23.4 (August 3, 2018)

{{ header }}

This is a minor bug-fix release in the 0.23.x series and includes some small regression fixes and bug fixes. We recommend that all users upgrade to this version.

**Warning:** Starting January 1, 2019, pandas feature releases will support Python 3 only. See [Dropping Python 2.7](#) for more.

#### What's new in v0.23.4

- *Fixed regressions*
- *Bug fixes*
- *Contributors*

## Fixed regressions

- Python 3.7 with Windows gave all missing values for rolling variance calculations (GH21813)

## Bug fixes

### Groupby/resample/rolling

- Bug where calling `DataFrameGroupBy.agg()` with a list of functions including `ohlcv` as the non-initial element would raise a `ValueError` (GH21716)
- Bug in `roll_quantile` caused a memory leak when calling `.rolling(...).quantile(q)` with `q` in `(0,1)` (GH21965)

### Missing

- Bug in `Series.clip()` and `DataFrame.clip()` cannot accept list-like threshold containing `NaN` (GH19992)

## Contributors

A total of 6 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

- Jeff Reback
- MeeseeksMachine +
- Tom Augspurger
- chris-b1
- h-vetinari
- meeseeksdev[bot]

## 6.4.2 What’s new in 0.23.3 (July 7, 2018)

{{ header }}

This release fixes a build issue with the sdist for Python 3.7 (GH21785) There are no other changes.

## Contributors

A total of 2 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

- Tom Augspurger
- meeseeksdev[bot] +

### 6.4.3 What's new in 0.23.2 (July 5, 2018)

{{ header }}

This is a minor bug-fix release in the 0.23.x series and includes some small regression fixes and bug fixes. We recommend that all users upgrade to this version.

---

**Note:** Pandas 0.23.2 is first pandas release that's compatible with Python 3.7 (GH20552)

---

**Warning:** Starting January 1, 2019, pandas feature releases will support Python 3 only. See [Dropping Python 2.7](#) for more.

#### What's new in v0.23.2

- *Logical reductions over entire DataFrame*
- *Fixed regressions*
- *Build changes*
- *Bug fixes*
- *Contributors*

#### Logical reductions over entire DataFrame

`DataFrame.all()` and `DataFrame.any()` now accept `axis=None` to reduce over all axes to a scalar (GH19976)

```
In [1]: df = pd.DataFrame({"A": [1, 2], "B": [True, False]})
In [2]: df.all(axis=None)
Out[2]: False
```

This also provides compatibility with NumPy 1.15, which now dispatches to `DataFrame.all`. With NumPy 1.15 and pandas 0.23.1 or earlier, `numpy.all()` will no longer reduce over every axis:

```
>>> # NumPy 1.15, pandas 0.23.1
>>> np.any(pd.DataFrame({"A": [False], "B": [False]}))
A    False
B    False
dtype: bool
```

With pandas 0.23.2, that will correctly return `False`, as it did with NumPy < 1.15.

```
In [3]: np.any(pd.DataFrame({"A": [False], "B": [False]}))
Out[3]: False
```

## Fixed regressions

- Fixed regression in `to_csv()` when handling file-like object incorrectly (GH21471)
- Re-allowed duplicate level names of a `MultiIndex`. Accessing a level that has a duplicate name by name still raises an error (GH19029).
- Bug in both `DataFrame.first_valid_index()` and `Series.first_valid_index()` raised for a row index having duplicate values (GH21441)
- Fixed printing of `DataFrames` with hierarchical columns with long names (GH21180)
- Fixed regression in `reindex()` and `groupby()` with a `MultiIndex` or multiple keys that contains categorical datetime-like values (GH21390).
- Fixed regression in unary negative operations with object dtype (GH21380)
- Bug in `Timestamp.ceil()` and `Timestamp.floor()` when timestamp is a multiple of the rounding frequency (GH21262)
- Fixed regression in `to_clipboard()` that defaulted to copying dataframes with space delimited instead of tab delimited (GH21104)

## Build changes

- The source and binary distributions no longer include test data files, resulting in smaller download sizes. Tests relying on these data files will be skipped when using `pandas.test()`. (GH19320)

## Bug fixes

### Conversion

- Bug in constructing `Index` with an iterator or generator (GH21470)
- Bug in `Series.nlargest()` for signed and unsigned integer dtypes when the minimum value is present (GH21426)

### Indexing

- Bug in `Index.get_indexer_non_unique()` with categorical key (GH21448)
- Bug in comparison operations for `MultiIndex` where error was raised on equality / inequality comparison involving a `MultiIndex` with `nlevels == 1` (GH21149)
- Bug in `DataFrame.drop()` behaviour is not consistent for unique and non-unique indexes (GH21494)
- Bug in `DataFrame.duplicated()` with a large number of columns causing a 'maximum recursion depth exceeded' (GH21524).

### I/O

- Bug in `read_csv()` that caused it to incorrectly raise an error when `nrows=0`, `low_memory=True`, and `index_col` was not `None` (GH21141)
- Bug in `json_normalize()` when formatting the `record_prefix` with integer columns (GH21536)

### Categorical

- Bug in rendering `Series` with `Categorical` dtype in rare conditions under Python 2.7 (GH21002)

### Timezones

- Bug in `Timestamp` and `DatetimeIndex` where passing a `Timestamp` localized after a DST transition would return a datetime before the DST transition ([GH20854](#))
- Bug in comparing `DataFrame` with tz-aware `DatetimeIndex` columns with a DST transition that raised a `KeyError` ([GH19970](#))
- Bug in `DatetimeIndex.shift()` where an `AssertionError` would raise when shifting across DST ([GH8616](#))
- Bug in `Timestamp` constructor where passing an invalid timezone offset designator (Z) would not raise a `ValueError` ([GH8910](#))
- Bug in `Timestamp.replace()` where replacing at a DST boundary would retain an incorrect offset ([GH7825](#))
- Bug in `DatetimeIndex.reindex()` when reindexing a tz-naive and tz-aware `DatetimeIndex` ([GH8306](#))
- Bug in `DatetimeIndex.resample()` when downsampling across a DST boundary ([GH8531](#))

### Timedelta

- Bug in `Timedelta` where non-zero timedeltas shorter than 1 microsecond were considered `False` ([GH21484](#))

### Contributors

A total of 17 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

## 6.4.4 What's new in 0.23.1 (June 12, 2018)

{{ header }}

This is a minor bug-fix release in the 0.23.x series and includes some small regression fixes and bug fixes. We recommend that all users upgrade to this version.

**Warning:** Starting January 1, 2019, pandas feature releases will support Python 3 only. See [Dropping Python 2.7](#) for more.

### What's new in v0.23.1

- *Fixed regressions*
- *Performance improvements*
- *Bug fixes*
- *Contributors*

### Fixed regressions

#### Comparing Series with datetime.date

We've reverted a 0.23.0 change to comparing a Series holding datetimes and a datetime.date object (GH21152). In pandas 0.22 and earlier, comparing a Series holding datetimes and datetime.date objects would coerce the datetime.date to a datetime before comparing. This was inconsistent with Python, NumPy, and DatetimeIndex, which never consider a datetime and datetime.date equal.

In 0.23.0, we unified operations between DatetimeIndex and Series, and in the process changed comparisons between a Series of datetimes and datetime.date without warning.

We've temporarily restored the 0.22.0 behavior, so datetimes and dates may again compare equal, but restore the 0.23.0 behavior in a future release.

To summarize, here's the behavior in 0.22.0, 0.23.0, 0.23.1:

```
# 0.22.0... Silently coerce the datetime.date
>>> import datetime
>>> pd.Series(pd.date_range('2017', periods=2)) == datetime.date(2017, 1, 1)
0      True
1      False
dtype: bool

# 0.23.0... Do not coerce the datetime.date
>>> pd.Series(pd.date_range('2017', periods=2)) == datetime.date(2017, 1, 1)
0      False
1      False
dtype: bool

# 0.23.1... Coerce the datetime.date with a warning
>>> pd.Series(pd.date_range('2017', periods=2)) == datetime.date(2017, 1, 1)
/bin/python:1: FutureWarning: Comparing Series of datetimes with 'datetime.date'.
↳Currently, the
'datetime.date' is coerced to a datetime. In the future pandas will
not coerce, and the values not compare equal to the 'datetime.date'.
```

(continues on next page)

(continued from previous page)

```
To retain the current behavior, convert the 'datetime.date' to a
datetime with 'pd.Timestamp'.
#!/bin/python3
0     True
1     False
dtype: bool
```

In addition, ordering comparisons will raise a `TypeError` in the future.

### Other fixes

- Reverted the ability of `to_sql()` to perform multivalued inserts as this caused regression in certain cases (GH21103). In the future this will be made configurable.
- Fixed regression in the `DatetimeIndex.date` and `DatetimeIndex.time` attributes in case of timezone-aware data: `DatetimeIndex.time` returned a tz-aware time instead of tz-naive (GH21267) and `DatetimeIndex.date` returned incorrect date when the input date has a non-UTC timezone (GH21230).
- Fixed regression in `pandas.io.json.json_normalize()` when called with `None` values in nested levels in JSON, and to not drop keys with value as `None` (GH21158, GH21356).
- Bug in `to_csv()` causes encoding error when compression and encoding are specified (GH21241, GH21118)
- Bug preventing pandas from being importable with -OO optimization (GH21071)
- Bug in `Categorical.fillna()` incorrectly raising a `TypeError` when `value` the individual categories are iterable and `value` is an iterable (GH21097, GH19788)
- Fixed regression in constructors coercing `NA` values like `None` to strings when passing `dtype=str` (GH21083)
- Regression in `pivot_table()` where an ordered `Categorical` with missing values for the pivot's index would give a mis-aligned result (GH21133)
- Fixed regression in merging on boolean index/columns (GH21119).

### Performance improvements

- Improved performance of `CategoricalIndex.is_monotonic_increasing()`, `CategoricalIndex.is_monotonic_decreasing()` and `CategoricalIndex.is_monotonic()` (GH21025)
- Improved performance of `CategoricalIndex.is_unique()` (GH21107)

### Bug fixes

#### Groupby/resample/rolling

- Bug in `DataFrame.agg()` where applying multiple aggregation functions to a `DataFrame` with duplicated column names would cause a stack overflow (GH21063)
- Bug in `pandas.core.groupby.GroupBy.ffill()` and `pandas.core.groupby.GroupBy.bfill()` where the fill within a grouping would not always be applied as intended due to the implementations' use of a non-stable sort (GH21207)
- Bug in `pandas.core.groupby.GroupBy.rank()` where results did not scale to 100% when specifying `method='dense'` and `pct=True`

- Bug in `pandas.DataFrame.rolling()` and `pandas.Series.rolling()` which incorrectly accepted a 0 window size rather than raising (GH21286)

### Data-type specific

- Bug in `Series.str.replace()` where the method throws `TypeError` on Python 3.5.2 (GH21078)
- Bug in `Timedelta` where passing a float with a unit would prematurely round the float precision (GH14156)
- Bug in `pandas.testing.assert_index_equal()` which raised `AssertionError` incorrectly, when comparing two `CategoricalIndex` objects with param `check_categorical=False` (GH19776)

### Sparse

- Bug in `SparseArray.shape` which previously only returned the shape `SparseArray.sp_values` (GH21126)

### Indexing

- Bug in `Series.reset_index()` where appropriate error was not raised with an invalid level name (GH20925)
- Bug in `interval_range()` when `start/periods` or `end/periods` are specified with float `start` or `end` (GH21161)
- Bug in `MultiIndex.set_names()` where error raised for a `MultiIndex` with `nlevels == 1` (GH21149)
- Bug in `IntervalIndex` constructors where creating an `IntervalIndex` from categorical data was not fully supported (GH21243, GH21253)
- Bug in `MultiIndex.sort_index()` which was not guaranteed to sort correctly with `level=1`; this was also causing data misalignment in particular `DataFrame.stack()` operations (GH20994, GH20945, GH21052)

### Plotting

- New keywords (`sharex`, `sharey`) to turn on/off sharing of x/y-axis by subplots generated with `pandas.DataFrame().groupby().boxplot()` (GH20968)

### I/O

- Bug in IO methods specifying `compression='zip'` which produced uncompressed zip archives (GH17778, GH21144)
- Bug in `DataFrame.to_stata()` which prevented exporting DataFrames to buffers and most file-like objects (GH21041)
- Bug in `read_stata()` and `StataReader` which did not correctly decode utf-8 strings on Python 3 from Stata 14 files (dta version 118) (GH21244)
- Bug in IO JSON `read_json()` reading empty JSON schema with `orient='table'` back to `DataFrame` caused an error (GH21287)

### Reshaping

- Bug in `concat()` where error was raised in concatenating `Series` with numpy scalar and tuple names (GH21015)
- Bug in `concat()` warning message providing the wrong guidance for future behavior (GH21101)

### Other

- Tab completion on `Index` in IPython no longer outputs deprecation warnings (GH21125)

- Bug preventing pandas being used on Windows without C++ redistributable installed ([GH21106](#))

### Contributors

## 6.4.5 What's new in 0.23.0 (May 15, 2018)

{{ header }}

This is a major release from 0.22.0 and includes a number of API changes, deprecations, new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

- *Round-trippable JSON format with 'table' orient.*
- *Instantiation from dicts respects order for Python 3.6+.*
- *Dependent column arguments for assign.*
- *Merging / sorting on a combination of columns and index levels.*
- *Extending pandas with custom types.*
- *Excluding unobserved categories from groupby.*
- *Changes to make output shape of DataFrame.apply consistent.*

Check the *API Changes* and *deprecations* before updating.

**Warning:** Starting January 1, 2019, pandas feature releases will support Python 3 only. See [Dropping Python 2.7](#) for more.

### What's new in v0.23.0

- *New features*
  - *JSON read/write round-trippable with orient='table'*
  - *.assign() accepts dependent arguments*
  - *Merging on a combination of columns and index levels*
  - *Sorting by a combination of columns and index levels*
  - *Extending pandas with custom types (experimental)*
  - *New observed keyword for excluding unobserved categories in groupby*
  - *Rolling/Expanding.apply() accepts raw=False to pass a Series to the function*
  - *DataFrame.interpolate has gained the limit\_area kwarg*
  - *get\_dummies now supports dtype argument*
  - *Timedelta mod method*
  - *.rank() handles inf values when NaN are present*
  - *Series.str.cat has gained the join kwarg*
  - *DataFrame.astype performs column-wise conversion to Categorical*
  - *Other enhancements*
- *Backwards incompatible API changes*
  - *Dependencies have increased minimum versions*

- *Instantiation from dicts preserves dict insertion order for python 3.6+*
- *Deprecate Panel*
- *pandas.core.common removals*
- *Changes to make output of DataFrame.apply consistent*
- *Concatenation will no longer sort*
- *Build changes*
- *Index division by zero fills correctly*
- *Extraction of matching patterns from strings*
- *Default value for the ordered parameter of CategoricalDtype*
- *Better pretty-printing of DataFrames in a terminal*
- *Datetimelike API changes*
- *Other API changes*
- *Deprecations*
- *Removal of prior version deprecations/changes*
- *Performance improvements*
- *Documentation changes*
- *Bug fixes*
  - *Categorical*
  - *Datetimelike*
  - *Timedelta*
  - *Timezones*
  - *Offsets*
  - *Numeric*
  - *Strings*
  - *Indexing*
  - *MultiIndex*
  - *I/O*
  - *Plotting*
  - *Groupby/resample/rolling*
  - *Sparse*
  - *Reshaping*
  - *Other*
- *Contributors*

## New features

### JSON read/write round-trippable with `orient='table'`

A `DataFrame` can now be written to and subsequently read back via JSON while preserving metadata through usage of the `orient='table'` argument (see [GH18912](#) and [GH9146](#)). Previously, none of the available `orient` values guaranteed the preservation of dtypes and index names, amongst other metadata.

```
In [1]: df = pd.DataFrame({'foo': [1, 2, 3, 4],
...:                      'bar': ['a', 'b', 'c', 'd'],
...:                      'baz': pd.date_range('2018-01-01', freq='d', periods=4),
...:                      'qux': pd.Categorical(['a', 'b', 'c', 'c'])},
...:                      index=pd.Index(range(4), name='idx'))
...:
In [2]: df
Out [2]:
   foo bar      baz qux
idx
0    1  a 2018-01-01  a
1    2  b 2018-01-02  b
2    3  c 2018-01-03  c
3    4  d 2018-01-04  c

[4 rows x 4 columns]

In [3]: df.dtypes
Out [3]:
foo          int64
bar          object
baz    datetime64[ns]
qux          category
Length: 4, dtype: object

In [4]: df.to_json('test.json', orient='table')

In [5]: new_df = pd.read_json('test.json', orient='table')

In [6]: new_df
Out [6]:
   foo bar      baz qux
idx
0    1  a 2018-01-01  a
1    2  b 2018-01-02  b
2    3  c 2018-01-03  c
3    4  d 2018-01-04  c

[4 rows x 4 columns]

In [7]: new_df.dtypes
Out [7]:
foo          int64
bar          object
baz    datetime64[ns]
qux          category
Length: 4, dtype: object
```

Please note that the string `index` is not supported with the round trip format, as it is used by default in `write_json`

to indicate a missing index name.

```
In [8]: df.index.name = 'index'

In [9]: df.to_json('test.json', orient='table')

In [10]: new_df = pd.read_json('test.json', orient='table')

In [11]: new_df
Out[11]:
   foo bar      baz qux
0    1  a 2018-01-01  a
1    2  b 2018-01-02  b
2    3  c 2018-01-03  c
3    4  d 2018-01-04  c

[4 rows x 4 columns]

In [12]: new_df.dtypes
Out[12]:
foo              int64
bar              object
baz      datetime64[ns]
qux              category
Length: 4, dtype: object
```

### `.assign()` accepts dependent arguments

The `DataFrame.assign()` now accepts dependent keyword arguments for python version later than 3.6 (see also [PEP 468](#)). Later keyword arguments may now refer to earlier ones if the argument is a callable. See the *documentation here* ([GH14207](#))

```
In [13]: df = pd.DataFrame({'A': [1, 2, 3]})

In [14]: df
Out[14]:
   A
0  1
1  2
2  3

[3 rows x 1 columns]

In [15]: df.assign(B=df.A, C=lambda x: x['A'] + x['B'])
Out[15]:
   A  B  C
0  1  1  2
1  2  2  4
2  3  3  6

[3 rows x 3 columns]
```

**Warning:** This may subtly change the behavior of your code when you're using `.assign()` to update an existing column. Previously, callables referring to other variables being updated would get the “old” values

Previous behavior:

```
In [2]: df = pd.DataFrame({"A": [1, 2, 3]})
```

```
In [3]: df.assign(A=lambda df: df.A + 1, C=lambda df: df.A * -1)
```

```
Out[3]:
```

```
   A  C
0  2 -1
1  3 -2
2  4 -3
```

New behavior:

```
In [16]: df.assign(A=df.A + 1, C=lambda df: df.A * -1)
```

```
Out[16]:
```

```
   A  C
0  2 -2
1  3 -3
2  4 -4
```

```
[3 rows x 2 columns]
```

## Merging on a combination of columns and index levels

Strings passed to `DataFrame.merge()` as the `on`, `left_on`, and `right_on` parameters may now refer to either column names or index level names. This enables merging `DataFrame` instances on a combination of index levels and columns without resetting indexes. See the *Merge on columns and levels* documentation section. (GH14355)

```
In [17]: left_index = pd.Index(['K0', 'K0', 'K1', 'K2'], name='key1')
```

```
In [18]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2', 'A3'],
.....:                       'B': ['B0', 'B1', 'B2', 'B3'],
.....:                       'key2': ['K0', 'K1', 'K0', 'K1']},
.....:                       index=left_index)
.....:
```

```
In [19]: right_index = pd.Index(['K0', 'K1', 'K2', 'K2'], name='key1')
```

```
In [20]: right = pd.DataFrame({'C': ['C0', 'C1', 'C2', 'C3'],
.....:                        'D': ['D0', 'D1', 'D2', 'D3'],
.....:                        'key2': ['K0', 'K0', 'K0', 'K1']},
.....:                        index=right_index)
.....:
```

```
In [21]: left.merge(right, on=['key1', 'key2'])
```

```
Out[21]:
```

```
   A  B key2  C  D
key1
K0  A0 B0  K0 C0 D0
K1  A2 B2  K0 C1 D1
K2  A3 B3  K1 C3 D3
```

```
[3 rows x 5 columns]
```

## Sorting by a combination of columns and index levels

Strings passed to `DataFrame.sort_values()` as the `by` parameter may now refer to either column names or index level names. This enables sorting `DataFrame` instances by a combination of index levels and columns without resetting indexes. See the *Sorting by Indexes and Values* documentation section. (GH14353)

```
# Build MultiIndex
In [22]: idx = pd.MultiIndex.from_tuples([('a', 1), ('a', 2), ('a', 2),
.....:                                  ('b', 2), ('b', 1), ('b', 1)])
.....:

In [23]: idx.names = ['first', 'second']

# Build DataFrame
In [24]: df_multi = pd.DataFrame({'A': np.arange(6, 0, -1)},
.....:                            index=idx)
.....:

In [25]: df_multi
Out[25]:
      first second  A
a      1      6   6
      2      5   5
      2      4   4
b      2      3   3
      1      2   2
      1      1   1

[6 rows x 1 columns]

# Sort by 'second' (index) and 'A' (column)
In [26]: df_multi.sort_values(by=['second', 'A'])
Out[26]:
      first second  A
b      1      1   1
      1      2   2
a      1      6   6
b      2      3   3
a      2      4   4
      2      5   5

[6 rows x 1 columns]
```

## Extending pandas with custom types (experimental)

Pandas now supports storing array-like objects that aren't necessarily 1-D NumPy arrays as columns in a `DataFrame` or values in a `Series`. This allows third-party libraries to implement extensions to NumPy's types, similar to how pandas implemented categoricals, datetimes with timezones, periods, and intervals.

As a demonstration, we'll use `cyberpandas`, which provides an `IPArray` type for storing ip addresses.

```
In [1]: from cyberpandas import IPArray

In [2]: values = IPArray([
```

(continues on next page)

(continued from previous page)

```

....:     0,
....:     3232235777,
....:     42540766452641154071740215577757643572
....: ])
....:
....:
....:

```

IPArray isn't a normal 1-D NumPy array, but because it's a pandas *ExtensionArray*, it can be stored properly inside pandas' containers.

```
In [3]: ser = pd.Series(values)
```

```
In [4]: ser
```

```
Out[4]:
```

```

0          0.0.0.0
1          192.168.1.1
2    2001:db8:85a3::8a2e:370:7334
dtype: ip

```

Notice that the dtype is `ip`. The missing value semantics of the underlying array are respected:

```
In [5]: ser.isna()
```

```
Out[5]:
```

```

0     True
1    False
2    False
dtype: bool

```

For more, see the *extension types* documentation. If you build an extension array, publicize it on our ecosystem page.

### New observed keyword for excluding unobserved categories in groupby

Grouping by a categorical includes the unobserved categories in the output. When grouping by multiple categorical columns, this means you get the cartesian product of all the categories, including combinations where there are no observations, which can result in a large number of groups. We have added a keyword `observed` to control this behavior, it defaults to `observed=False` for backward-compatibility. (GH14942, GH8138, GH15217, GH17594, GH8669, GH20583, GH20902)

```
In [27]: cat1 = pd.Categorical(["a", "a", "b", "b"],
....:                          categories=["a", "b", "z"], ordered=True)
....:
```

```
In [28]: cat2 = pd.Categorical(["c", "d", "c", "d"],
....:                          categories=["c", "d", "y"], ordered=True)
....:
```

```
In [29]: df = pd.DataFrame({"A": cat1, "B": cat2, "values": [1, 2, 3, 4]})
```

```
In [30]: df['C'] = ['foo', 'bar'] * 2
```

```
In [31]: df
```

```
Out[31]:
```

```

   A B  values  C
0  a c         1 foo
1  a d         2 bar

```

(continues on next page)

(continued from previous page)

```

2  b  c      3  foo
3  b  d      4  bar

[4 rows x 4 columns]

```

To show all values, the previous behavior:

```

In [32]: df.groupby(['A', 'B', 'C'], observed=False).count()
Out [32]:
      values
A B C
a c bar    NaN
   foo    1.0
   d bar    1.0
   foo    NaN
   y bar    NaN
   foo    NaN
b c bar    NaN
   foo    1.0
   d bar    1.0
   foo    NaN
   y bar    NaN
   foo    NaN
z c bar    NaN
   foo    NaN
   d bar    NaN
   foo    NaN
   y bar    NaN
   foo    NaN

[18 rows x 1 columns]

```

To show only observed values:

```

In [33]: df.groupby(['A', 'B', 'C'], observed=True).count()
Out [33]:
      values
A B C
a c foo     1
   d bar     1
b c foo     1
   d bar     1

[4 rows x 1 columns]

```

For pivoting operations, this behavior is *already* controlled by the `dropna` keyword:

```

In [34]: cat1 = pd.Categorical(["a", "a", "b", "b"],
.....:                        categories=["a", "b", "z"], ordered=True)
.....:

In [35]: cat2 = pd.Categorical(["c", "d", "c", "d"],
.....:                        categories=["c", "d", "y"], ordered=True)
.....:

In [36]: df = pd.DataFrame({"A": cat1, "B": cat2, "values": [1, 2, 3, 4]})

```

(continues on next page)

(continued from previous page)

```
In [37]: df
Out[37]:
   A B  values
0  a c      1
1  a d      2
2  b c      3
3  b d      4

[4 rows x 3 columns]
```

```
In [38]: pd.pivot_table(df, values='values', index=['A', 'B'],
.....:                  dropna=True)
.....:
Out[38]:
      values
A B
a c      1
  d      2
b c      3
  d      4

[4 rows x 1 columns]
```

```
In [39]: pd.pivot_table(df, values='values', index=['A', 'B'],
.....:                  dropna=False)
.....:
Out[39]:
      values
A B
a c      1.0
  d      2.0
  y      NaN
b c      3.0
  d      4.0
  y      NaN
z c      NaN
  d      NaN
  y      NaN

[9 rows x 1 columns]
```

### Rolling/Expanding.apply() accepts `raw=False` to pass a Series to the function

`Series.rolling().apply()`, `DataFrame.rolling().apply()`, `Series.expanding().apply()`, and `DataFrame.expanding().apply()` have gained a `raw=None` parameter. This is similar to `DataFrame.apply()`. This parameter, if `True` allows one to send a `np.ndarray` to the applied function. If `False` a `Series` will be passed. The default is `None`, which preserves backward compatibility, so this will default to `True`, sending an `np.ndarray`. In a future version the default will be changed to `False`, sending a `Series`. (GH5071, GH20584)

```
In [40]: s = pd.Series(np.arange(5), np.arange(5) + 1)
In [41]: s
Out[41]:
```

(continues on next page)

(continued from previous page)

```
1    0
2    1
3    2
4    3
5    4
Length: 5, dtype: int64
```

Pass a Series:

```
In [42]: s.rolling(2, min_periods=1).apply(lambda x: x.iloc[-1], raw=False)
Out [42]:
1    0.0
2    1.0
3    2.0
4    3.0
5    4.0
Length: 5, dtype: float64
```

Mimic the original behavior of passing a ndarray:

```
In [43]: s.rolling(2, min_periods=1).apply(lambda x: x[-1], raw=True)
Out [43]:
1    0.0
2    1.0
3    2.0
4    3.0
5    4.0
Length: 5, dtype: float64
```

### DataFrame.interpolate has gained the limit\_area kwarg

DataFrame.interpolate() has gained a limit\_area parameter to allow further control of which NaNs are replaced. Use limit\_area='inside' to fill only NaNs surrounded by valid values or use limit\_area='outside' to fill only NaNs outside the existing valid values while preserving those inside. (GH16284) See the [full documentation here](#).

```
In [44]: ser = pd.Series([np.nan, np.nan, 5, np.nan, np.nan,
.....:                    np.nan, 13, np.nan, np.nan])
.....:

In [45]: ser
Out [45]:
0    NaN
1    NaN
2    5.0
3    NaN
4    NaN
5    NaN
6    13.0
7    NaN
8    NaN
Length: 9, dtype: float64
```

Fill one consecutive inside value in both directions

```
In [46]: ser.interpolate(limit_direction='both', limit_area='inside', limit=1)
Out [46]:
0      NaN
1      NaN
2      5.0
3      7.0
4      NaN
5     11.0
6     13.0
7      NaN
8      NaN
Length: 9, dtype: float64
```

Fill all consecutive outside values backward

```
In [47]: ser.interpolate(limit_direction='backward', limit_area='outside')
Out [47]:
0      5.0
1      5.0
2      5.0
3      NaN
4      NaN
5      NaN
6     13.0
7      NaN
8      NaN
Length: 9, dtype: float64
```

Fill all consecutive outside values in both directions

```
In [48]: ser.interpolate(limit_direction='both', limit_area='outside')
Out [48]:
0      5.0
1      5.0
2      5.0
3      NaN
4      NaN
5      NaN
6     13.0
7     13.0
8     13.0
Length: 9, dtype: float64
```

### get\_dummies now supports dtype argument

The `get_dummies()` now accepts a `dtype` argument, which specifies a `dtype` for the new columns. The default remains `uint8`. (GH18330)

```
In [49]: df = pd.DataFrame({'a': [1, 2], 'b': [3, 4], 'c': [5, 6]})
In [50]: pd.get_dummies(df, columns=['c']).dtypes
Out [50]:
a      int64
b      int64
c_5    uint8
```

(continues on next page)

(continued from previous page)

```
c_6      uint8
Length: 4, dtype: object

In [51]: pd.get_dummies(df, columns=['c'], dtype=bool).dtypes
Out [51]:
a         int64
b         int64
c_5        bool
c_6        bool
Length: 4, dtype: object
```

### Timedelta mod method

mod (%) and divmod operations are now defined on Timedelta objects when operating with either timedelta-like or with numeric arguments. See the *documentation here*. (GH19365)

```
In [52]: td = pd.Timedelta(hours=37)

In [53]: td % pd.Timedelta(minutes=45)
Out [53]: Timedelta('0 days 00:15:00')
```

### .rank() handles inf values when NaN are present

In previous versions, .rank() would assign inf elements NaN as their ranks. Now ranks are calculated properly. (GH6945)

```
In [54]: s = pd.Series([-np.inf, 0, 1, np.nan, np.inf])

In [55]: s
Out [55]:
0    -inf
1     0.0
2     1.0
3     NaN
4     inf
Length: 5, dtype: float64
```

Previous behavior:

```
In [11]: s.rank()
Out [11]:
0     1.0
1     2.0
2     3.0
3     NaN
4     NaN
dtype: float64
```

Current behavior:

```
In [56]: s.rank()
Out [56]:
0     1.0
```

(continues on next page)

(continued from previous page)

```

1    2.0
2    3.0
3    NaN
4    4.0
Length: 5, dtype: float64

```

Furthermore, previously if you rank `inf` or `-inf` values together with `NaN` values, the calculation won't distinguish `NaN` from infinity when using 'top' or 'bottom' argument.

```
In [57]: s = pd.Series([np.nan, np.nan, -np.inf, -np.inf])
```

```
In [58]: s
```

```
Out [58]:
```

```

0    NaN
1    NaN
2   -inf
3   -inf
Length: 4, dtype: float64

```

Previous behavior:

```
In [15]: s.rank(na_option='top')
```

```
Out [15]:
```

```

0    2.5
1    2.5
2    2.5
3    2.5
dtype: float64

```

Current behavior:

```
In [59]: s.rank(na_option='top')
```

```
Out [59]:
```

```

0    1.5
1    1.5
2    3.5
3    3.5
Length: 4, dtype: float64

```

These bugs were squashed:

- Bug in `DataFrame.rank()` and `Series.rank()` when `method='dense'` and `pct=True` in which percentile ranks were not being used with the number of distinct observations ([GH15630](#))
- Bug in `Series.rank()` and `DataFrame.rank()` when `ascending='False'` failed to return correct ranks for infinity if `NaN` were present ([GH19538](#))
- Bug in `DataFrameGroupBy.rank()` where ranks were incorrect when both infinity and `NaN` were present ([GH20561](#))

### Series.str.cat has gained the join kwarg

Previously, `Series.str.cat()` did not – in contrast to most of pandas – align `Series` on their index before concatenation (see [GH18657](#)). The method has now gained a keyword `join` to control the manner of alignment, see examples below and [here](#).

In v.0.23 `join` will default to `None` (meaning no alignment), but this default will change to `'left'` in a future version of pandas.

```
In [60]: s = pd.Series(['a', 'b', 'c', 'd'])
In [61]: t = pd.Series(['b', 'd', 'e', 'c'], index=[1, 3, 4, 2])
In [62]: s.str.cat(t)
Out [62]:
0    NaN
1    bb
2    cc
3    dd
Length: 4, dtype: object

In [63]: s.str.cat(t, join='left', na_rep='-')
Out [63]:
0    a-
1    bb
2    cc
3    dd
Length: 4, dtype: object
```

Furthermore, `Series.str.cat()` now works for `CategoricalIndex` as well (previously raised a `ValueError`; see [GH20842](#)).

### DataFrame.astype performs column-wise conversion to Categorical

`DataFrame.astype()` can now perform column-wise conversion to `Categorical` by supplying the string `'category'` or a `CategoricalDtype`. Previously, attempting this would raise a `NotImplementedError`. See the *Object creation* section of the documentation for more details and examples. ([GH12860](#), [GH18099](#))

Supplying the string `'category'` performs column-wise conversion, with only labels appearing in a given column set as categories:

```
In [64]: df = pd.DataFrame({'A': list('abca'), 'B': list('bccd')})
In [65]: df = df.astype('category')
In [66]: df['A'].dtype
Out [66]: CategoricalDtype(categories=['a', 'b', 'c'], ordered=False)
In [67]: df['B'].dtype
Out [67]: CategoricalDtype(categories=['b', 'c', 'd'], ordered=False)
```

Supplying a `CategoricalDtype` will make the categories in each column consistent with the supplied dtype:

```
In [68]: from pandas.api.types import CategoricalDtype
In [69]: df = pd.DataFrame({'A': list('abca'), 'B': list('bccd')})
```

(continues on next page)

(continued from previous page)

```
In [70]: cdt = CategoricalDtype(categories=list('abcd'), ordered=True)
In [71]: df = df.astype(cdt)
In [72]: df['A'].dtype
Out [72]: CategoricalDtype(categories=['a', 'b', 'c', 'd'], ordered=True)
In [73]: df['B'].dtype
Out [73]: CategoricalDtype(categories=['a', 'b', 'c', 'd'], ordered=True)
```

## Other enhancements

- Unary + now permitted for Series and DataFrame as numeric operator (GH16073)
- Better support for `to_excel()` output with the `xlsxwriter` engine. (GH16149)
- `pandas.tseries.frequencies.to_offset()` now accepts leading '+' signs e.g. '+1h'. (GH18171)
- `MultiIndex.unique()` now supports the `level=` argument, to get unique values from a specific index level (GH17896)
- `pandas.io.formats.style.Styler` now has method `hide_index()` to determine whether the index will be rendered in output (GH14194)
- `pandas.io.formats.style.Styler` now has method `hide_columns()` to determine whether columns will be hidden in output (GH14194)
- Improved wording of `ValueError` raised in `to_datetime()` when `unit=` is passed with a non-convertible value (GH14350)
- `Series.fillna()` now accepts a Series or a dict as a value for a categorical dtype (GH17033)
- `pandas.read_clipboard()` updated to use `qtpy`, falling back to `PyQt5` and then `PyQt4`, adding compatibility with Python3 and multiple python-qt bindings (GH17722)
- Improved wording of `ValueError` raised in `read_csv()` when the `usecols` argument cannot match all columns. (GH17301)
- `DataFrame.corrwith()` now silently drops non-numeric columns when passed a Series. Before, an exception was raised (GH18570).
- `IntervalIndex` now supports time zone aware `Interval` objects (GH18537, GH18538)
- `Series()` / `DataFrame()` tab completion also returns identifiers in the first level of a `MultiIndex()`. (GH16326)
- `read_excel()` has gained the `nrows` parameter (GH16645)
- `DataFrame.append()` can now in more cases preserve the type of the calling dataframe's columns (e.g. if both are `CategoricalIndex`) (GH18359)
- `DataFrame.to_json()` and `Series.to_json()` now accept an `index` argument which allows the user to exclude the index from the JSON output (GH17394)
- `IntervalIndex.to_tuples()` has gained the `na_tuple` parameter to control whether NA is returned as a tuple of NA, or NA itself (GH18756)
- `Categorical.rename_categories`, `CategoricalIndex.rename_categories` and `Series.cat.rename_categories` can now take a callable as their argument (GH18862)

- `Interval` and `IntervalIndex` have gained a `length` attribute (GH18789)
- `Resampler` objects now have a functioning `pipe` method. Previously, calls to `pipe` were diverted to the `mean` method (GH17905).
- `is_scalar()` now returns `True` for `DateOffset` objects (GH18943).
- `DataFrame.pivot()` now accepts a list for the `values=` kwarg (GH17160).
- Added `pandas.api.extensions.register_dataframe_accessor()`, `pandas.api.extensions.register_series_accessor()`, and `pandas.api.extensions.register_index_accessor()`, accessor for libraries downstream of pandas to register custom accessors like `.cat` on pandas objects. See *Registering Custom Accessors* for more (GH14781).
- `IntervalIndex.astype` now supports conversions between subtypes when passed an `IntervalDtype` (GH19197)
- `IntervalIndex` and its associated constructor methods (`from_arrays`, `from_breaks`, `from_tuples`) have gained a `dtype` parameter (GH19262)
- Added `pandas.core.groupby.SeriesGroupBy.is_monotonic_increasing()` and `pandas.core.groupby.SeriesGroupBy.is_monotonic_decreasing()` (GH17015)
- For subclassed `DataFrames`, `DataFrame.apply()` will now preserve the `Series` subclass (if defined) when passing the data to the applied function (GH19822)
- `DataFrame.from_dict()` now accepts a `columns` argument that can be used to specify the column names when `orient='index'` is used (GH18529)
- Added option `display.html.use_mathjax` so `MathJax` can be disabled when rendering tables in Jupyter notebooks (GH19856, GH19824)
- `DataFrame.replace()` now supports the `method` parameter, which can be used to specify the replacement method when `to_replace` is a scalar, list or tuple and `value` is `None` (GH19632)
- `Timestamp.month_name()`, `DatetimeIndex.month_name()`, and `Series.dt.month_name()` are now available (GH12805)
- `Timestamp.day_name()` and `DatetimeIndex.day_name()` are now available to return day names with a specified locale (GH12806)
- `DataFrame.to_sql()` now performs a multi-value insert if the underlying connection supports itk rather than inserting row by row. SQLAlchemy dialects supporting multi-value inserts include: `mysql`, `postgresql`, `sqlite` and any dialect with `supports_multivalues_insert`. (GH14315, GH8953)
- `read_html()` now accepts a `displayed_only` keyword argument to controls whether or not hidden elements are parsed (`True` by default) (GH20027)
- `read_html()` now reads all `<tbody>` elements in a `<table>`, not just the first. (GH20690)
- `quantile()` and `quantile()` now accept the `interpolation` keyword, `linear` by default (GH20497)
- zip compression is supported via `compression=zip` in `DataFrame.to_pickle()`, `Series.to_pickle()`, `DataFrame.to_csv()`, `Series.to_csv()`, `DataFrame.to_json()`, `Series.to_json()`. (GH17778)
- `WeekOfMonth` constructor now supports `n=0` (GH20517).
- `DataFrame` and `Series` now support matrix multiplication (`@` operator (GH10259) for Python>=3.5)
- Updated `DataFrame.to_gbq()` and `pandas.read_gbq()` signature and documentation to reflect changes from the Pandas-GBQ library version 0.4.0. Adds intersphinx mapping to Pandas-GBQ library. (GH20564)

- Added new writer for exporting Stata dta files in version 117, `StataWriter117`. This format supports exporting strings with lengths up to 2,000,000 characters ([GH16450](#))
- `to_hdf()` and `read_hdf()` now accept an `errors` keyword argument to control encoding error handling ([GH20835](#))
- `cut()` has gained the `duplicates='raise'|'drop'` option to control whether to raise on duplicated edges ([GH20947](#))
- `date_range()`, `timedelta_range()`, and `interval_range()` now return a linearly spaced index if `start`, `stop`, and `periods` are specified, but `freq` is not. ([GH20808](#), [GH20983](#), [GH20976](#))

## Backwards incompatible API changes

### Dependencies have increased minimum versions

We have updated our minimum supported versions of dependencies ([GH15184](#)). If installed, we now require:

| Package         | Minimum Version | Required | Issue                   |
|-----------------|-----------------|----------|-------------------------|
| python-dateutil | 2.5.0           | X        | <a href="#">GH15184</a> |
| openpyxl        | 2.4.0           |          | <a href="#">GH15184</a> |
| beautifulsoup4  | 4.2.1           |          | <a href="#">GH20082</a> |
| setuptools      | 24.2.0          |          | <a href="#">GH20698</a> |

### Instantiation from dicts preserves dict insertion order for python 3.6+

Until Python 3.6, dicts in Python had no formally defined ordering. For Python version 3.6 and later, dicts are ordered by insertion order, see [PEP 468](#). Pandas will use the dict's insertion order, when creating a `Series` or `DataFrame` from a dict and you're using Python version 3.6 or higher. ([GH19884](#))

Previous behavior (and current behavior if on Python < 3.6):

```
In [16]: pd.Series({'Income': 2000,
.....:             'Expenses': -1500,
.....:             'Taxes': -200,
.....:             'Net result': 300})
Out [16]:
Expenses    -1500
Income      2000
Net result    300
Taxes       -200
dtype: int64
```

Note the `Series` above is ordered alphabetically by the index values.

New behavior (for Python >= 3.6):

```
In [74]: pd.Series({'Income': 2000,
.....:             'Expenses': -1500,
.....:             'Taxes': -200,
.....:             'Net result': 300})
.....:
Out [74]:
Income      2000
Expenses    -1500
```

(continues on next page)

(continued from previous page)

```
Taxes          -200
Net result      300
Length: 4, dtype: int64
```

Notice that the Series is now ordered by insertion order. This new behavior is used for all relevant pandas types (Series, DataFrame, SparseSeries and SparseDataFrame).

If you wish to retain the old behavior while using Python  $\geq$  3.6, you can use `.sort_index()`:

```
In [75]: pd.Series({'Income': 2000,
.....:             'Expenses': -1500,
.....:             'Taxes': -200,
.....:             'Net result': 300}).sort_index()
.....:
Out [75]:
Expenses      -1500
Income         2000
Net result     300
Taxes          -200
Length: 4, dtype: int64
```

## Deprecate Panel

Panel was deprecated in the 0.20.x release, showing as a DeprecationWarning. Using Panel will now show a FutureWarning. The recommended way to represent 3-D data are with a MultiIndex on a DataFrame via the `to_frame()` or with the `xarray` package. Pandas provides a `to_xarray()` method to automate this conversion (GH13563, GH18324).

```
In [75]: import pandas._testing as tm

In [76]: p = tm.makePanel()

In [77]: p
Out [77]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 3 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemC
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-05 00:00:00
Minor_axis axis: A to D
```

## Convert to a MultiIndex DataFrame

```
In [78]: p.to_frame()
Out [78]:
```

|            |       | ItemA     | ItemB     | ItemC     |
|------------|-------|-----------|-----------|-----------|
| major      | minor |           |           |           |
| 2000-01-03 | A     | 0.469112  | 0.721555  | 0.404705  |
|            | B     | -1.135632 | 0.271860  | -1.039268 |
|            | C     | 0.119209  | 0.276232  | -1.344312 |
|            | D     | -2.104569 | 0.113648  | -0.109050 |
| 2000-01-04 | A     | -0.282863 | -0.706771 | 0.577046  |
|            | B     | 1.212112  | -0.424972 | -0.370647 |
|            | C     | -1.044236 | -1.087401 | 0.844885  |
|            | D     | -0.494929 | -1.478427 | 1.643563  |
| 2000-01-05 | A     | -1.509059 | -1.039575 | -1.715002 |

(continues on next page)

(continued from previous page)

```

B      -0.173215  0.567020 -1.157892
C      -0.861849 -0.673690  1.075770
D       1.071804  0.524988 -1.469388

```

```
[12 rows x 3 columns]
```

### Convert to an xarray DataArray

```
In [79]: p.to_xarray()
```

```
Out [79]:
```

```
<xarray.DataArray (items: 3, major_axis: 3, minor_axis: 4)>
```

```
array([[ 0.469112, -1.135632,  0.119209, -2.104569],
       [-0.282863,  1.212112, -1.044236, -0.494929],
       [-1.509059, -0.173215, -0.861849,  1.071804]],
```

```

      [[ 0.721555,  0.27186 ,  0.276232,  0.113648],
       [-0.706771, -0.424972, -1.087401, -1.478427],
       [-1.039575,  0.56702 , -0.67369 ,  0.524988]],

```

```

      [[ 0.404705, -1.039268, -1.344312, -0.10905 ],
       [ 0.577046, -0.370647,  0.844885,  1.643563],
       [-1.715002, -1.157892,  1.07577 , -1.469388]])

```

```
Coordinates:
```

```

* items      (items) object 'ItemA' 'ItemB' 'ItemC'
* major_axis (major_axis) datetime64[ns] 2000-01-03 2000-01-04 2000-01-05
* minor_axis (minor_axis) object 'A' 'B' 'C' 'D'

```

### pandas.core.common removals

The following error & warning messages are removed from `pandas.core.common` (GH13634, GH19769):

- PerformanceWarning
- UnsupportedFunctionCall
- UnsortedIndexError
- AbstractMethodError

These are available from import from `pandas.errors` (since 0.19.0).

### Changes to make output of `DataFrame.apply` consistent

`DataFrame.apply()` was inconsistent when applying an arbitrary user-defined-function that returned a list-like with `axis=1`. Several bugs and inconsistencies are resolved. If the applied function returns a Series, then pandas will return a DataFrame; otherwise a Series will be returned, this includes the case where a list-like (e.g. tuple or list is returned) (GH16353, GH17437, GH17970, GH17348, GH17892, GH18573, GH17602, GH18775, GH18901, GH18919).

```
In [76]: df = pd.DataFrame(np.tile(np.arange(3), 6).reshape(6, -1) + 1,
.....:                    columns=['A', 'B', 'C'])
.....:
```

```
In [77]: df
```

```
Out [77]:
```

(continues on next page)

(continued from previous page)

```
   A  B  C
0  1  2  3
1  1  2  3
2  1  2  3
3  1  2  3
4  1  2  3
5  1  2  3

[6 rows x 3 columns]
```

Previous behavior: if the returned shape happened to match the length of original columns, this would return a DataFrame. If the return shape did not match, a Series with lists was returned.

```
In [3]: df.apply(lambda x: [1, 2, 3], axis=1)
Out[3]:
   A  B  C
0  1  2  3
1  1  2  3
2  1  2  3
3  1  2  3
4  1  2  3
5  1  2  3

In [4]: df.apply(lambda x: [1, 2], axis=1)
Out[4]:
0    [1, 2]
1    [1, 2]
2    [1, 2]
3    [1, 2]
4    [1, 2]
5    [1, 2]
dtype: object
```

New behavior: When the applied function returns a list-like, this will now *always* return a Series.

```
In [78]: df.apply(lambda x: [1, 2, 3], axis=1)
Out[78]:
0    [1, 2, 3]
1    [1, 2, 3]
2    [1, 2, 3]
3    [1, 2, 3]
4    [1, 2, 3]
5    [1, 2, 3]
Length: 6, dtype: object

In [79]: df.apply(lambda x: [1, 2], axis=1)
Out[79]:
0    [1, 2]
1    [1, 2]
2    [1, 2]
3    [1, 2]
4    [1, 2]
5    [1, 2]
Length: 6, dtype: object
```

To have expanded columns, you can use `result_type='expand'`

```
In [80]: df.apply(lambda x: [1, 2, 3], axis=1, result_type='expand')
```

```
Out [80]:
   0  1  2
0  1  2  3
1  1  2  3
2  1  2  3
3  1  2  3
4  1  2  3
5  1  2  3

[6 rows x 3 columns]
```

To broadcast the result across the original columns (the old behaviour for list-likes of the correct length), you can use `result_type='broadcast'`. The shape must match the original columns.

```
In [81]: df.apply(lambda x: [1, 2, 3], axis=1, result_type='broadcast')
```

```
Out [81]:
   A  B  C
0  1  2  3
1  1  2  3
2  1  2  3
3  1  2  3
4  1  2  3
5  1  2  3

[6 rows x 3 columns]
```

Returning a `Series` allows one to control the exact return structure and column names:

```
In [82]: df.apply(lambda x: pd.Series([1, 2, 3], index=['D', 'E', 'F']), axis=1)
```

```
Out [82]:
   D  E  F
0  1  2  3
1  1  2  3
2  1  2  3
3  1  2  3
4  1  2  3
5  1  2  3

[6 rows x 3 columns]
```

### Concatenation will no longer sort

In a future version of pandas `pandas.concat()` will no longer sort the non-concatenation axis when it is not already aligned. The current behavior is the same as the previous (sorting), but now a warning is issued when `sort` is not specified and the non-concatenation axis is not aligned (GH4588).

```
In [83]: df1 = pd.DataFrame({"a": [1, 2], "b": [1, 2]}, columns=['b', 'a'])
```

```
In [84]: df2 = pd.DataFrame({"a": [4, 5]})
```

```
In [85]: pd.concat([df1, df2])
```

```
Out [85]:
   b  a
0  1.0  1
```

(continues on next page)

(continued from previous page)

```
1 2.0 2
0 NaN 4
1 NaN 5

[4 rows x 2 columns]
```

To keep the previous behavior (sorting) and silence the warning, pass `sort=True`

```
In [86]: pd.concat([df1, df2], sort=True)
Out [86]:
   a    b
0  1  1.0
1  2  2.0
0  4  NaN
1  5  NaN

[4 rows x 2 columns]
```

To accept the future behavior (no sorting), pass `sort=False`

Note that this change also applies to `DataFrame.append()`, which has also received a `sort` keyword for controlling this behavior.

### Build changes

- Building pandas for development now requires `cython >= 0.24` (GH18613)
- Building from source now explicitly requires `setuptools` in `setup.py` (GH18113)
- Updated conda recipe to be in compliance with `conda-build 3.0+` (GH18002)

### Index division by zero fills correctly

Division operations on `Index` and subclasses will now fill division of positive numbers by zero with `np.inf`, division of negative numbers by zero with `-np.inf` and `0 / 0` with `np.nan`. This matches existing `Series` behavior. (GH19322, GH19347)

Previous behavior:

```
In [6]: index = pd.Int64Index([-1, 0, 1])
In [7]: index / 0
Out [7]: Int64Index([0, 0, 0], dtype='int64')

# Previous behavior yielded different results depending on the type of zero in the_
↳divisor
In [8]: index / 0.0
Out [8]: Float64Index([-inf, nan, inf], dtype='float64')

In [9]: index = pd.UInt64Index([0, 1])
In [10]: index / np.array([0, 0], dtype=np.uint64)
Out [10]: UInt64Index([0, 0], dtype='uint64')
```

(continues on next page)

(continued from previous page)

```
In [11]: pd.RangeIndex(1, 5) / 0
ZeroDivisionError: integer division or modulo by zero
```

Current behavior:

```
In [87]: index = pd.Int64Index([-1, 0, 1])

# division by zero gives -infinity where negative,
# +infinity where positive, and NaN for 0 / 0
In [88]: index / 0
Out [88]: Float64Index([-inf, nan, inf], dtype='float64')

# The result of division by zero should not depend on
# whether the zero is int or float
In [89]: index / 0.0
Out [89]: Float64Index([-inf, nan, inf], dtype='float64')

In [90]: index = pd.UInt64Index([0, 1])

In [91]: index / np.array([0, 0], dtype=np.uint64)
Out [91]: Float64Index([nan, inf], dtype='float64')

In [92]: pd.RangeIndex(1, 5) / 0
Out [92]: Float64Index([inf, inf, inf, inf], dtype='float64')
```

## Extraction of matching patterns from strings

By default, extracting matching patterns from strings with `str.extract()` used to return a Series if a single group was being extracted (a DataFrame if more than one group was extracted). As of Pandas 0.23.0 `str.extract()` always returns a DataFrame, unless `expand` is set to `False`. Finally, `None` was an accepted value for the `expand` parameter (which was equivalent to `False`), but now raises a `ValueError`. ([GH11386](#))

Previous behavior:

```
In [1]: s = pd.Series(['number 10', '12 eggs'])

In [2]: extracted = s.str.extract(r'.*(\d\d).*')

In [3]: extracted
Out [3]:
0    10
1    12
dtype: object

In [4]: type(extracted)
Out [4]:
pandas.core.series.Series
```

New behavior:

```
In [93]: s = pd.Series(['number 10', '12 eggs'])

In [94]: extracted = s.str.extract(r'.*(\d\d).*')

In [95]: extracted
```

(continues on next page)

(continued from previous page)

```
Out [95]:
  0
0 10
1 12

[2 rows x 1 columns]

In [96]: type(extracted)
Out [96]: pandas.core.frame.DataFrame
```

To restore previous behavior, simply set `expand` to `False`:

```
In [97]: s = pd.Series(['number 10', '12 eggs'])

In [98]: extracted = s.str.extract(r'.*(\d\d).*', expand=False)

In [99]: extracted
Out [99]:
0    10
1    12
Length: 2, dtype: object

In [100]: type(extracted)
Out [100]: pandas.core.series.Series
```

### Default value for the `ordered` parameter of `CategoricalDtype`

The default value of the `ordered` parameter for `CategoricalDtype` has changed from `False` to `None` to allow updating of categories without impacting `ordered`. Behavior should remain consistent for downstream objects, such as `Categorical` (GH18790)

In previous versions, the default value for the `ordered` parameter was `False`. This could potentially lead to the `ordered` parameter unintentionally being changed from `True` to `False` when users attempt to update categories if `ordered` is not explicitly specified, as it would silently default to `False`. The new behavior for `ordered=None` is to retain the existing value of `ordered`.

New behavior:

```
In [2]: from pandas.api.types import CategoricalDtype

In [3]: cat = pd.Categorical(list('abcaba'), ordered=True, categories=list('cba'))

In [4]: cat
Out [4]:
[a, b, c, a, b, a]
Categories (3, object): [c < b < a]

In [5]: cdt = CategoricalDtype(categories=list('cbad'))

In [6]: cat.astype(cdt)
Out [6]:
[a, b, c, a, b, a]
Categories (4, object): [c < b < a < d]
```

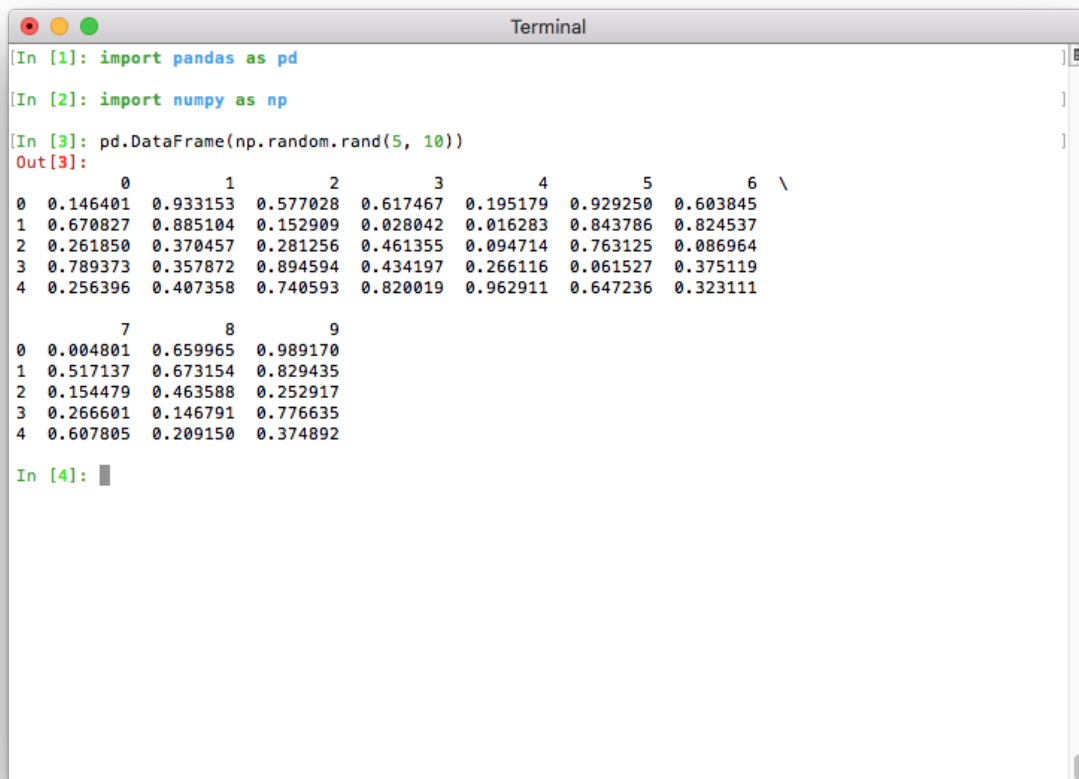

Notice in the example above that the converted `Categorical` has retained `ordered=True`. Had the default value for `ordered` remained as `False`, the converted `Categorical` would have become `unordered`, despite

`ordered=False` never being explicitly specified. To change the value of `ordered`, explicitly pass it to the new dtype, e.g. `CategoricalDtype(categories=list('cbad'), ordered=False)`.

Note that the unintentional conversion of `ordered` discussed above did not arise in previous versions due to separate bugs that prevented `astype` from doing any type of category to category conversion ([GH10696](#), [GH18593](#)). These bugs have been fixed in this release, and motivated changing the default value of `ordered`.

## Better pretty-printing of DataFrames in a terminal

Previously, the default value for the maximum number of columns was `pd.options.display.max_columns=20`. This meant that relatively wide data frames would not fit within the terminal width, and pandas would introduce line breaks to display these 20 columns. This resulted in an output that was relatively difficult to read:

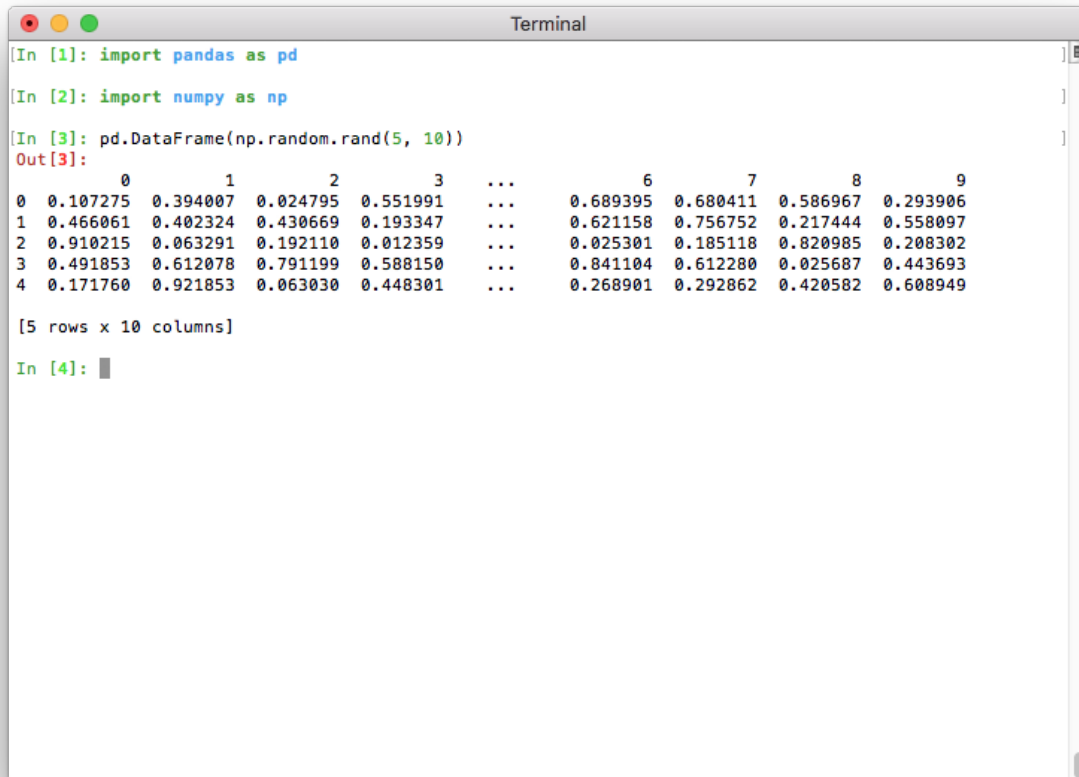

```
Terminal
In [1]: import pandas as pd
In [2]: import numpy as np
In [3]: pd.DataFrame(np.random.rand(5, 10))
Out[3]:
   0      1      2      3      4      5      6  \
0  0.146401  0.933153  0.577028  0.617467  0.195179  0.929250  0.603845
1  0.670827  0.885104  0.152909  0.028042  0.016283  0.843786  0.824537
2  0.261850  0.370457  0.281256  0.461355  0.094714  0.763125  0.086964
3  0.789373  0.357872  0.894594  0.434197  0.266116  0.061527  0.375119
4  0.256396  0.407358  0.740593  0.820019  0.962911  0.647236  0.323111

      7      8      9
0  0.004801  0.659965  0.989170
1  0.517137  0.673154  0.829435
2  0.154479  0.463588  0.252917
3  0.266601  0.146791  0.776635
4  0.607805  0.209150  0.374892

In [4]:
```

If Python runs in a terminal, the maximum number of columns is now determined automatically so that the printed data frame fits within the current terminal width (`pd.options.display.max_columns=0`) ([GH17023](#)). If Python runs as a Jupyter kernel (such as the Jupyter QtConsole or a Jupyter notebook, as well as in many IDEs), this value cannot be inferred automatically and is thus set to 20 as in previous versions. In a terminal, this results in a much nicer output:

A terminal window titled "Terminal" showing a Jupyter Notebook session. The user imports pandas as 'pd' and numpy as 'np'. Then, they create a DataFrame from a 5x10 array of random floats. The output shows a DataFrame with 5 rows and 10 columns, with values truncated with ellipses. The prompt for the next input is visible.

```
[In [1]: import pandas as pd
In [2]: import numpy as np
In [3]: pd.DataFrame(np.random.rand(5, 10))
Out[3]:
   0         1         2         3  ...         6         7         8         9
0  0.107275  0.394007  0.024795  0.551991  ...  0.689395  0.680411  0.586967  0.293906
1  0.466061  0.402324  0.430669  0.193347  ...  0.621158  0.756752  0.217444  0.558097
2  0.910215  0.063291  0.192110  0.012359  ...  0.025301  0.185118  0.820985  0.208302
3  0.491853  0.612078  0.791199  0.588150  ...  0.841104  0.612280  0.025687  0.443693
4  0.171760  0.921853  0.063030  0.448301  ...  0.268901  0.292862  0.420582  0.608949

[5 rows x 10 columns]
In [4]:
```

Note that if you don't like the new default, you can always set this option yourself. To revert to the old setting, you can run this line:

```
pd.options.display.max_columns = 20
```

## Datetimelike API changes

- The default `Timedelta` constructor now accepts an ISO 8601 Duration string as an argument (GH19040)
- Subtracting `NaT` from a Series with `dtype='datetime64[ns]'` returns a Series with `dtype='timedelta64[ns]'` instead of `dtype='datetime64[ns]'` (GH18808)
- Addition or subtraction of `NaT` from `TimedeltaIndex` will return `TimedeltaIndex` instead of `DatetimeIndex` (GH19124)
- `DatetimeIndex.shift()` and `TimedeltaIndex.shift()` will now raise `NullFrequencyError` (which subclasses `ValueError`, which was raised in older versions) when the index object frequency is `None` (GH19147)
- Addition and subtraction of `NaN` from a Series with `dtype='timedelta64[ns]'` will raise a `TypeError` instead of treating the `NaN` as `NaT` (GH19274)
- `NaT` division with `datetime.timedelta` will now return `NaN` instead of raising (GH17876)

- Operations between a Series with dtype `dtype='datetime64[ns]'` and a PeriodIndex will correctly raise `TypeError` (GH18850)
- Subtraction of Series with timezone-aware `dtype='datetime64[ns]'` with mis-matched timezones will raise `TypeError` instead of `ValueError` (GH18817)
- Timestamp will no longer silently ignore unused or invalid `tz` or `tzinfo` keyword arguments (GH17690)
- Timestamp will no longer silently ignore invalid `freq` arguments (GH5168)
- `CacheableOffset` and `WeekDay` are no longer available in the `pandas.tseries.offsets` module (GH17830)
- `pandas.tseries.frequencies.get_freq_group()` and `pandas.tseries.frequencies.DAYS` are removed from the public API (GH18034)
- `Series.truncate()` and `DataFrame.truncate()` will raise a `ValueError` if the index is not sorted instead of an unhelpful `KeyError` (GH17935)
- `Series.first` and `DataFrame.first` will now raise a `TypeError` rather than `NotImplementedError` when index is not a `DatetimeIndex` (GH20725).
- `Series.last` and `DataFrame.last` will now raise a `TypeError` rather than `NotImplementedError` when index is not a `DatetimeIndex` (GH20725).
- Restricted `DateOffset` keyword arguments. Previously, `DateOffset` subclasses allowed arbitrary keyword arguments which could lead to unexpected behavior. Now, only valid arguments will be accepted. (GH17176, GH18226).
- `pandas.merge()` provides a more informative error message when trying to merge on timezone-aware and timezone-naive columns (GH15800)
- For `DatetimeIndex` and `TimedeltaIndex` with `freq=None`, addition or subtraction of integer-dtyped array or Index will raise `NullFrequencyError` instead of `TypeError` (GH19895)
- Timestamp constructor now accepts a `nanosecond` keyword or positional argument (GH18898)
- `DatetimeIndex` will now raise an `AttributeError` when the `tz` attribute is set after instantiation (GH3746)
- `DatetimeIndex` with a `pytz` timezone will now return a consistent `pytz` timezone (GH18595)

## Other API changes

- `Series.astype()` and `Index.astype()` with an incompatible dtype will now raise a `TypeError` rather than a `ValueError` (GH18231)
- Series construction with an object dtyped tz-aware datetime and `dtype=object` specified, will now return an object dtyped Series, previously this would infer the datetime dtype (GH18231)
- A Series of `dtype=category` constructed from an empty dict will now have categories of `dtype=object` rather than `dtype=float64`, consistently with the case in which an empty list is passed (GH18515)
- All-NaN levels in a `MultiIndex` are now assigned `float` rather than `object` dtype, promoting consistency with `Index` (GH17929).
- Levels names of a `MultiIndex` (when not `None`) are now required to be unique: trying to create a `MultiIndex` with repeated names will raise a `ValueError` (GH18872)
- Both construction and renaming of `Index/MultiIndex` with non-hashable name/names will now raise `TypeError` (GH20527)

- `Index.map()` can now accept `Series` and dictionary input objects ([GH12756](#), [GH18482](#), [GH18509](#)).
- `DataFrame.unstack()` will now default to filling with `np.nan` for object columns. ([GH12815](#))
- `IntervalIndex` constructor will raise if the `closed` parameter conflicts with how the input data is inferred to be closed ([GH18421](#))
- Inserting missing values into indexes will work for all types of indexes and automatically insert the correct type of missing value (`NaN`, `NaT`, etc.) regardless of the type passed in ([GH18295](#))
- When created with duplicate labels, `MultiIndex` now raises a `ValueError`. ([GH17464](#))
- `Series.fillna()` now raises a `TypeError` instead of a `ValueError` when passed a list, tuple or `DataFrame` as a value ([GH18293](#))
- `pandas.DataFrame.merge()` no longer casts a float column to object when merging on int and float columns ([GH16572](#))
- `pandas.merge()` now raises a `ValueError` when trying to merge on incompatible data types ([GH9780](#))
- The default NA value for `UInt64Index` has changed from 0 to `NaN`, which impacts methods that mask with NA, such as `UInt64Index.where()` ([GH18398](#))
- Refactored `setup.py` to use `find_packages` instead of explicitly listing out all subpackages ([GH18535](#))
- Rearranged the order of keyword arguments in `read_excel()` to align with `read_csv()` ([GH16672](#))
- `wide_to_long()` previously kept numeric-like suffixes as object dtype. Now they are cast to numeric if possible ([GH17627](#))
- In `read_excel()`, the `comment` argument is now exposed as a named parameter ([GH18735](#))
- Rearranged the order of keyword arguments in `read_excel()` to align with `read_csv()` ([GH16672](#))
- The options `html.border` and `mode.use_inf_as_null` were deprecated in prior versions, these will now show `FutureWarning` rather than a `DeprecationWarning` ([GH19003](#))
- `IntervalIndex` and `IntervalDtype` no longer support categorical, object, and string subtypes ([GH19016](#))
- `IntervalDtype` now returns `True` when compared against 'interval' regardless of subtype, and `IntervalDtype.name` now returns 'interval' regardless of subtype ([GH18980](#))
- `KeyError` now raises instead of `ValueError` in `drop()`, `drop()`, `drop()`, `drop()` when dropping a non-existent element in an axis with duplicates ([GH19186](#))
- `Series.to_csv()` now accepts a compression argument that works in the same way as the compression argument in `DataFrame.to_csv()` ([GH18958](#))
- Set operations (union, difference...) on `IntervalIndex` with incompatible index types will now raise a `TypeError` rather than a `ValueError` ([GH19329](#))
- `DateOffset` objects render more simply, e.g. `<DateOffset: days=1>` instead of `<DateOffset: kwds={'days': 1}>` ([GH19403](#))
- `Categorical.fillna` now validates its value and method keyword arguments. It now raises when both or none are specified, matching the behavior of `Series.fillna()` ([GH19682](#))
- `pd.to_datetime('today')` now returns a datetime, consistent with `pd.Timestamp('today')`; previously `pd.to_datetime('today')` returned a `.normalized()` datetime ([GH19935](#))
- `Series.str.replace()` now takes an optional `regex` keyword which, when set to `False`, uses literal string replacement rather than regex replacement ([GH16808](#))
- `DatetimeIndex.strftime()` and `PeriodIndex.strftime()` now return an `Index` instead of a numpy array to be consistent with similar accessors ([GH20127](#))

- Constructing a Series from a list of length 1 no longer broadcasts this list when a longer index is specified (GH19714, GH20391).
- `DataFrame.to_dict()` with `orient='index'` no longer casts int columns to float for a DataFrame with only int and float columns (GH18580)
- A user-defined-function that is passed to `Series.rolling().aggregate()`, `DataFrame.rolling().aggregate()`, or its expanding cousins, will now *always* be passed a Series, rather than a `np.array`; `.apply()` only has the `raw` keyword, see *here*. This is consistent with the signatures of `.aggregate()` across pandas (GH20584)
- Rolling and Expanding types raise `NotImplementedError` upon iteration (GH11704).

## Deprecations

- `Series.from_array` and `SparseSeries.from_array` are deprecated. Use the normal constructor `Series(...)` and `SparseSeries(...)` instead (GH18213).
- `DataFrame.as_matrix` is deprecated. Use `DataFrame.values` instead (GH18458).
- `Series.asobject`, `DatetimeIndex.asobject`, `PeriodIndex.asobject` and `TimeDeltaIndex.asobject` have been deprecated. Use `.astype(object)` instead (GH18572)
- Grouping by a tuple of keys now emits a `FutureWarning` and is deprecated. In the future, a tuple passed to 'by' will always refer to a single key that is the actual tuple, instead of treating the tuple as multiple keys. To retain the previous behavior, use a list instead of a tuple (GH18314)
- `Series.valid` is deprecated. Use `Series.dropna()` instead (GH18800).
- `read_excel()` has deprecated the `skip_footer` parameter. Use `skipfooter` instead (GH18836)
- `ExcelFile.parse()` has deprecated `sheetname` in favor of `sheet_name` for consistency with `read_excel()` (GH20920).
- The `is_copy` attribute is deprecated and will be removed in a future version (GH18801).
- `IntervalIndex.from_intervals` is deprecated in favor of the `IntervalIndex` constructor (GH19263)
- `DataFrame.from_items` is deprecated. Use `DataFrame.from_dict()` instead, or `DataFrame.from_dict(OrderedDict())` if you wish to preserve the key order (GH17320, GH17312)
- Indexing a `MultiIndex` or a `FloatIndex` with a list containing some missing keys will now show a `FutureWarning`, which is consistent with other types of indexes (GH17758).
- The `broadcast` parameter of `.apply()` is deprecated in favor of `result_type='broadcast'` (GH18577)
- The `reduce` parameter of `.apply()` is deprecated in favor of `result_type='reduce'` (GH18577)
- The `order` parameter of `factorize()` is deprecated and will be removed in a future release (GH19727)
- `Timestamp.weekday_name`, `DatetimeIndex.weekday_name`, and `Series.dt.weekday_name` are deprecated in favor of `Timestamp.day_name()`, `DatetimeIndex.day_name()`, and `Series.dt.day_name()` (GH12806)
- `pandas.tseries.plotting.tsplot` is deprecated. Use `Series.plot()` instead (GH18627)
- `Index.summary()` is deprecated and will be removed in a future version (GH18217)
- `NDFrame.get_ftype_counts()` is deprecated and will be removed in a future version (GH18243)

- The `convert_datetime64` parameter in `DataFrame.to_records()` has been deprecated and will be removed in a future version. The NumPy bug motivating this parameter has been resolved. The default value for this parameter has also changed from `True` to `None` (GH18160).
- `Series.rolling().apply()`, `DataFrame.rolling().apply()`, `Series.expanding().apply()`, and `DataFrame.expanding().apply()` have deprecated passing an `np.array` by default. One will need to pass the new `raw` parameter to be explicit about what is passed (GH20584)
- The `data`, `base`, `strides`, `flags` and `itemsize` properties of the `Series` and `Index` classes have been deprecated and will be removed in a future version (GH20419).
- `DatetimeIndex.offset` is deprecated. Use `DatetimeIndex.freq` instead (GH20716)
- Floor division between an integer ndarray and a `Timedelta` is deprecated. Divide by `Timedelta.value` instead (GH19761)
- Setting `PeriodIndex.freq` (which was not guaranteed to work correctly) is deprecated. Use `PeriodIndex.asfreq()` instead (GH20678)
- `Index.get_duplicates()` is deprecated and will be removed in a future version (GH20239)
- The previous default behavior of negative indices in `Categorical.take` is deprecated. In a future version it will change from meaning missing values to meaning positional indices from the right. The future behavior is consistent with `Series.take()` (GH20664).
- Passing multiple axes to the `axis` parameter in `DataFrame.dropna()` has been deprecated and will be removed in a future version (GH20987)

### Removal of prior version deprecations/changes

- Warnings against the obsolete usage `Categorical(codes, categories)`, which were emitted for instance when the first two arguments to `Categorical()` had different dtypes, and recommended the use of `Categorical.from_codes`, have now been removed (GH8074)
- The `levels` and `labels` attributes of a `MultiIndex` can no longer be set directly (GH4039).
- `pd.tseries.util.pivot_annual` has been removed (deprecated since v0.19). Use `pivot_table` instead (GH18370)
- `pd.tseries.util.isleapyear` has been removed (deprecated since v0.19). Use `.is_leap_year` property in `Datetime`-likes instead (GH18370)
- `pd.ordered_merge` has been removed (deprecated since v0.19). Use `pd.merge_ordered` instead (GH18459)
- The `SparseList` class has been removed (GH14007)
- The `pandas.io.wb` and `pandas.io.data` stub modules have been removed (GH13735)
- `Categorical.from_array` has been removed (GH13854)
- The `freq` and `how` parameters have been removed from the `rolling/expanding/ewm` methods of `DataFrame` and `Series` (deprecated since v0.18). Instead, `resample` before calling the methods. (GH18601 & GH18668)
- `DatetimeIndex.to_datetime`, `Timestamp.to_datetime`, `PeriodIndex.to_datetime`, and `Index.to_datetime` have been removed (GH8254, GH14096, GH14113)
- `read_csv()` has dropped the `skip_footer` parameter (GH13386)
- `read_csv()` has dropped the `as_rearray` parameter (GH13373)
- `read_csv()` has dropped the `buffer_lines` parameter (GH13360)

- `read_csv()` has dropped the `compact_ints` and `use_unsigned` parameters (GH13323)
- The `Timestamp` class has dropped the `offset` attribute in favor of `freq` (GH13593)
- The `Series`, `Categorical`, and `Index` classes have dropped the `reshape` method (GH13012)
- `pandas.tseries.frequencies.get_standard_freq` has been removed in favor of `pandas.tseries.frequencies.to_offset(freq).rule_code` (GH13874)
- The `freqstr` keyword has been removed from `pandas.tseries.frequencies.to_offset` in favor of `freq` (GH13874)
- The `Panel4D` and `PanelND` classes have been removed (GH13776)
- The `Panel` class has dropped the `to_long` and `toLong` methods (GH19077)
- The options `display.line_with` and `display.height` are removed in favor of `display.width` and `display.max_rows` respectively (GH4391, GH19107)
- The `labels` attribute of the `Categorical` class has been removed in favor of `Categorical.codes` (GH7768)
- The `flavor` parameter have been removed from func:`to_sql` method (GH13611)
- The modules `pandas.tools.hashing` and `pandas.util.hashing` have been removed (GH16223)
- The top-level functions `pd.rolling_*`, `pd.expanding_*` and `pd.ewm*` have been removed (Deprecated since v0.18). Instead, use the `DataFrame/Series` methods `rolling`, `expanding` and `ewm` (GH18723)
- Imports from `pandas.core.common` for functions such as `is_datetime64_dtype` are now removed. These are located in `pandas.api.types`. (GH13634, GH19769)
- The `infer_dst` keyword in `Series.tz_localize()`, `DatetimeIndex.tz_localize()` and `DatetimeIndex` have been removed. `infer_dst=True` is equivalent to `ambiguous='infer'`, and `infer_dst=False` to `ambiguous='raise'` (GH7963).
- When `.resample()` was changed from an eager to a lazy operation, like `.groupby()` in v0.18.0, we put in place compatibility (with a `FutureWarning`), so operations would continue to work. This is now fully removed, so a `Resampler` will no longer forward compat operations (GH20554)
- Remove long deprecated `axis=None` parameter from `.replace()` (GH20271)

## Performance improvements

- Indexers on `Series` or `DataFrame` no longer create a reference cycle (GH17956)
- Added a keyword argument, `cache`, to `to_datetime()` that improved the performance of converting duplicate datetime arguments (GH11665)
- `DateOffset` arithmetic performance is improved (GH18218)
- Converting a `Series` of `Timedelta` objects to days, seconds, etc... sped up through vectorization of underlying methods (GH18092)
- Improved performance of `.map()` with a `Series/dict` input (GH15081)
- The overridden `Timedelta` properties of days, seconds and microseconds have been removed, leveraging their built-in Python versions instead (GH18242)
- `Series` construction will reduce the number of copies made of the input data in certain cases (GH17449)
- Improved performance of `Series.dt.date()` and `DatetimeIndex.date()` (GH18058)
- Improved performance of `Series.dt.time()` and `DatetimeIndex.time()` (GH18461)

- Improved performance of `IntervalIndex.symmetric_difference()` (GH18475)
- Improved performance of `DatetimeIndex` and `Series` arithmetic operations with `Business-Month` and `Business-Quarter` frequencies (GH18489)
- `Series()` / `DataFrame()` tab completion limits to 100 values, for better performance. (GH18587)
- Improved performance of `DataFrame.median()` with `axis=1` when `bottleneck` is not installed (GH16468)
- Improved performance of `MultiIndex.get_loc()` for large indexes, at the cost of a reduction in performance for small ones (GH18519)
- Improved performance of `MultiIndex.remove_unused_levels()` when there are no unused levels, at the cost of a reduction in performance when there are (GH19289)
- Improved performance of `Index.get_loc()` for non-unique indexes (GH19478)
- Improved performance of pairwise `.rolling()` and `.expanding()` with `.cov()` and `.corr()` operations (GH17917)
- Improved performance of `pandas.core.groupby.GroupBy.rank()` (GH15779)
- Improved performance of variable `.rolling()` on `.min()` and `.max()` (GH19521)
- Improved performance of `pandas.core.groupby.GroupBy.ffill()` and `pandas.core.groupby.GroupBy.bfill()` (GH11296)
- Improved performance of `pandas.core.groupby.GroupBy.any()` and `pandas.core.groupby.GroupBy.all()` (GH15435)
- Improved performance of `pandas.core.groupby.GroupBy.pct_change()` (GH19165)
- Improved performance of `Series.isin()` in the case of categorical dtypes (GH20003)
- Improved performance of `getattr(Series, attr)` when the `Series` has certain index types. This manifested in slow printing of large `Series` with a `DatetimeIndex` (GH19764)
- Fixed a performance regression for `GroupBy.nth()` and `GroupBy.last()` with some object columns (GH19283)
- Improved performance of `pandas.core.arrays.Categorical.from_codes()` (GH18501)

## Documentation changes

Thanks to all of the contributors who participated in the Pandas Documentation Sprint, which took place on March 10th. We had about 500 participants from over 30 locations across the world. You should notice that many of the *API docstrings* have greatly improved.

There were too many simultaneous contributions to include a release note for each improvement, but this [GitHub search](#) should give you an idea of how many docstrings were improved.

Special thanks to [Marc Garcia](#) for organizing the sprint. For more information, read the [NumFOCUS blogpost](#) recapping the sprint.

- Changed spelling of “numpy” to “NumPy”, and “python” to “Python”. (GH19017)
- Consistency when introducing code samples, using either colon or period. Rewrote some sentences for greater clarity, added more dynamic references to functions, methods and classes. (GH18941, GH18948, GH18973, GH19017)
- Added a reference to `DataFrame.assign()` in the concatenate section of the merging documentation (GH18665)

## Bug fixes

### Categorical

**Warning:** A class of bugs were introduced in pandas 0.21 with `CategoricalDtype` that affects the correctness of operations like `merge`, `concat`, and indexing when comparing multiple unordered `Categorical` arrays that have the same categories, but in a different order. We highly recommend upgrading or manually aligning your categories before doing these operations.

- Bug in `Categorical.equals` returning the wrong result when comparing two unordered `Categorical` arrays with the same categories, but in a different order ([GH16603](#))
- Bug in `pandas.api.types.union_categoricals()` returning the wrong result when for unordered categoricals with the categories in a different order. This affected `pandas.concat()` with `Categorical` data ([GH19096](#)).
- Bug in `pandas.merge()` returning the wrong result when joining on an unordered `Categorical` that had the same categories but in a different order ([GH19551](#))
- Bug in `CategoricalIndex.get_indexer()` returning the wrong result when target was an unordered `Categorical` that had the same categories as `self` but in a different order ([GH19551](#))
- Bug in `Index.astype()` with a categorical dtype where the resultant index is not converted to a `CategoricalIndex` for all types of index ([GH18630](#))
- Bug in `Series.astype()` and `Categorical.astype()` where an existing categorical data does not get updated ([GH10696](#), [GH18593](#))
- Bug in `Series.str.split()` with `expand=True` incorrectly raising an `IndexError` on empty strings ([GH20002](#)).
- Bug in `Index` constructor with `dtype=CategoricalDtype(...)` where categories and ordered are not maintained ([GH19032](#))
- Bug in `Series` constructor with scalar and `dtype=CategoricalDtype(...)` where categories and ordered are not maintained ([GH19565](#))
- Bug in `Categorical.__iter__` not converting to Python types ([GH19909](#))
- Bug in `pandas.factorize()` returning the unique codes for the uniques. This now returns a `Categorical` with the same dtype as the input ([GH19721](#))
- Bug in `pandas.factorize()` including an item for missing values in the uniques return value ([GH19721](#))
- Bug in `Series.take()` with categorical data interpreting `-1` in `indices` as missing value markers, rather than the last element of the `Series` ([GH20664](#))

## Datetimelike

- Bug in `Series.__sub__()` subtracting a non-nanosecond `np.datetime64` object from a `Series` gave incorrect results ([GH7996](#))
- Bug in `DatetimeIndex`, `TimedeltaIndex` addition and subtraction of zero-dimensional integer arrays gave incorrect results ([GH19012](#))
- Bug in `DatetimeIndex` and `TimedeltaIndex` where adding or subtracting an array-like of `DateOffset` objects either raised (`np.array`, `pd.Index`) or broadcast incorrectly (`pd.Series`) ([GH18849](#))
- Bug in `Series.__add__()` adding `Series` with `dtype timedelta64[ns]` to a timezone-aware `DatetimeIndex` incorrectly dropped timezone information ([GH13905](#))
- Adding a `Period` object to a `datetime` or `Timestamp` object will now correctly raise a `TypeError` ([GH17983](#))
- Bug in `Timestamp` where comparison with an array of `Timestamp` objects would result in a `RecursionError` ([GH15183](#))
- Bug in `Series` floor-division where operating on a scalar `timedelta` raises an exception ([GH18846](#))
- Bug in `DatetimeIndex` where the repr was not showing high-precision time values at the end of a day (e.g., `23:59:59.999999999`) ([GH19030](#))
- Bug in `.astype()` to non-ns `timedelta` units would hold the incorrect `dtype` ([GH19176](#), [GH19223](#), [GH12425](#))
- Bug in subtracting `Series` from `NaT` incorrectly returning `NaT` ([GH19158](#))
- Bug in `Series.truncate()` which raises `TypeError` with a monotonic `PeriodIndex` ([GH17717](#))
- Bug in `pct_change()` using `periods` and `freq` returned different length outputs ([GH7292](#))
- Bug in comparison of `DatetimeIndex` against `None` or `datetime.date` objects raising `TypeError` for `==` and `!=` comparisons instead of `all-False` and `all-True`, respectively ([GH19301](#))
- Bug in `Timestamp` and `to_datetime()` where a string representing a barely out-of-bounds timestamp would be incorrectly rounded down instead of raising `OutOfBoundsDatetime` ([GH19382](#))
- Bug in `Timestamp.floor()` `DatetimeIndex.floor()` where time stamps far in the future and past were not rounded correctly ([GH19206](#))
- Bug in `to_datetime()` where passing an out-of-bounds `datetime` with `errors='coerce'` and `utc=True` would raise `OutOfBoundsDatetime` instead of parsing to `NaT` ([GH19612](#))
- Bug in `DatetimeIndex` and `TimedeltaIndex` addition and subtraction where name of the returned object was not always set consistently. ([GH19744](#))
- Bug in `DatetimeIndex` and `TimedeltaIndex` addition and subtraction where operations with numpy arrays raised `TypeError` ([GH19847](#))
- Bug in `DatetimeIndex` and `TimedeltaIndex` where setting the `freq` attribute was not fully supported ([GH20678](#))

## Timedelta

- Bug in `Timedelta.__mul__()` where multiplying by `NaT` returned `NaT` instead of raising a `TypeError` (GH19819)
- Bug in `Series` with `dtype='timedelta64[ns]'` where addition or subtraction of `TimedeltaIndex` had results cast to `dtype='int64'` (GH17250)
- Bug in `Series` with `dtype='timedelta64[ns]'` where addition or subtraction of `TimedeltaIndex` could return a `Series` with an incorrect name (GH19043)
- Bug in `Timedelta.__floordiv__()` and `Timedelta.__rfloordiv__()` dividing by many incompatible numpy objects was incorrectly allowed (GH18846)
- Bug where dividing a scalar timedelta-like object with `TimedeltaIndex` performed the reciprocal operation (GH19125)
- Bug in `TimedeltaIndex` where division by a `Series` would return a `TimedeltaIndex` instead of a `Series` (GH19042)
- Bug in `Timedelta.__add__()`, `Timedelta.__sub__()` where adding or subtracting a `np.timedelta64` object would return another `np.timedelta64` instead of a `Timedelta` (GH19738)
- Bug in `Timedelta.__floordiv__()`, `Timedelta.__rfloordiv__()` where operating with a `Tick` object would raise a `TypeError` instead of returning a numeric value (GH19738)
- Bug in `Period.asfreq()` where periods near `datetime(1, 1, 1)` could be converted incorrectly (GH19643, GH19834)
- Bug in `Timedelta.total_seconds()` causing precision errors, for example `Timedelta('30S').total_seconds() == 30.000000000000004` (GH19458)
- Bug in `Timedelta.__rmod__()` where operating with a `numpy.timedelta64` returned a `timedelta64` object instead of a `Timedelta` (GH19820)
- Multiplication of `TimedeltaIndex` by `TimedeltaIndex` will now raise `TypeError` instead of raising `ValueError` in cases of length mis-match (GH19333)
- Bug in indexing a `TimedeltaIndex` with a `np.timedelta64` object which was raising a `TypeError` (GH20393)

## Timezones

- Bug in creating a `Series` from an array that contains both tz-naive and tz-aware values will result in a `Series` whose `dtype` is tz-aware instead of object (GH16406)
- Bug in comparison of timezone-aware `DatetimeIndex` against `NaT` incorrectly raising `TypeError` (GH19276)
- Bug in `DatetimeIndex.astype()` when converting between timezone aware dtypes, and converting from timezone aware to naive (GH18951)
- Bug in comparing `DatetimeIndex`, which failed to raise `TypeError` when attempting to compare timezone-aware and timezone-naive datetimelike objects (GH18162)
- Bug in localization of a naive, datetime string in a `Series` constructor with a `datetime64[ns, tz]` dtype (GH174151)
- `Timestamp.replace()` will now handle Daylight Savings transitions gracefully (GH18319)
- Bug in tz-aware `DatetimeIndex` where addition/subtraction with a `TimedeltaIndex` or array with `dtype='timedelta64[ns]'` was incorrect (GH17558)

- Bug in `DatetimeIndex.insert()` where inserting `NaT` into a timezone-aware index incorrectly raised (GH16357)
- Bug in `DataFrame` constructor, where tz-aware `Datetimeindex` and a given column name will result in an empty `DataFrame` (GH19157)
- Bug in `Timestamp.tz_localize()` where localizing a timestamp near the minimum or maximum valid values could overflow and return a timestamp with an incorrect nanosecond value (GH12677)
- Bug when iterating over `DatetimeIndex` that was localized with fixed timezone offset that rounded nanosecond precision to microseconds (GH19603)
- Bug in `DataFrame.diff()` that raised an `IndexError` with tz-aware values (GH18578)
- Bug in `melt()` that converted tz-aware dtypes to tz-naive (GH15785)
- Bug in `Dataframe.count()` that raised an `ValueError`, if `Dataframe.dropna()` was called for a single column with timezone-aware values. (GH13407)

## Offsets

- Bug in `WeekOfMonth` and `Week` where addition and subtraction did not roll correctly (GH18510, GH18672, GH18864)
- Bug in `WeekOfMonth` and `LastWeekOfMonth` where default keyword arguments for constructor raised `ValueError` (GH19142)
- Bug in `FY5253Quarter`, `LastWeekOfMonth` where rollback and rollforward behavior was inconsistent with addition and subtraction behavior (GH18854)
- Bug in `FY5253` where `datetime` addition and subtraction incremented incorrectly for dates on the year-end but not normalized to midnight (GH18854)
- Bug in `FY5253` where date offsets could incorrectly raise an `AssertionError` in arithmetic operations (GH14774)

## Numeric

- Bug in `Series` constructor with an int or float list where specifying `dtype=str`, `dtype='str'` or `dtype='U'` failed to convert the data elements to strings (GH16605)
- Bug in `Index` multiplication and division methods where operating with a `Series` would return an `Index` object instead of a `Series` object (GH19042)
- Bug in the `DataFrame` constructor in which data containing very large positive or very large negative numbers was causing `OverflowError` (GH18584)
- Bug in `Index` constructor with `dtype='uint64'` where int-like floats were not coerced to `UInt64Index` (GH18400)
- Bug in `DataFrame` flex arithmetic (e.g. `df.add(other, fill_value=foo)`) with a `fill_value` other than `None` failed to raise `NotImplementedError` in corner cases where either the frame or `other` has length zero (GH19522)
- Multiplication and division of numeric-dtyped `Index` objects with `timedelta`-like scalars returns `TimedeltaIndex` instead of raising `TypeError` (GH19333)
- Bug where `NaN` was returned instead of `0` by `Series.pct_change()` and `DataFrame.pct_change()` when `fill_method` is not `None` (GH19873)

## Strings

- Bug in `Series.str.get()` with a dictionary in the values and the index not in the keys, raising `KeyError` (GH20671)

## Indexing

- Bug in Index construction from list of mixed type tuples (GH18505)
- Bug in `Index.drop()` when passing a list of both tuples and non-tuples (GH18304)
- Bug in `DataFrame.drop()`, `Panel.drop()`, `Series.drop()`, `Index.drop()` where no `KeyError` is raised when dropping a non-existent element from an axis that contains duplicates (GH19186)
- Bug in indexing a datetimelike Index that raised `ValueError` instead of `IndexError` (GH18386).
- `Index.to_series()` now accepts `index` and `name` kwargs (GH18699)
- `DatetimeIndex.to_series()` now accepts `index` and `name` kwargs (GH18699)
- Bug in indexing non-scalar value from Series having non-unique Index will return value flattened (GH17610)
- Bug in indexing with iterator containing only missing keys, which raised no error (GH20748)
- Fixed inconsistency in `.ix` between list and scalar keys when the index has integer dtype and does not include the desired keys (GH20753)
- Bug in `__setitem__` when indexing a DataFrame with a 2-d boolean ndarray (GH18582)
- Bug in `str.extractall` when there were no matches empty Index was returned instead of appropriate `MultiIndex` (GH19034)
- Bug in `IntervalIndex` where empty and purely NA data was constructed inconsistently depending on the construction method (GH18421)
- Bug in `IntervalIndex.symmetric_difference()` where the symmetric difference with a non-`IntervalIndex` did not raise (GH18475)
- Bug in `IntervalIndex` where set operations that returned an empty `IntervalIndex` had the wrong dtype (GH19101)
- Bug in `DataFrame.drop_duplicates()` where no `KeyError` is raised when passing in columns that don't exist on the DataFrame (GH19726)
- Bug in Index subclasses constructors that ignore unexpected keyword arguments (GH19348)
- Bug in `Index.difference()` when taking difference of an Index with itself (GH20040)
- Bug in `DataFrame.first_valid_index()` and `DataFrame.last_valid_index()` in presence of entire rows of NaNs in the middle of values (GH20499).
- Bug in `IntervalIndex` where some indexing operations were not supported for overlapping or non-monotonic `uint64` data (GH20636)
- Bug in `Series.is_unique` where extraneous output in `stderr` is shown if Series contains objects with `__ne__` defined (GH20661)
- Bug in `.loc` assignment with a single-element list-like incorrectly assigns as a list (GH19474)
- Bug in partial string indexing on a Series/DataFrame with a monotonic decreasing `DatetimeIndex` (GH19362)
- Bug in performing in-place operations on a DataFrame with a duplicate Index (GH17105)

- Bug in `IntervalIndex.get_loc()` and `IntervalIndex.get_indexer()` when used with an `IntervalIndex` containing a single interval (GH17284, GH20921)
- Bug in `.loc` with a `uint64` indexer (GH20722)

## MultiIndex

- Bug in `MultiIndex.__contains__()` where non-tuple keys would return `True` even if they had been dropped (GH19027)
- Bug in `MultiIndex.set_labels()` which would cause casting (and potentially clipping) of the new labels if the `level` argument is not 0 or a list like `[0, 1, ... ]` (GH19057)
- Bug in `MultiIndex.get_level_values()` which would return an invalid index on level of ints with missing values (GH17924)
- Bug in `MultiIndex.unique()` when called on empty `MultiIndex` (GH20568)
- Bug in `MultiIndex.unique()` which would not preserve level names (GH20570)
- Bug in `MultiIndex.remove_unused_levels()` which would fill nan values (GH18417)
- Bug in `MultiIndex.from_tuples()` which would fail to take zipped tuples in python3 (GH18434)
- Bug in `MultiIndex.get_loc()` which would fail to automatically cast values between float and int (GH18818, GH15994)
- Bug in `MultiIndex.get_loc()` which would cast boolean to integer labels (GH19086)
- Bug in `MultiIndex.get_loc()` which would fail to locate keys containing `NaN` (GH18485)
- Bug in `MultiIndex.get_loc()` in large `MultiIndex`, would fail when levels had different dtypes (GH18520)
- Bug in indexing where nested indexers having only numpy arrays are handled incorrectly (GH19686)

## I/O

- `read_html()` now rewinds seekable IO objects after parse failure, before attempting to parse with a new parser. If a parser errors and the object is non-seekable, an informative error is raised suggesting the use of a different parser (GH17975)
- `DataFrame.to_html()` now has an option to add an id to the leading `<table>` tag (GH8496)
- Bug in `read_msgpack()` with a non-existent file is passed in Python 2 (GH15296)
- Bug in `read_csv()` where a `MultiIndex` with duplicate columns was not being mangled appropriately (GH18062)
- Bug in `read_csv()` where missing values were not being handled properly when `keep_default_na=False` with dictionary `na_values` (GH19227)
- Bug in `read_csv()` causing heap corruption on 32-bit, big-endian architectures (GH20785)
- Bug in `read_sas()` where a file with 0 variables gave an `AttributeError` incorrectly. Now it gives an `EmptyDataError` (GH18184)
- Bug in `DataFrame.to_latex()` where pairs of braces meant to serve as invisible placeholders were escaped (GH18667)
- Bug in `DataFrame.to_latex()` where a `NaN` in a `MultiIndex` would cause an `IndexError` or incorrect output (GH14249)

- Bug in `DataFrame.to_latex()` where a non-string index-level name would result in an `AttributeError` (GH19981)
- Bug in `DataFrame.to_latex()` where the combination of an index name and the `index_names=False` option would result in incorrect output (GH18326)
- Bug in `DataFrame.to_latex()` where a `MultiIndex` with an empty string as its name would result in incorrect output (GH18669)
- Bug in `DataFrame.to_latex()` where missing space characters caused wrong escaping and produced non-valid latex in some cases (GH20859)
- Bug in `read_json()` where large numeric values were causing an `OverflowError` (GH18842)
- Bug in `DataFrame.to_parquet()` where an exception was raised if the write destination is S3 (GH19134)
- Interval now supported in `DataFrame.to_excel()` for all Excel file types (GH19242)
- `Timedelta` now supported in `DataFrame.to_excel()` for all Excel file types (GH19242, GH9155, GH19900)
- Bug in `pandas.io.stata.StataReader.value_labels()` raising an `AttributeError` when called on very old files. Now returns an empty dict (GH19417)
- Bug in `read_pickle()` when unpickling objects with `TimedeltaIndex` or `Float64Index` created with pandas prior to version 0.20 (GH19939)
- Bug in `pandas.io.json.json_normalize()` where sub-records are not properly normalized if any sub-records values are `NoneType` (GH20030)
- Bug in `usecols` parameter in `read_csv()` where error is not raised correctly when passing a string. (GH20529)
- Bug in `HDFStore.keys()` when reading a file with a soft link causes exception (GH20523)
- Bug in `HDFStore.select_column()` where a key which is not a valid store raised an `AttributeError` instead of a `KeyError` (GH17912)

## Plotting

- Better error message when attempting to plot but `matplotlib` is not installed (GH19810).
- `DataFrame.plot()` now raises a `ValueError` when the `x` or `y` argument is improperly formed (GH18671)
- Bug in `DataFrame.plot()` when `x` and `y` arguments given as positions caused incorrect referenced columns for line, bar and area plots (GH20056)
- Bug in formatting tick labels with `datetime.time()` and fractional seconds (GH18478).
- `Series.plot.kde()` has exposed the args `ind` and `bw_method` in the docstring (GH18461). The argument `ind` may now also be an integer (number of sample points).
- `DataFrame.plot()` now supports multiple columns to the `y` argument (GH19699)

## Groupby/resample/rolling

- Bug when grouping by a single column and aggregating with a class like `list` or `tuple` (GH18079)
- Fixed regression in `DataFrame.groupby()` which would not emit an error when called with a tuple key not in the index (GH18798)
- Bug in `DataFrame.resample()` which silently ignored unsupported (or mistyped) options for `label`, `closed` and `convention` (GH19303)
- Bug in `DataFrame.groupby()` where tuples were interpreted as lists of keys rather than as keys (GH17979, GH18249)
- Bug in `DataFrame.groupby()` where aggregation by `first/last/min/max` was causing timestamps to lose precision (GH19526)
- Bug in `DataFrame.transform()` where particular aggregation functions were being incorrectly cast to match the dtype(s) of the grouped data (GH19200)
- Bug in `DataFrame.groupby()` passing the `on=` kwarg, and subsequently using `.apply()` (GH17813)
- Bug in `DataFrame.resample().aggregate` not raising a `KeyError` when aggregating a non-existent column (GH16766, GH19566)
- Bug in `DataFrameGroupBy.cumsum()` and `DataFrameGroupBy.cumprod()` when `skipna` was passed (GH19806)
- Bug in `DataFrame.resample()` that dropped timezone information (GH13238)
- Bug in `DataFrame.groupby()` where transformations using `np.all` and `np.any` were raising a `ValueError` (GH20653)
- Bug in `DataFrame.resample()` where `ffill`, `bfill`, `pad`, `backfill`, `fillna`, `interpolate`, and `asfreq` were ignoring `loffset`. (GH20744)
- Bug in `DataFrame.groupby()` when applying a function that has mixed data types and the user supplied function can fail on the grouping column (GH20949)
- Bug in `DataFrameGroupBy.rolling().apply()` where operations performed against the associated `DataFrameGroupBy` object could impact the inclusion of the grouped item(s) in the result (GH14013)

## Sparse

- Bug in which creating a `SparseDataFrame` from a dense `Series` or an unsupported type raised an uncontrolled exception (GH19374)
- Bug in `SparseDataFrame.to_csv` causing exception (GH19384)
- Bug in `SparseSeries.memory_usage` which caused segfault by accessing non sparse elements (GH19368)
- Bug in constructing a `SparseArray`: if data is a scalar and index is defined it will coerce to `float64` regardless of scalar's dtype. (GH19163)

## Reshaping

- Bug in `DataFrame.merge()` where referencing a `CategoricalIndex` by name, where the `by` kwarg would `KeyError` (GH20777)
- Bug in `DataFrame.stack()` which fails trying to sort mixed type levels under Python 3 (GH18310)
- Bug in `DataFrame.unstack()` which casts `int` to `float` if `columns` is a `MultiIndex` with unused levels (GH17845)
- Bug in `DataFrame.unstack()` which raises an error if `index` is a `MultiIndex` with unused labels on the unstacked level (GH18562)
- Fixed construction of a `Series` from a `dict` containing `NaN` as key (GH18480)
- Fixed construction of a `DataFrame` from a `dict` containing `NaN` as key (GH18455)
- Disabled construction of a `Series` where `len(index) > len(data) = 1`, which previously would broadcast the data item, and now raises a `ValueError` (GH18819)
- Suppressed error in the construction of a `DataFrame` from a `dict` containing scalar values when the corresponding keys are not included in the passed index (GH18600)
- Fixed (changed from `object` to `float64`) dtype of `DataFrame` initialized with axes, no data, and `dtype=int` (GH19646)
- Bug in `Series.rank()` where `Series` containing `NaT` modifies the `Series` inplace (GH18521)
- Bug in `cut()` which fails when using readonly arrays (GH18773)
- Bug in `DataFrame.pivot_table()` which fails when the `aggfunc` arg is of type string. The behavior is now consistent with other methods like `agg` and `apply` (GH18713)
- Bug in `DataFrame.merge()` in which merging using `Index` objects as vectors raised an `Exception` (GH19038)
- Bug in `DataFrame.stack()`, `DataFrame.unstack()`, `Series.unstack()` which were not returning subclasses (GH15563)
- Bug in timezone comparisons, manifesting as a conversion of the index to UTC in `.concat()` (GH18523)
- Bug in `concat()` when concatenating sparse and dense series it returns only a `SparseDataFrame`. Should be a `DataFrame`. (GH18914, GH18686, and GH16874)
- Improved error message for `DataFrame.merge()` when there is no common merge key (GH19427)
- Bug in `DataFrame.join()` which does an `outer` instead of a `left` join when being called with multiple `DataFrames` and some have non-unique indices (GH19624)
- `Series.rename()` now accepts `axis` as a kwarg (GH18589)
- Bug in `rename()` where an `Index` of same-length tuples was converted to a `MultiIndex` (GH19497)
- Comparisons between `Series` and `Index` would return a `Series` with an incorrect name, ignoring the `Index`'s name attribute (GH19582)
- Bug in `qcut()` where `datetime` and `timedelta` data with `NaT` present raised a `ValueError` (GH19768)
- Bug in `DataFrame.iterrows()`, which would infer strings not compliant to `ISO8601` to datetimes (GH19671)
- Bug in `Series` constructor with `Categorical` where a `ValueError` is not raised when an index of different length is given (GH19342)
- Bug in `DataFrame.astype()` where column metadata is lost when converting to categorical or a dictionary of dtypes (GH19920)

- Bug in `cut()` and `qcut()` where timezone information was dropped ([GH19872](#))
- Bug in `Series` constructor with a `dtype=str`, previously raised in some cases ([GH19853](#))
- Bug in `get_dummies()`, and `select_dtypes()`, where duplicate column names caused incorrect behavior ([GH20848](#))
- Bug in `isna()`, which cannot handle ambiguous typed lists ([GH20675](#))
- Bug in `concat()` which raises an error when concatenating TZ-aware dataframes and all-NaT dataframes ([GH12396](#))
- Bug in `concat()` which raises an error when concatenating empty TZ-aware series ([GH18447](#))

### Other

- Improved error message when attempting to use a Python keyword as an identifier in a `numexpr` backed query ([GH18221](#))
- Bug in accessing a `pandas.get_option()`, which raised `KeyError` rather than `OptionError` when looking up a non-existent option key in some cases ([GH19789](#))
- Bug in `testing.assert_series_equal()` and `testing.assert_frame_equal()` for `Series` or `DataFrames` with differing unicode data ([GH20503](#))

## 6.5 Version 0.22

### 6.5.1 v0.22.0 (December 29, 2017)

{{ header }}

This is a major release from 0.21.1 and includes a single, API-breaking change. We recommend that all users upgrade to this version after carefully reading the release note (singular!).

## Backwards incompatible API changes

Pandas 0.22.0 changes the handling of empty and all-*NA* sums and products. The summary is that

- The sum of an empty or all-*NA* Series is now 0
- The product of an empty or all-*NA* Series is now 1
- We've added a `min_count` parameter to `.sum()` and `.prod()` controlling the minimum number of valid values for the result to be valid. If fewer than `min_count` non-*NA* values are present, the result is *NA*. The default is 0. To return NaN, the 0.21 behavior, use `min_count=1`.

Some background: In pandas 0.21, we fixed a long-standing inconsistency in the return value of all-*NA* series depending on whether or not bottleneck was installed. See *Sum/Prod of all-*NaN* or empty Series/DataFrames is now consistently *NaN**. At the same time, we changed the sum and prod of an empty Series to also be NaN.

Based on feedback, we've partially reverted those changes.

## Arithmetic operations

The default sum for empty or all-*NA* Series is now 0.

*pandas 0.21.x*

```
In [1]: pd.Series([]).sum()
Out[1]: nan

In [2]: pd.Series([np.nan]).sum()
Out[2]: nan
```

*pandas 0.22.0*

```
In [1]: pd.Series([]).sum()
Out[1]: 0.0

In [2]: pd.Series([np.nan]).sum()
Out[2]: 0.0
```

The default behavior is the same as pandas 0.20.3 with bottleneck installed. It also matches the behavior of NumPy's `np.nansum` on empty and all-*NA* arrays.

To have the sum of an empty series return NaN (the default behavior of pandas 0.20.3 without bottleneck, or pandas 0.21.x), use the `min_count` keyword.

```
In [3]: pd.Series([]).sum(min_count=1)
Out[3]: nan
```

Thanks to the `skipna` parameter, the `.sum` on an all-*NA* series is conceptually the same as the `.sum` of an empty one with `skipna=True` (the default).

```
In [4]: pd.Series([np.nan]).sum(min_count=1) # skipna=True by default
Out[4]: nan
```

The `min_count` parameter refers to the minimum number of *non-null* values required for a non-*NA* sum or product. `Series.prod()` has been updated to behave the same as `Series.sum()`, returning 1 instead.

```
In [5]: pd.Series([]).prod()
Out[5]: 1.0

In [6]: pd.Series([np.nan]).prod()
Out[6]: 1.0

In [7]: pd.Series([]).prod(min_count=1)
Out[7]: nan
```

These changes affect `DataFrame.sum()` and `DataFrame.prod()` as well. Finally, a few less obvious places in pandas are affected by this change.

### Grouping by a categorical

Grouping by a `Categorical` and summing now returns 0 instead of NaN for categories with no observations. The product now returns 1 instead of NaN.

*pandas 0.21.x*

```
In [8]: grouper = pd.Categorical(['a', 'a'], categories=['a', 'b'])
In [9]: pd.Series([1, 2]).groupby(grouper).sum()
Out[9]:
a    3.0
b     NaN
dtype: float64
```

*pandas 0.22*

```
In [8]: grouper = pd.Categorical(['a', 'a'], categories=['a', 'b'])
In [9]: pd.Series([1, 2]).groupby(grouper).sum()
Out[9]:
a    3
b    0
Length: 2, dtype: int64
```

To restore the 0.21 behavior of returning NaN for unobserved groups, use `min_count>=1`.

```
In [10]: pd.Series([1, 2]).groupby(grouper).sum(min_count=1)
Out[10]:
a    3.0
b     NaN
Length: 2, dtype: float64
```

## Resample

The sum and product of all-*NA* bins has changed from NaN to 0 for sum and 1 for product.

*pandas 0.21.x*

```
In [11]: s = pd.Series([1, 1, np.nan, np.nan],
.....:                 index=pd.date_range('2017', periods=4))
.....: s
Out [11]:
2017-01-01    1.0
2017-01-02    1.0
2017-01-03    NaN
2017-01-04    NaN
Freq: D, dtype: float64

In [12]: s.resample('2d').sum()
Out [12]:
2017-01-01    2.0
2017-01-03    NaN
Freq: 2D, dtype: float64
```

*pandas 0.22.0*

```
In [11]: s = pd.Series([1, 1, np.nan, np.nan],
.....:                 index=pd.date_range('2017', periods=4))
.....:
In [12]: s.resample('2d').sum()
Out [12]:
2017-01-01    2.0
2017-01-03    0.0
Freq: 2D, Length: 2, dtype: float64
```

To restore the 0.21 behavior of returning NaN, use `min_count>=1`.

```
In [13]: s.resample('2d').sum(min_count=1)
Out [13]:
2017-01-01    2.0
2017-01-03    NaN
Freq: 2D, Length: 2, dtype: float64
```

In particular, upsampling and taking the sum or product is affected, as upsampling introduces missing values even if the original series was entirely valid.

*pandas 0.21.x*

```
In [14]: idx = pd.DatetimeIndex(['2017-01-01', '2017-01-02'])

In [15]: pd.Series([1, 2], index=idx).resample('12H').sum()
Out [15]:
2017-01-01 00:00:00    1.0
2017-01-01 12:00:00    NaN
2017-01-02 00:00:00    2.0
Freq: 12H, dtype: float64
```

*pandas 0.22.0*

```
In [14]: idx = pd.DatetimeIndex(['2017-01-01', '2017-01-02'])
In [15]: pd.Series([1, 2], index=idx).resample("12H").sum()
Out [15]:
2017-01-01 00:00:00    1
2017-01-01 12:00:00    0
2017-01-02 00:00:00    2
Freq: 12H, Length: 3, dtype: int64
```

Once again, the `min_count` keyword is available to restore the 0.21 behavior.

```
In [16]: pd.Series([1, 2], index=idx).resample("12H").sum(min_count=1)
Out [16]:
2017-01-01 00:00:00    1.0
2017-01-01 12:00:00    NaN
2017-01-02 00:00:00    2.0
Freq: 12H, Length: 3, dtype: float64
```

## Rolling and expanding

Rolling and expanding already have a `min_periods` keyword that behaves similar to `min_count`. The only case that changes is when doing a rolling or expanding sum with `min_periods=0`. Previously this returned `NaN`, when fewer than `min_periods` non-`NA` values were in the window. Now it returns 0.

*pandas 0.21.1*

```
In [17]: s = pd.Series([np.nan, np.nan])
In [18]: s.rolling(2, min_periods=0).sum()
Out [18]:
0    NaN
1    NaN
dtype: float64
```

*pandas 0.22.0*

```
In [17]: s = pd.Series([np.nan, np.nan])
In [18]: s.rolling(2, min_periods=0).sum()
Out [18]:
0    0.0
1    0.0
Length: 2, dtype: float64
```

The default behavior of `min_periods=None`, implying that `min_periods` equals the window size, is unchanged.

## Compatibility

If you maintain a library that should work across pandas versions, it may be easiest to exclude pandas 0.21 from your requirements. Otherwise, all your `sum()` calls would need to check if the `Series` is empty before summing.

With `setuptools`, in your `setup.py` use:

```
install_requires=['pandas!=0.21.*', ...]
```

With `conda`, use

```
requirements:
run:
- pandas !=0.21.0, !=0.21.1
```

Note that the inconsistency in the return value for all-*NA* series is still there for pandas 0.20.3 and earlier. Avoiding pandas 0.21 will only help with the empty case.

## 6.6 Version 0.21

### 6.6.1 v0.21.1 (December 12, 2017)

{{ header }}

This is a minor bug-fix release in the 0.21.x series and includes some small regression fixes, bug fixes and performance improvements. We recommend that all users upgrade to this version.

Highlights include:

- Temporarily restore `matplotlib` datetime plotting functionality. This should resolve issues for users who implicitly relied on pandas to plot datetimes with `matplotlib`. See *here*.
- Improvements to the Parquet IO functions introduced in 0.21.0. See *here*.

#### What's new in v0.21.1

- *Restore Matplotlib datetime converter registration*
- *New features*
  - *Improvements to the Parquet IO functionality*
  - *Other enhancements*
- *Deprecations*
- *Performance improvements*
- *Bug fixes*

## Restore Matplotlib datetime converter registration

Pandas implements some matplotlib converters for nicely formatting the axis labels on plots with `datetime` or `Period` values. Prior to pandas 0.21.0, these were implicitly registered with matplotlib, as a side effect of `import pandas`.

In pandas 0.21.0, we required users to explicitly register the converter. This caused problems for some users who relied on those converters being present for regular `matplotlib.pyplot` plotting methods, so we're temporarily reverting that change; pandas 0.21.1 again registers the converters on import, just like before 0.21.0.

We've added a new option to control the converters: `pd.options.plotting.matplotlib.register_converters`. By default, they are registered. Toggling this to `False` removes pandas' formatters and restore any converters we overwrote when registering them ([GH18301](#)).

We're working with the matplotlib developers to make this easier. We're trying to balance user convenience (automatically registering the converters) with import performance and best practices (importing pandas shouldn't have the side effect of overwriting any custom converters you've already set). In the future we hope to have most of the date-time formatting functionality in matplotlib, with just the pandas-specific converters in pandas. We'll then gracefully deprecate the automatic registration of converters in favor of users explicitly registering them when they want them.

## New features

### Improvements to the Parquet IO functionality

- `DataFrame.to_parquet()` will now write non-default indexes when the underlying engine supports it. The indexes will be preserved when reading back in with `read_parquet()` ([GH18581](#)).
- `read_parquet()` now allows to specify the columns to read from a parquet file ([GH18154](#))
- `read_parquet()` now allows to specify kwargs which are passed to the respective engine ([GH18216](#))

## Other enhancements

- `Timestamp.timestamp()` is now available in Python 2.7. (GH17329)
- `Grouper` and `TimeGrouper` now have a friendly repr output (GH18203).

## Deprecations

- `pandas.tseries.register` has been renamed to `pandas.plotting.register_matplotlib_converters()` (GH18301)

## Performance improvements

- Improved performance of plotting large series/dataframes (GH18236).

## Bug fixes

### Conversion

- Bug in `TimedeltaIndex` subtraction could incorrectly overflow when `NaT` is present (GH17791)
- Bug in `DatetimeIndex` subtracting datetimelike from `DatetimeIndex` could fail to overflow (GH18020)
- Bug in `IntervalIndex.copy()` when copying and `IntervalIndex` with non-default `closed` (GH18339)
- Bug in `DataFrame.to_dict()` where columns of datetime that are tz-aware were not converted to required arrays when used with `orient='records'`, raising `TypeError` (GH18372)
- Bug in `DatetimeIndex` and `date_range()` where mismatching tz-aware start and end timezones would not raise an err if `end.tzinfo` is `None` (GH18431)
- Bug in `Series.fillna()` which raised when passed a long integer on Python 2 (GH18159).

### Indexing

- Bug in a boolean comparison of a `datetime.datetime` and a `datetime64[ns]` dtype `Series` (GH17965)
- Bug where a `MultiIndex` with more than a million records was not raising `AttributeError` when trying to access a missing attribute (GH18165)
- Bug in `IntervalIndex` constructor when a list of intervals is passed with non-default `closed` (GH18334)
- Bug in `Index.putmask` when an invalid mask passed (GH18368)
- Bug in masked assignment of a `timedelta64[ns]` dtype `Series`, incorrectly coerced to float (GH18493)

## I/O

- Bug in class:~`pandas.io.stata.StataReader` not converting date/time columns with display formatting addressed (GH17990). Previously columns with display formatting were normally left as ordinal numbers and not converted to datetime objects.
- Bug in `read_csv()` when reading a compressed UTF-16 encoded file (GH18071)
- Bug in `read_csv()` for handling null values in index columns when specifying `na_filter=False` (GH5239)
- Bug in `read_csv()` when reading numeric category fields with high cardinality (GH18186)
- Bug in `DataFrame.to_csv()` when the table had `MultiIndex` columns, and a list of strings was passed in for header (GH5539)
- Bug in parsing integer datetime-like columns with specified format in `read_sql` (GH17855).
- Bug in `DataFrame.to_msgpack()` when serializing data of the `numpy.bool_` datatype (GH18390)
- Bug in `read_json()` not decoding when reading line delimited JSON from S3 (GH17200)
- Bug in `pandas.io.json.json_normalize()` to avoid modification of meta (GH18610)
- Bug in `to_latex()` where repeated `MultiIndex` values were not printed even though a higher level index differed from the previous row (GH14484)
- Bug when reading NaN-only categorical columns in `HDFStore` (GH18413)
- Bug in `DataFrame.to_latex()` with `longtable=True` where a latex multicolumn always spanned over three columns (GH17959)

## Plotting

- Bug in `DataFrame.plot()` and `Series.plot()` with `DatetimeIndex` where a figure generated by them is not pickleable in Python 3 (GH18439)

## Groupby/resample/rolling

- Bug in `DataFrame.resample(...).apply(...)` when there is a callable that returns different columns (GH15169)
- Bug in `DataFrame.resample(...)` when there is a time change (DST) and resampling frequency is 12h or higher (GH15549)
- Bug in `pd.DataFrameGroupBy.count()` when counting over a datetimelike column (GH13393)
- Bug in `rolling.var` where calculation is inaccurate with a zero-valued array (GH18430)

## Reshaping

- Error message in `pd.merge_asof()` for key datatype mismatch now includes datatype of left and right key (GH18068)
- Bug in `pd.concat` when empty and non-empty DataFrames or Series are concatenated (GH18178 GH18187)
- Bug in `DataFrame.filter(...)` when unicode is passed as a condition in Python 2 (GH13101)
- Bug when merging empty DataFrames when `np.seterr(divide='raise')` is set (GH17776)

## Numeric

- Bug in `pd.Series.rolling.skew()` and `rolling.kurt()` with all equal values has floating issue (GH18044)

## Categorical

- Bug in `DataFrame.astype()` where casting to 'category' on an empty DataFrame causes a segmentation fault (GH18004)
- Error messages in the testing module have been improved when items have different `CategoricalDtype` (GH18069)
- `CategoricalIndex` can now correctly take a `pd.api.types.CategoricalDtype` as its `dtype` (GH18116)
- Bug in `Categorical.unique()` returning read-only codes array when all categories were NaN (GH18051)
- Bug in `DataFrame.groupby(axis=1)` with a `CategoricalIndex` (GH18432)

## String

- `Series.str.split()` will now propagate NaN values across all expanded columns instead of None (GH18450)

## 6.6.2 v0.21.0 (October 27, 2017)

{{ header }}

This is a major release from 0.20.3 and includes a number of API changes, deprecations, new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

- Integration with [Apache Parquet](#), including a new top-level `read_parquet()` function and `DataFrame.to_parquet()` method, see [here](#).
- New user-facing `pandas.api.types.CategoricalDtype` for specifying categoricals independent of the data, see [here](#).
- The behavior of `sum` and `prod` on all-NaN Series/DataFrames is now consistent and no longer depends on whether `bottleneck` is installed, and `sum` and `prod` on empty Series now return NaN instead of 0, see [here](#).
- Compatibility fixes for pypy, see [here](#).
- Additions to the `drop`, `reindex` and `rename` API to make them more consistent, see [here](#).
- Addition of the new methods `DataFrame.infer_objects` (see [here](#)) and `GroupBy.pipe` (see [here](#)).
- Indexing with a list of labels, where one or more of the labels is missing, is deprecated and will raise a `KeyError` in a future version, see [here](#).

Check the *API Changes* and *deprecations* before updating.

### What's new in v0.21.0

- *New features*
  - *Integration with Apache Parquet file format*
  - *infer\_objects type conversion*
  - *Improved warnings when attempting to create columns*
  - *drop now also accepts index/columns keywords*
  - *rename, reindex now also accept axis keyword*
  - *CategoricalDtype for specifying categoricals*
  - *GroupBy objects now have a pipe method*
  - *Categorical.rename\_categories accepts a dict-like*
  - *Other enhancements*
- *Backwards incompatible API changes*
  - *Dependencies have increased minimum versions*
  - *Sum/Prod of all-NaN or empty Series/DataFrames is now consistently NaN*
  - *Indexing with a list with missing labels is deprecated*

- *NA naming changes*
- *Iteration of Series/Index will now return Python scalars*
- *Indexing with a Boolean Index*
- *PeriodIndex resampling*
- *Improved error handling during item assignment in pd.eval*
- *Dtype conversions*
- *MultiIndex constructor with a single level*
- *UTC Localization with Series*
- *Consistency of range functions*
- *No automatic Matplotlib converters*
- *Other API changes*
- *Deprecations*
  - *Series.select and DataFrame.select*
  - *Series.argmax and Series.argmin*
- *Removal of prior version deprecations/changes*
- *Performance improvements*
- *Documentation changes*
- *Bug fixes*
  - *Conversion*
  - *Indexing*
  - *I/O*
  - *Plotting*
  - *Groupby/resample/rolling*
  - *Sparse*
  - *Reshaping*
  - *Numeric*
  - *Categorical*
  - *PyPy*
  - *Other*
- *Contributors*

## New features

### Integration with Apache Parquet file format

Integration with [Apache Parquet](#), including a new top-level `read_parquet()` and `DataFrame.to_parquet()` method, see [here](#) ([GH15838](#), [GH17438](#)).

[Apache Parquet](#) provides a cross-language, binary file format for reading and writing data frames efficiently. Parquet is designed to faithfully serialize and de-serialize `DataFrame`s, supporting all of the pandas dtypes, including extension dtypes such as datetime with timezones.

This functionality depends on either the [pyarrow](#) or [fastparquet](#) library. For more details, see *see the IO docs on Parquet*.

### `infer_objects` type conversion

The `DataFrame.infer_objects()` and `Series.infer_objects()` methods have been added to perform dtype inference on object columns, replacing some of the functionality of the deprecated `convert_objects` method. See the documentation [here](#) for more details. ([GH11221](#))

This method only performs soft conversions on object columns, converting Python objects to native types, but not any coercive conversions. For example:

```
In [1]: df = pd.DataFrame({'A': [1, 2, 3],
...:                      'B': np.array([1, 2, 3], dtype='object'),
...:                      'C': ['1', '2', '3']})
...:

In [2]: df.dtypes
Out[2]:
A      int64
B      object
C      object
Length: 3, dtype: object

In [3]: df.infer_objects().dtypes
Out[3]:
A      int64
B      int64
C      object
Length: 3, dtype: object
```

Note that column 'C' was not converted - only scalar numeric types will be converted to a new type. Other types of conversion should be accomplished using the `to_numeric()` function (or `to_datetime()`, `to_timedelta()`).

```
In [4]: df = df.infer_objects()

In [5]: df['C'] = pd.to_numeric(df['C'], errors='coerce')

In [6]: df.dtypes
Out[6]:
A      int64
B      int64
C      int64
Length: 3, dtype: object
```

## Improved warnings when attempting to create columns

New users are often puzzled by the relationship between column operations and attribute access on `DataFrame` instances (GH7175). One specific instance of this confusion is attempting to create a new column by setting an attribute on the `DataFrame`:

```
In [1]: df = pd.DataFrame({'one': [1., 2., 3.]})
In [2]: df.two = [4, 5, 6]
```

This does not raise any obvious exceptions, but also does not create a new column:

```
In [3]: df
Out [3]:
   one
0  1.0
1  2.0
2  3.0
```

Setting a list-like data structure into a new attribute now raises a `UserWarning` about the potential for unexpected behavior. See *Attribute Access*.

## drop now also accepts index/columns keywords

The `drop()` method has gained `index/columns` keywords as an alternative to specifying the axis. This is similar to the behavior of `reindex` (GH12392).

For example:

```
In [7]: df = pd.DataFrame(np.arange(8).reshape(2, 4),
...:                      columns=['A', 'B', 'C', 'D'])
...:

In [8]: df
Out [8]:
   A  B  C  D
0  0  1  2  3
1  4  5  6  7

[2 rows x 4 columns]

In [9]: df.drop(['B', 'C'], axis=1)
Out [9]:
   A  D
0  0  3
1  4  7

[2 rows x 2 columns]

# the following is now equivalent
In [10]: df.drop(columns=['B', 'C'])
Out [10]:
   A  D
0  0  3
1  4  7

[2 rows x 2 columns]
```

### rename, reindex now also accept axis keyword

The `DataFrame.rename()` and `DataFrame.reindex()` methods have gained the `axis` keyword to specify the axis to target with the operation (GH12392).

Here's rename:

```
In [11]: df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6]})
In [12]: df.rename(str.lower, axis='columns')
Out[12]:
   a  b
0  1  4
1  2  5
2  3  6

[3 rows x 2 columns]
In [13]: df.rename(id, axis='index')
Out[13]:
           A  B
94378327233120  1  4
94378327233152  2  5
94378327233184  3  6

[3 rows x 2 columns]
```

And reindex:

```
In [14]: df.reindex(['A', 'B', 'C'], axis='columns')
Out[14]:
   A  B  C
0  1  4 NaN
1  2  5 NaN
2  3  6 NaN

[3 rows x 3 columns]
In [15]: df.reindex([0, 1, 3], axis='index')
Out[15]:
   A  B
0  1.0  4.0
1  2.0  5.0
3  NaN  NaN

[3 rows x 2 columns]
```

The “index, columns” style continues to work as before.

```
In [16]: df.rename(index=id, columns=str.lower)
Out[16]:
           a  b
94378327233120  1  4
94378327233152  2  5
94378327233184  3  6

[3 rows x 2 columns]
```

(continues on next page)

(continued from previous page)

```
In [17]: df.reindex(index=[0, 1, 3], columns=['A', 'B', 'C'])
Out [17]:
   A    B    C
0  1.0  4.0 NaN
1  2.0  5.0 NaN
3  NaN  NaN NaN

[3 rows x 3 columns]
```

We *highly* encourage using named arguments to avoid confusion when using either style.

### CategoricalDtype for specifying categoricals

`pandas.api.types.CategoricalDtype` has been added to the public API and expanded to include the categories and ordered attributes. A `CategoricalDtype` can be used to specify the set of categories and orderedness of an array, independent of the data. This can be useful for example, when converting string data to a `Categorical` (GH14711, GH15078, GH16015, GH17643):

```
In [18]: from pandas.api.types import CategoricalDtype
In [19]: s = pd.Series(['a', 'b', 'c', 'a']) # strings
In [20]: dtype = CategoricalDtype(categories=['a', 'b', 'c', 'd'], ordered=True)
In [21]: s.astype(dtype)
Out [21]:
0    a
1    b
2    c
3    a
Length: 4, dtype: category
Categories (4, object): [a < b < c < d]
```

One place that deserves special mention is in `read_csv()`. Previously, with `dtype={'col': 'category'}`, the returned values and categories would always be strings.

```
In [22]: data = 'A,B\na,1\nb,2\nc,3'
In [23]: pd.read_csv(StringIO(data), dtype={'B': 'category'}).B.cat.categories
Out [23]: Index(['1', '2', '3'], dtype='object')
```

Notice the “object” dtype.

With a `CategoricalDtype` of all numerics, datetimes, or timedeltas, we can automatically convert to the correct type

```
In [24]: dtype = {'B': CategoricalDtype([1, 2, 3])}
In [25]: pd.read_csv(StringIO(data), dtype=dtype).B.cat.categories
Out [25]: Int64Index([1, 2, 3], dtype='int64')
```

The values have been correctly interpreted as integers.

The `.dtype` property of a `Categorical`, `CategoricalIndex` or a `Series` with categorical type will now return an instance of `CategoricalDtype`. While the repr has changed, `str(CategoricalDtype())` is still

the string 'category'. We'll take this moment to remind users that the *preferred* way to detect categorical data is to use `pandas.api.types.is_categorical_dtype()`, and not `str(dtype) == 'category'`.

See the *CategoricalDtype docs* for more.

### GroupBy objects now have a pipe method

GroupBy objects now have a `pipe` method, similar to the one on `DataFrame` and `Series`, that allow for functions that take a `GroupBy` to be composed in a clean, readable syntax. (GH17871)

For a concrete example on combining `.groupby` and `.pipe`, imagine having a `DataFrame` with columns for stores, products, revenue and sold quantity. We'd like to do a groupwise calculation of *prices* (i.e. revenue/quantity) per store and per product. We could do this in a multi-step operation, but expressing it in terms of piping can make the code more readable.

First we set the data:

```
In [26]: import numpy as np
In [27]: n = 1000
In [28]: df = pd.DataFrame({'Store': np.random.choice(['Store_1', 'Store_2'], n),
.....:                    'Product': np.random.choice(['Product_1',
.....:                                                  'Product_2',
.....:                                                  'Product_3'
.....:                                                  ], n),
.....:                    'Revenue': (np.random.random(n) * 50 + 10).round(2),
.....:                    'Quantity': np.random.randint(1, 10, size=n)})
.....:
In [29]: df.head(2)
Out[29]:
   Store  Product  Revenue  Quantity
0  Store_2  Product_2    44.13         6
1  Store_1  Product_3    53.06         1

[2 rows x 4 columns]
```

Now, to find prices per store/product, we can simply do:

```
In [30]: (df.groupby(['Store', 'Product'])
.....:      .pipe(lambda grp: grp.Revenue.sum() / grp.Quantity.sum())
.....:      .unstack().round(2))
.....:
Out[30]:
Product  Product_1  Product_2  Product_3
Store

[2 rows x 3 columns]
```

See the *documentation* for more.

### Categorical.rename\_categories accepts a dict-like

`rename_categories()` now accepts a dict-like argument for `new_categories`. The previous categories are looked up in the dictionary's keys and replaced if found. The behavior of missing and extra keys is the same as in `DataFrame.rename()`.

```
In [31]: c = pd.Categorical(['a', 'a', 'b'])
In [32]: c.rename_categories({"a": "eh", "b": "bee"})
Out [32]:
[eh, eh, bee]
Categories (2, object): [eh, bee]
```

**Warning:** To assist with upgrading pandas, `rename_categories` treats Series as list-like. Typically, Series are considered to be dict-like (e.g. in `.rename`, `.map`). In a future version of pandas `rename_categories` will change to treat them as dict-like. Follow the warning message's recommendations for writing future-proof code.

```
In [33]: c.rename_categories(pd.Series([0, 1], index=['a', 'c']))
FutureWarning: Treating Series 'new_categories' as a list-like and using the values.
In a future version, 'rename_categories' will treat Series like a dictionary.
For dict-like, use 'new_categories.to_dict()'
For list-like, use 'new_categories.values'.
Out [33]:
[0, 0, 1]
Categories (2, int64): [0, 1]
```

### Other enhancements

#### New functions or methods

- `nearest()` is added to support nearest-neighbor upsampling (GH17496).
- `Index` has added support for a `to_frame` method (GH15230).

#### New keywords

- Added a `skipna` parameter to `infer_dtype()` to support type inference in the presence of missing values (GH17059).
- `Series.to_dict()` and `DataFrame.to_dict()` now support an `into` keyword which allows you to specify the `collections.Mapping` subclass that you would like returned. The default is `dict`, which is backwards compatible. (GH16122)
- `Series.set_axis()` and `DataFrame.set_axis()` now support the `inplace` parameter. (GH14636)
- `Series.to_pickle()` and `DataFrame.to_pickle()` have gained a `protocol` parameter (GH16252). By default, this parameter is set to `HIGHEST_PROTOCOL`
- `read_feather()` has gained the `nthreads` parameter for multi-threaded operations (GH16359)
- `DataFrame.clip()` and `Series.clip()` have gained an `inplace` argument. (GH15388)
- `crosstab()` has gained a `margins_name` parameter to define the name of the row / column that will contain the totals when `margins=True`. (GH15972)

- `read_json()` now accepts a `chunksize` parameter that can be used when `lines=True`. If `chunksize` is passed, `read_json` now returns an iterator which reads in `chunksize` lines with each iteration. (GH17048)
- `read_json()` and `to_json()` now accept a `compression` argument which allows them to transparently handle compressed files. (GH17798)

### Various enhancements

- Improved the import time of pandas by about 2.25x. (GH16764)
- Support for PEP 519 – Adding a file system path protocol on most readers (e.g. `read_csv()`) and writers (e.g. `DataFrame.to_csv()`) (GH13823).
- Added a `__fspath__` method to `pd.HDFStore`, `pd.ExcelFile`, and `pd.ExcelWriter` to work properly with the file system path protocol (GH13823).
- The `validate` argument for `merge()` now checks whether a merge is one-to-one, one-to-many, many-to-one, or many-to-many. If a merge is found to not be an example of specified merge type, an exception of type `MergeError` will be raised. For more, see *here* (GH16270)
- Added support for PEP 518 (`pyproject.toml`) to the build system (GH16745)
- `RangeIndex.append()` now returns a `RangeIndex` object when possible (GH16212)
- `Series.rename_axis()` and `DataFrame.rename_axis()` with `inplace=True` now return `None` while renaming the axis inplace. (GH15704)
- `api.types.infer_dtype()` now infers decimals. (GH15690)
- `DataFrame.select_dtypes()` now accepts scalar values for include/exclude as well as list-like. (GH16855)
- `date_range()` now accepts ‘YS’ in addition to ‘AS’ as an alias for start of year. (GH9313)
- `date_range()` now accepts ‘Y’ in addition to ‘A’ as an alias for end of year. (GH9313)
- `DataFrame.add_prefix()` and `DataFrame.add_suffix()` now accept strings containing the ‘%’ character. (GH17151)
- Read/write methods that infer compression (`read_csv()`, `read_table()`, `read_pickle()`, and `to_pickle()`) can now infer from path-like objects, such as `pathlib.Path`. (GH17206)
- `read_sas()` now recognizes much more of the most frequently used date (datetime) formats in SAS7BDAT files. (GH15871)
- `DataFrame.items()` and `Series.items()` are now present in both Python 2 and 3 and is lazy in all cases. (GH13918, GH17213)
- `pandas.io.formats.style.Styler.where()` has been implemented as a convenience for `pandas.io.formats.style.Styler.applymap()`. (GH17474)
- `MultiIndex.is_monotonic_decreasing()` has been implemented. Previously returned `False` in all cases. (GH16554)
- `read_excel()` raises `ImportError` with a better message if `xlrd` is not installed. (GH17613)
- `DataFrame.assign()` will preserve the original order of `**kwargs` for Python 3.6+ users instead of sorting the column names. (GH14207)
- `Series.reindex()`, `DataFrame.reindex()`, `Index.get_indexer()` now support list-like argument for `tolerance`. (GH17367)

## Backwards incompatible API changes

### Dependencies have increased minimum versions

We have updated our minimum supported versions of dependencies ([GH15206](#), [GH15543](#), [GH15214](#)). If installed, we now require:

| Package    | Minimum Version | Required |
|------------|-----------------|----------|
| Numpy      | 1.9.0           | X        |
| Matplotlib | 1.4.3           |          |
| Scipy      | 0.14.0          |          |
| Bottleneck | 1.0.0           |          |

Additionally, support has been dropped for Python 3.4 ([GH15251](#)).

### Sum/Prod of all-NaN or empty Series/DataFrames is now consistently NaN

---

**Note:** The changes described here have been partially reverted. See the *v0.22.0 Whatsnew* for more.

---

The behavior of `sum` and `prod` on all-NaN Series/DataFrames no longer depends on whether `bottleneck` is installed, and return value of `sum` and `prod` on an empty Series has changed ([GH9422](#), [GH15507](#)).

Calling `sum` or `prod` on an empty or all-NaN Series, or columns of a DataFrame, will result in NaN. See the *docs*.

```
In [33]: s = pd.Series([np.nan])
```

Previously WITHOUT `bottleneck` installed:

```
In [2]: s.sum()
Out[2]: np.nan
```

Previously WITH `bottleneck`:

```
In [2]: s.sum()
Out[2]: 0.0
```

New behavior, without regard to the `bottleneck` installation:

```
In [34]: s.sum()
Out[34]: 0.0
```

Note that this also changes the sum of an empty Series. Previously this always returned 0 regardless of a `bottleneck` installation:

```
In [1]: pd.Series([]).sum()
Out[1]: 0
```

but for consistency with the all-NaN case, this was changed to return NaN as well:

```
In [35]: pd.Series([]).sum()
Out[35]: 0.0
```

## Indexing with a list with missing labels is deprecated

Previously, selecting with a list of labels, where one or more labels were missing would always succeed, returning NaN for missing labels. This will now show a FutureWarning. In the future this will raise a `KeyError` (GH15747). This warning will trigger on a `DataFrame` or a `Series` for using `.loc[]` or `[][]` when passing a list-of-labels with at least 1 missing label. See the *deprecation docs*.

```
In [36]: s = pd.Series([1, 2, 3])
```

```
In [37]: s
```

```
Out [37]:
```

```
0    1
1    2
2    3
Length: 3, dtype: int64
```

### Previous behavior

```
In [4]: s.loc[[1, 2, 3]]
```

```
Out [4]:
```

```
1    2.0
2    3.0
3     NaN
dtype: float64
```

### Current behavior

```
In [4]: s.loc[[1, 2, 3]]
```

Passing list-likes to `.loc` or `[]` with any missing label will raise `KeyError` in the future, you can use `.reindex()` as an alternative.

See the documentation here:

<https://pandas.pydata.org/pandas-docs/stable/indexing.html#deprecate-loc-reindex->listlike>

```
Out [4]:
```

```
1    2.0
2    3.0
3     NaN
dtype: float64
```

The idiomatic way to achieve selecting potentially not-found elements is via `.reindex()`

```
In [38]: s.reindex([1, 2, 3])
```

```
Out [38]:
```

```
1    2.0
2    3.0
3     NaN
Length: 3, dtype: float64
```

Selection with all keys found is unchanged.

```
In [39]: s.loc[[1, 2]]
```

```
Out [39]:
```

```
1    2
2    3
Length: 2, dtype: int64
```

## NA naming changes

In order to promote more consistency among the pandas API, we have added additional top-level functions `isna()` and `notna()` that are aliases for `isnull()` and `notnull()`. The naming scheme is now more consistent with methods like `.dropna()` and `.fillna()`. Furthermore in all cases where `.isnull()` and `.notnull()` methods are defined, these have additional methods named `.isna()` and `.notna()`, these are included for classes `Categorical`, `Index`, `Series`, and `DataFrame`. (GH15001).

The configuration option `pd.options.mode.use_inf_as_null` is deprecated, and `pd.options.mode.use_inf_as_na` is added as a replacement.

## Iteration of Series/Index will now return Python scalars

Previously, when using certain iteration methods for a `Series` with dtype `int` or `float`, you would receive a numpy scalar, e.g. `np.int64`, rather than a Python `int`. Issue (GH10904) corrected this for `Series.tolist()` and `list(Series)`. This change makes all iteration methods consistent, in particular, for `__iter__()` and `.map()`; note that this only affects `int/float` dtypes. (GH13236, GH13258, GH14216).

```
In [40]: s = pd.Series([1, 2, 3])

In [41]: s
Out[41]:
0    1
1    2
2    3
Length: 3, dtype: int64
```

Previously:

```
In [2]: type(list(s)[0])
Out[2]: numpy.int64
```

New behavior:

```
In [42]: type(list(s)[0])
Out[42]: int
```

Furthermore this will now correctly box the results of iteration for `DataFrame.to_dict()` as well.

```
In [43]: d = {'a': [1], 'b': ['b']}

In [44]: df = pd.DataFrame(d)
```

Previously:

```
In [8]: type(df.to_dict()['a'][0])
Out[8]: numpy.int64
```

New behavior:

```
In [45]: type(df.to_dict()['a'][0])
Out[45]: int
```

## Indexing with a Boolean Index

Previously when passing a boolean Index to `.loc`, if the index of the Series/DataFrame had boolean labels, you would get a label based selection, potentially duplicating result labels, rather than a boolean indexing selection (where `True` selects elements), this was inconsistent how a boolean numpy array indexed. The new behavior is to act like a boolean numpy array indexer. (GH17738)

Previous behavior:

```
In [46]: s = pd.Series([1, 2, 3], index=[False, True, False])
```

```
In [47]: s
```

```
Out[47]:
```

```
False    1
True     2
False    3
Length: 3, dtype: int64
```

```
In [59]: s.loc[pd.Index([True, False, True])]
```

```
Out[59]:
```

```
True     2
False    1
False    3
True     2
dtype: int64
```

Current behavior

```
In [48]: s.loc[pd.Index([True, False, True])]
```

```
Out[48]:
```

```
False    1
False    3
Length: 2, dtype: int64
```

Furthermore, previously if you had an index that was non-numeric (e.g. strings), then a boolean Index would raise a `KeyError`. This will now be treated as a boolean indexer.

Previously behavior:

```
In [49]: s = pd.Series([1, 2, 3], index=['a', 'b', 'c'])
```

```
In [50]: s
```

```
Out[50]:
```

```
a     1
b     2
c     3
Length: 3, dtype: int64
```

```
In [39]: s.loc[pd.Index([True, False, True])]
```

```
KeyError: "None of [Index([True, False, True], dtype='object')] are in the [index]"
```

Current behavior

```
In [51]: s.loc[pd.Index([True, False, True])]
```

```
Out[51]:
```

```
a     1
```

(continues on next page)

(continued from previous page)

```
c      3
Length: 2, dtype: int64
```

### PeriodIndex resampling

In previous versions of pandas, resampling a Series/DataFrame indexed by a PeriodIndex returned a DatetimeIndex in some cases (GH12884). Resampling to a multiplied frequency now returns a PeriodIndex (GH15944). As a minor enhancement, resampling a PeriodIndex can now handle NaT values (GH13224).

Previous behavior:

```
In [1]: pi = pd.period_range('2017-01', periods=12, freq='M')

In [2]: s = pd.Series(np.arange(12), index=pi)

In [3]: resampled = s.resample('2Q').mean()

In [4]: resampled
Out [4]:
2017-03-31      1.0
2017-09-30      5.5
2018-03-31     10.0
Freq: 2Q-DEC, dtype: float64

In [5]: resampled.index
Out [5]: DatetimeIndex(['2017-03-31', '2017-09-30', '2018-03-31'], dtype=
↳ 'datetime64[ns]', freq='2Q-DEC')
```

New behavior:

```
In [52]: pi = pd.period_range('2017-01', periods=12, freq='M')

In [53]: s = pd.Series(np.arange(12), index=pi)

In [54]: resampled = s.resample('2Q').mean()

In [55]: resampled
Out [55]:
2017Q1      2.5
2017Q3      8.5
Freq: 2Q-DEC, Length: 2, dtype: float64

In [56]: resampled.index
Out [56]: PeriodIndex(['2017Q1', '2017Q3'], dtype='period[2Q-DEC]', freq='2Q-DEC')
```

Upsampling and calling `.ohlc()` previously returned a Series, basically identical to calling `.asfreq()`. OHLC upsampling now returns a DataFrame with columns open, high, low and close (GH13083). This is consistent with downsampling and DatetimeIndex behavior.

Previous behavior:

```
In [1]: pi = pd.period_range(start='2000-01-01', freq='D', periods=10)

In [2]: s = pd.Series(np.arange(10), index=pi)
```

(continues on next page)

(continued from previous page)

```
In [3]: s.resample('H').ohlc()
Out [3]:
2000-01-01 00:00    0.0
...
2000-01-10 23:00    NaN
Freq: H, Length: 240, dtype: float64

In [4]: s.resample('M').ohlc()
Out [4]:
           open  high  low  close
2000-01      0     9    0     9
```

New behavior:

```
In [57]: pi = pd.period_range(start='2000-01-01', freq='D', periods=10)

In [58]: s = pd.Series(np.arange(10), index=pi)

In [59]: s.resample('H').ohlc()
Out [59]:
           open  high  low  close
2000-01-01 00:00    0.0  0.0  0.0  0.0
2000-01-01 01:00    NaN  NaN  NaN  NaN
2000-01-01 02:00    NaN  NaN  NaN  NaN
2000-01-01 03:00    NaN  NaN  NaN  NaN
2000-01-01 04:00    NaN  NaN  NaN  NaN
...
2000-01-10 19:00    NaN  NaN  NaN  NaN
2000-01-10 20:00    NaN  NaN  NaN  NaN
2000-01-10 21:00    NaN  NaN  NaN  NaN
2000-01-10 22:00    NaN  NaN  NaN  NaN
2000-01-10 23:00    NaN  NaN  NaN  NaN

[240 rows x 4 columns]

In [60]: s.resample('M').ohlc()
Out [60]:
           open  high  low  close
2000-01      0     9    0     9

[1 rows x 4 columns]
```

### Improved error handling during item assignment in `pd.eval`

`eval()` will now raise a `ValueError` when item assignment malfunctions, or inplace operations are specified, but there is no item assignment in the expression (GH16732)

```
In [61]: arr = np.array([1, 2, 3])
```

Previously, if you attempted the following expression, you would get a not very helpful error message:

```
In [3]: pd.eval("a = 1 + 2", target=arr, inplace=True)
...
IndexError: only integers, slices (:``), ellipsis (`,`), numpy.newaxis (None)
and integer or boolean arrays are valid indices
```

This is a very long way of saying numpy arrays don't support string-item indexing. With this change, the error message is now this:

```
In [3]: pd.eval("a = 1 + 2", target=arr, inplace=True)
...
ValueError: Cannot assign expression output to target
```

It also used to be possible to evaluate expressions inplace, even if there was no item assignment:

```
In [4]: pd.eval("1 + 2", target=arr, inplace=True)
Out[4]: 3
```

However, this input does not make much sense because the output is not being assigned to the target. Now, a `ValueError` will be raised when such an input is passed in:

```
In [4]: pd.eval("1 + 2", target=arr, inplace=True)
...
ValueError: Cannot operate inplace if there is no assignment
```

## Dtype conversions

Previously assignments, `.where()` and `.fillna()` with a bool assignment, would coerce to same the type (e.g. int / float), or raise for datetimelikes. These will now preserve the bools with `object` dtypes. (GH16821).

```
In [62]: s = pd.Series([1, 2, 3])
```

```
In [5]: s[1] = True

In [6]: s
Out[6]:
0    1
1    1
2    3
dtype: int64
```

New behavior

```
In [63]: s[1] = True

In [64]: s
Out[64]:
0    1
1   True
2    3
Length: 3, dtype: object
```

Previously, as assignment to a datetimelike with a non-datetimelike would coerce the non-datetime-like item being assigned (GH14145).

```
In [65]: s = pd.Series([pd.Timestamp('2011-01-01'), pd.Timestamp('2012-01-01')])
```

```
In [1]: s[1] = 1

In [2]: s
Out[2]:
```

(continues on next page)

(continued from previous page)

```
0    2011-01-01 00:00:00.000000000
1    1970-01-01 00:00:00.000000001
dtype: datetime64[ns]
```

These now coerce to object dtype.

```
In [66]: s[1] = 1

In [67]: s
Out [67]:
0    2011-01-01 00:00:00
1                               1
Length: 2, dtype: object
```

- Inconsistent behavior in `.where()` with datetimelikes which would raise rather than coerce to object (GH16402)
- Bug in assignment against `int64` data with `np.ndarray` with `float64` dtype may keep `int64` dtype (GH14001)

### MultiIndex constructor with a single level

The `MultiIndex` constructors no longer squeezes a `MultiIndex` with all length-one levels down to a regular `Index`. This affects all the `MultiIndex` constructors. (GH17178)

Previous behavior:

```
In [2]: pd.MultiIndex.from_tuples([('a',), ('b',)])
Out [2]: Index(['a', 'b'], dtype='object')
```

Length 1 levels are no longer special-cased. They behave exactly as if you had length 2+ levels, so a `MultiIndex` is always returned from all of the `MultiIndex` constructors:

```
In [68]: pd.MultiIndex.from_tuples([('a',), ('b',)])
Out [68]:
MultiIndex([('a',),
            ('b',)],
           )
```

### UTC Localization with Series

Previously, `to_datetime()` did not localize datetime Series data when `utc=True` was passed. Now, `to_datetime()` will correctly localize Series with a `datetime64[ns, UTC]` dtype to be consistent with how list-like and `Index` data are handled. (GH6415).

Previous behavior

```
In [69]: s = pd.Series(['20130101 00:00:00'] * 3)
```

```
In [12]: pd.to_datetime(s, utc=True)
Out [12]:
0    2013-01-01
1    2013-01-01
```

(continues on next page)

(continued from previous page)

```
2    2013-01-01
dtype: datetime64[ns]
```

**New behavior**

```
In [70]: pd.to_datetime(s, utc=True)
Out [70]:
0    2013-01-01 00:00:00+00:00
1    2013-01-01 00:00:00+00:00
2    2013-01-01 00:00:00+00:00
Length: 3, dtype: datetime64[ns, UTC]
```

Additionally, DataFrames with datetime columns that were parsed by `read_sql_table()` and `read_sql_query()` will also be localized to UTC only if the original SQL columns were timezone aware datetime columns.

**Consistency of range functions**

In previous versions, there were some inconsistencies between the various range functions: `date_range()`, `bdate_range()`, `period_range()`, `timedelta_range()`, and `interval_range()`. (GH17471).

One of the inconsistent behaviors occurred when the `start`, `end` and `period` parameters were all specified, potentially leading to ambiguous ranges. When all three parameters were passed, `interval_range` ignored the `period` parameter, `period_range` ignored the `end` parameter, and the other range functions raised. To promote consistency among the range functions, and avoid potentially ambiguous ranges, `interval_range` and `period_range` will now raise when all three parameters are passed.

**Previous behavior:**

```
In [2]: pd.interval_range(start=0, end=4, periods=6)
Out [2]:
IntervalIndex([(0, 1], (1, 2], (2, 3]])
             closed='right',
             dtype='interval[int64]')

In [3]: pd.period_range(start='2017Q1', end='2017Q4', periods=6, freq='Q')
Out [3]: PeriodIndex(['2017Q1', '2017Q2', '2017Q3', '2017Q4', '2018Q1', '2018Q2'],
                    dtype='period[Q-DEC]', freq='Q-DEC')
```

**New behavior:**

```
In [2]: pd.interval_range(start=0, end=4, periods=6)
-----
ValueError: Of the three parameters: start, end, and periods, exactly two must be
specified

In [3]: pd.period_range(start='2017Q1', end='2017Q4', periods=6, freq='Q')
-----
ValueError: Of the three parameters: start, end, and periods, exactly two must be
specified
```

Additionally, the endpoint parameter `end` was not included in the intervals produced by `interval_range`. However, all other range functions include `end` in their output. To promote consistency among the range functions, `interval_range` will now include `end` as the right endpoint of the final interval, except if `freq` is specified in a way which skips `end`.

Previous behavior:

```
In [4]: pd.interval_range(start=0, end=4)
Out [4]:
IntervalIndex([(0, 1], (1, 2], (2, 3]])
             closed='right',
             dtype='interval[int64]')
```

New behavior:

```
In [71]: pd.interval_range(start=0, end=4)
Out [71]:
IntervalIndex([(0, 1], (1, 2], (2, 3], (3, 4]],
             closed='right',
             dtype='interval[int64]')
```

### No automatic Matplotlib converters

Pandas no longer registers our date, time, datetime, datetime64, and Period converters with matplotlib when pandas is imported. Matplotlib plot methods (`plt.plot`, `ax.plot`, ...), will not nicely format the x-axis for `DatetimeIndex` or `PeriodIndex` values. You must explicitly register these methods:

Pandas built-in `Series.plot` and `DataFrame.plot` will register these converters on first-use ([GH17710](#)).

---

**Note:** This change has been temporarily reverted in pandas 0.21.1, for more details see [here](#).

---

### Other API changes

- The Categorical constructor no longer accepts a scalar for the `categories` keyword. ([GH16022](#))
- Accessing a non-existent attribute on a closed `HDFStore` will now raise an `AttributeError` rather than a `ClosedFileError` ([GH16301](#))
- `read_csv()` now issues a `UserWarning` if the `names` parameter contains duplicates ([GH17095](#))
- `read_csv()` now treats 'null' and 'n/a' strings as missing values by default ([GH16471](#), [GH16078](#))
- `pandas.HDFStore`'s string representation is now faster and less detailed. For the previous behavior, use `pandas.HDFStore.info()`. ([GH16503](#)).
- Compression defaults in HDF stores now follow pytables standards. Default is no compression and if `complib` is missing and `complevel > 0` `zlib` is used ([GH15943](#))
- `Index.get_indexer_non_unique()` now returns a `ndarray` indexer rather than an `Index`; this is consistent with `Index.get_indexer()` ([GH16819](#))
- Removed the `@slow` decorator from `pandas._testing`, which caused issues for some downstream packages' test suites. Use `@pytest.mark.slow` instead, which achieves the same thing ([GH16850](#))
- Moved definition of `MergeError` to the `pandas.errors` module.
- The signature of `Series.set_axis()` and `DataFrame.set_axis()` has been changed from `set_axis(axis, labels)` to `set_axis(labels, axis=0)`, for consistency with the rest of the API. The old signature is deprecated and will show a `FutureWarning` ([GH14636](#))
- `Series.argmax()` and `Series.argmin()` will now raise a `TypeError` when used with object dtypes, instead of a `ValueError` ([GH13595](#))

- `Period` is now immutable, and will now raise an `AttributeError` when a user tries to assign a new value to the `ordinal` or `freq` attributes (GH17116).
- `to_datetime()` when passed a tz-aware `origin=` kwarg will now raise a more informative `ValueError` rather than a `TypeError` (GH16842)
- `to_datetime()` now raises a `ValueError` when format includes `%W` or `%U` without also including day of the week and calendar year (GH16774)
- Renamed non-functional `index` to `index_col` in `read_stata()` to improve API consistency (GH16342)
- Bug in `DataFrame.drop()` caused boolean labels `False` and `True` to be treated as labels 0 and 1 respectively when dropping indices from a numeric index. This will now raise a `ValueError` (GH16877)
- Restricted `DateOffset` keyword arguments. Previously, `DateOffset` subclasses allowed arbitrary keyword arguments which could lead to unexpected behavior. Now, only valid arguments will be accepted. (GH17176).

## Deprecations

- `DataFrame.from_csv()` and `Series.from_csv()` have been deprecated in favor of `read_csv()` (GH4191)
- `read_excel()` has deprecated `sheetname` in favor of `sheet_name` for consistency with `.to_excel()` (GH10559).
- `read_excel()` has deprecated `parse_cols` in favor of `usecols` for consistency with `read_csv()` (GH4988)
- `read_csv()` has deprecated the `tupleize_cols` argument. Column tuples will always be converted to a `MultiIndex` (GH17060)
- `DataFrame.to_csv()` has deprecated the `tupleize_cols` argument. `MultiIndex` columns will be always written as rows in the CSV file (GH17060)
- The `convert` parameter has been deprecated in the `.take()` method, as it was not being respected (GH16948)
- `pd.options.html.border` has been deprecated in favor of `pd.options.display.html.border` (GH15793).
- `SeriesGroupBy.nth()` has deprecated `True` in favor of `'all'` for its kwarg `dropna` (GH11038).
- `DataFrame.as_blocks()` is deprecated, as this is exposing the internal implementation (GH17302)
- `pd.TimeGrouper` is deprecated in favor of `pandas.Grouper` (GH16747)
- `cdate_range` has been deprecated in favor of `bdate_range()`, which has gained `weekmask` and `holidays` parameters for building custom frequency date ranges. See the *documentation* for more details (GH17596)
- passing `categories` or ordered kwargs to `Series.astype()` is deprecated, in favor of passing a `CategoricalDtype` (GH17636)
- `.get_value` and `.set_value` on `Series`, `DataFrame`, `Panel`, `SparseSeries`, and `SparseDataFrame` are deprecated in favor of using `.iat[]` or `.at[]` accessors (GH15269)
- Passing a non-existent column in `.to_excel(..., columns=)` is deprecated and will raise a `KeyError` in the future (GH17295)
- `raise_on_error` parameter to `Series.where()`, `Series.mask()`, `DataFrame.where()`, `DataFrame.mask()` is deprecated, in favor of `errors=` (GH14968)

- Using `DataFrame.rename_axis()` and `Series.rename_axis()` to alter index or column *labels* is now deprecated in favor of using `.rename`. `rename_axis` may still be used to alter the name of the index or columns (GH17833).
- `reindex_axis()` has been deprecated in favor of `reindex()`. See *here* for more (GH17833).

### Series.select and DataFrame.select

The `Series.select()` and `DataFrame.select()` methods are deprecated in favor of using `df.loc[labels.map(crit)]` (GH12401)

```
In [72]: df = pd.DataFrame({'A': [1, 2, 3]}, index=['foo', 'bar', 'baz'])
```

```
In [3]: df.select(lambda x: x in ['bar', 'baz'])
```

FutureWarning: select is deprecated and will be removed in a future release. You can use `.loc[crit]` as a replacement

```
Out [3]:
```

```
      A
bar  2
baz  3
```

```
In [73]: df.loc[df.index.map(lambda x: x in ['bar', 'baz'])]
```

```
Out [73]:
```

```
      A
bar  2
baz  3
```

```
[2 rows x 1 columns]
```

### Series.argmax and Series.argmin

The behavior of `Series.argmax()` and `Series.argmin()` have been deprecated in favor of `Series.idxmax()` and `Series.idxmin()`, respectively (GH16830).

For compatibility with NumPy arrays, `pd.Series` implements `argmax` and `argmin`. Since pandas 0.13.0, `argmax` has been an alias for `pandas.Series.idxmax()`, and `argmin` has been an alias for `pandas.Series.idxmin()`. They return the *label* of the maximum or minimum, rather than the *position*.

We've deprecated the current behavior of `Series.argmax` and `Series.argmin`. Using either of these will emit a `FutureWarning`. Use `Series.idxmax()` if you want the label of the maximum. Use `Series.values.argmax()` if you want the position of the maximum. Likewise for the minimum. In a future release `Series.argmax` and `Series.argmin` will return the position of the maximum or minimum.

### Removal of prior version deprecations/changes

- `read_excel()` has dropped the `has_index_names` parameter (GH10967)
- The `pd.options.display.height` configuration has been dropped (GH3663)
- The `pd.options.display.line_width` configuration has been dropped (GH2881)
- The `pd.options.display.mpl_style` configuration has been dropped (GH12190)
- `Index` has dropped the `.sym_diff()` method in favor of `.symmetric_difference()` (GH12591)

- Categorical has dropped the `.order()` and `.sort()` methods in favor of `.sort_values()` (GH12882)
- `eval()` and `DataFrame.eval()` have changed the default of `inplace` from `None` to `False` (GH11149)
- The function `get_offset_name` has been dropped in favor of the `.freqstr` attribute for an offset (GH11834)
- pandas no longer tests for compatibility with hdf5-files created with pandas < 0.11 (GH17404).

## Performance improvements

- Improved performance of instantiating `SparseDataFrame` (GH16773)
- `Series.dt` no longer performs frequency inference, yielding a large speedup when accessing the attribute (GH17210)
- Improved performance of `set_categories()` by not materializing the values (GH17508)
- `Timestamp.microsecond` no longer re-computes on attribute access (GH17331)
- Improved performance of the `CategoricalIndex` for data that is already categorical dtype (GH17513)
- Improved performance of `RangeIndex.min()` and `RangeIndex.max()` by using `RangeIndex` properties to perform the computations (GH17607)

## Documentation changes

- Several `NaT` method docstrings (e.g. `NaT.ctime()`) were incorrect (GH17327)
- The documentation has had references to versions < v0.17 removed and cleaned up (GH17442, GH17442, GH17404 & GH17504)

## Bug fixes

### Conversion

- Bug in assignment against datetime-like data with `int` may incorrectly convert to datetime-like (GH14145)
- Bug in assignment against `int64` data with `np.ndarray` with `float64` dtype may keep `int64` dtype (GH14001)
- Fixed the return type of `IntervalIndex.is_non_overlapping_monotonic` to be a Python `bool` for consistency with similar attributes/methods. Previously returned a `numpy.bool_`. (GH17237)
- Bug in `IntervalIndex.is_non_overlapping_monotonic` when intervals are closed on both sides and overlap at a point (GH16560)
- Bug in `Series.fillna()` returns frame when `inplace=True` and `value` is dict (GH16156)
- Bug in `Timestamp.weekday_name` returning a UTC-based weekday name when localized to a timezone (GH17354)
- Bug in `Timestamp.replace` when replacing `tzinfo` around DST changes (GH15683)
- Bug in `Timedelta` construction and arithmetic that would not propagate the `Overflow` exception (GH17367)
- Bug in `astype()` converting to object dtype when passed extension type classes (`DatetimeTZDtype`, `CategoricalDtype`) rather than instances. Now a `TypeError` is raised when a class is passed (GH17780).

- Bug in `to_numeric()` in which elements were not always being coerced to numeric when `errors='coerce'` (GH17007, GH17125)
- Bug in `DataFrame` and `Series` constructors where range objects are converted to `int32` dtype on Windows instead of `int64` (GH16804)

## Indexing

- When called with a null slice (e.g. `df.iloc[:]`), the `.iloc` and `.loc` indexers return a shallow copy of the original object. Previously they returned the original object. (GH13873).
- When called on an unsorted `MultiIndex`, the `loc` indexer now will raise `UnsortedIndexError` only if proper slicing is used on non-sorted levels (GH16734).
- Fixes regression in 0.20.3 when indexing with a string on a `TimedeltaIndex` (GH16896).
- Fixed `TimedeltaIndex.get_loc()` handling of `np.timedelta64` inputs (GH16909).
- Fix `MultiIndex.sort_index()` ordering when ascending argument is a list, but not all levels are specified, or are in a different order (GH16934).
- Fixes bug where indexing with `np.inf` caused an `OverflowError` to be raised (GH16957)
- Bug in reindexing on an empty `CategoricalIndex` (GH16770)
- Fixes `DataFrame.loc` for setting with alignment and tz-aware `DatetimeIndex` (GH16889)
- Avoids `IndexError` when passing an `Index` or `Series` to `.iloc` with older numpy (GH17193)
- Allow unicode empty strings as placeholders in multilevel columns in Python 2 (GH17099)
- Bug in `.iloc` when used with inplace addition or assignment and an int indexer on a `MultiIndex` causing the wrong indexes to be read from and written to (GH17148)
- Bug in `.isin()` in which checking membership in empty `Series` objects raised an error (GH16991)
- Bug in `CategoricalIndex` reindexing in which specified indices containing duplicates were not being respected (GH17323)
- Bug in intersection of `RangeIndex` with negative step (GH17296)
- Bug in `IntervalIndex` where performing a scalar lookup fails for included right endpoints of non-overlapping monotonic decreasing indexes (GH16417, GH17271)
- Bug in `DataFrame.first_valid_index()` and `DataFrame.last_valid_index()` when no valid entry (GH17400)
- Bug in `Series.rename()` when called with a callable, incorrectly alters the name of the `Series`, rather than the name of the `Index`. (GH17407)
- Bug in `String.str_get()` raises `IndexError` instead of inserting NaNs when using a negative index. (GH17704)

## I/O

- Bug in `read_hdf()` when reading a timezone aware index from `fixed` format `HDFStore` (GH17618)
- Bug in `read_csv()` in which columns were not being thoroughly de-duplicated (GH17060)
- Bug in `read_csv()` in which specified column names were not being thoroughly de-duplicated (GH17095)
- Bug in `read_csv()` in which non integer values for the header argument generated an unhelpful / unrelated error message (GH16338)
- Bug in `read_csv()` in which memory management issues in exception handling, under certain conditions, would cause the interpreter to segfault (GH14696, GH16798).
- Bug in `read_csv()` when called with `low_memory=False` in which a CSV with at least one column > 2GB in size would incorrectly raise a `MemoryError` (GH16798).
- Bug in `read_csv()` when called with a single-element list `header` would return a `DataFrame` of all NaN values (GH7757)
- Bug in `DataFrame.to_csv()` defaulting to 'ascii' encoding in Python 3, instead of 'utf-8' (GH17097)
- Bug in `read_stata()` where value labels could not be read when using an iterator (GH16923)
- Bug in `read_stata()` where the index was not set (GH16342)
- Bug in `read_html()` where import check fails when run in multiple threads (GH16928)
- Bug in `read_csv()` where automatic delimiter detection caused a `TypeError` to be thrown when a bad line was encountered rather than the correct error message (GH13374)
- Bug in `DataFrame.to_html()` with `notebook=True` where `DataFrames` with named indices or non-`MultiIndex` indices had undesired horizontal or vertical alignment for column or row labels, respectively (GH16792)
- Bug in `DataFrame.to_html()` in which there was no validation of the `justify` parameter (GH17527)
- Bug in `HDFStore.select()` when reading a contiguous mixed-data table featuring `VLAarray` (GH17021)
- Bug in `to_json()` where several conditions (including objects with unprintable symbols, objects with deep recursion, overlong labels) caused segfaults instead of raising the appropriate exception (GH14256)

## Plotting

- Bug in plotting methods using `secondary_y` and `fontsize` not setting secondary axis font size (GH12565)
- Bug when plotting `timedelta` and `datetime` dtypes on y-axis (GH16953)
- Line plots no longer assume monotonic x data when calculating `xlims`, they show the entire lines now even for unsorted x data. (GH11310, GH11471)
- With `matplotlib` 2.0.0 and above, calculation of x limits for line plots is left to `matplotlib`, so that its new default settings are applied. (GH15495)
- Bug in `Series.plot.bar` or `DataFrame.plot.bar` with `y` not respecting user-passed `color` (GH16822)
- Bug causing `plotting.parallel_coordinates` to reset the random seed when using random colors (GH17525)

## Groupby/resample/rolling

- Bug in `DataFrame.resample(...).size()` where an empty `DataFrame` did not return a `Series` (GH14962)
- Bug in `infer_freq()` causing indices with 2-day gaps during the working week to be wrongly inferred as business daily (GH16624)
- Bug in `.rolling(...).quantile()` which incorrectly used different defaults than `Series.quantile()` and `DataFrame.quantile()` (GH9413, GH16211)
- Bug in `groupby.transform()` that would coerce boolean dtypes back to float (GH16875)
- Bug in `Series.resample(...).apply()` where an empty `Series` modified the source index and did not return the name of a `Series` (GH14313)
- Bug in `.rolling(...).apply(...)` with a `DataFrame` with a `DatetimeIndex`, a window of a `timedelta`-convertible and `min_periods >= 1` (GH15305)
- Bug in `DataFrame.groupby` where index and column keys were not recognized correctly when the number of keys equaled the number of elements on the groupby axis (GH16859)
- Bug in `groupby.nunique()` with `TimeGrouper` which cannot handle `NaT` correctly (GH17575)
- Bug in `DataFrame.groupby` where a single level selection from a `MultiIndex` unexpectedly sorts (GH17537)
- Bug in `DataFrame.groupby` where spurious warning is raised when `Grouper` object is used to override ambiguous column name (GH17383)
- Bug in `TimeGrouper` differs when passes as a list and as a scalar (GH17530)

## Sparse

- Bug in `SparseSeries` raises `AttributeError` when a dictionary is passed in as data (GH16905)
- Bug in `SparseDataFrame.fillna()` not filling all `NaNs` when frame was instantiated from SciPy sparse matrix (GH16112)
- Bug in `SparseSeries.unstack()` and `SparseDataFrame.stack()` (GH16614, GH15045)
- Bug in `make_sparse()` treating two numeric/boolean data, which have same bits, as same when array dtype is object (GH17574)
- `SparseArray.all()` and `SparseArray.any()` are now implemented to handle `SparseArray`, these were used but not implemented (GH17570)

## Reshaping

- Joining/Merging with a non unique `PeriodIndex` raised a `TypeError` (GH16871)
- Bug in `crosstab()` where non-aligned series of integers were casted to float (GH17005)
- Bug in merging with categorical dtypes with `datetimelikes` incorrectly raised a `TypeError` (GH16900)
- Bug when using `isin()` on a large object series and large comparison array (GH16012)
- Fixes regression from 0.20, `Series.aggregate()` and `DataFrame.aggregate()` allow dictionaries as return values again (GH16741)

- Fixes dtype of result with integer dtype input, from `pivot_table()` when called with `margins=True` (GH17013)
- Bug in `crosstab()` where passing two Series with the same name raised a `KeyError` (GH13279)
- `Series.argmax()`, `Series.argmin()`, and their counterparts on `DataFrame` and `groupby` objects work correctly with floating point data that contains infinite values (GH13595).
- Bug in `unique()` where checking a tuple of strings raised a `TypeError` (GH17108)
- Bug in `concat()` where order of result index was unpredictable if it contained non-comparable elements (GH17344)
- Fixes regression when sorting by multiple columns on a `datetime64` dtype Series with `NaT` values (GH16836)
- Bug in `pivot_table()` where the result's columns did not preserve the categorical dtype of columns when `dropna` was `False` (GH17842)
- Bug in `DataFrame.drop_duplicates` where dropping with non-unique column names raised a `ValueError` (GH17836)
- Bug in `unstack()` which, when called on a list of levels, would discard the `fillna` argument (GH13971)
- Bug in the alignment of `range` objects and other list-likes with `DataFrame` leading to operations being performed row-wise instead of column-wise (GH17901)

## Numeric

- Bug in `.clip()` with `axis=1` and a list-like for `threshold` is passed; previously this raised `ValueError` (GH15390)
- `Series.clip()` and `DataFrame.clip()` now treat NA values for upper and lower arguments as `None` instead of raising `ValueError` (GH17276).

## Categorical

- Bug in `Series.isin()` when called with a categorical (GH16639)
- Bug in the categorical constructor with empty values and categories causing the `.categories` to be an empty `Float64Index` rather than an empty `Index` with object dtype (GH17248)
- Bug in categorical operations with `Series.cat` not preserving the original Series' name (GH17509)
- Bug in `DataFrame.merge()` failing for categorical columns with boolean/int data types (GH17187)
- Bug in constructing a `Categorical/CategoricalDtype` when the specified categories are of categorical type (GH17884).

## PyPy

- Compatibility with PyPy in `read_csv()` with `usecols=[<unsorted ints>]` and `read_json()` (GH17351)
- Split tests into cases for CPython and PyPy where needed, which highlights the fragility of index matching with `float('nan')`, `np.nan` and `NAT` (GH17351)
- Fix `DataFrame.memory_usage()` to support PyPy. Objects on PyPy do not have a fixed size, so an approximation is used instead (GH17228)

## Other

- Bug where some inplace operators were not being wrapped and produced a copy when invoked (GH12962)
- Bug in `eval()` where the `inplace` parameter was being incorrectly handled (GH16732)

## Contributors

A total of 206 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

## 6.7 Version 0.20

### 6.7.1 v0.20.3 (July 7, 2017)

{{ header }}

This is a minor bug-fix release in the 0.20.x series and includes some small regression fixes and bug fixes. We recommend that all users upgrade to this version.

#### What's new in v0.20.3

- *Bug fixes*
  - *Conversion*
  - *Indexing*
  - *I/O*
  - *Plotting*
  - *Reshaping*
  - *Categorical*
- *Contributors*

#### Bug fixes

- Fixed a bug in failing to compute rolling computations of a column-MultiIndexed DataFrame ([GH16789](#), [GH16825](#))
- Fixed a pytest marker failing downstream packages' tests suites ([GH16680](#))

#### Conversion

- Bug in pickle compat prior to the v0.20.x series, when UTC is a timezone in a Series/DataFrame/Index ([GH16608](#))
- Bug in Series construction when passing a Series with dtype='category' ([GH16524](#)).
- Bug in DataFrame.astype() when passing a Series as the dtype kwarg. ([GH16717](#)).

## Indexing

- Bug in `Float64Index` causing an empty array instead of `None` to be returned from `.get(np.nan)` on a `Series` whose index did not contain any `NaN`s ([GH8569](#))
- Bug in `MultiIndex.isin` causing an error when passing an empty iterable ([GH16777](#))
- Fixed a bug in a slicing `DataFrame/Series` that have a `TimedeltaIndex` ([GH16637](#))

## I/O

- Bug in `read_csv()` in which files weren't opened as binary files by the C engine on Windows, causing EOF characters mid-field, which would fail ([GH16039](#), [GH16559](#), [GH16675](#))
- Bug in `read_hdf()` in which reading a `Series` saved to an HDF file in 'fixed' format fails when an explicit `mode='r'` argument is supplied ([GH16583](#))
- Bug in `DataFrame.to_latex()` where `bold_rows` was wrongly specified to be `True` by default, whereas in reality row labels remained non-bold whatever parameter provided. ([GH16707](#))
- Fixed an issue with `DataFrame.style()` where generated element ids were not unique ([GH16780](#))
- Fixed loading a `DataFrame` with a `PeriodIndex`, from a `format='fixed'` `HDFStore`, in Python 3, that was written in Python 2 ([GH16781](#))

## Plotting

- Fixed regression that prevented `RGB` and `RGBA` tuples from being used as color arguments ([GH16233](#))
- Fixed an issue with `DataFrame.plot.scatter()` that incorrectly raised a `KeyError` when categorical data is used for plotting ([GH16199](#))

## Reshaping

- `PeriodIndex/TimedeltaIndex.join` was missing the `sort=` kwarg ([GH16541](#))
- Bug in joining on a `MultiIndex` with a `category` dtype for a level ([GH16627](#)).
- Bug in `merge()` when merging/joining with multiple categorical columns ([GH16767](#))

## Categorical

- Bug in `DataFrame.sort_values` not respecting the `kind` parameter with categorical data ([GH16793](#))

## Contributors

A total of 20 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

### 6.7.2 v0.20.2 (June 4, 2017)

{{ header }}

This is a minor bug-fix release in the 0.20.x series and includes some small regression fixes, bug fixes and performance improvements. We recommend that all users upgrade to this version.

#### **What's new in v0.20.2**

- *Enhancements*
- *Performance improvements*
- *Bug fixes*
  - *Conversion*
  - *Indexing*
  - *I/O*

- *Plotting*
- *Groupby/resample/rolling*
- *Sparse*
- *Reshaping*
- *Numeric*
- *Categorical*
- *Other*
- *Contributors*

## Enhancements

- Unblocked access to additional compression types supported in pytables: ‘blosc:blosclz’, ‘blosc:lz4’, ‘blosc:lz4hc’, ‘blosc:snappy’, ‘blosc:zlib’, ‘blosc:zstd’ (GH14478)
- Series provides a `to_latex` method (GH16180)
- A new groupby method `ngroup()`, parallel to the existing `cumcount()`, has been added to return the group order (GH11642); see *here*.

## Performance improvements

- Performance regression fix when indexing with a list-like (GH16285)
- Performance regression fix for MultiIndexes (GH16319, GH16346)
- Improved performance of `.clip()` with scalar arguments (GH15400)
- Improved performance of groupby with categorical groupers (GH16413)
- Improved performance of `MultiIndex.remove_unused_levels()` (GH16556)

## Bug fixes

- Silenced a warning on some Windows environments about “tput: terminal attributes: No such device or address” when detecting the terminal size. This fix only applies to python 3 (GH16496)
- Bug in using `pathlib.Path` or `py.path.local` objects with io functions (GH16291)
- Bug in `Index.symmetric_difference()` on two equal MultiIndex’s, results in a `TypeError` (GH13490)
- Bug in `DataFrame.update()` with `overwrite=False` and NaN values (GH15593)
- Passing an invalid engine to `read_csv()` now raises an informative `ValueError` rather than `UnboundLocalError`. (GH16511)
- Bug in `unique()` on an array of tuples (GH16519)
- Bug in `cut()` when labels are set, resulting in incorrect label ordering (GH16459)
- Fixed a compatibility issue with IPython 6.0’s tab completion showing deprecation warnings on Categoricals (GH16409)

## Conversion

- Bug in `to_numeric()` in which empty data inputs were causing a segfault of the interpreter (GH16302)
- Silence numpy warnings when broadcasting DataFrame to Series with comparison ops (GH16378, GH16306)

## Indexing

- Bug in `DataFrame.reset_index(level=)` with single level index (GH16263)
- Bug in partial string indexing with a monotonic, but not strictly-monotonic, index incorrectly reversing the slice bounds (GH16515)
- Bug in `MultiIndex.remove_unused_levels()` that would not return a MultiIndex equal to the original. (GH16556)

## I/O

- Bug in `read_csv()` when `comment` is passed in a space delimited text file (GH16472)
- Bug in `read_csv()` not raising an exception with nonexistent columns in `usecols` when it had the correct length (GH14671)
- Bug that would force importing of the clipboard routines unnecessarily, potentially causing an import error on startup (GH16288)
- Bug that raised `IndexError` when HTML-rendering an empty DataFrame (GH15953)
- Bug in `read_csv()` in which tarfile object inputs were raising an error in Python 2.x for the C engine (GH16530)
- Bug where `DataFrame.to_html()` ignored the `index_names` parameter (GH16493)
- Bug where `pd.read_hdf()` returns numpy strings for index names (GH13492)
- Bug in `HDFStore.select_as_multiple()` where start/stop arguments were not respected (GH16209)

## Plotting

- Bug in `DataFrame.plot` with a single column and a list-like `color` (GH3486)
- Bug in plot where `NaT` in `DatetimeIndex` results in `Timestamp.min` (GH12405)
- Bug in `DataFrame.boxplot` where `figsize` keyword was not respected for non-grouped boxplots (GH11959)

## Groupby/resample/rolling

- Bug in creating a time-based rolling window on an empty DataFrame (GH15819)
- Bug in `rolling.cov()` with offset window (GH16058)
- Bug in `.resample()` and `.groupby()` when aggregating on integers (GH16361)

## Sparse

- Bug in construction of `SparseDataFrame` from `scipy.sparse.dok_matrix` (GH16179)

## Reshaping

- Bug in `DataFrame.stack` with unsorted levels in `MultiIndex` columns (GH16323)
- Bug in `pd.wide_to_long()` where no error was raised when `i` was not a unique identifier (GH16382)
- Bug in `Series.isin(..)` with a list of tuples (GH16394)
- Bug in construction of a `DataFrame` with mixed dtypes including an all-`NaT` column. (GH16395)
- Bug in `DataFrame.agg()` and `Series.agg()` with aggregating on non-callable attributes (GH16405)

## Numeric

- Bug in `.interpolate()`, where `limit_direction` was not respected when `limit=None` (default) was passed (GH16282)

## Categorical

- Fixed comparison operations considering the order of the categories when both categoricals are unordered (GH16014)

## Other

- Bug in `DataFrame.drop()` with an empty-list with non-unique indices (GH16270)

## Contributors

A total of 34 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

### **6.7.3 v0.20.1 (May 5, 2017)**

{{ header }}

This is a major release from 0.19.2 and includes a number of API changes, deprecations, new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

- New `.agg()` API for Series/DataFrame similar to the groupby-rolling-resample API's, see *here*

- Integration with the feather-format, including a new top-level `pd.read_feather()` and `DataFrame.to_feather()` method, see [here](#).
- The `.ix` indexer has been deprecated, see [here](#)
- Panel has been deprecated, see [here](#)
- Addition of an `IntervalIndex` and `Interval` scalar type, see [here](#)
- Improved user API when grouping by index levels in `.groupby()`, see [here](#)
- Improved support for `UInt64` dtypes, see [here](#)
- A new orient for JSON serialization, `orient='table'`, that uses the Table Schema spec and that gives the possibility for a more interactive repr in the Jupyter Notebook, see [here](#)
- Experimental support for exporting styled DataFrames (`DataFrame.style`) to Excel, see [here](#)
- Window binary corr/cov operations now return a `MultiIndexed DataFrame` rather than a `Panel`, as `Panel` is now deprecated, see [here](#)
- Support for S3 handling now uses `s3fs`, see [here](#)
- Google BigQuery support now uses the `pandas-gbq` library, see [here](#)

**Warning:** Pandas has changed the internal structure and layout of the code base. This can affect imports that are not from the top-level `pandas.*` namespace, please see the changes [here](#).

Check the *API Changes* and *deprecations* before updating.

**Note:** This is a combined release for 0.20.0 and 0.20.1. Version 0.20.1 contains one additional change for backwards-compatibility with downstream projects using pandas' `utils` routines. ([GH16250](#))

### What's new in v0.20.0

- *New features*
  - *agg API for DataFrame/Series*
  - *dtype keyword for data IO*
  - *.to\_datetime() has gained an origin parameter*
  - *Groupby enhancements*
  - *Better support for compressed URLs in read\_csv*
  - *Pickle file I/O now supports compression*
  - *UInt64 support improved*
  - *GroupBy on categoricals*
  - *Table schema output*
  - *SciPy sparse matrix from/to SparseDataFrame*
  - *Excel output for styled DataFrames*
  - *IntervalIndex*

- *Other enhancements*
- *Backwards incompatible API changes*
  - *Possible incompatibility for HDF5 formats created with pandas < 0.13.0*
  - *Map on Index types now return other Index types*
  - *Accessing datetime fields of Index now return Index*
  - *pd.unique will now be consistent with extension types*
  - *S3 file handling*
  - *Partial string indexing changes*
  - *Concat of different float dtypes will not automatically upcast*
  - *Pandas Google BigQuery support has moved*
  - *Memory usage for Index is more accurate*
  - *DataFrame.sort\_index changes*
  - *Groupby describe formatting*
  - *Window binary corr/cov operations return a MultiIndex DataFrame*
  - *HDFStore where string comparison*
  - *Index.intersection and inner join now preserve the order of the left Index*
  - *Pivot table always returns a DataFrame*
  - *Other API changes*
- *Reorganization of the library: privacy changes*
  - *Modules privacy has changed*
  - *pandas.errors*
  - *pandas.testing*
  - *pandas.plotting*
  - *Other Development Changes*
- *Deprecations*
  - *Deprecate .ix*
  - *Deprecate Panel*
  - *Deprecate groupby.agg() with a dictionary when renaming*
  - *Deprecate .plotting*
  - *Other deprecations*
- *Removal of prior version deprecations/changes*
- *Performance improvements*
- *Bug fixes*
  - *Conversion*
  - *Indexing*

- *I/O*
- *Plotting*
- *Groupby/resample/rolling*
- *Sparse*
- *Reshaping*
- *Numeric*
- *Other*
- *Contributors*

## New features

### agg API for DataFrame/Series

Series & DataFrame have been enhanced to support the aggregation API. This is a familiar API from groupby, window operations, and resampling. This allows aggregation operations in a concise way by using `agg()` and `transform()`. The full documentation is [here \(GH1623\)](#).

Here is a sample

```
In [1]: df = pd.DataFrame(np.random.randn(10, 3), columns=['A', 'B', 'C'],
...:                      index=pd.date_range('1/1/2000', periods=10))
...:

In [2]: df.iloc[3:7] = np.nan

In [3]: df
Out [3]:
```

|            | A         | B         | C         |
|------------|-----------|-----------|-----------|
| 2000-01-01 | -1.392054 | 1.153922  | 1.181944  |
| 2000-01-02 | 0.391371  | -0.881047 | 0.295080  |
| 2000-01-03 | 1.863801  | -1.712274 | -1.407085 |
| 2000-01-04 | NaN       | NaN       | NaN       |
| 2000-01-05 | NaN       | NaN       | NaN       |
| 2000-01-06 | NaN       | NaN       | NaN       |
| 2000-01-07 | NaN       | NaN       | NaN       |
| 2000-01-08 | 1.076541  | 0.363177  | 1.893680  |
| 2000-01-09 | -0.485753 | 0.387674  | 0.023558  |
| 2000-01-10 | -0.660230 | -0.318685 | -0.722662 |

```
[10 rows x 3 columns]
```

One can operate using string function names, callables, lists, or dictionaries of these.

Using a single function is equivalent to `.apply`.

```
In [4]: df.agg('sum')
Out [4]:
```

|   |           |
|---|-----------|
| A | 0.793677  |
| B | -1.007232 |
| C | 1.264515  |

```
Length: 3, dtype: float64
```

Multiple aggregations with a list of functions.

```
In [5]: df.agg(['sum', 'min'])
Out [5]:
```

|     | A         | B         | C         |
|-----|-----------|-----------|-----------|
| sum | 0.793677  | -1.007232 | 1.264515  |
| min | -1.392054 | -1.712274 | -1.407085 |

```
[2 rows x 3 columns]
```

Using a dict provides the ability to apply specific aggregations per column. You will get a matrix-like output of all of the aggregators. The output has one column per unique function. Those functions applied to a particular column will be NaN:

```
In [6]: df.agg({'A': ['sum', 'min'], 'B': ['min', 'max']})
Out [6]:
```

|     | A         | B         |
|-----|-----------|-----------|
| max | NaN       | 1.153922  |
| min | -1.392054 | -1.712274 |
| sum | 0.793677  | NaN       |

```
[3 rows x 2 columns]
```

The API also supports a `.transform()` function for broadcasting results.

```
In [7]: df.transform(['abs', lambda x: x - x.min()])
Out [7]:
```

|            | A        |          | B        |          | C        |          |
|------------|----------|----------|----------|----------|----------|----------|
|            | abs      | <lambda> | abs      | <lambda> | abs      | <lambda> |
| 2000-01-01 | 1.392054 | 0.000000 | 1.153922 | 2.866196 | 1.181944 | 2.589029 |
| 2000-01-02 | 0.391371 | 1.783426 | 0.881047 | 0.831227 | 0.295080 | 1.702165 |
| 2000-01-03 | 1.863801 | 3.255855 | 1.712274 | 0.000000 | 1.407085 | 0.000000 |
| 2000-01-04 | NaN      | NaN      | NaN      | NaN      | NaN      | NaN      |
| 2000-01-05 | NaN      | NaN      | NaN      | NaN      | NaN      | NaN      |
| 2000-01-06 | NaN      | NaN      | NaN      | NaN      | NaN      | NaN      |
| 2000-01-07 | NaN      | NaN      | NaN      | NaN      | NaN      | NaN      |
| 2000-01-08 | 1.076541 | 2.468595 | 0.363177 | 2.075451 | 1.893680 | 3.300764 |
| 2000-01-09 | 0.485753 | 0.906301 | 0.387674 | 2.099948 | 0.023558 | 1.430642 |
| 2000-01-10 | 0.660230 | 0.731825 | 0.318685 | 1.393589 | 0.722662 | 0.684422 |

```
[10 rows x 6 columns]
```

When presented with mixed dtypes that cannot be aggregated, `.agg()` will only take the valid aggregations. This is similar to how `groupby .agg()` works. (GH15015)

```
In [8]: df = pd.DataFrame({'A': [1, 2, 3],
...:                      'B': [1., 2., 3.],
...:                      'C': ['foo', 'bar', 'baz'],
...:                      'D': pd.date_range('20130101', periods=3)})
...:

In [9]: df.dtypes
Out [9]:
```

|   |                |
|---|----------------|
| A | int64          |
| B | float64        |
| C | object         |
| D | datetime64[ns] |

```
Length: 4, dtype: object
```

```
In [10]: df.agg(['min', 'sum'])
Out[10]:
```

|     | A | B   | C         | D          |
|-----|---|-----|-----------|------------|
| min | 1 | 1.0 | bar       | 2013-01-01 |
| sum | 6 | 6.0 | foobarbaz | NaT        |

```
[2 rows x 4 columns]
```

### dtype keyword for data IO

The 'python' engine for `read_csv()`, as well as the `read_fwf()` function for parsing fixed-width text files and `read_excel()` for parsing Excel files, now accept the `dtype` keyword argument for specifying the types of specific columns ([GH14295](#)). See the *io docs* for more information.

```
In [11]: data = "a b\n1 2\n3 4"

In [12]: pd.read_fwf(StringIO(data)).dtypes
Out[12]:
a    int64
b    int64
Length: 2, dtype: object

In [13]: pd.read_fwf(StringIO(data), dtype={'a': 'float64', 'b': 'object'}).dtypes
Out[13]:
a    float64
b     object
Length: 2, dtype: object
```

### .to\_datetime() has gained an origin parameter

`to_datetime()` has gained a new parameter, `origin`, to define a reference date from where to compute the resulting timestamps when parsing numerical values with a specific unit specified. ([GH11276](#), [GH11745](#))

For example, with 1960-01-01 as the starting date:

```
In [14]: pd.to_datetime([1, 2, 3], unit='D', origin=pd.Timestamp('1960-01-01'))
Out[14]: DatetimeIndex(['1960-01-02', '1960-01-03', '1960-01-04'], dtype=
↳ 'datetime64[ns]', freq=None)
```

The default is set at `origin='unix'`, which defaults to 1970-01-01 00:00:00, which is commonly called 'unix epoch' or POSIX time. This was the previous default, so this is a backward compatible change.

```
In [15]: pd.to_datetime([1, 2, 3], unit='D')
Out[15]: DatetimeIndex(['1970-01-02', '1970-01-03', '1970-01-04'], dtype=
↳ 'datetime64[ns]', freq=None)
```

## Groupby enhancements

Strings passed to `DataFrame.groupby()` as the `by` parameter may now reference either column names or index level names. Previously, only column names could be referenced. This allows to easily group by a column and index level at the same time. (GH5677)

```
In [16]: arrays = [['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'],
.....:             ['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two']]
.....:

In [17]: index = pd.MultiIndex.from_arrays(arrays, names=['first', 'second'])

In [18]: df = pd.DataFrame({'A': [1, 1, 1, 1, 2, 2, 3, 3],
.....:                      'B': np.arange(8)},
.....:                      index=index)
.....:

In [19]: df
Out [19]:
```

|       |        | A | B |
|-------|--------|---|---|
| first | second |   |   |
| bar   | one    | 1 | 0 |
|       | two    | 1 | 1 |
| baz   | one    | 1 | 2 |
|       | two    | 1 | 3 |
| foo   | one    | 2 | 4 |
|       | two    | 2 | 5 |
| qux   | one    | 3 | 6 |
|       | two    | 3 | 7 |

```
[8 rows x 2 columns]

In [20]: df.groupby(['second', 'A']).sum()
Out [20]:
```

|        |   | B |
|--------|---|---|
| second | A |   |
| one    | 1 | 2 |
|        | 2 | 4 |
|        | 3 | 6 |
| two    | 1 | 4 |
|        | 2 | 5 |
|        | 3 | 7 |

```
[6 rows x 1 columns]
```

## Better support for compressed URLs in `read_csv`

The compression code was refactored (GH12688). As a result, reading dataframes from URLs in `read_csv()` or `read_table()` now supports additional compression methods: `xz`, `bz2`, and `zip` (GH14570). Previously, only `gzip` compression was supported. By default, compression of URLs and paths are now inferred using their file extensions. Additionally, support for `bz2` compression in the python 2 C-engine improved (GH14874).

```
In [21]: url = ('https://github.com/{repo}/raw/{branch}/{path}'
.....:           .format(repo='pandas-dev/pandas',
.....:                   branch='master',
```

(continues on next page)

(continued from previous page)

```

.....:         path='pandas/tests/io/parser/data/salaries.csv.bz2'))
.....:
# default, infer compression
In [22]: df = pd.read_csv(url, sep='\t', compression='infer')

# explicitly specify compression
In [23]: df = pd.read_csv(url, sep='\t', compression='bz2')

In [24]: df.head(2)
Out[24]:
      S  X  E  M
0  13876  1  1  1
1  11608  1  3  0

[2 rows x 4 columns]

```

### Pickle file I/O now supports compression

`read_pickle()`, `DataFrame.to_pickle()` and `Series.to_pickle()` can now read from and write to compressed pickle files. Compression methods can be an explicit parameter or be inferred from the file extension. See [the docs here](#).

```

In [25]: df = pd.DataFrame({'A': np.random.randn(1000),
.....:                      'B': 'foo',
.....:                      'C': pd.date_range('20130101', periods=1000, freq='s')})
.....:

```

Using an explicit compression type

```

In [26]: df.to_pickle("data.pkl.compress", compression="gzip")

In [27]: rt = pd.read_pickle("data.pkl.compress", compression="gzip")

In [28]: rt.head()
Out[28]:
      A      B      C
0  0.177387  foo  2013-01-01 00:00:00
1  0.983513  foo  2013-01-01 00:00:01

[5 rows x 3 columns]

In [32]: df["A"].to_pickle("s1.pkl.bz2")

In [33]: rt = pd.read_pickle("s1.pkl.bz2")

In [34]: rt.head()
Out[34]:
0    0.177387
1    0.983513
2    0.023505
3    0.553777
4    0.353769
Name: A, Length: 5, dtype: float64
```

### UInt64 support improved

Pandas has significantly improved support for operations involving unsigned, or purely non-negative, integers. Previously, handling these integers would result in improper rounding or data-type casting, leading to incorrect results. Notably, a new numerical index, `UInt64Index`, has been created ([GH14937](#))

```
In [35]: idx = pd.UInt64Index([1, 2, 3])

In [36]: df = pd.DataFrame({'A': ['a', 'b', 'c']}, index=idx)

In [37]: df.index
Out[37]: UInt64Index([1, 2, 3], dtype='uint64')
```

- Bug in converting object elements of array-like objects to unsigned 64-bit integers ([GH4471](#), [GH14982](#))
- Bug in `Series.unique()` in which unsigned 64-bit integers were causing overflow ([GH14721](#))
- Bug in `DataFrame` construction in which unsigned 64-bit integer elements were being converted to objects ([GH14881](#))
- Bug in `pd.read_csv()` in which unsigned 64-bit integer elements were being improperly converted to the wrong data types ([GH14983](#))
- Bug in `pd.unique()` in which unsigned 64-bit integers were causing overflow ([GH14915](#))
- Bug in `pd.value_counts()` in which unsigned 64-bit integers were being erroneously truncated in the output ([GH14934](#))

## GroupBy on categoricals

In previous versions, `.groupby(..., sort=False)` would fail with a `ValueError` when grouping on a categorical series with some categories not appearing in the data. (GH13179)

```
In [38]: chromosomes = np.r_[np.arange(1, 23).astype(str), ['X', 'Y']]

In [39]: df = pd.DataFrame({
.....:     'A': np.random.randint(100),
.....:     'B': np.random.randint(100),
.....:     'C': np.random.randint(100),
.....:     'chromosomes': pd.Categorical(np.random.choice(chromosomes, 100),
.....:                                     categories=chromosomes,
.....:                                     ordered=True)})
.....:

In [40]: df
Out [40]:
```

|    | A  | B  | C  | chromosomes |
|----|----|----|----|-------------|
| 0  | 64 | 56 | 54 | 1           |
| 1  | 64 | 56 | 54 | Y           |
| 2  | 64 | 56 | 54 | Y           |
| 3  | 64 | 56 | 54 | Y           |
| 4  | 64 | 56 | 54 | 11          |
| .. | .. | .. | .. | ...         |

```

```
[24 rows x 3 columns]
```

## Table schema output

The new orient `'table'` for `DataFrame.to_json()` will generate a [Table Schema](#) compatible string representation of the data.

```

In [42]: df = pd.DataFrame(
.....:     {'A': [1, 2, 3],
.....:      'B': ['a', 'b', 'c'],
.....:      'C': pd.date_range('2016-01-01', freq='d', periods=3)},
.....:     index=pd.Index(range(3), name='idx'))
.....:

```

```
In [43]: df
```

```

Out [43]:
   A B      C
idx
0  1 a 2016-01-01
1  2 b 2016-01-02
2  3 c 2016-01-03

```

```
[3 rows x 3 columns]
```

```
In [44]: df.to_json(orient='table')
```

```

Out [44]: '{"schema":{"fields":[{"name":"idx","type":"integer"}, {"name":"A","type":
↪ "integer"}, {"name":"B","type":"string"}, {"name":"C","type":"datetime"}], "primaryKey
↪ ": ["idx"], "pandas_version":"0.20.0"}, "data":[{"idx":0, "A":1, "B":"a", "C":"2016-01-
↪ 01T00:00:00.000Z"}, {"idx":1, "A":2, "B":"b", "C":"2016-01-02T00:00:00.000Z"}, {"idx":2,
↪ "A":3, "B":"c", "C":"2016-01-03T00:00:00.000Z"}]}'

```

See [IO: Table Schema](#) for more information.

Additionally, the repr for `DataFrame` and `Series` can now publish this JSON Table schema representation of the `Series` or `DataFrame` if you are using IPython (or another frontend like `nteract` using the Jupyter messaging protocol). This gives frontends like the Jupyter notebook and `nteract` more flexibility in how they display pandas objects, since they have more information about the data. You must enable this by setting the `display.html.table_schema` option to `True`.

## SciPy sparse matrix from/to SparseDataFrame

Pandas now supports creating sparse dataframes directly from `scipy.sparse.spmatrix` instances. See the *documentation* for more information. (GH4343)

All sparse formats are supported, but matrices that are not in `COOrdinate` format will be converted, copying data as needed.

```
from scipy.sparse import csr_matrix
arr = np.random.random(size=(1000, 5))
arr[arr < .9] = 0
sp_arr = csr_matrix(arr)
sp_arr
sdf = pd.SparseDataFrame(sp_arr)
sdf
```

To convert a `SparseDataFrame` back to sparse SciPy matrix in COO format, you can use:

```
sdf.to_coo()
```

## Excel output for styled DataFrames

Experimental support has been added to export `DataFrame.style` formats to Excel using the `openpyxl` engine. (GH15530)

For example, after running the following, `styled.xlsx` renders as below:

```
In [45]: np.random.seed(24)

In [46]: df = pd.DataFrame({'A': np.linspace(1, 10, 10)})

In [47]: df = pd.concat([df, pd.DataFrame(np.random.RandomState(24).randn(10, 4),
.....:                                     columns=list('BCDE'))],
.....:                   axis=1)
.....:

In [48]: df.iloc[0, 2] = np.nan

In [49]: df
Out[49]:
   A         B         C         D         E
0  1.0  1.329212      NaN -0.316280 -0.990810

| 11 | 9 | 10 | -0.12982  | 0.631523  | -0.586538 | 0.29072   |

See the *Style documentation* for more detail.

## IntervalIndex

pandas has gained an `IntervalIndex` with its own dtype, `interval` as well as the `Interval` scalar type. These allow first-class support for interval notation, specifically as a return type for the categories in `cut()` and `qcut()`. The `IntervalIndex` allows some unique indexing, see the *docs*. (GH7640, GH8625)

**Warning:** These indexing behaviors of the `IntervalIndex` are provisional and may change in a future version of pandas. Feedback on usage is welcome.

Previous behavior:

The returned categories were strings, representing Intervals

```

In [1]: c = pd.cut(range(4), bins=2)

In [2]: c
Out[2]:
[(-0.003, 1.5], (-0.003, 1.5], (1.5, 3], (1.5, 3]]
Categories (2, object): [(-0.003, 1.5] < (1.5, 3]]

In [3]: c.categories
Out[3]: Index(['(-0.003, 1.5]', '(1.5, 3]'], dtype='object')

```

New behavior:

```

In [52]: c = pd.cut(range(4), bins=2)

In [53]: c
Out[53]:

```

(continues on next page)

(continued from previous page)

```
[(-0.003, 1.5], (-0.003, 1.5], (1.5, 3.0], (1.5, 3.0]]
Categories (2, interval[float64]): [(-0.003, 1.5] < (1.5, 3.0]]

In [54]: c.categories
Out [54]:
IntervalIndex([(-0.003, 1.5], (1.5, 3.0]],
              closed='right',
              dtype='interval[float64]')
```

Furthermore, this allows one to bin *other* data with these same bins, with NaN representing a missing value similar to other dtypes.

```
In [55]: pd.cut([0, 3, 5, 1], bins=c.categories)
Out [55]:
[(-0.003, 1.5], (1.5, 3.0], NaN, (-0.003, 1.5]]
Categories (2, interval[float64]): [(-0.003, 1.5] < (1.5, 3.0]]
```

An IntervalIndex can also be used in Series and DataFrame as the index.

```
In [56]: df = pd.DataFrame({'A': range(4),
.....:                    'B': pd.cut([0, 3, 1, 1], bins=c.categories)
.....:                    }).set_index('B')
.....:

In [57]: df
Out [57]:
```

| B             | A |
|---------------|---|
| (-0.003, 1.5] | 0 |
| (1.5, 3.0]    | 1 |
| (-0.003, 1.5] | 2 |
| (-0.003, 1.5] | 3 |

```
[4 rows x 1 columns]
```

Selecting via a specific interval:

```
In [58]: df.loc[pd.Interval(1.5, 3.0)]
Out [58]:
```

| A |
|---|
| 1 |

```
Name: (1.5, 3.0], Length: 1, dtype: int64
```

Selecting via a scalar value that is contained *in* the intervals.

```
In [59]: df.loc[0]
Out [59]:
```

| A             |
|---------------|
| (-0.003, 1.5] |
| (-0.003, 1.5] |
| (-0.003, 1.5] |

```
[3 rows x 1 columns]
```

## Other enhancements

- `DataFrame.rolling()` now accepts the parameter `closed='right'|'left'|'both'|'neither'` to choose the rolling window-endpoint closedness. See the *documentation* (GH13965)
- Integration with the `feather-format`, including a new top-level `pd.read_feather()` and `DataFrame.to_feather()` method, see *here*.
- `Series.str.replace()` now accepts a callable, as replacement, which is passed to `re.sub` (GH15055)
- `Series.str.replace()` now accepts a compiled regular expression as a pattern (GH15446)
- `Series.sort_index` accepts parameters `kind` and `na_position` (GH13589, GH14444)
- `DataFrame` and `DataFrame.groupby()` have gained a `nunique()` method to count the distinct values over an axis (GH14336, GH15197).
- `DataFrame` has gained a `melt()` method, equivalent to `pd.melt()`, for unpivoting from a wide to long format (GH12640).
- `pd.read_excel()` now preserves sheet order when using `sheetname=None` (GH9930)
- Multiple offset aliases with decimal points are now supported (e.g. `0.5min` is parsed as `30s`) (GH8419)
- `.isnull()` and `.notnull()` have been added to `Index` object to make them more consistent with the `Series` API (GH15300)
- New `UnsortedIndexError` (subclass of `KeyError`) raised when indexing/slicing into an unsorted `MultiIndex` (GH11897). This allows differentiation between errors due to lack of sorting or an incorrect key. See *here*
- `MultiIndex` has gained a `.to_frame()` method to convert to a `DataFrame` (GH12397)
- `pd.cut` and `pd.qcut` now support `datetime64` and `timedelta64` dtypes (GH14714, GH14798)
- `pd.qcut` has gained the `duplicates='raise'|'drop'` option to control whether to raise on duplicated edges (GH7751)
- `Series` provides a `to_excel` method to output Excel files (GH8825)
- The `usecols` argument in `pd.read_csv()` now accepts a callable function as a value (GH14154)
- The `skiprows` argument in `pd.read_csv()` now accepts a callable function as a value (GH10882)
- The `nrows` and `chunksize` arguments in `pd.read_csv()` are supported if both are passed (GH6774, GH15755)
- `DataFrame.plot` now prints a title above each subplot if `suplots=True` and `title` is a list of strings (GH14753)
- `DataFrame.plot` can pass the `matplotlib 2.0` default color cycle as a single string as `color` parameter, see *here*. (GH15516)
- `Series.interpolate()` now supports `timedelta` as an index type with `method='time'` (GH6424)
- Addition of a `level` keyword to `DataFrame/Series.rename` to rename labels in the specified level of a `MultiIndex` (GH4160).
- `DataFrame.reset_index()` will now interpret a tuple `index.name` as a key spanning across levels of columns, if this is a `MultiIndex` (GH16164)
- `Timedelta.isoformat` method added for formatting `Timedeltas` as an `ISO 8601 duration`. See the *Timedelta docs* (GH15136)
- `.select_dtypes()` now allows the string `datetimez` to generically select datetimes with `tz` (GH14910)

- The `.to_latex()` method will now accept `multicolumn` and `multirow` arguments to use the accompanying LaTeX enhancements
- `pd.merge_asof()` gained the option `direction='backward'|'forward'|'nearest'` (GH14887)
- `Series/DataFrame.asfreq()` have gained a `fill_value` parameter, to fill missing values (GH3715).
- `Series/DataFrame.resample.asfreq` have gained a `fill_value` parameter, to fill missing values during resampling (GH3715).
- `pandas.util.hash_pandas_object()` has gained the ability to hash a `MultiIndex` (GH15224)
- `Series/DataFrame.squeeze()` have gained the `axis` parameter. (GH15339)
- `DataFrame.to_excel()` has a new `freeze_panes` parameter to turn on Freeze Panes when exporting to Excel (GH15160)
- `pd.read_html()` will parse multiple header rows, creating a `MultiIndex` header. (GH13434).
- HTML table output skips `colspan` or `rowspan` attribute if equal to 1. (GH15403)
- `pandas.io.formats.style.Styler` template now has blocks for easier extension, see the *example notebook* (GH15649)
- `Styler.render()` now accepts `**kwargs` to allow user-defined variables in the template (GH15649)
- Compatibility with Jupyter notebook 5.0; `MultiIndex` column labels are left-aligned and `MultiIndex` row-labels are top-aligned (GH15379)
- `TimedeltaIndex` now has a custom date-tick formatter specifically designed for nanosecond level precision (GH8711)
- `pd.api.types.union_categoricals` gained the `ignore_ordered` argument to allow ignoring the ordered attribute of unioned categoricals (GH13410). See the *categorical union docs* for more information.
- `DataFrame.to_latex()` and `DataFrame.to_string()` now allow optional header aliases. (GH15536)
- Re-enable the `parse_dates` keyword of `pd.read_excel()` to parse string columns as dates (GH14326)
- Added `.empty` property to subclasses of `Index`. (GH15270)
- Enabled floor division for `Timedelta` and `TimedeltaIndex` (GH15828)
- `pandas.io.json.json_normalize()` gained the option `errors='ignore'|'raise'`; the default is `errors='raise'` which is backward compatible. (GH14583)
- `pandas.io.json.json_normalize()` with an empty list will return an empty `DataFrame` (GH15534)
- `pandas.io.json.json_normalize()` has gained a `sep` option that accepts `str` to separate joined fields; the default is `“.”`, which is backward compatible. (GH14883)
- `MultiIndex.remove_unused_levels()` has been added to facilitate *removing unused levels*. (GH15694)
- `pd.read_csv()` will now raise a `ParserError` error whenever any parsing error occurs (GH15913, GH15925)
- `pd.read_csv()` now supports the `error_bad_lines` and `warn_bad_lines` arguments for the Python parser (GH15925)
- The `display.show_dimensions` option can now also be used to specify whether the length of a `Series` should be shown in its repr (GH7117).

- `parallel_coordinates()` has gained a `sort_labels` keyword argument that sorts class labels and the colors assigned to them (GH15908)
- Options added to allow one to turn on/off using `bottleneck` and `numexpr`, see *here* (GH16157)
- `DataFrame.style.bar()` now accepts two more options to further customize the bar chart. Bar alignment is set with `align='left'|'mid'|'zero'`, the default is “left”, which is backward compatible; You can now pass a list of `color=[color_negative, color_positive]`. (GH14757)

### Backwards incompatible API changes

#### Possible incompatibility for HDF5 formats created with pandas < 0.13.0

`pd.TimeSeries` was deprecated officially in 0.17.0, though has already been an alias since 0.13.0. It has been dropped in favor of `pd.Series`. (GH15098).

This *may* cause HDF5 files that were created in prior versions to become unreadable if `pd.TimeSeries` was used. This is most likely to be for pandas < 0.13.0. If you find yourself in this situation. You can use a recent prior version of pandas to read in your HDF5 files, then write them out again after applying the procedure below.

```
In [2]: s = pd.TimeSeries([1, 2, 3], index=pd.date_range('20130101', periods=3))
```

```
In [3]: s
```

```
Out [3]:
```

```
2013-01-01    1
2013-01-02    2
2013-01-03    3
Freq: D, dtype: int64
```

```
In [4]: type(s)
```

```
Out [4]: pandas.core.series.TimeSeries
```

```
In [5]: s = pd.Series(s)
```

```
In [6]: s
```

```
Out [6]:
```

```
2013-01-01    1
2013-01-02    2
2013-01-03    3
Freq: D, dtype: int64
```

```
In [7]: type(s)
```

```
Out [7]: pandas.core.series.Series
```

### Map on Index types now return other Index types

`map` on an Index now returns an Index, not a numpy array (GH12766)

```
In [60]: idx = pd.Index([1, 2])
```

```
In [61]: idx
```

```
Out [61]: Int64Index([1, 2], dtype='int64')
```

```
In [62]: mi = pd.MultiIndex.from_tuples([(1, 2), (2, 4)])
```

(continues on next page)

(continued from previous page)

```
In [63]: mi
Out [63]:
MultiIndex([(1, 2),
            (2, 4)],
           )
```

Previous behavior:

```
In [5]: idx.map(lambda x: x * 2)
Out [5]: array([2, 4])

In [6]: idx.map(lambda x: (x, x * 2))
Out [6]: array([(1, 2), (2, 4)], dtype=object)

In [7]: mi.map(lambda x: x)
Out [7]: array([(1, 2), (2, 4)], dtype=object)

In [8]: mi.map(lambda x: x[0])
Out [8]: array([1, 2])
```

New behavior:

```
In [64]: idx.map(lambda x: x * 2)
Out [64]: Int64Index([2, 4], dtype='int64')

In [65]: idx.map(lambda x: (x, x * 2))
Out [65]:
MultiIndex([(1, 2),
            (2, 4)],
           )

In [66]: mi.map(lambda x: x)
Out [66]:
MultiIndex([(1, 2),
            (2, 4)],
           )

In [67]: mi.map(lambda x: x[0])
Out [67]: Int64Index([1, 2], dtype='int64')
```

map on a Series with datetime64 values may return int64 dtypes rather than int32

```
In [68]: s = pd.Series(pd.date_range('2011-01-02T00:00', '2011-01-02T02:00', freq='H')
.....:                  .tz_localize('Asia/Tokyo'))
.....:

In [69]: s
Out [69]:
0    2011-01-02 00:00:00+09:00
1    2011-01-02 01:00:00+09:00
2    2011-01-02 02:00:00+09:00
Length: 3, dtype: datetime64[ns, Asia/Tokyo]
```

Previous behavior:

```
In [9]: s.map(lambda x: x.hour)
Out [9]:
```

(continues on next page)

(continued from previous page)

```
0    0
1    1
2    2
dtype: int32
```

New behavior:

```
In [70]: s.map(lambda x: x.hour)
Out [70]:
0    0
1    1
2    2
Length: 3, dtype: int64
```

### Accessing datetime fields of Index now return Index

The datetime-related attributes (see *here* for an overview) of `DatetimeIndex`, `PeriodIndex` and `TimedeltaIndex` previously returned numpy arrays. They will now return a new `Index` object, except in the case of a boolean field, where the result will still be a boolean ndarray. (GH15022)

Previous behaviour:

```
In [1]: idx = pd.date_range("2015-01-01", periods=5, freq='10H')
In [2]: idx.hour
Out [2]: array([ 0, 10, 20,  6, 16], dtype=int32)
```

New behavior:

```
In [71]: idx = pd.date_range("2015-01-01", periods=5, freq='10H')
In [72]: idx.hour
Out [72]: Int64Index([0, 10, 20, 6, 16], dtype='int64')
```

This has the advantage that specific `Index` methods are still available on the result. On the other hand, this might have backward incompatibilities: e.g. compared to numpy arrays, `Index` objects are not mutable. To get the original ndarray, you can always convert explicitly using `np.asarray(idx.hour)`.

### pd.unique will now be consistent with extension types

In prior versions, using `Series.unique()` and `pandas.unique()` on `Categorical` and `tz-aware` data-types would yield different return types. These are now made consistent. (GH15903)

- Datetime tz-aware

Previous behaviour:

```
# Series
In [5]: pd.Series([pd.Timestamp('20160101', tz='US/Eastern'),
...:              pd.Timestamp('20160101', tz='US/Eastern')]).unique()
Out [5]: array([Timestamp('2016-01-01 00:00:00-0500', tz='US/Eastern')],
↳dtype=object)

In [6]: pd.unique(pd.Series([pd.Timestamp('20160101', tz='US/Eastern'),
```

(continues on next page)

(continued from previous page)

```

....:         pd.Timestamp('20160101', tz='US/Eastern'))))
Out [6]: array(['2016-01-01T05:00:00.000000000'], dtype='datetime64[ns]')

# Index
In [7]: pd.Index([pd.Timestamp('20160101', tz='US/Eastern'),
....:             pd.Timestamp('20160101', tz='US/Eastern')]).unique()
Out [7]: DatetimeIndex(['2016-01-01 00:00:00-05:00'], dtype='datetime64[ns, US/
↪Eastern]', freq=None)

In [8]: pd.unique([pd.Timestamp('20160101', tz='US/Eastern'),
....:              pd.Timestamp('20160101', tz='US/Eastern')])
Out [8]: array(['2016-01-01T05:00:00.000000000'], dtype='datetime64[ns]')

```

New behavior:

```

# Series, returns an array of Timestamp tz-aware
In [73]: pd.Series([pd.Timestamp(r'20160101', tz=r'US/Eastern'),
....:              pd.Timestamp(r'20160101', tz=r'US/Eastern')]).unique()
....:
Out [73]:
<DatetimeArray>
['2016-01-01 00:00:00-05:00']
Length: 1, dtype: datetime64[ns, US/Eastern]

In [74]: pd.unique(pd.Series([pd.Timestamp('20160101', tz='US/Eastern'),
....:                         pd.Timestamp('20160101', tz='US/Eastern')]))
....:
Out [74]:
<DatetimeArray>
['2016-01-01 00:00:00-05:00']
Length: 1, dtype: datetime64[ns, US/Eastern]

# Index, returns a DatetimeIndex
In [75]: pd.Index([pd.Timestamp('20160101', tz='US/Eastern'),
....:              pd.Timestamp('20160101', tz='US/Eastern')]).unique()
....:
Out [75]: DatetimeIndex(['2016-01-01 00:00:00-05:00'], dtype='datetime64[ns, US/
↪Eastern]', freq=None)

In [76]: pd.unique(pd.Index([pd.Timestamp('20160101', tz='US/Eastern'),
....:                         pd.Timestamp('20160101', tz='US/Eastern')]))
....:
Out [76]: DatetimeIndex(['2016-01-01 00:00:00-05:00'], dtype='datetime64[ns, US/
↪Eastern]', freq=None)

```

- Categoricals

Previous behaviour:

```

In [1]: pd.Series(list('baabc'), dtype='category').unique()
Out [1]:
[b, a, c]
Categories (3, object): [b, a, c]

In [2]: pd.unique(pd.Series(list('baabc'), dtype='category'))
Out [2]: array(['b', 'a', 'c'], dtype=object)

```

New behavior:

```
# returns a Categorical
In [77]: pd.Series(list('baabc'), dtype='category').unique()
Out [77]:
[b, a, c]
Categories (3, object): [b, a, c]

In [78]: pd.unique(pd.Series(list('baabc'), dtype='category'))
Out [78]:
[b, a, c]
Categories (3, object): [b, a, c]
```

### S3 file handling

pandas now uses `s3fs` for handling S3 connections. This shouldn't break any code. However, since `s3fs` is not a required dependency, you will need to install it separately, like `botocore` in prior versions of pandas. (GH11915).

### Partial string indexing changes

*DatetimeIndex Partial String Indexing* now works as an exact match, provided that string resolution coincides with index resolution, including a case when both are seconds (GH14826). See *Slice vs. Exact Match* for details.

```
In [79]: df = pd.DataFrame({'a': [1, 2, 3]}, pd.DatetimeIndex(['2011-12-31 23:59:59',
.....:                                                         '2012-01-01 00:00:00',
.....:                                                         '2012-01-01 00:00:01
↪ ]]))
.....:
```

Previous behavior:

```
In [4]: df['2011-12-31 23:59:59']
Out [4]:
           a
2011-12-31 23:59:59    1

In [5]: df['a']['2011-12-31 23:59:59']
Out [5]:
2011-12-31 23:59:59    1
Name: a, dtype: int64
```

New behavior:

```
In [4]: df['2011-12-31 23:59:59']
KeyError: '2011-12-31 23:59:59'

In [5]: df['a']['2011-12-31 23:59:59']
Out [5]: 1
```

## Concat of different float dtypes will not automatically upcast

Previously, concat of multiple objects with different float dtypes would automatically upcast results to a dtype of float64. Now the smallest acceptable dtype will be used (GH13247)

```
In [80]: df1 = pd.DataFrame(np.array([1.0], dtype=np.float32, ndmin=2))
In [81]: df1.dtypes
Out[81]:
0    float32
Length: 1, dtype: object
In [82]: df2 = pd.DataFrame(np.array([np.nan], dtype=np.float32, ndmin=2))
In [83]: df2.dtypes
Out[83]:
0    float32
Length: 1, dtype: object
```

Previous behavior:

```
In [7]: pd.concat([df1, df2]).dtypes
Out[7]:
0    float64
dtype: object
```

New behavior:

```
In [84]: pd.concat([df1, df2]).dtypes
Out[84]:
0    float32
Length: 1, dtype: object
```

## Pandas Google BigQuery support has moved

pandas has split off Google BigQuery support into a separate package pandas-gbq. You can conda install pandas-gbq -c conda-forge or pip install pandas-gbq to get it. The functionality of read\_gbq() and DataFrame.to\_gbq() remain the same with the currently released version of pandas-gbq=0.1.4. Documentation is now hosted [here](#) (GH15347)

## Memory usage for Index is more accurate

In previous versions, showing .memory\_usage() on a pandas structure that has an index, would only include actual index values and not include structures that facilitated fast indexing. This will generally be different for Index and MultiIndex and less-so for other index types. (GH15237)

Previous behavior:

```
In [8]: index = pd.Index(['foo', 'bar', 'baz'])
In [9]: index.memory_usage(deep=True)
Out[9]: 180
In [10]: index.get_loc('foo')
```

(continues on next page)

(continued from previous page)

```
Out [10]: 0
In [11]: index.memory_usage(deep=True)
Out [11]: 180
```

New behavior:

```
In [8]: index = pd.Index(['foo', 'bar', 'baz'])
In [9]: index.memory_usage(deep=True)
Out [9]: 180
In [10]: index.get_loc('foo')
Out [10]: 0
In [11]: index.memory_usage(deep=True)
Out [11]: 260
```

### DataFrame.sort\_index changes

In certain cases, calling `.sort_index()` on a MultiIndexed DataFrame would return the *same* DataFrame without seeming to sort. This would happen with a `lexsorted`, but non-monotonic levels. (GH15622, GH15687, GH14015, GH13431, GH15797)

This is *unchanged* from prior versions, but shown for illustration purposes:

```
In [85]: df = pd.DataFrame(np.arange(6), columns=['value'],
.....:                      index=pd.MultiIndex.from_product([list('BA'), range(3)]))
.....:
```

```
In [86]: df
Out [86]:
```

|     | value |
|-----|-------|
| B 0 | 0     |
| 1   | 1     |
| 2   | 2     |
| A 0 | 3     |
| 1   | 4     |
| 2   | 5     |

[6 rows x 1 columns]

```
In [87]: df.index.is_lexsorted()
Out [87]: False
```

```
In [88]: df.index.is_monotonic
Out [88]: False
```

Sorting works as expected

```
In [89]: df.sort_index()
Out [89]:
   value
A 0     3
```

(continues on next page)

(continued from previous page)

```

1      4
2      5
B 0    0
   1    1
   2    2

[6 rows x 1 columns]

```

```

In [90]: df.sort_index().index.is_lexsorted()
Out[90]: True

```

```

In [91]: df.sort_index().index.is_monotonic
Out[91]: True

```

However, this example, which has a non-monotonic 2nd level, doesn't behave as desired.

```

In [92]: df = pd.DataFrame({'value': [1, 2, 3, 4]},
.....:                    index=pd.MultiIndex([['a', 'b'], ['bb', 'aa']],
.....:                                       [[0, 0, 1, 1], [0, 1, 0, 1]]))
.....:

In [93]: df
Out[93]:
   value
a bb    1
  aa    2
b bb    3
  aa    4

[4 rows x 1 columns]

```

Previous behavior:

```

In [11]: df.sort_index()
Out[11]:
   value
a bb    1
  aa    2
b bb    3
  aa    4

In [14]: df.sort_index().index.is_lexsorted()
Out[14]: True

In [15]: df.sort_index().index.is_monotonic
Out[15]: False

```

New behavior:

```

In [94]: df.sort_index()
Out[94]:
   value
a aa    2
  bb    1
b aa    4
  bb    3

```

(continues on next page)

(continued from previous page)

```
[4 rows x 1 columns]
In [95]: df.sort_index().index.is_lexsorted()
Out [95]: True
In [96]: df.sort_index().index.is_monotonic
Out [96]: True
```

## Groupby describe formatting

The output formatting of `groupby.describe()` now labels the `describe()` metrics in the columns instead of the index. This format is consistent with `groupby.agg()` when applying multiple functions at once. (GH4792)

Previous behavior:

```
In [1]: df = pd.DataFrame({'A': [1, 1, 2, 2], 'B': [1, 2, 3, 4]})
In [2]: df.groupby('A').describe()
Out [2]:
```

|   |       | B        |  |  |  |  |  |  |
|---|-------|----------|--|--|--|--|--|--|
| A |       |          |  |  |  |  |  |  |
| 1 | count | 2.000000 |  |  |  |  |  |  |
|   | mean  | 1.500000 |  |  |  |  |  |  |
|   | std   | 0.707107 |  |  |  |  |  |  |
|   | min   | 1.000000 |  |  |  |  |  |  |
|   | 25%   | 1.250000 |  |  |  |  |  |  |
|   | 50%   | 1.500000 |  |  |  |  |  |  |
|   | 75%   | 1.750000 |  |  |  |  |  |  |
|   | max   | 2.000000 |  |  |  |  |  |  |
| 2 | count | 2.000000 |  |  |  |  |  |  |
|   | mean  | 3.500000 |  |  |  |  |  |  |
|   | std   | 0.707107 |  |  |  |  |  |  |
|   | min   | 3.000000 |  |  |  |  |  |  |
|   | 25%   | 3.250000 |  |  |  |  |  |  |
|   | 50%   | 3.500000 |  |  |  |  |  |  |
|   | 75%   | 3.750000 |  |  |  |  |  |  |
|   | max   | 4.000000 |  |  |  |  |  |  |

```
In [3]: df.groupby('A').agg([np.mean, np.std, np.min, np.max])
Out [3]:
```

|   |  | B    |          |      |      |
|---|--|------|----------|------|------|
|   |  | mean | std      | amin | amax |
| A |  |      |          |      |      |
| 1 |  | 1.5  | 0.707107 | 1    | 2    |
| 2 |  | 3.5  | 0.707107 | 3    | 4    |

New behavior:

```
In [97]: df = pd.DataFrame({'A': [1, 1, 2, 2], 'B': [1, 2, 3, 4]})
In [98]: df.groupby('A').describe()
Out [98]:
```

|   |  | B     |      |          |     |      |     |      |     |
|---|--|-------|------|----------|-----|------|-----|------|-----|
|   |  | count | mean | std      | min | 25%  | 50% | 75%  | max |
| A |  |       |      |          |     |      |     |      |     |
| 1 |  | 2     | 1.5  | 0.707107 | 1   | 1.25 | 1.5 | 1.75 | 2   |
| 2 |  | 2     | 3.5  | 0.707107 | 3   | 3.25 | 3.5 | 3.75 | 4   |

(continues on next page)

(continued from previous page)

```

A
1  2.0  1.5  0.707107  1.0  1.25  1.5  1.75  2.0
2  2.0  3.5  0.707107  3.0  3.25  3.5  3.75  4.0

[2 rows x 8 columns]

In [99]: df.groupby('A').agg([np.mean, np.std, np.min, np.max])
Out [99]:
      B
      mean      std amin amax
A
1  1.5  0.707107    1    2
2  3.5  0.707107    3    4

[2 rows x 4 columns]

```

### Window binary corr/cov operations return a MultiIndex DataFrame

A binary window operation, like `.corr()` or `.cov()`, when operating on a `.rolling(...)`, `.expanding(...)`, or `.ewm(...)` object, will now return a 2-level MultiIndexed DataFrame rather than a Panel, as Panel is now deprecated, see [here](#). These are equivalent in function, but a MultiIndexed DataFrame enjoys more support in pandas. See the section on *Windowed Binary Operations* for more information. (GH15677)

```

In [100]: np.random.seed(1234)

In [101]: df = pd.DataFrame(np.random.rand(100, 2),
.....:                      columns=pd.Index(['A', 'B'], name='bar'),
.....:                      index=pd.date_range('20160101',
.....:                                          periods=100, freq='D', name='foo'))

In [102]: df.tail()
Out [102]:
bar      A      B
foo
2016-04-05  0.640880  0.126205
2016-04-06  0.171465  0.737086
2016-04-07  0.127029  0.369650
2016-04-08  0.604334  0.103104
2016-04-09  0.802374  0.945553

[5 rows x 2 columns]

```

Previous behavior:

```

In [2]: df.rolling(12).corr()
Out [2]:
<class 'pandas.core.panel.Panel'>
Dimensions: 100 (items) x 2 (major_axis) x 2 (minor_axis)
Items axis: 2016-01-01 00:00:00 to 2016-04-09 00:00:00
Major_axis axis: A to B
Minor_axis axis: A to B

```

New behavior:

```
In [103]: res = df.rolling(12).corr()

In [104]: res.tail()
Out[104]:
bar                A          B
foo      bar
2016-04-07 B   -0.132090  1.000000
2016-04-08 A    1.000000 -0.145775
           B   -0.145775  1.000000
2016-04-09 A    1.000000  0.119645
           B    0.119645  1.000000

[5 rows x 2 columns]
```

#### Retrieving a correlation matrix for a cross-section

```
In [105]: df.rolling(12).corr().loc['2016-04-07']
Out[105]:
bar                A          B
foo      bar
2016-04-07 A    1.000000 -0.13209
           B   -0.13209  1.00000

[2 rows x 2 columns]
```

#### HDFStore where string comparison

In previous versions most types could be compared to string column in a `HDFStore` usually resulting in an invalid comparison, returning an empty result frame. These comparisons will now raise a `TypeError` (GH15492)

```
In [106]: df = pd.DataFrame({'unparsed_date': ['2014-01-01', '2014-01-01']})

In [107]: df.to_hdf('store.h5', 'key', format='table', data_columns=True)

In [108]: df.dtypes
Out[108]:
unparsed_date    object
Length: 1, dtype: object
```

#### Previous behavior:

```
In [4]: pd.read_hdf('store.h5', 'key', where='unparsed_date > ts')
File "<string>", line 1
      (unparsed_date > 1970-01-01 00:00:01.388552400)
                        ^
SyntaxError: invalid token
```

#### New behavior:

```
In [18]: ts = pd.Timestamp('2014-01-01')

In [19]: pd.read_hdf('store.h5', 'key', where='unparsed_date > ts')
TypeError: Cannot compare 2014-01-01 00:00:00 of
type <class 'pandas.tseries.Timestamp'> to string column
```

## Index.intersection and inner join now preserve the order of the left Index

`Index.intersection()` now preserves the order of the calling Index (left) instead of the other Index (right) (GH15582). This affects inner joins, `DataFrame.join()` and `merge()`, and the `.align` method.

- `Index.intersection`

```
In [109]: left = pd.Index([2, 1, 0])
In [110]: left
Out[110]: Int64Index([2, 1, 0], dtype='int64')
In [111]: right = pd.Index([1, 2, 3])
In [112]: right
Out[112]: Int64Index([1, 2, 3], dtype='int64')
```

Previous behavior:

```
In [4]: left.intersection(right)
Out[4]: Int64Index([1, 2], dtype='int64')
```

New behavior:

```
In [113]: left.intersection(right)
Out[113]: Int64Index([2, 1], dtype='int64')
```

- `DataFrame.join` and `pd.merge`

```
In [114]: left = pd.DataFrame({'a': [20, 10, 0]}, index=[2, 1, 0])
In [115]: left
Out[115]:
   a
2  20
1  10
0   0

[3 rows x 1 columns]
In [116]: right = pd.DataFrame({'b': [100, 200, 300]}, index=[1, 2, 3])
In [117]: right
Out[117]:
   b
1  100
2  200
3  300

[3 rows x 1 columns]
```

Previous behavior:

```
In [4]: left.join(right, how='inner')
Out[4]:
   a  b
1  10 100
2  20 200
```

New behavior:

```
In [118]: left.join(right, how='inner')
Out[118]:
   a    b
2  20  200
1  10  100

[2 rows x 2 columns]
```

### Pivot table always returns a DataFrame

The documentation for `pivot_table()` states that a `DataFrame` is *always* returned. Here a bug is fixed that allowed this to return a `Series` under certain circumstance. (GH4386)

```
In [119]: df = pd.DataFrame({'col1': [3, 4, 5],
.....:                      'col2': ['C', 'D', 'E'],
.....:                      'col3': [1, 3, 9]})
.....:

In [120]: df
Out[120]:
   col1 col2 col3
0     3    C     1
1     4    D     3
2     5    E     9

[3 rows x 3 columns]
```

Previous behavior:

```
In [2]: df.pivot_table('col1', index=['col3', 'col2'], aggfunc=np.sum)
Out[2]:
col3 col2
1     C     3
3     D     4
9     E     5
Name: col1, dtype: int64
```

New behavior:

```
In [121]: df.pivot_table('col1', index=['col3', 'col2'], aggfunc=np.sum)
Out[121]:
           col1
col3 col2
1     C         3
3     D         4
9     E         5

[3 rows x 1 columns]
```

## Other API changes

- `numexpr` version is now required to be  $\geq 2.4.6$  and it will not be used at all if this requisite is not fulfilled (GH15213).
- `CParserError` has been renamed to `ParserError` in `pd.read_csv()` and will be removed in the future (GH12665)
- `SparseArray.cumsum()` and `SparseSeries.cumsum()` will now always return `SparseArray` and `SparseSeries` respectively (GH12855)
- `DataFrame.applymap()` with an empty `DataFrame` will return a copy of the empty `DataFrame` instead of a `Series` (GH8222)
- `Series.map()` now respects default values of dictionary subclasses with a `__missing__` method, such as `collections.Counter` (GH15999)
- `.loc` has compat with `.ix` for accepting iterators, and `NamedTuples` (GH15120)
- `interpolate()` and `fillna()` will raise a `ValueError` if the `limit` keyword argument is not greater than 0. (GH9217)
- `pd.read_csv()` will now issue a `ParserWarning` whenever there are conflicting values provided by the `dialect` parameter and the user (GH14898)
- `pd.read_csv()` will now raise a `ValueError` for the C engine if the quote character is larger than one byte (GH11592)
- `inplace` arguments now require a boolean value, else a `ValueError` is thrown (GH14189)
- `pandas.api.types.is_datetime64_ns_dtype` will now report `True` on a tz-aware dtype, similar to `pandas.api.types.is_datetime64_any_dtype`
- `DataFrame.asof()` will return a null filled `Series` instead the scalar `NaN` if a match is not found (GH15118)
- Specific support for `copy.copy()` and `copy.deepcopy()` functions on `NDFrame` objects (GH15444)
- `Series.sort_values()` accepts a one element list of `bool` for consistency with the behavior of `DataFrame.sort_values()` (GH15604)
- `.merge()` and `.join()` on `category` dtype columns will now preserve the `category` dtype when possible (GH10409)
- `SparseDataFrame.default_fill_value` will be 0, previously was `nan` in the return from `pd.get_dummies(..., sparse=True)` (GH15594)
- The default behaviour of `Series.str.match` has changed from extracting groups to matching the pattern. The extracting behaviour was deprecated since pandas version 0.13.0 and can be done with the `Series.str.extract` method (GH5224). As a consequence, the `as_indexer` keyword is ignored (no longer needed to specify the new behaviour) and is deprecated.
- `NaT` will now correctly report `False` for datetimelike boolean operations such as `is_month_start` (GH15781)
- `NaT` will now correctly return `np.nan` for `Timedelta` and `Period` accessors such as `days` and `quarter` (GH15782)
- `NaT` will now returns `NaT` for `tz_localize` and `tz_convert` methods (GH15830)
- `DataFrame` and `Panel` constructors with invalid input will now raise `ValueError` rather than `PandasError`, if called with scalar inputs and not axes (GH15541)

- `DataFrame` and `Panel` constructors with invalid input will now raise `ValueError` rather than `pandas.core.common.PandasError`, if called with scalar inputs and not axes; The exception `PandasError` is removed as well. (GH15541)
- The exception `pandas.core.common.AmbiguousIndexError` is removed as it is not referenced (GH15541)

## Reorganization of the library: privacy changes

### Modules privacy has changed

Some formerly public python/c/c++/cython extension modules have been moved and/or renamed. These are all removed from the public API. Furthermore, the `pandas.core`, `pandas.compat`, and `pandas.util` top-level modules are now considered to be PRIVATE. If indicated, a deprecation warning will be issued if you reference these modules. (GH12588)

Some new subpackages are created with public functionality that is not directly exposed in the top-level namespace: `pandas.errors`, `pandas.plotting` and `pandas.testing` (more details below). Together with `pandas.api.types` and certain functions in the `pandas.io` and `pandas.tseries` submodules, these are now the public subpackages.

Further changes:

- The function `union_categoricals()` is now importable from `pandas.api.types`, formerly from `pandas.types.concat` (GH15998)
- The type `import pandas.tslib.NaTType` is deprecated and can be replaced by using `type(pandas.NaT)` (GH16146)
- The public functions in `pandas.tools.hashing` deprecated from that locations, but are now importable from `pandas.util` (GH16223)

- The modules in `pandas.util`: `decorators`, `print_versions`, `doctools`, `validators`, `depr_module` are now private. Only the functions exposed in `pandas.util` itself are public (GH16223)

### `pandas.errors`

We are adding a standard public module for all pandas exceptions & warnings `pandas.errors`. (GH14800). Previously these exceptions & warnings could be imported from `pandas.core.common` or `pandas.io.common`. These exceptions and warnings will be removed from the `*.common` locations in a future release. (GH15541)

The following are now part of this API:

```
['DtypeWarning',  
'EmptyDataError',  
'OutOfBoundsDatetime',  
'ParserError',  
'ParserWarning',  
'PerformanceWarning',  
'UnsortedIndexError',  
'UnsupportedFunctionCall']
```

### `pandas.testing`

We are adding a standard module that exposes the public testing functions in `pandas.testing` (GH9895). Those functions can be used when writing tests for functionality using pandas objects.

The following testing functions are now part of this API:

- `testing.assert_frame_equal()`
- `testing.assert_series_equal()`
- `testing.assert_index_equal()`

### `pandas.plotting`

A new public `pandas.plotting` module has been added that holds plotting functionality that was previously in either `pandas.tools.plotting` or in the top-level namespace. See the *deprecations sections* for more details.

## Other Development Changes

- Building pandas for development now requires `cython >= 0.23` (GH14831)
- Require at least 0.23 version of cython to avoid problems with character encodings (GH14699)
- Switched the test framework to use `pytest` (GH13097)
- Reorganization of tests directory layout (GH14854, GH15707).

## Deprecations

### Deprecate `.ix`

The `.ix` indexer is deprecated, in favor of the more strict `.iloc` and `.loc` indexers. `.ix` offers a lot of magic on the inference of what the user wants to do. To wit, `.ix` can decide to index *positionally* OR via *labels*, depending on the data type of the index. This has caused quite a bit of user confusion over the years. The full indexing documentation is [here](#). (GH14218)

The recommended methods of indexing are:

- `.loc` if you want to *label* index
- `.iloc` if you want to *positionally* index.

Using `.ix` will now show a `DeprecationWarning` with a link to some examples of how to convert code [here](#).

```
In [122]: df = pd.DataFrame({'A': [1, 2, 3],
.....:                      'B': [4, 5, 6]},
.....:                      index=list('abc'))
.....:

In [123]: df
Out [123]:
   A  B
a  1  4
b  2  5
c  3  6

[3 rows x 2 columns]
```

Previous behavior, where you wish to get the 0th and the 2nd elements from the index in the 'A' column.

```
In [3]: df.ix[[0, 2], 'A']
Out [3]:
a    1
c    3
Name: A, dtype: int64
```

Using `.loc`. Here we will select the appropriate indexes from the index, then use *label* indexing.

```
In [124]: df.loc[df.index[[0, 2]], 'A']
Out [124]:
a    1
c    3
Name: A, Length: 2, dtype: int64
```

Using `.iloc`. Here we will get the location of the 'A' column, then use *positional* indexing to select things.

```
In [125]: df.iloc[[0, 2], df.columns.get_loc('A')]
Out [125]:
a    1
c    3
Name: A, Length: 2, dtype: int64
```

## Deprecate Panel

Panel is deprecated and will be removed in a future version. The recommended way to represent 3-D data are with a MultiIndex on a DataFrame via the `to_frame()` or with the `xarray` package. Pandas provides a `to_xarray()` method to automate this conversion ([GH13563](#)).

```
In [133]: import pandas._testing as tm

In [134]: p = tm.makePanel()

In [135]: p
Out[135]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 3 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemC
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-05 00:00:00
Minor_axis axis: A to D
```

## Convert to a MultiIndex DataFrame

```
In [136]: p.to_frame()
Out[136]:
```

| major      | minor | ItemA     | ItemB     | ItemC     |
|------------|-------|-----------|-----------|-----------|
| 2000-01-03 | A     | 0.628776  | -1.409432 | 0.209395  |
|            | B     | 0.988138  | -1.347533 | -0.896581 |
|            | C     | -0.938153 | 1.272395  | -0.161137 |
|            | D     | -0.223019 | -0.591863 | -1.051539 |
| 2000-01-04 | A     | 0.186494  | 1.422986  | -0.592886 |
|            | B     | -0.072608 | 0.363565  | 1.104352  |
|            | C     | -1.239072 | -1.449567 | 0.889157  |
|            | D     | 2.123692  | -0.414505 | -0.319561 |
| 2000-01-05 | A     | 0.952478  | -2.147855 | -1.473116 |
|            | B     | -0.550603 | -0.014752 | -0.431550 |
|            | C     | 0.139683  | -1.195524 | 0.288377  |
|            | D     | 0.122273  | -1.425795 | -0.619993 |

```
[12 rows x 3 columns]
```

## Convert to an xarray DataArray

```
In [137]: p.to_xarray()
Out[137]:
<xarray.DataArray (items: 3, major_axis: 3, minor_axis: 4)>
array([[[[ 0.628776,  0.988138, -0.938153, -0.223019],
          [ 0.186494, -0.072608, -1.239072,  2.123692],
          [ 0.952478, -0.550603,  0.139683,  0.122273]],

         [[-1.409432, -1.347533,  1.272395, -0.591863],
          [ 1.422986,  0.363565, -1.449567, -0.414505],
          [-2.147855, -0.014752, -1.195524, -1.425795]],

         [[ 0.209395, -0.896581, -0.161137, -1.051539],
          [-0.592886,  1.104352,  0.889157, -0.319561],
          [-1.473116, -0.43155 ,  0.288377, -0.619993]]])
Coordinates:
  * items      (items) object 'ItemA' 'ItemB' 'ItemC'
```

(continues on next page)

(continued from previous page)

```
* major_axis (major_axis) datetime64[ns] 2000-01-03 2000-01-04 2000-01-05
* minor_axis (minor_axis) object 'A' 'B' 'C' 'D'
```

## Deprecate `groupby.agg()` with a dictionary when renaming

The `.groupby(...).agg(...)`, `.rolling(...).agg(...)`, and `.resample(...).agg(...)` syntax can accept a variable of inputs, including scalars, list, and a dict of column names to scalars or lists. This provides a useful syntax for constructing multiple (potentially different) aggregations.

However, `.agg(...)` can *also* accept a dict that allows ‘renaming’ of the result columns. This is a complicated and confusing syntax, as well as not consistent between `Series` and `DataFrame`. We are deprecating this ‘renaming’ functionality.

- We are deprecating passing a dict to a grouped/rolled/resampled `Series`. This allowed one to rename the resulting aggregation, but this had a completely different meaning than passing a dictionary to a grouped `DataFrame`, which accepts column-to-aggregations.
- We are deprecating passing a dict-of-dicts to a grouped/rolled/resampled `DataFrame` in a similar manner.

This is an illustrative example:

```
In [126]: df = pd.DataFrame({'A': [1, 1, 1, 2, 2],
.....:                      'B': range(5),
.....:                      'C': range(5)})
.....:

In [127]: df
Out[127]:
   A  B  C
0  1  0  0
1  1  1  1
2  1  2  2
3  2  3  3
4  2  4  4

[5 rows x 3 columns]
```

Here is a typical useful syntax for computing different aggregations for different columns. This is a natural, and useful syntax. We aggregate from the dict-to-list by taking the specified columns and applying the list of functions. This returns a `MultiIndex` for the columns (this is *not* deprecated).

```
In [128]: df.groupby('A').agg({'B': 'sum', 'C': 'min'})
Out[128]:
   B  C
A
1  3  0
2  7  3

[2 rows x 2 columns]
```

Here’s an example of the first deprecation, passing a dict to a grouped `Series`. This is a combination aggregation & renaming:

```
In [6]: df.groupby('A').B.agg({'foo': 'count'})
FutureWarning: using a dict on a Series for aggregation
```

(continues on next page)

(continued from previous page)

```
is deprecated and will be removed in a future version
```

```
Out [6]:
```

```
   foo
A
1     3
2     2
```

You can accomplish the same operation, more idiomatically by:

```
In [129]: df.groupby('A').B.agg(['count']).rename(columns={'count': 'foo'})
```

```
Out [129]:
```

```
   foo
A
1     3
2     2
```

```
[2 rows x 1 columns]
```

Here's an example of the second deprecation, passing a dict-of-dict to a grouped DataFrame:

```
In [23]: (df.groupby('A')
...:      .agg({'B': {'foo': 'sum'}, 'C': {'bar': 'min'}})
...:      )
```

```
FutureWarning: using a dict with renaming is deprecated and
will be removed in a future version
```

```
Out [23]:
```

```
   B  C
   foo bar
A
1   3  0
2   7  3
```

You can accomplish nearly the same by:

```
In [130]: (df.groupby('A')
...:      .agg({'B': 'sum', 'C': 'min'})
...:      .rename(columns={'B': 'foo', 'C': 'bar'})
...:      )
...:      )
```

```
Out [130]:
```

```
   foo bar
A
1     3  0
2     7  3
```

```
[2 rows x 2 columns]
```

## Deprecate `.plotting`

The `pandas.tools.plotting` module has been deprecated, in favor of the top level `pandas.plotting` module. All the public plotting functions are now available from `pandas.plotting` ([GH12548](#)).

Furthermore, the top-level `pandas.scatter_matrix` and `pandas.plot_params` are deprecated. Users can import these from `pandas.plotting` as well.

Previous script:

```
pd.tools.plotting.scatter_matrix(df)
pd.scatter_matrix(df)
```

Should be changed to:

```
pd.plotting.scatter_matrix(df)
```

## Other deprecations

- `SparseArray.to_dense()` has deprecated the `fill` parameter, as that parameter was not being respected ([GH14647](#))
- `SparseSeries.to_dense()` has deprecated the `sparse_only` parameter ([GH14647](#))
- `Series.repeat()` has deprecated the `reps` parameter in favor of `repeats` ([GH12662](#))
- The `Series` constructor and `.astype` method have deprecated accepting timestamp dtypes without a frequency (e.g. `np.datetime64`) for the `dtype` parameter ([GH15524](#))
- `Index.repeat()` and `MultiIndex.repeat()` have deprecated the `n` parameter in favor of `repeats` ([GH12662](#))
- `Categorical.searchsorted()` and `Series.searchsorted()` have deprecated the `v` parameter in favor of `value` ([GH12662](#))
- `TimedeltaIndex.searchsorted()`, `DatetimeIndex.searchsorted()`, and `PeriodIndex.searchsorted()` have deprecated the `key` parameter in favor of `value` ([GH12662](#))
- `DataFrame.astype()` has deprecated the `raise_on_error` parameter in favor of `errors` ([GH14878](#))
- `Series.sortlevel` and `DataFrame.sortlevel` have been deprecated in favor of `Series.sort_index` and `DataFrame.sort_index` ([GH15099](#))
- importing `concat` from `pandas.tools.merge` has been deprecated in favor of imports from the `pandas` namespace. This should only affect explicit imports ([GH15358](#))
- `Series/DataFrame/Panel.consolidate()` been deprecated as a public method. ([GH15483](#))
- The `as_indexer` keyword of `Series.str.match()` has been deprecated (ignored keyword) ([GH15257](#)).
- The following top-level `pandas` functions have been deprecated and will be removed in a future version ([GH13790](#), [GH15940](#))
  - `pd.pnow()`, replaced by `Period.now()`
  - `pd.Term`, is removed, as it is not applicable to user code. Instead use in-line string expressions in the `where` clause when searching in `HDFSStore`
  - `pd.Expr`, is removed, as it is not applicable to user code.
  - `pd.match()`, is removed.

- `pd.groupby()`, replaced by using the `.groupby()` method directly on a `Series/DataFrame`
- `pd.get_store()`, replaced by a direct call to `pd.HDFStore(...)`
- `is_any_int_dtype`, `is_floating_dtype`, and `is_sequence` are deprecated from `pandas.api.types` (GH16042)

## Removal of prior version deprecations/changes

- The `pandas.rpy` module is removed. Similar functionality can be accessed through the `rpy2` project. See the [R interfacing docs](#) for more details.
- The `pandas.io.ga` module with a `google-analytics` interface is removed (GH11308). Similar functionality can be found in the [Google2Pandas](#) package.
- `pd.to_datetime` and `pd.to_timedelta` have dropped the `coerce` parameter in favor of errors (GH13602)
- `pandas.stats.fama_macbeth`, `pandas.stats.ols`, `pandas.stats.plm` and `pandas.stats.var`, as well as the top-level `pandas.fama_macbeth` and `pandas.ols` routines are removed. Similar functionality can be found in the [statsmodels](#) package. (GH11898)
- The `TimeSeries` and `SparseTimeSeries` classes, aliases of `Series` and `SparseSeries`, are removed (GH10890, GH15098).
- `Series.is_time_series` is dropped in favor of `Series.index.is_all_dates` (GH15098)
- The deprecated `irow`, `icol`, `iget` and `iget_value` methods are removed in favor of `iloc` and `iat` as explained [here](#) (GH10711).
- The deprecated `DataFrame.iterkv()` has been removed in favor of `DataFrame.iteritems()` (GH10711)
- The `Categorical` constructor has dropped the `name` parameter (GH10632)
- `Categorical` has dropped support for `NaN` categories (GH10748)
- The `take_last` parameter has been dropped from `duplicated()`, `drop_duplicates()`, `nlargest()`, and `nsmallest()` methods (GH10236, GH10792, GH10920)
- `Series`, `Index`, and `DataFrame` have dropped the `sort` and `order` methods (GH10726)
- Where clauses in `pytables` are only accepted as strings and expressions types and not other data-types (GH12027)
- `DataFrame` has dropped the `combineAdd` and `combineMult` methods in favor of `add` and `mul` respectively (GH10735)

## Performance improvements

- Improved performance of `pd.wide_to_long()` (GH14779)
- Improved performance of `pd.factorize()` by releasing the GIL with `object` dtype when inferred as strings (GH14859, GH16057)
- Improved performance of timeseries plotting with an irregular `DatetimeIndex` (or with `compat_x=True`) (GH15073).
- Improved performance of `groupby().cummin()` and `groupby().cummax()` (GH15048, GH15109, GH15561, GH15635)
- Improved performance and reduced memory when indexing with a `MultiIndex` (GH15245)

- When reading buffer object in `read_sas()` method without specified format, filepath string is inferred rather than buffer object. (GH14947)
- Improved performance of `.rank()` for categorical data (GH15498)
- Improved performance when using `.unstack()` (GH15503)
- Improved performance of merge/join on category columns (GH10409)
- Improved performance of `drop_duplicates()` on bool columns (GH12963)
- Improve performance of `pd.core.groupby.GroupBy.apply` when the applied function used the `.name` attribute of the group DataFrame (GH15062).
- Improved performance of `iloc` indexing with a list or array (GH15504).
- Improved performance of `Series.sort_index()` with a monotonic index (GH15694)
- Improved performance in `pd.read_csv()` on some platforms with buffered reads (GH16039)

## Bug fixes

### Conversion

- Bug in `Timestamp.replace` now raises `TypeError` when incorrect argument names are given; previously this raised `ValueError` (GH15240)
- Bug in `Timestamp.replace` with `compat` for passing long integers (GH15030)
- Bug in `Timestamp` returning UTC based time/date attributes when a timezone was provided (GH13303, GH6538)
- Bug in `Timestamp` incorrectly localizing timezones during construction (GH11481, GH15777)
- Bug in `TimedeltaIndex` addition where overflow was being allowed without error (GH14816)
- Bug in `TimedeltaIndex` raising a `ValueError` when boolean indexing with `loc` (GH14946)
- Bug in catching an overflow in `Timestamp + Timedelta/Offset` operations (GH15126)
- Bug in `DatetimeIndex.round()` and `Timestamp.round()` floating point accuracy when rounding by milliseconds or less (GH14440, GH15578)
- Bug in `astype()` where `inf` values were incorrectly converted to integers. Now raises error now with `astype()` for `Series` and `DataFrames` (GH14265)
- Bug in `DataFrame(...).apply(to_numeric)` when values are of type `decimal.Decimal`. (GH14827)
- Bug in `describe()` when passing a numpy array which does not contain the median to the percentiles keyword argument (GH14908)
- Cleaned up `PeriodIndex` constructor, including raising on floats more consistently (GH13277)
- Bug in using `__deepcopy__` on empty `NDFrame` objects (GH15370)
- Bug in `.replace()` may result in incorrect dtypes. (GH12747, GH15765)
- Bug in `Series.replace` and `DataFrame.replace` which failed on empty replacement dicts (GH15289)
- Bug in `Series.replace` which replaced a numeric by string (GH15743)
- Bug in `Index` construction with `NaN` elements and integer dtype specified (GH15187)
- Bug in `Series` construction with a `datetimetz` (GH14928)
- Bug in `Series.dt.round()` inconsistent behaviour on `NaT` 's with different arguments (GH14940)

- Bug in `Series` constructor when both `copy=True` and `dtype` arguments are provided (GH15125)
- Incorrect dtypes `Series` was returned by comparison methods (e.g., `lt`, `gt`, ...) against a constant for an empty `DataFrame` (GH15077)
- Bug in `Series.ffill()` with mixed dtypes containing tz-aware datetimes. (GH14956)
- Bug in `DataFrame.fillna()` where the argument `downcast` was ignored when `fillna` value was of type `dict` (GH15277)
- Bug in `.asfreq()`, where frequency was not set for empty `Series` (GH14320)
- Bug in `DataFrame` construction with nulls and datetimes in a list-like (GH15869)
- Bug in `DataFrame.fillna()` with tz-aware datetimes (GH15855)
- Bug in `is_string_dtype`, `is_timedelta64_ns_dtype`, and `is_string_like_dtype` in which an error was raised when `None` was passed in (GH15941)
- Bug in the return type of `pd.unique` on a `Categorical`, which was returning an `ndarray` and not a `Categorical` (GH15903)
- Bug in `Index.to_series()` where the index was not copied (and so mutating later would change the original), (GH15949)
- Bug in indexing with partial string indexing with a len-1 `DataFrame` (GH16071)
- Bug in `Series` construction where passing invalid dtype didn't raise an error. (GH15520)

## Indexing

- Bug in `Index` power operations with reversed operands (GH14973)
- Bug in `DataFrame.sort_values()` when sorting by multiple columns where one column is of type `int64` and contains `NaT` (GH14922)
- Bug in `DataFrame.reindex()` in which `method` was ignored when passing `columns` (GH14992)
- Bug in `DataFrame.loc` with indexing a `MultiIndex` with a `Series` indexer (GH14730, GH15424)
- Bug in `DataFrame.loc` with indexing a `MultiIndex` with a numpy array (GH15434)
- Bug in `Series.asof` which raised if the series contained all `np.nan` (GH15713)
- Bug in `.at` when selecting from a tz-aware column (GH15822)
- Bug in `Series.where()` and `DataFrame.where()` where array-like conditionals were being rejected (GH15414)
- Bug in `Series.where()` where TZ-aware data was converted to float representation (GH15701)
- Bug in `.loc` that would not return the correct dtype for scalar access for a `DataFrame` (GH11617)
- Bug in output formatting of a `MultiIndex` when names are integers (GH12223, GH15262)
- Bug in `Categorical.searchsorted()` where alphabetical instead of the provided categorical order was used (GH14522)
- Bug in `Series.iloc` where a `Categorical` object for list-like indexes input was returned, where a `Series` was expected. (GH14580)
- Bug in `DataFrame.isin` comparing datetimelike to empty frame (GH15473)
- Bug in `.reset_index()` when an all `NaN` level of a `MultiIndex` would fail (GH6322)

- Bug in `.reset_index()` when raising error for index name already present in `MultiIndex` columns ([GH16120](#))
- Bug in creating a `MultiIndex` with tuples and not passing a list of names; this will now raise `ValueError` ([GH15110](#))
- Bug in the HTML display with with a `MultiIndex` and truncation ([GH14882](#))
- Bug in the display of `.info()` where a qualifier (+) would always be displayed with a `MultiIndex` that contains only non-strings ([GH15245](#))
- Bug in `pd.concat()` where the names of `MultiIndex` of resulting `DataFrame` are not handled correctly when `None` is presented in the names of `MultiIndex` of input `DataFrame` ([GH15787](#))
- Bug in `DataFrame.sort_index()` and `Series.sort_index()` where `na_position` doesn't work with a `MultiIndex` ([GH14784](#), [GH16604](#))
- Bug in in `pd.concat()` when combining objects with a `CategoricalIndex` ([GH16111](#))
- Bug in indexing with a scalar and a `CategoricalIndex` ([GH16123](#))

## I/O

- Bug in `pd.to_numeric()` in which float and unsigned integer elements were being improperly casted ([GH14941](#), [GH15005](#))
- Bug in `pd.read_fwf()` where the `skiprows` parameter was not being respected during column width inference ([GH11256](#))
- Bug in `pd.read_csv()` in which the `dialect` parameter was not being verified before processing ([GH14898](#))
- Bug in `pd.read_csv()` in which missing data was being improperly handled with `usecols` ([GH6710](#))
- Bug in `pd.read_csv()` in which a file containing a row with many columns followed by rows with fewer columns would cause a crash ([GH14125](#))
- Bug in `pd.read_csv()` for the C engine where `usecols` were being indexed incorrectly with `parse_dates` ([GH14792](#))
- Bug in `pd.read_csv()` with `parse_dates` when multi-line headers are specified ([GH15376](#))
- Bug in `pd.read_csv()` with `float_precision='round_trip'` which caused a segfault when a text entry is parsed ([GH15140](#))
- Bug in `pd.read_csv()` when an index was specified and no values were specified as null values ([GH15835](#))
- Bug in `pd.read_csv()` in which certain invalid file objects caused the Python interpreter to crash ([GH15337](#))
- Bug in `pd.read_csv()` in which invalid values for `nrows` and `chunksize` were allowed ([GH15767](#))
- Bug in `pd.read_csv()` for the Python engine in which unhelpful error messages were being raised when parsing errors occurred ([GH15910](#))
- Bug in `pd.read_csv()` in which the `skipfooter` parameter was not being properly validated ([GH15925](#))
- Bug in `pd.to_csv()` in which there was numeric overflow when a timestamp index was being written ([GH15982](#))
- Bug in `pd.util.hashing.hash_pandas_object()` in which hashing of categoricals depended on the ordering of categories, instead of just their values. ([GH15143](#))
- Bug in `.to_json()` where `lines=True` and contents (keys or values) contain escaped characters ([GH15096](#))

- Bug in `.to_json()` causing single byte ascii characters to be expanded to four byte unicode (GH15344)
- Bug in `.to_json()` for the C engine where rollover was not correctly handled for case where frac is odd and diff is exactly 0.5 (GH15716, GH15864)
- Bug in `pd.read_json()` for Python 2 where `lines=True` and contents contain non-ascii unicode characters (GH15132)
- Bug in `pd.read_msgpack()` in which `Series` categoricals were being improperly processed (GH14901)
- Bug in `pd.read_msgpack()` which did not allow loading of a dataframe with an index of type `CategoricalIndex` (GH15487)
- Bug in `pd.read_msgpack()` when deserializing a `CategoricalIndex` (GH15487)
- Bug in `DataFrame.to_records()` with converting a `DatetimeIndex` with a timezone (GH13937)
- Bug in `DataFrame.to_records()` which failed with unicode characters in column names (GH11879)
- Bug in `.to_sql()` when writing a `DataFrame` with numeric index names (GH15404).
- Bug in `DataFrame.to_html()` with `index=False` and `max_rows` raising in `IndexError` (GH14998)
- Bug in `pd.read_hdf()` passing a `Timestamp` to the `where` parameter with a non date column (GH15492)
- Bug in `DataFrame.to_stata()` and `StataWriter` which produces incorrectly formatted files to be produced for some locales (GH13856)
- Bug in `StataReader` and `StataWriter` which allows invalid encodings (GH15723)
- Bug in the `Series` repr not showing the length when the output was truncated (GH15962).

## Plotting

- Bug in `DataFrame.hist` where `plt.tight_layout` caused an `AttributeError` (use `matplotlib >= 2.0.1`) (GH9351)
- Bug in `DataFrame.boxplot` where `fontsize` was not applied to the tick labels on both axes (GH15108)
- Bug in the date and time converters pandas registers with `matplotlib` not handling multiple dimensions (GH16026)
- Bug in `pd.scatter_matrix()` could accept either `color` or `c`, but not both (GH14855)

## Groupby/resample/rolling

- Bug in `.groupby(...).resample()` when passed the `on=` kwarg. (GH15021)
- Properly set `__name__` and `__qualname__` for `Groupby.*` functions (GH14620)
- Bug in `GroupBy.get_group()` failing with a categorical grouper (GH15155)
- Bug in `.groupby(...).rolling(...)` when `on` is specified and using a `DatetimeIndex` (GH15130, GH13966)
- Bug in `groupby` operations with `timedelta64` when passing `numeric_only=False` (GH5724)
- Bug in `groupby.apply()` coercing object dtypes to numeric types, when not all values were numeric (GH14423, GH15421, GH15670)
- Bug in `resample`, where a non-string `loffset` argument would not be applied when resampling a timeseries (GH13218)

- Bug in `DataFrame.groupby().describe()` when grouping on Index containing tuples (GH14848)
- Bug in `groupby().nunique()` with a datetimelike-grouper where bins counts were incorrect (GH13453)
- Bug in `groupby.transform()` that would coerce the resultant dtypes back to the original (GH10972, GH11444)
- Bug in `groupby.agg()` incorrectly localizing timezone on datetime (GH15426, GH10668, GH13046)
- Bug in `.rolling/expanding()` functions where `count()` was not counting `np.Inf`, nor handling object dtypes (GH12541)
- Bug in `.rolling()` where `pd.Timedelta` or `datetime.timedelta` was not accepted as a window argument (GH15440)
- Bug in `Rolling.quantile` function that caused a segmentation fault when called with a quantile value outside of the range `[0, 1]` (GH15463)
- Bug in `DataFrame.resample().median()` if duplicate column names are present (GH14233)

## Sparse

- Bug in `SparseSeries.reindex` on single level with list of length 1 (GH15447)
- Bug in repr-formatting a `SparseDataFrame` after a value was set on (a copy of) one of its series (GH15488)
- Bug in `SparseDataFrame` construction with lists not coercing to dtype (GH15682)
- Bug in sparse array indexing in which indices were not being validated (GH15863)

## Reshaping

- Bug in `pd.merge_asof()` where `left_index` or `right_index` caused a failure when multiple `by` was specified (GH15676)
- Bug in `pd.merge_asof()` where `left_index/right_index` together caused a failure when `tolerance` was specified (GH15135)
- Bug in `DataFrame.pivot_table()` where `dropna=True` would not drop all-NaN columns when the columns was a category dtype (GH15193)
- Bug in `pd.melt()` where passing a tuple value for `value_vars` caused a `TypeError` (GH15348)
- Bug in `pd.pivot_table()` where no error was raised when values argument was not in the columns (GH14938)
- Bug in `pd.concat()` in which concatenating with an empty dataframe with `join='inner'` was being improperly handled (GH15328)
- Bug with `sort=True` in `DataFrame.join` and `pd.merge` when joining on indexes (GH15582)
- Bug in `DataFrame.nsmallest` and `DataFrame.nlargest` where identical values resulted in duplicated rows (GH15297)
- Bug in `pandas.pivot_table()` incorrectly raising `UnicodeError` when passing unicode input for margins keyword (GH13292)

## Numeric

- Bug in `.rank()` which incorrectly ranks ordered categories (GH15420)
- Bug in `.corr()` and `.cov()` where the column and index were the same object (GH14617)
- Bug in `.mode()` where mode was not returned if was only a single value (GH15714)
- Bug in `pd.cut()` with a single bin on an all 0s array (GH15428)
- Bug in `pd.qcut()` with a single quantile and an array with identical values (GH15431)
- Bug in `pandas.tools.utils.cartesian_product()` with large input can cause overflow on windows (GH15265)
- Bug in `.eval()` which caused multi-line evals to fail with local variables not on the first line (GH15342)

## Other

- Compat with SciPy 0.19.0 for testing on `.interpolate()` (GH15662)
- Compat for 32-bit platforms for `.qcut/cut`; bins will now be `int64` dtype (GH14866)
- Bug in interactions with Qt when a `QtApplication` already exists (GH14372)
- Avoid use of `np.finfo()` during `import pandas` removed to mitigate deadlock on Python GIL misuse (GH14641)

## Contributors

A total of 204 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

## 6.8 Version 0.19

### 6.8.1 v0.19.2 (December 24, 2016)

{{ header }}

This is a minor bug-fix release in the 0.19.x series and includes some small regression fixes, bug fixes and performance improvements. We recommend that all users upgrade to this version.

Highlights include:

- Compatibility with Python 3.6
- Added a [Pandas Cheat Sheet](#). (GH13202).

#### What's new in v0.19.2

- *Enhancements*
- *Performance improvements*
- *Bug fixes*
- *Contributors*

#### Enhancements

The `pd.merge_asof()`, added in 0.19.0, gained some improvements:

- `pd.merge_asof()` gained `left_index/right_index` and `left_by/right_by` arguments (GH14253)
- `pd.merge_asof()` can take multiple columns in `by` parameter and has specialized dtypes for better performance (GH13936)

## Performance improvements

- Performance regression with `PeriodIndex` (GH14822)
- Performance regression in indexing with `getitem` (GH14930)
- Improved performance of `.replace()` (GH12745)
- Improved performance `Series` creation with a datetime index and dictionary data (GH14894)

## Bug fixes

- Compat with python 3.6 for pickling of some offsets (GH14685)
- Compat with python 3.6 for some indexing exception types (GH14684, GH14689)
- Compat with python 3.6 for deprecation warnings in the test suite (GH14681)
- Compat with python 3.6 for Timestamp pickles (GH14689)
- Compat with `dateutil==2.6.0`; segfault reported in the testing suite (GH14621)
- Allow nanoseconds in `Timestamp.replace` as a kwarg (GH14621)
- Bug in `pd.read_csv` in which aliasing was being done for `na_values` when passed in as a dictionary (GH14203)
- Bug in `pd.read_csv` in which column indices for a dict-like `na_values` were not being respected (GH14203)
- Bug in `pd.read_csv` where reading files fails, if the number of headers is equal to the number of lines in the file (GH14515)
- Bug in `pd.read_csv` for the Python engine in which an unhelpful error message was being raised when multi-char delimiters were not being respected with quotes (GH14582)
- Fix bugs (GH14734, GH13654) in `pd.read_sas` and `pandas.io.sas.sas7bdat.SAS7BDATReader` that caused problems when reading a SAS file incrementally.
- Bug in `pd.read_csv` for the Python engine in which an unhelpful error message was being raised when `skipfooter` was not being respected by Python's CSV library (GH13879)
- Bug in `.fillna()` in which timezone aware `datetime64` values were incorrectly rounded (GH14872)
- Bug in `.groupby(..., sort=True)` of a non-lexsorted `MultiIndex` when grouping with multiple levels (GH14776)
- Bug in `pd.cut` with negative values and a single bin (GH14652)
- Bug in `pd.to_numeric` where a 0 was not unsigned on a `downcast='unsigned'` argument (GH14401)
- Bug in plotting regular and irregular timeseries using shared axes (`sharex=True` or `ax.twinx()`) (GH13341, GH14322).
- Bug in not propagating exceptions in parsing invalid datetimes, noted in python 3.6 (GH14561)
- Bug in resampling a `DatetimeIndex` in local TZ, covering a DST change, which would raise `AmbiguousTimeError` (GH14682)
- Bug in indexing that transformed `RecursionError` into `KeyError` or `IndexingError` (GH14554)
- Bug in `HDFStore` when writing a `MultiIndex` when using `data_columns=True` (GH14435)
- Bug in `HDFStore.append()` when writing a `Series` and passing a `min_itemsize` argument containing a value for the `index` (GH11412)

- Bug when writing to a `HDFStore` in table format with a `min_itemsize` value for the index and without asking to append (GH10381)
- Bug in `Series.groupby.nunique()` raising an `IndexError` for an empty `Series` (GH12553)
- Bug in `DataFrame.nlargest` and `DataFrame.nsmallest` when the index had duplicate values (GH13412)
- Bug in clipboard functions on linux with python2 with unicode and separators (GH13747)
- Bug in clipboard functions on Windows 10 and python 3 (GH14362, GH12807)
- Bug in `.to_clipboard()` and Excel compat (GH12529)
- Bug in `DataFrame.combine_first()` for integer columns (GH14687).
- Bug in `pd.read_csv()` in which the `dtype` parameter was not being respected for empty data (GH14712)
- Bug in `pd.read_csv()` in which the `nrows` parameter was not being respected for large input when using the C engine for parsing (GH7626)
- Bug in `pd.merge_asof()` could not handle timezone-aware `DatetimeIndex` when a tolerance was specified (GH14844)
- Explicit check in `to_stata` and `StataWriter` for out-of-range values when writing doubles (GH14618)
- Bug in `.plot(kind='kde')` which did not drop missing values to generate the KDE Plot, instead generating an empty plot. (GH14821)
- Bug in `unstack()` if called with a list of column(s) as an argument, regardless of the dtypes of all columns, they get coerced to `object` (GH11847)

## 6.8.2 v0.19.1 (November 3, 2016)

{{ header }}

This is a minor bug-fix release from 0.19.0 and includes some small regression fixes, bug fixes and performance improvements. We recommend that all users upgrade to this version.

### What's new in v0.19.1

- *Performance improvements*
- *Bug fixes*
- *Contributors*

### Performance improvements

- Fixed performance regression in factorization of `Period` data ([GH14338](#))
- Fixed performance regression in `Series.asof(where)` when `where` is a scalar ([GH14461](#))
- Improved performance in `DataFrame.asof(where)` when `where` is a scalar ([GH14461](#))
- Improved performance in `.to_json()` when `lines=True` ([GH14408](#))
- Improved performance in certain types of *loc* indexing with a `MultiIndex` ([GH14551](#)).

## Bug fixes

- Source installs from PyPI will now again work without `cython` installed, as in previous versions (GH14204)
- Compat with Cython 0.25 for building (GH14496)
- Fixed regression where user-provided file handles were closed in `read_csv` (c engine) (GH14418).
- Fixed regression in `DataFrame.quantile` when missing values were present in some columns (GH14357).
- Fixed regression in `Index.difference` where the `freq` of a `DatetimeIndex` was incorrectly set (GH14323)
- Added back `pandas.core.common.array_equivalent` with a deprecation warning (GH14555).
- Bug in `pd.read_csv` for the C engine in which quotation marks were improperly parsed in skipped rows (GH14459)
- Bug in `pd.read_csv` for Python 2.x in which Unicode quote characters were no longer being respected (GH14477)
- Fixed regression in `Index.append` when categorical indices were appended (GH14545).
- Fixed regression in `pd.DataFrame` where constructor fails when given dict with `None` value (GH14381)
- Fixed regression in `DatetimeIndex._maybe_cast_slice_bound` when index is empty (GH14354).
- Bug in localizing an ambiguous timezone when a boolean is passed (GH14402)
- Bug in `TimedeltaIndex` addition with a `Datetime`-like object where addition overflow in the negative direction was not being caught (GH14068, GH14453)
- Bug in string indexing against data with object `Index` may raise `AttributeError` (GH14424)
- Correctly raise `ValueError` on empty input to `pd.eval()` and `df.query()` (GH13139)
- Bug in `RangeIndex.intersection` when result is a empty set (GH14364).
- Bug in groupby-transform broadcasting that could cause incorrect dtype coercion (GH14457)
- Bug in `Series.__setitem__` which allowed mutating read-only arrays (GH14359).
- Bug in `DataFrame.insert` where multiple calls with duplicate columns can fail (GH14291)
- `pd.merge()` will raise `ValueError` with non-boolean parameters in passed boolean type arguments (GH14434)
- Bug in `Timestamp` where dates very near the minimum (1677-09) could underflow on creation (GH14415)
- Bug in `pd.concat` where names of the keys were not propagated to the resulting `MultiIndex` (GH14252)
- Bug in `pd.concat` where axis cannot take string parameters 'rows' or 'columns' (GH14369)
- Bug in `pd.concat` with dataframes heterogeneous in length and tuple keys (GH14438)
- Bug in `MultiIndex.set_levels` where illegal level values were still set after raising an error (GH13754)
- Bug in `DataFrame.to_json` where `lines=True` and a value contained a `}` character (GH14391)
- Bug in `df.groupby` causing an `AttributeError` when grouping a single index frame by a column and the index level (GH14327)
- Bug in `df.groupby` where `TypeError` raised when `pd.Grouper(key=...)` is passed in a list (GH14334)
- Bug in `pd.pivot_table` may raise `TypeError` or `ValueError` when `index` or `columns` is not scalar and `values` is not specified (GH14380)

### 6.8.3 v0.19.0 (October 2, 2016)

{{ header }}

This is a major release from 0.18.1 and includes number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

- `merge_asof()` for asof-style time-series joining, see [here](#)
- `.rolling()` is now time-series aware, see [here](#)
- `read_csv()` now supports parsing Categorical data, see [here](#)
- A function `union_categorical()` has been added for combining categoricals, see [here](#)
- `PeriodIndex` now has its own `period` dtype, and changed to be more consistent with other `Index` classes. See [here](#)
- Sparse data structures gained enhanced support of `int` and `bool` dtypes, see [here](#)
- Comparison operations with `Series` no longer ignores the index, see [here](#) for an overview of the API changes.
- Introduction of a pandas development API for utility functions, see [here](#).
- Deprecation of `Panel4D` and `PanelND`. We recommend to represent these types of n-dimensional data with the [xarray](#) package.
- Removal of the previously deprecated modules `pandas.io.data`, `pandas.io.wb`, `pandas.tools.rplot`.

**Warning:** pandas >= 0.19.0 will no longer silence numpy ufunc warnings upon import, see [here](#).

#### What's new in v0.19.0

- *New features*
  - *merge\_asof for asof-style time-series joining*
  - *.rolling() is now time-series aware*
  - *read\_csv has improved support for duplicate column names*
  - *read\_csv supports parsing Categorical directly*
  - *Categorical concatenation*
  - *Semi-month offsets*
  - *New Index methods*
  - *Google BigQuery Enhancements*
  - *Fine-grained numpy errstate*
  - *get\_dummies now returns integer dtypes*
  - *Downcast values to smallest possible dtype in to\_numeric*
  - *pandas development API*
  - *Other enhancements*

- *API changes*
  - *Series.tolist() will now return Python types*
  - *Series operators for different indexes*
    - \* *Arithmetic operators*
    - \* *Comparison operators*
    - \* *Logical operators*
    - \* *Flexible comparison methods*
  - *Series type promotion on assignment*
  - *.to\_datetime() changes*
  - *Merging changes*
  - *.describe() changes*
  - *Period changes*
    - \* *PeriodIndex now has period dtype*
    - \* *Period('NaT') now returns pd.NaT*
    - \* *PeriodIndex.values now returns array of Period object*
  - *Index +/- no longer used for set operations*
  - *Index.difference and .symmetric\_difference changes*
  - *Index.unique consistently returns Index*
  - *MultiIndex constructors, groupby and set\_index preserve categorical dtypes*
  - *read\_csv will progressively enumerate chunks*
  - *Sparse Changes*
    - \* *int64 and bool support enhancements*
    - \* *Operators now preserve dtypes*
    - \* *Other sparse fixes*
  - *Indexer dtype changes*
  - *Other API changes*
- *Deprecations*
- *Removal of prior version deprecations/changes*
- *Performance improvements*
- *Bug fixes*
- *Contributors*

## New features

### merge\_asof for asof-style time-series joining

A long-time requested feature has been added through the `merge_asof()` function, to support asof style joining of time-series ([GH1870](#), [GH13695](#), [GH13709](#), [GH13902](#)). Full documentation is [here](#).

The `merge_asof()` performs an asof merge, which is similar to a left-join except that we match on nearest key rather than equal keys.

```
In [1]: left = pd.DataFrame({'a': [1, 5, 10],
...:                        'left_val': ['a', 'b', 'c']})
...:
...:

In [2]: right = pd.DataFrame({'a': [1, 2, 3, 6, 7],
...:                          'right_val': [1, 2, 3, 6, 7]})
...:
...:

In [3]: left
Out[3]:
   a left_val
0  1         a
1  5         b
2 10         c

[3 rows x 2 columns]

In [4]: right
Out[4]:
   a right_val
0  1          1
1  2          2
2  3          3
3  6          6
4  7          7

[5 rows x 2 columns]
```

We typically want to match exactly when possible, and use the most recent value otherwise.

```
In [5]: pd.merge_asof(left, right, on='a')
Out[5]:
   a left_val right_val
0  1         a         1
1  5         b         3
2 10         c         7

[3 rows x 3 columns]
```

We can also match rows ONLY with prior data, and not an exact match.

```
In [6]: pd.merge_asof(left, right, on='a', allow_exact_matches=False)
Out[6]:
   a left_val right_val
0  1         a      NaN
1  5         b      3.0
2 10         c      7.0
```

(continues on next page)

(continued from previous page)

[3 rows x 3 columns]

In a typical time-series example, we have trades and quotes and we want to asof-join them. This also illustrates using the `by` parameter to group data before merging.

```
In [7]: trades = pd.DataFrame({
...:     'time': pd.to_datetime(['20160525 13:30:00.023',
...:                             '20160525 13:30:00.038',
...:                             '20160525 13:30:00.048',
...:                             '20160525 13:30:00.048',
...:                             '20160525 13:30:00.048']),
...:     'ticker': ['MSFT', 'MSFT',
...:                'GOOG', 'GOOG', 'AAPL'],
...:     'price': [51.95, 51.95,
...:               720.77, 720.92, 98.00],
...:     'quantity': [75, 155,
...:                  100, 100, 100]},
...:     columns=['time', 'ticker', 'price', 'quantity'])
...:
```

```
In [8]: quotes = pd.DataFrame({
...:     'time': pd.to_datetime(['20160525 13:30:00.023',
...:                             '20160525 13:30:00.023',
...:                             '20160525 13:30:00.030',
...:                             '20160525 13:30:00.041',
...:                             '20160525 13:30:00.048',
...:                             '20160525 13:30:00.049',
...:                             '20160525 13:30:00.072',
...:                             '20160525 13:30:00.075']),
...:     'ticker': ['GOOG', 'MSFT', 'MSFT', 'MSFT',
...:                'GOOG', 'AAPL', 'GOOG', 'MSFT'],
...:     'bid': [720.50, 51.95, 51.97, 51.99,
...:             720.50, 97.99, 720.50, 52.01],
...:     'ask': [720.93, 51.96, 51.98, 52.00,
...:             720.93, 98.01, 720.88, 52.03]},
...:     columns=['time', 'ticker', 'bid', 'ask'])
...:
```

In [9]: trades

Out [9]:

|   | time                    | ticker | price  | quantity |
|---|-------------------------|--------|--------|----------|
| 0 | 2016-05-25 13:30:00.023 | MSFT   | 51.95  | 75       |
| 1 | 2016-05-25 13:30:00.038 | MSFT   | 51.95  | 155      |

| 2 | 2016-05-25 13:30:00.030 | MSFT   | 51.97  | 51.98  |

(continues on next page)

(continued from previous page)

```

3 2016-05-25 13:30:00.041  MSFT  51.99  52.00
4 2016-05-25 13:30:00.048  GOOG  720.50  720.93
5 2016-05-25 13:30:00.049  AAPL  97.99  98.01
6 2016-05-25 13:30:00.072  GOOG  720.50  720.88
7 2016-05-25 13:30:00.075  MSFT  52.01  52.03

```

[8 rows x 4 columns]

An asof merge joins on the `on`, typically a datetimelike field, which is ordered, and in this case we are using a grouper in the `by` field. This is like a left-outer join, except that forward filling happens automatically taking the most recent non-NaN value.

```

In [11]: pd.merge_asof(trades, quotes,
.....:                 on='time',
.....:                 by='ticker')
.....:

```

Out [11]:

```

           time ticker  price  quantity  bid  ask
0 2016-05-25 13:30:00.023  MSFT   51.95         75  51.95  51.96
1 2016-05-25 13:30:00.038  MSFT   51.95         155  51.97  51.98
2 2016-05-25 13:30:00.048  GOOG  720.77         100  720.50  720.93
3 2016-05-25 13:30:00.048  GOOG  720.92         100  720.50  720.93
4 2016-05-25 13:30:00.048  AAPL   98.00         100    NaN    NaN

```

[5 rows x 6 columns]

This returns a merged DataFrame with the entries in the same order as the original left passed DataFrame (`trades` in this case), with the fields of the `quotes` merged.

### `.rolling()` is now time-series aware

`.rolling()` objects are now time-series aware and can accept a time-series offset (or convertible) for the window argument (GH13327, GH12995). See the full documentation *here*.

```

In [12]: dft = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]},
.....:                      index=pd.date_range('20130101 09:00:00',
.....:                                           periods=5, freq='s'))
.....:

```

In [13]: dft

Out [13]:

```

           B
2013-01-01 09:00:00  0.0
2013-01-01 09:00:01  1.0
2013-01-01 09:00:02  2.0
2013-01-01 09:00:03  NaN
2013-01-01 09:00:04  4.0

```

[5 rows x 1 columns]

This is a regular frequency index. Using an integer window parameter works to roll along the window frequency.

In [14]: dft.rolling(2).sum()

Out [14]:

B

(continues on next page)

(continued from previous page)

```

2013-01-01 09:00:00 NaN
2013-01-01 09:00:01 1.0
2013-01-01 09:00:02 3.0
2013-01-01 09:00:03 NaN
2013-01-01 09:00:04 NaN

[5 rows x 1 columns]

In [15]: dft.rolling(2, min_periods=1).sum()
Out [15]:

```

## read\_csv has improved support for duplicate column names

Duplicate column names are now supported in `read_csv()` whether they are in the file or passed in as the `names` parameter (GH7160, GH9424)

```
In [24]: data = '0,1,2\n3,4,5'
```

```
In [25]: names = ['a', 'b', 'a']
```

### Previous behavior:

```
In [2]: pd.read_csv(StringIO(data), names=names)
```

```
Out[2]:
```

```
   a  b  a
0  2  1  2
1  5  4  5
```

The first `a` column contained the same data as the second `a` column, when it should have contained the values `[0, 3]`.

### New behavior:

```
In [26]: pd.read_csv(StringIO(data), names=names)
```

```

```

## read\_csv supports parsing Categorical directly

The `read_csv()` function now supports parsing a `Categorical` column when specified as a dtype (GH10153). Depending on the structure of the data, this can result in a faster parse time and lower memory usage compared to converting to `Categorical` after parsing. See the *io docs* [here](#).

```
In [27]: data = 'col1,col2,col3\na,b,1\na,b,2\nc,d,3'

In [28]: pd.read_csv(StringIO(data))
Out[28]:
   col1 col2 col3
0     a     b     1
1     a     b     2
2     c     d     3

[3 rows x 3 columns]

In [29]: pd.read_csv(StringIO(data)).dtypes
Out[29]:
col1     object
col2     object
col3     int64
Length: 3, dtype: object

In [30]: pd.read_csv(StringIO(data), dtype='category').dtypes
Out[30]:
col1     category
col2     category
col3     category
Length: 3, dtype: object
```

Individual columns can be parsed as a `Categorical` using a dict specification

```
In [31]: pd.read_csv(StringIO(data), dtype={'col1': 'category'}).dtypes
Out[31]:
col1     category
col2     object
col3     int64
Length: 3, dtype: object
```

**Note:** The resulting categories will always be parsed as strings (object dtype). If the categories are numeric they can be converted using the `to_numeric()` function, or as appropriate, another converter such as `to_datetime()`.

```
In [32]: df = pd.read_csv(StringIO(data), dtype='category')

In [33]: df.dtypes
Out[33]:
col1     category
col2     category
col3     category
Length: 3, dtype: object

In [34]: df['col3']
Out[34]:
0     1
1     2
```

(continues on next page)

(continued from previous page)

```

2      3
Name: col3, Length: 3, dtype: category
Categories (3, object): [1, 2, 3]

In [35]: df['col3'].cat.categories = pd.to_numeric(df['col3'].cat.categories)

In [36]: df['col3']
Out[36]:
0      1
1      2
2      3
Name: col3, Length: 3, dtype: category
Categories (3, int64): [1, 2, 3]

```

### Categorical concatenation

- A function `union_categoricals()` has been added for combining categoricals, see *Unioning Categoricals* (GH13361, GH13763, GH13846, GH14173)

```

In [37]: from pandas.api.types import union_categoricals

In [38]: a = pd.Categorical(["b", "c"])

In [39]: b = pd.Categorical(["a", "b"])

In [40]: union_categoricals([a, b])
Out[40]:
[b, c, a, b]
Categories (3, object): [b, c, a]

```

- `concat` and `append` now can concat category dtypes with different categories as object dtype (GH13524)

```

In [41]: s1 = pd.Series(['a', 'b'], dtype='category')

In [42]: s2 = pd.Series(['b', 'c'], dtype='category')

```

#### Previous behavior:

```

In [1]: pd.concat([s1, s2])
ValueError: incompatible categories in categorical concat

```

#### New behavior:

```

In [43]: pd.concat([s1, s2])
Out[43]:
0      a
1      b
0      b
1      c
Length: 4, dtype: object

```

## Semi-month offsets

Pandas has gained new frequency offsets, `SemiMonthEnd` ('SM') and `SemiMonthBegin` ('SMS'). These provide date offsets anchored (by default) to the 15th and end of month, and 15th and 1st of month respectively. (GH1543)

```
In [44]: from pandas.tseries.offsets import SemiMonthEnd, SemiMonthBegin
```

### SemiMonthEnd:

```
In [45]: pd.Timestamp('2016-01-01') + SemiMonthEnd()
Out[45]: Timestamp('2016-01-15 00:00:00')

In [46]: pd.date_range('2015-01-01', freq='SM', periods=4)
Out[46]: DatetimeIndex(['2015-01-15', '2015-01-31', '2015-02-15', '2015-02-28'],
↳dtype='datetime64[ns]', freq='SM-15')
```

### SemiMonthBegin:

```
In [47]: pd.Timestamp('2016-01-01') + SemiMonthBegin()
Out[47]: Timestamp('2016-01-15 00:00:00')

In [48]: pd.date_range('2015-01-01', freq='SMS', periods=4)
Out[48]: DatetimeIndex(['2015-01-01', '2015-01-15', '2015-02-01', '2015-02-15'],
↳dtype='datetime64[ns]', freq='SMS-15')
```

Using the anchoring suffix, you can also specify the day of month to use instead of the 15th.

```
In [49]: pd.date_range('2015-01-01', freq='SMS-16', periods=4)
Out[49]: DatetimeIndex(['2015-01-01', '2015-01-16', '2015-02-01', '2015-02-16'],
↳dtype='datetime64[ns]', freq='SMS-16')

In [50]: pd.date_range('2015-01-01', freq='SM-14', periods=4)
Out[50]: DatetimeIndex(['2015-01-14', '2015-01-31', '2015-02-14', '2015-02-28'],
↳dtype='datetime64[ns]', freq='SM-14')
```

## New Index methods

The following methods and options are added to `Index`, to be more consistent with the `Series` and `DataFrame` API.

`Index` now supports the `.where()` function for same shape indexing (GH13170)

```
In [51]: idx = pd.Index(['a', 'b', 'c'])
In [52]: idx.where([True, False, True])
Out[52]: Index(['a', nan, 'c'], dtype='object')
```

`Index` now supports `.dropna()` to exclude missing values (GH6194)

```
In [53]: idx = pd.Index([1, 2, np.nan, 4])
In [54]: idx.dropna()
Out[54]: Float64Index([1.0, 2.0, 4.0], dtype='float64')
```

For `MultiIndex`, values are dropped if any level is missing by default. Specifying `how='all'` only drops values where all levels are missing.

```
In [55]: midx = pd.MultiIndex.from_arrays([[1, 2, np.nan, 4],
.....:                                  [1, 2, np.nan, np.nan]])
.....:

In [56]: midx
Out [56]:
MultiIndex([(1.0, 1.0),
            (2.0, 2.0),
            (nan, nan),
            (4.0, nan)],
           )

In [57]: midx.dropna()
Out [57]:
MultiIndex([(1, 1),
            (2, 2)],
           )

In [58]: midx.dropna(how='all')
Out [58]:
MultiIndex([(1, 1.0),
            (2, 2.0),
            (4, nan)],
           )
```

Index now supports `.str.extractall()` which returns a DataFrame, see the *docs here* (GH10008, GH13156)

```
In [59]: idx = pd.Index(["a1a2", "b1", "c1"])

In [60]: idx.str.extractall(r"[ab](?P<digit>\d)")
Out [60]:
      digit
match
0 0      1
  1      2
1 0      1

[3 rows x 1 columns]
```

`Index.astype()` now accepts an optional boolean argument `copy`, which allows optional copying if the requirements on dtype are satisfied (GH13209)

## Google BigQuery Enhancements

- The `read_gbq()` method has gained the `dialect` argument to allow users to specify whether to use BigQuery's legacy SQL or BigQuery's standard SQL. See the *docs* for more details (GH13615).
- The `to_gbq()` method now allows the DataFrame column order to differ from the destination table schema (GH11359).

## Fine-grained numpy errstate

Previous versions of pandas would permanently silence numpy's ufunc error handling when pandas was imported. Pandas did this in order to silence the warnings that would arise from using numpy ufuncs on missing data, which are usually represented as NaNs. Unfortunately, this silenced legitimate warnings arising in non-pandas code in the application. Starting with 0.19.0, pandas will use the `numpy.errstate` context manager to silence these warnings in a more fine-grained manner, only around where these operations are actually used in the pandas code base. (GH13109, GH13145)

After upgrading pandas, you may see *new* `RuntimeWarnings` being issued from your code. These are likely legitimate, and the underlying cause likely existed in the code when using previous versions of pandas that simply silenced the warning. Use `numpy.errstate` around the source of the `RuntimeWarning` to control how these conditions are handled.

## get\_dummies now returns integer dtypes

The `pd.get_dummies` function now returns dummy-encoded columns as small integers, rather than floats (GH8725). This should provide an improved memory footprint.

### Previous behavior:

```
In [1]: pd.get_dummies(['a', 'b', 'a', 'c']).dtypes
Out[1]:
a    float64
b    float64
c    float64
dtype: object
```

### New behavior:

```
In [61]: pd.get_dummies(['a', 'b', 'a', 'c']).dtypes
Out[61]:
a    uint8
b    uint8
c    uint8
Length: 3, dtype: object
```

## Downcast values to smallest possible dtype in to\_numeric

`pd.to_numeric()` now accepts a `downcast` parameter, which will downcast the data if possible to smallest specified numerical dtype (GH13352)

```
In [62]: s = ['1', 2, 3]
In [63]: pd.to_numeric(s, downcast='unsigned')
Out[63]: array([1, 2, 3], dtype=uint8)
In [64]: pd.to_numeric(s, downcast='integer')
Out[64]: array([1, 2, 3], dtype=int8)
```

## pandas development API

As part of making pandas API more uniform and accessible in the future, we have created a standard sub-package of pandas, `pandas.api` to hold public API's. We are starting by exposing type introspection functions in `pandas.api.types`. More sub-packages and officially sanctioned API's will be published in future versions of pandas (GH13147, GH13634)

The following are now part of this API:

```
In [65]: import pprint

In [66]: from pandas.api import types

In [67]: funcs = [f for f in dir(types) if not f.startswith('_')]

In [68]: pprint.pprint(funcs)
['CategoricalDtype',
 'DatetimeTZDtype',
 'IntervalDtype',
 'PeriodDtype',
 'infer_dtype',
 'is_array_like',
 'is_bool',
 'is_bool_dtype',
 'is_categorical',
 'is_categorical_dtype',
 'is_complex',
 'is_complex_dtype',
 'is_datetime64_any_dtype',
 'is_datetime64_dtype',
 'is_datetime64_ns_dtype',
 'is_datetime64tz_dtype',
 'is_dict_like',
 'is_dtype_equal',
 'is_extension_array_dtype',
 'is_extension_type',
 'is_file_like',
 'is_float',
 'is_float_dtype',
 'is_hashable',
 'is_int64_dtype',
 'is_integer',
 'is_integer_dtype',
 'is_interval',
 'is_interval_dtype',
 'is_iterator',
 'is_list_like',
 'is_named_tuple',
 'is_number',
 'is_numeric_dtype',
 'is_object_dtype',
 'is_period_dtype',
 'is_re',
 'is_re_compilable',
 'is_scalar',
 'is_signed_integer_dtype',
 'is_sparse',
 'is_string_dtype',
```

(continues on next page)

(continued from previous page)

```
'is_timedelta64_dtype',
'is_timedelta64_ns_dtype',
'is_unsigned_integer_dtype',
'pandas_dtype',
'union_categoricals']
```

**Note:** Calling these functions from the internal module `pandas.core.common` will now show a `DeprecationWarning` (GH13990)

## Other enhancements

- `Timestamp` can now accept positional and keyword parameters similar to `datetime.datetime()` (GH10758, GH11630)

```
In [69]: pd.Timestamp(2012, 1, 1)
Out [69]: Timestamp('2012-01-01 00:00:00')

In [70]: pd.Timestamp(year=2012, month=1, day=1, hour=8, minute=30)
Out [70]: Timestamp('2012-01-01 08:30:00')
```

- The `.resample()` function now accepts a `on=` or `level=` parameter for resampling on a datetimelike column or `MultiIndex` level (GH13500)

```
In [71]: df = pd.DataFrame({'date': pd.date_range('2015-01-01', freq='W',
↳ periods=5),
    ....:                   'a': np.arange(5)},
    ....:                   index=pd.MultiIndex.from_arrays([[1, 2, 3, 4, 5],
    ....:                                                     pd.date_range('2015-
↳ 01-01',
    ....:                                     freq='W
↳ ',
    ....:                                     )
    ....:                   ], names=['v', 'd']))
↳ periods=5)

In [72]: df
Out [72]:
```

|     | date       | a          |   |
|-----|------------|------------|---|
| v d |            |            |   |
| 1   | 2015-01-04 | 2015-01-04 | 0 |
| 2   | 2015-01-11 | 2015-01-11 | 1 |
| 3   | 2015-01-18 | 2015-01-18 | 2 |
| 4   | 2015-01-25 | 2015-01-25 | 3 |
| 5   | 2015-02-01 | 2015-02-01 | 4 |

```
[5 rows x 2 columns]

In [73]: df.resample('M', on='date').sum()
Out [73]:
```

|            | a |
|------------|---|
| date       |   |
| 2015-01-31 | 6 |

(continues on next page)

(continued from previous page)

```

2015-02-28  4

[2 rows x 1 columns]

In [74]: df.resample('M', level='d').sum()
Out [74]:
           a
d
2015-01-31  6
2015-02-28  4

[2 rows x 1 columns]

```

- The `.get_credentials()` method of `GbqConnector` can now first try to fetch the application default credentials. See the docs for more details ([GH13577](#)).
- The `.tz_localize()` method of `DatetimeIndex` and `Timestamp` has gained the `errors` keyword, so you can potentially coerce nonexistent timestamps to `NaT`. The default behavior remains to raising a `NonExistentTimeError` ([GH13057](#)).
- `.to_hdf/read_hdf()` now accept path objects (e.g. `pathlib.Path`, `py.path.local`) for the file path ([GH11773](#)).
- The `pd.read_csv()` with `engine='python'` has gained support for the `decimal` ([GH12933](#)), `na_filter` ([GH13321](#)) and the `memory_map` option ([GH13381](#)).
- Consistent with the Python API, `pd.read_csv()` will now interpret `+inf` as positive infinity ([GH13274](#)).
- The `pd.read_html()` has gained support for the `na_values`, `converters`, `keep_default_na` options ([GH13461](#)).
- `Categorical.astype()` now accepts an optional boolean argument `copy`, effective when `dtype` is categorical ([GH13209](#)).
- `DataFrame` has gained the `.asof()` method to return the last non-`NaN` values according to the selected subset ([GH13358](#)).
- The `DataFrame` constructor will now respect key ordering if a list of `OrderedDict` objects are passed in ([GH13304](#)).
- `pd.read_html()` has gained support for the `decimal` option ([GH12907](#)).
- `Series` has gained the properties `.is_monotonic`, `.is_monotonic_increasing`, `.is_monotonic_decreasing`, similar to `Index` ([GH13336](#)).
- `DataFrame.to_sql()` now allows a single value as the SQL type for all columns ([GH11886](#)).
- `Series.append` now supports the `ignore_index` option ([GH13677](#)).
- `.to_stata()` and `StataWriter` can now write variable labels to Stata `dta` files using a dictionary to make column names to labels ([GH13535](#), [GH13536](#)).
- `.to_stata()` and `StataWriter` will automatically convert `datetime64[ns]` columns to Stata format `%tc`, rather than raising a `ValueError` ([GH12259](#)).
- `read_stata()` and `StataReader` raise with a more explicit error message when reading Stata files with repeated value labels when `convert_categoricals=True` ([GH13923](#)).
- `DataFrame.style` will now render sparsified `MultiIndexes` ([GH11655](#)).
- `DataFrame.style` will now show column level names (e.g. `DataFrame.columns.names`) ([GH13775](#)).

- DataFrame has gained support to re-order the columns based on the values in a row using `df.sort_values(by='...', axis=1)` (GH10806)

```
In [75]: df = pd.DataFrame({'A': [2, 7], 'B': [3, 5], 'C': [4, 8]},
.....:                      index=['row1', 'row2'])
.....:

In [76]: df
Out[76]:
   A  B  C
row1 2  3  4
row2 7  5  8

[2 rows x 3 columns]

In [77]: df.sort_values(by='row2', axis=1)
Out[77]:
   B  A  C
row1 3  2  4
row2 5  7  8

[2 rows x 3 columns]
```

- Added documentation to *I/O* regarding the perils of reading in columns with mixed dtypes and how to handle it (GH13746)
- `to_html()` now has a `border` argument to control the value in the opening `<table>` tag. The default is the value of the `html.border` option, which defaults to 1. This also affects the notebook HTML repr, but since Jupyter's CSS includes a `border-width` attribute, the visual effect is the same. (GH11563).
- Raise `ImportError` in the `sql` functions when `sqlalchemy` is not installed and a connection string is used (GH11920).
- Compatibility with `matplotlib 2.0`. Older versions of `pandas` should also work with `matplotlib 2.0` (GH13333)
- `Timestamp`, `Period`, `DatetimeIndex`, `PeriodIndex` and `.dt` accessor have gained a `.is_leap_year` property to check whether the date belongs to a leap year. (GH13727)
- `astype()` will now accept a dict of column name to data types mapping as the `dtype` argument. (GH12086)
- The `pd.read_json` and `DataFrame.to_json` has gained support for reading and writing json lines with `lines` option see *Line delimited json* (GH9180)
- `read_excel()` now supports the `true_values` and `false_values` keyword arguments (GH13347)
- `groupby()` will now accept a scalar and a single-element list for specifying `level` on a non-`MultiIndex` grouper. (GH13907)
- Non-convertible dates in an excel date column will be returned without conversion and the column will be object dtype, rather than raising an exception (GH10001).
- `pd.Timedelta(None)` is now accepted and will return `NaT`, mirroring `pd.Timestamp` (GH13687)
- `pd.read_stata()` can now handle some format 111 files, which are produced by SAS when generating Stata dta files (GH11526)
- `Series` and `Index` now support `divmod` which will return a tuple of series or indices. This behaves like a standard binary operator with regards to broadcasting rules (GH14208).

## API changes

### Series.tolist() will now return Python types

Series.tolist() will now return Python types in the output, mimicking NumPy .tolist() behavior (GH10904)

```
In [78]: s = pd.Series([1, 2, 3])
```

#### Previous behavior:

```
In [7]: type(s.tolist()[0])
Out [7]:
<class 'numpy.int64'>
```

#### New behavior:

```
In [79]: type(s.tolist()[0])
Out [79]: int
```

### Series operators for different indexes

Following Series operators have been changed to make all operators consistent, including DataFrame (GH1134, GH4581, GH13538)

- Series comparison operators now raise ValueError when index are different.
- Series logical operators align both index of left and right hand side.

**Warning:** Until 0.18.1, comparing Series with the same length, would succeed even if the .index are different (the result ignores .index). As of 0.19.0, this will raises ValueError to be more strict. This section also describes how to keep previous behavior or align different indexes, using the flexible comparison methods like .eq.

As a result, Series and DataFrame operators behave as below:

### Arithmetic operators

Arithmetic operators align both index (no changes).

```
In [80]: s1 = pd.Series([1, 2, 3], index=list('ABC'))
In [81]: s2 = pd.Series([2, 2, 2], index=list('ABD'))
In [82]: s1 + s2
Out [82]:
A    3.0
B    4.0
C     NaN
D     NaN
Length: 4, dtype: float64
```

(continues on next page)

(continued from previous page)

```
In [83]: df1 = pd.DataFrame([1, 2, 3], index=list('ABC'))
In [84]: df2 = pd.DataFrame([2, 2, 2], index=list('ABD'))
In [85]: df1 + df2
Out [85]:
      0
A    3.0
B    4.0
C    NaN
D    NaN

[4 rows x 1 columns]
```

## Comparison operators

Comparison operators raise `ValueError` when `.index` are different.

**Previous behavior** (Series):

Series compared values ignoring the `.index` as long as both had the same length:

```
In [1]: s1 == s2
Out [1]:
A    False
B     True
C    False
dtype: bool
```

**New behavior** (Series):

```
In [2]: s1 == s2
Out [2]:
ValueError: Can only compare identically-labeled Series objects
```

**Note:** To achieve the same result as previous versions (compare values based on locations ignoring `.index`), compare both `.values`.

```
In [86]: s1.values == s2.values
Out [86]: array([False,  True,  False])
```

If you want to compare Series aligning its `.index`, see flexible comparison methods section below:

```
In [87]: s1.eq(s2)
Out [87]:
A    False
B     True
C    False
D    False
Length: 4, dtype: bool
```

**Current behavior** (DataFrame, no change):

```
In [3]: df1 == df2
Out[3]:
ValueError: Can only compare identically-labeled DataFrame objects
```

## Logical operators

Logical operators align both `.index` of left and right hand side.

**Previous behavior** (Series), only left hand side index was kept:

```
In [4]: s1 = pd.Series([True, False, True], index=list('ABC'))
In [5]: s2 = pd.Series([True, True, True], index=list('ABD'))
In [6]: s1 & s2
Out[6]:
A      True
B     False
C     False
dtype: bool
```

**New behavior** (Series):

```
In [88]: s1 = pd.Series([True, False, True], index=list('ABC'))
In [89]: s2 = pd.Series([True, True, True], index=list('ABD'))

In [90]: s1 & s2
Out[90]:
A      True
B     False
C     False
D     False
Length: 4, dtype: bool
```

---

**Note:** Series logical operators fill a NaN result with False.

---

**Note:** To achieve the same result as previous versions (compare values based on only left hand side index), you can use `reindex_like`:

```
In [91]: s1 & s2.reindex_like(s1)
Out[91]:
A      True
B     False
C     False
Length: 3, dtype: bool
```

**Current behavior** (DataFrame, no change):

```
In [92]: df1 = pd.DataFrame([True, False, True], index=list('ABC'))
In [93]: df2 = pd.DataFrame([True, True, True], index=list('ABD'))
In [94]: df1 & df2
```

(continues on next page)

(continued from previous page)

```
Out [94]:
      0
A   True
B  False
C  False
D  False

[4 rows x 1 columns]
```

## Flexible comparison methods

Series flexible comparison methods like `eq`, `ne`, `le`, `lt`, `ge` and `gt` now align both index. Use these operators if you want to compare two Series which has the different index.

```
In [95]: s1 = pd.Series([1, 2, 3], index=['a', 'b', 'c'])
In [96]: s2 = pd.Series([2, 2, 2], index=['b', 'c', 'd'])
In [97]: s1.eq(s2)
Out [97]:
a   False
b    True
c   False
d   False
Length: 4, dtype: bool

In [98]: s1.ge(s2)
Out [98]:
a   False
b    True
c    True
d   False
Length: 4, dtype: bool
```

Previously, this worked the same as comparison operators (see above).

## Series type promotion on assignment

A Series will now correctly promote its dtype for assignment with incompat values to the current dtype ([GH13234](#))

```
In [99]: s = pd.Series()
```

### Previous behavior:

```
In [2]: s["a"] = pd.Timestamp("2016-01-01")
In [3]: s["b"] = 3.0
TypeError: invalid type promotion
```

### New behavior:

```
In [100]: s["a"] = pd.Timestamp("2016-01-01")
```

(continues on next page)

(continued from previous page)

```
In [101]: s["b"] = 3.0

In [102]: s
Out[102]:
a    2016-01-01 00:00:00
b                                     3
Length: 2, dtype: object

In [103]: s.dtype
Out[103]: dtype('O')
```

### `.to_datetime()` changes

Previously if `.to_datetime()` encountered mixed integers/floats and strings, but no datetimes with `errors='coerce'` it would convert all to `NaT`.

#### Previous behavior:

```
In [2]: pd.to_datetime([1, 'foo'], errors='coerce')
Out[2]: DatetimeIndex(['NaT', 'NaT'], dtype='datetime64[ns]', freq=None)
```

#### Current behavior:

This will now convert integers/floats with the default unit of `ns`.

```
In [104]: pd.to_datetime([1, 'foo'], errors='coerce')
Out[104]: DatetimeIndex(['1970-01-01 00:00:00.000000001', 'NaT'], dtype=
↳ 'datetime64[ns]', freq=None)
```

Bug fixes related to `.to_datetime()`:

- Bug in `pd.to_datetime()` when passing integers or floats, and no unit and `errors='coerce'` ([GH13180](#)).
- Bug in `pd.to_datetime()` when passing invalid data types (e.g. `bool`); will now respect the `errors` keyword ([GH13176](#)).
- Bug in `pd.to_datetime()` which overflowed on `int8`, and `int16` dtypes ([GH13451](#)).
- Bug in `pd.to_datetime()` raise `AttributeError` with `NaN` and the other string is not valid when `errors='ignore'` ([GH12424](#)).
- Bug in `pd.to_datetime()` did not cast floats correctly when unit was specified, resulting in truncated datetime ([GH13834](#)).

### Merging changes

Merging will now preserve the dtype of the join keys ([GH8596](#))

```
In [105]: df1 = pd.DataFrame({'key': [1], 'v1': [10]})

In [106]: df1
Out[106]:
   key  v1
0    1  10
```

(continues on next page)

(continued from previous page)

```
[1 rows x 2 columns]

In [107]: df2 = pd.DataFrame({'key': [1, 2], 'v1': [20, 30]})

In [108]: df2
Out [108]:
   key  v1
0    1  20
1    2  30

[2 rows x 2 columns]
```

**Previous behavior:**

```
In [5]: pd.merge(df1, df2, how='outer')
Out [5]:
   key   v1
0  1.0  10.0
1  1.0  20.0
2  2.0  30.0

In [6]: pd.merge(df1, df2, how='outer').dtypes
Out [6]:
key    float64
v1     float64
dtype: object
```

**New behavior:**

We are able to preserve the join keys

```
In [109]: pd.merge(df1, df2, how='outer')
Out [109]:
   key  v1
0    1  10
1    1  20
2    2  30

[3 rows x 2 columns]

In [110]: pd.merge(df1, df2, how='outer').dtypes
Out [110]:
key    int64
v1     int64
Length: 2, dtype: object
```

Of course if you have missing values that are introduced, then the resulting dtype will be upcast, which is unchanged from previous.

```
In [111]: pd.merge(df1, df2, how='outer', on='key')
Out [111]:
   key  v1_x  v1_y
0    1  10.0   20
1    2   NaN   30

[2 rows x 3 columns]
```

(continues on next page)

(continued from previous page)

```
In [112]: pd.merge(df1, df2, how='outer', on='key').dtypes
Out[112]:
key          int64
v1_x        float64
v1_y        int64
Length: 3, dtype: object
```

### **.describe() changes**

Percentile identifiers in the index of a `.describe()` output will now be rounded to the least precision that keeps them distinct (GH13104)

```
In [113]: s = pd.Series([0, 1, 2, 3, 4])
```

```
In [114]: df = pd.DataFrame([0, 1, 2, 3, 4])
```

#### **Previous behavior:**

The percentiles were rounded to at most one decimal place, which could raise `ValueError` for a data frame if the percentiles were duplicated.

```
In [3]: s.describe(percentiles=[0.0001, 0.0005, 0.001, 0.999, 0.9995, 0.9999])
```

```
Out[3]:
count      5.000000
mean       2.000000
std        1.581139
min        0.000000
0.0%       0.000400
0.1%       0.002000
0.1%       0.004000
50%        2.000000
99.9%      3.996000
100.0%     3.998000
100.0%     3.999600
max        4.000000
dtype: float64
```

```
In [4]: df.describe(percentiles=[0.0001, 0.0005, 0.001, 0.999, 0.9995, 0.9999])
```

```
Out[4]:
...
ValueError: cannot reindex from a duplicate axis
```

#### **New behavior:**

```
In [115]: s.describe(percentiles=[0.0001, 0.0005, 0.001, 0.999, 0.9995, 0.9999])
```

```
Out[115]:
count      5.000000
mean       2.000000
std        1.581139
min        0.000000
0.01%     0.000400
0.05%     0.002000
0.1%      0.004000
50%       2.000000
```

(continues on next page)

(continued from previous page)

```

99.9%      3.996000
99.95%     3.998000
99.99%     3.999600
max        4.000000
Length: 12, dtype: float64

In [116]: df.describe(percentiles=[0.0001, 0.0005, 0.001, 0.999, 0.9995, 0.9999])
Out [116]:
          0
count    5.000000
mean     2.000000
std      1.581139
min      0.000000
0.01%    0.000400
0.05%    0.002000
0.1%     0.004000
50%      2.000000
99.9%    3.996000
99.95%   3.998000
99.99%   3.999600
max      4.000000

[12 rows x 1 columns]

```

Furthermore:

- Passing duplicated percentiles will now raise a `ValueError`.
- Bug in `.describe()` on a `DataFrame` with a mixed-dtype column index, which would previously raise a `TypeError` ([GH13288](#))

## Period changes

### PeriodIndex now has period dtype

`PeriodIndex` now has its own `period` dtype. The `period` dtype is a pandas extension dtype like `category` or the *timezone aware dtype* (`datetime64[ns, tz]`) ([GH13941](#)). As a consequence of this change, `PeriodIndex` no longer has an integer dtype:

**Previous behavior:**

```

In [1]: pi = pd.PeriodIndex(['2016-08-01'], freq='D')

In [2]: pi
Out [2]: PeriodIndex(['2016-08-01'], dtype='int64', freq='D')

In [3]: pd.api.types.is_integer_dtype(pi)
Out [3]: True

In [4]: pi.dtype
Out [4]: dtype('int64')

```

**New behavior:**

```
In [117]: pi = pd.PeriodIndex(['2016-08-01'], freq='D')
In [118]: pi
Out[118]: PeriodIndex(['2016-08-01'], dtype='period[D]', freq='D')
In [119]: pd.api.types.is_integer_dtype(pi)
Out[119]: False
In [120]: pd.api.types.is_period_dtype(pi)
Out[120]: True
In [121]: pi.dtype
Out[121]: period[D]
In [122]: type(pi.dtype)
Out[122]: pandas.core.dtypes.dtypes.PeriodDtype
```

### Period('NaT') now returns pd.NaT

Previously, Period has its own Period('NaT') representation different from pd.NaT. Now Period('NaT') has been changed to return pd.NaT. (GH12759, GH13582)

#### Previous behavior:

```
In [5]: pd.Period('NaT', freq='D')
Out[5]: Period('NaT', 'D')
```

#### New behavior:

These result in pd.NaT without providing freq option.

```
In [123]: pd.Period('NaT')
Out[123]: NaT
In [124]: pd.Period(None)
Out[124]: NaT
```

To be compatible with Period addition and subtraction, pd.NaT now supports addition and subtraction with int. Previously it raised ValueError.

#### Previous behavior:

```
In [5]: pd.NaT + 1
...
ValueError: Cannot add integral value to Timestamp without freq.
```

#### New behavior:

```
In [125]: pd.NaT + 1
Out[125]: NaT
In [126]: pd.NaT - 1
Out[126]: NaT
```

## PeriodIndex.values now returns array of Period object

.values is changed to return an array of Period objects, rather than an array of integers (GH13988).

### Previous behavior:

```
In [6]: pi = pd.PeriodIndex(['2011-01', '2011-02'], freq='M')
In [7]: pi.values
Out [7]: array([492, 493])
```

### New behavior:

```
In [127]: pi = pd.PeriodIndex(['2011-01', '2011-02'], freq='M')
In [128]: pi.values
Out [128]: array([Period('2011-01', 'M'), Period('2011-02', 'M')], dtype=object)
```

## Index + / - no longer used for set operations

Addition and subtraction of the base Index type and of DatetimeIndex (not the numeric index types) previously performed set operations (set union and difference). This behavior was already deprecated since 0.15.0 (in favor using the specific .union() and .difference() methods), and is now disabled. When possible, + and - are now used for element-wise operations, for example for concatenating strings or subtracting datetimes (GH8227, GH14127).

### Previous behavior:

```
In [1]: pd.Index(['a', 'b']) + pd.Index(['a', 'c'])
FutureWarning: using '+' to provide set union with Indexes is deprecated, use '|' or .
->union()
Out [1]: Index(['a', 'b', 'c'], dtype='object')
```

### New behavior: the same operation will now perform element-wise addition:

```
In [129]: pd.Index(['a', 'b']) + pd.Index(['a', 'c'])
Out [129]: Index(['aa', 'bc'], dtype='object')
```

Note that numeric Index objects already performed element-wise operations. For example, the behavior of adding two integer Indexes is unchanged. The base Index is now made consistent with this behavior.

```
In [130]: pd.Index([1, 2, 3]) + pd.Index([2, 3, 4])
Out [130]: Int64Index([3, 5, 7], dtype='int64')
```

Further, because of this change, it is now possible to subtract two DatetimeIndex objects resulting in a TimedeltaIndex:

### Previous behavior:

```
In [1]: (pd.DatetimeIndex(['2016-01-01', '2016-01-02'])
...: - pd.DatetimeIndex(['2016-01-02', '2016-01-03']))
FutureWarning: using '-' to provide set differences with datetimelike Indexes is
->deprecated, use .difference()
Out [1]: DatetimeIndex(['2016-01-01'], dtype='datetime64[ns]', freq=None)
```

### New behavior:

```
In [131]: (pd.DatetimeIndex(['2016-01-01', '2016-01-02'])
...: - pd.DatetimeIndex(['2016-01-02', '2016-01-03']))
```

(continues on next page)

(continued from previous page)

```
.....:
Out [131]: TimedeltaIndex(['-1 days', '-1 days'], dtype='timedelta64[ns]', freq=None)
```

### Index.difference and .symmetric\_difference changes

Index.difference and Index.symmetric\_difference will now, more consistently, treat NaN values as any other values. (GH13514)

```
In [132]: idx1 = pd.Index([1, 2, 3, np.nan])
```

```
In [133]: idx2 = pd.Index([0, 1, np.nan])
```

#### Previous behavior:

```
In [3]: idx1.difference(idx2)
```

```
Out [3]: Float64Index([nan, 2.0, 3.0], dtype='float64')
```

```
In [4]: idx1.symmetric_difference(idx2)
```

```
Out [4]: Float64Index([0.0, nan, 2.0, 3.0], dtype='float64')
```

#### New behavior:

```
In [134]: idx1.difference(idx2)
```

```
Out [134]: Float64Index([2.0, 3.0], dtype='float64')
```

```
In [135]: idx1.symmetric_difference(idx2)
```

```
Out [135]: Float64Index([0.0, 2.0, 3.0], dtype='float64')
```

### Index.unique consistently returns Index

Index.unique() now returns unique values as an Index of the appropriate dtype. (GH13395). Previously, most Index classes returned np.ndarray, and DatetimeIndex, TimedeltaIndex and PeriodIndex returned Index to keep metadata like timezone.

#### Previous behavior:

```
In [1]: pd.Index([1, 2, 3]).unique()
```

```
Out [1]: array([1, 2, 3])
```

```
In [2]: pd.DatetimeIndex(['2011-01-01', '2011-01-02',
.....:                    '2011-01-03'], tz='Asia/Tokyo').unique()
```

```
Out [2]:
```

```
DatetimeIndex(['2011-01-01 00:00:00+09:00', '2011-01-02 00:00:00+09:00',
              '2011-01-03 00:00:00+09:00'],
              dtype='datetime64[ns, Asia/Tokyo]', freq=None)
```

#### New behavior:

```
In [136]: pd.Index([1, 2, 3]).unique()
```

```
Out [136]: Int64Index([1, 2, 3], dtype='int64')
```

```
In [137]: pd.DatetimeIndex(['2011-01-01', '2011-01-02', '2011-01-03'],
.....:                    tz='Asia/Tokyo').unique()
```

(continues on next page)

(continued from previous page)

```
.....:
Out [137]:
DatetimeIndex(['2011-01-01 00:00:00+09:00', '2011-01-02 00:00:00+09:00',
              '2011-01-03 00:00:00+09:00'],
              dtype='datetime64[ns, Asia/Tokyo]', freq=None)
```

### MultiIndex constructors, groupby and set\_index preserve categorical dtypes

MultiIndex.from\_arrays and MultiIndex.from\_product will now preserve categorical dtype in MultiIndex levels (GH13743, GH13854).

```
In [138]: cat = pd.Categorical(['a', 'b'], categories=list("bac"))
In [139]: lvl1 = ['foo', 'bar']
In [140]: midx = pd.MultiIndex.from_arrays([cat, lvl1])
In [141]: midx
Out [141]:
MultiIndex([('a', 'foo'),
            ('b', 'bar')],
           )
```

#### Previous behavior:

```
In [4]: midx.levels[0]
Out [4]: Index(['b', 'a', 'c'], dtype='object')
In [5]: midx.get_level_values[0]
Out [5]: Index(['a', 'b'], dtype='object')
```

#### New behavior: the single level is now a CategoricalIndex:

```
In [142]: midx.levels[0]
Out [142]: CategoricalIndex(['b', 'a', 'c'], categories=['b', 'a', 'c'], ordered=False,
→ dtype='category')
In [143]: midx.get_level_values(0)
Out [143]: CategoricalIndex(['a', 'b'], categories=['b', 'a', 'c'], ordered=False,
→ dtype='category')
```

An analogous change has been made to MultiIndex.from\_product. As a consequence, groupby and set\_index also preserve categorical dtypes in indexes

```
In [144]: df = pd.DataFrame({'A': [0, 1], 'B': [10, 11], 'C': cat})
In [145]: df_grouped = df.groupby(by=['A', 'C']).first()
In [146]: df_set_idx = df.set_index(['A', 'C'])
```

#### Previous behavior:

```
In [11]: df_grouped.index.levels[1]
Out [11]: Index(['b', 'a', 'c'], dtype='object', name='C')
```

(continues on next page)

(continued from previous page)

```

In [12]: df_grouped.reset_index().dtypes
Out[12]:
A      int64
C      object
B      float64
dtype: object

In [13]: df_set_idx.index.levels[1]
Out[13]: Index(['b', 'a', 'c'], dtype='object', name='C')
In [14]: df_set_idx.reset_index().dtypes
Out[14]:
A      int64
C      object
B      int64
dtype: object

```

**New behavior:**

```

In [147]: df_grouped.index.levels[1]
Out[147]: CategoricalIndex(['b', 'a', 'c'], categories=['b', 'a', 'c'], ordered=False,
↳ name='C', dtype='category')

In [148]: df_grouped.reset_index().dtypes
Out[148]:
A      int64
C      category
B      float64
Length: 3, dtype: object

In [149]: df_set_idx.index.levels[1]
Out[149]: CategoricalIndex(['b', 'a', 'c'], categories=['b', 'a', 'c'], ordered=False,
↳ name='C', dtype='category')

In [150]: df_set_idx.reset_index().dtypes
Out[150]:
A      int64
C      category
B      int64
Length: 3, dtype: object

```

**read\_csv will progressively enumerate chunks**

When `read_csv()` is called with `chunksize=n` and without specifying an index, each chunk used to have an independently generated index from 0 to `n-1`. They are now given instead a progressive index, starting from 0 for the first chunk, from `n` for the second, and so on, so that, when concatenated, they are identical to the result of calling `read_csv()` without the `chunksize=` argument (GH12185).

```
In [151]: data = 'A,B\n0,1\n2,3\n4,5\n6,7'
```

**Previous behavior:**

```

In [2]: pd.concat(pd.read_csv(StringIO(data), chunksize=2))
Out[2]:
   A  B

```

(continues on next page)

(continued from previous page)

```
0 0 1
1 2 3
0 4 5
1 6 7
```

**New behavior:**

```
In [152]: pd.concat(pd.read_csv(StringIO(data), chunksize=2))
Out [152]:
   A  B
0  0  1
1  2  3
2  4  5
3  6  7

[4 rows x 2 columns]
```

**Sparse Changes**

These changes allow pandas to handle sparse data with more dtypes, and for work to make a smoother experience with data handling.

**int64 and bool support enhancements**

Sparse data structures now gained enhanced support of `int64` and `bool` dtype ([GH667](#), [GH13849](#)).

Previously, sparse data were `float64` dtype by default, even if all inputs were of `int` or `bool` dtype. You had to specify dtype explicitly to create sparse data with `int64` dtype. Also, `fill_value` had to be specified explicitly because the default was `np.nan` which doesn't appear in `int64` or `bool` data.

```
In [1]: pd.SparseArray([1, 2, 0, 0])
Out [1]:
[1.0, 2.0, 0.0, 0.0]
Fill: nan
IntIndex
Indices: array([0, 1, 2, 3], dtype=int32)

# specifying int64 dtype, but all values are stored in sp_values because
# fill_value default is np.nan
In [2]: pd.SparseArray([1, 2, 0, 0], dtype=np.int64)
Out [2]:
[1, 2, 0, 0]
Fill: nan
IntIndex
Indices: array([0, 1, 2, 3], dtype=int32)

In [3]: pd.SparseArray([1, 2, 0, 0], dtype=np.int64, fill_value=0)
Out [3]:
[1, 2, 0, 0]
Fill: 0
IntIndex
Indices: array([0, 1], dtype=int32)
```

As of v0.19.0, sparse data keeps the input dtype, and uses more appropriate `fill_value` defaults (0 for `int64` dtype, `False` for `bool` dtype).

```
In [153]: pd.SparseArray([1, 2, 0, 0], dtype=np.int64)
Out [153]:
[1, 2, 0, 0]
Fill: 0
IntIndex
Indices: array([0, 1], dtype=int32)

In [154]: pd.SparseArray([True, False, False, False])
Out [154]:
[True, False, False, False]
Fill: False
IntIndex
Indices: array([0], dtype=int32)
```

See the *docs* for more details.

### Operators now preserve dtypes

- Sparse data structure now can preserve dtype after arithmetic ops ([GH13848](#))

```
s = pd.SparseSeries([0, 2, 0, 1], fill_value=0, dtype=np.int64)
s.dtype

s + 1
```

- Sparse data structure now support `astype` to convert internal dtype ([GH13900](#))

```
s = pd.SparseSeries([1., 0., 2., 0.], fill_value=0)
s
s.astype(np.int64)
```

`astype` fails if data contains values which cannot be converted to specified dtype. Note that the limitation is applied to `fill_value` which default is `np.nan`.

```
In [7]: pd.SparseSeries([1., np.nan, 2., np.nan], fill_value=np.nan).astype(np.int64)
Out [7]:
ValueError: unable to coerce current fill_value nan to int64 dtype
```

### Other sparse fixes

- Subclassed `SparseDataFrame` and `SparseSeries` now preserve class types when slicing or transposing. ([GH13787](#))
- `SparseArray` with `bool` dtype now supports logical (`bool`) operators ([GH14000](#))
- Bug in `SparseSeries` with `MultiIndex []` indexing may raise `IndexError` ([GH13144](#))
- Bug in `SparseSeries` with `MultiIndex []` indexing result may have normal `Index` ([GH13144](#))
- Bug in `SparseDataFrame` in which `axis=None` did not default to `axis=0` ([GH13048](#))
- Bug in `SparseSeries` and `SparseDataFrame` creation with `object` dtype may raise `TypeError` ([GH11633](#))

- Bug in `SparseDataFrame` doesn't respect passed `SparseArray` or `SparseSeries`'s `dtype` and `fill_value` (GH13866)
- Bug in `SparseArray` and `SparseSeries` don't apply `ufunc` to `fill_value` (GH13853)
- Bug in `SparseSeries.abs` incorrectly keeps negative `fill_value` (GH13853)
- Bug in single row slicing on multi-type `SparseDataFrame`s, types were previously forced to `float` (GH13917)
- Bug in `SparseSeries` slicing changes integer `dtype` to `float` (GH8292)
- Bug in `SparseDataFrame` comparison ops may raise `TypeError` (GH13001)
- Bug in `SparseDataFrame.isnull` raises `ValueError` (GH8276)
- Bug in `SparseSeries` representation with `bool` `dtype` may raise `IndexError` (GH13110)
- Bug in `SparseSeries` and `SparseDataFrame` of `bool` or `int64` `dtype` may display its values like `float64` `dtype` (GH13110)
- Bug in sparse indexing using `SparseArray` with `bool` `dtype` may return incorrect result (GH13985)
- Bug in `SparseArray` created from `SparseSeries` may lose `dtype` (GH13999)
- Bug in `SparseSeries` comparison with dense returns normal `Series` rather than `SparseSeries` (GH13999)

## Indexer dtype changes

**Note:** This change only affects 64 bit python running on Windows, and only affects relatively advanced indexing operations

Methods such as `Index.get_indexer` that return an indexer array, coerce that array to a “platform int”, so that it can be directly used in 3rd party library operations like `numpy.take`. Previously, a platform int was defined as `np.int_` which corresponds to a C integer, but the correct type, and what is being used now, is `np.intp`, which corresponds to the C integer size that can hold a pointer (GH3033, GH13972).

These types are the same on many platform, but for 64 bit python on Windows, `np.int_` is 32 bits, and `np.intp` is 64 bits. Changing this behavior improves performance for many operations on that platform.

### Previous behavior:

```
In [1]: i = pd.Index(['a', 'b', 'c'])
In [2]: i.get_indexer(['b', 'b', 'c']).dtype
Out[2]: dtype('int32')
```

### New behavior:

```
In [1]: i = pd.Index(['a', 'b', 'c'])
In [2]: i.get_indexer(['b', 'b', 'c']).dtype
Out[2]: dtype('int64')
```

## Other API changes

- `Timestamp.to_pydatetime` will issue a `UserWarning` when `warn=True`, and the instance has a non-zero number of nanoseconds, previously this would print a message to `stdout` (GH14101).
- `Series.unique()` with `datetime` and `timezone` now returns return array of `Timestamp` with `timezone` (GH13565).
- `Panel.to_sparse()` will raise a `NotImplementedError` exception when called (GH13778).
- `Index.reshape()` will raise a `NotImplementedError` exception when called (GH12882).
- `.filter()` enforces mutual exclusion of the keyword arguments (GH12399).
- `eval`'s upcasting rules for `float32` types have been updated to be more consistent with NumPy's rules. New behavior will not upcast to `float64` if you multiply a pandas `float32` object by a scalar `float64` (GH12388).
- An `UnsupportedFunctionCall` error is now raised if NumPy ufuncs like `np.mean` are called on `groupby` or `resample` objects (GH12811).
- `__setitem__` will no longer apply a callable rhs as a function instead of storing it. Call `where` directly to get the previous behavior (GH13299).
- Calls to `.sample()` will respect the random seed set via `numpy.random.seed(n)` (GH13161)
- `Styler.apply` is now more strict about the outputs your function must return. For `axis=0` or `axis=1`, the output shape must be identical. For `axis=None`, the output must be a `DataFrame` with identical columns and index labels (GH13222).
- `Float64Index.astype(int)` will now raise `ValueError` if `Float64Index` contains `NaN` values (GH13149)
- `TimedeltaIndex.astype(int)` and `DatetimeIndex.astype(int)` will now return `Int64Index` instead of `np.array` (GH13209)
- Passing `Period` with multiple frequencies to normal `Index` now returns `Index` with `object` dtype (GH13664)
- `PeriodIndex.fillna` with `Period` has different `freq` now coerces to `object` dtype (GH13664)
- Faceted boxplots from `DataFrame.boxplot(by=col)` now return a `Series` when `return_type` is not `None`. Previously these returned an `OrderedDict`. Note that when `return_type=None`, the default, these still return a 2-D NumPy array (GH12216, GH7096).
- `pd.read_hdf` will now raise a `ValueError` instead of `KeyError`, if a mode other than `r`, `r+` and `a` is supplied. (GH13623)
- `pd.read_csv()`, `pd.read_table()`, and `pd.read_hdf()` raise the builtin `FileNotFoundError` exception for Python 3.x when called on a nonexistent file; this is back-ported as `IOError` in Python 2.x (GH14086)
- More informative exceptions are passed through the csv parser. The exception type would now be the original exception type instead of `CParserError` (GH13652).
- `pd.read_csv()` in the C engine will now issue a `ParserWarning` or raise a `ValueError` when `sep` encoded is more than one character long (GH14065)
- `DataFrame.values` will now return `float64` with a `DataFrame` of mixed `int64` and `uint64` dtypes, conforming to `np.find_common_type` (GH10364, GH13917)
- `.groupby.groups` will now return a dictionary of `Index` objects, rather than a dictionary of `np.ndarray` or `lists` (GH14293)

## Deprecations

- `Series.reshape` and `Categorical.reshape` have been deprecated and will be removed in a subsequent release ([GH12882](#), [GH12882](#))
- `PeriodIndex.to_datetime` has been deprecated in favor of `PeriodIndex.to_timestamp` ([GH8254](#))
- `Timestamp.to_datetime` has been deprecated in favor of `Timestamp.to_pydatetime` ([GH8254](#))
- `Index.to_datetime` and `DatetimeIndex.to_datetime` have been deprecated in favor of `pd.to_datetime` ([GH8254](#))
- `pandas.core.datetools` module has been deprecated and will be removed in a subsequent release ([GH14094](#))
- `SparseList` has been deprecated and will be removed in a future version ([GH13784](#))
- `DataFrame.to_html()` and `DataFrame.to_latex()` have dropped the `colSpace` parameter in favor of `col_space` ([GH13857](#))
- `DataFrame.to_sql()` has deprecated the `flavor` parameter, as it is superfluous when SQLAlchemy is not installed ([GH13611](#))
- Deprecated `read_csv` keywords:
  - `compact_ints` and `use_unsigned` have been deprecated and will be removed in a future version ([GH13320](#))
  - `buffer_lines` has been deprecated and will be removed in a future version ([GH13360](#))
  - `as_reccarray` has been deprecated and will be removed in a future version ([GH13373](#))
  - `skip_footer` has been deprecated in favor of `skipfooter` and will be removed in a future version ([GH13349](#))
- top-level `pd.ordered_merge()` has been renamed to `pd.merge_ordered()` and the original name will be removed in a future version ([GH13358](#))
- `Timestamp.offset` property (and named arg in the constructor), has been deprecated in favor of `freq` ([GH12160](#))
- `pd.tseries.util.pivot_annual` is deprecated. Use `pivot_table` as alternative, an example is [here](#) ([GH736](#))
- `pd.tseries.util.isleapyear` has been deprecated and will be removed in a subsequent release. `Datetime`-likes now have a `.is_leap_year` property ([GH13727](#))
- `Panel4D` and `PanelND` constructors are deprecated and will be removed in a future version. The recommended way to represent these types of n-dimensional data are with the [xarray](#) package. Pandas provides a `to_xarray()` method to automate this conversion ([GH13564](#)).
- `pandas.tseries.frequencies.get_standard_freq` is deprecated. Use `pandas.tseries.frequencies.to_offset(freq).rule_code` instead ([GH13874](#))
- `pandas.tseries.frequencies.to_offset`'s `freqstr` keyword is deprecated in favor of `freq` ([GH13874](#))
- `Categorical.from_array` has been deprecated and will be removed in a future version ([GH13854](#))

## Removal of prior version deprecations/changes

- The `SparsePanel` class has been removed ([GH13778](#))
- The `pd.sandbox` module has been removed in favor of the external library `pandas-qt` ([GH13670](#))
- The `pandas.io.data` and `pandas.io.wb` modules are removed in favor of the `pandas-datareader` package ([GH13724](#)).
- The `pandas.tools.rplot` module has been removed in favor of the `seaborn` package ([GH13855](#))
- `DataFrame.to_csv()` has dropped the `engine` parameter, as was deprecated in 0.17.1 ([GH11274](#), [GH13419](#))
- `DataFrame.to_dict()` has dropped the `outtype` parameter in favor of `orient` ([GH13627](#), [GH8486](#))
- `pd.Categorical` has dropped setting of the `ordered` attribute directly in favor of the `set_ordered` method ([GH13671](#))
- `pd.Categorical` has dropped the `levels` attribute in favor of `categories` ([GH8376](#))
- `DataFrame.to_sql()` has dropped the `mysql` option for the `flavor` parameter ([GH13611](#))
- `Panel.shift()` has dropped the `lags` parameter in favor of `periods` ([GH14041](#))
- `pd.Index` has dropped the `diff` method in favor of `difference` ([GH13669](#))
- `pd.DataFrame` has dropped the `to_wide` method in favor of `to_panel` ([GH14039](#))
- `Series.to_csv` has dropped the `nanRep` parameter in favor of `na_rep` ([GH13804](#))
- `Series.xs`, `DataFrame.xs`, `Panel.xs`, `Panel.major_xs`, and `Panel.minor_xs` have dropped the `copy` parameter ([GH13781](#))
- `str.split` has dropped the `return_type` parameter in favor of `expand` ([GH13701](#))
- Removal of the legacy time rules (offset aliases), deprecated since 0.17.0 (this has been alias since 0.8.0) ([GH13590](#), [GH13868](#)). Now legacy time rules raises `ValueError`. For the list of currently supported offsets, see [here](#).
- The default value for the `return_type` parameter for `DataFrame.plot.box` and `DataFrame.boxplot` changed from `None` to `"axes"`. These methods will now return a matplotlib axes by default instead of a dictionary of artists. See [here](#) ([GH6581](#)).
- The `tquery` and `uquery` functions in the `pandas.io.sql` module are removed ([GH5950](#)).

## Performance improvements

- Improved performance of sparse `IntIndex.intersect` ([GH13082](#))
- Improved performance of sparse arithmetic with `BlockIndex` when the number of blocks are large, though recommended to use `IntIndex` in such cases ([GH13082](#))
- Improved performance of `DataFrame.quantile()` as it now operates per-block ([GH11623](#))
- Improved performance of float64 hash table operations, fixing some very slow indexing and groupby operations in python 3 ([GH13166](#), [GH13334](#))
- Improved performance of `DataFrameGroupBy.transform` ([GH12737](#))
- Improved performance of `Index` and `Series.duplicated` ([GH10235](#))
- Improved performance of `Index.difference` ([GH12044](#))

- Improved performance of `RangeIndex.is_monotonic_increasing` and `is_monotonic_decreasing` (GH13749)
- Improved performance of datetime string parsing in `DatetimeIndex` (GH13692)
- Improved performance of hashing `Period` (GH12817)
- Improved performance of `factorize` of datetime with timezone (GH13750)
- Improved performance of by lazily creating indexing hashtables on larger Indexes (GH14266)
- Improved performance of `groupby.groups` (GH14293)
- Unnecessary materializing of a `MultiIndex` when introspecting for memory usage (GH14308)

## Bug fixes

- Bug in `groupby().shift()`, which could cause a segfault or corruption in rare circumstances when grouping by columns with missing values (GH13813)
- Bug in `groupby().cumsum()` calculating `cumprod` when `axis=1`. (GH13994)
- Bug in `pd.to_timedelta()` in which the `errors` parameter was not being respected (GH13613)
- Bug in `io.json.json_normalize()`, where non-ascii keys raised an exception (GH13213)
- Bug when passing a not-default-indexed `Series` as `xerr` or `yerr` in `.plot()` (GH11858)
- Bug in area plot draws legend incorrectly if subplot is enabled or legend is moved after plot (matplotlib 1.5.0 is required to draw area plot legend properly) (GH9161, GH13544)
- Bug in `DataFrame` assignment with an object-dtyped `Index` where the resultant column is mutable to the original object. (GH13522)
- Bug in matplotlib `AutoDataFormatter`; this restores the second scaled formatting and re-adds micro-second scaled formatting (GH13131)
- Bug in selection from a `HDFStore` with a fixed format and `start` and/or `stop` specified will now return the selected range (GH8287)
- Bug in `Categorical.from_codes()` where an unhelpful error was raised when an invalid ordered parameter was passed in (GH14058)
- Bug in `Series` construction from a tuple of integers on windows not returning default dtype (`int64`) (GH13646)
- Bug in `TimedeltaIndex` addition with a `Datetime`-like object where addition overflow was not being caught (GH14068)
- Bug in `.groupby(...).resample(...)` when the same object is called multiple times (GH13174)
- Bug in `.to_records()` when index name is a unicode string (GH13172)
- Bug in calling `.memory_usage()` on object which doesn't implement (GH12924)
- Regression in `Series.quantile` with nans (also shows up in `.median()` and `.describe()`); furthermore now names the `Series` with the quantile (GH13098, GH13146)
- Bug in `SeriesGroupBy.transform` with datetime values and missing groups (GH13191)
- Bug where empty `Series` were incorrectly coerced in datetime-like numeric operations (GH13844)
- Bug in `Categorical` constructor when passed a `Categorical` containing datetimes with timezones (GH14190)
- Bug in `Series.str.extractall()` with `str` index raises `ValueError` (GH13156)

- Bug in `Series.str.extractall()` with single group and quantifier (GH13382)
- Bug in `DatetimeIndex` and `Period` subtraction raises `ValueError` or `AttributeError` rather than `TypeError` (GH13078)
- Bug in `Index` and `Series` created with `NaN` and `NaT` mixed data may not have `datetime64` dtype (GH13324)
- Bug in `Index` and `Series` may ignore `np.datetime64('nat')` and `np.timedelta64('nat')` to infer dtype (GH13324)
- Bug in `PeriodIndex` and `Period` subtraction raises `AttributeError` (GH13071)
- Bug in `PeriodIndex` construction returning a `float64` index in some circumstances (GH13067)
- Bug in `.resample(...)` with a `PeriodIndex` not changing its `freq` appropriately when empty (GH13067)
- Bug in `.resample(...)` with a `PeriodIndex` not retaining its type or name with an empty `DataFrame` appropriately when empty (GH13212)
- Bug in `groupby(...).apply(...)` when the passed function returns scalar values per group (GH13468).
- Bug in `groupby(...).resample(...)` where passing some keywords would raise an exception (GH13235)
- Bug in `.tz_convert` on a tz-aware `DateTimeIndex` that relied on index being sorted for correct results (GH13306)
- Bug in `.tz_localize` with `dateutil.tz.tzlocal` may return incorrect result (GH13583)
- Bug in `DatetimeTZDtype` dtype with `dateutil.tz.tzlocal` cannot be regarded as valid dtype (GH13583)
- Bug in `pd.read_hdf()` where attempting to load an HDF file with a single dataset, that had one or more categorical columns, failed unless the `key` argument was set to the name of the dataset. (GH13231)
- Bug in `.rolling()` that allowed a negative integer window in construction of the `Rolling()` object, but would later fail on aggregation (GH13383)
- Bug in `Series` indexing with tuple-valued data and a numeric index (GH13509)
- Bug in printing `pd.DataFrame` where unusual elements with the `object` dtype were causing segfaults (GH13717)
- Bug in ranking `Series` which could result in segfaults (GH13445)
- Bug in various index types, which did not propagate the name of passed index (GH12309)
- Bug in `DatetimeIndex`, which did not honour the `copy=True` (GH13205)
- Bug in `DatetimeIndex.is_normalized` returns incorrectly for normalized `date_range` in case of local timezones (GH13459)
- Bug in `pd.concat` and `.append` may coerces `datetime64` and `timedelta` to `object` dtype containing python built-in `datetime` or `timedelta` rather than `Timestamp` or `Timedelta` (GH13626)
- Bug in `PeriodIndex.append` may raises `AttributeError` when the result is `object` dtype (GH13221)
- Bug in `CategoricalIndex.append` may accept normal list (GH13626)
- Bug in `pd.concat` and `.append` with the same timezone get reset to UTC (GH7795)
- Bug in `Series` and `DataFrame.append` raises `AmbiguousTimeError` if data contains `datetime` near DST boundary (GH13626)
- Bug in `DataFrame.to_csv()` in which float values were being quoted even though quotations were specified for non-numeric values only (GH12922, GH13259)

- Bug in `DataFrame.describe()` raising `ValueError` with only boolean columns ([GH13898](#))
- Bug in `MultiIndex` slicing where extra elements were returned when level is non-unique ([GH12896](#))
- Bug in `.str.replace` does not raise `TypeError` for invalid replacement ([GH13438](#))
- Bug in `MultiIndex.from_arrays` which didn't check for input array lengths matching ([GH13599](#))
- Bug in `cartesian_product` and `MultiIndex.from_product` which may raise with empty input arrays ([GH12258](#))
- Bug in `pd.read_csv()` which may cause a segfault or corruption when iterating in large chunks over a stream/file under rare circumstances ([GH13703](#))
- Bug in `pd.read_csv()` which caused errors to be raised when a dictionary containing scalars is passed in for `na_values` ([GH12224](#))
- Bug in `pd.read_csv()` which caused BOM files to be incorrectly parsed by not ignoring the BOM ([GH4793](#))
- Bug in `pd.read_csv()` with `engine='python'` which raised errors when a numpy array was passed in for `usecols` ([GH12546](#))
- Bug in `pd.read_csv()` where the index columns were being incorrectly parsed when parsed as dates with a `thousands` parameter ([GH14066](#))
- Bug in `pd.read_csv()` with `engine='python'` in which `NaN` values weren't being detected after data was converted to numeric values ([GH13314](#))
- Bug in `pd.read_csv()` in which the `nrows` argument was not properly validated for both engines ([GH10476](#))
- Bug in `pd.read_csv()` with `engine='python'` in which infinities of mixed-case forms were not being interpreted properly ([GH13274](#))
- Bug in `pd.read_csv()` with `engine='python'` in which trailing `NaN` values were not being parsed ([GH13320](#))
- Bug in `pd.read_csv()` with `engine='python'` when reading from a `tempfile.TemporaryFile` on Windows with Python 3 ([GH13398](#))
- Bug in `pd.read_csv()` that prevents `usecols` kwarg from accepting single-byte unicode strings ([GH13219](#))
- Bug in `pd.read_csv()` that prevents `usecols` from being an empty set ([GH13402](#))
- Bug in `pd.read_csv()` in the C engine where the `NULL` character was not being parsed as `NULL` ([GH14012](#))
- Bug in `pd.read_csv()` with `engine='c'` in which `NULL` quotechar was not accepted even though quoting was specified as `None` ([GH13411](#))
- Bug in `pd.read_csv()` with `engine='c'` in which fields were not properly cast to float when quoting was specified as non-numeric ([GH13411](#))
- Bug in `pd.read_csv()` in Python 2.x with non-UTF8 encoded, multi-character separated data ([GH3404](#))
- Bug in `pd.read_csv()`, where aliases for utf-xx (e.g. `UTF-xx`, `UTF_xx`, `utf_xx`) raised `UnicodeDecodeError` ([GH13549](#))
- Bug in `pd.read_csv`, `pd.read_table`, `pd.read_fwf`, `pd.read_stata` and `pd.read_sas` where files were opened by parsers but not closed if both `chunksize` and `iterator` were `None`. ([GH13940](#))
- Bug in `StataReader`, `StataWriter`, `XportReader` and `SAS7BDATReader` where a file was not properly closed when an error was raised. ([GH13940](#))
- Bug in `pd.pivot_table()` where `margins_name` is ignored when `aggfunc` is a list ([GH13354](#))

- Bug in `pd.Series.str.zfill`, `center`, `ljust`, `rjust`, and `pad` when passing non-integers, did not raise `TypeError` (GH13598)
- Bug in checking for any null objects in a `TimedeltaIndex`, which always returned `True` (GH13603)
- Bug in `Series` arithmetic raises `TypeError` if it contains datetime-like as object `dtype` (GH13043)
- Bug `Series.isnull()` and `Series.notnull()` ignore `Period('NaT')` (GH13737)
- Bug `Series.fillna()` and `Series.dropna()` don't affect to `Period('NaT')` (GH13737)
- Bug in `.fillna(value=np.nan)` incorrectly raises `KeyError` on a category `dtype` `Series` (GH14021)
- Bug in extension `dtype` creation where the created types were not is/identical (GH13285)
- Bug in `.resample(...)` where incorrect warnings were triggered by IPython introspection (GH13618)
- Bug in `NaT - Period` raises `AttributeError` (GH13071)
- Bug in `Series` comparison may output incorrect result if rhs contains `NaT` (GH9005)
- Bug in `Series` and `Index` comparison may output incorrect result if it contains `NaT` with object `dtype` (GH13592)
- Bug in `Period` addition raises `TypeError` if `Period` is on right hand side (GH13069)
- Bug in `Period` and `Series` or `Index` comparison raises `TypeError` (GH13200)
- Bug in `pd.set_eng_float_format()` that would prevent `NaN` and `Inf` from formatting (GH11981)
- Bug in `.unstack` with `Categorical dtype` resets `.ordered` to `True` (GH13249)
- Clean some compile time warnings in datetime parsing (GH13607)
- Bug in `factorize` raises `AmbiguousTimeError` if data contains datetime near DST boundary (GH13750)
- Bug in `.set_index` raises `AmbiguousTimeError` if new index contains DST boundary and multi levels (GH12920)
- Bug in `.shift` raises `AmbiguousTimeError` if data contains datetime near DST boundary (GH13926)
- Bug in `pd.read_hdf()` returns incorrect result when a `DataFrame` with a categorical column and a query which doesn't match any values (GH13792)
- Bug in `.iloc` when indexing with a non lexsorted `MultiIndex` (GH13797)
- Bug in `.loc` when indexing with date strings in a reverse sorted `DatetimeIndex` (GH14316)
- Bug in `Series` comparison operators when dealing with zero dim `NumPy` arrays (GH13006)
- Bug in `.combine_first` may return incorrect `dtype` (GH7630, GH10567)
- Bug in `groupby` where `apply` returns different result depending on whether first result is `None` or not (GH12824)
- Bug in `groupby(...).nth()` where the group key is included inconsistently if called after `.head()` / `.tail()` (GH12839)
- Bug in `.to_html`, `.to_latex` and `.to_string` silently ignore custom datetime formatter passed through the `formatters` key word (GH10690)
- Bug in `DataFrame.iterrows()`, not yielding a `Series` subclasse if defined (GH13977)
- Bug in `pd.to_numeric` when `errors='coerce'` and input contains non-hashable objects (GH13324)
- Bug in invalid `Timedelta` arithmetic and comparison may raise `ValueError` rather than `TypeError` (GH13624)

- Bug in invalid datetime parsing in `to_datetime` and `DatetimeIndex` may raise `TypeError` rather than `ValueError` (GH11169, GH11287)
- Bug in `Index` created with tz-aware `Timestamp` and mismatched `tz` option incorrectly coerces timezone (GH13692)
- Bug in `DatetimeIndex` with nanosecond frequency does not include timestamp specified with `end` (GH13672)
- Bug in `Series` when setting a slice with a `np.timedelta64` (GH14155)
- Bug in `Index` raises `OutOfBoundsDatetime` if datetime exceeds `datetime64[ns]` bounds, rather than coercing to object dtype (GH13663)
- Bug in `Index` may ignore specified `datetime64` or `timedelta64` passed as dtype (GH13981)
- Bug in `RangeIndex` can be created without no arguments rather than raises `TypeError` (GH13793)
- Bug in `.value_counts()` raises `OutOfBoundsDatetime` if data exceeds `datetime64[ns]` bounds (GH13663)
- Bug in `DatetimeIndex` may raise `OutOfBoundsDatetime` if input `np.datetime64` has other unit than `ns` (GH9114)
- Bug in `Series` creation with `np.datetime64` which has other unit than `ns` as object dtype results in incorrect values (GH13876)
- Bug in `resample` with `timedelta` data where data was casted to float (GH13119).
- Bug in `pd.isnull()` `pd.notnull()` raise `TypeError` if input datetime-like has other unit than `ns` (GH13389)
- Bug in `pd.merge()` may raise `TypeError` if input datetime-like has other unit than `ns` (GH13389)
- Bug in `HDFStore/read_hdf()` discarded `DatetimeIndex.name` if `tz` was set (GH13884)
- Bug in `Categorical.remove_unused_categories()` changes `.codes` dtype to platform int (GH13261)
- Bug in `groupby` with `as_index=False` returns all NaN's when grouping on multiple columns including a categorical one (GH13204)
- Bug in `df.groupby(...)[...]` where `getitem` with `Int64Index` raised an error (GH13731)
- Bug in the CSS classes assigned to `DataFrame.style` for index names. Previously they were assigned `"col_heading level<n> col<c>"` where `n` was the number of levels + 1. Now they are assigned `"index_name level<n>"`, where `n` is the correct level for that `MultiIndex`.
- Bug where `pd.read_gbq()` could throw `ImportError: No module named discovery` as a result of a naming conflict with another python package called `apiclient` (GH13454)
- Bug in `Index.union` returns an incorrect result with a named empty index (GH13432)
- Bugs in `Index.difference` and `DataFrame.join` raise in Python3 when using mixed-integer indexes (GH13432, GH12814)
- Bug in subtract tz-aware `datetime.datetime` from tz-aware `datetime64` series (GH14088)
- Bug in `.to_excel()` when `DataFrame` contains a `MultiIndex` which contains a label with a NaN value (GH13511)
- Bug in invalid frequency offset string like "D1", "-2-3H" may not raise `ValueError` (GH13930)
- Bug in `concat` and `groupby` for hierarchical frames with `RangeIndex` levels (GH13542).
- Bug in `Series.str.contains()` for `Series` containing only NaN values of object dtype (GH14171)

- Bug in `agg()` function on groupby dataframe changes dtype of `datetime64[ns]` column to `float64` (GH12821)
- Bug in using NumPy `ufunc` with `PeriodIndex` to add or subtract integer raise `IncompatibleFrequency`. Note that using standard operator like `+` or `-` is recommended, because standard operators use more efficient path (GH13980)
- Bug in operations on `NaT` returning `float` instead of `datetime64[ns]` (GH12941)
- Bug in Series flexible arithmetic methods (like `.add()`) raises `ValueError` when `axis=None` (GH13894)
- Bug in `DataFrame.to_csv()` with `MultiIndex` columns in which a stray empty line was added (GH6618)
- Bug in `DatetimeIndex`, `TimedeltaIndex` and `PeriodIndex.equals()` may return `True` when input isn't `Index` but contains the same values (GH13107)
- Bug in assignment against `datetime` with `timezone` may not work if it contains `datetime` near DST boundary (GH14146)
- Bug in `pd.eval()` and `HDFStore` query truncating long float literals with python 2 (GH14241)
- Bug in `Index` raises `KeyError` displaying incorrect column when column is not in the `df` and columns contains duplicate values (GH13822)
- Bug in `Period` and `PeriodIndex` creating wrong dates when frequency has combined offset aliases (GH13874)
- Bug in `.to_string()` when called with an integer `line_width` and `index=False` raises an `UnboundLocalError` exception because `idx` referenced before assignment.
- Bug in `eval()` where the `resolvers` argument would not accept a list (GH14095)
- Bugs in `stack`, `get_dummies`, `make_axis_dummies` which don't preserve categorical dtypes in (multi)indexes (GH13854)
- `PeriodIndex` can now accept list and array which contains `pd.NaT` (GH13430)
- Bug in `df.groupby` where `.median()` returns arbitrary values if grouped dataframe contains empty bins (GH13629)
- Bug in `Index.copy()` where `name` parameter was ignored (GH14302)

## 6.9 Version 0.18

### 6.9.1 v0.18.1 (May 3, 2016)

{{ header }}

This is a minor bug-fix release from 0.18.0 and includes a large number of bug fixes along with several new features, enhancements, and performance improvements. We recommend that all users upgrade to this version.

Highlights include:

- `.groupby(...)` has been enhanced to provide convenient syntax when working with `.rolling(...)`, `.expanding(...)` and `.resample(...)` per group, see [here](#)
- `pd.to_datetime()` has gained the ability to assemble dates from a DataFrame, see [here](#)
- Method chaining improvements, see [here](#).
- Custom business hour offset, see [here](#).
- Many bug fixes in the handling of sparse, see [here](#)
- Expanded the *Tutorials section* with a feature on modern pandas, courtesy of [@TomAugsburger](#). (GH13045).

#### What's new in v0.18.1

- *New features*
  - Custom business hour
  - `.groupby(...)` syntax with window and resample operations
  - Method chaining improvements
    - \* `.where()` and `.mask()`
    - \* `.loc[], .iloc[], .ix[]`
    - \* `[]` indexing
  - Partial string indexing on `DateTimeIndex` when part of a `MultiIndex`
  - Assembling datetimes
  - Other enhancements
- *Sparse changes*
- *API changes*
  - `.groupby(...).nth()` changes
  - numpy function compatibility
  - Using `.apply` on groupby resampling
  - Changes in `read_csv` exceptions
  - `to_datetime` error changes
  - Other API changes

*– Deprecations*

- *Performance improvements*
- *Bug fixes*
- *Contributors*

**New features****Custom business hour**

The `CustomBusinessHour` is a mixture of `BusinessHour` and `CustomBusinessDay` which allows you to specify arbitrary holidays. For details, see *Custom Business Hour* ([GH11514](#))

```
In [1]: from pandas.tseries.offsets import CustomBusinessHour
In [2]: from pandas.tseries.holiday import USFederalHolidayCalendar
In [3]: bhour_us = CustomBusinessHour(calendar=USFederalHolidayCalendar())
```

## Friday before MLK Day

```
In [4]: import datetime
In [5]: dt = datetime.datetime(2014, 1, 17, 15)
In [6]: dt + bhour_us
Out [6]: Timestamp('2014-01-17 16:00:00')
```

## Tuesday after MLK Day (Monday is skipped because it's a holiday)

```
In [7]: dt + bhour_us * 2
Out [7]: Timestamp('2014-01-20 09:00:00')
```

**.groupby(...) syntax with window and resample operations**

`.groupby(...)` has been enhanced to provide convenient syntax when working with `.rolling(...)`, `.expanding(...)` and `.resample(...)` per group, see ([GH12486](#), [GH12738](#)).

You can now use `.rolling(...)` and `.expanding(...)` as methods on groupbys. These return another deferred object (similar to what `.rolling()` and `.expanding()` do on ungrouped pandas objects). You can then operate on these `RollingGroupby` objects in a similar manner.

Previously you would have to do this to get a rolling window mean per-group:

```
In [8]: df = pd.DataFrame({'A': [1] * 20 + [2] * 12 + [3] * 8,
...:                      'B': np.arange(40)})
...:
...:
In [9]: df
Out [9]:
   A  B
0  1  0
1  1  1
```

```

For `.resample(...)` type of operations, previously you would have to:

```

In [12]: df = pd.DataFrame({'date': pd.date_range(start='2016-01-01',
.....:                                     periods=4,
.....:                                     freq='W'),
.....:                    'group': [1, 1, 2, 2],
.....:                    'val': [5, 6, 7, 8]}).set_index('date')
.....:

In [13]: df
Out[13]:
      group  val
date
2016-01-03    1    5
2016-01-10    1    6
2016-01-17    2    7
2016-01-24    2    8

[4 rows x 2 columns]

```

```

In [14]: df.groupby('group').apply(lambda x: x.resample('1D').ffill())
Out[14]:
      group  val
group date
1 2016-01-03    5

   2016-01-23    7
   2016-01-24    8

```

[16 rows x 2 columns]

## Method chaining improvements

The following methods / indexers now accept a callable. It is intended to make these more useful in method chains, see the *documentation*. (GH11485, GH12533)

- `.where()` and `.mask()`
- `.loc[], iloc[]` and `.ix[]`
- `[]` indexing

### `.where()` and `.mask()`

These can accept a callable for the condition and other arguments.

```
In [16]: df = pd.DataFrame({'A': [1, 2, 3],
.....:                    'B': [4, 5, 6],
.....:                    'C': [7, 8, 9]})
.....:
```

```
In [17]: df.where(lambda x: x > 4, lambda x: x + 10)
```

Out [17]:

(continues on next page)

(continued from previous page)

```

   A  B  C
0  11 14  7
1  12  5  8
2  13  6  9

[3 rows x 3 columns]
```

`.loc[]`, `.iloc[]`, `.ix[]`

These can accept a callable, and a tuple of callable as a slicer. The callable can return a valid boolean indexer or anything which is valid for these indexer's input.

```

# callable returns bool indexer
In [18]: df.loc[lambda x: x.A >= 2, lambda x: x.sum() > 10]
Out[18]:
   B  C
1  5  8
2  6  9

[2 rows x 2 columns]

# callable returns list of labels
In [19]: df.loc[lambda x: [1, 2], lambda x: ['A', 'B']]
Out[19]:
   A  B
1  2  5
2  3  6

[2 rows x 2 columns]
```

## [ ] indexing

Finally, you can use a callable in [ ] indexing of Series, DataFrame and Panel. The callable must return a valid input for [ ] indexing depending on its class and index type.

```

In [20]: df[lambda x: 'A']
Out[20]:
0    1
1    2
2    3
Name: A, Length: 3, dtype: int64
```

Using these methods / indexers, you can chain data selection operations without using temporary variable.

```

In [21]: bb = pd.read_csv('data/baseball.csv', index_col='id')

In [22]: (bb.groupby(['year', 'team'])
.....:         .sum()
.....:         .loc[lambda df: df.r > 100])
.....:
Out[22]:
      stint  g  ab  r  h  X2b  X3b  hr  rbi  sb  cs  bb  so
->ibb  hbp  sh  sf  gidp
```

(continues on next page)

### Partial string indexing on DateTimeIndex when part of a MultiIndex

Partial string indexing now matches on DateTimeIndex when part of a MultiIndex (GH10331)

```

In [23]: dft2 = pd.DataFrame(
.....:     np.random.randn(20, 1),
.....:     columns=['A'],
.....:     index=pd.MultiIndex.from_product([pd.date_range('20130101',
.....:                                             periods=10,
.....:                                             freq='12H'),
.....:                                     ['a', 'b']]))
.....:

```

```
[4 rows x 1 columns]
```

## Assembling datetimes

`pd.to_datetime()` has gained the ability to assemble datetimes from a passed in DataFrame or a dict. (GH8158).

```
In [30]: df = pd.DataFrame({'year': [2015, 2016],
.....:                    'month': [2, 3],
.....:                    'day': [4, 5],
.....:                    'hour': [2, 3]})
.....:
```

```
In [31]: df
```

```
Out [31]:
   year  month  day  hour
0  2015     2    4     2
1  2016     3    5     3

[2 rows x 4 columns]
```

Assembling using the passed frame.

```
In [32]: pd.to_datetime(df)
```

```
Out [32]:
0    2015-02-04 02:00:00
1    2016-03-05 03:00:00
Length: 2, dtype: datetime64[ns]
```

You can pass only the columns that you need to assemble.

```
In [33]: pd.to_datetime(df[['year', 'month', 'day']])
```

```
Out [33]:
0    2015-02-04
1    2016-03-05
Length: 2, dtype: datetime64[ns]
```

## Other enhancements

- `pd.read_csv()` now supports `delim_whitespace=True` for the Python engine (GH12958)
- `pd.read_csv()` now supports opening ZIP files that contains a single CSV, via extension inference or explicit `compression='zip'` (GH12175)
- `pd.read_csv()` now supports opening files using xz compression, via extension inference or explicit `compression='xz'` is specified; xz compressions is also supported by `DataFrame.to_csv` in the same way (GH11852)
- `pd.read_msgpack()` now always gives writable ndarrays even when compression is used (GH12359).
- `pd.read_msgpack()` now supports serializing and de-serializing categoricals with msgpack (GH12573)
- `.to_json()` now supports NDframes that contain categorical and sparse data (GH10778)
- `interpolate()` now supports `method='akima'` (GH7588).
- `pd.read_excel()` now accepts path objects (e.g. `pathlib.Path`, `py.path.local`) for the file path, in line with other `read_*` functions (GH12655)
- Added `.weekday_name` property as a component to `DatetimeIndex` and the `.dt` accessor. (GH11128)

- `Index.take` now handles `allow_fill` and `fill_value` consistently (GH12631)

```
In [34]: idx = pd.Index([1., 2., 3., 4.], dtype='float')
# default, allow_fill=True, fill_value=None
In [35]: idx.take([2, -1])
Out [35]: Float64Index([3.0, 4.0], dtype='float64')

In [36]: idx.take([2, -1], fill_value=True)
Out [36]: Float64Index([3.0, nan], dtype='float64')
```

- `Index` now supports `.str.get_dummies()` which returns `MultiIndex`, see *Creating Indicator Variables* (GH10008, GH10103)

```
In [37]: idx = pd.Index(['a|b', 'a|c', 'b|c'])

In [38]: idx.str.get_dummies('|')
Out [38]:
MultiIndex([(1, 1, 0),
            (1, 0, 1),
            (0, 1, 1)],
           names=['a', 'b', 'c'])
```

- `pd.crosstab()` has gained a `normalize` argument for normalizing frequency tables (GH12569). Examples in the updated docs *here*.
- `.resample(..).interpolate()` is now supported (GH12925)
- `.isin()` now accepts passed sets (GH12988)

## Sparse changes

These changes conform sparse handling to return the correct types and work to make a smoother experience with indexing.

`SparseArray.take` now returns a scalar for scalar input, `SparseArray` for others. Furthermore, it handles a negative indexer with the same rule as `Index` (GH10560, GH12796)

```
s = pd.SparseArray([np.nan, np.nan, 1, 2, 3, np.nan, 4, 5, np.nan, 6])
s.take(0)
s.take([1, 2, 3])
```

- Bug in `SparseSeries[]` indexing with Ellipsis raises `KeyError` (GH9467)
- Bug in `SparseArray[]` indexing with tuples are not handled properly (GH12966)
- Bug in `SparseSeries.loc[]` with list-like input raises `TypeError` (GH10560)
- Bug in `SparseSeries.iloc[]` with scalar input may raise `IndexError` (GH10560)
- Bug in `SparseSeries.loc[], .iloc[]` with slice returns `SparseArray`, rather than `SparseSeries` (GH10560)
- Bug in `SparseDataFrame.loc[], .iloc[]` may results in dense `Series`, rather than `SparseSeries` (GH12787)
- Bug in `SparseArray` addition ignores `fill_value` of right hand side (GH12910)
- Bug in `SparseArray` mod raises `AttributeError` (GH12910)
- Bug in `SparseArray` pow calculates `1 ** np.nan` as `np.nan` which must be 1 (GH12910)

- Bug in `SparseArray` comparison output may incorrect result or raise `ValueError` (GH12971)
- Bug in `SparseSeries.__repr__` raises `TypeError` when it is longer than `max_rows` (GH10560)
- Bug in `SparseSeries.shape` ignores `fill_value` (GH10452)
- Bug in `SparseSeries` and `SparseArray` may have different `dtype` from its dense values (GH12908)
- Bug in `SparseSeries.reindex` incorrectly handle `fill_value` (GH12797)
- Bug in `SparseArray.to_frame()` results in `DataFrame`, rather than `SparseDataFrame` (GH9850)
- Bug in `SparseSeries.value_counts()` does not count `fill_value` (GH6749)
- Bug in `SparseArray.to_dense()` does not preserve `dtype` (GH10648)
- Bug in `SparseArray.to_dense()` incorrectly handle `fill_value` (GH12797)
- Bug in `pd.concat()` of `SparseSeries` results in dense (GH10536)
- Bug in `pd.concat()` of `SparseDataFrame` incorrectly handle `fill_value` (GH9765)
- Bug in `pd.concat()` of `SparseDataFrame` may raise `AttributeError` (GH12174)
- Bug in `SparseArray.shift()` may raise `NameError` or `TypeError` (GH12908)

## API changes

### `.groupby(...).nth()` changes

The index in `.groupby(...).nth()` output is now more consistent when the `as_index` argument is passed (GH11039):

```
In [39]: df = pd.DataFrame({'A': ['a', 'b', 'a'],
.....:                    'B': [1, 2, 3]})
.....:

In [40]: df
Out[40]:
   A  B
0  a  1
1  b  2
2  a  3

[3 rows x 2 columns]
```

Previous behavior:

```
In [3]: df.groupby('A', as_index=True)['B'].nth(0)
Out[3]:
0    1
1    2
Name: B, dtype: int64

In [4]: df.groupby('A', as_index=False)['B'].nth(0)
Out[4]:
0    1
1    2
Name: B, dtype: int64
```

New behavior:

```
In [41]: df.groupby('A', as_index=True)['B'].nth(0)
```

```
Out[41]:
```

```
A
a    1
b    2
Name: B, Length: 2, dtype: int64
```

```
In [42]: df.groupby('A', as_index=False)['B'].nth(0)
```

```
Out[42]:
```

```
0    1
1    2
Name: B, Length: 2, dtype: int64
```

Furthermore, previously, a `.groupby` would always sort, regardless if `sort=False` was passed with `.nth()`.

```
In [43]: np.random.seed(1234)
```

```
In [44]: df = pd.DataFrame(np.random.randn(100, 2), columns=['a', 'b'])
```

```
In [45]: df['c'] = np.random.randint(0, 4, 100)
```

Previous behavior:

```
In [4]: df.groupby('c', sort=True).nth(1)
```

```
Out[4]:
```

```
      a      b
c
0 -0.334077  0.002118
1  0.036142 -2.074978
2 -0.720589  0.887163
3  0.859588 -0.636524
```

```
In [5]: df.groupby('c', sort=False).nth(1)
```

```
Out[5]:
```

```
      a      b
c
0 -0.334077  0.002118
1  0.036142 -2.074978
2 -0.720589  0.887163
3  0.859588 -0.636524
```

New behavior:

```
In [46]: df.groupby('c', sort=True).nth(1)
```

```
Out[46]:
```

```
      a      b
c
0 -0.334077  0.002118
1  0.036142 -2.074978
2 -0.720589  0.887163
3  0.859588 -0.636524
```

```
[4 rows x 2 columns]
```

```
In [47]: df.groupby('c', sort=False).nth(1)
```

```
Out[47]:
```

```
      a      b
```

(continues on next page)

(continued from previous page)

```
c
2 -0.720589  0.887163
3  0.859588 -0.636524
0 -0.334077  0.002118
1  0.036142 -2.074978

[4 rows x 2 columns]
```

## numpy function compatibility

Compatibility between pandas array-like methods (e.g. `sum` and `take`) and their `numpy` counterparts has been greatly increased by augmenting the signatures of the pandas methods so as to accept arguments that can be passed in from `numpy`, even if they are not necessarily used in the pandas implementation ([GH12644](#), [GH12638](#), [GH12687](#))

- `.searchsorted()` for `Index` and `TimedeltaIndex` now accept a `sorter` argument to maintain compatibility with `numpy`'s `searchsorted` function ([GH12238](#))
- Bug in `numpy` compatibility of `np.round()` on a `Series` ([GH12600](#))

An example of this signature augmentation is illustrated below:

```
sp = pd.SparseDataFrame([1, 2, 3])
sp
```

Previous behaviour:

```
In [2]: np.cumsum(sp, axis=0)
...
TypeError: cumsum() takes at most 2 arguments (4 given)
```

New behaviour:

```
np.cumsum(sp, axis=0)
```

## Using `.apply` on `groupby` resampling

Using `apply` on resampling `groupby` operations (using a `pd.TimeGrouper`) now has the same output types as similar `apply` calls on other `groupby` operations. ([GH11742](#)).

```
In [48]: df = pd.DataFrame({'date': pd.to_datetime(['10/10/2000', '11/10/2000']),
.....:                    'value': [10, 13]})
.....:

In [49]: df
Out[49]:
   date      value
0 2000-10-10      10
1 2000-11-10      13

[2 rows x 2 columns]
```

Previous behavior:

```
In [1]: df.groupby(pd.TimeGrouper(key='date',
...:                               freq='M')).apply(lambda x: x.value.sum())
Out[1]:
...
TypeError: cannot concatenate a non-NDFrame object

# Output is a Series
In [2]: df.groupby(pd.TimeGrouper(key='date',
...:                               freq='M')).apply(lambda x: x[['value']].sum())
Out[2]:
date
2000-10-31  value    10
2000-11-30  value    13
dtype: int64
```

New behavior:

```
# Output is a Series
In [55]: df.groupby(pd.TimeGrouper(key='date',
...:                               freq='M')).apply(lambda x: x.value.sum())
Out[55]:
date
2000-10-31    10
2000-11-30    13
Freq: M, dtype: int64

# Output is a DataFrame
In [56]: df.groupby(pd.TimeGrouper(key='date',
...:                               freq='M')).apply(lambda x: x[['value']].sum())
Out[56]:
      value
date

```

## Changes in read\_csv exceptions

In order to standardize the `read_csv` API for both the `c` and `python` engines, both will now raise an `EmptyDataError`, a subclass of `ValueError`, in response to empty columns or header ([GH12493](#), [GH12506](#))

Previous behaviour:

```
In [1]: import io

In [2]: df = pd.read_csv(io.StringIO(''), engine='c')
...
ValueError: No columns to parse from file

In [3]: df = pd.read_csv(io.StringIO(''), engine='python')
...
StopIteration
```

New behaviour:

```
In [1]: df = pd.read_csv(io.StringIO(''), engine='c')
...
```

(continues on next page)

(continued from previous page)

```
pandas.io.common.EmptyDataError: No columns to parse from file
In [2]: df = pd.read_csv(io.StringIO(''), engine='python')
...
pandas.io.common.EmptyDataError: No columns to parse from file
```

In addition to this error change, several others have been made as well:

- `CParserError` now sub-classes `ValueError` instead of just a `Exception` ([GH12551](#))
- A `CParserError` is now raised instead of a generic `Exception` in `read_csv` when the `c` engine cannot parse a column ([GH12506](#))
- A `ValueError` is now raised instead of a generic `Exception` in `read_csv` when the `c` engine encounters a `NaN` value in an integer column ([GH12506](#))
- A `ValueError` is now raised instead of a generic `Exception` in `read_csv` when `true_values` is specified, and the `c` engine encounters an element in a column containing unencodable bytes ([GH12506](#))
- `pandas.parser.OverflowError` exception has been removed and has been replaced with Python's built-in `OverflowError` exception ([GH12506](#))
- `pd.read_csv()` no longer allows a combination of strings and integers for the `usecols` parameter ([GH12678](#))

### to\_datetime error changes

Bugs in `pd.to_datetime()` when passing a unit with convertible entries and `errors='coerce'` or non-convertible with `errors='ignore'`. Furthermore, an `OutOfBoundsDatetime` exception will be raised when an out-of-range value is encountered for that unit when `errors='raise'`. ([GH11758](#), [GH13052](#), [GH13059](#))

Previous behaviour:

```
In [27]: pd.to_datetime(1420043460, unit='s', errors='coerce')
Out[27]: NaT

In [28]: pd.to_datetime(11111111, unit='D', errors='ignore')
OverflowError: Python int too large to convert to C long

In [29]: pd.to_datetime(11111111, unit='D', errors='raise')
OverflowError: Python int too large to convert to C long
```

New behaviour:

```
In [2]: pd.to_datetime(1420043460, unit='s', errors='coerce')
Out[2]: Timestamp('2014-12-31 16:31:00')

In [3]: pd.to_datetime(11111111, unit='D', errors='ignore')
Out[3]: 11111111

In [4]: pd.to_datetime(11111111, unit='D', errors='raise')
OutOfBoundsDatetime: cannot convert input with unit 'D'
```

## Other API changes

- `.swaplevel()` for `Series`, `DataFrame`, `Panel`, and `MultiIndex` now features defaults for its first two parameters `i` and `j` that swap the two innermost levels of the index. (GH12934)
- `.searchsorted()` for `Index` and `TimedeltaIndex` now accept a `sorter` argument to maintain compatibility with `numpy`'s `searchsorted` function (GH12238)
- `Period` and `PeriodIndex` now raises `IncompatibleFrequency` error which inherits `ValueError` rather than raw `ValueError` (GH12615)
- `Series.apply` for category dtype now applies the passed function to each of the `.categories` (and not the `.codes`), and returns a category dtype if possible (GH12473)
- `read_csv` will now raise a `TypeError` if `parse_dates` is neither a boolean, list, or dictionary (matches the doc-string) (GH5636)
- The default for `.query()/eval()` is now `engine=None`, which will use `numexpr` if it's installed; otherwise it will fallback to the `python` engine. This mimics the pre-0.18.1 behavior if `numexpr` is installed (and which, previously, if `numexpr` was not installed, `.query()/eval()` would raise). (GH12749)
- `pd.show_versions()` now includes `pandas_datareader` version (GH12740)
- Provide a proper `__name__` and `__qualname__` attributes for generic functions (GH12021)
- `pd.concat(ignore_index=True)` now uses `RangeIndex` as default (GH12695)
- `pd.merge()` and `DataFrame.join()` will show a `UserWarning` when merging/joining a single- with a multi-leveled dataframe (GH9455, GH12219)
- Compat with `scipy > 0.17` for deprecated `piecewise_polynomial` interpolation method; support for the replacement `from_derivatives` method (GH12887)

## Deprecations

- The method name `Index.sym_diff()` is deprecated and can be replaced by `Index.symmetric_difference()` (GH12591)
- The method name `Categorical.sort()` is deprecated in favor of `Categorical.sort_values()` (GH12882)

## Performance improvements

- Improved speed of SAS reader (GH12656, GH12961)
- Performance improvements in `.groupby(...).cumcount()` (GH11039)
- Improved memory usage in `pd.read_csv()` when using `skiprows=an_integer` (GH13005)
- Improved performance of `DataFrame.to_sql` when checking case sensitivity for tables. Now only checks if table has been created correctly when table name is not lower case. (GH12876)
- Improved performance of `Period` construction and time series plotting (GH12903, GH11831).
- Improved performance of `.str.encode()` and `.str.decode()` methods (GH13008)
- Improved performance of `to_numeric` if input is numeric dtype (GH12777)
- Improved performance of sparse arithmetic with `IntIndex` (GH13036)

## Bug fixes

- `usecols` parameter in `pd.read_csv` is now respected even when the lines of a CSV file are not even (GH12203)
- Bug in `groupby.transform(..)` when `axis=1` is specified with a non-monotonic ordered index (GH12713)
- Bug in `Period` and `PeriodIndex` creation raises `KeyError` if `freq="Minute"` is specified. Note that “Minute” freq is deprecated in v0.17.0, and recommended to use `freq="T"` instead (GH11854)
- Bug in `.resample(...).count()` with a `PeriodIndex` always raising a `TypeError` (GH12774)
- Bug in `.resample(...)` with a `PeriodIndex` casting to a `DatetimeIndex` when empty (GH12868)
- Bug in `.resample(...)` with a `PeriodIndex` when resampling to an existing frequency (GH12770)
- Bug in printing data which contains `Period` with different `freq` raises `ValueError` (GH12615)
- Bug in `Series` construction with `Categorical` and `dtype='category'` is specified (GH12574)
- Bugs in concatenation with a coercible `dtype` was too aggressive, resulting in different `dtypes` in output formatting when an object was longer than `display.max_rows` (GH12411, GH12045, GH11594, GH10571, GH12211)
- Bug in `float_format` option with option not being validated as a callable. (GH12706)
- Bug in `GroupBy.filter` when `dropna=False` and no groups fulfilled the criteria (GH12768)
- Bug in `__name__` of `.cum*` functions (GH12021)
- Bug in `.astype()` of a `Float64Index/Int64Index` to an `Int64Index` (GH12881)
- Bug in round tripping an integer based index in `.to_json()/read_json()` when `orient='index'` (the default) (GH12866)
- Bug in plotting `Categorical` `dtypes` cause error when attempting stacked bar plot (GH13019)
- Compat with `>= numpy 1.11` for `NaT` comparisons (GH12969)
- Bug in `.drop()` with a non-unique `MultiIndex`. (GH12701)
- Bug in `.concat` of datetime tz-aware and naive `DataFrames` (GH12467)
- Bug in correctly raising a `ValueError` in `.resample(..).fillna(..)` when passing a non-string (GH12952)
- Bug fixes in various encoding and header processing issues in `pd.read_sas()` (GH12659, GH12654, GH12647, GH12809)
- Bug in `pd.crosstab()` where would silently ignore `aggfunc` if `values=None` (GH12569).
- Potential segfault in `DataFrame.to_json` when serialising `datetime.time` (GH11473).
- Potential segfault in `DataFrame.to_json` when attempting to serialise `0d` array (GH11299).
- Segfault in `to_json` when attempting to serialise a `DataFrame` or `Series` with non-ndarray values; now supports serialization of `category`, `sparse`, and `datetime64[ns, tz]` `dtypes` (GH10778).
- Bug in `DataFrame.to_json` with unsupported `dtype` not passed to default handler (GH12554).
- Bug in `.align` not returning the sub-class (GH12983)
- Bug in aligning a `Series` with a `DataFrame` (GH13037)
- Bug in `ABCPanel` in which `Panel4D` was not being considered as a valid instance of this generic type (GH12810)

- Bug in consistency of `.name` on `.groupby(..).apply(..)` cases (GH12363)
- Bug in `Timestamp.__repr__` that caused `pprint` to fail in nested structures (GH12622)
- Bug in `Timedelta.min` and `Timedelta.max`, the properties now report the true minimum/maximum `timedeltas` as recognized by pandas. See the *documentation*. (GH12727)
- Bug in `.quantile()` with interpolation may coerce to `float` unexpectedly (GH12772)
- Bug in `.quantile()` with empty `Series` may return scalar rather than empty `Series` (GH12772)
- Bug in `.loc` with out-of-bounds in a large indexer would raise `IndexError` rather than `KeyError` (GH12527)
- Bug in resampling when using a `TimedeltaIndex` and `.asfreq()`, would previously not include the final fencepost (GH12926)
- Bug in equality testing with a `Categorical` in a `DataFrame` (GH12564)
- Bug in `GroupBy.first()`, `.last()` returns incorrect row when `TimeGrouper` is used (GH7453)
- Bug in `pd.read_csv()` with the `c` engine when specifying `skiprows` with newlines in quoted items (GH10911, GH12775)
- Bug in `DataFrame` timezone lost when assigning tz-aware `datetime Series` with alignment (GH12981)
- Bug in `.value_counts()` when `normalize=True` and `dropna=True` where nulls still contributed to the normalized count (GH12558)
- Bug in `Series.value_counts()` loses name if its `dtype` is `category` (GH12835)
- Bug in `Series.value_counts()` loses timezone info (GH12835)
- Bug in `Series.value_counts(normalize=True)` with `Categorical` raises `UnboundLocalError` (GH12835)
- Bug in `Panel.fillna()` ignoring `inplace=True` (GH12633)
- Bug in `pd.read_csv()` when specifying `names`, `usecols`, and `parse_dates` simultaneously with the `c` engine (GH9755)
- Bug in `pd.read_csv()` when specifying `delim_whitespace=True` and `lineterminator` simultaneously with the `c` engine (GH12912)
- Bug in `Series.rename`, `DataFrame.rename` and `DataFrame.rename_axis` not treating `Series` as mappings to relabel (GH12623).
- Clean in `.rolling.min` and `.rolling.max` to enhance `dtype` handling (GH12373)
- Bug in `groupby` where complex types are coerced to `float` (GH12902)
- Bug in `Series.map` raises `TypeError` if its `dtype` is `category` or tz-aware `datetime` (GH12473)
- Bugs on 32bit platforms for some test comparisons (GH12972)
- Bug in index coercion when falling back from `RangeIndex` construction (GH12893)
- Better error message in window functions when invalid argument (e.g. a float window) is passed (GH12669)
- Bug in slicing subclassed `DataFrame` defined to return subclassed `Series` may return normal `Series` (GH11559)
- Bug in `.str` accessor methods may raise `ValueError` if input has name and the result is `DataFrame` or `MultiIndex` (GH12617)
- Bug in `DataFrame.last_valid_index()` and `DataFrame.first_valid_index()` on empty frames (GH12800)

- Bug in `CategoricalIndex.get_loc` returns different result from regular `Index` (GH12531)
- Bug in `PeriodIndex.resample` where name not propagated (GH12769)
- Bug in `date_range` closed keyword and timezones (GH12684).
- Bug in `pd.concat` raises `AttributeError` when input data contains tz-aware datetime and timedelta (GH12620)
- Bug in `pd.concat` did not handle empty `Series` properly (GH11082)
- Bug in `.plot.bar` alignment when width is specified with `int` (GH12979)
- Bug in `fill_value` is ignored if the argument to a binary operator is a constant (GH12723)
- Bug in `pd.read_html()` when using `bs4` flavor and parsing table with a header and only one column (GH9178)
- Bug in `.pivot_table` when `margins=True` and `dropna=True` where nulls still contributed to margin count (GH12577)
- Bug in `.pivot_table` when `dropna=False` where table index/column names disappear (GH12133)
- Bug in `pd.crosstab()` when `margins=True` and `dropna=False` which raised (GH12642)
- Bug in `Series.name` when name attribute can be a hashable type (GH12610)
- Bug in `.describe()` resets categorical columns information (GH11558)
- Bug where `loffset` argument was not applied when calling `resample().count()` on a timeseries (GH12725)
- `pd.read_excel()` now accepts column names associated with keyword argument `names` (GH12870)
- Bug in `pd.to_numeric()` with `Index` returns `np.ndarray`, rather than `Index` (GH12777)
- Bug in `pd.to_numeric()` with datetime-like may raise `TypeError` (GH12777)
- Bug in `pd.to_numeric()` with scalar raises `ValueError` (GH12777)

## 6.9.2 v0.18.0 (March 13, 2016)

{{ header }}

This is a major release from 0.17.1 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

**Warning:** pandas >= 0.18.0 no longer supports compatibility with Python version 2.6 and 3.3 ([GH7718](#), [GH11273](#))

**Warning:** numexpr version 2.4.4 will now show a warning and not be used as a computation back-end for pandas because of some buggy behavior. This does not affect other versions (>= 2.1 and >= 2.4.6). ([GH12489](#))

Highlights include:

- Moving and expanding window functions are now methods on Series and DataFrame, similar to `.groupby`, see [here](#).
- Adding support for a `RangeIndex` as a specialized form of the `Int64Index` for memory savings, see [here](#).
- API breaking change to the `.resample` method to make it more `.groupby` like, see [here](#).
- Removal of support for positional indexing with floats, which was deprecated since 0.14.0. This will now raise a `TypeError`, see [here](#).
- The `.to_xarray()` function has been added for compatibility with the `xarray` package, see [here](#).
- The `read_sas` function has been enhanced to read `sas7bdat` files, see [here](#).
- Addition of the `.str.extractall()` method, and API changes to the `.str.extract()` method and `.str.cat()` method.
- `pd.test()` top-level nose test runner is available ([GH4327](#)).

Check the *API Changes* and *deprecations* before updating.

### What's new in v0.18.0

- *New features*
  - *Window functions are now methods*
  - *Changes to rename*
  - *Range index*
  - *Changes to str.extract*
  - *Addition of str.extractall*
  - *Changes to str.cat*
  - *Datetimelike rounding*
  - *Formatting of integers in FloatIndex*
  - *Changes to dtype assignment behaviors*
  - *to\_xarray*
  - *Latex representation*
  - *pd.read\_sas() changes*
  - *Other enhancements*
- *Backwards incompatible API changes*
  - *NaT and Timedelta operations*
  - *Changes to msgpack*
  - *Signature change for .rank*
  - *Bug in QuarterBegin with n=0*
  - *Resample API*
    - \* *Downsampling*
    - \* *Upsampling*
    - \* *Previous API will work but with deprecations*
  - *Changes to eval*
  - *Other API changes*
  - *Deprecations*
  - *Removal of deprecated float indexers*
  - *Removal of prior version deprecations/changes*
- *Performance improvements*
- *Bug Fixes*
- *Contributors*

## New features

### Window functions are now methods

Window functions have been refactored to be methods on `Series/DataFrame` objects, rather than top-level functions, which are now deprecated. This allows these window-type functions, to have a similar API to that of `.groupby`. See the full documentation *here* ([GH11603](#), [GH12373](#))

```
In [1]: np.random.seed(1234)

In [2]: df = pd.DataFrame({'A': range(10), 'B': np.random.randn(10)})

In [3]: df
Out[3]:
   A      B
0  0  0.471435
1  1 -1.190976
2  2  1.432707
3  3 -0.312652
4  4 -0.720589
5  5  0.887163
6  6  0.859588
7  7 -0.636524
8  8  0.015696
9  9 -2.242685

[10 rows x 2 columns]
```

Previous behavior:

```
In [8]: pd.rolling_mean(df, window=3)
FutureWarning: pd.rolling_mean is deprecated for DataFrame and will be
↳removed in a future version, replace with
      DataFrame.rolling(window=3,center=False).mean()

Out[8]:
   A      B
0 NaN     NaN
1 NaN     NaN
2  1  0.237722
3  2 -0.023640
4  3  0.133155
5  4 -0.048693
6  5  0.342054
7  6  0.370076
8  7  0.079587
9  8 -0.954504
```

New behavior:

```
In [4]: r = df.rolling(window=3)
```

These show a descriptive repr

```
In [5]: r
Out[5]: Rolling [window=3,center=False,axis=0]
```

with tab-completion of available methods and properties.

```
In [9]: r.<TAB> # noqa E225, E999
r.A      r.agg      r.apply      r.count      r.exclusions  r.max      r.
↳median  r.name      r.skew      r.sum
r.B      r.aggregate  r.corr      r.cov        r.kurt        r.mean     r.
↳min     r.quantile  r.std      r.var
```

The methods operate on the Rolling object itself

```
In [6]: r.mean()
Out [6]:
      A      B
0  NaN    NaN
1  NaN    NaN
2  1.0  0.237722
3  2.0 -0.023640
4  3.0  0.133155
5  4.0 -0.048693
6  5.0  0.342054
7  6.0  0.370076
8  7.0  0.079587
9  8.0 -0.954504

[10 rows x 2 columns]
```

They provide getitem accessors

```
In [7]: r['A'].mean()
Out [7]:

```

(continues on next page)

(continued from previous page)

```
9  8.0  1.0 -0.954504  1.162285
[10 rows x 4 columns]
```

## Changes to rename

`Series.rename` and `NDFrame.rename_axis` can now take a scalar or list-like argument for altering the Series or axis *name*, in addition to their old behaviors of altering labels. ([GH9494](#), [GH11965](#))

```
In [9]: s = pd.Series(np.random.randn(5))
```

```
In [10]: s.rename('newname')
```

```
Out [10]:
```

```
0    1.150036
1    0.991946
2    0.953324
3   -2.021255
4   -0.334077
```

```
Name: newname, Length: 5, dtype: float64
```

```
In [11]: df = pd.DataFrame(np.random.randn(5, 2))
```

```
In [12]: (df.rename_axis("indexname")
.....:         .rename_axis("columns_name", axis="columns"))
.....:
```

```
Out [12]:
```

```
columns_name      0      1
indexname
0      0.002118  0.405453
1      0.289092  1.321158
2     -1.546906 -0.202646
3     -0.655969  0.193421
4      0.553439  1.318152
```

```
[5 rows x 2 columns]
```

The new functionality works well in method chains. Previously these methods only accepted functions or dicts mapping a *label* to a new label. This continues to work as before for function or dict-like values.

## Range index

A `RangeIndex` has been added to the `Int64Index` sub-classes to support a memory saving alternative for common use cases. This has a similar implementation to the python `range` object (`xrange` in python 2), in that it only stores the start, stop, and step values for the index. It will transparently interact with the user API, converting to `Int64Index` if needed.

This will now be the default constructed index for `NDFrame` objects, rather than previous an `Int64Index`. ([GH939](#), [GH12070](#), [GH12071](#), [GH12109](#), [GH12888](#))

Previous behavior:

```
In [3]: s = pd.Series(range(1000))
```

(continues on next page)

(continued from previous page)

```
In [4]: s.index
Out [4]:
Int64Index([ 0,  1,  2,  3,  4,  5,  6,  7,  8,  9,
            ...
            990, 991, 992, 993, 994, 995, 996, 997, 998, 999], dtype='int64',
            ↪length=1000)

In [6]: s.index.nbytes
Out [6]: 8000
```

New behavior:

```
In [13]: s = pd.Series(range(1000))

In [14]: s.index
Out [14]: RangeIndex(start=0, stop=1000, step=1)

In [15]: s.index.nbytes
Out [15]: 128
```

## Changes to str.extract

The `.str.extract` method takes a regular expression with capture groups, finds the first match in each subject string, and returns the contents of the capture groups (GH11386).

In v0.18.0, the `expand` argument was added to `extract`.

- `expand=False`: it returns a `Series`, `Index`, or `DataFrame`, depending on the subject and regular expression pattern (same behavior as pre-0.18.0).
- `expand=True`: it always returns a `DataFrame`, which is more consistent and less confusing from the perspective of a user.

Currently the default is `expand=None` which gives a `FutureWarning` and uses `expand=False`. To avoid this warning, please explicitly specify `expand`.

```
In [1]: pd.Series(['a1', 'b2', 'c3']).str.extract(r'[ab](\d)', expand=None)
FutureWarning: currently extract(expand=None) means expand=False (return Index/Series/
↪DataFrame)
but in a future version of pandas this will be changed to expand=True (return
↪DataFrame)

Out [1]:
0      1
1      2
2     NaN
dtype: object
```

Extracting a regular expression with one group returns a `Series` if `expand=False`.

```
In [16]: pd.Series(['a1', 'b2', 'c3']).str.extract(r'[ab](\d)', expand=False)
Out [16]:
0      1
1      2
2     NaN
Length: 3, dtype: object
```

It returns a DataFrame with one column if `expand=True`.

```
In [17]: pd.Series(['a1', 'b2', 'c3']).str.extract(r'[ab](\d)', expand=True)
Out [17]:
      0
0     1
1     2
2  NaN

[3 rows x 1 columns]
```

Calling on an Index with a regex with exactly one capture group returns an Index if `expand=False`.

```
In [18]: s = pd.Series(["a1", "b2", "c3"], ["A11", "B22", "C33"])

In [19]: s.index
Out [19]: Index(['A11', 'B22', 'C33'], dtype='object')

In [20]: s.index.str.extract("(?P<letter>[a-zA-Z])", expand=False)
Out [20]: Index(['A', 'B', 'C'], dtype='object', name='letter')
```

It returns a DataFrame with one column if `expand=True`.

```
In [21]: s.index.str.extract("(?P<letter>[a-zA-Z])", expand=True)
Out [21]:
  letter
0      A
1      B
2      C

[3 rows x 1 columns]
```

Calling on an Index with a regex with more than one capture group raises `ValueError` if `expand=False`.

```
>>> s.index.str.extract("(?P<letter>[a-zA-Z])([0-9]+)", expand=False)
ValueError: only one regex group is supported with Index
```

It returns a DataFrame if `expand=True`.

```
In [22]: s.index.str.extract("(?P<letter>[a-zA-Z])([0-9]+)", expand=True)
Out [22]:
  letter  1
0      A  11
1      B  22
2      C  33

[3 rows x 2 columns]
```

In summary, `extract (expand=True)` always returns a DataFrame with a row for every subject string, and a column for every capture group.

## Addition of str.extractall

The `.str.extractall` method was added (GH11386). Unlike `extract`, which returns only the first match.

```
In [23]: s = pd.Series(["a1a2", "b1", "c1"], ["A", "B", "C"])

In [24]: s
Out[24]:
A    a1a2
B     b1
C     c1
Length: 3, dtype: object

In [25]: s.str.extract(r"(?P<letter>[ab])(?P<digit>\d)", expand=False)
Out[25]:
   letter digit
A      a      1
B      b      1
C    NaN    NaN

[3 rows x 2 columns]
```

The `extractall` method returns all matches.

```
In [26]: s.str.extractall(r"(?P<letter>[ab])(?P<digit>\d)")
Out[26]:
   letter digit
match
A 0      a      1
  1      a      2
B 0      b      1

[3 rows x 2 columns]
```

## Changes to str.cat

The method `.str.cat()` concatenates the members of a `Series`. Before, if `NaN` values were present in the `Series`, calling `.str.cat()` on it would return `NaN`, unlike the rest of the `Series.str.*` API. This behavior has been amended to ignore `NaN` values by default. (GH11435).

A new, friendlier `ValueError` is added to protect against the mistake of supplying the `sep` as an arg, rather than as a kwarg. (GH11334).

```
In [27]: pd.Series(['a', 'b', np.nan, 'c']).str.cat(sep=' ')
Out[27]: 'a b c'

In [28]: pd.Series(['a', 'b', np.nan, 'c']).str.cat(sep=' ', na_rep='?')
Out[28]: 'a b ? c'
```

```
In [2]: pd.Series(['a', 'b', np.nan, 'c']).str.cat(' ')
ValueError: Did you mean to supply a `sep` keyword?
```

## Datetimelike rounding

DatetimeIndex, Timestamp, TimedeltaIndex, Timedelta have gained the `.round()`, `.floor()` and `.ceil()` method for datetimelike rounding, flooring and ceiling. (GH4314, GH11963)

### Naive datetimes

```
In [29]: dr = pd.date_range('20130101 09:12:56.1234', periods=3)

In [30]: dr
Out [30]:
DatetimeIndex(['2013-01-01 09:12:56.123400', '2013-01-02 09:12:56.123400',
              '2013-01-03 09:12:56.123400'],
              dtype='datetime64[ns]', freq='D')

In [31]: dr.round('s')
Out [31]:
DatetimeIndex(['2013-01-01 09:12:56', '2013-01-02 09:12:56',
              '2013-01-03 09:12:56'],
              dtype='datetime64[ns]', freq=None)

# Timestamp scalar
In [32]: dr[0]
Out [32]: Timestamp('2013-01-01 09:12:56.123400', freq='D')

In [33]: dr[0].round('10s')
Out [33]: Timestamp('2013-01-01 09:13:00')
```

### Tz-aware are rounded, floored and ceiled in local times

```
In [34]: dr = dr.tz_localize('US/Eastern')

In [35]: dr
Out [35]:
DatetimeIndex(['2013-01-01 09:12:56.123400-05:00',
              '2013-01-02 09:12:56.123400-05:00',
              '2013-01-03 09:12:56.123400-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq='D')

In [36]: dr.round('s')
Out [36]:
DatetimeIndex(['2013-01-01 09:12:56-05:00', '2013-01-02 09:12:56-05:00',
              '2013-01-03 09:12:56-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq=None)
```

### Timedeltas

```
In [37]: t = pd.timedelta_range('1 days 2 hr 13 min 45 us', periods=3, freq='d')

In [38]: t
Out [38]:
TimedeltaIndex(['1 days 02:13:00.000045', '2 days 02:13:00.000045',
              '3 days 02:13:00.000045'],
              dtype='timedelta64[ns]', freq='D')

In [39]: t.round('10min')
Out [39]: TimedeltaIndex(['1 days 02:10:00', '2 days 02:10:00', '3 days 02:10:00'],
                          ↪ dtype='timedelta64[ns]', freq=None)
```

(continues on next page)

(continued from previous page)

```
# Timedelta scalar
In [40]: t[0]
Out[40]: Timedelta('1 days 02:13:00.000045')

In [41]: t[0].round('2h')
Out[41]: Timedelta('1 days 02:00:00')
```

In addition, `.round()`, `.floor()` and `.ceil()` will be available through the `.dt` accessor of `Series`.

```
In [42]: s = pd.Series(dr)

In [43]: s
Out[43]:
0    2013-01-01 09:12:56.123400-05:00
1    2013-01-02 09:12:56.123400-05:00
2    2013-01-03 09:12:56.123400-05:00
Length: 3, dtype: datetime64[ns, US/Eastern]

In [44]: s.dt.round('D')
Out[44]:
0    2013-01-01 00:00:00-05:00
1    2013-01-02 00:00:00-05:00
2    2013-01-03 00:00:00-05:00
Length: 3, dtype: datetime64[ns, US/Eastern]
```

## Formatting of integers in `FloatIndex`

Integers in `FloatIndex`, e.g. 1., are now formatted with a decimal point and a 0 digit, e.g. 1.0 (GH11713) This change not only affects the display to the console, but also the output of IO methods like `.to_csv` or `.to_html`.

Previous behavior:

```
In [2]: s = pd.Series([1, 2, 3], index=np.arange(3.))

In [3]: s
Out[3]:
0    1
1    2
2    3
dtype: int64

In [4]: s.index
Out[4]: Float64Index([0.0, 1.0, 2.0], dtype='float64')

In [5]: print(s.to_csv(path=None))
0,1
1,2
2,3
```

New behavior:

```
In [45]: s = pd.Series([1, 2, 3], index=np.arange(3.))

In [46]: s
```

(continues on next page)

(continued from previous page)

```

Out [46]:
0.0    1
1.0    2
2.0    3
Length: 3, dtype: int64

In [47]: s.index
Out [47]: Float64Index([0.0, 1.0, 2.0], dtype='float64')

In [48]: print(s.to_csv(path_or_buf=None, header=False))
0.0,1
1.0,2
2.0,3

```

## Changes to dtype assignment behaviors

When a DataFrame's slice is updated with a new slice of the same dtype, the dtype of the DataFrame will now remain the same. (GH10503)

Previous behavior:

```

In [5]: df = pd.DataFrame({'a': [0, 1, 1],
                          'b': pd.Series([100, 200, 300], dtype='uint32')})

In [7]: df.dtypes
Out [7]:
a      int64
b      uint32
dtype: object

In [8]: ix = df['a'] == 1

In [9]: df.loc[ix, 'b'] = df.loc[ix, 'b']

In [11]: df.dtypes
Out [11]:
a      int64
b      int64
dtype: object

```

New behavior:

```

In [49]: df = pd.DataFrame({'a': [0, 1, 1],
    ....:                  'b': pd.Series([100, 200, 300], dtype='uint32')})
    ....:

In [50]: df.dtypes
Out [50]:
a      int64
b      uint32
Length: 2, dtype: object

In [51]: ix = df['a'] == 1

In [52]: df.loc[ix, 'b'] = df.loc[ix, 'b']

```

(continues on next page)

(continued from previous page)

```
In [53]: df.dtypes
Out [53]:
a      int64
b      uint32
Length: 2, dtype: object
```

When a DataFrame's integer slice is partially updated with a new slice of floats that could potentially be down-casted to integer without losing precision, the dtype of the slice will be set to float instead of integer.

Previous behavior:

```
In [4]: df = pd.DataFrame(np.array(range(1,10)).reshape(3,3),
                          columns=list('abc'),
                          index=[[4,4,8], [8,10,12]])

In [5]: df
Out [5]:
   a  b  c
4  8  1  2  3
   10  4  5  6
8  12  7  8  9

In [7]: df.ix[4, 'c'] = np.array([0., 1.])

In [8]: df
Out [8]:
   a  b  c
4  8  1  2  0
   10  4  5  1
8  12  7  8  9
```

New behavior:

```
In [54]: df = pd.DataFrame(np.array(range(1,10)).reshape(3,3),
.....:                      columns=list('abc'),
.....:                      index=[[4,4,8], [8,10,12]])
.....:

In [55]: df
Out [55]:
   a  b  c
4  8  1  2  3
   10  4  5  6
8  12  7  8  9

[3 rows x 3 columns]

In [56]: df.loc[4, 'c'] = np.array([0., 1.])

In [57]: df
Out [57]:
   a  b  c
4  8  1  2  0.0
   10  4  5  1.0
8  12  7  8  9.0
```

(continues on next page)

(continued from previous page)

```
[3 rows x 3 columns]
```

## to\_xarray

In a future version of pandas, we will be deprecating Panel and other > 2 ndim objects. In order to provide for continuity, all NDFrame objects have gained the `.to_xarray()` method in order to convert to xarray objects, which has a pandas-like interface for > 2 ndim. (GH11972)

See the [xarray full-documentation](#) here.

```
In [1]: p = Panel(np.arange(2*3*4).reshape(2,3,4))

In [2]: p.to_xarray()
Out [2]:
<xarray.DataArray (items: 2, major_axis: 3, minor_axis: 4)>
array([[[ 0,  1,  2,  3],
         [ 4,  5,  6,  7],
         [ 8,  9, 10, 11]],

       [[12, 13, 14, 15],
        [16, 17, 18, 19],
        [20, 21, 22, 23]])
Coordinates:
  * items          (items) int64 0 1
  * major_axis     (major_axis) int64 0 1 2
  * minor_axis     (minor_axis) int64 0 1 2 3
```

## Latex representation

DataFrame has gained a `._repr_latex_()` method in order to allow for conversion to latex in a ipython/jupyter notebook using nbconvert. (GH11778)

Note that this must be activated by setting the option `pd.display.latex.repr=True` (GH12182)

For example, if you have a jupyter notebook you plan to convert to latex using nbconvert, place the statement `pd.display.latex.repr=True` in the first cell to have the contained DataFrame output also stored as latex.

The options `display.latex.escape` and `display.latex.longtable` have also been added to the configuration and are used automatically by the `to_latex` method. See the *available options docs* for more info.

## pd.read\_sas() changes

`read_sas` has gained the ability to read SAS7BDAT files, including compressed files. The files can be read in entirety, or incrementally. For full details see [here](#). (GH4052)

## Other enhancements

- Handle truncated floats in SAS xport files (GH11713)
- Added option to hide index in `Series.to_string` (GH11729)
- `read_excel` now supports s3 urls of the format `s3://bucketname/filename` (GH11447)
- add support for `AWS_S3_HOST` env variable when reading from s3 (GH12198)
- A simple version of `Panel.round()` is now implemented (GH11763)
- For Python 3.x, `round(DataFrame)`, `round(Series)`, `round(Panel)` will work (GH11763)
- `sys.getsizeof(obj)` returns the memory usage of a pandas object, including the values it contains (GH11597)
- `Series` gained an `is_unique` attribute (GH11946)
- `DataFrame.quantile` and `Series.quantile` now accept interpolation keyword (GH10174).
- Added `DataFrame.style.format` for more flexible formatting of cell values (GH11692)
- `DataFrame.select_dtypes` now allows the `np.float16` type code (GH11990)
- `pivot_table()` now accepts most iterables for the `values` parameter (GH12017)
- Added Google BigQuery service account authentication support, which enables authentication on remote servers. (GH11881, GH12572). For further details see [here](#)
- `HDFStore` is now iterable: `for k in store` is equivalent to `for k in store.keys()` (GH12221).
- Add missing methods/fields to `.dt` for `Period` (GH8848)
- The entire code base has been PEP-ified (GH12096)

## Backwards incompatible API changes

- the leading white spaces have been removed from the output of `.to_string(index=False)` method (GH11833)
- the `out` parameter has been removed from the `Series.round()` method. (GH11763)
- `DataFrame.round()` leaves non-numeric columns unchanged in its return, rather than raises. (GH11885)
- `DataFrame.head(0)` and `DataFrame.tail(0)` return empty frames, rather than `self`. (GH11937)
- `Series.head(0)` and `Series.tail(0)` return empty series, rather than `self`. (GH11937)
- `to_msgpack` and `read_msgpack` encoding now defaults to 'utf-8'. (GH12170)
- the order of keyword arguments to text file parsing functions (`.read_csv()`, `.read_table()`, `.read_fwf()`) changed to group related arguments. (GH11555)
- `NaTType.isoformat` now returns the string 'NaT' to allow the result to be passed to the constructor of `Timestamp`. (GH12300)

## NaT and Timedelta operations

NaT and Timedelta have expanded arithmetic operations, which are extended to Series arithmetic where applicable. Operations defined for `datetime64[ns]` or `timedelta64[ns]` are now also defined for NaT ([GH11564](#)).

NaT now supports arithmetic operations with integers and floats.

```
In [58]: pd.NaT * 1
Out[58]: NaT

In [59]: pd.NaT * 1.5
Out[59]: NaT

In [60]: pd.NaT / 2
Out[60]: NaT

In [61]: pd.NaT * np.nan
Out[61]: NaT
```

NaT defines more arithmetic operations with `datetime64[ns]` and `timedelta64[ns]`.

```
In [62]: pd.NaT / pd.NaT
Out[62]: nan

In [63]: pd.Timedelta('1s') / pd.NaT
Out[63]: nan
```

NaT may represent either a `datetime64[ns]` null or a `timedelta64[ns]` null. Given the ambiguity, it is treated as a `timedelta64[ns]`, which allows more operations to succeed.

```
In [64]: pd.NaT + pd.NaT
Out[64]: NaT

# same as
In [65]: pd.Timedelta('1s') + pd.Timedelta('1s')
Out[65]: Timedelta('0 days 00:00:02')
```

as opposed to

```
In [3]: pd.Timestamp('19900315') + pd.Timestamp('19900315')
TypeError: unsupported operand type(s) for +: 'Timestamp' and 'Timestamp'
```

However, when wrapped in a Series whose dtype is `datetime64[ns]` or `timedelta64[ns]`, the dtype information is respected.

```
In [1]: pd.Series([pd.NaT], dtype='<M8[ns]') + pd.Series([pd.NaT], dtype='<M8[ns]')
TypeError: can only operate on a datetimes for subtraction,
but the operator [__add__] was passed
```

```
In [66]: pd.Series([pd.NaT], dtype='<m8[ns]') + pd.Series([pd.NaT], dtype='<m8[ns]')
Out[66]:
0    NaT
Length: 1, dtype: timedelta64[ns]
```

Timedelta division by floats now works.

```
In [67]: pd.Timedelta('1s') / 2.0
Out [67]: Timedelta('0 days 00:00:00.500000')
```

**Subtraction by Timedelta in a Series by a Timestamp works (GH11925)**

```
In [68]: ser = pd.Series(pd.timedelta_range('1 day', periods=3))

In [69]: ser
Out [69]:
0    1 days
1    2 days
2    3 days
Length: 3, dtype: timedelta64[ns]

In [70]: pd.Timestamp('2012-01-01') - ser
Out [70]:
0    2011-12-31
1    2011-12-30
2    2011-12-29
Length: 3, dtype: datetime64[ns]
```

`NaT.isoformat()` now returns 'NaT'. This change allows `pd.Timestamp` to rehydrate any timestamp like object from its `isoformat` (GH12300).

### Changes to msgpack

Forward incompatible changes in `msgpack` writing format were made over 0.17.0 and 0.18.0; older versions of pandas cannot read files packed by newer versions (GH12129, GH10527)

Bugs in `to_msgpack` and `read_msgpack` introduced in 0.17.0 and fixed in 0.18.0, caused files packed in Python 2 unreadable by Python 3 (GH12142). The following table describes the backward and forward compat of msgpacks.

**Warning:**

| Packed with         | Can be unpacked with                                                                                 |
|---------------------|------------------------------------------------------------------------------------------------------|
| pre-0.17 / Python 2 | any                                                                                                  |
| pre-0.17 / Python 3 | any                                                                                                  |
| 0.17 / Python 2     | <ul style="list-style-type: none"><li>• ==0.17 / Python 2</li><li>• &gt;=0.18 / any Python</li></ul> |
| 0.17 / Python 3     | >=0.18 / any Python                                                                                  |
| 0.18                | >= 0.18                                                                                              |

0.18.0 is backward-compatible for reading files packed by older versions, except for files packed with 0.17 in Python 2, in which case only they can only be unpacked in Python 2.

## Signature change for .rank

Series.rank and DataFrame.rank now have the same signature (GH11759)

Previous signature

```
In [3]: pd.Series([0,1]).rank(method='average', na_option='keep',
                             ascending=True, pct=False)

Out [3]:
0    1
1    2
dtype: float64

In [4]: pd.DataFrame([0,1]).rank(axis=0, numeric_only=None,
                                method='average', na_option='keep',
                                ascending=True, pct=False)

Out [4]:
    0
0   1
1   2
```

New signature

```
In [71]: pd.Series([0,1]).rank(axis=0, method='average', numeric_only=None,
    ....:                    na_option='keep', ascending=True, pct=False)
    ....:
Out [71]:
0    1.0
1    2.0
Length: 2, dtype: float64

In [72]: pd.DataFrame([0,1]).rank(axis=0, method='average', numeric_only=None,
    ....:                        na_option='keep', ascending=True, pct=False)
    ....:
Out [72]:
    0
0   1.0
1   2.0

[2 rows x 1 columns]
```

## Bug in QuarterBegin with n=0

In previous versions, the behavior of the QuarterBegin offset was inconsistent depending on the date when the n parameter was 0. (GH11406)

The general semantics of anchored offsets for n=0 is to not move the date when it is an anchor point (e.g., a quarter start date), and otherwise roll forward to the next anchor point.

```
In [73]: d = pd.Timestamp('2014-02-01')

In [74]: d
Out [74]: Timestamp('2014-02-01 00:00:00')

In [75]: d + pd.offsets.QuarterBegin(n=0, startingMonth=2)
Out [75]: Timestamp('2014-02-01 00:00:00')
```

(continues on next page)

(continued from previous page)

```
In [76]: d + pd.offsets.QuarterBegin(n=0, startingMonth=1)
Out[76]: Timestamp('2014-04-01 00:00:00')
```

For the `QuarterBegin` offset in previous versions, the date would be rolled *backwards* if date was in the same month as the quarter start date.

```
In [3]: d = pd.Timestamp('2014-02-15')

In [4]: d + pd.offsets.QuarterBegin(n=0, startingMonth=2)
Out[4]: Timestamp('2014-02-01 00:00:00')
```

This behavior has been corrected in version 0.18.0, which is consistent with other anchored offsets like `MonthBegin` and `YearBegin`.

```
In [77]: d = pd.Timestamp('2014-02-15')

In [78]: d + pd.offsets.QuarterBegin(n=0, startingMonth=2)
Out[78]: Timestamp('2014-05-01 00:00:00')
```

## Resample API

Like the change in the window functions API *above*, `.resample(...)` is changing to have a more groupby-like API. ([GH11732](#), [GH12702](#), [GH12202](#), [GH12332](#), [GH12334](#), [GH12348](#), [GH12448](#)).

```
In [79]: np.random.seed(1234)

In [80]: df = pd.DataFrame(np.random.rand(10,4),
.....:                      columns=list('ABCD'),
.....:                      index=pd.date_range('2010-01-01 09:00:00',
.....:                                          periods=10, freq='s'))
.....:

In [81]: df
Out[81]:
```

|                     | A        | B        | C        | D        |
|---------------------|----------|----------|----------|----------|
| 2010-01-01 09:00:00 | 0.191519 | 0.622109 | 0.437728 | 0.785359 |
| 2010-01-01 09:00:01 | 0.779976 | 0.272593 | 0.276464 | 0.801872 |
| 2010-01-01 09:00:02 | 0.958139 | 0.875933 | 0.357817 | 0.500995 |
| 2010-01-01 09:00:03 | 0.683463 | 0.712702 | 0.370251 | 0.561196 |
| 2010-01-01 09:00:04 | 0.503083 | 0.013768 | 0.772827 | 0.882641 |
| 2010-01-01 09:00:05 | 0.364886 | 0.615396 | 0.075381 | 0.368824 |
| 2010-01-01 09:00:06 | 0.933140 | 0.651378 | 0.397203 | 0.788730 |
| 2010-01-01 09:00:07 | 0.316836 | 0.568099 | 0.869127 | 0.436173 |
| 2010-01-01 09:00:08 | 0.802148 | 0.143767 | 0.704261 | 0.704581 |
| 2010-01-01 09:00:09 | 0.218792 | 0.924868 | 0.442141 | 0.909316 |

```
[10 rows x 4 columns]
```

## Previous API:

You would write a resampling operation that immediately evaluates. If a `how` parameter was not provided, it would default to `how='mean'`.

```
In [6]: df.resample('2s')
```

```
Out [6]:
```

|                     | A        | B        | C        | D        |
|---------------------|----------|----------|----------|----------|
| 2010-01-01 09:00:00 | 0.485748 | 0.447351 | 0.357096 | 0.793615 |
| 2010-01-01 09:00:02 | 0.820801 | 0.794317 | 0.364034 | 0.531096 |
| 2010-01-01 09:00:04 | 0.433985 | 0.314582 | 0.424104 | 0.625733 |
| 2010-01-01 09:00:06 | 0.624988 | 0.609738 | 0.633165 | 0.612452 |
| 2010-01-01 09:00:08 | 0.510470 | 0.534317 | 0.573201 | 0.806949 |

You could also specify a how directly

```
In [7]: df.resample('2s', how='sum')
```

```
Out [7]:
```

|                     | A        | B        | C        | D        |
|---------------------|----------|----------|----------|----------|
| 2010-01-01 09:00:00 | 0.971495 | 0.894701 | 0.714192 | 1.587231 |
| 2010-01-01 09:00:02 | 1.641602 | 1.588635 | 0.728068 | 1.062191 |
| 2010-01-01 09:00:04 | 0.867969 | 0.629165 | 0.848208 | 1.251465 |
| 2010-01-01 09:00:06 | 1.249976 | 1.219477 | 1.266330 | 1.224904 |
| 2010-01-01 09:00:08 | 1.020940 | 1.068634 | 1.146402 | 1.613897 |

### New API:

Now, you can write `.resample(...)` as a 2-stage operation like `.groupby(...)`, which yields a Resampler.

```
In [82]: r = df.resample('2s')
```

```
In [83]: r
```

```
Out [83]: <pandas.core.resample.DatetimeIndexResampler object at 0x7f7fd2d21410>
```

### Downsampling

You can then use this object to perform operations. These are downsampling operations (going from a higher frequency to a lower one).

```
In [84]: r.mean()
```

```
Out [84]:
```

|                     | A        | B        | C        | D        |
|---------------------|----------|----------|----------|----------|
| 2010-01-01 09:00:00 | 0.485748 | 0.447351 | 0.357096 | 0.793615 |
| 2010-01-01 09:00:02 | 0.820801 | 0.794317 | 0.364034 | 0.531096 |
| 2010-01-01 09:00:04 | 0.433985 | 0.314582 | 0.424104 | 0.625733 |
| 2010-01-01 09:00:06 | 0.624988 | 0.609738 | 0.633165 | 0.612452 |
| 2010-01-01 09:00:08 | 0.510470 | 0.534317 | 0.573201 | 0.806949 |

```
[5 rows x 4 columns]
```

```
In [85]: r.sum()
```

```
Out [85]:
```

|                     | A        | B        | C        | D        |
|---------------------|----------|----------|----------|----------|
| 2010-01-01 09:00:00 | 0.971495 | 0.894701 | 0.714192 | 1.587231 |
| 2010-01-01 09:00:02 | 1.641602 | 1.588635 | 0.728068 | 1.062191 |
| 2010-01-01 09:00:04 | 0.867969 | 0.629165 | 0.848208 | 1.251465 |
| 2010-01-01 09:00:06 | 1.249976 | 1.219477 | 1.266330 | 1.224904 |
| 2010-01-01 09:00:08 | 1.020940 | 1.068634 | 1.146402 | 1.613897 |

```
[5 rows x 4 columns]
```

Furthermore, `resample` now supports `getitem` operations to perform the `resample` on specific columns.

```
In [86]: r[['A', 'C']].mean()
Out [86]:
```

|                     | A        | C        |
|---------------------|----------|----------|
| 2010-01-01 09:00:00 | 0.485748 | 0.357096 |
| 2010-01-01 09:00:02 | 0.820801 | 0.364034 |
| 2010-01-01 09:00:04 | 0.433985 | 0.424104 |
| 2010-01-01 09:00:06 | 0.624988 | 0.633165 |
| 2010-01-01 09:00:08 | 0.510470 | 0.573201 |

```
[5 rows x 2 columns]
```

and `.aggregate` type operations.

```
In [87]: r.agg({'A' : 'mean', 'B' : 'sum'})
Out [87]:
```

|                     | A        | B        |
|---------------------|----------|----------|
| 2010-01-01 09:00:00 | 0.485748 | 0.894701 |
| 2010-01-01 09:00:02 | 0.820801 | 1.588635 |
| 2010-01-01 09:00:04 | 0.433985 | 0.629165 |
| 2010-01-01 09:00:06 | 0.624988 | 1.219477 |
| 2010-01-01 09:00:08 | 0.510470 | 1.068634 |

```
[5 rows x 2 columns]
```

These accessors can of course, be combined

```
In [88]: r[['A', 'B']].agg(['mean', 'sum'])
Out [88]:
```

|                     | A        |          | B        |          |
|---------------------|----------|----------|----------|----------|
|                     | mean     | sum      | mean     | sum      |
| 2010-01-01 09:00:00 | 0.485748 | 0.971495 | 0.447351 | 0.894701 |
| 2010-01-01 09:00:02 | 0.820801 | 1.641602 | 0.794317 | 1.588635 |
| 2010-01-01 09:00:04 | 0.433985 | 0.867969 | 0.314582 | 0.629165 |
| 2010-01-01 09:00:06 | 0.624988 | 1.249976 | 0.609738 | 1.219477 |
| 2010-01-01 09:00:08 | 0.510470 | 1.020940 | 0.534317 | 1.068634 |

```
[5 rows x 4 columns]
```

## Upsampling

Upsampling operations take you from a lower frequency to a higher frequency. These are now performed with the `Resampler` objects with `backfill()`, `ffill()`, `fillna()` and `asfreq()` methods.

```
In [89]: s = pd.Series(np.arange(5, dtype='int64'),
.....:                  index=pd.date_range('2010-01-01', periods=5, freq='Q'))
.....:

In [90]: s
Out [90]:
```

|            |   |
|------------|---|
| 2010-03-31 | 0 |
| 2010-06-30 | 1 |
| 2010-09-30 | 2 |
| 2010-12-31 | 3 |
| 2011-03-31 | 4 |

```
Freq: Q-DEC, Length: 5, dtype: int64
```

## Previously

```
In [6]: s.resample('M', fill_method='ffill')
Out [6]:
2010-03-31    0
2010-04-30    0
2010-05-31    0
2010-06-30    1
2010-07-31    1
2010-08-31    1
2010-09-30    2
2010-10-31    2
2010-11-30    2
2010-12-31    3
2011-01-31    3
2011-02-28    3
2011-03-31    4
Freq: M, dtype: int64
```

## New API

```
In [91]: s.resample('M').ffill()
Out [91]:
2010-03-31    0
2010-04-30    0
2010-05-31    0
2010-06-30    1
2010-07-31    1
2010-08-31    1
2010-09-30    2
2010-10-31    2
2010-11-30    2
2010-12-31    3
2011-01-31    3
2011-02-28    3
2011-03-31    4
Freq: M, Length: 13, dtype: int64
```

**Note:** In the new API, you can either downsample OR upsample. The prior implementation would allow you to pass an aggregator function (like mean) even though you were upsampling, providing a bit of confusion.

## Previous API will work but with deprecations

**Warning:** This new API for resample includes some internal changes for the prior-to-0.18.0 API, to work with a deprecation warning in most cases, as the resample operation returns a deferred object. We can intercept operations and just do what the (pre 0.18.0) API did (with a warning). Here is a typical use case:

```
In [4]: r = df.resample('2s')
```

```
In [6]: r*10
```

```
pandas/tseries/resample.py:80: FutureWarning: .resample() is now a deferred_
↳operation
use .resample(...).mean() instead of .resample(...)
```

Out [6] :

|                     | A        | B        | C        | D        |
|---------------------|----------|----------|----------|----------|
| 2010-01-01 09:00:00 | 4.857476 | 4.473507 | 3.570960 | 7.936154 |
| 2010-01-01 09:00:02 | 8.208011 | 7.943173 | 3.640340 | 5.310957 |
| 2010-01-01 09:00:04 | 4.339846 | 3.145823 | 4.241039 | 6.257326 |
| 2010-01-01 09:00:06 | 6.249881 | 6.097384 | 6.331650 | 6.124518 |
| 2010-01-01 09:00:08 | 5.104699 | 5.343172 | 5.732009 | 8.069486 |

However, getting and assignment operations directly on a Resampler will raise a ValueError:

```
In [7]: r.iloc[0] = 5
ValueError: .resample() is now a deferred operation
use .resample(...).mean() instead of .resample(...)
```

There is a situation where the new API can not perform all the operations when using original code. This code is intending to resample every 2s, take the mean AND then take the min of those results.

```
In [4]: df.resample('2s').min()
```

Out [4] :

```
A    0.433985
B    0.314582
C    0.357096
D    0.531096
dtype: float64
```

The new API will:

```
In [92]: df.resample('2s').min()
```

Out [92] :

|                     | A        | B        | C        | D        |
|---------------------|----------|----------|----------|----------|
| 2010-01-01 09:00:00 | 0.191519 | 0.272593 | 0.276464 | 0.785359 |
| 2010-01-01 09:00:02 | 0.683463 | 0.712702 | 0.357817 | 0.500995 |
| 2010-01-01 09:00:04 | 0.364886 | 0.013768 | 0.075381 | 0.368824 |
| 2010-01-01 09:00:06 | 0.316836 | 0.568099 | 0.397203 | 0.436173 |
| 2010-01-01 09:00:08 | 0.218792 | 0.143767 | 0.442141 | 0.704581 |

[5 rows x 4 columns]

The good news is the return dimensions will differ between the new API and the old API, so this should loudly raise an exception.

To replicate the original operation

```
In [93]: df.resample('2s').mean().min()
```

Out [93] :

```
A    0.433985
B    0.314582
C    0.357096
D    0.531096
Length: 4, dtype: float64
```

## Changes to eval

In prior versions, new columns assignments in an `eval` expression resulted in an inplace change to the `DataFrame`. (GH9297, GH8664, GH10486)

```
In [94]: df = pd.DataFrame({'a': np.linspace(0, 10, 5), 'b': range(5)})
```

```
In [95]: df
```

```
Out [95]:
```

```
   a  b
0  0.0  0
1  2.5  1
2  5.0  2
3  7.5  3
4 10.0  4
```

```
[5 rows x 2 columns]
```

```
In [12]: df.eval('c = a + b')
```

```
FutureWarning: eval expressions containing an assignment currently default to
↳operating inplace.
This will change in a future version of pandas, use inplace=True to avoid this
↳warning.
```

```
In [13]: df
```

```
Out [13]:
```

```
   a  b  c
0  0.0  0  0.0
1  2.5  1  3.5
2  5.0  2  7.0
3  7.5  3 10.5
4 10.0  4 14.0
```

In version 0.18.0, a new `inplace` keyword was added to choose whether the assignment should be done inplace or return a copy.

```
In [96]: df
```

```
Out [96]:
```

```
   a  b  c
0  0.0  0  0.0
1  2.5  1  3.5
2  5.0  2  7.0
3  7.5  3 10.5
4 10.0  4 14.0
```

```
[5 rows x 3 columns]
```

```
In [97]: df.eval('d = c - b', inplace=False)
```

```
Out [97]:
```

```
   a  b  c  d
0  0.0  0  0.0  0.0
1  2.5  1  3.5  2.5
2  5.0  2  7.0  5.0
3  7.5  3 10.5  7.5
4 10.0  4 14.0 10.0
```

```
[5 rows x 4 columns]
```

(continues on next page)

(continued from previous page)

```
In [98]: df
Out[98]:
   a  b   c
0  0.0 0  0.0
1  2.5 1  3.5
2  5.0 2  7.0
3  7.5 3 10.5
4 10.0 4 14.0

[5 rows x 3 columns]

In [99]: df.eval('d = c - b', inplace=True)

In [100]: df
Out[100]:
   a  b   c   d
0  0.0 0  0.0  0.0
1  2.5 1  3.5  2.5
2  5.0 2  7.0  5.0
3  7.5 3 10.5  7.5
4 10.0 4 14.0 10.0

[5 rows x 4 columns]
```

**Warning:** For backwards compatibility, `inplace` defaults to `True` if not specified. This will change in a future version of pandas. If your code depends on an `inplace` assignment you should update to explicitly set `inplace=True`

The `inplace` keyword parameter was also added the `query` method.

```
In [101]: df.query('a > 5')
Out[101]:
   a  b   c   d
3  7.5 3 10.5  7.5
4 10.0 4 14.0 10.0

[2 rows x 4 columns]

In [102]: df.query('a > 5', inplace=True)

In [103]: df
Out[103]:
   a  b   c   d
3  7.5 3 10.5  7.5
4 10.0 4 14.0 10.0

[2 rows x 4 columns]
```

**Warning:** Note that the default value for `inplace` in a `query` is `False`, which is consistent with prior versions.

`eval` has also been updated to allow multi-line expressions for multiple assignments. These expressions will be evaluated one at a time in order. Only assignments are valid for multi-line expressions.

```

In [104]: df
Out[104]:
   a  b   c   d
3  7.5 3 10.5  7.5
4 10.0 4 14.0 10.0

[2 rows x 4 columns]

In [105]: df.eval("""
.....: e = d + a
.....: f = e - 22
.....: g = f / 2.0""", inplace=True)
.....:

In [106]: df
Out[106]:
   a  b   c   d   e   f   g
3  7.5 3 10.5  7.5 15.0 -7.0 -3.5
4 10.0 4 14.0 10.0 20.0 -2.0 -1.0

[2 rows x 7 columns]

```

## Other API changes

- `DataFrame.between_time` and `Series.between_time` now only parse a fixed set of time strings. Parsing of date strings is no longer supported and raises a `ValueError`. (GH11818)

```

In [107]: s = pd.Series(range(10), pd.date_range('2015-01-01', freq='H',
↳ periods=10))

In [108]: s.between_time("7:00am", "9:00am")
Out[108]:
2015-01-01 07:00:00    7
2015-01-01 08:00:00    8
2015-01-01 09:00:00    9
Freq: H, Length: 3, dtype: int64

```

This will now raise.

```

In [2]: s.between_time('20150101 07:00:00', '20150101 09:00:00')
ValueError: Cannot convert arg ['20150101 07:00:00'] to a time.

```

- `.memory_usage()` now includes values in the index, as does `memory_usage` in `.info()` (GH11597)
- `DataFrame.to_latex()` now supports non-ascii encodings (eg `utf-8`) in Python 2 with the parameter `encoding` (GH7061)
- `pandas.merge()` and `DataFrame.merge()` will show a specific error message when trying to merge with an object that is not of type `DataFrame` or a subclass (GH12081)
- `DataFrame.unstack` and `Series.unstack` now take `fill_value` keyword to allow direct replacement of missing values when an unstack results in missing values in the resulting `DataFrame`. As an added benefit, specifying `fill_value` will preserve the data type of the original stacked data. (GH9746)
- As part of the new API for *window functions* and *resampling*, aggregation functions have been clarified, raising more informative error messages on invalid aggregations. (GH9052). A full set of examples are presented in *groupby*.

- Statistical functions for NDFrame objects (like `sum()`, `mean()`, `min()`) will now raise if non-numpy-compatible arguments are passed in for `**kwargs` (GH12301)
- `.to_latex` and `.to_html` gain a `decimal` parameter like `.to_csv`; the default is `'.'` (GH12031)
- More helpful error message when constructing a DataFrame with empty data but with indices (GH8020)
- `.describe()` will now properly handle `bool` dtype as a categorical (GH6625)
- More helpful error message with an invalid `.transform` with user defined input (GH10165)
- Exponentially weighted functions now allow specifying `alpha` directly (GH10789) and raise `ValueError` if parameters violate  $0 < \alpha \leq 1$  (GH12492)

## Deprecations

- The functions `pd.rolling_*`, `pd.expanding_*`, and `pd.ewm*` are deprecated and replaced by the corresponding method call. Note that the new suggested syntax includes all of the arguments (even if default) (GH11603)

```
In [1]: s = pd.Series(range(3))

In [2]: pd.rolling_mean(s, window=2, min_periods=1)
FutureWarning: pd.rolling_mean is deprecated for Series and
will be removed in a future version, replace with
Series.rolling(min_periods=1, window=2, center=False).mean()

Out [2]:
0    0.0
1    0.5
2    1.5
dtype: float64

In [3]: pd.rolling_cov(s, s, window=2)
FutureWarning: pd.rolling_cov is deprecated for Series and
will be removed in a future version, replace with
Series.rolling(window=2).cov(other=<Series>)

Out [3]:
0    NaN
1    0.5
2    0.5
dtype: float64
```

- The `freq` and `how` arguments to the `.rolling`, `.expanding`, and `.ewm` (new) functions are deprecated, and will be removed in a future version. You can simply resample the input prior to creating a window function. (GH11603).

For example, instead of `s.rolling(window=5, freq='D').max()` to get the max value on a rolling 5 Day window, one could use `s.resample('D').mean().rolling(window=5).max()`, which first resamples the data to daily data, then provides a rolling 5 day window.

- `pd.tseries.frequencies.get_offset_name` function is deprecated. Use `offset's .freqstr` property as alternative (GH11192)
- `pandas.stats.fama_macbeth` routines are deprecated and will be removed in a future version (GH6077)
- `pandas.stats.ols`, `pandas.stats.plm` and `pandas.stats.var` routines are deprecated and will be removed in a future version (GH6077)
- show a `FutureWarning` rather than a `DeprecationWarning` on using long-time deprecated syntax in `HDFStore.select`, where the `where` clause is not a string-like (GH12027)

- The `pandas.options.display.mpl_style` configuration has been deprecated and will be removed in a future version of pandas. This functionality is better handled by matplotlib's [style sheets](#) (GH11783).

## Removal of deprecated float indexers

In [GH4892](#) indexing with floating point numbers on a non-Float64Index was deprecated (in version 0.14.0). In 0.18.0, this deprecation warning is removed and these will now raise a `TypeError`. ([GH12165](#), [GH12333](#))

```
In [109]: s = pd.Series([1, 2, 3], index=[4, 5, 6])

In [110]: s
Out[110]:
4    1
5    2
6    3
Length: 3, dtype: int64

In [111]: s2 = pd.Series([1, 2, 3], index=list('abc'))

In [112]: s2
Out[112]:
a    1
b    2
c    3
Length: 3, dtype: int64
```

Previous behavior:

```
# this is label indexing
In [2]: s[5.0]
FutureWarning: scalar indexers for index type Int64Index should be integers and not_
↳floating point
Out[2]: 2

# this is positional indexing
In [3]: s.iloc[1.0]
FutureWarning: scalar indexers for index type Int64Index should be integers and not_
↳floating point
Out[3]: 2

# this is label indexing
In [4]: s.loc[5.0]
FutureWarning: scalar indexers for index type Int64Index should be integers and not_
↳floating point
Out[4]: 2

# .ix would coerce 1.0 to the positional 1, and index
In [5]: s2.ix[1.0] = 10
FutureWarning: scalar indexers for index type Index should be integers and not_
↳floating point

In [6]: s2
Out[6]:
a    1
b   10
c    3
dtype: int64
```

New behavior:

For `iloc`, getting & setting via a float scalar will always raise.

```
In [3]: s.iloc[2.0]
TypeError: cannot do label indexing on <class 'pandas.indexes.numeric.Int64Index'>
↳with these indexers [2.0] of <type 'float'>
```

Other indexers will coerce to a like integer for both getting and setting. The `FutureWarning` has been dropped for `.loc`, `.ix` and `[]`.

```
In [113]: s[5.0]
Out[113]: 2

In [114]: s.loc[5.0]
Out[114]: 2
```

and setting

```
In [115]: s_copy = s.copy()

In [116]: s_copy[5.0] = 10

In [117]: s_copy
Out[117]:
4    1
5   10
6    3
Length: 3, dtype: int64

In [118]: s_copy = s.copy()

In [119]: s_copy.loc[5.0] = 10

In [120]: s_copy
Out[120]:
4    1
5   10
6    3
Length: 3, dtype: int64
```

Positional setting with `.ix` and a float indexer will ADD this value to the index, rather than previously setting the value by position.

```
In [3]: s2.ix[1.0] = 10
In [4]: s2
Out[4]:
a    1
b    2
c    3
1.0  10
dtype: int64
```

Slicing will also coerce integer-like floats to integers for a non-`Float64Index`.

```
In [121]: s.loc[5.0:6]
Out[121]:
5    2
```

(continues on next page)

(continued from previous page)

```
6    3
Length: 2, dtype: int64
```

Note that for floats that are NOT coercible to ints, the label based bounds will be excluded

```
In [122]: s.loc[5.1:6]
Out [122]:
6    3
Length: 1, dtype: int64
```

Float indexing on a `Float64Index` is unchanged.

```
In [123]: s = pd.Series([1, 2, 3], index=np.arange(3.))

In [124]: s[1.0]
Out [124]: 2

In [125]: s[1.0:2.5]
Out [125]:
1.0    2
2.0    3
Length: 2, dtype: int64
```

## Removal of prior version deprecations/changes

- Removal of `rolling_corr_pairwise` in favor of `.rolling().corr(pairwise=True)` (GH4950)
- Removal of `expanding_corr_pairwise` in favor of `.expanding().corr(pairwise=True)` (GH4950)
- Removal of `DataMatrix` module. This was not imported into the pandas namespace in any event (GH12111)
- Removal of `cols` keyword in favor of `subset` in `DataFrame.duplicated()` and `DataFrame.drop_duplicates()` (GH6680)
- Removal of the `read_frame` and `frame_query` (both aliases for `pd.read_sql`) and `write_frame` (alias of `to_sql`) functions in the `pd.io.sql` namespace, deprecated since 0.14.0 (GH6292).
- Removal of the `order` keyword from `.factorize()` (GH6930)

## Performance improvements

- Improved performance of `andrews_curves` (GH11534)
- Improved huge `DatetimeIndex`, `PeriodIndex` and `TimedeltaIndex`'s ops performance including `NaT` (GH10277)
- Improved performance of `pandas.concat` (GH11958)
- Improved performance of `StataReader` (GH11591)
- Improved performance in construction of `Categoricals` with `Series` of datetimes containing `NaT` (GH12077)
- Improved performance of ISO 8601 date parsing for dates without separators (GH11899), leading zeros (GH11871) and with white space preceding the time zone (GH9714)

## Bug Fixes

- Bug in `GroupBy.size` when data-frame is empty. (GH11699)
- Bug in `Period.end_time` when a multiple of time period is requested (GH11738)
- Regression in `.clip` with tz-aware datetimes (GH11838)
- Bug in `date_range` when the boundaries fell on the frequency (GH11804, GH12409)
- Bug in consistency of passing nested dicts to `.groupby(...).agg(...)` (GH9052)
- Accept unicode in `Timedelta` constructor (GH11995)
- Bug in value label reading for `StataReader` when reading incrementally (GH12014)
- Bug in vectorized `DateOffset` when `n` parameter is 0 (GH11370)
- Compat for numpy 1.11 w.r.t. `NaT` comparison changes (GH12049)
- Bug in `read_csv` when reading from a `StringIO` in threads (GH11790)
- Bug in not treating `NaT` as a missing value in datetimelikes when factorizing & with `Categoricals` (GH12077)
- Bug in `getitem` when the values of a `Series` were tz-aware (GH12089)
- Bug in `Series.str.get_dummies` when one of the variables was 'name' (GH12180)
- Bug in `pd.concat` while concatenating tz-aware `NaT` series. (GH11693, GH11755, GH12217)
- Bug in `pd.read_stata` with version `<= 108` files (GH12232)
- Bug in `Series.resample` using a frequency of `Nano` when the index is a `DatetimeIndex` and contains non-zero nanosecond parts (GH12037)
- Bug in resampling with `.nunique` and a sparse index (GH12352)
- Removed some compiler warnings (GH12471)
- Work around compat issues with `boto` in python 3.5 (GH11915)
- Bug in `NaT` subtraction from `Timestamp` or `DatetimeIndex` with timezones (GH11718)
- Bug in subtraction of `Series` of a single tz-aware `Timestamp` (GH12290)
- Use compat iterators in PY2 to support `.next()` (GH12299)
- Bug in `Timedelta.round` with negative values (GH11690)
- Bug in `.loc` against `CategoricalIndex` may result in normal `Index` (GH11586)
- Bug in `DataFrame.info` when duplicated column names exist (GH11761)
- Bug in `.copy` of datetime tz-aware objects (GH11794)
- Bug in `Series.apply` and `Series.map` where `timedelta64` was not boxed (GH11349)
- Bug in `DataFrame.set_index()` with tz-aware `Series` (GH12358)
- Bug in subclasses of `DataFrame` where `AttributeError` did not propagate (GH11808)
- Bug groupby on tz-aware data where selection not returning `Timestamp` (GH11616)
- Bug in `pd.read_clipboard` and `pd.to_clipboard` functions not supporting Unicode; upgrade included `pyperclip` to v1.5.15 (GH9263)
- Bug in `DataFrame.query` containing an assignment (GH8664)

- Bug in `from_msgpack` where `__contains__()` fails for columns of the unpacked `DataFrame`, if the `DataFrame` has object columns. (GH11880)
- Bug in `.resample` on categorical data with `TimedeltaIndex` (GH12169)
- Bug in timezone info lost when broadcasting scalar datetime to `DataFrame` (GH11682)
- Bug in Index creation from `Timestamp` with mixed tz coerces to UTC (GH11488)
- Bug in `to_numeric` where it does not raise if input is more than one dimension (GH11776)
- Bug in parsing timezone offset strings with non-zero minutes (GH11708)
- Bug in `df.plot` using incorrect colors for bar plots under `matplotlib 1.5+` (GH11614)
- Bug in the `groupby` plot method when using keyword arguments (GH11805).
- Bug in `DataFrame.duplicated` and `drop_duplicates` causing spurious matches when setting `keep=False` (GH11864)
- Bug in `.loc` result with duplicated key may have Index with incorrect dtype (GH11497)
- Bug in `pd.rolling_median` where memory allocation failed even with sufficient memory (GH11696)
- Bug in `DataFrame.style` with spurious zeros (GH12134)
- Bug in `DataFrame.style` with integer columns not starting at 0 (GH12125)
- Bug in `.style.bar` may not rendered properly using specific browser (GH11678)
- Bug in rich comparison of `Timedelta` with a `numpy.array` of `Timedelta` that caused an infinite recursion (GH11835)
- Bug in `DataFrame.round` dropping column index name (GH11986)
- Bug in `df.replace` while replacing value in mixed dtype `Dataframe` (GH11698)
- Bug in Index prevents copying name of passed Index, when a new name is not provided (GH11193)
- Bug in `read_excel` failing to read any non-empty sheets when empty sheets exist and `sheetname=None` (GH11711)
- Bug in `read_excel` failing to raise `NotImplemented` error when keywords `parse_dates` and `date_parser` are provided (GH11544)
- Bug in `read_sql` with `pymysql` connections failing to return chunked data (GH11522)
- Bug in `.to_csv` ignoring formatting parameters `decimal`, `na_rep`, `float_format` for float indexes (GH11553)
- Bug in `Int64Index` and `Float64Index` preventing the use of the modulo operator (GH9244)
- Bug in `MultiIndex.drop` for not lexsorted `MultiIndexes` (GH12078)
- Bug in `DataFrame` when masking an empty `DataFrame` (GH11859)
- Bug in `.plot` potentially modifying the `colors` input when the number of columns didn't match the number of series provided (GH12039).
- Bug in `Series.plot` failing when index has a `CustomBusinessDay` frequency (GH7222).
- Bug in `.to_sql` for `datetime.time` values with `sqlite` fallback (GH8341)
- Bug in `read_excel` failing to read data with one column when `squeeze=True` (GH12157)
- Bug in `read_excel` failing to read one empty column (GH12292, GH9002)
- Bug in `.groupby` where a `KeyError` was not raised for a wrong column if there was only one row in the dataframe (GH11741)

- Bug in `.read_csv` with `dtype` specified on empty data producing an error (GH12048)
- Bug in `.read_csv` where strings like '2E' are treated as valid floats (GH12237)
- Bug in building *pandas* with debugging symbols (GH12123)
- Removed `millisecond` property of `DatetimeIndex`. This would always raise a `ValueError` (GH12019).
- Bug in `Series` constructor with read-only data (GH11502)
- Removed `pandas._testing.choice()`. Should use `np.random.choice()`, instead. (GH12386)
- Bug in `.loc` setitem indexer preventing the use of a TZ-aware `DatetimeIndex` (GH12050)
- Bug in `.style` indexes and `MultiIndexes` not appearing (GH11655)
- Bug in `to_msgpack` and `from_msgpack` which did not correctly serialize or deserialize `NaT` (GH12307).
- Bug in `.skew` and `.kurt` due to roundoff error for highly similar values (GH11974)
- Bug in `Timestamp` constructor where microsecond resolution was lost if `HHMMSS` were not separated with ':' (GH10041)
- Bug in `buffer_rd_bytes` `src->buffer` could be freed more than once if reading failed, causing a segfault (GH12098)
- Bug in `crosstab` where arguments with non-overlapping indexes would return a `KeyError` (GH10291)
- Bug in `DataFrame.apply` in which reduction was not being prevented for cases in which `dtype` was not a numpy `dtype` (GH12244)
- Bug when initializing categorical series with a scalar value. (GH12336)
- Bug when specifying a UTC `DatetimeIndex` by setting `utc=True` in `.to_datetime` (GH11934)
- Bug when increasing the buffer size of CSV reader in `read_csv` (GH12494)
- Bug when setting columns of a `DataFrame` with duplicate column names (GH12344)

## 6.10 Version 0.17

### 6.10.1 v0.17.1 (November 21, 2015)

{{ header }}

---

**Note:** We are proud to announce that *pandas* has become a sponsored project of the (NumFOCUS organization). This will help ensure the success of development of *pandas* as a world-class open-source project.

---

This is a minor bug-fix release from 0.17.0 and includes a large number of bug fixes along several new features, enhancements, and performance improvements. We recommend that all users upgrade to this version.

Highlights include:

- Support for Conditional HTML Formatting, see *here*
- Releasing the GIL on the csv reader & other ops, see *here*
- Fixed regression in `DataFrame.drop_duplicates` from 0.16.2, causing incorrect results on integer values (GH11376)

#### What's new in v0.17.1

- *New features*
  - *Conditional HTML formatting*

- *Enhancements*
- *API changes*
  - *Deprecations*
- *Performance improvements*
- *Bug fixes*
- *Contributors*

## New features

### Conditional HTML formatting

**Warning:** This is a new feature and is under active development. We'll be adding features and possibly making breaking changes in future releases. Feedback is [welcome](#).

We've added *experimental* support for conditional HTML formatting: the visual styling of a DataFrame based on the data. The styling is accomplished with HTML and CSS. Accesses the styler class with the `pandas.DataFrame.style` attribute, an instance of `Styler` with your data attached.

Here's a quick example:

```
In [1]: np.random.seed(123)

In [2]: df = pd.DataFrame(np.random.randn(10, 5), columns=list('abcde'))

In [3]: html = df.style.background_gradient(cmap='viridis', low=.5)
```

We can render the HTML to get the following table.

`Styler` interacts nicely with the Jupyter Notebook. See the *documentation* for more.

## Enhancements

- `DatetimeIndex` now supports conversion to strings with `astype(str)` (GH10442)
- Support for compression (`gzip/bz2`) in `pandas.DataFrame.to_csv()` (GH7615)
- `pd.read_*` functions can now also accept `pathlib.Path`, or `py._path.local.LocalPath` objects for the `filepath_or_buffer` argument. (GH11033) - The `DataFrame` and `Series` functions `.to_csv()`, `.to_html()` and `.to_latex()` can now handle paths beginning with tildes (e.g. `~/Documents/`) (GH11438)
- `DataFrame` now uses the fields of a `namedtuple` as columns, if columns are not supplied (GH11181)
- `DataFrame.itertuples()` now returns `namedtuple` objects, when possible. (GH11269, GH11625)
- Added `axvlines_kwds` to parallel coordinates plot (GH10709)
- Option to `.info()` and `.memory_usage()` to provide for deep introspection of memory consumption. Note that this can be expensive to compute and therefore is an optional parameter. (GH11595)

```
In [4]: df = pd.DataFrame({'A': ['foo'] * 1000}) # noqa: F821

In [5]: df['B'] = df['A'].astype('category')

# shows the '+' as we have object dtypes
In [6]: df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 1000 entries, 0 to 999
Data columns (total 2 columns):
#   Column  Non-Null Count  Dtype
---  ---
0    A      1000 non-null    object
1    B      1000 non-null    category
dtypes: category(1), object(1)
memory usage: 9.0+ KB

# we have an accurate memory assessment (but can be expensive to compute this)
In [7]: df.info(memory_usage='deep')
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 1000 entries, 0 to 999
Data columns (total 2 columns):
#   Column  Non-Null Count  Dtype
---  ---
0    A      1000 non-null    object
1    B      1000 non-null    category
dtypes: category(1), object(1)
memory usage: 75.5 KB
```

- Index now has a `fillna` method (GH10089)

```
In [8]: pd.Index([1, np.nan, 3]).fillna(2)
Out [8]: Float64Index([1.0, 2.0, 3.0], dtype='float64')
```

- Series of type `category` now make `.str.<...>` and `.dt.<...>` accessor methods / properties available, if the categories are of that type. (GH10661)

```
In [9]: s = pd.Series(list('aabb')).astype('category')

In [10]: s
Out [10]:
0    a
1    a
2    b
3    b
Length: 4, dtype: category
Categories (2, object): [a, b]

In [11]: s.str.contains("a")
Out [11]:
0     True
1     True
2    False
3    False
Length: 4, dtype: bool

In [12]: date = pd.Series(pd.date_range('1/1/2015', periods=5)).astype('category')
```

(continues on next page)

(continued from previous page)

```
In [13]: date
Out[13]:
0    2015-01-01
1    2015-01-02
2    2015-01-03
3    2015-01-04
4    2015-01-05
Length: 5, dtype: category
Categories (5, datetime64[ns]): [2015-01-01, 2015-01-02, 2015-01-03, 2015-01-04,
↳2015-01-05]

In [14]: date.dt.day
Out[14]:
0     1
1     2
2     3
3     4
4     5
Length: 5, dtype: int64
```

- `pivot_table` now has a `margins_name` argument so you can use something other than the default of 'All' ([GH3335](#))
- Implement export of `datetime64[ns, tz]` dtypes with a fixed HDF5 store ([GH11411](#))
- Pretty printing sets (e.g. in `DataFrame` cells) now uses set literal syntax (`{x, y}`) instead of Legacy Python syntax (`set([x, y])`) ([GH11215](#))
- Improve the error message in `pandas.io.gbq.to_gbq()` when a streaming insert fails ([GH11285](#)) and when the `DataFrame` does not match the schema of the destination table ([GH11359](#))

## API changes

- raise `NotImplementedError` in `Index.shift` for non-supported index types ([GH8038](#))
- `min` and `max` reductions on `datetime64` and `timedelta64` dtyped series now result in `NaT` and not `nan` ([GH11245](#)).
- Indexing with a null key will raise a `TypeError`, instead of a `ValueError` ([GH11356](#))
- `Series.ptp` will now ignore missing values by default ([GH11163](#))

## Deprecations

- The `pandas.io.ga` module which implements `google-analytics` support is deprecated and will be removed in a future version ([GH11308](#))
- Deprecate the `engine` keyword in `.to_csv()`, which will be removed in a future version ([GH11274](#))

## Performance improvements

- Checking monotonic-ness before sorting on an index (GH11080)
- `Series.dropna` performance improvement when its dtype can't contain NaN (GH11159)
- Release the GIL on most datetime field operations (e.g. `DatetimeIndex.year`, `Series.dt.year`), normalization, and conversion to and from `Period`, `DatetimeIndex.to_period` and `PeriodIndex.to_timestamp` (GH11263)
- Release the GIL on some rolling algos: `rolling_median`, `rolling_mean`, `rolling_max`, `rolling_min`, `rolling_var`, `rolling_kurt`, `rolling_skew` (GH11450)
- Release the GIL when reading and parsing text files in `read_csv`, `read_table` (GH11272)
- Improved performance of `rolling_median` (GH11450)
- Improved performance of `to_excel` (GH11352)
- Performance bug in repr of Categorical categories, which was rendering the strings before chopping them for display (GH11305)
- Performance improvement in `Categorical.remove_unused_categories`, (GH11643).
- Improved performance of `Series` constructor with no data and `DatetimeIndex` (GH11433)
- Improved performance of `shift`, `cumprod`, and `cumsum` with `groupby` (GH4095)

## Bug fixes

- `SparseArray.__iter__()` now does not cause `PendingDeprecationWarning` in Python 3.5 (GH11622)
- Regression from 0.16.2 for output formatting of long floats/nan, restored in (GH11302)
- `Series.sort_index()` now correctly handles the `inplace` option (GH11402)
- Incorrectly distributed `.c` file in the build on PyPi when reading a csv of floats and passing `na_values=<a scalar>` would show an exception (GH11374)
- Bug in `.to_latex()` output broken when the index has a name (GH10660)
- Bug in `HDFStore.append` with strings whose encoded length exceeded the max unencoded length (GH11234)
- Bug in merging `datetime64[ns, tz]` dtypes (GH11405)
- Bug in `HDFStore.select` when comparing with a numpy scalar in a `where` clause (GH11283)
- Bug in using `DataFrame.ix` with a `MultiIndex` indexer (GH11372)
- Bug in `date_range` with ambiguous endpoints (GH11626)
- Prevent adding new attributes to the accessors `.str`, `.dt` and `.cat`. Retrieving such a value was not possible, so error out on setting it. (GH10673)
- Bug in `tz`-conversions with an ambiguous time and `.dt` accessors (GH11295)
- Bug in output formatting when using an index of ambiguous times (GH11619)
- Bug in comparisons of `Series` vs list-likes (GH11339)
- Bug in `DataFrame.replace` with a `datetime64[ns, tz]` and a non-compatible `to_replace` (GH11326, GH11153)

- Bug in `isnull` where `numpy.datetime64('NaT')` in a `numpy.array` was not determined to be null (GH11206)
- Bug in list-like indexing with a mixed-integer Index (GH11320)
- Bug in `pivot_table` with `margins=True` when indexes are of Categorical dtype (GH10993)
- Bug in `DataFrame.plot` cannot use hex strings colors (GH10299)
- Regression in `DataFrame.drop_duplicates` from 0.16.2, causing incorrect results on integer values (GH11376)
- Bug in `pd.eval` where unary ops in a list error (GH11235)
- Bug in `squeeze()` with zero length arrays (GH11230, GH8999)
- Bug in `describe()` dropping column names for hierarchical indexes (GH11517)
- Bug in `DataFrame.pct_change()` not propagating `axis` keyword on `.fillna` method (GH11150)
- Bug in `.to_csv()` when a mix of integer and string column names are passed as the `columns` parameter (GH11637)
- Bug in indexing with a range, (GH11652)
- Bug in inference of numpy scalars and preserving dtype when setting columns (GH11638)
- Bug in `to_sql` using unicode column names giving `UnicodeEncodeError` with (GH11431).
- Fix regression in setting of `xticks` in `plot` (GH11529).
- Bug in `holiday.dates` where observance rules could not be applied to holiday and doc enhancement (GH11477, GH11533)
- Fix plotting issues when having plain `Axes` instances instead of `SubplotAxes` (GH11520, GH11556).
- Bug in `DataFrame.to_latex()` produces an extra rule when `header=False` (GH7124)
- Bug in `df.groupby(...).apply(func)` when a `func` returns a `Series` containing a new datetimelike column (GH11324)
- Bug in `pandas.json` when file to load is big (GH11344)
- Bugs in `to_excel` with duplicate columns (GH11007, GH10982, GH10970)
- Fixed a bug that prevented the construction of an empty series of dtype `datetime64[ns, tz]` (GH11245).
- Bug in `read_excel` with `MultiIndex` containing integers (GH11317)
- Bug in `to_excel` with `openpyxl 2.2+` and merging (GH11408)
- Bug in `DataFrame.to_dict()` produces a `np.datetime64` object instead of `Timestamp` when only `datetime` is present in data (GH11327)
- Bug in `DataFrame.corr()` raises exception when computes Kendall correlation for `DataFrames` with boolean and not boolean columns (GH11560)
- Bug in the link-time error caused by `C inline` functions on FreeBSD 10+ (with `clang`) (GH10510)
- Bug in `DataFrame.to_csv` in passing through arguments for formatting `MultiIndexes`, including `date_format` (GH7791)
- Bug in `DataFrame.join()` with `how='right'` producing a `TypeError` (GH11519)
- Bug in `Series.quantile` with empty list results has `Index` with `object` dtype (GH11588)
- Bug in `pd.merge` results in empty `Int64Index` rather than `Index(dtype=object)` when the merge result is empty (GH11588)

- Bug in `Categorical.remove_unused_categories` when having NaN values (GH11599)
- Bug in `DataFrame.to_sparse()` loses column names for MultiIndexes (GH11600)
- Bug in `DataFrame.round()` with non-unique column index producing a Fatal Python error (GH11611)
- Bug in `DataFrame.round()` with `decimals` being a non-unique indexed Series producing extra columns (GH11618)

## 6.10.2 v0.17.0 (October 9, 2015)

{{ header }}

This is a major release from 0.16.2 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

**Warning:** pandas >= 0.17.0 will no longer support compatibility with Python version 3.2 (GH9118)

**Warning:** The `pandas.io.data` package is deprecated and will be replaced by the `pandas-datareader` package. This will allow the data modules to be independently updated to your pandas installation. The API for `pandas-datareader v0.1.1` is exactly the same as in `pandas v0.17.0` (GH8961, GH10861).

After installing `pandas-datareader`, you can easily change your imports:

```
from pandas.io import data, wb
```

becomes

```
from pandas_datareader import data, wb
```

Highlights include:

- Release the Global Interpreter Lock (GIL) on some cython operations, see [here](#)
- Plotting methods are now available as attributes of the `.plot` accessor, see [here](#)
- The sorting API has been revamped to remove some long-time inconsistencies, see [here](#)
- Support for a `datetime64[ns]` with timezones as a first-class dtype, see [here](#)
- The default for `to_datetime` will now be to `raise` when presented with unparseable formats, previously this would return the original input. Also, date parse functions now return consistent results. See [here](#)
- The default for `dropna` in `HDFStore` has changed to `False`, to store by default all rows even if they are all `NaN`, see [here](#)
- Datetime accessor (`dt`) now supports `Series.dt.strftime` to generate formatted strings for datetime-likes, and `Series.dt.total_seconds` to generate each duration of the `timedelta` in seconds. See [here](#)
- `Period` and `PeriodIndex` can handle multiplied `freq` like `3D`, which corresponding to 3 days span. See [here](#)
- Development installed versions of pandas will now have PEP440 compliant version strings (GH9518)
- Development support for benchmarking with the [Air Speed Velocity](#) library (GH8361)
- Support for reading SAS `xport` files, see [here](#)
- Documentation comparing SAS to `pandas`, see [here](#)
- Removal of the automatic `TimeSeries` broadcasting, deprecated since 0.8.0, see [here](#)
- Display format with plain text can optionally align with Unicode East Asian Width, see [here](#)
- Compatibility with Python 3.5 (GH11097)
- Compatibility with `matplotlib 1.5.0` (GH11111)

Check the *API Changes* and *deprecations* before updating.

### What's new in v0.17.0

- *New features*
  - *Datetime with TZ*
  - *Releasing the GIL*
  - *Plot submethods*
  - *Additional methods for dt accessor*
    - \* *strftime*
    - \* *total\_seconds*
  - *Period frequency enhancement*
  - *Support for SAS XPORT files*
  - *Support for math functions in .eval()*
  - *Changes to Excel with MultiIndex*
  - *Google BigQuery enhancements*
  - *Display alignment with Unicode East Asian width*
  - *Other enhancements*
- *Backwards incompatible API changes*
  - *Changes to sorting API*
  - *Changes to to\_datetime and to\_timedelta*
    - \* *Error handling*
    - \* *Consistent parsing*
  - *Changes to Index comparisons*
  - *Changes to boolean comparisons vs. None*
  - *HDFStore dropna behavior*
  - *Changes to display.precision option*
  - *Changes to Categorical.unique*
  - *Changes to bool passed as header in parsers*
  - *Other API changes*
  - *Deprecations*
  - *Removal of prior version deprecations/changes*
- *Performance improvements*
- *Bug fixes*
- *Contributors*

## New features

### Datetime with TZ

We are adding an implementation that natively supports datetime with timezones. A Series or a DataFrame column previously *could* be assigned a datetime with timezones, and would work as an object dtype. This had performance issues with a large number rows. See the *docs* for more details. (GH8260, GH10763, GH11034).

The new implementation allows for having a single-timezone across all rows, with operations in a performant manner.

```
In [1]: df = pd.DataFrame({'A': pd.date_range('20130101', periods=3),
...:                      'B': pd.date_range('20130101', periods=3, tz='US/Eastern'),
...:                      'C': pd.date_range('20130101', periods=3, tz='CET')})
...:
```

```
In [2]: df
```

```
Out [2]:
```

```
      A      B      C
0 2013-01-01 2013-01-01 00:00:00-05:00 2013-01-01 00:00:00+01:00
1 2013-01-02 2013-01-02 00:00:00-05:00 2013-01-02 00:00:00+01:00
2 2013-01-03 2013-01-03 00:00:00-05:00 2013-01-03 00:00:00+01:00
```

```
[3 rows x 3 columns]
```

```
In [3]: df.dtypes
```

```
Out [3]:
```

```
A      datetime64[ns]
B      datetime64[ns, US/Eastern]
C      datetime64[ns, CET]
Length: 3, dtype: object
```

```
In [4]: df.B
```

```
Out [4]:
```

```
0    2013-01-01 00:00:00-05:00
1    2013-01-02 00:00:00-05:00
2    2013-01-03 00:00:00-05:00
Name: B, Length: 3, dtype: datetime64[ns, US/Eastern]
```

```
In [5]: df.B.dt.tz_localize(None)
```

```
Out [5]:
```

```
0    2013-01-01
1    2013-01-02
2    2013-01-03
Name: B, Length: 3, dtype: datetime64[ns]
```

This uses a new-dtype representation as well, that is very similar in look-and-feel to its numpy cousin `datetime64[ns]`

```
In [6]: df['B'].dtype
```

```
Out [6]: datetime64[ns, US/Eastern]
```

```
In [7]: type(df['B'].dtype)
```

```
Out [7]: pandas.core.dtypes.dtypes.DatetimeTZDtype
```

**Note:** There is a slightly different string repr for the underlying `DatetimeIndex` as a result of the dtype changes, but functionally these are the same.

Previous behavior:

```
In [1]: pd.date_range('20130101', periods=3, tz='US/Eastern')
Out [1]: DatetimeIndex(['2013-01-01 00:00:00-05:00', '2013-01-02 00:00:00-05:00',
                        '2013-01-03 00:00:00-05:00'],
                        dtype='datetime64[ns]', freq='D', tz='US/Eastern')

In [2]: pd.date_range('20130101', periods=3, tz='US/Eastern').dtype
Out [2]: dtype('<M8[ns]')
```

New behavior:

```
In [8]: pd.date_range('20130101', periods=3, tz='US/Eastern')
Out [8]:
DatetimeIndex(['2013-01-01 00:00:00-05:00', '2013-01-02 00:00:00-05:00',
                '2013-01-03 00:00:00-05:00'],
                dtype='datetime64[ns, US/Eastern]', freq='D')

In [9]: pd.date_range('20130101', periods=3, tz='US/Eastern').dtype
Out [9]: datetime64[ns, US/Eastern]
```

## Releasing the GIL

We are releasing the global-interpreter-lock (GIL) on some cython operations. This will allow other threads to run simultaneously during computation, potentially allowing performance improvements from multi-threading. Notably `groupby`, `nsmallest`, `value_counts` and some indexing operations benefit from this. (GH8882)

For example the `groupby` expression in the following code will have the GIL released during the factorization step, e.g. `df.groupby('key')` as well as the `.sum()` operation.

```
N = 1000000
ngroups = 10
df = DataFrame({'key': np.random.randint(0, ngroups, size=N),
               'data': np.random.randn(N)})
df.groupby('key')['data'].sum()
```

Releasing of the GIL could benefit an application that uses threads for user interactions (e.g. QT), or performing multi-threaded computations. A nice example of a library that can handle these types of computation-in-parallel is the `dask` library.

## Plot submethods

The `Series` and `DataFrame` `.plot()` method allows for customizing *plot types* by supplying the `kind` keyword arguments. Unfortunately, many of these kinds of plots use different required and optional keyword arguments, which makes it difficult to discover what any given plot kind uses out of the dozens of possible arguments.

To alleviate this issue, we have added a new, optional plotting interface, which exposes each kind of plot as a method of the `.plot` attribute. Instead of writing `series.plot(kind=<kind>, ...)`, you can now also use `series.plot.<kind>(...)`:

```
In [10]: df = pd.DataFrame(np.random.rand(10, 2), columns=['a', 'b'])
In [11]: df.plot.bar()
```

As a result of this change, these methods are now all discoverable via tab-completion:

```
In [12]: df.plot.<TAB> # noqa: E225, E999
df.plot.area      df.plot.barh      df.plot.density  df.plot.hist     df.plot.line
->df.plot.scatter
df.plot.bar       df.plot.box       df.plot.hexbin   df.plot.kde      df.plot.pie
```

Each method signature only includes relevant arguments. Currently, these are limited to required arguments, but in the future these will include optional arguments, as well. For an overview, see the new *Plotting API* documentation.

## Additional methods for dt accessor

### strftime

We are now supporting a `Series.dt.strftime` method for datetime-likes to generate a formatted string (GH10110). Examples:

```
# DatetimeIndex
In [13]: s = pd.Series(pd.date_range('20130101', periods=4))

In [14]: s
Out[14]:
0    2013-01-01
1    2013-01-02
2    2013-01-03
3    2013-01-04
Length: 4, dtype: datetime64[ns]

In [15]: s.dt.strftime('%Y/%m/%d')
Out[15]:
0    2013/01/01
1    2013/01/02
2    2013/01/03
3    2013/01/04
Length: 4, dtype: object
```

```
# PeriodIndex
In [16]: s = pd.Series(pd.period_range('20130101', periods=4))
```

(continues on next page)

(continued from previous page)

```
In [17]: s
Out[17]:
0    2013-01-01
1    2013-01-02
2    2013-01-03
3    2013-01-04
Length: 4, dtype: period[D]

In [18]: s.dt.strftime('%Y/%m/%d')
Out[18]:
0    2013/01/01
1    2013/01/02
2    2013/01/03
3    2013/01/04
Length: 4, dtype: object
```

The string format is as the python standard library and details can be found [here](#)

## total\_seconds

pd.Series of type timedelta64 has new method `.dt.total_seconds()` returning the duration of the timedelta in seconds ([GH10817](#))

```
# TimedeltaIndex
In [19]: s = pd.Series(pd.timedelta_range('1 minutes', periods=4))

In [20]: s
Out[20]:
0    0 days 00:01:00
1    1 days 00:01:00
2    2 days 00:01:00
3    3 days 00:01:00
Length: 4, dtype: timedelta64[ns]

In [21]: s.dt.total_seconds()
Out[21]:
0         60.0
1    86460.0
2   172860.0
3   259260.0
Length: 4, dtype: float64
```

## Period frequency enhancement

Period, PeriodIndex and period\_range can now accept multiplied freq. Also, Period.freq and PeriodIndex.freq are now stored as a DateOffset instance like DatetimeIndex, and not as str ([GH7811](#))

A multiplied freq represents a span of corresponding length. The example below creates a period of 3 days. Addition and subtraction will shift the period by its span.

```
In [22]: p = pd.Period('2015-08-01', freq='3D')

In [23]: p
Out[23]: Period('2015-08-01', '3D')

In [24]: p + 1
Out[24]: Period('2015-08-04', '3D')

In [25]: p - 2
Out[25]: Period('2015-07-26', '3D')

In [26]: p.to_timestamp()
Out[26]: Timestamp('2015-08-01 00:00:00')

In [27]: p.to_timestamp(how='E')
Out[27]: Timestamp('2015-08-03 23:59:59.999999999')
```

You can use the multiplied freq in PeriodIndex and period\_range.

```
In [28]: idx = pd.period_range('2015-08-01', periods=4, freq='2D')

In [29]: idx
Out[29]: PeriodIndex(['2015-08-01', '2015-08-03', '2015-08-05', '2015-08-07'], dtype=
↪ 'period[2D]', freq='2D')

In [30]: idx + 1
Out[30]: PeriodIndex(['2015-08-03', '2015-08-05', '2015-08-07', '2015-08-09'], dtype=
↪ 'period[2D]', freq='2D')
```

## Support for SAS XPORT files

`read_sas()` provides support for reading *SAS XPORT* format files. (GH4052).

```
df = pd.read_sas('sas_xport.xpt')
```

It is also possible to obtain an iterator and read an XPORT file incrementally.

```
for df in pd.read_sas('sas_xport.xpt', chunksize=10000):
    do_something(df)
```

See the *docs* for more details.

## Support for math functions in .eval()

`eval()` now supports calling math functions (GH4893)

```
df = pd.DataFrame({'a': np.random.randn(10)})
df.eval("b = sin(a)")
```

The support math functions are *sin*, *cos*, *exp*, *log*, *expm1*, *log1p*, *sqrt*, *sinh*, *cosh*, *tanh*, *arcsin*, *arccos*, *arctan*, *arccosh*, *arcsinh*, *arctanh*, *abs* and *arctan2*.

These functions map to the intrinsics for the NumExpr engine. For the Python engine, they are mapped to NumPy calls.

## Changes to Excel with MultiIndex

In version 0.16.2 a DataFrame with MultiIndex columns could not be written to Excel via `to_excel`. That functionality has been added (GH10564), along with updating `read_excel` so that the data can be read back with, no loss of information, by specifying which columns/rows make up the MultiIndex in the header and `index_col` parameters (GH4679)

See the *documentation* for more details.

```
In [31]: df = pd.DataFrame([[1, 2, 3, 4], [5, 6, 7, 8]],
.....:                    columns=pd.MultiIndex.from_product(
.....:                    [['foo', 'bar'], ['a', 'b']], names=['col1', 'col2']),
.....:                    index=pd.MultiIndex.from_product(['j', 'k'],
.....:                    names=['i1', 'i2']))
.....:

In [32]: df
Out[32]:
col1 foo   bar
col2  a  b   a  b
i1 i2
j  1    1  2    3  4
   k    5  6    7  8

[2 rows x 4 columns]

In [33]: df.to_excel('test.xlsx')

In [34]: df = pd.read_excel('test.xlsx', header=[0, 1], index_col=[0, 1])

In [35]: df
Out[35]:
col1 foo   bar
col2  a  b   a  b
i1 i2
j  1    1  2    3  4
   k    5  6    7  8

[2 rows x 4 columns]
```

Previously, it was necessary to specify the `has_index_names` argument in `read_excel`, if the serialized data had index names. For version 0.17.0 the output format of `to_excel` has been changed to make this keyword unnecessary - the change is shown below.

### Old

|   | A                   | B        | C        | D        | E        | F |
|---|---------------------|----------|----------|----------|----------|---|
| 1 |                     | A        | B        | C        | D        |   |
| 2 | idx_name            |          |          |          |          |   |

| 2 | 2000-01-07 00:00:00 | 0.968129 | 0.906529 | 0.05343  | 0.02619  |
| 3 | 2000-01-10 00:00:00 | -0.16632 | 1.981993 | 1.833093 | 0.803685 |
| 4 | 2000-01-11 00:00:00 | 0.121057 | 0.36946  | -0.02888 | 1.683975 |
| 5 | 2000-01-12 00:00:00 | -1.70456 | -0.73098 | -0.38088 | 0.020946 |
| 6 | 2000-01-13 00:00:00 | -1.20024 | 1.907733 | 0.629318 | 1.507033 |
| 7 | 2000-01-14 00:00:00 | -0.66344 | 0.073188 | 1.583482 | 0.735205 |
| 8 | 2000-01-17 00:00:00 | 0.716635 | -2.07952 | 1.760536 | 0.970309 |
| 9 | 2000-01-18 00:00:00 | 0.727628 | 2.22267  | 2.706276 | 0.681842 |

**Warning:** Excel files saved in version 0.16.2 or prior that had index names will still be able to be read in, but the `has_index_names` argument must be specified to `True`.

## Google BigQuery enhancements

- Added ability to automatically create a table/dataset using the `pandas.io.gbq.to_gbq()` function if the destination table/dataset does not exist. (GH8325, GH11121).
- Added ability to replace an existing table and schema when calling the `pandas.io.gbq.to_gbq()` function via the `if_exists` argument. See the docs for more details (GH8325).
- `InvalidColumnOrder` and `InvalidPageToken` in the `gbq` module will raise `ValueError` instead of `IOError`.
- The `generate_bq_schema()` function is now deprecated and will be removed in a future version (GH11121).
- The `gbq` module will now support Python 3 (GH11094).

## Display alignment with Unicode East Asian width

**Warning:** Enabling this option will affect the performance for printing of `DataFrame` and `Series` (about 2 times slower). Use only when it is actually required.

Some East Asian countries use Unicode characters its width is corresponding to 2 alphabets. If a `DataFrame` or `Series` contains these characters, the default output cannot be aligned properly. The following options are added to enable precise handling for these characters.

- `display.unicode.east_asian_width`: Whether to use the Unicode East Asian Width to calculate the display text width. (GH2612)
- `display.unicode.ambiguous_as_wide`: Whether to handle Unicode characters belong to Ambiguous as Wide. (GH11102)

```
In [36]: df = pd.DataFrame({'u': ['UK', u'], u': ['Alice', u']})
```

```
In [37]: df;
```

```
>>> df = pd.DataFrame({'u'国籍': ['UK', u'日本'], u'名前': ['Alice', u'しのぶ']})
>>> df
   名前  国籍
0 Alice UK
1 しのぶ 日本
```

```
In [38]: pd.set_option('display.unicode.east_asian_width', True)
```

```
In [39]: df;
```

```
>>> pd.set_option('display.unicode.east_asian_width', True)
>>> df
   名前  国籍
0 Alice UK
1 しのぶ 日本
```

For further details, see [here](#)

## Other enhancements

- Support for `openpyxl >= 2.2`. The API for style support is now stable (GH10125)
- `merge` now accepts the argument `indicator` which adds a Categorical-type column (by default called `_merge`) to the output object that takes on the values (GH8790)

| Observation Origin              | <code>_merge</code> value |
|---------------------------------|---------------------------|
| Merge key only in 'left' frame  | <code>left_only</code>    |
| Merge key only in 'right' frame | <code>right_only</code>   |
| Merge key in both frames        | <code>both</code>         |

```
In [40]: df1 = pd.DataFrame({'col1':[0,1], 'col_left':['a','b']})
```

```
In [41]: df2 = pd.DataFrame({'col1':[1,2,2], 'col_right':[2,2,2]})
```

(continues on next page)

(continued from previous page)

```
In [42]: pd.merge(df1, df2, on='coll', how='outer', indicator=True)
Out[42]:
   coll col_left col_right  _merge
0     0         a        NaN  left_only
1     1         b         2.0    both
2     2        NaN         2.0  right_only
3     2        NaN         2.0  right_only

[4 rows x 4 columns]
```

For more, see the *updated docs*

- `pd.to_numeric` is a new function to coerce strings to numbers (possibly with coercion) ([GH11133](#))
- `pd.merge` will now allow duplicate column names if they are not merged upon ([GH10639](#)).
- `pd.pivot` will now allow passing index as `None` ([GH3962](#)).
- `pd.concat` will now use existing Series names if provided ([GH10698](#)).

```
In [43]: foo = pd.Series([1, 2], name='foo')
In [44]: bar = pd.Series([1, 2])
In [45]: baz = pd.Series([4, 5])
```

Previous behavior:

```
In [1]: pd.concat([foo, bar, baz], 1)
Out[1]:
   0  1  2
0  1  1  4
1  2  2  5
```

New behavior:

```
In [46]: pd.concat([foo, bar, baz], 1)
Out[46]:
   foo  0  1
0    1  1  4
1    2  2  5

[2 rows x 3 columns]
```

- `DataFrame` has gained the `nlargest` and `nsmallest` methods ([GH10393](#))
- Add a `limit_direction` keyword argument that works with `limit` to enable interpolate to fill NaN values forward, backward, or both ([GH9218](#), [GH10420](#), [GH11115](#))

```
In [47]: ser = pd.Series([np.nan, np.nan, 5, np.nan, np.nan, 13])
In [48]: ser.interpolate(limit=1, limit_direction='both')
Out[48]:
0    NaN
1     5.0
2     5.0
3     7.0
4    NaN
```

(continues on next page)

(continued from previous page)

```

5    11.0
6    13.0
Length: 7, dtype: float64

```

- Added a `DataFrame.round` method to round the values to a variable number of decimal places ([GH10568](#)).

```

In [49]: df = pd.DataFrame(np.random.random([3, 3]),
.....:                      columns=['A', 'B', 'C'],
.....:                      index=['first', 'second', 'third'])
.....:

```

```
In [50]: df
```

```

Out [50]:
           A         B         C
first  0.865702  0.618053  0.874058
second 0.262670  0.058815  0.042868
third   0.321131  0.244171  0.973007

```

```
[3 rows x 3 columns]
```

```
In [51]: df.round(2)
```

```

Out [51]:
           A         B         C
first    0.87    0.62    0.87
second   0.26    0.06    0.04
third    0.32    0.24    0.97

```

```
[3 rows x 3 columns]
```

```
In [52]: df.round({'A': 0, 'C': 2})
```

```

Out [52]:
           A         B         C
first    1.0    0.618053    0.87
second   0.0    0.058815    0.04
third    0.0    0.244171    0.97

```

```
[3 rows x 3 columns]
```

- `drop_duplicates` and `duplicated` now accept a `keep` keyword to target first, last, and all duplicates. The `take_last` keyword is deprecated, see [here](#) ([GH6511](#), [GH8505](#))

```
In [53]: s = pd.Series(['A', 'B', 'C', 'A', 'B', 'D'])
```

```
In [54]: s.drop_duplicates()
```

```

Out [54]:
0    A
1    B
2    C
5    D
Length: 4, dtype: object

```

```
In [55]: s.drop_duplicates(keep='last')
```

```

Out [55]:
2    C
3    A
4    B

```

(continues on next page)

(continued from previous page)

```
5    D
Length: 4, dtype: object
```

```
In [56]: s.drop_duplicates(keep=False)
```

```
Out [56]:
```

```
2    C
5    D
Length: 2, dtype: object
```

- Reindex now has a `tolerance` argument that allows for finer control of *Limits on filling while reindexing* (GH10411):

```
In [57]: df = pd.DataFrame({'x': range(5),
.....:                      't': pd.date_range('2000-01-01', periods=5)})
.....:
```

```
In [58]: df.reindex([0.1, 1.9, 3.5],
.....:               method='nearest',
.....:               tolerance=0.2)
.....:
```

```
Out [58]:
```

```
      x      t
0.1  0.0  2000-01-01
1.9  2.0  2000-01-03
3.5  NaN      NaT
```

```
[3 rows x 2 columns]
```

When used on a `DatetimeIndex`, `TimedeltaIndex` or `PeriodIndex`, `tolerance` will be coerced into a `Timedelta` if possible. This allows you to specify tolerance with a string:

```
In [59]: df = df.set_index('t')
```

```
In [60]: df.reindex(pd.to_datetime(['1999-12-31']),
.....:               method='nearest',
.....:               tolerance='1 day')
.....:
```

```
Out [60]:
```

```
      x
1999-12-31  0
```

```
[1 rows x 1 columns]
```

`tolerance` is also exposed by the lower level `Index.get_indexer` and `Index.get_loc` methods.

- Added functionality to use the `base` argument when resampling a `TimeDeltaIndex` (GH10530)
- `DatetimeIndex` can be instantiated using strings that contain `NaT` (GH7599)
- `to_datetime` can now accept the `yearfirst` keyword (GH7599)
- `pandas.tseries.offsets` larger than the `Day` offset can now be used with a `Series` for addition/subtraction (GH10699). See the *docs* for more details.
- `pd.Timedelta.total_seconds()` now returns `Timedelta` duration to ns precision (previously microsecond precision) (GH10939)
- `PeriodIndex` now supports arithmetic with `np.ndarray` (GH10638)

- Support pickling of `Period` objects (GH10439)
- `.as_blocks` will now take a `copy` optional argument to return a copy of the data, default is to copy (no change in behavior from prior versions), (GH9607)
- `regex` argument to `DataFrame.filter` now handles numeric column names instead of raising `ValueError` (GH10384).
- Enable reading gzip compressed files via URL, either by explicitly setting the compression parameter or by inferring from the presence of the HTTP Content-Encoding header in the response (GH8685)
- Enable writing Excel files in *memory* using `StringIO/BytesIO` (GH7074)
- Enable serialization of lists and dicts to strings in `ExcelWriter` (GH8188)
- SQL io functions now accept a SQLAlchemy connectable. (GH7877)
- `pd.read_sql` and `to_sql` can accept database URI as `con` parameter (GH10214)
- `read_sql_table` will now allow reading from views (GH10750).
- Enable writing complex values to `HDFStores` when using the `table` format (GH10447)
- Enable `pd.read_hdf` to be used without specifying a key when the HDF file contains a single dataset (GH10443)
- `pd.read_stata` will now read Stata 118 type files. (GH9882)
- `msgpack` submodule has been updated to 0.4.6 with backward compatibility (GH10581)
- `DataFrame.to_dict` now accepts `orient='index'` keyword argument (GH10844).
- `DataFrame.apply` will return a `Series` of dicts if the passed function returns a dict and `reduce=True` (GH8735).
- Allow passing *kwargs* to the interpolation methods (GH10378).
- Improved error message when concatenating an empty iterable of `Dataframe` objects (GH9157)
- `pd.read_csv` can now read bz2-compressed files incrementally, and the C parser can read bz2-compressed files from AWS S3 (GH11070, GH11072).
- In `pd.read_csv`, recognize `s3n://` and `s3a://` URLs as designating S3 file storage (GH11070, GH11071).
- Read CSV files from AWS S3 incrementally, instead of first downloading the entire file. (Full file download still required for compressed files in Python 2.) (GH11070, GH11073)
- `pd.read_csv` is now able to infer compression type for files read from AWS S3 storage (GH11070, GH11074).

## Backwards incompatible API changes

### Changes to sorting API

The sorting API has had some longtime inconsistencies. (GH9816, GH8239).

Here is a summary of the API **PRIOR** to 0.17.0:

- `Series.sort` is **INPLACE** while `DataFrame.sort` returns a new object.
- `Series.order` returns a new object
- It was possible to use `Series/DataFrame.sort_index` to sort by **values** by passing the `by` keyword.

- `Series/DataFrame.sortlevel` worked only on a `MultiIndex` for sorting by index.

To address these issues, we have revamped the API:

- We have introduced a new method, `DataFrame.sort_values()`, which is the merger of `DataFrame.sort()`, `Series.sort()`, and `Series.order()`, to handle sorting of **values**.
- The existing methods `Series.sort()`, `Series.order()`, and `DataFrame.sort()` have been deprecated and will be removed in a future version.
- The `by` argument of `DataFrame.sort_index()` has been deprecated and will be removed in a future version.
- The existing method `.sort_index()` will gain the `level` keyword to enable level sorting.

We now have two distinct and non-overlapping methods of sorting. A \* marks items that will show a `FutureWarning`.

To sort by the **values**:

| Previous                                   | Replacement                                   |
|--------------------------------------------|-----------------------------------------------|
| * <code>Series.order()</code>              | <code>Series.sort_values()</code>             |
| * <code>Series.sort()</code>               | <code>Series.sort_values(inplace=True)</code> |
| * <code>DataFrame.sort(columns=...)</code> | <code>DataFrame.sort_values(by=...)</code>    |

To sort by the **index**:

| Previous                                    | Replacement                                  |
|---------------------------------------------|----------------------------------------------|
| <code>Series.sort_index()</code>            | <code>Series.sort_index()</code>             |
| <code>Series.sortlevel(level=...)</code>    | <code>Series.sort_index(level=...)</code>    |
| <code>DataFrame.sort_index()</code>         | <code>DataFrame.sort_index()</code>          |
| <code>DataFrame.sortlevel(level=...)</code> | <code>DataFrame.sort_index(level=...)</code> |
| * <code>DataFrame.sort()</code>             | <code>DataFrame.sort_index()</code>          |

We have also deprecated and changed similar methods in two `Series`-like classes, `Index` and `Categorical`.

| Previous                           | Replacement                            |
|------------------------------------|----------------------------------------|
| * <code>Index.order()</code>       | <code>Index.sort_values()</code>       |
| * <code>Categorical.order()</code> | <code>Categorical.sort_values()</code> |

## Changes to `to_datetime` and `timedelta`

### Error handling

The default for `pd.to_datetime` error handling has changed to `errors='raise'`. In prior versions it was `errors='ignore'`. Furthermore, the `coerce` argument has been deprecated in favor of `errors='coerce'`. This means that invalid parsing will raise rather than return the original input as in previous versions. ([GH10636](#))

Previous behavior:

```
In [2]: pd.to_datetime(['2009-07-31', 'asd'])
Out[2]: array(['2009-07-31', 'asd'], dtype=object)
```

New behavior:

```
In [3]: pd.to_datetime(['2009-07-31', 'asd'])
ValueError: Unknown string format
```

Of course you can coerce this as well.

```
In [61]: pd.to_datetime(['2009-07-31', 'asd'], errors='coerce')
Out [61]: DatetimeIndex(['2009-07-31', 'NaT'], dtype='datetime64[ns]', freq=None)
```

To keep the previous behavior, you can use `errors='ignore'`:

```
In [62]: pd.to_datetime(['2009-07-31', 'asd'], errors='ignore')
Out [62]: Index(['2009-07-31', 'asd'], dtype='object')
```

Furthermore, `pd.to_timedelta` has gained a similar API, of `errors='raise' | 'ignore' | 'coerce'`, and the `coerce` keyword has been deprecated in favor of `errors='coerce'`.

## Consistent parsing

The string parsing of `to_datetime`, `Timestamp` and `DatetimeIndex` has been made consistent. (GH7599)

Prior to v0.17.0, `Timestamp` and `to_datetime` may parse year-only datetime-string incorrectly using today's date, otherwise `DatetimeIndex` uses the beginning of the year. `Timestamp` and `to_datetime` may raise `ValueError` in some types of datetime-string which `DatetimeIndex` can parse, such as a quarterly string.

Previous behavior:

```
In [1]: pd.Timestamp('2012Q2')
Traceback
...
ValueError: Unable to parse 2012Q2

# Results in today's date.
In [2]: pd.Timestamp('2014')
Out [2]: 2014-08-12 00:00:00
```

v0.17.0 can parse them as below. It works on `DatetimeIndex` also.

New behavior:

```
In [63]: pd.Timestamp('2012Q2')
Out [63]: Timestamp('2012-04-01 00:00:00')

In [64]: pd.Timestamp('2014')
Out [64]: Timestamp('2014-01-01 00:00:00')

In [65]: pd.DatetimeIndex(['2012Q2', '2014'])
Out [65]: DatetimeIndex(['2012-04-01', '2014-01-01'], dtype='datetime64[ns]',
↳ freq=None)
```

---

**Note:** If you want to perform calculations based on today's date, use `Timestamp.now()` and `pandas.tseries.offsets`.

```
In [66]: import pandas.tseries.offsets as offsets

In [67]: pd.Timestamp.now()
```

(continues on next page)

(continued from previous page)

```
Out [67]: Timestamp('2020-01-29 22:48:33.793432')
In [68]: pd.Timestamp.now() + offsets.DateOffset(years=1)
Out [68]: Timestamp('2021-01-29 22:48:33.795041')
```

## Changes to Index comparisons

Operator equal on Index should behavior similarly to Series ([GH9947](#), [GH10637](#))

Starting in v0.17.0, comparing Index objects of different lengths will raise a `ValueError`. This is to be consistent with the behavior of `Series`.

Previous behavior:

```
In [2]: pd.Index([1, 2, 3]) == pd.Index([1, 4, 5])
Out [2]: array([ True, False, False], dtype=bool)

In [3]: pd.Index([1, 2, 3]) == pd.Index([2])
Out [3]: array([False,  True, False], dtype=bool)

In [4]: pd.Index([1, 2, 3]) == pd.Index([1, 2])
Out [4]: False
```

New behavior:

```
In [8]: pd.Index([1, 2, 3]) == pd.Index([1, 4, 5])
Out [8]: array([ True, False, False], dtype=bool)

In [9]: pd.Index([1, 2, 3]) == pd.Index([2])
ValueError: Lengths must match to compare

In [10]: pd.Index([1, 2, 3]) == pd.Index([1, 2])
ValueError: Lengths must match to compare
```

Note that this is different from the `numpy` behavior where a comparison can be broadcast:

```
In [69]: np.array([1, 2, 3]) == np.array([1])
Out [69]: array([ True, False, False])
```

or it can return `False` if broadcasting can not be done:

```
In [70]: np.array([1, 2, 3]) == np.array([1, 2])
Out [70]: False
```

## Changes to boolean comparisons vs. None

Boolean comparisons of a Series vs None will now be equivalent to comparing with `np.nan`, rather than raise `TypeError`. (GH1079).

```
In [71]: s = pd.Series(range(3))
```

```
In [72]: s.iloc[1] = None
```

```
In [73]: s
```

```
Out [73]:
```

```
0    0.0
```

```
1    NaN
```

```
2    2.0
```

```
Length: 3, dtype: float64
```

Previous behavior:

```
In [5]: s == None
```

```
TypeError: Could not compare <type 'NoneType'> type with Series
```

New behavior:

```
In [74]: s == None
```

```
Out [74]:
```

```
0    False
```

```
1    False
```

```
2    False
```

```
Length: 3, dtype: bool
```

Usually you simply want to know which values are null.

```
In [75]: s.isnull()
```

```
Out [75]:
```

```
0    False
```

```
1     True
```

```
2    False
```

```
Length: 3, dtype: bool
```

**Warning:** You generally will want to use `isnull/notnull` for these types of comparisons, as `isnull/notnull` tells you which elements are null. One has to be mindful that `nan`'s don't compare equal, but `None`'s do. Note that Pandas/numpy uses the fact that `np.nan != np.nan`, and treats `None` like `np.nan`.

```
In [76]: None == None
```

```
Out [76]: True
```

```
In [77]: np.nan == np.nan
```

```
Out [77]: False
```

## HDFStore dropna behavior

The default behavior for HDFStore write functions with `format='table'` is now to keep rows that are all missing. Previously, the behavior was to drop rows that were all missing save the index. The previous behavior can be replicated using the `dropna=True` option. (GH9382)

Previous behavior:

```
In [78]: df_with_missing = pd.DataFrame({'col1': [0, np.nan, 2],
.....:                                'col2': [1, np.nan, np.nan]})
.....:

In [79]: df_with_missing
Out [79]:
   col1  col2
0    0.0    1.0
1    NaN    NaN
2    2.0    NaN

[3 rows x 2 columns]
```

```
In [27]: df_with_missing.to_hdf('file.h5',
.....:                          'df_with_missing',
.....:                          format='table',
.....:                          mode='w')

In [28]: pd.read_hdf('file.h5', 'df_with_missing')

Out [28]:
   col1  col2
0     0     1
2     2    NaN
```

New behavior:

```
In [80]: df_with_missing.to_hdf('file.h5',
.....:                          'df_with_missing',
.....:                          format='table',
.....:                          mode='w')
.....:

In [81]: pd.read_hdf('file.h5', 'df_with_missing')
Out [81]:
   col1  col2
0    0.0    1.0
1    NaN    NaN
2    2.0    NaN

[3 rows x 2 columns]
```

See the *docs* for more details.

## Changes to `display.precision` option

The `display.precision` option has been clarified to refer to decimal places ([GH10451](#)).

Earlier versions of pandas would format floating point numbers to have one less decimal place than the value in `display.precision`.

```
In [1]: pd.set_option('display.precision', 2)

In [2]: pd.DataFrame({'x': [123.456789]})
Out[2]:
      x
0  123.5
```

If interpreting precision as “significant figures” this did work for scientific notation but that same interpretation did not work for values with standard formatting. It was also out of step with how numpy handles formatting.

Going forward the value of `display.precision` will directly control the number of places after the decimal, for regular formatting as well as scientific notation, similar to how numpy’s `precision` print option works.

```
In [82]: pd.set_option('display.precision', 2)

In [83]: pd.DataFrame({'x': [123.456789]})
Out[83]:
      x
0  123.46

[1 rows x 1 columns]
```

To preserve output behavior with prior versions the default value of `display.precision` has been reduced to 6 from 7.

## Changes to `Categorical.unique`

`Categorical.unique` now returns new `Categoricals` with categories and codes that are unique, rather than returning `np.array` ([GH10508](#))

- unordered category: values and categories are sorted by appearance order.
- ordered category: values are sorted by appearance order, categories keep existing order.

```
In [84]: cat = pd.Categorical(['C', 'A', 'B', 'C'],
.....:                       categories=['A', 'B', 'C'],
.....:                       ordered=True)
.....:

In [85]: cat
Out[85]:
[C, A, B, C]
Categories (3, object): [A < B < C]

In [86]: cat.unique()
Out[86]:
[C, A, B]
Categories (3, object): [A < B < C]

In [87]: cat = pd.Categorical(['C', 'A', 'B', 'C'],
```

(continues on next page)

(continued from previous page)

```

.....:                                     categories=['A', 'B', 'C'])
.....:
In [88]: cat
Out[88]:
[C, A, B, C]
Categories (3, object): [A, B, C]

In [89]: cat.unique()
Out[89]:
[C, A, B]
Categories (3, object): [C, A, B]

```

### Changes to `bool` passed as header in parsers

In earlier versions of pandas, if a `bool` was passed the `header` argument of `read_csv`, `read_excel`, or `read_html` it was implicitly converted to an integer, resulting in `header=0` for `False` and `header=1` for `True` (GH6113)

A `bool` input to `header` will now raise a `TypeError`

```

In [29]: df = pd.read_csv('data.csv', header=False)
TypeError: Passing a bool to header is invalid. Use header=None for no header or
header=int or list-like of ints to specify the row(s) making up the column names

```

### Other API changes

- Line and kde plot with `subplots=True` now uses default colors, not all black. Specify `color='k'` to draw all lines in black (GH9894)
- Calling the `.value_counts()` method on a `Series` with a categorical dtype now returns a `Series` with a `CategoricalIndex` (GH10704)
- The metadata properties of subclasses of pandas objects will now be serialized (GH10553).
- `groupby` using `Categorical` follows the same rule as `Categorical.unique` described above (GH10508)
- When constructing `DataFrame` with an array of `complex64` dtype previously meant the corresponding column was automatically promoted to the `complex128` dtype. Pandas will now preserve the `itemsizes` of the input for complex data (GH10952)
- some numeric reduction operators would return `ValueError`, rather than `TypeError` on object types that includes strings and numbers (GH11131)
- Passing currently unsupported `chunksize` argument to `read_excel` or `ExcelFile.parse` will now raise `NotImplementedError` (GH8011)
- Allow an `ExcelFile` object to be passed into `read_excel` (GH11198)
- `DatetimeIndex.union` does not infer `freq` if self and the input have `None` as `freq` (GH11086)
- `NaT`'s methods now either raise `ValueError`, or return `np.nan` or `NaT` (GH9513)

| Behavior                                 | Methods                                                         |
|------------------------------------------|-----------------------------------------------------------------|
| return <code>np.nan</code>               | <code>weekday, isoweekday</code>                                |
| return <code>NaT</code>                  | <code>date, now, replace, to_datetime, today</code>             |
| return <code>np.datetime64('NaT')</code> | <code>to_datetime64</code> (unchanged)                          |
| raise <code>ValueError</code>            | All other public methods (names not beginning with underscores) |

## Deprecations

- For `Series` the following indexing functions are deprecated (GH10177).

| Deprecated Function         | Replacement                                   |
|-----------------------------|-----------------------------------------------|
| <code>.irow(i)</code>       | <code>.iloc[i]</code> or <code>.iat[i]</code> |
| <code>.iget(i)</code>       | <code>.iloc[i]</code> or <code>.iat[i]</code> |
| <code>.iget_value(i)</code> | <code>.iloc[i]</code> or <code>.iat[i]</code> |

- For `DataFrame` the following indexing functions are deprecated (GH10177).

| Deprecated Function            | Replacement                                         |
|--------------------------------|-----------------------------------------------------|
| <code>.irow(i)</code>          | <code>.iloc[i]</code>                               |
| <code>.iget_value(i, j)</code> | <code>.iloc[i, j]</code> or <code>.iat[i, j]</code> |
| <code>.icol(j)</code>          | <code>.iloc[:, j]</code>                            |

---

**Note:** These indexing function have been deprecated in the documentation since 0.11.0.

---

- `Categorical.name` was deprecated to make `Categorical` more `numpy.ndarray` like. Use `Series(cat, name="whatever")` instead (GH10482).
- Setting missing values (`NaN`) in a `Categorical`'s categories will issue a warning (GH10748). You can still have missing values in the values.
- `drop_duplicates` and `duplicated`'s `take_last` keyword was deprecated in favor of `keep`. (GH6511, GH8505)
- `Series.nsmallest` and `nlargest`'s `take_last` keyword was deprecated in favor of `keep`. (GH10792)
- `DataFrame.combineAdd` and `DataFrame.combineMult` are deprecated. They can easily be replaced by using the `add` and `mul` methods: `DataFrame.add(other, fill_value=0)` and `DataFrame.mul(other, fill_value=1.)` (GH10735).
- `TimeSeries` deprecated in favor of `Series` (note that this has been an alias since 0.13.0), (GH10890)
- `SparsePanel` deprecated and will be removed in a future version (GH11157).
- `Series.is_time_series` deprecated in favor of `Series.index.is_all_dates` (GH11135)
- Legacy offsets (like `'A@JAN'`) are deprecated (note that this has been alias since 0.8.0) (GH10878)
- `WidePanel` deprecated in favor of `Panel`, `LongPanel` in favor of `DataFrame` (note these have been aliases since < 0.11.0), (GH10892)
- `DataFrame.convert_objects` has been deprecated in favor of type-specific functions `pd.to_datetime`, `pd.to_timestamp` and `pd.to_numeric` (new in 0.17.0) (GH11133).

## Removal of prior version deprecations/changes

- Removal of `na_last` parameters from `Series.order()` and `Series.sort()`, in favor of `na_position`. (GH5231)
- Remove of `percentile_width` from `.describe()`, in favor of `percentiles`. (GH7088)
- Removal of `colSpace` parameter from `DataFrame.to_string()`, in favor of `col_space`, circa 0.8.0 version.
- Removal of automatic time-series broadcasting (GH2304)

```
In [90]: np.random.seed(1234)

In [91]: df = pd.DataFrame(np.random.randn(5, 2),
.....:                    columns=list('AB'),
.....:                    index=pd.date_range('2013-01-01', periods=5))
.....:

In [92]: df

[5 rows x 2 columns]
```

- Remove `table` keyword in `HDFStore.put/append`, in favor of using `format=` (GH4645)
- Remove `kind` in `read_excel/ExcelFile` as its unused (GH4712)
- Remove `infer_type` keyword from `pd.read_html` as its unused (GH4770, GH7032)
- Remove `offset` and `timeRule` keywords from `Series.tshift/shift`, in favor of `freq` (GH4853, GH4864)
- Remove `pd.load/pd.save` aliases in favor of `pd.to_pickle/pd.read_pickle` (GH3787)

## Performance improvements

- Development support for benchmarking with the `Air Speed Velocity` library (GH8361)
- Added `vbench` benchmarks for alternative `ExcelWriter` engines and reading Excel files (GH7171)
- Performance improvements in `Categorical.value_counts` (GH10804)
- Performance improvements in `SeriesGroupBy.nunique` and `SeriesGroupBy.value_counts` and `SeriesGroupBy.transform` (GH10820, GH11077)
- Performance improvements in `DataFrame.drop_duplicates` with integer dtypes (GH10917)
- Performance improvements in `DataFrame.duplicated` with wide frames. (GH10161, GH11180)
- 4x improvement in `timedelta` string parsing (GH6755, GH10426)
- 8x improvement in `timedelta64` and `datetime64` ops (GH6755)
- Significantly improved performance of indexing `MultiIndex` with slicers (GH10287)
- 8x improvement in `iloc` using list-like input (GH10791)
- Improved performance of `Series.isin` for `datetimelike/integer Series` (GH10287)
- 20x improvement in `concat` of `Categoricals` when categories are identical (GH10587)
- Improved performance of `to_datetime` when specified format string is `ISO8601` (GH10178)
- 2x improvement of `Series.value_counts` for float dtype (GH10821)
- Enable `infer_datetime_format` in `to_datetime` when date components do not have 0 padding (GH11142)
- Regression from 0.16.1 in constructing `DataFrame` from nested dictionary (GH11084)
- Performance improvements in addition/subtraction operations for `DateOffset` with `Series` or `DatetimeIndex` (GH10744, GH11205)

## Bug fixes

- Bug in incorrect computation of `.mean()` on `timedelta64[ns]` because of overflow (GH9442)
- Bug in `.isin` on older `numpy`s (GH11232)
- Bug in `DataFrame.to_html(index=False)` renders unnecessary name row (GH10344)
- Bug in `DataFrame.to_latex()` the `column_format` argument could not be passed (GH9402)
- Bug in `DatetimeIndex` when localizing with `NaT` (GH10477)
- Bug in `Series.dt` ops in preserving meta-data (GH10477)
- Bug in preserving `NaT` when passed in an otherwise invalid `to_datetime` construction (GH10477)

- Bug in `DataFrame.apply` when function returns categorical series. (GH9573)
- Bug in `to_datetime` with invalid dates and formats supplied (GH10154)
- Bug in `Index.drop_duplicates` dropping name(s) (GH10115)
- Bug in `Series.quantile` dropping name (GH10881)
- Bug in `pd.Series` when setting a value on an empty `Series` whose index has a frequency. (GH10193)
- Bug in `pd.Series.interpolate` with invalid order keyword values. (GH10633)
- Bug in `DataFrame.plot` raises `ValueError` when color name is specified by multiple characters (GH10387)
- Bug in `Index` construction with a mixed list of tuples (GH10697)
- Bug in `DataFrame.reset_index` when index contains `NaT`. (GH10388)
- Bug in `ExcelReader` when worksheet is empty (GH6403)
- Bug in `BinGrouper.group_info` where returned values are not compatible with base class (GH10914)
- Bug in clearing the cache on `DataFrame.pop` and a subsequent inplace op (GH10912)
- Bug in indexing with a mixed-integer `Index` causing an `ImportError` (GH10610)
- Bug in `Series.count` when index has nulls (GH10946)
- Bug in pickling of a non-regular freq `DatetimeIndex` (GH11002)
- Bug causing `DataFrame.where` to not respect the `axis` parameter when the frame has a symmetric shape. (GH9736)
- Bug in `Table.select_column` where name is not preserved (GH10392)
- Bug in `offsets.generate_range` where `start` and `end` have finer precision than `offset` (GH9907)
- Bug in `pd.rolling_*` where `Series.name` would be lost in the output (GH10565)
- Bug in `stack` when index or columns are not unique. (GH10417)
- Bug in setting a `Panel` when an axis has a `MultiIndex` (GH10360)
- Bug in `USFederalHolidayCalendar` where `USMemorialDay` and `USMartinLutherKingJr` were incorrect (GH10278 and GH9760)
- Bug in `.sample()` where returned object, if set, gives unnecessary `SettingWithCopyWarning` (GH10738)
- Bug in `.sample()` where weights passed as `Series` were not aligned along axis before being treated positionally, potentially causing problems if weight indices were not aligned with sampled object. (GH10738)
- Regression fixed in (GH9311, GH6620, GH9345), where `groupby` with a datetime-like converting to float with certain aggregators (GH10979)
- Bug in `DataFrame.interpolate` with `axis=1` and `inplace=True` (GH10395)
- Bug in `io.sql.get_schema` when specifying multiple columns as primary key (GH10385).
- Bug in `groupby(sort=False)` with datetime-like `Categorical` raises `ValueError` (GH10505)
- Bug in `groupby(axis=1)` with `filter()` throws `IndexError` (GH11041)
- Bug in `test_categorical` on big-endian builds (GH10425)
- Bug in `Series.shift` and `DataFrame.shift` not supporting categorical data (GH9416)
- Bug in `Series.map` using categorical `Series` raises `AttributeError` (GH10324)

- Bug in `MultiIndex.get_level_values` including Categorical raises `AttributeError` (GH10460)
- Bug in `pd.get_dummies` with `sparse=True` not returning `SparseDataFrame` (GH10531)
- Bug in Index subtypes (such as `PeriodIndex`) not returning their own type for `.drop` and `.insert` methods (GH10620)
- Bug in `algos.outer_join_indexer` when right array is empty (GH10618)
- Bug in `filter` (regression from 0.16.0) and `transform` when grouping on multiple keys, one of which is datetime-like (GH10114)
- Bug in `to_datetime` and `to_timedelta` causing Index name to be lost (GH10875)
- Bug in `len(DataFrame.groupby)` causing `IndexError` when there's a column containing only NaNs (GH11016)
- Bug that caused segfault when resampling an empty Series (GH10228)
- Bug in `DatetimeIndex` and `PeriodIndex.value_counts` resets name from its result, but retains in result's Index. (GH10150)
- Bug in `pd.eval` using `numexpr` engine coerces 1 element numpy array to scalar (GH10546)
- Bug in `pd.concat` with `axis=0` when column is of dtype category (GH10177)
- Bug in `read_msgpack` where input type is not always checked (GH10369, GH10630)
- Bug in `pd.read_csv` with kwargs `index_col=False`, `index_col=['a', 'b']` or dtype (GH10413, GH10467, GH10577)
- Bug in `Series.from_csv` with `header` kwarg not setting the `Series.name` or the `Series.index.name` (GH10483)
- Bug in `groupby.var` which caused variance to be inaccurate for small float values (GH10448)
- Bug in `Series.plot(kind='hist')` Y Label not informative (GH10485)
- Bug in `read_csv` when using a converter which generates a `uint8` type (GH9266)
- Bug causes memory leak in time-series line and area plot (GH9003)
- Bug when setting a Panel sliced along the major or minor axes when the right-hand side is a DataFrame (GH11014)
- Bug that returns `None` and does not raise `NotImplementedError` when operator functions (e.g. `.add`) of Panel are not implemented (GH7692)
- Bug in line and kde plot cannot accept multiple colors when `subplots=True` (GH9894)
- Bug in `DataFrame.plot` raises `ValueError` when color name is specified by multiple characters (GH10387)
- Bug in left and right align of Series with MultiIndex may be inverted (GH10665)
- Bug in left and right join of with MultiIndex may be inverted (GH10741)
- Bug in `read_stata` when reading a file with a different order set in columns (GH10757)
- Bug in Categorical may not representing properly when category contains `tz` or `Period` (GH10713)
- Bug in `Categorical.__iter__` may not returning correct datetime and Period (GH10713)
- Bug in indexing with a `PeriodIndex` on an object with a `PeriodIndex` (GH4125)
- Bug in `read_csv` with `engine='c'`: EOF preceded by a comment, blank line, etc. was not handled correctly (GH10728, GH10548)

- Reading “famafrench” data via `DataReader` results in HTTP 404 error because of the website url is changed (GH10591).
- Bug in `read_msgpack` where `DataFrame` to decode has duplicate column names (GH9618)
- Bug in `io.common.get_filepath_or_buffer` which caused reading of valid S3 files to fail if the bucket also contained keys for which the user does not have read permission (GH10604)
- Bug in vectorised setting of timestamp columns with `python datetime.date` and `numpy datetime64` (GH10408, GH10412)
- Bug in `Index.take` may add unnecessary `freq` attribute (GH10791)
- Bug in merge with empty `DataFrame` may raise `IndexError` (GH10824)
- Bug in `to_latex` where unexpected keyword argument for some documented arguments (GH10888)
- Bug in indexing of large `DataFrame` where `IndexError` is uncaught (GH10645 and GH10692)
- Bug in `read_csv` when using the `nrows` or `chunksize` parameters if file contains only a header line (GH9535)
- Bug in serialization of `category` types in HDF5 in presence of alternate encodings. (GH10366)
- Bug in `pd.DataFrame` when constructing an empty `DataFrame` with a string dtype (GH9428)
- Bug in `pd.DataFrame.diff` when `DataFrame` is not consolidated (GH10907)
- Bug in `pd.unique` for arrays with the `datetime64` or `timedelta64` dtype that meant an array with object dtype was returned instead the original dtype (GH9431)
- Bug in `Timedelta` raising error when slicing from 0s (GH10583)
- Bug in `DatetimeIndex.take` and `TimedeltaIndex.take` may not raise `IndexError` against invalid index (GH10295)
- Bug in `Series([np.nan]).astype('M8[ms]')`, which now returns `Series([pd.NaT])` (GH10747)
- Bug in `PeriodIndex.order` reset `freq` (GH10295)
- Bug in `date_range` when `freq` divides `end` as `nanos` (GH10885)
- Bug in `iloc` allowing memory outside bounds of a `Series` to be accessed with negative integers (GH10779)
- Bug in `read_msgpack` where encoding is not respected (GH10581)
- Bug preventing access to the first index when using `iloc` with a list containing the appropriate negative integer (GH10547, GH10779)
- Bug in `TimedeltaIndex` formatter causing error while trying to save `DataFrame` with `TimedeltaIndex` using `to_csv` (GH10833)
- Bug in `DataFrame.where` when handling `Series` slicing (GH10218, GH9558)
- Bug where `pd.read_gbq` throws `ValueError` when Bigquery returns zero rows (GH10273)
- Bug in `to_json` which was causing segmentation fault when serializing 0-rank `ndarray` (GH9576)
- Bug in plotting functions may raise `IndexError` when plotted on `GridSpec` (GH10819)
- Bug in plot result may show unnecessary minor ticklabels (GH10657)
- Bug in `groupby` incorrect computation for aggregation on `DataFrame` with `NaT` (E.g `first`, `last`, `min`). (GH10590, GH11010)
- Bug when constructing `DataFrame` where passing a dictionary with only scalar values and specifying columns did not raise an error (GH10856)

- Bug in `.var()` causing roundoff errors for highly similar values (GH10242)
- Bug in `DataFrame.plot(subplots=True)` with duplicated columns outputs incorrect result (GH10962)
- Bug in Index arithmetic may result in incorrect class (GH10638)
- Bug in `date_range` results in empty if freq is negative annually, quarterly and monthly (GH11018)
- Bug in `DatetimeIndex` cannot infer negative freq (GH11018)
- Remove use of some deprecated numpy comparison operations, mainly in tests. (GH10569)
- Bug in Index dtype may not applied properly (GH11017)
- Bug in `io.gbq` when testing for minimum google api client version (GH10652)
- Bug in `DataFrame` construction from nested dict with `timedelta` keys (GH11129)
- Bug in `.fillna` against may raise `TypeError` when data contains datetime dtype (GH7095, GH11153)
- Bug in `.groupby` when number of keys to group by is same as length of index (GH11185)
- Bug in `convert_objects` where converted values might not be returned if all null and `coerce` (GH9589)
- Bug in `convert_objects` where `copy` keyword was not respected (GH9589)

## 6.11 Version 0.16

### 6.11.1 v0.16.2 (June 12, 2015)

{{ header }}

This is a minor bug-fix release from 0.16.1 and includes a large number of bug fixes along some new features (`pipe()` method), enhancements, and performance improvements.

We recommend that all users upgrade to this version.

Highlights include:

- A new `pipe` method, see *here*
- Documentation on how to use `numba` with `pandas`, see *here*

#### What's new in v0.16.2

- *New features*
  - *Pipe*

– Other enhancements

- API changes
- Performance improvements
- Bug fixes
- Contributors

## New features

### Pipe

We've introduced a new method `DataFrame.pipe()`. As suggested by the name, `pipe` should be used to pipe data through a chain of function calls. The goal is to avoid confusing nested function calls like

```
# df is a DataFrame
# f, g, and h are functions that take and return DataFrames
f(g(h(df), arg1=1), arg2=2, arg3=3) # noqa F821
```

The logic flows from inside out, and function names are separated from their keyword arguments. This can be rewritten as

```
(df.pipe(h)
 .pipe(g, arg1=1)
 .pipe(f, arg2=2, arg3=3)
)
```

Now both the code and the logic flow from top to bottom. Keyword arguments are next to their functions. Overall the code is much more readable.

In the example above, the functions `f`, `g`, and `h` each expected the `DataFrame` as the first positional argument. When the function you wish to apply takes its data anywhere other than the first argument, pass a tuple of `(function, keyword)` indicating where the `DataFrame` should flow. For example:

```
In [1]: import statsmodels.formula.api as sm

In [2]: bb = pd.read_csv('data/baseball.csv', index_col='id')

# sm.ols takes (formula, data)
In [3]: (bb.query('h > 0')
...:     .assign(ln_h=lambda df: np.log(df.h))
...:     .pipe((sm.ols, 'data'), 'hr ~ ln_h + year + g + C(lg)')
...:     .fit()
...:     .summary()
...: )
...:
```

```
Out [3]:
<class 'statsmodels.iolib.summary.Summary'>
"""

    strong multicollinearity or other numerical problems.
"""

```

The pipe method is inspired by unix pipes, which stream text through processes. More recently `dplyr` and `magrittr` have introduced the popular `(%>%)` pipe operator for R.

See the *documentation* for more. (GH10129)

## Other enhancements

- Added `rsplit` to Index/Series StringMethods (GH10303)
- Removed the hard-coded size limits on the DataFrame HTML representation in the IPython notebook, and leave this to IPython itself (only for IPython v3.0 or greater). This eliminates the duplicate scroll bars that appeared in the notebook with large frames (GH10231).

Note that the notebook has a `toggle output scrolling` feature to limit the display of very large frames (by clicking left of the output). You can also configure the way DataFrames are displayed using the pandas options, see here *here*.

- `axis` parameter of `DataFrame.quantile` now accepts also `index` and `column`. (GH9543)

## API changes

- `Holiday` now raises `NotImplementedError` if both `offset` and `observance` are used in the constructor instead of returning an incorrect result (GH10217).

## Performance improvements

- Improved `Series.resample` performance with `dtype=datetime64[ns]` (GH7754)
- Increase performance of `str.split` when `expand=True` (GH10081)

## Bug fixes

- Bug in `Series.hist` raises an error when a one row `Series` was given (GH10214)
- Bug where `HDFStore.select` modifies the passed columns list (GH7212)
- Bug in `Categorical` repr with `display.width` of `None` in Python 3 (GH10087)
- Bug in `to_json` with certain `orients` and a `CategoricalIndex` would segfault (GH10317)
- Bug where some of the nan functions do not have consistent return dtypes (GH10251)
- Bug in `DataFrame.quantile` on checking that a valid axis was passed (GH9543)
- Bug in `groupby.apply` aggregation for `Categorical` not preserving categories (GH10138)
- Bug in `to_csv` where `date_format` is ignored if the `datetime` is fractional (GH10209)
- Bug in `DataFrame.to_json` with mixed data types (GH10289)
- Bug in cache updating when consolidating (GH10264)
- Bug in `mean()` where integer dtypes can overflow (GH10172)
- Bug where `Panel.from_dict` does not set `dtype` when specified (GH10058)
- Bug in `Index.union` raises `AttributeError` when passing array-likes. (GH10149)
- Bug in `Timestamp`'s `microsecond`, `quarter`, `dayofyear`, `week` and `daysinmonth` properties return `np.int` type, not built-in `int`. (GH10050)
- Bug in `NaT` raises `AttributeError` when accessing to `daysinmonth`, `dayofweek` properties. (GH10096)
- Bug in `Index` repr when using the `max_seq_items=None` setting (GH10182).
- Bug in getting timezone data with `dateutil` on various platforms ( GH9059, GH8639, GH9663, GH10121)
- Bug in displaying datetimes with mixed frequencies; display 'ms' datetimes to the proper precision. (GH10170)
- Bug in `setitem` where type promotion is applied to the entire block (GH10280)
- Bug in `Series` arithmetic methods may incorrectly hold names (GH10068)
- Bug in `GroupBy.get_group` when grouping on multiple keys, one of which is categorical. (GH10132)
- Bug in `DatetimeIndex` and `TimedeltaIndex` names are lost after `timedelta` arithmetics ( GH9926)
- Bug in `DataFrame` construction from nested dict with `datetime64` (GH10160)
- Bug in `Series` construction from dict with `datetime64` keys (GH9456)
- Bug in `Series.plot(label="LABEL")` not correctly setting the label (GH10119)

- Bug in `plot` not defaulting to `matplotlib axes.grid` setting (GH9792)
- Bug causing strings containing an exponent, but no decimal to be parsed as `int` instead of `float` in `engine='python'` for the `read_csv` parser (GH9565)
- Bug in `Series.align` resets name when `fill_value` is specified (GH10067)
- Bug in `read_csv` causing index name not to be set on an empty `DataFrame` (GH10184)
- Bug in `SparseSeries.abs` resets name (GH10241)
- Bug in `TimedeltaIndex` slicing may reset `freq` (GH10292)
- Bug in `GroupBy.get_group` raises `ValueError` when group key contains `NaT` (GH6992)
- Bug in `SparseSeries` constructor ignores input data name (GH10258)
- Bug in `Categorical.remove_categories` causing a `ValueError` when removing the `NaN` category if underlying `dtype` is floating-point (GH10156)
- Bug where `infer_freq` infers time rule (WOM-5XXX) unsupported by `to_offset` (GH9425)
- Bug in `DataFrame.to_hdf()` where table format would raise a seemingly unrelated error for invalid (non-string) column names. This is now explicitly forbidden. (GH9057)
- Bug to handle masking empty `DataFrame` (GH10126).
- Bug where `MySQL` interface could not handle numeric table/column names (GH10255)
- Bug in `read_csv` with a `date_parser` that returned a `datetime64` array of other time resolution than `[ns]` (GH10245)
- Bug in `Panel.apply` when the result has `ndim=0` (GH10332)
- Bug in `read_hdf` where `auto_close` could not be passed (GH9327).
- Bug in `read_hdf` where open stores could not be used (GH10330).
- Bug in adding empty `DataFrames`, now results in a `DataFrame` that `.equals` an empty `DataFrame` (GH10181).
- Bug in `to_hdf` and `HDFStore` which did not check that `complib` choices were valid (GH4582, GH8874).

### 6.11.2 v0.16.1 (May 11, 2015)

{{ header }}

This is a minor bug-fix release from 0.16.0 and includes a a large number of bug fixes along several new features, enhancements, and performance improvements. We recommend that all users upgrade to this version.

Highlights include:

- Support for a `CategoricalIndex`, a category based index, see *here*
- New section on how-to-contribute to *pandas*, see *here*
- Revised “Merge, join, and concatenate” documentation, including graphical examples to make it easier to understand each operations, see *here*
- New method `sample` for drawing random samples from Series, DataFrames and Panels. See *here*
- The default Index printing has changed to a more uniform format, see *here*
- `BusinessHour` datetime-offset is now supported, see *here*

- Further enhancement to the `.str` accessor to make string operations easier, see [here](#)

### What's new in v0.16.1

- *Enhancements*
  - *CategoricalIndex*
  - *Sample*
  - *String methods enhancements*
  - *Other enhancements*
- *API changes*
  - *Deprecations*
- *Index representation*
- *Performance improvements*
- *Bug fixes*
- *Contributors*

**Warning:** In pandas 0.17.0, the sub-package `pandas.io.data` will be removed in favor of a separately installable package ([GH8961](#)).

## Enhancements

### CategoricalIndex

We introduce a `CategoricalIndex`, a new type of index object that is useful for supporting indexing with duplicates. This is a container around a `Categorical` (introduced in v0.15.0) and allows efficient indexing and storage of an index with a large number of duplicated elements. Prior to 0.16.1, setting the index of a `DataFrame`/`Series` with a `category` dtype would convert this to regular object-based `Index`.

```
In [1]: df = pd.DataFrame({'A': np.arange(6),
...:                      'B': pd.Series(list('aabbca'))
...:                      .astype('category', categories=list('cab'))
...:                      })
...:
```

```
In [2]: df
```

```
Out[2]:
```

```
  A  B
0  0  a
1  1  a
2  2  b
3  3  b
4  4  c
5  5  a
```

```
In [3]: df.dtypes
```

```
Out[3]:
```

(continues on next page)

(continued from previous page)

```
A      int64
B      category
dtype: object

In [4]: df.B.cat.categories
Out [4]: Index(['c', 'a', 'b'], dtype='object')
```

setting the index, will create create a CategoricalIndex

```
In [5]: df2 = df.set_index('B')

In [6]: df2.index
Out [6]: CategoricalIndex(['a', 'a', 'b', 'b', 'c', 'a'], categories=['c', 'a', 'b'],
↳ordered=False, name='B', dtype='category')
```

indexing with `__getitem__/.iloc/.loc/.ix` works similarly to an Index with duplicates. The indexers MUST be in the category or the operation will raise.

```
In [7]: df2.loc['a']
Out [7]:
A
B
a  0
a  1
a  5
```

and preserves the CategoricalIndex

```
In [8]: df2.loc['a'].index
Out [8]: CategoricalIndex(['a', 'a', 'a'], categories=['c', 'a', 'b'], ordered=False,
↳name='B', dtype='category')
```

sorting will order by the order of the categories

```
In [9]: df2.sort_index()
Out [9]:
A
B
c  4
a  0
a  1
a  5
b  2
b  3
```

groupby operations on the index will preserve the index nature as well

```
In [10]: df2.groupby(level=0).sum()
Out [10]:
A
B
c  4
a  6
b  5

In [11]: df2.groupby(level=0).sum().index
```

(continues on next page)

(continued from previous page)

```
Out [11]: CategoricalIndex(['c', 'a', 'b'], categories=['c', 'a', 'b'], ordered=False,
↳ name='B', dtype='category')
```

reindexing operations, will return a resulting index based on the type of the passed indexer, meaning that passing a list will return a plain-old-Index; indexing with a Categorical will return a CategoricalIndex, indexed according to the categories of the PASSED Categorical dtype. This allows one to arbitrarily index these even with values NOT in the categories, similarly to how you can reindex ANY pandas index.

```
In [12]: df2.reindex(['a', 'e'])
Out [12]:
   A
B
a  0.0
a  1.0
a  5.0
e  NaN

In [13]: df2.reindex(['a', 'e']).index
Out [13]: pd.Index(['a', 'a', 'a', 'e'], dtype='object', name='B')

In [14]: df2.reindex(pd.Categorical(['a', 'e'], categories=list('abcde')))
Out [14]:
   A
B
a  0.0
a  1.0
a  5.0
e  NaN

In [15]: df2.reindex(pd.Categorical(['a', 'e'], categories=list('abcde'))).index
Out [15]: pd.CategoricalIndex(['a', 'a', 'a', 'e'],
                             categories=['a', 'b', 'c', 'd', 'e'],
                             ordered=False, name='B',
                             dtype='category')
```

See the *documentation* for more. ([GH7629](#), [GH10038](#), [GH10039](#))

## Sample

Series, DataFrames, and Panels now have a new method: `sample()`. The method accepts a specific number of rows or columns to return, or a fraction of the total number or rows or columns. It also has options for sampling with or without replacement, for passing in a column for weights for non-uniform sampling, and for setting seed values to facilitate replication. ([GH2419](#))

```
In [1]: example_series = pd.Series([0, 1, 2, 3, 4, 5])

# When no arguments are passed, returns 1
In [2]: example_series.sample()
Out [2]:
4      4
Length: 1, dtype: int64

# One may specify either a number of rows:
In [3]: example_series.sample(n=3)
Out [3]:
```

(continues on next page)

(continued from previous page)

```
0    0
2    2
1    1
Length: 3, dtype: int64

# Or a fraction of the rows:
In [4]: example_series.sample(frac=0.5)
Out [4]:
0    0
1    1
2    2
Length: 3, dtype: int64

# weights are accepted.
In [5]: example_weights = [0, 0, 0.2, 0.2, 0.2, 0.4]

In [6]: example_series.sample(n=3, weights=example_weights)
Out [6]:
5    5
2    2
3    3
Length: 3, dtype: int64

# weights will also be normalized if they do not sum to one,
# and missing values will be treated as zeros.
In [7]: example_weights2 = [0.5, 0, 0, 0, None, np.nan]

In [8]: example_series.sample(n=1, weights=example_weights2)
Out [8]:
0    0
Length: 1, dtype: int64
```

When applied to a `DataFrame`, one may pass the name of a column to specify sampling weights when sampling from rows.

```
In [9]: df = pd.DataFrame({'coll': [9, 8, 7, 6],
...:                      'weight_column': [0.5, 0.4, 0.1, 0]})
...:

In [10]: df.sample(n=3, weights='weight_column')
Out [10]:
   coll  weight_column
0     9             0.5
1     8             0.4
2     7             0.1

[3 rows x 2 columns]
```

## String methods enhancements

Continuing from v0.16.0, the following enhancements make string operations easier and more consistent with standard python string operations.

- Added StringMethods (.str accessor) to Index ([GH9068](#))

The .str accessor is now available for both Series and Index.

```
In [11]: idx = pd.Index([' jack', 'jill ', ' jesse ', 'frank'])
In [12]: idx.str.strip()
Out[12]: Index(['jack', 'jill', 'jesse', 'frank'], dtype='object')
```

One special case for the .str accessor on Index is that if a string method returns bool, the .str accessor will return a np.array instead of a boolean Index ([GH8875](#)). This enables the following expression to work naturally:

```
In [13]: idx = pd.Index(['a1', 'a2', 'b1', 'b2'])
In [14]: s = pd.Series(range(4), index=idx)
In [15]: s
Out[15]:
a1    0
a2    1
b1    2
b2    3
Length: 4, dtype: int64
In [16]: idx.str.startswith('a')
Out[16]: array([ True,  True, False, False])
In [17]: s[s.index.str.startswith('a')]
Out[17]:
a1    0
a2    1
Length: 2, dtype: int64
```

- The following new methods are accessible via .str accessor to apply the function to each values. ([GH9766](#), [GH9773](#), [GH10031](#), [GH10045](#), [GH10052](#))

|              |            | Methods     |             |              |
|--------------|------------|-------------|-------------|--------------|
| capitalize() | swapcase() | normalize() | partition() | rpartition() |
| index()      | rindex()   | translate() |             |              |

- split now takes expand keyword to specify whether to expand dimensionality. return\_type is deprecated. ([GH9847](#))

```
In [18]: s = pd.Series(['a,b', 'a,c', 'b,c'])
# return Series
In [19]: s.str.split(',')
Out[19]:
0    [a, b]
1    [a, c]
```

(continues on next page)

(continued from previous page)

```

2     [b, c]
Length: 3, dtype: object

# return DataFrame
In [20]: s.str.split(',', expand=True)
Out [20]:
   0 1
0  a b
1  a c
2  b c

[3 rows x 2 columns]

In [21]: idx = pd.Index(['a,b', 'a,c', 'b,c'])

# return Index
In [22]: idx.str.split(',')
Out [22]: Index(['a', 'b'], ['a', 'c'], ['b', 'c'], dtype='object')

# return MultiIndex
In [23]: idx.str.split(',', expand=True)
Out [23]:
MultiIndex([('a', 'b'),
            ('a', 'c'),
            ('b', 'c')],
           )

```

- Improved `extract` and `get_dummies` methods for `Index.str` (GH9980)

## Other enhancements

- `BusinessHour` offset is now supported, which represents business hours starting from 09:00 - 17:00 on `BusinessDay` by default. See [Here](#) for details. (GH7905)

```

In [24]: pd.Timestamp('2014-08-01 09:00') + pd.tseries.offsets.BusinessHour()
Out [24]: Timestamp('2014-08-01 10:00:00')

In [25]: pd.Timestamp('2014-08-01 07:00') + pd.tseries.offsets.BusinessHour()
Out [25]: Timestamp('2014-08-01 10:00:00')

In [26]: pd.Timestamp('2014-08-01 16:30') + pd.tseries.offsets.BusinessHour()
Out [26]: Timestamp('2014-08-04 09:30:00')

```

- `DataFrame.diff` now takes an `axis` parameter that determines the direction of differencing (GH9727)
- Allow `clip`, `clip_lower`, and `clip_upper` to accept array-like arguments as thresholds (This is a regression from 0.11.0). These methods now have an `axis` parameter which determines how the Series or DataFrame will be aligned with the threshold(s). (GH6966)
- `DataFrame.mask()` and `Series.mask()` now support same keywords as `where` (GH8801)
- `drop` function can now accept `errors` keyword to suppress `ValueError` raised when any of label does not exist in the target data. (GH6736)

```

In [27]: df = pd.DataFrame(np.random.randn(3, 3), columns=['A', 'B', 'C'])

```

(continues on next page)

(continued from previous page)

```
In [28]: df.drop(['A', 'X'], axis=1, errors='ignore')
Out[28]:
```

|   | B         | C        |
|---|-----------|----------|
| 0 | 0.937250  | 0.077640 |
| 1 | -2.190412 | 0.936805 |
| 2 | -0.003335 | 0.611459 |

```
[3 rows x 2 columns]
```

- Add support for separating years and quarters using dashes, for example 2014-Q1. (GH9688)
- Allow conversion of values with dtype `datetime64` or `timedelta64` to strings using `astype(str)` (GH9757)
- `get_dummies` function now accepts `sparse` keyword. If set to `True`, the return `DataFrame` is sparse, e.g. `SparseDataFrame`. (GH8823)
- `Period` now accepts `datetime64` as value input. (GH9054)
- Allow `timedelta` string conversion when leading zero is missing from time definition, ie `0:00:00` vs `00:00:00`. (GH9570)
- Allow `Panel.shift` with `axis='items'` (GH9890)
- Trying to write an excel file now raises `NotImplementedError` if the `DataFrame` has a `MultiIndex` instead of writing a broken Excel file. (GH9794)
- Allow `Categorical.add_categories` to accept `Series` or `np.array`. (GH9927)
- Add/delete `str/dt/cat` accessors dynamically from `__dir__`. (GH9910)
- Add `normalize` as a `dt` accessor method. (GH10047)
- `DataFrame` and `Series` now have `_constructor_expanddim` property as overridable constructor for one higher dimensionality data. This should be used only when it is really needed, see [here](#)
- `pd.lib.infer_dtype` now returns `'bytes'` in Python 3 where appropriate. (GH10032)

## API changes

- When passing in an `ax` to `df.plot(..., ax=ax)`, the `sharex` kwarg will now default to `False`. The result is that the visibility of `xlabels` and `xticklabels` will not anymore be changed. You have to do that by yourself for the right axes in your figure or set `sharex=True` explicitly (but this changes the visible for all axes in the figure, not only the one which is passed in!). If pandas creates the subplots itself (e.g. no passed in `ax` kwarg), then the default is still `sharex=True` and the visibility changes are applied.
- `assign()` now inserts new columns in alphabetical order. Previously the order was arbitrary. (GH9777)
- By default, `read_csv` and `read_table` will now try to infer the compression type based on the file extension. Set `compression=None` to restore the previous behavior (no decompression). (GH9770)

## Deprecations

- `Series.str.split`'s `return_type` keyword was removed in favor of `expand` (GH9847)

## Index representation

The string representation of `Index` and its sub-classes have now been unified. These will show a single-line display if there are few values; a wrapped multi-line display for a lot of values (but less than `display.max_seq_items`; if lots of items ( $> \text{display.max\_seq\_items}$ ) will show a truncated display (the head and tail of the data). The formatting for `MultiIndex` is unchanged (a multi-line wrapped display). The display width responds to the option `display.max_seq_items`, which is defaulted to 100. (GH6482)

### Previous behavior

```
In [2]: pd.Index(range(4), name='foo')
Out[2]: Int64Index([0, 1, 2, 3], dtype='int64')
```

```
In [3]: pd.Index(range(104), name='foo')
Out[3]: Int64Index([0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18,
↳19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39,
↳40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60,
↳61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81,
↳82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, ...], dtype=
↳'int64')
```

```
In [4]: pd.date_range('20130101', periods=4, name='foo', tz='US/Eastern')
Out[4]:
<class 'pandas.tseries.index.DatetimeIndex'>
[2013-01-01 00:00:00-05:00, ..., 2013-01-04 00:00:00-05:00]
Length: 4, Freq: D, Timezone: US/Eastern
```

```
In [5]: pd.date_range('20130101', periods=104, name='foo', tz='US/Eastern')
Out[5]:
<class 'pandas.tseries.index.DatetimeIndex'>

```

## Performance improvements

- Improved csv write performance with mixed dtypes, including datetimes by up to 5x (GH9940)
- Improved csv write performance generally by 2x (GH9940)
- Improved the performance of `pd.lib.max_len_string_array` by 5-7x (GH10024)

## Bug fixes

- Bug where labels did not appear properly in the legend of `DataFrame.plot()`, passing `label=` arguments works, and Series indices are no longer mutated. (GH9542)
- Bug in json serialization causing a segfault when a frame had zero length. (GH9805)
- Bug in `read_csv` where missing trailing delimiters would cause segfault. (GH5664)
- Bug in retaining index name on appending (GH9862)
- Bug in `scatter_matrix` draws unexpected axis ticklabels (GH5662)
- Fixed bug in `StataWriter` resulting in changes to input `DataFrame` upon save (GH9795).
- Bug in `transform` causing length mismatch when null entries were present and a fast aggregator was being used (GH9697)
- Bug in `equals` causing false negatives when block order differed (GH9330)
- Bug in grouping with multiple `pd.Grouper` where one is non-time based (GH10063)
- Bug in `read_sql_table` error when reading postgres table with timezone (GH7139)
- Bug in `DataFrame` slicing may not retain metadata (GH9776)
- Bug where `TimedeltaIndex` were not properly serialized in fixed `HDFStore` (GH9635)
- Bug with `TimedeltaIndex` constructor ignoring name when given another `TimedeltaIndex` as data (GH10025).
- Bug in `DataFrameFormatter._get_formatted_index` with not applying `max_colwidth` to the `DataFrame` index (GH7856)
- Bug in `.loc` with a read-only ndarray data source (GH10043)
- Bug in `groupby.apply()` that would raise if a passed user defined function either returned only `None` (for all input). (GH9685)
- Always use temporary files in pytables tests (GH9992)
- Bug in plotting continuously using `secondary_y` may not show legend properly. (GH9610, GH9779)
- Bug in `DataFrame.plot(kind="hist")` results in `TypeError` when `DataFrame` contains non-numeric columns (GH9853)
- Bug where repeated plotting of `DataFrame` with a `DatetimeIndex` may raise `TypeError` (GH9852)
- Bug in `setup.py` that would allow an incompat cython version to build (GH9827)
- Bug in plotting `secondary_y` incorrectly attaches `right_ax` property to secondary axes specifying itself recursively. (GH9861)
- Bug in `Series.quantile` on empty Series of type `Datetime` or `Timedelta` (GH9675)
- Bug in `where` causing incorrect results when upcasting was required (GH9731)

- Bug in `FloatArrayFormatter` where decision boundary for displaying “small” floats in decimal format is off by one order of magnitude for a given `display.precision` (GH9764)
- Fixed bug where `DataFrame.plot()` raised an error when both `color` and `style` keywords were passed and there was no color symbol in the style strings (GH9671)
- Not showing a `DeprecationWarning` on combining list-likes with an `Index` (GH10083)
- Bug in `read_csv` and `read_table` when using `skip_rows` parameter if blank lines are present. (GH9832)
- Bug in `read_csv()` interprets `index_col=True` as 1 (GH9798)
- Bug in index equality comparisons using `==` failing on `Index/MultiIndex` type incompatibility (GH9785)
- Bug in which `SparseDataFrame` could not take `nan` as a column name (GH8822)
- Bug in `to_msgpack` and `read_msgpack` zlib and blosc compression support (GH9783)
- Bug `GroupBy.size` doesn’t attach index name properly if grouped by `TimeGrouper` (GH9925)
- Bug causing an exception in slice assignments because `length_of_indexer` returns wrong results (GH9995)
- Bug in csv parser causing lines with initial white space plus one non-space character to be skipped. (GH9710)
- Bug in C csv parser causing spurious NaNs when data started with newline followed by white space. (GH10022)
- Bug causing elements with a null group to spill into the final group when grouping by a `Categorical` (GH9603)
- Bug where `.iloc` and `.loc` behavior is not consistent on empty dataframes (GH9964)
- Bug in invalid attribute access on a `TimedeltaIndex` incorrectly raised `ValueError` instead of `AttributeError` (GH9680)
- Bug in unequal comparisons between categorical data and a scalar, which was not in the categories (e.g. `Series(Categorical(list("abc")), ordered=True) > "d"`). This returned `False` for all elements, but now raises a `TypeError`. Equality comparisons also now return `False` for `==` and `True` for `!=`. (GH9848)
- Bug in `DataFrame.__setitem__` when right hand side is a dictionary (GH9874)
- Bug in `where` when `dtype` is `datetime64/timedelta64`, but `dtype` of other is not (GH9804)
- Bug in `MultiIndex.sortlevel()` results in unicode level name breaks (GH9856)
- Bug in which `groupby.transform` incorrectly enforced output dtypes to match input dtypes. (GH9807)
- Bug in `DataFrame` constructor when `columns` parameter is set, and `data` is an empty list (GH9939)
- Bug in bar plot with `log=True` raises `TypeError` if all values are less than 1 (GH9905)
- Bug in horizontal bar plot ignores `log=True` (GH9905)
- Bug in PyTables queries that did not return proper results using the index (GH8265, GH9676)
- Bug where dividing a dataframe containing values of type `Decimal` by another `Decimal` would raise. (GH9787)
- Bug where using `DataFrames.asfreq` would remove the name of the index. (GH9885)
- Bug causing extra index point when `resample` BM/BQ (GH9756)
- Changed caching in `AbstractHolidayCalendar` to be at the instance level rather than at the class level as the latter can result in unexpected behaviour. (GH9552)
- Fixed latex output for `MultiIndexed` dataframes (GH9778)

- Bug causing an exception when setting an empty range using `DataFrame.loc` (GH9596)
- Bug in hiding ticklabels with subplots and shared axes when adding a new plot to an existing grid of axes (GH9158)
- Bug in `transform` and `filter` when grouping on a categorical variable (GH9921)
- Bug in `transform` when groups are equal in number and dtype to the input index (GH9700)
- Google BigQuery connector now imports dependencies on a per-method basis.(GH9713)
- Updated BigQuery connector to no longer use deprecated `oauth2client.tools.run()` (GH8327)
- Bug in subclassed `DataFrame`. It may not return the correct class, when slicing or subsetting it. (GH9632)
- Bug in `.median()` where non-float null values are not handled correctly (GH10040)
- Bug in `Series.fillna()` where it raises if a numerically convertible string is given (GH10092)

### 6.11.3 v0.16.0 (March 22, 2015)

{{ header }}

This is a major release from 0.15.2 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

- `DataFrame.assign` method, see *here*
- `Series.to_coo/from_coo` methods to interact with `scipy.sparse`, see *here*
- Backwards incompatible change to `Timedelta` to conform the `.seconds` attribute with `datetime.timedelta`, see *here*
- Changes to the `.loc` slicing API to conform with the behavior of `.ix` see *here*
- Changes to the default for ordering in the `Categorical` constructor, see *here*
- Enhancement to the `.str` accessor to make string operations easier, see *here*
- The `pandas.tools.rplot`, `pandas.sandbox.qtpandas` and `pandas.rpy` modules are deprecated. We refer users to external packages like `seaborn`, `pandas-qt` and `rpy2` for similar or equivalent functionality, see *here*

Check the *API Changes* and *deprecations* before updating.

#### What's new in v0.16.0

- *New features*
  - *DataFrame assign*
  - *Interaction with scipy.sparse*
  - *String methods enhancements*
  - *Other enhancements*
- *Backwards incompatible API changes*
  - *Changes in Timedelta*
  - *Indexing changes*
  - *Categorical changes*
  - *Other API changes*
  - *Deprecations*
  - *Removal of prior version deprecations/changes*
- *Performance improvements*
- *Bug fixes*
- *Contributors*

## New features

### DataFrame assign

Inspired by `dplyr`'s `mutate` verb, `DataFrame` has a new `assign()` method. The function signature for `assign` is simply `**kwargs`. The keys are the column names for the new fields, and the values are either a value to be inserted (for example, a `Series` or `NumPy` array), or a function of one argument to be called on the `DataFrame`. The new values are inserted, and the entire `DataFrame` (with all original and new columns) is returned.

```
In [1]: iris = pd.read_csv('data/iris.data')

In [2]: iris.head()
Out[2]:
```

|   | SepalLength | SepalWidth | PetalLength | PetalWidth | Name        |
|---|-------------|------------|-------------|------------|-------------|
| 0 | 5.1         | 3.5        | 1.4         | 0.2        | Iris-setosa |
| 1 | 4.9         | 3.0        | 1.4         | 0.2        | Iris-setosa |
| 2 | 4.7         | 3.2        | 1.3         | 0.2        | Iris-setosa |
| 3 | 4.6         | 3.1        | 1.5         | 0.2        | Iris-setosa |
| 4 | 5.0         | 3.6        | 1.4         | 0.2        | Iris-setosa |

[5 rows x 5 columns]

```
In [3]: iris.assign(sepal_ratio=iris['SepalWidth'] / iris['SepalLength']).head()
Out[3]:
```

|   | SepalLength | SepalWidth | PetalLength | PetalWidth | Name        | sepal_ratio |
|---|-------------|------------|-------------|------------|-------------|-------------|
| 0 | 5.1         | 3.5        | 1.4         | 0.2        | Iris-setosa | 0.686275    |
| 1 | 4.9         | 3.0        | 1.4         | 0.2        | Iris-setosa | 0.612245    |
| 2 | 4.7         | 3.2        | 1.3         | 0.2        | Iris-setosa | 0.680851    |
| 3 | 4.6         | 3.1        | 1.5         | 0.2        | Iris-setosa | 0.673913    |
| 4 | 5.0         | 3.6        | 1.4         | 0.2        | Iris-setosa | 0.720000    |

[5 rows x 6 columns]

Above was an example of inserting a precomputed value. We can also pass in a function to be evaluated.

```
In [4]: iris.assign(sepal_ratio=lambda x: (x['SepalWidth']
...:                                     / x['SepalLength'])).head()
...:
Out[4]:
```

|   | SepalLength | SepalWidth | PetalLength | PetalWidth | Name        | sepal_ratio |
|---|-------------|------------|-------------|------------|-------------|-------------|
| 0 | 5.1         | 3.5        | 1.4         | 0.2        | Iris-setosa | 0.686275    |
| 1 | 4.9         | 3.0        | 1.4         | 0.2        | Iris-setosa | 0.612245    |
| 2 | 4.7         | 3.2        | 1.3         | 0.2        | Iris-setosa | 0.680851    |
| 3 | 4.6         | 3.1        | 1.5         | 0.2        | Iris-setosa | 0.673913    |
| 4 | 5.0         | 3.6        | 1.4         | 0.2        | Iris-setosa | 0.720000    |

[5 rows x 6 columns]

The power of `assign` comes when used in chains of operations. For example, we can limit the `DataFrame` to just those with a `Sepal Length` greater than 5, calculate the ratio, and plot

```
In [5]: iris = pd.read_csv('data/iris.data')

In [6]: (iris.query('SepalLength > 5')
...:      .assign(SepalRatio=lambda x: x.SepalWidth / x.SepalLength,
...:              PetalRatio=lambda x: x.PetalWidth / x.PetalLength)
...:      .plot(kind='scatter', x='SepalRatio', y='PetalRatio'))
```

(continues on next page)

(continued from previous page)

```
Out [6]: <matplotlib.axes._subplots.AxesSubplot at 0x7f80728b0590>
```

See the *documentation* for more. ([GH9229](#))

## Interaction with `scipy.sparse`

Added `SparseSeries.to_coo()` and `SparseSeries.from_coo()` methods ([GH8048](#)) for converting to and from `scipy.sparse.coo_matrix` instances (see *here*). For example, given a `SparseSeries` with `MultiIndex` we can convert to a `scipy.sparse.coo_matrix` by specifying the row and column labels as index levels:

```
s = pd.Series([3.0, np.nan, 1.0, 3.0, np.nan, np.nan])
s.index = pd.MultiIndex.from_tuples([(1, 2, 'a', 0),
                                     (1, 2, 'a', 1),
                                     (1, 1, 'b', 0),
                                     (1, 1, 'b', 1),
                                     (2, 1, 'b', 0),
                                     (2, 1, 'b', 1)],
                                    names=['A', 'B', 'C', 'D'])

s

# SparseSeries
ss = s.to_sparse()
ss

A, rows, columns = ss.to_coo(row_levels=['A', 'B'],
                             column_levels=['C', 'D'],
                             sort_labels=False)

A
A.todense()
rows
columns
```

The `from_coo` method is a convenience method for creating a `SparseSeries` from a `scipy.sparse.coo_matrix`:

```
from scipy import sparse
A = sparse.coo_matrix(([3.0, 1.0, 2.0], ([1, 0, 0], [0, 2, 3])),
                      shape=(3, 4))

A
```

(continues on next page)

(continued from previous page)

```
A.todense()

ss = pd.SparseSeries.from_coo(A)
ss
```

## String methods enhancements

- Following new methods are accessible via `.str` accessor to apply the function to each values. This is intended to make it more consistent with standard methods on strings. ([GH9282](#), [GH9352](#), [GH9386](#), [GH9387](#), [GH9439](#))

| Methods                |                        |                        |                          |                          |
|------------------------|------------------------|------------------------|--------------------------|--------------------------|
| <code>isalnum()</code> | <code>isalpha()</code> | <code>isdigit()</code> | <code>isdigit()</code>   | <code>isspace()</code>   |
| <code>islower()</code> | <code>isupper()</code> | <code>istitle()</code> | <code>isnumeric()</code> | <code>isdecimal()</code> |
| <code>find()</code>    | <code>rfind()</code>   | <code>ljust()</code>   | <code>rjust()</code>     | <code>zfill()</code>     |

```
In [7]: s = pd.Series(['abcd', '3456', 'EFGH'])
```

```
In [8]: s.str.isalpha()
```

```
Out [8]:
```

```
0    True
1   False
2    True
Length: 3, dtype: bool
```

```
In [9]: s.str.find('ab')
```

```
Out [9]:
```

```
0    0
1   -1
2   -1
Length: 3, dtype: int64
```

- `Series.str.pad()` and `Series.str.center()` now accept `fillchar` option to specify filling character ([GH9352](#))

```
In [10]: s = pd.Series(['12', '300', '25'])
```

```
In [11]: s.str.pad(5, fillchar='_')
```

```
Out [11]:
```

```
0    __12
1    __300
2    __25
Length: 3, dtype: object
```

- Added `Series.str.slice_replace()`, which previously raised `NotImplementedError` ([GH8888](#))

```
In [12]: s = pd.Series(['ABCD', 'EFGH', 'IJK'])
```

```
In [13]: s.str.slice_replace(1, 3, 'X')
```

```
Out [13]:
```

```
0    AXD
1    EXH
2    IX
Length: 3, dtype: object
```

(continues on next page)

(continued from previous page)

```
# replaced with empty char
In [14]: s.str.slice_replace(0, 1)
Out [14]:
0      BCD
1      FGH
2       JK
Length: 3, dtype: object
```

## Other enhancements

- Reindex now supports `method='nearest'` for frames or series with a monotonic increasing or decreasing index (GH9258):

```
In [15]: df = pd.DataFrame({'x': range(5)})

In [16]: df.reindex([0.2, 1.8, 3.5], method='nearest')
Out [16]:
      x
0.2  0
1.8  2
3.5  4

[3 rows x 1 columns]
```

This method is also exposed by the lower level `Index.get_indexer` and `Index.get_loc` methods.

- The `read_excel()` function's `sheetname` argument now accepts a list and `None`, to get multiple or all sheets respectively. If more than one sheet is specified, a dictionary is returned. (GH9450)

```
# Returns the 1st and 4th sheet, as a dictionary of DataFrames.
pd.read_excel('path_to_file.xls', sheetname=['Sheet1', 3])
```

- Allow Stata files to be read incrementally with an iterator; support for long strings in Stata files. See the docs [here](#) (GH9493:).
- Paths beginning with `~` will now be expanded to begin with the user's home directory (GH9066)
- Added time interval selection in `get_data_yahoo` (GH9071)
- Added `Timestamp.to_datetime64()` to complement `Timedelta.to_timedelta64()` (GH9255)
- `tseries.frequencies.to_offset()` now accepts `Timedelta` as input (GH9064)
- Lag parameter was added to the autocorrelation method of `Series`, defaults to lag-1 autocorrelation (GH9192)
- `Timedelta` will now accept `nanoseconds` keyword in constructor (GH9273)
- SQL code now safely escapes table and column names (GH8986)
- Added auto-complete for `Series.str.<tab>`, `Series.dt.<tab>` and `Series.cat.<tab>` (GH9322)
- `Index.get_indexer` now supports `method='pad'` and `method='backfill'` even for any target array, not just monotonic targets. These methods also work for monotonic decreasing as well as monotonic increasing indexes (GH9258).
- `Index.asof` now works on all index types (GH9258).

- A verbose argument has been augmented in `io.read_excel()`, defaults to `False`. Set to `True` to print sheet names as they are parsed. (GH9450)
- Added `days_in_month` (compatibility alias `daysinmonth`) property to `Timestamp`, `DatetimeIndex`, `Period`, `PeriodIndex`, and `Series.dt` (GH9572)
- Added decimal option in `to_csv` to provide formatting for non-‘.’ decimal separators (GH781)
- Added `normalize` option for `Timestamp` to normalized to midnight (GH8794)
- Added example for `DataFrame` import to R using HDF5 file and `rhdf5` library. See the *documentation* for more (GH9636).

## Backwards incompatible API changes

### Changes in Timedelta

In v0.15.0 a new scalar type `Timedelta` was introduced, that is a sub-class of `datetime.timedelta`. Mentioned *here* was a notice of an API change w.r.t. the `.seconds` accessor. The intent was to provide a user-friendly set of accessors that give the ‘natural’ value for that unit, e.g. if you had a `Timedelta('1 day, 10:11:12')`, then `.seconds` would return 12. However, this is at odds with the definition of `datetime.timedelta`, which defines `.seconds` as  $10 * 3600 + 11 * 60 + 12 == 36672$ .

So in v0.16.0, we are restoring the API to match that of `datetime.timedelta`. Further, the component values are still available through the `.components` accessor. This affects the `.seconds` and `.microseconds` accessors, and removes the `.hours`, `.minutes`, `.milliseconds` accessors. These changes affect `TimedeltaIndex` and the `Series.dt` accessor as well. (GH9185, GH9139)

#### Previous behavior

```
In [2]: t = pd.Timedelta('1 day, 10:11:12.100123')

In [3]: t.days
Out[3]: 1

In [4]: t.seconds
Out[4]: 12

In [5]: t.microseconds
Out[5]: 123
```

#### New behavior

```
In [17]: t = pd.Timedelta('1 day, 10:11:12.100123')

In [18]: t.days
Out[18]: 1

In [19]: t.seconds
Out[19]: 36672

In [20]: t.microseconds
Out[20]: 100123
```

Using `.components` allows the full component access

```
In [21]: t.components
Out [21]: Components(days=1, hours=10, minutes=11, seconds=12, milliseconds=100,
↳microseconds=123, nanoseconds=0)

In [22]: t.components.seconds
Out [22]: 12
```

## Indexing changes

The behavior of a small sub-set of edge cases for using `.loc` have changed (GH8613). Furthermore we have improved the content of the error messages that are raised:

- Slicing with `.loc` where the start and/or stop bound is not found in the index is now allowed; this previously would raise a `KeyError`. This makes the behavior the same as `.ix` in this case. This change is only for slicing, not when indexing with a single label.

```
In [23]: df = pd.DataFrame(np.random.randn(5, 4),
.....:                    columns=list('ABCD'),
.....:                    index=pd.date_range('20130101', periods=5))
.....:

In [24]: df
Out [24]:
```

|            | A         | B         | C         | D        |
|------------|-----------|-----------|-----------|----------|
| 2013-01-01 | 0.196775  | -0.858708 | 0.182296  | 0.168542 |
| 2013-01-02 | -1.295414 | 0.781481  | -0.028292 | 0.485222 |
| 2013-01-03 | -1.024658 | 0.275110  | -0.007452 | 0.044767 |
| 2013-01-04 | 0.827741  | -1.298262 | -0.338087 | 0.488600 |
| 2013-01-05 | -1.939301 | -0.344219 | 0.386524  | 2.056936 |

```
[5 rows x 4 columns]

In [25]: s = pd.Series(range(5), [-2, -1, 1, 2, 3])

In [26]: s
Out [26]:
```

|    |   |
|----|---|
| -2 | 0 |
| -1 | 1 |
| 1  | 2 |
| 2  | 3 |
| 3  | 4 |

```
Length: 5, dtype: int64
```

### Previous behavior

```
In [4]: df.loc['2013-01-02':'2013-01-10']
KeyError: 'stop bound [2013-01-10] is not in the [index]'

In [6]: s.loc[-10:3]
KeyError: 'start bound [-10] is not the [index]'
```

### New behavior

```
In [27]: df.loc['2013-01-02':'2013-01-10']
Out [27]:
```

|  | A | B | C | D |
|--|---|---|---|---|
|--|---|---|---|---|

(continues on next page)

(continued from previous page)

```

2013-01-02 -1.295414  0.781481 -0.028292  0.485222
2013-01-03 -1.024658  0.275110 -0.007452  0.044767
2013-01-04  0.827741 -1.298262 -0.338087  0.488600
2013-01-05 -1.939301 -0.344219  0.386524  2.056936

```

```
[4 rows x 4 columns]
```

```
In [28]: s.loc[-10:3]
```

```
Out [28]:
```

```

-2    0
-1    1
 1    2
 2    3
 3    4

```

```
Length: 5, dtype: int64
```

- Allow slicing with float-like values on an integer index for `.ix`. Previously this was only enabled for `.loc`:

Previous behavior

```
In [8]: s.ix[-1.0:2]
```

```

TypeError: the slice start value [-1.0] is not a proper indexer for this index
↳type (Int64Index)

```

New behavior

```
In [2]: s.ix[-1.0:2]
```

```
Out [2]:
```

```

-1    1
 1    2
 2    3

```

```
dtype: int64
```

- Provide a useful exception for indexing with an invalid type for that index when using `.loc`. For example trying to use `.loc` on an index of type `DatetimeIndex` or `PeriodIndex` or `TimedeltaIndex`, with an integer (or a float).

Previous behavior

```
In [4]: df.loc[2:3]
```

```
KeyError: 'start bound [2] is not the [index]'
```

New behavior

```
In [4]: df.loc[2:3]
```

```

TypeError: Cannot do slice indexing on <class 'pandas.tseries.index.DatetimeIndex
↳'> with <type 'int'> keys

```

## Categorical changes

In prior versions, Categoricals that had an unspecified ordering (meaning no `ordered` keyword was passed) were defaulted as ordered Categoricals. Going forward, the `ordered` keyword in the `Categorical` constructor will default to `False`. Ordering must now be explicit.

Furthermore, previously you *could* change the `ordered` attribute of a `Categorical` by just setting the attribute, e.g. `cat.ordered=True`; This is now deprecated and you should use `cat.as_ordered()` or `cat.as_unordered()`. These will by default return a **new** object and not modify the existing object. (GH9347, GH9190)

### Previous behavior

```
In [3]: s = pd.Series([0, 1, 2], dtype='category')
```

```
In [4]: s
```

```
Out[4]:
```

```
0    0
1    1
2    2
dtype: category
Categories (3, int64): [0 < 1 < 2]
```

```
In [5]: s.cat.ordered
```

```
Out[5]: True
```

```
In [6]: s.cat.ordered = False
```

```
In [7]: s
```

```
Out[7]:
```

```
0    0
1    1
2    2
dtype: category
Categories (3, int64): [0, 1, 2]
```

### New behavior

```
In [29]: s = pd.Series([0, 1, 2], dtype='category')
```

```
In [30]: s
```

```
Out[30]:
```

```
0    0
1    1
2    2
Length: 3, dtype: category
Categories (3, int64): [0, 1, 2]
```

```
In [31]: s.cat.ordered
```

```
Out[31]: False
```

```
In [32]: s = s.cat.as_ordered()
```

```
In [33]: s
```

```
Out[33]:
```

```
0    0
1    1
2    2
```

(continues on next page)

(continued from previous page)

```

Length: 3, dtype: category
Categories (3, int64): [0 < 1 < 2]

In [34]: s.cat.ordered
Out[34]: True

# you can set in the constructor of the Categorical
In [35]: s = pd.Series(pd.Categorical([0, 1, 2], ordered=True))

In [36]: s
Out[36]:
0    0
1    1
2    2
Length: 3, dtype: category
Categories (3, int64): [0 < 1 < 2]

In [37]: s.cat.ordered
Out[37]: True

```

For ease of creation of series of categorical data, we have added the ability to pass keywords when calling `.astype()`. These are passed directly to the constructor.

```

In [54]: s = pd.Series(["a", "b", "c", "a"]).astype('category', ordered=True)

In [55]: s
Out[55]:
0    a
1    b
2    c
3    a
dtype: category
Categories (3, object): [a < b < c]

In [56]: s = (pd.Series(["a", "b", "c", "a"])
....:         .astype('category', categories=list('abcdef'), ordered=False))

In [57]: s
Out[57]:
0    a
1    b
2    c
3    a
dtype: category
Categories (6, object): [a, b, c, d, e, f]

```

## Other API changes

- `Index.duplicated` now returns `np.array(dtype=bool)` rather than `Index(dtype=object)` containing `bool` values. (GH8875)
- `DataFrame.to_json` now returns accurate type serialisation for each column for frames of mixed dtype (GH9037)

Previously data was coerced to a common dtype before serialisation, which for example resulted in integers being serialised to floats:

```
In [2]: pd.DataFrame({'i': [1,2], 'f': [3.0, 4.2]}).to_json()
Out [2]: '{"f":{"0":3.0,"1":4.2},"i":{"0":1.0,"1":2.0}}'
```

Now each column is serialised using its correct dtype:

```
In [2]: pd.DataFrame({'i': [1,2], 'f': [3.0, 4.2]}).to_json()
Out [2]: '{"f":{"0":3.0,"1":4.2},"i":{"0":1,"1":2}}'
```

- `DatetimeIndex`, `PeriodIndex` and `TimedeltaIndex.summary` now output the same format. (GH9116)
- `TimedeltaIndex.freqstr` now output the same string format as `DatetimeIndex`. (GH9116)
- Bar and horizontal bar plots no longer add a dashed line along the info axis. The prior style can be achieved with matplotlib's `axhline` or `axvline` methods (GH9088).
- Series accessors `.dt`, `.cat` and `.str` now raise `AttributeError` instead of `TypeError` if the series does not contain the appropriate type of data (GH9617). This follows Python's built-in exception hierarchy more closely and ensures that tests like `hasattr(s, 'cat')` are consistent on both Python 2 and 3.
- Series now supports bitwise operation for integral types (GH9016). Previously even if the input dtypes were integral, the output dtype was coerced to `bool`.

Previous behavior

```
In [2]: pd.Series([0, 1, 2, 3], list('abcd')) | pd.Series([4, 4, 4, 4], list('abcd'
↳'))
Out [2]:
a    True
b    True
c    True
d    True
dtype: bool
```

New behavior. If the input dtypes are integral, the output dtype is also integral and the output values are the result of the bitwise operation.

```
In [2]: pd.Series([0, 1, 2, 3], list('abcd')) | pd.Series([4, 4, 4, 4], list('abcd'
↳'))
Out [2]:
a     4
b     5
c     6
d     7
dtype: int64
```

- During division involving a `Series` or `DataFrame`, `0/0` and `0//0` now give `np.nan` instead of `np.inf`. (GH9144, GH8445)

## Previous behavior

```
In [2]: p = pd.Series([0, 1])

In [3]: p / 0
Out[3]:
0    inf
1    inf
dtype: float64

In [4]: p // 0
Out[4]:
0    inf
1    inf
dtype: float64
```

## New behavior

```
In [38]: p = pd.Series([0, 1])

In [39]: p / 0
Out[39]:
0    NaN
1    inf
Length: 2, dtype: float64

In [40]: p // 0
Out[40]:
0    NaN
1    inf
Length: 2, dtype: float64
```

- `Series.values_counts` and `Series.describe` for categorical data will now put NaN entries at the end. (GH9443)
- `Series.describe` for categorical data will now give counts and frequencies of 0, not NaN, for unused categories (GH9443)
- Due to a bug fix, looking up a partial string label with `DatetimeIndex.asof` now includes values that match the string, even if they are after the start of the partial string label (GH9258).

## Old behavior:

```
In [4]: pd.to_datetime(['2000-01-31', '2000-02-28']).asof('2000-02')
Out[4]: Timestamp('2000-01-31 00:00:00')
```

## Fixed behavior:

```
In [41]: pd.to_datetime(['2000-01-31', '2000-02-28']).asof('2000-02')
Out[41]: Timestamp('2000-02-28 00:00:00')
```

To reproduce the old behavior, simply add more precision to the label (e.g., use `2000-02-01` instead of `2000-02`).

## Deprecations

- The `rplot` trellis plotting interface is deprecated and will be removed in a future version. We refer to external packages like `seaborn` for similar but more refined functionality (GH3445). The documentation includes some examples how to convert your existing code from `rplot` to `seaborn` [here](#).
- The `pandas.sandbox.qtpandas` interface is deprecated and will be removed in a future version. We refer users to the external package `pandas-qt`. (GH9615)
- The `pandas.rpy` interface is deprecated and will be removed in a future version. Similar functionality can be accessed through the `rpy2` project (GH9602)
- Adding `DatetimeIndex/PeriodIndex` to another `DatetimeIndex/PeriodIndex` is being deprecated as a set-operation. This will be changed to a `TypeError` in a future version. `.union()` should be used for the union set operation. (GH9094)
- Subtracting `DatetimeIndex/PeriodIndex` from another `DatetimeIndex/PeriodIndex` is being deprecated as a set-operation. This will be changed to an actual numeric subtraction yielding a `TimeDeltaIndex` in a future version. `.difference()` should be used for the differencing set operation. (GH9094)

## Removal of prior version deprecations/changes

- `DataFrame.pivot_table` and `crosstab`'s `rows` and `cols` keyword arguments were removed in favor of `index` and `columns` (GH6581)
- `DataFrame.to_excel` and `DataFrame.to_csv` `cols` keyword argument was removed in favor of `columns` (GH6581)
- Removed `convert_dummies` in favor of `get_dummies` (GH6581)
- Removed `value_range` in favor of `describe` (GH6581)

## Performance improvements

- Fixed a performance regression for `.loc` indexing with an array or list-like (GH9126:).
- `DataFrame.to_json` 30x performance improvement for mixed dtype frames. (GH9037)
- Performance improvements in `MultiIndex.duplicated` by working with labels instead of values (GH9125)
- Improved the speed of `nunique` by calling `unique` instead of `value_counts` (GH9129, GH7771)
- Performance improvement of up to 10x in `DataFrame.count` and `DataFrame.dropna` by taking advantage of homogeneous/heterogeneous dtypes appropriately (GH9136)
- Performance improvement of up to 20x in `DataFrame.count` when using a `MultiIndex` and the `level` keyword argument (GH9163)
- Performance and memory usage improvements in `merge` when key space exceeds `int64` bounds (GH9151)
- Performance improvements in multi-key `groupby` (GH9429)
- Performance improvements in `MultiIndex.sortlevel` (GH9445)
- Performance and memory usage improvements in `DataFrame.duplicated` (GH9398)
- Cythonized `Period` (GH9440)
- Decreased memory usage on `to_hdf` (GH9648)

## Bug fixes

- Changed `.to_html` to remove leading/trailing spaces in table body (GH4987)
- Fixed issue using `read_csv` on s3 with Python 3 (GH9452)
- Fixed compatibility issue in `DatetimeIndex` affecting architectures where `numpy.int_` defaults to `numpy.int32` (GH8943)
- Bug in Panel indexing with an object-like (GH9140)
- Bug in the returned `Series.dt.components` index was reset to the default index (GH9247)
- Bug in `Categorical.__getitem__/_setitem__` with listlike input getting incorrect results from indexer coercion (GH9469)
- Bug in partial setting with a `DatetimeIndex` (GH9478)
- Bug in `groupby` for integer and `datetime64` columns when applying an aggregator that caused the value to be changed when the number was sufficiently large (GH9311, GH6620)
- Fixed bug in `to_sql` when mapping a `Timestamp` object column (datetime column with timezone info) to the appropriate sqlalchemy type (GH9085).
- Fixed bug in `to_sql` `dtype` argument not accepting an instantiated SQLAlchemy type (GH9083).
- Bug in `.loc` partial setting with a `np.datetime64` (GH9516)
- Incorrect dtypes inferred on datetimelike looking `Series` & on `.xs` slices (GH9477)
- Items in `Categorical.unique()` (and `s.unique()` if `s` is of dtype `category`) now appear in the order in which they are originally found, not in sorted order (GH9331). This is now consistent with the behavior for other dtypes in pandas.
- Fixed bug on big endian platforms which produced incorrect results in `StataReader` (GH8688).
- Bug in `MultiIndex.has_duplicates` when having many levels causes an indexer overflow (GH9075, GH5873)
- Bug in `pivot` and `unstack` where nan values would break index alignment (GH4862, GH7401, GH7403, GH7405, GH7466, GH9497)
- Bug in left `join` on `MultiIndex` with `sort=True` or null values (GH9210).
- Bug in `MultiIndex` where inserting new keys would fail (GH9250).
- Bug in `groupby` when key space exceeds `int64` bounds (GH9096).
- Bug in `unstack` with `TimedeltaIndex` or `DatetimeIndex` and nulls (GH9491).
- Bug in `rank` where comparing floats with tolerance will cause inconsistent behaviour (GH8365).
- Fixed character encoding bug in `read_stata` and `StataReader` when loading data from a URL (GH9231).
- Bug in adding offsets. `Nano` to other offsets raises `TypeError` (GH9284)
- Bug in `DatetimeIndex` iteration, related to (GH8890), fixed in (GH9100)
- Bugs in `resample` around DST transitions. This required fixing offset classes so they behave correctly on DST transitions. (GH5172, GH8744, GH8653, GH9173, GH9468).
- Bug in binary operator method (eg `.mul()`) alignment with integer levels (GH9463).
- Bug in `boxplot`, `scatter` and `hexbin` plot may show an unnecessary warning (GH8877)
- Bug in `subplot` with `layout` kw may show unnecessary warning (GH9464)

- Bug in using grouper functions that need passed through arguments (e.g. `axis`), when using wrapped function (e.g. `fillna`), (GH9221)
- `DataFrame` now properly supports simultaneous `copy` and `dtype` arguments in constructor (GH9099)
- Bug in `read_csv` when using `skiprows` on a file with CR line endings with the `c` engine. (GH9079)
- `isnull` now detects `NaT` in `PeriodIndex` (GH9129)
- Bug in `groupby .nth()` with a multiple column `groupby` (GH8979)
- Bug in `DataFrame.where` and `Series.where` coerce numerics to string incorrectly (GH9280)
- Bug in `DataFrame.where` and `Series.where` raise `ValueError` when string list-like is passed. (GH9280)
- Accessing `Series.str` methods on with non-string values now raises `TypeError` instead of producing incorrect results (GH9184)
- Bug in `DatetimeIndex.__contains__` when index has duplicates and is not monotonic increasing (GH9512)
- Fixed division by zero error for `Series.kurt()` when all values are equal (GH9197)
- Fixed issue in the `xlsxwriter` engine where it added a default 'General' format to cells if no other format was applied. This prevented other row or column formatting being applied. (GH9167)
- Fixes issue with `index_col=False` when `usecols` is also specified in `read_csv`. (GH9082)
- Bug where `wide_to_long` would modify the input stub names list (GH9204)
- Bug in `to_sql` not storing `float64` values using double precision. (GH9009)
- `SparseSeries` and `SparsePanel` now accept zero argument constructors (same as their non-sparse counterparts) (GH9272).
- Regression in merging `Categorical` and `object` dtypes (GH9426)
- Bug in `read_csv` with buffer overflows with certain malformed input files (GH9205)
- Bug in `groupby MultiIndex` with missing pair (GH9049, GH9344)
- Fixed bug in `Series.groupby` where grouping on `MultiIndex` levels would ignore the sort argument (GH9444)
- Fix bug in `DataFrame.Groupby` where `sort=False` is ignored in the case of `Categorical` columns. (GH8868)
- Fixed bug with reading CSV files from Amazon S3 on python 3 raising a `TypeError` (GH9452)
- Bug in the Google BigQuery reader where the 'jobComplete' key may be present but `False` in the query results (GH8728)
- Bug in `Series.values_counts` with excluding `NaN` for categorical type `Series` with `dropna=True` (GH9443)
- Fixed missing `numeric_only` option for `DataFrame.std/var/sem` (GH9201)
- Support constructing `Panel` or `Panel4D` with scalar data (GH8285)
- `Series` text representation disconnected from `max_rows/max_columns` (GH7508).
- `Series` number formatting inconsistent when truncated (GH8532).

Previous behavior

```
In [2]: pd.options.display.max_rows = 10
In [3]: s = pd.Series([1,1,1,1,1,1,1,1,1,1,0.9999,1,1]*10)
In [4]: s
Out[4]:
0      1
1      1
2      1
...
127    0.9999
128    1.0000
129    1.0000
Length: 130, dtype: float64
```

#### New behavior

```
0      1.0000
1      1.0000
2      1.0000
3      1.0000
4      1.0000
...
125    1.0000
126    1.0000
127    0.9999
128    1.0000
129    1.0000
dtype: float64
```

- A Spurious SettingWithCopy Warning was generated when setting a new item in a frame in some cases (GH8730)

The following would previously report a SettingWithCopy Warning.

```
In [42]: df1 = pd.DataFrame({'x': pd.Series(['a', 'b', 'c']),
.....:                      'y': pd.Series(['d', 'e', 'f'])})
.....:

In [43]: df2 = df1[['x']]

In [44]: df2['y'] = ['g', 'h', 'i']
```

## 6.12 Version 0.15

### 6.12.1 v0.15.2 (December 12, 2014)

{{ header }}

This is a minor release from 0.15.1 and includes a large number of bug fixes along with several new features, enhancements, and performance improvements. A small number of API changes were necessary to fix existing bugs. We recommend that all users upgrade to this version.

- *Enhancements*
- *API Changes*
- *Performance Improvements*
- *Bug Fixes*

## API changes

- Indexing in `MultiIndex` beyond lex-sort depth is now supported, though a lexically sorted index will have a better performance. (GH2646)

```
In [1]: df = pd.DataFrame({'jim':[0, 0, 1, 1],
...:                      'joe':['x', 'x', 'z', 'y'],
...:                      'jolie':np.random.rand(4)}).set_index(['jim', 'joe'])
...:

In [2]: df
Out[2]:
```

|     |     | jolie    |
|-----|-----|----------|
| jim | joe |          |
| 0   | x   | 0.823868 |
|     | x   | 0.400987 |
| 1   | z   | 0.310430 |
|     | y   | 0.142428 |

```
[4 rows x 1 columns]

In [3]: df.index.lexsort_depth
Out[3]: 1

# in prior versions this would raise a KeyError
# will now show a PerformanceWarning
In [4]: df.loc[(1, 'z')]
Out[4]:
```

|     |     | jolie   |
|-----|-----|---------|
| jim | joe |         |
| 1   | z   | 0.31043 |

```
[1 rows x 1 columns]

# lexically sorting
In [5]: df2 = df.sort_index()

In [6]: df2
Out[6]:
```

|     |     | jolie    |
|-----|-----|----------|
| jim | joe |          |
| 0   | x   | 0.823868 |
|     | x   | 0.400987 |
| 1   | y   | 0.142428 |
|     | z   | 0.310430 |

```
[4 rows x 1 columns]

In [7]: df2.index.lexsort_depth
Out[7]: 2

In [8]: df2.loc[(1, 'z')]
Out[8]:
```

|     |     | jolie   |
|-----|-----|---------|
| jim | joe |         |
| 1   | z   | 0.31043 |

```
[1 rows x 1 columns]
```

- Bug in unique of Series with `category` dtype, which returned all categories regardless whether they were “used” or not (see [GH8559](#) for the discussion). Previous behaviour was to return all categories:

```
In [3]: cat = pd.Categorical(['a', 'b', 'a'], categories=['a', 'b', 'c'])
In [4]: cat
Out [4]:
[a, b, a]
Categories (3, object): [a < b < c]
In [5]: cat.unique()
Out [5]: array(['a', 'b', 'c'], dtype=object)
```

Now, only the categories that do effectively occur in the array are returned:

```
In [9]: cat = pd.Categorical(['a', 'b', 'a'], categories=['a', 'b', 'c'])
In [10]: cat.unique()
Out [10]:
[a, b]
Categories (2, object): [a, b]
```

- `Series.all` and `Series.any` now support the `level` and `skipna` parameters. `Series.all`, `Series.any`, `Index.all`, and `Index.any` no longer support the `out` and `keepdims` parameters, which existed for compatibility with `ndarray`. Various index types no longer support the `all` and `any` aggregation functions and will now raise `TypeError`. ([GH8302](#)).
- Allow equality comparisons of Series with a categorical dtype and object dtype; previously these would raise `TypeError` ([GH8938](#)).
- Bug in `NDFrame`: conflicting attribute/column names now behave consistently between getting and setting. Previously, when both a column and attribute named `y` existed, `data.y` would return the attribute, while `data.y = z` would update the column ([GH8994](#)).

```
In [11]: data = pd.DataFrame({'x': [1, 2, 3]})
In [12]: data.y = 2
In [13]: data['y'] = [2, 4, 6]
In [14]: data
Out [14]:
   x  y
0  1  2
1  2  4
2  3  6

[3 rows x 2 columns]

# this assignment was inconsistent
In [15]: data.y = 5
```

Old behavior:

```
In [6]: data.y
Out [6]: 2
```

(continues on next page)

(continued from previous page)

```
In [7]: data['y'].values
Out[7]: array([5, 5, 5])
```

New behavior:

```
In [16]: data.y
Out[16]: 5

In [17]: data['y'].values
Out[17]: array([2, 4, 6])
```

- `Timestamp('now')` is now equivalent to `Timestamp.now()` in that it returns the local time rather than UTC. Also, `Timestamp('today')` is now equivalent to `Timestamp.today()` and both have `tz` as a possible argument. (GH9000)
- Fix negative step support for label-based slices (GH8753)

Old behavior:

```
In [1]: s = pd.Series(np.arange(3), ['a', 'b', 'c'])
Out[1]:
a    0
b    1
c    2
dtype: int64

In [2]: s.loc['c':'a':-1]
Out[2]:
c    2
dtype: int64
```

New behavior:

```
In [18]: s = pd.Series(np.arange(3), ['a', 'b', 'c'])

In [19]: s.loc['c':'a':-1]
Out[19]:
c    2
b    1
a    0
Length: 3, dtype: int64
```

## Enhancements

Categorical enhancements:

- Added ability to export Categorical data to Stata (GH8633). See [here](#) for limitations of categorical variables exported to Stata data files.
- Added flag `order_categoricals` to `StataReader` and `read_stata` to select whether to order imported categorical data (GH8836). See [here](#) for more information on importing categorical variables from Stata data files.
- Added ability to export Categorical data to to/from HDF5 (GH7621). Queries work the same as if it was an object array. However, the `category` dtyped data is stored in a more efficient manner. See [here](#) for an example and caveats w.r.t. prior versions of pandas.

- Added support for `searchsorted()` on *Categorical* class (GH8420).

Other enhancements:

- Added the ability to specify the SQL type of columns when writing a DataFrame to a database (GH8778). For example, specifying to use the sqlalchemy *String* type instead of the default *Text* type for string columns:

```
from sqlalchemy.types import String
data.to_sql('data_dtype', engine, dtype={'Col_1': String}) # noqa F821
```

- `Series.all` and `Series.any` now support the `level` and `skipna` parameters (GH8302):

```
In [20]: s = pd.Series([False, True, False], index=[0, 0, 1])
In [21]: s.any(level=0)
Out[21]:
0      True
1     False
Length: 2, dtype: bool
```

- `Panel` now supports the `all` and `any` aggregation functions. (GH8302):

```
>>> p = pd.Panel(np.random.rand(2, 5, 4) > 0.1)
>>> p.all()
   0      1      2      3
0  True  True  True  True
1  True False  True  True
2  True  True  True  True
3 False  True False  True
4  True  True  True  True
```

- Added support for `utcfromtimestamp()`, `fromtimestamp()`, and `combine()` on *Timestamp* class (GH5351).
- Added Google Analytics (*pandas.io.ga*) basic documentation (GH8835). See [here](#).
- `Timedelta` arithmetic returns `NotImplemented` in unknown cases, allowing extensions by custom classes (GH8813).
- `Timedelta` now supports arithmetic with `numpy.ndarray` objects of the appropriate dtype (numpy 1.8 or newer only) (GH8884).
- Added `Timedelta.to_timedelta64()` method to the public API (GH8884).
- Added `gbq.generate_bq_schema()` function to the `gbq` module (GH8325).
- `Series` now works with `map` objects the same way as generators (GH8909).
- Added context manager to `HDFStore` for automatic closing (GH8791).
- `to_datetime` gains an `exact` keyword to allow for a format to not require an exact match for a provided format string (if its `False`). `exact` defaults to `True` (meaning that exact matching is still the default) (GH8904)
- Added `axvlines` boolean option to `parallel_coordinates` plot function, determines whether vertical lines will be printed, default is `True`
- Added ability to read table footers to `read_html` (GH8552)
- `to_sql` now infers data types of non-NA values for columns that contain NA values and have dtype object (GH8778).

## Performance

- Reduce memory usage when skiprows is an integer in read\_csv (GH8681)
- Performance boost for to\_datetime conversions with a passed format=, and the exact=False (GH8904)

## Bug fixes

- Bug in concat of Series with category dtype which were coercing to object. (GH8641)
- Bug in Timestamp-Timestamp not returning a Timedelta type and datelike-datelike ops with timezones (GH8865)
- Made consistent a timezone mismatch exception (either tz operated with None or incompatible timezone), will now return TypeError rather than ValueError (a couple of edge cases only), (GH8865)
- Bug in using a pd.Grouper(key=...) with no level/axis or level only (GH8795, GH8866)
- Report a TypeError when invalid/no parameters are passed in a groupby (GH8015)
- Bug in packaging pandas with py2app/cx\_Freeze (GH8602, GH8831)
- Bug in groupby signatures that didn't include \*args or \*\*kwargs (GH8733).
- io.data.Options now raises RemoteDataError when no expiry dates are available from Yahoo and when it receives no data from Yahoo (GH8761), (GH8783).
- Unclear error message in csv parsing when passing dtype and names and the parsed data is a different data type (GH8833)
- Bug in slicing a MultiIndex with an empty list and at least one boolean indexer (GH8781)
- io.data.Options now raises RemoteDataError when no expiry dates are available from Yahoo (GH8761).
- Timedelta kwargs may now be numpy ints and floats (GH8757).
- Fixed several outstanding bugs for Timedelta arithmetic and comparisons (GH8813, GH5963, GH5436).
- sql\_schema now generates dialect appropriate CREATE TABLE statements (GH8697)
- slice string method now takes step into account (GH8754)
- Bug in BlockManager where setting values with different type would break block integrity (GH8850)
- Bug in DatetimeIndex when using time object as key (GH8667)
- Bug in merge where how='left' and sort=False would not preserve left frame order (GH7331)
- Bug in MultiIndex.reindex where reindexing at level would not reorder labels (GH4088)
- Bug in certain operations with dateutil timezones, manifesting with dateutil 2.3 (GH8639)
- Regression in DatetimeIndex iteration with a Fixed/Local offset timezone (GH8890)
- Bug in to\_datetime when parsing a nanoseconds using the %f format (GH8989)
- io.data.Options now raises RemoteDataError when no expiry dates are available from Yahoo and when it receives no data from Yahoo (GH8761), (GH8783).
- Fix: The font size was only set on x axis if vertical or the y axis if horizontal. (GH8765)
- Fixed division by 0 when reading big csv files in python 3 (GH8621)
- Bug in outputting a MultiIndex with to\_html, index=False which would add an extra column (GH8452)

- Imported categorical variables from Stata files retain the ordinal information in the underlying data (GH8836).
- Defined `.size` attribute across `NDFrame` objects to provide compat with numpy  $\geq 1.9.1$ ; buggy with `np.array_split` (GH8846)
- Skip testing of histogram plots for matplotlib  $\leq 1.2$  (GH8648).
- Bug where `get_data_google` returned object dtypes (GH3995)
- Bug in `DataFrame.stack(..., dropna=False)` when the `DataFrame`'s columns is a `MultiIndex` whose labels do not reference all its levels. (GH8844)
- Bug in that `Option` context applied on `__enter__` (GH8514)
- Bug in `resample` that causes a `ValueError` when resampling across multiple days and the last offset is not calculated from the start of the range (GH8683)
- Bug where `DataFrame.plot(kind='scatter')` fails when checking if an `np.array` is in the `DataFrame` (GH8852)
- Bug in `pd.infer_freq/DataFrame.inferred_freq` that prevented proper sub-daily frequency inference when the index contained DST days (GH8772).
- Bug where index name was still used when plotting a series with `use_index=False` (GH8558).
- Bugs when trying to stack multiple columns, when some (or all) of the level names are numbers (GH8584).
- Bug in `MultiIndex` where `__contains__` returns wrong result if index is not lexically sorted or unique (GH7724)
- BUG CSV: fix problem with trailing white space in skipped rows, (GH8679), (GH8661), (GH8983)
- Regression in `Timestamp` does not parse 'Z' zone designator for UTC (GH8771)
- Bug in `StataWriter` the produces writes strings with 244 characters irrespective of actual size (GH8969)
- Fixed `ValueError` raised by `cummin/cummax` when `datetime64` Series contains `NaT`. (GH8965)
- Bug in `DataReader` returns object dtype if there are missing values (GH8980)
- Bug in plotting if `sharex` was enabled and index was a timeseries, would show labels on multiple axes (GH3964).
- Bug where passing a unit to the `TimedeltaIndex` constructor applied the to nano-second conversion twice. (GH9011).
- Bug in plotting of a period-like array (GH9012)

## Contributors

A total of 49 people contributed patches to this release. People with a "+" by their names contributed a patch for the first time.

## 6.12.2 v0.15.1 (November 9, 2014)

{{ header }}

This is a minor bug-fix release from 0.15.0 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

- *Enhancements*
- *API Changes*
- *Bug Fixes*

### API changes

- `s.dt.hour` and other `.dt` accessors will now return `np.nan` for missing values (rather than previously `-1`), (GH8689)

```
In [1]: s = pd.Series(pd.date_range('20130101', periods=5, freq='D'))
In [2]: s.iloc[2] = np.nan
In [3]: s
Out [3]:
0    2013-01-01
1    2013-01-02
2             NaT
3    2013-01-04
4    2013-01-05
Length: 5, dtype: datetime64[ns]
```

previous behavior:

```
In [6]: s.dt.hour
Out [6]:
0     0
1     0
2    -1
3     0
4     0
dtype: int64
```

current behavior:

```
In [4]: s.dt.hour
Out [4]:
0     0.0
```

(continues on next page)

(continued from previous page)

```

1    0.0
2    NaN
3    0.0
4    0.0
Length: 5, dtype: float64

```

- `groupby` with `as_index=False` will not add erroneous extra columns to result (GH8582):

```

In [5]: np.random.seed(2718281)

In [6]: df = pd.DataFrame(np.random.randint(0, 100, (10, 2)),
...:                      columns=['jim', 'joe'])
...:

In [7]: df.head()
Out[7]:
   jim  joe
0   61   81
1   96   49
2   55   65
3   72   51
4   77   12

[5 rows x 2 columns]

In [8]: ts = pd.Series(5 * np.random.randint(0, 3, 10))

```

previous behavior:

```

In [4]: df.groupby(ts, as_index=False).max()
Out[4]:
   NaN  jim  joe
0     0   72  83
1     5   77  84
2    10   96  65

```

current behavior:

```

In [9]: df.groupby(ts, as_index=False).max()
Out[9]:
   jim  joe
0   72  83
1   77  84
2   96  65

[3 rows x 2 columns]

```

- `groupby` will not erroneously exclude columns if the column name conflicts with the grouper name (GH8112):

```

In [10]: df = pd.DataFrame({'jim': range(5), 'joe': range(5, 10)})

In [11]: df
Out[11]:
   jim  joe
0     0    5
1     1    6

```

(continues on next page)

(continued from previous page)

```
2    2    7
3    3    8
4    4    9
```

```
[5 rows x 2 columns]
```

```
In [12]: gr = df.groupby(df['jim'] < 2)
```

previous behavior (excludes 1st column from output):

```
In [4]: gr.apply(sum)
```

```
Out [4]:
      joe
jim
False  24
True   11
```

current behavior:

```
In [13]: gr.apply(sum)
```

```
Out [13]:
      jim  joe
jim
False    9   24
True     1   11
```

```
[2 rows x 2 columns]
```

- Support for slicing with monotonic decreasing indexes, even if start or stop is not found in the index (GH7860):

```
In [14]: s = pd.Series(['a', 'b', 'c', 'd'], [4, 3, 2, 1])
```

```
In [15]: s
```

```
Out [15]:
4    a
3    b
2    c
1    d
Length: 4, dtype: object
```

previous behavior:

```
In [8]: s.loc[3.5:1.5]
```

```
KeyError: 3.5
```

current behavior:

```
In [16]: s.loc[3.5:1.5]
```

```
Out [16]:
3    b
2    c
Length: 2, dtype: object
```

- `io.data.Options` has been fixed for a change in the format of the Yahoo Options page (GH8612), (GH8741)

---

**Note:** As a result of a change in Yahoo’s option page layout, when an expiry date is given, `Options` methods now return data for a single expiry date. Previously, methods returned all data for the selected month.

---

The `month` and `year` parameters have been undeprecated and can be used to get all options data for a given month.

If an expiry date that is not valid is given, data for the next expiry after the given date is returned.

Option data frames are now saved on the instance as `callsYYMMDD` or `putsYYMMDD`. Previously they were saved as `callsSMMYY` and `putsSMMYY`. The next expiry is saved as `calls` and `puts`.

New features:

- The expiry parameter can now be a single date or a list-like object containing dates.
- A new property `expiry_dates` was added, which returns all available expiry dates.

Current behavior:

```
In [17]: from pandas.io.data import Options
In [18]: aapl = Options('aapl', 'yahoo')
In [19]: aapl.get_call_data().iloc[0:5, 0:1]
Out[19]:
```

| Strike | Expiry     | Type | Symbol              | Last  |
|--------|------------|------|---------------------|-------|
| 80     | 2014-11-14 | call | AAPL141114C00080000 | 29.05 |
| 84     | 2014-11-14 | call | AAPL141114C00084000 | 24.80 |
| 85     | 2014-11-14 | call | AAPL141114C00085000 | 24.05 |
| 86     | 2014-11-14 | call | AAPL141114C00086000 | 22.76 |
| 87     | 2014-11-14 | call | AAPL141114C00087000 | 21.74 |

```
In [20]: aapl.expiry_dates
Out[20]:
```

```
[datetime.date(2014, 11, 14),
 datetime.date(2014, 11, 22),
 datetime.date(2014, 11, 28),
 datetime.date(2014, 12, 5),
 datetime.date(2014, 12, 12),
 datetime.date(2014, 12, 20),
 datetime.date(2015, 1, 17),
 datetime.date(2015, 2, 20),
 datetime.date(2015, 4, 17),
 datetime.date(2015, 7, 17),
 datetime.date(2016, 1, 15),
 datetime.date(2017, 1, 20)]
```

```
In [21]: aapl.get_near_stock_price(expiry=aapl.expiry_dates[0:3]).iloc[0:5, 0:1]
Out[21]:
```

| Strike | Expiry     | Type | Symbol              | Last |
|--------|------------|------|---------------------|------|
| 109    | 2014-11-22 | call | AAPL141122C00109000 | 1.48 |
|        | 2014-11-28 | call | AAPL141128C00109000 | 1.79 |
| 110    | 2014-11-14 | call | AAPL141114C00110000 | 0.55 |
|        | 2014-11-22 | call | AAPL141122C00110000 | 1.02 |
|        | 2014-11-28 | call | AAPL141128C00110000 | 1.32 |

- pandas now also registers the `datetime64` dtype in matplotlib’s units registry to plot such values as datetimes.

This is activated once pandas is imported. In previous versions, plotting an array of `datetime64` values will have resulted in plotted integer values. To keep the previous behaviour, you can do `del matplotlib.units.registry[np.datetime64]` (GH8614).

## Enhancements

- `concat` permits a wider variety of iterables of pandas objects to be passed as the first parameter (GH8645):

```
In [17]: from collections import deque
In [18]: df1 = pd.DataFrame([1, 2, 3])
In [19]: df2 = pd.DataFrame([4, 5, 6])
```

previous behavior:

```
In [7]: pd.concat(deque((df1, df2)))
TypeError: first argument must be a list-like of pandas objects, you passed an_
↳object of type "deque"
```

current behavior:

```
In [20]: pd.concat(deque((df1, df2)))
Out [20]:
  0
0  1
1  2
2  3
0  4
1  5
2  6

[6 rows x 1 columns]
```

- Represent `MultiIndex` labels with a dtype that utilizes memory based on the level size. In prior versions, the memory usage was a constant 8 bytes per element in each level. In addition, in prior versions, the *reported* memory usage was incorrect as it didn't show the usage for the memory occupied by the underlying data array. (GH8456)

```
In [21]: dfi = pd.DataFrame(1, index=pd.MultiIndex.from_product([[ 'a' ],
.....:                                                         range(1000)]), columns=['A'])
.....:
```

previous behavior:

```
# this was underreported in prior versions
In [1]: dfi.memory_usage(index=True)
Out [1]:
Index      8000 # took about 24008 bytes in < 0.15.1
A          8000
dtype: int64
```

current behavior:

```
In [22]: dfi.memory_usage(index=True)
Out [22]:
```

(continues on next page)

(continued from previous page)

```

Index      11040
A          8000
Length: 2, dtype: int64

```

- Added Index properties `is_monotonic_increasing` and `is_monotonic_decreasing` (GH8680).
- Added option to select columns when importing Stata files (GH7935)
- Qualify memory usage in `DataFrame.info()` by adding `+` if it is a lower bound (GH8578)
- Raise errors in certain aggregation cases where an argument such as `numeric_only` is not handled (GH8592).
- Added support for 3-character ISO and non-standard country codes in `io.wb.download()` (GH8482)
- World Bank data requests now will warn/raise based on an `errors` argument, as well as a list of hard-coded country codes and the World Bank's JSON response. In prior versions, the error messages didn't look at the World Bank's JSON response. Problem-inducing input were simply dropped prior to the request. The issue was that many good countries were cropped in the hard-coded approach. All countries will work now, but some bad countries will raise exceptions because some edge cases break the entire response. (GH8482)
- Added option to `Series.str.split()` to return a `DataFrame` rather than a `Series` (GH8428)
- Added option to `df.info(null_counts=None|True|False)` to override the default display options and force showing of the null-counts (GH8701)

## Bug fixes

- Bug in unpickling of a `CustomBusinessDay` object (GH8591)
- Bug in coercing `Categorical` to a records array, e.g. `df.to_records()` (GH8626)
- Bug in `Categorical` not created properly with `Series.to_frame()` (GH8626)
- Bug in coercing in `astype` of a `Categorical` of a passed `pd.Categorical` (this now raises `TypeError` correctly), (GH8626)
- Bug in `cut/qcut` when using `Series` and `retbins=True` (GH8589)
- Bug in writing `Categorical` columns to an SQL database with `to_sql` (GH8624).
- Bug in comparing `Categorical` of datetime raising when being compared to a scalar datetime (GH8687)
- Bug in selecting from a `Categorical` with `.iloc` (GH8623)
- Bug in groupby-transform with a `Categorical` (GH8623)
- Bug in duplicated/drop\_duplicates with a `Categorical` (GH8623)
- Bug in `Categorical` reflected comparison operator raising if the first argument was a numpy array scalar (e.g. `np.int64`) (GH8658)
- Bug in Panel indexing with a list-like (GH8710)
- Compat issue is `DataFrame.dtypes` when `options.mode.use_inf_as_null` is `True` (GH8722)
- Bug in `read_csv`, `dialect` parameter would not take a string (GH8703)
- Bug in slicing a `MultiIndex` level with an empty-list (GH8737)
- Bug in numeric index operations of add/sub with `Float/Index Index` with numpy arrays (GH8608)
- Bug in `setitem` with empty indexer and unwanted coercion of dtypes (GH8669)
- Bug in `ix/loc` block splitting on `setitem` (manifests with integer-like dtypes, e.g. `datetime64`) (GH8607)

- Bug when doing label based indexing with integers not found in the index for non-unique but monotonic indexes (GH8680).
- Bug when indexing a Float64Index with `np.nan` on numpy 1.7 (GH8980).
- Fix `shape` attribute for `MultiIndex` (GH8609)
- Bug in `GroupBy` where a name conflict between the grouper and columns would break `groupby` operations (GH7115, GH8112)
- Fixed a bug where plotting a column `y` and specifying a label would mutate the index name of the original `DataFrame` (GH8494)
- Fix regression in plotting of a `DatetimeIndex` directly with `matplotlib` (GH8614).
- Bug in `date_range` where partially-specified dates would incorporate current date (GH6961)
- Bug in Setting by indexer to a scalar value with a mixed-dtype `Panel4d` was failing (GH8702)
- Bug where `DataReader`'s would fail if one of the symbols passed was invalid. Now returns data for valid symbols and `np.nan` for invalid (GH8494)
- Bug in `get_quote_yahoo` that wouldn't allow non-float return values (GH5229).

### 6.12.3 v0.15.0 (October 18, 2014)

{{ header }}

This is a major release from 0.14.1 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

**Warning:** pandas  $\geq$  0.15.0 will no longer support compatibility with NumPy versions  $<$  1.7.0. If you want to use the latest versions of pandas, please upgrade to NumPy  $\geq$  1.7.0 ([GH7711](#))

- Highlights include:
  - The `Categorical` type was integrated as a first-class pandas type, see [here](#)
  - New scalar type `Timedelta`, and a new index type `TimedeltaIndex`, see [here](#)
  - New datetimelike properties accessor `.dt` for Series, see [Datetimelike Properties](#)
  - New DataFrame default display for `df.info()` to include memory usage, see [Memory Usage](#)
  - `read_csv` will now by default ignore blank lines when parsing, see [here](#)
  - API change in using Indexes in set operations, see [here](#)
  - Enhancements in the handling of timezones, see [here](#)
  - A lot of improvements to the rolling and expanding moment functions, see [here](#)
  - Internal refactoring of the `Index` class to no longer sub-class `ndarray`, see [Internal Refactoring](#)
  - dropping support for `PyTables` less than version 3.0.0, and `numexpr` less than version 2.1 ([GH7990](#))
  - Split indexing documentation into [Indexing and Selecting Data](#) and [MultiIndex / Advanced Indexing](#)
  - Split out string methods documentation into [Working with Text Data](#)
- Check the [API Changes](#) and [deprecations](#) before updating
- [Other Enhancements](#)
- [Performance Improvements](#)
- [Bug Fixes](#)

**Warning:** In 0.15.0 `Index` has internally been refactored to no longer sub-class `ndarray` but instead subclass `PandasObject`, similarly to the rest of the pandas objects. This change allows very easy sub-classing and creation of new index types. This should be a transparent change with only very limited API implications (See the [Internal Refactoring](#))

**Warning:** The refactoring in *Categorical* changed the two argument constructor from “codes/labels and levels” to “values and levels (now called ‘categories’)”. This can lead to subtle bugs. If you use *Categorical* directly, please audit your code before updating to this pandas version and change it to use the `from_codes()` constructor. See more on *Categorical* [here](#)

## New features

### Categoricals in Series/DataFrame

*Categorical* can now be included in *Series* and *DataFrames* and gained new methods to manipulate. Thanks to Jan Schulz for much of this API/implementation. (GH3943, GH5313, GH5314, GH7444, GH7839, GH7848, GH7864, GH7914, GH7768, GH8006, GH3678, GH8075, GH8076, GH8143, GH8453, GH8518).

For full docs, see the *categorical introduction* and the *API documentation*.

```
In [1]: df = pd.DataFrame({"id": [1, 2, 3, 4, 5, 6],
...:                     "raw_grade": ['a', 'b', 'b', 'a', 'a', 'e']})
...:

In [2]: df["grade"] = df["raw_grade"].astype("category")

In [3]: df["grade"]
Out[3]:
0    a
1    b
2    b
3    a
4    a
5    e
Name: grade, Length: 6, dtype: category
Categories (3, object): [a, b, e]

# Rename the categories
In [4]: df["grade"].cat.categories = ["very good", "good", "very bad"]

# Reorder the categories and simultaneously add the missing categories
In [5]: df["grade"] = df["grade"].cat.set_categories(["very bad", "bad",
...:                                               "medium", "good", "very good"])
...:

In [6]: df["grade"]
Out[6]:
0    very good

Out [8]:
```

```

grade
very bad    1
bad         0
medium      0
good        2
very good   3
Length: 5, dtype: int64

```

- `pandas.core.group_agg` and `pandas.core.factor_agg` were removed. As an alternative, construct a dataframe and use `df.groupby(<group>).agg(<func>)`.
- Supplying “codes/labels and levels” to the *Categorical* constructor is not supported anymore. Supplying two arguments to the constructor is now interpreted as “values and levels (now called ‘categories’)”. Please change your code to use the `from_codes()` constructor.
- The `Categorical.labels` attribute was renamed to `Categorical.codes` and is read only. If you want to manipulate codes, please use one of the *API methods on Categoricals*.
- The `Categorical.levels` attribute is renamed to `Categorical.categories`.

## TimedeltaIndex/Scalar

We introduce a new scalar type `Timedelta`, which is a subclass of `datetime.timedelta`, and behaves in a similar manner, but allows compatibility with `np.timedelta64` types as well as a host of custom representation, parsing, and attributes. This type is very similar to how `Timestamp` works for datetimes. It is a nice-API box for the type. See the *docs*. ([GH3009](#), [GH4533](#), [GH8209](#), [GH8187](#), [GH8190](#), [GH7869](#), [GH7661](#), [GH8345](#), [GH8471](#))

**Warning:** `Timedelta` scalars (and `TimedeltaIndex`) component fields are *not the same* as the component fields on a `datetime.timedelta` object. For example, `.seconds` on a `datetime.timedelta` object returns the total number of seconds combined between hours, minutes and seconds. In contrast, the pandas `Timedelta` breaks out hours, minutes, microseconds and nanoseconds separately.

```
# Timedelta accessor
In [9]: tds = pd.Timedelta('31 days 5 min 3 sec')
```

```
In [10]: tds.minutes
Out [10]: 5L
```

```
In [11]: tds.seconds
Out [11]: 3L
```

```
# datetime.timedelta accessor
# this is 5 minutes * 60 + 3 seconds
In [12]: tds.to_pytimedelta().seconds
Out [12]: 303
```

**Note:** this is no longer true starting from v0.16.0, where full compatibility with `datetime.timedelta` is introduced. See the *0.16.0 whatsnew entry*

**Warning:** Prior to 0.15.0 `pd.to_timedelta` would return a `Series` for list-like/`Series` input, and a `np.timedelta64` for scalar input. It will now return a `TimedeltaIndex` for list-like input, `Series` for `Series` input, and `Timedelta` for scalar input.

The arguments to `pd.to_timedelta` are now `(arg, unit='ns', box=True, coerce=False)`, previously were `(arg, box=True, unit='ns')` as these are more logical.

### Construct a scalar

```
In [9]: pd.Timedelta('1 days 06:05:01.00003')
Out[9]: Timedelta('1 days 06:05:01.000030')

In [10]: pd.Timedelta('15.5us')
Out[10]: Timedelta('0 days 00:00:00.000015')

In [11]: pd.Timedelta('1 hour 15.5us')
Out[11]: Timedelta('0 days 01:00:00.000015')

# negative Timedeltas have this string repr
# to be more consistent with datetime.timedelta conventions
In [12]: pd.Timedelta('-1us')
Out[12]: Timedelta('-1 days +23:59:59.999999')

# a NaT
In [13]: pd.Timedelta('nan')
Out[13]: NaT
```

### Access fields for a Timedelta

```
In [14]: td = pd.Timedelta('1 hour 3m 15.5us')

In [15]: td.seconds
Out[15]: 3780

In [16]: td.microseconds
Out[16]: 16

In [17]: td.nanoseconds
Out[17]: 500
```

### Construct a TimedeltaIndex

```
In [18]: pd.TimedeltaIndex(['1 days', '1 days, 00:00:05',
.....:                      np.timedelta64(2, 'D'),
.....:                      datetime.timedelta(days=2, seconds=2)])
Out[18]:
TimedeltaIndex(['1 days 00:00:00', '1 days 00:00:05', '2 days 00:00:00',
                '2 days 00:00:02'],
                dtype='timedelta64[ns]', freq=None)
```

### Constructing a TimedeltaIndex with a regular range

```

In [19]: pd.timedelta_range('1 days', periods=5, freq='D')
Out[19]: TimedeltaIndex(['1 days', '2 days', '3 days', '4 days', '5 days'], dtype=
→ 'timedelta64[ns]', freq='D')

In [20]: pd.timedelta_range(start='1 days', end='2 days', freq='30T')
Out[20]:
TimedeltaIndex(['1 days 00:00:00', '1 days 00:30:00', '1 days 01:00:00',
                '1 days 01:30:00', '1 days 02:00:00', '1 days 02:30:00',
                '1 days 03:00:00', '1 days 03:30:00', '1 days 04:00:00',
                '1 days 04:30:00', '1 days 05:00:00', '1 days 05:30:00',
                '1 days 06:00:00', '1 days 06:30:00', '1 days 07:00:00',
                '1 days 07:30:00', '1 days 08:00:00', '1 days 08:30:00',
                '1 days 09:00:00', '1 days 09:30:00', '1 days 10:00:00',
                '1 days 10:30:00', '1 days 11:00:00', '1 days 11:30:00',
                '1 days 12:00:00', '1 days 12:30:00', '1 days 13:00:00',
                '1 days 13:30:00', '1 days 14:00:00', '1 days 14:30:00',
                '1 days 15:00:00', '1 days 15:30:00', '1 days 16:00:00',
                '1 days 16:30:00', '1 days 17:00:00', '1 days 17:30:00',
                '1 days 18:00:00', '1 days 18:30:00', '1 days 19:00:00',
                '1 days 19:30:00', '1 days 20:00:00', '1 days 20:30:00',
                '1 days 21:00:00', '1 days 21:30:00', '1 days 22:00:00',
                '1 days 22:30:00', '1 days 23:00:00', '1 days 23:30:00',
                '2 days 00:00:00'],
                dtype='timedelta64[ns]', freq='30T')

```

You can now use a `TimedeltaIndex` as the index of a pandas object

```

In [21]: s = pd.Series(np.arange(5),
.....:                  index=pd.timedelta_range('1 days', periods=5, freq='s'))
.....:

In [22]: s
Out[22]:
1 days 00:00:00    0
1 days 00:00:01    1
1 days 00:00:02    2
1 days 00:00:03    3
1 days 00:00:04    4
Freq: S, Length: 5, dtype: int64

```

You can select with partial string selections

```

In [23]: s['1 day 00:00:02']
Out[23]: 2

In [24]: s['1 day':'1 day 00:00:02']
Out[24]:
1 days 00:00:00    0
1 days 00:00:01    1
1 days 00:00:02    2
Freq: S, Length: 3, dtype: int64

```

Finally, the combination of `TimedeltaIndex` with `DatetimeIndex` allow certain combination operations that are NaT preserving:

```

In [25]: tdi = pd.TimedeltaIndex(['1 days', pd.NaT, '2 days'])

```

(continues on next page)

(continued from previous page)

```

In [26]: tdi.tolist()
Out[26]: [Timedelta('1 days 00:00:00'), NaT, Timedelta('2 days 00:00:00')]

In [27]: dti = pd.date_range('20130101', periods=3)

In [28]: dti.tolist()
Out[28]:
[Timestamp('2013-01-01 00:00:00', freq='D'),
 Timestamp('2013-01-02 00:00:00', freq='D'),
 Timestamp('2013-01-03 00:00:00', freq='D')]

In [29]: (dti + tdi).tolist()
Out[29]: [Timestamp('2013-01-02 00:00:00'), NaT, Timestamp('2013-01-05 00:00:00')]

In [30]: (dti - tdi).tolist()
Out[30]: [Timestamp('2012-12-31 00:00:00'), NaT, Timestamp('2013-01-01 00:00:00')]

```

- iteration of a Series e.g. `list(Series(...))` of `timedelta64[ns]` would prior to v0.15.0 return `np.timedelta64` for each element. These will now be wrapped in `Timedelta`.

## Memory usage

Implemented methods to find memory usage of a DataFrame. See the *FAQ* for more. ([GH6852](#)).

A new display option `display.memory_usage` (see options) sets the default behavior of the `memory_usage` argument in the `df.info()` method. By default `display.memory_usage` is `True`.

```

In [31]: dtypes = ['int64', 'float64', 'datetime64[ns]', 'timedelta64[ns]',
.....:             'complex128', 'object', 'bool']
.....:

In [32]: n = 5000

In [33]: data = {t: np.random.randint(100, size=n).astype(t) for t in dtypes}

In [34]: df = pd.DataFrame(data)

In [35]: df['categorical'] = df['object'].astype('category')

In [36]: df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5000 entries, 0 to 4999
Data columns (total 8 columns):
#   Column                Non-Null Count  Dtype
---  ---                -
0   int64                 5000 non-null   int64
1   float64               5000 non-null   float64
2   datetime64[ns]       5000 non-null   datetime64[ns]
3   timedelta64[ns]     5000 non-null   timedelta64[ns]
4   complex128            5000 non-null   complex128
5   object                5000 non-null   object
6   bool                  5000 non-null   bool
7   categorical           5000 non-null   category
dtypes: bool(1), category(1), complex128(1), datetime64[ns](1), float64(1), int64(1),
↳object(1), timedelta64[ns](1)
memory usage: 289.1+ KB

```

Additionally `memory_usage()` is an available method for a dataframe object which returns the memory usage of each column.

```
In [37]: df.memory_usage(index=True)
Out [37]:
Index          128
int64          40000
float64        40000
datetime64[ns] 40000
timedelta64[ns] 40000
complex128     80000
object         40000
bool           5000
categorical    10920
Length: 9, dtype: int64
```

### **.dt accessor**

Series has gained an accessor to succinctly return datetime like properties for the *values* of the Series, if its a datetime/period like Series. (GH7207) This will return a Series, indexed like the existing Series. See the *docs*

```
# datetime
In [38]: s = pd.Series(pd.date_range('20130101 09:10:12', periods=4))

In [39]: s
Out [39]:
0    2013-01-01 09:10:12
1    2013-01-02 09:10:12
2    2013-01-03 09:10:12
3    2013-01-04 09:10:12
Length: 4, dtype: datetime64[ns]

In [40]: s.dt.hour
Out [40]:
0     9
1     9
2     9
3     9
Length: 4, dtype: int64

In [41]: s.dt.second
Out [41]:
0    12
1    12
2    12
3    12
Length: 4, dtype: int64

In [42]: s.dt.day
Out [42]:
0     1
1     2
2     3
3     4
Length: 4, dtype: int64
```

(continues on next page)

(continued from previous page)

```
In [43]: s.dt.freq
Out [43]: 'D'
```

This enables nice expressions like this:

```
In [44]: s[s.dt.day == 2]
Out [44]:
1    2013-01-02 09:10:12
Length: 1, dtype: datetime64[ns]
```

You can easily produce tz aware transformations:

```
In [45]: stz = s.dt.tz_localize('US/Eastern')

In [46]: stz
Out [46]:
0    2013-01-01 09:10:12-05:00
1    2013-01-02 09:10:12-05:00
2    2013-01-03 09:10:12-05:00
3    2013-01-04 09:10:12-05:00
Length: 4, dtype: datetime64[ns, US/Eastern]

In [47]: stz.dt.tz
Out [47]: <DstTzInfo 'US/Eastern' LMT-1 day, 19:04:00 STD>
```

You can also chain these types of operations:

```
In [48]: s.dt.tz_localize('UTC').dt.tz_convert('US/Eastern')
Out [48]:
0    2013-01-01 04:10:12-05:00
1    2013-01-02 04:10:12-05:00
2    2013-01-03 04:10:12-05:00
3    2013-01-04 04:10:12-05:00
Length: 4, dtype: datetime64[ns, US/Eastern]
```

The `.dt` accessor works for period and timedelta dtypes.

```
# period
In [49]: s = pd.Series(pd.period_range('20130101', periods=4, freq='D'))

In [50]: s
Out [50]:
0    2013-01-01
1    2013-01-02
2    2013-01-03
3    2013-01-04
Length: 4, dtype: period[D]

In [51]: s.dt.year
Out [51]:
0    2013
1    2013
2    2013
3    2013
Length: 4, dtype: int64
```

(continues on next page)

(continued from previous page)

```
In [52]: s.dt.day
Out [52]:
0      1
1      2
2      3
3      4
Length: 4, dtype: int64
```

```
# timedelta
In [53]: s = pd.Series(pd.timedelta_range('1 day 00:00:05', periods=4, freq='s'))
```

```
In [54]: s
Out [54]:
0      1 days 00:00:05
1      1 days 00:00:06
2      1 days 00:00:07
3      1 days 00:00:08
Length: 4, dtype: timedelta64[ns]
```

```
In [55]: s.dt.days
Out [55]:
0      1
1      1
2      1
3      1
Length: 4, dtype: int64
```

```
In [56]: s.dt.seconds
Out [56]:
0      5
1      6
2      7
3      8
Length: 4, dtype: int64
```

```
In [57]: s.dt.components
Out [57]:
   days  hours  minutes  seconds  milliseconds  microseconds  nanoseconds
0      1     0         0         5              0              0              0
1      1     0         0         6              0              0              0
2      1     0         0         7              0              0              0
3      1     0         0         8              0              0              0

[4 rows x 7 columns]
```

## Timezone handling improvements

- `tz_localize` (None) for tz-aware Timestamp and DatetimeIndex now removes timezone holding local time, previously this resulted in Exception or TypeError (GH7812)

```
In [58]: ts = pd.Timestamp('2014-08-01 09:00', tz='US/Eastern')
```

```
In [59]: ts
```

```
Out [59]: Timestamp('2014-08-01 09:00:00-0400', tz='US/Eastern')
```

(continues on next page)

(continued from previous page)

```

In [60]: ts.tz_localize(None)
Out [60]: Timestamp('2014-08-01 09:00:00')

In [61]: didx = pd.date_range(start='2014-08-01 09:00', freq='H',
.....:                        periods=10, tz='US/Eastern')
.....:

In [62]: didx
Out [62]:
DatetimeIndex(['2014-08-01 09:00:00-04:00', '2014-08-01 10:00:00-04:00',
              '2014-08-01 11:00:00-04:00', '2014-08-01 12:00:00-04:00',
              '2014-08-01 13:00:00-04:00', '2014-08-01 14:00:00-04:00',
              '2014-08-01 15:00:00-04:00', '2014-08-01 16:00:00-04:00',
              '2014-08-01 17:00:00-04:00', '2014-08-01 18:00:00-04:00'],
              dtype='datetime64[ns, US/Eastern]', freq='H')

In [63]: didx.tz_localize(None)
Out [63]:
DatetimeIndex(['2014-08-01 09:00:00', '2014-08-01 10:00:00',
              '2014-08-01 11:00:00', '2014-08-01 12:00:00',
              '2014-08-01 13:00:00', '2014-08-01 14:00:00',
              '2014-08-01 15:00:00', '2014-08-01 16:00:00',
              '2014-08-01 17:00:00', '2014-08-01 18:00:00'],
              dtype='datetime64[ns]', freq='H')

```

- `tz_localize` now accepts the ambiguous keyword which allows for passing an array of bools indicating whether the date belongs in DST or not, 'NaT' for setting transition times to NaT, 'infer' for inferring DST/non-DST, and 'raise' (default) for an `AmbiguousTimeError` to be raised. See *the docs* for more details ([GH7943](#))
- `DataFrame.tz_localize` and `DataFrame.tz_convert` now accepts an optional `level` argument for localizing a specific level of a `MultiIndex` ([GH7846](#))
- `Timestamp.tz_localize` and `Timestamp.tz_convert` now raise `TypeError` in error cases, rather than `Exception` ([GH8025](#))
- a `timeseries/index` localized to UTC when inserted into a `Series/DataFrame` will preserve the UTC timezone (rather than being a naive `datetime64[ns]`) as object `dtype` ([GH8411](#))
- `Timestamp.__repr__` displays `dateutil.tz.tzoffset` info ([GH7907](#))

## Rolling/expanding moments improvements

- `rolling_min()`, `rolling_max()`, `rolling_cov()`, and `rolling_corr()` now return objects with all NaN when `len(arg) < min_periods <= window` rather than raising. (This makes all rolling functions consistent in this behavior). ([GH7766](#))

Prior to 0.15.0

```
In [64]: s = pd.Series([10, 11, 12, 13])
```

```
In [15]: pd.rolling_min(s, window=10, min_periods=5)
ValueError: min_periods (5) must be <= window (4)
```

New behavior

```
In [4]: pd.rolling_min(s, window=10, min_periods=5)
Out [4]:
0    NaN
1    NaN
2    NaN
3    NaN
dtype: float64
```

- `rolling_max()`, `rolling_min()`, `rolling_sum()`, `rolling_mean()`, `rolling_median()`, `rolling_std()`, `rolling_var()`, `rolling_skew()`, `rolling_kurt()`, `rolling_quantile()`, `rolling_cov()`, `rolling_corr()`, `rolling_corr_pairwise()`, `rolling_window()`, and `rolling_apply()` with `center=True` previously would return a result of the same structure as the input arg with NaN in the final  $(window-1)/2$  entries.

Now the final  $(window-1)/2$  entries of the result are calculated as if the input arg were followed by  $(window-1)/2$  NaN values (or with shrinking windows, in the case of `rolling_apply()`). (GH7925, GH8269)

Prior behavior (note final value is NaN):

```
In [7]: pd.rolling_sum(Series(range(4)), window=3, min_periods=0, center=True)
Out [7]:
0     1
1     3
2     6
3    NaN
dtype: float64
```

New behavior (note final value is 5 = `sum([2, 3, NaN])`):

```
In [7]: pd.rolling_sum(pd.Series(range(4)), window=3,
....:                  min_periods=0, center=True)
Out [7]:
0     1
1     3
2     6
3     5
dtype: float64
```

- `rolling_window()` now normalizes the weights properly in rolling mean mode (`mean=True`) so that the calculated weighted means (e.g. ‘triang’, ‘gaussian’) are distributed about the same means as those calculated without weighting (i.e. ‘boxcar’). See *the note on normalization* for further details. (GH7618)

```
In [65]: s = pd.Series([10.5, 8.8, 11.4, 9.7, 9.3])
```

Behavior prior to 0.15.0:

```
In [39]: pd.rolling_window(s, window=3, win_type='triang', center=True)
Out [39]:
0         NaN
1    6.583333
2    6.883333
3    6.683333
4         NaN
dtype: float64
```

New behavior

```
In [10]: pd.rolling_window(s, window=3, win_type='triang', center=True)
Out [10]:
0      NaN
1      9.875
2     10.325
3     10.025
4      NaN
dtype: float64
```

- Removed `center` argument from all `expanding_*` functions (see *list*), as the results produced when `center=True` did not make much sense. (GH7925)
- Added optional `ddof` argument to `expanding_cov()` and `rolling_cov()`. The default value of 1 is backwards-compatible. (GH8279)
- Documented the `ddof` argument to `expanding_var()`, `expanding_std()`, `rolling_var()`, and `rolling_std()`. These functions' support of a `ddof` argument (with a default value of 1) was previously undocumented. (GH8064)
- `ewma()`, `ewmstd()`, `ewmvol()`, `ewmvar()`, `ewmcov()`, and `ewmcorr()` now interpret `min_periods` in the same manner that the `rolling_*` and `expanding_*` functions do: a given result entry will be NaN if the (expanding, in this case) window does not contain at least `min_periods` values. The previous behavior was to set to NaN the `min_periods` entries starting with the first non-NaN value. (GH7977)

Prior behavior (note values start at index 2, which is `min_periods` after index 0 (the index of the first non-empty value)):

```
In [66]: s = pd.Series([1, None, None, None, 2, 3])
```

```
In [51]: ewma(s, com=3., min_periods=2)
Out [51]:
0      NaN
1      NaN
2     1.000000
3     1.000000
4     1.571429
5     2.189189
dtype: float64
```

New behavior (note values start at index 4, the location of the 2nd (since `min_periods=2`) non-empty value):

```
In [2]: pd.ewma(s, com=3., min_periods=2)
Out [2]:
0      NaN
1      NaN
2      NaN
3      NaN
4     1.759644
5     2.383784
dtype: float64
```

- `ewmstd()`, `ewmvol()`, `ewmvar()`, `ewmcov()`, and `ewmcorr()` now have an optional `adjust` argument, just like `ewma()` does, affecting how the weights are calculated. The default value of `adjust` is `True`, which is backwards-compatible. See *Exponentially weighted moment functions* for details. (GH7911)
- `ewma()`, `ewmstd()`, `ewmvol()`, `ewmvar()`, `ewmcov()`, and `ewmcorr()` now have an optional `ignore_na` argument. When `ignore_na=False` (the default), missing values are taken into account in

the weights calculation. When `ignore_na=True` (which reproduces the pre-0.15.0 behavior), missing values are ignored in the weights calculation. (GH7543)

```
In [7]: pd.ewma(pd.Series([None, 1., 8.]), com=2.)
Out[7]:
0    NaN
1    1.0
2    5.2
dtype: float64

In [8]: pd.ewma(pd.Series([1., None, 8.]), com=2.,
....:           ignore_na=True) # pre-0.15.0 behavior
Out[8]:
0    1.0
1    1.0
2    5.2
dtype: float64

In [9]: pd.ewma(pd.Series([1., None, 8.]), com=2.,
....:           ignore_na=False) # new default
Out[9]:
0    1.000000
1    1.000000
2    5.846154
dtype: float64
```

**Warning:** By default (`ignore_na=False`) the `ewm*()` functions' weights calculation in the presence of missing values is different than in pre-0.15.0 versions. To reproduce the pre-0.15.0 calculation of weights in the presence of missing values one must specify explicitly `ignore_na=True`.

- Bug in `expanding_cov()`, `expanding_corr()`, `rolling_cov()`, `rolling_cor()`, `ewmcov()`, and `ewmcorr()` returning results with columns sorted by name and producing an error for non-unique columns; now handles non-unique columns and returns columns in original order (except for the case of two DataFrames with `pairwise=False`, where behavior is unchanged) (GH7542)
- Bug in `rolling_count()` and `expanding_*()` functions unnecessarily producing error message for zero-length data (GH8056)
- Bug in `rolling_apply()` and `expanding_apply()` interpreting `min_periods=0` as `min_periods=1` (GH8080)
- Bug in `expanding_std()` and `expanding_var()` for a single value producing a confusing error message (GH7900)
- Bug in `rolling_std()` and `rolling_var()` for a single value producing 0 rather than NaN (GH7900)
- Bug in `ewmstd()`, `ewmvol()`, `ewmvar()`, and `ewmcov()` calculation of de-biasing factors when `bias=False` (the default). Previously an incorrect constant factor was used, based on `adjust=True`, `ignore_na=True`, and an infinite number of observations. Now a different factor is used for each entry, based on the actual weights (analogous to the usual  $N / (N-1)$  factor). In particular, for a single point a value of NaN is returned when `bias=False`, whereas previously a value of (approximately) 0 was returned.

For example, consider the following pre-0.15.0 results for `ewmvar(..., bias=False)`, and the corresponding debiasing factors:

```
In [67]: s = pd.Series([1., 2., 0., 4.])
```

```

In [89]: ewmvar(s, com=2., bias=False)
Out [89]:
0    -2.775558e-16
1     3.000000e-01
2     9.556787e-01
3     3.585799e+00
dtype: float64

In [90]: ewmvar(s, com=2., bias=False) / ewmvar(s, com=2., bias=True)
Out [90]:
0     1.25
1     1.25
2     1.25
3     1.25
dtype: float64

```

Note that entry 0 is approximately 0, and the debiasing factors are a constant 1.25. By comparison, the following 0.15.0 results have a NaN for entry 0, and the debiasing factors are decreasing (towards 1.25):

```

In [14]: pd.ewmvar(s, com=2., bias=False)
Out [14]:
0         NaN
1     0.500000
2     1.210526
3     4.089069
dtype: float64

In [15]: pd.ewmvar(s, com=2., bias=False) / pd.ewmvar(s, com=2., bias=True)
Out [15]:
0         NaN
1     2.083333
2     1.583333
3     1.425439
dtype: float64

```

See *Exponentially weighted moment functions* for details. (GH7912)

## Improvements in the sql io module

- Added support for a `chunksize` parameter to `to_sql` function. This allows DataFrame to be written in chunks and avoid packet-size overflow errors (GH8062).
- Added support for a `chunksize` parameter to `read_sql` function. Specifying this argument will return an iterator through chunks of the query result (GH2908).
- Added support for writing `datetime.date` and `datetime.time` object columns with `to_sql` (GH6932).
- Added support for specifying a `schema` to read from/write to with `read_sql_table` and `to_sql` (GH7441, GH7952). For example:

```

df.to_sql('table', engine, schema='other_schema') # noqa F821
pd.read_sql_table('table', engine, schema='other_schema') # noqa F821

```

- Added support for writing NaN values with `to_sql` (GH2754).
- Added support for writing `datetime64` columns with `to_sql` for all database flavors (GH7103).

## Backwards incompatible API changes

### Breaking changes

API changes related to `Categorical` (see [here](#) for more details):

- The `Categorical` constructor with two arguments changed from “codes/labels and levels” to “values and levels (now called ‘categories’)”. This can lead to subtle bugs. If you use `Categorical` directly, please audit your code by changing it to use the `from_codes()` constructor.

An old function call like (prior to 0.15.0):

```
pd.Categorical([0,1,0,2,1], levels=['a', 'b', 'c'])
```

will have to adapted to the following to keep the same behaviour:

```
In [2]: pd.Categorical.from_codes([0,1,0,2,1], categories=['a', 'b', 'c'])
Out [2]:
[a, b, a, c, b]
Categories (3, object): [a, b, c]
```

API changes related to the introduction of the `Timedelta` scalar (see [above](#) for more details):

- Prior to 0.15.0 `to_timedelta()` would return a `Series` for list-like/`Series` input, and a `np.timedelta64` for scalar input. It will now return a `TimedeltaIndex` for list-like input, `Series` for `Series` input, and `Timedelta` for scalar input.

For API changes related to the rolling and expanding functions, see detailed overview [above](#).

Other notable API changes:

- Consistency when indexing with `.loc` and a list-like indexer when no values are found.

```
In [68]: df = pd.DataFrame(['a'], ['b'], index=[1, 2])

In [69]: df
Out [69]:
0
1 a
2 b

[2 rows x 1 columns]
```

In prior versions there was a difference in these two constructs:

- `df.loc[[3]]` would return a frame reindexed by 3 (with all `np.nan` values)
- `df.loc[[3], :]` would raise `KeyError`.

Both will now raise a `KeyError`. The rule is that *at least 1* indexer must be found when using a list-like and `.loc` ([GH7999](#))

Furthermore in prior versions these were also different:

- `df.loc[[1, 3]]` would return a frame reindexed by [1,3]
- `df.loc[[1, 3], :]` would raise `KeyError`.

Both will now return a frame reindex by [1,3]. E.g.

```
In [3]: df.loc[[1, 3]]
Out[3]:
    0
1   a
3  NaN

In [4]: df.loc[[1, 3], :]
Out[4]:
    0
1   a
3  NaN
```

This can also be seen in multi-axis indexing with a Panel.

```
>>> p = pd.Panel(np.arange(2 * 3 * 4).reshape(2, 3, 4),
...              items=['ItemA', 'ItemB'],
...              major_axis=[1, 2, 3],
...              minor_axis=['A', 'B', 'C', 'D'])
>>> p
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 3 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemB
Major_axis axis: 1 to 3
Minor_axis axis: A to D
```

The following would raise `KeyError` prior to 0.15.0:

```
In [5]:
Out[5]:
   ItemA  ItemD
1      3     NaN
2      7     NaN
3     11     NaN
```

Furthermore, `.loc` will raise `If` no values are found in a `MultiIndex` with a list-like indexer:

```
In [70]: s = pd.Series(np.arange(3, dtype='int64'),
...                   index=pd.MultiIndex.from_product(['A'],
...                                                     ['foo', 'bar', 'baz']],
...                   names=['one', 'two'])
...                   ).sort_index()
...                   )

In [71]: s
Out[71]:
one two
A   bar  1
    baz  2
    foo  0
Length: 3, dtype: int64

In [72]: try:
...     s.loc[['D']]
... except KeyError as e:
...     print("KeyError: " + str(e))
... 
```

- Assigning values to `None` now considers the dtype when choosing an 'empty' value (GH7941).

Previously, assigning to `None` in numeric containers changed the dtype to object (or errored, depending on the call). It now uses `NaN`:

```
In [73]: s = pd.Series([1, 2, 3])

In [74]: s.loc[0] = None

In [75]: s
Out[75]:
0    NaN
1     2.0
2     3.0
Length: 3, dtype: float64
```

`NaN` is now used similarly for datetime containers.

For object containers, we now preserve `None` values (previously these were converted to `NaN` values).

```
In [76]: s = pd.Series(["a", "b", "c"])

In [77]: s.loc[0] = None

In [78]: s
Out[78]:
0    None
1     b
2     c
Length: 3, dtype: object
```

To insert a `NaN`, you must explicitly use `np.nan`. See the *docs*.

- In prior versions, updating a pandas object inplace would not reflect in other python references to this object. (GH8511, GH5104)

```
In [79]: s = pd.Series([1, 2, 3])

In [80]: s2 = s

In [81]: s += 1.5
```

Behavior prior to v0.15.0

```
# the original object
In [5]: s
Out[5]:
0    2.5
1    3.5
2    4.5
dtype: float64

# a reference to the original object
In [7]: s2
Out[7]:
0    1
1    2
2    3
dtype: int64
```

This is now the correct behavior

```
# the original object
In [82]: s
Out [82]:
0    2.5
1    3.5
2    4.5
Length: 3, dtype: float64

# a reference to the original object
In [83]: s2
Out [83]:
0    2.5
1    3.5
2    4.5
Length: 3, dtype: float64
```

- Made both the C-based and Python engines for `read_csv` and `read_table` ignore empty lines in input as well as white space-filled lines, as long as `sep` is not white space. This is an API change that can be controlled by the keyword parameter `skip_blank_lines`. See *the docs* ([GH4466](#))
- A timeseries/index localized to UTC when inserted into a Series/DataFrame will preserve the UTC timezone and inserted as `object` dtype rather than being converted to a naive `datetime64[ns]` ([GH8411](#)).
- Bug in passing a `DatetimeIndex` with a timezone that was not being retained in `DataFrame` construction from a dict ([GH7822](#))

In prior versions this would drop the timezone, now it retains the timezone, but gives a column of `object` dtype:

```
In [84]: i = pd.date_range('1/1/2011', periods=3, freq='10s', tz='US/Eastern')

In [85]: i
Out [85]:
DatetimeIndex(['2011-01-01 00:00:00-05:00', '2011-01-01 00:00:10-05:00',
              '2011-01-01 00:00:20-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq='10S')

In [86]: df = pd.DataFrame({'a': i})

In [87]: df
Out [87]:
           a
0 2011-01-01 00:00:00-05:00
1 2011-01-01 00:00:10-05:00
2 2011-01-01 00:00:20-05:00

[3 rows x 1 columns]

In [88]: df.dtypes
Out [88]:
a    datetime64[ns, US/Eastern]
Length: 1, dtype: object
```

Previously this would have yielded a column of `datetime64` dtype, but without timezone info.

The behaviour of assigning a column to an existing dataframe as `df['a'] = i` remains unchanged (this already returned an `object` column with a timezone).

- When passing multiple levels to `stack()`, it will now raise a `ValueError` when the levels aren't all level names or all level numbers (GH7660). See *Reshaping by stacking and unstacking*.
- Raise a `ValueError` in `df.to_hdf` with 'fixed' format, if `df` has non-unique columns as the resulting file will be broken (GH7761)
- `SettingWithCopy` raise/warnings (according to the option `mode.chained_assignment`) will now be issued when setting a value on a sliced mixed-dtype `DataFrame` using chained-assignment. (GH7845, GH7950)

```
In [1]: df = pd.DataFrame(np.arange(0, 9), columns=['count'])

In [2]: df['group'] = 'b'

In [3]: df.iloc[0:5]['group'] = 'a'
/usr/local/bin/ipython:1: SettingWithCopyWarning:
A value is trying to be set on a copy of a slice from a DataFrame.
Try using .loc[row_indexer,col_indexer] = value instead

See the caveats in the documentation: https://pandas.pydata.org/pandas-docs/
↪stable/indexing.html#indexing-view-versus-copy
```

- `merge`, `DataFrame.merge`, and `ordered_merge` now return the same type as the left argument (GH7737).
- Previously an enlargement with a mixed-dtype frame would act unlike `.append` which will preserve dtypes (related GH2578, GH8176):

```
In [89]: df = pd.DataFrame([[True, 1], [False, 2]],
.....:                      columns=["female", "fitness"])
.....:

In [90]: df
Out[90]:
   female  fitness
0    True         1
1   False         2

[2 rows x 2 columns]

In [91]: df.dtypes
Out[91]:
female      bool
fitness    int64
Length: 2, dtype: object

# dtypes are now preserved
In [92]: df.loc[2] = df.loc[1]

In [93]: df
Out[93]:
   female  fitness
0    True         1
1   False         2
2   False         2

[3 rows x 2 columns]

In [94]: df.dtypes
Out[94]:
```

(continues on next page)

(continued from previous page)

```
female      bool
fitness    int64
Length: 2, dtype: object
```

- `Series.to_csv()` now returns a string when `path=None`, matching the behaviour of `DataFrame.to_csv()` (GH8215).
- `read_hdf` now raises `IOError` when a file that doesn't exist is passed in. Previously, a new, empty file was created, and a `KeyError` raised (GH7715).
- `DataFrame.info()` now ends its output with a newline character (GH8114)
- Concatenating no objects will now raise a `ValueError` rather than a bare `Exception`.
- Merge errors will now be sub-classes of `ValueError` rather than raw `Exception` (GH8501)
- `DataFrame.plot` and `Series.plot` keywords are now have consistent orders (GH8037)

## Internal refactoring

In 0.15.0 `Index` has internally been refactored to no longer sub-class `ndarray` but instead subclass `PandasObject`, similarly to the rest of the pandas objects. This change allows very easy sub-classing and creation of new index types. This should be a transparent change with only very limited API implications (GH5080, GH7439, GH7796, GH8024, GH8367, GH7997, GH8522):

- you may need to unpickle pandas version < 0.15.0 pickles using `pd.read_pickle` rather than `pickle.load`. See *pickle docs*
- when plotting with a `PeriodIndex`, the matplotlib internal axes will now be arrays of `Period` rather than a `PeriodIndex` (this is similar to how a `DatetimeIndex` passes arrays of datetimes now)
- `MultiIndex`s will now raise similarly to other pandas objects w.r.t. truth testing, see *here* (GH7897).
- When plotting a `DatetimeIndex` directly with matplotlib's `plot` function, the axis labels will no longer be formatted as dates but as integers (the internal representation of a `datetime64`). **UPDATE** This is fixed in 0.15.1, see *here*.

## Deprecations

- The attributes `Categorical.labels` and `levels` attributes are deprecated and renamed to `codes` and `categories`.
- The `outtype` argument to `pd.DataFrame.to_dict` has been deprecated in favor of `orient`. (GH7840)
- The `convert_dummies` method has been deprecated in favor of `get_dummies` (GH8140)
- The `infer_dst` argument in `tz_localize` will be deprecated in favor of `ambiguous` to allow for more flexibility in dealing with DST transitions. Replace `infer_dst=True` with `ambiguous='infer'` for the same behavior (GH7943). See *the docs* for more details.
- The top-level `pd.value_range` has been deprecated and can be replaced by `.describe()` (GH8481)
- The `Index` set operations `+` and `-` were deprecated in order to provide these for numeric type operations on certain index types. `+` can be replaced by `.union()` or `|`, and `-` by `.difference()`. Further the method name `Index.diff()` is deprecated and can be replaced by `Index.difference()` (GH8226)

```
# +
pd.Index(['a', 'b', 'c']) + pd.Index(['b', 'c', 'd'])

# should be replaced by
pd.Index(['a', 'b', 'c']).union(pd.Index(['b', 'c', 'd']))
```

```
# -
pd.Index(['a', 'b', 'c']) - pd.Index(['b', 'c', 'd'])

# should be replaced by
pd.Index(['a', 'b', 'c']).difference(pd.Index(['b', 'c', 'd']))
```

- The `infer_types` argument to `read_html()` now has no effect and is deprecated (GH7762, GH7032).

## Removal of prior version deprecations/changes

- Remove `DataFrame.delevel` method in favor of `DataFrame.reset_index`

## Enhancements

Enhancements in the importing/exporting of Stata files:

- Added support for `bool`, `uint8`, `uint16` and `uint32` data types in `to_stata` (GH7097, GH7365)
- Added conversion option when importing Stata files (GH8527)
- `DataFrame.to_stata` and `StataWriter` check string length for compatibility with limitations imposed in dta files where fixed-width strings must contain 244 or fewer characters. Attempting to write Stata dta files with strings longer than 244 characters raises a `ValueError`. (GH7858)
- `read_stata` and `StataReader` can import missing data information into a `DataFrame` by setting the argument `convert_missing` to `True`. When using this options, missing values are returned as `StataMissingValue` objects and columns containing missing values have object data type. (GH8045)

Enhancements in the plotting functions:

- Added `layout` keyword to `DataFrame.plot`. You can pass a tuple of `(rows, columns)`, one of which can be `-1` to automatically infer (GH6667, GH8071).
- Allow to pass multiple axes to `DataFrame.plot`, `hist` and `boxplot` (GH5353, GH6970, GH7069)
- Added support for `c`, `colormap` and `colorbar` arguments for `DataFrame.plot` with `kind='scatter'` (GH7780)
- Histogram from `DataFrame.plot` with `kind='hist'` (GH7809), See *the docs*.
- Boxplot from `DataFrame.plot` with `kind='box'` (GH7998), See *the docs*.

Other:

- `read_csv` now has a keyword parameter `float_precision` which specifies which floating-point converter the C engine should use during parsing, see *here* (GH8002, GH8044)
- Added `searchsorted` method to `Series` objects (GH7447)
- `describe()` on mixed-types `DataFrames` is more flexible. Type-based column filtering is now possible via the `include/exclude` arguments. See *the docs* (GH8164).

```
In [95]: df = pd.DataFrame({'catA': ['foo', 'foo', 'bar'] * 8,
.....:                    'catB': ['a', 'b', 'c', 'd'] * 6,
.....:                    'numC': np.arange(24),
.....:                    'numD': np.arange(24.) + .5})
.....:
```

```
In [96]: df.describe(include=["object"])
Out[96]:
```

|        | catA | catB |
|--------|------|------|
| count  | 24   | 24   |
| unique | 2    | 4    |
| top    | foo  | d    |
| freq   | 16   | 6    |

[4 rows x 2 columns]

```
In [97]: df.describe(include=["number", "object"], exclude=["float"])
Out[97]:
```

|        | catA | catB | numC      |
|--------|------|------|-----------|
| count  | 24   | 24   | 24.000000 |
| unique | 2    | 4    | NaN       |
| top    | foo  | d    | NaN       |
| freq   | 16   | 6    | NaN       |
| mean   | NaN  | NaN  | 11.500000 |
| std    | NaN  | NaN  | 7.071068  |
| min    | NaN  | NaN  | 0.000000  |
| 25%    | NaN  | NaN  | 5.750000  |
| 50%    | NaN  | NaN  | 11.500000 |
| 75%    | NaN  | NaN  | 17.250000 |
| max    | NaN  | NaN  | 23.000000 |

[11 rows x 3 columns]

Requesting all columns is possible with the shorthand 'all'

```
In [98]: df.describe(include='all')
Out[98]:
```

|        | catA | catB | numC      | numD      |
|--------|------|------|-----------|-----------|
| count  | 24   | 24   | 24.000000 | 24.000000 |
| unique | 2    | 4    | NaN       | NaN       |
| top    | foo  | d    | NaN       | NaN       |
| freq   | 16   | 6    | NaN       | NaN       |
| mean   | NaN  | NaN  | 11.500000 | 12.000000 |
| std    | NaN  | NaN  | 7.071068  | 7.071068  |
| min    | NaN  | NaN  | 0.000000  | 0.500000  |
| 25%    | NaN  | NaN  | 5.750000  | 6.250000  |
| 50%    | NaN  | NaN  | 11.500000 | 12.000000 |
| 75%    | NaN  | NaN  | 17.250000 | 17.750000 |
| max    | NaN  | NaN  | 23.000000 | 23.500000 |

[11 rows x 4 columns]

Without those arguments, `describe` will behave as before, including only numerical columns or, if none are, only categorical columns. See also the *docs*

- Added `split` as an option to the `orient` argument in `pd.DataFrame.to_dict`. (GH7840)
- The `get_dummies` method can now be used on DataFrames. By default only categorical columns are encoded as 0's and 1's, while other columns are left untouched.

```
In [99]: df = pd.DataFrame({'A': ['a', 'b', 'a'], 'B': ['c', 'c', 'b'],
.....:                    'C': [1, 2, 3]})
.....:

In [100]: pd.get_dummies(df)
Out[100]:
   C  A_a  A_b  B_b  B_c
0  1    1    0    0    1
1  2    0    1    0    1
2  3    1    0    1    0

[3 rows x 5 columns]
```

- `PeriodIndex` supports resolution as the same as `DatetimeIndex` (GH7708)
- `pandas.tseries.holiday` has added support for additional holidays and ways to observe holidays (GH7070)
- `pandas.tseries.holiday.Holiday` now supports a list of offsets in Python3 (GH7070)
- `pandas.tseries.holiday.Holiday` now supports a `days_of_week` parameter (GH7070)
- `GroupBy.nth()` now supports selecting multiple `nth` values (GH7910)

```
In [101]: business_dates = pd.date_range(start='4/1/2014', end='6/30/2014', freq=
↪ 'B')

In [102]: df = pd.DataFrame(1, index=business_dates, columns=['a', 'b'])

# get the first, 4th, and last date index for each month
In [103]: df.groupby([df.index.year, df.index.month]).nth([0, 3, -1])
Out[103]:
      a  b
2014 4  1  1
      4  1  1
      4  1  1
      5  1  1
      5  1  1
      5  1  1
      6  1  1
      6  1  1
      6  1  1

[9 rows x 2 columns]
```

- `Period` and `PeriodIndex` supports addition/subtraction with `timedelta`-likes (GH7966)

If `Period` `freq` is `D`, `H`, `T`, `S`, `L`, `U`, `N`, `Timedelta`-like can be added if the result can have same `freq`. Otherwise, only the same offsets can be added.

```
In [104]: idx = pd.period_range('2014-07-01 09:00', periods=5, freq='H')

In [105]: idx
Out[105]:
PeriodIndex(['2014-07-01 09:00', '2014-07-01 10:00', '2014-07-01 11:00',
            '2014-07-01 12:00', '2014-07-01 13:00'],
            dtype='period[H]', freq='H')

In [106]: idx + pd.offsets.Hour(2)
```

(continues on next page)

(continued from previous page)

```

Out [106]:
PeriodIndex(['2014-07-01 11:00', '2014-07-01 12:00', '2014-07-01 13:00',
            '2014-07-01 14:00', '2014-07-01 15:00'],
            dtype='period[H]', freq='H')

In [107]: idx + pd.Timedelta('120m')
Out [107]:
PeriodIndex(['2014-07-01 11:00', '2014-07-01 12:00', '2014-07-01 13:00',
            '2014-07-01 14:00', '2014-07-01 15:00'],
            dtype='period[H]', freq='H')

In [108]: idx = pd.period_range('2014-07', periods=5, freq='M')

In [109]: idx
Out [109]: PeriodIndex(['2014-07', '2014-08', '2014-09', '2014-10', '2014-11'],
            ↪dtype='period[M]', freq='M')

In [110]: idx + pd.offsets.MonthEnd(3)
Out [110]: PeriodIndex(['2014-10', '2014-11', '2014-12', '2015-01', '2015-02'],
            ↪dtype='period[M]', freq='M')

```

- Added experimental compatibility with `openpyxl` for versions  $\geq 2.0$ . The `DataFrame.to_excel` method engine keyword now recognizes `openpyxl1` and `openpyxl2` which will explicitly require `openpyxl v1` and `v2` respectively, failing if the requested version is not available. The `openpyxl` engine is now a meta-engine that automatically uses whichever version of `openpyxl` is installed. ([GH7177](#))
- `DataFrame.fillna` can now accept a `DataFrame` as a fill value ([GH8377](#))
- Passing multiple levels to `stack()` will now work when multiple level numbers are passed ([GH7660](#)). See *Reshaping by stacking and unstacking*.
- `set_names()`, `set_labels()`, and `set_levels()` methods now take an optional `level` keyword argument to all modification of specific level(s) of a `MultiIndex`. Additionally `set_names()` now accepts a scalar string value when operating on an `Index` or on a specific level of a `MultiIndex` ([GH7792](#))

```

In [111]: idx = pd.MultiIndex.from_product(['a'], range(3), list("pqr")),
            .....:                      names=['foo', 'bar', 'baz'])
            .....:

In [112]: idx.set_names('qux', level=0)
Out [112]:
MultiIndex([('a', 0, 'p'),
            ('a', 0, 'q'),
            ('a', 0, 'r'),
            ('a', 1, 'p'),
            ('a', 1, 'q'),
            ('a', 1, 'r'),
            ('a', 2, 'p'),
            ('a', 2, 'q'),
            ('a', 2, 'r')],
            names=['qux', 'bar', 'baz'])

In [113]: idx.set_names(['qux', 'corge'], level=[0, 1])
Out [113]:
MultiIndex([('a', 0, 'p'),
            ('a', 0, 'q'),
            ('a', 0, 'r'),

```

(continues on next page)

(continued from previous page)

```

        ('a', 1, 'p'),
        ('a', 1, 'q'),
        ('a', 1, 'r'),
        ('a', 2, 'p'),
        ('a', 2, 'q'),
        ('a', 2, 'r')],
        names=['qux', 'corge', 'baz'])

In [114]: idx.set_levels(['a', 'b', 'c'], level='bar')
Out[114]:
MultiIndex([(a, 'a', 'p'),
            (a, 'a', 'q'),
            (a, 'a', 'r'),
            (a, 'b', 'p'),
            (a, 'b', 'q'),
            (a, 'b', 'r'),
            (a, 'c', 'p'),
            (a, 'c', 'q'),
            (a, 'c', 'r')],
            names=['foo', 'bar', 'baz'])

In [115]: idx.set_levels(['a', 'b', 'c'], [1, 2, 3], level=[1, 2])
Out[115]:
MultiIndex([(a, 'a', 1),
            (a, 'a', 2),
            (a, 'a', 3),
            (a, 'b', 1),
            (a, 'b', 2),
            (a, 'b', 3),
            (a, 'c', 1),
            (a, 'c', 2),
            (a, 'c', 3)],
            names=['foo', 'bar', 'baz'])

```

- `Index.isin` now supports a `level` argument to specify which index level to use for membership tests (GH7892, GH7890)

```

In [1]: idx = pd.MultiIndex.from_product([[0, 1], ['a', 'b', 'c']])
In [2]: idx.values
Out[2]: array([(0, 'a'), (0, 'b'), (0, 'c'), (1, 'a'), (1, 'b'), (1, 'c')],
             dtype=object)

In [3]: idx.isin(['a', 'c', 'e'], level=1)
Out[3]: array([ True, False,  True,  True, False,  True], dtype=bool)

```

- Index now supports duplicated and `drop_duplicates`. (GH4060)

```

In [116]: idx = pd.Index([1, 2, 3, 4, 1, 2])
In [117]: idx
Out[117]: Int64Index([1, 2, 3, 4, 1, 2], dtype='int64')

In [118]: idx.duplicated()
Out[118]: array([False, False, False, False,  True,  True])

```

(continues on next page)

(continued from previous page)

```
In [119]: idx.drop_duplicates()
Out[119]: Int64Index([1, 2, 3, 4], dtype='int64')
```

- add `copy=True` argument to `pd.concat` to enable pass through of complete blocks (GH8252)
- Added support for numpy 1.8+ data types (`bool_`, `int_`, `float_`, `string_`) for conversion to R dataframe (GH8400)

## Performance

- Performance improvements in `DatetimeIndex.__iter__` to allow faster iteration (GH7683)
- Performance improvements in `Period` creation (and `PeriodIndex.setitem`) (GH5155)
- Improvements in `Series.transform` for significant performance gains (revised) (GH6496)
- Performance improvements in `StataReader` when reading large files (GH8040, GH8073)
- Performance improvements in `StataWriter` when writing large files (GH8079)
- Performance and memory usage improvements in multi-key `groupby` (GH8128)
- Performance improvements in `groupby .agg` and `.apply` where builtins `max/min` were not mapped to numpy/cythonized versions (GH7722)
- Performance improvement in writing to sql (`to_sql`) of up to 50% (GH8208).
- Performance benchmarking of `groupby` for large value of `ngroups` (GH6787)
- Performance improvement in `CustomBusinessDay`, `CustomBusinessMonth` (GH8236)
- Performance improvement for `MultiIndex.values` for multi-level indexes containing datetimes (GH8543)

## Bug fixes

- Bug in `pivot_table`, when using margins and a dict `aggfunc` (GH8349)
- Bug in `read_csv` where `squeeze=True` would return a view (GH8217)
- Bug in checking of table name in `read_sql` in certain cases (GH7826).
- Bug in `DataFrame.groupby` where `Groupby` does not recognize level when frequency is specified (GH7885)
- Bug in multiindexes dtypes getting mixed up when `DataFrame` is saved to SQL table (GH8021)
- Bug in `Series` 0-division with a float and integer operand dtypes (GH7785)
- Bug in `Series.astype("unicode")` not calling `unicode` on the values correctly (GH7758)
- Bug in `DataFrame.as_matrix()` with mixed `datetime64[ns]` and `timedelta64[ns]` dtypes (GH7778)
- Bug in `HDFStore.select_column()` not preserving UTC timezone info when selecting a `DatetimeIndex` (GH7777)
- Bug in `to_datetime` when `format='%Y%m%d'` and `coerce=True` are specified, where previously an object array was returned (rather than a coerced time-series with `NaT`), (GH7930)
- Bug in `DatetimeIndex` and `PeriodIndex` in-place addition and subtraction cause different result from normal one (GH6527)

- Bug in adding and subtracting `PeriodIndex` with `PeriodIndex` raise `TypeError` (GH7741)
- Bug in `combine_first` with `PeriodIndex` data raises `TypeError` (GH3367)
- Bug in `MultiIndex` slicing with missing indexers (GH7866)
- Bug in `MultiIndex` slicing with various edge cases (GH8132)
- Regression in `MultiIndex` indexing with a non-scalar type object (GH7914)
- Bug in `Timestamp` comparisons with `==` and `int64` dtype (GH8058)
- Bug in pickles contains `DateOffset` may raise `AttributeError` when `normalize` attribute is referred internally (GH7748)
- Bug in `Panel` when using `major_xs` and `copy=False` is passed (deprecation warning fails because of missing warnings) (GH8152).
- Bug in pickle deserialization that failed for pre-0.14.1 containers with dup items trying to avoid ambiguity when matching block and manager items, when there's only one block there's no ambiguity (GH7794)
- Bug in putting a `PeriodIndex` into a `Series` would convert to `int64` dtype, rather than object of `Periods` (GH7932)
- Bug in `HDFStore` iteration when passing a `where` (GH8014)
- Bug in `DataFrameGroupby.transform` when transforming with a passed non-sorted key (GH8046, GH8430)
- Bug in repeated timeseries line and area plot may result in `ValueError` or incorrect kind (GH7733)
- Bug in inference in a `MultiIndex` with `datetime.date` inputs (GH7888)
- Bug in `get` where an `IndexError` would not cause the default value to be returned (GH7725)
- Bug in `offsets.apply`, `rollforward` and `rollback` may reset nanosecond (GH7697)
- Bug in `offsets.apply`, `rollforward` and `rollback` may raise `AttributeError` if `Timestamp` has `dateutil.tzinfo` (GH7697)
- Bug in sorting a `MultiIndex` frame with a `Float64Index` (GH8017)
- Bug in inconsistent panel setitem with a rhs of a `DataFrame` for alignment (GH7763)
- Bug in `is_superperiod` and `is_subperiod` cannot handle higher frequencies than `S` (GH7760, GH7772, GH7803)
- Bug in 32-bit platforms with `Series.shift` (GH8129)
- Bug in `PeriodIndex.unique` returns `int64 np.ndarray` (GH7540)
- Bug in `groupby.apply` with a non-affecting mutation in the function (GH8467)
- Bug in `DataFrame.reset_index` which has `MultiIndex` contains `PeriodIndex` or `DatetimeIndex` with `tz` raises `ValueError` (GH7746, GH7793)
- Bug in `DataFrame.plot` with `subplots=True` may draw unnecessary minor xticks and yticks (GH7801)
- Bug in `StataReader` which did not read variable labels in 117 files due to difference between Stata documentation and implementation (GH7816)
- Bug in `StataReader` where strings were always converted to 244 characters-fixed width irrespective of underlying string size (GH7858)
- Bug in `DataFrame.plot` and `Series.plot` may ignore `rot` and `fontsize` keywords (GH7844)
- Bug in `DatetimeIndex.value_counts` doesn't preserve `tz` (GH7735)

- Bug in `PeriodIndex.value_counts` results in `Int64Index` (GH7735)
- Bug in `DataFrame.join` when doing left join on index and there are multiple matches (GH5391)
- Bug in `GroupBy.transform()` where int groups with a transform that didn't preserve the index were incorrectly truncated (GH7972).
- Bug in `groupby` where callable objects without name attributes would take the wrong path, and produce a `DataFrame` instead of a `Series` (GH7929)
- Bug in `groupby` error message when a `DataFrame` grouping column is duplicated (GH7511)
- Bug in `read_html` where the `infer_types` argument forced coercion of date-likes incorrectly (GH7762, GH7032).
- Bug in `Series.str.cat` with an index which was filtered as to not include the first item (GH7857)
- Bug in `Timestamp` cannot parse nanosecond from string (GH7878)
- Bug in `Timestamp` with string offset and `tz` results incorrect (GH7833)
- Bug in `tslib.tz_convert` and `tslib.tz_convert_single` may return different results (GH7798)
- Bug in `DatetimeIndex.intersection` of non-overlapping timestamps with `tz` raises `IndexError` (GH7880)
- Bug in alignment with `TimeOps` and non-unique indexes (GH8363)
- Bug in `GroupBy.filter()` where fast path vs. slow path made the filter return a non scalar value that appeared valid but wasn't (GH7870).
- Bug in `date_range()/DatetimeIndex()` when the timezone was inferred from input dates yet incorrect times were returned when crossing DST boundaries (GH7835, GH7901).
- Bug in `to_excel()` where a negative sign was being prepended to positive infinity and was absent for negative infinity (GH7949)
- Bug in area plot draws legend with incorrect alpha when `stacked=True` (GH8027)
- `Period` and `PeriodIndex` addition/subtraction with `np.timedelta64` results in incorrect internal representations (GH7740)
- Bug in `Holiday` with no offset or observance (GH7987)
- Bug in `DataFrame.to_latex` formatting when columns or index is a `MultiIndex` (GH7982).
- Bug in `DateOffset` around Daylight Savings Time produces unexpected results (GH5175).
- Bug in `DataFrame.shift` where empty columns would throw `ZeroDivisionError` on numpy 1.7 (GH8019)
- Bug in installation where `html_encoding/*.html` wasn't installed and therefore some tests were not running correctly (GH7927).
- Bug in `read_html` where bytes objects were not tested for in `_read` (GH7927).
- Bug in `DataFrame.stack()` when one of the column levels was a datelike (GH8039)
- Bug in broadcasting numpy scalars with `DataFrame` (GH8116)
- Bug in `pivot_table` performed with nameless index and columns raises `KeyError` (GH8103)
- Bug in `DataFrame.plot(kind='scatter')` draws points and errorbars with different colors when the color is specified by `c` keyword (GH8081)
- Bug in `Float64Index` where `iat` and `at` were not testing and were failing (GH8092).

- Bug in `DataFrame.boxplot()` where y-limits were not set correctly when producing multiple axes (GH7528, GH5517).
- Bug in `read_csv` where line comments were not handled correctly given a custom line terminator or `delim_whitespace=True` (GH8122).
- Bug in `read_html` where empty tables caused a `StopIteration` (GH7575)
- Bug in casting when setting a column in a same-dtype block (GH7704)
- Bug in accessing groups from a `GroupBy` when the original grouper was a tuple (GH8121).
- Bug in `.at` that would accept integer indexers on a non-integer index and do fallback (GH7814)
- Bug with kde plot and NaNs (GH8182)
- Bug in `GroupBy.count` with float32 data type where nan values were not excluded (GH8169).
- Bug with stacked barplots and NaNs (GH8175).
- Bug in `resample` with non evenly divisible offsets (e.g. '7s') (GH8371)
- Bug in interpolation methods with the `limit` keyword when no values needed interpolating (GH7173).
- Bug where `col_space` was ignored in `DataFrame.to_string()` when `header=False` (GH8230).
- Bug with `DatetimeIndex.asof` incorrectly matching partial strings and returning the wrong date (GH8245).
- Bug in plotting methods modifying the global matplotlib rcParams (GH8242).
- Bug in `DataFrame.__setitem__` that caused errors when setting a dataframe column to a sparse array (GH8131)
- Bug where `Dataframe.boxplot()` failed when entire column was empty (GH8181).
- Bug with messed variables in `radviz` visualization (GH8199).
- Bug in interpolation methods with the `limit` keyword when no values needed interpolating (GH7173).
- Bug where `col_space` was ignored in `DataFrame.to_string()` when `header=False` (GH8230).
- Bug in `to_clipboard` that would clip long column data (GH8305)
- Bug in `DataFrame` terminal display: Setting `max_column/max_rows` to zero did not trigger auto-resizing of dfs to fit terminal width/height (GH7180).
- Bug in OLS where running with "cluster" and "nw\_lags" parameters did not work correctly, but also did not throw an error (GH5884).
- Bug in `DataFrame.dropna` that interpreted non-existent columns in the subset argument as the 'last column' (GH8303)
- Bug in `Index.intersection` on non-monotonic non-unique indexes (GH8362).
- Bug in masked series assignment where mismatching types would break alignment (GH8387)
- Bug in `NDFrame.equals` gives false negatives with `dtype=object` (GH8437)
- Bug in assignment with indexer where type diversity would break alignment (GH8258)
- Bug in `NDFrame.loc` indexing when row/column names were lost when target was a list/ndarray (GH6552)
- Regression in `NDFrame.loc` indexing when rows/columns were converted to `Float64Index` if target was an empty list/ndarray (GH7774)
- Bug in `Series` that allows it to be indexed by a `DataFrame` which has unexpected results. Such indexing is no longer permitted (GH8444)

- Bug in item assignment of a `DataFrame` with `MultiIndex` columns where right-hand-side columns were not aligned ([GH7655](#))
- Suppress `FutureWarning` generated by `NumPy` when comparing object arrays containing `NaN` for equality ([GH7065](#))
- Bug in `DataFrame.eval()` where the `dtype` of the `not` operator (`~`) was not correctly inferred as `bool`.

## 6.13 Version 0.14

### 6.13.1 v0.14.1 (July 11, 2014)

{{ header }}

This is a minor release from 0.14.0 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

- Highlights include:
  - New methods `select_dtypes()` to select columns based on the dtype and `sem()` to calculate the standard error of the mean.
  - Support for dateutil timezones (see *docs*).
  - Support for ignoring full line comments in the `read_csv()` text parser.
  - New documentation section on *Options and Settings*.
  - Lots of bug fixes.
- *Enhancements*
- *API Changes*
- *Performance Improvements*
- *Experimental Changes*
- *Bug Fixes*

## API changes

- Openpyxl now raises a `ValueError` on construction of the openpyxl writer instead of warning on pandas import (GH7284).
- For `StringMethods.extract`, when no match is found, the result - only containing NaN values - now also has `dtype=object` instead of `float` (GH7242)
- `Period` objects no longer raise a `TypeError` when compared using `==` with another object that *isn't* a `Period`. Instead when comparing a `Period` with another object using `==` if the other object isn't a `Period` `False` is returned. (GH7376)
- Previously, the behaviour on resetting the time or not in `offsets.apply`, `rollforward` and `rollback` operations differed between offsets. With the support of the `normalize` keyword for all offsets (see below) with a default value of `False` (preserve time), the behaviour changed for certain offsets (`BusinessMonthBegin`, `MonthEnd`, `BusinessMonthEnd`, `CustomBusinessMonthEnd`, `BusinessYearBegin`, `LastWeekOfMonth`, `FY5253Quarter`, `LastWeekOfMonth`, `Easter`):

```
In [6]: from pandas.tseries import offsets
In [7]: d = pd.Timestamp('2014-01-01 09:00')
# old behaviour < 0.14.1
In [8]: d + offsets.MonthEnd()
Out[8]: pd.Timestamp('2014-01-31 00:00:00')
```

Starting from 0.14.1 all offsets preserve time by default. The old behaviour can be obtained with `normalize=True`

```
# new behaviour
In [1]: d + offsets.MonthEnd()
Out[1]: Timestamp('2014-01-31 09:00:00')
In [2]: d + offsets.MonthEnd(normalize=True)
Out[2]: Timestamp('2014-01-31 00:00:00')
```

Note that for the other offsets the default behaviour did not change.

- Add back `#N/A` `N/A` as a default NA value in text parsing, (regression from 0.12) (GH5521)
- Raise a `TypeError` on inplace-setting with a `.where` and a non `np.nan` value as this is inconsistent with a set-item expression like `df[mask] = None` (GH7656)

## Enhancements

- Add `dropna` argument to `value_counts` and `nunique` (GH5569).
- Add `select_dtypes()` method to allow selection of columns based on dtype (GH7316). See *the docs*.
- All offsets supports the `normalize` keyword to specify whether `offsets.apply`, `rollforward` and `rollback` resets the time (hour, minute, etc) or not (default `False`, preserves time) (GH7156):

```
import pandas.tseries.offsets as offsets

day = offsets.Day()
day.apply(pd.Timestamp('2014-01-01 09:00'))

day = offsets.Day(normalize=True)
day.apply(pd.Timestamp('2014-01-01 09:00'))
```

- `PeriodIndex` is represented as the same format as `DatetimeIndex` (GH7601)
- `StringMethods` now work on empty `Series` (GH7242)
- The file parsers `read_csv` and `read_table` now ignore line comments provided by the parameter `comment`, which accepts only a single character for the C reader. In particular, they allow for comments before file data begins (GH2685)
- Add `NotImplementedError` for simultaneous use of `chunksize` and `nrows` for `read_csv()` (GH6774).
- Tests for basic reading of public S3 buckets now exist (GH7281).
- `read_html` now sports an `encoding` argument that is passed to the underlying parser library. You can use this to read non-ascii encoded web pages (GH7323).
- `read_excel` now supports reading from URLs in the same way that `read_csv` does. (GH6809)
- Support for `dateutil` timezones, which can now be used in the same way as `pytz` timezones across pandas. (GH4688)

```
In [3]: rng = pd.date_range('3/6/2012 00:00', periods=10, freq='D',
...:                       tz='dateutil/Europe/London')
...:
...:

In [4]: rng.tz
Out [4]: tzfile('/usr/share/zoneinfo/Europe/London')
```

See the docs.

- Implemented `sem` (standard error of the mean) operation for `Series`, `DataFrame`, `Panel`, and `Groupby` (GH6897)
- Add `nlargest` and `nsmallest` to the `Series` `groupby` whitelist, which means you can now use these methods on a `SeriesGroupBy` object (GH7053).
- All offsets apply, `rollforward` and `rollback` can now handle `np.datetime64`, previously results in `ApplyTypeError` (GH7452)
- `Period` and `PeriodIndex` can contain `NaT` in its values (GH7485)
- Support pickling `Series`, `DataFrame` and `Panel` objects with non-unique labels along `item` axis (`index`, `columns` and `items` respectively) (GH7370).
- Improved inference of `datetime/timedelta` with mixed null objects. Regression from 0.13.1 in interpretation of an object `Index` with all null elements (GH7431)

## Performance

- Improvements in `dtype` inference for numeric operations involving yielding performance gains for dtypes: `int64`, `timedelta64`, `datetime64` (GH7223)
- Improvements in `Series.transform` for significant performance gains (GH6496)
- Improvements in `DataFrame.transform` with `ufuncs` and built-in grouper functions for significant performance gains (GH7383)
- Regression in `groupby` aggregation of `datetime64` dtypes (GH7555)
- Improvements in `MultiIndex.from_product` for large iterables (GH7627)

## Experimental

- `pandas.io.data.Options` has a new method, `get_all_data` method, and now consistently returns a `MultiIndexed DataFrame` (GH5602)
- `io.gbq.read_gbq` and `io.gbq.to_gbq` were refactored to remove the dependency on the Google `bq.py` command line client. This submodule now uses `httplib2` and the Google `apiclient` and `oauth2client` API client libraries which should be more stable and, therefore, reliable than `bq.py`. See *the docs*. (GH6937).

## Bug fixes

- Bug in `DataFrame.where` with a symmetric shaped frame and a passed other of a `DataFrame` (GH7506)
- Bug in `Panel` indexing with a `MultiIndex` axis (GH7516)
- Regression in datetimelike slice indexing with a duplicated index and non-exact end-points (GH7523)
- Bug in `setitem` with list-of-lists and single vs mixed types (GH7551:)
- Bug in time ops with non-aligned `Series` (GH7500)
- Bug in `timedelta` inference when assigning an incomplete `Series` (GH7592)
- Bug in `groupby.nth` with a `Series` and integer-like column name (GH7559)
- Bug in `Series.get` with a boolean accessor (GH7407)
- Bug in `value_counts` where `NaT` did not qualify as missing (`NaN`) (GH7423)
- Bug in `to_timedelta` that accepted invalid units and misinterpreted 'm/h' (GH7611, GH6423)
- Bug in line plot doesn't set correct `xlim` if `secondary_y=True` (GH7459)
- Bug in grouped `hist` and `scatter` plots use old `figsize` default (GH7394)
- Bug in plotting subplots with `DataFrame.plot`, `hist` clears passed `ax` even if the number of subplots is one (GH7391).
- Bug in plotting subplots with `DataFrame.boxplot` with `by` kw raises `ValueError` if the number of subplots exceeds 1 (GH7391).
- Bug in subplots displays `ticklabels` and `labels` in different rule (GH5897)
- Bug in `Panel.apply` with a `MultiIndex` as an axis (GH7469)
- Bug in `DatetimeIndex.insert` doesn't preserve name and `tz` (GH7299)
- Bug in `DatetimeIndex.asobject` doesn't preserve name (GH7299)
- Bug in `MultiIndex` slicing with datetimelike ranges (strings and `Timestamps`), (GH7429)
- Bug in `Index.min` and `max` doesn't handle `nan` and `NaT` properly (GH7261)
- Bug in `PeriodIndex.min/max` results in `int` (GH7609)
- Bug in `resample` where `fill_method` was ignored if you passed `how` (GH2073)
- Bug in `TimeGrouper` doesn't exclude column specified by `key` (GH7227)
- Bug in `DataFrame` and `Series` `bar` and `barh` plot raises `TypeError` when `bottom` and `left` keyword is specified (GH7226)
- Bug in `DataFrame.hist` raises `TypeError` when it contains non numeric column (GH7277)
- Bug in `Index.delete` does not preserve name and `freq` attributes (GH7302)

- Bug in `DataFrame.query()/eval` where local string variables with the `@` sign were being treated as temporaries attempting to be deleted (GH7300).
- Bug in `Float64Index` which didn't allow duplicates (GH7149).
- Bug in `DataFrame.replace()` where truthy values were being replaced (GH7140).
- Bug in `StringMethods.extract()` where a single match group Series would use the matcher's name instead of the group name (GH7313).
- Bug in `isnull()` when `mode.use_inf_as_null == True` where `isnull` wouldn't test `True` when it encountered an `inf/-inf` (GH7315).
- Bug in `inferred_freq` results in `None` for eastern hemisphere timezones (GH7310)
- Bug in `Easter` returns incorrect date when offset is negative (GH7195)
- Bug in broadcasting with `.div`, integer dtypes and divide-by-zero (GH7325)
- Bug in `CustomBusinessDay.apply` raises `NameError` when `np.datetime64` object is passed (GH7196)
- Bug in `MultiIndex.append, concat` and `pivot_table` don't preserve timezone (GH6606)
- Bug in `.loc` with a list of indexers on a single-multi index level (that is not nested) (GH7349)
- Bug in `Series.map` when mapping a dict with tuple keys of different lengths (GH7333)
- Bug all `StringMethods` now work on empty Series (GH7242)
- Fix delegation of `read_sql` to `read_sql_query` when query does not contain 'select' (GH7324).
- Bug where a string column name assignment to a `DataFrame` with a `Float64Index` raised a `TypeError` during a call to `np.isnan` (GH7366).
- Bug where `NDFrame.replace()` didn't correctly replace objects with `Period` values (GH7379).
- Bug in `.ix` `getitem` should always return a `Series` (GH7150)
- Bug in `MultiIndex` slicing with incomplete indexers (GH7399)
- Bug in `MultiIndex` slicing with a step in a sliced level (GH7400)
- Bug where negative indexers in `DatetimeIndex` were not correctly sliced (GH7408)
- Bug where `NaT` wasn't repr'd correctly in a `MultiIndex` (GH7406, GH7409).
- Bug where `bool` objects were converted to `nan` in `convert_objects` (GH7416).
- Bug in `quantile` ignoring the `axis` keyword argument (GH7306)
- Bug where `nanops._maybe_null_out` doesn't work with complex numbers (GH7353)
- Bug in several `nanops` functions when `axis==0` for 1-dimensional `nan` arrays (GH7354)
- Bug where `nanops.nanmedian` doesn't work when `axis==None` (GH7352)
- Bug where `nanops._has_infs` doesn't work with many dtypes (GH7357)
- Bug in `StataReader.data` where reading a 0-observation `dta` failed (GH7369)
- Bug in `StataReader` when reading `Stata 13 (117)` files containing fixed width strings (GH7360)
- Bug in `StataWriter` where encoding was ignored (GH7286)
- Bug in `DatetimeIndex` comparison doesn't handle `NaT` properly (GH7529)
- Bug in passing input with `tzinfo` to some offsets `apply, rollforward` or `rollback` resets `tzinfo` or raises `ValueError` (GH7465)

- Bug in `DatetimeIndex.to_period`, `PeriodIndex.asobject`, `PeriodIndex.to_timestamp` doesn't preserve name (GH7485)
- Bug in `DatetimeIndex.to_period` and `PeriodIndex.to_timestamp` handle NaT incorrectly (GH7228)
- Bug in `offsets.apply`, `rollforward` and `rollback` may return normal datetime (GH7502)
- Bug in `resample` raises `ValueError` when target contains NaT (GH7227)
- Bug in `Timestamp.tz_localize` resets nanosecond info (GH7534)
- Bug in `DatetimeIndex.asobject` raises `ValueError` when it contains NaT (GH7539)
- Bug in `Timestamp.__new__` doesn't preserve nanosecond properly (GH7610)
- Bug in `Index.astype(float)` where it would return an object dtype `Index` (GH7464).
- Bug in `DataFrame.reset_index` loses tz (GH3950)
- Bug in `DatetimeIndex.freqstr` raises `AttributeError` when `freq` is `None` (GH7606)
- Bug in `GroupBy.size` created by `TimeGrouper` raises `AttributeError` (GH7453)
- Bug in single column bar plot is misaligned (GH7498).
- Bug in area plot with tz-aware time series raises `ValueError` (GH7471)
- Bug in non-monotonic `Index.union` may preserve name incorrectly (GH7458)
- Bug in `DatetimeIndex.intersection` doesn't preserve timezone (GH4690)
- Bug in `rolling_var` where a window larger than the array would raise an error (GH7297)
- Bug with last plotted timeseries dictating `xlim` (GH2960)
- Bug with secondary y axis not being considered for timeseries `xlim` (GH3490)
- Bug in `Float64Index` assignment with a non scalar indexer (GH7586)
- Bug in `pandas.core.strings.str_contains` does not properly match in a case insensitive fashion when `regex=False` and `case=False` (GH7505)
- Bug in `expanding_cov`, `expanding_corr`, `rolling_cov`, and `rolling_corr` for two arguments with mismatched index (GH7512)
- Bug in `to_sql` taking the boolean column as text column (GH7678)
- Bug in grouped `hist` doesn't handle `rot` kw and `sharex` kw properly (GH7234)
- Bug in `.loc` performing fallback integer indexing with object dtype indices (GH7496)
- Bug (regression) in `PeriodIndex` constructor when passed `Series` objects (GH7701).

### 6.13.2 v0.14.0 (May 31 , 2014)

{{ header }}

This is a major release from 0.13.1 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

- Highlights include:
  - Officially support Python 3.4
  - SQL interfaces updated to use `sqlalchemy`, See *Here*.
  - Display interface changes, See *Here*
  - MultiIndexing Using Slicers, See *Here*.
  - Ability to join a singly-indexed DataFrame with a MultiIndexed DataFrame, see *Here*
  - More consistency in groupby results and more flexible groupby specifications, See *Here*
  - Holiday calendars are now supported in `CustomBusinessDay`, see *Here*
  - Several improvements in plotting functions, including: hexbin, area and pie plots, see *Here*.
  - Performance doc section on I/O operations, See *Here*
- *Other Enhancements*
- *API Changes*
- *Text Parsing API Changes*
- *Groupby API Changes*
- *Performance Improvements*
- *Prior Deprecations*
- *Deprecations*
- *Known Issues*
- *Bug Fixes*

**Warning:** In 0.14.0 all `NDFrame` based containers have undergone significant internal refactoring. Before that each block of homogeneous data had its own labels and extra care was necessary to keep those in sync with the parent container's labels. This should not have any visible user/API behavior changes ([GH6745](#))

## API changes

- `read_excel` uses 0 as the default sheet ([GH6573](#))
- `iloc` will now accept out-of-bounds indexers for slices, e.g. a value that exceeds the length of the object being indexed. These will be excluded. This will make pandas conform more with python/numpy indexing of out-of-bounds values. A single indexer that is out-of-bounds and drops the dimensions of the object will still raise `IndexError` ([GH6296](#), [GH6299](#)). This could result in an empty axis (e.g. an empty DataFrame being returned)

```
In [1]: df1 = pd.DataFrame(np.random.randn(5, 2), columns=list('AB'))
```

```
In [2]: df1
```

```
Out [2]:
```

```
      A      B
0 -0.259720 -0.070382
1 -1.379393 -0.259478
2 -0.396654  0.084603
3 -0.102432  0.187827
4 -0.711440  0.208490
```

```
[5 rows x 2 columns]
```

```
In [3]: df1.iloc[:, 2:3]
```

```
Out [3]:
```

```
Empty DataFrame
```

```
Columns: []
```

```
Index: [0, 1, 2, 3, 4]
```

```
[5 rows x 0 columns]
```

```
In [4]: df1.iloc[:, 1:3]
```

```
Out [4]:
```

```
      B
0 -0.070382
1 -0.259478
2  0.084603
3  0.187827
4  0.208490
```

```
[5 rows x 1 columns]
```

```
In [5]: df1.iloc[4:6]
```

```
Out [5]:
```

```
      A      B
4 -0.71144  0.20849
```

```
[1 rows x 2 columns]
```

These are out-of-bounds selections

```
>>> df1.iloc[[4, 5, 6]]
```

```
IndexError: positional indexers are out-of-bounds
```

```
>>> df1.iloc[:, 4]
```

```
IndexError: single positional indexer is out-of-bounds
```

- Slicing with negative start, stop & step values handles corner cases better ([GH6531](#)):

- `df.iloc[:-len(df)]` is now empty
- `df.iloc[len(df)::-1]` now enumerates all elements in reverse
- The `DataFrame.interpolate()` keyword `downcast` default has been changed from `infer` to `None`. This is to preserve the original dtype unless explicitly requested otherwise (GH6290).
- When converting a dataframe to HTML it used to return `Empty DataFrame`. This special case has been removed, instead a header with the column names is returned (GH6062).
- `Series` and `Index` now internally share more common operations, e.g. `factorize()`, `nunique()`, `value_counts()` are now supported on `Index` types as well. The `Series.weekday` property from is removed from `Series` for API consistency. Using a `DatetimeIndex/PeriodIndex` method on a `Series` will now raise a `TypeError`. (GH4551, GH4056, GH5519, GH6380, GH7206).
- Add `is_month_start`, `is_month_end`, `is_quarter_start`, `is_quarter_end`, `is_year_start`, `is_year_end` accessors for `DatetimeIndex / Timestamp` which return a boolean array of whether the timestamp(s) are at the start/end of the month/quarter/year defined by the frequency of the `DatetimeIndex / Timestamp` (GH4565, GH6998)
- Local variable usage has changed in `pandas.eval()/DataFrame.eval()/DataFrame.query()` (GH5987). For the `DataFrame` methods, two things have changed
  - Column names are now given precedence over locals
  - Local variables must be referred to explicitly. This means that even if you have a local variable that is *not* a column you must still refer to it with the '@' prefix.
  - You can have an expression like `df.query('@a < a')` with no complaints from pandas about ambiguity of the name `a`.
  - The top-level `pandas.eval()` function does not allow you use the '@' prefix and provides you with an error message telling you so.
  - `NameResolutionError` was removed because it isn't necessary anymore.
- Define and document the order of column vs index names in `query/eval` (GH6676)
- `concat` will now concatenate mixed `Series` and `DataFrames` using the `Series` name or numbering columns as needed (GH2385). See *the docs*
- Slicing and advanced/boolean indexing operations on `Index` classes as well as `Index.delete()` and `Index.drop()` methods will no longer change the type of the resulting index (GH6440, GH7040)

```
In [6]: i = pd.Index([1, 2, 3, 'a', 'b', 'c'])
In [7]: i[[0, 1, 2]]
Out [7]: Index([1, 2, 3], dtype='object')
In [8]: i.drop(['a', 'b', 'c'])
Out [8]: Index([1, 2, 3], dtype='object')
```

Previously, the above operation would return `Int64Index`. If you'd like to do this manually, use `Index.astype()`

```
In [9]: i[[0, 1, 2]].astype(np.int_)
Out [9]: Int64Index([1, 2, 3], dtype='int64')
```

- `set_index` no longer converts `MultiIndexes` to an `Index` of tuples. For example, the old behavior returned an `Index` in this case (GH6459):

```

# Old behavior, casted MultiIndex to an Index
In [10]: tuple_ind
Out [10]: Index([('a', 'c'), ('a', 'd'), ('b', 'c'), ('b', 'd')], dtype='object')

In [11]: df_multi.set_index(tuple_ind)
Out [11]:
           0         1
(a, c)  0.471435 -1.190976
(a, d)  1.432707 -0.312652
(b, c) -0.720589  0.887163
(b, d)  0.859588 -0.636524

[4 rows x 2 columns]

# New behavior
In [12]: mi
Out [12]:
MultiIndex([('a', 'c'),
            ('a', 'd'),
            ('b', 'c'),
            ('b', 'd')],
           )

In [13]: df_multi.set_index(mi)
Out [13]:
           0         1
a c  0.471435 -1.190976
   d  1.432707 -0.312652
b c -0.720589  0.887163
   d  0.859588 -0.636524

[4 rows x 2 columns]

```

This also applies when passing multiple indices to `set_index`:

```

# Old output, 2-level MultiIndex of tuples
In [14]: df_multi.set_index([df_multi.index, df_multi.index])
Out [14]:
           0         1
(a, c) (a, c)  0.471435 -1.190976
(a, d) (a, d)  1.432707 -0.312652

```

- `pairwise` keyword was added to the statistical moment functions `rolling_cov`, `rolling_corr`,

ewmcorr, expanding\_cov, expanding\_corr to allow the calculation of moving window covariance and correlation matrices (GH4950). See *Computing rolling pairwise covariances and correlations* in the docs.

```
In [1]: df = pd.DataFrame(np.random.randn(10, 4), columns=list('ABCD'))
```

```
In [4]: covs = pd.rolling_cov(df[['A', 'B', 'C']],
.....:                       df[['B', 'C', 'D']],
.....:                       5,
.....:                       pairwise=True)
```

```
In [5]: covs[df.index[-1]]
```

```
Out [5]:
```

|   | B         | C         | D         |
|---|-----------|-----------|-----------|
| A | 0.035310  | 0.326593  | -0.505430 |
| B | 0.137748  | -0.006888 | -0.005383 |
| C | -0.006888 | 0.861040  | 0.020762  |

- `Series.iteritems()` is now lazy (returns an iterator rather than a list). This was the documented behavior prior to 0.14. (GH6760)
- Added `nunique` and `value_counts` functions to `Index` for counting unique elements. (GH6734)
- `stack` and `unstack` now raise a `ValueError` when the `level` keyword refers to a non-unique item in the `Index` (previously raised a `KeyError`). (GH6738)
- drop unused `order` argument from `Series.sort`; args now are in the same order as `Series.order`; add `na_position` arg to conform to `Series.order` (GH6847)
- default sorting algorithm for `Series.order` is now `quicksort`, to conform with `Series.sort` (and `numpy` defaults)
- add `inplace` keyword to `Series.order/sort` to make them inverses (GH6859)
- `DataFrame.sort` now places NaNs at the beginning or end of the sort according to the `na_position` parameter. (GH3917)
- accept `TextFileReader` in `concat`, which was affecting a common user idiom (GH6583), this was a regression from 0.13.1
- Added `factorize` functions to `Index` and `Series` to get indexer and unique values (GH7090)
- `describe` on a `DataFrame` with a mix of `Timestamp` and string like objects returns a different `Index` (GH7088). Previously the index was unintentionally sorted.
- Arithmetic operations with **only** `bool` dtypes now give a warning indicating that they are evaluated in Python space for `+`, `-`, and `*` operations and raise for all others (GH7011, GH6762, GH7015, GH7210)

```
>>> x = pd.Series(np.random.rand(10) > 0.5)
>>> y = True
>>> x + y # warning generated: should do x | y instead
UserWarning: evaluating in Python space because the '+' operator is not
supported by numexpr for the bool dtype, use '|' instead
>>> x / y # this raises because it doesn't make sense
NotImplementedError: operator '/' not implemented for bool dtypes
```

- In `HDFStore`, `select_as_multiple` will always raise a `KeyError`, when a key or the selector is not found (GH6177)
- `df['col'] = value` and `df.loc[:, 'col'] = value` are now completely equivalent; previously the `.loc` would not necessarily coerce the dtype of the resultant series (GH6149)

- `dtypes` and `ftypes` now return a series with `dtype=object` on empty containers (GH5740)
- `df.to_csv` will now return a string of the CSV data if neither a target path nor a buffer is provided (GH6061)
- `pd.infer_freq()` will now raise a `TypeError` if given an invalid `Series/Index` type (GH6407, GH6463)
- A tuple passed to `DataFrame.sort_index` will be interpreted as the levels of the index, rather than requiring a list of tuple (GH4370)
- all offset operations now return `Timestamp` types (rather than `datetime`), `Business/Week` frequencies were incorrect (GH4069)
- `to_excel` now converts `np.inf` into a string representation, customizable by the `inf_rep` keyword argument (Excel has no native `inf` representation) (GH6782)
- Replace `pandas.compat.scipy.scoreatpercentile` with `numpy.percentile` (GH6810)
- `.quantile` on a `datetime[ns]` series now returns `Timestamp` instead of `np.datetime64` objects (GH6810)
- change `AssertionError` to `TypeError` for invalid types passed to `concat` (GH6583)
- Raise a `TypeError` when `DataFrame` is passed an iterator as the `data` argument (GH5357)

## Display changes

- The default way of printing large `DataFrames` has changed. `DataFrames` exceeding `max_rows` and/or `max_columns` are now displayed in a centrally truncated view, consistent with the printing of a `pandas.Series` (GH5603).

In previous versions, a `DataFrame` was truncated once the dimension constraints were reached and an ellipse (...) signaled that part of the data was cut off.

```
In [1]: import pandas as pd
```

```
In [2]: import numpy as np
```

```
In [3]: pd.options.display.max_rows = 6
```

```
In [4]: pd.options.display.max_columns = 6
```

```
In [5]: index = pd.DatetimeIndex(start='20010101', freq='D', periods=10)
```

```
In [6]: pd.DataFrame(np.arange(10*10).reshape((10,10)), index=index)
```

```
Out[6]:
```

```

      0  1  2  3  4  5
2001-01-01  0  1  2  3  4  5 ...
2001-01-02 10 11 12 13 14 15 ...
2001-01-03 20 21 22 23 24 25 ...
2001-01-04 30 31 32 33 34 35 ...
2001-01-05 40 41 42 43 44 45 ...
2001-01-06 50 51 52 53 54 55 ...
      ... ..
```

```
[10 rows x 10 columns]
```

In the current version, large DataFrames are centrally truncated, showing a preview of head and tail in both dimensions.

```
In [24]: pd.DataFrame(np.arange(10*10).reshape((10,10)),index=index)
Out[24]:
```

```

      0  1  2  ...  7  8  9
2001-01-01  0  1  2  ...  7  8  9
2001-01-02 10 11 12  ... 17 18 19
2001-01-03 20 21 22  ... 27 28 29
...
2001-01-08 70 71 72  ... 77 78 79
2001-01-09 80 81 82  ... 87 88 89
2001-01-10 90 91 92  ... 97 98 99
```

```
[10 rows x 10 columns]
```

- allow option 'truncate' for `display.show_dimensions` to only show the dimensions if the frame is truncated (GH6547).

The default for `display.show_dimensions` will now be `truncate`. This is consistent with how Series display length.

```
In [16]: dfd = pd.DataFrame(np.arange(25).reshape(-1, 5),
.....:                      index=[0, 1, 2, 3, 4],
.....:                      columns=[0, 1, 2, 3, 4])
.....:

# show dimensions since this is truncated
In [17]: with pd.option_context('display.max_rows', 2, 'display.max_columns', 2,
.....:                          'display.show_dimensions', 'truncate'):
.....:     print(dfd)
.....:
      0  ...  4
0     0  ...  4
..  ..  ...  ..
4    20  ...  24

[5 rows x 5 columns]

# will not show dimensions since it is not truncated
In [18]: with pd.option_context('display.max_rows', 10, 'display.max_columns', 40,
.....:                          'display.show_dimensions', 'truncate'):
.....:     print(dfd)
.....:
      0  1  2  3  4
0     0  1  2  3  4
1     5  6  7  8  9
2    10 11 12 13 14
3    15 16 17 18 19
4    20 21 22 23 24
```

- Regression in the display of a MultiIndexed Series with `display.max_rows` is less than the length of the series (GH7101)
- Fixed a bug in the HTML repr of a truncated Series or DataFrame not showing the class name with the `large_repr` set to 'info' (GH7105)

- The *verbose* keyword in `DataFrame.info()`, which controls whether to shorten the *info* representation, is now `None` by default. This will follow the global setting in `display.max_info_columns`. The global setting can be overridden with `verbose=True` or `verbose=False`.
- Fixed a bug with the *info* repr not honoring the `display.max_info_columns` setting (GH6939)
- Offset/freq info now in `Timestamp.__repr__` (GH4553)

## Text parsing API changes

`read_csv()/read_table()` will now be noisier w.r.t invalid options rather than falling back to the `PythonParser`.

- Raise `ValueError` when `sep` specified with `delim_whitespace=True` in `read_csv()/read_table()` (GH6607)
- Raise `ValueError` when `engine='c'` specified with unsupported options in `read_csv()/read_table()` (GH6607)
- Raise `ValueError` when fallback to python parser causes options to be ignored (GH6607)
- Produce `ParserWarning` on fallback to python parser when no options are ignored (GH6607)
- Translate `sep='\s+'` to `delim_whitespace=True` in `read_csv()/read_table()` if no other C-unsupported options specified (GH6607)

## Groupby API changes

More consistent behavior for some groupby methods:

- `groupby` `head` and `tail` now act more like `filter` rather than an aggregation:

```
In [19]: df = pd.DataFrame([[1, 2], [1, 4], [5, 6]], columns=['A', 'B'])
In [20]: g = df.groupby('A')
In [21]: g.head(1) # filters DataFrame
Out [21]:
   A  B
0  1  2
2  5  6

[2 rows x 2 columns]

In [22]: g.apply(lambda x: x.head(1)) # used to simply fall-through
Out [22]:
   A  B
A
1  0  1  2
5  2  5  6

[2 rows x 2 columns]
```

- `groupby` `head` and `tail` respect column selection:

```
In [23]: g[['B']].head(1)
Out [23]:
   B
0  2
```

(continues on next page)

(continued from previous page)

```
0  2
2  6

[2 rows x 1 columns]
```

- `groupby` `nth` now reduces by default; filtering can be achieved by passing `as_index=False`. With an optional `dropna` argument to ignore NaN. See *the docs*.

### Reducing

```
In [24]: df = pd.DataFrame([[1, np.nan], [1, 4], [5, 6]], columns=['A', 'B'])

In [25]: g = df.groupby('A')

In [26]: g.nth(0)
Out[26]:
      B
A
1  NaN
5  6.0

[2 rows x 1 columns]

# this is equivalent to g.first()
In [27]: g.nth(0, dropna='any')
Out[27]:
      B
A
1  4.0
5  6.0

[2 rows x 1 columns]

# this is equivalent to g.last()
In [28]: g.nth(-1, dropna='any')
Out[28]:
      B
A
1  4.0
5  6.0

[2 rows x 1 columns]
```

### Filtering

```
In [29]: gf = df.groupby('A', as_index=False)

In [30]: gf.nth(0)
Out[30]:
      A      B
0  1  NaN
2  5  6.0

[2 rows x 2 columns]

In [31]: gf.nth(0, dropna='any')
Out[31]:
```

(continues on next page)

(continued from previous page)

```

      A      B
A
1  1  4.0
5  5  6.0

[2 rows x 2 columns]

```

- `groupby` will now not return the grouped column for non-cython functions (GH5610, GH5614, GH6732), as its already the index

```

In [32]: df = pd.DataFrame([[1, np.nan], [1, 4], [5, 6], [5, 8]], columns=['A', 'B
→'])

In [33]: g = df.groupby('A')

In [34]: g.count()
Out[34]:
      B
A
1  1
5  2

[2 rows x 1 columns]

In [35]: g.describe()
Out[35]:
      B
count mean      std  min  25%  50%  75%  max
A
1   1.0  4.0      NaN  4.0  4.0  4.0  4.0  4.0
5   2.0  7.0  1.414214  6.0  6.5  7.0  7.5  8.0

[2 rows x 8 columns]

```

- passing `as_index` will leave the grouped column in-place (this is not change in 0.14.0)

```

In [36]: df = pd.DataFrame([[1, np.nan], [1, 4], [5, 6], [5, 8]], columns=['A', 'B
→'])

In [37]: g = df.groupby('A', as_index=False)

In [38]: g.count()
Out[38]:
      A  B
0  1  1
1  5  2

[2 rows x 2 columns]

In [39]: g.describe()
Out[39]:
      A      B
count mean      std  min  25%  50%  75%  max count mean      std  min  25%  50%  75
→%  max
0   2.0  1.0  0.0  1.0  1.0  1.0  1.0  1.0  1.0  4.0      NaN  4.0  4.0  4.0  4.
→0  4.0

```

(continues on next page)

(continued from previous page)

```

1    2.0  5.0  0.0  5.0  5.0  5.0  5.0  5.0  2.0  7.0  1.414214  6.0  6.5  7.0  7.
↪5    8.0

[2 rows x 16 columns]
```

- Allow specification of a more complex groupby via `pd.Grouper`, such as grouping by a Time and a string field simultaneously. See *the docs*. (GH3794)
- Better propagation/preservation of Series names when performing groupby operations:
  - `SeriesGroupBy.agg` will ensure that the name attribute of the original series is propagated to the result (GH6265).
  - If the function provided to `GroupBy.apply` returns a named series, the name of the series will be kept as the name of the column index of the DataFrame returned by `GroupBy.apply` (GH6124). This facilitates `DataFrame.stack` operations where the name of the column index is used as the name of the inserted column containing the pivoted data.

## SQL

The SQL reading and writing functions now support more database flavors through SQLAlchemy (GH2717, GH4163, GH5950, GH6292). All databases supported by SQLAlchemy can be used, such as PostgreSQL, MySQL, Oracle, Microsoft SQL server (see documentation of SQLAlchemy on *included dialects*).

The functionality of providing DBAPI connection objects will only be supported for `sqlite3` in the future. The `'mysql'` flavor is deprecated.

The new functions `read_sql_query()` and `read_sql_table()` are introduced. The function `read_sql()` is kept as a convenience wrapper around the other two and will delegate to specific function depending on the provided input (database table name or sql query).

In practice, you have to provide a SQLAlchemy engine to the sql functions. To connect with SQLAlchemy you use the `create_engine()` function to create an engine object from database URI. You only need to create the engine once per database you are connecting to. For an in-memory sqlite database:

```

In [40]: from sqlalchemy import create_engine

# Create your connection.
In [41]: engine = create_engine('sqlite:///memory:')
```

This engine can then be used to write or read data to/from this database:

```

In [42]: df = pd.DataFrame({'A': [1, 2, 3], 'B': ['a', 'b', 'c']})

In [43]: df.to_sql('db_table', engine, index=False)
```

You can read data from a database by specifying the table name:

```

In [44]: pd.read_sql_table('db_table', engine)
Out[44]:
   A  B
0  1  a
1  2  b
2  3  c

[3 rows x 2 columns]
```

or by specifying a sql query:

```
In [45]: pd.read_sql_query('SELECT * FROM db_table', engine)
Out [45]:
   A  B
0  1  a
1  2  b
2  3  c

[3 rows x 2 columns]
```

Some other enhancements to the sql functions include:

- support for writing the index. This can be controlled with the `index` keyword (default is `True`).
- specify the column label to use when writing the index with `index_label`.
- specify string columns to parse as datetimes with the `parse_dates` keyword in `read_sql_query()` and `read_sql_table()`.

**Warning:** Some of the existing functions or function aliases have been deprecated and will be removed in future versions. This includes: `tquery`, `uquery`, `read_frame`, `frame_query`, `write_frame`.

**Warning:** The support for the 'mysql' flavor when using DBAPI connection objects has been deprecated. MySQL will be further supported with SQLAlchemy engines ([GH6900](#)).

## Multindexing using slicers

In 0.14.0 we added a new way to slice MultiIndexed objects. You can slice a MultiIndex by providing multiple indexers.

You can provide any of the selectors as if you are indexing by label, see *Selection by Label*, including slices, lists of labels, labels, and boolean indexers.

You can use `slice(None)` to select all the contents of *that* level. You do not need to specify all the *deeper* levels, they will be implied as `slice(None)`.

As usual, **both sides** of the slicers are included as this is label indexing.

See *the docs* See also issues ([GH6134](#), [GH4036](#), [GH3057](#), [GH2598](#), [GH5641](#), [GH7106](#))

### Warning:

You should specify all axes in the `.loc` specifier, meaning the indexer for the **index** and for the **columns**. There are some ambiguous cases where the passed indexer could be mis-interpreted as indexing *both* axes, rather than into say the MultiIndex for the rows.

You should do this:

```
>>> df.loc[(slice('A1', 'A3'), ...), :] # noqa: E901
```

rather than this:

```
>>> df.loc[(slice('A1', 'A3'), ...)] # noqa: E901
```

**Warning:** You will need to make sure that the selection axes are fully lexsorted!

```
In [46]: def mklbl(prefix, n):
.....:     return ["%s%s" % (prefix, i) for i in range(n)]
.....:

In [47]: index = pd.MultiIndex.from_product([mklbl('A', 4),
.....:                                     mklbl('B', 2),
.....:                                     mklbl('C', 4),
.....:                                     mklbl('D', 2)])
.....:

In [48]: columns = pd.MultiIndex.from_tuples([('a', 'foo'), ('a', 'bar'),
.....:                                       ('b', 'foo'), ('b', 'bah')],
.....:                                       names=['lv10', 'lv11'])

You can use a `pd.IndexSlice` to shortcut the creation of these slices

```
In [52]: idx = pd.IndexSlice
```

```
In [53]: df.loc[idx[:, :, ['C1', 'C3']], idx[:, 'foo']]
```

```
Out [53]:
```

```

lvl0      a      b
lvl1      foo    foo

```

## Plotting

- Hexagonal bin plots from `DataFrame.plot` with `kind='hexbin'` ([GH5478](#)), See *the docs*.
- `DataFrame.plot` and `Series.plot` now supports area plot with specifying `kind='area'` ([GH6656](#)), See *the docs*
- Pie plots from `Series.plot` and `DataFrame.plot` with `kind='pie'` ([GH6976](#)), See *the docs*.
- Plotting with Error Bars is now supported in the `.plot` method of `DataFrame` and `Series` objects ([GH3796](#), [GH6834](#)), See *the docs*.
- `DataFrame.plot` and `Series.plot` now support a `table` keyword for plotting `matplotlib.Table`, See *the docs*. The `table` keyword can receive the following values.
  - `False`: Do nothing (default).
  - `True`: Draw a table using the `DataFrame` or `Series` called `plot` method. Data will be transposed to meet `matplotlib`'s default layout.
  - `DataFrame` or `Series`: Draw `matplotlib.table` using the passed data. The data will be drawn as displayed in `print` method (not transposed automatically). Also, helper function `pandas.tools.plotting.table` is added to create a table from `DataFrame` and `Series`, and add it to an `matplotlib.Axes`.
- `plot(legend='reverse')` will now reverse the order of legend labels for most plot kinds. ([GH6014](#))
- Line plot and area plot can be stacked by `stacked=True` ([GH6656](#))
- Following keywords are now acceptable for `DataFrame.plot()` with `kind='bar'` and `kind='barh'`:
  - `width`: Specify the bar width. In previous versions, static value 0.5 was passed to `matplotlib` and it cannot be overwritten. ([GH6604](#))
  - `align`: Specify the bar alignment. Default is `center` (different from `matplotlib`). In previous versions, `pandas` passes `align='edge'` to `matplotlib` and adjust the location to `center` by itself, and it results `align` keyword is not applied as expected. ([GH4525](#))
  - `position`: Specify relative alignments for bar plot layout. From 0 (left/bottom-end) to 1(right/top-end). Default is 0.5 (center). ([GH6604](#))

Because of the default `align` value changes, coordinates of bar plots are now located on integer values (0.0, 1.0, 2.0 ...). This is intended to make bar plot be located on the same coordinates as line plot. However, bar plot may differs unexpectedly when you manually adjust the bar location or drawing area, such as using `set_xlim`, `set_ylim`, etc. In this cases, please modify your script to meet with new coordinates.

- The `parallel_coordinates()` function now takes argument `color` instead of `colors`. A `FutureWarning` is raised to alert that the old `colors` argument will not be supported in a future release. ([GH6956](#))
- The `parallel_coordinates()` and `andrews_curves()` functions now take positional argument `frame` instead of `data`. A `FutureWarning` is raised if the old `data` argument is used by name. ([GH6956](#))
- `DataFrame.boxplot()` now supports `layout` keyword ([GH6769](#))
- `DataFrame.boxplot()` has a new keyword argument, `return_type`. It accepts `'dict'`, `'axes'`, or `'both'`, in which case a namedtuple with the `matplotlib` axes and a dict of `matplotlib` Lines is returned.

## Prior version deprecations/changes

There are prior version deprecations that are taking effect as of 0.14.0.

- Remove `DateRange` in favor of `DatetimeIndex` (GH6816)
- Remove `column` keyword from `DataFrame.sort` (GH4370)
- Remove `precision` keyword from `set_eng_float_format()` (GH395)
- Remove `force_unicode` keyword from `DataFrame.to_string()`, `DataFrame.to_latex()`, and `DataFrame.to_html()`; these function encode in unicode by default (GH2224, GH2225)
- Remove `nanRep` keyword from `DataFrame.to_csv()` and `DataFrame.to_string()` (GH275)
- Remove `unique` keyword from `HDFStore.select_column()` (GH3256)
- Remove `inferTimeRule` keyword from `Timestamp.offset()` (GH391)
- Remove `name` keyword from `get_data_yahoo()` and `get_data_google()` (commit b921d1a)
- Remove `offset` keyword from `DatetimeIndex` constructor (commit 3136390)
- Remove `time_rule` from several rolling-moment statistical functions, such as `rolling_sum()` (GH1042)
- Removed `neg` – boolean operations on numpy arrays in favor of `inv ~`, as this is going to be deprecated in numpy 1.9 (GH6960)

## Deprecations

- The `pivot_table()/DataFrame.pivot_table()` and `crosstab()` functions now take arguments `index` and `columns` instead of `rows` and `cols`. A `FutureWarning` is raised to alert that the old `rows` and `cols` arguments will not be supported in a future release (GH5505)
- The `DataFrame.drop_duplicates()` and `DataFrame.duplicated()` methods now take argument `subset` instead of `cols` to better align with `DataFrame.dropna()`. A `FutureWarning` is raised to alert that the old `cols` arguments will not be supported in a future release (GH6680)
- The `DataFrame.to_csv()` and `DataFrame.to_excel()` functions now takes argument `columns` instead of `cols`. A `FutureWarning` is raised to alert that the old `cols` arguments will not be supported in a future release (GH6645)
- Indexers will warn `FutureWarning` when used with a scalar indexer and a non-floating point `Index` (GH4892, GH6960)

```
# non-floating point indexes can only be indexed by integers / labels
In [1]: pd.Series(1, np.arange(5))[3.0]
pandas/core/index.py:469: FutureWarning: scalar indexers for index type_
↳Int64Index should be integers and not floating point
Out [1]: 1

In [2]: pd.Series(1, np.arange(5)).iloc[3.0]
pandas/core/index.py:469: FutureWarning: scalar indexers for index type_
↳Int64Index should be integers and not floating point
Out [2]: 1

In [3]: pd.Series(1, np.arange(5)).iloc[3.0:4]
pandas/core/index.py:527: FutureWarning: slice indexers when using iloc_
↳should be integers and not floating point
Out [3]:
3    1
```

(continues on next page)

(continued from previous page)

```

dtype: int64

# these are Float64Indexes, so integer or floating point is acceptable
In [4]: pd.Series(1, np.arange(5.))[3]
Out [4]: 1

In [5]: pd.Series(1, np.arange(5.))[3.0]
Out [6]: 1

```

- Numpy 1.9 compat w.r.t. deprecation warnings ([GH6960](#))
- `Panel.shift()` now has a function signature that matches `DataFrame.shift()`. The old positional argument `lags` has been changed to a keyword argument `periods` with a default value of 1. A `FutureWarning` is raised if the old argument `lags` is used by name. ([GH6910](#))
- The `order` keyword argument of `factorize()` will be removed. ([GH6926](#)).
- Remove the `copy` keyword from `DataFrame.xs()`, `Panel.major_xs()`, `Panel.minor_xs()`. A view will be returned if possible, otherwise a copy will be made. Previously the user could think that `copy=False` would ALWAYS return a view. ([GH6894](#))
- The `parallel_coordinates()` function now takes argument `color` instead of `colors`. A `FutureWarning` is raised to alert that the old `colors` argument will not be supported in a future release. ([GH6956](#))
- The `parallel_coordinates()` and `andrews_curves()` functions now take positional argument `frame` instead of `data`. A `FutureWarning` is raised if the old `data` argument is used by name. ([GH6956](#))
- The support for the 'mysql' flavor when using DBAPI connection objects has been deprecated. MySQL will be further supported with SQLAlchemy engines ([GH6900](#)).
- The following `io.sql` functions have been deprecated: `tquery`, `uquery`, `read_frame`, `frame_query`, `write_frame`.
- The `percentile_width` keyword argument in `describe()` has been deprecated. Use the `percentiles` keyword instead, which takes a list of percentiles to display. The default output is unchanged.
- The default return type of `boxplot()` will change from a dict to a matplotlib Axes in a future release. You can use the future behavior now by passing `return_type='axes'` to `boxplot`.

## Known issues

- OpenPyXL 2.0.0 breaks backwards compatibility ([GH7169](#))

## Enhancements

- `DataFrame` and `Series` will create a `MultiIndex` object if passed a tuples dict, See *the docs* ([GH3323](#))

```

In [65]: pd.Series({'a', 'b'): 1, ('a', 'a'): 0,
.....:             ('a', 'c'): 2, ('b', 'a'): 3, ('b', 'b'): 4})
.....:
Out [65]:
a b    1
  a    0
  c    2
b a    3
  b    4

```

(continues on next page)

(continued from previous page)

```

Length: 5, dtype: int64
In [66]: pd.DataFrame({'a', 'b'): {'(A', 'B)': 1, ('A', 'C)': 2},
.....:                ('a', 'a'): {'(A', 'C)': 3, ('A', 'B)': 4},

D  NaN  NaN  NaN  NaN  9.0

[3 rows x 5 columns]

```

- Added the `sym_diff` method to `Index` (GH5543)
- `DataFrame.to_latex` now takes a `longtable` keyword, which if `True` will return a table in a longtable environment. (GH6617)
- Add option to turn off escaping in `DataFrame.to_latex` (GH6472)
- `pd.read_clipboard` will, if the keyword `sep` is unspecified, try to detect data copied from a spreadsheet and parse accordingly. (GH6223)
- Joining a singly-indexed `DataFrame` with a `MultiIndexed DataFrame` (GH3662)

See *the docs*. Joining `MultiIndex DataFrame`s on both the left and right is not yet supported ATM.

```

In [67]: household = pd.DataFrame({'household_id': [1, 2, 3],

```

(continues on next page)

- Float64Index is now backed by a float64 dtype ndarray instead of an object dtype array (GH6471).
- Implemented Panel.pct\_change (GH6904)
- Added how option to rolling-moment functions to dictate how to handle resampling; rolling\_max() defaults to max, rolling\_min() defaults to min, and all others default to mean (GH6297)
- CustomBusinessMonthBegin and CustomBusinessMonthEnd are now available (GH6866)
- Series.quantile() and DataFrame.quantile() now accept an array of quantiles.
- describe() now accepts an array of percentiles to include in the summary statistics (GH4196)
- pivot\_table can now accept Grouper by index and columns keywords (GH6913)

```
In [72]: import datetime

In [73]: df = pd.DataFrame({
.....:     'Branch': 'A A A A B'.split(),
.....:     'Buyer': 'Carl Mark Carl Carl Joe'.split(),
.....:     'Quantity': [1, 3, 5, 1, 8, 1],

```

- Arrays of strings can be wrapped to a specified width (`str.wrap`) (GH6999)
- Add `nsmallest()` and `Series.nlargest()` methods to `Series`, See *the docs* (GH3960)
- `PeriodIndex` fully supports partial string indexing like `DatetimeIndex` (GH7043)

```
In [76]: prng = pd.period_range('2013-01-01 09:00', periods=100, freq='H')
```

```

- `read_excel` can now read milliseconds in Excel dates and times with `xlrd >= 0.9.3`. (GH5945)
- `pd.stats.moments.rolling_var` now uses Welford's method for increased numerical stability (GH6817)
- `pd.expanding_apply` and `pd.rolling_apply` now take `args` and `kwargs` that are passed on to the `func` (GH6289)

- `DataFrame.rank()` now has a percentage rank option (GH5971)
- `Series.rank()` now has a percentage rank option (GH5971)
- `Series.rank()` and `DataFrame.rank()` now accept `method='dense'` for ranks without gaps (GH6514)
- Support passing encoding with `xlwt` (GH3710)
- Refactor Block classes removing `Block.items` attributes to avoid duplication in item handling (GH6745, GH6988).
- Testing statements updated to use specialized asserts (GH6175)

### Performance

- Performance improvement when converting `DatetimeIndex` to floating ordinals using `DatetimeConverter` (GH6636)
- Performance improvement for `DataFrame.shift` (GH5609)
- Performance improvement in indexing into a `MultiIndexed Series` (GH5567)
- Performance improvements in single-dtyped indexing (GH6484)
- Improve performance of `DataFrame` construction with certain offsets, by removing faulty caching (e.g. `MonthEnd`, `BusinessMonthEnd`), (GH6479)
- Improve performance of `CustomBusinessDay` (GH6584)
- improve performance of slice indexing on `Series` with string keys (GH6341, GH6372)
- Performance improvement for `DataFrame.from_records` when reading a specified number of rows from an iterable (GH6700)
- Performance improvements in `timedelta` conversions for integer dtypes (GH6754)
- Improved performance of compatible pickles (GH6899)
- Improve performance in certain reindexing operations by optimizing `take_2d` (GH6749)
- `GroupBy.count()` is now implemented in Cython and is much faster for large numbers of groups (GH7016).

### Experimental

There are no experimental changes in 0.14.0

### Bug Fixes

- Bug in `Series ValueError` when index doesn't match data (GH6532)
- Prevent segfault due to `MultiIndex` not being supported in `HDFStore` table format (GH1848)
- Bug in `pd.DataFrame.sort_index` where `mergesort` wasn't stable when `ascending=False` (GH6399)
- Bug in `pd.tseries.frequencies.to_offset` when argument has leading zeros (GH6391)
- Bug in version string gen. for dev versions with shallow clones / install from tarball (GH6127)
- Inconsistent tz parsing `Timestamp` / `to_datetime` for current year (GH5958)
- Indexing bugs with reordered indexes (GH6252, GH6254)

- Bug in `.xs` with a Series multiindex (GH6258, GH5684)
- Bug in conversion of a string types to a DatetimeIndex with a specified frequency (GH6273, GH6274)
- Bug in `eval` where type-promotion failed for large expressions (GH6205)
- Bug in `interpolate` with `inplace=True` (GH6281)
- `HDFStore.remove` now handles start and stop (GH6177)
- `HDFStore.select_as_multiple` handles start and stop the same way as `select` (GH6177)
- `HDFStore.select_as_coordinates` and `select_column` works with a where clause that results in filters (GH6177)
- Regression in join of non\_unique\_indexes (GH6329)
- Issue with `groupby agg` with a single function and a mixed-type frame (GH6337)
- Bug in `DataFrame.replace()` when passing a non-bool `to_replace` argument (GH6332)
- Raise when trying to align on different levels of a MultiIndex assignment (GH3738)
- Bug in setting complex dtypes via boolean indexing (GH6345)
- Bug in `TimeGrouper/resample` when presented with a non-monotonic DatetimeIndex that would return invalid results. (GH4161)
- Bug in index name propagation in `TimeGrouper/resample` (GH4161)
- `TimeGrouper` has a more compatible API to the rest of the groupers (e.g. `groups` was missing) (GH3881)
- Bug in multiple grouping with a `TimeGrouper` depending on target column order (GH6764)
- Bug in `pd.eval` when parsing strings with possible tokens like `'&'` (GH6351)
- Bug correctly handle placements of `-inf` in Panels when dividing by integer 0 (GH6178)
- `DataFrame.shift` with `axis=1` was raising (GH6371)
- Disabled clipboard tests until release time (run locally with `nosetests -A disabled`) (GH6048).
- Bug in `DataFrame.replace()` when passing a nested dict that contained keys not in the values to be replaced (GH6342)
- `str.match` ignored the `na` flag (GH6609).
- Bug in `take` with duplicate columns that were not consolidated (GH6240)
- Bug in `interpolate` changing dtypes (GH6290)
- Bug in `Series.get`, was using a buggy access method (GH6383)
- Bug in `hdfstore` queries of the form `where=[('date', '>=', datetime(2013,1,1)), ('date', '<=', datetime(2014,1,1))]` (GH6313)
- Bug in `DataFrame.dropna` with duplicate indices (GH6355)
- Regression in chained `getitem` indexing with embedded list-like from 0.12 (GH6394)
- `Float64Index` with nans not comparing correctly (GH6401)
- `eval/query` expressions with strings containing the `@` character will now work (GH6366).
- Bug in `Series.reindex` when specifying a method with some nan values was inconsistent (noted on a `resample`) (GH6418)
- Bug in `DataFrame.replace()` where nested dicts were erroneously depending on the order of dictionary keys and values (GH5338).

- Performance issue in concatenating with empty objects (GH3259)
- Clarify sorting of `sym_diff` on Index objects with NaN values (GH6444)
- Regression in `MultiIndex.from_product` with a `DatetimeIndex` as input (GH6439)
- Bug in `str.extract` when passed a non-default index (GH6348)
- Bug in `str.split` when passed `pat=None` and `n=1` (GH6466)
- Bug in `io.data.DataReader` when passed "F-F\_Momentum\_Factor" and `data_source="famafrench"` (GH6460)
- Bug in sum of a `timedelta64[ns]` series (GH6462)
- Bug in `resample` with a `timezone` and certain offsets (GH6397)
- Bug in `iat/iloc` with duplicate indices on a Series (GH6493)
- Bug in `read_html` where nan's were incorrectly being used to indicate missing values in text. Should use the empty string for consistency with the rest of pandas (GH5129).
- Bug in `read_html` tests where redirected invalid URLs would make one test fail (GH6445).
- Bug in multi-axis indexing using `.loc` on non-unique indices (GH6504)
- Bug that caused `_ref_locs` corruption when slice indexing across columns axis of a DataFrame (GH6525)
- Regression from 0.13 in the treatment of `numpy.datetime64` non-ns dtypes in Series creation (GH6529)
- `.names` attribute of `MultiIndexes` passed to `set_index` are now preserved (GH6459).
- Bug in `setitem` with a duplicate index and an alignable rhs (GH6541)
- Bug in `setitem` with `.loc` on mixed integer Indexes (GH6546)
- Bug in `pd.read_stata` which would use the wrong data types and missing values (GH6327)
- Bug in `DataFrame.to_stata` that lead to data loss in certain cases, and could be exported using the wrong data types and missing values (GH6335)
- `StataWriter` replaces missing values in string columns by empty string (GH6802)
- Inconsistent types in `Timestamp` addition/subtraction (GH6543)
- Bug in preserving frequency across `Timestamp` addition/subtraction (GH4547)
- Bug in empty list lookup caused `IndexError` exceptions (GH6536, GH6551)
- `Series.quantile` raising on an object dtype (GH6555)
- Bug in `.xs` with a nan in level when dropped (GH6574)
- Bug in `fillna` with `method='bfill/ffill'` and `datetime64[ns]` dtype (GH6587)
- Bug in `sql` writing with mixed dtypes possibly leading to data loss (GH6509)
- Bug in `Series.pop` (GH6600)
- Bug in `iloc` indexing when positional indexer matched `Int64Index` of the corresponding axis and no re-ordering happened (GH6612)
- Bug in `fillna` with `limit` and `value` specified
- Bug in `DataFrame.to_stata` when columns have non-string names (GH4558)
- Bug in `compat` with `np.compress`, surfaced in (GH6658)
- Bug in binary operations with a rhs of a Series not aligning (GH6681)

- Bug in `DataFrame.to_stata` which incorrectly handles nan values and ignores `with_index` keyword argument (GH6685)
- Bug in `resample` with extra bins when using an evenly divisible frequency (GH4076)
- Bug in consistency of `groupby` aggregation when passing a custom function (GH6715)
- Bug in `resample` when `how=None` `resample` freq is the same as the axis frequency (GH5955)
- Bug in downcasting inference with empty arrays (GH6733)
- Bug in `obj.blocks` on sparse containers dropping all but the last items of same for dtype (GH6748)
- Bug in unpickling `NaT` (`NaTType`) (GH4606)
- Bug in `DataFrame.replace()` where regex meta characters were being treated as regex even when `regex=False` (GH6777).
- Bug in `timedelta` ops on 32-bit platforms (GH6808)
- Bug in setting a tz-aware index directly via `.index` (GH6785)
- Bug in `expressions.py` where `numexpr` would try to evaluate arithmetic ops (GH6762).
- Bug in `Makefile` where it didn't remove Cython generated C files with `make clean` (GH6768)
- Bug with `numpy < 1.7.2` when reading long strings from `HDFStore` (GH6166)
- Bug in `DataFrame._reduce` where non bool-like (0/1) integers were being converted into bools. (GH6806)
- Regression from 0.13 with `fillna` and a `Series` on datetime-like (GH6344)
- Bug in adding `np.timedelta64` to `DatetimeIndex` with `timezone` outputs incorrect results (GH6818)
- Bug in `DataFrame.replace()` where changing a dtype through replacement would only replace the first occurrence of a value (GH6689)
- Better error message when passing a frequency of 'MS' in `Period` construction (GH5332)
- Bug in `Series.__unicode__` when `max_rows=None` and the `Series` has more than 1000 rows. (GH6863)
- Bug in `groupby.get_group` where a datelike wasn't always accepted (GH5267)
- Bug in `groupBy.get_group` created by `TimeGrouper` raises `AttributeError` (GH6914)
- Bug in `DatetimeIndex.tz_localize` and `DatetimeIndex.tz_convert` converting `NaT` incorrectly (GH5546)
- Bug in arithmetic operations affecting `NaT` (GH6873)
- Bug in `Series.str.extract` where the resulting `Series` from a single group match wasn't renamed to the group name
- Bug in `DataFrame.to_csv` where setting `index=False` ignored the header kwarg (GH6186)
- Bug in `DataFrame.plot` and `Series.plot`, where the legend behave inconsistently when plotting to the same axes repeatedly (GH6678)
- Internal tests for patching `__finalize__` / bug in `merge` not finalizing (GH6923, GH6927)
- accept `TextFileReader` in `concat`, which was affecting a common user idiom (GH6583)
- Bug in C parser with leading white space (GH3374)
- Bug in C parser with `delim_whitespace=True` and `\r`-delimited lines
- Bug in python parser with explicit `MultiIndex` in row following column header (GH6893)

- Bug in `Series.rank` and `DataFrame.rank` that caused small floats ( $<1e-13$ ) to all receive the same rank (GH6886)
- Bug in `DataFrame.apply` with functions that used `*args` or `**kwargs` and returned an empty result (GH6952)
- Bug in `sum/mean` on 32-bit platforms on overflows (GH6915)
- Moved `Panel.shift` to `NDFrame.slice_shift` and fixed to respect multiple dtypes. (GH6959)
- Bug in enabling `subplots=True` in `DataFrame.plot` only has single column raises `TypeError`, and `Series.plot` raises `AttributeError` (GH6951)
- Bug in `DataFrame.plot` draws unnecessary axes when enabling `subplots` and `kind=scatter` (GH6951)
- Bug in `read_csv` from a filesystem with non-utf-8 encoding (GH6807)
- Bug in `iloc` when setting / aligning (GH6766)
- Bug causing `UnicodeEncodeError` when `get_dummies` called with unicode values and a prefix (GH6885)
- Bug in `timeseries-with-frequency` plot cursor display (GH5453)
- Bug surfaced in `groupby.plot` when using a `Float64Index` (GH7025)
- Stopped tests from failing if options data isn't able to be downloaded from Yahoo (GH7034)
- Bug in `parallel_coordinates` and `radviz` where reordering of class column caused possible color/class mismatch (GH6956)
- Bug in `radviz` and `andrews_curves` where multiple values of 'color' were being passed to plotting method (GH6956)
- Bug in `Float64Index.isin()` where containing `nan`s would make indices claim that they contained all the things (GH7066).
- Bug in `DataFrame.boxplot` where it failed to use the axis passed as the `ax` argument (GH3578)
- Bug in the `XlsxWriter` and `XlwtWriter` implementations that resulted in `datetime` columns being formatted without the time (GH7075) were being passed to plotting method
- `read_fwf()` treats `None` in `colspec` like regular python slices. It now reads from the beginning or until the end of the line when `colspec` contains a `None` (previously raised a `TypeError`)
- Bug in cache coherence with chained indexing and slicing; add `_is_view` property to `NDFrame` to correctly predict views; mark `is_copy` on `xs` only if its an actual copy (and not a view) (GH7084)
- Bug in `DatetimeIndex` creation from string `ndarray` with `dayfirst=True` (GH5917)
- Bug in `MultiIndex.from_arrays` created from `DatetimeIndex` doesn't preserve `freq` and `tz` (GH7090)
- Bug in `unstack` raises `ValueError` when `MultiIndex` contains `PeriodIndex` (GH4342)
- Bug in `boxplot` and `hist` draws unnecessary axes (GH6769)
- Regression in `groupby.nth()` for out-of-bounds indexers (GH6621)
- Bug in `quantile` with `datetime` values (GH6965)
- Bug in `Dataframe.set_index`, `reindex` and `pivot` don't preserve `DatetimeIndex` and `PeriodIndex` attributes (GH3950, GH5878, GH6631)
- Bug in `MultiIndex.get_level_values` doesn't preserve `DatetimeIndex` and `PeriodIndex` attributes (GH7092)

- Bug in `Groupby` doesn't preserve `tz` (GH3950)
- Bug in `PeriodIndex` partial string slicing (GH6716)
- Bug in the HTML repr of a truncated `Series` or `DataFrame` not showing the class name with the `large_repr` set to 'info' (GH7105)
- Bug in `DatetimeIndex` specifying `freq` raises `ValueError` when passed value is too short (GH7098)
- Fixed a bug with the `info` repr not honoring the `display.max_info_columns` setting (GH6939)
- Bug `PeriodIndex` string slicing with out of bounds values (GH5407)
- Fixed a memory error in the hashtable implementation/factorizer on resizing of large tables (GH7157)
- Bug in `isnull` when applied to 0-dimensional object arrays (GH7176)
- Bug in `query/eval` where global constants were not looked up correctly (GH7178)
- Bug in recognizing out-of-bounds positional list indexers with `iloc` and a multi-axis tuple indexer (GH7189)
- Bug in `setitem` with a single value, `MultiIndex` and integer indices (GH7190, GH7218)
- Bug in expressions evaluation with reversed ops, showing in series-dataframe ops (GH7198, GH7192)
- Bug in multi-axis indexing with `> 2` `ndim` and a `MultiIndex` (GH7199)
- Fix a bug where invalid `eval/query` operations would blow the stack (GH5198)

## 6.14 Version 0.13

### 6.14.1 v0.13.1 (February 3, 2014)

{{ header }}

This is a minor release from 0.13.0 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

- Added `infer_datetime_format` keyword to `read_csv/to_datetime` to allow speedups for homogeneously formatted datetimes.
- Will intelligently limit display precision for datetime/timedelta formats.
- Enhanced Panel `apply()` method.
- Suggested tutorials in new *Tutorials* section.
- Our pandas ecosystem is growing, We now feature related projects in a new Pandas Ecosystem section.
- Much work has been taking place on improving the docs, and a new *Contributing* section has been added.
- Even though it may only be of interest to devs, we <3 our new CI status page: [ScatterCI](#).

**Warning:** 0.13.1 fixes a bug that was caused by a combination of having `numpy < 1.8`, and doing chained assignment on a string-like array. Please review *the docs*, chained indexing can have unexpected results and should generally be avoided.

This would previously segfault:

```
In [1]: df = pd.DataFrame({'A': np.array(['foo', 'bar', 'bah', 'foo', 'bar'])})
In [2]: df['A'].iloc[0] = np.nan
In [3]: df
Out[3]:
   A
0 NaN
1 bar
2 bah
3 foo
4 bar
```

The recommended way to do this type of assignment is:

```
In [4]: df = pd.DataFrame({'A': np.array(['foo', 'bar', 'bah', 'foo', 'bar'])})

In [5]: df.loc[0, 'A'] = np.nan

In [6]: df
Out[6]:
   A
0 NaN
1 bar
2 bah
3 foo
4 bar
```

## Output formatting enhancements

- `df.info()` view now display dtype info per column (GH5682)
- `df.info()` now honors the option `max_info_rows`, to disable null counts for large frames (GH5974)

```
In [7]: max_info_rows = pd.get_option('max_info_rows')

In [8]: df = pd.DataFrame({'A': np.random.randn(10),
...:                      'B': np.random.randn(10),
...:                      'C': pd.date_range('20130101', periods=10)
...:                      })

In [9]: df.iloc[3:6, [0, 2]] = np.nan
```

```
# set to not display the null counts
In [10]: pd.set_option('max_info_rows', 0)

In [11]: df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 10 entries, 0 to 9
Data columns (total 3 columns):
#   Column  Dtype
---  ---
0    A      float64
1    B      float64
2    C      datetime64[ns]
dtypes: datetime64[ns](1), float64(2)
memory usage: 368.0 bytes
```

```
# this is the default (same as in 0.13.0)
In [12]: pd.set_option('max_info_rows', max_info_rows)

In [13]: df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 10 entries, 0 to 9
Data columns (total 3 columns):
#   Column  Non-Null Count  Dtype
---  ---
0    A      7 non-null      float64
```

(continues on next page)

(continued from previous page)

```

1  B      10 non-null    float64
2  C       7 non-null    datetime64[ns]
dtypes: datetime64[ns](1), float64(2)
memory usage: 368.0 bytes

```

- Add `show_dimensions` display option for the new DataFrame repr to control whether the dimensions print.

```

In [14]: df = pd.DataFrame([[1, 2], [3, 4]])

In [15]: pd.set_option('show_dimensions', False)

In [16]: df
Out[16]:
   0  1
0  1  2
1  3  4

In [17]: pd.set_option('show_dimensions', True)

In [18]: df
Out[18]:
   0  1
0  1  2
1  3  4

[2 rows x 2 columns]

```

- The `ArrayFormatter` for `datetime` and `timedelta64` now intelligently limit precision based on the values in the array ([GH3401](#))

Previously output might look like:

```

   age                today                diff
0 2001-01-01 00:00:00 2013-04-19 00:00:00 4491 days, 00:00:00
1 2004-06-01 00:00:00 2013-04-19 00:00:00 3244 days, 00:00:00

```

Now the output looks like:

```

In [19]: df = pd.DataFrame([pd.Timestamp('20010101'),
.....:                      pd.Timestamp('20040601')], columns=['age'])
.....:

In [20]: df['today'] = pd.Timestamp('20130419')

In [21]: df['diff'] = df['today'] - df['age']

In [22]: df
Out[22]:
   age                today                diff
0 2001-01-01 2013-04-19 4491 days
1 2004-06-01 2013-04-19 3244 days

[2 rows x 3 columns]

```

## API changes

- Add `-NaN` and `-nan` to the default set of NA values (GH5952). See *NA Values*.
- Added `Series.str.get_dummies` vectorized string method (GH6021), to extract dummy/indicator variables for separated string columns:

```
In [23]: s = pd.Series(['a', 'a|b', np.nan, 'a|c'])

In [24]: s.str.get_dummies(sep='|')
Out[24]:
   a  b  c
0  1  0  0
1  1  1  0
2  0  0  0
3  1  0  1

[4 rows x 3 columns]
```

- Added the `NDFrame.equals()` method to compare if two `NDFrames` are equal have equal axes, dtypes, and values. Added the `array_equivalent` function to compare if two `ndarrays` are equal. `NaNs` in identical locations are treated as equal. (GH5283) See also *the docs* for a motivating example.

```
df = pd.DataFrame({'col': ['foo', 0, np.nan]})
df2 = pd.DataFrame({'col': [np.nan, 0, 'foo']}, index=[2, 1, 0])
df.equals(df2)
df.equals(df2.sort_index())
```

- `DataFrame.apply` will use the `reduce` argument to determine whether a `Series` or a `DataFrame` should be returned when the `DataFrame` is empty (GH6007).

Previously, calling `DataFrame.apply` an empty `DataFrame` would return either a `DataFrame` if there were no columns, or the function being applied would be called with an empty `Series` to guess whether a `Series` or `DataFrame` should be returned:

```
In [32]: def applied_func(col):
....:     print("Apply function being called with: ", col)
....:     return col.sum()
....:

In [33]: empty = DataFrame(columns=['a', 'b'])

In [34]: empty.apply(applied_func)
Apply function being called with: Series([], Length: 0, dtype: float64)
Out[34]:
a    NaN
b    NaN
Length: 2, dtype: float64
```

Now, when `apply` is called on an empty `DataFrame`: if the `reduce` argument is `True` a `Series` will be returned, if it is `False` a `DataFrame` will be returned, and if it is `None` (the default) the function being applied will be called with an empty `Series` to try and guess the return type.

```
In [35]: empty.apply(applied_func, reduce=True)
Out[35]:
a    NaN
b    NaN
Length: 2, dtype: float64
```

(continues on next page)

(continued from previous page)

```
In [36]: empty.apply(applied_func, reduce=False)
Out[36]:
Empty DataFrame
Columns: [a, b]
Index: []

[0 rows x 2 columns]
```

## Prior version deprecations/changes

There are no announced changes in 0.13 or prior that are taking effect as of 0.13.1

## Deprecations

There are no deprecations of prior behavior in 0.13.1

## Enhancements

- `pd.read_csv` and `pd.to_datetime` learned a new `infer_datetime_format` keyword which greatly improves parsing perf in many cases. Thanks to @lexical for suggesting and @danbirken for rapidly implementing. (GH5490, GH6021)

If `parse_dates` is enabled and this flag is set, pandas will attempt to infer the format of the datetime strings in the columns, and if it can be inferred, switch to a faster method of parsing them. In some cases this can increase the parsing speed by ~5-10x.

```
# Try to infer the format for the index column
df = pd.read_csv('foo.csv', index_col=0, parse_dates=True,
                 infer_datetime_format=True)
```

- `date_format` and `datetime_format` keywords can now be specified when writing to excel files (GH4133)
- `MultiIndex.from_product` convenience function for creating a `MultiIndex` from the cartesian product of a set of iterables (GH6055):

```
In [25]: shades = ['light', 'dark']
In [26]: colors = ['red', 'green', 'blue']
In [27]: pd.MultiIndex.from_product([shades, colors], names=['shade', 'color'])
Out[27]:
MultiIndex([('light', 'red'),
            ('light', 'green'),
            ('light', 'blue'),
            ('dark', 'red'),
            ('dark', 'green'),
            ('dark', 'blue')],
           names=['shade', 'color'])
```

- `Panel.apply()` will work on non-ufuncs. See *the docs*.

```
In [28]: import pandas._testing as tm

In [29]: panel = tm.makePanel(5)

In [30]: panel
Out[30]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 5 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemC
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-07 00:00:00
Minor_axis axis: A to D

In [31]: panel['ItemA']
Out[31]:
```

|            | A         | B         | C         | D         |
|------------|-----------|-----------|-----------|-----------|
| 2000-01-03 | -0.673690 | 0.577046  | -1.344312 | -1.469388 |
| 2000-01-04 | 0.113648  | -1.715002 | 0.844885  | 0.357021  |
| 2000-01-05 | -1.478427 | -1.039268 | 1.075770  | -0.674600 |
| 2000-01-06 | 0.524988  | -0.370647 | -0.109050 | -1.776904 |
| 2000-01-07 | 0.404705  | -1.157892 | 1.643563  | -0.968914 |

```
[5 rows x 4 columns]
```

Specifying an apply that operates on a Series (to return a single element)

```
In [32]: panel.apply(lambda x: x.dtype, axis='items')
Out[32]:
```

|            | A       | B       | C       | D       |
|------------|---------|---------|---------|---------|
| 2000-01-03 | float64 | float64 | float64 | float64 |
| 2000-01-04 | float64 | float64 | float64 | float64 |
| 2000-01-05 | float64 | float64 | float64 | float64 |
| 2000-01-06 | float64 | float64 | float64 | float64 |
| 2000-01-07 | float64 | float64 | float64 | float64 |

```
[5 rows x 4 columns]
```

A similar reduction type operation

```
In [33]: panel.apply(lambda x: x.sum(), axis='major_axis')
Out[33]:
```

|   | ItemA     | ItemB     | ItemC     |
|---|-----------|-----------|-----------|
| A | -1.108775 | -1.090118 | -2.984435 |
| B | -3.705764 | 0.409204  | 1.866240  |
| C | 2.110856  | 2.960500  | -0.974967 |
| D | -4.532785 | 0.303202  | -3.685193 |

```
[4 rows x 3 columns]
```

This is equivalent to

```
In [34]: panel.sum('major_axis')
Out[34]:
```

|   | ItemA     | ItemB     | ItemC     |
|---|-----------|-----------|-----------|
| A | -1.108775 | -1.090118 | -2.984435 |
| B | -3.705764 | 0.409204  | 1.866240  |
| C | 2.110856  | 2.960500  | -0.974967 |
| D | -4.532785 | 0.303202  | -3.685193 |

(continues on next page)

(continued from previous page)

```
[4 rows x 3 columns]
```

A transformation operation that returns a Panel, but is computing the z-score across the major\_axis

```
In [35]: result = panel.apply(lambda x: (x - x.mean()) / x.std(),
.....:                        axis='major_axis')
.....:
```

```
In [36]: result
```

```
Out[36]:
```

```
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 5 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemC
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-07 00:00:00
Minor_axis axis: A to D
```

```
In [37]: result['ItemA'] # noqa E999
```

```
Out[37]:
```

|            | A         | B         | C         | D         |
|------------|-----------|-----------|-----------|-----------|
| 2000-01-03 | -0.535778 | 1.500802  | -1.506416 | -0.681456 |
| 2000-01-04 | 0.397628  | -1.108752 | 0.360481  | 1.529895  |
| 2000-01-05 | -1.489811 | -0.339412 | 0.557374  | 0.280845  |
| 2000-01-06 | 0.885279  | 0.421830  | -0.453013 | -1.053785 |
| 2000-01-07 | 0.742682  | -0.474468 | 1.041575  | -0.075499 |

```
[5 rows x 4 columns]
```

- Panel apply() operating on cross-sectional slabs. (GH1148)

```
In [38]: def f(x):
.....:     return ((x.T - x.mean(1)) / x.std(1)).T
.....:
```

```
In [39]: result = panel.apply(f, axis=['items', 'major_axis'])
```

```
In [40]: result
```

```
Out[40]:
```

```
<class 'pandas.core.panel.Panel'>
Dimensions: 4 (items) x 5 (major_axis) x 3 (minor_axis)
Items axis: A to D
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-07 00:00:00
Minor_axis axis: ItemA to ItemC
```

```
In [41]: result.loc[:, :, 'ItemA']
```

```
Out[41]:
```

|            | A         | B         | C         | D         |
|------------|-----------|-----------|-----------|-----------|
| 2000-01-03 | 0.012922  | -0.030874 | -0.629546 | -0.757034 |
| 2000-01-04 | 0.392053  | -1.071665 | 0.163228  | 0.548188  |
| 2000-01-05 | -1.093650 | -0.640898 | 0.385734  | -1.154310 |
| 2000-01-06 | 1.005446  | -1.154593 | -0.595615 | -0.809185 |
| 2000-01-07 | 0.783051  | -0.198053 | 0.919339  | -1.052721 |

```
[5 rows x 4 columns]
```

This is equivalent to the following

```

In [42]: result = pd.Panel({ax: f(panel.loc[:, :, ax]) for ax in panel.minor_axis}
↳)

In [43]: result
Out[43]:
<class 'pandas.core.panel.Panel'>
Dimensions: 4 (items) x 5 (major_axis) x 3 (minor_axis)
Items axis: A to D
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-07 00:00:00
Minor_axis axis: ItemA to ItemC

In [44]: result.loc[:, :, 'ItemA']
Out[44]:
           A          B          C          D
2000-01-03  0.012922 -0.030874 -0.629546 -0.757034
2000-01-04  0.392053 -1.071665  0.163228  0.548188
2000-01-05 -1.093650 -0.640898  0.385734 -1.154310
2000-01-06  1.005446 -1.154593 -0.595615 -0.809185
2000-01-07  0.783051 -0.198053  0.919339 -1.052721

[5 rows x 4 columns]

```

## Performance

### Performance improvements for 0.13.1

- Series datetime/timedelta binary operations ([GH5801](#))
- DataFrame count/dropna for axis=1
- Series.str.contains now has a *regex=False* keyword which can be faster for plain (non-regex) string patterns. ([GH5879](#))
- Series.str.extract ([GH5944](#))
- dtypes/ftypes methods ([GH5968](#))
- indexing with object dtypes ([GH5968](#))
- DataFrame.apply ([GH6013](#))
- Regression in JSON IO ([GH5765](#))
- Index construction from Series ([GH6150](#))

## Experimental

There are no experimental changes in 0.13.1

## Bug fixes

- Bug in `io.wb.get_countries` not including all countries (GH6008)
- Bug in Series `replace` with timestamp dict (GH5797)
- `read_csv/read_table` now respects the `prefix` kwarg (GH5732).
- Bug in selection with missing values via `.ix` from a duplicate indexed DataFrame failing (GH5835)
- Fix issue of boolean comparison on empty DataFrames (GH5808)
- Bug in `isnull` handling NaT in an object array (GH5443)
- Bug in `to_datetime` when passed a `np.nan` or integer datelike and a format string (GH5863)
- Bug in `groupby` dtype conversion with datetimelike (GH5869)
- Regression in handling of empty Series as indexers to Series (GH5877)
- Bug in internal caching, related to (GH5727)
- Testing bug in reading JSON/msgpack from a non-filepath on windows under py3 (GH5874)
- Bug when assigning to `.ix[tuple(...)]` (GH5896)
- Bug in fully reindexing a Panel (GH5905)
- Bug in `idxmin/max` with object dtypes (GH5914)
- Bug in `BusinessDay` when adding `n` days to a date not on offset when `n>5` and `n%5==0` (GH5890)
- Bug in assigning to chained series with a series via `ix` (GH5928)
- Bug in creating an empty DataFrame, copying, then assigning (GH5932)
- Bug in `DataFrame.tail` with empty frame (GH5846)
- Bug in propagating metadata on `resample` (GH5862)
- Fixed string-representation of NaT to be “NaT” (GH5708)
- Fixed string-representation for Timestamp to show nanoseconds if present (GH5912)
- `pd.match` not returning passed sentinel
- `Panel.to_frame()` no longer fails when `major_axis` is a `MultiIndex` (GH5402).
- Bug in `pd.read_msgpack` with inferring a `DateTimeIndex` frequency incorrectly (GH5947)
- Fixed `to_datetime` for array with both Tz-aware datetimes and NaT’s (GH5961)
- Bug in rolling skew/kurtosis when passed a Series with bad data (GH5749)
- Bug in `scipy.interpolate` methods with a datetime index (GH5975)
- Bug in NaT comparison if a mixed `datetime/np.datetime64` with NaT were passed (GH5968)
- Fixed bug with `pd.concat` losing dtype information if all inputs are empty (GH5742)
- Recent changes in IPython cause warnings to be emitted when using previous versions of pandas in QTConsole, now fixed. If you’re using an older version and need to suppress the warnings, see (GH5922).
- Bug in merging `timedelta` dtypes (GH5695)
- Bug in `plotting.scatter_matrix` function. Wrong alignment among diagonal and off-diagonal plots, see (GH5497).
- Regression in Series with a `MultiIndex` via `ix` (GH6018)

- Bug in Series.xs with a MultiIndex (GH6018)
- Bug in Series construction of mixed type with datelike and an integer (which should result in object type and not automatic conversion) (GH6028)
- Possible segfault when chained indexing with an object array under NumPy 1.7.1 (GH6026, GH6056)
- Bug in setting using fancy indexing a single element with a non-scalar (e.g. a list), (GH6043)
- to\_sql did not respect if\_exists (GH4110 GH4304)
- Regression in .get (None) indexing from 0.12 (GH5652)
- Subtle iloc indexing bug, surfaced in (GH6059)
- Bug with insert of strings into DatetimeIndex (GH5818)
- Fixed unicode bug in to\_html/HTML repr (GH6098)
- Fixed missing arg validation in get\_options\_data (GH6105)
- Bug in assignment with duplicate columns in a frame where the locations are a slice (e.g. next to each other) (GH6120)
- Bug in propagating \_ref\_locs during construction of a DataFrame with dups index/columns (GH6121)
- Bug in DataFrame.apply when using mixed datelike reductions (GH6125)
- Bug in DataFrame.append when appending a row with different columns (GH6129)
- Bug in DataFrame construction with rearray and non-ns datetime dtype (GH6140)
- Bug in .loc setitem indexing with a dataframe on rhs, multiple item setting, and a datetimelike (GH6152)
- Fixed a bug in query/eval during lexicographic string comparisons (GH6155).
- Fixed a bug in query where the index of a single-element Series was being thrown away (GH6148).
- Bug in HDFStore on appending a dataframe with MultiIndexed columns to an existing table (GH6167)
- Consistency with dtypes in setting an empty DataFrame (GH6171)
- Bug in selecting on a MultiIndex HDFStore even in the presence of under specified column spec (GH6169)
- Bug in nanops.var with ddof=1 and 1 elements would sometimes return inf rather than nan on some platforms (GH6136)
- Bug in Series and DataFrame bar plots ignoring the use\_index keyword (GH6209)
- Bug in groupby with mixed str/int under python3 fixed; argsort was failing (GH6212)

### 6.14.2 v0.13.0 (January 3, 2014)

{{ header }}

This is a major release from 0.12.0 and includes a number of API changes, several new features and enhancements along with a large number of bug fixes.

Highlights include:

- support for a new index type `Float64Index`, and other Indexing enhancements
- `HDFStore` has a new string based syntax for query specification
- support for new methods of interpolation
- updated `timedelta` operations
- a new string manipulation method `extract`
- Nanosecond support for Offsets
- `isin` for DataFrames

Several experimental features are added, including:

- new `eval/query` methods for expression evaluation
- support for `msgpack` serialization
- an i/o interface to Google's `BigQuery`

There are several new or updated docs sections including:

- *Comparison with SQL*, which should be useful for those familiar with SQL but still learning pandas.
- *Comparison with R*, idiom translations from R to pandas.
- *Enhancing Performance*, ways to enhance pandas performance with `eval/query`.

**Warning:** In 0.13.0 `Series` has internally been refactored to no longer sub-class `ndarray` but instead subclass `NDFrame`, similar to the rest of the pandas containers. This should be a transparent change with only very limited API implications. See *Internal Refactoring*

## API changes

- `read_excel` now supports an integer in its `sheetname` argument giving the index of the sheet to read in (GH4301).
- Text parser now treats anything that reads like `inf` (“inf”, “Inf”, “-Inf”, “iNf”, etc.) as infinity. (GH4220, GH4219), affecting `read_table`, `read_csv`, etc.
- pandas now is Python 2/3 compatible without the need for `2to3` thanks to @jtratner. As a result, pandas now uses iterators more extensively. This also led to the introduction of substantive parts of the Benjamin Peterson’s `six` library into `compat`. (GH4384, GH4375, GH4372)
- `pandas.util.compat` and `pandas.util.py3compat` have been merged into `pandas.compat`. `pandas.compat` now includes many functions allowing 2/3 compatibility. It contains both list and iterator versions of `range`, `filter`, `map` and `zip`, plus other necessary elements for Python 3 compatibility. `lmap`, `lzip`, `lrange` and `lfilter` all produce lists instead of iterators, for compatibility with `numpy`, subscripting and pandas constructors. (GH4384, GH4375, GH4372)
- `Series.get` with negative indexers now returns the same as `[]` (GH4390)
- Changes to how `Index` and `MultiIndex` handle metadata (`levels`, `labels`, and `names`) (GH4039):

```
# previously, you would have set levels or labels directly
>>> pd.index.levels = [[1, 2, 3, 4], [1, 2, 4, 4]]

# now, you use the set_levels or set_labels methods
>>> index = pd.index.set_levels([[1, 2, 3, 4], [1, 2, 4, 4]])

# similarly, for names, you can rename the object
# but setting names is not deprecated
>>> index = pd.index.set_names(["bob", "cranberry"])

# and all methods take an inplace kwarg - but return None
>>> pd.index.set_names(["bob", "cranberry"], inplace=True)
```

- All division with `NDFrame` objects is now *truedivision*, regardless of the future import. This means that operating on pandas objects will by default use *floating point* division, and return a floating point dtype. You can use `//` and `floordiv` to do integer division.

### Integer division

```
In [3]: arr = np.array([1, 2, 3, 4])

In [4]: arr2 = np.array([5, 3, 2, 1])

In [5]: arr / arr2
Out [5]: array([0, 0, 1, 4])

In [6]: pd.Series(arr) // pd.Series(arr2)
Out [6]:
0    0
1    0
2    1
3    4
dtype: int64
```

### True Division

```
In [7]: pd.Series(arr) / pd.Series(arr2) # no future import required
Out[7]:
0    0.200000
1    0.666667
2    1.500000
3    4.000000
dtype: float64
```

- Infer and downcast dtype if `downcast='infer'` is passed to `fillna/ffill/bfill` (GH4604)
- `__nonzero__` for all NDFrame objects, will now raise a `ValueError`, this reverts back to (GH1073, GH4633) behavior. See *gotchas* for a more detailed discussion.

This prevents doing boolean comparison on *entire* pandas objects, which is inherently ambiguous. These all will raise a `ValueError`.

```
>>> df = pd.DataFrame({'A': np.random.randn(10),
...                    'B': np.random.randn(10),
...                    'C': pd.date_range('20130101', periods=10)
...                    })
...
>>> if df:
...     pass
...
Traceback (most recent call last):
...
ValueError: The truth value of a DataFrame is ambiguous. Use a.empty,
a.bool(), a.item(), a.any() or a.all().

>>> df1 = df
>>> df2 = df
>>> df1 and df2
Traceback (most recent call last):
...
ValueError: The truth value of a DataFrame is ambiguous. Use a.empty,
a.bool(), a.item(), a.any() or a.all().

>>> d = [1, 2, 3]
>>> s1 = pd.Series(d)
>>> s2 = pd.Series(d)
>>> s1 and s2
Traceback (most recent call last):
...
ValueError: The truth value of a DataFrame is ambiguous. Use a.empty,
a.bool(), a.item(), a.any() or a.all().
```

Added the `.bool()` method to NDFrame objects to facilitate evaluating of single-element boolean Series:

```
In [1]: pd.Series([True]).bool()
Out[1]: True

In [2]: pd.Series([False]).bool()
Out[2]: False

In [3]: pd.DataFrame([[True]]).bool()
Out[3]: True

In [4]: pd.DataFrame([[False]]).bool()
```

(continues on next page)

(continued from previous page)

```
Out [4]: False
```

- All non-Index NDFrame (Series, DataFrame, Panel, Panel4D, SparsePanel, etc.), now support the entire set of arithmetic operators and arithmetic flex methods (add, sub, mul, etc.). SparsePanel does not support pow or mod with non-scalars. (GH3765)
- Series and DataFrame now have a mode() method to calculate the statistical mode(s) by axis/Series. (GH5367)
- Chained assignment will now by default warn if the user is assigning to a copy. This can be changed with the option mode.chained\_assignment, allowed options are raise/warn/None. See the docs.

```
In [5]: dfc = pd.DataFrame({'A': ['aaa', 'bbb', 'ccc'], 'B': [1, 2, 3]})
```

```
In [6]: pd.set_option('chained_assignment', 'warn')
```

The following warning / exception will show if this is attempted.

```
In [7]: dfc.loc[0]['A'] = 1111
```

```
Traceback (most recent call last)
...
SettingWithCopyWarning:
  A value is trying to be set on a copy of a slice from a DataFrame.
  Try using .loc[row_index,col_indexer] = value instead
```

Here is the correct method of assignment.

```
In [8]: dfc.loc[0, 'A'] = 11
```

```
In [9]: dfc
```

```
Out [9]:
   A  B
0  11  1
1  bbb  2
2  ccc  3
```

- **Panel.reindex** has the following call signature `Panel.reindex(items=None, major_axis=None, minor_axis=None)` to conform with other NDFrame objects. See *Internal Refactoring* for more information.
- **Series.argmax** and **Series.argmin** are now aliased to **Series.idxmax** and **Series.idxmin**. These return the index of the min or max element respectively. Prior to 0.13.0 these would return the position of the min / max element. (GH6214)

## Prior version deprecations/changes

These were announced changes in 0.12 or prior that are taking effect as of 0.13.0

- Remove deprecated Factor (GH3650)
- Remove deprecated set\_printoptions/reset\_printoptions (GH3046)
- Remove deprecated \_verbose\_info (GH3215)
- Remove deprecated read\_clipboard/to\_clipboard/ExcelFile/ExcelWriter from pandas.io.parsers (GH3717) These are available as functions in the main pandas namespace (e.g. pd.read\_clipboard)

- default for `tupleize_cols` is now `False` for both `to_csv` and `read_csv`. Fair warning in 0.12 (GH3604)
- default for `display.max_seq_len` is now 100 rather than `None`. This activates truncated display (“...”) of long sequences in various places. (GH3391)

## Deprecations

Deprecated in 0.13.0

- deprecated `iterkv`, which will be removed in a future release (this was an alias of `iteritems` used to bypass 2to3’s changes). (GH4384, GH4375, GH4372)
- deprecated the string method `match`, whose role is now performed more idiomatically by `extract`. In a future release, the default behavior of `match` will change to become analogous to `contains`, which returns a boolean indexer. (Their distinction is strictness: `match` relies on `re.match` while `contains` relies on `re.search`.) In this release, the deprecated behavior is the default, but the new behavior is available through the keyword argument `as_indexer=True`.

## Indexing API changes

Prior to 0.13, it was impossible to use a label indexer (`.loc/.ix`) to set a value that was not contained in the index of a particular axis. (GH2578). See *the docs*

In the `Series` case this is effectively an appending operation

```
In [10]: s = pd.Series([1, 2, 3])
```

```
In [11]: s
Out[11]:
0    1
1    2
2    3
dtype: int64
```

```
In [12]: s[5] = 5.
```

```
In [13]: s
Out[13]:
0    1.0
1    2.0
2    3.0
5    5.0
dtype: float64
```

```
In [14]: dfi = pd.DataFrame(np.arange(6).reshape(3, 2),
.....:                      columns=['A', 'B'])
.....:
```

```
In [15]: dfi
Out[15]:
   A  B
0  0  1
1  2  3
2  4  5
```

This would previously `KeyError`

```
In [16]: dfi.loc[:, 'C'] = dfi.loc[:, 'A']
```

```
In [17]: dfi
```

```
Out [17]:
```

```
   A  B  C
0  0  1  0
1  2  3  2
2  4  5  4
```

This is like an append operation.

```
In [18]: dfi.loc[3] = 5
```

```
In [19]: dfi
```

```
Out [19]:
```

```
   A  B  C
0  0  1  0
1  2  3  2
2  4  5  4
3  5  5  5
```

A Panel setting operation on an arbitrary axis aligns the input to the Panel

```
In [20]: p = pd.Panel(np.arange(16).reshape(2, 4, 2),
.....:                items=['Item1', 'Item2'],
.....:                major_axis=pd.date_range('2001/1/12', periods=4),
.....:                minor_axis=['A', 'B'], dtype='float64')
.....:
```

```
In [21]: p
```

```
Out [21]:
```

```
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 4 (major_axis) x 2 (minor_axis)
Items axis: Item1 to Item2
Major_axis axis: 2001-01-12 00:00:00 to 2001-01-15 00:00:00
Minor_axis axis: A to B
```

```
In [22]: p.loc[:, :, 'C'] = pd.Series([30, 32], index=p.items)
```

```
In [23]: p
```

```
Out [23]:
```

```
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 4 (major_axis) x 3 (minor_axis)
Items axis: Item1 to Item2
Major_axis axis: 2001-01-12 00:00:00 to 2001-01-15 00:00:00
Minor_axis axis: A to C
```

```
In [24]: p.loc[:, :, 'C']
```

```
Out [24]:
```

```
   Item1  Item2
2001-01-12  30.0  32.0
2001-01-13  30.0  32.0
2001-01-14  30.0  32.0
2001-01-15  30.0  32.0
```

## Float64Index API change

- Added a new index type, `Float64Index`. This will be automatically created when passing floating values in index creation. This enables a pure label-based slicing paradigm that makes `[], ix, loc` for scalar indexing and slicing work exactly the same. See *the docs*, ([GH263](#))

Construction is by default for floating type values.

```
In [20]: index = pd.Index([1.5, 2, 3, 4.5, 5])
In [21]: index
Out [21]: Float64Index([1.5, 2.0, 3.0, 4.5, 5.0], dtype='float64')
In [22]: s = pd.Series(range(5), index=index)
In [23]: s
Out [23]:
1.5    0
2.0    1
3.0    2
4.5    3
5.0    4
dtype: int64
```

Scalar selection for `[], .ix, .loc` will always be label based. An integer will match an equal float index (e.g. 3 is equivalent to 3.0)

```
In [24]: s[3]
Out [24]: 2
In [25]: s.loc[3]
Out [25]: 2
```

The only positional indexing is via `iloc`

```
In [26]: s.iloc[3]
Out [26]: 3
```

A scalar index that is not found will raise `KeyError`

Slicing is ALWAYS on the values of the index, for `[], ix, loc` and ALWAYS positional with `iloc`

```
In [27]: s[2:4]
Out [27]:
2.0    1
3.0    2
dtype: int64
In [28]: s.loc[2:4]
Out [28]:
2.0    1
3.0    2
dtype: int64
In [29]: s.iloc[2:4]
Out [29]:
3.0    2
4.5    3
dtype: int64
```

In float indexes, slicing using floats are allowed

```
In [30]: s[2.1:4.6]
Out[30]:
3.0    2
4.5    3
dtype: int64

In [31]: s.loc[2.1:4.6]
Out[31]:
3.0    2
4.5    3
dtype: int64
```

- Indexing on other index types are preserved (and positional fallback for `[]`, `ix`), with the exception, that floating point slicing on indexes on non `Float64Index` will now raise a `TypeError`.

```
In [1]: pd.Series(range(5))[3.5]
TypeError: the label [3.5] is not a proper indexer for this index type
↳ (Int64Index)

In [1]: pd.Series(range(5))[3.5:4.5]
TypeError: the slice start [3.5] is not a proper indexer for this index type
↳ (Int64Index)
```

Using a scalar float indexer will be deprecated in a future version, but is allowed for now.

```
In [3]: pd.Series(range(5))[3.0]
Out[3]: 3
```

## HDFStore API changes

- Query Format Changes. A much more string-like query format is now supported. See *the docs*.

```
In [32]: path = 'test.h5'

In [33]: dfq = pd.DataFrame(np.random.randn(10, 4),
.....:                      columns=list('ABCD'),
.....:                      index=pd.date_range('20130101', periods=10))
.....:

In [34]: dfq.to_hdf(path, 'dfq', format='table', data_columns=True)
```

Use boolean expressions, with in-line function evaluation.

```
In [35]: pd.read_hdf(path, 'dfq',
.....:                 where="index>Timestamp('20130104') & columns=['A', 'B']")
.....:
Out[35]:
           A         B
2013-01-05 -0.271020  1.288393
2013-01-06  0.846974 -0.685597
2013-01-07  0.625555 -0.059268
2013-01-08 -1.087532  1.998044
2013-01-09  0.886313 -1.350722
2013-01-10  1.920906 -0.388231
```

Use an inline column reference

```
In [36]: pd.read_hdf(path, 'dfq',
....:               where="A>0 or C>0")
....:
Out[36]:
```

|            | A         | B         | C         | D         |
|------------|-----------|-----------|-----------|-----------|
| 2013-01-02 | -0.486768 | 1.685148  | 0.112572  | -1.495309 |
| 2013-01-03 | 0.898435  | -0.148217 | -1.596070 | 0.159653  |
| 2013-01-04 | 0.262136  | 0.036220  | 0.184735  | -0.255069 |
| 2013-01-05 | -0.271020 | 1.288393  | 0.294633  | -1.165787 |
| 2013-01-06 | 0.846974  | -0.685597 | 0.609099  | -0.303961 |
| 2013-01-07 | 0.625555  | -0.059268 | 0.249698  | 1.103949  |
| 2013-01-09 | 0.886313  | -1.350722 | -0.886348 | -1.013316 |
| 2013-01-10 | 1.920906  | -0.388231 | -2.314394 | 0.665508  |

- the format keyword now replaces the table keyword; allowed values are fixed(f) or table(t) the same defaults as prior < 0.13.0 remain, e.g. put implies fixed format and append implies table format. This default format can be set as an option by setting `io.hdf.default_format`.

```
In [37]: path = 'test.h5'

In [38]: df = pd.DataFrame(np.random.randn(10, 2))

In [39]: df.to_hdf(path, 'df_table', format='table')

In [40]: df.to_hdf(path, 'df_table2', append=True)

In [41]: df.to_hdf(path, 'df_fixed')

In [42]: with pd.HDFStore(path) as store:
....:     print(store)
....:
<class 'pandas.io.pytables.HDFStore'>
File path: test.h5
```

- Significant table writing performance improvements
- handle a passed Series in table format ([GH4330](#))
- can now serialize a `timedelta64[ns]` dtype in a table ([GH3577](#)), See *the docs*.
- added an `is_open` property to indicate if the underlying file handle is open; a closed store will now report 'CLOSED' when viewing the store (rather than raising an error) ([GH4409](#))
- a close of a `HDFStore` now will close that instance of the `HDFStore` but will only close the actual file if the ref count (by PyTables) w.r.t. all of the open handles are 0. Essentially you have a local instance of `HDFStore` referenced by a variable. Once you close it, it will report closed. Other references (to the same file) will continue to operate until they themselves are closed. Performing an action on a closed file will raise `ClosedFileError`

```
In [43]: path = 'test.h5'

In [44]: df = pd.DataFrame(np.random.randn(10, 2))

In [45]: store1 = pd.HDFStore(path)

In [46]: store2 = pd.HDFStore(path)
```

(continues on next page)

(continued from previous page)

```

In [47]: store1.append('df', df)

In [48]: store2.append('df2', df)

In [49]: store1
Out [49]:
<class 'pandas.io.pytables.HDFStore'>
File path: test.h5

In [50]: store2
Out [50]:
<class 'pandas.io.pytables.HDFStore'>
File path: test.h5

In [51]: store1.close()

In [52]: store2
Out [52]:
<class 'pandas.io.pytables.HDFStore'>
File path: test.h5

In [53]: store2.close()

In [54]: store2
Out [54]:
<class 'pandas.io.pytables.HDFStore'>
File path: test.h5

```

- removed the `_quiet` attribute, replace by a `DuplicateWarning` if retrieving duplicate rows from a table (GH4367)
- removed the `warn` argument from `open`. Instead a `PossibleDataLossError` exception will be raised if you try to use `mode='w'` with an OPEN file handle (GH4367)
- allow a passed locations array or mask as a `where` condition (GH4467). See *the docs* for an example.
- add the keyword `dropna=True` to `append` to change whether ALL nan rows are not written to the store (default is True, ALL nan rows are NOT written), also settable via the option `io.hdf.dropna_table` (GH4625)
- pass through store creation arguments; can be used to support in-memory stores

### DataFrame repr changes

The HTML and plain text representations of `DataFrame` now show a truncated view of the table once it exceeds a certain size, rather than switching to the short info view (GH4886, GH5550). This makes the representation more consistent as small `DataFrames` get larger.

|            |       |       |       |       |           |       |
|------------|-------|-------|-------|-------|-----------|-------|
| 2010-03-29 | 13.70 | 13.88 | 13.39 | 13.57 | 158225000 | 12.98 |
| 2010-03-30 | 13.55 | 13.64 | 13.18 | 13.28 | 142055200 | 12.70 |
|            | ...   | ...   | ...   | ...   | ...       | ...   |

771 rows × 6 columns

To get the info view, call `DataFrame.info()`. If you prefer the info view as the repr for large DataFrames, you can set this by running `set_option('display.large_repr', 'info')`.

## Enhancements

- `df.to_clipboard()` learned a new `excel` keyword that let's you paste df data directly into excel (enabled by default). (GH5070).
- `read_html` now raises a `URLError` instead of catching and raising a `ValueError` (GH4303, GH4305)
- Added a test for `read_clipboard()` and `to_clipboard()` (GH4282)
- Clipboard functionality now works with PySide (GH4282)
- Added a more informative error message when plot arguments contain overlapping color and style arguments (GH4402)
- `to_dict` now takes records as a possible out type. Returns an array of column-keyed dictionaries. (GH4936)
- NaN handling in `get_dummies` (GH4446) with `dummy_na`

```
# previously, nan was erroneously counted as 2 here
# now it is not counted at all
In [55]: pd.get_dummies([1, 2, np.nan])
Out [55]:
   1.0  2.0
0    1    0
1    0    1
2    0    0

# unless requested
In [56]: pd.get_dummies([1, 2, np.nan], dummy_na=True)
Out [56]:
   1.0  2.0  NaN
0    1    0    0
1    0    1    0
2    0    0    1
```

- `timedelta64[ns]` operations. See *the docs*.

**Warning:** Most of these operations require `numpy >= 1.7`

Using the new top-level `to_timedelta`, you can convert a scalar or array from the standard `timedelta` format (produced by `to_csv`) into a `timedelta` type (`np.timedelta64` in nanoseconds).

```
In [57]: pd.to_timedelta('1 days 06:05:01.00003')
Out [57]: Timedelta('1 days 06:05:01.000030')

In [58]: pd.to_timedelta('15.5us')
Out [58]: Timedelta('0 days 00:00:00.000015')

In [59]: pd.to_timedelta(['1 days 06:05:01.00003', '15.5us', 'nan'])
Out [59]: TimedeltaIndex(['1 days 06:05:01.000030', '0 days 00:00:00.000015', NaT],
  → dtype='timedelta64[ns]', freq=None)

In [60]: pd.to_timedelta(np.arange(5), unit='s')
```

(continues on next page)

(continued from previous page)

```

Out [60]: TimedeltaIndex(['00:00:00', '00:00:01', '00:00:02', '00:00:03', '00:00:04
↪'], dtype='timedelta64[ns]', freq=None)

In [61]: pd.to_timedelta(np.arange(5), unit='d')
Out [61]: TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'], dtype=
↪'timedelta64[ns]', freq=None)

```

A Series of dtype `timedelta64[ns]` can now be divided by another `timedelta64[ns]` object, or astyped to yield a `float64` typed Series. This is frequency conversion. See *the docs* for the docs.

```

In [62]: import datetime

In [63]: td = pd.Series(pd.date_range('20130101', periods=4)) - pd.Series(
.....:     pd.date_range('20121201', periods=4))
.....:

In [64]: td[2] += np.timedelta64(datetime.timedelta(minutes=5, seconds=3))

In [65]: td[3] = np.nan

In [66]: td
Out [66]:
0    31 days 00:00:00
1    31 days 00:00:00
2    31 days 00:05:03
3                NaT
dtype: timedelta64[ns]

# to days
In [67]: td / np.timedelta64(1, 'D')
Out [67]:
0    31.000000
1    31.000000
2    31.003507
3             NaN
dtype: float64

In [68]: td.astype('timedelta64[D]')
Out [68]:
0    31.0
1    31.0
2    31.0
3     NaN
dtype: float64

# to seconds
In [69]: td / np.timedelta64(1, 's')
Out [69]:
0    2678400.0
1    2678400.0
2    2678703.0
3             NaN
dtype: float64

In [70]: td.astype('timedelta64[s]')
Out [70]:

```

(continues on next page)

(continued from previous page)

```

0    2678400.0
1    2678400.0
2    2678703.0
3         NaN
dtype: float64

```

Dividing or multiplying a `timedelta64[ns]` Series by an integer or integer Series

```

In [71]: td * -1
Out [71]:
0    -31 days +00:00:00
1    -31 days +00:00:00
2    -32 days +23:54:57
3         NaT
dtype: timedelta64[ns]

In [72]: td * pd.Series([1, 2, 3, 4])
Out [72]:
0    31 days 00:00:00
1    62 days 00:00:00
2    93 days 00:15:09
3         NaT
dtype: timedelta64[ns]

```

Absolute `DateOffset` objects can act equivalently to `timedeltas`

```

In [73]: from pandas import offsets

In [74]: td + offsets.Minute(5) + offsets.Milli(5)
Out [74]:
0    31 days 00:05:00.005000
1    31 days 00:05:00.005000
2    31 days 00:10:03.005000
3         NaT
dtype: timedelta64[ns]

```

`fillna` is now supported for `timedeltas`

```

In [75]: td.fillna(pd.Timedelta(0))
Out [75]:
0    31 days 00:00:00
1    31 days 00:00:00
2    31 days 00:05:03
3     0 days 00:00:00
dtype: timedelta64[ns]

In [76]: td.fillna(datetime.timedelta(days=1, seconds=5))
Out [76]:
0    31 days 00:00:00
1    31 days 00:00:00
2    31 days 00:05:03
3     1 days 00:00:05
dtype: timedelta64[ns]

```

You can do numeric reduction operations on `timedeltas`.

```
In [77]: td.mean()
Out [77]: Timedelta('31 days 00:01:41')
```

```
In [78]: td.quantile(.1)
Out [78]: Timedelta('31 days 00:00:00')
```

- `plot(kind='kde')` now accepts the optional parameters `bw_method` and `ind`, passed to `scipy.stats.gaussian_kde()` (for `scipy >= 0.11.0`) to set the bandwidth, and to `gkde.evaluate()` to specify the indices at which it is evaluated, respectively. See `scipy` docs. (GH4298)
- `DataFrame` constructor now accepts a `numpy` masked record array (GH3478)
- The new vectorized string method `extract` return regular expression matches more conveniently.

```
In [79]: pd.Series(['a1', 'b2', 'c3']).str.extract('[ab](\d)')
Out [79]:
   0
0   1
1   2
2  NaN
```

Elements that do not match return `NaN`. Extracting a regular expression with more than one group returns a `DataFrame` with one column per group.

```
In [80]: pd.Series(['a1', 'b2', 'c3']).str.extract('([ab])(\d)')
Out [80]:
   0  1
0   a  1
1   b  2
2  NaN NaN
```

Elements that do not match return a row of `NaN`. Thus, a `Series` of messy strings can be *converted* into a like-indexed `Series` or `DataFrame` of cleaned-up or more useful strings, without necessitating `get()` to access tuples or `re.match` objects.

Named groups like

```
In [81]: pd.Series(['a1', 'b2', 'c3']).str.extract(
.....:     '(?P<letter>[ab])(?P<digit>\d)')
.....:
Out [81]:
   letter digit
0      a      1
1      b      2
2    NaN    NaN
```

and optional groups can also be used.

```
In [82]: pd.Series(['a1', 'b2', '3']).str.extract(
.....:     '(?P<letter>[ab])?(?P<digit>\d)')
.....:
Out [82]:
   letter digit
0      a      1
1      b      2
2    NaN      3
```

- `read_stata` now accepts Stata 13 format (GH4291)

- `read_fwf` now infers the column specifications from the first 100 rows of the file if the data has correctly separated and properly aligned columns using the delimiter provided to the function (GH4488).
- support for nanosecond times as an offset

**Warning:** These operations require `numpy >= 1.7`

Period conversions in the range of seconds and below were reworked and extended up to nanoseconds. Periods in the nanosecond range are now available.

```
In [83]: pd.date_range('2013-01-01', periods=5, freq='5N')
Out [83]:
DatetimeIndex([
    '2013-01-01 00:00:00',
    '2013-01-01 00:00:00.000000005',
    '2013-01-01 00:00:00.000000010',
    '2013-01-01 00:00:00.000000015',
    '2013-01-01 00:00:00.000000020'],
    dtype='datetime64[ns]', freq='5N')
```

or with frequency as offset

```
In [84]: pd.date_range('2013-01-01', periods=5, freq=pd.offsets.Nano(5))
Out [84]:
DatetimeIndex([
    '2013-01-01 00:00:00',
    '2013-01-01 00:00:00.000000005',
    '2013-01-01 00:00:00.000000010',
    '2013-01-01 00:00:00.000000015',
    '2013-01-01 00:00:00.000000020'],
    dtype='datetime64[ns]', freq='5N')
```

Timestamps can be modified in the nanosecond range

```
In [85]: t = pd.Timestamp('20130101 09:01:02')

In [86]: t + pd.tseries.offsets.Nano(123)
Out [86]: Timestamp('2013-01-01 09:01:02.000000123')
```

- A new method, `isin` for DataFrames, which plays nicely with boolean indexing. The argument to `isin`, what we're comparing the DataFrame to, can be a DataFrame, Series, dict, or array of values. See *the docs* for more.

To get the rows where any of the conditions are met:

```
In [87]: dfi = pd.DataFrame({'A': [1, 2, 3, 4], 'B': ['a', 'b', 'f', 'n']})

In [88]: dfi
Out [88]:
   A  B
0  1  a
1  2  b
2  3  f
3  4  n

In [89]: other = pd.DataFrame({'A': [1, 3, 3, 7], 'B': ['e', 'f', 'f', 'e']})

In [90]: mask = dfi.isin(other)
```

(continues on next page)

(continued from previous page)

```
In [91]: mask
Out[91]:
      A      B
0  True  False
1  False False
2   True   True
3  False  False

In [92]: dfi[mask.any(1)]
Out[92]:
      A  B
0    1  a
2    3  f
```

- Series now supports a `to_frame` method to convert it to a single-column DataFrame (GH5164)
- All R datasets listed here <http://stat.ethz.ch/R-manual/R-devel/library/datasets/html/00Index.html> can now be loaded into Pandas objects

```
# note that pandas.rpy was deprecated in v0.16.0
import pandas.rpy.common as com
com.load_data('Titanic')
```

- `tz_localize` can infer a fall daylight savings transition based on the structure of the unlocalized data (GH4230), see *the docs*
- `DatetimeIndex` is now in the API documentation, see *the docs*
- `json_normalize()` is a new method to allow you to create a flat table from semi-structured JSON data. See *the docs* (GH1067)
- Added PySide support for the `qtpandas DataFrameModel` and `DataFrameWidget`.
- Python csv parser now supports `usecols` (GH4335)
- Frequencies gained several new offsets:
  - `LastWeekOfMonth` (GH4637)
  - `FY5253`, and `FY5253Quarter` (GH4511)
- DataFrame has a new `interpolate` method, similar to Series (GH4434, GH1892)

```
In [93]: df = pd.DataFrame({'A': [1, 2.1, np.nan, 4.7, 5.6, 6.8],
.....:                      'B': [.25, np.nan, np.nan, 4, 12.2, 14.4]})
.....:

In [94]: df.interpolate()
Out[94]:
      A      B
0  1.0  0.25
1  2.1  1.50
2  3.4  2.75
3  4.7  4.00
4  5.6 12.20
5  6.8 14.40
```

Additionally, the method argument to `interpolate` has been expanded to include 'nearest', 'zero', 'slinear', 'quadratic', 'cubic', 'barycentric', 'krogh',

'piecewise\_polynomial', 'pchip', 'polynomial', 'spline' The new methods require `scipy`. Consult the Scipy reference [guide](#) and [documentation](#) for more information about when the various methods are appropriate. See *the docs*.

Interpolate now also accepts a `limit` keyword argument. This works similar to `fillna`'s `limit`:

```
In [95]: ser = pd.Series([1, 3, np.nan, np.nan, np.nan, 11])
In [96]: ser.interpolate(limit=2)
Out[96]:
0      1.0
1      3.0
2      5.0
3      7.0
4      NaN
5     11.0
dtype: float64
```

- Added `wide_to_long` panel data convenience function. See *the docs*.

```
In [97]: np.random.seed(123)
In [98]: df = pd.DataFrame({"A1970" : {0 : "a", 1 : "b", 2 : "c"},
.....:                    "A1980" : {0 : "d", 1 : "e", 2 : "f"},
.....:                    "B1970" : {0 : 2.5, 1 : 1.2, 2 : .7},
.....:                    "B1980" : {0 : 3.2, 1 : 1.3, 2 : .1},
.....:                    "X"      : dict(zip(range(3), np.random.randn(3)))
.....:                    })
In [99]: df["id"] = df.index
In [100]: df
Out[100]:
   A1970 A1980  B1970  B1980         X  id
0      a     d    2.5    3.2 -1.085631  0
1      b     e    1.2    1.3  0.997345  1
2      c     f    0.7    0.1  0.282978  2
In [101]: pd.wide_to_long(df, ["A", "B"], i="id", j="year")
Out[101]:
           X  A    B
id year
0  1970 -1.085631  a  2.5
1  1970  0.997345  b  1.2
2  1970  0.282978  c  0.7
0  1980 -1.085631  d  3.2
1  1980  0.997345  e  1.3
2  1980  0.282978  f  0.1
```

- `to_csv` now takes a `date_format` keyword argument that specifies how output datetime objects should be formatted. Datetimes encountered in the index, columns, and values will all have this formatting applied. ([GH4313](#))
- `DataFrame.plot` will scatter plot `x` versus `y` by passing `kind='scatter'` ([GH2215](#))
- Added support for Google Analytics v3 API segment IDs that also supports v2 IDs. ([GH5271](#))

## Experimental

- The new `eval()` function implements expression evaluation using `numexpr` behind the scenes. This results in large speedups for complicated expressions involving large DataFrames/Series. For example,

```
In [102]: nrows, ncols = 20000, 100
```

```
In [103]: df1, df2, df3, df4 = [pd.DataFrame(np.random.randn(nrows, ncols))
.....:                               for _ in range(4)]
.....:
```

```
# eval with NumExpr backend
```

```
In [104]: %timeit pd.eval('df1 + df2 + df3 + df4')
8.63 ms +- 865 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

```
# pure Python evaluation
```

```
In [105]: %timeit df1 + df2 + df3 + df4
11.8 ms +- 548 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

For more details, see the *the docs*

- Similar to `pandas.eval`, `DataFrame` has a new `DataFrame.eval` method that evaluates an expression in the context of the `DataFrame`. For example,

```
In [106]: df = pd.DataFrame(np.random.randn(10, 2), columns=['a', 'b'])
```

```
In [107]: df.eval('a + b')
```

```
Out[107]:
0    -0.685204
1     1.589745
2     0.325441
3    -1.784153
4    -0.432893
5     0.171850
6     1.895919
7     3.065587
8    -0.092759
9     1.391365
dtype: float64
```

- `query()` method has been added that allows you to select elements of a `DataFrame` using a natural query syntax nearly identical to Python syntax. For example,

```
In [108]: n = 20
```

```
In [109]: df = pd.DataFrame(np.random.randint(n, size=(n, 3)), columns=['a', 'b',
↪ 'c'])
```

```
In [110]: df.query('a < b < c')
```

```
Out[110]:
   a  b  c
11  1  5  8
15  8 16 19
```

selects all the rows of `df` where `a < b < c` evaluates to `True`. For more details see the *the docs*.

- `pd.read_msgpack()` and `pd.to_msgpack()` are now a supported method of serialization of arbitrary pandas (and python objects) in a lightweight portable binary format. See *the docs*

**Warning:** Since this is an EXPERIMENTAL LIBRARY, the storage format may not be stable until a future release.

```
df = pd.DataFrame(np.random.rand(5, 2), columns=list('AB'))
df.to_msgpack('foo.msg')
pd.read_msgpack('foo.msg')

s = pd.Series(np.random.rand(5), index=pd.date_range('20130101', periods=5))
pd.to_msgpack('foo.msg', df, s)
pd.read_msgpack('foo.msg')
```

You can pass `iterator=True` to iterate over the unpacked results

```
for o in pd.read_msgpack('foo.msg', iterator=True):
    print(o)
```

- `pandas.io.gbq` provides a simple way to extract from, and load data into, Google's BigQuery Data Sets by way of pandas DataFrames. BigQuery is a high performance SQL-like database service, useful for performing ad-hoc queries against extremely large datasets. *See the docs*

```
from pandas.io import gbq

# A query to select the average monthly temperatures in the
# in the year 2000 across the USA. The dataset,
# publicdata:samples.gsod, is available on all BigQuery accounts,
# and is based on NOAA gsod data.

query = """SELECT station_number as STATION,
month as MONTH, AVG(mean_temp) as MEAN_TEMP
FROM publicdata:samples.gsod
WHERE YEAR = 2000
GROUP BY STATION, MONTH
ORDER BY STATION, MONTH ASC"""

# Fetch the result set for this query

# Your Google BigQuery Project ID
# To find this, see your dashboard:
# https://console.developers.google.com/iam-admin/projects?authuser=0
projectid = 'xxxxxxxxx'
df = gbq.read_gbq(query, project_id=projectid)

# Use pandas to process and reshape the dataset

df2 = df.pivot(index='STATION', columns='MONTH', values='MEAN_TEMP')
df3 = pd.concat([df2.min(), df2.mean(), df2.max()],
                axis=1, keys=["Min Tem", "Mean Temp", "Max Temp"])
```

The resulting DataFrame is:

```
> df3
      Min Tem  Mean Temp  Max Temp
MONTH
1    -53.336667  39.827892  89.770968
2    -49.837500  43.685219  93.437932
3    -77.926087  48.708355  96.099998
```

(continues on next page)

(continued from previous page)

```

4      -82.892858  55.070087   97.317240
5      -92.378261  61.428117  102.042856
6      -77.703334  65.858888  102.900000
7      -87.821428  68.169663  106.510714
8      -89.431999  68.614215  105.500000
9      -86.611112  63.436935  107.142856
10     -78.209677  56.880838   92.103333
11     -50.125000  48.861228   94.996428
12     -50.332258  42.286879   94.396774

```

**Warning:** To use this module, you will need a BigQuery account. See <https://cloud.google.com/products/big-query> for details.

As of 10/10/13, there is a bug in Google's API preventing result sets from being larger than 100,000 rows. A patch is scheduled for the week of 10/14/13.

## Internal refactoring

In 0.13.0 there is a major refactor primarily to subclass `Series` from `NDFrame`, which is the base class currently for `DataFrame` and `Panel`, to unify methods and behaviors. `Series` formerly subclassed directly from `ndarray`. (GH4080, GH3862, GH816)

**Warning:** There are two potential incompatibilities from < 0.13.0

- Using certain numpy functions would previously return a `Series` if passed a `Series` as an argument. This seems only to affect `np.ones_like`, `np.empty_like`, `np.diff` and `np.where`. These now return `ndarrays`.

```
In [111]: s = pd.Series([1, 2, 3, 4])
```

### Numpy Usage

```
In [112]: np.ones_like(s)
Out [112]: array([1, 1, 1, 1])
```

```
In [113]: np.diff(s)
Out [113]: array([1, 1, 1])
```

```
In [114]: np.where(s > 1, s, np.nan)
Out [114]: array([nan, 2., 3., 4.])
```

### Pandonic Usage

```
In [115]: pd.Series(1, index=s.index)
Out [115]:
0      1
1      1
2      1
3      1
dtype: int64
```

```
In [116]: s.diff()
Out [116]:
0      NaN
1      1.0
2      1.0
3      1.0
```

```
dtype: float64
```

```
In [117]: s.where(s > 1)
Out [117]:
0      NaN
```

- Passing a `Series` directly to a cython function expecting an `ndarray` type will no long work directly, you must pass `Series.values`, See *Enhancing Performance*
- `Series(0.5)` would previously return the scalar `0.5`, instead this will return a 1-element `Series`
- This change breaks `ipy2<=2.3.8`. an Issue has been opened against `ipy2` and a workaround is detailed in [GH5698](#). Thanks @JanSchulz.

- Pickle compatibility is preserved for pickles created prior to 0.13. These must be unpickled with `pd.read_pickle`, see *Pickling*.
- Refactor of `series.py/frame.py/panel.py` to move common code to `generic.py`
  - added `_setup_axes` to created generic `NDFrame` structures
  - moved methods
    - \* `from_axes, _wrap_array, axes, ix, loc, iloc, shape, empty, swapaxes, transpose, pop`
    - \* `__iter__, keys, __contains__, __len__, __neg__, __invert__`
    - \* `convert_objects, as_blocks, as_matrix, values`
    - \* `__getstate__, __setstate__` (compat remains in `frame/panel`)
    - \* `__getattr__, __setattr__`
    - \* `_indexed_same, reindex_like, align, where, mask`
    - \* `fillna, replace` (`Series` `replace` is now consistent with `DataFrame`)
    - \* `filter` (also added `axis` argument to selectively filter on a different axis)
    - \* `reindex, reindex_axis, take`
    - \* `truncate` (moved to become part of `NDFrame`)
- These are API changes which make `Panel` more consistent with `DataFrame`
  - `swapaxes` on a `Panel` with the same axes specified now return a copy
  - support attribute access for setting
  - `filter` supports the same API as the original `DataFrame` `filter`
- `Reindex` called with no arguments will now return a copy of the input object
- `TimeSeries` is now an alias for `Series`. the property `is_time_series` can be used to distinguish (if desired)
- Refactor of Sparse objects to use `BlockManager`
  - Created a new block type in `internals`, `SparseBlock`, which can hold multi-dtypes and is non-consolidatable. `SparseSeries` and `SparseDataFrame` now inherit more methods from there hierarchy (`Series/DataFrame`), and no longer inherit from `SparseArray` (which instead is the object of the `SparseBlock`)
  - Sparse suite now supports integration with non-sparse data. Non-float sparse data is supportable (partially implemented)
  - Operations on sparse structures within `DataFrames` should preserve sparseness, merging type operations will convert to dense (and back to sparse), so might be somewhat inefficient
  - enable `setitem` on `SparseSeries` for `boolean/integer/slices`
  - `SparsePanels` implementation is unchanged (e.g. not using `BlockManager`, needs work)

- added `ftypes` method to Series/DataFrame, similar to `dtypes`, but indicates if the underlying is sparse/dense (as well as the dtype)
- All NDFrame objects can now use `__finalize__()` to specify various values to propagate to new objects from an existing one (e.g. `name` in Series will follow more automatically now)
- Internal type checking is now done via a suite of generated classes, allowing `isinstance(value, klass)` without having to directly import the class, courtesy of @jtratner
- Bug in Series update where the parent frame is not updating its cache based on changes (GH4080) or types (GH3217), `fillna` (GH3386)
- Indexing with dtype conversions fixed (GH4463, GH4204)
- Refactor `Series.reindex` to `core/generic.py` (GH4604, GH4618), allow `method=` in reindexing on a Series to work
- `Series.copy` no longer accepts the `order` parameter and is now consistent with NDFrame `copy`
- Refactor `rename` methods to `core/generic.py`; fixes `Series.rename` for (GH4605), and adds `rename` with the same signature for Panel
- Refactor `clip` methods to `core/generic.py` (GH4798)
- Refactor of `_get_numeric_data/_get_bool_data` to `core/generic.py`, allowing Series/Panel functionality
- Series (for index) / Panel (for items) now allow attribute access to its elements (GH1903)

```
In [118]: s = pd.Series([1, 2, 3], index=list('abc'))

In [119]: s.b
Out[119]: 2

In [120]: s.a = 5

In [121]: s
Out[121]:
a    5
b    2
c    3
dtype: int64
```

## Bug fixes

- HDFStore
  - raising an invalid `TypeError` rather than `ValueError` when appending with a different block ordering (GH4096)
  - `read_hdf` was not respecting `as` passed mode (GH4504)
  - appending a 0-len table will work correctly (GH4273)
  - `to_hdf` was raising when passing both arguments `append` and `table` (GH4584)
  - reading from a store with duplicate columns across dtypes would raise (GH4767)
  - Fixed a bug where `ValueError` wasn't correctly raised when column names weren't strings (GH4956)
  - A zero length series written in Fixed format not deserializing properly. (GH4708)
  - Fixed decoding perf issue on py3 (GH5441)

- Validate levels in a MultiIndex before storing (GH5527)
- Correctly handle `data_columns` with a Panel (GH5717)
- Fixed bug in `tslib.tz_convert(vals, tz1, tz2)`: it could raise `IndexError` exception while trying to access `trans[pos + 1]` (GH4496)
- The `by` argument now works correctly with the `layout` argument (GH4102, GH4014) in `*.hist` plotting methods
- Fixed bug in `PeriodIndex.map` where using `str` would return the `str` representation of the index (GH4136)
- Fixed test failure `test_time_series_plot_color_with_empty_kwargs` when using custom matplotlib default colors (GH4345)
- Fix running of stata IO tests. Now uses temporary files to write (GH4353)
- Fixed an issue where `DataFrame.sum` was slower than `DataFrame.mean` for integer valued frames (GH4365)
- `read_html` tests now work with Python 2.6 (GH4351)
- Fixed bug where `network` testing was throwing `NameError` because a local variable was undefined (GH4381)
- In `to_json`, raise if a passed `orient` would cause loss of data because of a duplicate index (GH4359)
- In `to_json`, fix date handling so milliseconds are the default timestamp as the docstring says (GH4362).
- `as_index` is no longer ignored when doing `groupby` apply (GH4648, GH3417)
- JSON NaT handling fixed, NaTs are now serialized to `null` (GH4498)
- Fixed JSON handling of escapable characters in JSON object keys (GH4593)
- Fixed passing `keep_default_na=False` when `na_values=None` (GH4318)
- Fixed bug with `values` raising an error on a `DataFrame` with duplicate columns and mixed dtypes, surfaced in (GH4377)
- Fixed bug with duplicate columns and type conversion in `read_json` when `orient='split'` (GH4377)
- Fixed JSON bug where locales with decimal separators other than `'.'` threw exceptions when encoding / decoding certain values. (GH4918)
- Fix `.iat` indexing with a `PeriodIndex` (GH4390)
- Fixed an issue where `PeriodIndex` joining with `self` was returning a new instance rather than the same instance (GH4379); also adds a test for this for the other index types
- Fixed a bug with all the dtypes being converted to object when using the CSV cparser with the `usecols` parameter (GH3192)
- Fix an issue in merging blocks where the resulting `DataFrame` had partially set `_ref_locs` (GH4403)
- Fixed an issue where hist subplots were being overwritten when they were called using the top level matplotlib API (GH4408)
- Fixed a bug where calling `Series.astype(str)` would truncate the string (GH4405, GH4437)
- Fixed a py3 compat issue where bytes were being repr'd as tuples (GH4455)
- Fixed Panel attribute naming conflict if item is named `'a'` (GH3440)
- Fixed an issue where duplicate indexes were raising when plotting (GH4486)
- Fixed an issue where `cumsum` and `cumprod` didn't work with bool dtypes (GH4170, GH4440)

- Fixed Panel slicing issued in `xs` that was returning an incorrect dimmed object (GH4016)
- Fix resampling bug where custom reduce function not used if only one group (GH3849, GH4494)
- Fixed Panel assignment with a transposed frame (GH3830)
- Raise on set indexing with a Panel and a Panel as a value which needs alignment (GH3777)
- frozenset objects now raise in the `Series` constructor (GH4482, GH4480)
- Fixed issue with sorting a duplicate `MultiIndex` that has multiple dtypes (GH4516)
- Fixed bug in `DataFrame.set_values` which was causing name attributes to be lost when expanding the index. (GH3742, GH4039)
- Fixed issue where individual `names`, `levels` and `labels` could be set on `MultiIndex` without validation (GH3714, GH4039)
- Fixed (GH3334) in `pivot_table`. Margins did not compute if values is the index.
- Fix bug in having a rhs of `np.timedelta64` or `np.offsets.DateOffset` when operating with date-times (GH4532)
- Fix arithmetic with series/datetimeindex and `np.timedelta64` not working the same (GH4134) and buggy `timedelta` in NumPy 1.6 (GH4135)
- Fix bug in `pd.read_clipboard` on windows with PY3 (GH4561); not decoding properly
- `tslib.get_period_field()` and `tslib.get_period_field_arr()` now raise if code argument out of range (GH4519, GH4520)
- Fix boolean indexing on an empty series loses index names (GH4235), `infer_dtype` works with empty arrays.
- Fix reindexing with multiple axes; if an axes match was not replacing the current axes, leading to a possible lazy frequency inference issue (GH3317)
- Fixed issue where `DataFrame.apply` was reraising exceptions incorrectly (causing the original stack trace to be truncated).
- Fix selection with `ix/loc` and `non_unique` selectors (GH4619)
- Fix assignment with `iloc/loc` involving a dtype change in an existing column (GH4312, GH5702) have internal `setitem_with_indexer` in `core/indexing` to use `Block.setitem`
- Fixed bug where thousands operator was not handled correctly for floating point numbers in `csv_import` (GH4322)
- Fix an issue with `CacheableOffset` not properly being used by many `DateOffset`; this prevented the `DateOffset` from being cached (GH4609)
- Fix boolean comparison with a `DataFrame` on the lhs, and a list/tuple on the rhs (GH4576)
- Fix error/dtype conversion with `setitem` of `None` on `Series/DataFrame` (GH4667)
- Fix decoding based on a passed in non-default encoding in `pd.read_stata` (GH4626)
- Fix `DataFrame.from_records` with a plain-vanilla `ndarray`. (GH4727)
- Fix some inconsistencies with `Index.rename` and `MultiIndex.rename`, etc. (GH4718, GH4628)
- Bug in using `iloc/loc` with a cross-sectional and duplicate indices (GH4726)
- Bug with using `QUOTE_NONE` with `to_csv` causing `Exception`. (GH4328)
- Bug with `Series` indexing not raising an error when the right-hand-side has an incorrect length (GH2702)
- Bug in `MultiIndexing` with a partial string selection as one part of a `MultiIndex` (GH4758)

- Bug with reindexing on the index with a non-unique index will now raise `ValueError` (GH4746)
- Bug in setting with `loc/ix` a single indexer with a `MultiIndex` axis and a `NumPy` array, related to (GH3777)
- Bug in concatenation with duplicate columns across dtypes not merging with `axis=0` (GH4771, GH4975)
- Bug in `iloc` with a slice index failing (GH4771)
- Incorrect error message with no colspecs or width in `read_fwf`. (GH4774)
- Fix bugs in indexing in a `Series` with a duplicate index (GH4548, GH4550)
- Fixed bug with reading compressed files with `read_fwf` in Python 3. (GH3963)
- Fixed an issue with a duplicate index and assignment with a dtype change (GH4686)
- Fixed bug with reading compressed files in as `bytes` rather than `str` in Python 3. Simplifies bytes-producing file-handling in Python 3 (GH3963, GH4785).
- Fixed an issue related to `ticklocs/ticklabels` with log scale bar plots across different versions of `matplotlib` (GH4789)
- Suppressed `DeprecationWarning` associated with internal calls issued by `repr()` (GH4391)
- Fixed an issue with a duplicate index and duplicate selector with `.loc` (GH4825)
- Fixed an issue with `DataFrame.sort_index` where, when sorting by a single column and passing a list for `ascending`, the argument for `ascending` was being interpreted as `True` (GH4839, GH4846)
- Fixed `Panel.tshift` not working. Added `freq` support to `Panel.shift` (GH4853)
- Fix an issue in `TextFileReader` w/ Python engine (i.e. `PythonParser`) with thousands != “;” (GH4596)
- Bug in `getitem` with a duplicate index when using `where` (GH4879)
- Fix Type inference code coerces float column into `datetime` (GH4601)
- Fixed `_ensure_numeric` does not check for complex numbers (GH4902)
- Fixed a bug in `Series.hist` where two figures were being created when the `by` argument was passed (GH4112, GH4113).
- Fixed a bug in `convert_objects` for > 2 ndims (GH4937)
- Fixed a bug in `DataFrame/Panel` cache insertion and subsequent indexing (GH4939, GH5424)
- Fixed string methods for `FrozenNDArray` and `FrozenList` (GH4929)
- Fixed a bug with setting invalid or out-of-range values in indexing enlargement scenarios (GH4940)
- Tests for `fillna` on empty `Series` (GH4346), thanks @immerrr
- Fixed `copy()` to shallow copy axes/indices as well and thereby keep separate metadata. (GH4202, GH4830)
- Fixed `skiprows` option in Python parser for `read_csv` (GH4382)
- Fixed bug preventing `cut` from working with `np.inf` levels without explicitly passing labels (GH3415)
- Fixed wrong check for overlapping in `DatetimeIndex.union` (GH4564)
- Fixed conflict between thousands separator and date parser in `csv_parser` (GH4678)
- Fix appending when dtypes are not the same (error showing mixing float/np.datetime64) (GH4993)
- Fix `repr` for `DateOffset`. No longer show duplicate entries in `kwds`. Removed unused offset fields. (GH4638)
- Fixed wrong index name during `read_csv` if using `usecols`. Applies to `c` parser only. (GH4201)
- `Timestamp` objects can now appear in the left hand side of a comparison operation with a `Series` or `DataFrame` object (GH4982).

- Fix a bug when indexing with `np.nan` via `iloc/loc` (GH5016)
- Fixed a bug where low memory `c` parser could create different types in different chunks of the same file. Now coerces to numerical type or raises warning. (GH3866)
- Fix a bug where reshaping a `Series` to its own shape raised `TypeError` (GH4554) and other reshaping issues.
- Bug in setting with `ix/loc` and a mixed int/string index (GH4544)
- Make sure series-series boolean comparisons are label based (GH4947)
- Bug in multi-level indexing with a `Timestamp` partial indexer (GH4294)
- Tests/fix for `MultiIndex` construction of an all-nan frame (GH4078)
- Fixed a bug where `read_html()` wasn't correctly inferring values of tables with commas (GH5029)
- Fixed a bug where `read_html()` wasn't providing a stable ordering of returned tables (GH4770, GH5029).
- Fixed a bug where `read_html()` was incorrectly parsing when passed `index_col=0` (GH5066).
- Fixed a bug where `read_html()` was incorrectly inferring the type of headers (GH5048).
- Fixed a bug where `DatetimeIndex` joins with `PeriodIndex` caused a stack overflow (GH3899).
- Fixed a bug where `groupby` objects didn't allow plots (GH5102).
- Fixed a bug where `groupby` objects weren't tab-completing column names (GH5102).
- Fixed a bug where `groupby.plot()` and friends were duplicating figures multiple times (GH5102).
- Provide automatic conversion of `object` dtypes on `fillna`, related (GH5103)
- Fixed a bug where default options were being overwritten in the option parser cleaning (GH5121).
- Treat a list/ndarray identically for `iloc` indexing with list-like (GH5006)
- Fix `MultiIndex.get_level_values()` with missing values (GH5074)
- Fix bound checking for `Timestamp()` with `datetime64` input (GH4065)
- Fix a bug where `TestReadHtml` wasn't calling the correct `read_html()` function (GH5150).
- Fix a bug with `NDFrame.replace()` which made replacement appear as though it was (incorrectly) using regular expressions (GH5143).
- Fix better error message for `to_datetime` (GH4928)
- Made sure different locales are tested on `travis-ci` (GH4918). Also adds a couple of utilities for getting locales and setting locales with a context manager.
- Fixed `segfault` on `isnull(MultiIndex)` (now raises an error instead) (GH5123, GH5125)
- Allow duplicate indices when performing operations that align (GH5185, GH5639)
- Compound dtypes in a constructor raise `NotImplementedError` (GH5191)
- Bug in comparing duplicate frames (GH4421) related
- Bug in `describe` on duplicate frames
- Bug in `to_datetime` with a `format` and `coerce=True` not raising (GH5195)
- Bug in `loc` setting with multiple indexers and a `rhs` of a `Series` that needs broadcasting (GH5206)
- Fixed bug where inplace setting of levels or labels on `MultiIndex` would not clear `cached values` property and therefore return wrong values. (GH5215)
- Fixed bug where filtering a grouped `DataFrame` or `Series` did not maintain the original ordering (GH4621).

- Fixed `Period` with a business date freq to always roll-forward if on a non-business date. (GH5203)
- Fixed bug in Excel writers where frames with duplicate column names weren't written correctly. (GH5235)
- Fixed issue with `drop` and a non-unique index on `Series` (GH5248)
- Fixed segfault in C parser caused by passing more names than columns in the file. (GH5156)
- Fix `Series.isin` with date/time-like dtypes (GH5021)
- C and Python Parser can now handle the more common `MultiIndex` column format which doesn't have a row for index names (GH4702)
- Bug when trying to use an out-of-bounds date as an object dtype (GH5312)
- Bug when trying to display an embedded `PandasObject` (GH5324)
- Allows operating of `Timestamps` to return a `datetime` if the result is out-of-bounds related (GH5312)
- Fix return value/type signature of `initObjToJSON()` to be compatible with `numpy's import_array()` (GH5334, GH5326)
- Bug when renaming then `set_index` on a `DataFrame` (GH5344)
- Test suite no longer leaves around temporary files when testing graphics. (GH5347) (thanks for catching this @yarikoptic!)
- Fixed html tests on win32. (GH4580)
- Make sure that `head/tail` are `iloc` based, (GH5370)
- Fixed bug for `PeriodIndex` string representation if there are 1 or 2 elements. (GH5372)
- The `GroupBy` methods `transform` and `filter` can be used on `Series` and `DataFrames` that have repeated (non-unique) indices. (GH4620)
- Fix empty series not printing name in `repr` (GH4651)
- Make tests create temp files in temp directory by default. (GH5419)
- `pd.to_timedelta` of a scalar returns a scalar (GH5410)
- `pd.to_timedelta` accepts `NaN` and `NaT`, returning `NaT` instead of raising (GH5437)
- performance improvements in `isnull` on larger size pandas objects
- Fixed various `setitem` with `1d ndarray` that does not have a matching length to the indexer (GH5508)
- Bug in `getitem` with a `MultiIndex` and `iloc` (GH5528)
- Bug in `delitem` on a `Series` (GH5542)
- Bug fix in `apply` when using custom function and objects are not mutated (GH5545)
- Bug in selecting from a non-unique index with `loc` (GH5553)
- Bug in `groupby` returning non-consistent types when user function returns a `None`, (GH5592)
- Work around regression in `numpy 1.7.0` which erroneously raises `IndexError` from `ndarray.item` (GH5666)
- Bug in repeated indexing of object with resultant non-unique index (GH5678)
- Bug in `fillna` with `Series` and a passed series/dict (GH5703)
- Bug in `groupby transform` with a `datetime-like grouper` (GH5712)
- Bug in `MultiIndex` selection in `PY3` when using certain keys (GH5725)
- Row-wise `concat` of differing dtypes failing in certain cases (GH5754)

## 6.15 Version 0.12

### 6.15.1 v0.12.0 (July 24, 2013)

```
{{ header }}
```

This is a major release from 0.11.0 and includes several new features and enhancements along with a large number of bug fixes.

Highlights include a consistent I/O API naming scheme, routines to read html, write MultiIndexes to csv files, read & write STATA data files, read & write JSON format files, Python 3 support for HDFStore, filtering of groupby expressions via `filter`, and a revamped `replace` routine that accepts regular expressions.

#### API changes

- The I/O API is now much more consistent with a set of top level reader functions accessed like `pd.read_csv()` that generally return a pandas object.

- `read_csv`
- `read_excel`
- `read_hdf`
- `read_sql`
- `read_json`
- `read_html`
- `read_stata`
- `read_clipboard`

The corresponding writer functions are object methods that are accessed like `df.to_csv()`

- `to_csv`
- `to_excel`
- `to_hdf`
- `to_sql`
- `to_json`
- `to_html`

```
- to_stata
- to_clipboard
```

- Fix modulo and integer division on Series,DataFrames to act similarly to float dtypes to return `np.nan` or `np.inf` as appropriate (GH3590). This correct a numpy bug that treats integer and float dtypes differently.

```
In [1]: p = pd.DataFrame({'first': [4, 5, 8], 'second': [0, 0, 3]})
```

```
In [2]: p % 0
```

```
Out [2]:
   first  second
0   NaN   NaN
1   NaN   NaN
2   NaN   NaN
```

```
In [3]: p % p
```

```
Out [3]:
   first  second
0   0.0   NaN
1   0.0   NaN
2   0.0   0.0
```

```
In [4]: p / p
```

```
Out [4]:
   first  second
0   1.0   NaN
1   1.0   NaN
2   1.0   1.0
```

```
In [5]: p / 0
```

```
Out [5]:
   first  second
0   inf   NaN
1   inf   NaN
2   inf   inf
```

- Add `squeeze` keyword to `groupby` to allow reduction from DataFrame -> Series if groups are unique. This is a Regression from 0.10.1. We are reverting back to the prior behavior. This means `groupby` will return the same shaped objects whether the groups are unique or not. Revert this issue (GH2893) with (GH3596).

```
In [6]: df2 = pd.DataFrame([{"val1": 1, "val2": 20},
...:                       {"val1": 1, "val2": 19},
...:                       {"val1": 1, "val2": 27},
...:                       {"val1": 1, "val2": 12}])
...:
```

```
In [7]: def func(dataf):
...:     return dataf["val2"] - dataf["val2"].mean()
...:
```

```
# squeezing the result frame to a series (because we have unique groups)
```

```
In [8]: df2.groupby("val1", squeeze=True).apply(func)
```

```
Out [8]:
0    0.5
1   -0.5
2    7.5
```

(continues on next page)

(continued from previous page)

```

3    -7.5
Name: 1, dtype: float64

# no squeezing (the default, and behavior in 0.10.1)
In [9]: df2.groupby("val1").apply(func)
Out [9]:
val2    0    1    2    3
val1
1      0.5 -0.5  7.5 -7.5

```

- Raise on `iloc` when boolean indexing with a label based indexer mask e.g. a boolean Series, even with integer labels, will raise. Since `iloc` is purely positional based, the labels on the Series are not alignable (GH3631)

This case is rarely used, and there are plenty of alternatives. This preserves the `iloc` API to be *purely* positional based.

```

In [10]: df = pd.DataFrame(range(5), index=list('ABCDE'), columns=['a'])

In [11]: mask = (df.a % 2 == 0)

In [12]: mask
Out [12]:
A    True
B   False
C    True
D   False
E    True
Name: a, dtype: bool

# this is what you should use
In [13]: df.loc[mask]
Out [13]:
a
A    0
C    2
E    4

# this will work as well
In [14]: df.iloc[mask.values]
Out [14]:
a
A    0
C    2
E    4

```

`df.iloc[mask]` will raise a `ValueError`

- The `raise_on_error` argument to plotting functions is removed. Instead, plotting functions raise a `TypeError` when the `dtype` of the object is `object` to remind you to avoid `object` arrays whenever possible and thus you should cast to an appropriate numeric `dtype` if you need to plot something.
- Add `colormap` keyword to `DataFrame` plotting methods. Accepts either a matplotlib colormap object (ie, `matplotlib.cm.jet`) or a string name of such an object (ie, `'jet'`). The colormap is sampled to select the color for each column. Please see *Colormaps* for more information. (GH3860)
- `DataFrame.interpolate()` is now deprecated. Please use `DataFrame.fillna()` and `DataFrame.replace()` instead. (GH3582, GH3675, GH3676)

- the method and axis arguments of `DataFrame.replace()` are deprecated
- `DataFrame.replace`'s `infer_types` parameter is removed and now performs conversion by default. (GH3907)
- Add the keyword `allow_duplicates` to `DataFrame.insert` to allow a duplicate column to be inserted if `True`, default is `False` (same as prior to 0.12) (GH3679)
- Implement `__nonzero__` for `NDFrame` objects (GH3691, GH3696)
- IO api
  - added top-level function `read_excel` to replace the following, The original API is deprecated and will be removed in a future version

```
from pandas.io.parsers import ExcelFile
xls = ExcelFile('path_to_file.xls')
xls.parse('Sheet1', index_col=None, na_values=['NA'])
```

With

```
import pandas as pd
pd.read_excel('path_to_file.xls', 'Sheet1', index_col=None, na_values=['NA'])
```

- added top-level function `read_sql` that is equivalent to the following

```
from pandas.io.sql import read_frame
read_frame(...)
```

- `DataFrame.to_html` and `DataFrame.to_latex` now accept a path for their first argument (GH3702)
- Do not allow astypes on `datetime64[ns]` except to object, and `timedelta64[ns]` to object/int (GH3425)
- The behavior of `datetime64` dtypes has changed with respect to certain so-called reduction operations (GH3726). The following operations now raise a `TypeError` when performed on a `Series` and return an *empty Series* when performed on a `DataFrame` similar to performing these operations on, for example, a `DataFrame` of `slice` objects:
  - `sum`, `prod`, `mean`, `std`, `var`, `skew`, `kurt`, `corr`, and `cov`
- `read_html` now defaults to `None` when reading, and falls back on `bs4` + `html5lib` when `lxml` fails to parse. a list of parsers to try until success is also valid
- The internal pandas class hierarchy has changed (slightly). The previous `PandasObject` now is called `PandasContainer` and a new `PandasObject` has become the base class for `PandasContainer` as well as `Index`, `Categorical`, `GroupBy`, `SparseList`, and `SparseArray` (+ their base classes). Currently, `PandasObject` provides string methods (from `StringMixin`). (GH4090, GH4092)
- New `StringMixin` that, given a `__unicode__` method, gets python 2 and python 3 compatible string methods (`__str__`, `__bytes__`, and `__repr__`). Plus string safety throughout. Now employed in many places throughout the pandas library. (GH4090, GH4092)

## I/O enhancements

- `pd.read_html()` can now parse HTML strings, files or urls and return DataFrames, courtesy of @cpcloud. (GH3477, GH3605, GH3606, GH3616). It works with a *single* parser backend: BeautifulSoup4 + html5lib *See the docs*

You can use `pd.read_html()` to read the output from `DataFrame.to_html()` like so

```
In [15]: df = pd.DataFrame({'a': range(3), 'b': list('abc')})

In [16]: print(df)
   a b
0  0 a
1  1 b
2  2 c

In [17]: html = df.to_html()

In [18]: alist = pd.read_html(html, index_col=0)

In [19]: print(df == alist[0])
   a    b
0  True True
1  True True
2  True True
```

Note that `alist` here is a Python list so `pd.read_html()` and `DataFrame.to_html()` are not inverses.

- `pd.read_html()` no longer performs hard conversion of date strings (GH3656).

**Warning:** You may have to install an older version of BeautifulSoup4, *See the installation docs*

- Added module for reading and writing Stata files: `pandas.io.stata` (GH1512) accessible via `read_stata` top-level function for reading, and `to_stata` DataFrame method for writing, *See the docs*
- Added module for reading and writing json format files: `pandas.io.json` accessible via `read_json` top-level function for reading, and `to_json` DataFrame method for writing, *See the docs* various issues (GH1226, GH3804, GH3876, GH3867, GH1305)
- MultiIndex column support for reading and writing csv format files
  - The `header` option in `read_csv` now accepts a list of the rows from which to read the index.
  - The option, `tupleize_cols` can now be specified in both `to_csv` and `read_csv`, to provide compatibility for the pre 0.12 behavior of writing and reading MultiIndex columns via a list of tuples. The default in 0.12 is to write lists of tuples and *not* interpret list of tuples as a MultiIndex column.
 

Note: The default behavior in 0.12 remains unchanged from prior versions, but starting with 0.13, the default *to* write and read MultiIndex columns will be in the new format. (GH3571, GH1651, GH3141)
  - If an `index_col` is not specified (e.g. you don't have an index, or wrote it with `df.to_csv(..., index=False)`), then any names on the columns index will be *lost*.

```
In [20]: from pandas._testing import makeCustomDataframe as mkdf

In [21]: df = mkdf(5, 3, r_idx_nlevels=2, c_idx_nlevels=4)
```

(continues on next page)

(continued from previous page)

```

```

- Support for HDFStore (via PyTables 3.0.0) on Python3
- Iterator support via `read_hdf` that automatically opens and closes the store when iteration is finished. This is only for *tables*

```

In [25]: path = 'store_iterator.h5'

In [26]: pd.DataFrame(np.random.randn(10, 2)).to_hdf(path, 'df', table=True)

In [27]: for df in pd.read_hdf(path, 'df', chunksize=3):
....:     print(df)
....:
      0      1
0  0.713216 -0.778461
1 -0.661062  0.862877
2  0.344342  0.149565
      0      1
3 -0.626968 -0.875772
4 -0.930687 -0.218983
5  0.949965 -0.442354
      0      1
6 -0.402985  1.111358
7 -0.241527 -0.670477
8  0.049355  0.632633
      0      1
9 -1.502767 -1.225492

```

- `read_csv` will now throw a more informative error message when a file contains no columns, e.g., all newline characters

## Other enhancements

- `DataFrame.replace()` now allows regular expressions on contained `Series` with object dtype. See the examples section in the regular docs *Replacing via String Expression*

For example you can do

```
In [25]: df = pd.DataFrame({'a': list('ab..'), 'b': [1, 2, 3, 4]})
In [26]: df.replace(regex=r'\s*\.\s*', value=np.nan)
Out[26]:
```

|   | a   | b |
|---|-----|---|
| 0 | a   | 1 |
| 1 | b   | 2 |
| 2 | NaN | 3 |
| 3 | NaN | 4 |

to replace all occurrences of the string `'.'` with zero or more instances of surrounding white space with `NaN`.

Regular string replacement still works as expected. For example, you can do

```
In [27]: df.replace('.', np.nan)
Out[27]:
```

|   | a   | b |
|---|-----|---|
| 0 | a   | 1 |
| 1 | b   | 2 |
| 2 | NaN | 3 |
| 3 | NaN | 4 |

to replace all occurrences of the string `'.'` with `NaN`.

- `pd.melt()` now accepts the optional parameters `var_name` and `value_name` to specify custom column names of the returned `DataFrame`.
- `pd.set_option()` now allows `N` option, value pairs ([GH3667](#)).

Let's say that we had an option `'a.b'` and another option `'b.c'`. We can set them at the same time:

```
In [31]: pd.get_option('a.b')
Out[31]: 2

In [32]: pd.get_option('b.c')
Out[32]: 3

In [33]: pd.set_option('a.b', 1, 'b.c', 4)

In [34]: pd.get_option('a.b')
Out[34]: 1

In [35]: pd.get_option('b.c')
Out[35]: 4
```

- The `filter` method for group objects returns a subset of the original object. Suppose we want to take only elements that belong to groups with a group sum greater than 2.

```
In [28]: sf = pd.Series([1, 1, 2, 3, 3, 3])
In [29]: sf.groupby(sf).filter(lambda x: x.sum() > 2)
Out[29]:
```

(continues on next page)

(continued from previous page)

```
3    3
4    3
5    3
dtype: int64
```

The argument of `filter` must be a function that, applied to the group as a whole, returns `True` or `False`.

Another useful operation is filtering out elements that belong to groups with only a couple members.

```
In [30]: dff = pd.DataFrame({'A': np.arange(8), 'B': list('aabbbbcc')})
```

```
In [31]: dff.groupby('B').filter(lambda x: len(x) > 2)
```

```
Out [31]:
```

```
   A  B
2  2  b
3  3  b
4  4  b
5  5  b
```

Alternatively, instead of dropping the offending groups, we can return a like-indexed objects where the groups that do not pass the filter are filled with `NaNs`.

```
In [32]: dff.groupby('B').filter(lambda x: len(x) > 2, dropna=False)
```

```
Out [32]:
```

```
   A  B
0 NaN NaN
1 NaN NaN
2 2.0  b
3 3.0  b
4 4.0  b
5 5.0  b
6 NaN NaN
7 NaN NaN
```

- Series and DataFrame `hist` methods now take a `figsize` argument (GH3834)
- DatetimeIndexes no longer try to convert mixed-integer indexes during join operations (GH3877)
- `Timestamp.min` and `Timestamp.max` now represent valid `Timestamp` instances instead of the default `datetime.min` and `datetime.max` (respectively), thanks @SleepingPills
- `read_html` now raises when no tables are found and `BeautifulSoup==4.2.0` is detected (GH4214)

## Experimental features

- Added experimental `CustomBusinessDay` class to support `DateOffsets` with custom holiday calendars and custom weekmasks. (GH2301)

---

**Note:** This uses the `numpy.busdaycalendar` API introduced in `Numpy 1.7` and therefore requires `Numpy 1.7.0` or newer.

---

```
In [33]: from pandas.tseries.offsets import CustomBusinessDay
```

```
In [34]: from datetime import datetime
```

(continues on next page)

(continued from previous page)

```

# As an interesting example, let's look at Egypt where
# a Friday-Saturday weekend is observed.
In [35]: weekmask_egypt = 'Sun Mon Tue Wed Thu'

# They also observe International Workers' Day so let's
# add that for a couple of years
In [36]: holidays = ['2012-05-01', datetime(2013, 5, 1), np.datetime64('2014-05-01
↳')]

In [37]: bday_egypt = CustomBusinessDay(holidays=holidays, weekmask=weekmask_
↳egypt)

In [38]: dt = datetime(2013, 4, 30)

In [39]: print(dt + 2 * bday_egypt)
2013-05-05 00:00:00

In [40]: dts = pd.date_range(dt, periods=5, freq=bday_egypt)

In [41]: print(pd.Series(dts.weekday, dts).map(pd.Series('Mon Tue Wed Thu Fri Sat_
↳Sun'.split()))
2013-04-30    Tue
2013-05-02    Thu
2013-05-05    Sun
2013-05-06    Mon
2013-05-07    Tue
Freq: C, dtype: object

```

## Bug fixes

- Plotting functions now raise a `TypeError` before trying to plot anything if the associated objects have a `dtype` of `object` (GH1818, GH3572, GH3911, GH3912), but they will try to convert object arrays to numeric arrays if possible so that you can still plot, for example, an object array with floats. This happens before any drawing takes place which eliminates any spurious plots from showing up.
- `fillna` methods now raise a `TypeError` if the `value` parameter is a list or tuple.
- `Series.str` now supports iteration (GH3638). You can iterate over the individual elements of each string in the `Series`. Each iteration yields a `Series` with either a single character at each index of the original `Series` or `NaN`. For example,

```

In [42]: strs = 'go', 'bow', 'joe', 'slow'

In [43]: ds = pd.Series(strs)

In [44]: for s in ds.str:
.....:     print(s)
.....:
0    g
1    b
2    j
3    s
dtype: object
0    o
1    o

```

(continues on next page)

(continued from previous page)

```

2    o
3    l
dtype: object
0    NaN
1    w
2    e
3    o
dtype: object
0    NaN
1    NaN
2    NaN
3    w
dtype: object

In [45]: s
Out [45]:
0    NaN
1    NaN
2    NaN
3    w
dtype: object

In [46]: s.dropna().values.item() == 'w'
Out [46]: True

```

The last element yielded by the iterator will be a `Series` containing the last element of the longest string in the `Series` with all other elements being `NaN`. Here since `'slow'` is the longest string and there are no other strings with the same length `'w'` is the only non-null string in the yielded `Series`.

- `HDFStore`
  - will retain index attributes (`freq,tz,name`) on recreation ([GH3499](#))
  - will warn with a `AttributeConflictWarning` if you are attempting to append an index with a different frequency than the existing, or attempting to append an index with a different name than the existing
  - support datelike columns with a timezone as `data_columns` ([GH2852](#))
- Non-unique index support clarified ([GH3468](#)).
  - Fix assigning a new index to a duplicate index in a `DataFrame` would fail ([GH3468](#))
  - Fix construction of a `DataFrame` with a duplicate index
  - `ref_locs` support to allow duplicative indices across dtypes, allows `iget` support to always find the index (even across dtypes) ([GH2194](#))
  - `applymap` on a `DataFrame` with a non-unique index now works (removed warning) ([GH2786](#)), and fix ([GH3230](#))
  - Fix `to_csv` to handle non-unique columns ([GH3495](#))
  - Duplicate indexes with `getitem` will return items in the correct order ([GH3455](#), [GH3457](#)) and handle missing elements like unique indices ([GH3561](#))
  - Duplicate indexes with an empty `DataFrame.from_records` will return a correct frame ([GH3562](#))
  - Concat to produce a non-unique columns when duplicates are across dtypes is fixed ([GH3602](#))
  - Allow `insert/delete` to non-unique columns ([GH3679](#))

- Non-unique indexing with a slice via `loc` and friends fixed (GH3659)
- Allow insert/delete to non-unique columns (GH3679)
- Extend `reindex` to correctly deal with non-unique indices (GH3679)
- `DataFrame.itertuples()` now works with frames with duplicate column names (GH3873)
- Bug in non-unique indexing via `iloc` (GH4017); added `takeable` argument to `reindex` for location-based taking
- Allow non-unique indexing in series via `.ix/.loc` and `__getitem__` (GH4246)
- Fixed non-unique indexing memory allocation issue with `.ix/.loc` (GH4280)
- `DataFrame.from_records` did not accept empty recarrays (GH3682)
- `read_html` now correctly skips tests (GH3741)
- Fixed a bug where `DataFrame.replace` with a compiled regular expression in the `to_replace` argument wasn't working (GH3907)
- Improved `network` test decorator to catch `IOError` (and therefore `URLError` as well). Added `with_connectivity_check` decorator to allow explicitly checking a website as a proxy for seeing if there is network connectivity. Plus, new `optional_args` decorator factory for decorators. (GH3910, GH3914)
- Fixed testing issue where too many sockets were open thus leading to a connection reset issue (GH3982, GH3985, GH4028, GH4054)
- Fixed failing tests in `test_yahoo`, `test_google` where symbols were not retrieved but were being accessed (GH3982, GH3985, GH4028, GH4054)
- `Series.hist` will now take the figure from the current environment if one is not passed
- Fixed bug where a 1xN `DataFrame` would barf on a 1xN mask (GH4071)
- Fixed running of `tox` under python3 where the `pickle` import was getting rewritten in an incompatible way (GH4062, GH4063)
- Fixed bug where `sharex` and `sharey` were not being passed to `grouped_hist` (GH4089)
- Fixed bug in `DataFrame.replace` where a nested dict wasn't being iterated over when `regex=False` (GH4115)
- Fixed bug in the parsing of microseconds when using the `format` argument in `to_datetime` (GH4152)
- Fixed bug in `PandasAutoDateLocator` where `invert_xaxis` triggered incorrectly `MilliSecondLocator` (GH3990)
- Fixed bug in plotting that wasn't raising on invalid colormap for matplotlib 1.1.1 (GH4215)
- Fixed the legend displaying in `DataFrame.plot(kind='kde')` (GH4216)
- Fixed bug where `Index` slices weren't carrying the name attribute (GH4226)
- Fixed bug in initializing `DatetimeIndex` with an array of strings in a certain time zone (GH4229)
- Fixed bug where `html5lib` wasn't being properly skipped (GH4265)
- Fixed bug where `get_data_famafrench` wasn't using the correct file edges (GH4281)

See the *full release notes* or issue tracker on GitHub for a complete list.

## 6.16 Version 0.11

### 6.16.1 v0.11.0 (April 22, 2013)

{{ header }}

This is a major release from 0.10.1 and includes many new features and enhancements along with a large number of bug fixes. The methods of Selecting Data have had quite a number of additions, and Dtype support is now full-fledged. There are also a number of important API changes that long-time pandas users should pay close attention to.

There is a new section in the documentation, *10 Minutes to Pandas*, primarily geared to new users.

There is a new section in the documentation, *Cookbook*, a collection of useful recipes in pandas (and that we want contributions!).

There are several libraries that are now *Recommended Dependencies*

#### Selection choices

Starting in 0.11.0, object selection has had a number of user-requested additions in order to support more explicit location based indexing. Pandas now supports three types of multi-axis indexing.

- `.loc` is strictly label based, will raise `KeyError` when the items are not found, allowed inputs are:
  - A single label, e.g. 5 or 'a', (note that 5 is interpreted as a *label* of the index. This use is **not** an integer position along the index)
  - A list or array of labels ['a', 'b', 'c']

- A slice object with labels 'a' : 'f', (note that contrary to usual python slices, **both** the start and the stop are included!)
- A boolean array

See more at *Selection by Label*

- `.iloc` is strictly integer position based (from 0 to `length-1` of the axis), will raise `IndexError` when the requested indices are out of bounds. Allowed inputs are:
  - An integer e.g. 5
  - A list or array of integers [4, 3, 0]
  - A slice object with ints 1 : 7
  - A boolean array

See more at *Selection by Position*

- `.ix` supports mixed integer and label based access. It is primarily label based, but will fallback to integer positional access. `.ix` is the most general and will support any of the inputs to `.loc` and `.iloc`, as well as support for floating point label schemes. `.ix` is especially useful when dealing with mixed positional and label based hierarchical indexes.

As using integer slices with `.ix` have different behavior depending on whether the slice is interpreted as position based or label based, it's usually better to be explicit and use `.iloc` or `.loc`.

See more at *Advanced Indexing* and *Advanced Hierarchical*.

## Selection deprecations

Starting in version 0.11.0, these methods *may* be deprecated in future versions.

- `irow`
- `icol`
- `iget_value`

See the section *Selection by Position* for substitutes.

## Dtypes

Numeric dtypes will propagate and can coexist in DataFrames. If a dtype is passed (either directly via the `dtype` keyword, a passed `ndarray`, or a passed `Series`, then it will be preserved in DataFrame operations. Furthermore, different numeric dtypes will **NOT** be combined. The following example will give you a taste.

```
In [1]: df1 = pd.DataFrame(np.random.randn(8, 1), columns=['A'], dtype='float32')
```

```
In [2]: df1
```

```
Out [2]:
      A
0 -1.061137
1 -0.232825
2  0.430793
3 -0.665478
4  1.829808
5 -1.406509
6  1.078248
```

(continues on next page)

```
7 0.322774

In [6]: df2.dtypes
Out[6]:
A    float16
B    float64
C     uint8
dtype: object

# here you get some upcasting
In [7]: df3 = df1.reindex_like(df2).fillna(value=0.0) + df2

In [8]: df3
Out[8]:
   A         B  C
0 -0.860820 -0.116619  0.0
1  0.657312  0.295575  1.0
2  0.625618 -1.047704  2.0
3 -0.313915  1.640556  3.0
4  2.278782  1.905836  4.0
5 -1.604385  2.772115  5.0
6  2.044068  0.088787  6.0
7 -1.199687 -1.144197  7.0

In [9]: df3.dtypes
Out[9]:
A    float32
B    float64
C    float64
dtype: object
```

## Dtype conversion

This is lower-common-denominator upcasting, meaning you get the dtype which can accommodate all of the types

```
In [10]: df3.values.dtype
Out[10]: dtype('float64')
```

### Conversion

```
In [11]: df3.astype('float32').dtypes
Out[11]:
A    float32
B    float32
C    float32
dtype: object
```

### Mixed conversion

```
In [12]: df3['D'] = '1.'

In [13]: df3['E'] = '1'

In [14]: df3.convert_objects(convert_numeric=True).dtypes
Out[14]:
A    float32
B    float64
C    float64
D    float64
E     int64
dtype: object

# same, but specific dtype conversion
In [15]: df3['D'] = df3['D'].astype('float16')

In [16]: df3['E'] = df3['E'].astype('int32')

In [17]: df3.dtypes
Out[17]:
A    float32
B    float64
C    float64
D    float16
E     int32
dtype: object
```

### Forcing date coercion (and setting NaT when not datelike)

```
In [18]: import datetime

In [19]: s = pd.Series([datetime.datetime(2001, 1, 1, 0, 0), 'foo', 1.0, 1,
.....:                  pd.Timestamp('20010104'), '20010105'], dtype='O')
.....:

In [20]: s.convert_objects(convert_dates='coerce')
Out[20]:
0    2001-01-01
1         NaT
2         NaT
```

(continues on next page)

(continued from previous page)

```
3          NaT
4  2001-01-04
5  2001-01-05
dtype: datetime64[ns]
```

## Dtype gotchas

### Platform gotchas

Starting in 0.11.0, construction of DataFrame/Series will use default dtypes of `int64` and `float64`, *regardless of platform*. This is not an apparent change from earlier versions of pandas. If you specify dtypes, they *WILL* be respected, however ([GH2837](#))

The following will all result in `int64` dtypes

```
In [21]: pd.DataFrame([1, 2], columns=['a']).dtypes
Out [21]:
a      int64
dtype: object

In [22]: pd.DataFrame({'a': [1, 2]}).dtypes
Out [22]:
a      int64
dtype: object

In [23]: pd.DataFrame({'a': 1}, index=range(2)).dtypes
Out [23]:
a      int64
dtype: object
```

Keep in mind that `DataFrame(np.array([1, 2]))` **WILL** result in `int32` on 32-bit platforms!

### Upcasting gotchas

Performing indexing operations on integer type data can easily upcast the data. The dtype of the input data will be preserved in cases where nans are not introduced.

```
In [24]: dfi = df3.astype('int32')

In [25]: dfi['D'] = dfi['D'].astype('int64')

In [26]: dfi
Out [26]:
   A  B  C  D  E
0  0  0  0  1  1
1 -2  0  1  1  1
2 -2  0  2  1  1
3  0 -1  3  1  1
4  1  0  4  1  1
5  0  0  5  1  1
6  0 -1  6  1  1
7  0  0  7  1  1

In [27]: dfi.dtypes
Out [27]:
A      int32
```

(continues on next page)

(continued from previous page)

```
B    int32
C    int32
D    int64
E    int32
dtype: object
```

```
In [28]: casted = dfi[dfi > 0]
```

```
In [29]: casted
```

```
Out [29]:
```

```
   A    B    C  D  E
0  NaN NaN  NaN  1  1
1  NaN NaN  1.0  1  1
2  NaN NaN  2.0  1  1
3  NaN NaN  3.0  1  1
4  1.0 NaN  4.0  1  1
5  NaN NaN  5.0  1  1
6  NaN NaN  6.0  1  1
7  NaN NaN  7.0  1  1
```

```
In [30]: casted.dtypes
```

```
Out [30]:

5  NaN  0.113648  5.0  1.0  1
6  NaN      NaN  6.0  1.0  1
7  NaN  0.524988  7.0  1.0  1
```

(continues on next page)

(continued from previous page)

```
In [36]: casted.dtypes
Out[36]:
A      float32
B      float64
C      float64
D      float16
E       int32
dtype: object
```

## Datetimes conversion

Datetime64[ns] columns in a DataFrame (or a Series) allow the use of `np.nan` to indicate a nan value, in addition to the traditional NaT, or not-a-time. This allows convenient nan setting in a generic way. Furthermore datetime64 [ns] columns are created by default, when passed datetimelike objects (*this change was introduced in 0.10.1*) (GH2809, GH2810)

```
In [12]: df = pd.DataFrame(np.random.randn(6, 2), pd.date_range('20010102',
↳ periods=6),
.....:                      columns=['A', ' B'])
.....:
```

```
In [13]: df['timestamp'] = pd.Timestamp('20010103')
```

```
In [14]: df
```

```
Out[14]:
           A          B timestamp
2001-01-02 -0.633372  0.925372 2001-01-03
2001-01-03 -0.006438 -0.820408 2001-01-03
2001-01-04 -0.600874 -1.039266 2001-01-03
2001-01-05  0.824758 -0.824095 2001-01-03
2001-01-06 -0.337730 -0.927764 2001-01-03
2001-01-07 -0.840123  0.248505 2001-01-03
```

```
# datetime64[ns] out of the box
```

```
In [15]: df.dtypes.value_counts()
```

```
Out[15]:
float64          2
datetime64[ns]   1
dtype: int64
```

```
# use the traditional nan, which is mapped to NaT internally
```

```
In [16]: df.loc[df.index[2:4], ['A', 'timestamp']] = np.nan
```

```
In [17]: df
```

```
Out[17]:
           A          B timestamp
2001-01-02 -0.633372  0.925372 2001-01-03
2001-01-03 -0.006438 -0.820408 2001-01-03
2001-01-04      NaN -1.039266      NaT
2001-01-05      NaN -0.824095      NaT
2001-01-06 -0.337730 -0.927764 2001-01-03
2001-01-07 -0.840123  0.248505 2001-01-03
```

Astype conversion on `datetime64[ns]` to object, implicitly converts NaT to `np.nan`

```

In [18]: s = pd.Series([datetime.datetime(2001, 1, 2, 0, 0) for i in range(3)])

In [19]: s.dtype
Out[19]: dtype('<M8[ns]')

In [20]: s[1] = np.nan

In [21]: s
Out[21]:
0    2001-01-02
1           NaT
2    2001-01-02
dtype: datetime64[ns]

In [22]: s.dtype
Out[22]: dtype('<M8[ns]')

In [23]: s = s.astype('O')

In [24]: s
Out[24]:
0    2001-01-02 00:00:00
1           NaT
2    2001-01-02 00:00:00
dtype: object

In [25]: s.dtype
Out[25]: dtype('O')

```

## API changes

- Added `to_series()` method to indices, to facilitate the creation of indexers ([GH3275](#))
- `HDFStore`
  - added the method `select_column` to select a single column from a table as a `Series`.
  - deprecated the `unique` method, can be replicated by `select_column(key, column).unique()`
  - `min_itemsize` parameter to `append` will now automatically create `data_columns` for passed keys

## Enhancements

- Improved performance of `df.to_csv()` by up to 10x in some cases. ([GH3059](#))
- `Numexpr` is now a *Recommended Dependencies*, to accelerate certain types of numerical and boolean operations
- `Bottleneck` is now a *Recommended Dependencies*, to accelerate certain types of nan operations
- `HDFStore`
  - support `read_hdf/to_hdf` API similar to `read_csv/to_csv`

```

In [26]: df = pd.DataFrame({'A': range(5), 'B': range(5)})

In [27]: df.to_hdf('store.h5', 'table', append=True)

In [28]: pd.read_hdf('store.h5', 'table', where=['index > 2'])

```

(continues on next page)

(continued from previous page)

**Out [28]:**

|   | A | B |
|---|---|---|
| 3 | 3 | 3 |
| 4 | 4 | 4 |

- provide dotted attribute access to get from stores, e.g. `store.df == store['df']`
- new keywords `iterator=boolean`, and `chunksizе=number_in_a_chunk` are provided to support iteration on `select` and `select_as_multiple` (GH3076)

- You can now select timestamps from an *unordered* timeseries similarly to an *ordered* timeseries (GH2437)
- You can now select with a string from a DataFrame with a datelike index, in a similar way to a Series (GH3070)

```
In [29]: idx = pd.date_range("2001-10-1", periods=5, freq='M')
```

```
In [30]: ts = pd.Series(np.random.rand(len(idx)), index=idx)
```

```

```

- In `pd.io.data.Options`,
  - Fix bug when trying to fetch data for the current month when already past expiry.
  - Now using `lxml` to scrape html instead of `BeautifulSoup` (`lxml` was faster).
  - New instance variables for calls and puts are automatically created when a method that creates them is called. This works for current month where the instance variables are simply `calls` and `puts`. Also works for future expiry months and save the instance variable as `callsMMYY` or `putsMMYY`, where `MMYY` are, respectively, the month and year of the option's expiry.
  - `Options.get_near_stock_price` now allows the user to specify the month for which to get relevant options data.
  - `Options.get_forward_data` now has optional kwargs `near` and `above_below`. This allows the user to specify if they would like to only return forward looking data for options near the current stock price. This just obtains the data from `Options.get_near_stock_price` instead of `Options.get_xxx_data()` (GH2758).
- Cursor coordinate information is now displayed in time-series plots.
- added option `display.max_seq_items` to control the number of elements printed per sequence pprinting it. (GH2979)
- added option `display.chop_threshold` to control display of small numerical values. (GH2739)
- added option `display.max_info_rows` to prevent `verbose_info` from being calculated for frames above 1M rows (configurable). (GH2807, GH2918)
- `value_counts()` now accepts a “normalize” argument, for normalized histograms. (GH2710).
- `DataFrame.from_records` now accepts not only dicts but any instance of the `collections.Mapping` ABC.
- added option `display.mpl_style` providing a sleeker visual style for plots. Based on <https://gist.github.com/huyng/816622> (GH3075).
- Treat boolean values as integers (values 1 and 0) for numeric operations. (GH2641)
- `to_html()` now accepts an optional “escape” argument to control reserved HTML character escaping (enabled by default) and escapes `&`, in addition to `<` and `>`. (GH2919)

See the *full release notes* or issue tracker on GitHub for a complete list.

## 6.17 Version 0.10

### 6.17.1 v0.10.1 (January 22, 2013)

{{ header }}

This is a minor release from 0.10.0 and includes new features, enhancements, and bug fixes. In particular, there is substantial new HDFStore functionality contributed by Jeff Reback.

An undesired API breakage with functions taking the `inplace` option has been reverted and deprecation warnings added.

#### API changes

- Functions taking an `inplace` option return the calling object as before. A deprecation message has been added
- Groupby aggregations Max/Min no longer exclude non-numeric data ([GH2700](#))
- Resampling an empty DataFrame now returns an empty DataFrame instead of raising an exception ([GH2640](#))
- The file reader will now raise an exception when NA values are found in an explicitly specified integer column instead of converting the column to float ([GH2631](#))
- `DatetimeIndex.unique` now returns a `DatetimeIndex` with the same name and
- `timezone` instead of an array ([GH2563](#))

#### New features

- MySQL support for database (contribution from Dan Allan)

#### HDFStore

You may need to upgrade your existing data files. Please visit the **compatibility** section in the main docs.

You can designate (and index) certain columns that you want to be able to perform queries on a table, by passing a list to `data_columns`

```

In [1]: store = pd.HDFStore('store.h5')

In [2]: df = pd.DataFrame(np.random.randn(8, 3),
...:                      index=pd.date_range('1/1/2000', periods=8),
...:                      columns=['A', 'B', 'C'])
...:

In [3]: df['string'] = 'foo'

In [4]: df.loc[df.index[4:6], 'string'] = np.nan

In [5]: df.loc[df.index[7:9], 'string'] = 'bar'

In [6]: df['string2'] = 'cool'

In [7]: df
Out[7]:
           A         B         C string string2

2000-01-04 -0.090255 -0.748199  1.318931   foo   cool
2000-01-05 -2.029766  0.792652  0.461007  NaN   cool
2000-01-06 -0.542749 -0.305384 -0.479195  NaN   cool
2000-01-07  0.095031 -0.270099 -0.707140   foo   cool
2000-01-08 -0.773882  0.229453  0.304418   bar   cool

# on-disk operations
In [8]: store.append('df', df, data_columns=['B', 'C', 'string', 'string2'])

In [9]: store.select('df', "B>0 and string=='foo'")
Out[9]:
           A         B         C string string2
2000-01-02  0.053897  0.194889 -0.381994   foo   cool
2000-01-03  0.318587  2.089075 -0.728293   foo   cool

# this is in-memory version of this type of selection
In [10]: df[(df.B > 0) & (df.string == 'foo')]
Out[10]:
           A         B         C string string2
2000-01-02  0.053897  0.194889 -0.381994   foo   cool
2000-01-03  0.318587  2.089075 -0.728293   foo   cool

```

Retrieving unique values in an indexable or data column.

```

# note that this is deprecated as of 0.14.0
# can be replicated by: store.select_column('df', 'index').unique()
store.unique('df', 'index')
store.unique('df', 'string')

```

You can now store `datetime64` in data columns

```

In [11]: df_mixed = df.copy()

In [12]: df_mixed['datetime64'] = pd.Timestamp('20010102')

In [13]: df_mixed.loc[df_mixed.index[3:4], ['A', 'B']] = np.nan

```

(continues on next page)

(continued from previous page)

```

In [14]: store.append('df_mixed', df_mixed)

In [15]: df_mixed1 = store.select('df_mixed')

In [16]: df_mixed1
Out [16]:

```

Multi-table creation via `append_to_multiple` and selection via `select_as_multiple` can create/select from multiple tables and return a combined result, by using `where` on a selector table.

```
In [19]: df_mt = pd.DataFrame(np.random.randn(8, 6),
.....:                        index=pd.date_range('1/1/2000', periods=8),
.....:                        columns=['A', 'B', 'C', 'D', 'E', 'F'])
.....:
```

```
In [20]: df_mt['foo'] = 'bar'
```

```
# you can also create the tables individually
```

```
In [21]: store.append_to_multiple({'df1_mt': ['A', 'B'], 'df2_mt': None},
.....:                            df_mt, selector='df1_mt')
.....:
```

```
In [22]: store
```

```
Out [22]:
```

```
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5
```

```

## Enhancements

- HDFStore now can read native PyTables table format tables
- You can pass `nan_rep = 'my_nan_rep'` to `append`, to change the default nan representation on disk (which converts to/from `np.nan`), this defaults to `nan`.
- You can pass `index` to `append`. This defaults to `True`. This will automatically create indices on the *indexes* and *data columns* of the table
- You can pass `chunksize=an integer` to `append`, to change the writing chunksize (default is 50000). This will significantly lower your memory usage on writing.
- You can pass `expectedrows=an integer` to the first `append`, to set the TOTAL number of expected rows that PyTables will expected. This will optimize read/write performance.
- `Select` now supports passing `start` and `stop` to provide selection space limiting in selection.
- Greatly improved ISO8601 (e.g., yyyy-mm-dd) date parsing for file parsers (GH2698)
- Allow `DataFrame.merge` to handle combinatorial sizes too large for 64-bit integer (GH2690)
- `Series` now has unary negation (`-series`) and inversion (`~series`) operators (GH2686)
- `DataFrame.plot` now includes a `logx` parameter to change the x-axis to log scale (GH2327)
- `Series` arithmetic operators can now handle constant and `ndarray` input (GH2574)

- `ExcelFile` now takes a `kind` argument to specify the file type (GH2613)
- A faster implementation for `Series.str` methods (GH2602)

### Bug Fixes

- `HDFStore` tables can now store `float32` types correctly (cannot be mixed with `float64` however)
- Fixed Google Analytics prefix when specifying request segment (GH2713).
- Function to reset Google Analytics token store so users can recover from improperly setup client secrets (GH2687).
- Fixed `groupby` bug resulting in `segfault` when passing in `MultiIndex` (GH2706)
- Fixed bug where passing a `Series` with `datetime64` values into `to_datetime` results in bogus output values (GH2699)
- Fixed bug in `pattern` in `HDFStore` expressions when `pattern` is not a valid regex (GH2694)
- Fixed performance issues while aggregating boolean data (GH2692)
- When given a boolean mask key and a `Series` of new values, `Series.__setitem__` will now align the incoming values with the original `Series` (GH2686)
- Fixed `MemoryError` caused by performing counting sort on sorting `MultiIndex` levels with a very large number of combinatorial values (GH2684)
- Fixed bug that causes plotting to fail when the index is a `DatetimeIndex` with a fixed-offset timezone (GH2683)
- Corrected business day subtraction logic when the offset is more than 5 bdays and the starting date is on a weekend (GH2680)
- Fixed C file parser behavior when the file has more columns than data (GH2668)
- Fixed file reader bug that misaligned columns with data in the presence of an implicit column and a specified `usecols` value
- `DataFrames` with numerical or datetime indices are now sorted prior to plotting (GH2609)
- Fixed `DataFrame.from_records` error when passed columns, index, but empty records (GH2633)
- Several bug fixed for `Series` operations when `dtype` is `datetime64` (GH2689, GH2629, GH2626)

See the *full release notes* or issue tracker on GitHub for a complete list.

### 6.17.2 v0.10.0 (December 17, 2012)

{{ header }}

This is a major release from 0.9.1 and includes many new features and enhancements along with a large number of bug fixes. There are also a number of important API changes that long-time pandas users should pay close attention to.

#### File parsing new features

The delimited file parsing engine (the guts of `read_csv` and `read_table`) has been rewritten from the ground up and now uses a fraction the amount of memory while parsing, while being 40% or more faster in most use cases (in some cases much faster).

There are also many new features:

- Much-improved Unicode handling via the `encoding` option.
- Column filtering (`usecols`)
- Dtype specification (`dtype` argument)
- Ability to specify strings to be recognized as True/False
- Ability to yield NumPy record arrays (`as_reccarray`)
- High performance `delim_whitespace` option
- Decimal format (e.g. European format) specification
- Easier CSV dialect options: `escapechar`, `lineterminator`, `quotechar`, etc.
- More robust handling of many exceptional kinds of files observed in the wild

## API changes

### Deprecated DataFrame BINOP TimeSeries special case behavior

The default behavior of binary operations between a DataFrame and a Series has always been to align on the DataFrame's columns and broadcast down the rows, **except** in the special case that the DataFrame contains time series. Since there are now method for each binary operator enabling you to specify how you want to broadcast, we are phasing out this special case (Zen of Python: *Special cases aren't special enough to break the rules*). Here's what I'm talking about:

```
In [1]: import pandas as pd

In [2]: df = pd.DataFrame(np.random.randn(6, 4),
...:                      index=pd.date_range('1/1/2000', periods=6))
...:

In [3]: df
Out [3]:
```

| 2000-01-05 | 0.0 | 3.011571  | -0.388828 | 2.217647  |
| 2000-01-06 | 0.0 | 0.673365  | 0.942776  | 0.291820  |

You will get a deprecation warning in the 0.10.x series, and the deprecated functionality will be removed in 0.11 or

later.

### Altered resample default behavior

The default time series resample binning behavior of daily D and *higher* frequencies has been changed to `closed='left', label='left'`. Lower frequencies are unaffected. The prior defaults were causing a great deal of confusion for users, especially resampling data to daily frequency (which labeled the aggregated group with the end of the interval: the next day).

```
In [1]: dates = pd.date_range('1/1/2000', '1/5/2000', freq='4h')

In [2]: series = pd.Series(np.arange(len(dates)), index=dates)

In [3]: series

- Infinity and negative infinity are no longer treated as NA by `isnull` and `notnull`. That they ever were was a relic of early pandas. This behavior can be re-enabled globally by the `mode.use_inf_as_null` option:

```
In [6]: s = pd.Series([1.5, np.inf, 3.4, -np.inf])
```

```
In [7]: pd.isnull(s)
```

```
Out [7]:
```

```
0    False
1    False
2    False
3    False
Length: 4, dtype: bool
```

```
In [8]: s.fillna(0)
```

```
Out [8]:
```

```
0    1.500000
1         inf
2    3.400000
3    -inf
Length: 4, dtype: float64
```

```
In [9]: pd.set_option('use_inf_as_null', True)
```

```
In [10]: pd.isnull(s)
```

```
Out [10]:
```

```
0    False
1     True
2    False
3     True
Length: 4, dtype: bool
```

```
In [11]: s.fillna(0)
```

```
Out [11]:
```

```
0    1.5
1    0.0
2    3.4
3    0.0
Length: 4, dtype: float64
```

```
In [12]: pd.reset_option('use_inf_as_null')
```

- Methods with the `inplace` option now all return `None` instead of the calling object. E.g. code written like `df = df.fillna(0, inplace=True)` may stop working. To fix, simply delete the unnecessary variable assignment.
- `pandas.merge` no longer sorts the group keys (`sort=False`) by default. This was done for performance reasons: the group-key sorting is often one of the more expensive parts of the computation and is often unnecessary.
- The default column names for a file with no header have been changed to the integers 0 through  $N - 1$ . This is to create consistency with the `DataFrame` constructor with no columns specified. The v0.9.0 behavior (names `X0, X1, ...`) can be reproduced by specifying `prefix='X'`:

```

In [6]: import io

In [7]: data = ('a,b,c\n'
...:          '1,Yes,2\n'
...:          '3,No,4')
...:

In [8]: print(data)
a,b,c
1,Yes,2
3,No,4

In [9]: pd.read_csv(io.StringIO(data), header=None)
Out[9]:
   0  1  2
0  a  b  c
1  1  Yes  2
2  3  No  4

In [10]: pd.read_csv(io.StringIO(data), header=None, prefix='X')
Out[10]:
   X0  X1  X2
0  a   b   c
1  1  Yes  2
2  3  No  4

```

- Values like 'Yes' and 'No' are not interpreted as boolean by default, though this can be controlled by new `true_values` and `false_values` arguments:

```

In [11]: print(data)
a,b,c
1,Yes,2
3,No,4

In [12]: pd.read_csv(io.StringIO(data))
Out[12]:
   a  b  c
0  1  Yes  2
1  3  No  4

In [13]: pd.read_csv(io.StringIO(data), true_values=['Yes'], false_values=['No'])
Out[13]:
   a  b  c
0  1  True  2
1  3  False  4

```

- The file parsers will not recognize non-string values arising from a converter function as NA if passed in the `na_values` argument. It's better to do post-processing using the `replace` function instead.
- Calling `fillna` on Series or DataFrame with no arguments is no longer valid code. You must either specify a fill value or an interpolation method:

```

In [14]: s = pd.Series([np.nan, 1., 2., np.nan, 4])

In [15]: s
Out[15]:
0    NaN

```

(continues on next page)

(continued from previous page)

```
1    1.0
2    2.0
3    NaN
4    4.0
dtype: float64
```

```
In [16]: s.fillna(0)
```

```
Out [16]:
0    0.0
1    1.0
2    2.0
3    0.0
4    4.0
dtype: float64
```

```
In [17]: s.fillna(method='pad')
```

```
Out [17]:
0    NaN
1    1.0
2    2.0
3    2.0
4    4.0
dtype: float64
```

Convenience methods `ffill` and `bfill` have been added:

```
In [18]: s.fffll()
```

```
Out [18]:
0    NaN
1    1.0
2    2.0
3    2.0
4    4.0
dtype: float64
```

- `Series.apply` will now operate on a returned value from the applied function, that is itself a series, and possibly upcast the result to a `DataFrame`

```
In [19]: def f(x):
.....:     return pd.Series([x, x**2], index=['x', 'x^2'])
.....:
```

```
In [20]: s = pd.Series(np.random.rand(5))
```

```
In [21]: s
```

```
Out [21]:
0    0.123872
1    0.924168
2    0.325076
3    0.303746
4    0.116822
dtype: float64
```

```
In [22]: s.apply(f)
```

```
Out [22]:
      x      x^2
```

(continues on next page)

(continued from previous page)

```

0  0.123872  0.015344
1  0.924168  0.854086
2  0.325076  0.105674
3  0.303746  0.092262
4  0.116822  0.013647

```

- New API functions for working with pandas options ([GH2097](#)):

- `get_option` / `set_option` - get/set the value of an option. Partial names are accepted.
- `reset_option` - reset one or more options to their default value. Partial names are accepted.
- `describe_option` - print a description of one or more options. When called with no arguments, print all registered options.

Note: `set_printoptions`/`reset_printoptions` are now deprecated (but functioning), the print options now live under “`display.XYZ`”. For example:

```

In [23]: pd.get_option("display.max_rows")
Out [23]: 60

```

- `to_string()` methods now always return unicode strings ([GH2224](#)).

## New features

### Wide DataFrame printing

Instead of printing the summary information, pandas now splits the string representation across multiple rows by default:

```

In [24]: wide_frame = pd.DataFrame(np.random.randn(5, 16))

In [25]: wide_frame
Out [25]:
      0         1         2         3         4         5  ...         10
↪11  12      13      14      15
0 -0.711411 -2.122599  1.962935  1.672027 -0.880984  0.997289  ...  0.912560 -1.
↪003401  1.632781 -0.724626  0.178219  0.310610
1 -0.108002 -0.974226 -1.147708 -2.281374  0.760010 -0.742532  ...  0.043520  0.
↪112246  0.871721 -0.816064 -0.784880  1.030659
2  0.187483 -1.933946  0.377312  0.734122  2.141616 -0.011225  ... -0.231595 -0.
↪527750 -1.296337  0.150680  0.123836  0.571764
3  1.555563 -0.823761  0.535420 -1.032853  1.469725  1.304124  ... -0.962723  1.
↪382083 -0.938794  0.669142 -0.433567 -0.273610
4  0.680433 -0.308450 -0.276099 -1.821168 -1.993606 -1.927385  ...  0.455264 -0.
↪030740  0.935716  1.061192 -2.107852  0.199905

[5 rows x 16 columns]

```

The old behavior of printing out summary information can be achieved via the ‘`expand_frame_repr`’ print option:

```

In [26]: pd.set_option('expand_frame_repr', False)

In [27]: wide_frame
Out [27]:
      0         1         2         3         4         5         6         7
↪      8         9        10        11        12        13        14        15

```

(continues on next page)

(continued from previous page)

```

```

The width of each line can be changed via 'line\_width' (80 by default):

```
pd.set_option('line_width', 40)

wide_frame
```

## Updated PyTables support

Docs for PyTables Table format & several enhancements to the api. Here is a taste of what to expect.

```
In [41]: store = pd.HDFStore('store.h5')

In [42]: df = pd.DataFrame(np.random.randn(8, 3),
.....:                      index=pd.date_range('1/1/2000', periods=8),
.....:                      columns=['A', 'B', 'C'])

In [43]: df
Out [43]:

```

- performance improvements on table writing
- support for arbitrarily indexed dimensions
- SparseSeries now has a density property (GH2384)
- enable Series.str.strip/lstrip/rstrip methods to take an input argument to strip arbitrary characters (GH2411)
- implement value\_vars in melt to limit values to certain columns and add melt to pandas namespace (GH2412)

### Bug Fixes

- added Term method of specifying where conditions (GH1996).
- del store['df'] now call store.remove('df') for store deletion
- deleting of consecutive rows is much faster than before
- min\_itemsize parameter can be specified in table creation to force a minimum size for indexing columns (the previous implementation would set the column size based on the first append)
- indexing support via create\_table\_index (requires PyTables >= 2.3) (GH698).
- appending on a store would fail if the table was not first created via put
- fixed issue with missing attributes after loading a pickled dataframe (GH2431)
- minor change to select and remove: require a table ONLY if where is also provided (and not None)

### Compatibility

0.10 of HDFStore is backwards compatible for reading tables created in a prior version of pandas, however, query terms using the prior (undocumented) methodology are unsupported. You must read in the entire file and write it out using the new format to take advantage of the updates.

## N dimensional Panels (experimental)

Adding experimental support for Panel4D and factory functions to create n-dimensional named panels. Here is a taste of what to expect.

```
In [58]: p4d = Panel4D(np.random.randn(2, 2, 5, 4),
....:      labels=['Label1', 'Label2'],
....:      items=['Item1', 'Item2'],
....:      major_axis=date_range('1/1/2000', periods=5),
....:      minor_axis=['A', 'B', 'C', 'D'])
....:

In [59]: p4d
Out [59]:
<class 'pandas.core.panelnd.Panel4D'>
Dimensions: 2 (labels) x 2 (items) x 5 (major_axis) x 4 (minor_axis)
Labels axis: Label1 to Label2
Items axis: Item1 to Item2
Major_axis axis: 2000-01-01 00:00:00 to 2000-01-05 00:00:00
Minor_axis axis: A to D
```

## 6.18 Version 0.9

### 6.18.1 v0.9.1 (November 14, 2012)

{{ header }}

This is a bug fix release from 0.9.0 and includes several new features and enhancements along with a large number of bug fixes. The new features include by-column sort order for DataFrame and Series, improved NA handling for the rank method, masking functions for DataFrame, and intraday time-series filtering for DataFrame.

#### New features

- *Series.sort*, *DataFrame.sort*, and *DataFrame.sort\_index* can now be specified in a per-column manner to support multiple sort orders ([GH928](#))

```
In [2]: df = pd.DataFrame(np.random.randint(0, 2, (6, 3)),
...:                      columns=['A', 'B', 'C'])
```

```
In [3]: df.sort(['A', 'B'], ascending=[1, 0])
```

Out [3]:

```
   A  B  C
3  0  1  1
4  0  1  1
2  0  0  1
0  1  0  0
1  1  0  0
5  1  0  0
```

- *DataFrame.rank* now supports additional argument values for the *na\_option* parameter so missing values can be assigned either the largest or the smallest rank ([GH1508](#), [GH2159](#))

```
In [1]: df = pd.DataFrame(np.random.randn(6, 3), columns=['A', 'B', 'C'])
```

```
In [2]: df.loc[2:4] = np.nan
```

```
In [3]: df.rank()
```

Out [3]:

```
   A    B    C
0  2.0  3.0  3.0
1  3.0  1.0  1.0
```

(continues on next page)

(continued from previous page)

```

2 NaN NaN NaN
3 NaN NaN NaN
4 NaN NaN NaN
5 1.0 2.0 2.0

```

```
[6 rows x 3 columns]
```

```
In [4]: df.rank(na_option='top')
```

```
Out [4]:
```

|   | A   | B   | C   |
|---|-----|-----|-----|
| 0 | 5.0 | 6.0 | 6.0 |
| 1 | 6.0 | 4.0 | 4.0 |
| 2 | 2.0 | 2.0 | 2.0 |
| 3 | 2.0 | 2.0 | 2.0 |
| 4 | 2.0 | 2.0 | 2.0 |
| 5 | 4.0 | 5.0 | 5.0 |

```
[6 rows x 3 columns]
```

```
In [5]: df.rank(na_option='bottom')
```

```
Out [5]:
```

|   | A   | B   | C   |
|---|-----|-----|-----|
| 0 | 2.0 | 3.0 | 3.0 |
| 1 | 3.0 | 1.0 | 1.0 |
| 2 | 5.0 | 5.0 | 5.0 |
| 3 | 5.0 | 5.0 | 5.0 |
| 4 | 5.0 | 5.0 | 5.0 |
| 5 | 1.0 | 2.0 | 2.0 |

```
[6 rows x 3 columns]
```

- DataFrame has new *where* and *mask* methods to select values according to a given boolean mask ([GH2109](#), [GH2151](#))

DataFrame currently supports slicing via a boolean vector the same length as the DataFrame (inside the `[]`). The returned DataFrame has the same number of columns as the original, but is sliced on its index.

```
In [6]: df = DataFrame(np.random.randn(5, 3), columns = ['A', 'B', 'C'])
```

```
In [7]: df
```

```
Out [7]:
```

|   | A         | B         | C         |
|---|-----------|-----------|-----------|
| 0 | -1.170647 | -0.881989 | -0.485793 |
| 1 | 0.174369  | -1.500438 | 0.155944  |
| 2 | -1.426978 | 0.189856  | -0.465137 |
| 3 | -1.226494 | 1.017240  | 0.715402  |
| 4 | -0.640726 | -1.196583 | 0.110529  |

```
[5 rows x 3 columns]
```

```
In [8]: df[df['A'] > 0]
```

```
Out [8]:
```

|   | A        | B         | C        |
|---|----------|-----------|----------|
| 1 | 0.174369 | -1.500438 | 0.155944 |

```
[1 rows x 3 columns]
```

If a DataFrame is sliced with a DataFrame based boolean condition (with the same size as the original DataFrame), then a DataFrame the same size (index and columns) as the original is returned, with elements that do not meet the boolean condition as *NaN*. This is accomplished via the new method *DataFrame.where*. In addition, *where* takes an optional *other* argument for replacement.

```
In [9]: df[df>0]
Out [9]:
```

|   | A        | B        | C        |
|---|----------|----------|----------|
| 0 | NaN      | NaN      | NaN      |
| 1 | 0.174369 | NaN      | 0.155944 |
| 2 | NaN      | 0.189856 | NaN      |
| 3 | NaN      | 1.017240 | 0.715402 |
| 4 | NaN      | NaN      | 0.110529 |

```
[5 rows x 3 columns]
```

```
In [10]: df.where(df>0)
Out [10]:
```

|   | A        | B        | C        |
|---|----------|----------|----------|
| 0 | NaN      | NaN      | NaN      |
| 1 | 0.174369 | NaN      | 0.155944 |
| 2 | NaN      | 0.189856 | NaN      |
| 3 | NaN      | 1.017240 | 0.715402 |
| 4 | NaN      | NaN      | 0.110529 |

```
[5 rows x 3 columns]
```

```
In [11]: df.where(df>0,-df)
Out [11]:
```

|   | A        | B        | C        |
|---|----------|----------|----------|
| 0 | 1.170647 | 0.881989 | 0.485793 |
| 1 | 0.174369 | 1.500438 | 0.155944 |
| 2 | 1.426978 | 0.189856 | 0.465137 |
| 3 | 1.226494 | 1.017240 | 0.715402 |
| 4 | 0.640726 | 1.196583 | 0.110529 |

```
[5 rows x 3 columns]
```

Furthermore, *where* now aligns the input boolean condition (ndarray or DataFrame), such that partial selection with setting is possible. This is analogous to partial setting via *.ix* (but on the contents rather than the axis labels)

```
In [12]: df2 = df.copy()
In [13]: df2[ df2[1:4] > 0 ] = 3
In [14]: df2
Out [14]:
```

|   | A         | B         | C         |
|---|-----------|-----------|-----------|
| 0 | -1.170647 | -0.881989 | -0.485793 |
| 1 | 3.000000  | -1.500438 | 3.000000  |
| 2 | -1.426978 | 3.000000  | -0.465137 |
| 3 | -1.226494 | 3.000000  | 3.000000  |
| 4 | -0.640726 | -1.196583 | 0.110529  |

```
[5 rows x 3 columns]
```

*DataFrame.mask* is the inverse boolean operation of *where*.

```
In [15]: df.mask(df<=0)
Out [15]:
```

|   | A        | B        | C        |
|---|----------|----------|----------|
| 0 | NaN      | NaN      | NaN      |
| 1 | 0.174369 | NaN      | 0.155944 |
| 2 | NaN      | 0.189856 | NaN      |
| 3 | NaN      | 1.017240 | 0.715402 |
| 4 | NaN      | NaN      | 0.110529 |

[5 rows x 3 columns]

- Enable referencing of Excel columns by their column names (GH1936)

```
In [16]: xl = pd.ExcelFile('data/test.xls')
In [17]: xl.parse('Sheet1', index_col=0, parse_dates=True,
.....:           parse_cols='A:D')
.....:
Out [17]:
```

|            | A         | B         | C         | D         |
|------------|-----------|-----------|-----------|-----------|
| 2000-01-03 | 0.980269  | 3.685731  | -0.364217 | -1.159738 |
| 2000-01-04 | 1.047916  | -0.041232 | -0.161812 | 0.212549  |
| 2000-01-05 | 0.498581  | 0.731168  | -0.537677 | 1.346270  |
| 2000-01-06 | 1.120202  | 1.567621  | 0.003641  | 0.675253  |
| 2000-01-07 | -0.487094 | 0.571455  | -1.611639 | 0.103469  |
| 2000-01-10 | 0.836649  | 0.246462  | 0.588543  | 1.062782  |
| 2000-01-11 | -0.157161 | 1.340307  | 1.195778  | -1.097007 |

[7 rows x 4 columns]

- Added option to disable pandas-style tick locators and formatters using `series.plot(x_compat=True)` or `pandas.plot_params['x_compat'] = True` (GH2205)
- Existing TimeSeries methods `at_time` and `between_time` were added to DataFrame (GH2149)
- DataFrame.dot can now accept ndarrays (GH2042)
- DataFrame.drop now supports non-unique indexes (GH2101)
- Panel.shift now supports negative periods (GH2164)
- DataFrame now support unary `~` operator (GH2110)

## API changes

- Upsampling data with a PeriodIndex will result in a higher frequency TimeSeries that spans the original time window

```
In [1]: prng = pd.period_range('2012Q1', periods=2, freq='Q')
In [2]: s = pd.Series(np.random.randn(len(prng)), prng)
In [4]: s.resample('M')
Out [4]:
```

|         |           |
|---------|-----------|
| 2012-01 | -1.471992 |
| 2012-02 | NaN       |
| 2012-03 | NaN       |
| 2012-04 | -0.493593 |

(continues on next page)

(continued from previous page)

```

2012-05      NaN
2012-06      NaN
Freq: M, dtype: float64

```

- `Period.end_time` now returns the last nanosecond in the time interval ([GH2124](#), [GH2125](#), [GH1764](#))

```

In [18]: p = pd.Period('2012')

In [19]: p.end_time
Out[19]: Timestamp('2012-12-31 23:59:59.999999999')

```

- File parsers no longer coerce to float or bool for columns that have custom converters specified ([GH2184](#))

```

In [20]: import io

In [21]: data = ('A,B,C\n'
.....:          '00001,001,5\n'
.....:          '00002,002,6')
.....:

In [22]: pd.read_csv(io.StringIO(data), converters={'A': lambda x: x.strip()})
Out[22]:
   A  B  C
0  00001  1  5
1  00002  2  6

[2 rows x 3 columns]

```

See the *full release notes* or issue tracker on GitHub for a complete list.

## 6.18.2 v0.9.0 (October 7, 2012)

This is a major release from 0.8.1 and includes several new features and enhancements along with a large number of bug fixes. New features include vectorized unicode encoding/decoding for `Series.str`, `to_latex` method to `DataFrame`, more flexible parsing of boolean values, and enabling the download of options data from Yahoo! Finance.

### New features

- Add `encode` and `decode` for unicode handling to *vectorized string processing methods* in `Series.str` (GH1706)
- Add `DataFrame.to_latex` method (GH1735)
- Add convenient expanding window equivalents of all `rolling_*` ops (GH1785)
- Add `Options` class to `pandas.io.data` for fetching options data from Yahoo! Finance (GH1748, GH1739)
- More flexible parsing of boolean values (Yes, No, TRUE, FALSE, etc) (GH1691, GH1295)
- Add `level` parameter to `Series.reset_index`
- `TimeSeries.between_time` can now select times across midnight (GH1871)
- `Series` constructor can now handle generator as input (GH1679)
- `DataFrame.dropna` can now take multiple axes (tuple/list) as input (GH924)
- Enable `skip_footer` parameter in `ExcelFile.parse` (GH1843)

### API changes

- The default column names when `header=None` and no columns names passed to functions like `read_csv` has changed to be more Pythonic and amenable to attribute access:

```
In [1]: import io

In [2]: data = ('0,0,1\n'
...:          '1,1,0\n'
...:          '0,1,0')
...:

In [3]: df = pd.read_csv(io.StringIO(data), header=None)

In [4]: df
Out[4]:
   0  1  2
0  0  0  1
1  1  1  0
2  0  1  0

[3 rows x 3 columns]
```

- Creating a `Series` from another `Series`, passing an index, will cause reindexing to happen inside rather than treating the `Series` like an `ndarray`. Technically improper usages like `Series(df[col1], index=df[col2])` that worked before “by accident” (this was never intended) will lead to all NA `Series` in some cases. To be perfectly clear:

```

In [5]: s1 = pd.Series([1, 2, 3])

In [6]: s1
Out[6]:
0    1
1    2
2    3
Length: 3, dtype: int64

In [7]: s2 = pd.Series(s1, index=['foo', 'bar', 'baz'])

In [8]: s2
Out[8]:
foo    NaN
bar    NaN
baz    NaN
Length: 3, dtype: float64

```

- Deprecated `day_of_year` API removed from `PeriodIndex`, use `dayofyear` ([GH1723](#))
- Don't modify NumPy `suppress_printoption` to `True` at import time
- The internal HDF5 data arrangement for DataFrames has been transposed. Legacy files will still be readable by `HDFStore` ([GH1834](#), [GH1824](#))
- Legacy cruft removed: `pandas.stats.misc.quantileTS`
- Use ISO8601 format for `Period` repr: `monthly`, `daily`, and on down ([GH1776](#))
- Empty `DataFrame` columns are now created as `object` dtype. This will prevent a class of `TypeError`s that was occurring in code where the dtype of a column would depend on the presence of data or not (e.g. a SQL query having results) ([GH1783](#))
- Setting parts of `DataFrame/Panel` using `ix` now aligns input `Series/DataFrame` ([GH1630](#))
- `first` and `last` methods in `GroupBy` no longer drop non-numeric columns ([GH1809](#))
- Resolved inconsistencies in specifying custom NA values in text parser. `na_values` of type `dict` no longer override default NAs unless `keep_default_na` is set to `false` explicitly ([GH1657](#))
- `DataFrame.dot` will not do data alignment, and also work with `Series` ([GH1915](#))

See the *full release notes* or issue tracker on GitHub for a complete list.

## 6.19 Version 0.8

### 6.19.1 v0.8.1 (July 22, 2012)

{{ header }}

This release includes a few new features, performance enhancements, and over 30 bug fixes from 0.8.0. New features include notably NA friendly string processing functionality and a series of new plot types and options.

#### New features

- Add *vectorized string processing methods* accessible via `Series.str` (GH620)
- Add option to disable adjustment in EWMA (GH1584)
- *Radviz plot* (GH1566)
- *Parallel coordinates plot*
- *Bootstrap plot*
- Per column styles and secondary y-axis plotting (GH1559)
- New datetime converters millisecond plotting (GH1599)
- Add option to disable “sparse” display of hierarchical indexes (GH1538)
- `Series/DataFrame`’s `set_index` method can *append levels* to an existing `Index/MultiIndex` (GH1569, GH1577)

## Performance improvements

- Improved implementation of rolling min and max (thanks to [Bottleneck](#) !)
- Add accelerated 'median' GroupBy option ([GH1358](#))
- Significantly improve the performance of parsing ISO8601-format date strings with `DatetimeIndex` or `to_datetime` ([GH1571](#))
- Improve the performance of GroupBy on single-key aggregations and use with Categorical types
- Significant datetime parsing performance improvements

## Contributors

A total of 5 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

- Chang She
- Skipper Seabold
- Todd DeLuca +
- Vytautas Jancauskas
- Wes McKinney

## 6.19.2 v0.8.0 (June 29, 2012)

{{ header }}

This is a major release from 0.7.3 and includes extensive work on the time series handling and processing infrastructure as well as a great deal of new functionality throughout the library. It includes over 700 commits from more than 20 distinct authors. Most pandas 0.7.3 and earlier users should not experience any issues upgrading, but due to the migration to the NumPy `datetime64` dtype, there may be a number of bugs and incompatibilities lurking. Lingering incompatibilities will be fixed ASAP in a 0.8.1 release if necessary. See the *full release notes* or issue tracker on GitHub for a complete list.

### Support for non-unique indexes

All objects can now work with non-unique indexes. Data alignment / join operations work according to SQL join semantics (including, if application, index duplication in many-to-many joins)

### NumPy `datetime64` dtype and 1.6 dependency

Time series data are now represented using NumPy’s `datetime64` dtype; thus, pandas 0.8.0 now requires at least NumPy 1.6. It has been tested and verified to work with the development version (1.7+) of NumPy as well which includes some significant user-facing API changes. NumPy 1.6 also has a number of bugs having to do with nanosecond resolution data, so I recommend that you steer clear of NumPy 1.6’s `datetime64` API functions (though limited as they are) and only interact with this data using the interface that pandas provides.

See the end of the 0.8.0 section for a “porting” guide listing potential issues for users migrating legacy code bases from pandas 0.7 or earlier to 0.8.0.

Bug fixes to the 0.7.x series for legacy NumPy < 1.6 users will be provided as they arise. There will be no more further development in 0.7.x beyond bug fixes.

## Time series changes and improvements

---

**Note:** With this release, legacy scikits.timeseries users should be able to port their code to use pandas.

---

---

**Note:** See *documentation* for overview of pandas timeseries API.

---

- New `datetime64` representation **speeds up join operations and data alignment, reduces memory usage**, and improve serialization / deserialization performance significantly over `datetime.datetime`
- High performance and flexible **resample** method for converting from high-to-low and low-to-high frequency. Supports interpolation, user-defined aggregation functions, and control over how the intervals and result labeling are defined. A suite of high performance Cython/C-based resampling functions (including Open-High-Low-Close) have also been implemented.
- Revamp of *frequency aliases* and support for **frequency shortcuts** like ‘15min’, or ‘1h30min’
- New `DatetimeIndex` class supports both fixed frequency and irregular time series. Replaces now deprecated `DateRange` class
- New `PeriodIndex` and `Period` classes for representing *time spans* and performing **calendar logic**, including the *12 fiscal quarterly frequencies* `<timeseries.quarterly>`. This is a partial port of, and a substantial enhancement to, elements of the scikits.timeseries code base. Support for conversion between `PeriodIndex` and `DatetimeIndex`
- New `Timestamp` data type subclasses `datetime.datetime`, providing the same interface while enabling working with nanosecond-resolution data. Also provides *easy time zone conversions*.
- Enhanced support for *time zones*. Add `tz_convert` and `tz_localize` methods to `TimeSeries` and `DataFrame`. All timestamps are stored as UTC; Timestamps from `DatetimeIndex` objects with time zone set will be localized to local time. Time zone conversions are therefore essentially free. User needs to know very little about `pytz` library now; only time zone names as strings are required. Time zone-aware timestamps are equal if and only if their UTC timestamps match. Operations between time zone-aware time series with different time zones will result in a UTC-indexed time series.
- Time series **string indexing conveniences** / shortcuts: slice years, year and month, and index values with strings
- Enhanced time series **plotting**; adaptation of scikits.timeseries matplotlib-based plotting code
- New `date_range`, `bdate_range`, and `period_range` *factory functions*
- Robust **frequency inference** function `infer_freq` and `inferred_freq` property of `DatetimeIndex`, with option to infer frequency on construction of `DatetimeIndex`
- `to_datetime` function efficiently **parses array of strings** to `DatetimeIndex`. `DatetimeIndex` will parse array or list of strings to `datetime64`
- **Optimized** support for `datetime64-dtype` data in `Series` and `DataFrame` columns
- New `NaT` (Not-a-Time) type to represent **NA** in timestamp arrays
- Optimize `Series.asof` for looking up **“as of” values** for arrays of timestamps
- Milli, Micro, Nano date offset objects
- Can index time series with `datetime.time` objects to select all data at particular **time of day** (`TimeSeries.at_time`) or **between two times** (`TimeSeries.between_time`)
- Add `tshift` method for leading/lagging using the frequency (if any) of the index, as opposed to a naive lead/lag using `shift`

## Other new features

- New `cut` and `qcut` functions (like R's `cut` function) for computing a categorical variable from a continuous variable by binning values either into value-based (`cut`) or quantile-based (`qcut`) bins
- Rename `Factor` to `Categorical` and add a number of usability features
- Add `limit` argument to `fillna/reindex`
- More flexible multiple function application in `GroupBy`, and can pass list (name, function) tuples to get result in particular order with given names
- Add flexible `replace` method for efficiently substituting values
- Enhanced `read_csv/read_table` for reading time series data and converting multiple columns to dates
- Add `comments` option to parser functions: `read_csv`, etc.
- Add `dayfirst` option to parser functions for parsing international DD/MM/YYYY dates
- Allow the user to specify the CSV reader `dialect` to control quoting etc.
- Handling `thousands` separators in `read_csv` to improve integer parsing.
- Enable unstacking of multiple levels in one shot. Alleviate `pivot_table` bugs (empty columns being introduced)
- Move to `klib`-based hash tables for indexing; better performance and less memory usage than Python's `dict`
- Add `first`, `last`, `min`, `max`, and `prod` optimized `GroupBy` functions
- New `ordered_merge` function
- Add flexible `comparison` instance methods `eq`, `ne`, `lt`, `gt`, etc. to `DataFrame`, `Series`
- Improve `scatter_matrix` plotting function and add histogram or kernel density estimates to diagonal
- Add `'kde'` plot option for density plots
- Support for converting `DataFrame` to R `data.frame` through `rpy2`
- Improved support for complex numbers in `Series` and `DataFrame`
- Add `pct_change` method to all data structures
- Add `max_colwidth` configuration option for `DataFrame` console output
- `Interpolate` `Series` values using index values
- Can select multiple columns from `GroupBy`
- Add `update` methods to `Series/DataFrame` for updating values in place
- Add `any` and `all` method to `DataFrame`

## New plotting methods

```
import pandas as pd
fx = pd.read_pickle('data/fx_prices')
import matplotlib.pyplot as plt
```

`Series.plot` now supports a `secondary_y` option:

```
plt.figure()

fx['FR'].plot(style='g')

fx['IT'].plot(style='k--', secondary_y=True)
```

Vytautas Jancauskas, the 2012 GSOC participant, has added many new plot types. For example, 'kde' is a new option:

```
In [1]: s = pd.Series(np.concatenate((np.random.randn(1000),
...:                                np.random.randn(1000) * 0.5 + 3)))
...:

In [2]: plt.figure()
Out[2]: <Figure size 640x480 with 0 Axes>

In [3]: s.hist(density=True, alpha=0.2)
Out[3]: <matplotlib.axes._subplots.AxesSubplot at 0x7f7fd12bdfd0>

In [4]: s.plot(kind='kde')
Out[4]: <matplotlib.axes._subplots.AxesSubplot at 0x7f7fd12bdfd0>
```

See *the plotting page* for much more.

## Other API changes

- Deprecation of `offset`, `time_rule`, and `timeRule` arguments names in time series functions. Warnings will be printed until pandas 0.9 or 1.0.

## Potential porting issues for pandas <= 0.7.3 users

The major change that may affect you in pandas 0.8.0 is that time series indexes use NumPy's `datetime64` data type instead of `dtype=object` arrays of Python's built-in `datetime.datetime` objects. `DateRange` has been replaced by `DatetimeIndex` but otherwise behaved identically. But, if you have code that converts `DateRange` or `Index` objects that used to contain `datetime.datetime` values to plain NumPy arrays, you may have bugs lurking with code using scalar values because you are handing control over to NumPy:

```
In [5]: import datetime

In [6]: rng = pd.date_range('1/1/2000', periods=10)

In [7]: rng[5]
Out[7]: Timestamp('2000-01-06 00:00:00', freq='D')

In [8]: isinstance(rng[5], datetime.datetime)
Out[8]: True

In [9]: rng_asarray = np.asarray(rng)

In [10]: scalar_val = rng_asarray[5]

In [11]: type(scalar_val)
Out[11]: numpy.datetime64
```

pandas's `Timestamp` object is a subclass of `datetime.datetime` that has nanosecond support (the nanosecond field store the nanosecond value between 0 and 999). It should substitute directly into any code that used `datetime.datetime` values before. Thus, I recommend not casting `DatetimeIndex` to regular NumPy arrays.

If you have code that requires an array of `datetime.datetime` objects, you have a couple of options. First, the `astype(object)` method of `DatetimeIndex` produces an array of `Timestamp` objects:

```
In [12]: stamp_array = rng.astype(object)

In [13]: stamp_array
Out [13]:
Index([2000-01-01 00:00:00, 2000-01-02 00:00:00, 2000-01-03 00:00:00,
       2000-01-04 00:00:00, 2000-01-05 00:00:00, 2000-01-06 00:00:00,
       2000-01-07 00:00:00, 2000-01-08 00:00:00, 2000-01-09 00:00:00,
       2000-01-10 00:00:00],
      dtype='object')

In [14]: stamp_array[5]
Out [14]: Timestamp('2000-01-06 00:00:00', freq='D')
```

To get an array of proper `datetime.datetime` objects, use the `to_pydatetime` method:

```
In [15]: dt_array = rng.to_pydatetime()

In [16]: dt_array
Out [16]:
array([datetime.datetime(2000, 1, 1, 0, 0),
       datetime.datetime(2000, 1, 2, 0, 0),
       datetime.datetime(2000, 1, 3, 0, 0),
       datetime.datetime(2000, 1, 4, 0, 0),
       datetime.datetime(2000, 1, 5, 0, 0),
       datetime.datetime(2000, 1, 6, 0, 0),
       datetime.datetime(2000, 1, 7, 0, 0),
       datetime.datetime(2000, 1, 8, 0, 0),
       datetime.datetime(2000, 1, 9, 0, 0),
       datetime.datetime(2000, 1, 10, 0, 0)], dtype=object)

In [17]: dt_array[5]
Out [17]: datetime.datetime(2000, 1, 6, 0, 0)
```

matplotlib knows how to handle `datetime.datetime` but not `Timestamp` objects. While I recommend that you plot time series using `TimeSeries.plot`, you can either use `to_pydatetime` or register a converter for the `Timestamp` type. See [matplotlib documentation](#) for more on this.

**Warning:** There are bugs in the user-facing API with the nanosecond `datetime64` unit in NumPy 1.6. In particular, the string version of the array shows garbage values, and conversion to `dtype=object` is similarly broken.

```
In [18]: rng = pd.date_range('1/1/2000', periods=10)

In [19]: rng
Out [19]:
DatetimeIndex(['2000-01-01', '2000-01-02', '2000-01-03', '2000-01-04',
              '2000-01-05', '2000-01-06', '2000-01-07', '2000-01-08',
              '2000-01-09', '2000-01-10'],
             dtype='datetime64[ns]', freq='D')

In [20]: np.asarray(rng)
```

```
Out [20]:
array(['2000-01-01T00:00:00.000000000', '2000-01-02T00:00:00.000000000',
      '2000-01-03T00:00:00.000000000', '2000-01-04T00:00:00.000000000',
      '2000-01-05T00:00:00.000000000', '2000-01-06T00:00:00.000000000',
      '2000-01-07T00:00:00.000000000', '2000-01-08T00:00:00.000000000',
      '2000-01-09T00:00:00.000000000', '2000-01-10T00:00:00.000000000'],
      dtype='datetime64[ns]')
```

```
In [21]: converted = np.asarray(rng, dtype=object)
```

```
In [22]: converted[5]
```

```
Out [22]: Timestamp('2000-01-06 00:00:00', freq='D')
```

**Trust me: don't panic.** If you are using NumPy 1.6 and restrict your interaction with `datetime64` values to pandas's API you will be just fine. There is nothing wrong with the data-type (a 64-bit integer internally); all of the important data processing happens in pandas and is heavily tested. I strongly recommend that you **do not work directly with `datetime64` arrays in NumPy 1.6** and only use the pandas API.

**Support for non-unique indexes:** In the latter case, you may have code inside a `try:... catch:` block that failed due to the index not being unique. In many cases it will no longer fail (some method like `append` still check for uniqueness unless disabled). However, all is not lost: you can inspect `index.is_unique` and raise an exception explicitly if it is `False` or go to a different code branch.

## 6.20 Version 0.7

### 6.20.1 v.0.7.3 (April 12, 2012)

{{ header }}

This is a minor release from 0.7.2 and fixes many minor bugs and adds a number of nice new features. There are also a couple of API changes to note; these should not affect very many users, and we are inclined to call them “bug fixes” even though they do constitute a change in behavior. See the *full release notes* or issue tracker on GitHub for a complete list.

#### New features

- New *fixed width file reader*, `read_fwf`
- New *scatter\_matrix* function for making a scatter plot matrix

```
from pandas.tools.plotting import scatter_matrix
scatter_matrix(df, alpha=0.2) # noqa F821
```

- Add `stacked` argument to `Series` and `DataFrame`’s `plot` method for *stacked bar plots*.

```
df.plot(kind='bar', stacked=True) # noqa F821
```

```
df.plot(kind='barh', stacked=True) # noqa F821
```

- Add `log x` and `y scaling options` to `DataFrame.plot` and `Series.plot`
- Add `kurt` methods to `Series` and `DataFrame` for computing kurtosis

## NA Boolean comparison API change

Reverted some changes to how NA values (represented typically as NaN or None) are handled in non-numeric Series:

```
In [1]: series = pd.Series(['Steve', np.nan, 'Joe'])
```

```
In [2]: series == 'Steve'
```

```
Out [2]:
0      True
1     False
2     False
Length: 3, dtype: bool
```

```
In [3]: series != 'Steve'
```

```
Out [3]:
0     False
1       True
2       True
Length: 3, dtype: bool
```

In comparisons, NA / NaN will always come through as `False` except with `!=` which is `True`. *Be very careful* with boolean arithmetic, especially negation, in the presence of NA data. You may wish to add an explicit NA filter into boolean array operations if you are worried about this:

```
In [4]: mask = series == 'Steve'
```

```
In [5]: series[mask & series.notnull()]
```

```
Out [5]:
0      Steve
Length: 1, dtype: object
```

While propagating NA in comparisons may seem like the right behavior to some users (and you could argue on purely technical grounds that this is the right thing to do), the evaluation was made that propagating NA everywhere, including in numerical arrays, would cause a large amount of problems for users. Thus, a “practicality beats purity” approach was taken. This issue may be revisited at some point in the future.

## Other API changes

When calling `apply` on a grouped Series, the return value will also be a Series, to be more consistent with the `groupby` behavior with `DataFrame`:

```
In [6]: df = pd.DataFrame({'A': ['foo', 'bar', 'foo', 'bar',
...:                            'foo', 'bar', 'foo', 'foo'],
...:                      'B': ['one', 'one', 'two', 'three',
...:                            'two', 'two', 'one', 'three'],
...:                      'C': np.random.randn(8), 'D': np.random.randn(8)})
```

```
In [7]: df
```

```
Out [7]:
   A      B      C      D
0  foo  one  0.669989 -0.368946
1  bar  one -0.138094 -0.073951
2  foo  two  0.058206 -0.799669
3  bar three -0.780498  0.124687
4  foo  two  0.337542 -1.289728
```

(continues on next page)

(continued from previous page)

```

5 bar    two -0.166920  1.292333
6 foo    one  0.105766 -1.292147
7 foo   three 0.044486  1.322568

[8 rows x 4 columns]

In [8]: grouped = df.groupby('A')['C']

In [9]: grouped.describe()
Out [9]:

```

|     | count | mean      | std      | min       | 25%       | 50%       | 75%       | max       |
|-----|-------|-----------|----------|-----------|-----------|-----------|-----------|-----------|
| A   |       |           |          |           |           |           |           |           |
| bar | 3.0   | -0.361837 | 0.362857 | -0.780498 | -0.473709 | -0.166920 | -0.152507 | -0.138094 |
| foo | 5.0   | 0.243198  | 0.266293 | 0.044486  | 0.058206  | 0.105766  | 0.337542  | 0.669989  |

```

[2 rows x 8 columns]

In [10]: grouped.apply(lambda x: x.sort_values()[-2:]) # top 2 values
Out [10]:
A
bar  5  -0.166920
     1  -0.138094
foo  4   0.337542
     0   0.669989
Name: C, Length: 4, dtype: float64

```

## 6.20.2 v.0.7.2 (March 16, 2012)

{{ header }}

This release targets bugs in 0.7.1, and adds a few minor features.

### New features

- Add additional tie-breaking methods in `DataFrame.rank` (GH874)
- Add ascending parameter to rank in `Series`, `DataFrame` (GH875)
- Add `coerce_float` option to `DataFrame.from_records` (GH893)
- Add `sort_columns` parameter to allow unsorted plots (GH918)
- Enable column access via attributes on `GroupBy` (GH882)
- Can pass dict of values to `DataFrame.fillna` (GH661)
- Can select multiple hierarchical groups by passing list of values in `.ix` (GH134)
- Add `axis` option to `DataFrame.fillna` (GH174)
- Add `level` keyword to `drop` for dropping values from a level (GH159)

### Performance improvements

- Use `khash` for `Series.value_counts`, add `raw` function to `algorithms.py` (GH861)
- Intercept `__builtin__.sum` in `groupby` (GH885)

### Contributors

A total of 12 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

### 6.20.3 v.0.7.1 (February 29, 2012)

{{ header }}

This release includes a few new features and addresses over a dozen bugs in 0.7.0.

#### New features

- Add `to_clipboard` function to pandas namespace for writing objects to the system clipboard (GH774)
- Add `itertuples` method to DataFrame for iterating through the rows of a dataframe as tuples (GH818)
- Add ability to pass `fill_value` and method to DataFrame and Series `align` method (GH806, GH807)
- Add `fill_value` option to `reindex`, `align` methods (GH784)
- Enable `concat` to produce DataFrame from Series (GH787)
- Add `between` method to Series (GH802)
- Add HTML representation hook to DataFrame for the IPython HTML notebook (GH773)
- Support for reading Excel 2007 XML documents using `openpyxl`

#### Performance improvements

- Improve performance and memory usage of `fillna` on DataFrame
- Can concatenate a list of Series along `axis=1` to obtain a DataFrame (GH787)

#### Contributors

A total of 9 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

- Adam Klein
- Brian Granger +

## 6.20.4 v.0.7.0 (February 9, 2012)

```
{{ header }}
```

### New features

- New unified *merge function* for efficiently performing full gamut of database / relational-algebra operations. Refactored existing join methods to use the new infrastructure, resulting in substantial performance gains (GH220, GH249, GH267)
- New *unified concatenation function* for concatenating Series, DataFrame or Panel objects along an axis. Can form union or intersection of the other axes. Improves performance of `Series.append` and `DataFrame.append` (GH468, GH479, GH273)
- Can pass multiple DataFrames to `DataFrame.append` to concatenate (stack) and multiple Series to `Series.append` too
- Can pass list of dicts (e.g., a list of JSON objects) to DataFrame constructor (GH526)
- You can now *set multiple columns* in a DataFrame via `__getitem__`, useful for transformation (GH342)
- Handle differently-indexed output values in `DataFrame.apply` (GH498)

```
In [1]: df = pd.DataFrame(np.random.randn(10, 4))
```

```
In [2]: df.apply(lambda x: x.describe())
```

```
Out [2]:
```

|       | 0         | 1         | 2         | 3         |
|-------|-----------|-----------|-----------|-----------|
| count | 10.000000 | 10.000000 | 10.000000 | 10.000000 |
| mean  | -1.011527 | 0.151890  | -0.257279 | -0.072454 |
| std   | 0.749428  | 1.010975  | 1.010855  | 1.155960  |
| min   | -2.397242 | -1.719758 | -2.230079 | -1.495080 |
| 25%   | -1.448791 | -0.057220 | -0.743645 | -0.966763 |
| 50%   | -0.980020 | 0.295064  | -0.133701 | -0.209559 |
| 75%   | -0.488954 | 0.463099  | 0.096806  | 0.533345  |
| max   | 0.161458  | 2.050599  | 1.493995  | 2.271243  |

```
[8 rows x 4 columns]
```

- Add `reorder_levels` method to Series and DataFrame (GH534)
- Add dict-like `get` function to DataFrame and Panel (GH521)
- Add `DataFrame.iterrows` method for efficiently iterating through the rows of a DataFrame
- Add `DataFrame.to_panel` with code adapted from `LongPanel.to_long`
- Add `reindex_axis` method added to DataFrame
- Add `level` option to binary arithmetic functions on DataFrame and Series
- Add `level` option to the `reindex` and `align` methods on Series and DataFrame for broadcasting values across a level (GH542, GH552, others)
- Add attribute-based item access to Panel and add IPython completion (GH563)
- Add `logy` option to `Series.plot` for log-scaling on the Y axis
- Add `index` and `header` options to `DataFrame.to_string`
- Can pass multiple DataFrames to `DataFrame.join` to join on index (GH115)
- Can pass multiple Panels to `Panel.join` (GH115)

- *Added* `justify` argument to `DataFrame.to_string` to allow different alignment of column headers
- *Add* `sort` option to `GroupBy` to allow disabling sorting of the group keys for potential speedups (GH595)
- *Can* pass `MaskedArray` to `Series` constructor (GH563)
- *Add* Panel item access via attributes and IPython completion (GH554)
- *Implement* `DataFrame.lookup`, fancy-indexing analogue for retrieving values given a sequence of row and column labels (GH338)
- *Can* pass a *list of functions* to aggregate with `groupby` on a `DataFrame`, yielding an aggregated result with hierarchical columns (GH166)
- *Can* call `cummin` and `cummax` on `Series` and `DataFrame` to get cumulative minimum and maximum, respectively (GH647)
- `value_range` added as utility function to get min and max of a dataframe (GH288)
- *Added* `encoding` argument to `read_csv`, `read_table`, `to_csv` and `from_csv` for non-ascii text (GH717)
- *Added* `abs` method to pandas objects
- *Added* `crosstab` function for easily computing frequency tables
- *Added* `isin` method to index objects
- *Added* `level` argument to `xs` method of `DataFrame`.

### API changes to integer indexing

One of the potentially riskiest API changes in 0.7.0, but also one of the most important, was a complete review of how **integer indexes** are handled with regard to label-based indexing. Here is an example:

```
In [3]: s = pd.Series(np.random.randn(10), index=range(0, 20, 2))

In [4]: s
Out[4]:
0      0.241988
2     -0.140924
4     -0.653255
6      1.735856
8      0.493223
10     0.699761
12    -0.490215
14     0.296281
16     0.574774
18    -0.505160
Length: 10, dtype: float64

In [5]: s[0]
Out[5]: 0.2419875382715906

In [6]: s[2]
Out[6]: -0.14092373781454884

In [7]: s[4]
Out[7]: -0.6532545931074317
```

This is all exactly identical to the behavior before. However, if you ask for a key **not** contained in the Series, in versions 0.6.1 and prior, Series would *fall back* on a location-based lookup. This now raises a `KeyError`:

```
In [2]: s[1]
KeyError: 1
```

This change also has the same impact on `DataFrame`:

```
In [3]: df = pd.DataFrame(np.random.randn(8, 4), index=range(0, 16, 2))
```

```
In [4]: df
   0      1      2      3
0  0.88427  0.3363 -0.1787  0.03162
2  0.14451 -0.1415  0.2504  0.58374
4 -1.44779 -0.9186 -1.4996  0.27163
6 -0.26598 -2.4184 -0.2658  0.11503
8 -0.58776  0.3144 -0.8566  0.61941
10  0.10940 -0.7175 -1.0108  0.47990
12 -1.16919 -0.3087 -0.6049 -0.43544
14 -0.07337  0.3410  0.0424 -0.16037
```

```
In [5]: df.ix[3]
KeyError: 3
```

In order to support purely integer-based indexing, the following methods have been added:

| Method                                  | Description                                                        |
|-----------------------------------------|--------------------------------------------------------------------|
| <code>Series.iget_value(i)</code>       | Retrieve value stored at location <code>i</code>                   |
| <code>Series.iget(i)</code>             | Alias for <code>iget_value</code>                                  |
| <code>DataFrame.irow(i)</code>          | Retrieve the <code>i</code> -th row                                |
| <code>DataFrame.icol(j)</code>          | Retrieve the <code>j</code> -th column                             |
| <code>DataFrame.iget_value(i, j)</code> | Retrieve the value at row <code>i</code> and column <code>j</code> |

### API tweaks regarding label-based slicing

Label-based slicing using `ix` now requires that the index be sorted (monotonic) **unless** both the start and endpoint are contained in the index:

```
In [1]: s = pd.Series(np.random.randn(6), index=list('gmkaec'))

In [2]: s
Out[2]:
g   -1.182230
m   -0.276183
k   -0.243550
a    1.628992
e    0.073308
c   -0.539890
dtype: float64
```

Then this is OK:

```
In [3]: s.ix['k':'e']
Out[3]:
k   -0.243550
```

(continues on next page)

(continued from previous page)

```
a    1.628992
e    0.073308
dtype: float64
```

But this is not:

```
In [12]: s.ix['b':'h']
KeyError 'b'
```

If the index had been sorted, the “range selection” would have been possible:

```
In [4]: s2 = s.sort_index()
```

```
In [5]: s2
Out[5]:
a    1.628992
c   -0.539890
e    0.073308
g   -1.182230
k   -0.243550
m   -0.276183
dtype: float64
```

```
In [6]: s2.ix['b':'h']
Out[6]:
c   -0.539890
e    0.073308
g   -1.182230
dtype: float64
```

### Changes to Series [] operator

As a notational convenience, you can pass a sequence of labels or a label slice to a Series when getting and setting values via [] (i.e. the `__getitem__` and `__setitem__` methods). The behavior will be the same as passing similar input to `ix` **except in the case of integer indexing**:

```
In [8]: s = pd.Series(np.random.randn(6), index=list('acegkm'))
```

```
In [9]: s
Out[9]:
a    0.702548
c   -0.554585
e    0.728336
g   -1.243858
k   -1.107822
m   -0.426698
Length: 6, dtype: float64
```

```
In [10]: s[['m', 'a', 'c', 'e']]
Out[10]:
m   -0.426698
a    0.702548
c   -0.554585
e    0.728336
Length: 4, dtype: float64
```

(continues on next page)

(continued from previous page)

```
In [11]: s['b':'l']
Out[11]:
c    -0.554585
e     0.728336
g    -1.243858
k    -1.107822
Length: 4, dtype: float64

In [12]: s['c':'k']
Out[12]:
c    -0.554585
e     0.728336
g    -1.243858
k    -1.107822
Length: 4, dtype: float64
```

In the case of integer indexes, the behavior will be exactly as before (shadowing ndarray):

```
In [13]: s = pd.Series(np.random.randn(6), index=range(0, 12, 2))

In [14]: s[[4, 0, 2]]
Out[14]:
4    -1.234677
0    -2.755651
2    -1.148347
Length: 3, dtype: float64

In [15]: s[1:5]
Out[15]:
2    -1.148347
4    -1.234677
6    -0.589450
8    -1.313248
Length: 4, dtype: float64
```

If you wish to do indexing with sequences and slicing on an integer index with label semantics, use `ix`.

### Other API changes

- The deprecated `LongPanel` class has been completely removed
- If `Series.sort` is called on a column of a `DataFrame`, an exception will now be raised. Before it was possible to accidentally mutate a `DataFrame`'s column by doing `df[col].sort()` instead of the side-effect free method `df[col].order()` ([GH316](#))
- Miscellaneous renames and deprecations which will (harmlessly) raise `FutureWarning`
- `drop` added as an optional parameter to `DataFrame.reset_index` ([GH699](#))

## Performance improvements

- *Cythonized GroupBy aggregations* no longer presort the data, thus achieving a significant speedup (GH93). GroupBy aggregations with Python functions significantly sped up by clever manipulation of the ndarray data type in Cython (GH496).
- Better error message in DataFrame constructor when passed column labels don't match data (GH497)
- Substantially improve performance of multi-GroupBy aggregation when a Python function is passed, reuse ndarray object in Cython (GH496)
- Can store objects indexed by tuples and floats in HDFStore (GH492)
- Don't print length by default in Series.to\_string, add *length* option (GH489)
- Improve Cython code for multi-groupby to aggregate without having to sort the data (GH93)
- Improve MultiIndex reindexing speed by storing tuples in the MultiIndex, test for backwards unpickling compatibility
- Improve column reindexing performance by using specialized Cython take function
- Further performance tweaking of Series.\_\_getitem\_\_ for standard use cases
- Avoid Index dict creation in some cases (i.e. when getting slices, etc.), regression from prior versions
- Friendlier error message in setup.py if NumPy not installed
- Use common set of NA-handling operations (sum, mean, etc.) in Panel class also (GH536)
- Default name assignment when calling `reset_index` on DataFrame with a regular (non-hierarchical) index (GH476)
- Use Cythonized groupers when possible in Series/DataFrame stat ops with `level` parameter passed (GH545)
- Ported skiplist data structure to C to speed up `rolling_median` by about 5-10x in most typical use cases (GH374)

## 6.21 Version 0.6

### 6.21.1 v.0.6.1 (December 13, 2011)

#### New features

- Can *append single rows* (as Series) to a DataFrame
- Add Spearman and Kendall rank *correlation* options to Series.corr and DataFrame.corr (GH428)
- *Added* `get_value` and `set_value` methods to Series, DataFrame, and Panel for very low-overhead access (>2x faster in many cases) to scalar elements (GH437, GH438). `set_value` is capable of producing an enlarged object.
- Add PyQt table widget to sandbox (GH435)
- DataFrame.align can *accept Series arguments* and an *axis option* (GH461)
- Implement new *SparseArray* and *SparseList* data structures. SparseSeries now derives from SparseArray (GH463)
- *Better console printing options* (GH453)
- Implement fast *data ranking* for Series and DataFrame, fast versions of `scipy.stats.rankdata` (GH428)
- Implement *DataFrame.from\_items* alternate constructor (GH444)
- DataFrame.convert\_objects method for *inferring better dtypes* for object columns (GH302)
- Add *rolling\_corr\_pairwise* function for computing Panel of correlation matrices (GH189)
- Add *margins* option to *pivot\_table* for computing subgroup aggregates (GH114)
- Add `Series.from_csv` function (GH482)
- *Can pass* DataFrame/DataFrame and DataFrame/Series to `rolling_corr/rolling_cov` (GH #462)
- MultiIndex.get\_level\_values can *accept the level name*

## Performance improvements

- Improve memory usage of `DataFrame.describe` (do not copy data unnecessarily) (PR #425)
- Optimize scalar value lookups in the general case by 25% or more in Series and DataFrame
- Fix performance regression in cross-sectional count in DataFrame, affecting `DataFrame.dropna` speed
- Column deletion in DataFrame copies no data (computes views on blocks) (GH #158)

## Contributors

A total of 7 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

## 6.21.2 v.0.6.0 (November 25, 2011)

{{ header }}

### New features

- *Added* `melt` function to `pandas.core.reshape`
- *Added* `level` parameter to `group` by level in Series and DataFrame descriptive statistics (GH313)
- *Added* `head` and `tail` methods to Series, analogous to to DataFrame (GH296)
- *Added* `Series.isin` function which checks if each value is contained in a passed sequence (GH289)
- *Added* `float_format` option to `Series.to_string`
- *Added* `skip_footer` (GH291) and `converters` (GH343) options to `read_csv` and `read_table`
- *Added* `drop_duplicates` and `duplicated` functions for removing duplicate DataFrame rows and checking for duplicate rows, respectively (GH319)
- *Implemented* operators `&`, `|`, `^`, `-` on DataFrame (GH347)
- *Added* `Series.mad`, mean absolute deviation
- *Added* `QuarterEnd` `DateOffset` (GH321)
- *Added* `dot` to DataFrame (GH65)
- *Added* `orient` option to `Panel.from_dict` (GH359, GH301)
- *Added* `orient` option to `DataFrame.from_dict`
- *Added* passing list of tuples or list of lists to `DataFrame.from_records` (GH357)

- *Added* multiple levels to `groupby` (GH103)
- *Allow* multiple columns in `by` argument of `DataFrame.sort_index` (GH92, GH362)
- *Added* `fast_get_value` and `fast_put_value` methods to `DataFrame` (GH360)
- *Added* `cov` instance methods to `Series` and `DataFrame` (GH194, GH362)
- *Added* `kind='bar'` option to `DataFrame.plot` (GH348)
- *Added* `idxmin` and `idxmax` to `Series` and `DataFrame` (GH286)
- *Added* `read_clipboard` function to parse `DataFrame` from clipboard (GH300)
- *Added* `nunique` function to `Series` for counting unique elements (GH297)
- *Made* `DataFrame` constructor use `Series` name if no columns passed (GH373)
- *Support* regular expressions in `read_table/read_csv` (GH364)
- *Added* `DataFrame.to_html` for writing `DataFrame` to HTML (GH387)
- *Added* support for `MaskedArray` data in `DataFrame`, masked values converted to `NaN` (GH396)
- *Added* `DataFrame.boxplot` function (GH368)
- *Can* pass extra args, `kwds` to `DataFrame.apply` (GH376)
- *Implement* `DataFrame.join` with vector on argument (GH312)
- *Added* `legend` boolean flag to `DataFrame.plot` (GH324)
- *Can* pass multiple levels to `stack` and `unstack` (GH370)
- *Can* pass multiple values columns to `pivot_table` (GH381)
- *Use* `Series` name in `GroupBy` for result index (GH363)
- *Added* `raw` option to `DataFrame.apply` for performance if only need `ndarray` (GH309)
- *Added* proper, tested weighted least squares to standard and panel OLS (GH303)

## Performance enhancements

- VBENCH Cythonized `cache_readonly`, resulting in substantial micro-performance enhancements throughout the code base (GH361)
- VBENCH Special Cython matrix iterator for applying arbitrary reduction operations with 3-5x better performance than `np.apply_along_axis` (GH309)
- VBENCH Improved performance of `MultiIndex.from_tuples`
- VBENCH Special Cython matrix iterator for applying arbitrary reduction operations
- VBENCH + DOCUMENT Add `raw` option to `DataFrame.apply` for getting better performance when
- VBENCH Faster cythonized count by level in `Series` and `DataFrame` (GH341)
- VBENCH? Significant `GroupBy` performance enhancement with multiple keys with many “empty” combinations
- VBENCH New Cython vectorized function `map_infer` speeds up `Series.apply` and `Series.map` significantly when passed elementwise Python function, motivated by (GH355)
- VBENCH Significantly improved performance of `Series.order`, which also makes `np.unique` called on a `Series` faster (GH327)
- VBENCH Vastly improved performance of `GroupBy` on axes with a `MultiIndex` (GH299)

## Contributors

A total of 8 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

## 6.22 Version 0.5

### 6.22.1 v.0.5.0 (October 24, 2011)

{{ header }}

#### New features

- *Added* `DataFrame.align` method with standard join options
- *Added* `parse_dates` option to `read_csv` and `read_table` methods to optionally try to parse dates in the index columns
- *Added* `nrows`, `chunksize`, and `iterator` arguments to `read_csv` and `read_table`. The last two return a new `TextParser` class capable of lazily iterating through chunks of a flat file (GH242)
- *Added* ability to join on multiple columns in `DataFrame.join` (GH214)
- *Added* private `_get_duplicates` function to `Index` for identifying duplicate values more easily (ENH5c)
- *Added* column attribute access to `DataFrame`.
- *Added* Python tab completion hook for `DataFrame` columns. (GH233, GH230)
- *Implemented* `Series.describe` for `Series` containing objects (GH241)
- *Added* inner join option to `DataFrame.join` when joining on key(s) (GH248)
- *Implemented* selecting `DataFrame` columns by passing a list to `__getitem__` (GH253)
- *Implemented* `&` and `|` to intersect / union `Index` objects, respectively (GH261)
- *Added* `pivot_table` convenience function to pandas namespace (GH234)
- *Implemented* `Panel.rename_axis` function (GH243)
- `DataFrame` will show index level names in console output (GH334)
- *Implemented* `Panel.take`
- *Added* `set_eng_float_format` for alternate `DataFrame` floating point string formatting (ENH61)

- *Added* convenience `set_index` function for creating a `DataFrame` index from its existing columns
- *Implemented* `groupby` hierarchical index level name (GH223)
- *Added* support for different delimiters in `DataFrame.to_csv` (GH244)
- TODO: DOCS ABOUT TAKE METHODS

### Performance enhancements

- VBENCH Major performance improvements in file parsing functions `read_csv` and `read_table`
- VBENCH Added Cython function for converting tuples to `ndarray` very fast. Speeds up many `MultiIndex`-related operations
- VBENCH Refactored merging / joining code into a tidy class and disabled unnecessary computations in the float/object case, thus getting about 10% better performance (GH211)
- VBENCH Improved speed of `DataFrame.xs` on mixed-type `DataFrame` objects by about 5x, regression from 0.3.0 (GH215)
- VBENCH With new `DataFrame.align` method, speeding up binary operations between differently-indexed `DataFrame` objects by 10-25%.
- VBENCH Significantly sped up conversion of nested dict into `DataFrame` (GH212)
- VBENCH Significantly speed up `DataFrame.__repr__` and `count` on large mixed-type `DataFrame` objects

### Contributors

## 6.23 Version 0.4

### 6.23.1 v.0.4.1 through v0.4.3 (September 25 - October 9, 2011)

{{ header }}

## New features

- Added Python 3 support using 2to3 (GH200)
- *Added* name attribute to Series, now prints as part of Series.\_\_repr\_\_
- *Added* instance methods isnull and notnull to Series (GH209, GH203)
- *Added* Series.align method for aligning two series with choice of join method (ENH56)
- *Added* method get\_level\_values to MultiIndex (GH188)
- Set values in mixed-type DataFrame objects via .ix indexing attribute (GH135)
- *Added* new DataFrame methods get\_dtype\_counts and property dtypes (ENHdc)
- *Added* ignore\_index option to DataFrame.append to stack DataFrames (ENH1b)
- read\_csv tries to sniff delimiters using csv.Sniffer (GH146)
- read\_csv can read multiple columns into a MultiIndex; DataFrame's to\_csv method writes out a corresponding MultiIndex (GH151)
- DataFrame.rename has a new copy parameter to rename a DataFrame in place (ENHed)
- *Enable* unstacking by name (GH142)
- *Enable* sortlevel to work by level (GH141)

## Performance enhancements

- Altered binary operations on differently-indexed SparseSeries objects to use the integer-based (dense) alignment logic which is faster with a larger number of blocks (GH205)
- Wrote faster Cython data alignment / merging routines resulting in substantial speed increases
- Improved performance of isnull and notnull, a regression from v0.3.0 (GH187)
- Refactored code related to DataFrame.join so that intermediate aligned copies of the data in each DataFrame argument do not need to be created. Substantial performance increases result (GH176)
- Substantially improved performance of generic Index.intersection and Index.union
- Implemented BlockManager.take resulting in significantly faster take performance on mixed-type DataFrame objects (GH104)
- Improved performance of Series.sort\_index
- Significant groupby performance enhancement: removed unnecessary integrity checks in DataFrame internals that were slowing down slicing operations to retrieve groups
- Optimized \_ensure\_index function resulting in performance savings in type-checking Index objects
- Wrote fast time series merging / joining methods in Cython. Will be integrated later into DataFrame.join and related functions

## **Contributors**
